This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software, software documentation, data (as defined in the Federal Acquisition Regulation), or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software," "commercial computer software documentation," or "limited rights data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle®, Java, MySQL, and NetSuite are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

1 Overview

What's New 1-1
- July 2025 1-2
- June 2025 1-2
- May 2025 1-4
- April 2025 1-7
- March 2025 1-8
- February 2025 1-10
- January 2025 1-10

About Autonomous Database 1-11
- What is Oracle Autonomous Database? 1-11
- Key features 1-12
- About Autonomous Database Workload Types 1-15
  - About Oracle Autonomous Data Warehouse 1-16
  - About Oracle Autonomous Transaction Processing 1-16
  - About Autonomous JSON Database 1-17
  - About Oracle APEX Application Development 1-18
- Autonomous Database Region Availability 1-18

Get Help and Contact Support 1-18
- Post Questions on Forums 1-19
- Open a Support Ticket to Create a Service Request 1-19
- Create a Service Request in My Oracle Cloud Support 1-20
- Register to My Oracle Cloud Support as a New User 1-21

Service Level Objectives (SLOs) 1-22
- RTO and RPO Objectives 1-23
- Built-In Tool Availability 1-23
- Zero-Regression Service Level Objective 1-24

How Is Autonomous Database Billed? 1-25
Autonomous Database Billing Summary 1-25
Compute Models in Autonomous Database 1-27
ECPU Compute Model Billing Information 1-28
OCPU Compute Model Billing Information 1-35
Oracle Autonomous Database Serverless Features Billing 1-40
Oracle Autonomous Database Serverless Billing for Database Tools 1-46
Autonomous Database for Developers Billing and Tenancy Service Limit 1-48
Always Free Autonomous Database 1-49
Upgrade an Always Free Autonomous Database to a Paid Instance 1-52
Autonomous Database for Developers 1-53
Resource Restrictions with Autonomous Database for Developers 1-54
Oracle Database Versions with Autonomous Database for Developers 1-54
Supported Features with Autonomous Database for Developers 1-54
Provisioning and Cloning Workflow with Autonomous Database for Developers 1-55
Upgrade Autonomous Database for Developers Instance to a Full Paid Instance 1-55
Features Not Available in Autonomous Database for Developers 1-56

2 Quick Start

Before You Begin 2-1
Autonomous Database 15 Minute Quick Start 2-2

3 Tasks

Provision an Autonomous Database 3-2
Connect to Autonomous Database 3-2
About Connecting to an Autonomous Database Instance 3-3
Secure Connections to Autonomous Database with mTLS or with TLS 3-4
Connect to Autonomous Database Through a Firewall 3-7
Using Application Continuity 3-7
Connect to Autonomous Database Using a Client Application 3-8
About Connecting to Autonomous Database Using a Client Application 3-9
Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections with Wallets (mTLS) 3-9
Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections Using TLS Authentication 3-12
Prepare for JDBC Thin Connections 3-13
Connect Microsoft .NET, Visual Studio Code, and Visual Studio with a Wallet (mTLS) 3-14
Connect Microsoft .NET, Visual Studio Code, and Visual Studio Without a Wallet 3-15
Connect Node.js and other Scripting Languages (mTLS) 3-16
Connect Node.js, and Other Scripting Languages Without a Wallet 3-19
Connect Power BI and Microsoft Data Tools to Autonomous Database 3-21

Connect Python Applications to Autonomous Database 3-22
Connect Go Applications to Autonomous Database 3-32
Download Database Connection Information 3-38
Download Client Credentials (Wallets) 3-39
Wallet README File 3-41
View TNS Names and Connection Strings for an Autonomous Database Instance 3-43
Connect to Autonomous Database Using Oracle Database Tools 3-44
Connect Oracle SQL Developer with a Wallet (mTLS) 3-44
Connect Oracle SQL Developer Without a Wallet 3-46
Connect SQL*Plus with a Wallet (mTLS) 3-48
Connect SQL*Plus Without a Wallet 3-49
Connect Oracle SQLcl Cloud with a Wallet (mTLS) 3-50
Connect Oracle SQLcl Cloud Without a Wallet 3-52
Connect with Built-In Oracle Database Actions 3-54
About Database Actions (SQL Developer Web) 3-54
Access Database Actions as ADMIN 3-55
Provide Database Actions Access to Database Users 3-56
Required Roles to Access Tools from Database Actions 3-57
IAM Policies to Access Database Actions and Tools from the OCI Console 3-57
Access Database Actions, Oracle APEX, Oracle REST Data Services, and Developer Tools Using a Vanity URL 3-58
Connect with JDBC Thin Driver 3-58
JDBC Thin Connections with a Wallet (mTLS) 3-59
JDBC Thin Connections Without a Wallet (TLS) 3-67
Preparing for Oracle Call Interface Connections 3-68
Oracle Call Interface (OCI) Connections and Wallets (mTLS) 3-69
Oracle Call Interface (OCI) Connections with TLS Authentication 3-69
Predefined Database Service Names for Autonomous Database 3-69
Connect with Oracle Analytics Desktop 3-70
Connect with Oracle Analytics Cloud 3-70
Connection and Networking Options and Features 3-70
Using ACLs, VCNs, and Private Endpoints with Autonomous Database 3-71
Connect with Oracle Cloud Infrastructure FastConnect 3-74
Access Autonomous Database with VCN Transit Routing 3-74
Access Autonomous Database with Service Gateway 3-74
Use Database Resident Connection Pooling with Autonomous Database 3-75
Use TCP Fast Open (TFO) to Connect Clients to Autonomous Database 3-75
Best Practices for Low Latency Connections with Autonomous Database 3-79
View Network Information on the OCI Console 3-86
Manage Users 3-89
Create Users on Autonomous Database 3-90
Create Users on Autonomous Database with Database Actions 3-90

Create Users on Autonomous Database - Connecting with a Client Tool 3-92
Unlock User Accounts on Autonomous Database 3-93
About User Passwords on Autonomous Database 3-93
Manage the Administrator Account on Autonomous Database 3-94
Remove Users 3-96
Manage User Profiles with Autonomous Database 3-96
Manage Password Complexity on Autonomous Database 3-98
Gradual Database Password Rollover for Applications 3-99
Manage User Roles and Privileges 3-100
Manage Users and User Roles on Autonomous Database - Connecting with Database Actions 3-100
Manage User Privileges on Autonomous Database - Connecting with a Client Tool 3-101
Create and Update User Accounts for Oracle Machine Learning 3-102
Create User 3-103
Add Existing Database User Account to Oracle Machine Learning Components 3-104
Use Identity and Access Management (IAM) Authentication with Autonomous Database 3-106
About Identity and Access Management (IAM) Authentication with Autonomous Database 3-107
Prerequisites for Identity and Access Management (IAM) Authentication on Autonomous Database 3-108
Enable Identity and Access Management (IAM) Authentication on Autonomous Database 3-109
Create Identity and Access Management (IAM) Groups and Policies for IAM Users 3-110
Add IAM Users on Autonomous Database 3-112
Add IAM Roles on Autonomous Database 3-113
Create IAM Database Password for IAM Users 3-115
Connect to Autonomous Database with Identity and Access Management (IAM) Authentication 3-115
Configure IAM Proxy Authentication 3-120
Disable Identity and Access Management (IAM) Authentication on Autonomous Database 3-122
Accessing a Database Cross-Tenancy Using an IAM Integration 3-123
Notes for Using Autonomous Database Tools with Identity and Access Management (IAM) Authentication 3-128
Use Microsoft Entra ID with Autonomous Database 3-128
About Integrating Oracle Autonomous Database with Microsoft Entra ID 3-129
Enable Microsoft Entra ID Authentication on Autonomous Database 3-134
Map Oracle Database Schemas and Roles for Azure AD 3-142
Microsoft Entra ID Client Configuration and Access for Autonomous Database 3-144
Testing the Accessibility of the Entra ID Endpoint 3-144
Use Microsoft Active Directory with Autonomous Database 3-146
Prerequisites to Configure CMU with Microsoft Active Directory on Autonomous Database 3-147
Configure CMU with Microsoft Active Directory on Autonomous Database 3-148

Kerberos Authentication for CMU with Microsoft Active Directory 3-150
Add Microsoft Active Directory Roles on Autonomous Database 3-154
Add Microsoft Active Directory Users on Autonomous Database 3-155
Tools Restrictions with Active Directory on Autonomous Database 3-156
Connect to Autonomous Database with Active Directory User Credentials 3-156
Verify Active Directory User Connection Information with Autonomous Database 3-157
Remove Active Directory Users and Roles on Autonomous Database 3-158
Disable Active Directory Access on Autonomous Database 3-158
Configure Kerberos Authentication with Autonomous Database 3-159
About Kerberos Authentication 3-159
Components of the Kerberos Authentication System 3-160
Enable Kerberos Authentication on Autonomous Database 3-161
Disable Kerberos Authentication on Autonomous Database 3-163
Notes for Kerberos Authentication on Autonomous Database 3-163
Create Credentials or Configure Policies and Roles 3-163
Manage Credentials 3-164
Create Credentials to Access Cloud Services 3-164
Create Credentials to Access Cloud Services in Cloud Shell 3-165
List Credentials 3-171
Delete Credentials 3-171
Use Vault Secret Credentials 3-171
Use Vault Secret Credentials with Oracle Cloud Infrastructure Vault 3-172
Use Vault Secret Credential with Azure Key Vault 3-175
Use Vault Secret Credential with AWS Secrets Manager 3-177
Use Vault Secret Credential with GCP Secret Manager 3-179
Refresh Vault Secret Credentials 3-181
Update Vault Secret Credentials 3-182
Configure Policies and Roles to Access Resources 3-182
Use Resource Principal to Access Oracle Cloud Infrastructure Resources 3-183
Use Amazon Resource Names (ARNs) to Access AWS Resources 3-189
Use Azure Service Principal to Access Azure Resources 3-197
Use Google Service Account to Access Google Cloud Platform Resources 3-202
Load Data 3-211
About Data Loading 3-212
Load Data with Oracle Database Actions 3-213
Load Data from Files in the Cloud 3-213
Create Credentials and Copy Data into an Existing Table 3-214
Create Credentials and Load Data Pump Dump Files into an Existing Table 3-216
Load JSON on Autonomous Database 3-217
Monitor and Troubleshoot Loads 3-229
Examples for Loading Data into Autonomous Database 3-230
Import Data Using Oracle Data Pump on Autonomous Database 3-242

Export Your Existing Oracle Database to Import into Autonomous Database 3-243
Import Data with Oracle Data Pump Latest Version or an Older Version 3-245
Access Log Files for Data Pump Import 3-253
Oracle Data Pump Import and Table Compression 3-254
Notes for Importing with Oracle Data Pump 3-254
Load Data from Local Files with Oracle Database Actions 3-255
Load Data into Existing Autonomous Database Table with Oracle Database Actions 3-255
Load Data or Query Data from Files in a Directory 3-258
Load Data from Local Files Using SQL*Loader 3-260
Use Data Pipelines for Continuous Load and Export 3-260
About Data Pipelines on Autonomous Database 3-260
Create and Configure Pipelines 3-264
Test Pipelines 3-270
Control Pipelines (Start, Stop, Drop, or Reset a Pipeline) 3-270
Monitor and Troubleshoot Pipelines 3-273
Use Oracle Maintained Pipelines 3-277
The Data Load Page 3-278
The Data Load Page 3-278
Augment Data using Table AI Assist Tool 3-411
The Table AI Assist Tool 3-411
Transform Data Using Data Studio 3-424
The Data Transforms Page 3-425
Data Marketplace 3-594
The Data Marketplace Tool 3-594
View Data Pump Jobs and Import Data with Data Pump 3-607
Link Data 3-607
Link to Object Storage Data 3-608
Query External Data 3-609
Access ORC, Parquet or Avro file types 3-612
Query External Tables with Implicit Partitioning 3-618
Access partitioned object storage data 3-624
Querying External Partitioned Data 3-637
Query Data that Uses Table Hyperlink Source 3-639
Query Hybrid Partitioned Data 3-641
Query External Data Pump Dump Files 3-643
Query Big Data Service Hadoop (HDFS) Data from Autonomous Database 3-644
Integrate Data Lake metadata with Data Catalog 3-644
Query External Data with AWS Glue Data Catalog 3-660
Query Apache Iceberg Tables 3-667
Validate External Data 3-672
Validate External Partitioned Data 3-673
Validate Hybrid Partitioned Data 3-674

View Logs for Data Validation 3-675
Use Database Links 3-676
Create Database Links from Autonomous Database to Another Autonomous Database 3-677
Create Database Links to an Oracle Database that is not an Autonomous Database 3-690
Create Database Links to Non-Oracle Databases 3-702
Create Database Links from Other Databases to Autonomous Database 3-723
Drop Database Links 3-724
Call Web Services 3-725
Submit an HTTP Request to a Public Host 3-726
Submit an HTTP Request to a Private Host 3-726
Submit an HTTP Request to Private Site with a Proxy 3-727
Use Credential Objects to Set HTTP Authentication 3-729
Notes for Submitting HTTP Requests with Oracle APEX or Database Actions 3-730
Move Files 3-731
Create and Manage Directories 3-731
Create Directory in Autonomous Database 3-732
Drop Directory in Autonomous Database 3-733
List Contents of Directory in Autonomous Database 3-734
Access Network File System from Autonomous Database 3-734
Load Data from Directories in Autonomous Database 3-740
Copy Files Between Object Store and a Directory in Autonomous Database 3-742
Bulk Operations for Files in the Cloud 3-742
About Bulk File Operations 3-743
Bulk Copy Files in Cloud Object Storage 3-744
Bulk Move Files Across Cloud Object Storage 3-745
Bulk Download Files from Cloud Object Storage 3-746
Bulk Upload Files to Cloud Object Storage 3-746
Bulk Delete Files from Cloud Object Storage 3-747
Monitor and Troubleshoot Bulk File Loads 3-748
Notes for Bulk File Operations 3-750
Replicate Data 3-750
Replicate Data with Oracle GoldenGate 3-750
Export Data 3-751
Export Data to Object Store as CSV, JSON, or XML using EXPORT_DATA 3-752
Export JSON Data to Cloud Object Storage 3-752
Export Data as CSV to Cloud Object Storage 3-754
Export Data as Parquet to Cloud Object Storage 3-756
Export Data as XML to Cloud Object Storage 3-758
File Naming for Text Output (CSV, JSON, Parquet, or XML) 3-759
Export Data to a Directory Location 3-762
Export Data as CSV to a Directory 3-763

Export Data as JSON a Directory 3-764
Export Data as Parquet to a Directory 3-766
Export Data as XML to a Directory 3-768
Export Data to a Directory as Oracle Data Pump Files 3-769
Export Data with Data Pump to an Autonomous Database Directory 3-771
Use Data Pump to Create a Dump File Set on Autonomous Database 3-772
Move Dump File Set from Autonomous Database to Your Cloud Object Store 3-774
Export Data with Data Pump to Object Store 3-775
Use Oracle Data Pump to Export Data to Object Store Using CREDENTIAL Parameter (Version 19.9 or Later) 3-776
Use Oracle Data Pump to Export Data to Object Store Setting DEFAULT_CREDENTIAL Property 3-779
Export Data to Object Store as Oracle Data Pump Files using EXPORT_DATA 3-781
Download Dump Files, Run Data Pump Import, and Clean Up Object Store 3-783
Access Log Files for Data Pump Export 3-784
Oracle GoldenGate Capture for Oracle Autonomous Database 3-785
Data Sharing 3-785
Use Cloud Links for Read Only Data Access on Autonomous Database 3-785
About Cloud Links on Autonomous Database 3-786
Grant Cloud Links Access for Database Users 3-790
Register a Data Set 3-793
Find Data Sets and Use Cloud Links 3-807
Use Cloud Links Consumer Options 3-808
Monitor and View Cloud Links Information 3-812
Define a Virtual Private Database Policy to Secure a Registered Data Set 3-812
Notes for Cloud Links 3-814
Use Table Hyperlinks for Read Only Data Access on Autonomous Database 3-816
About Table Hyperlinks on Autonomous Database 3-816
Generate, List, Invalidate, and Monitor Table Hyperlinks 3-818
Use Table Hyperlink to Access Data 3-827
Use Table Hyperlinks to Access Data in Table Format 3-830
Use Table Hyperlinks to Create an External Table 3-837
Share Data with Data Studio 3-837
The Data Share Tool 3-838
Develop 3-879
Create Applications with Oracle APEX 3-880
About Oracle APEX 3-881
Access Oracle APEX Administration Services 3-882
Create Oracle APEX Workspaces in Autonomous Database 3-884
Access Oracle APEX App Builder 3-885
Create Oracle APEX Developer Accounts 3-885
Load Data from the Cloud into Oracle APEX 3-886

Use JSON Data with Oracle APEX 3-887
Use Web Services with Oracle APEX 3-888
Send Email from Oracle APEX 3-892
Control Oracle APEX Upgrades 3-895
Access Oracle APEX, Oracle REST Data Services, and Developer Tools Using a Vanity URL 3-899
Oracle APEX Limitations on Autonomous Database 3-899
Use JSON with Autonomous Database 3-901
Work with Simple Oracle Document Access (SODA) in Autonomous Database 3-902
Work with JSON Documents Using SQL and PL/SQL APIs on Autonomous Database 3-904
Load JSON Documents with Autonomous Database 3-904
Import SODA Collection Data Using Oracle Data Pump Version 19.6 or Later 3-904
Develop RESTful Services in Autonomous Database 3-908
About Oracle REST Data Services in Autonomous Database 3-908
Access RESTful Services and SODA for REST 3-909
Develop with Oracle REST Data Services on Autonomous Database 3-910
Use SODA for REST with Autonomous Database 3-910
Access Oracle REST Data Services, Oracle APEX, and Developer Tools Using a Vanity URL 3-916
About Customer Managed Oracle REST Data Services on Autonomous Database 3-916
Use Oracle Database API for MongoDB 3-917
Configure Access for MongoDB and Enable MongoDB 3-918
User Management for MongoDB 3-922
Create a Test Autonomous Database User for MongoDB 3-923
Connect MongoDB Applications to Autonomous Database 3-924
Send Email and Notifications on Autonomous Database 3-929
Send Email on Autonomous Database 3-930
Send Slack Notifications from Autonomous Database 3-939
Send Messages to OCI Notifications Service from Autonomous Database 3-941
Send Microsoft Teams Notifications from Autonomous Database 3-944
User Defined Notification Handler for Scheduler Jobs 3-948
About User Defined Notification Handler for Scheduler Jobs 3-948
Create a Job Notification Handler Procedure 3-948
Register the Job Handler Notification Procedure 3-950
Trigger the Job Handler Notification Procedure 3-951
De-Register the Job Handler Notification Procedure 3-953
Oracle Extensions for IDEs 3-953
Use Oracle Cloud Infrastructure Toolkit for Eclipse 3-954
Use Oracle Developer Tools for Visual Studio 3-954
Use Oracle Developer Tools for VS Code 3-955
Use Oracle Java on Autonomous Database 3-956
Enable Oracle Java 3-956

Check Oracle Java Version 3-956
Load Java classes and JAR Files into Autonomous Database 3-957
Notes for Oracle Java on Autonomous Database 3-957
Test Workloads with Oracle Real Application Testing 3-958
About Oracle Real Application Testing 3-958
Capture-Replay Workloads between Autonomous Databases 3-959
Capture-Replay Workloads between non-Autonomous and Autonomous Databases 3-966
Test Workloads Against an Upcoming Patch 3-968
Manage and Store Files in a Cloud Code Repository with Autonomous Database 3-971
About Cloud Code Repositories with Autonomous Database 3-971
Initialize a Cloud Code Repository 3-972
Create and Manage a Cloud Code Repository 3-973
Create and Manage Branches in a Cloud Code Repository 3-974
Export Schema Objects to the Cloud Code Repository Branch 3-976
Use File Operations with a Cloud Code Repository 3-977
Use SQL Install Operations with a Cloud Code Repository 3-978
Invoke User Defined Functions 3-980
About User Defined Functions 3-980
Steps to Invoke OCI Cloud Functions as SQL Functions 3-981
Steps to Invoke AWS Lambda as SQL Functions 3-986
Steps to Invoke Azure Functions as SQL Functions 3-991
Steps to Invoke Google Cloud Run Functions as SQL Functions 3-994
Invoke External Procedures as SQL Functions 3-997
Make External Calls Using a Customer-Managed Wallet 3-1010
About Using a Customer-Managed Wallet with External Calls 3-1011
Prerequisites to Use a Customer-Managed Wallet with External Calls 3-1013
Use a Customer-Managed Wallet for External Calls with UTL_HTTP 3-1013
Use a Customer-Managed Wallet with Scheduler Email Notifications 3-1015
Notes for Using a Customer-Managed Wallet with External Calls 3-1017
Use Cloud Tables to Store Logging and Diagnostic Information 3-1019
About Cloud Tables 3-1019
Create Cloud Tables 3-1020
Cloud Table Notes 3-1021
Analyze 3-1023
Build Reports and Dashboards Using Oracle Analytics 3-1023
Create Dashboards, Reports, and Notebooks 3-1023
Create Dashboards and Reports to Analyze and Visualize Your Data 3-1024
Create Notebooks, Workspaces, and Projects with Oracle Machine Learning Notebooks 3-1025
Spatial Analytics with Oracle Spatial 3-1027
About Oracle Spatial with Autonomous Database 3-1027
Oracle Spatial Limitations with Autonomous Database 3-1028

The Data Analysis Tool 3-1029
Searching and obtaining information about Analytic Views 3-1033
Creating Analytic Views 3-1034
Working with Analyses 3-1045
Viewing Analyses 3-1045
Workflow to build Analyses 3-1045
Format Numeric Columns in the Data Analysis Tool 3-1045
Creating Analyses 3-1046
Creating Reports 3-1047
Run Natural Language Query in the Data Analysis Tool 3-1058
Generate Natural Language explanation from SQL Query using AI Explain 3-1063
Vector Search in the Data Analysis Tool 3-1065
Using Calculation Templates 3-1070
Oracle Autonomous Database for Excel 3-1077
Oracle Autonomous Database for Google Sheets 3-1122
The Catalog Tool 3-1158
About the Catalog Page 3-1160
Browse and Search Catalogs 3-1164
Sorting and Filtering Entities 3-1165
Filter Entities 3-1165
Display Entity Search 3-1166
Catalog Settings 3-1167
Manage Catalogs 3-1170
Viewing Entity Details 3-1197
Registering Cloud Links to Access Data 3-1206
Export Data to Cloud 3-1207
Gathering Statistics for Tables 3-1208
Editing Tables 3-1209
The Data Insights Page 3-1217
About Insights 3-1218
Generate Insights and View Reports 3-1219
Use Oracle OLAP with Autonomous Database 3-1220
Enable Oracle OLAP on Autonomous Database 3-1220
Manage the Service 3-1221
Lifecycle Operations 3-1222
Provision an Autonomous Database Instance 3-1223
Start Autonomous Database 3-1228
Stop Autonomous Database 3-1228
Restart Autonomous Database 3-1229
Rename Autonomous Database 3-1229
Update the Display Name for an Autonomous Database Instance 3-1230
Terminate an Autonomous Database Instance 3-1231

Undelete a Terminated Autonomous Database Instance 3-1232
Change Autonomous Database Operation Mode to Read/Write Read-Only or Restricted 3-1234
Schedule Start and Stop Times for an Autonomous Database Instance 3-1236
Concurrent Operations on Autonomous Database 3-1238
Updating Compute and storage limits 3-1239
Add CPU or Storage Resources or Enable Auto Scaling 3-1240
Remove CPU or Storage Resources or Disable Auto Scaling 3-1242
Use Auto Scaling 3-1245
Update Billing Model, Choose Bring Your Own License, or Update Instance to a Paid Instance 3-1250
Choose Bring Your Own License Option While Provisioning or Cloning 3-1251
Choose Bring Your Own License on Autonomous Database (ECPU Compute Model) 3-1252
Choose Bring Your Own License on Autonomous Database (OCPU Compute Model) 3-1255
Update to ECPU Billing Model on Autonomous Database 3-1257
Update Always Free Instance to Paid with Autonomous Database 3-1258
Upgrade Autonomous JSON Database to Autonomous Transaction Processing 3-1259
Upgrade APEX Service to Autonomous Transaction Processing 3-1260
Clone, Move, or Upgrade Autonomous Database 3-1260
About Cloning on Autonomous Database 3-1261
Prerequisites for Cloning 3-1262
Clone an Autonomous Database Instance 3-1263
Clone an Autonomous Database from a Backup 3-1268
Cross Tenancy and Cross-Region Cloning 3-1276
Clone Autonomous Database to Change Workload Type 3-1282
Notes for Cloning Autonomous Database 3-1283
Move an Autonomous Database to a Different Compartment 3-1286
Upgrade an Autonomous Database Instance to Oracle Database 23ai 3-1287
Use Refreshable Clones with Autonomous Database 3-1289
About Refreshable Clones on Autonomous Database 3-1289
Prerequisites for Creating a Refreshable Clone 3-1295
Create and Manage Refreshable Clones 3-1295
View Refreshable Clones for an Autonomous Database Instance 3-1306
Use the API 3-1307
Refreshable Clone Notes 3-1307
Manage Autonomous Database Built-in Tools 3-1309
About Autonomous Database Built-in Tools 3-1309
About Configuring Built-in Tools Compute Resources and Limits 3-1310
View Autonomous Database Built-in Tools Status 3-1311
Configure Autonomous Database Built-in Tools 3-1313
Configure Autonomous Database Built-in Tools when you Provision or Clone an Instance 3-1314
Notes for Autonomous Database Built-in Tools 3-1316

Use Autonomous Database Events 3-1317
About Events Based Notification and Automation on Autonomous Database 3-1317
Critical Events on Autonomous Database 3-1318
Information Events on Autonomous Database 3-1320
Autonomous Database Lifecycle Events 3-1325
Get Notified of Autonomous Database Events 3-1328
Manage Time Zone File Updates on Autonomous Database 3-1330

Manage Encryption Keys on Autonomous Database 5-135
About Master Encryption Key Management on Autonomous Database 5-136
Manage Master Encryption Keys in OCI Vault 5-137
Manage Master Encryption Keys in Azure Key Vault 5-147
Manage Master Encryption Keys in AWS Key Management Service 5-154
Manage Master Encryption Keys in Oracle Key Vault 5-162
Switch to Oracle-Managed Encryption Keys on Autonomous Database 5-170
View History for Customer-Managed Encryption Keys on Autonomous Database 5-170
Notes for Using Customer-Managed Keys with Autonomous Database 5-171
Configure Network Access with Access Control Rules (ACLs) and Private Endpoints 5-175
Configure Network Access with Access Control Rules 5-175

Configure Network Access with Private Endpoints 5-182
Use Zero Trust Packet Routing on Autonomous Database 5-201
Update Network Options to Allow TLS or Require Only Mutual TLS (mTLS) Authentication on Autonomous Database 5-203
Audit Autonomous Database 5-206
About Auditing Autonomous Database 5-207
Register Oracle Data Safe on Autonomous Database 5-209
Extend Audit Record Retention with Oracle Data Safe on Autonomous Database 5-210
View and Manage Oracle Data Safe Audit Trails on Autonomous Database 5-210
View and Manage Audit Policies with Oracle Data Safe on Autonomous Database 5-210
Generate Audit Reports with Data Safe on Autonomous Database 5-211
Rotate Wallets for Autonomous Database 5-211
About Wallet Rotation 5-211
Rotate Wallets with Immediate Rotation 5-211
Rotate Wallets with Grace Period 5-213
Use Oracle Database Vault with Autonomous Database 5-216
Oracle Database Vault Users and Roles on Autonomous Database 5-216
Enable Oracle Database Vault on Autonomous Database 5-217
Disable Oracle Database Vault on Autonomous Database 5-218
Disable User Management with Oracle Database Vault on Autonomous Database 5-218
Enable User Management with Oracle Database Vault on Autonomous Database 5-219
IAM Policies for Autonomous Database 5-219
Policy Details for Autonomous Database 5-219
IAM Permissions and API Operations for Autonomous Database 5-225
Provide Specific Privileges in IAM Policies to Manage Autonomous Database 5-228
Use Oracle Data Safe 5-230
About Data Safe 5-230
Register Data Safe 5-231
Use Data Safe Features 5-232
Break Glass Access for SaaS on Autonomous Database 5-233
About Break Glass Access on Autonomous Database 5-233
Enable Break Glass Access 5-235
Disable Break Glass Access 5-237
Notes for Break Glass Access 5-238
Encrypt Data While Exporting or Decrypt Data While Importing 5-239
Encrypt Data While Exporting to Object Storage 5-239
Decrypt Data While Importing from Object Storage 5-244
Manage Oracle Cloud Operator Access 5-248
Enable Cloud Operator Access 5-249
Disable Cloud Operator Access 5-250
Performance Monitor and Management 5-250
Use OCI Ops Insights on Autonomous Database 5-250

Manage Optimizer Statistics on Autonomous Database 5-251
Manage Optimizer Statistics and Hints with Data Warehouse Workloads 5-251
Manage Optimizer Statistics and Hints with Transaction Processing and JSON Database Workloads 5-252
Manage Automatic Indexing on Autonomous Database 5-253
Manage Automatic Partitioning on Autonomous Database 5-253
About Automatic Partitioning 5-254
How Automatic Partitioning Works 5-255
Configure Automatic Partitioning 5-255
Use Automatic Partitioning 5-257
Generate Automatic Partitioning Reports 5-258
Example Automatic Partitioning Scenarios 5-259
Data Dictionary Views for Automatic Partitioning 5-264
Graph Analytics using Graph Studio 5-265
Use Oracle Graph Analytics 5-266
Build Applications Using Graph APIs 5-266
Use Oracle Machine Learning with Autonomous Database 5-267
OML Machine Learning 5-267
Creating Analytic Views 5-269
Use Select AI for Natural Language Interaction with your Database 5-280
About Select AI 5-281
Usage Guidelines 5-282
Supported Platforms 5-283
Select your AI Provider and LLMs 5-283
Select AI Concepts 5-291
Actions 5-291
AI Profile 5-292
AI Provider 5-292
Conversations 5-292
Database Credentials 5-292
Hallucination in LLM 5-292
IAM 5-292
Large Language Model (LLM) 5-293
Metadata 5-293
Metadata Clone 5-293
Natural Language Prompts 5-293
Network Access Control List (ACL) 5-293
Retrieval Augmented Generation (RAG) 5-293
Semantic Similarity Search 5-294
Vector Distance 5-294
Vector Index 5-294
Vector Store 5-294

Select AI Use Cases 5-294
Getting Started with Select AI 5-295
Manage AI Profiles 5-296
Use DBMS_CLOUD_AI to Configure AI Profiles 5-296
Perform Prerequisites for Select AI 5-296
Create and Set an AI Profile 5-303
Use AI Keyword to Enter Prompts 5-303
Enable Conversations to Enhance User Interaction 5-305
Select AI with Retrieval Augmented Generation (RAG) 5-306
Build your Vector Store 5-306
Use DBMS_CLOUD_AI to Create and Manage Vector Indexes 5-308
Use In-database Transformer Models 5-308
Benefits of Select AI RAG 5-309
Synthetic Data Generation 5-309
Benefits of Synthetic Data Generation 5-310
Generate Synthetic Data 5-310
Monitor and Troubleshoot Synthetic Data Generation 5-310
Examples of Using Select AI 5-312
Example: Select AI Actions 5-314
Example: Select AI with OCI Generative AI 5-315
Example: Select AI with OpenAI 5-325
Example: Select AI with Cohere 5-329
Example: Select AI with Azure OpenAI Service 5-331
Example: Select AI with Google 5-338
Example: Select AI with Anthropic 5-341
Example: Select AI with Hugging Face 5-344
Example: Enable Conversations in Select AI 5-349
Example: Set Up and Use Select AI with RAG 5-352
Example: Select AI with In-database Transformer Models 5-354
Example: Improve SQL Query Generation 5-361
Example: Generate Synthetic Data 5-366
Example: Enable or Disable Data Access 5-371
Example: Restrict Table Access in AI Profile 5-374
Example: Specify Case Sensitivity for Columns 5-375
JSON Document Stores 5-376
Cache Messages with Singleton Pipes and Using Pipes for Persistent Messaging 5-376
Cache Messages with Singleton Pipes 5-377
About Caching Messages with Singleton Pipes 5-377
Automatic Refresh of Cached Message with a Cache Function 5-380
Create an Explicit Singleton Pipe 5-381
Create an Explicit Singleton Pipe with a Cache Function 5-383
Use Persistent Messaging with Messages Stored in Cloud Object Store 5-384

About Persistent Messaging with DBMS_PIPE 5-385
Create an Explicit Persistent Pipe and Send a Message 5-387
Retrieve a Persistent Message on Same Database 5-389
Retrieve a Persistent Message by Creating a Pipe on a Different Database 5-390
Remove a Persistent Pipe 5-392
Full-Text Search Queries 5-393
Use Full-Text Search on Files in Object Storage 5-393
About Full-Text Search on Files in Object Storage 5-393
Create a Text Index on Object Storage Files 5-394
Drop an Index on the Cloud Storage Files 5-395
Text Index Reference Table 5-395
Monitor Text Index Creation 5-396
Use JSON Search on Documents in Object Storage 5-397
Use JSON Search on Documents in Object Storage 5-397
Create a JSON Search Index on JSON Documents in Files 5-398
Drop a JSON Search Index 5-399
Monitor JSON Search Index Creation 5-399
JSON Search Index Reference Table 5-400
JSON Search Index Reference View 5-401
Error Log Table 5-401
Use Oracle Workspace Manager on Autonomous Database 5-401
About Using Oracle Workspace Manager on Autonomous Database 5-402
Enable Oracle Workspace Manager on Autonomous Database 5-402
Disable Oracle Workspace Manager on Autonomous Database 5-403
Use and Manage Elastic Pools on Autonomous Database 5-403
About Elastic Pools 5-404
About Elastic Pool Billing 5-408
About Elastic Pool Billing with Autonomous Data Guard Enabled 5-415
About Elastic Pool Billing with Autonomous Data Guard Enabled with a Local Standby 5-415
About Elastic Pool Billing with a Cross-Region Standby 5-415
Prerequisites for Elastic Pool Usage Across Parent/Child Tenancies 5-416
Create, Join or Manage an Elastic Pool 5-417
Create an Elastic Pool 5-418
Create an Elastic Pool While Provisioning or Cloning an Instance 5-419
Join an Existing Elastic Pool 5-420
Join an Elastic Pool While Provisioning or Cloning an Instance 5-421
Change the Elastic Pool Shape 5-423
List Elastic Pool Members 5-423
Offload Queries to Member Refreshable Clones 5-424
About Query Offloading 5-424
Enable Query Offload 5-427

Disable Query Offload 5-430
Query Offload from PL/SQL 5-430
Query Offload from a Scheduler Job 5-432
Notes for Offloading Queries 5-433
Remove Pool Members from an Elastic Pool 5-434
As Pool Leader Remove Members from an Elastic Pool 5-435
Notes for Leaving an Elastic Pool 5-435
Terminate an Elastic Pool 5-435
Elastic Pool Notes 5-436
Migrate to Autonomous Database 5-437
Migrate Oracle Databases to Autonomous Database 5-437
Migration Prerequisites 5-438
Recommended Migration Methods 5-438
Migrate Existing SQL Execution Plans to Autonomous Database to Mitigate the Risk of SQL Performance Regressions 5-440
Migrate Applications from Non-Oracle SQL to Oracle SQL 5-444
Migrate Applications from PostgreSQL Databases to Autonomous Database 5-445
Migrate Applications from MySQL Databases to Autonomous Database 5-453
Migrate Applications from SQL Server Databases to Autonomous Database 5-460
Use Database In-Memory with Autonomous Database 5-468
About Database In-Memory 5-468
Enabling Objects for In-Memory Population 5-469
Sizing the In-Memory Column Store 5-471
Disabling the In-Memory Column Store 5-471

Preface

This document describes how to manage, monitor, and use Oracle Autonomous Database and provides references to related documentation.

- Audience
- Documentation Accessibility
- Related Documents
- Conventions

Audience

This document is intended for Oracle Cloud users who want to manage and monitor Oracle Autonomous Database.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customer access to and use of Oracle support services will be pursuant to the terms and conditions specified in their Oracle order for the applicable services.

Related Documents

Depending on the region and when you provisioned your database, and in some cases depending on your provisioning choice, the Oracle Database version for your Autonomous Database is one of: Oracle Database 19c or Oracle Database 23ai.

If you have Oracle Database 19c, then many database concepts and features of this service are further documented here:

Oracle Database 19c

Oracle Database 23ai

If you are using Always Free Autonomous Database with Oracle Database 23ai, then many concepts and features of this service are further documented here:

Oracle Database 23ai

For additional information, see these Oracle resources:

- Welcome to Oracle Cloud Infrastructure

- *Oracle Cloud Infrastructure Object Storage*
- Get Started Using Autonomous JSON Database
- GoldenGate Real-Time Data Replication in Cloud
- *Getting Started with Oracle Analytics Cloud*
- *User's Guide for Oracle Analytics Desktop*

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
`monospace`	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Overview

- What's New for Oracle Autonomous Database Serverless
  Here's a summary of the noteworthy Oracle Autonomous Database additions and enhancements.
- About Autonomous Database
  Provides information about Autonomous Database features, workload types, and regions.
- Get Help, Search Forums, and Contact Support
  When you use Oracle Autonomous Database, sometimes you need to get help from the community or to talk to someone in Oracle support. This topic provides more information about getting help by viewing and posting questions on forums and using Oracle Cloud Support to create a support request.
- Service Level Objectives (SLOs)
  Describes the Service Level Objectives (SLOs) for Oracle Autonomous Database Serverless.
- How Is Autonomous Database Billed?
  Provides details for Autonomous Database billing.
- Always Free Autonomous Database
  You have the option to create a limited number of Always Free Autonomous Databases that do not consume cloud credits. Always Free databases can be created in Oracle Cloud Infrastructure accounts that are in a trial period, have paying status, or are always free.
- Autonomous Database for Developers
  Autonomous Database for Developers provides you with low cost instances for developers and others to build and test new Autonomous Database applications.

What's New for Oracle Autonomous Database Serverless

Here's a summary of the noteworthy Oracle Autonomous Database additions and enhancements.

July 2025

Feature	Description
Oracle Cloud Infrastructure Redwood UI	Oracle Cloud Infrastructure (OCI) has introduced new designs in the Oracle Cloud Console to enhance usability and consistency across services and experiences. See Get to Know the Console for more information.
Documentation Addition: Best Practices for Application Availability During Maintenance	Autonomous Database patches are applied during a scheduled maintenance window as rolling patches. Using rolling patches, your Autonomous Database instance is made available on new cluster nodes before patching starts on the original nodes where it was running. After the database is available on new cluster nodes, all new connections are directed to the new nodes. This means the database remains online and available during maintenance and new database connection requests will succeed during the maintenance window. See Best Practices to Maintain Application Availability During Maintenance Windows for more information.

June 2025

Feature	Description
Elastic Pool Support for Child Tenancies	You can combine Organization Management with the benefits of elastic pools. If your organization uses the parent/child tenancy model you can apply elastic pool cost savings by using an elastic pool that spans parent and child tenancies. In this way an elastic pool can operate across tenancies, where the elastic pool leader is in the parent tenancy and the elastic pool member is in a child tenancy. See "Use Elastic Pools with Oracle Cloud Infrastructure Organization Management (Parent and Child Tenancies)" in About Elastic Pools for more information.
Table Hyperlink Network Access Checking with ACLs	You can generate a Table Hyperlink with ACL checking enabled. When you generate a Table Hyperlink and you enable ACL checking, Table Hyperlink data is only accessible to a consumer database after the incoming request's IP address is validated based on the ACLs defined on the producer database. See Generate, List, Invalidate, and Monitor Table Hyperlinks for more information.
Send Notifications to an OCI Notifications Service Topic	You can send messages from Autonomous Database to an OCI Notifications service topic. See Send Messages to OCI Notifications Service from Autonomous Database for more information.
Critical and Information Events with Event Category	Critical events and Information events include an event category attribute. Optionally you can subscribe to events and add an event category to receive notifications about events in a category, or to perform other types of automation for events by event type and event category. The event categories are: Incident, Maintenance, Performance, Security, and Other. See Use Autonomous Database Events for more information.

Feature	Description
Data Studio Enhancements:	The Data Studio is updated with new features and changes: • **Use SQL Syntax to Query Remote Catalogs**: You can access external data by mounting catalogs and querying them using a simplified SQL syntax. This capability enables you to discover and analyze external data effortlessly. See Query Remote Catalogs and Databases for more information. • **Use Table Hyperlinks to Access Data using Spreadsheet Add-ins**: You can read and access data with a Table Hyperlink in a MS Excel Sheet using Oracle Autonomous Database Add-in for Excel. See Read and Access Data Using Table Hyperlinks in Excel Sheet for more information.
Select AI Enhancements	Select AI includes the following new features: • Select AI enables you to add table comments to the metadata of the LLM for a better SQL generation. You can achieve this by specifying `comments` to *true* in your AI profile. See "*Example: Improve SQL Generation with Table and Column Comments*" in Example: Improve SQL Query Generation. • Select AI integrates annotations in Oracle Database 23ai by adding it to the metadata that is sent to the LLM. You can achieve this by specifying `annotations` to *true* in your AI profile. See "*Example: Improve SQL Query Generation with Table and Column Annotations*" in Example: Improve SQL Query Generation • Select AI adds foreign key and referential key constraints into the metadata of the LLM to generate accurate `JOIN` conditions. You can achieve this by specifying `constraints` to *true* in your AI profile. See "*Example: Improve SQL Query Generation with Foreign Key and Referential Key Constraints*" in Example: Improve SQL Query Generation.
Cross-region Standby can be an Elastic Pool Member or an Elastic Pool Leader	A cross-region standby can be added to an elastic pool or can be an elastic pool leader. Elastic pools do not operate across regions; when a cross-region standby is added to an elastic pool, the primary and the standby cannot be in the same elastic pool. See Use and Manage Elastic Pools on Autonomous Database for more information.
Google Drive Support for Database Links with Oracle-Managed Heterogeneous Connectivity	Use Autonomous Database Oracle-managed heterogeneous connectivity to create database links to Google Drive. When you use database links with Oracle-managed heterogeneous connectivity, Autonomous Database configures and sets up the connection. See Create Database Links to Non-Oracle Databases with Oracle-Managed Heterogeneous Connectivity for more information.
Built-in Tools Billing and Default Configuration Changes	In the ECPU compute model, the built-in database tools that use a VM, including: OML, Graph Studio, and Data Transforms have default configuration changes and billing changes. See About Configuring Built-in Tools Compute Resources and Limits and Oracle Autonomous Database Serverless Billing for Database Tools for more information.
Elastic Pool Cost and Usage Information in Cost Reports	Elastic pool cost and usage details are recorded in the Oracle Cloud Infrastructure cost reports and in the `OCI_COST_DATA` view. See About Elastic Pool Billing and Compute Models in Autonomous Database for more information.

Feature	Description
Offload Queries from Elastic Pool Member to Member Refreshable Clones: Includes Queries from PL/SQL and from Oracle Scheduler Jobs	When you have heavy read workloads, where a relatively small amount of data is scanned by multiple queries, including from PL/SQL or from Oracle Scheduler Jobs, you can offload queries (reads) from either an elastic pool leader or from an elastic pool member to Refreshable Clones. See Offload Queries to Member Refreshable Clones for more information.
Data Transforms Enhancements	Data Transforms is updated with new features and changes in the following areas: • Extract data from Oracle Enterprise Resource Planning (ERP) Cloud using BI Publisher You can now use the Oracle ERP Cloud connector to create a connection to the Business Intelligence (BI) Publisher server and load data from BI Publisher reports to Autonomous Database. You can use this as an alternate method to extract ERP data when BICC based extract is not sufficient. See Create an Oracle Enterprise Resource Planning Cloud Connection. • Load Data to Apache Iceberg tables Data Transforms includes support for Apache Iceberg as a target to load data from SQL-based data sources. See Create an Apache Iceberg Connection. • Settings button on the Data Load Detail page The options under Advanced Options have moved into a separate window. Click the Settings button to use these options in addition to a few more. .

May 2025

Feature	Description
Remove OCPU Compute Model Option for Data Warehouse and Transaction Processing Workloads During Provisioning or Cloning	The OCPU compute model option is removed when you provision or clone a new Autonomous Database instance with Data Warehouse or Transaction Processing workloads. See Oracle Support Document 2998742.1 for more information.
Support Zstd Compression in `DBMS_CLOUD`	`DBMS_CLOUD` supports loading and querying data using external tables as well as exporting and importing of data from Autonomous Database to object storage. `DBMS_CLOUD` supports Zstd (Zstandard) format for compression or decompression. See DBMS_CLOUD Package Format Options and DBMS_CLOUD Package Format Options for EXPORT_DATA for more information.
Specify Default Bind Variables in Table Hyperlinks	You can specify default values for one or more bind variables in a SQL statement when the `default_bind_values` parameter is included with `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL`. See Generate a Table Hyperlink with a Select Statement and Use Table Hyperlink to Access Data for more information.

Feature	Description
Select AI Enhancements	Select AI includes the following new features: • Select AI automatically detects relevant tables and sends metadata only for those specific tables, relevant to the query, in Oracle Database 23ai. You can achieve this by specifying `object_list_mode` as *automated*. See "*Automatically Detect Relevant Table Metadata*" in Example: Improve SQL Query Generation. • Select AI enables you to restrict table access by considering only the tables listed in the AI profile attributes for SQL generation. You can achieve this by specifying `enforce_object_list` to *true*. See Example: Restrict Table Access in AI Profile. • Select AI enables you to specify case sensitivity such that the LLM produces case-insensitive responses from the database and LLM. You can achieve this by specifying `case_sensitive_values` to *false*. See Example: Specify Case Sensitivity for Columns. • Administrators can control data access such that actual schema tables are not sent to the LLM using Select AI. See ENABLE_DATA_ACCESS Procedure, DISABLE_DATA_ACCESS Procedure, and Example: Enable or Disable Data Access.
Use In-database Transformer Model with Select AI RAG	You can use in-database transformers (also known as embedding models) that you imported into your Oracle Database 23ai instance with Select AI RAG to generate vector embeddings for document chunks and user prompts. See Use In-database Transformer Models and Example: Select AI with In-database Transformer Models to explore this feature.

Feature	Description
Data Transforms Updates	Data Transforms is updated with new features and changes in the following areas: • Run Data Studio Data Load using Data Transforms workflows You can now define a Data Studio Data Load in a Data Transforms workflow and then execute that data load as part of a Data Flow. You can then schedule the workflow to replay the Data Studio Data Load to capture any updates made to the files and load it into Autonomous Database. See Define a Data Studio Data Load in a Work Flow for more information about how you can run a Data Studio Data Load in Data Transforms. • Vector Embeddings in Data Flows Data Transforms now supports the integration of vector embeddings in a data flow using the Oracle Cloud Infrastructure (OCI) Generative AI service. Note that you need to have an Oracle Database 23ai connection to use this feature. For more information, see Use Text Embedding Vector in a Data Flow. • Use Machine Learning (ML) models in Data Flows Data Transforms now includes a new data entity type called ML Model. You can use ML Models in a data flow to apply prediction logic on source data and store the output in a target server. See Machine Learning (ML) Models for more information. • Set Custom Variable Value at Runtime For data flows and workflows that include variables as part of the flow, when you run the data flow or workflow you can choose to use the default value, the refresh value, or set a custom value at runtime to use for the current run. See Use Variables in a Data Flow and Use Variables in a Workflow for more information. • Show Queued/Waiting Jobs The Show Queued/Waiting Jobs option helps improve the overall performance when fetching the list of records to display on the Jobs page. See the Search for a Job section in Create and Manage Jobs for more information.

April 2025

Feature	Description
Data Studio Enhancements	The Data Studio is updated with new features and changes: • **The Autonomous Database Federated Database Catalog Enhancements**: You can connect multiple catalogs to make it easier to find and work with your data, including popular Iceberg Data Catalogs like Unity and Polaris. You can also link to remote Autonomous Database instances using Database Links, allowing you to query tables from those databases directly within your catalog — helping you get more from your data catalog without extra steps. One of the major improvements in the Federated Catalog is the ability to easily load a Delta Share directly from the Catalog tool itself — no need to switch to a separate data loading tool. See Inline Data Load of Delta Share from the Catalog Tool for more details. • **The Oracle Autonomous Database for Excel Add-in** can now be installed from the Microsoft Store. See Install the add-in from Microsoft AppSource for more details. • **UX Improvements for AI Table Assistant** - The Table AI Assist tool includes the ability to edit recipes, has auto-save of recipes, UX improvements such as showing new column header in italics. See The Table AI Assist Tool for more details. • **Live Feed Reporting enhancements**: Using the existing Simple Mail Transfer Protocol (SMTP) email registration setup in the Live Feed, you receive email when: – New rows are added: You receive email notifications when Live Feed runs and loads your table with new data. – Data Validation Issues Occur: You receive email notifications when inconsistencies arise, such as when the tool attempts to load non-numeric values into a numeric field. – Live Feed throws an Error: You receive email notifications if errors occur such as when the bucket containing your files is deleted or your credential for that bucket was dropped. See Send Email using Live Feed Tool for more details.
Long Pending Transaction Event	The `LongPendingTransaction` event is generated when a transaction is open for longer than 24 hours. See Information Events on Autonomous Database for more information.
Recovery Time Objective (RTO) for a Cross-region Autonomous Data Guard Standby	The Recovery Time Objective (RTO) for cross-region Autonomous Data Guard Standby databases is lowered to less than ten (10) minutes. See Autonomous Data Guard Recovery Time Objective (RTO) and Recovery Point Objective (RPO) for more information.
Documentation Addition: Automatic Regression Detection	Automatic Regression Detection in Autonomous Database provides proactive handling of regressions and enables automated issue detection, diagnosis, and mitigation. See About Scheduled Maintenance and Patching for more information.
Average Active Sessions and Session Utilization Metrics	The `AverageActiveSessions` metric shows the average number of sessions that are actively executing or waiting for resources. The `SessionUtilization` metric shows the maximum session utilization. See Available Metrics: oci_autonomous_database for more information.

Feature	Description
Credential Comments in `DBMS_CLOUD.CREATE_CREDENTIAL`	The `DBMS_CLOUD.CREATE_CREDENTIAL` procedure supports comments when you use the `comments` parameter. See Create Credentials to Access Cloud Services and CREATE_CREDENTIAL Procedure for more information.
Migration from PostgreSQL, MySQL, or SQL Server to Oracle SQL	You can migrate SQL statements from PostgreSQL, MySQL, or SQL Server, to Oracle SQL and run the statements on Autonomous Database. See Migrate Applications from Non-Oracle SQL to Oracle SQL for more information.
Documentation Change: Pre-Authenticated Request (PAR) URLs Renamed to Table Hyperlinks	You can generate and manage Table Hyperlinks to access data on Autonomous Database. See Use Table Hyperlinks for Read Only Data Access on Autonomous Database for more information.
Additional File Types Supported for Select AI RAG Vector Index Creation	Select AI Retrieval Augmented Generation (RAG) supports multiple file formats, including PDF, DOCX, JSON, XML, and HTML, among others. For more information, see Select AI with Retrieval Augmented Generation (RAG) and, for the complete list of supported file formats, Build your Vector Store.

March 2025

Feature	Description
Elastic Pool with Any Workload Leader	When you create an elastic pool, the workload type of the leader is not restricted. The workload type of an elastic pool leader can be one of: Transaction Processing, Data Warehouse, JSON, or APEX. See About Elastic Pools and About Autonomous Database Workload Types for more information.
SQL Parse Error Warning Event: `SQLParseErrorWarning`	If a SQL parse error occurs several times in a certain time window, for example 200 times or more in an hour, this generates "`Too Many Parse Errors`" entries in the alert log. The `SQLParseErrorWarning` event is triggered when there is a new entry in the alert log, indicating that a SQL statement has too many parse errors. For example, when an invalid query runs 200 times in less than an hour, this triggers the `SQLParseErrorWarning` event. See Information Events on Autonomous Database for more information.
Create Refreshable Clone with 19c Source and 23ai Refreshable Clone	When you create a refreshable clone from an Oracle Database 19c source, you can select Oracle Database 23ai for the refreshable clone. You can use the refreshable clone to test your database on Oracle Database 23ai. After your testing is complete, you can disconnect the refreshable clone to upgrade to Oracle Database 23ai. See Upgrade an Autonomous Database Instance to Oracle Database 23ai and Create a Refreshable Clone for an Autonomous Database Instance for more information.
Offload Queries from Elastic Pool Leader to Member Refreshable Clones: Includes Queries from PL/SQL and from Oracle Scheduler Jobs	When you have heavy read workloads, where a relatively small amount of data is scanned by multiple queries, including from PL/SQL or from Oracle Scheduler Jobs, you can offload queries (reads) from an elastic pool leader to Refreshable Clones. See Offload Queries to Member Refreshable Clones for more information.

Feature	Description
Connections Dropped Metrics	The `ConnectionsDroppedByClient` metric shows the sum of the number of connections dropped by the client. The `ConnectionsDroppedByServer` metric shows the sum of the number of connections dropped by the server. See Available Metrics: oci_autonomous_database for more information.
Oracle APEX 24.2	Autonomous Database uses Oracle APEX Release 24.2. See Create Applications with Oracle APEX in Autonomous Database for more information.
Data Studio Enhancements	The Data Studio is updated with new features and changes: • The Table AI Assist Tool: The Data Studio suite of tools now features an AI-powered Table Assist Tool to effortlessly enhance your local data tables with the power of AI. You can use natural language prompts to augment and correct your information with this tool. See The Table AI Assist Tool for more information. • Catalog Tool Enhancements: The new multi-catalog capabilities of the Autonomous Database catalog mean you can add catalogs to enable data search, discovery and use across a wide range of external systems, including other Autonomous Databases, on-premises databases, cloud storage systems, shared data, and other data catalogs such as Oracle Cloud Infrastructure Data Catalog and AWS Glue. See The Catalog Tool for more information. • The Data Marketplace Tool: Using Data Studio Marketplace, Autonomous Database users can easily collaborate by sharing data with other users of the same or another Autonomous Database. Data providers publish data sets in just minutes, no coding required. Data consumers can browse available data sets, and query live data or copy it to their own Autonomous Database Instance. See The Data Marketplace Tool for more information. • Data Load Livefeed Enhancements: – With the new Basic mode, creating a Livefeed is as simple as selecting a folder from a drop-down menu. – New ability to use Merge semantics in livefeeds. The Livefeed feature automatically updates existing data in your tables with new information, eliminating redundant rows and ensuring data integrity. – With newly introduced **Show code** icon, you can view the underlying SQL code behind your livefeeds and even run the code manually in the SQL worksheet. See Feeding Data for more information.
Documentation Addition: Migrate Existing SQL Execution Plans to Autonomous Database	You can use Real-time SQL Plan Management when you migrate from a source Oracle Database to Autonomous Database. See Migrate Existing SQL Execution Plans to Autonomous Database to Mitigate the Risk of SQL Performance Regressions for more information.

February 2025

Feature	Description
Offload Queries from Elastic Pool Leader to Member Refreshable Clones	When you have heavy read workloads, where a relatively small amount of data is scanned by multiple queries, you can offload queries (reads) from an elastic pool leader to Refreshable Clones. See Offload Queries to Member Refreshable Clones for more information.
Create External Tables Over PAR URLs	You can create an external table over Pre-Authenticated Request (PAR) URLs. See Query Data that Uses Table Hyperlink Source for more information.
Update Cloud Links Registrations	With Cloud Links, a data owner registers a table or view for remote access for a selected audience as defined by the data owner, and the data is then accessible to those with access granted at registration time. After you register a data set you can update data set attributes. See Update Data Set Registration Attributes for more information.
Database User Password Warning Event: `DatabaseUserPasswordWarning`	The database user password warning event provides a message that the Autonomous Database user password is expiring within the specified grace period (default 30 days) or has already expired. See Critical Events on Autonomous Database for more information.

January 2025

Feature	Description
Documentation Addition: Create and Use Custom Metrics	You can create custom metrics to collect, publish, and analyze metrics. A custom metric collects specified data from your Autonomous Database instance and publishes the data to the OCI Monitoring service using a REST API provided by the OCI SDK. See Use Custom Metrics on Autonomous Database for more information.
Disconnect a Peer Database	You can disconnect an Autonomous Data Guard standby or a Backup-Based Disaster Recovery peer. When you disconnect a cross-region peer, the database is permanently disassociated from the Primary database. This converts the database from a peer database to a standalone database. See Disconnect a Peer Database for more information.
Change Patch Level After Provisioning	When you provision or clone an Autonomous Database instance you can select a patch level to apply to upcoming patches. You can also change the patch level after an Autonomous Database instance is provisioned. There are two patch level options: **Regular** and **Early**. See Set the Patch Level for more information.
Service Name Mapping for Cloud Links Consumers	You can set the service name mapping to use when Cloud Links consumers access data from a data set owner. See Set Database Service Name Mapping for Cloud Links Consumers for more information.

Feature	Description
External Tables with ORC, Parquet, and Avro Provide an Option to Set Size of String Columns	When you access ORC, Parquet, or Avro data stored in object store using external tables, you can either automatically or explicitly set the maximum size of text columns. By default the text column size is set based on the value of `MAX_STRING_SIZE`. See Query External Data with ORC, Parquet, or Avro Source Files and Explicitly Set the Text Column Size for more information.
Invoke Google Cloud Platform Cloud Run Functions	You can invoke Google Cloud Platform Cloud Run functions as SQL functions. See Steps to Invoke Google Cloud Run Functions as SQL Functions for more information.

About Autonomous Database

Provides information about Autonomous Database features, workload types, and regions.

- What is Oracle Autonomous Database?
  Autonomous Database provides an easy-to-use, fully autonomous database that scales elastically and delivers fast query performance. As a service, Autonomous Database does not require database administration.
- Key Features of Autonomous Database
  Provides information on key features of Autonomous Database, an affordable, feature-rich service in the cloud.
- About Autonomous Database Workload Types
  Autonomous Database supports different workload types, including: Data Warehouse, Transaction Processing, JSON Database, and APEX Service. Each of these workload types provides performance improvements and additional features that support operations for the specified workload.
- Autonomous Database Region Availability
  Describes availability information for Autonomous Database in commercial regions and government cloud regions.

What is Oracle Autonomous Database?

Autonomous Database provides an easy-to-use, fully autonomous database that scales elastically and delivers fast query performance. As a service, Autonomous Database does not require database administration.

With Autonomous Database you do not need to configure or manage any hardware or install any software. Autonomous Database handles provisioning the database, backing up the database, patching and upgrading the database, and growing or shrinking the database. Autonomous Database is a completely elastic service.

At any time you can scale, increase or decrease, either the compute or the storage capacity. When you make resource changes for your Autonomous Database instance, the resources automatically shrink or grow without requiring any downtime or service interruptions.

Autonomous Database is built upon Oracle Database, so that the applications and tools that support Oracle Database also support Autonomous Database. These tools and applications connect to Autonomous Database using standard SQL*Net connections. The tools and applications can either be in your data center or in a public cloud. Oracle Analytics Cloud and other Oracle Cloud services provide support for Autonomous Database connections.

Autonomous Database provides the following:

- **Increase your app development velocity**: Build and deploy quickly on unified platform supporting vector, JSON, graph, and more. Leverage scalable, cost-effective solutions with flexible cloud, multi-cloud, or on-premises deployment, advanced security, and self-service tools.
- **Fully automated database service**: Supports all modern Oracle data types, workloads including transaction processing, AI and analytics, reducing the need for multiple specialty databases.
- **Maximizes data security and availability**: With Oracle's automation services, you can keep your mission critical applications running by leveraging 99.995% availability.
- **Allows you to bring AI to your data**: Use LLMs with built-in AI Vector Search and your proprietary data to get more accurate answers. There’s no need to duplicate data to a separate vector database.

Autonomous Database also includes the following:

- **Oracle APEX**: a low-code development platform that enables you to build scalable, secure enterprise apps with world-class features.

  See About Oracle APEX for more information.
- **Oracle REST Data Services (ORDS)**: a Java Enterprise Edition based data service that makes it easy to develop modern REST interfaces for relational data and JSON Document Store.

  See Developing RESTful Services in Autonomous Database for more information.
- **Database Actions**: is a web-based interface that uses Oracle REST Data Services to provide development, data tools, administration, and monitoring features for Autonomous Database.

  See About Database Actions for more information.
- **Oracle Machine Learning**: is a set of components supporting data scientists, ML engineers, and data analysts, as well as SQL, R, and Python users. Components include SQL, R, and Python APIs, a built-in notebook interface, and no-code interfaces for AutoML, data and model monitoring, and model deployment, along with model management, deployment, and monitoring via REST endpoints.

  See Oracle Machine Learning for more information.

Key Features of Autonomous Database

Provides information on key features of Autonomous Database, an affordable, feature-rich service in the cloud.

Key Features

- **Managed**: Oracle simplifies end-to-end management of the database:
  - Provisioning new databases
  - Growing or shrinking storage and compute resources
  - Patching and upgrades
  - Backup and recovery
- **Fully elastic scaling**: Scale compute and storage independently to fit your database workload with no downtime:

  - Size the database to the exact compute and storage required
  - Scale the database on demand: Independently scale compute or storage
  - Shut off idle compute to save money
- **Auto scaling**: Allows your database to use more CPU and IO resources or to use additional storage automatically when the workload or storage demand requires additional resources:
  - Specify the number of CPUs for your Autonomous Database workload.
  - Use compute auto scaling to allow the database to use up to three times more CPU and IO resources, depending on workload requirements. Compute auto scaling is enabled by default when you create an Autonomous Database.
  - Use storage auto scaling to allow the database to expand to use up to three times the reserved base storage, depending on your storage requirements. Storage auto scaling is disabled by default when you create an Autonomous Database.
  - Manage auto scaling from the Oracle Cloud Infrastructure Console to enable or disable compute auto scaling or storage auto scaling for your Autonomous Database.
- **Autonomous Database supports**:
  - Existing applications, running in the cloud or on premises
  - Connectivity via SQL*Net, JDBC, ODBC

    See Connect to Autonomous Database for more information.
  - Third-party data-integration tools
  - Oracle cloud services: Oracle Analytics Cloud, Oracle GoldenGate Marketplace, and others
- **High-performance queries and concurrent workloads**: Optimized query performance with preconfigured resource profiles for different types of users.
- **Oracle SQL**: Autonomous Database is compatible with existing applications that support Oracle Database.
- **Built-in web-based data analysis tool**: Web-based notebook tool for designing and sharing SQL based data-driven, interactive documents.
- **Database migration utility**: Easily migrate from MySQL, Amazon AWS Redshift, PostgreSQL, SQL Server, and other databases.

Simple Cloud-based Data Loading

Autonomous Database provides:

- Fast, scalable data-loading from Oracle Cloud Infrastructure Object Storage, Azure Blob Storage or Azure Data Lake Storage, Amazon S3, Amazon S3-Compatible, GitHub Repository, Google Cloud Storage, or on-premises data sources.

Oracle Database Actions

Database Actions is a web-based interface that uses Oracle REST Data Services to provide development, data tools, and administration and monitoring features for Autonomous Database, including the following:

- **Development Tools**
  - SQL Navigator and Worksheet: view objects and enter and run SQL and PL/SQL statements, and create database objects

  - Data Modeler: provides an integrated version of Oracle SQL Developer Data Modeler with basic reporting features. You can create diagrams from existing schemas, retrieve data dictionary information, generate DDL statements, and export diagrams
  - REST: An IDE for your REST APIs that enables you to manage templates, handlers and OAuth clients, generate API documentation, and test APIs.
  - LIQUIBASE: View ChangeLogs applied to your schema.
  - JSON: Create collections, upload documents, query and filter your data, create diagrams for your JSON document structures, and create relational views and indexes.
  - Charts: Use SQL queries to build rich charts and dashboards containing multiple charts.
  - Scheduling: An interface for `DBMS_SCHEDULER` that enables you to monitor jobs, view execution history, forecast upcoming jobs, and visualize scheduler chains.
  - Oracle Machine Learning: provides several components accessible through a common user interface. OML Notebooks supports Python, R, SQL, PL/SQL, and Markdown interpreters, with access to in-database ML through OML4Py, OML4R, and OML4SQL. OML Models supports managing and deploying in-database models. OML AutoML UI provides a no-code user interface to build, evaluate, and deploy in-database models using automated machine learning.
  - APEX: Login to APEX, develop and run rich, low-code web applications.
  - Graph Studio: Oracle Graph Studio lets you create property graph databases and automates the creation of graph models and in-memory graphs from database tables.
- **Data Studio**
  - Data Load: load or access data from local files or remote databases.
  - Catalog: understand data dependencies and the impact of changes.
  - Data Insights: discover anomalies, outliers and hidden patterns in your data.
  - Data Analysis: analyze your data
  - Data Transforms: transform data for analysis and other applications.
- **Administration and Monitoring**
  - Manage users
  - Database Dashboard: Monitor database activity charts such as CPU usage, number of executing SQL statements, and wait events formerly found on your Autonomous Database Service Console.
  - Performance Hub: Access SQL Monitoring reports and Active Session History (ASH) Analytics.

Disaster Recovery Options

Autonomous Data Guard Autonomous Database provides Autonomous Data Guard to enable a standby (peer) database to provide data protection and disaster recovery for your Autonomous Database instance.When you add an Autonomous Data Guard standby database, the system creates a standby database that continuously gets updated with the changes from the primary database. You can use Autonomous Data Guard with a standby in the current region, a local standby, or with a standby in a different region, a cross-region standby. You can also use Autonomous Data Guard with both a local standby and a cross-region standby.

Backup-Based Disaster Recovery uses backups to instantiate a peer database at the time of switchover or failover. This enables you to have a lower cost and higher Recovery Time

Objective (RTO) disaster recovery option for your Autonomous Database, as compared with Autonomous Data Guard. For local backup-based disaster recovery, existing local backups are utilized. There are no additional costs for a local Backup-Based Disaster Recovery. Cross-Region Backup-Based Disaster Recovery incurs an additional cost.

SQL Developer Support

Using Autonomous Database with SQL Developer you can do the following:

- Connect to Autonomous Database
- Create tables, indexes, and materialized views in Autonomous Database
- Load data into an Autonomous Database
- Copy tables to Autonomous Database
- Transfer a schema to Autonomous Database

Business Intelligence Tools Support

Autonomous Database is compatible with a number of business intelligence and data visualization tools from Oracle and from trusted third parties:

- Oracle Analytics Cloud
- Oracle Analytics Desktop
- Third-party Business Intelligence tools

About Autonomous Database Workload Types

Autonomous Database supports different workload types, including: Data Warehouse, Transaction Processing, JSON Database, and APEX Service. Each of these workload types provides performance improvements and additional features that support operations for the specified workload.

- About Oracle Autonomous Data Warehouse
  Autonomous Database is designed as a "load and go" service: you start the service, define tables, load data, and then run queries.
- About Oracle Autonomous Transaction Processing
  Autonomous Database is designed to support all standard business applications and deliver scalable query performance.
- About Autonomous JSON Database
  Oracle Autonomous JSON Database is Oracle Autonomous Transaction Processing, but designed for developing NoSQL-style applications that use JavaScript Object Notation (JSON) documents. You can promote an Autonomous JSON Database service to an Autonomous Transaction Processing service.
- About Oracle APEX Application Development
  Oracle APEX Application Development (APEX Service) is a low cost, Oracle Cloud service offering convenient access to the Oracle APEX platform for rapidly building and deploying low-code applications.

About Oracle Autonomous Data Warehouse

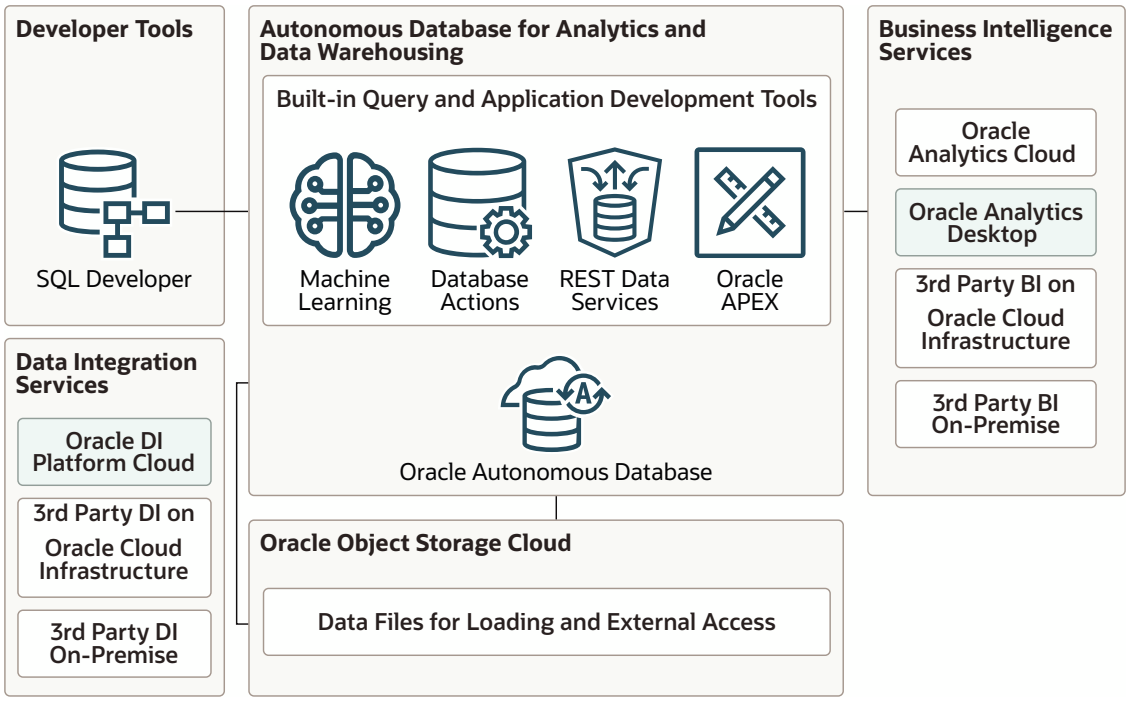
Autonomous Database is designed as a "load and go" service: you start the service, define tables, load data, and then run queries.

Autonomous Database is designed to support all standard SQL and business intelligence (BI) tools, and provides all of the performance of the market-leading Oracle Database in an environment that is tuned and optimized for data warehouse workloads.

To get started you create an Autonomous Database with workload type Data Warehouse and specify the number of ECPUs and the storage capacity in TB's for the Autonomous Database.

You can use Autonomous Database with Oracle Analytics Cloud or Oracle Analytics Desktop to easily create visualizations and projects that reveal trends in your company's data and help you answer questions and discover important insights about your business.

The following figure shows the Autonomous Database architecture with related components for analytics and data warehousing.



About Oracle Autonomous Transaction Processing

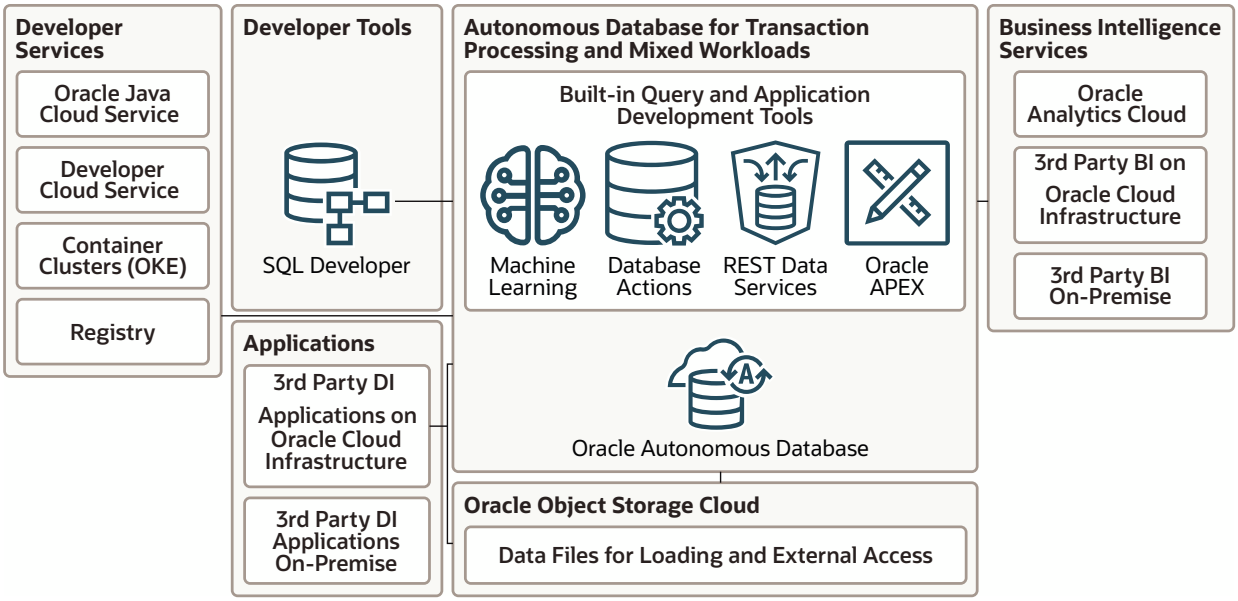
Autonomous Database is designed to support all standard business applications and deliver scalable query performance.

Autonomous Database provides all of the performance of the market-leading Oracle Database in an environment that is tuned and optimized to meet the demands of a variety of applications, including: mission-critical transaction processing, mixed transactions and analytics, IoT, and JSON document store.

To get started you create an Autonomous Database with the workload type Transaction Processing and specify the number of ECPUs and the storage capacity for the database.

You can use Autonomous Database with Oracle Analytics Cloud or Oracle Analytics Desktop to easily create visualizations and projects that reveal trends in your company's operational data and help you answer questions and discover important insights about your business.

The following figure shows the Autonomous Database architecture with related components for transaction processing and mixed workloads.



About Autonomous JSON Database

Oracle Autonomous JSON Database is Oracle Autonomous Transaction Processing, but designed for developing NoSQL-style applications that use JavaScript Object Notation (JSON) documents. You can promote an Autonomous JSON Database service to an Autonomous Transaction Processing service.

Oracle Autonomous JSON Database provides all of the same features as Autonomous Transaction Processing, with this *important limitation*: you can store only up to 20 GB of data other than JSON document collections. There is no storage limit for JSON collections.

Development of NoSQL-style, document-centric applications is particularly flexible because the applications use *schemaless* data. This lets you quickly react to changing application requirements. There's no need to normalize the data into relational tables, and no impediment to changing data structure or organization at any time, in any way. A JSON document has internal structure, but no relation is imposed on separate JSON documents.

With Oracle Autonomous JSON Database your JSON document-centric applications typically use Simple Oracle Document Access (SODA), which is a set of NoSQL-style APIs for various application-development languages and for the representational state transfer (REST) architectural style. You can use any SODA API to access any SODA collection.

SODA document collections are backed by ordinary database tables and views. To use other kinds of data, subject to the 20 GB limit, you typically need some knowledge of Structured Query Language (SQL) and how that data is stored in the database.

With Oracle Autonomous JSON Database, a SODA collection *can only contain JSON data*. For example, you cannot have a collection of image documents or a collection that contains both JSON documents and image documents. This is a limitation relative to Autonomous Transaction Processing, where you can define such heterogeneous collections.

No matter what kind of data your applications use, whether JSON or something else, you can take advantage of all Oracle Database features. This is true regardless of the kind of Oracle Autonomous Database you use.

JSON data is stored natively in the database. In a SODA collection on an Autonomous Database JSON data is stored in Oracle's native binary format, OSON.

About Oracle APEX Application Development

Oracle APEX Application Development (APEX Service) is a low cost, Oracle Cloud service offering convenient access to the Oracle APEX platform for rapidly building and deploying low-code applications.

APEX Service is designed to support all standard business applications and deliver scalable query performance. You can promote APEX Service to Autonomous Transaction Processing service.

See Oracle APEX Application Development and Upgrade APEX Service to Autonomous Transaction Processing for more information.

Autonomous Database Region Availability

Describes availability information for Autonomous Database in commercial regions and government cloud regions.

Commercial Regions and Availability Domains

Autonomous Database is available in all regions of the commercial realm.

Government Cloud

See Oracle Cloud Infrastructure Government Cloud for information about availability in Government Cloud regions.

Get Help, Search Forums, and Contact Support

When you use Oracle Autonomous Database, sometimes you need to get help from the community or to talk to someone in Oracle support. This topic provides more information about getting help by viewing and posting questions on forums and using Oracle Cloud Support to create a support request.

- Post Questions on Forums
  If you can't find an answer to a question through search, you can submit a question to one of the forums. This option is available to all customers.
- Open a Support Ticket to Create a Service Request
  If forums and other search options do not resolve your issue and you need to talk to someone, you can create a support request.
- Create a Service Request in My Oracle Cloud Support
- Register to My Oracle Cloud Support as a New User

Post Questions on Forums

If you can't find an answer to a question through search, you can submit a question to one of the forums. This option is available to all customers.

Cloud Customer Connect Forums

For any issue related to Autonomous Database or Oracle Cloud Infrastructure, you can post a question to Cloud Customer Connect:

- Autonomous Data Warehouse
- Autonomous Transaction Processing
- Oracle Cloud Infrastructure and Platform

Stack Overflow Knowledge Forum

If you are working with Autonomous Database and you have technical questions, you can use stackoverflow to post questions and to find answers or to help others answer their questions. When you post, tag your question with oracle-autonomous-db, as follows:

Questions tagged [oracle-autonomous-db]

Open a Support Ticket to Create a Service Request

If forums and other search options do not resolve your issue and you need to talk to someone, you can create a support request.

If you need to file a service request use Oracle Cloud Support or contact your support representative and provide the tenancy details. In addition to support for technical issues, you can open support requests if you need to:

Create a Support Ticket from Oracle Cloud Infrastructure Console

The first time you open a support ticket, you're automatically taken through a series of steps to provision your support account. If you want to make changes or if you run into problems, see Configuring Your Oracle Support Account.

To create a support request from the Oracle Cloud Infrastructure Console:

1. On the Oracle Cloud Infrastructure open the **Help** menu (?) and under **Request Help**, click **Create Support Request**.
2. Enter the following:
   - **Issue Summary**: Enter a title that summarizes your issue. Avoid entering confidential information.
   - **Describe Your Issue**: Provide a brief overview of your issue.
     - Include all the information that support needs to route and respond to your request.
       See Obtain Tenancy Details for details on obtaining Autonomous Database information.
     - Include troubleshooting steps taken and any available test results.
   - Select the severity level for this request.
3. Click **Create Support Request.**

Create a Service Request in My Oracle Cloud Support

If you are having a technical issue using Oracle Autonomous Database, you can contact Oracle Support by creating a service request in My Oracle Cloud Support.

If you are an Oracle Commercial Cloud customer, and you need the ability to request support for a tenancy that your cloud administrator created *after November 8th, 2024*, then you need to sign into My Oracle Cloud Support using **Sign in with your commercial cloud account**, and enter the new tenancy credentials. If you are unsure about your tenancy credentials, please contact your cloud administrator.

> **Tip:**
>
> Before following these steps, sign in to your Oracle Cloud account at cloud.oracle.com in a separate browser tab or window so that you can quickly and easily get any information you need to complete your service request.

- Oracle Commercial Cloud customer
- Oracle Non-Commercial Cloud Customer

Oracle Commercial Cloud customer

If you are an Oracle Commercial Cloud customer and you know your cloud account login information:

1. Go to support.oracle.com.
2. Enter your *email address* and click **Next**.
   - If you see a message that your email address is not recognized, follow the instructions outlined in Register to My Oracle Cloud Support as a New User.
   - If your email is registered with Oracle Support, you'll be directed to sign in to the applicable support portal for your products and services. Continue with step 3.
3. Click **Sign in with your commercial cloud account**.
4. Enter your *OCI credentials* (Tenancy, domain if applicable, username, and password).

   If this is your first time signing in to My Oracle Cloud Support, you will be prompted to associate your cloud account to My Oracle Cloud Support by verifying your email.
5. Accept the **Terms of Use**.
6. Complete your **personal Info**.
   - For **Security Pin**, enter a 6 digit number not starting with a 0. When you call Oracle support line, you will be asked to provide this pin.
   - If this is the first time you are filling the **personal Info**, you may have to verify your **Mobile Phone** using a one-time password sent to your mobile number.
7. Click **Save** an you will be routed to the **My Oracle Cloud Support** portal.
8. To create a new service request, click **Create Service Request**.

9. Provide the details prompted on the **Create a new service request** page, clicking **Next**, as needed.
10. When you see **Proceed with the next step to submit the SR.**, click **Next**.

Oracle Non-Commercial Cloud Customer

If you are an Oracle Cloud customer and you do not have cloud account login information OR you have a non-commercial cloud account (government realm or dedicated realm):

1. Go to support.oracle.com.
2. Enter your *Oracle account username* and *password*.
3. If this your first time signing in to My Oracle Cloud Support, you will be prompted to accept the **Terms of use**, and complete your *personal profile*. Refer to Register to My Oracle Cloud Support as a New User for more details.
4. Once you get access to My Oracle Cloud Support, sign in to support.oracle.com.
5. You are routed to the **My Oracle Cloud Support** portal.
6. To create a new service request, click **Create Service Request**.
7. Provide the details prompted on the **Create a new service request** page, clicking **Next**, as needed.
8. When you see **Proceed with the next step to submit the SR.**, click **Next**.

> **Note:**
>
> If you are the first user logging in using a specific Subscription ID and Account name, you will be prompted to accept the Administrator role.

Register to My Oracle Cloud Support as a New User

- Oracle Commercial Cloud customer
- Oracle Non-Commercial Cloud Customer

Oracle Commercial Cloud customer

If you are an Oracle Commercial Cloud customer:

1. Go to support.oracle.com.
2. Enter your *email address* and click **Next**.
3. Click **Sign in** with your commercial cloud account.
4. Enter your *Tenancy*, then click **Continue**.

   If you do not know your tenancy information, please contact your cloud administrator.
5. Choose an **Identity domain** if applicable, then click **Next**.
6. Enter your *cloud account user name* and *password*.

7. Associate your cloud account to My Oracle Cloud Support by verifying your email.
8. Accept **Terms of Use**.
9. Complete your **personal Info**.
    - For **Security Pin**, enter a 6 digit number not starting with a 0. When you call Oracle support line, you will be asked to provide this pin.
    - If this is the first time you are filling the **personal Info**, you may have to verify your **Mobile Phone** using a one-time password sent to your mobile number.
10. You will be directed to the My Oracle Cloud Support profile page as an **approved user**.

Oracle Non-Commercial Cloud Customer

If you are an Oracle Cloud customer and you do not have cloud account login information OR you have a non-commercial cloud account (government realm or dedicated realm):

1. Click **Create an Oracle Account**.
2. In **Create Your Oracle Account**, provide the required information and click **Create Account**.
3. You will receive a verification email to enable your new account. Once your email has been verified, you will be prompted to log in with your newly created Oracle account username and password.
4. Enter *subscription ID* and *Account or Company name* to complete identity verification.

    Contact your Cloud administrator for the subscription ID and Account name.
5. Complete your **personal Info**.
    - For **Security Pin**, enter a 6 digit number not starting with a 0. When you call Oracle support line, you will be asked to provide this pin.
    - If this is the first time you are filling the **personal Info**, you may have to verify your **Mobile Phone** using a one-time password sent to your mobile number.
6. You will be directed to the My Oracle Cloud Support profile page as a **pending user**. If approval is not granted within a reasonable amount of time, contact your administrator. Once you are approved, you will have access to My Oracle Cloud Support.

> **Note:**
>
> The first user logging in using a Subscription ID and Account name will be prompted to accept the Admin or CUA role.

Service Level Objectives (SLOs)

Describes the Service Level Objectives (SLOs) for Oracle Autonomous Database Serverless.

- Recovery Time Objective and Recovery Point Objective
  Oracle Autonomous Database Serverless is engineered to return an application online following an unplanned outage or a planned maintenance activity within single-digit seconds.

- Built-In Tool Availability
  Oracle will use commercially reasonable efforts to have the following tools with a Monthly Uptime Percentage (Availability) objective as defined below, during the service commitment of a calendar month.
- Zero-Regression Service Level Objective
  Oracle Autonomous Database Serverless automatically applies patches on your database. Oracle provides a service level objective of zero regressions in your production database due to these patches.

Recovery Time Objective and Recovery Point Objective

Oracle Autonomous Database Serverless is engineered to return an application online following an unplanned outage or a planned maintenance activity within single-digit seconds.

The following table outlines the target Recovery Time Objective (RTO) SLOs for different failure events.

Event	Recovery Time Objective (RTO) Service Level Objective	Recovery Point Objective (RPO) Service Level Objective, Maximum Possible Data Loss
Events requiring failover to a standby database when Autonomous Data Guard is enabled, such as: • Data corruptions • Full database failures • Complete storage failures • Availability Domain or Region failures	With an Autonomous Data Guard standby: **Local Standby Database**: two (2) minutes **Cross-Region Standby Database:** less than ten (10) minutes See Autonomous Data Guard Recovery Time Objective (RTO) and Recovery Point Objective (RPO) for more information.	**Local Standby Database**: The maximum possible data loss objective is < 10 seconds **Cross-Region Standby Database:** The maximum possible data loss objective is 1 minute
Events requiring failover to a backup copy or restoring from a backup (when there is not an Autonomous Data Guard standby) such as: • Data corruptions • Full database failures • Complete storage failures • Availability Domain or Region failures	With Backup-Based Disaster Recovery, based on the size of the database: **Local backup copy**: 1 hour + (1 hour per 5 TB) **Cross-Region backup copy**: 1 hour + (1 hour per 5 TB) For example, a 5 TB database has a Recovery Time Objective (RTO) of up to 2 hours. See Backup-Based Disaster Recovery Recovery Time Objective (RTO) and Recovery Point Objective (RPO) for more information.	**Local backup copy**: The maximum possible data loss objective is < 10 seconds **Cross-Region backup copy**: The maximum possible data loss objective is 1 minute

Built-In Tool Availability

Oracle will use commercially reasonable efforts to have the following tools with a Monthly Uptime Percentage (Availability) objective as defined below, during the service commitment of a calendar month.

Oracle Autonomous Database Built-in Tool	Availability Service Level Objective
Oracle REST Data Services (ORDS)	99.95%
Oracle APEX (on Autonomous Database)	99.95%
Database Actions	99.95%
Graph Studio	99.95%
Oracle Machine Learning: • Oracle Machine Learning Notebooks • Oracle Machine Learning Services • Oracle Machine Learning for Python/R • Oracle Machine Learning AutoML User Interface	99.95%
Data Transforms	99.95%

The following terms apply to the Availability Service Level Objective for the Oracle Autonomous Database Built-in Tools listed in this table:

- “HTTP Error Rate” applies separately to each Database Built-in Tool and means the percentage value corresponds to: (i) the total number of failed HTTP calls made to the applicable tool with a status of “Bad Gateway” or “Service Unavailable” in a minute period during a calendar month, divided by (ii) the total number of HTTP calls made to the tool in a minute period.
- “Monthly Uptime Percentage” is calculated by subtracting from 100%, the average of the HTTP Error Rate for each minute period during the applicable calendar month.

Oracle Autonomous Database Built-in Tool	Availability Service Level Objective
Oracle Database API for MongoDB	99.95%

The following terms apply to the Availability Service Level Objective for Oracle Database API for MongoDB:

- A "Connection through Oracle Database API for MongoDB" is a direct connection established from any tool or application to the Cloud Service using Oracle Database API for MongoDB.
- “Monthly Uptime Percentage” is calculated by subtracting from 100%, the percentage of minutes during the calendar month in which the applicable Cloud Service was "Unavailable".
- “Unavailable” means a minute period when: (i) no connection through Oracle Database API for MongoDB is or can be established and (ii) all continuous attempts, at least five, to establish such a connection fail.

Zero-Regression Service Level Objective

Oracle Autonomous Database Serverless automatically applies patches on your database. Oracle provides a service level objective of zero regressions in your production database due to these patches.

Oracle Autonomous Database Serverless automatically applies patches containing bug and security fixes during the maintenance windows announced on your database console. When you provision your test or pre-prod database using the Early patch level option, you can test the patches on these instances before the patches are applied to your production database. If you see issues in your test or pre-prod database, you can file service requests to get the issues addressed before the patch is applied to your production database.

Oracle provides a service level objective of zero regressions in your production database. "Regression" in this document is described as issues introduced by patches or updates to the Autonomous Database performed during the maintenance window announced on your database console.

After a patch is applied to your database on the Early patch level, if you find and report an issue on that database through a service request, Oracle will use commercially reasonable efforts to address the problem so that the same issue does not occur in your production database.

See Set the Patch Level for more information.

How Is Autonomous Database Billed?

Provides details for Autonomous Database billing.

- Autonomous Database Billing Summary
  You are billed for Autonomous Database usage according to the values of two parameters: **compute** and **storage**. You select values for these parameters when you provision or scale an Autonomous Database instance.
- Compute Models in Autonomous Database
  Autonomous Database provides the ECPU compute model when you create or clone an instance. The legacy OCPU billing metric has been retired and Oracle recommends using ECPUs for all new and existing Autonomous Database deployments.
- Oracle Autonomous Database Serverless Features Billing
- Oracle Autonomous Database Serverless Billing for Database Tools
  Shows billing information for Autonomous Database database tools for ECPU and OCPU compute models.
- Autonomous Database for Developers Billing and Tenancy Service Limit
  You are billed for Autonomous Database for Developers usage hourly, on a per instance basis.

Autonomous Database Billing Summary

You are billed for Autonomous Database usage according to the values of two parameters: **compute** and **storage**. You select values for these parameters when you provision or scale an Autonomous Database instance.

When you provision an instance you select a workload type based on the workloads you want to run on your database. The pricing for compute and storage resources is based on the workload type you select.

The workload types are:

- **Data Warehouse**: optimized for analytic workloads, including data marts, data warehouses, data lakes, and data lakehouses.
- **Transaction Processing**: optimized to run transactional, analytical, and batch workloads concurrently.
- **JSON**: a cloud document database service that makes it simple to develop JSON-centric applications.
- **APEX**: a fully managed, low-code application development platform for building and deploying modern cloud, mobile, and data-driven applications.

Depending on the workload type, you select an Autonomous Database billing model:

- **ECPU Billing Model**: (Recommended billing model) Based on the number of cores allocated from the pool of compute servers and storage servers.
- **OCPU Billing Model**: (Legacy billing model) Provides compute capacity equivalent of a physical core of a processor with hyper-threading enabled.

See the Autonomous Database Cloud Price List for up-to-date pricing for each workload type.

Use the Cloud Cost Estimator to estimate the monthly cost for an Autonomous Database.

For complete cost details, refer to the *Oracle PaaS and IaaS Universal Credits Service Descriptions* document available on the Oracle Cloud Services contracts page.

Compute and Storage Billing Summary

- ECPU Compute Model
- OCPU Compute Model

ECPU Compute Model

Compute Billing

Compute billing is based on the value you specify for **ECPU Count** and on the additional features you use. For example, if you use additional compute resources with **Compute auto scaling** selected, you are billed for the additional compute resources.

- Data Warehouse workload: See Billing Information: Autonomous Data Warehouse ECPU Compute Model
- Transaction Processing workload: See Billing Information: Autonomous Transaction Processing ECPU Compute Model
- JSON workload: See Billing Information: Autonomous JSON Database ECPU Compute Model
- APEX workload: See Billing Information: APEX Service ECPU Compute Model

Storage Billing

Billing for database storage is based on the value you specify for **Storage** and based on the features you use that require additional storage. For example, you are billed for additional storage usage if you select **Storage auto scaling** and you use additional storage resources.

The storage for backups is billed in addition to database storage.

- Data Warehouse workloads:
  - Database storage is provisioned in Terabytes (TBs) and charged in TB increments. The minimum database storage size is 1 TB.
  - Backup storage is separately charged in TB increments.

  See Billing Information: Autonomous Data Warehouse ECPU Compute Model.
- Transaction Processing, JSON, or APEX workloads:
  - Database storage is provisioned in Gigabytes or Terabytes (GBs or TBs) and charged in Gigabyte increments. The minimum database storage size is 20 GB.
  - Backup storage is separately charged in GB increments.

  See ECPU Compute Model Billing Information.

Also see Oracle Autonomous Database Serverless Features Billing

OCPU Compute Model

Compute Billing

Compute billing is based on the value you specify for **OCPU Count** and on the additional features you use. For example, if you use additional compute resources with **Compute auto scaling** selected, you are billed for the additional compute resources.

- Data Warehouse workload: See Billing Information: Autonomous Data Warehouse OCPU Compute Model
- Transaction Processing, JSON, or APEX workloads: See Billing Information: Autonomous Transaction Processing OCPU Compute Model

Storage Billing

Billing for database storage is based on the value you specify for **Storage** and based on the features you use that require additional storage. For example, you are billed for additional storage usage if you select **Storage auto scaling** and you use additional storage resources.

- For all workload types database storage is provisioned in Terabytes (TBs) and charged in TB increments.
- For all workload types, the storage for automatic backups is included in the cost of database storage at no additional cost.

See OCPU Compute Model Billing Information and Oracle Autonomous Database Serverless Features Billing

Compute Models in Autonomous Database

Autonomous Database provides the ECPU compute model when you create or clone an instance. The legacy OCPU billing metric has been retired and Oracle recommends using ECPUs for all new and existing Autonomous Database deployments.

- **ECPU**: An ECPU is an abstracted measure of compute resources. ECPUs are based on the number of cores elastically allocated from a pool of compute and storage servers.

  While provisioning a new database or cloning an existing database:

  – The CPU count defaults to 2 ECPUs.

  – For databases that need more than 2 ECPUs, you must specify the number of assigned ECPUs as an integer. For example, you cannot assign 3.5 ECPUs to a database. The next available number of ECPUs above 3 is 4.

- **OCPU**: An OCPU is a physical measure of compute resources. OCPUs are based on the physical core of a processor with hyper-threading enabled.

> **Note:**
>
> OCPU is a legacy billing metric and has been retired on Autonomous Database. ECPUs are the replacement billing metric for all new and existing Autonomous Database deployments. See Oracle Support Document 2998742.1 for more information.

See Provision an Autonomous Database Instance and Clone an Autonomous Database Instance for more information.

- ECPU Compute Model Billing Information
- OCPU Compute Model Billing Information
  Provides billing information for Autonomous Transaction Processing, Autonomous Data Warehouse, Autonomous JSON Database, and APEX Service with the OCPU compute model.

ECPU Compute Model Billing Information

Provides billing information for Autonomous Transaction Processing, Autonomous Data Warehouse, Autonomous JSON Database, and APEX Service with the ECPU compute model. Cost and usage reports are available from the Oracle Cloud Infrastructure Console, under **Billing and Cost Management**.

Cost reports look like this: `reports/cost-csv/0001000001010101-00001.csv.gz`. Download the zip file and extract to view the details.

Usage reports look like this: `reports/usage-csv/0001000001010101.csv.gz`. Download the zip file extract to view the details.

> **Note:**
>
> You can use OCI usage reports and `OCI_USAGE_DATA` view for information on usage *before* January 31st, 2025. The OCI usage reports are deprecated. You can continue to access your existing usage report CSV files until July 31, 2025. See Cost and Usage Reports for more information.

Billing Information: Autonomous Transaction Processing ECPU Compute Model

Shows billing information for Autonomous Transaction Processing with the ECPU billing model.

Resource Description	SKU Name	Part Number	Metric	Minimum and Minimum Increment
ECPU usage	Oracle Autonomous Transaction Processing – ECPU	B95702	ECPU per hour	Minimum ECPUs: 2 Minimum increment: 1
ECPU usage (Bring your own license)	Oracle Autonomous Transaction Processing – ECPU – BYOL	B95704	ECPU per hour	Minimum ECPUs: 2 Minimum increment: 1

Resource Description	SKU Name	Part Number	Metric	Minimum and Minimum Increment
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	Oracle Autonomous Transaction Processing – ECPU – BYOL	B95704	ECPU per hour	Minimum ECPUs: 8 Minimum increment: 2 (and only even numbers are allowed)
Database Storage usage	Oracle Autonomous Database Storage for Transaction Processing	B95706	Gigabyte Storage Capacity Per Month	1 GB Minimum storage size is 20 GB
Backup Storage usage	Oracle Autonomous Database Storage	B95754	Gigabyte Storage Capacity Per Month	1 GB Backups are billed per GB

The following tables show how to view cost and usage information for Autonomous Transaction Processing with the ECPU billing model.

See Cost and Usage Reports Overview for details on the cost and usage reports.

ECPU Cost and Usage Information for Oracle Autonomous Transaction Processing for Records Until January 31, 2025

Resource Description	Part Number	Cost Report	Usage Report
ECPU usage	B95702	Cost report: in the `product/Description` column, find, "Oracle Autonomous Transaction Processing – ECPU"	Usage report: in the `product/resource` column, find `PIC_ATP_ECPU_LI`
ECPU usage (Bring your own license)	B95704	Cost report: in the `product/Description` column, find, "Oracle Autonomous Transaction Processing – ECPU – BYOL"	Usage report: in the `product/resource` column, find `PIC_ATP_ECPU_BYOL`
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	B95704	Cost report: in the `product/Description` column, find, "Oracle Autonomous Transaction Processing – ECPU – BYOL"	Usage report: in the `product/resource` column, find `PIC_ADBS_TOOLS_ECPU`
Database Storage usage	B95706	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database Storage for Transaction Processing"	Usage report: in the `product/resource` column, find `PIC_ADB_STORAGE_ATP`
Backup Storage usage	B95754	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database Backup Storage"	Usage report: in the `product/resource` column, find `PIC_ADB_STORAGE`

ECPU Cost and Usage Information for Oracle Autonomous Transaction Processing for Records After January 31, 2025

Resource Description	Part Number	Cost Report	Usage Information
ECPU usage	B95702	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Transaction Processing – ECPU"	Usage is in the cost report in the `usage/billedQuantity` column.
ECPU usage (Bring your own license)	B95704	To find cost information, in the cost report find your OCID in the column `product/resourceId` and in the `product/Description` column, find, "Oracle Autonomous Transaction Processing – ECPU – BYOL"	Usage is in the cost report in the `usage/billedQuantity` column.
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	B95704	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Transaction Processing – ECPU – BYOL"	Usage is in the cost report in the `usage/billedQuantity` column.
Database Storage usage	B95706	To find cost information, in the cost report find your OCID in the `product/resourceId` and in the `product/Description` column, find, "Oracle Autonomous Database Storage for Transaction Processing"	Usage is in the cost report in the `usage/billedQuantity` column.
Backup Storage usage	B95754	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Database Backup Storage"	Usage is in the cost report in the `usage/billedQuantity` column.

Billing Information: Autonomous Data Warehouse ECPU Compute Model

Shows billing information for Autonomous Data Warehouse with the ECPU compute model.

Resource Description	SKU Name	Part Number	Metric	Minimum and Minimum Increment
ECPU usage	Oracle Autonomous Data Warehouse – ECPU	B95701	ECPU per hour	Minimum ECPUs: 2 Minimum increment: 1
ECPU usage (Bring your own license)	Oracle Autonomous Data Warehouse – ECPU – BYOL	B95703	ECPU per hour	Minimum ECPUs: 2 Minimum increment: 1
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	Oracle Autonomous Data Warehouse – ECPU – BYOL	B95703	ECPU per hour	Minimum ECPUs: 8 Minimum increment: 2 (and only even numbers are allowed)

Resource Description	SKU Name	Part Number	Metric	Minimum and Minimum Increment
Database Storage usage	Oracle Autonomous Database Storage	B95754	Gigabyte Storage Capacity Per Month	1 TB (1024 GB)
Backup Storage usage	Oracle Autonomous Database Storage	B95754	Gigabyte Storage Capacity Per Month	1 GB Backups are billed per GB

The following table shows how to view cost and usage information for Autonomous Data Warehouse with the ECPU compute model.

See Cost and Usage Reports Overview for details on the cost and usage reports.

ECPU Cost and Usage Information for Autonomous Data Warehouse for Records Until January 31, 2025

Resource Description	Part Number	Cost Report	Usage Report
ECPU usage	B95701	Cost report: in the `product/Description` column, find, "Oracle Autonomous Data Warehouse – ECPU"	Usage report: in the `product/resource` column, find `PIC_ADW_ECPU_LI`
ECPU usage (Bring your own license)	B95703	Cost report: in the `product/Description` column, find, "Oracle Autonomous Data Warehouse – ECPU – BYOL"	Usage report: in the `product/resource` column, find `PIC_ADW_ECPU_BYOL`
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	B95703	Cost report: in the `product/Description` column, find, "Oracle Autonomous Data Warehouse – ECPU – BYOL"	Usage report: in the `product/resource` column, find `PIC_ADBS_TOOLS_ECPU`
Database Storage usage	B95754	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database Storage"	Usage report: in the `product/resource` column, find `PIC_ADB_STORAGE`
Backup Storage usage	B95754	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database Backup Storage"	Usage report: in the `product/resource` column, find `PIC_ADB_STORAGE`

ECPU Cost and Usage Information for Autonomous Data Warehouse for Records After January 31, 2025

Resource Description	Part Number	Cost Report	Usage Information
ECPU usage	B95701	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Data Warehouse – ECPU"	Usage is in the cost report in the `usage/billedQuantity` column.
ECPU usage (Bring your own license)	B95703	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Data Warehouse – ECPU – BYOL"	Usage is in the cost report in the `usage/billedQuantity` column.

Resource Description	Part Number	Cost Report	Usage Information
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	B95703	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Data Warehouse – ECPU – BYOL"	Usage is in the cost report in the `usage/billedQuantity` column.
Database Storage usage	B95754	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Database Storage"	Usage is in the cost report in the `usage/billedQuantity` column.
Backup Storage usage	B95754	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Database Backup Storage"	Usage is in the cost report in the `usage/billedQuantity` column.

Billing Information: Autonomous JSON Database ECPU Compute Model

Shows billing information for Autonomous JSON Database with the ECPU compute model.

Resource Description	SKU Name	Part Number	Metric	Minimum and Minimum Increment
ECPU usage	Autonomous JSON Database – ECPU	B99708	ECPU per hour	Minimum ECPUs: 2 Minimum increment: 1
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	Autonomous JSON Database – ECPU	B99708	ECPU per hour	Minimum ECPUs: 8 Minimum increment: 2 (and only even numbers are allowed)
Database Storage usage	Oracle Autonomous Database Storage for Transaction Processing	B95706	Gigabyte Storage Capacity Per Month	1 GB Minimum storage size is 20 GB
Backup Storage usage	Oracle Autonomous Database Storage	B95754	Gigabyte Storage Capacity Per Month	1 GB Backups are billed per GB

The following table shows how to view cost and usage information for Autonomous JSON Database with the ECPU compute model.

See Cost and Usage Reports Overview for details on the cost and usage reports.

ECPU Cost and Usage Information for Autonomous JSON Database for Records Until January 31, 2025

Resource Description	Part Number	Cost Report	Usage Report
ECPU usage	B99708	Cost report: in the `product/Description` column, find, "Autonomous JSON Database – ECPU"	Usage report: in the `product/resource` column, find `PIC_AJD_ECPU_LI`

Resource Description	Part Number	Cost Report	Usage Report
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	B99708	Cost report: in the `product/Description` column, find, "Autonomous JSON Database – ECPU"	Usage report: in the `product/resource` column, find `PIC_AJD_ECPU_LI`
Database Storage usage	B95706	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database Storage for Transaction Processing"	Usage report: in the `product/resource` column, find `PIC_ADB_STORAGE_ATP`
Backup Storage usage	B95754	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database Backup Storage"	Usage report: in the `product/resource` column, find `PIC_ADB_STORAGE`

ECPU Cost and Usage Information for Autonomous JSON Database for Records After January 31, 2025

Resource Description	Part Number	Cost Report	Usage Information
ECPU usage	B99708	To find cost information, in the cost report find your OCID in the `product/resourceId` column, and in the `product/Description` column, find, "Autonomous JSON Database – ECPU"	Usage is in the cost report in the `usage/billedQuantity` column.
ECPU usage for built-in-tools: Graph Studio, Oracle Machine Learning, Data Transforms	B99708	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Autonomous JSON Database – ECPU"	Usage is in the cost report in the `usage/billedQuantity` column.
Database Storage usage	B95706	To find cost information, in the cost report find your OCID in the `product/resourceId` and in the `product/Description` column, find, "Oracle Autonomous Database Storage for Transaction Processing"	Usage is in the cost report in the `usage/billedQuantity` column.
Backup Storage usage	B95754	To find cost information, in the cost report find your OCID in the `product/resourceId` and in the `product/Description` column, find, "Oracle Autonomous Database Backup Storage"	Usage is in the cost report in the `usage/billedQuantity` column.

Billing Information: APEX Service ECPU Compute Model

Shows billing information for APEX Service with the ECPU compute model.

Resource Description	SKU Name	Part Number	Metric	Minimum and Minimum Increment
ECPU usage	APEX Service – ECPU	B99709	ECPU per hour	Minimum ECPUs: 2 Minimum Increment: 1

Resource Description	SKU Name	Part Number	Metric	Minimum and Minimum Increment
Database Storage usage	Oracle Autonomous Database Storage for Transaction Processing	B95706	Gigabyte Storage Capacity Per Month	1 GB Minimum storage size is 20 GB
Backup Storage usage	Oracle Autonomous Database Storage	B95754	Gigabyte Storage Capacity Per Month	1 GB Backups are billed per GB

The following table shows how to view cost and usage information for APEX Service with the ECPU compute model.

See Cost and Usage Reports Overview for details on the cost and usage reports.

ECPU Cost and Usage Information for APEX Service for Records Until January 31, 2025

Resource Description	Part Number	Cost Report	Usage Report
ECPU usage	B99709	Cost report: in the `product/Description` column, find, "APEX Service – ECPU"	Usage report: in the `product/resource` column, find `PIC_APEX_ECPU_LI`
Database Storage usage	B95706	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database Storage for Transaction Processing"	Usage report: in the `product/resource` column, find `PIC_ADB_STORAGE_ATP`
Backup Storage usage	B95754	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database Backup Storage"	Usage report: in the `product/resource` column, find `PIC_ADB_STORAGE`

ECPU Cost and Usage Information for APEX Service for Records After January 31, 2025

Resource Description	Part Number	Cost Report	Usage Information
ECPU usage	B99709	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "APEX Service – ECPU"	Usage is in the cost report in the `usage/billedQuantity` column.
Database Storage usage	B95706	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Database Storage for Transaction Processing"	Usage is in the cost report in the `usage/billedQuantity` column.
Backup Storage usage	B95754	To find cost information, in the cost report find your OCID in the `product/resourceId` column and in the `product/Description` column, find, "Oracle Autonomous Database Backup Storage"	Usage is in the cost report in the `usage/billedQuantity` column.

Billing Information: Autonomous Database for Developers

Shows billing information for Autonomous Database for Developers with the ECPU compute model.

Resource Description	SKU Name	Part Number	Metric	Min. Increments Allowed
Instance usage (includes ECPU and storage)	Oracle Autonomous Database - Developer	B110316	Instance per hour	Fixed 4 ECPUs and 20 GB storage included

The following table shows cost and usage reports information for Autonomous Database for Developers with the ECPU compute model.

See Cost and Usage Reports Overview for details on the cost and usage reports.

Billing Information for Autonomous Database for Developers for Records Until January 31, 2025

Resource Description	Part Number	Cost Report	Usage Report
Instance usage (includes ECPU and storage)	B110316	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database – Developer"	Usage report: in the`product/resource` column, find `PIC_ADB_DEVELOPER_LI` in the `product/Description` column.

Billing Information for Autonomous Database for Developers for Records After January 31, 2025

Resource Description	Part Number	Cost Reports	Usage Information
Instance usage (includes ECPU and storage)	B110316	Cost report: in the `product/Description` column, find, "Oracle Autonomous Database – Developer"	Usage is in the cost report in the `usage/billedQuantity` column.

OCPU Compute Model Billing Information

Provides billing information for Autonomous Transaction Processing, Autonomous Data Warehouse, Autonomous JSON Database, and APEX Service with the OCPU compute model.

OCPU is a legacy billing metric and has been retired on Autonomous Database. ECPUs are the replacement billing metric for all new and existing Autonomous Database deployments. See Oracle Support Document 2998742.1 for more information.

> **Note:**
>
> You can use OCI usage reports and `OCI_USAGE_DATA` view for information on usage *before* February 1, 2025. The OCI usage reports are deprecated. You can continue to access your existing usage report CSV files until July 31, 2025. See Cost and Usage Reports for more information.

- Billing Information: Autonomous Transaction Processing OCPU Compute Model
  Shows billing information for Autonomous Transaction Processing with the OCPU compute model.
- Billing Information: Autonomous Data Warehouse OCPU Compute Model
  Shows billing information for Autonomous Data Warehouse with the OCPU compute model.
- Billing Information: Autonomous JSON Database OCPU Compute Model
  Shows billing information for Autonomous JSON Database with the OCPU compute model.
- Billing Information: APEX Service OCPU Compute Model
  Shows billing information for APEX Service with the OCPU compute model.

Billing Information: Autonomous Transaction Processing OCPU Compute Model

Shows billing information for Autonomous Transaction Processing with the OCPU compute model.

Resource Description	SKU Name	Part Number	Metric	Min. Increments Allowed	Cost and Usage Reports
OCPU usage	Oracle Autonomous Transaction Processing	B90453	OCPU per hour	1 OCPU	Cost report: In the `product/Description` column, find "Oracle Autonomous Transaction Processing" Usage report: in the `product/resource` column, find `PIC_ATP_COMPUTE`
OCPU usage (Bring your own license)	Oracle Autonomous Transaction Processing – BYOL	B90454	OCPU per hour	1 OCPU	Cost report: Cost report: in the `product/Description` column, find, "Oracle Autonomous Transaction Processing – BYOL" Usage report: in the `product/resourceID` column, find `PIC_ATP_COMPUTE_BYOL`

Resource Description	SKU Name	Part Number	Metric	Min. Increments Allowed	Cost and Usage Reports
Database Storage usage	Oracle Autonomous Transaction Processing - Exadata Storage	B90455	Terabyte Storage Capacity Per Month	1 TB	Cost report: in the `product/Description` column, find, "Oracle Autonomous Transaction Processing - Exadata Storage" Usage report: in the `product/resource` column, find `PIC_ATP_EXADATA_STORAGE`

See Cost and Usage Reports Overview for details on the cost and usage reports.

Billing Information: Autonomous Data Warehouse OCPU Compute Model

Shows billing information for Autonomous Data Warehouse with the OCPU compute model.

Resource Description	SKU Name	Part Number	Metric	Min. Increments Allowed	Cost and Usage Reports
OCPU usage	Oracle Autonomous Data Warehouse	B89040	OCPU per hour	1 OCPU	Cost report: in the `product/Description` column, find "Oracle Autonomous Data Warehouse" Usage report: in the `product/resource` column, find `PIC_ADWC_COMPUTE`
OCPU usage (Bring your own license)	Oracle Autonomous Data Warehouse – BYOL	B89039	OCPU per hour	1 OCPU	Cost report: in the `product/Description` column, find "Oracle Autonomous Data Warehouse – BYOL" Usage report: in the `product/resource` column, find `PIC_ADWC_COMPUTE_BYOL`

Resource Description	SKU Name	Part Number	Metric	Min. Increments Allowed	Cost and Usage Reports
Database Storage usage	Oracle Autonomous Data Warehouse - Exadata Storage	B89041	Terabyte Storage Capacity Per Month	1 TB	Cost report: in the `product/Description` column, find "Oracle Autonomous Data Warehouse - Exadata Storage" Usage report: in the `product/resource` column, find `PIC_ADWC_EXADATA_STORAGE`

See Cost and Usage Reports Overview for details on the cost and usage reports.

Billing Information: Autonomous JSON Database OCPU Compute Model

Shows billing information for Autonomous JSON Database with the OCPU compute model.

Resource Description	SKU Name	Part Number	Metric	Min. Increments Allowed	Cost and Usage Reports
OCPU usage	Oracle Autonomous JSON Database	B92212	OCPU per hour	1 OCPU	Cost report: in the `product/Description` column, find "Oracle Autonomous JSON Database" Usage report: in the `product/resource` column, find `PIC_AJD_COMPUTE`
Database Storage usage	Oracle Autonomous Transaction Processing - Exadata Storage	B90453	Terabyte Storage Capacity Per Month	1 TB	Cost report: in the `product/Description` column, find "Oracle Autonomous JSON Database - Exadata Storage" Usage report: in the `product/resource` column, find `PIC_ATP_EXADATA_STORAGE`

> **Note:**
>
> In the OCPU model, 60 days of automatic backups are included in the cost of database storage and have no additional charge. Long-term backups are billed additionally, as database storage (Part Number: B90453).

See Cost and Usage Reports Overview for details on the cost and usage reports.

Billing Information: APEX Service OCPU Compute Model

Shows billing information for APEX Service with the OCPU compute model.

Resource Description	SKU Name	Part Number	Metric	Min. Increments Allowed	Cost and Usage Reports
OCPU usage	Oracle APEX Application Development	B92911	OCPU per hour	1 OCPU	Cost report: In the `product/Description` column, find "Oracle APEX Application Development" Usage report: in the `product/resource` column, find `PIC_ADBS_APEX_LI`
Database Storage usage	Oracle Autonomous Transaction Processing - Exadata Storage	B90453	Terabyte Storage Capacity Per Month	1 TB	Cost report: in the `product/Description` column, find, "Oracle Autonomous Transaction Processing - Exadata Storage" Usage report: in the `product/resource` column, find `PIC_ATP_EXADATA_STORAGE`

> **Note:**
>
> In the OCPU model, 60 days of automatic backups are included in the cost of database storage and have no additional charge. Long-term backups are billed additionally, as database storage (Part Number: B90453).

See Cost and Usage Reports Overview for details on the cost and usage reports.

Oracle Autonomous Database Serverless Features Billing

Shows billing information for Autonomous Database features for ECPU and OCPU compute models.

- ECPU Compute Model
- OCPU Compute Model

ECPU Compute Model

- **Automatic Backups**: The storage for backups is billed, per GB, in addition to your selected database storage.

  For example, if backups are occupying 200 GB of storage you are billed for 200 GB of backup storage (in addition to the usage billed for your selected number of ECPUs and database storage). See ECPU Compute Model Billing Information for more detail about which SKUs are billed for backups.

- **Long-Term Backups**: The storage for long-term backups is billed, per GB, as backup storage, in addition to your database storage.

  For example, if automatic backups are currently occupying 200 GB and long-term backups are occupying 600 GB of storage, you are billed for 800 GB of backup storage, in addition to the usage billed for your selected ECPUs and database storage. See ECPU Compute Model Billing Information for more detail about which SKUs are billed for each workload type and backups.

- **Compute Auto-Scaling**: When compute auto scaling is enabled, your database may use and you may be billed for additional ECPU consumption as needed by your workload, up to three times (3x) the number of base ECPUs, as shown in the **ECPU count** on the Oracle Cloud Infrastructure Console.

  – Your billed ECPU usage per hour while your database is running is based on the base number of ECPUs you selected for your database, plus any additional ECPU usage due to auto-scaling.

  – A stopped Autonomous Database instance has zero ECPU usage.

  – ECPU usage is measured each second, in units of whole ECPUs and averaged across an hour. If your database is running for less than an hour or auto-scales for only part of an hour, it is billed per second for the average ECPU consumption, over the base ECPUs, during that hour. The minimum ECPU consumption is one minute.

  For example, if your database has ECPU count 4 with **Compute auto scaling** enabled:

  – Assume in hour one your database is Available for the entire hour and ECPU utilization is below 4 ECPUs. Your database will be billed for 4 ECPUs.

  – Assume in hour two your database is Available for the entire hour and ECPU utilization is below 4 ECPUs for 30 minutes, 50% of the hour, and auto scales to 8 ECPUs for 30 minutes (the other 50% of the hour). The usage for this period, for billing, is 6 ECPUs (based on the average per-second ECPU usage for hour two).

- **Storage Auto-Scaling**:

  – For storage usage below your reserved base storage, you are billed based on your base storage.

- After your allocated storage exceeds your reserved base storage, storage usage is billed based on your allocated storage rounded up to the nearest TB, in a given hour.

For example, if your reserved base storage is 4 TB, until your allocated storage exceeds 4 TB of storage, you are billed based on your base storage (4 TB). After you exceed 4 TB, storage is billed based on the allocated storage rounded up to the nearest TB, in a given hour. In this example, if the allocated storage grows over 4 TB in a given hour, say to 4.9 TB, you are billed for 5 TB of storage from that hour onward.

If you then delete 1 TB of data, your allocated storage remains at 4.9 TB and you are billed for 5 TB until you perform a shrink operation. When you perform a shrink operation, may be able to shrink /reduce your allocated storage back to 3.9 TB. After the shrink operation completes and your allocated storage (3.9 TB) is once again below your reserved base storage (4 TB), you will once again be billed for your reserved base storage of 4 TB. See Shrink Storage for more information.

- **Autonomous Data Guard Standby – Local (Same-Region)**

  Local Autonomous Data Guard peer databases incur the additional cost of the base ECPUs and the storage of the Primary database, including any auto-scaled storage usage, billed on the Primary database itself. Auto-scaled ECPUs of the Primary database are not billed for additionally on the local Autonomous Data Guard peer database. The number of base ECPUs is specified by the number of ECPUs as shown in the **ECPU count** on the Oracle Cloud Infrastructure Console.

  For example, if you enable a local Autonomous Data Guard peer on a source database with:

  - 2 (base) ECPUs with **Compute auto-scaling** enabled and are consuming about 4 ECPUs per hour
  - 1 TB of (base) storage with storage auto-scaling, consuming a total of 2 TB of database storage

  For the local Autonomous Data Guard peer you are billed for an additional 2 ECPUs (your base ECPU selection), plus an additional 2 TB of storage (that is, the same amount of storage reserved for the source Primary with auto-scale, on the Primary database).

  When the Primary database is stopped, neither the primary nor the peer database is billed for ECPU.

- **Autonomous Data Guard Standby – Remote (Cross-Region)**

  Autonomous Data Guard cross-region peer databases incur the additional cost of the base ECPUs and twice (2x) the storage of the Primary database, including any auto-scaled storage usage, billed on the remote peer database. Auto-scaled ECPUs of the Primary are not billed for additionally on the remote peer database. The number of base ECPUs is specified by the number of ECPUs as shown in the **ECPU count** on the Oracle Cloud Infrastructure Console.

  For example, if you enable a cross-region Autonomous Data Guard peer for a source database with:

  - 2 (base) ECPUs with **Compute auto-scaling** enabled and are consuming about 4 ECPUs per hour
  - 1 TB of (base) storage with storage auto-scaling, consuming a total of 2 TB of database storage

  For the cross-region Autonomous Data Guard peer you are billed an additional 2 ECPUs (your base ECPU selection), plus 4 TB of storage (that is 2x the storage reserved for the source Primary with auto-scaling, billed on the remote peer database).

When the Primary database is stopped, neither the primary nor the peer database are billed for ECPU.

When the option **Enable cross-region backup replication to disaster recovery peer** is selected, you are billed for twice (2x) the backup storage size required for the replicated backups, billed to the remote standby.

When a cross-region peer operates as a Snapshot standby, the Snapshot standby CPU usage is billed based on the base CPU count and any additional CPU usage if compute auto scaling is enabled. The number of base CPUs is specified by the number of ECPUs as shown in the **ECPU count** field on the Oracle Cloud Infrastructure Console.

- **Backup-Based Disaster Recovery – Local (Same-Region) Backup Copies** There are no additional costs for local Backup-Based Disaster Recovery, other than the cost of storage for automatic backups.
- **Backup-Based Disaster Recovery – Remote (Cross-Region) Backup Copies** Billing for a cross-region Backup-Based Disaster Recovery is twice (2x) the amount of backup storage required for the replicated cross-region backups, billed to the remote peer.

  For example, if you enable a cross-region backup copy on a source database with:

  – 2 (base) ECPUs

  – 2 TB of database storage

  If the backups replicated to the remote region take up 1.9 TB of storage, you will be billed for 3.8 TB of backup storage on the remote backup copy peer database.

  When the option **Enable cross-region backup replication to disaster recovery peer** is selected, you are billed for twice (2x) the amount of backup storage size required for the additional replicated backups, billed to the remote peer. This billing is based on the number of days set for the backup retention on the Primary, as follows:

  – When automatic backup retention is set to 7 days or greater, billing is based on the storage size for 7 days of replicated backups.

  – When automatic backup retention is set to less than 7 days, billing is based on the storage size for the specified number of days of data that is replicated to the cross-region standby.
- **Refreshable Clone Local (Same-Region)** Local refreshable clones have their own configurable ECPU selection, and so they are billed for ECPU based on the user-selected number of ECPUs, with or without auto scaling; they do not get billed additionally over the ECPU selection. The number of ECPUs is specified by the number of ECPUs as shown in the **ECPU count** on the Oracle Cloud Infrastructure Console.

  Local refreshable clones are billed for the same amount of storage as their source database.

  For example, if you create a 2 ECPU local refreshable clone from a source database with:

  – 4 ECPUs

  – 1 TB of storage with storage auto-scaling and consuming 2 TB of storage

  For the local refreshable clone you will be billed for 2 ECPUs, that is, the refreshable clone's **ECPU count** value, and 2 TB of storage (that is, the storage reserved for the source database).

  When you start or stop the source database, your actions on the source database do not affect the refreshable clone. A refreshable clone is started or stopped independently of the source database.
- **Refreshable Clone Remote (Cross-Region)** Remote refreshable clones have their own configurable ECPU selection, and so they are billed for ECPU based on the user-selected

ECPU (with or without auto scaling); they do not get billed additionally over the ECPU selection. The number of ECPUs is specified by the number of ECPUs as shown in the **ECPU count** on the Oracle Cloud Infrastructure Console.

Remote refreshable clones are billed for twice (2x) the amount of storage as their source database.

For example, if you create a 2 ECPU remote refreshable clone from a source database with:

- 4 ECPUs
- 1 TB of storage with storage auto-scaling and consuming 2 TB of storage

For the remote refreshable clone you are billed for 2 ECPUs (that is, the refreshable clone's ECPU selection) and 4 TB of storage (that is, 2x the storage reserved for the source database)

Starting or stopping the source database does not affect the refreshable clone - The refreshable clone can be started or stopped independently.

- **Snapshot Standby for Remote (Cross-Region) Disaster Recovery**

  Snapshot standby ECPU usage is billed based on the base ECPU count and any additional ECPU usage if compute auto-scaling is enabled. The number of base ECPUs is specified by the number of ECPUs, as shown in the **ECPU count** on the Oracle Cloud Infrastructure Console.

  Snapshot standby storage usage is billed based on the storage of the snapshot standby plus (1x) the storage of the source primary database.

  For example, if you have a 2 ECPU and 3 TB snapshot standby from a source database with:

  - 4 ECPUs
  - 1 TB of storage with storage auto-scaling and consuming 2 TB of storage

  Your snapshot standby will be billed for 2 ECPUs (that is, the snapshot standby's ECPU selection) and 3 TB + 2 TB = 5 TB of database storage (that is, the storage reserved on the snapshot standby + the storage reserved on its source database)

- **Elastic Pools**: An elastic pool allows you to provision 4 times the ECPU count that you have as your pool size. For example, if you have a pool with pool size of 128 ECPUs, you can provision up to 512 ECPUs in this pool. In other words, when your pool size is 128 ECPUs, your pool capacity is four times the pool size (in this example, 512 ECPUs).

  Databases that belong to a pool are not billed individually for compute. The compute billing for all the pool members and the leader happens through the leader. In other words, individual members of an elastic pool do not get billed for compute as long as they are part of the pool. This applies no matter what the workload type is for the pool member. For example, when a pool member with workload type **Data Warehouse** is added to a pool, it's compute usage is billed to the pool leader at the **Transaction Processing** compute usage rate. The storage billing, on the other hand, continues to be billed to individual Autonomous Database instances irrespective of them being part of a pool or not.

  Let’s assume you have an elastic pool with pool size of 128 ECPUs. Given the pool size, the pool capacity is 512 ECPUs (pool capacity = 4x pool size). For this sample, here are some common billing questions and answers:

  - What is the maximum number of Autonomous Database instances allowed in this pool? A total of 512 Autonomous Database instances with 1 ECPU each (elastic pool members or the leader can have an individual ECPU allocation as low as 1 ECPU).

  - What happens if the aggregated ECPU utilization high watermark of the pool is greater than the pool size? If the aggregated ECPU utilization high watermark is less than or equal to the pool size in a given billing hour, the hourly charge is in the amount of the pool size. If the aggregated ECPU utilization high watermark is more than the pool size but less than or equal to the 2x pool size in a given billing hour, the hourly charge is in the amount of 2x pool size. If the aggregated ECPU utilization high watermark is more than 2x pool size in a given billing hour, the hourly charge is in the amount of 4x pool size.

    For example, let's assume 512 Autonomous Database instances with 1 ECPU each are in an elastic pool with a pool size of 128 ECPUs. If the aggregated ECPU utilization high watermark of these databases is 100 ECPUs between 1pm-2pm, and 250 ECPUs between 2pm-3pm; then the billing is 128 ECPU hours between 1pm-2pm and 256 ECPU hours between 2pm-3pm.

  See About Elastic Pool Billing for more information.

- **Undelete an Autonomous Database Instance**

  If you undelete an Autonomous Database instance, in the first hour after the undelete operation you are billed for the base CPU and Storage, including database storage and long term backups, for the total time when the database was deleted, as if the database was never deleted and was running.

  For example, if you terminate an Autonomous Database instance with:

  - 4 ECPU with **Compute auto scaling** enabled
  - 2 TB Storage, with 100 GB of automatic backup storage and 20 GB of long-term backup storage

  If after 5 hours and 30 minutes you undelete the terminated instance, in the first hour after the undelete operation the billing includes the additional costs as if the database was never deleted and was running, including:

  - 5 hours and 30 minutes for the base 4 ECPUs
  - 2 TB Storage
  - 100 GB of automatic backup storage
  - 20 GB of long-term backup storage

OCPU Compute Model

- **Automatic Backups**: The storage for automatic backups is included in the cost of database storage. See OCPU Compute Model Billing Information for more detail about which SKUs for database storage.
- **Long-Term Backups**: The storage for long-term backups is billed per TB as additional database storage, in addition to your selected database storage usage.

  For example, if automatic backups occupy 200 GB and long-term backups occupy 600 GB of storage, you will be billed for 1 TB (600 GB of long-term backup storage rounded up to the nearest TB) as database storage, in addition to the usage billed for your selected OCPU and database storage. See OCPU Compute Model Billing Information for more detail about which SKUs are billed for each workload type and backups.
- **Compute auto-scaling**: When compute auto scaling is enabled your database may use and you may be billed for additional OCPU consumption as needed by your workload, up to three times (3x) the number of base OCPUs (as shown in **OCPU count** on the Oracle Cloud Infrastructure Console)

  - Your billed OCPU usage per hour while your database is running is based on the base number of OCPUs you selected for your database, plus any additional OCPU usage due to auto-scaling.
  - A stopped Autonomous Database instance has zero OCPU usage.
  - OCPU usage is measured each second, in units of whole OCPUs and averaged across an hour. If your database is running for less than an hour or auto-scales for only part of an hour, it will be billed per second for the average OCPU consumption (over the base OCPU) during that hour. The minimum OCPU consumption is one minute.

- **Storage Auto-Scaling**:
  - For storage usage below your reserved base storage, you are billed based on your base storage.
  - After your allocated storage exceeds your reserved base storage, storage usage is billed based on your allocated storage rounded up to the nearest TB, in a given hour.

  For example, if your reserved base storage is 4 TB, until your allocated storage exceeds 4 TB of storage, you are billed based on your base storage (4 TB). After you exceed 4 TB, storage is billed based on the allocated storage rounded up to the nearest TB, in a given hour. In this example, if the allocated storage grows over 4 TB in a given hour, say to 4.9 TB, you are billed for 5 TB of storage from that hour onward.

  If you then delete 1 TB of data, your allocated storage remains at 4.9 TB and you are billed for 5 TB until you perform a shrink operation. When you perform a shrink operation, Autonomous Database may be able to shrink / reduce your allocated storage back to 3.9 TB. After the shrink operation completes and your allocated storage (3.9TB) is once again below your reserved base storage (4 TB), you will once again be billed for your reserved base storage of 4 TB. See Shrink Storage for more information.

- **Autonomous Data Guard Standby Local (same-region)**

  Local Autonomous Data Guard peer databases incur the additional cost of the base OCPUs and the storage of the Primary database, including any auto-scaled storage usage, billed on the Primary database itself. Auto-scaled OCPUs of the Primary database are not billed for additionally on the local Autonomous Data Guard peer database. The number of base OCPUs is specified by the number of OCPUs, as shown in the **OCPU count** on the Oracle Cloud Infrastructure Console.

  When the Primary database is stopped, neither the primary nor the peer database is billed for OCPU.

- **Autonomous Data Guard Standby Remote (cross-region)**

  Autonomous Data Guard cross-region standby databases incur the additional cost of the base OCPUs and twice (2x) the storage of the Primary database, including any auto-scaled storage usage, billed on the remote peer database. Auto-scaled OCPUs of the Primary are not billed for additionally on the remote peer database. The number of base OCPUs is specified by the number of OCPUs, as shown in **OCPU count** on the Oracle Cloud Infrastructure Console.

  When the Primary database is stopped, neither the primary nor the peer database is billed for OCPU.

  When the option **Enable cross-region backup replication to disaster recovery peer** is selected, you are billed to the remote standby database's OCPU database storage, for twice (2x) the 7 day replicated backup storage size, rounded up to the nearest TB.

- **Backup-based Disaster Recovery Local (same-region) Backup Copies** There are no additional costs for local Backup-Based Disaster Recovery, other than the cost of keeping automatic backups.

- **Backup-Based Disaster Recovery Remote (cross-region) Backup Copies**

  Billing for a cross-region Backup-Based Disaster Recovery with OCPUs is twice (2x) the amount of storage required for backups replicated to the remote region, billed as database storage to the remote peer, rounded up to the nearest TB.

  When the option **Enable cross-region backup replication to disaster recovery peer** is selected, you are billed to the remote peer database's OCPU database storage, for twice (2x) the replicated backup storage size, rounded up to the nearest TB.

- **Refreshable Clone Local (same-region)**

  Local refreshable clones have their own configurable OCPU selection, and so they are billed for OCPU based on the user-selected OCPU (with or without auto scaling); they do not get billed additionally over the OCPU selection. The number of OCPUs is specified by the number OCPUs as shown in the **OCPU count** on the Oracle Cloud Infrastructure Console.

  Local refreshable clones are billed for the same amount of storage as their source database.

  Starting or stopping the source database does not affect the refreshable clone. The refreshable clone can be started or stopped independently.

- **Refreshable Clone Remote (cross-region)**

  Remote refreshable clones have their own configurable OCPU selection, and so they are billed for OCPU based on the user-selected OCPU (with or without auto scaling); they do not get billed additionally over the OCPU selection. The number of OCPUs is specified by the number of OCPUs as shown in the **OCPU count** on the Oracle Cloud Infrastructure Console.

  Remote refreshable clones are billed for twice (2x) the amount of storage as their source database.

  Starting or stopping the source database does not affect the refreshable clone. The refreshable clone can be started or stopped independently.

- **Snapshot Standby for Remote (cross-region) disaster recovery**

  Snapshot standby OCPU usage is billed based on the base OCPU count and any additional OCPU usage if compute auto-scaling is enabled. The number of base OCPUs is specified by the OCPUs as shown in the **OCPU count** on the Oracle Cloud Infrastructure Console.

  Snapshot standby storage usage is billed based on the storage of the snapshot standby plus (1x) the storage of the source primary database.

Oracle Autonomous Database Serverless Billing for Database Tools

Shows billing information for Autonomous Database database tools for ECPU and OCPU compute models.

- ECPU Compute Model
- OCPU Compute Model

ECPU Compute Model

The following built-in tools have separate, configurable compute resource limits:

- Graph Studio
- Oracle Machine Learning
- Data Transforms

For these tools compute resource usage does not use the database's base compute, as specified with the **ECPU count**, or any auto-scaled ECPUs. These tools have separate ECPU allocation, independent from the database compute **ECPU count** (and independent of **Compute auto scaling**).

For Graph Studio, Oracle Machine Learning, and Data Transforms, the ECPU count and Maximum idle time configuration options let you specify compute resource allocation for the VMs that run the associated built-in tool. When you configure these built-in tools, the values for these configuration options mean the following in terms of resource usage and billing:

- You do not pay for a tool's ECPU allocation if you do not use the tool.
- The VMs associated with a tool are provisioned when you start using a tool. For example, if Graph Studio is disabled, billing does not begin when you enable the tool. Billing begins when you start using Graph Studio.
- The ECPU count specifies the compute resource allocation that is dedicated to the tool. The value you enter for ECPU count applies in addition to the database ECPU count you specify for the instance.

  After you start using a tool you are billed per ECPU hour reserved from the time the built-in Tool is launched. ECPU usage is measured each second, in units of whole ECPUs and averaged across an hour. If your database is running for less than an hour or you change the number of ECPUs for only part of an hour, your built-in Tool ECPU usage is billed per second for the average ECPU consumption during that hour. The minimum ECPU consumption is one minute.
- Billing stops for a built-in tool's allocated ECPUs when the built-in tool is disabled, the instance stops or is terminated, or when the built-in tool is idle for more than the specified Maximum idle time. The default maximum idle times depend on the tool:

For example, assume you allocate 4 ECPUs as the base ECPU count for the Autonomous Database instance, with compute auto-scaling disabled, and you use 8 ECPUs for Graph Studio with the maximum idle time set to 30 minutes. If you use Graph Studio for 30 minutes starting at 2 pm, your bill for the specified time period (2-3pm) is a total of 12 ECPUs. This sum includes the 4 base ECPUs plus the additional tools usage of 8 ECPUs for Graph Studio (including 30 minutes of actual usage and 30 minutes of idle time).

As another example, assume you allocate 6 ECPUs as the base ECPU count for the Autonomous Database instance, with compute auto-scaling disabled, and you use the default 8 ECPUs for Oracle Machine Learning (OML) with the maximum idle time set to 15 minutes. When the database is open and available for the hour between 2 to 3 pm, and you use OML for 15 min starting at 2 pm, with the specified 15 minute maximum idle time, you are charged for 8 ECPUs for OML compute usage for 30 minutes plus 6 ECPUs for the database compute resources for the full hour, for a total of 14 ECPUs assuming no other tools are used in this period.

Note: After you start using a tool with a specified **ECPU count** you are billed per ECPU hour reserved from the time the built-in Tool is launched. ECPU usage is measured each second, in units of whole ECPUs and averaged across an hour. If your database is running for less than an hour or you change the number of ECPUs for only part of an hour, it is billed per second for

the average ECPU consumption during that hour. The minimum ECPU consumption is one minute.

Depending on the workload type of the Autonomous Database instance, built-in tool usage is charged to the following SKUs:

- Oracle Autonomous Transaction Processing – ECPU – BYOL
- Oracle Autonomous Data Warehouse – ECPU – BYOL
- Autonomous JSON Database – ECPU

See ECPU Compute Model Billing Information for details on built-in tools billing.

OCPU Compute Model

Built-in tools do not have separate, configurable compute resource limits. The built-in tools use compute from the database's selected OCPU count. Tool usage may also use auto-scaled OCPUs, if necessary.

Autonomous Database for Developers Billing and Tenancy Service Limit

You are billed for Autonomous Database for Developers usage hourly, on a per instance basis.

Autonomous Database for Developers databases are billed as follows:

- Each instance is billed at a flat rate, per hour.
- An instance cannot be stopped for billing. After an Autonomous Database for Developers instance is created, it is billed until the instance is terminated.
- An Autonomous Database for Developers instance may be stopped and started as required, but this does not affect billing.
- Terminating an Autonomous Database for Developers instance stops the billing for the instance.

See Billing Information: Autonomous Database for Developers for compute and storage billing details.

When you provision an instance you select a workload type based on the workloads you want to run on your database. The pricing is the same for each workload type.

See the Autonomous Database Cloud Price List for up-to-date pricing.

Use the Cloud Cost Estimator to estimate the monthly cost for an Autonomous Database for Developers instance.

Autonomous Database for Developers Service Limit

The number of Autonomous Database for Developers instances in a tenancy is limited based on the `adb-developer-count` service limit. The default limit is 100, and you may request a limit increase for more. See Subscribed Region Limits for more information.

Always Free Autonomous Database

You have the option to create a limited number of Always Free Autonomous Databases that do not consume cloud credits. Always Free databases can be created in Oracle Cloud Infrastructure accounts that are in a trial period, have paying status, or are always free.

Sign Up with Oracle Cloud Free Tier

These are the services you can use for an unlimited time:

- Two Oracle Autonomous Databases with powerful tools like Oracle APEX and Oracle SQL Developer
- Two Oracle Cloud Infrastructure Compute VMs; Block, Object, and Archive Storage; Load Balancer and data egress; Monitoring and Notifications

See Oracle Cloud Free Tier to start for free.

Resource Restrictions for Always Free Autonomous Database

- The Always Free option provides databases that have CPU and storage included and you are never billed for an Always Free instance until the instance is upgraded to a paid Autonomous Database.
- Maximum of approximately 20 GB Exadata storage per database (you may see more than this)
- Maximum of 30 simultaneous database sessions
- Maximum of 2 Always Free Autonomous Database instances per Oracle Cloud Infrastructure tenancy. The Always Free Autonomous Database workload types are: Data Warehouse, Transaction Processing, JSON Database, and APEX Service. If you create 2 Always Free instances, they can be the same or different Autonomous Database workload types.
- The HTTP interface for Always Free Autonomous Databases is rate limited to restrict the number of simultaneous service users. Approximately 3-6 simultaneous users can be supported across all of the APEX, Oracle REST Data Services, and Database Actions running on your Always Free Autonomous Databases. Additional simultaneous users beyond that may result in users encountering HTTP errors such as HTTP status code 429.

  This HTTP interface rate limit applies only for Always Free Autonomous Databases.

Notes:

- For details on Always Free Oracle APEX Application Development (APEX Service), see Always Free Oracle APEX Application Development.
- Always Free Autonomous Databases cannot be scaled manually or automatically beyond the fixed resource restrictions described above.
- The Maximum of 30 simultaneous database sessions limit for Always Free allows you to work with Autonomous Database; however, if your usage includes many simultaneous users and/or many concurrent database client connections then you can exceed these limits, resulting in errors. To avoid such errors, obtain more resources for your Autonomous Database by upgrading to paid service.
- Always Free Autonomous Databases cannot be provisioned as a private endpoint and cannot reside within a Virtual Cloud Network (VCN). See Configure Private Endpoints When You Provision or Clone an Instance for further information on private endpoints.

Oracle Database Versions for Always Free Autonomous Database

The available Database versions for Always Free Autonomous Database are:

- **Oracle Database 19c**

  If you have Oracle Database 19c, then many database concepts and features of this service are further documented here:

  – Oracle Database 19c

- **Oracle Database 23ai**

  If you are using Always Free Autonomous Database with Oracle Database 23ai, then many of the concepts and features of this service are further documented here:

  – Oracle Database 23ai

  – *Oracle Database New Features*

  Notes for Always Free Autonomous Database with Oracle Database 23ai:

  – Always Free Autonomous Database with Oracle Database 23ai is available in the following regions:

    * US West: Phoenix (PHX)
    * US East: Ashburn (IAD)
    * UK South: London (LHR)
    * France Central: Paris (CDG)
    * Australia East: Sydney (SYD)
    * India West: Mumbai (BOM)
    * Singapore (SIN)
    * Japan East: Tokyo (NRT)

  – To take advantage of new features available with Oracle Database 23ai, your tenancy must have a home region of one of these regions and you must provision your Always Free Autonomous Database in your home region.

See Autonomous Database with Oracle Database 23ai Notes for additional information and limitations on Always Free Autonomous Database with Oracle Database 23ai.

Regional Availability for Always Free Autonomous Database

- Always Free Autonomous Databases are available worldwide in a subset of Oracle Cloud Infrastructure data regions. See Data Regions for more details on where Always Free databases are supported.
- When you sign up for Oracle Cloud Infrastructure, Oracle creates a tenancy and designates a home data region for the tenancy that you specify. You can create Always Free Autonomous Databases only in this home data region. You cannot create an Always Free Autonomous Database in other data regions that you subsequently subscribe to. See The Home Region for more information.

Backup Functionality Not Available in Always Free Autonomous Database

- Always Free Autonomous Databases do not support long-term backups or manual backups to your Oracle Cloud Infrastructure object storage.
- Always Free Autonomous Databases do not support restore (you cannot restore the current database to the selected past backup or timestamp).
- To use backup and restore functionality on Autonomous Database you must upgrade an Always Free Autonomous Database to a paid instance.

See Backup and Restore Autonomous Database Instances and Upgrade an Always Free Autonomous Database to a Paid Instance for more information.

Autonomous Data Guard Not Available for Always Free Autonomous Database

Autonomous Data Guard is not available with Always Free Autonomous Databases. See Use Standby Databases with Autonomous Data Guard for Disaster Recovery for more information.

Tools Configuration Options Not Available for Always Free Autonomous Database

Always Free Autonomous Database does not provide configuration options for Autonomous Database tools and does not allow you to disable Autonomous Database tools. For example, you cannot specifically disable HTTP access to Oracle APEX and REST Data Services on Always Free databases.

Supplemental Logging and Oracle GoldenGate Extract are Not Available for Always Free Autonomous Database

The following are not available for Always Free Autonomous Databases:

- Supplemental logging
- Oracle GoldenGate Extract

See Supplemental Logging and Configuring Extract to Capture from an Autonomous Database for more information.

Inactivity Monitoring and Database Stoppage

Persistently inactive Always Free Autonomous Databases are detected and handled as follows:

- After being inactive for 7 days, the database will be stopped automatically, preserving its stored data. Inactivity measurements leading up to 7 days are based on database connections and CPU usage. Successfully making a SQL*Net or HTTPS connection and running SQL commands on your database resets these measurements to zero.

- A database that is automatically or manually stopped and stays inactive for 90 days, cumulative, may be reclaimed and permanently deleted. Inactivity measurements leading up to 90 days are based on the database being inactive or in the stopped state. Starting a stopped database resets these measurements to zero.

  Start an Always Free Autonomous Database by clicking the **Start** button on the Oracle Cloud Infrastructure console. Start a stopped Always Free Autonomous Database before 90 days to avoid losing access to its data.

  When you start an Always Free Autonomous Database from the stopped state, you need to wait about 5 minutes before attempting to connect to an APEX application or to an Oracle REST Data Services (ORDS) endpoint. If you attempt to connect before the background APEX and ORDS startup completes, then you may see HTTP error messages.
- On an Always Free database the Oracle Cloud Infrastructure console shows banner alerts prior to automatic stop and permanent delete operations occurring. If you subscribe to Oracle Cloud Infrastructure Alerts and Notifications, you also will receive email notifications.

> **Note:**
>
> After an Always Free Autonomous Database has been stopped and is later started, you may need to reconnect to the database from SQL*Net database clients. You can use the same Oracle Wallet and database user credentials to reconnect.

Topics

- Upgrade an Always Free Autonomous Database to a Paid Instance
  You can upgrade an Always Free Autonomous Database to a paid instance to provide the instance with additional compute and storage resources.

Upgrade an Always Free Autonomous Database to a Paid Instance

You can upgrade an Always Free Autonomous Database to a paid instance to provide the instance with additional compute and storage resources.

If your Oracle Cloud Infrastructure account is in a trial period or has paying status, you can upgrade the Always Free database to a paid instance as follows:

1. From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
2. On the Autonomous Databases page select an Always Free Autonomous Database from the links under the **Display name** column.
3. On the Autonomous Database Details page, from the **More actions** drop-down list select **Upgrade instance to paid**.
4. Click **Upgrade instance to paid**.

When you upgrade from an Always Free instance to a paid instance you get a paid instance of the same workload type with the minimum CPU and minimum storage available for that workload type. After you upgrade you can scale up CPU and storage resources to fit your needs.

For example:

- **Data Warehouse** workload type: When you upgrade to paid from an Always Free instance, the upgrade process provides a paid Autonomous Database instance with workload type **Data Warehouse**, with 2 ECPUs and 1 TB of database storage.
- **Transaction Processing** workload type: When you upgrade to paid from an Always Free instance, the upgrade process provides a paid Autonomous Database instance with workload type **Transaction Processing**, with 2 ECPUs and 1 TB of database storage.

Notes for upgrading an Always Free Autonomous Database to a paid instance:

- If have an Always Free Autonomous Database and you want an Autonomous Database for Developers instance you can clone the Always Free instance. To create the paid Autonomous Database for Developers instance, perform the clone operation and in the configure the database step, select the **Developer** option. See Clone an Autonomous Database Instance for more information.
- If your account has finished a trial without upgrading to paying status, you can continue using Always Free databases but you cannot upgrade Always Free instances to paid instances until the account is first upgraded to paying status. See Upgrade Your Free Oracle Cloud Promotion for more information.
- For details on upgrading your Always Free APEX Service to an Oracle APEX Application Development paid instance, see Upgrading Always Free APEX Service to a Paid Version.

Autonomous Database for Developers

Autonomous Database for Developers provides you with low cost instances for developers and others to build and test new Autonomous Database applications.

Billing for Autonomous Database for Developers databases is hourly per instance. See Autonomous Database for Developers Billing and Tenancy Service Limit for details.

Autonomous Database for Developers are low-cost, fixed shape databases intended for development and testing uses cases, and are not recommended for production use cases. When you need more compute or storage resources or you want to take advantage of additional Autonomous Database features, you can upgrade your Autonomous Database for Developers instance to a full paid service instance.

Topics

- Resource Restrictions with Autonomous Database for Developers
  Autonomous Database for Developers instances come with compute and storage resources included.
- Oracle Database Versions with Autonomous Database for Developers
  Shows the available Oracle Database versions for Autonomous Database for Developers.
- Supported Features with Autonomous Database for Developers
  Autonomous Database for Developers supports most but not all of the Autonomous Database features.
- Provisioning and Cloning Workflow with Autonomous Database for Developers
  You can provision or clone Autonomous Database for Developers from the Oracle Cloud Infrastructure(OCI) console or using the API.
- Upgrade Autonomous Database for Developers Instance to a Full Paid Instance
  You can upgrade an Autonomous Database for Developers instance to a full paid service instance.

- Features Not Available in Autonomous Database for Developers
  There are some features that are not available with an Autonomous Database for Developers instance, compared to a full paid service instance.

Resource Restrictions with Autonomous Database for Developers

Autonomous Database for Developers instances come with compute and storage resources included.

- 4 ECPUs per instance. The number of ECPUs cannot be scaled manually or automatically unless you upgrade to a full paid service instance.
- Maximum of approximately 20 GB storage per database (you may see more than this). The storage size cannot be scaled manually or automatically unless you upgrade to a full paid service instance.
- Maximum of 30 simultaneous database sessions
- The HTTP interface for Autonomous Database for Developers is rate limited to restrict the number of simultaneous service users. Approximately 3-6 simultaneous users can be supported across all of the APEX, Oracle REST Data Services, and Database Actions running on an Autonomous Database for Developers instance.

  Additional simultaneous users beyond that number may result in users encountering HTTP errors such as HTTP status code 429.
- The Maximum of 30 simultaneous database sessions limit for Autonomous Database for Developers allows you to work with Autonomous Database; however, if your usage includes many simultaneous users and/or many concurrent database client connections then you can exceed these limits, resulting in errors. To avoid such errors, obtain more resources for your Autonomous Database by upgrading to a full paid service instance. See Upgrade Autonomous Database for Developers Instance to a Full Paid Instance for more information.

Oracle Database Versions with Autonomous Database for Developers

Shows the available Oracle Database versions for Autonomous Database for Developers.

- **Oracle Database 19c**

  If you are using Autonomous Database for Developers with Oracle Database 19c, then many of the concepts and features of this service are further documented here:

  – Oracle Database 19c
- **Oracle Database 23ai**

  If you are using Autonomous Database for Developers with Oracle Database 23ai, then many of the concepts and features of this service are further documented here:

  – Oracle Database 23ai

  – *Oracle Database New Features*

Supported Features with Autonomous Database for Developers

Autonomous Database for Developers supports most but not all of the Autonomous Database features.

The following features help you use your Autonomous Database instance for development tasks:

- **Cloning**: Autonomous Database for Developers instances are low-cost, fixed shape databases intended for development and testing uses cases, and are not recommended for production use cases. For uses such as full scale load testing and production deployments or to access all Autonomous Database features, you can clone an Autonomous Database for Developers instance to a full paid service instance. See Clone an Autonomous Database Instance for instructions.
- **Service Maintenance:** Autonomous Database for Developers instances have the same patching schedule as full paid service instances.

  See About Scheduled Maintenance and Patching for more information.
- **Database Application Development and Developer Tools:** Autonomous Database for Developers provides all of the developer-related features and built-in tools that a full paid service Autonomous Database offers.

  See About Autonomous Database Built-in Tools for more information.

Autonomous Database for Developers comes with a service level objective (SLO) of 99.5%, and you can log service requests (SRs) to Oracle Support for assistance. However, there is no Severity 1 SR support for Autonomous Database for Developers instances. See Get Help, Search Forums, and Contact Support to learn how to contact Oracle Support for assistance.

Provisioning and Cloning Workflow with Autonomous Database for Developers

You can provision or clone Autonomous Database for Developers from the Oracle Cloud Infrastructure(OCI) console or using the API.

Provisioning or cloning Autonomous Database for Developers instances from the OCI console follows the same workflow as provisioning or cloning a full paid service Autonomous Database. In the **Configure the database** step, select **Autonomous Database for Developers**.

See Provision an Autonomous Database Instance and Clone an Autonomous Database Instance for more information.

Upgrade Autonomous Database for Developers Instance to a Full Paid Instance

You can upgrade an Autonomous Database for Developers instance to a full paid service instance.

If your Oracle Cloud Infrastructure account is in a trial period or has paying status you can upgrade your Autonomous Database for Developers database to a full paid service instance as follows:

1. From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
2. On the Autonomous Databases page select an Autonomous Database for Developers (**Developer**) instance from the links under the **Display name** column.
3. On the Autonomous Database Details page, from the **More actions** drop-down list select **Upgrade instance to full paid service**.
4. Click **Upgrade instance to full paid service**.

When you upgrade from an Autonomous Database for Developers instance to a full paid service instance, you get an instance with the same workload type. The ECPU and storage in

the upgraded paid instance are initially set to the minimum ECPU and storage values based on your workload type.

> **Note:**
>
> After you upgrade you can scale up your compute and storage resources to fit your needs.

Autonomous Database for Developers Workload Type	Workload Type, ECPU and Storage Values
Data Warehouse	When you upgrade to full paid service from an Autonomous Database for Developers instance, the upgrade process provides a full paid service instance with workload type Data Warehouse, with 2 ECPUs and 1 TB of database storage.
Transaction Processing, JSON, or APEX	When you upgrade to full paid service from an Autonomous Database for Developers instance, the upgrade process provides a full paid service instance with the same workload type as you had, with 2 ECPUs and 20 GB of database storage.

Features Not Available in Autonomous Database for Developers

There are some features that are not available with an Autonomous Database for Developers instance, compared to a full paid service instance.

The limitations for Autonomous Database for Developers are in place to ensure that instances are specifically used as a development sandbox and to assist you in working with Autonomous Database. When you want to use a feature that is not available, you can upgrade to a full paid service Autonomous Database.

Autonomous Database for Developers restrictions and exclusions:

- Do not support disaster recovery options, including: Autonomous Data Guard, Backup-Based Disaster Recovery, or OCI Full Stack Disaster Recovery
- Supports ECPUs only
- Comes with fixed compute and storage sizing and does not support manual or auto-scaling and storage scaling.
- Does not support elastic pools
- Does not provide an SLA Guarantee
- Use of refreshable clones is not allowed
- Does not provide auto start-stop schedules
- Does not support Bring Your Own License (BYOL) licensing
- Autonomous Database for Developers databases cannot be provisioned as a private endpoint and cannot reside within a Virtual Cloud Network (VCN). See Configure Private Endpoints When You Provision or Clone an Instance for further information on private endpoints.
- Does not provide backup or restore operations:
  - No backups can be used (backups are shown)
  - Does not support long-term backups

- Does not support restore (you cannot restore the current database to a selected past backup or timestamp).

To use backup and restore functionality on Autonomous Database you must upgrade an Autonomous Database for Developers to a full paid service instance.

See Upgrade Autonomous Database for Developers Instance to a Full Paid Instance for more information.

2
Quick Start

- Before You Begin with Oracle Autonomous Database
  Before you begin using Oracle Autonomous Database, you should be familiar with Oracle Cloud.
- Autonomous Database 15 Minute Quick Start
  Learn about Autonomous Database Serverless and learn how to create an Autonomous Database in just a few clicks.

Before You Begin with Oracle Autonomous Database

Before you begin using Oracle Autonomous Database, you should be familiar with Oracle Cloud.

Before you create an Autonomous Database:

- On Oracle Cloud, sign up for Oracle Cloud Free Tier or sign up for a paid Cloud Account. You cannot create an Autonomous Database deployment until you do so.

  See Welcome to Oracle Cloud Infrastructure for more information.
- (Optional) if you want to leverage an object store for data loading you need your object store credentials to use with Oracle Autonomous Database, including a *username* and a *password*. For details on the required credentials, depending on the object store you want to use, see the following:
  - **Oracle Cloud Infrastructure Object Storage**, the `username` is your Oracle Cloud Infrastructure user name. The `password` is your auth token. See Working with Auth Tokens.
  - **Oracle Cloud Infrastructure Object Storage Classic**, the `username` is your Oracle Cloud Infrastructure Classic user name and the `password` is your Oracle Cloud Infrastructure Classic password.
  - **Amazon S3**, the `username` is your AWS access key ID and the `password` is your AWS secret access key. See AWS Identity and Access Management.
  - **Azure Blob Storage or Azure Data Lake Storage**, the `username` is your Azure storage account name and the `password` is an Azure storage account access key. See About Azure storage accounts.
  - **Amazon S3-Compatible**, such as Oracle Cloud Infrastructure Object Storage, Google Cloud Storage, and Wasabi Hot Cloud Storage. See CREATE_CREDENTIAL Procedure for more information.
  - **GitHub Repository**, the `username` is your GitHub email and the `password` is your GitHub personal access token. See Creating a personal access token for more information.

Autonomous Database 15 Minute Quick Start

Learn about Autonomous Database Serverless and learn how to create an Autonomous Database in just a few clicks.

Autonomous Database 15 Minute Quick Start Workshop

- Deploy an Autonomous Database instance that is optimized for data warehousing workloads.
- Use Autonomous Database tools to load object storage sources.
- Use advanced SQL to uncover issues and possibilities

3 Tasks

- Provision or Clone an Autonomous Database
  Provisioning a new Autonomous Database is easy. You can also provision a new Autonomous Database by cloning an existing instance.
- Connect to Autonomous Database
  Describes methods to securely connect to Autonomous Database.
- Manage Users
  Describes administration tasks for managing database users on Autonomous Database.
- Manage Credentials or Configure Policies and Roles to Access Resources
  Describes the methods in which Autonomous Database connects to other resources, either with credentials, or by configuring policies and roles for access.
- Load Data into Autonomous Database
  Describes packages and tools to load data with Autonomous Database.
- Link Data
  You can link to data in remote databases, in cloud storage, or in connected file systems or the local file system. You can also use Database Links to access objects on another database.
- Call Web Services from Autonomous Database
  Describes options for calling Web Services from Autonomous Database.
- Move Files
  Describes how to create directories and copy files to Autonomous Database.
- Replicate Data
  Describes using Oracle GoldenGate to replicate data between an Autonomous Database instance and to any target database or platform that Oracle GoldenGate supports.
- Exporting Data from Autonomous Database to Object Store or to Other Oracle Databases
  To export data from an Autonomous Database, use one of the following methods:
- Data Sharing
  Share data on Autonomous Database
- Develop
  Describes developer tasks and procedures on Autonomous Database.
- Analyze
  Provides information on the built-in tools that allow you to explore your data with reports, analytics, and visualization.
- Manage the Service
  Describes basic tasks for managing an Autonomous Database instance.
- Managing and Viewing Maintenance Windows, Patching Options, Work Requests, and Customer Contacts
- Monitor and Manage Performance
  Describes the Database Dashboard card in Database Actions where you can find information about the performance of an Autonomous Database instance.

- Use Sample Data Sets in Autonomous Database
  For users who want to start using the service without creating their own tables, Autonomous Database provides the read-only Sales History and Star Schema Benchmark data sets.
- Use the Autonomous Database Free Container Image

Provision or Clone an Autonomous Database

Provisioning a new Autonomous Database is easy. You can also provision a new Autonomous Database by cloning an existing instance.

See Provision an Autonomous Database Instance for details on how to create an Autonomous Database for your workload type using the Create Autonomous Database dialog.

See Clone an Autonomous Database Instance for details on cloning.

To get started, you can also try the LiveLabs Autonomous Database 15 Minute Quick Start.

After you create an Autonomous Database:

- (Optional) Reset the administrator password:

  When you create an Autonomous Database you are required to set the administrator password. If you want to change the administrator password or if you need to unlock the administrator account, see Manage the Administrator Account on Autonomous Database.
- (Optional) Add Oracle Machine Learning component users. See Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database for more information.
- (Optional) Download Oracle Analytics Desktop and add a connection to Autonomous Database. See Create Dashboards and Reports to Analyze and Visualize Your Data.

Connect to Autonomous Database

Describes methods to securely connect to Autonomous Database.

- About Connecting to an Autonomous Database Instance
  After you create database users, applications and tools connect to Autonomous Databases using Oracle Net Services (also known as SQL*Net). Oracle Net Services enables a network session from a client application to an Oracle Database server.
- Connect to Autonomous Database Using a Client Application
  Autonomous Database is preconfigured to support Oracle Net Services (a TNS listener is installed and configured to use secure TCPS).
- Download Database Connection Information
- Connect to Autonomous Database Using Oracle Database Tools
  Oracle Database Tools such as SQL Developer, SQL*Plus, and SQLcl can be used with Autonomous Database.
- Connect with Built-In Oracle Database Actions
  You can access Database Actions from Autonomous Database. Database Actions provides development tools, data tools, administration, and monitoring features for Autonomous Database. Using Database Actions you can run SQL statements, queries, and scripts in a worksheet.

- Connect with JDBC Thin Driver
  Autonomous Database mandates a secure connection that uses Transport Layer Security (TLSv1.2).
- Preparing for Oracle Call Interface Connections
  Using TLS with Oracle Call Interface connections with newer Oracle Instant Client/Oracle Database Client versions, a wallet is not required. For TLS connections with Oracle Call Interface running on older Oracle Instant Client/Oracle Database Client versions, a wallet is required for both mTLS authenticated connections and TLS authenticated connections.
- Predefined Database Service Names for Autonomous Database
  The `tnsnames.ora` file provided with the credentials zip file contains the database service names that allow you to connect to your database.
- Connect with Oracle Analytics Desktop
  Oracle Analytics Desktop makes it easy to visualize your data so you can focus on exploring interesting data patterns. Just connect to Autonomous Database, select the elements that you're interested in, and let Oracle Analytics Desktop find the best way to visualize it. Choose from a variety of visualizations to look at data in a specific way.
- Connect with Oracle Analytics Cloud
  Oracle Analytics Cloud is a scalable and secure public cloud service that provides a full set of capabilities to explore and perform collaborative analytics for you, your workgroup, and your enterprise.
- Connection and Networking Options and Features
  Autonomous Database provides a number of different connection and networking options and features for connecting to a database.

About Connecting to an Autonomous Database Instance

After you create database users, applications and tools connect to Autonomous Databases using Oracle Net Services (also known as SQL*Net). Oracle Net Services enables a network session from a client application to an Oracle Database server.

When a network session is established, Oracle Net Services acts as the data courier for both the client application and the database. It is responsible for establishing and maintaining the connection between the client application and the database, as well as exchanging messages between them.

Oracle Net Services supports a variety of connection types to connect to an Autonomous Database instance, including:

- **JDBC Thin Driver**: for Java applications, the JDBC Thin Driver is a pure Java driver. Many applications, including Oracle SQL Developer support JDBC Thin Driver connections.
- **JDBC OCI**: which is used by Java language applications. JDBC OCI adds a layer over Oracle Call Interface for Java applications. The Oracle SQLcl command-line interface uses JDBC OCI.
- **Oracle Call Interface (OCI)**: used by many applications written in C language. Examples that use Oracle Call Interface include Oracle utilities such as Oracle SQL*Plus, SQL*Loader, and Oracle Data Pump.
- **ODBC Drivers**: used by applications running on Microsoft Windows, that are layered over Oracle Call Interface (OCI).

Third-party products and custom applications may use any of these connection types.

Topics

- Secure Connections to Autonomous Database with mTLS or with TLS
  Connections to Autonomous Database are made either over the public Internet, optionally with Access Control Rules (ACLs) defined, or using a private endpoint inside a Virtual Cloud Network (VCN) in your tenancy.
- Connect to Autonomous Database Through a Firewall
  Most organizations protect networks and devices on a network using a firewall. A firewall controls incoming and outgoing network traffic using rules which allow the use of certain ports and access to certain computers (or, more specifically IP addresses or host names). An important function of a firewall is to provide separation between internal networks and the public internet.
- Using Application Continuity
  Application Continuity masks outages from end users and applications by recovering the in-flight work for impacted database sessions following outages. Application Continuity performs this recovery beneath the application so that the outage appears to the application as a slightly delayed execution.

Secure Connections to Autonomous Database with mTLS or with TLS

Connections to Autonomous Database are made either over the public Internet, optionally with Access Control Rules (ACLs) defined, or using a private endpoint inside a Virtual Cloud Network (VCN) in your tenancy.

When you specify a private endpoint configuration, this only allows traffic from the virtual cloud network you specify and blocks access to the database from all public IPs or VCNs. Configuring a private endpoint allows you to keep all traffic to and from your database off of the public internet. With a private endpoint, when public access is enabled with **Allow public access**, the instance has both a private endpoint and a public endpoint:

- The private hostname, endpoint URL, and private IP address allow you to connect to the database from the VCN where the database resides.
- The public hostname allows you to connect to the database from specific public IP addresses or from specific VCNs if those VCNs are configured to privately connect to Autonomous Database using a Service Gateway.

Many applications provide support for more than one connection type, but each type of connection to Autonomous Database uses certificate authentication and TCPS (Secure TCP) database connection using standard TLS 1.2. This ensures that there is no unauthorized access to the Autonomous Database and that communications between the client and server are fully encrypted and cannot be intercepted or altered.

Autonomous Database by default supports Mutual TLS (mTLS) connections (use port 1522 to connect with mTLS). You have the option to configure an Autonomous Database instance to support both mTLS and TLS connections (use either port 1521 or 1522 to connect with TLS).

There are advantages for clients using TLS authentication with Autonomous Database, including the following:

- TLS connections do not require that you download a wallet. For TLS connections using JDBC Thin Driver with JDK8 or higher, a wallet is not required. This includes connections coming from the clients such as SQL Developer and SQL Command Line (SQLcl).
- Clients connecting with TLS do not need to worry about wallet rotation. Wallet rotation is a regular procedure for mTLS connections.

- TLS connections can be faster (providing less connection latency). TLS authentication can provide reduced connection latency compared to mTLS.
- TLS and mTLS connections are not mutually exclusive. Mutual TLS (mTLS) authentication is enabled by default and always available. When you enable TLS authentication, you can use either mTLS or TLS authentication.
- Using TLS authentication does not compromise the fully encrypted end-to-end communication between a client and Autonomous Database.

See View TNS Names and Connection Strings for an Autonomous Database Instance for details on obtaining the mTLS connection strings for your Autonomous Database Instance.

About Mutual TLS (mTLS) Authentication

Using Mutual Transport Layer Security (mTLS), clients connect through a TCPS (Secure TCP) database connection using standard TLS 1.2 with a trusted client certificate authority (CA) certificate.

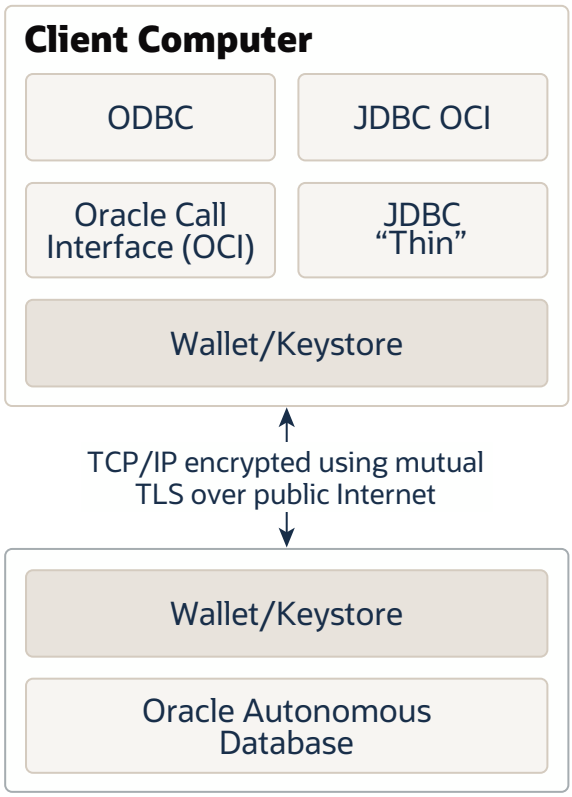
With mutual authentication both the client application and Autonomous Database authenticate each other. Autonomous Database uses mTLS authentication by default. Use port 1522 to connect to an Autonomous Database instance with mTLS (the 1522 port assignment cannot be changed).

Mutual TLS authentication requires that the client downloads or obtains a trusted client CA certificate for connecting to an Autonomous Database instance. Autonomous Database then uses the certificate to authenticate the client. This provides increased security and specifies the clients that can communicate with an Autonomous Database instance.

Certification authentication with Mutual TLS uses an encrypted key stored in a *wallet* on both the client (where the application is running) and the server (where your database service on the Autonomous Database is running). The key on the client must match the key on the server to make a connection. A wallet contains a collection of files, including the key and other information needed to connect to your Autonomous Database instance. All communications between the client and the server are encrypted.

To secure the connection to your Autonomous Database instance a service administrator downloads the client credentials (wallet files) from Autonomous Database. If you are not an Autonomous Database service administrator, your administrator provides you with the client credentials. See Download Client Credentials (Wallets) for more information.

The following figure shows client secure connections to Oracle Autonomous Database over the public Internet using Mutual TLS connections. If you configure your database to use private endpoints, then the public internet is not used and the connection uses a private endpoint inside a Virtual Cloud Network (VCN) in your tenancy.



See View TNS Names and Connection Strings for an Autonomous Database Instance for details on obtaining the mTLS connection strings for your Autonomous Database Instance.

About TLS Authentication

Using Transport Layer Security (TLS), clients connect through a TCPS (Secure TCP) database connection using standard TLS 1.2. A client uses its list of trusted Certificate Authorities (CA)s to validate the server's CA root certificate. If the issuing CA is trusted, the client verifies that the certificate is authentic.

This allows the client and Autonomous Database to establish the encrypted connection before exchanging any messages. Use either port 1521 or 1522 to connect to an Autonomous Database instance with TLS (these port assignments cannot be changed).

When you connect with TLS authentication using JDBC Thin Driver clients, including Oracle SQL Developer and Oracle SQLcl, you do not need to download a wallet to secure the connection to your Autonomous Database instance. TLS authentication enables the client to verify the identity of the Autonomous Database service to provide secure communication.

Depending on the type of client, a TLS connection has the following support with Autonomous Database:

- For connections with JDBC Thin Driver using JDK8u162 or higher, including connections with Oracle SQL Developer and Oracle SQLcl, a wallet is not required.
- Oracle Call Interface (OCI) clients support TLS authentication without a wallet if you are using the following client versions:
  - Oracle Instant Client/Oracle Database Client 19.13 - only on Linux x64
  - Oracle Instant Client/Oracle Database Client 19.14 (or later) and 21.5 (or later) - only on Linux x64 and Windows
- If the client is connecting with managed ODP.NET or ODP.NET Core versions 19.13 or 21.4 (or above) using TLS authentication, the client can connect without providing a wallet.

There are network access prerequisites for TLS connections. See Network Access Prerequisites for TLS Connections for more information.

See View TNS Names and Connection Strings for an Autonomous Database Instance for details on obtaining the TLS connection strings for your Autonomous Database Instance.

Connect to Autonomous Database Through a Firewall

Most organizations protect networks and devices on a network using a firewall. A firewall controls incoming and outgoing network traffic using rules which allow the use of certain ports and access to certain computers (or, more specifically IP addresses or host names). An important function of a firewall is to provide separation between internal networks and the public internet.

When Autonomous Database is configured for access using the public internet, you must configure the firewall to allow access to Autonomous Database servers.

To access the Autonomous Database from behind a firewall, the firewall must permit the use of the port specified in the database connection when connecting to the servers in the connection. Use port 1522 for Autonomous Database mTLS connections (you can see the port number in the connection string from the `tnsnames.ora` file in your `credentials ZIP` file). For example, see the `port` value in the following `tnsnames.ora` file:

```
db2022adb_high = (description = (
                address=(protocol=tcps)
                (port=1522)
                (host=adb.example.oraclecloud.com))
                (connect_data=(service_name=example_high.adb.oraclecloud.com))
                (security=(ssl_server_dn_match=yes)))
```

Your firewall must allow access to servers within the `.oraclecloud.com` domain using port 1522. To connect to Autonomous Database, depending upon your organization's network configuration, you may need to use a proxy server to access this port or you may need to request that your network administrator open this port.

See IP Address Ranges for information about the public IP address ranges in Oracle Cloud Infrastructure. You must allow traffic to these CIDR blocks to ensure access to an Autonomous Database instance on a public endpoint.

Using Application Continuity

Application Continuity masks outages from end users and applications by recovering the in-flight work for impacted database sessions following outages. Application Continuity performs this recovery beneath the application so that the outage appears to the application as a slightly delayed execution.

> **Note:**
>
> By default Application Continuity is disabled.

See Use Application Continuity on Autonomous Database for more information on Application Continuity.

Connect to Autonomous Database Using a Client Application

Autonomous Database is preconfigured to support Oracle Net Services (a TNS listener is installed and configured to use secure TCPS).

The client computer must be prepared to use Oracle Net Services to connect to Autonomous Database.

- About Connecting to Autonomous Database Using a Client Application
  Applications can connect to Autonomous Database using any of the connection types supported by Oracle Net Services.
- Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections with Wallets (mTLS)
  Preparing for any type of Oracle Call Interface (OCI) connection with mTLS authentication requires the installation of client software, downloading client credentials, and configuring certain files and environment variables.
- Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections Using TLS Authentication
  Preparing for any type of Oracle Call Interface (OCI) connection with TLS authentication requires the installation of client software and configuring certain files and environment variables.
- Prepare for JDBC Thin Connections
  Applications that use JDBC Thin connections include the software necessary to make an Oracle Net Services connection. It is not necessary to download and install Oracle Client software.
- Connect Microsoft .NET, Visual Studio Code, and Visual Studio with a Wallet (mTLS)
  Oracle Autonomous Database supports connectivity to the Microsoft .NET Framework, .NET Core, Visual Studio, and Visual Studio Code.
- Connect Microsoft .NET, Visual Studio Code, and Visual Studio Without a Wallet
  Oracle Autonomous Database supports connectivity to the Microsoft .NET Framework, .NET Core, Visual Studio, and Visual Studio Code using TLS authentication without a wallet.
- Connect Node.js and other Scripting Languages (mTLS)
  You can use programs in different languages, including Python, Node.js, PHP, Ruby, R, Go, and Perl to connect to an Autonomous Database instance using mTLS (with wallets). Security is enforced using client credentials.
- Connect Node.js, and Other Scripting Languages Without a Wallet
  You can use programs in different languages, including Python, Node.js, PHP, Ruby, R, Go, and Perl to connect to an Autonomous Database instance using TLS authentication without a wallet.
- Connect Power BI and Microsoft Data Tools to Autonomous Database
  Oracle Client for Microsoft Tools (OCMT) is a graphical user interface (GUI) native Microsoft Software installer (MSI) that simplifies ODP.NET setup and Oracle database connectivity to multiple Microsoft data tools.
- Connect Python Applications to Autonomous Database
  You can connect Python applications to your Autonomous Database instance either with a wallet (mTLS) or without a wallet (TLS).
- Connect Go Applications to Autonomous Database
  You can connect Go applications to your Autonomous Database instance either with a wallet (mTLS) or without a wallet (TLS).

About Connecting to Autonomous Database Using a Client Application

Applications can connect to Autonomous Database using any of the connection types supported by Oracle Net Services.

Consult your application documentation for details about how your application connects to Oracle.

The following steps describe the process of connecting to Autonomous Database using a client application:

1. Determine what connection type your application uses, (for example OCI, ODBC, JDBC Thin, and so on).
2. The steps required to prepare the client computer depend on the type of connection the client application uses. Determine what authentication type your application uses, either mTLS or TLS and prepare your client computer:
   - **Mutual TLS authentication connections**: In all cases, with mTLS connections, client credentials in the form of a wallet file must be downloaded to the client.
   - **TLS authentication connections**: For connections with JDBC Thin Driver using JDK8u162 or higher, including connections with Oracle SQL Developer and Oracle SQLcl, a wallet is not required.

     Oracle Call Interface (OCI) clients support TLS authentication without a wallet if you are using the following client versions:

     – Oracle Instant Client/Oracle Database Client 19.13 - only on Linux x64

     – Oracle Instant Client/Oracle Database Client 19.14 (or later) and 21.5 (or later) - only on Linux x64 and Windows

   See the details for each driver type for information on the steps required to prepare your application to connect to Autonomous Database.
3. Within your application, set up the connection.

Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections with Wallets (mTLS)

Preparing for any type of Oracle Call Interface (OCI) connection with mTLS authentication requires the installation of client software, downloading client credentials, and configuring certain files and environment variables.

This topic covers the steps to prepare an application to connect using mTLS authentication with a wallet that you download from an Autonomous Database instance. See Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections Using TLS Authentication for information on the steps to prepare for TLS authentication with these connection types.

New Oracle Client Installation

The following steps assume Oracle client software has not already been installed on the client computer. If Oracle client software has already been installed and there are working copies of `sqlnet.ora` and `tnsnames.ora`, see Updating an Existing Oracle Client Installation.

Before making an Oracle Call Interface (OCI), ODBC, or JDBC OCI connection, do the following:

1. Install Oracle Client software on your computer.

- **Oracle Instant Client/Oracle Database Client**: 18.19 (or later), 19.2 (or later), or 21 (base release or later). The Instant Client contains the minimal software needed to make an Oracle Call Interface connection.

2. Download client credentials and store the file in a secure folder on your client computer. See Download Client Credentials (Wallets).
3. Unzip/uncompress the credentials file into a secure folder on your client computer.
4. Edit the `sqlnet.ora` file in the folder where you unzip the credentials file, replacing `"?/network/admin"` with the name of the folder containing the client credentials.

   For example, edit `sqlnet.ora` as follows:

   ```
   WALLET_LOCATION = (SOURCE = (METHOD = file) (METHOD_DATA = (DIRECTORY="?/
   network/admin")))
   SSL_SERVER_DN_MATCH=yes
   ```

   The changed value on UNIX/Linux is:

   ```
   WALLET_LOCATION = (SOURCE = (METHOD = file) (METHOD_DATA = (DIRECTORY="/
   home/adb_credentials")))
   SSL_SERVER_DN_MATCH=yes
   ```

   The changed value for Windows is:

   ```
   WALLET_LOCATION = (SOURCE = (METHOD = file) (METHOD_DATA = (DIRECTORY="D:\
   \myapp\\adb_credentials")))
   SSL_SERVER_DN_MATCH=yes
   ```

5. Create the `TNS_ADMIN` environment variable and set it to the location of the credentials file.

   Use this environment variable to change the directory path of Oracle Net Services configuration files from the default location of `ORACLE_HOME\network\admin` to the location of the secure folder containing the credentials file you saved in Step 2. Set the `TNS_ADMIN` environment variable to the directory where the unzipped credentials files are, not to the credentials file itself.

   For example, on UNIX/Linux set `TNS_ADMIN` to the full path of the directory where you unzipped the client credentials:

   ```
   export TNS_ADMIN=/home/adb_credentials
   ```

   For example on Windows:

   ```
   set TNS_ADMIN=d:\myapp\adb_credentials
   ```

Connections with an HTTP Proxy

If the client is behind a firewall and your network configuration requires an HTTP proxy to connect to the internet, then perform the following steps to update the `sqlnet.ora` and `tnsnames.ora` files. Connections through an HTTP proxy are only available with Oracle Client software version 12.2.0.1 or later.

> **Note:**
>
> To avoid manual updates in `sqlnet.ora` and `tnsnames.ora` files, you can use SQLcl and specify the HTTP proxy on the command line. See Connect Oracle SQLcl Cloud with a Wallet (mTLS) for more information.

1. Add the following line to the `sqlnet.ora` file to enable connections through an HTTP proxy:

   ```
   SQLNET.USE_HTTPS_PROXY=on
   ```

2. Add the HTTP proxy hostname and port to the connection definitions in `tnsnames.ora`. You need to add the `https_proxy` and `https_proxy_port` parameters in the address section of connection definitions. For example, the following sets the HTTP proxy to `proxyhostname` and the HTTP proxy port to `80`; replace these values with your HTTP proxy information:

   ```
   ADB1_high =
          (description=
                (address=
                      (https_proxy=proxyhostname)(https_proxy_port=80)
   (protocol=tcps)(port=1522)(host=adb.example.oraclecloud.com)
                )
                (connect_data=(service_name=adb1_high.adb.oraclecloud.com)
                )
                (security=(ssl_server_dn_match=yes))
                )
          )
   ```

> **Note:**
>
> Configuring `sqlnet.ora` and `tnsnames.ora` for the HTTP proxy may not be enough depending on your organization's network configuration and security policies. For example, some networks require a `username` and `password` for the HTTP proxy. In such cases contact your network administrator to open outbound connections to hosts in the oraclecloud.com domain using port 1522 without going through an HTTP proxy.

For more information on `SQLNET.USE_HTTPS_PROXY`, see *Net Services Reference*.

For information on `HTTPS_PROXY` and `HTTPS_PROXY_PORT`, see Protocol Address Section.

Updating an Existing Oracle Client Installation

If you have an existing Oracle Client installation, you already have `sqlnet.ora` and `tnsnames.ora` files and the `TNS_ADMIN` environment variable. In this case, do the following:

1. Update your `sqlnet.ora` file by adding the following:

   ```
   WALLET_LOCATION = (SOURCE = (METHOD = file) (METHOD_DATA = (DIRECTORY="/
   home/adb_credentials")))
   ```

2. Copy the entries in the `tnsnames.ora` file provided in the Autonomous Database wallet to your existing `tnsnames.ora` file.

Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections Using TLS Authentication

Preparing for any type of Oracle Call Interface (OCI) connection with TLS authentication requires the installation of client software and configuring certain files and environment variables.

Oracle Call Interface (OCI) clients support TLS authentication without a wallet if you are using the following client versions:

- Oracle Instant Client/Oracle Database Client 19.13 - only on Linux x64
- Oracle Instant Client/Oracle Database Client 19.14 (or later) and 21.5 (or later) - only on Linux x64 and Windows

See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for information on allowing TLS connections.

1. Install Oracle Instant Client.
   a. Got to the Oracle Instant Client page and click **Download Now**: Oracle Instant Client
   b. On the Oracle Instant Client Downloads page, select your platform.

      For example, under **Instant Client for Linux**, select the Instant Client for Linux x86-64 architecture (for this example, to download the Linux x86-64 version).
   c. Under **Version 19.14.0.0.0 (Requires glibc 2.14)**, select an Instant Client package to download.
   d. If you are building a language API or driver from source code, you may also need to download the Instant Client SDK Package version 19.14: Oracle Instant Client
   e. Unzip the base package you selected. If you also download the SDK, unzip it in the same directory.
   f. On Linux, create a symbolic link if it does not exist. For example:

      ```
      cd /home/myuser/instantclient_19_14
      ln -s libclntsh.so.19.1 libclntsh.so
      ```

      If there is no other Oracle software on your system that will be impacted, add Instant Client to the runtime link path. For example:

      ```
      sudo sh -c "echo /home/myuser/instantclient_19_14 > /etc/ld.so.conf.d/
      oic.conf"
      sudo ldconfig
      ```

      Alternatively set the library path in each shell that runs your application. For example:

      ```
      export LD_LIBRARY_PATH=/home/myuser/instantclient_19_14:$LD_LIBRARY_PATH
      ```

> **Note:**
>
> The Linux Instant Client download files are available as `.zip` files or `.rpm` files. You can use either version.

2. If you have not already done so, enable TLS connections on your Autonomous Database instance.

   See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for details.

3. Run Your Application

   a. Update your application to connect using your database username, your password, and the Oracle Net connect name given in the unzipped `tnsnames.ora` file. For example, user, `adb_user`, *password*, and `db2022adb_low` as the connect string.

   b. Alternatively, change the connect string in `tnsnames.ora` to match the string used by your application.

   c. Run your application.

Allowing TLS connections to Autonomous Database does not disallow mutual TLS (mTLS) connections. Both Mutual TLS (mTLS) and TLS connections are valid when an Autonomous Database instance is configured to allow TLS connections. See Connect Node.js and other Scripting Languages (mTLS) for information on connecting using mutual TLS (mTLS) with a wallet.

In this case, update your `sqlnet.ora` file by adding the following:

```
WALLET_LOCATION = (SOURCE = (METHOD = file) (METHOD_DATA = (DIRECTORY="/home/
wallet1")))
```

Prepare for JDBC Thin Connections

Applications that use JDBC Thin connections include the software necessary to make an Oracle Net Services connection. It is not necessary to download and install Oracle Client software.

Some applications use the JDK installed on your computer while others use a JDK that is embedded in the application installation. If your application uses the JDK installed on your computer and that JDK is version 8, 8u161 or later, no additional preparation is required. If your computer does not have JDK version 8, 8u161 or later, already installed then install the latest JDK first. You can download the latest JDK from https://www.java.com/.

If your application is using a JDK version 8, prior to 8u161, then the JCE Policy Files must be updated within your application.

See Connect with JDBC Thin Driver for the steps required to use JDBC Thin connections to connect to an Oracle Database server.

- Set JVM Networking Properties
  Autonomous Database uses DNS names that map to multiple IP addresses (multiple load balancers) for better availability and performance. Depending on your application, you may want to configure certain JVM networking properties.

Set JVM Networking Properties

Autonomous Database uses DNS names that map to multiple IP addresses (multiple load balancers) for better availability and performance. Depending on your application, you may want to configure certain JVM networking properties.

For the Java Virtual Machine (JVM) address cache, any address resolution attempt caches the result whether it was successful or not, so that subsequent identical requests do not have to access the naming service. The address cache properties allow you to tune how the cache operates. In particular, the `networkaddress.cache.ttl` value specifies the number of seconds a successful name lookup is kept in the cache. A value of -1, the default value, indicates a “cache forever” policy, while a value of `0` (zero) means no caching.

If your Java Virtual Machine (JVM) is configured to cache DNS address lookups, your application may be using only one IP address to connect to your Autonomous Database, resulting in lower throughput. To prevent this you can change your JVM's `networkaddress.cache.ttl` value to `0`, so that every connection request does a new DNS lookup. This ensures that different threads in your application are distributed over multiple load balancers.

To change the `networkaddress.cache.ttl` value for all applications, or in your application, do one of the following:

- Configure the security policy to set the value for all applications:
  Set `networkaddress.cache.ttl=0` in the file `$JAVA_HOME/jre/lib/security/java.security`
- Set the following property in your application code:

```
java.security.Security.setProperty("networkaddress.cache.ttl" , "0");
```

Connect Microsoft .NET, Visual Studio Code, and Visual Studio with a Wallet (mTLS)

Oracle Autonomous Database supports connectivity to the Microsoft .NET Framework, .NET Core, Visual Studio, and Visual Studio Code.

Oracle Data Provider for .NET (ODP.NET) provides run-time ADO.NET data access to a database.

ODP.NET has the following driver types:

- Unmanaged ODP.NET for .NET Framework applications
- Managed ODP.NET for .NET Framework applications
- ODP.NET Core for .NET Core applications

The following minimum versions are required:

- **ODP.NET**: 12.1 (Starting with April 2022 WINDBBP; ODP.NET Managed only), 18 (base release or later), 19.4 (or later, except for 19.10), 21 (base release or later), or 23 (base release or later).

Oracle Developer Tools for Visual Studio and Oracle Developer Tools for VS Code provide database application design-time support in the Microsoft development environment, including tools for managing Autonomous Databases in the Oracle Cloud.

Oracle Developer Tools for VS Code provides database application design-time support in Visual Studio Code.

These software components are available as a free download from the following sites:

- Managed ODP.NET and ODP.NET Core: NuGet Gallery
- Unmanaged ODP.NET: Oracle Data Access Components Downloads
- Oracle Developer Tools for Visual Studio Code: VS Code Marketplace
- Oracle Developer Tools for Visual Studio: Oracle Developer Tools for Visual Studio

Oracle recommends using the latest provider and tools version with Oracle Autonomous Database.

Click the following link for instructions to download, install, and configure these components for use with mutual TLS (mTLS) and wallets:

- Developing .NET Applications for Oracle Autonomous Database

To use mutual TLS (mTLS) authentication to connect to Autonomous Database, you must download a wallet. See Download Client Credentials (Wallets) for information downloading wallets.

ODP.NET connectivity to Oracle Autonomous Database supports mutual TLS (mTLS) with wallets as well as TLS. See Connect Microsoft .NET, Visual Studio Code, and Visual Studio Without a Wallet for information on using TLS connections.

To learn more about using Oracle Autonomous Database and .NET, try the free .NET Development with Oracle Autonomous Database Quick Start. This lab walks you through setting up a .NET web server on Oracle Cloud Infrastructure that connects to Oracle Autonomous Database. Next, the lab guides developing and deploying a simple ASP.NET Core web application that uses all these components. By the end, you will have a live, working website on the Internet.

Connect Microsoft .NET, Visual Studio Code, and Visual Studio Without a Wallet

Oracle Autonomous Database supports connectivity to the Microsoft .NET Framework, .NET Core, Visual Studio, and Visual Studio Code using TLS authentication without a wallet.

Oracle Data Provider for .NET (ODP.NET) provides run-time ADO.NET data access to Autonomous Database. ODP.NET has the following driver types:

- Unmanaged ODP.NET for .NET Framework applications
- Managed ODP.NET for .NET Framework applications
- ODP.NET Core for .NET Core applications

Oracle Developer Tools for Visual Studio and Oracle Developer Tools for VS Code provide database application design-time support in the Microsoft development environment, including tools for managing Autonomous Databases in the Oracle Cloud.

Oracle Developer Tools for VS Code provides database application design-time support in Visual Studio Code.

These software components are available as a free download from the following sites:

- Managed ODP.NET and ODP.NET Core: NuGet Gallery
- Unmanaged ODP.NET: Oracle Data Access Components Downloads
- Oracle Developer Tools for Visual Studio Code: VS Code Marketplace
- Oracle Developer Tools for Visual Studio: Oracle Developer Tools for Visual Studio

Oracle recommends using the latest provider and tools version with Oracle Autonomous Database.

When you connect using TLS authentication with managed ODP.NET and ODP.NET Core you do not need to deploy the Oracle wallet or the Oracle network configuration files `sqlnet.ora` or `tnsnames.ora` with your application. Instead, you supply the data source attribute, a TLS connection string, with the configuration information in the ODP.NET connection.

To use TLS connections with Managed ODP.NET and ODP.NET Core, do the following:

1. Obtain managed ODP.NET or ODP.NET Core versions 19.14 (or later), 21.5 (or later), or 23 (base release or later). Lower level versions do not support TLS connections with Oracle Autonomous Database.
2. Enable TLS connections on your Autonomous Database instance. See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for details.
3. After you enable TLS connections, supply a TLS connection string in the ODP.NET data source to connect to an Autonomous Database instance. See View TNS Names and Connection Strings for an Autonomous Database Instance for details on viewing or copying TLS connection strings.

Allowing TLS connections to Autonomous Database does not disallow mutual TLS (mTLS) connections. Both Mutual TLS (mTLS) and TLS connections are valid when an Autonomous Database instance is configured to allow TLS connections. See Connect Microsoft .NET, Visual Studio Code, and Visual Studio with a Wallet (mTLS) for information on connecting using mutual TLS (mTLS) with a wallet.

To learn more about using Oracle Autonomous Database and .NET, try the free .NET Development with Oracle Autonomous Database Quick Start. This lab walks you through setting up a .NET web server on Oracle Cloud Infrastructure that connects to Oracle Autonomous Database. Next, the lab guides developing and deploying a simple ASP.NET Core web application that uses all these components. By the end, you will have a live, working website on the Internet.

Connect Node.js and other Scripting Languages (mTLS)

You can use programs in different languages, including Python, Node.js, PHP, Ruby, R, Go, and Perl to connect to an Autonomous Database instance using mTLS (with wallets). Security is enforced using client credentials.

These scripting languages have database access APIs or drivers that use the Oracle Call Interface libraries.

> **Note:**
>
> Oracle Call Interface (OCI) clients support mTLS authentication with a wallet if you are connecting using the following client versions:
>
> - Oracle Instant Client/Oracle Database Client: 18.19 (or later), 19.2 (or later), or 21 (base release or later).
>
> For details on connecting Node.js or other scripting languages without a wallet, see Connect Node.js, and Other Scripting Languages Without a Wallet.

For additional details, see the following video:

- Connect Node.js Apps to Autonomous Transaction Processing

Install the Language Driver and Client Libraries

To connect to Autonomous Database from your scripting language, first install the language driver and client libraries as follows:

1. Install Oracle Instant Client/Oracle Database Client: 18.19 (or later), 19.2 (or later), or 21 (base release or later).

   The Instant Client works well for most applications. To install the Instant Client do the following:

   a. Select your desired architecture from the Instant Client Downloads page and download a Basic Package (available on the download page): Oracle Instant Client Downloads.

      Alternatively download the Basic Light Package from the download page for your desired architecture if the Basic Light globalization limitations suit your use.

   b. If you are building a language API or driver from source code, you may also need to download the Instant Client SDK: Oracle Instant Client

   c. Unzip the base package you selected. For example unzip to `C:\instantclient_12_2` or `/home/myuser/instantclient_18_5`. If you also download the SDK, unzip it in the same directory.

   d. On Windows, add the path to the `PATH` variable in the "System variables" section of the Environment Variables pane (for example add `C:\instantclient_12_2`). On Windows 8 access the `PATH` variable setting area by navigating to Control Panel>System>Advanced System Settings>Environment Variables. If you have multiple versions of Oracle libraries installed make sure the new directory occurs first in the path.

   e. On non-Windows platforms, create a symbolic link if it does not exist. For example:

      ```
      cd /home/myuser/instantclient_18_5
      ln -s libclntsh.so.18.1 libclntsh.so
      ```

      If there is no other Oracle software on your system that will be impacted, add Instant Client to the runtime link path. For example:

      ```
      sudo sh -c "echo /home/myuser/instantclient_18_5 > /etc/ld.so.conf.d/
      oic.conf"
      sudo ldconfig
      ```

      Alternatively set the library path in each shell that runs your application. For example:

      ```
      export LD_LIBRARY_PATH=/home/myuser/instantclient_18_5:$LD_LIBRARY_PATH
      ```

      > **Note:**
      >
      > The Linux Instant Client download files are available as `.zip` files or `.rpm` files. You can use either version.

2. Install the relevant language driver for Oracle Database:

   - **Node.js** : To install node-oracledb for Node.js,, use the instructions on the following page: Installing node-oracledb.

- **ROracle**: To install ROracle for R, use the instructions on the following page: ROracle
- **PHP**: To install PHP OCI8 for PHP, use the instructions on the following page: Configuring PHP with OCI8.

  Windows DLLs are available on http://php.net/downloads.php and are also available from PECL oci8.
- **PHP PDO_OCI**: To install PHP PDO_OCI for PHP, use the instructions on the following page: Oracle Functions (PDO_OCI).

  Windows DLLs are available on http://php.net/downloads.php included in PHP.
- **Ruby**: To install ruby-oci8 for Ruby, use the instructions on the following page: Install for Oracle Instant Client
- **DBD for Perl**: To install DBD::Oracle for Perl, set `ORACLE_HOME` and your library search path such as `LD_LIBRARY_PATH` or `PATH` to the Instant Client directory and use the instructions on the following page: Installing DBD-Oracle.
- **Python**: For instructions for connecting Python applications, see Connect Python Applications with a Wallet (mTLS)

Enable Oracle Network Connectivity and Obtain the Security Credentials (Oracle Wallet)

1. Obtain client security credentials to connect to Autonomous Database. You obtain a zip file containing client security credentials and network configuration settings required to access your database. You must protect this file and its contents to prevent unauthorized database access. Obtain the client security credentials file as follows:
   - ADMIN user: Click **Database connection**. See Download Client Credentials (Wallets).
   - Other user (non-administrator): Obtain the Oracle Wallet from the administrator for your Autonomous Database.
2. Extract the client credentials (wallet) files:
   a. Unzip the client credentials zip file.
   b. If you are using Instant Client, make a `network/admin` subdirectory hierarchy under the Instant Client directory if necessary. Then move the files to this subdirectory. For example depending on the architecture or your client system and where you installed Instant Client, the files should be in the directory:

      ```
      C:\instantclient_12_2\network\admin
      ```

      or

      ```
      /home/myuser/instantclient_18_5/network/admin
      ```

      or

      ```
      /usr/lib/oracle/18.5/client64/lib/network/admin
      ```

      - If you are using a full Oracle Client move the file to `$ORACLE_HOME/network/admin`.

   c. Alternatively, put the unzipped wallet files in a secure directory and set the `TNS_ADMIN` environment variable to that directory name.

> **Note:**
>
> From the zip file, only these files are required: `tnsnames.ora`, `sqlnet.ora`, `cwallet.sso`, and `ewallet.p12`.

3. If you are behind a proxy follow the steps in “Connections with an HTTP Proxy”, in Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections with Wallets (mTLS).

Run Your Application

1. Update your application to connect using your database username, your password, and the Oracle Net connect name given in the unzipped `tnsnames.ora` file. For example, user, `adb_user`, *password*, and `db2022adb_low` as the connect string.
2. Alternatively, change the connect string in `tnsnames.ora` to match the string used by your application.
3. Run your application.

Connect Node.js, and Other Scripting Languages Without a Wallet

You can use programs in different languages, including Python, Node.js, PHP, Ruby, R, Go, and Perl to connect to an Autonomous Database instance using TLS authentication without a wallet.

These scripting languages have database access APIs or drivers that use the Oracle Call Interface libraries. The Oracle Call Interface libraries can be either from the full Oracle Client or from Oracle Instant Client.

> **Note:**
>
> Oracle Call Interface (OCI) clients support TLS authentication without a wallet if you are using the following client versions:
>
> - Oracle Instant Client/Oracle Database Client 19.13 - only on Linux x64
> - Oracle Instant Client/Oracle Database Client 19.14 (or later) and 21.5 (or later) - only on Linux x64 and Windows

1. Install Oracle Instant Client.
   a. Got to the Oracle Instant Client page and click **Download Now**: Oracle Instant Client
   b. On the Oracle Instant Client Downloads page, select your platform.

      For example, under **Instant Client for Linux**, select the Instant Client for Linux x86-64 architecture (for this example, to download the Linux x86-64 version).
   c. Under **Version 19.14.0.0.0 (Requires glibc 2.14)**, select an Instant Client package to download.
   d. If you are building a language API or driver from source code, you may also need to download the Instant Client SDK Package version 19.14: Oracle Instant Client
   e. Unzip the base package you selected. If you also download the SDK, unzip it in the same directory.

f. On Linux, create a symbolic link if it does not exist. For example:

```
cd /home/myuser/instantclient_19_14
ln -s libclntsh.so.19.1 libclntsh.so
```

If there is no other Oracle software on your system that will be impacted, add Instant Client to the runtime link path. For example:

```
sudo sh -c "echo /home/myuser/instantclient_19_14 > /etc/ld.so.conf.d/
oic.conf"
sudo ldconfig
```

Alternatively set the library path in each shell that runs your application. For example:

```
export LD_LIBRARY_PATH=/home/myuser/instantclient_19_14:$LD_LIBRARY_PATH
```

> **Note:**
>
> The Linux Instant Client download files are available as `.zip` files or `.rpm` files. You can use either version.

2. Install the relevant language driver for Oracle Database:
   - **Node.js** : To install node-oracledb for Node.js,, use the instructions on the following page: Installing node-oracledb.
   - **ROracle**: To install ROracle for R, use the instructions on the following page: ROracle
   - **PHP**: To install PHP OCI8 for PHP, use the instructions on the following page: Configuring PHP with OCI8.

     Windows DLLs are available on http://php.net/downloads.php and are also available from PECL oci8.
   - **PHP PDO_OCI**: To install PHP PDO_OCI for PHP, use the instructions on the following page: Oracle Functions (PDO_OCI).

     Windows DLLs are available on http://php.net/downloads.php included in PHP.
   - **Ruby**: To install ruby-oci8 for Ruby, use the instructions on the following page: Install for Oracle Instant Client
   - **DBD for Perl**: To install DBD::Oracle for Perl, set `ORACLE_HOME` and your library search path such as `LD_LIBRARY_PATH` or `PATH` to the Instant Client directory and use the instructions on the following page: Installing DBD-Oracle.
   - **Python**: For instructions for connecting Python applications, see Connect Python Applications Without a Wallet (TLS)
3. If you have not already done so, enable TLS connections on your Autonomous Database instance.

   See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for details.
4. Run Your Application

a. Update your application to connect using your database username, your password, and the Oracle Net connect name given in the unzipped `tnsnames.ora` file. For example, user, `adb_user`, *password*, and `db2022adb_low` as the connect string.

b. Alternatively, change the connect string in `tnsnames.ora` to match the string used by your application.

c. Run your application.

Allowing TLS connections to Autonomous Database does not disallow mutual TLS (mTLS) connections. Both Mutual TLS (mTLS) and TLS connections are valid when an Autonomous Database instance is configured to allow TLS connections. See Connect Node.js and other Scripting Languages (mTLS) for information on connecting using mutual TLS (mTLS) with a wallet.

Connect Power BI and Microsoft Data Tools to Autonomous Database

Oracle Client for Microsoft Tools (OCMT) is a graphical user interface (GUI) native Microsoft Software installer (MSI) that simplifies ODP.NET setup and Oracle database connectivity to multiple Microsoft data tools.

OCMT supports the following Microsoft tools:

- Power BI Desktop (unmanaged ODP.NET)
- Power BI service (unmanaged ODP.NET)
- Excel (unmanaged ODP.NET)
- SQL Server Analysis Services (unmanaged ODP.NET)
- BizTalk Server (unmanaged ODP.NET)
- SQL Server Data Tools (managed ODP.NET)
- SQL Server Integration Services (managed ODP.NET)
- SQL Server Reporting Services (managed ODP.NET)

To begin with, you must download this tool from the Oracle Client for Microsoft Tools page by clicking the **64-bit Oracle Client for Microsoft Tools** link. Save the **Oracle-Client-for-Microsoft-Tools.exe** file to your Windows machine and double-click the file to run the GUI installer.

By default, OCMT installs with both the managed and unmanaged ODP.NET providers. However, you can choose to have only managed ODP.NET or unmanaged ODP.NET driver while installing the Oracle client. The ODP.NET driver type each Microsoft data tool uses is shown in parenthesis in the above list.

Managed ODP.NET works with both 64-bit and 32-bit MS tool runtimes. In the case of unmanaged ODP.NET provider, OCMT installs the 64-bit driver. Thus, it supports 64-bit tools, such as 64-bit Power BI Desktop and 64-bit Excel, but not their 32-bit counterparts. 32-bit MS tools can continue using 32-bit Oracle Data Access Client (ODAC) 19c xcopy installs to set up 32-bit unmanaged ODP.NET as before.

Irrespective of the Microsoft tool that you want to connect to your Autonomous Database, you must follow a sequence of steps to use OCMT. They are:

- Provision an Autonomous Database. Refer to Provision Autonomous Database for instructions.
- Download database credentials to the Windows client. Refer to Download Client Credentials (Wallets) for instructions.

- Depending on the Microsoft (MS) tool that you want to connect to the Autonomous Database, you can install any of the following MS tools to the Windows client:
  - Visual Studio and Microsoft Reporting Services extension
  - Visual Studio and Microsoft Analysis Services extension
  - Visual Studio with the SQL Server Integration Services extension, which also supports SQL Server Data Tools
  - Power BI On-premises Data gateway
  - Power BI Desktop
- Install and configure ODP.NET on the Windows client
- Validate the MS tool connection to Autonomous Database

Below are step-by-step connectivity tutorials for each of the MS tools listed above. These tutorials show how to connect these MS tools with either on-premises Oracle databases or Oracle Autonomous Database:

- Power BI Desktop: Connect to Oracle Database
- Power BI Service: Connect to Oracle Database
- SQL Server Data Tools and Integration Services: Connect to Oracle Database
- SQL Server Analysis Services: Connect to Oracle Database
- SQL Server Reporting Services: Connect to Oracle Database

Connect Python Applications to Autonomous Database

You can connect Python applications to your Autonomous Database instance either with a wallet (mTLS) or without a wallet (TLS).

- Install Python and the python-oracledb Driver
  To connect to Autonomous Database from your Python application, install Python and the python-oracledb driver.
- Connect Python Applications Without a Wallet (TLS)
- Connect Python Applications with a Wallet (mTLS)

Install Python and the python-oracledb Driver

To connect to Autonomous Database from your Python application, install Python and the python-oracledb driver.

1. Install Python 3, if it is not already available.

   The version of Python you use depends on your client-side OS and hardware. For example Windows, Linux, macOS, and others.

   > **Note:**
   >
   > Oracle recommends you keep up to date with Python and python-oracledb driver releases.

2. Install the python-oracledb driver from PyPI.

The python-oracledb driver is a Python programming language extension module allowing Python programs to connect to Oracle Database. The python-oracledb driver is the renamed, new major release of the popular cx_Oracle driver.

Supported python-oracledb driver versions: python-oracledb 1.0 (or later)

Run the following command to upgrade python:

```
python -m pip install oracledb --upgrade
```

You should see output similar to the following:

```
Collecting oracledb
  Downloading oracledb-1.0.3-cp310-cp310-win_amd64.whl (1.0 MB)
     ---------------------------------------- 1.0/1.0 MB 1.8 MB/s eta
0:00:00
Collecting cryptography>=3.4
  Downloading cryptography-37.0.4-cp36-abi3-win_amd64.whl (2.4 MB)
     ---------------------------------------- 2.4/2.4 MB 3.5 MB/s eta
0:00:00
Collecting cffi>=1.12
  Downloading cffi-1.15.1-cp310-cp310-win_amd64.whl (179 kB)
     ---------------------------------------- 179.1/179.1 kB 5.4 MB/s eta
0:00:00
Collecting pycparser
  Downloading pycparser-2.21-py2.py3-none-any.whl (118 kB)
     ---------------------------------------- 118.7/118.7 kB 7.2 MB/s eta
0:00:00
Installing collected packages: pycparser, cffi, cryptography, oracledb
Successfully installed cffi-1.15.1 cryptography-37.0.4 oracledb-1.0.3
pycparser-2.21
```

Notes for installing python-oracledb:

- If you are behind a proxy, use the `--proxy` option to add a proxy server to the command. For example:

  ```
  python -m pip install oracledb --upgrade --proxy=http://
  proxy.example.com:80
  ```

- In the case where you do not have permission to write to system directories, include the `--user` option. For example:

  ```
  python -m pip install oracledb --upgrade --user
  ```

- If a binary package is not available for your platform, running `pip` will download the source package instead. The source is compiled and the resulting binary is installed.

See Installing python-oracledb for additional options and tips.

3. If you want to use the python-oracledb driver in Thick mode, install Oracle Client software.

   By default, python-oracledb runs in Thin mode which connects directly to Oracle Database. Thin mode does not require Oracle Client libraries. However, some additional functionality is available when python-oracledb runs in Thick mode.

> **Note:**
>
> See Oracle Database Features Supported by python-oracledb for information on supported features in python-oracledb Thin and Thick modes. Not all of the features shown in this link are available with Autonomous Database.

Python-oracledb uses Thick mode when you use either the Oracle Instant client libraries or the Oracle Database Client libraries and you call `oracledb.init_oracle_client()` in your Python code.

When you install Oracle Client Software, there are differences in required minimum versions for mTLS and TLS connections, as follows:

- **Mutual TLS (mTLS) Connections**:
  - If your database is on a remote computer, then download the free Oracle Instant Client “Basic” or “Basic Light” package for your operating system architecture. Use a supported version: **Oracle Instant Client**: 18.19 (or later), 19.2 (or later), or 21 (base release or later).
  - Alternatively, you can use the Full Oracle Database client libraries when they are available on your system (including Full Oracle Database Client: **Oracle Database Client**: 18.19 (or later), 19.2 (or later), or 21 (base release or later).
- **TLS Connections**: Oracle Call Interface (OCI) clients support TLS authentication without a wallet if you are using the following client versions:
  - Oracle Instant Client/Oracle Database Client 19.14 (or later) and 21.5 (or later) - only on Linux x64 and Windows
  - Alternatively, you can use the Full Oracle Database client libraries when they are available on your system, including Full Oracle Database Client 19.14 (or later) and 21.5 (or later).

Connect Python Applications Without a Wallet (TLS)

You can connect Python applications to your Autonomous Database instance without a wallet. Connecting a Python application without a wallet (TLS) provides security for authentication and encryption, and security is enforced using client credentials (by providing a username and password).
The python-oracledb driver's default "Thin mode" connects directly to Oracle Database. It can optionally use Oracle Client libraries, "Thick mode", for some additional functionality. The Oracle Client libraries can be from Oracle Instant Client, the full Oracle Client, or an Oracle Database installation.

Follow these steps to connect your Python application to an Autonomous Database instance without a wallet (TLS):

1. Install Python and the python-oracledb Driver
2. Enable TLS on Autonomous Database and Obtain Connection String
3. Run Python Application Without a Wallet

See Enabling python-oracledb Thick mode for information on Thick mode.

Topics

- Enable TLS on Autonomous Database and Obtain Connection String

- Run Python Application Without a Wallet
  A Python application can connect to your Autonomous Database instance without a wallet (TLS) using the database credentials and a connect descriptor.

Enable TLS on Autonomous Database and Obtain Connection String

To run a Python application without a wallet, enable the Autonomous Database instance for TLS connections and obtain a connection string to contact the database from the Python application.

1. Determine if your Autonomous Database instance is enabled for TLS connections.

   If the instance is enabled for TLS connections, in the **Network** area on the Oracle Cloud Infrastructure Console the **Mutual TLS (mTLS) authentication** field shows: **Not Required**:

   
   If your instance requires Mutual TLS authentication, allow TLS connections on your Autonomous Database instance. See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for details.

2. Obtain an Autonomous Database service connection string to access the database as follows:

   a. On the Oracle Cloud Infrastructure Console, click **Database connection**.

   b. Select **TLS** in the Database Connection dialog box, under **Connection Strings**, in the **TLS Authentication** drop-down list.

   > **Note:**
   >
   > You must select **TLS** in the **TLS Authentication** drop-down to obtain the TLS connection strings before you copy a connection string (when the value is **Mutual TLS** the connection strings have different values and do not work with TLS connections).

   c. Copy the Connection String for the database service you want to use with your application.

   See View TNS Names and Connection Strings for an Autonomous Database Instance for more information.

Run Python Application Without a Wallet

A Python application can connect to your Autonomous Database instance without a wallet (TLS) using the database credentials and a connect descriptor.

1. Obtain the connection string, as described in Enable TLS on Autonomous Database and Obtain Connection String.

2. In your Python application, set the following connection parameters to connect to an Autonomous Database instance:

- `dsn`: Use the connection string to specify the desired database service name.
- `password`: Specifies the database user password.
- `user`: Specifies the database user.

For example:

```
cs='''(description = (retry_count=20)(retry_delay=3)
(address=(protocol=tcps)
     (port=1521)(host=xxx.oraclecloud.com))
     (connect_data=(service_name=xxx.adb.oraclecloud.com))
     (security=(ssl_server_dn_match=yes)))'''

connection=oracledb.connect(
     user="admin",
     password=password,
     dsn=cs)
```

3. If you want to connect in Thick mode, include `oracledb.init_oracle_client()` in your Python application.

   For example:

```
cs='''(description = (retry_count=20)(retry_delay=3)
(address=(protocol=tcps)
     (port=1521)(host=xxx.oraclecloud.com))
     (connect_data=(service_name=xxx.adb.oraclecloud.com))
     (security=(ssl_server_dn_match=yes)))'''

oracledb.init_oracle_client()
connection=oracledb.connect(
     user="admin",
     password=password,
     dsn=cs)
```

Connect Python Applications with a Wallet (mTLS)

You can connect Python applications to your Autonomous Database instance with a wallet.

Connecting a Python application with a wallet (mTLS) provides enhanced security for authentication and encryption, and security is enforced using client credentials (by providing a username and password).

The python-oracledb driver's default "Thin mode" connects directly to Oracle Database. The driver can optionally use Oracle Client libraries, "Thick mode", for some additional functionality. The Oracle Client libraries can be from Oracle Instant Client, the full Oracle Client, or from an Oracle Database installation.

Follow these steps to connect your Python application to an Autonomous Database instance using a wallet (mTLS):

1. Install Python and the python-oracledb Driver
2. Obtain Security Credentials (Oracle Wallet) and Enable Network Connectivity
3. Perform this step if you only want to connect in Thin mode: Run Python Application with python-oracledb Thin Mode with a Wallet (mTLS)

4. Perform this step if you want to connect in Thick mode: Run Python Application with python-oracledb Thick Mode with a Wallet (mTLS)

Topics

- Obtain Security Credentials (Oracle Wallet) and Enable Network Connectivity
  Obtain client security credentials to connect to an Autonomous Database instance.
- Run Python Application with python-oracledb Thin Mode with a Wallet (mTLS)
  By default, python-oracledb uses Thin mode to connect directly to your Autonomous Database instance.
- Run Python Application with python-oracledb Thick Mode with a Wallet (mTLS)

Obtain Security Credentials (Oracle Wallet) and Enable Network Connectivity

Obtain client security credentials to connect to an Autonomous Database instance.

1. Download a wallet file from the Autonomous Database instance to obtain a zip file that contains the client security credentials and network configuration settings required to access an Autonomous Database instance.

   Obtain the client security credentials (`wallet.zip` file):

   - ADMIN user: On the Oracle Cloud Infrastructure Console, click **Database connection**. See Download Client Credentials (Wallets).
   - Other user (non-administrator): Obtain the Oracle Wallet from the administrator for your Autonomous Database instance.

   > **Note:**
   >
   > Protect the `wallet.zip` file and its contents to prevent unauthorized database access.

2. Unzip the client credentials file (`wallet.zip`).

Run Python Application with python-oracledb Thin Mode with a Wallet (mTLS)

By default, python-oracledb uses Thin mode to connect directly to your Autonomous Database instance.

In Thin mode only two files from the wallet zip are needed:

- `tnsnames.ora`: Maps net service names used for application connection strings to your database services.
- `ewallet.pem`: Enables SSL/TLS connections in Thin mode.

To connect in Thin mode:

1. Move `tnsnames.ora` and `ewallet.pem` files to a location on your system.

   - Linux
   - Windows

Linux

For example on Linux:

```
/opt/OracleCloud/MYDB
```

Windows

For example on Windows:

```
C:\opt\OracleCloud\MYDB
```

2. In your Python application, set the following connection parameters to connect to an Autonomous Database instance:
   - `config_dir`: Specifies the directory containing `tnsnames.ora`.
   - `dsn`: Use to specify the desired network alias from the `tnsnames.ora` file.
   - `password`: Specifies the database user password.
   - `user`: Specifies the database user.
   - `wallet_location`: Specifies the directory containing the PEM file (`ewallet.pem`).
   - `wallet_password`: Specifies the password for the PEM file (`ewallet.pem`). You set this password when you download the `wallet.zip` file.

- Linux
- Windows

Linux

For example, on Linux to connect as the ADMIN user using `oracledb.connect` with the `db2024_low` network service name (the service name is found in `tnsnames.ora`):

```
connection=oracledb.connect(
     config_dir="/opt/OracleCloud/MYDB",
     user="admin",
     password=password,
     dsn="db2024_low",
     wallet_location="/opt/OracleCloud/MYDB",
     wallet_password=wallet_pw)
```

Windows

For example, on Windows to connect as the ADMIN user using `oracledb.connect` with the `db2024_low` network service name (the service name is found in `tnsnames.ora`):

```
connection=oracledb.connect(
     config_dir=r"C:\opt\OracleCloud\MYDB",
     user="admin",
     password=password,
```

```
    dsn="db2024_low",
    wallet_location=r"C:\opt\OracleCloud\MYDB",
    wallet_password=wallet_pw)
```

The use of a 'raw' string `r"..."` means that backslashes are treated as directory separators.

As shown in this example, `wallet_location` and `config_dir` are set to the same directory (and the directory contains `tnsnames.ora` and `ewallet.pem`). Specifying the same directory for these files is not required.

If you are behind a firewall, you can tunnel TLS/SSL connections through a proxy using HTTPS_PROXY in the connect descriptor or by setting connection attributes. Successful connection depends on specific proxy configurations. Oracle does not recommend using a proxy in a production environment, due to the possible impact on performance.

In Thin mode you can specify a proxy by adding the `https_proxy` and `http_proxy_port` parameters.

For example, on Linux:

```
connection=oracledb.connect(
     config_dir="/opt/OracleCloud/MYDB",
     user="admin",
     password=password,
     dsn="db2024_low",
     wallet_location="/opt/OracleCloud/MYDB",
     wallet_password=wallet_pw,
     https_proxy='myproxy.example.com',
     https_proxy_port=80)
```

For example, on Windows:

```
connection=oracledb.connect(
     config_dir=r"C:\opt\OracleCloud\MYDB",
     user="admin",
     password=password,
     dsn="db2024_low",
     wallet_location=r"C:\opt\OracleCloud\MYDB",
     wallet_password=wallet_pw,
     https_proxy='myproxy.example.com',
     https_proxy_port=80)
```

Run Python Application with python-oracledb Thick Mode with a Wallet (mTLS)

By default, python-oracledb runs in Thin mode which connects directly to Oracle Database. Additional python-oracledb features are available when the driver runs in Thick mode.

> **Note:**
>
> Thick mode requires that the Oracle Client libraries are installed where you run Python. You must also call `oracledb.init_oracle_client()` in your Python code.

In Thick mode the following three files from the wallet zip file are required:

- `tnsnames.ora`: Contains the net service names used for application connection strings and maps the strings to your database services.
- `sqlnet.ora`: Specifies the SQL*Net client side configuration.
- `cwallet.sso`: Contains the auto-open SSO wallet.

To connect in Thick mode:

1. Place the files `tnsnames.ora`, `sqlnet.ora`, and `cwallet.sso` on your system.

   Use one of two options to place these files on your system:

   - If you are using Instant Client, move the files to a `network/admin` subdirectory hierarchy under the Instant Client directory. For example depending on the architecture or your client system and where you installed Instant Client, the files should placed be in a directory location such as:

     ```
     /home/myuser/instantclient_19_21/network/admin
     ```

     or

     ```
     /usr/lib/oracle/19.21/client64/lib/network/admin
     ```

     For example, on Linux if you are using the full Oracle Client move the files to `$ORACLE_HOME/network/admin`.

   - Alternatively, move the files to any accessible directory.

     For example, on Linux move the files to the directory `/opt/OracleCloud/MYDB` and edit `sqlnet.ora` to change the wallet location directory to the directory containing the `cwallet.sso` file.

     For example, on Linux edit `sqlnet.ora` as follows:

     ```
     WALLET_LOCATION = (SOURCE = (METHOD=file) (METHOD_DATA =
     (DIRECTORY="/opt/OracleCloud/MYDB")))
     SSL_SERVER_DN_MATCH=yes
     ```

     When the configuration files are not in the default location, your application needs to indicate where they are, either with the `config_dir` parameter in the call `oracledb.init_oracle_client()` or by setting the `TNS_ADMIN` environment variable.

     > **Note:**
     >
     > Neither of these settings are needed, and you do not need to edit `sqlnet.ora` if you put all the configuration files in the `network/admin` directory.

2. In your Python application set the following initialization and connection parameters to connect to the Autonomous Database instance:

   - `config_dir`: Specifies the configuration directory when you are putting the configuration files. This is only required when the configuration files are placed in a directory outside of the instant client configuration directory `network/admin`.

- `dsn`: Specifies the desired network alias from the `tnsnames.ora` file.
- `password`: Specifies the database user password.
- `user`: Specifies the database user.

In the first case for placement of the configuration files, connect to the Autonomous Database instance using your database credentials by setting the `dsn` parameter to the desired network alias from `tnsnames.ora`.

For example, to connect as the ADMIN user using `oracledb.init_oracle_client` and connect with the `db2024_low` network service name (where the service name is found in `tnsnames.ora`):

```
oracledb.init_oracle_client()
   connection=oracledb.connect(
       user="admin",
       password=password,
       dsn="db2024_low")
```

When configuration files are in a directory outside of the instant client configuration directory, set the `config_dir` parameter when you call `oracledb.init_oracle_client`.

- Linux
- Windows

Linux

For example, on Linux to connect as the ADMIN user using the `db2024_low` network service name:

```
oracledb.init_oracle_client(config_dir="/opt/OracleCloud/MYDB")
   connection=oracledb.connect(
      user="admin",
      password=password,
      dsn="db2024_low")
```

Windows

For example, on Windows to connect as the ADMIN user using the `db2024_low` network service name:

```
oracledb.init_oracle_client(config_dir=r"C:\opt\OracleCloud\MYDB")
   connection=oracledb.connect(
      user="admin",
      password=password,
      dsn="db2024_low")
```

The use of a ‘raw’ string `r"..."` means that backslashes are treated as directory separators.

If you are behind a firewall, you can tunnel TLS/SSL connections through a proxy using HTTPS_PROXY in the connect descriptor or by setting connection attributes. Successful connection depends on specific proxy configurations. Oracle does not recommend using a proxy in a production environment, due to the possible impact on performance.

In Thick mode you can specify a proxy by editing the `sqlnet.ora` file and adding a line:

```
SQLNET.USE_HTTPS_PROXY=on
```

In addition, edit `tnsnames.ora` and add an `HTTPS_PROXY` proxy name and `HTTPS_PROXY_PORT` port to the connect descriptor address list of any service name you plan to use.

For example:

```
mydb_high=(description=
(address=(https_proxy=myproxy.example.com)
(https_proxy_port=80)
(protocol=tcps)(port=1522)(host=...)
```

See Enabling python-oracledb Thick mode for information on Thick mode.

Connect Go Applications to Autonomous Database

You can connect Go applications to your Autonomous Database instance either with a wallet (mTLS) or without a wallet (TLS).

The Go language is an open source language and has support for SQL interactions. You can connect any Go program to your Autonomous Database using the Godror driver. The `godror` driver requires Oracle Client libraries such as from Oracle Instant Client.

> **Note:**
>
> The `godror` driver is a third party driver. It is not an Oracle driver.

- Install Go and the Godror driver
  To connect to Autonomous Database from your Go application, install Go and the `godror` driver.
- Connect Go Applications Without a Wallet (TLS) Using TLS
  You can connect Go applications to your Autonomous Database instance without a wallet using TLS.
- Connect Go Applications with a Wallet (mTLS)
  You can connect Go applications to your Autonomous Database instance with a wallet.

Install Go and the Godror driver

To connect to Autonomous Database from your Go application, install Go and the `godror` driver.

1. Download and install Go based on your operating system and the version of the operating system. This method installs from precompiled binary packages.

> **Note:**
>
> These steps describe installation of Go application for Microsoft Windows operating system. For Linux and Mac operating system, you can check out the link mentioned in this step.

2. Open the MSI file you downloaded and follow the prompts to download Go. The installer will install the `godror` driver.
3. Go to Program Files (x86).

   After installing, close and reopen any open command prompts so that changes to the environment made by the installer are reflected at the command prompt.
4. Verify that you've installed Go.
   - In **Windows**, click the **Start** menu.
   - In the menu's search box, type `cmd`, then press the **Enter** key.
   - In the Command Prompt window that appears, type the following command:

     ```
     go version
     ```

   - Confirm that the command prints the installed version of Go.
5. Install `godror`:

   To install `godror`, run the following command:

   ```
   go get github.com/godror/godror
   ```

   `Godror` is an open source database package in Go that allows a Go application user to connect and work with Autonomous Database using ODPI-C.

   See Go DRiver for ORacle User Guide (godror) for additional tips on installation.
6. Install an Oracle Client library to use `Godror`.

   `Godror` uses Oracle Database Programming Interface for C (ODPI-C) which supports connection to Oracle databases.
   Follow the ODPI-C installation instructions to install and configure the Oracle client libraries.

   You can use the optional `libDir` parameter to specify the Oracle Client library directory on macOS and Windows. For example,

   ```
   db, err := sql.Open("godror", `user="scott" password="tiger"
   connectString="dbhost:1521/orclpdb1"
                                 libDir="/Users/myname/instantclient_19_3"`)
   ```

   In this example, the `libDir` parameter value is set to the path to the location where you unzip the Oracle Instant Client zip files.

> **Note:**
>
> Oracle recommends you keep up to date with Go and `godror` releases.

Connect Go Applications Without a Wallet (TLS) Using TLS

You can connect Go applications to your Autonomous Database instance without a wallet using TLS.

Connecting a Go application without a wallet (TLS) provides security for authentication and encryption, and security is enforced using client credentials (by providing a username and password).

Topics

- Enable TLS on Autonomous Database and Obtain Connection String
  To run a Go application without a wallet using TLS, enable the Autonomous Database instance for TLS connections and obtain a connection string to contact the database from the Go application.
- Run Go Application Without a Wallet Using TLS
  The following section describes the steps to run a Go application on an Autonomous Database instance.

Enable TLS on Autonomous Database and Obtain Connection String

To run a Go application without a wallet using TLS, enable the Autonomous Database instance for TLS connections and obtain a connection string to contact the database from the Go application.

1. Determine if your Autonomous Database instance is enabled for TLS connections.

   If the instance is enabled for TLS connections, in the **Network** area on the Console the **Mutual TLS (mTLS) authentication** field shows: **Not Required**:

   
   If your instance requires Mutual TLS authentication, allow TLS connections on your Autonomous Database instance. See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for details.

2. Obtain an Autonomous Database service connection string to access the database as follows:

   a. On the Oracle Cloud Infrastructure Console, click **Database connection**.

   b. Select **TLS** in the Database Connection dialog box, under **Connection Strings**, in the **TLS Authentication** drop-down list.

> **Note:**
>
> You must select **TLS** in the **TLS Authentication** drop-down to obtain the TLS connection strings before you copy a connection string (when the value is **Mutual TLS** the connection strings have different values and do not work with TLS connections).

c. Copy the connection string for the database service you want to use with your application.

   See View TNS Names and Connection Strings for an Autonomous Database Instance for more information.

Run Go Application Without a Wallet Using TLS

The following section describes the steps to run a Go application on an Autonomous Database instance.

1. Obtain the connection string, as described in Enable TLS on Autonomous Database and Obtain Connection String.
2. In your Go application, set the following parameters to connect to an Autonomous Database instance:
   - `password`: Specifies the database user password.
   - `user`: Specifies the database user.
   - `libDir`: Single directory where you unzip the Oracle Instant Client zip package.
   - `connectString`: Use the connection string you obtained from the previous step to connect using the desired database service name.

   To run a Go application using the `godror` driver, you must first import the `godror` package.

   Following is a sample code in the Go Application which enables you to connect to an Autonomous Database:

```
package main

import (
    "database/sql"
    "fmt"

    _ "github.com/godror/godror"
)

func main() {
    connectToADb()
}

func connectToADb() {
    fmt.Println("Connecting to Oracle Autonomous database !!!")
    db, err := sql.Open("godror", `user="admin" password="password"
    connectString="tcps://adb.ap-mumbai-1.oraclecloud.com:1522/
abcd_xxxx_medium.adb.oraclecloud.com?wallet_location=/Users/user/tool/
wallet_DB/"
    libDir="/home/user/tool/instantclient_19_8/"`)
```

```
    if err != nil {
        fmt.Println(err)
        return
    }
    defer db.Close()

    rows, err := db.Query("select 'hello' from dual")
    if err != nil {
        fmt.Println("Error running query")
        fmt.Println(err)
        return
    }
    defer rows.Close()

    var resData string
    for rows.Next() {

        rows.Scan(&resData)
    }
    fmt.Printf("The response is: %s\n", resData)
}
```

This code will return records retrieved from the Autonomous Database.

Connect Go Applications with a Wallet (mTLS)

You can connect Go applications to your Autonomous Database instance with a wallet.

Topics

- Download an Oracle Wallet File
  You must download an Oracle Wallet (mTLS) file to obtain client security credentials that enable you to connect to an Autonomous Database instance.
- Run Go Applications with a Wallet (mTLS)
  You can connect Go applications to your Autonomous Database instance with a wallet. You must download a zipped wallet file from the Autonomous Database instance that contains the client security credentials.

Download an Oracle Wallet File

You must download an Oracle Wallet (mTLS) file to obtain client security credentials that enable you to connect to an Autonomous Database instance.

1. Download a wallet file from the Autonomous Database instance to obtain a zip file that contains the client security credentials and network configuration settings required to access an Autonomous Database instance.

   Depending on whether you are an Admin user or a non-Admin user, obtain the client security credentials (wallet.zip file) as follows:

   - ADMIN user: On the Oracle Cloud Infrastructure Console, click **Database connection**. See Download Client Credentials (Wallets).
   - Other user (non-administrator): Obtain the Oracle Wallet from the administrator for your Autonomous Database instance.

> **Note:**
>
> Protect the `wallet.zip` file and its contents to prevent unauthorized database access.

2. Unzip the client credentials file (`wallet.zip`).

Run Go Applications with a Wallet (mTLS)

You can connect Go applications to your Autonomous Database instance with a wallet. You must download a zipped wallet file from the Autonomous Database instance that contains the client security credentials.

The `godror` driver requires Oracle Client Libraries. See Install Oracle Client Library to use Godror. The Oracle Client libraries are installed where you run the Go Application.

The wallet file is in a zip archive format. The database service names can be found in the `tnsnames.ora` file in the wallet zip file. In the example given below, you will use the `mydb_high` network service name found in the `tnsnames.ora` file.

The following three files from the wallet zip file are required:

- `tnsnames.ora`: Contains the net service names used for application connection strings and maps the strings to your database services.
- `sqlnet.ora`: Specifies the SQLNet client side configuration.
- `cwallet.sso`: Contains the auto-open SSO wallet.

Follow these steps to connect your Go application to an Autonomous Database instance using a wallet (mTLS):

1. Place the files `tnsnames.ora`, `sqlnet.ora`, and `cwallet.sso` on the optional (`opt`) directory of your Linux system. The /`opt` directory is used to install optional or add-on software packages that are not part of the core operating system. You can place the files anywhere on your Microsoft Windows operating system. For example, subdirectory on C drive (`C:`) of your Microsoft Windows operating system.

   You can move the files to any accessible directory.

   For example, on Linux move the files to the directory `/opt/OracleCloud/MYDB` and edit `sqlnet.ora` to change the wallet location directory to the directory containing the `cwallet.sso` file.

   For example, on Linux edit `sqlnet.ora` as follows:

   ```
   WALLET_LOCATION = (SOURCE = (METHOD=file) (METHOD_DATA = (DIRECTORY="/opt/
   OracleCloud/MYDB")))
   SSL_SERVER_DN_MATCH=yes
   ```

   When the configuration files are not in the default location, your Go application needs to indicate where they are with the `config_dir` parameter.

> **Note:**
>
> Neither of these settings are needed, and you do not need to edit `sqlnet.ora` if you put all the configuration files in the `network/admin` directory.

2. In your Go application set the following connection parameters to connect to the Autonomous Database instance:
   - `user`: Specifies the Cloud Database user.
   - `password`: Specifies the Cloud Database user's password.
   - `config_dir`: Specifies the configuration directory where you are placing the `tnsnames.ora` and `sqlnet.ora` files. This is required when the configuration files are placed in a directory outside of the instant client configuration directory `network/admin`.
   - `dsn`: Specifies the desired network alias from the `tnsnames.ora` file.

   For example, to connect as the ADMIN user and connect with the `mydb_high` network service name (where the service name is found in `/opt/OracleCloud/MYDB/tnsnames.ora`):

```
dsn := `user="admin"
      password="password"
      connectString="mydb_high"
      configDir="/opt/OracleCloud/MYDB"`
db, _ := sql.Open("godror", dsn)
```

   You can use the above code in your Go application to create a connection string and connect to the Autonomous Database.

Download Database Connection Information

You can download Oracle client credentials, wallet files, from an Autonomous Database instance.

If you are not an Autonomous Database administrator and your application requires a wallet to connect, then your administrator should provide you with the client credentials. You can also view TNS names and connection strings for your database.

- Download Client Credentials (Wallets)
  To download client credentials you can use the Oracle Cloud Infrastructure Console or Database Actions.
- Wallet README File
  The wallet `README` file contains the wallet expiration information and details for Autonomous Database tools and resources.
- View TNS Names and Connection Strings for an Autonomous Database Instance
  From the Database Connection page on the Oracle Cloud Infrastructure Console you can view Autonomous Database TNS names and connection strings.

Download Client Credentials (Wallets)

To download client credentials you can use the Oracle Cloud Infrastructure Console or Database Actions.

> **Note:**
>
> The password you provide when you download the wallet protects the downloaded Client Credentials wallet.

For commercial regions, the wallet password complexity for the password you supply requires the following:

- Minimum of 8 characters
- Minimum of 1 letter
- Minimum of 1 numeric character or 1 special character

For US Government regions, the wallet password complexity requires all of the following:

- Minimum of 15 characters
- Minimum of 1 lowercase letter
- Minimum of 1 uppercase letter
- Minimum of 1 numeric character
- Minimum 1 special character

To download client credentials from the Oracle Cloud Infrastructure Console:

1. Navigate to the Autonomous Database details page.
2. Click **Database connection**.
3. On the **Database connection** page select the **Wallet type**:
   - **Instance wallet**: Wallet for a single database only; this provides a database-specific wallet.
   - **Regional wallet**: Wallet for all Autonomous Databases for a given tenant and region (this includes all service instances that a cloud account owns).

   > **Note:**
   >
   > Oracle recommends you provide a database-specific wallet, using **Instance wallet**, to end users and for application use whenever possible. Regional wallets should only be used for administrative purposes that require potential access to all Autonomous Databases within a region.
4. Click **Download wallet**.
5. In the **Download wallet** dialog, enter a wallet password in the **Password** field and confirm the password in the **Confirm password** field.
6. Click **Download** to save the client security credentials zip file.

By default the filename is: `Wallet_`*databasename*`.zip`. You can save this file as any filename you want.

You must protect this file to prevent unauthorized database access.

To download client credentials from Database Actions:

First, access Database Actions as the ADMIN user. See Access Database Actions as ADMIN for more information.

1. Access Database Actions as the ADMIN user. See Access Database Actions as ADMIN for more information.
2. On the Database Actions Launchpad, under **Administration**, select **Download Client Credentials (Wallet)**.
3. On the **Download Client Credentials (Wallet)** page, enter a wallet password in the **Password** field and confirm the password in the **Confirm Password** field.
4. Click **Download** to save the client security credentials zip file. By default the filename is: `Wallet_`*databasename*`.zip`. You can save this file as any filename you want. You must protect this file to prevent unauthorized database access.

> **Note:**
>
> When you use Database Actions to download a wallet there is no **Wallet type** option on the **Download Client Credentials (Wallet)** page and you always download an instance wallet. If you need to download the regional wallet click **Database connection** on the Oracle Cloud Infrastructure Console.

The zip file includes the following:

File	Description
`cwallet.sso`	Auto-open SSO wallet
`ewallet.p12`	PKCS12 file. The PKCS12 file is protected by the wallet password provided while downloading the wallet.
`ewallet.pem`	Encoded certificate file used to authenticate with certificate authority (CA) server certificate.
`keystore.jks`	Java keystore file. This file is protected by the wallet password provided while downloading the wallet.
`ojdbc.properties`	Contains the wallet related connection property required for JDBC connection. This should be in the same path as `tnsnames.ora`.
`README`	Contains wallet expiration information and links for Autonomous Database tools and resources. See Wallet README File for information on the contents of the `README` file.
`sqlnet.ora`	SQL*Net client side configuration.
`tnsnames.ora`	Network configuration file storing connect descriptors.

File	Description
`truststore.jks`	Java truststore file. This file is protected by the wallet password provided while downloading the wallet.

Notes for wallet files and the wallet password:

- To invalidate database client certification keys associated with a wallet, see Rotate Wallets with Immediate Rotation.
- Wallet files, along with the Database user ID and password provide access to data in your database. Store wallet files in a secure location. Share wallet files only with authorized users. If wallet files are transmitted in a way that might be accessed by unauthorized users (for example, over public email), transmit the wallet password separately and securely.
- For better security, Oracle recommends using restricted permissions on wallet files. This means setting the file permissions to 600 on Linux/Unix. Similar restrictions can be achieved on Windows by letting the file owner have Read and Write permissions while all other users have no permissions.
- Autonomous Database uses strong password complexity rules for all users based on Oracle Cloud security standards. For more information on the password complexity rules see Create Users on Autonomous Database - Connecting with a Client Tool.
- The `README` file that contains wallet expiration information is not available in wallet zip files that were downloaded before April 2020.
- Starting six weeks before the wallet expiration date Autonomous Database sends notification emails each week, indicating the wallet expiration date. These emails provide notice before your wallet expires that you need to download a new wallet. You will receive these notification emails only if there is a connection that uses a wallet that is about to expire.

  You can also use the `WalletExpirationWarning` event to be notified when a wallet is due to expire. You will receive these notification events only if you are subscribed to Critical events and there is a connection that uses a wallet that is about to expire. See About Events Based Notification and Automation on Autonomous Database for more information.

Wallet README File

The wallet `README` file contains the wallet expiration information and details for Autonomous Database tools and resources.

The wallet expiration information at the top of the `README` file shows the following information:

- The date when the wallet was downloaded.
- The date when the wallet SSL certificate provided in the wallet expires. If your wallet is nearing expiration or is expired, then download a new wallet or obtain a new wallet from your Autonomous Database administrator. If you do not download a new wallet before the expiration date, you will no longer be able to connect to your database.

The Autonomous Database tools and resources area provides the following information:

Tool or Resource	Description
Database Actions	Load, explore, transform, model, and catalog your data. Use an SQL worksheet, build REST interfaces and low-code apps, manage users and connections, build and apply machine learning models. Access Link: provides the link to use Database Actions. See Connect with Built-In Oracle Database Actions for more information.
Graph Studio	Oracle Graph Studio lets you create scalable property graph databases. Graph Studio automates the creation of graph models and in-memory graphs from database tables. It includes notebooks and developer APIs that allow you to execute graph queries using PGQL (an SQL-like graph query language) and over 50 built-in graph algorithms. Graph Studio also offers dozens of visualization, including native graph visualization. Access Link provides the link to use Graph Studio. See About Oracle Graph Studio on Autonomous Database for more information.
Oracle APEX	Oracle APEX is a low-code development platform that enables you to build scalable, secure enterprise apps that can be deployed anywhere. Access Link: provides the link to use Oracle APEX. See Access Oracle APEX Administration Services for more information.
Oracle Machine Learning User Management	Create new Oracle Machine Learning user accounts and manage the credentials for existing Oracle Machine Learning users. Access Link: provides the link to use Oracle Machine Learning User Management. See Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database for more information.
Oracle Machine Learning User Notebooks	Oracle Machine Learning notebooks provide easy access to Oracle's parallelized, scalable in-database implementations of a library of Oracle Advanced Analytics' machine learning algorithms (classification, regression, anomaly detection, clustering, associations, attribute importance, feature extraction, times series, and so on), SQL, PL/SQL and Oracle's statistical and analytical SQL functions. Access Link: provides the link to use Oracle Machine Learning User Notebooks. See Work with Oracle Machine Learning User Interface for Data Access, Analysis, and Discovery for more information.
SODA Drivers	Simple Oracle Document Access (SODA) is a set of APIs that let you work with JSON documents managed by the Oracle Database without needing to use SQL. SODA drivers are available for REST, Java, Node.js, Python, PL/SQL, and C. Access Link: provides the link to download the SODA drivers. See Work with Simple Oracle Document Access (SODA) in Autonomous Database for more information.

Notes for wallet `README` file:

- If you rename your Autonomous Database instance, the tools links change and the old links no longer work. To obtain valid tools links you must download a new Wallet zip file with an updated `README` file. The SODA drivers link is a resource link and this link does not change when you rename an instance.

- The `README` in a regional wallet does not contain the Autonomous Database tools and resources links.
- If your Autonomous Database instance is on a private endpoint and you enable the **Allow public access** option, the `README` file includes two links for each tool: one link to use from the private endpoint when you are connecting from the same VCN where the database resides, and another link to use from specific public IP addresses or from specific VCNs if those VCNs are configured to privately connect to Autonomous Database using a Service Gateway. See Use a Private Endpoint with Public Access Allowed for more information.

View TNS Names and Connection Strings for an Autonomous Database Instance

From the Database Connection page on the Oracle Cloud Infrastructure Console you can view Autonomous Database TNS names and connection strings.

> **Note:**
>
> See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for information on allowing TLS connections.

Perform the following steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select your Autonomous Database from the links under the **Display name** column.

To view the TNS names and connection strings, do the following:

1. On the Autonomous Database details page, click **Database connection**.

   By default this shows the Mutual TLS connection information in a table with the TNS names and connection strings for the Autonomous Database instance.

2. When both Mutual TLS (mTLS) and TLS connections are allowed, under **TLS authentication** select **TLS** to view the TNS names and connection strings for connections with TLS authentication.

   The TNS names are the same for mTLS and TLS authentication. The connection strings differ for mTLS and TLS connections, with different port definitions. Mutual TLS (mTLS) connections use port 1522. TLS connections use either port 1521 or 1522. The port assignments of 1522 for Mutual TLS (mTLS) and either 1521 or 1522 for TLS cannot be changed.

   In the Connection String column, click **Show** to display the full value of a connection string or click **Copy** to copy a connection string.

   For example, when you click **Show** you see the full connection string.

3. When your Autonomous Database instance is on a private endpoint and you enable the **Allow public access** option, also select an access type to show or copy the private or the public endpoint information.

   The private connection strings are the connections strings you use from within the VCN where the private endpoint database resides. Use the the public connection strings to

connect from public IPs or from other allowed VCNs. See Use a Private Endpoint with Public Access Allowed for more information.

Under **Access**, select either **Private endpoint** or **Public endpoint URL**.

Connect to Autonomous Database Using Oracle Database Tools

Oracle Database Tools such as SQL Developer, SQL*Plus, and SQLcl can be used with Autonomous Database.

The following sections provide step-by-step instructions for connecting to Autonomous Database using these tools.

- Connect Oracle SQL Developer with a Wallet (mTLS)
  Oracle SQL Developer is a free integrated development environment that simplifies the development and management of Autonomous Database.
- Connect Oracle SQL Developer Without a Wallet
  Oracle SQL Developer is a free integrated development environment that simplifies the development and management of Autonomous Database. Oracle SQL Developer provides support for connecting using TLS authentication without a wallet.
- Connect SQL*Plus with a Wallet (mTLS)
  SQL*Plus is a command-line interface used to enter SQL commands. SQL*Plus connects to an Oracle database.
- Connect SQL*Plus Without a Wallet
  SQL*Plus is a command-line interface used to enter SQL commands. SQL*Plus connects to an Oracle database.
- Connect Oracle SQLcl Cloud with a Wallet (mTLS)
  SQLcl is a command-line interface used to enter SQL commands. You can use SQLcl to connect to an Autonomous Database with client credentials configured (mTLS).
- Connect Oracle SQLcl Cloud Without a Wallet
  SQLcl is a command-line interface used to enter SQL commands. You can use SQLcl to connect to an Autonomous Database with TLS authentication without a wallet.

Connect Oracle SQL Developer with a Wallet (mTLS)

Oracle SQL Developer is a free integrated development environment that simplifies the development and management of Autonomous Database.

SQL Developer can connect to Autonomous Database and contains enhancements for key Autonomous Database features. You can download the latest version of Oracle SQL Developer for your platform from the **Download** link on this page: Oracle SQL Developer.

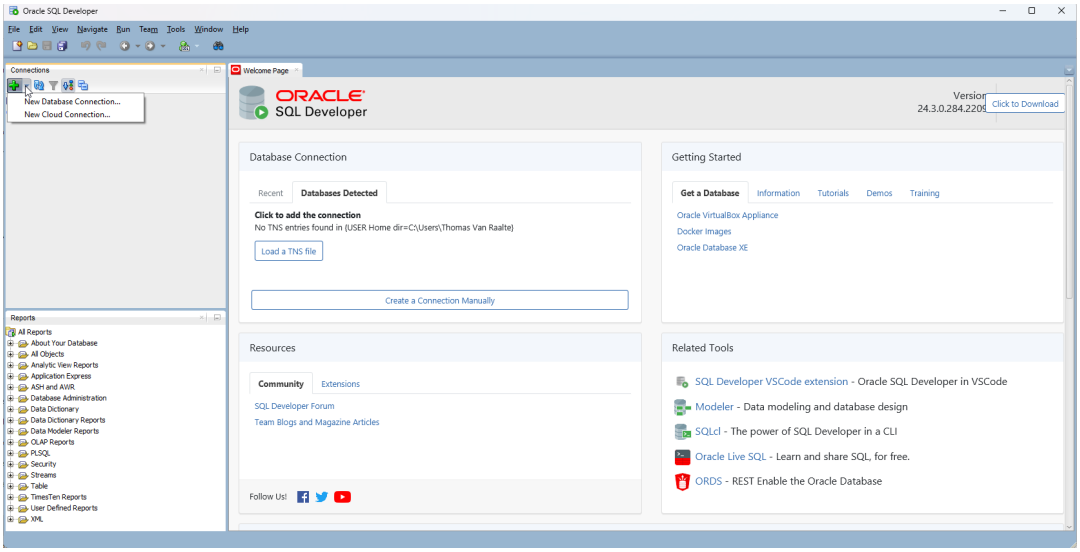
For connecting with mTLS authentication, Oracle SQL Developer provides support for wallet files using the **Cloud Wallet** Connection Type. Oracle recommends that you use version 18.2 (or later); however, earlier versions of SQL Developer will work with Autonomous Database using an Oracle Wallet.

For connecting with TLS authentication, Oracle SQL Developer provides support using the **Custom JDBC** Connection Type. See Connect with Oracle SQL Developer with TLS Authentication for details on connecting using TLS authentication.

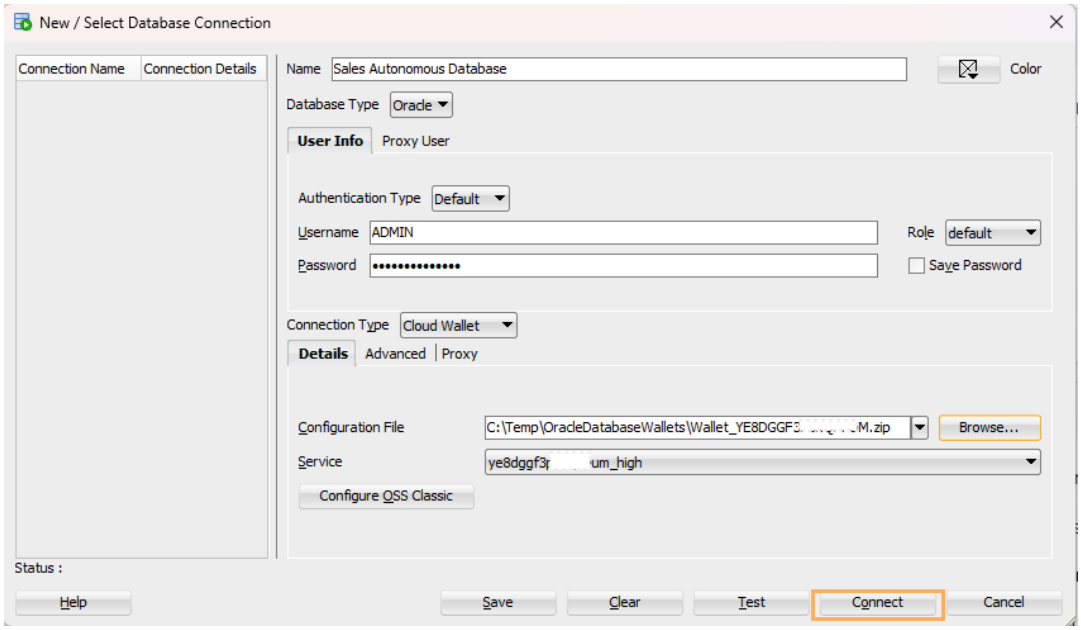
To create a new mTLS connection to Autonomous Database, do the following:

Obtain your credentials to access Autonomous Database. For more information, see Download Client Credentials (Wallets).

1. Start Oracle SQL Developer and in the connections panel, right-click **Connections** and select **New Database Connection...**.



2. Choose the Connection Type **Cloud Wallet**.
3. Enter the following information:
   - **Connection Name**: Enter the name for this connection.
   - **Username**: Enter the database username. You can either use the default administrator database account (`ADMIN`) provided as part of the service or create a new schema, and use it.
   - **Password**: Enter the password for the database user.
   - **Connection Type**: Select **Cloud Wallet**
   - **Configuration File** : Click **Browse**, and select the client credentials zip file.
   - **Service**: Enter the database TNS name. The client credentials file includes a `tnsnames.ora` file that provides database TNS names with corresponding services.



4. Click **Connect** to connect to the database.

> **Note:**
>
> If you are using Microsoft Active Directory, then for **Username** enter the Active Directory "*AD_domain\AD_username*" (you may include double quotes), and for the **Password**, enter the password for the Active Directory user. See Use Microsoft Active Directory with Autonomous Database for more information.

Connect Oracle SQL Developer Without a Wallet

Oracle SQL Developer is a free integrated development environment that simplifies the development and management of Autonomous Database. Oracle SQL Developer provides support for connecting using TLS authentication without a wallet.

> **Note:**
>
> See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for information on allowing TLS connections.

To create a new TLS connection to Autonomous Database:

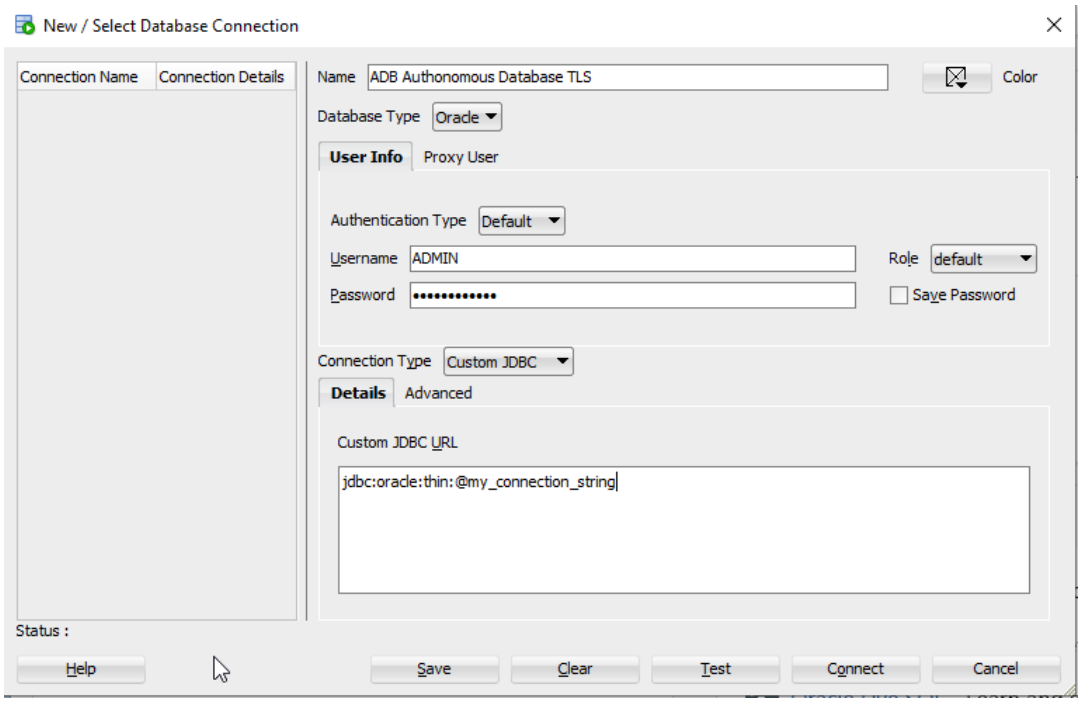
1. Copy a connection string for the Autonomous Database.

   To connect with TLS authentication copy a TLS connection string. On the Database Connection page, under **TLS Authentication**, select **TLS** to view the connection strings for connecting with TLS authentication.

   See View TNS Names and Connection Strings for an Autonomous Database Instance for information on viewing and copying connection stings.

2. Start Oracle SQL Developer and in the connections panel, right-click **Connections** and select **New Database Connection...**.
3. Choose the Connection Type **Custom JDBC**.
4. Enter the following information:
   - **Name**: Enter the name for this connection.
   - **Username**: Enter the database username. You can either use the default administrator database account `ADMIN` provided as part of the service or create a new schema, and use it.
   - **Password**: Enter the password for the database user.
   - **Connection Type**: Select **Custom JDBC**.
   - **Custom JDBC URL**: Enter the following:

     `jdbc:oracle:thin:@` followed by the connection string you copied in step one.



For example, a sample value for the Custom JDBC URL field is:

```
jdbc:oracle:thin:@(description= (retry_count=20)(retry_delay=3)
(address=(protocol=tcps)
(port=1521)(host=adb-preprod.us-phoenix-1.oraclecloud.com))
(connect_data=(service_name=u9adutfb2_fmexample1_medium.adb.oraclecloud.com
))
(security=(ssl_server_dn_match=yes)))
```

When you copy the connection string, the values for *`region`* and *`databasename`* are for your Autonomous Database instance.

5. Click **Connect** to connect to the database.

> **Note:**
>
> If you are using Microsoft Active Directory, then for **Username** enter the Active Directory "*AD_domain\AD_username*" (you may include double quotes), and for the **Password**, enter the password for the Active Directory user. See Use Microsoft Active Directory with Autonomous Database for more information.

Connect SQL*Plus with a Wallet (mTLS)

SQL*Plus is a command-line interface used to enter SQL commands. SQL*Plus connects to an Oracle database.

To install and configure the client and connect to the Autonomous Database using SQL*Plus with client credentials (mTLS), do the following:

1. Prepare for Oracle Call Interface (OCI), ODBC and JDBC OCI Connections. See Prepare for Oracle Call Interface (OCI), ODBC, and JDBC OCI Connections with Wallets (mTLS).
2. Connect using a database user, *password*, and database TNS name provided in the `tnsnames.ora` file.

   For example:

```
sqlplus adb_user@db2022adb_medium

SQL*Plus: Release 19.0.0.0.0 - Production on Mon Nov 23 15:08:48 2020
Version 19.8.0.0.0

Copyright (c) 1982, 2020, Oracle.  All rights reserved.

Enter password:
Last Successful login time: Wed Nov 18 2020 12:36:56 -08:00

Connected to:
Oracle Database 19c Enterprise Edition Release 19.0.0.0.0 - Production
Version 19.5.0.0.0

SQL>
```

> **Notes:**
>
> - The Oracle Wallet is transparent to SQL*Plus because the wallet location is specified in the `sqlnet.ora` file. This is true for any Oracle Call Interface (OCI), ODBC, or JDBC OCI connection.
> - If you are connecting to a database using Microsoft Active Directory credentials, then connect using an Active Directory user name in the form of "*AD_domain\AD_username*" (double quotes must be included), and Active Directory user password. See Use Microsoft Active Directory with Autonomous Database for more information.

Connect SQL*Plus Without a Wallet

SQL*Plus is a command-line interface used to enter SQL commands. SQL*Plus connects to an Oracle database.

> **Note:**
>
> See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for information on allowing TLS connections.

To install and configure the client and connect to the Autonomous Database using SQL*Plus with TLS authentication, do the following:

1. Prepare for Oracle Call Interface (OCI) connections.

   You can use TLS authentication without a wallet in SQL*Plus if you are using the following client versions:

   - Oracle Instant Client/Oracle Database Client 19.13 - only on Linux x64
   - Oracle Instant Client/Oracle Database Client 19.14 (or later) and 21.5 (or later) - only on Linux x64 and Windows

   See Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections Using TLS Authentication for more information.

2. Copy a connection string for the Autonomous Database.

   To connect with TLS authentication copy a TLS connection string. On the Database Connection page, under **TLS Authentication**, select **TLS** to view the connection strings for connecting with TLS authentication.

   See View TNS Names and Connection Strings for an Autonomous Database Instance for information on viewing and copying connection stings.

   See Database Service Names for Autonomous Database for information on the different databases services for each connection string.

3. Connect using a database user and *password*, and provide the connection string you copied in Step 2.

   On UNIX/Linux start `sqlplus` with the connection string, enclosed in quotes on the command line, as follows:

   ```
   sqlplus username/password@'my_connect_string'
   ```

   For example (for clarity line breaks added):

   ```
   sqlplus adb_user/password@'(description= (retry_count=20)(retry_delay=3)
   (address=(protocol=tcps)
   (port=1521)(host=adb.region.oraclecloud.com))
   (connect_data=(service_name=u9adutfb2ba8x4d_database_medium.adb.oraclecloud
   .com))
   (security=(ssl_server_dn_match=yes))'
   ```

On Windows, start `sqlplus` with the database user and password with the copied connection string, as follows (as compared to UNIX/Linux, on Windows do not surround the connection string with quotes):

```
sqlplus username/password@my_connect_string
```

For example (for clarity line breaks added in the connection string):

```
sqlplus adb_user/password@(description= (retry_count=20)(retry_delay=3)
(address=(protocol=tcps)
(port=1521)(host=adb.region.oraclecloud.com))
(connect_data=(service_name=u9adutfb2ba8x4d_database_medium.adb.oraclecloud
.com))
(security=(ssl_server_dn_match=yes))
```

> **Note:**
>
> If you are connecting to an Autonomous Database instance using Microsoft Active Directory credentials, then connect using an Active Directory user name in the form of "*AD_domain\AD_username*" (double quotes must be included), and Active Directory user password. See Use Microsoft Active Directory with Autonomous Database for more information.

Connect Oracle SQLcl Cloud with a Wallet (mTLS)

SQLcl is a command-line interface used to enter SQL commands. You can use SQLcl to connect to an Autonomous Database with client credentials configured (mTLS).

You can use SQLcl version 4.2 or later with Autonomous Database. Download SQLcl from oracle.com.

SQLcl can connect to an Autonomous Database instance using either an Oracle Call Interface (OCI) or a JDBC thin connection.

- If you use Oracle Call Interface (OCI), prepare for OCI, ODBC and JDBC OCI Connections. See Prepare for Oracle Call Interface (OCI), ODBC, and JDBC OCI Connections.
- If you use JDBC Thin, prepare for JDBC Thin Connections. See Prepare for JDBC Thin Connections.

SQLcl with Oracle Call Interface

To connect using Oracle Call Interface, use the `-oci` option, supply the database user name, a password, and the database service name provided in the `tnsnames.ora` file. For example:

```
sql -oci

SQLcl: Release 22.1 Production on Fri May 06 16:07:46 2022

Copyright (c) 1982, 2022, Oracle.  All rights reserved.

Username? (''?) adb_user@db2022adb_medium
Password? (**********?) ***************
```

```
Connected.
SQL>
```

When connecting using Oracle Call Interface, the Oracle Wallet is transparent to SQLcl.

SQLcl with a JDBC Thin Connection

To connect using a JDBC Thin connection, first configure the SQLcl cloud configuration and then connect to the database.

1. Start SQLcl with the /nolog option.

   ```
   sql /nolog
   ```

2. Configure the SQLcl session to use your Oracle Wallet:

   ```
   SQL> set cloudconfig directory/client_credentials.zip
   ```

3. Connect to the database:

   ```
   SQL> connect username@servicename
   password
   ```

   To avoid the prompt, connect and supply the password inline:

   ```
   SQL> connect username/password@servicename
   ```

   For example:

   ```
   sql /nolog

   SQLcl: Release 22.1 Production on Fri May 06 14:48:26 2022

   Copyright (c) 1982, 2022, Oracle.  All rights reserved.

   SQL> set cloudconfig /home/adb/Wallet_db2022ADB.zip

   SQL> connect adb_user@db2022adb_medium

   Password? (**********?) ***************
   Connected.
   SQL>
   ```

SQLcl with a JDBC Thin Connection with an HTTP Proxy

1. Start SQLcl with the /nolog option.

   ```
   sql /nolog
   ```

2. Configure the SQLcl session to use a proxy host and your Oracle Wallet:

   ```
   SQL> set cloudconfig -proxy=proxyhost:port directory/client_credentials.zip
   ```

3. Connect to the database.

   ```
   SQL> connect username@servicename
   password
   ```

   To avoid the prompt, connect and supply the password inline:

   ```
   SQL> connect username/password@servicename
   ```

For example:

```
sql /nolog

SQLcl: Release 22.1 Production on Fri May 06 11:59:38 2022

Copyright (c) 1982, 2022, Oracle.  All rights reserved.
SQL> set cloudconfig -proxy=http://myproxyhost.com:80 /home/adb/
Wallet_db2022.zip

SQL> connect adb_user@db2022adb_medium

Password? (**********?) ***************
Connected.
SQL>
```

> **Note:**
>
> If you are connecting to Autonomous Database using Microsoft Active Directory credentials, then connect using an Active Directory user name in the form of "*AD_domain\AD_username*" (double quotes must be included), and Active Directory user password. See Use Microsoft Active Directory with Autonomous Database for more information.

For more information, on the connection types specified in `tnsnames.ora`, see Manage Concurrency and Priorities on Autonomous Database.

For information on SQLcl, see Oracle SQLcl.

Connect Oracle SQLcl Cloud Without a Wallet

SQLcl is a command-line interface used to enter SQL commands. You can use SQLcl to connect to an Autonomous Database with TLS authentication without a wallet.

> **Note:**
>
> See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for information on allowing TLS connections.

You can use SQLcl version 4.2 or later with Autonomous Database. Download SQLcl from oracle.com.

If you use JDBC Thin Driver, prepare for JDBC Thin connections. See Prepare for JDBC Thin Connections.

To connect using a JDBC Thin Driver with TLS authentication, do the following to connect to the database.

1. Copy a connection string for the Autonomous Database.

To connect with TLS authentication copy a TLS connection string. On the Database Connection page, under **TLS Authentication**, select **TLS** to view the connection strings for connecting with TLS authentication.

See View TNS Names and Connection Strings for an Autonomous Database Instance for information on viewing and copying connection stings.

See Database Service Names for Autonomous Database for information on the different databases services for each connection string.

2. Start SQLcl and connect to the database:

   On UNIX/Linux start `sql` with the connection string, enclosed in quotes on the command line, as follows:

   ```
   sql username/password@'my_connect_string'
   ```

   For example (for clarity line breaks added):

   ```
   $ sql admin/password@'(description= (retry_count=20)(retry_delay=3)
   (address=(protocol=tcps)(port=1521)(host=adb.region.oraclecloud.com))
   (connect_data=(service_name=u9adutfb2ba8x4d_database_medium.adb.oraclecloud
   .com))
   (security=(ssl_server_dn_match=yes)))'

   SQLcl: Release 21.2 Production on Thu Sep 16 10:43:00 2021
   Copyright (c) 1982, 2021, Oracle. All rights reserved.

   Last Successful login time: Thu Sep 16 2021 10:43:01 -07:00

> **Note:**
>
> If you are connecting to Autonomous Database using Microsoft Active Directory credentials, then connect using an Active Directory user name in the form of "*AD_domain\AD_username*" (double quotes must be included), and Active Directory user password. See Use Microsoft Active Directory with Autonomous Database for more information.

For information on SQLcl, see Oracle SQLcl.

Connect with Built-In Oracle Database Actions

You can access Database Actions from Autonomous Database. Database Actions provides development tools, data tools, administration, and monitoring features for Autonomous Database. Using Database Actions you can run SQL statements, queries, and scripts in a worksheet.

- About Database Actions (SQL Developer Web)
  Database Actions provides a web-based interface with development, data tools, administration, monitoring, and download features for Autonomous Database.
- Access Database Actions as ADMIN
  Database Actions (also known as SQL Developer Web) is bundled with each Autonomous Database instance.
- Provide Database Actions Access to Database Users
  The ADMIN user provides access to Database Actions for other database users.
- Required Roles to Access Tools from Database Actions
  Lists the database roles required to use the built-in Autonomous Database tools.
- IAM Policies to Access Database Actions and Tools from the OCI Console
  Lists the IAM policies required to access built-in Autonomous Database tools and Database Actions from the OCI Console.
- Access Database Actions, Oracle APEX, Oracle REST Data Services, and Developer Tools Using a Vanity URL
  By default you access Oracle APEX apps, REST endpoints, and developer tools on Autonomous Database using the `oraclecloudapps.com` domain name. You can optionally configure a vanity URL or custom domain name that is easy to remember to help promote your brand identity.

About Database Actions (SQL Developer Web)

Database Actions provides a web-based interface with development, data tools, administration, monitoring, and download features for Autonomous Database.

The following table lists the main features of Database Actions. Database Actions on your Autonomous Database instance may include additional cards if you download applications from Oracle Cloud Marketplace.

Feature Area	Database Actions Cards
Development	SQL, Data Modeler, REST, JSON, Charts, Scheduling, Oracle Machine Learning, Graph Studio, and Oracle APEX
Data Studio	Data Load, Catalog, Data Insights, Data Transforms, and Data Analysis
Administration	Database Users, APEX Workspaces, Data Pump, Download Client Credentials, and Set Resource Management Rules
Monitoring	Performance Hub and Database Dashboard
Downloads	Download Oracle Instant Client and Download SODA Drivers
Related Services	Restful Data Services (ORDS) and SODA and Access Oracle Machine Learning Restful Services

See About Database Actions in *Using Oracle Database Actions* for more information.

Access Database Actions as ADMIN

Database Actions (also known as SQL Developer Web) is bundled with each Autonomous Database instance.

Database Actions runs in Oracle REST Data Services and access is provided through schema-based authentication. To use Database Actions, you must sign in as a database user whose schema is enabled for Database Actions. By default the ADMIN user is enabled to access Database Actions.

See Provide Database Actions Access to Database Users to enable another database user's schema to access Database Actions.

> **Note:**
>
> If your Autonomous Database is configured to use a Private Endpoint, then you can only access Database Actions from clients in the same Virtual Cloud Network (VCN). See Configure Network Access with Private Endpoints for more information.

To access Database Actions from the Oracle Cloud Infrastructure Console:

1. On the Autonomous Database Details page click the **Database actions** dropdown list.
2. Select a quick link to go directly to a quick link action or select **View all database actions** to access the full Database Actions Launchpad.

   For example, click **SQL** to use a SQL Worksheet. On the SQL Worksheet you can use the **Consumer Group** drop-down list to select the consumer group to run your SQL or PL/SQL code. See Executing SQL Statements in the Worksheet Editor for more information.

Depending on your browser, if the Console cannot access the database as ADMIN you will be prompted for your database ADMIN username and password.

Provide Database Actions Access to Database Users

The ADMIN user provides access to Database Actions for other database users.

Database users who are not service administrators do not have access to the Oracle Cloud Infrastructure Console. The ADMIN user provides access to Database Actions as follows:

- Use Database Actions to create a user and assign roles to the user. If the user already exists, check that Web Access is selected for the schema (with Web Access selected, the user's card shows **REST Enabled**).

  See Create Users on Autonomous Database for information on adding database users.

  See Required Roles to Access Tools from Database Actions for information on required roles for Database Actions.

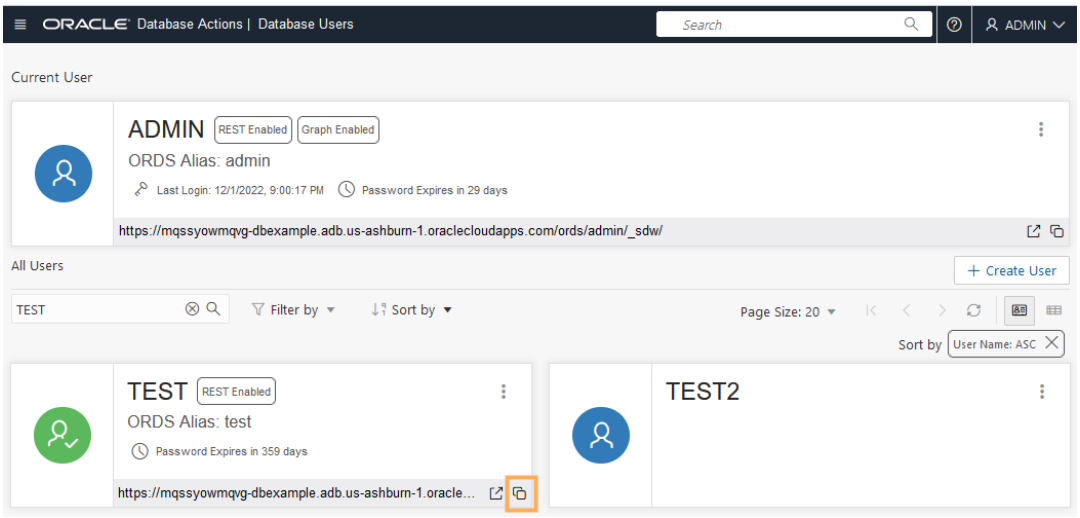
- Provide the user with a URL to access Database Actions.

After adding a user and selecting Web Access, the ADMIN provides a user with the URL to access Database Actions:

1. In Database Actions, click ☰ to show the available actions.
2. Under **Administration** select **Database Users**.

   This displays information about users, such as user names, whether a user is REST Enabled, and the last login date and time. On a user's card, the icon on the left displays the user status with one of the following colors: green (Open), blue (Locked), or red (Expired).

   The default view is Card View. You can select either grid view or card view by clicking the **Card View** or **Grid View** icons.
3. A URL is displayed in the user's card only if the user is REST Enabled. It provides the URL to access Database Actions. Click ⧉ to copy the URL to the clipboard.



4. Provide the user with the URL you copied.

After you provide the URL to a user, to access Database Actions the user pastes the URL into their browser and then enters their Username and Password in the Sign-in dialog.

See Manage Users and User Roles on Autonomous Database - Connecting with Database Actions for more information.

Required Roles to Access Tools from Database Actions

Lists the database roles required to use the built-in Autonomous Database tools.

When you connect to Database Actions as the ADMIN user, many database roles are set to allow you to access the available Autonomous Database tools. When you connect to Database Actions as a non-ADMIN user, some of the Database Actions cards for Autonomous Database tools are hidden if you do not have required permissions.

As the ADMIN user, set the appropriate roles to allow user access to Autonomous Database tools. See Manage User Roles and Privileges on Autonomous Database for more information.

Autonomous Database Tool	Required Role	More Information
Oracle Machine Learning (OML)	`OML_DEVELOPER`	Oracle Machine Learning
Graph Studio	`GRAPH_DEVELOPER`	Using Oracle Graph with Autonomous Database
Data Studio (including: Catalog, Data Load, Data Analysis, Data Insights)	`DWROLE`	The Data Studio Overview Page
Data Transforms	`DATA_TRANSFORM_USER`	The Data Transforms Page

IAM Policies to Access Database Actions and Tools from the OCI Console

Lists the IAM policies required to access built-in Autonomous Database tools and Database Actions from the OCI Console.

In addition to having database roles to access the built-in tools and Database Actions, you must set OCI Identity and Access Management policies to either restrict access from the OCI Console or grant privileges to automatically login as ADMIN to tools or to Database Actions from the OCI Console.

IAM Policy	Description

`read autonomous-databases`
or
`inspect autonomous-databases`
	With these policies you must provide a *username* and *password* to access Database Actions from the OCI Console.
	For example, this policy allows members of the group `ADB-Admins` to review the details of an instance but not automatically login as ADMIN to Database Actions or Tools:
	`allow group ADB-Admins to inspect autonomous-databases in tenancy`

`use autonomous-databases`
or
`manage autonomous-databases`
	These policies provide automatic access to login to Database Actions from the OCI Console as ADMIN.
	For example, this policy allows members of the group `ADB-Admins2` to automatically login as ADMIN to Database Actions or Tools:
	`allow group ADB-Admins2 to manage autonomous-databases in tenancy`

See IAM Policies for Autonomous Database for more information.

Access Database Actions, Oracle APEX, Oracle REST Data Services, and Developer Tools Using a Vanity URL

By default you access Oracle APEX apps, REST endpoints, and developer tools on Autonomous Database using the `oraclecloudapps.com` domain name. You can optionally configure a vanity URL or custom domain name that is easy to remember to help promote your brand identity.

After you acquire a desired domain name and matching SSL certificate from a vendor of your choice, deploy an Oracle Cloud Infrastructure Load Balancer in your Virtual Cloud Network (VCN) using your Autonomous Database as the backend. Your Autonomous Database instance must be configured with a private endpoint in the same VCN. See Configuring Network Access with Private Endpoints for more information.

To learn more, see the following:

- Introducing Vanity URLs for APEX and ORDS on Oracle Autonomous Database
- Automate Vanity URL Configuration Using Terraform

Connect with JDBC Thin Driver

Autonomous Database mandates a secure connection that uses Transport Layer Security (TLSv1.2).

Java applications that use JDBC Thin driver connect with one of the following:

- **Mutual TLS (mTLS) Authentication**: requires either Oracle Wallet or Java KeyStore (JKS) where both the client and Autonomous Database authenticate each other.

  The wallet and keystore files are included in the client credentials `.zip` file that is available by clicking **Database connection** on the Oracle Cloud Infrastructure Console

- **TLS Authentication**: The client computer matches the server's CA root certificate against the client's list of trusted CAs. If the issuing CA is trusted, the client verifies that the certificate is authentic. This allows the client and Autonomous Database to establish the encrypted connection before exchanging any messages.

See Connecting to Oracle Database Manually for additional information on how to connect your Java applications to Autonomous Database using Oracle JDBC driver and Universal Connection Pool.

Topics

- JDBC Thin Connections with a Wallet (mTLS)
  Autonomous Database mandates a secure connection that uses Transport Layer Security (TLSv1.2). Depending on the network configuration options, Autonomous Database supports mTLS and TLS authentication.
- JDBC Thin Connections Without a Wallet (TLS)
  Autonomous Database mandates a secure connection that uses Transport Layer Security (TLSv1.2). Depending on the configuration options, Autonomous Database supports mTLS and TLS authentication. This section covers using JDBC Thin Connections with TLS authentication without a wallet.

JDBC Thin Connections with a Wallet (mTLS)

Autonomous Database mandates a secure connection that uses Transport Layer Security (TLSv1.2). Depending on the network configuration options, Autonomous Database supports mTLS and TLS authentication.

> **Note:**
>
> If you use TLS, instead of mTLS, for your connections using JDBC Thin Driver with JDK8u162 or higher, a wallet is not required.
>
> TLS connections are enabled for the following network configurations:
>
> - **Private endpoint access only**: network configuration with a private endpoint
> - **Secure access from allowed IPs and VCNs only**: configuration with an Access Control List (ACL)
>
>   If your Autonomous Database is on a public endpoint without any ACL, you can add `0.0.0.0/0` as your CIDR ACL and enable TLS authentication. Adding `0.0.0.0/0` as your CIDR ACL is identical to having your Autonomous Database on public endpoint with no ACL.
>
> See Secure Connections to Autonomous Database with mTLS or with TLS for more information.

- JDBC Thin Driver Connection Prerequisites Connections with Wallets (mTLS)
  Applications that use JDBC Thin driver support TLS and mutual TLS (mTLS) authentication. Using mTLS authentication requires that you supply Oracle database credentials including the Oracle wallets or Java KeyStore (JKS) files when connecting to the database.

- Using a JDBC URL Connection String with JDBC Thin Driver and Wallets
  The connection string is found in the file `tnsnames.ora` which is part of the client credentials download. The `tnsnames.ora` file contains the predefined service names. Each service has its own TNS alias and connection string.
- Using a JDBC Connection with 18.3 JDBC Driver
  Applications that use JDBC Thin driver can connect to Autonomous Databases using either Oracle Wallets or Java KeyStore (JKS).
- Connecting Using JDBC Thin Driver 12.2 or Older
  If you are using the JDBC driver 12.2.0.2 or older, set the Java properties prior to starting the application. Usually you set the properties in the application's startup script.
- JDBC Thin Connections with an HTTP Proxy
  If the client is behind a firewall and your network configuration requires an HTTP proxy to connect to the internet, you need to use the JDBC Thin Client 18.1 or higher which enables connections through HTTP proxies.

JDBC Thin Driver Connection Prerequisites Connections with Wallets (mTLS)

Applications that use JDBC Thin driver support TLS and mutual TLS (mTLS) authentication. Using mTLS authentication requires that you supply Oracle database credentials including the Oracle wallets or Java KeyStore (JKS) files when connecting to the database.

Perform the following steps before connecting to the database:

1. **Provision Autonomous Database**: Create a database and obtain your database credentials (username and password).

   See Provision an Autonomous Database Instance for more information.

2. For mutual TLS connections, **Download Client Credentials**: Unzip the `wallet_`*databasename*`.zip` to a secure location. Make sure that only authorized users have access to these files.

   See Download Client Credentials (Wallets) for information on downloading client credentials for Autonomous Database.

3. **Verify your JDK version for security**: If you are using JDK11, JDK10, or JDK9 then you don't need to do anything for this step. If your JDK version is less than JDK8u162 then you need to download the JCE Unlimited Strength Jurisdiction Policy Files. Refer to the `README` file for installation notes. Download the JCE files from Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 8 Download.

4. **Check JDBC Driver Version**: Download a supported JDBC Thin driver (`ojdbc8.jar` and `ucp.jar`). You also need the additional jars: `oraclepki.jar`, `osdt_core.jar`, and `osdt_cert.jar` for use with Oracle wallets.

   Supported versions are:

   - **JDBC Thin**: 11.2.0.4 (or later with one-off patch for Bug 28492769), 12.2 (or later with one-off patch for Bug 28492769), 18 (base release or later with one-off patch for Bug 28492769), 19 (base release or later), or 21 (base release or later)

   For applications that use the Universal Connection Pool (UCP) feature of JDBC, it is highly recommended to use 19.13 or higher or 21.3 or higher versions of the JDBC driver. These versions include proper draining behavior to minimize impact to applications when planned maintenance is performed in Autonomous Database. UCP will replenish connections in the pool proactively so that active connections are not impacted by maintenance.

   For older versions of the driver, a patch for bug 31112088 can also be requested by filing a Service Request.

Download supported versions: Oracle Database JDBC driver and Companion Jars Downloads .

Using a JDBC URL Connection String with JDBC Thin Driver and Wallets

The connection string is found in the file `tnsnames.ora` which is part of the client credentials download. The `tnsnames.ora` file contains the predefined service names. Each service has its own TNS alias and connection string.

A sample entry, with `dbname_high` as the TNS alias and a connection string in `tnsnames.ora` follows:

```
dbname_high= (description=
      (address=(protocol=tcps)(port=1522)(host=adb.example.oraclecloud.com))
      (connect_data=(service_name=dbname_high.oraclecloud.com))
(security=(ssl_server_dn_match=yes)))
```

Set the location of `tnsnames.ora` with the property `TNS_ADMIN` in one of the following ways:

- As part of the connection string (only with the 18.3 or newer JDBC driver)
- As a system property, `-Doracle.net.tns_admin`
- As a connection property (`OracleConnection.CONNECTION_PROPERTY_TNS_ADMIN`)

Using the 18.3 JDBC driver, the connection string includes the TNS alias and the `TNS_ADMIN` connection property.

Sample connection string using 18.3 JDBC driver (Linux):

```
DB_URL="jdbc:oracle:thin:@dbname_high?TNS_ADMIN=/Users/test/wallet_dbname"
```

Sample connection string using 18.3 JDBC driver (Windows):

```
DB_URL="jdbc:oracle:thin:@dbname_high?TNS_ADMIN=C:\\Users\\test\
\wallet_dbname"
```

The `TNS_ADMIN` connection property specifies the following:

- The location of `tnsnames.ora`.
- The location of Oracle Wallet (`ewallet.sso`, `ewallet.p12`) or Java KeyStore (JKS) files (`truststore.jks`, `keystore.jks`).
- The location of `ojdbc.properties`. This file contains the connection properties required to use Oracle Wallets or Java KeyStore (JKS).

> **Note:**
>
> If you are using 12.2.0.1 or older JDBC drivers, then the connection string contains only the TNS alias. To connect using older JDBC drivers:
>
> - Set the location of the `tnsnames.ora`, either as a system property with `-Doracle.net.tns_admin` or as a connection property (`OracleConnection.CONNECTION_PROPERTY_TNS_ADMIN`).
> - Set the wallet or JKS related connection properties in addition to `TNS_ADMIN`.
>
> For example, in this case you set the TNS alias in the `DB_URL` without the `TNS_ADMIN` part as:
>
> ```
> DB_URL=”jdbc:oracle:thin:@dbname_high”
> ```

See Database Service Names for Autonomous Database for more details.

Using a JDBC Connection with 18.3 JDBC Driver

Applications that use JDBC Thin driver can connect to Autonomous Databases using either Oracle Wallets or Java KeyStore (JKS).

Using Oracle Wallet

To use Java and the 18.3 JDBC Thin Driver to connect to Autonomous Database with the Oracle Wallet, do the following:

1. **Make sure that the prerequisites are met:** See JDBC Thin Driver Connection Prerequisites Connections with Wallets (mTLS) for more information.
2. **Verify the connection**: You can either use a Java program, a servlet, or IDEs to verify the connection to the database. A simple test is to download DataSourceSample.java or UCPSample.java from JDBC code samples and update the connection URL to have the required TNS alias and pass `TNS_ADMIN`, providing the path for `tnsnames.ora` and the wallet files. Also, in the sample source code update the database username and password. For example:

   ```
   DB_URL="jdbc:oracle:thin:@dbname_high?TNS_ADMIN=/Users/test/wallet_dbname"
   ```

   > **Note:**
   >
   > If you are using Microsoft Active Directory with a database, then in the sample source code update the username with the Active Directory username and update the password with the Active Directory user password. See Use Microsoft Active Directory with Autonomous Database for more information.

3. **Set the wallet location**: The properties file `ojdbc.properties` is pre-loaded with the wallet related connection property.

   ```
   oracle.net.wallet_location=(SOURCE=(METHOD=FILE)(METHOD_DATA=(DIRECTORY=${TNS_ADMIN})))
   ```

> **Note:**
>
> You do not modify the file `ojdbc.properties`. The value of `TNS_ADMIN` determines the wallet location.

4. **Compile and Run:** Compile and run the sample to get a successful connection. Make sure you have `oraclepki.jar` , `osdt_core.jar`, and `osdt_cert.jar`, in the `classpath`. For example:

```
java -classpath
      ./lib/ojdbc8.jar:./lib/ucp.jar:./lib/oraclepki.jar:./lib/
osdt_core.jar:./lib/osdt_cert.jar:. UCPSample
```

> **Note:**
>
> The auto-login wallet part of Autonomous Database downloaded client credentials zip file removes the need for your application to use username/password authentication.

Using Java KeyStore

To use Java and the 18.3 JDBC Thin Driver to connect to Autonomous Database with Java KeyStore (JKS), do the following:

1. **Make sure that the prerequisites are met:** See JDBC Thin Driver Connection Prerequisites Connections with Wallets (mTLS) for more information.
2. **Ready the database details**: You can either use a Java program, a servlet, or IDEs to check the connection to your database. A simple test is to download DataSourceSample.java or UCPSample.java from JDBC code samples. In this sample, use the connection URL as shown. Note that the connection `DB_URL` contains the TNS alias, for example, `dbname_high` present in `tnsnames.ora`. You can provide the path for `tnsnames.ora` file through `TNS_ADMIN` property as shown in the URL. Make sure to use the database username and password related to your database.

```
DB_URL="jdbc:oracle:thin:@dbname_high?TNS_ADMIN=/Users/test/wallet_dbname"
```

> **Note:**
>
> If you are using Microsoft Active Directory with Autonomous Database, then make sure to change the sample source code to use the Active Directory username and the Active Directory user password. See Use Microsoft Active Directory with Autonomous Database for more information.

3. **Set JKS related connection properties**: Add the JKS related connection properties to `ojdbc.properties` file. The keyStore and truststore password are the password specified when you downloading the client credentials `.zip` file.

To use SSL connectivity instead of Oracle Wallet, specify the keystore and truststore files and their respective password in the `ojdbc.properties` file as follows:

```
# Properties for using Java KeyStore (JKS)
oracle.net.ssl_server_dn_match=true
javax.net.ssl.trustStore==${TNS_ADMIN}/truststore.jks
javax.net.ssl.trustStorePassword=password
javax.net.ssl.keyStore==${TNS_ADMIN}/keystore.jks
javax.net.ssl.keyStorePassword=password
```

> **Note:**
>
> Make sure to comment the wallet related property in `ojdbc.properties`. For example:
>
> ```
> # Property for using Oracle Wallets
> # oracle.net.wallet_location=(SOURCE=(METHOD=FILE)
> (METHOD_DATA=(DIRECTORY=${TNS_ADMIN})))
> ```

4. **Compile and Run:** Compile and run the sample to get a successful connection. For example:

```
java -classpath ./lib/ojdbc8.jar:./lib/ucp.jar UCPSample
```

Connecting Using JDBC Thin Driver 12.2 or Older

If you are using the JDBC driver 12.2.0.2 or older, set the Java properties prior to starting the application. Usually you set the properties in the application's startup script.

If you are not able to use the latest JDBC drivers, then you can connect to Autonomous Database using 12.2.0.2 or other older JDBC drivers. The 12.2 or older JDBC drivers do not support the `ojdbc.properties` file. With older JDBC driver versions, you need to pass wallets or JKS related properties either as system properties or as connection properties to establish a connection.

Using Oracle Wallet

To use Java and the 12.2 or older JDBC Drivers to connect to Autonomous Database with the Oracle Wallet, do the following:

1. **Make sure that the prerequisites are met:** See JDBC Thin Driver Connection Prerequisites Connections with Wallets (mTLS) for more information.
2. **Verify the connection**: You can either use a Java program, a servlet, or IDEs to verify the connection to the database. A simple test is to download DataSourceSample.java or UCPSample.java from JDBC code samples and update the connection URL to have the required TNS alias. Also, update the sample source code to use the database username and password. For example:

```
DB_URL="jdbc:oracle:thin:@dbname_high"
```

> **Note:**
>
> If you are using Microsoft Active Directory with Autonomous Database, then update the sample source code to use the Active Directory username and Active Directory user password. See Use Microsoft Active Directory with Autonomous Database for more information.

3. **Set the wallet location**: Add the `OraclePKIProvider` at the end of the provider list in the file `java.security` (this file is part of your JRE install located at `$JRE_HOME/jre/lib/security/java.security`) which typically looks like:

```
security.provider.14=oracle.security.pki.OraclePKIProvider
```

4. **Compile and Run:** Compile and run the sample to get a successful connection. Make sure to have `oraclepki.jar` , `osdt_core.jar`, and `osdt_cert.jar`, in the `classpath`. Also, you need to pass the connection properties. Update the properties with the location where `tnsnames.ora` and wallet files are located.

```
java -classpath
./lib/ojdbc8.jar:./lib/ucp.jar:./lib/oraclepki.jar:./lib/
osdt_core.jar:./lib/osdt_cert.jar:.
-Doracle.net.tns_admin=/users/test/wallet_dbname
-Doracle.net.ssl_server_dn_match=true
-Doracle.net.ssl_version=1.2  (Not required for 12.2)
-Doracle.net.wallet_location= "(SOURCE=(METHOD=FILE)
(METHOD_DATA=(DIRECTORY=/users/test/wallet_dbname)))"
UCPSample
```

> **Note:**
>
> These are Windows system examples. Add a `\` continuation character if you are setting `-D` properties on multiple lines on UNIX (Linux or a Mac).

Using Java KeyStore

To use Java and the 12.2 or older JDBC Thin Drivers to connect to Autonomous Database with Java KeyStore (JKS), do the following:

1. **Make sure that the prerequisites are met:** See JDBC Thin Driver Connection Prerequisites Connections with Wallets (mTLS) for more information.
2. **Verify the connection**: You can either use a Java program, a servlet, or IDEs to verify the connection to the database. A simple test is to download DataSourceSample.java or UCPSample.java from JDBC code samples and update the connection URL to have the required TNS alias and pass `TNS_ADMIN`, providing the path for `tnsnames.ora` and update the connection URL to have the required TNS alias. Also, in the sample source code update the database username and password. For example:

```
DB_URL="jdbc:oracle:thin:@dbname_high"
```

> **Note:**
>
> If you are using Microsoft Active Directory with Autonomous Database, then update the sample source code to use the Active Directory username and Active Directory user password. See Use Microsoft Active Directory with Autonomous Database for more information.

3. **Compile and Run**: Compile and run the sample to get a successful connection. You need to pass the connection properties as shown. Update the properties with the location where `tnsnames.ora` and JKS files are placed. If you want to pass these connection properties programmatically then refer to DataSourceForJKS.java. For example:

```
java
-Doracle.net.tns_admin=/users/test/wallet_dbname
-Djavax.net.ssl.trustStore=truststore.jks
-Djavax.net.ssl.trustStorePassword=**********
-Djavax.net.ssl.keyStore=keystore.jks
-Djavax.net.ssl.keyStorePassword=************
-Doracle.net.ssl_server_dn_match=true
-Doracle.net.ssl_version=1.2 // Not required for 12.2
```

JDBC Thin Connections with an HTTP Proxy

If the client is behind a firewall and your network configuration requires an HTTP proxy to connect to the internet, you need to use the JDBC Thin Client 18.1 or higher which enables connections through HTTP proxies.

To connect to Autonomous Database through an HTTPS proxy, open and update your `tnsnames.ora` file. Add the HTTP proxy hostname(https_proxy) and port (https_proxy_port) to the connection string. Replace the values with your HTTPS proxy information. For example:

1. Add the HTTP proxy hostname and port to the connection definitions in `tnsnames.ora`. You need to add the https_proxy and https_proxy_port parameters in the address section of connection definitions. For example, the following sets the HTTP proxy to `proxyhostname` and the HTTP proxy port to `80`; replace these values with your HTTP proxy information:

```
db2022adb_high =
       (description=
             (address=
                   (https_proxy=proxyhostname)(https_proxy_port=80)
(protocol=tcps)(port=1522)(host=adb.example.oraclecloud.com)
             )
             (connect_data=(service_name=db2022adb_high.adb.oraclecloud.com)
             )
             (security=security=(ssl_server_dn_match=yes)
             )
       )
```

Notes:

- JDBC Thin client versions earlier than 18.1 do not support connections through HTTP proxy.
- Successful connection depends on specific proxy configurations and the performance of data transfers would depend on proxy capacity. Oracle does not recommend using this feature in Production environments where performance is critical.
- Configuring `tnsnames.ora` for the HTTP proxy may not be enough depending on your organization's network configuration and security policies. For example, some networks require a username and password for the HTTP proxy.
- In all cases, contact your network administrator to open outbound connections to hosts in the `oraclecloud.com` domain using the relevant port without going through an HTTP proxy.

JDBC Thin Connections Without a Wallet (TLS)

Autonomous Database mandates a secure connection that uses Transport Layer Security (TLSv1.2). Depending on the configuration options, Autonomous Database supports mTLS and TLS authentication. This section covers using JDBC Thin Connections with TLS authentication without a wallet.

- JDBC Thin Driver Connection Prerequisites for TLS Connections Without a Wallet
  Applications that use JDBC Thin driver support TLS and mutual TLS (mTLS) authentication. Connecting to an Autonomous Database instance with TLS authentication requires database credentials (username and password) and provides a secure connection, but does not require that you download Oracle wallets or Java KeyStore (JKS) files.
- Using a JDBC URL TLS Connection String for JDBC Thin Driver Without a Wallet
  To connect the database using JDBC Thin Driver with TLS without a wallet, you need to provide a connection string. Each database service has its own TNS Name and connection string.

JDBC Thin Driver Connection Prerequisites for TLS Connections Without a Wallet

Applications that use JDBC Thin driver support TLS and mutual TLS (mTLS) authentication. Connecting to an Autonomous Database instance with TLS authentication requires database credentials (username and password) and provides a secure connection, but does not require that you download Oracle wallets or Java KeyStore (JKS) files.

Note:

See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for information on allowing TLS connections.

Perform the following steps before connecting to the database:

1. **Provision Autonomous Database**: Create a database and obtain your database credentials (username and password).

See Provision an Autonomous Database Instance for more information.

2. **Verify your JDK version for security**: If you are using JDK11, JDK10, or JDK9 then you don't need to do anything for this step. If your JDK version is less than JDK8u162 then you need to download the JCE Unlimited Strength Jurisdiction Policy Files. Refer to the `README` file for installation notes. Download the JCE files from Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 8 Download.
3. **Check JDBC Driver Version**: The JDBC Thin client versions from 12.2.0.1 or higher are supported. However, it is recommended to use the latest release update from 19c or 23ai to take advantage of recent enhancements that simplify connections and provide easy steps for configuration. Obtain one of these from Oracle Database JDBC driver and Companion Jars Downloads.

Using a JDBC URL TLS Connection String for JDBC Thin Driver Without a Wallet

To connect the database using JDBC Thin Driver with TLS without a wallet, you need to provide a connection string. Each database service has its own TNS Name and connection string.

To run an application using the JDBC Thin Driver with TLS authentication without a wallet:

1. Copy a connection string for the Autonomous Database.

   To connect with TLS authentication copy a TLS connection string.

   a. From the Oracle Cloud Infrastructure Console, on the Autonomous Database details page click **Database connection**.
   b. Under **TLS Authentication**, select **TLS** to view the connection strings for connecting with TLS authentication.
   c. Copy a connection string.

   See View TNS Names and Connection Strings for an Autonomous Database Instance for information on viewing and copying connection stings.

   See Database Service Names for Autonomous Database for information on the different databases services for each connection string.
2. Set the `DB_URL` parameter.

   Use the following format for the `DB_URL` parameter:

   ```
   DB_URL=jdbc:oracle:thin:@my_connect_string
   ```

   For example:

   ```
   DB_URL=jdbc:oracle:thin:@(description= (retry_count=20)(retry_delay=3)
   (address=(protocol=tcps)
   (port=1521)(host=adb.region.oraclecloud.com))
   (connect_data=(service_name=u9adutfb2ba8x4d_database_medium.adb.oraclecloud
   .com))
   (security=(ssl_server_dn_match=yes)))
   ```

Preparing for Oracle Call Interface Connections

Using TLS with Oracle Call Interface connections with newer Oracle Instant Client/Oracle Database Client versions, a wallet is not required. For TLS connections with Oracle Call

Interface running on older Oracle Instant Client/Oracle Database Client versions, a wallet is required for both mTLS authenticated connections and TLS authenticated connections.

- Oracle Call Interface (OCI) Connections and Wallets (mTLS)
  Oracle Net Services can find the location of the Autonomous Database wallet using the `WALLET_LOCATION` parameter in the `sqlnet.ora` file.
- Oracle Call Interface (OCI) Connections with TLS Authentication
  Using TLS with Oracle Call Interface, connections with newer Oracle Instant Client/Oracle Database Client versions, a wallet is not required.

Oracle Call Interface (OCI) Connections and Wallets (mTLS)

Oracle Net Services can find the location of the Autonomous Database wallet using the `WALLET_LOCATION` parameter in the `sqlnet.ora` file.

When `WALLET_LOCATION` is used, Oracle Net Services automatically uses the wallet. The wallet is used transparently to the application. See Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections with Wallets (mTLS) for information on setting `WALLET_LOCATION`.

See Download Client Credentials (Wallets) for information on downloading client credentials for Autonomous Database.

Oracle Call Interface (OCI) Connections with TLS Authentication

Using TLS with Oracle Call Interface, connections with newer Oracle Instant Client/Oracle Database Client versions, a wallet is not required.

Oracle Call Interface (OCI) clients support TLS authentication without a wallet if you are using the following client versions:

- Oracle Instant Client/Oracle Database Client 19.13 - only on Linux x64
- Oracle Instant Client/Oracle Database Client 19.14 (or later) and 21.5 (or later) - only on Linux x64 and Windows

> **Note:**
>
> See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for information on allowing TLS connections.

See Prepare for Oracle Call Interface, ODBC, and JDBC OCI Connections Using TLS Authentication to prepare for Oracle Call Interface connections.

When a wallet is required and you set `WALLET_LOCATION` parameter in the `sqlnet.ora` file, Oracle Net Services finds the location of the wallet and uses the wallet (use of the wallet is transparent to the application).

Predefined Database Service Names for Autonomous Database

The `tnsnames.ora` file provided with the credentials zip file contains the database service names that allow you to connect to your database.

The available predefined service names differ depending on your workload. The different services provide different levels of performance and concurrency for Autonomous Database connections.

Workload Type	Database Service Names
Data Warehouse	*dbname*_high *dbname*_medium *dbname*_low See Database Service Names for Autonomous Database for more information.
Transaction Processing	*dbname*_tpurgent *dbname*_tp *dbname*_high *dbname*_medium *dbname*_low See Database Service Names for Autonomous Database for more information.
JSON Database	*dbname*_tpurgent *dbname*_tp *dbname*_high *dbname*_medium *dbname*_low See Database Service Names for Autonomous Database for more information.

Connect with Oracle Analytics Desktop

Oracle Analytics Desktop makes it easy to visualize your data so you can focus on exploring interesting data patterns. Just connect to Autonomous Database, select the elements that you're interested in, and let Oracle Analytics Desktop find the best way to visualize it. Choose from a variety of visualizations to look at data in a specific way.

For details on connecting Autonomous Database with Oracle Analytics Desktop, see *User's Guide for Oracle Analytics Desktop*.

Connect with Oracle Analytics Cloud

Oracle Analytics Cloud is a scalable and secure public cloud service that provides a full set of capabilities to explore and perform collaborative analytics for you, your workgroup, and your enterprise.

For details for connecting Autonomous Database with Oracle Analytics Cloud, see *Visualizing Data and Building Reports in Oracle Analytics Cloud*.

Connection and Networking Options and Features

Autonomous Database provides a number of different connection and networking options and features for connecting to a database.

- Using ACLs, VCNs, and Private Endpoints with Autonomous Database
  Describes the options for restricting network access to your Autonomous Database by specifying access control rules or using a virtual cloud network (private access with a private endpoint).

- Connect with Oracle Cloud Infrastructure FastConnect
  Oracle Cloud Infrastructure FastConnect provides an easy way for you to connect your on-premises network to Autonomous Database using FastConnect Public Peering. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.
- Access Autonomous Database with VCN Transit Routing
  Oracle Cloud Infrastructure supports private access from your on-premises network to a database with virtual cloud network (VCN) Transit Routing.
- Access Autonomous Database with Service Gateway
  Autonomous Database supports private access from Oracle Cloud Infrastructure resources in a VCN through a service gateway.
- Use Database Resident Connection Pooling with Autonomous Database
  Database Resident Connection Pool (DRCP) in Autonomous Database supports easier and more efficient management of open connections. Using DRCP provides you with access to a connection pool in your database that enables a significant reduction in key database resources required to support many client connections and when the database needs to scale for many simultaneous connections.
- Use TCP Fast Open (TFO) to Connect Clients to Autonomous Database
  If your application is sensitive to network latency and you want to decrease the network latency between your application and the database, you can enable TCP Fast Open (TFO).
- Best Practices for Low Latency Connections with Autonomous Database
  Taking steps to reduce the latency for connections between an application and Autonomous Database is critical if your application performs many round-trips between the application and the database.
- View Network Information on the OCI Console
  On the Oracle Cloud Infrastructure Console you can view the network information for your Autonomous Database.

Using ACLs, VCNs, and Private Endpoints with Autonomous Database

Describes the options for restricting network access to your Autonomous Database by specifying access control rules or using a virtual cloud network (private access with a private endpoint).

- About Network Access Options
  Provides an overview of the network access options available when you provision or clone Autonomous Database.
- Overview of Restricting Access with ACLs
  When you select the network access **Secure access from allowed IPs and VCNs only** option when you provision or clone an instance, you can restrict network access by defining an Access Control List (ACL). You can also add, update, or remove an ACL for an active instance.
- Overview of Private Endpoints
  You can specify that Autonomous Database uses a private endpoint inside your Virtual Cloud Network (VCN) in your tenancy. You can configure a private endpoint during provisioning or cloning your Autonomous Database, or you can switch to using private endpoints in existing databases that use public endpoints. This allows you to keep all traffic to and from your Autonomous Database off of the public internet.

About Network Access Options

Provides an overview of the network access options available when you provision or clone Autonomous Database.

> **Note:**
>
> For all of these options, the connections to your Autonomous Database use certificate-based authentication and Secure Sockets Layer (SSL).

When you provision or clone your Autonomous Database you specify one of the following network access options:

- **Secure access from everywhere**: This option assigns a public endpoint, public IP and hostname, to your database. With this selection you have two options:
  - The database is accessible from all IP addresses: this is the default option when you provision or clone Autonomous Database.

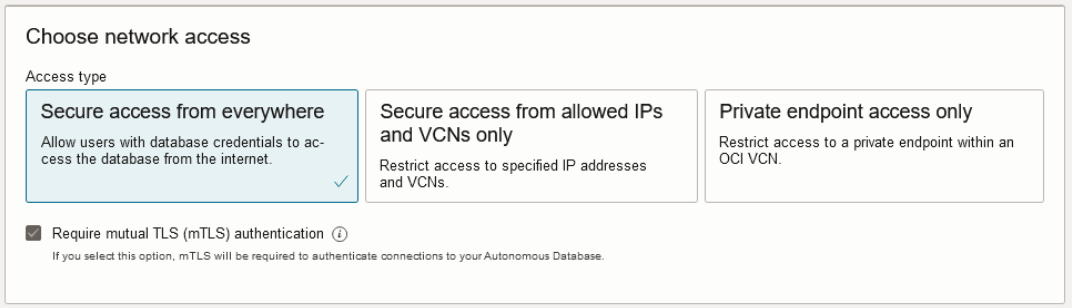
  If you configure your database with the **Secure access from everywhere** option, you can add, modify, or remove ACLs after you provision or clone the database.

  See Overview of Restricting Access with ACLs for more information.
- **Secure access from allowed IPs and VCNs only**: This option assigns a public endpoint, public IP and hostname, to your database. With this selection you must configure access control rules to restrict access by defining access control rules in an Access Control List (ACL). By specifying an ACL, the database will be accessible from allowed set of IP addresses or VCNs.

  If you configure your database with the **Secure access from everywhere** option, you can add, modify, or remove ACLs after you provision or clone the database.

  See Overview of Restricting Access with ACLs for more information.
- **Private endpoint access only**: This option assigns a private endpoint, private IP, and hostname to your database. Specifying this option allows traffic only from the VCN you specify; access to the database from all public IPs or VCNs is blocked. This allows you to define security rules, ingress/egress, at the Network Security Group (NSG) level and to control traffic to your Autonomous Database.

  See Configure Private Endpoints When You Provision or Clone an Instance for more information.



> **Note:**
>
> After you provision or clone your database, you can change the selection you make.

See Configure Network Access with Access Control Rules (ACLs) and Private Endpoints for more information.

Overview of Restricting Access with ACLs

When you select the network access **Secure access from allowed IPs and VCNs only** option when you provision or clone an instance, you can restrict network access by defining an Access Control List (ACL). You can also add, update, or remove an ACL for an active instance.

Specifying an access control list blocks all IP addresses that are not in the ACL list from accessing the database. After you specify an access control list, the database only accepts connections from addresses on the access control list and the database rejects all other client connections.

Depending on where the client machines that connect to your database are located you have the following options with ACLs:

- If your client machines connect to your database through the public internet, then you can use ACLs to specify the client machine's public IP addresses or their public CIDR blocks. In this case only the specified public IP addresses can access your database.
- If the client machines reside in an Oracle Cloud Infrastructure Virtual Cloud Network (VCN), you can configure a Service Gateway to connect to your database. In this case, you can specify the VCN in your ACL, this allows all client machines in that VCN to access your database and blocks all other connections. Furthermore, you can specify the VCN and a list of private IP addresses or CIDR blocks in that VCN. This allows only those client machines with the specified IP addresses or CIDR blocks to access your database and blocks all other connections.

  See VCNs and Subnets for details on Virtual Cloud Networks (VCN).

  See Access to Oracle Services: Service Gateway for details on setting up a Service Gateway.
- If you have on-premises clients that connect to your database through Transit Routing, you can specify the VCN and also the private IP addresses or CIDR blocks of these on-premises clients to access to your database.

  See Transit Routing: Private Access to Oracle Services for details on Transit Routing.
- You can use these options together to set multiple rules to allow access from different types of clients. Multiple rules do not exclude each other.

See Configuring Network Access with Access Control Rules (ACLs) for the steps for configuring network access with ACLs, either when you provision or clone your database, or whenever you want to add, modify or remove ACLs.

Overview of Private Endpoints

You can specify that Autonomous Database uses a private endpoint inside your Virtual Cloud Network (VCN) in your tenancy. You can configure a private endpoint during provisioning or cloning your Autonomous Database, or you can switch to using private endpoints in existing databases that use public endpoints. This allows you to keep all traffic to and from your Autonomous Database off of the public internet.

Specifying the **Private endpoint access only** configuration option only allows traffic from the VCN you specify and blocks access to the database from all public IPs or VCNs. This allows you to define security rules, ingress/egress, at the Network Security Group (NSG) level and to control traffic to your database.

Select the **Allow public access** option when you want to configure an Autonomous Database to use a private endpoint and you also want to allow connections from specific public IP addresses or from specific VCNs (if the VCNs are configured to privately connect to Autonomous Database using a Service Gateway).

See Configure Network Access with Private Endpoints for the steps for configuring network access with a private endpoint, either when you provision or clone your database or when you modify a private endpoint.

Connect with Oracle Cloud Infrastructure FastConnect

Oracle Cloud Infrastructure FastConnect provides an easy way for you to connect your on-premises network to Autonomous Database using FastConnect Public Peering. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.

Use FastConnect to access public services in Oracle Cloud Infrastructure without using the internet, for example, access to Object Storage, or the Oracle Cloud Infrastructure Console and APIs. Without FastConnect, the traffic destined for public IP addresses would be routed over the internet. With FastConnect, that traffic goes over your private physical connection.

For details for connecting Autonomous Database with Oracle Cloud Infrastructure FastConnect see FastConnect Overview.

Access Autonomous Database with VCN Transit Routing

Oracle Cloud Infrastructure supports private access from your on-premises network to a database with virtual cloud network (VCN) Transit Routing.

Transit routing refers to a network setup in which your on-premises network uses a connected virtual cloud network (VCN), through a service gateway on the VCN for connectivity to a database. You connect the on-premises network to the VCN with FastConnect or VPN Connect, and then configure the VCN routing so that traffic transits through the VCN to a database beyond the VCN.

After transit routing is configured, there are no special steps required to access Oracle APEX or Database Actions, or to consume RESTful services published in Oracle REST Data Services.

See Transit Routing: Private Access to Oracle Services for more details and options available with Transit Routing.

See VPN Connect for more information on VPN Connect.

Access Autonomous Database with Service Gateway

Autonomous Database supports private access from Oracle Cloud Infrastructure resources in a VCN through a service gateway.

A service gateway allows connectivity to Autonomous Database from private IP addresses in private subnets without requiring a NAT Gateway in your VCN. After a service gateway is configured, there are no special steps required to connect to Autonomous Database. Use the

same connection steps as described in this chapter, depending on your application type or the client tool you are using to connect to the database.

After a service gateway is configured, there are no special steps required to access Oracle APEX or Database Actions, or to consume RESTful services published in Oracle REST Data Services.

See Access to Oracle Services: Service Gateway for details.

Use Database Resident Connection Pooling with Autonomous Database

Database Resident Connection Pool (DRCP) in Autonomous Database supports easier and more efficient management of open connections. Using DRCP provides you with access to a connection pool in your database that enables a significant reduction in key database resources required to support many client connections and when the database needs to scale for many simultaneous connections.

When you connect to Autonomous Database you choose one of the following depending on values specified in the `tnsnames.ora` configuration file:

- A dedicated server process, which services only one user process.
- A pooled server process, obtained from DRCP, which can service multiple user processes.

To connect with a pooled DRCP server process, do the following:

1. Locate or obtain the `tnsnames.ora` file you are using to connect to your Autonomous Database.

   See Download Client Credentials (Wallets) for more information.

2. Modify the `tnsnames.ora` file to add the server type `SERVER=POOLED`.

   For example:

   ```
   example_high= (description=
        (address=(protocol=tcps)(port=1522)(host=adb.example.oraclecloud.com))
        (connect_data=(service_name=example_high.oraclecloud.com)
   (SERVER=POOLED))
        (security=(ssl_server_dn_match=yes)))
   ```

   When you connect with `(SERVER=POOLED)` specified in the `tnsnames.ora` file you obtain a connection from DRCP.

For Autonomous Database, note the following for working with Database Resident Connection Pools (DRCP):

- DRCP is enabled by default; however using DRCP is optional. To choose a pooled connection specify `SERVER=POOLED` in `tnsnames.ora`. If you do not specify `SERVER=POOLED`, you connect with a dedicated connection.
- You cannot start or stop DRCP.

See Using Database Resident Connection Pool for more information.

Use TCP Fast Open (TFO) to Connect Clients to Autonomous Database

If your application is sensitive to network latency and you want to decrease the network latency between your application and the database, you can enable TCP Fast Open (TFO).

Depending on the characteristics of your application, TFO connections can improve application performance by decreasing network latency for client connections.

- Prerequisites for TCP Fast Open (TFO) Connections
  Lists the prerequisites to use TCP Fast Open (TFO) connections with Autonomous Database.
- JDBC Thin Connections with TCP Fast Open
  Describes the requirements to use JDBC Thin connections with TCP Fast Open (TFO) on Autonomous Database.
- TCP Fast Open Connections with Python
  Describes the requirements to use Python with TCP Fast Open (TFO) connections on Autonomous Database.
- TCP Fast Open Connections with Oracle Call Interface Client for C or SQL*Plus Connections
  Describes the requirements to use Oracle Call Interface Client with TCP Fast Open (TFO) to connect with C or SQL*Plus to Autonomous Database.

Prerequisites for TCP Fast Open (TFO) Connections

Lists the prerequisites to use TCP Fast Open (TFO) connections with Autonomous Database.

To use TCP Fast Open (TFO) to connect to an Autonomous Database instance, the client application requires the following:

- The client must run on a VM in Oracle Cloud Infrastructure.
- One of the following must be true:
  - The Autonomous Database is on a private endpoint.
  - When the Autonomous Database is on a public endpoint, the routing rules between the client VM and the database must be configured so that the traffic goes through a Service Gateway.

    See Access Autonomous Database with Service Gateway and Configure Network Access with Private Endpoints for more information.
- The VM must be running on Linux. Supported platforms are: Oracle Linux x86_64 and Oracle Linux Arm (aarch64).
- The following OS level kernel parameters must be set:
  - As root user, set the following parameters:
    * `sysctl -w net.ipv4.tcp_fastopen=5`
    * `sysctl -w net.ipv4.tcp_fastopen_blackhole_timeout_sec=0`

    Verify the OS level kernel parameter values:

```
cat /proc/sys/net/ipv4/tcp_fastopen
5
cat /proc/sys/net/ipv4/tcp_fastopen_blackhole_timeout_sec
0
```

JDBC Thin Connections with TCP Fast Open

Describes the requirements to use JDBC Thin connections with TCP Fast Open (TFO) on Autonomous Database.

Assure that the client environment and client prerequisites are met. See Prerequisites for TCP Fast Open (TFO) Connections for more information.

To use JDBC with TCP Fast Open (TFO), perform the following steps:

1. Download the latest JDBC-thin driver.

   From the page Oracle Database JDBC driver and Companion Jars Downloads:

   - Select a driver version 23.4 or higher from the available drivers under **Oracle Database 23ai JDBC Driver & UCP Downloads - Free Release**.
   - Select a driver version 19.23 or higher from the available drivers under **Oracle Database 19c JDBC Driver & UCP Downloads - Long Term Release**

2. Download the Oracle JDBC TCP Fast Open (TFO) Library File.

   a. On the page Oracle Database JDBC driver and Companion Jars Downloads, expand **Oracle JDBC TCP Fast Open (TFO) Library v1**

   b. Download the native library .zip for your client platform:

      - JDBC TFO Library for Linux x86_64, library file for “x86_64” for Linux on Intel.
      - JDBC TFO Library for Linux AARCH64 library file for “arm64” for Linux on Arm.

3. Load the native library in the environment where you run your application.

   Set the following environment variables in the library path:

   a. Export `LD_PRELOAD`.

   ```
   export LD_PRELOAD=path_to/libtfojdbc1.so;
   ```

   b. If you are using JDK 8, export `LD_LIBRARY_PATH`.

   For example:

   ```
   export LD_LIBRARY_PATH=path_of_libtfojdbc1.so:path_to/jdk_8_home/jre/lib/
   amd64:path_to/jdk_8_home/jre/lib/amd64/server;
   ```

   c. If you are using JDK 17, export `LD_LIBRARY_PATH`.

   For example:

   ```
   export LD_LIBRARY_PATH=extracted_binaries_path:path_to/jdk_17_home/lib;
   ```

4. Enable the TCP Fast Open (TFO) option for your application.

   The following shows some of the options for enabling TFO in the client connection to the database:

   - In the client application, set the following connection property:

     ```
     properties.put(OracleConnection.CONNECTION_PROPERTY_NET_USE_TCP_FAST_OPEN,
     "true");
     ```

     By default the property `OracleConnection.CONNECTION_PROPERTY_NET_USE_TCP_FAST_OPEN` is set to false (disabled).

   - Add the TFO property in the JDBC URL.

For example:

```
jdbc:oracle:thin:@tcps://xxx.adb.yyy.oraclecloud.com:1521/
zzz.adb.oraclecloud.com?oracle.net.useTcpFastOpen=true
```

Or

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=tcps)
(HOST=xxx.adb.yyy.oraclecloud.com) (PORT=1521))
(CONNECT_DATA=(SERVICE_NAME=zzz.adb.oraclecloud.com)))?
oracle.net.useTcpFastOpen=true
```

- Add the following TNS parameter in the `CONNECT_DATA` section of the connection URL.

  For example:

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=tcps)
(HOST=xxx.adb.yyy.oraclecloud.com)(PORT=1521))
        (CONNECT_DATA=(USE_TCP_FAST_OPEN =ON)
(SERVICE_NAME=zzz.adb.oraclecloud.com)))
```

- Add the following TNS parameter in the `CONNECT_DATA` section of the connection URL.

  For example:

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=tcps)
(HOST=xxx.adb.yyy.oraclecloud.com)(PORT=1521))(CONNECT_DATA=(TFO=ON)
(SERVICE_NAME=zzz.adb.oraclecloud.com)))
```

5. Run the application.

TCP Fast Open Connections with Python

Describes the requirements to use Python with TCP Fast Open (TFO) connections on Autonomous Database.

Assure that the client environment and client prerequisites are met. See Prerequisites for TCP Fast Open (TFO) Connections for more information.

To use Python with TCP Fast Open (TFO), perform the following steps:

1. Install Python and the `python-oracledb` Driver.

   Use the latest version of `python-orabledb` (Version 2.1.0 or newer is required).

   See Install Python and the python-oracledb Driver for more information.

2. Add the `use_tcp_fast_open` connection parameter when you connect to an Autonomous Database instance.

   For example, use this option with one of:

   - oracledb.connect()
   - oracledb.connect_async()
   - oracledb.create_pool()
   - oracledb.create_pool_async()

   See Connect Python Applications to Autonomous Database for more information.

TCP Fast Open Connections with Oracle Call Interface Client for C or SQL*Plus Connections

Describes the requirements to use Oracle Call Interface Client with TCP Fast Open (TFO) to connect with C or SQL*Plus to Autonomous Database.

Assure that the client environment and client prerequisites are met. See Prerequisites for TCP Fast Open (TFO) Connections for more information.

> **Note:**
>
> You can enable TCP Fast Open (TFO) with either mTLS or TLS connections. See Secure Connections to Autonomous Database with mTLS or with TLS and Update Network Options to Allow TLS or Require Only Mutual TLS (mTLS) Authentication on Autonomous Database for more information.

To use Oracle Call Interface with TCP Fast Open (TFO), perform the following steps:

1. Download the latest Oracle instant client for Linux, either version 23.4 or higher or 19.23 or higher.

   See Oracle Instant Client Downloads for Linux x86-64 (64-bit) for Linux x86-64.

   See Oracle Instant Client Downloads for Linux ARM (aarch64) for Linux ARM.

2. Connect with the `USE_TCP_FAST_OPEN` parameter set to the value `YES`.

   For example, add the parameter `USE_TCP_FAST_OPEN` to `connect_data` in the connection string you use to connect to Autonomous Database:

   ```
   (description= (retry_count=20)(retry_delay=3)(address=(protocol=tcps)
      (port=1522)(host=example.us-phoenix-1.oraclecloud.com))
      (connect_data= (USE_TCP_FAST_OPEN=yes)
   (service_name=example_medium.adb.oraclecloud.com))
          (security=(ssl_server_dn_match=yes)))
   ```

   Or set the `sqlnet.ora` parameter:

   ```
   USE_TCP_FAST_OPEN=yes
   ```

Best Practices for Low Latency Connections with Autonomous Database

Taking steps to reduce the latency for connections between an application and Autonomous Database is critical if your application performs many round-trips between the application and the database.

For example, consider an OLTP application connecting to Autonomous Database and submitting thousands of SQL statements to the database individually to execute a sales order. In this case, the application requires thousands of round-trips, and reducing the latency for each round-trip can considerably speed up the sales order process. For such applications there are best practices that you can follow to reduce the latency for database connections.

- Steps to Reduce Latency for Database Connections
  You can follow these recommendations to reduce the latency for connections between your applications and the database.

- Steps to Reduce Latency for Database Connections for Databases with Autonomous Data Guard
  Provides steps to take to configure an Autonomous Data Guard standby environment, clients and mid-tiers, to reduce latency for database connections when you connect after a failover or after a switchover (when the standby becomes the Primary).
- Conceptual Network Diagram for Low Latency Database Connections
  Shows the conceptual network diagram for low latency connections using public endpoints and private endpoints for your database.

Steps to Reduce Latency for Database Connections

You can follow these recommendations to reduce the latency for connections between your applications and the database.

First determine the database's availability domain. To find an Autonomous Database instance's availability domain, connect as ADMIN and run the following query:

```
SELECT json_value(cloud_identity, '$.AVAILABILITY_DOMAIN')
AVAILABILITY_DOMAIN FROM v$pdbs;
```

For example:

```
SELECT json_value(cloud_identity, '$.AVAILABILITY_DOMAIN') AVAILABILITY_DOMAIN
             FROM v$pdbs;

AVAILABILITY_DOMAIN
-------------------
SoSC:US-ASHBURN-AD-1
```

You can also view the availability domain information on the Oracle Cloud Infrastructure Console. See View Network Information on the OCI Console for more information.

To reduce latency, do the following:

1. Place clients or the mid-tier servers in the same availability domain as the Autonomous Database instance.

   For example, if your application runs on an Oracle Cloud Infrastructure Compute VM, select the same availability domain as the Autonomous Database instance when you create the compute instance.

   If the application runs in another cloud or in an on-premises data center, use OCI FastConnect to reduce the latency for the connection to your OCI region. See FastConnect Overview for more information.
2. Configure the network routing.
   - If you are using an Autonomous Database instance on a public endpoint, configure your network routing so that the connection from the client to the database goes through a Service Gateway.

     See the following for more information.
     - Setting Up a Service Gateway in the Console
     - Access to Oracle Services: Service Gateway

- If you are using an Autonomous Database instance on a private endpoint, you connect to the database using the private endpoint visible in your network, without the need to configure a Service Gateway.

3. Use one-way TLS connections without a wallet.

   As a best practice for lower latency, configure the Autonomous Database instance to allow both mTLS and TLS connections and use TLS connections to connect your application to the database.

   See the following for more information:

   - Secure Connections to Autonomous Database with mTLS or with TLS
   - Update Network Options to Allow TLS or Require Only Mutual TLS (mTLS) Authentication on Autonomous Database

4. Use TCP Fast Open (TFO) to connect to the database.

   See Use TCP Fast Open (TFO) to Connect Clients to Autonomous Database for more information.

Steps to Reduce Latency for Database Connections for Databases with Autonomous Data Guard

Provides steps to take to configure an Autonomous Data Guard standby environment, clients and mid-tiers, to reduce latency for database connections when you connect after a failover or after a switchover (when the standby becomes the Primary).

- Reduce Latency for Database Connections with Local Autonomous Data Guard
  Follow these steps to reduce the latency for the database connections you make when you use Autonomous Data Guard and you either failover or switchover to a local standby database.
- Reduce Latency for Database Connections with Cross-Region Autonomous Data Guard
  Follow these steps to reduce the latency for the database connections you make when you use Autonomous Data Guard and you either fail over or switch over to a cross-region standby database.

Reduce Latency for Database Connections with Local Autonomous Data Guard

Follow these steps to reduce the latency for the database connections you make when you use Autonomous Data Guard and you either failover or switchover to a local standby database.

If you have an Autonomous Data Guard local standby and you are in a region with multiple availability domains, Autonomous Data Guard creates the local standby database in a different availability domain. When you failover or switchover to the standby database, the local standby becomes the Primary database. To prepare for a failover or a switchover it is recommended to have standby clients and mid-tiers available to enable, so that after a failure or after a switchover, your applications can continue working in the event of an availability domain failure.

First, verify that the disaster recovery type for your local peer is Autonomous Data Guard. See Enable Autonomous Data Guard for more information.

Perform the following tasks to configure standby clients and mid-tiers for low latency when you are using Autonomous Data Guard with a local standby in a region with multiple availability domains.

1. Place the standby clients or mid-tiers in the same availability domain as the local standby database (all components should be configured to use the same availability domain).

For example, if your application runs on an Oracle Cloud Infrastructure Compute VM, when you create the compute instance select the same availability domain for the Compute VM as the standby database. This prepares the disaster recovery configuration so that the standby database and the standby Compute VM use the same availability domain after a failover or switchover. This will reduce latency for connections to the database compared to a configuration where the components use different availability domains.

To determine the availability domain of the standby database, connect to the Primary database as the ADMIN user and run the following query:

```
SELECT availability_domain FROM v$pdbs,
     JSON_TABLE(
       cloud_identity,
       '$.AUTONOMOUS_DATA_GUARD[*]'
       COLUMNS (
         standby_type PATH '$.STANDBY_TYPE',
         availability_domain PATH '$.AVAILABILITY_DOMAIN'
       )
     ) jt
WHERE jt.standby_type = 'local';
```

For example, this command shows the availability domain for a local standby database:

```
AVAILABILITY_DOMAIN
-------------------
SoSC:US-ASHBURN-AD-3
```

2. You do not need to do additional network configuration or allow one-way TLS connections for the local standby database. A local standby database has the same setup network configuration as the Primary database.
3. Configure your clients and mid-tiers to use TCP Fast Open.

   See Use TCP Fast Open (TFO) to Connect Clients to Autonomous Database for more information.

Reduce Latency for Database Connections with Cross-Region Autonomous Data Guard

Follow these steps to reduce the latency for the database connections you make when you use Autonomous Data Guard and you either fail over or switch over to a cross-region standby database.

If you add one or more cross-region Autonomous Data Guard standby databases, the cross-region standby databases are added in the regions that you select when you add a cross-region peer. When you failover or switchover to a cross-region Autonomous Data Guard standby database, the cross-region standby becomes the Primary database. To prepare for a regional failover or switchover, it is recommended to have standby clients and mid-tiers available in the remote region. This prepares the clients and the mid-tier in the remote region so that in the case of a failure or after a switchover, your applications can continue working.

First, verify that your disaster recovery includes at least one cross-region Autonomous Data Guard standby. See Add a Cross-Region Standby Database for more information.

Follow these steps to configure clients and mid-tiers for low latency when using Autonomous Data Guard with one or more cross-region standby databases.

1. Place the standby clients or mid-tiers in the same availability domain as the cross-region standby databases.

To determine the availability domains for cross-region Autonomous Data Guard standby databases, connect to the Primary database as the ADMIN user and run the following query:

```
SELECT availability_domain FROM v$pdbs,
     JSON_TABLE(
       cloud_identity,
       '$.AUTONOMOUS_DATA_GUARD[*]'
       COLUMNS (
         standby_type PATH '$.STANDBY_TYPE',
         availability_domain PATH '$.AVAILABILITY_DOMAIN'
       )
     ) jt
WHERE jt.standby_type = 'cross-region';
```

For example, when you have two cross-region standby databases, running this command shows the availability domains for each cross-region standby database:

```
AVAILABILITY_DOMAIN
---------------------
SoSC:PHX-AD-3
SoSC:US-SANJOSE-1-AD-1
```

a. If you have one cross-region standby, the query shows a single availability domain. Place the standby clients and mid-tiers in the same region and use the same availability domain as the cross-region standby database.

   For example, if your application runs on an Oracle Cloud Infrastructure Compute VM, when you create the compute instance select the same availability domain for the Compute VM as the Autonomous Data Guard standby database. This assures that the cross-region standby database and the standby Compute VM are in the same region and use the same availability domain after a failover or switchover.

b. If you have more than one cross-region standby, in each region use the appropriate availability domain that matches the region and the availability domain for each corresponding standby database. You will need to perform this setup multiple times (all components in an individual region should use the same availability domain as the Autonomous Data Guard standby).

If the application runs in another cloud or in an on-premises data center, use OCI FastConnect to reduce the latency for the connection to your OCI region. See FastConnect Overview for more information.

2. Configure the network routing in the region where the standby database resides. Perform this step multiple times if you have more than one cross-region standby database.

   a. If the standby database is on a public endpoint, configure your network routing so that the connection from the clients in the region where the cross-region standby database is, go through a Service Gateway.

      See the following for more information:

      - Setting Up a Service Gateway in the Console
      - Access to Oracle Services: Service Gateway

   b. If the standby database is on a private endpoint, you connect to the database using the private endpoint visible in your network, without the need to configure a Service Gateway.

3. Use one-way TLS connections without a wallet.

   If you configured one-way TLS for your primary database, standby databases will already have on-way TLS configured. You do not need to do any additional configuration on cross-region standby databases.

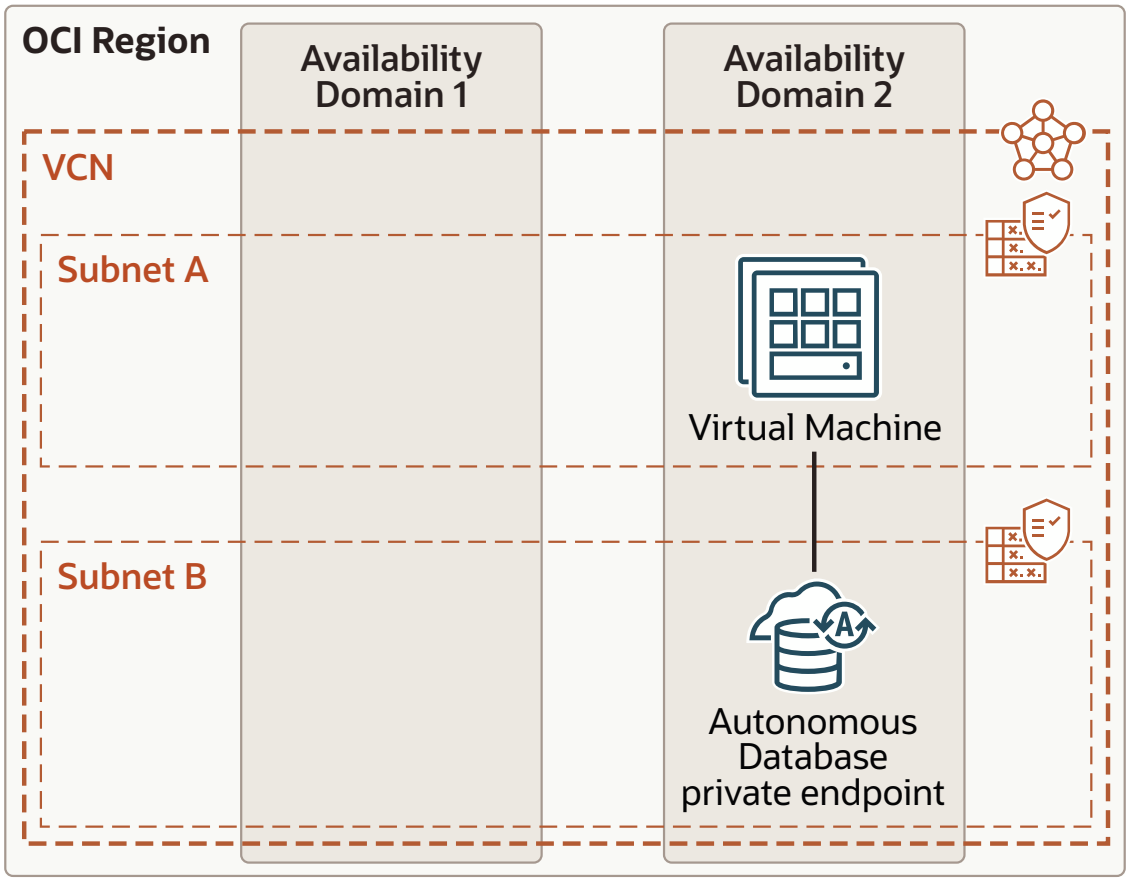
4. Configure your clients and mid-tiers to use TCP Fast Open.

   See Use TCP Fast Open (TFO) to Connect Clients to Autonomous Database for more information.

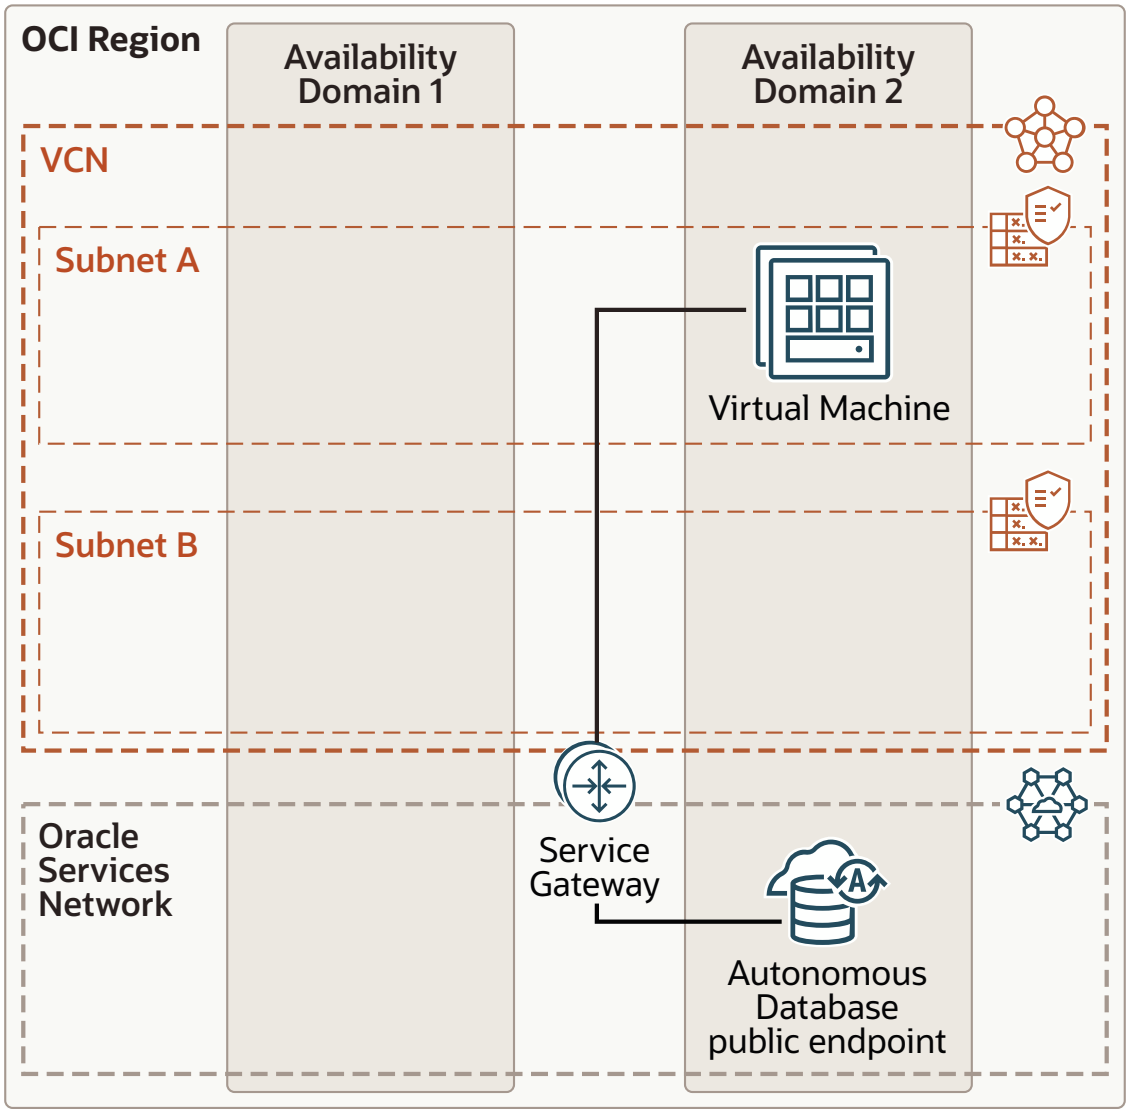
Conceptual Network Diagram for Low Latency Database Connections

Shows the conceptual network diagram for low latency connections using public endpoints and private endpoints for your database.

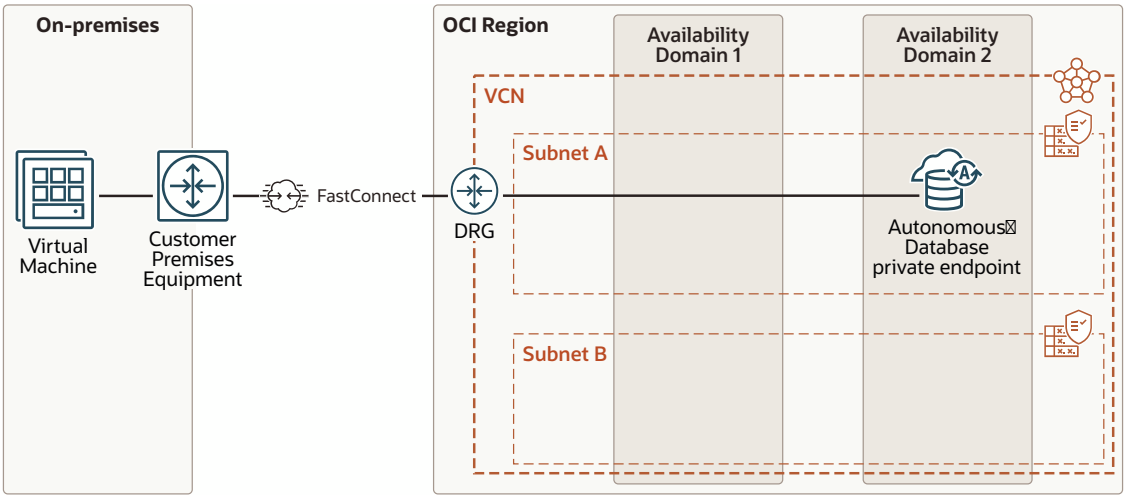
Low Latency Connections Using Private Endpoint with Application Running Inside the OCI Region



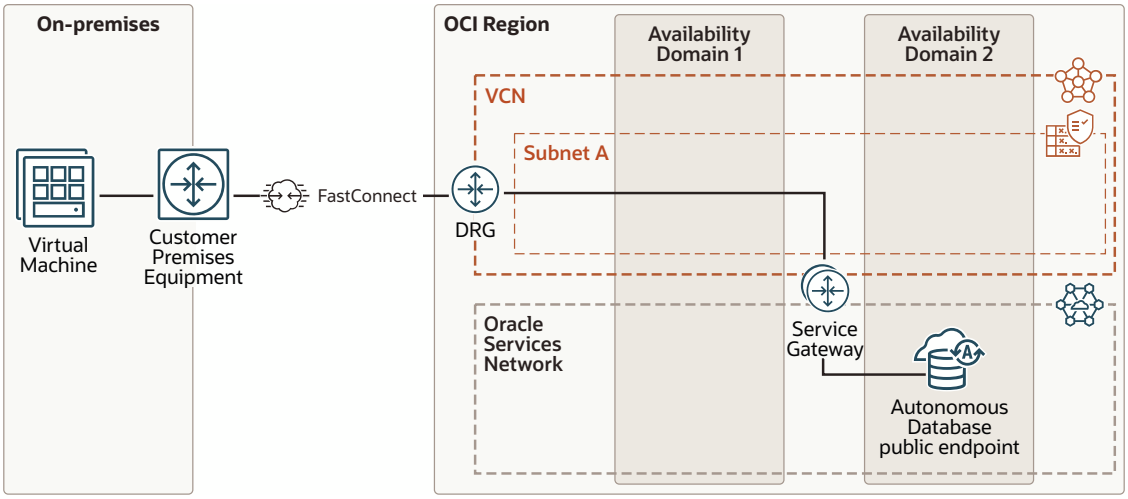
Low Latency Connections Using Public Endpoint with Application Running Inside the OCI Region



Low Latency Connections Using a Private Endpoint with Application Running In On-Premises Data Center Connected to OCI Using FastConnect



Low Latency Connections Using a Public Endpoint with Application Running In Your in On-Premises Data Center Connected to OCI Using FastConnect



View Network Information on the OCI Console

On the Oracle Cloud Infrastructure Console you can view the network information for your Autonomous Database.

The network information on the OCI Console includes the access type, the availability domain, and other network configuration information for your database.

Field	Description
Mutual TLS	Shows the configuration options for Mutual TLS (mTLS) and TLS for the Autonomous Database instance. See Secure Connections to Autonomous Database with mTLS or with TLS and Update Network Options to Allow TLS or Require Only Mutual TLS (mTLS) Authentication on Autonomous Database for information on Mutual TLS and TLS connections.

Field	Description
Access type	Shows the specified access type for the Autonomous Database instance. See the following for more information: • About Network Access Options • Configure Access Control Lists When You Provision or Clone an Instance • Configure Private Endpoints When You Provision or Clone an Instance
Access control list	This field shows if Access Control Lists (ACLs) of an Autonomous Database Instance are defined. It can display the following two values: • **Enabled**: The field displays Enabled when ACLs of the Autonomous Database Instance are defined. • **Disabled**: The field displays Disabled when ACLs of the Autonomous Database Instance are not defined. See Configuring Network Access with Access Control Rules (ACLs) for more information.
Availability domain	The Availability Domain field displays the availability domain of your Autonomous Database instance. See Regions and Availability Domains for more information on Availability Domains.

Field	Description
Availability domain (local peer)	If there is a local peer database, Autonomous Data Guard standby, this field shows the local standby's availability domain. For example, the following shows the network information with the Autonomous Database instance availability domain and the availability domain for the local Autonomous Data Guard standby:  You can also view information on Autonomous Data Guard with Local Standby.

The following fields are shown when the Autonomous Database is configured with a private endpoint.

Field	Description
Public access	This field shows if public access for an Autonomous Database Instance on a Private Endpoint is enabled. This field can display the following two values: • **Enabled**: A data recipient on the public internet can access data when the data resides on an Autonomous Database instance on a private endpoint. • **Disabled**: A data recipient on the public internet cannot access data when the data resides on an Autonomous Database instance on a private endpoint.
Virtual cloud network	The Virtual Cloud Network field specifies the VCN for use with an Oracle Cloud Infrastructure Service Gateway. This field includes a link for the VCN associated with the private endpoint. See Access to Oracle Services: Service Gateway.
Subnet	The Subnet field includes a link for the subnet associated with the private endpoint. See VCN and Subnet Management for more information.
Public Endpoint URL	This field shows the public endpoint URL for the resource when public access is enabled.
Private endpoint IP	This field displays the private endpoint IP address for the resource.
Private endpoint URL	This field displays the private endpoint URL for the resource.
Network Security Group	Shows a Network Security Group (NSG) within your VCN. The NSG specifies rules for connections to your Autonomous Database. You can define security rules in an NSG to allow connections to the Autonomous Database instance which creates a virtual firewall for your Autonomous Database. See Network Security Groups for more information.

Manage Users

Describes administration tasks for managing database users on Autonomous Database.

- Create Users on Autonomous Database
  There are several options to create users on Autonomous Database. You can use Oracle Database Actions Database Users card or use client-side tools that connect to the database to create database users.
- Remove Users on Autonomous Database
  To remove users from your database, connect to the database as the ADMIN user using any SQL client tool.
- Manage User Profiles with Autonomous Database
  You can create and alter user profiles in Autonomous Database. After you create or alter a profile, you can specify the profile clause with `CREATE USER` or `ALTER USER`. You can also import existing user profiles from another environment with Oracle Data Pump Import.
- Manage User Roles and Privileges on Autonomous Database
  There are several ways to manage user privileges and roles on Autonomous Database. You can use Oracle Database Actions Database Users card or client-side tools to connect to the database to mange privileges and roles.

- Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database
  An administrator can add an existing database user account to use with Oracle Machine Learning components or create a new user account and user credentials with the Oracle Machine Learning User Management interface.
- Use Identity and Access Management (IAM) Authentication with Autonomous Database
- Use Microsoft Entra ID with Autonomous Database
  You can configure an Autonomous Database instance for Microsoft Entra ID users to connect using Entra ID (Azure AD) `OAuth2` tokens.
- Use Microsoft Active Directory with Autonomous Database
- Configure Kerberos Authentication with Autonomous Database
  Describes how to configure Kerberos to authenticate Oracle Autonomous Database users.

Create Users on Autonomous Database

There are several options to create users on Autonomous Database. You can use Oracle Database Actions Database Users card or use client-side tools that connect to the database to create database users.

- Create Users on Autonomous Database with Database Actions
  You can quickly create Autonomous Database users with Database Actions.
- Create Users on Autonomous Database - Connecting with a Client Tool
  You can create users by connecting to the database as the ADMIN user using any SQL client tool.
- Unlock User Accounts on Autonomous Database
  If a user account is locked, as the ADMIN user you can unlock the account.
- About User Passwords on Autonomous Database
  Autonomous Database requires strong passwords; the password you specify for a user must meet the minimum default password complexity rules.
- Manage the Administrator Account on Autonomous Database
  The administrator user for Autonomous Database is ADMIN, and this administrator account has several system privileges granted to be able to manage users and other areas of the database.

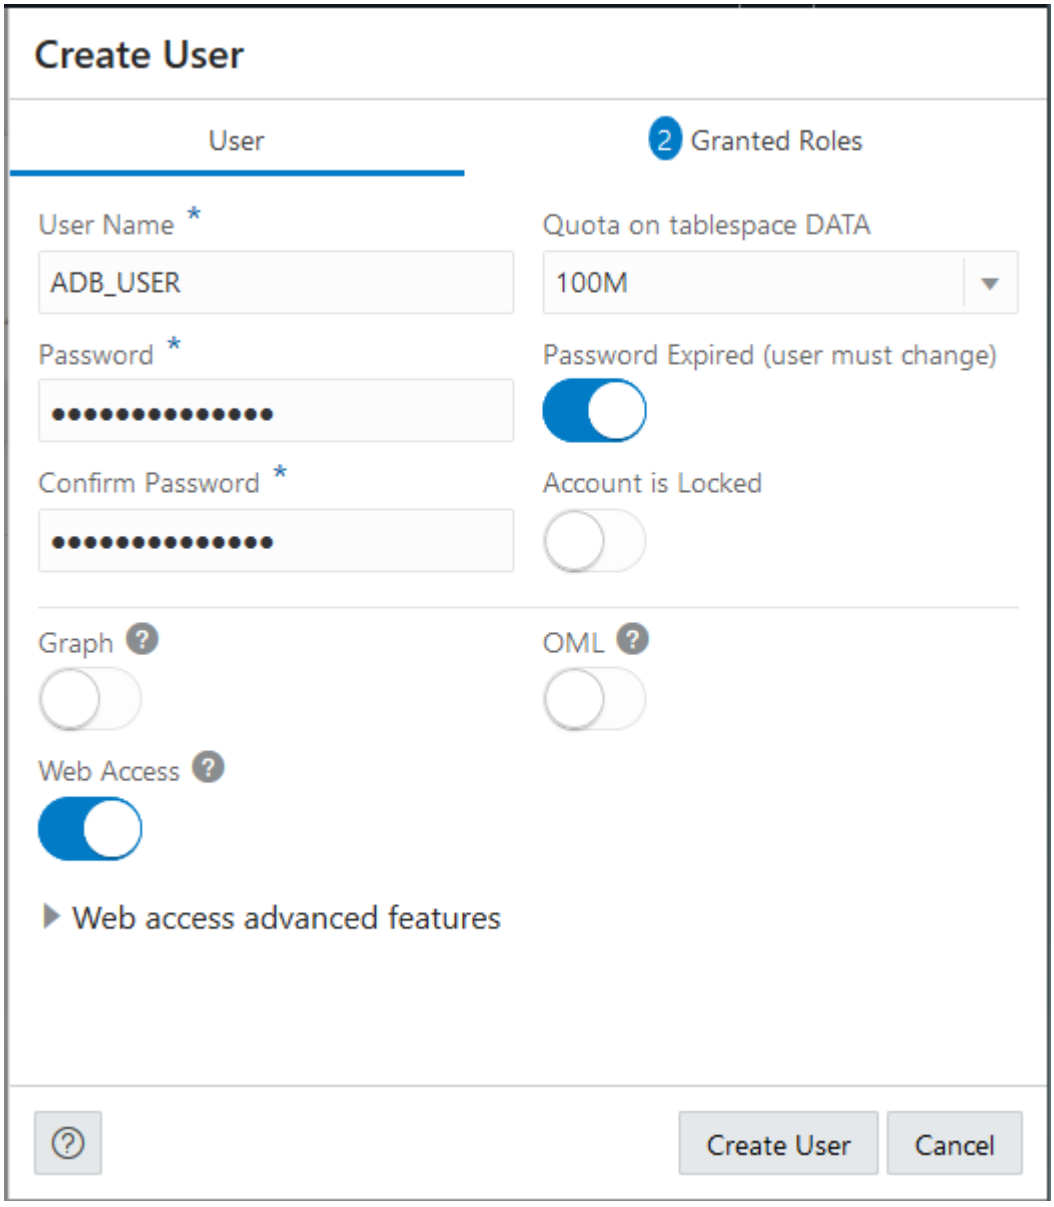
Create Users on Autonomous Database with Database Actions

You can quickly create Autonomous Database users with Database Actions.

First, access Database Actions as the ADMIN user. See Access Database Actions as ADMIN for more information.

1. Click the top left ☰ next to Oracle Database Actions.

   This shows the Database Actions menu, including **Development**, **Data Studio**, **Administration**, **Downloads**, **Monitoring**, and **Related Services**.
2. Under **Administration** click **Database Users**.
3. On the Database Users page, in the All Users area click **+ Create User**.
4. To create a new user, enter a user name, a password, and enter the password again to confirm the password. Also select any options you want to enable for the user: **Graph**, **OML**, or **Web Access**.



5. Set a value for the **Quota on tablespace DATA** for the user.
6. If you want to grant roles for the new user, click the **Granted Roles** tab and select the roles for the user. For example, select DWROLE and CONNECT.
7. Click **Create User**.

   Database Actions shows the User Created confirmation message.

See Manage User Roles and Privileges on Autonomous Database for more information on granting roles and adding or updating privileges for a user.

See The Database Users Page for detailed information on Database Actions Database Users.

If you provide Web Access for the new user, then you need to send a URL to the new user. See Provide Database Actions Access to Database Users for more information.

The administrator needs to provide the credentials wallet to the new user for client-side access. See Connect to Autonomous Database for more information on client-side access credentials.

> **Note:**
>
> Autonomous Database requires strong passwords; the password you specify must meet the default password complexity rules. See About User Passwords on Autonomous Database for more information.

See Create Oracle APEX Workspaces in Autonomous Database for information on creating APEX workspaces.

See Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database to add user accounts for Oracle Machine Learning Notebooks.

Create Users on Autonomous Database - Connecting with a Client Tool

You can create users by connecting to the database as the ADMIN user using any SQL client tool.

For example, connect using Oracle SQL Developer (see Connect Oracle SQL Developer with a Wallet (mTLS)).

1. Connect as the ADMIN user.
2. Run the following SQL statements:

```
CREATE USER new_user IDENTIFIED BY password;
GRANT CREATE SESSION TO new_user;
```

> **Note:**
>
> `IDENTIFIED` with the `EXTERNALLY` clause is not supported with Autonomous Database.
> In addition, `IDENTIFIED` with the `BY VALUES` clause is not allowed.

This creates *new_user* with connect privileges. This user can now connect to the database and run queries. To grant additional privileges to users, see Manage User Roles and Privileges on Autonomous Database.

The administrator needs to provide the credentials wallet to the user *new_user*. See Connect to Autonomous Database for more information on client credentials.

> **Note:**
>
> Autonomous Database requires strong passwords; the password you specify must meet the default password complexity rules. See About User Passwords on Autonomous Database for more information.

See Provide Database Actions Access to Database Users to add users for Database Actions.

See Create Oracle APEX Workspaces in Autonomous Database for information on creating APEX workspaces.

See Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database to add user accounts for Oracle Machine Learning components.

Unlock User Accounts on Autonomous Database

If a user account is locked, as the ADMIN user you can unlock the account.

To unlock an account, connect to your database as the ADMIN user and run the following command:

```
ALTER USER username IDENTIFIED BY password ACCOUNT UNLOCK;
```

See *SQL Language Reference* for information on the `ALTER USER` command.

About User Passwords on Autonomous Database

Autonomous Database requires strong passwords; the password you specify for a user must meet the minimum default password complexity rules.

Autonomous Database sets minimum standards for passwords, and the default profile sets parameters to limit the number of failed login attempts.

- The password must be between 12 and 30 characters long and must include at least one uppercase letter, one lowercase letter, and one numeric character.

  Note, the password limit is shown as 60 characters in some help tooltip popups. Limit passwords to a maximum of 30 characters.
- The password cannot contain the *username*.
- The password cannot be one of the last four passwords used for the same *username*.
- The password cannot contain the double quote (") character.
- The password must not be the same password that is set less than 24 hours ago.

To change the password complexity rules and password parameter values you can alter the default profile or create a new profile and assign it to users. See Manage User Profiles with Autonomous Database for more information.

The following are the Autonomous Database default profile password parameter values:

Password Parameter	Description	Value
`FAILED_LOGIN_ATTEMPTS`	The maximum times a user can try to log in and fail before locking the account. This limit applies for regular database user accounts.	10
`PASSWORD_GRACE_TIME`	The number of days after the grace period begins during which a warning is issued and login is allowed.	30
`PASSWORD_LIFE_TIME`	The number of days the same password can be used for authentication.	360
`PASSWORD_LOCK_TIME`	The number of days an account will be locked after the specified number of consecutive failed login attempts.	1
`PASSWORD_REUSE_MAX`	The number of password changes required before the current password can be reused.	4
`PASSWORD_REUSE_TIME`	The number of days before which a password cannot be reused.	1

See Manage User Profiles with Autonomous Database for information on using `CREATE USER` or `ALTER USER` with a profile clause.

See *SQL Language Reference* for information on the `ALTER USER` command.

Manage the Administrator Account on Autonomous Database

The administrator user for Autonomous Database is ADMIN, and this administrator account has several system privileges granted to be able to manage users and other areas of the database.

You can change the administrator user (ADMIN) password and when locked, unlock the administrator user account on Autonomous Database. When you use the APIs to create an Autonomous Database or to reset the ADMIN password, you can optionally use an Oracle Cloud Infrastructure Vault secret to store the password.

See CreateAutonomousDatabase for more information.

See ADMIN User Roles and Privileges for more information on the ADMIN user.

- Set the ADMIN Password in Autonomous Database
  Provides the steps to set the ADMIN password.
- Unlock the ADMIN Account in Autonomous Database
  Shows the steps to unlock the ADMIN user account.
- Use Oracle Cloud Infrastructure Vault Secret for ADMIN Password

Set the ADMIN Password in Autonomous Database

Provides the steps to set the ADMIN password.

From the Oracle Cloud Infrastructure Console, change the password for the ADMIN user by following these steps:

1. On the **Details** page, from the **More actions** drop-down list, select **Administrator password**.
2. On the **Administrator password** panel enter the new password and confirm.
3. Click **Change**.

> **Note:**
>
> You can also use Database Actions to change the password for the ADMIN user. See Manage Users and User Roles on Autonomous Database - Connecting with Database Actions for more information.

The password for the default administrator account, ADMIN, has the same password complexity rules mentioned in the section About User Passwords on Autonomous Database.

Unlock the ADMIN Account in Autonomous Database

Shows the steps to unlock the ADMIN user account.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.

- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

Use the following steps to unlock the ADMIN account by updating the ADMIN password:

1. On the **Details** page, from the **More actions** drop-down list, select **Administrator password**.
2. On the **Administrator password** enter the new password and confirm.
3. Click **Change**.

This operation unlocks the ADMIN account if it was locked.

The password for the default administrator account, ADMIN, has the same password complexity rules mentioned in the section About User Passwords on Autonomous Database.

Use Oracle Cloud Infrastructure Vault Secret for ADMIN Password

When you create or clone an Autonomous Database instance or when you reset the ADMIN password, you can use an Oracle Cloud Infrastructure vault secret to specify the ADMIN password.

Autonomous Database allows you to use the APIs to provide a protected vault secret as the ADMIN password, with secure access to the vault secret granted through Oracle Cloud Infrastructure IAM policies.

> **Note:**
>
> Using an Oracle Cloud Infrastructure vault secret for the ADMIN password is only supported with the APIs.

Oracle Cloud Infrastructure Vault secrets are credentials that you use with Oracle Cloud Infrastructure services. Storing secrets in a vault provides greater security than you might achieve storing them elsewhere, such as in code or in configuration files. By calling database APIs you can use secrets from the Vault Service to set the ADMIN password. The vault secret password option is available when you create or clone an Autonomous Database instance, or when you set or reset the ADMIN password.

You create secrets using the Oracle Cloud Infrastructure Console, CLI, or API.

Notes for using a vault secret to set or reset the ADMIN password:

- In order for Autonomous Database to reach the secret in a vault, the following conditions must apply:
  - The secret must be in `current` or `previous` state.
  - If you specify a secret version in the API call, the specified secret version is used. If you do not specify a secret version, the call uses the latest secret version.
  - You must have the proper user group policy that allows `READ` access to the specific secret in a given compartment. For example:

    ```
    Allow userGroup1 to read secret-bundles in compartment training
    ```

- The password stored in the secret must conform to Autonomous Database password requirements.

See the following for more information:

- Overview of Vault
- CreateAutonomousDatabase
- UpdateAutonomousDatabaseDetails
- About User Passwords on Autonomous Database
- Managing Secrets

Remove Users on Autonomous Database

To remove users from your database, connect to the database as the ADMIN user using any SQL client tool.

For example, connect using Oracle SQL Developer.

1. Connect as the ADMIN user.
2. Run the following SQL statement:

```
DROP USER user_name CASCADE;
```

This removes *user_name* and the objects owned by that user.

> **Note:**
>
> This removes all *user_name* objects and the data owned by *user_name* is deleted.

You can also remove a database user with Oracle Database Actions. To remove a user, from the Database Users page, click the ⋮ to open the context menu for a user, and then select **Delete**. See Manage Users and User Roles on Autonomous Database - Connecting with Database Actions for more information on using Oracle Database Actions Database Users.

Manage User Profiles with Autonomous Database

You can create and alter user profiles in Autonomous Database. After you create or alter a profile, you can specify the profile clause with `CREATE USER` or `ALTER USER`. You can also import existing user profiles from another environment with Oracle Data Pump Import.

> **Note:**
>
> Autonomous Database has restrictions on the profile clause. See SQL Commands for information on `CREATE PROFILE` and `ALTER PROFILE` restrictions.

To add, modify, or remove a password parameter in a profile, including the `DEFAULT` profile you must have the `ALTER PROFILE` system privilege.

1. To add or alter a profile, as the ADMIN user run either `CREATE PROFILE` or `ALTER PROFILE`. For example:

   ```
   CREATE PROFILE new_profile
     LIMIT PASSWORD_REUSE_MAX 10
     PASSWORD_LOCK_TIME 5;
   ```

   If you are not the ADMIN user, then you must have `CREATE PROFILE` privilege to run `CREATE PROFILE`. If you run `ALTER PROFILE`, then you must have `ALTER PROFILE` privilege.

2. Use the new or altered profile with a `CREATE USER` or `ALTER USER` command. For example:

   ```
   CREATE USER new_user IDENTIFIED BY password PROFILE new_profile;
   GRANT CREATE SESSION TO new_user;
   ```

This creates *new_user* with profile *new_profile* and with connect privileges. The *new_user* can now connect to the database and run queries. To grant additional privileges to users, see Manage User Privileges on Autonomous Database - Connecting with a Client Tool.

See CREATE PROFILE for information on using `CREATE PROFILE` or `ALTER PROFILE`.

You can import existing profiles created in other environments using Oracle Data Pump Import (`impdp`). Any existing profile association with database users is preserved after importing into Autonomous Database. When a newly created user, created from an Oracle Data Pump import, attempts to login for the first time, the login is handled as follows:

- The password complexity restrictions are the same as the restrictions for any user on Autonomous Database.
- If the user's password violates the password complexity requirements, the account is expired with a 30-day grace period. In this case the user is required to change their password before the grace period ends.

> **Note:**
>
> Profile assignments for users with profile `ORA_PROTECTED_PROFILE` and `ORA_ADMIN_PROFILE` cannot be modified.

The following users share the `ORA_PROTECTED_PROFILE` profile and the profile assignment of these users cannot be changed:

- `ADBSNMP`
- `ADB_APP_STORE`
- `DCAT_ADMIN`
- `GGADMIN`
- `RMAN$CATALOG`

The `ADMIN` user is assigned to `ORA_ADMIN_PROFILE`.

When you create or alter a profile, you can specify a Password Verification Function (PVF) to manage password complexity. See Manage Password Complexity on Autonomous Database for more information.

- Manage Password Complexity on Autonomous Database
  You can create a Password Verify Function (PVF) and associate the PVF with a profile to manage the complexity of user passwords.
- Gradual Database Password Rollover for Applications

Manage Password Complexity on Autonomous Database

You can create a Password Verify Function (PVF) and associate the PVF with a profile to manage the complexity of user passwords.

> **Note:**
>
> The minimum password length for a user specified PVF is 8 characters and must include at least one upper case letter, one lower case letter and one numeric character. The minimum password length for the DEFAULT profile is 12 characters (the DEFAULT profile uses the `CLOUD_VERIFY_FUNCTION` PVF). The password cannot contain the username.
> Oracle recommends using a minimum password length of 12 characters. If you define a profile's PVF, and set the minimum password length to less than 12 characters, then tools such as Oracle Database Security Assessment Tool (DBSAT) and Qualys report this as a database security risk.

For example, to specify a PVF for a profile, use the following command:

```
CREATE PROFILE example_profile LIMIT PASSWORD_VERIFY_FUNCTION
ADMIN.EXAMPLE_PVF
```

If the profile is created or altered by any user other than the ADMIN user, then you must grant the `EXECUTE` privilege on the PVF. If you create a PVF and the password check fails, the database reports the `ORA-28219` error.

You can specify an Oracle supplied PVF, from one of the following:

- `CLOUD_VERIFY_FUNCTION` (this is the default password verification function for Autonomous Database):
  This function checks for the following requirements when users create or modify passwords:
  - The password must be between 12 and 30 characters long and must include at least one uppercase letter, one lowercase letter, and one numeric character.
  - The password cannot contain the username.
  - The password cannot be one of the last four passwords used for the same username.
  - The password cannot contain the double quote (") character.
  - The password must not be the same password that is set less than 24 hours ago.
- `ORA12C_STIG_VERIFY_FUNCTION`
  This function checks for the following requirements when users create or modify passwords:
  - The password has at least 15 characters.
  - The password has at least 1 lower case character and at least 1 upper case character.

  - The password has at least 1 digit.
  - The password has at least 1 special character.
  - The password differs from the previous password by at least 8 characters.

  See ora12c_stig_verify_function Password Requirements for more information.

Note the following restrictions for a Password Verification Function (PVF) that you create and assign to a profile:

- If you specify a user profile, the minimum password length depends on how you define the associated PVF, as follows:
  - If a PVF is defined, then the minimum password length enforced is 8 characters with at least one upper case letter, one lower case letter and one numeric character. The password cannot contain the username.
  - If the PVF is defined as `NULL`, then the minimum password length enforced is 8 characters with at least one upper case letter, one lower case letter and one numeric character. The password cannot contain the username.
  - If the profile does not have a PVF defined, then the DEFAULT profile's PVF (`CLOUD_VERIFY_FUNCTION`) is assigned and the minimum password length enforced is 12 characters.
- If you specify a Password Verify Function (PVF) that is more strict than the default `CLOUD_VERIFY_FUNCTION`, then the new verify function is used.
- A PVF that you create must be created as a `DEFINER RIGHTS` PL/SQL function. If a `INVOKER` rights PVF is provided as input to `CREATE` or `ALTER PROFILE`, then `ORA-28220` error is thrown.
- Any PVF that you create must be created in the ADMIN user schema. If a non-ADMIN user owned PVF is provided as input to `CREATE` or `ALTER PROFILE`, then `ORA-28220` error is thrown.
- A PVF cannot be altered or dropped by a non-ADMIN user. That is, any user with the `CREATE` or `DROP ANY PROCEDURE` privilege is not allowed to alter or drop a PVF.
- If the PVF associated with a profile is dropped, then any attempt to change the password for a user who uses the PVF in their profile throws the error `ORA-7443`. Users can still login when the PVF associated with their profile is dropped. However, if a user's password is expired and the PVF is dropped, then the user cannot login.

  To recover from the `ORA-7443` error, the ADMIN user must recreate the dropped PVF and assign it to the profile, or assign an existing PVF to the profile. This allows a user change their password and login.
- The `CREATE ANY PROCEDURE` system privilege and `DROP ANY PROCEDURE` system privilege are audited for PVF security. See the `PROCEDURES` list in Listings of System and Object Privileges for more information.

See Managing the Complexity of Passwords for more information.

Gradual Database Password Rollover for Applications

An application can change its database passwords without an administrator having to schedule downtime.

To accomplish this, you can associate a profile having a non-zero limit for the `PASSWORD_ROLLOVER_TIME` password profile parameter, with an application schema. This allows the database password of the application user to be altered while allowing the older password

to remain valid for the time specified by the `PASSWORD_ROLLOVER_TIME` limit. During the rollover period of time, the application instance can use either the old password or the new password to connect to the database server. When the rollover time expires, only the new password is allowed.

See Managing Gradual Database Password Rollover for Applications for more information.

Manage User Roles and Privileges on Autonomous Database

There are several ways to manage user privileges and roles on Autonomous Database. You can use Oracle Database Actions Database Users card or client-side tools to connect to the database to mange privileges and roles.

- Manage Users and User Roles on Autonomous Database - Connecting with Database Actions
  You can manage user roles for Autonomous Database users with Oracle Database Actions. The same steps also let you modify account settings for a user.
- Manage User Privileges on Autonomous Database - Connecting with a Client Tool
  Autonomous Databases come with a predefined database role named `DWROLE`. This role provides the common privileges for Autonomous Database users. Depending on the usage requirements you may also need to grant individual privileges to users.

Manage Users and User Roles on Autonomous Database - Connecting with Database Actions

You can manage user roles for Autonomous Database users with Oracle Database Actions. The same steps also let you modify account settings for a user.

First, access Database Actions as the ADMIN user. See Access Database Actions as ADMIN for more information.

1. Click the top left ☰ next to Oracle Database Actions.

   This shows the Database Actions menu, including **Development** and **Administration**.
2. Under **Administration** click **Database Users**.
3. On the Database Users page, in the card for the user you want to modify click the ⋮ to open the context menu for the user, then select **Edit**.

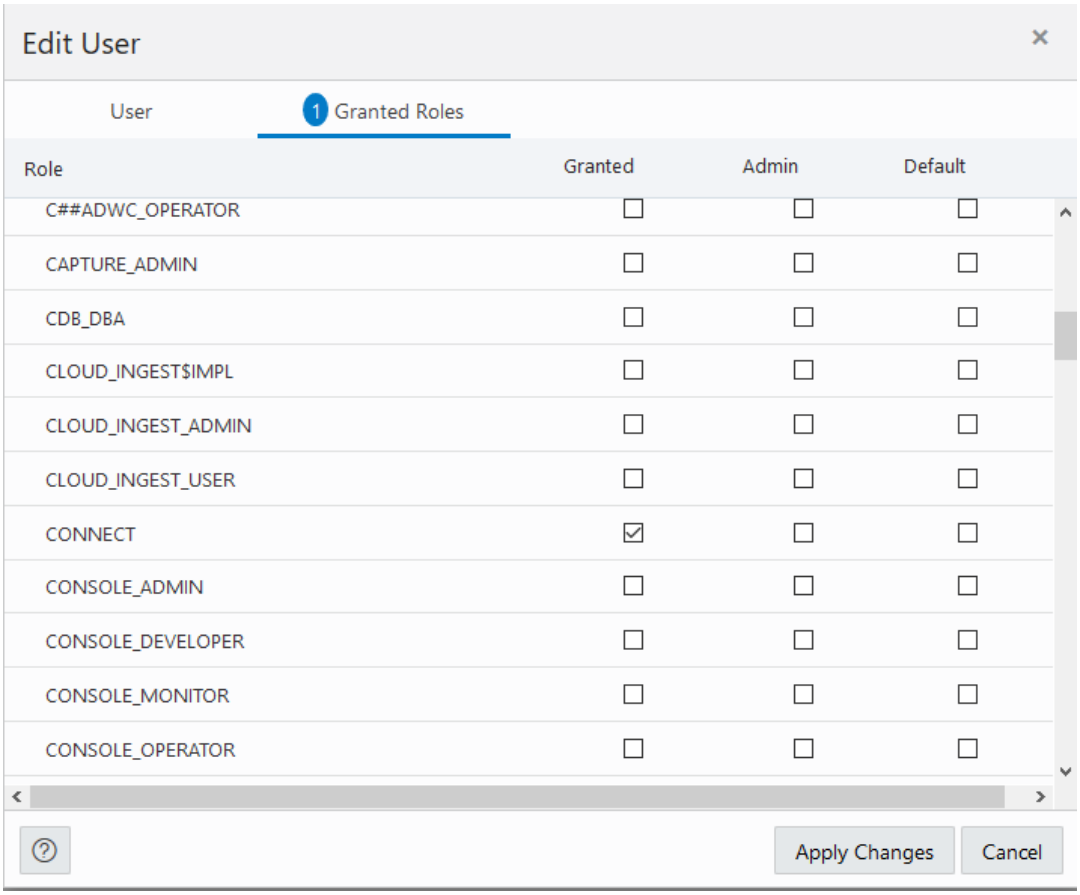
   This shows the Edit User area with the User tab selected.

   > **Note:**
   >
   > If you want to manage the user's account settings, for example if you want to provide Web Access to provide access to Database Actions, or if you want to lock the user's account, you can do this from the User tab.
4. In the Edit User area, click **Granted Roles**.

   This displays the Granted Roles tab with a list of available roles and selection boxes. For each role, you can check **Granted** to grant the role, **Admin** to permit the user to grant the role to other users, and **Default** to use the default settings for **Granted** and **Admin**.
5. Select the roles you want to grant to the user.

   For example, select CONNECT and DWROLE.

For each role, you can select **Granted** to grant the role, **Admin** to permit the user to grant the role to other users, and **Default** to use the default settings for Granted and Admin. A new user is granted CONNECT and RESOURCE roles when **Web Access** is selected.



6. Click **Apply Changes**.

See The Database Users Page for more information on Database Actions Database Users.

See Create Users on Autonomous Database with Database Actions for information on using Database Actions.

Manage User Privileges on Autonomous Database - Connecting with a Client Tool

Autonomous Databases come with a predefined database role named `DWROLE`. This role provides the common privileges for Autonomous Database users. Depending on the usage requirements you may also need to grant individual privileges to users.

1. To grant `DWROLE` role, connect to the database as ADMIN user using any SQL client tool. For example, connect using Oracle SQL Developer (see Connect Oracle SQL Developer with a Wallet (mTLS)).
2. As the ADMIN user grant `DWROLE`. For example, the following command grants `DWROLE` to the user `adb_user`:

```
GRANT DWROLE TO adb_user;
```

3. Grant individual privileges to users with the `GRANT` command instead of or in addition to granting `DWROLE` privileges. See *Oracle Database SQL Language Reference*.

4. If a user needs to load data, do one of the following to add the privileges required to load data:

   - Add quota to a new user with `CREATE USER` or alter the quota for an existing user with `ALTER USER`. For example:

     ```
     CREATE USER sales
          QUOTA 5M on DATA;
     ALTER USER sales
          QUOTA 1G on DATA;
     ```

   - Grant `UNLIMITED TABLESPACE` privileges to a user. For example, the following command grants unlimited tablespace privileges to the user `adb_user`:

     ```
     GRANT UNLIMITED TABLESPACE TO adb_user;
     ```

> **Note:**
>
> Granting `UNLIMITED TABLESPACE` privilege allows a user to use all the allocated storage space. You cannot selectively revoke tablespace access from a user with the `UNLIMITED TABLESPACE` privilege. You can grant selective or restricted access only after revoking the privilege.

The privileges in `DWROLE` are the following:

```
CREATE ANALYTIC VIEW
CREATE ATTRIBUTE DIMENSION
ALTER SESSION
CREATE HIERARCHY
CREATE JOB
CREATE MATERIALIZED VIEW
CREATE MINING MODEL
CREATE PROCEDURE
CREATE SEQUENCE
CREATE SESSION
CREATE SYNONYM
CREATE TABLE
CREATE TRIGGER
CREATE TYPE
CREATE VIEW
READ,WRITE ON directory DATA_PUMP_DIR
EXECUTE privilege on the PL/SQL package DBMS_CLOUD
EXECUTE privilege on OCI PL/SQL SDK
```

Create and Update User Accounts for Oracle Machine Learning Components on Autonomous Database

An administrator can add an existing database user account to use with Oracle Machine Learning components or create a new user account and user credentials with the Oracle Machine Learning User Management interface.

- Create User
  An administrator creates new user accounts and user credentials for Oracle Machine Learning in Database Actions.

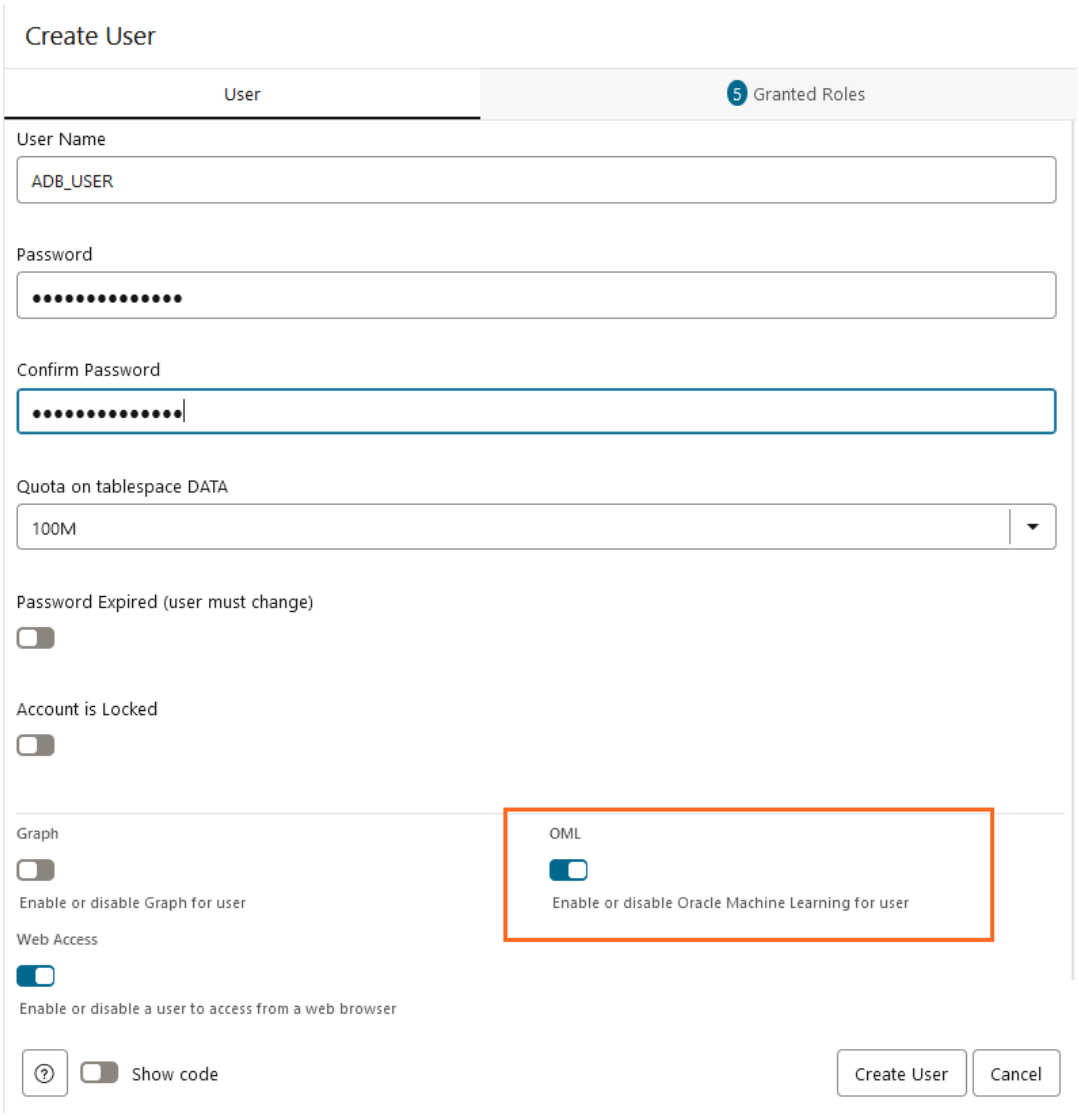
- Add Existing Database User Account to Oracle Machine Learning Components
  As the ADMIN user you can add an existing database user account to provide access to Oracle Machine Learning components.

Create User

An administrator creates new user accounts and user credentials for Oracle Machine Learning in Database Actions.

To create a user account:

1. On the Autonomous Databases page, under the **Display Name** column, select an Autonomous Database.
2. On the Autonomous Database Details page, select **Database Actions** and click **Database Users**.
3. On the Database Users page, in the All Users area click **+ Create User**.
4. To create a new user enter a user name, a password, and enter the password again to confirm the password.
5. Select the options you want for the user and select **OML** to enable Oracle Machine Learning for the user.



6. Click **Create User**.

This creates a new database user and grants the required privileges to use Oracle Machine Learning.

> **Note:**
>
> With a new database user, an administrator needs to issue grant commands on the database to grant table access to the new user for the tables associated with the user's Oracle Machine Learning notebooks.

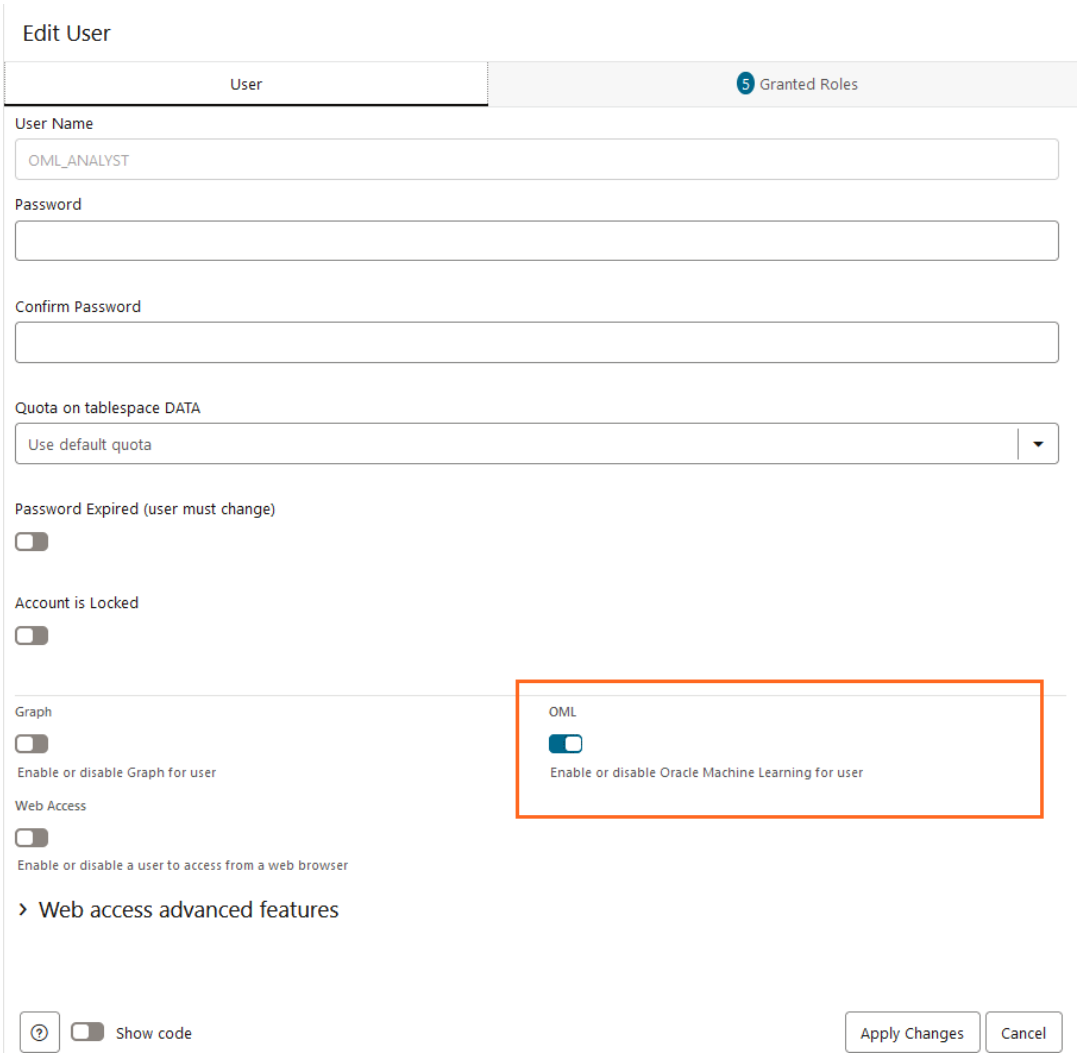
Add Existing Database User Account to Oracle Machine Learning Components

As the ADMIN user you can add an existing database user account to provide access to Oracle Machine Learning components.

To add an existing database user account:

1. On the Autonomous Databases page, under the **Display Name** column, select an Autonomous Database.
2. On the Autonomous Database Details page, select **Database Actions** and click **Database Users**.
3. In the All Users, search for the user of interest or select the user. For example, search the user **OML_ANALYST**.
4. In the user's card, click ··· and select **Edit**
5. In the Edit User panel, select **OML**.

   For example:



6. Click **Apply Changes**.

This grants the required privileges to use the Oracle Machine Learning application. In Oracle Machine Learning this user can then access any tables the user has privileges to access in the database.

Use Identity and Access Management (IAM) Authentication with Autonomous Database

You can configure Autonomous Database to use Oracle Cloud Infrastructure Identity and Access Management (IAM) authentication and authorization to allow IAM users to access an Autonomous Database with IAM credentials.

> **Note:**
>
> Autonomous Database integration with Oracle Cloud Infrastructure IAM is supported in commercial regions with identity domains as well as in the legacy IAM, which does not include identity domains. IAM with identity domains was introduced with new Oracle Cloud Infrastructure tenancies that were created after November 8, 2021. Autonomous Database supports users and groups in default and non-default identity domains.

- About Identity and Access Management (IAM) Authentication with Autonomous Database
  You can enable an Autonomous Database instance to use Oracle Cloud Infrastructure (IAM) authentication and authorization for users.
- Prerequisites for Identity and Access Management (IAM) Authentication on Autonomous Database
  Describes the prerequisites for enabling IAM user access on Autonomous Database.
- Enable Identity and Access Management (IAM) Authentication on Autonomous Database
  Describes the steps to enable IAM user access on Autonomous Database.
- Create Identity and Access Management (IAM) Groups and Policies for IAM Users
  Describes the steps to write policy statements for an IAM group to enable IAM user access to Oracle Cloud Infrastructure resources, specifically Autonomous Database instances.
- Add IAM Users on Autonomous Database
  To add IAM users to allow access to Autonomous Database, map database global users to IAM groups or users with `CREATE USER` or `ALTER USER` statements (with `IDENTIFIED GLOBALLY AS` clause).
- Add IAM Roles on Autonomous Database
  Optionally, create global roles to provide additional database roles and privileges to IAM users when multiple IAM users are mapped to the same shared global user.
- Create IAM Database Password for IAM Users
  To add an IAM user and allow the IAM user to login to Autonomous Database by supplying a username and password, you must create an IAM database password.
- Connect to Autonomous Database with Identity and Access Management (IAM) Authentication
  After the ADMIN user enables Oracle Cloud Infrastructure IAM on Autonomous Database, users log in to the Autonomous Database instance using their Oracle Cloud Infrastructure IAM credentials or access the database through an Oracle Cloud Infrastructure IAM database token.
- Configure IAM Proxy Authentication
  Proxy authentication allows an IAM user to proxy to a database schema for tasks such as application maintenance.

- Disable Identity and Access Management (IAM) Authentication on Autonomous Database
  Describes the steps to disable IAM external authentication user access for Autonomous Database.
- Accessing a Database Cross-Tenancy Using an IAM Integration
  Users and groups in one tenancy can access DBaaS database instances in another tenancy if policies in both tenancies allow this.
- Notes for Using Autonomous Database Tools with Identity and Access Management (IAM) Authentication
  Provides notes for using Autonomous Database tools with IAM authentication enabled.

About Identity and Access Management (IAM) Authentication with Autonomous Database

You can enable an Autonomous Database instance to use Oracle Cloud Infrastructure (IAM) authentication and authorization for users.

> **Note:**
>
> Autonomous Database integration with Oracle Cloud Infrastructure IAM is supported in commercial regions with identity domains as well as in the legacy IAM, which does not include identity domains. IAM with identity domains was introduced with new Oracle Cloud Infrastructure tenancies that were created after November 8, 2021. Autonomous Database supports users and groups in default and non-default identity domains.

Oracle Cloud Infrastructure IAM integration with Autonomous Database supports the following:

- IAM Database Password Authentication
- Identity and Access Management (IAM) SSO Token Based Authentication

See Authenticating and Authorizing IAM Users for Oracle Autonomous Databases for complete details about the architecture for using IAM users on Autonomous Database.

- IAM Database Password Authentication
  You can enable an Autonomous Database instance to allow user access with an Oracle Cloud Infrastructure IAM database password (using a password verifier).
- Identity and Access Management (IAM) SSO Token Based Authentication
  You can enable an Autonomous Database instance to use Oracle Cloud Infrastructure (OCI) Identity and Access Management (IAM) SSO tokens.

IAM Database Password Authentication

You can enable an Autonomous Database instance to allow user access with an Oracle Cloud Infrastructure IAM database password (using a password verifier).

> **Note:**
>
> Any supported 12c and above database client can be used for IAM database password access to Autonomous Database.

An Oracle Cloud Infrastructure IAM database password allows an IAM user to log in to an Autonomous Database instance as Oracle Database users typically log in with a user name and password. The user enters their IAM user name and IAM database password. An IAM database password is a different password than the Oracle Cloud Infrastructure Console password. Using an IAM user with the password verifier you can login to Autonomous Database with any supported database client.

For password verifier database access, you create the mappings for IAM users and OCI applications to the Autonomous Database instance. The IAM user accounts themselves are managed in IAM. The user accounts and user groups can be in either the default domain or in a custom, non-default domain.

Identity and Access Management (IAM) SSO Token Based Authentication

You can enable an Autonomous Database instance to use Oracle Cloud Infrastructure (OCI) Identity and Access Management (IAM) SSO tokens.

For token verifier database access, you create the mappings for IAM users and OCI applications to the Autonomous Database instance. The IAM user accounts themselves are managed in IAM. The user accounts and user groups can be in either the default domain or in a custom, non-default domain.

There are several ways a database client can obtain an IAM database token:

- A client application or tool can request the database token from IAM for the user and can pass the database token through the client API. Using the API to send the token overrides other settings in the database client. Using IAM tokens requires the latest Oracle Database client 19c (at least 19.16). Some earlier clients provide a limited set of capabilities for token access.
- If the application or tool does not support requesting an IAM database token through the client API, the IAM user can first use Oracle Cloud Infrastructure command line interface (CLI) to retrieve the IAM database token and save it in a file location. For example, to use SQL*Plus and other applications and tools using this connection method, you first obtain the database token using the Oracle Cloud Infrastructure (OCI) Command Line Interface (CLI). If the database client is configured for IAM database tokens, when a user logs in with the slash login form, the database driver uses the IAM database token that has been saved in a default or specified file location.
- A client application or tool can use an Oracle Cloud Infrastructure IAM instance principal or resource principal to get an IAM database token, and use the IAM database token to authenticate itself to an Autonomous Database instance.
- IAM users and OCI applications can request a database token from IAM with several methods, including using an API-key. See Configuring a Client Connection for SQL*Plus That Uses an IAM Token for an example. See About Authenticating and Authorizing IAM Users for an Oracle Autonomous Database for a description of other methods such as using a delegation token within an OCI cloud shell.

Prerequisites for Identity and Access Management (IAM) Authentication on Autonomous Database

Describes the prerequisites for enabling IAM user access on Autonomous Database.

If the database is enabled for another external authentication scheme, verify that you want to use IAM on the Autonomous Database instance. There can only be one external authentication scheme enabled at any given time.

If you want to use IAM and another external authentication scheme is enabled, you can either first disable the other external authentication scheme or use the `force` parameter with the value set to true when you enable IAM authentication. See Enable Identity and Access Management (IAM) Authentication on Autonomous Database for information on using the `force` parameter.

Enable Identity and Access Management (IAM) Authentication on Autonomous Database

Describes the steps to enable IAM user access on Autonomous Database.

> **Note:**
>
> Autonomous Database integration with Oracle Cloud Infrastructure IAM is supported in commercial regions with identity domains as well as in the legacy IAM, which does not include identity domains. IAM with identity domains was introduced with new Oracle Cloud Infrastructure tenancies that were created after November 8, 2021. Autonomous Database supports users and groups in default and non-default identity domains.

To enable Autonomous Database to allow IAM users to connect to the database:

1. Perform the prerequisites for IAM authorization and authentication on Autonomous Database. See Prerequisites for Identity and Access Management (IAM) Authentication on Autonomous Database for more information.
2. Use the procedure `DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION` to enable Oracle Cloud Infrastructure IAM authentication.

   When you perform these steps, connect to the Autonomous Database instance as the ADMIN user or as a user with ADMIN privileges.

   For example:

   ```
   BEGIN
      DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
         type => 'OCI_IAM' );
   END;
   /
   ```

   By default the `force` parameter is false. When another external authentication method is enabled and `force` is false, `DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION` reports the following error:

   ```
   ORA-20004: Another external authentication is already enabled.
   ```

   If you want to disable the external authentication that is currently enabled and use IAM authentication instead, include the `force` parameter.

   For example:

   ```
   BEGIN
      DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
         type => 'OCI_IAM',
   ```

```
      force => TRUE );
END;
/
```

This sets the `IDENTITY_PROVIDER_TYPE` system parameter.

For example, you can use the following to verify `IDENTITY_PROVIDER_TYPE`:

```
SELECT NAME, VALUE FROM V$PARAMETER WHERE NAME='identity_provider_type';

NAME                    VALUE
----------------------- -------
identity_provider_type OCI_IAM
```

Create Identity and Access Management (IAM) Groups and Policies for IAM Users

Describes the steps to write policy statements for an IAM group to enable IAM user access to Oracle Cloud Infrastructure resources, specifically Autonomous Database instances.

A policy is a group of statements that specifies who can access particular resources, and how. Access can be granted for the entire tenancy, databases in a compartment, or individual databases. This means you write a policy statement that gives a specific group a specific type of access to a specific type of resource within a specific compartment.

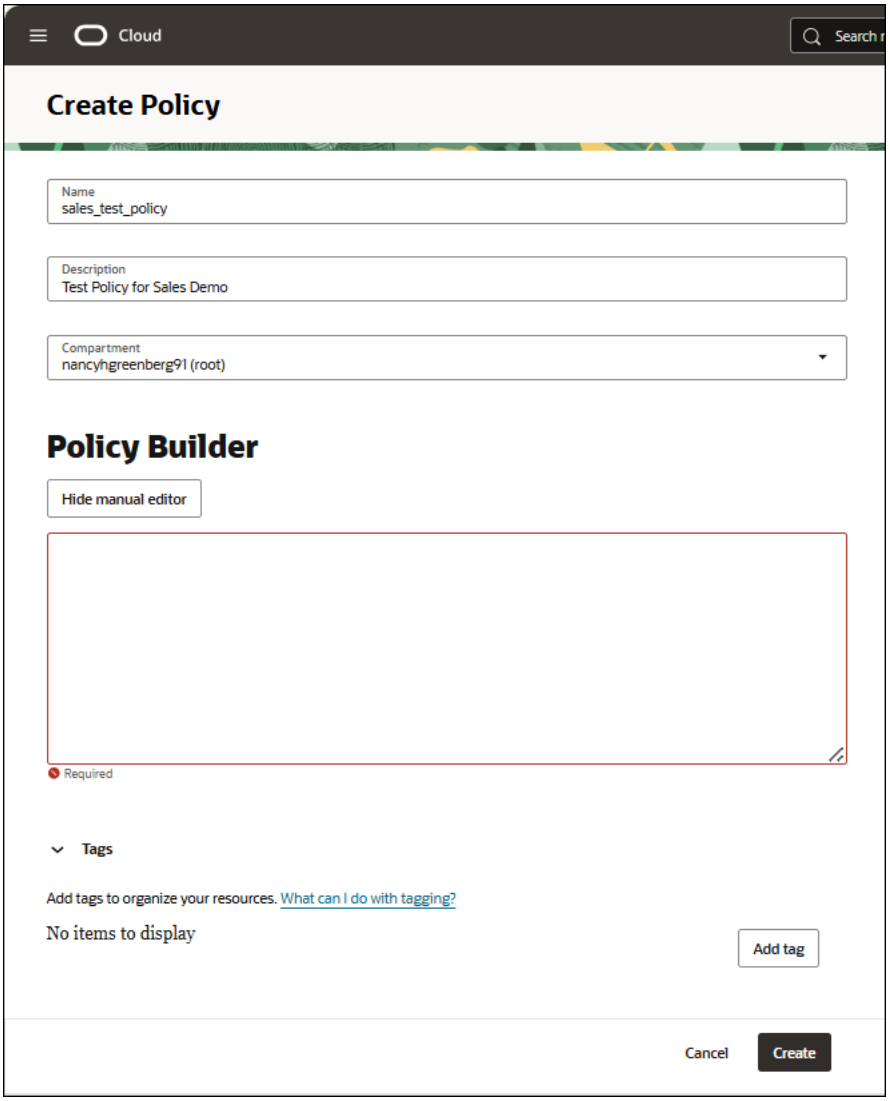
> **Note:**
>
> Defining a policy is required to use IAM tokens to access Autonomous Database. A policy is not required when using IAM database passwords to access Autonomous Database.

To enable Autonomous Database to allow IAM users to connect to the database using IAM tokens:

1. Perform Oracle Cloud Infrastructure Identity and Access Management prerequisites by creating a group and adding users to the group.

   For example, create the group `sales_dbusers`.

   See Managing Groups for more information.
2. Write policy statements to enable access to Oracle Cloud Infrastructure resources.
   a. In the Oracle Cloud Infrastructure console click **Identity & Security**.
   b. Under **Identity & Security** click **Policies**.
   c. To a write policy, click **Create Policy**.
   d. On the Create Policy page, enter a Name and a Description.
   e. On the Create Policy page, select **Show manual editor**.



f. Use the **Policy Builder** to create a policy.

For example to create a policy to allow users in IAM group `DBUsers` to access any Autonomous Database in their tenancy:

```
Allow group DBUsers to use autonomous-database-family in tenancy
```

For example to create a policy that limits members of `DBUsers` group to access Autonomous Databases in compartment `testing_compartment` only:

```
allow group DBUsers to use autonomous-database-family in compartment
testing_compartment
```

For example to create a policy that limits group access to a single database in a compartment:

```
allow group DBUsers to use autonomous-database-family in compartment
testing_compartment
```

```
                    where target.id =
'ocid1.autonomousdatabase.oc1.iad.aaaabbbbcccc...b5678ca'
```

Refer to Creating an IAM Policy to Authorize Users Authenticating with Tokens in *Database Security Guide* for more information on IAM policies to access the database.

g. Click **Create**.

See Managing Policies for more information on policies.

Notes for creating policies for use with IAM users on Autonomous Database:

- Policies can allow IAM users to access Autonomous Database instances across the entire tenancy, in a compartment, or can limit access to a single Autonomous Database instance.
- You can use either instance principal or resource principal to retrieve database tokens to establish a connection from your application to an Autonomous Database instance. If you are using an instance principal or resource principal, you must map a dynamic group. Thus, you cannot exclusively map instance and resource principals; you only can map them through a shared mapping and putting the instance or resource instance in an IAM dynamic group.

  You can create Dynamic Groups and reference dynamic groups in the policies you create to access Oracle Cloud Infrastructure. See Configure Policies and Roles to Access Resources and Managing Dynamic Groups for details.

Add IAM Users on Autonomous Database

To add IAM users to allow access to Autonomous Database, map database global users to IAM groups or users with `CREATE USER` or `ALTER USER` statements (with `IDENTIFIED GLOBALLY AS` clause).

The authorization of IAM users to an Autonomous Database instance works by mapping IAM global users (schemas) to IAM users (exclusive mapping) or IAM groups (shared schema mapping).

To authorize IAM users on an Autonomous Database instance:

1. Log in as the ADMIN user to the database that is enabled to use IAM (the ADMIN user has the required `CREATE USER` and `ALTER USER` system privileges that you need for these steps).
2. Create a mapping between the Autonomous Database user (schema) with `CREATE USER` or `ALTER USER` statements and include the `IDENTIFIED GLOBALLY AS` clause, specifying the IAM group name.

   Use the following syntax to map a global user to an IAM group:

   ```
   CREATE USER global_user IDENTIFIED GLOBALLY AS
   'IAM_GROUP_NAME=IAM_GROUP_NAME';
   ```

   For example, to map an IAM group named `db_sales_group` to a shared database global user named `sales_group`:

   ```
   CREATE USER sales_group IDENTIFIED GLOBALLY AS
        'IAM_GROUP_NAME=db_sales_group';
   ```

This creates a shared global user mapping. The mapping, with global user `sales_group`, is effective for all users in the IAM group. Thus, anyone in the `db_sales_group` can log in to the database using their IAM credentials (through the shared mapping of the `sales_group` global user).

The following example shows how to accomplish this for a non-default domain:

```
CREATE USER shared_sales_schema IDENTIFIED GLOBALLY AS
     'IAM_GROUP_NAME=sales_domain/db_sales_group';
```

3. If you want to create additional global user mappings for other IAM groups or users, follow these steps for each IAM group or user.

> **Note:**
>
> Database users that are not `IDENTIFIED GLOBALLY` can continue to login as before, even when the Autonomous Database is enabled for IAM authentication.

To exclusively map a local IAM user to an Oracle Database Global User:

1. Log in as the ADMIN user to the database that is enabled to use IAM (the ADMIN user has the required `CREATE USER` and `ALTER USER` system privileges that you need for these steps).
2. Create a mapping between the Autonomous Database user (schema) with `CREATE USER` or `ALTER USER` statements and include the `IDENTIFIED GLOBALLY AS` clause, specifying the IAM local IAM user name.

   For example, to create a new database global user named `peter_fitch` and map this user to an existing local IAM user named `peterfitch`:

   ```
   CREATE USER peter_fitch IDENTIFIED GLOBALLY AS
   'IAM_PRINCIPAL_NAME=peterfitch'
   ```

   The following example shows how to create the user by specifying a non-default domain, `sales_domain`:

   ```
   CREATE USER peter_fitch2 IDENTIFIED GLOBALLY AS
   'IAM_PRINCIPAL_NAME=sales_domain/peterfitch';
   ```

Add IAM Roles on Autonomous Database

Optionally, create global roles to provide additional database roles and privileges to IAM users when multiple IAM users are mapped to the same shared global user.

The use of global roles is optional when using either an exclusive IAM mapping to user (schema) or shared user mapping on Autonomous Database. For example, all privileges and roles can be granted to the shared schema and all IAM users who map to the shared schema would be granted the privileges and roles assigned to the shared schema.

You can use a global role to optionally differentiate users who use the same shared schema. For example, a set of users can all have the same shared schema and the shared schema could have the `CREATE SESSION` privilege. Then global roles can be used to provide

differentiated privileges and roles assigned to different groups of users who all use the same shared schema.

Granting additional roles to IAM users in Autonomous Database works by mapping Autonomous Database global roles to IAM groups.

To map Autonomous Database global roles to IAM groups:

1. Log in as the ADMIN user to the database that is enabled to use IAM (the ADMIN user has the required `CREATE USER` and `ALTER USER` system privileges that you need for these steps).
2. Set database authorization for Autonomous Database roles with `CREATE ROLE` or `ALTER ROLE` statements and include the `IDENTIFIED GLOBALLY AS` clause, specifying the IAM group name.

   Use the following syntax to map a global role to an IAM group:

   ```
   CREATE ROLE global_role IDENTIFIED GLOBALLY AS
       'IAM_GROUP_NAME=IAM_GROUP_of_WHICH_the_IAM_USER_IS_a_MEMBER';
   ```

   For example, to map an IAM group named `ExporterGroup` to a shared database global role named `export_role`:

   ```
   CREATE ROLE export_role IDENTIFIED GLOBALLY AS
        'IAM_GROUP_NAME=ExporterGroup';
   ```

   The following example shows how to create the role by specifying a non-default domain, `sales_domain`:

   ```
   CREATE ROLE export_role IDENTIFIED GLOBALLY AS
        'IAM_GROUP_NAME=sales_domain/ExporterGroup';
   ```

   All members of the `ExporterGroup` in the `sales_domain` domain will be authorized with the database global role `export_role` when they log in to the database.
3. Use `GRANT` statements to grant the required privileges or other roles to the global role.

   ```
   GRANT CREATE SESSION TO export_role;
   GRANT DWROLE TO export_role;
   ```

4. If you want an existing database role to be associated with an IAM group, then use `ALTER ROLE` statement to alter the existing database role to map the role to an IAM group. Use the following syntax to alter an existing database role to map it to an IAM group:

   ```
   ALTER ROLE existing_database_role
      IDENTIFIED GLOBALLY AS 'IAM_GROUP_NAME=IAM_Group_Name';
   ```

If you want to add additional global role mappings for other IAM groups, follow these steps for each IAM group.

Create IAM Database Password for IAM Users

To add an IAM user and allow the IAM user to login to Autonomous Database by supplying a username and password, you must create an IAM database password.

See Working with IAM Database Passwords for more information.

Connect to Autonomous Database with Identity and Access Management (IAM) Authentication

After the ADMIN user enables Oracle Cloud Infrastructure IAM on Autonomous Database, users log in to the Autonomous Database instance using their Oracle Cloud Infrastructure IAM credentials or access the database through an Oracle Cloud Infrastructure IAM database token.

After you enable Oracle Cloud Infrastructure IAM user access, you can also log in to the Autonomous Database using your local database account username and password (non-global database user account).

You can use a database client to access an Autonomous Database instance as an Oracle Cloud Infrastructure IAM user. To use a client with Oracle Cloud Infrastructure IAM username and password credentials and a password verifier, the database client must be 12c or newer.

Alternatively, you can use an Oracle Cloud Infrastructure IAM database token to access an Autonomous Database instance. Using IAM tokens requires the latest Oracle Database client 19c (at least 19.16). Some earlier clients provide a limited set of capabilities for token access.

The following examples show password verifier with SQL*Plus to access the database with an Oracle Cloud Infrastructure IAM username and password and the steps required to use SQL*Plus with an Oracle Cloud Infrastructure IAM database token.

> **Note:**
>
> If your Autonomous Database instance is in Restricted Mode, only the users with the `RESTRICTED SESSION` privilege such as ADMIN can connect to the database.

You can use an Oracle Cloud Infrastructure IAM database token to access an Autonomous Database instance with supported clients, including the following:

- JDBC-Thin with support for IAM Token Authentication is supported with the following:
  - JDBC version 19.13.0.0.1 (or later): See JDBC and UCP Downloads for JDBC drivers.
  - JDBC version 21.4.0.0.1 (or later): See JDBC and UCP Downloads for JDBC drivers.

  See Support for IAM Token-Based Authentication for more information:
- SQL*Plus and Oracle Instant Client: Supported with SQL*Plus and Instant Client on Linux versions 19.13 or later, and Instant Client on Linux versions 21.4 or later.
  See Identity and Access Management (IAM) Token-Based Authentication for more information.
- The database client can also be configured to retrieve a database token using the IAM username and IAM database password.

See Client Connections That Use a Token Requested by an IAM User Name and Database Password for more information.

- .NET clients (latest version of Linux or Windows). .NET software components are available as a free download from the following sites:
  - Oracle Data Access Components - .NET Downloads
  - NuGet Gallery
  - Visual Studio Code Marketplace
- About Connecting to an Autonomous Database Instance Using IAM
  IAM users can connect to the Autonomous Database instance by using either an IAM database password verifier or an IAM token.
- Configuring a Client Connection for SQL*Plus That Uses an IAM Database Password
  You can configure SQL*Plus to use an IAM database password.
- Configuring a Client Connection for SQL*Plus That Uses an IAM Token
  You can configure a client connection for SQL*Plus that uses an IAM token.
- Use Instance Principal to Access Autonomous Database with Identity and Access Management (IAM) Authentication
  After the ADMIN user enables Oracle Cloud Infrastructure IAM on Autonomous Database, an application can access the database through an Oracle Cloud Infrastructure IAM database token using an instance principal.

About Connecting to an Autonomous Database Instance Using IAM

IAM users can connect to the Autonomous Database instance by using either an IAM database password verifier or an IAM token.

Using the IAM database password verifier is similar to the Oracle Database password authentication process. However, instead of the password verifier (encrypted hash of the password) being stored in the Oracle database, the verifier is instead stored as part of the Oracle Cloud Infrastructure (OCI) IAM user profile.

The second connection method, the use of an IAM token for the database, is more modern. The use of token-based access is a better fit for Cloud resources such as Autonomous Database. The token is based on the strength that the IAM endpoint can enforce. This can be multi-factor authentication, which is stronger than the use of passwords alone. Another benefit of using tokens is that the password verifier (which is considered sensitive) is never stored or available in memory. A TCPS (TLS) connection is required when using tokens for database access.

> **Note:**
>
> You cannot configure native network encryption when passing an IAM token. Only Transport Layer Security (TLS) by itself is supported, not native network encryption or native network encryption with TLS.

- Client Connections That Use an IAM Database Password Verifier
  After you have configured the authorization needed for the IAM user, this user can log in using existing client application, such as SQL*Plus or SQLcl without additional configuration.

- Client Connections That Use a Token Requested by a Client Application or Tool
  For IAM token access to the Autonomous Database, the client application or tool requests a database token from IAM for the IAM user.

Client Connections That Use an IAM Database Password Verifier

After you have configured the authorization needed for the IAM user, this user can log in using existing client application, such as SQL*Plus or SQLcl without additional configuration.

The IAM user enters the IAM user name and IAM database password (not the Oracle Cloud Infrastructure (OCI) console password) using any currently supported database client. The only constraint is that the database client version be either Oracle Database release 12.1.0.2 or later to use Oracle Database 12c passwords. The database client must be able to use the `12C` password verifier. Using the `11G` verifier encryption is not supported with IAM. No special client or tool configuration is needed for the IAM user to connect to the OCI DBaaS instance.

Client Connections That Use a Token Requested by a Client Application or Tool

For IAM token access to the Autonomous Database, the client application or tool requests a database token from IAM for the IAM user.

The client application will pass the database token directly to the database client through the database client API.

If the application or tool has not been updated to request an IAM token, then the IAM user can use Oracle Cloud Infrastructure (OCI) command line interface (CLI) to request and store the database token. You can request a database access token (`db-token`) using the following credentials:

- Security tokens (with IAM authentication), delegation tokens (in the OCI cloud shell) and `API-keys`, which are credentials that represent the IAM user to enable the authentication
- Instance principal tokens, which enable instances to be authorized actors (or principals) to perform actions on service resources after authenticating
- Resource principal token, which is a credential that enables the application to authenticate itself to other Oracle Cloud Infrastructure services
- Using an IAM user name and IAM database password (can only be requested by database client).

When the IAM users logs into the client with a slash `/` login and the `OCI_IAM` parameter is configured (`sqlnet.ora`, `tnsnames.ora`, or as part of a connect string), then the database client retrieves the database token from a file. If the IAM user submits a user name and password, the connection will use the IAM database verifier access described for client connections that use IAM database password verifiers. The instructions in this guide show how to use the OCI CLI as a helper for the database token. If the application or tool has been updated to work with IAM, then follow the instructions for the application or tool. Some common use cases include the following: SQLPlus on-premises, SQLcl on-premises, SQL*Plus in Cloud Shell, or applications that use SEP wallets.

Configuring a Client Connection for SQL*Plus That Uses an IAM Database Password

You can configure SQL*Plus to use an IAM database password.

- As the IAM user, log in to the Autonomous Database instance by using the following syntax:

  ```
  CONNECT user_name@db_connect_string
  Enter password: password
  ```

  In this specification, *user_name* is the IAM user name. There is a limit of 128 bytes for the combined *domain_name*/*user_name*.

  The following example shows how IAM user `peter_fitch` can log in to an Autonomous Database instance.

  ```
  sqlplus /nolog
  connect peter_fitch@db_connect_string
  Enter password: password
  ```

  Some special characters will require double quotation marks around *user_name* and *password*. For example:

  ```
  "peter_fitch@example.com"@db_connect_string

  "IAM database password"
  ```

Configuring a Client Connection for SQL*Plus That Uses an IAM Token

You can configure a client connection for SQL*Plus that uses an IAM token.

1. Ensure you have an IAM user account.
2. Check with an IAM administrator and an Oracle Database administrator to ensure you have a policy allowing you to access the database in the compartment or your tenancy and that you are mapped to a global schema in the database.
3. If your application or tool does not support direct IAM integration, then download, install, and configure the OCI CLI. (See *OCI Command Line Interface Quickstart*.) Set up an API key as part of the OCI CLI configuration and select default values.
   a. Set up the API key access for the IAM user.
   b. Retrieve the `db-token`. For example:
      - Retrieving a `db-token` with an `API-key` using the Oracle Cloud Infrastructure (OCI) command-line interface:

        ```
        oci iam db-token get
        ```

      - Retrieving a `db-token` with a security (or session) token:

        ```
        oci iam db-token get --auth security_token
        ```

        If the security token has expired, a window will appear so the user can log in to OCI again. This generates the security token for the user. OCI CLI will use this refreshed token to get the `db-token`.

- Retrieving a `db-token` with a delegation token: When you log in to the cloud shell, the delegation token is automatically generated and placed in the `/etc` directory. To get this token, run the following command in the cloud shell:

  ```
  oci iam db-token get
  ```

- Retrieving an instance token by using the OCI command-line interface:

  ```
  oci iam db-token get --auth instance_principal
  ```

c. The database client can also be configured to retrieve a database token using the IAM username and IAM database password.

   See Client Connections That Use a Token Requested by an IAM User Name and Database Password for more information.

See Required Keys and OCIDs for more information.

4. Ensure that you are using the latest release updates for the Oracle Database client releases 19c, 21c, or 23ai.

   This configuration only works with the Oracle Database client release 19c, 21c, or 23ai.

5. Follow the existing process to download the wallet from the Autonomous Database and then follow the directions for configuring it for use with SQL*Plus.

   a. Confirm that DN matching is enabled by looking for `SSL_SERVER_DN_MATCH=ON` in `sqlnet.ora`.

   > **Note:**
   >
   > Partial or full DN matching is required when sending a token from the database client to Autonomous Database. If Autonomous Database is using a private endpoint, you need to specify a host value for the connect string parameter. Using an IP address for the host parameter in the connect string will not work with DN matching and the IAM token will not be sent to the database.
   > See Private Endpoints Configuration Examples on Autonomous Database for configuration information on how to set the host parameter when using a private endpoint.

   b. Configure the database client to use the IAM token by adding `TOKEN_AUTH=OCI_TOKEN` to the `sqlnet.ora` file. Because you will be using the default locations for the database token file, you do not need to include the token location.

The `TOKEN_AUTH` and `TOKEN_LOCATION` values in the `tnsnames.ora` connect strings take precedence over the `sqlnet.ora` settings for that connection. For example, for the connect string, assuming that the token is in the default location (`~/.oci/db-token` for Linux):

```
(description=
  (retry_count=20)(retry_delay=3)
  (address=(protocol=tcps)(port=1522)
  (host=example.us-phoenix-1.oraclecloud.com))

(connect_data=(service_name=aaabbbccc_exampledb_high.example.oraclecloud.co
m))
```

```
    (security=(ssl_server_dn_match=yes)
    (TOKEN_AUTH=OCI_TOKEN)))
```

After the connect string is updated with the `TOKEN_AUTH` parameter, the IAM user can log in to the Autonomous Database instance by running the following command to start SQL*Plus. You can include the connect descriptor itself or use the name of the descriptor from the `tnsnames.ora` file.

```
connect /@exampledb_high
```

Or:

```
connect /@(description=
  (retry_count=20)(retry_delay=3)
  (address=(protocol=tcps)(port=1522)
  (host=example.us-phoenix-1.oraclecloud.com))

(connect_data=(service_name=aaabbbccc_exampledb_high.example.oraclecloud.com))
  (security=(ssl_server_cert_dn="CN=example.uscom-east-1.oraclecloud.com,
     O=Example Corporation,
     L=Redwood City, ST=California, C=US")
  (TOKEN_AUTH=OCI_TOKEN)))
```

The database client is already configured to get a `db-token` because `TOKEN_AUTH` has already been set, either through the `sqlnet.ora` file or in a connect string. The database client gets the `db-token` and signs it using the private key and then sends the token to the Autonomous Database. If an IAM user name and IAM database password are specified instead of slash `/`, then the database client will connect using the password instead of using the `db-token`.

Use Instance Principal to Access Autonomous Database with Identity and Access Management (IAM) Authentication

After the ADMIN user enables Oracle Cloud Infrastructure IAM on Autonomous Database, an application can access the database through an Oracle Cloud Infrastructure IAM database token using an instance principal.

See Accessing the Oracle Cloud Infrastructure API Using Instance Principals for more information.

Configure IAM Proxy Authentication

Proxy authentication allows an IAM user to proxy to a database schema for tasks such as application maintenance.

- About Configuring IAM Proxy Authentication
  IAM users can connect to Oracle DBaaS by using proxy authentication.
- Configure Proxy Authentication for the IAM User
  To configure proxy authentication for an IAM user, the IAM user must already have a mapping to a global schema (exclusive or shared mapping). A separate database schema for the IAM user to proxy to must also be available.
- Validate the IAM User Proxy Authentication
  You can validate the IAM user proxy configuration for both password and token authentication methods.

About Configuring IAM Proxy Authentication

IAM users can connect to Oracle DBaaS by using proxy authentication.

Proxy authentication is typically used to authenticate the real user and then authorize them to use a database schema with the schema privileges and roles in order to manage an application. Alternatives such as sharing the application schema password are considered insecure and unable to audit which actual user performed an action.

A use case can be in an environment in which a named IAM user who is an application database administrator can authenticate by using their credentials and then proxy to a database schema user (for example, `hrapp`). This authentication enables the IAM administrator to use the `hrapp` privileges and roles as user `hrapp` in order to perform application maintenance, yet still use their IAM credentials for authentication. An application database administrator can sign in to the database and then proxy to an application schema to manage this schema.

You can configure proxy authentication for both the password authentication and token authentication methods.

Configure Proxy Authentication for the IAM User

To configure proxy authentication for an IAM user, the IAM user must already have a mapping to a global schema (exclusive or shared mapping). A separate database schema for the IAM user to proxy to must also be available.

After you ensure that you have this type of user, alter the database user to allow the IAM user to proxy to it.

1. Log in to the Autonomous Database instance as a user who has the `ALTER USER` system privileges.
2. Grant permission for the IAM user to proxy to the local database user account.

   An IAM user cannot be referenced in the command so the proxy must be created between the database global user (mapped to the IAM user) and the target database user.

   In the following example, `hrapp` is the database schema to proxy to, and `peterfitch_schema` is the database global user exclusively mapped to user `peterfitch`.

   ```
   ALTER USER hrapp GRANT CONNECT THROUGH peterfitch_schema;
   ```

At this stage, the IAM user can log in to the database instance using the proxy. For example, to connect using a password verifier:

```
CONNECT peterfitch[hrapp]@connect_string
Enter password: password
```

To connect using a token:

```
CONNECT [hrapp]/@connect_string
```

Validate the IAM User Proxy Authentication

You can validate the IAM user proxy configuration for both password and token authentication methods.

1. Log in to the Autonomous Database instance as a user who has the `CREATE USER` and `ALTER USER` system privileges.
2. Connect as the IAM user and run the `SHOW USER` and `SELECT SYS_CONTEXT` commands.

   For example, suppose you want to check the proxy authentication of the IAM user `peterfitch` when they proxy to database user `hrapp`. Run the following queries after you proxy to the database using an IAM user. Depending on how you authenticate and access the database, you will get different values for these queries.

   - For password authentication, assuming the IAM user is in the default domain:

     ```
     CONNECT peterfitch[hrapp]/password\!@connect_string
     SHOW USER;
     --The output should be USER is "HRAPP"
     SELECT SYS_CONTEXT('USERENV','AUTHENTICATION_METHOD') FROM DUAL;
     --The output should be "PASSWORD_GLOBAL_PROXY"
     SELECT SYS_CONTEXT('USERENV','PROXY_USER') FROM DUAL;
     --The output should be "PETERFITCH_SCHEMA"
     SELECT SYS_CONTEXT('USERENV','CURRENT_USER') FROM DUAL;
     --The output should be "HRAPP"
     ```

   - For token authentication, for a user who is in a non-default domain, `sales_domain`:

     ```
     CONNECT [hrapp]/@connect_string
     SHOW USER;
     --The output should be USER is "HRAPP"
     SELECT SYS_CONTEXT('USERENV','AUTHENTICATION_METHOD') FROM DUAL;
     --The output should be "TOKEN_GLOBAL_PROXY"
     SELECT SYS_CONTEXT('USERENV','PROXY_USER') FROM DUAL;
     --The output should be "PETERFITCH_SCHEMA"
     SELECT SYS_CONTEXT('USERENV','CURRENT_USER') FROM DUAL;
     --The output should be "HRAPP"
     ```

Disable Identity and Access Management (IAM) Authentication on Autonomous Database

Describes the steps to disable IAM external authentication user access for Autonomous Database.

You can disable IAM user access on your Autonomous Database instance as follows:

1. Run the `DBMS_CLOUD_ADMIN.DISABLE_EXTERNAL_AUTHENTICATION` procedure.

   For example:

   ```
   BEGIN
      DBMS_CLOUD_ADMIN.DISABLE_EXTERNAL_AUTHENTICATION;
   END;
   /
   ```

2. If you also want to update access to IAM from the resource, in this case the Autonomous Database instance, you may need to remove or modify the IAM group and the policies you set up to allow access to IAM from the Autonomous Database instance.

Accessing a Database Cross-Tenancy Using an IAM Integration

Users and groups in one tenancy can access DBaaS database instances in another tenancy if policies in both tenancies allow this.

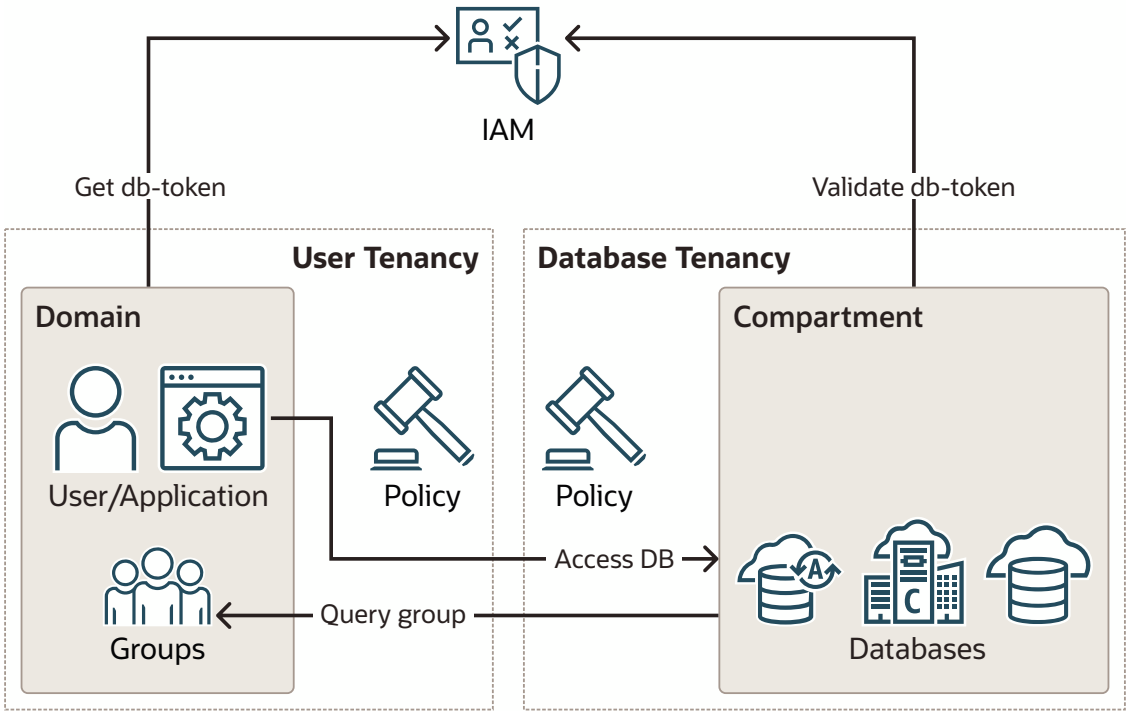
- About Cross-Tenancy Access for IAM Users to DBaaS Instances
  Cross-tenancy access to an Oracle Cloud Infrastructure (OCI) DBaaS instance is similar to a single tenancy scenario except that tenancy information is required for mappings and token requests and a policy is required in both tenancies to allow this cross tenancy database resource access.
- Configuring Policies
  You must create policies in both the user tenancy and the database resource tenancy to allow cross-tenancy database access.
- Mapping Database Schemas and Roles to Users and Groups in Another Tenancy
  When you perform this type of mapping, you must add the tenancy OCID to the mapping information so the database knows it is cross-tenancy access.
- Configuring Database Clients for Cross-Tenancy Access
  You can configure some database clients directly.
- Requesting Cross-Tenancy Tokens Using the OCI Command-Line Interface
  You must add the `--scope` parameter to the Oracle Cloud Infrastructure (OCI) command-line interface command to get a `db-token` for a cross-tenancy request. If the database you are accessing is in a different region than the user tenancy home region, then the region must also be added to the OCI CLI command using the --region parameter.

About Cross-Tenancy Access for IAM Users to DBaaS Instances

Cross-tenancy access to an Oracle Cloud Infrastructure (OCI) DBaaS instance is similar to a single tenancy scenario except that tenancy information is required for mappings and token requests and a policy is required in both tenancies to allow this cross tenancy database resource access.

The following figure illustrates the process for a cross-tenancy access to an OCI DBaaS instance.

Figure 3-1 Cross-Tenancy Access to an OCI DBaaS Instance



The cross-tenancy process is as follows:

1. The policy is required in both tenancies to endorse and admit access cross tenancy.
2. The IAM principal (user or application) requests a db-token for a cross-tenancy resource.
3. The `db-token` is returned and is used to access the database in a different tenancy
4. The database will make a cross-tenancy group query for the user's groups and map principal to global schema and optional global roles.

You must subscribe the user tenancy to the same regions in which the databases are located. For example, if the databases in the database tenancy are in the `PHX` and `IAD` regions, then you must subscribe the user tenancy to these regions. This is not the home region, just the additional subscribed regions in the user tenancy.

Configuring Policies

You must create policies in both the user tenancy and the database resource tenancy to allow cross-tenancy database access.

- Configuring the Source User Tenancy
  Two policies are required to allow cross-tenancy access in the user tenancy.
- Configuring the Target Database Resource Tenancy
  The database tenancy will need matching policies to enable access to the users from the user tenancy as well as allow its own databases to query group information in the user tenancy
- Policy Examples for Cross-Tenancy Access
  Examples include using a `WHERE` clause to refine the cross-tenancy configuration, and other methods of performing this type of configuration.

Configuring the Source User Tenancy

Two policies are required to allow cross-tenancy access in the user tenancy.

The first policy is to allow a user tenancy group to access a database in a different tenancy. The second policy allows a database in the database tenancy to query group information in the user tenancy.

1. In the OCI console, select **Identity & Security**.
2. Under **Identity**, select **Policies**.
3. Click **Create Policy** and in the Policy Builder select **Show manual editor**.
4. Use the `DEFINE` statement to make it easier to read the actual policies.

   For example:

   ```
   DEFINE tenancy database_tenancy as ocid1.tenancy.OCID
   ```

5. Endorse the tenancy group `domainA/xt_db_users` to use database_connections in tenancy `database_tenancy`.

   This allows users of the `xt_db_users` group in `domainA` to access any database in tenancy `database_tenancy`.

   ```
   ENDORSE group domainA/xt_db_users to use database-connections in tenancy
   database_tenancy
   ```

6. Use the `ADMIT` statement to create an Admit policy to allow any database in the database tenancy to query group information for specific IAM users in the user tenancy.

   ```
   ADMIT any-user of tenancy database_tenancy to {GROUP_MEMBERSHIP_INSPECT,
   AUTHENTICATION_INSPECT} in tenancy
   ```

Configuring the Target Database Resource Tenancy

The database tenancy will need matching policies to enable access to the users from the user tenancy as well as allow its own databases to query group information in the user tenancy

1. In the OCI console, select **Identity & Security**.
2. Under **Identity**, select **Policies**.
3. Click **Create Policy** and in the Policy Builder select **Show manual editor**.
4. Use `DEFINE` to make it easier to troubleshoot and read the policies.

   ```
   DEFINE tenancy user_tenancy as ocid1.tenancy.OCID
   DEFINE group xt_db_users as ocid1.group.defg
   ```

5. Use `ADMIT` to create an Admit policy in the tenancy to match the Endorse policy from the user tenancy.

   The Admit policy must match the `ENDORSE` policy in the user tenancy so that it can enable users from the `user_tenancy` to access databases in this tenancy.

   ```
   ADMIT group xt_db_users of tenancy user_tenancy to use database-
   connections in tenancy
   ```

6. Create an Endorse policy, which will match the Admit policy created in the User tenancy.

   The Endorse policy will enable databases in the database tenancy to query group information from the user_tenancy.

   ```
   ENDORSE any-user to {GROUP_MEMBERSHIP_INSPECT, AUTHENTICATION_INSPECT} in
   tenancy user_tenancy
   ```

While using `any-user` makes it easy to understand the required policies, Oracle recommends that you use stronger constraints in addition to or instead of using `any-user`. The `any-user` option will allow any principal or resource to query user groups in the `user_tenancy`. Ideally, you should limit this to just allowing the database resources (resource principals) to make the group queries. You can do this by adding a `WHERE` clause to the policies or by adding a dynamic group that limits it to the members of the dynamic group. Defining every possible way to specify dynamic groups and policies is outside the scope of this topic. You can find more information from these sources:

- Managing Dynamic Groups
- Managing Policies

Policy Examples for Cross-Tenancy Access

Examples include using a `WHERE` clause to refine the cross-tenancy configuration, and other methods of performing this type of configuration.

You can add a `WHERE` clause to limit the database resources allowed to make the cross-tenancy group query:

```
ADMIT any-user of tenancy db_tenancy to {GROUP_MEMBERSHIP_INSPECT,
AUTHENTICATION_INSPECT} in tenancy where request.principal.type = 'dbsystem'
```

This Admit policy allows any Base Database Service (resource type: `dbsystem`) in the `db_tenancy` to query a user's group information from the user tenancy. Resource type names are in the table below.

A similar method can be done by putting the same resource type into a dynamic group:

```
dynamic group: db_principals
any {resource.type = 'dbsystem', resource.type = 'vmcluster', resource.type =
'cloudvmcluster'}
```

The dynamic group in the preceding example includes database instances for Oracle Base Database Service (`dbsystem`), Oracle Exadata Cloud@Customer (`vmcluster`), and Oracle Exadata Database Service (`cloudvmcluster`).

This example uses a dynamic group instead of `any-user`:

```
ADMIT dynamic group db_principals of tenancy db_tenancy to
{GROUP_MEMBERSHIP_INSPECT, AUTHENTICATION_INSPECT} in tenancy
```

You can also add all resource principals in a compartment using `resource.compartment.id`. However, this might also allow other non-database resource principals to make the cross-tenancy group query. The following table provides a mapping of the various resource types with the DBaaS platform name:

DBaaS Platform Name	Resource Type Name
ADB-S	`autonomousdatabase`
ADB-D (OPC)	`cloudautonomousvmcluster*`
Base DBS	`dbsystem`
ExaCS	`cloudvmcluster`
ExaCC	`vmcluster`

* Older ADBD instances may still be using the `autonomousexainfrastructure` resource type.

Mapping Database Schemas and Roles to Users and Groups in Another Tenancy

When you perform this type of mapping, you must add the tenancy OCID to the mapping information so the database knows it is cross-tenancy access.

Use a full colon to separate the tenancy OCID when you use the `CREATE USER` and `CREATE ROLE` statements in SQL*Plus.

- To use the `CREATE USER` statement to perform the mapping:

  The following examples show exclusive and shared schema mapping with principals and groups in default and non-default domains. When using default domains, you do not need to include a domain name.

```
CREATE USER schema1 IDENTIFIED GLOBALLY
AS 'IAM_PRINCIPAL_NAME=ocid1.tenancy.OCID:example_domain/
peter.fitch@oracle.com';

CREATE USER schema2 IDENTIFIED GLOBALLY
AS 'IAM_PRINCIPAL_NAME=ocid1.tenancy.OCID:peter.fitch@oracle.com';

CREATE USER qa_db_user_group IDENTIFIED GLOBALLY
AS 'IAM_GROUP_NAME=ocid1.tenancy.OCID:example_domain/xt_db_users';

CREATE USER qa_sales_user_group IDENTIFIED GLOBALLY
AS 'IAM_GROUP_NAME=ocid1.tenancy.OCID:sales_users';

CREATE USER xt_ip_user IDENTIFIED GLOBALLY
AS 'IAM_PRINCIPAL_OCID=ocid1.instance.region1.sea.OCID';
GRANT CREATE SESSION TO xt_ip_user;

CREATE USER xt_iam_dg IDENTIFIED GLOBALLY
AS 'IAM_GROUP_NAME=ocid1.tenancy.region1.OCID:sales_principals';
GRANT CREATE SESSION TO xt_iam_dg;
```

- To use the `CREATE ROLE` statement to perform the mapping:

  The following examples show global role mapping with groups in default and non-default domains. When using default domains, you do not need to include a domain name.

```
CREATE ROLE globalrole1 IDENTIFIED GLOBALLY
AS 'IAM_GROUP_NAME=ocid1.tenancy.abcdef:example_domain/xt_db_users';
```

```
CREATE ROLE globalrole2 IDENTIFIED GLOBALLY
AS 'IAM_GROUP_NAME=ocid1.tenancy.abcdef:sales_users';
```

Configuring Database Clients for Cross-Tenancy Access

You can configure some database clients directly.

The database tenancy must be identified in either the connect string or in `sqlnet.ora` if the client is configured to directly get the access token from OCI IAM. Review client-specific documentation for specific parameter values (JDBC-thin, ODP.NET-core, managed).

Requesting Cross-Tenancy Tokens Using the OCI Command-Line Interface

You must add the `--scope` parameter to the Oracle Cloud Infrastructure (OCI) command-line interface command to get a `db-token` for a cross-tenancy request. If the database you are accessing is in a different region than the user tenancy home region, then the region must also be added to the OCI CLI command using the --region parameter.

See Optional Parameters for more details about using the optional parameters of the `oci get` command.

You can scope it for the entire tenancy or scope it to a compartment or database in the tenancy. When scoping for cross tenancy compartment or database, you do not need to also add the tenancy information because the compartment and database OCIDs are unique across OCI.

Certain clients can request the tokens directly from MSEI. Refer to their documentation on setting the parameters to get the MSEI `OAuth2` access tokens.

Notes for Using Autonomous Database Tools with Identity and Access Management (IAM) Authentication

Provides notes for using Autonomous Database tools with IAM authentication enabled.

- Oracle APEX is not supported for IAM users with Autonomous Database. See Create Oracle APEX Workspaces in Autonomous Database for information on using regular database users with Autonomous Database.
- Database Actions is not supported for IAM users with Autonomous Database. See Provide Database Actions Access to Database Users for information on using regular database users with Autonomous Database.
- Oracle Machine Learning Notebooks and other components are not supported for IAM Authorized users with Autonomous Database. See Add Existing Database User Account to Oracle Machine Learning Components for information on using regular database users with Autonomous Database.

Use Microsoft Entra ID with Autonomous Database

You can configure an Autonomous Database instance for Microsoft Entra ID users to connect using Entra ID (Azure AD) `OAuth2` tokens.

> **Note:**
>
> Microsoft recently changed the name of Microsoft Azure AD to Microsoft Entra ID.

- About Integrating Oracle Autonomous Database with Microsoft Entra ID
  Oracle Autonomous Database and Microsoft Entra ID can be configured to allow users and applications to connect to the database using their Entra ID credentials.
- Enable Microsoft Entra ID Authentication on Autonomous Database
  A Microsoft Entra ID administrator and an Autonomous Database administrator perform steps to configure Entra ID authentication on Autonomous Database.
- Role and Schema Mapping for Entra ID Authentication on Autonomous Database
  Microsoft Entra ID (Azure AD) users are mapped to one database schema and optionally to one or more database roles. After mapping Entra ID users, user can connect to the Autonomous Database instance.
- Microsoft Entra ID Client Configuration and Access for Autonomous Database
  After you configure Entra ID on your Autonomous Database and you map Entra ID users, there are numerous ways that a user can configure a client to the Autonomous Database instance using Entra ID tokens.
- Testing the Accessibility of the Entra ID Endpoint
  You must ensure that your Oracle Database can access the Entra ID endpoint.

About Integrating Oracle Autonomous Database with Microsoft Entra ID

Oracle Autonomous Database and Microsoft Entra ID can be configured to allow users and applications to connect to the database using their Entra ID credentials.

Azure users and applications can log in with Entra ID Single Sign On (SSO) credentials to access the database. This is done with an Entra ID `OAuth2` access token that the user or application first requests from Entra ID. This `OAuth2` access token contains the user identity and database access information and is then sent to the database. Refer to Refer to the Microsoft article Passwordless authentication options for Azure Active Directory for information about configuring multi-factor and passwordless authentication.

You can perform this integration in the following Oracle Database environments:

- On-premises Oracle Database release 19.18 and later, excluding 21c
- All Oracle Database server platforms: Linux, Windows, AIX, Solaris, and HPUX
- Oracle Autonomous Database Serverless
- Oracle Autonomous Database on Dedicated Exadata Infrastructure
- Oracle Autonomous Database on Exadata Cloud@Customer
- Oracle Exadata Database Service on Dedicated Infrastructure
- Oracle Exadata Database Service on Cloud@Customer
- Oracle Base Database Service

The instructions for configuring Entra ID use the term "Oracle Database" to encompass these environments.

This type of integration enables the Azure user to access an Oracle Autonomous Database instance. Azure users and applications can log in with Entra ID Single Sign On (SSO) credentials to get an Entra ID `OAuth2` access token to send to the database.

The Entra ID administrator creates and registers Oracle Autonomous Database with Entra ID. Within Entra ID, this is called an app registration, which is short for application registration. This is the digital information that Entra ID must know about the software that is using Entra ID. The Entra ID administrator also creates application (app) roles for the database app registration in Entra ID. App roles connect Azure users, groups, and applications to database

schemas and roles. The Entra ID administrator assigns Azure users, groups, or applications to the app roles. These app roles are mapped to a database global schema or a global role or to both a schema and a role. An Azure user, group, or application that is assigned to an app role will be mapped to a database global schema, global role, or to both a schema and a role. An Oracle global schema can also be mapped exclusively to an Azure user. An Azure guest user (non-organization user) or an Entra ID service principal (application) can only be mapped to a database global schema through an Entra ID app role. An Oracle global role can only be mapped from an Azure app role and cannot be mapped from an Azure user.

Oracle Autonomous Database tools including Oracle APEX, Database Actions, Oracle Graph Studio, and Oracle Database API for MongoDB are not compatible with using Entra ID tokens to connect with the database.

Tools and applications that are updated to support Entra ID tokens can authenticate users directly with Entra ID and pass the database access token to the Oracle Autonomous Database instance. You can configure existing database tools such as SQL*Plus to use an Entra ID token from a file location. In these cases, Entra ID tokens can be retrieved using tools like Microsoft PowerShell or Azure CLI and put into a file location. An Entra ID `OAuth2` database access tokens are issued with an expiration time. The Oracle Database client driver will ensure that the token is in a valid format and that it has not expired before passing it to the database. The token is scoped for the database, which means that there is information in the token about the database where the token will be used. The app roles the Entra ID principal was assigned to in the database Entra ID app registration are included as part of the access token. The directory location for the Entra ID token should only have enough permission for the user to write the token file to the location and the database client to retrieve these files (for example, just read and write by the user). Because the token allows access to the database, it should be protected within the file system.

Azure users can request a token from Entra ID using a number of methods to open an Azure login window to enter their Entra ID credentials.

Oracle Autonomous Database accepts tokens representing the following Entra ID principals:

- Azure user, who is registered user in the Entra ID tenancy
- Guest user, who is registered as a guest user in the Entra ID tenancy
- Service, which is the registered application connecting to the database as itself with the client credential flow (connection pool use case)

Oracle Autonomous Database supports the following Entra ID authentication flows:

- Interactive flow (also called authorization code flow) using Proof Key for Code Exchange (PKCE), most commonly used for human users (not applications) to authenticate to Entra ID in a client environment with a browser
- Client credentials, which are for database applications that connect as themselves (and not the end-user)
- On-Behalf-Of (OBO), where an application requests an access token on behalf of a logged-in user to send to the database
- Resource owner password credential (ROPC), which is not recommended for production use, but can be used in test environments where a pop-up browser user authentication would be difficult to incorporate. ROPC needs the Entra ID user name and password credential to be part of the token request call.

> **Note:**
>
> The DBaaS integration with Microsoft Entra ID does not support users with administrative privileges (`SYSDBA`, `SYSOPER`, `SYSBACKUP`, `SYSDG`, `SYSKM`, and `SYSRAC`).

Topics

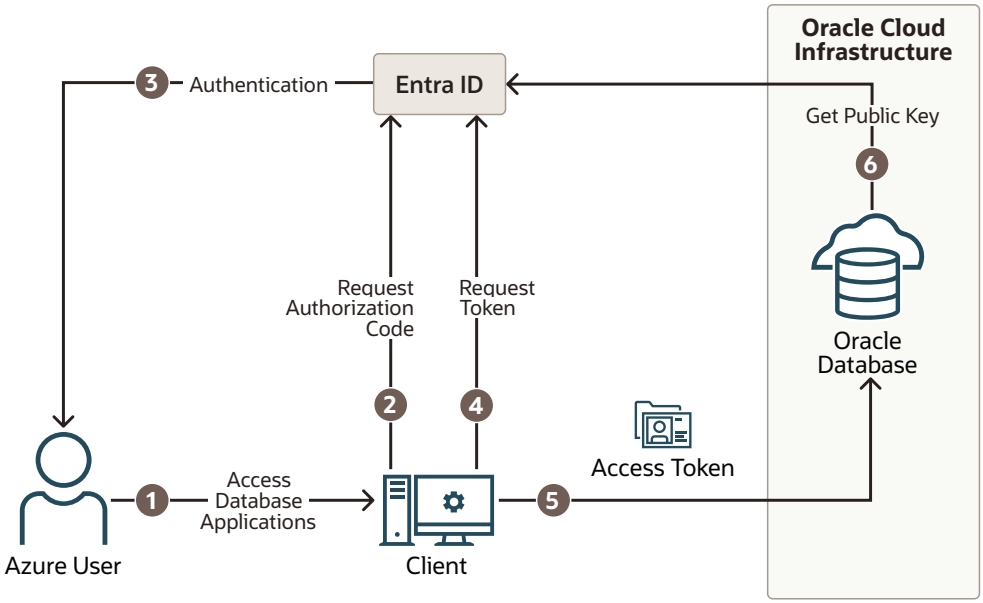
- Architecture of Oracle Database Integration with Microsoft Entra ID
  Microsoft Azure Active Directory access tokens follow the OAuth 2.0 standard with extensions.
- Azure Users Mapping to an Oracle Database Schema and Roles
  Microsoft Azure users must be mapped to an Oracle Database schema and have the necessary privileges (through roles) before being able to authenticate to the Oracle Database instance.
- Use Cases for Connecting to an Oracle Database Using Entra ID
  Oracle Database supports several use cases for connecting to the database.

Architecture of Oracle Database Integration with Microsoft Entra ID

Microsoft Azure Active Directory access tokens follow the OAuth 2.0 standard with extensions.

The Entra ID access token will be needed before you access the database from the database client (for example, with SQLPlus or SQLcl). The Oracle clients (for example, OCI, JDBC, and ODP) can be configured to pick up an Entra ID token from a file location or the token can be passed to the client through the database client API. An Azure user can use a script (examples available from Microsoft) to retrieve a token and put it into a file location for the database client to retrieve. Applications can use the Azure SDK to get an access token and pass the token through the database client API. Command-line tools such as Microsoft PowerShell or the Azure command-line interface can be used to retrieve the Entra ID token if the application cannot directly get the token.

The following diagram is a generalized flow diagram for OAuth 2.0 standard, using the `OAuth2` token. See Authentication flow support in MSAL in the Microsoft Entra ID documentation for more details about each supported flow.



The authorization code flow is an OAuth2 standard and is described in detail as part of the standards. There are two steps in the flow. The first step authenticates the user and retrieves the authorization code. The second step uses the authorization code to get the database access token.

1. The Azure user requests access to the resource, the Oracle Database instance.
2. The database client or application requests an authorization code from Entra ID.
3. Entra ID authenticates the Azure user and returns the authorization code.
4. The helper tool or application uses the authorization code with Entra ID to exchange it for the `OAuth2` token.
5. The database client sends the `OAuth2` access token to the Oracle database. The token includes the database app roles the user was assigned to in the Entra ID app registration for the database.
6. The Oracle Database instance uses the Entra ID public key to verify that the access token was created by Entra ID.

Both the database client and the database server must be registered with the **app registrations** feature in the Azure Active Directory section of the Azure portal. The database client must be registered with Entra ID app registration. Permission must also be granted to allow the database client to get an access token for the database.

Azure Users Mapping to an Oracle Database Schema and Roles

Microsoft Azure users must be mapped to an Oracle Database schema and have the necessary privileges (through roles) before being able to authenticate to the Oracle Database instance.

In Microsoft Azure, an Entra ID administrator can assign users, groups, and applications to the database app roles.

Exclusively mapping an Entra ID user to a database schema requires the database administrator to create and manage a database schema for the lifecycle of the user (joining, moving, leaving). The database administrator must create the schema when the user joins the organization. The database administrator must also modify the privileges and roles that are granted to the database schema to align them with the tasks the Azure user is assigned to. When the Azure user leaves the organization, the database administrator must drop the database schema so that an unused account is not left on the database. Using the database app roles enables the Entra ID administrator to control access and roles by assigning users to app roles that are mapped to global schemas and global roles. This way, user access to the database is managed by Entra ID administrators and database administrators do not need to create, manage, and drop schemas for every user.

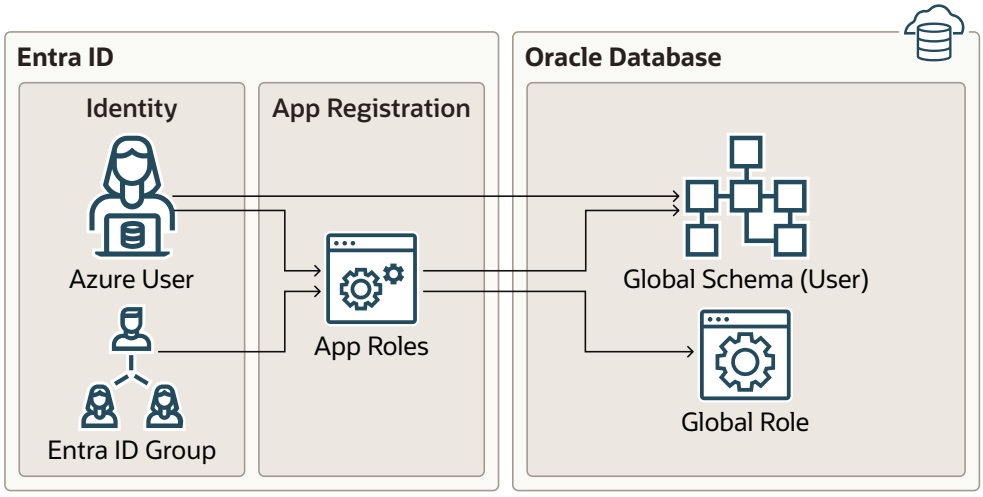
An Azure user can be mapped to a database schema (user) either exclusively or through an app role.

- **Creating an exclusive mapping between an Azure user and an Oracle Database schema.** In this type of mapping, the database schema must be created for the Azure user. Database privileges and roles that are needed by the Azure user must be granted to the database schema. The database schema not only must be created when the Azure user is authorized to the database, but the granted privileges and roles must be modified as the Entra ID roles and tasks change. Finally, the database schema must be dropped when the Azure user leaves the organization.
- **Creating a shared mapping between an Entra ID app role and an Oracle Database schema.** This type of mapping, which is more common than exclusive mappings, is for Azure users who have been assigned directly to the app role or is a member of an Entra ID

group that is assigned to the app role. The app role is mapped to an Oracle Database schema (shared schema mapping). Shared schema mapping allows multiple Azure users to share the same Oracle Database schema so a new database schema is not required to be created every time a new user joins the organization. This operational efficiency allows database administrators to focus on database application maintenance, performance, and tuning tasks instead of configuring new users, updating privileges and roles, and removing accounts.

In addition to database roles and privileges being granted directly to the mapped global schema, additional roles and privileges can be granted through mapped global roles. Different Azure users mapped to the same shared global schema may need different privileges and roles. Azure app roles can be mapped to Oracle Database global roles. Azure users who are assigned to the app role or are a member of an Entra ID group that is assigned to the app role will be granted the Oracle Database global role when they access the database.

The following diagram illustrates the different types of assignments and mappings that are available.



These mappings are as follows:

- An Azure user can be mapped directly to an Oracle Database global schema (user).
- An Azure user, Entra ID group, or application is assigned to an app role, which is then mapped to either an Oracle Database global schema (user) or a global role.

Use Cases for Connecting to an Oracle Database Using Entra ID

Oracle Database supports several use cases for connecting to the database.

- **OAuth2 authorization code flow:** This is the most common flow for human users. The client directs the Azure user to Entra ID to get the authorization code. This code is used to get the database access token. See the Microsoft Azure article Microsoft identity platform and OAuth 2.0 authorization code flow.
- **Resource owner password credentials (ROPC):** This flow is not recommended for production servers. It is useful for test software that cannot work with a pop-up authentication window. It is used in non-graphic user interface environments when a pop-up window cannot be used to authenticate a user.
- **Client credentials:** This flow is used for applications to connect with the database. The application must register with Entra ID app registration and needs a client ID and client

password. These client credentials must be used to get the database access token from Entra ID when the application connects to the database. The application can pass the token through the file system or through the database client API.

- **On-behalf-of (OBO) token:** An Azure application requests an OBO token for a logged in user. The OBO token will also be an access token for the database with the Azure user identity and assigned app roles for the database. This enables the Azure user to log in to the database as the user and not the application. Only an application can request an OBO token for its Azure user and pass it to the database client through the API.

Enable Microsoft Entra ID Authentication on Autonomous Database

A Microsoft Entra ID administrator and an Autonomous Database administrator perform steps to configure Entra ID authentication on Autonomous Database.

- Registering the Oracle Database Instance with a Microsoft Entra ID Tenancy
  A user with Entra ID administrator privileges uses Microsoft Entra ID to register the Oracle Database instance with the Microsoft Entra ID tenancy.
- Enabling Microsoft Entra ID v2 Access Tokens
  Oracle Database supports integration with the v1 and v2 Azure AD `OAuth2` access token.
- Managing App Roles in Microsoft Entra ID
  In Entra ID, you can create and manage app roles that will be assigned to Azure users and groups and also be mapped to Oracle Database global schemas and roles.
- Configuring Microsoft Entra ID as an External Identity Provider for Autonomous Database
  An Autonomous Database administrator can enable Entra ID as an external identity provider on an Autonomous Database instance.

Enabling Microsoft Entra ID v2 Access Tokens

Oracle Database supports integration with the v1 and v2 Azure AD `OAuth2` access token.

Oracle Database supports the Entra ID v2 token as well as the default v1 token. However, to use the Entra ID v2 token, you must perform some additional steps to ensure it works with the Oracle Database. You can use this token with applications that are registered in the Azure portal using the **App registrations** experience.

When you use the Azure AD v2 `OAuth2` access token, the credential flow continues to work as it did before without any changes. However, the `upn:` claim must be added when you use v2 tokens with the interactive flow.

1. Check the version of the Entra ID access token that you are using.
2. Log in to the Microsoft Entra ID portal.
3. Search for and select **Entra ID**.
4. Under **Manage**, select **App registrations**.
5. Choose the application for which you want to configure optional claims based on your scenario and desired outcome.
6. Under **Manage**, select **Token configuration**.
7. Click **Add optional claim** and select **upn**.

When you use v2 tokens, the `aud:` claim only reflects the APP ID value. You do not need to set the `https:domain` prefix to the APP ID URI when v2 tokens are being used. This simplifies the configuration for the database because the default APP ID URI can be used.

- Checking the Entra ID Access Token Version
  You can check the version of the Entra ID access token that your site uses by using the JSON Web Tokens web site.

Related Topics

- Checking the Entra ID Access Token Version
  You can check the version of the Entra ID access token that your site uses by using the JSON Web Tokens web site.

Checking the Entra ID Access Token Version

You can check the version of the Entra ID access token that your site uses by using the JSON Web Tokens web site.

By default, Entra ID v1 access token, but your site may have chosen to use v2. Oracle Database supports v1 tokens and Autonomous Database Serverless supports v2 tokens, as well. If you want to use the v2 access tokens, then you can enable their use for the Oracle database. To find the version of the Entra ID access token that you are using, you can either check with your Entra ID administrator, or confirm the version from the JSON Web Tokens website, as follows.

1. Go to the JSON Web Tokens website.

   ```
   https://jwt.io/
   ```

2. Copy and paste the token string into the **Encoded** field.
3. Check the **Decoded** field, which displays information about the token string.

   Near or at the bottom of the field, you will see a claim entitled `ver`, which indicates either of the following versions:

   - `"ver": "1.0"`
   - `"ver": "2.0"`

- Enabling Microsoft Entra ID v2 Access Tokens
  Oracle Database supports integration with the v1 and v2 Azure AD `OAuth2` access token.

Configuring Microsoft Entra ID as an External Identity Provider for Autonomous Database

An Autonomous Database administrator can enable Entra ID as an external identity provider on an Autonomous Database instance.

To enable Entra ID as an external identity provider:

1. Log in to the Autonomous Database instance as a user who has the `EXECUTE` privilege on the `DBMS_CLOUD_ADMIN` PL/SQL package. The `ADMIN` user has this privilege.
2. Run the `DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION` procedure with the Entra ID required parameters.

   ```
   BEGIN
     DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
         type   =>'AZURE_AD',
         params => JSON_OBJECT('tenant_id' VALUE 'tenant_id',
                               'application_id' VALUE 'application_id',
                               'application_id_uri' VALUE
   ```

```
'application_id_uri'),
      force => TRUE
  );
END;
```

In this procedure the Entra ID parameters are:

- `type`: Specifies the external authentication provider. For Entra ID, as shown, use `'AZURE_AD'`.
- `params`: Values for the required Entra ID parameters are available from the Azure portal on the app registration Overview pane for Azure Active Directory. The required `params` for Entra ID are:
  - `tenant_id`: Tenant ID of the Azure Account. Tenant Id specifies the Autonomous Database instance's Entra ID application registration.
  - `application_id`: Azure Application ID created in Entra ID to assign roles/schema mappings for external authentication in the Autonomous Database instance.
  - `application_id_uri`: Unique URI assigned to the Azure Application.
    This it the identifier for the Autonomous Database instance. The name must be domain qualified (this supports cross tenancy resource access).

    The maximum length for this parameter is 256 characters.
- `force`: Set this parameter to `TRUE` if another `EXTERNAL AUTHENTICATION` method is configured for the Autonomous Database instance and you want to disable it.

For example:

```
BEGIN
  DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
      type   =>'AZURE_AD',
      params => JSON_OBJECT('tenant_id' VALUE '29981886-6fb3-44e3-82',
                            'application_id' VALUE '11aa1a11-aaa',
                            'application_id_uri' VALUE 'https://
example.com/111aa1aa'),
      force  => TRUE
  );
END;
```

This sets the `IDENTITY_PROVIDER_TYPE` system parameter.

For example, you can use the following to verify `IDENTITY_PROVIDER_TYPE`:

```
SELECT NAME, VALUE FROM V$PARAMETER WHERE NAME='identity_provider_type';

NAME                   VALUE
---------------------- --------
identity_provider_type AZURE_AD
```

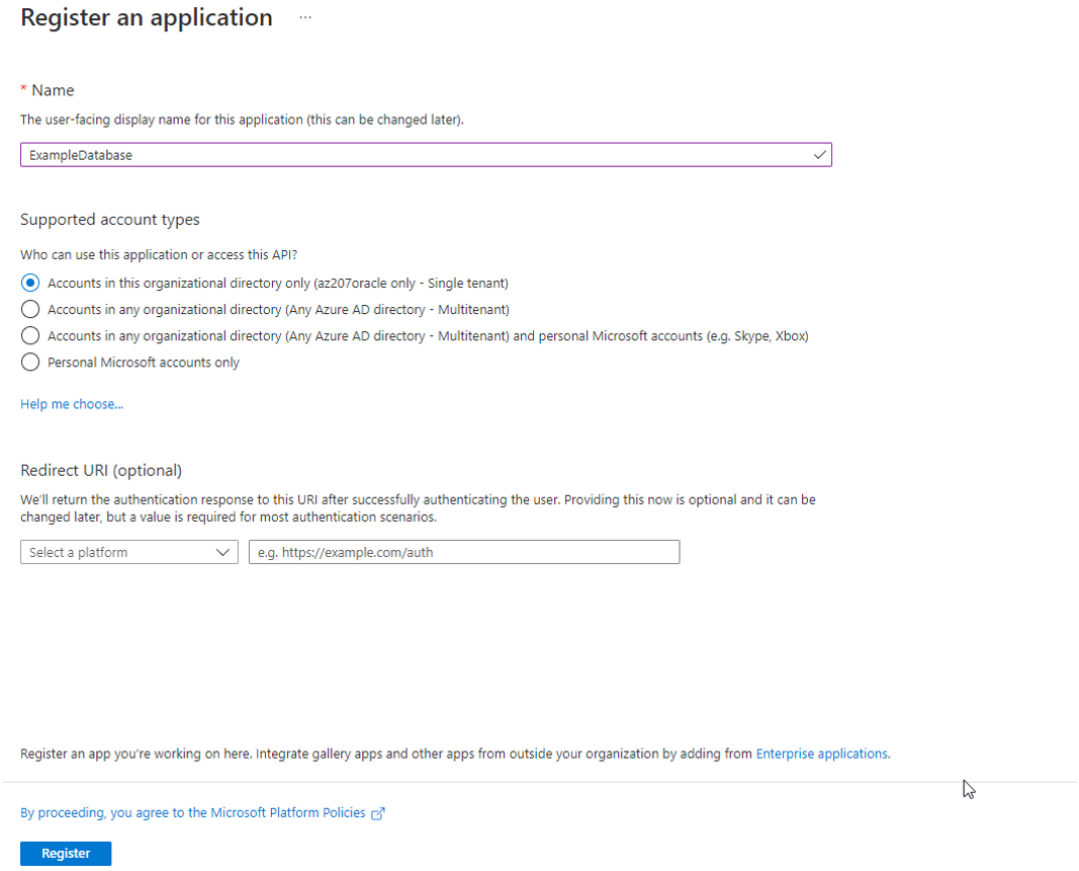
See ENABLE_EXTERNAL_AUTHENTICATION Procedure for more information.

Registering the Oracle Database Instance with a Microsoft Entra ID Tenancy

A user with Entra ID administrator privileges uses Microsoft Entra ID to register the Oracle Database instance with the Microsoft Entra ID tenancy.

1. Log in to the Azure portal as an administrator who has Microsoft Entra ID privileges to register applications.
2. In the Azure Active directory admin center page, from the left navigation bar, select **Azure Active Directory**.
3. In the MS - App registrations page, select **App registrations** from the left navigation bar.
4. Select **New registration**.

   The Register an application window appears.



5. In the Register an application page, enter the following Oracle Database instance registration information:
   - In the **Name** field, enter a name for the Oracle Database instance connection (for example, `Example Database`).
   - Under Supported account types, select the account type that matches your use case.
     - **Accounts in this organizational directory only (*tenant_name* only - Single tenant)**
     - **Accounts in any organizational directory (Any Entra ID directory - Multitenant)**
     - **Accounts in any organizational directory (Any Entra ID directory - Multitenant) and personal Microsoft accounts (e.g. Skype, Xbox)**
     - **Personal Microsoft accounts only**
6. Bypass the Redirect URI (Optional) settings. You do not need to create a redirect URI because Entra ID does not need one for the database server.
7. Click **Register**.

After you click **Register**, Entra ID displays the app registration's Overview pane, which will show the Application (client) ID under Essentials. This value is a unique identifier for the application in the Microsoft identity platform. Note the term Application refers to the Oracle Database instance.

8. Register a scope for the database app registration.

   A scope is a permission to access the database. Each database will need a scope so that clients can establish a trust with the database by requesting permission to use the database scope. This allows the database client to get access tokens for the database.

   a. In the left navigation bar, select **Expose an API**.

   b. Under Set the App ID URI, in the **Application ID URI** field, enter the app ID URI for the database connection using the following format, and then click **Save**:

      ```
      your_tenancy_url/application_(client)_id
      ```

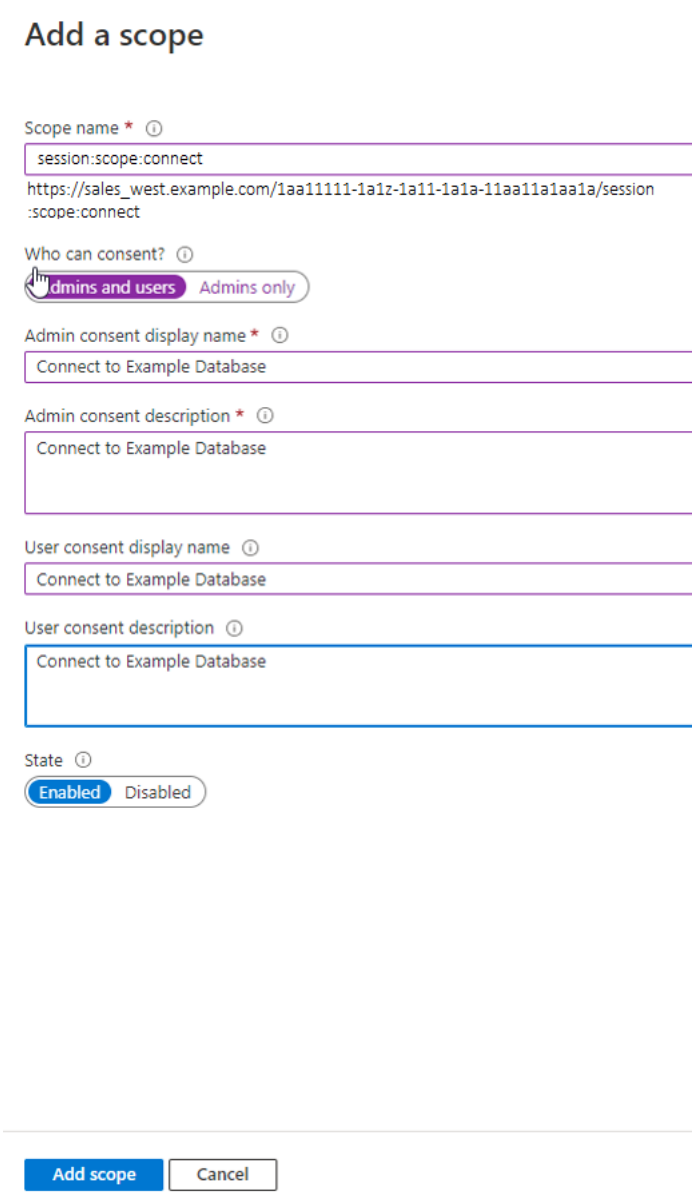
      In this specification:

      - *your_tenancy_url* must include `https` as the prefix and the fully qualified domain name of your Entra ID tenancy.
      - *application_(client)_id* is the ID that was generated when you registered the Oracle Database instance with Entra ID. It is displayed in the Overview pane of the app registration.

      For example:

      ```
      https://sales_west.example.com/1aa11111-1a1z-1a11-1a1a-11aa11a1aa1a
      ```

   c. Select **Add a scope** and then enter the following settings:



- **Scope name** specifies a name for the scope. Enter the following name:

  ```
  session:scope:connect
  ```

  This name can be any text. However, a scope name must be provided. You will need to use this scope name later when you give consent to the database client application to access the database.
- **Who can consent** specifies the necessary permissions. Select **Admins and users**, or for higher restrictions, **Admins only**.
- **Admin consent** display name describes the scope's purpose (for example, `Connect to Oracle`), which only administrators can see.
- **Admin consent display name** describes the scope's purpose (for example, `Connect to Example Database`), which only administrators can see.

- **User consent display name** is a short description of the purpose of the scope (for example, `Connect to Example Database`), which users can see if you specify **Admins and users** in **Who can consent**.
- **User consent description** is a more detailed description of the purpose of the scope (for example, `Connect to Example Database`), which users can see if you specify **Admins and users** in **Who can consent**.
- **State** enables or disables the connection. Select **Enabled**.

After you complete these steps, you are ready to add one or more Azure app roles, and then perform the mappings of Oracle schemas and roles.

Related Topics

- Quickstart: Register an application with the Microsoft identity platform

Managing App Roles in Microsoft Entra ID

In Entra ID, you can create and manage app roles that will be assigned to Azure users and groups and also be mapped to Oracle Database global schemas and roles.

- Creating a Microsoft Entra ID App Role
  Azure users, groups, and applications that need to connect to the database will be assigned to the database app roles.
- Assigning Users and Groups to the Microsoft Entra ID App Role
  Before Microsoft Azure users can have access to the Oracle database, they must first be assigned to the app roles that will be mapped to Oracle Database schema users or roles.
- Assigning an Application to an App Role
  An application that must connect to the database using the client credential flow must to be assigned to an app role.

Creating a Microsoft Entra ID App Role

Azure users, groups, and applications that need to connect to the database will be assigned to the database app roles.

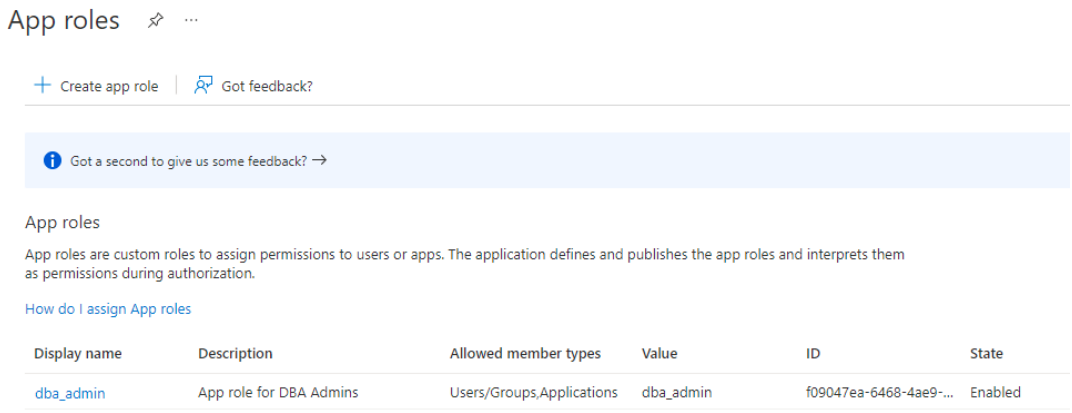
See the Microsoft Azure article Create and assign a custom role in Azure Active Directory for detailed steps on how to create an app role. The following steps describe how to create the app role for use with an Oracle database.

1. Log in to Entra ID as an administrator who has privileges for creating app roles.
2. Access the Oracle Database app registration that you created.
   a. Use the **Directory + subscription** filter to locate the Entra ID tenant that contains the Oracle Database app registration.
   b. Select **Azure Active Directory**.
   c. Under **Manage**, select **App registrations**, and then select the Oracle Database instance that you registered earlier.
3. Under **Manage**, select **App roles**.
4. In the App roles page, select **Create app role**.
5. In the Create app role page, enter the following information:
   - **Display name** is the displayed name of the role (for example, `HR App Schema`). You can include spaces in this name.

- **Value** is the actual name of the role (for example, `HR_APP`). Ensure that this setting matches exactly the string that is referenced in the database mapping to a schema or role. Do not include spaces in this name.
- **Description** provides a description of the purpose of this role.
- **Do you want to enable this app role?** enables you to activate the role.

6. Click **Apply**.

   The app role appears in the App roles pane.



Assigning Users and Groups to the Microsoft Entra ID App Role

Before Microsoft Azure users can have access to the Oracle database, they must first be assigned to the app roles that will be mapped to Oracle Database schema users or roles.

See the Microsoft Azure article Add app roles to your application and receive them in the token for detailed steps assigning users and groups to an app role. The following steps explain how to do this for an Oracle database.

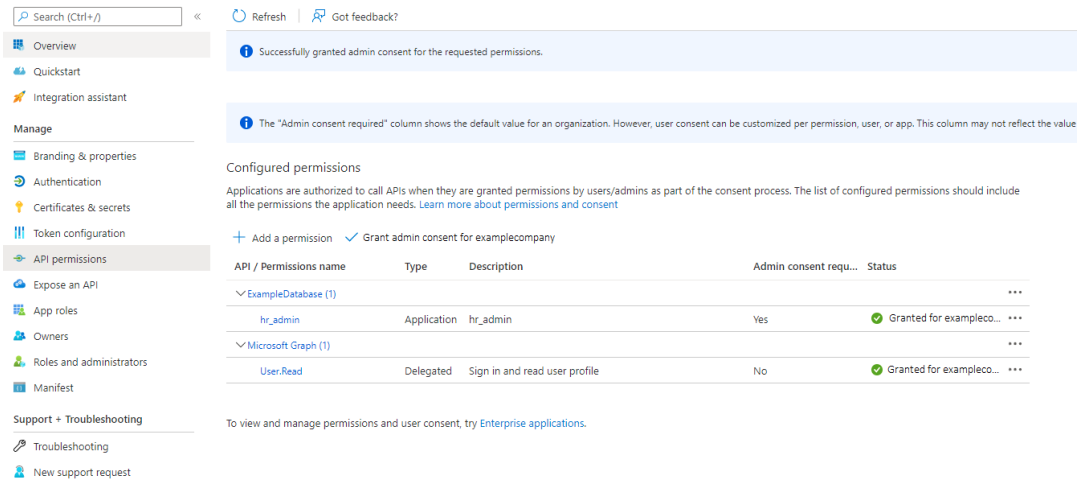
1. Log in to Entra ID as an administrator who has privileges for assigning Azure users and Entra ID groups to app roles.
2. In enterprise applications, find the name of the Oracle Database app registration that you created. This is automatically created when you create an app registration.
   a. Use the **Directory + subscription** filter to locate the Azure Active Directory tenant that contains the Oracle connection.
   b. Select **Azure Active Directory**.
   c. Under **Manage**, select **Enterprise applications**, and then select the Oracle Database app registration name that you registered earlier.
3. Under Getting Started, select **Assign users and groups**.
4. Select **Add user/group**.
5. In the Add assignment window, select **Users and groups** to display a list of users and security groups.
6. From this list, select the users and groups that you want to assign to the app role, and then click **Select**.
7. In the Add assignment window, select **Select a role** to display a list of the app roles that you have created.

8. Select the app role and then select **Select**.
9. Click **Assign**.

Assigning an Application to an App Role

An application that must connect to the database using the client credential flow must to be assigned to an app role.

1. Log in to Entra ID as an administrator who has privileges for assigning Azure users and Entra ID groups to app roles.
2. Access the app registration for the application.
3. Under Manage, select **API permissions**.
4. In the Configured permissions area, select **+ Add a permission**.
5. In the Request API permission pane, select the **My APIs** tab.
6. Select the Oracle Database app that you want to give permission for this application to access. Then select the **Application permissions** option.
7. Select the database app roles to assign to the application and then click the **Add Permission** box at the bottom of the screen to assign the app roles and close the dialog box. Ensure that the app roles that you just assigned appear under Configured permissions.



8. Select **Grant admin consent for *tenancy*** to grant consent for the tenancy users, then select **Yes** in the confirmation dialog box.

Role and Schema Mapping for Entra ID Authentication on Autonomous Database

Microsoft Entra ID (Azure AD) users are mapped to one database schema and optionally to one or more database roles. After mapping Entra ID users, user can connect to the Autonomous Database instance.

- Exclusively Mapping an Oracle Database Schema to a Microsoft Azure User
  You can exclusively map an Oracle Database schema to a Microsoft Azure user.

- Mapping a Shared Oracle Schema to an App Role
  In this mapping, an Oracle schema is mapped to an app role. Therefore, anyone who has that app role would get the same shared schema.
- Mapping an Oracle Database Global Role to an App Role
  Oracle Database global roles that are mapped to Entra ID app roles give Azure users and applications additional privileges and roles above those that they have been granted through their login schemas.

Exclusively Mapping an Oracle Database Schema to a Microsoft Azure User

You can exclusively map an Oracle Database schema to a Microsoft Azure user.

1. Log in to the Oracle Database instance as a user who has been granted the `CREATE USER` or `ALTER USER` system privilege.
2. Run the `CREATE USER` or `ALTER USER` statement with the `IDENTIFIED GLOBALLY AS` clause specifying the Azure user name.

   For example, to create a new database schema user named `peter_fitch` and map this user to an existing Azure user named `peter.fitch@example.com`:

   ```
   CREATE USER peter_fitch IDENTIFIED GLOBALLY AS
   'AZURE_USER=peter.fitch@example.com';
   ```

3. Grant the `CREATE SESSION` privilege to the user.

   ```
   GRANT CREATE SESSION TO peter_fitch;
   ```

Mapping a Shared Oracle Schema to an App Role

In this mapping, an Oracle schema is mapped to an app role. Therefore, anyone who has that app role would get the same shared schema.

1. Log in to the Oracle Database instance as a user who has the `CREATE USER` or `ALTER USER` system privilege.
2. Run the `CREATE USER` or `ALTER USER` statement with the `IDENTIFIED GLOBALLY AS` clause specifying the Azure application role name.

   For example, to create a new database global user account (schema) named `dba_azure` and map it to an existing Entra ID application role named `AZURE_DBA`:

   ```
   CREATE USER dba_azure IDENTIFIED GLOBALLY AS 'AZURE_ROLE=AZURE_DBA';
   ```

Mapping an Oracle Database Global Role to an App Role

Oracle Database global roles that are mapped to Entra ID app roles give Azure users and applications additional privileges and roles above those that they have been granted through their login schemas.

1. Log in to the Oracle Database instance as a user who has been granted the `CREATE ROLE` or `ALTER ROLE` system privilege
2. Run the `CREATE ROLE` or `ALTER ROLE` statement with the `IDENTIFIED GLOBALLY AS` clause specifying the name of the Entra ID application role.

For example, to create a new database global role named `widget_sales_role` and map it to an existing Entra ID application role named `WidgetManagerGroup`:

```
CREATE ROLE widget_sales_role IDENTIFIED GLOBALLY AS
'AZURE_ROLE=WidgetManagerGroup';
```

Microsoft Entra ID Client Configuration and Access for Autonomous Database

After you configure Entra ID on your Autonomous Database and you map Entra ID users, there are numerous ways that a user can configure a client to the Autonomous Database instance using Entra ID tokens.

If you use a wallet for your client connection (mTLS), download the wallet from the Autonomous Database instance and then follow the directions for configuring it for use with your client.

Confirm that DN matching is enabled by looking for `SSL_SERVER_DN_MATCH=ON` in `sqlnet.ora`. Partial or full DN matching is required when sending a token from the database client to Autonomous Database.

> **Note:**
>
> If Autonomous Database is using a private endpoint, you need to specify a host value for the connect string parameter. Using an IP address for the host parameter in the connect string will not work with DN matching and the Entra ID token will not be sent to the database.
> See Private Endpoints Configuration Examples on Autonomous Database for configuration information on how to set the host parameter when using a private endpoint.

See Configuring Entra ID Client Connections to the Oracle Database for more information.

Testing the Accessibility of the Entra ID Endpoint

You must ensure that your Oracle Database can access the Entra ID endpoint.

If your database client is configured to get Microsoft Entra ID OAuth2 tokens, then the database client must be able to access the Entra ID endpoint. Run the following command to check if you have internet access:

```
curl https://login.windows.net/common/discovery/keys
```

A status code of 200 indicates success.

Check with your IT help desk for the proxy information if you weren't successful running this command.

For an Oracle database to accept Entra ID `OAuth2` tokens, the database must request the public key from the Microsoft Entra ID endpoint.

- Run the following test to determine if the database can connect with the Microsoft Entra ID endpoint:

```
SET SERVEROUTPUT ON SIZE 40000
DECLARE
  req UTL_HTTP.REQ;
  resp UTL_HTTP.RESP;
BEGIN
  UTL_HTTP.SET_WALLET(path => 'system:');
  req := UTL_HTTP.BEGIN_REQUEST('https://login.windows.net/common/
discovery/keys');
  resp := UTL_HTTP.GET_RESPONSE(req);
  DBMS_OUTPUT.PUT_LINE('HTTP response status code: ' || resp.status_code);
  UTL_HTTP.END_RESPONSE(resp);
END;
/
```

If this test is successful, then a `PL/SQL procedure successfully completed` message appears.

If the following messages appear, then it means that a database network access control list (ACL) policy blocked your test and you will need to temporarily set an access control list policy to allow you to test this:

```
ORA-29273: HTTP request failed
ORA-24247: network access denied by access control list (ACL)
```

1. Set the ACL as follows:

```
BEGIN
DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
  host => '*',
  ace  =>  xs$ace_type(privilege_list => xs$name_list('connect'),
                       principal_name => 'username_placeholder',
                       principal_type => xs_acl.ptype_db));
END;
/
```

   Replace *username_placeholder* with the user name of the database user who is running the test. For example:

```
BEGIN
DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
  host => '*',
  ace  =>  xs$ace_type(privilege_list => xs$name_list('connect'),
                       principal_name => 'DBA_DEBRA',
                       principal_type => xs_acl.ptype_db));
END;
/
```

2. Try running the test again.

3. Remove the ACL, because you now no longer need it. For example, assuming your user name is `dba_debra`:

```
BEGIN
DBMS_NETWORK_ACL_ADMIN.REMOVE_HOST_ACE(
  host => '*',
  ace  =>  xs$ace_type(privilege_list => xs$name_list('connect'),
                       principal_name => 'DBA_DEBRA',
                       principal_type => xs_acl.ptype_db));
END;
/
```

If the database cannot connect with the Microsoft Entra ID endpoint, even after you set the ACL policy, you will most likely need to set the `HTTP_PROXY` package for your database. Review the topics listed in Related Topics, depending if you are using a default Oracle Database environment or an Oracle Real Application Clusters RAC environment. Your network administrator should be able to tell you what the correct `HTTP_PROXY` setting should be.

Use Microsoft Active Directory with Autonomous Database

You can configure Autonomous Database to authenticate and authorize Microsoft Active Directory users.

This configuration allows Active Directory users to access Autonomous Database using their Active Directory credentials including passwords and Kerberos.

- Prerequisites to Configure CMU with Microsoft Active Directory on Autonomous Database
- Configure CMU with Microsoft Active Directory on Autonomous Database
- Kerberos Authentication for CMU with Microsoft Active Directory
- Add Microsoft Active Directory Roles on Autonomous Database
  To add Active Directory roles, map the database global roles to Active Directory groups with `CREATE ROLE` or `ALTER ROLE` statements (and include the `IDENTIFIED GLOBALLY AS` clause).
- Add Microsoft Active Directory Users on Autonomous Database
  To add Active Directory users to access a database, map database global users to Active Directory groups or users with `CREATE USER` or `ALTER USER` statements (with `IDENTIFIED GLOBALLY AS` clause).
- Tools Restrictions with Active Directory on Autonomous Database
- Connect to Autonomous Database with Active Directory User Credentials
  After the ADMIN user completes the CMU Active Directory configuration steps and creates global roles and global users, users log in to the database using their Active Directory username and password.
- Verify Active Directory User Connection Information with Autonomous Database
  When users log in to the database using their Active Directory username and password, you can verify and audit the user activity.
- Remove Active Directory Users and Roles on Autonomous Database
  To remove Active Directory users and roles from Autonomous Databases, use standard database commands. This does not remove the related Active Directory users or groups that were mapped from the dropped database users or roles.

- Disable Active Directory Access on Autonomous Database
  Describes the steps to remove the CMU configuration from your Autonomous Database (and disable the LDAP access from your Autonomous Database to Active Directory).

Prerequisites to Configure CMU with Microsoft Active Directory on Autonomous Database

You can configure Autonomous Database to authenticate and authorize Microsoft Active Directory users.

Depending on where the Active Directory servers reside, there are two options for configuring Autonomous Database with Centrally Managed Users (CMU) with Microsoft Active Directory:

- **Active Directory (AD) servers publicly accessible**: the Active Directory servers are accessible from Autonomous Database through the public internet.
- **Active Directory (AD) servers reside on a private endpoint**: the Active Directory servers reside on a private endpoint and are not accessible from Autonomous Database through the public internet. For this case, an extra configuration step is required as shown in last step in Configure CMU with Microsoft Active Directory on Autonomous Database where you set the database property `ROUTE_OUTBOUND_CONNECTIONS`.

> **Note:**
>
> See Use Microsoft Entra ID with Autonomous Database for information on using Azure Active Directory with Autonomous Database. The CMU option supports Microsoft Active Directory servers but does not support the Azure Active Directory service.

The integration of Autonomous Database with Centrally Managed Users (CMU) provides integration with Microsoft Active Directory. CMU with Active Directory works by mapping Oracle database global users and global roles to Microsoft Active Directory users and groups.

The following are required prerequisites to configure the connection from Autonomous Database to Active Directory:

- You must have Microsoft Active Directory installed and configured. See AD DS Getting Started for more information.
- You must create an Oracle service directory user in Active Directory. See Connecting to Microsoft Active Directory for information on the Oracle service directory user account.
- An Active Directory system administrator must have installed Oracle password filter on the Active Directory servers, and set up Active Directory groups with Active Directory users to meet your requirements.

> **Note:**
>
> This is not required if you are using Kerberos authentication for CMU Active Directory. See Kerberos Authentication for CMU with Microsoft Active Directory for more information.

If you use password authentication with CMU Active Directory for Autonomous Database, you must use the included utility `opwdintg.exe` to install the Oracle password filter on

Active Directory, extend the schema, and create three new `ORA_VFR` groups for three types of password verifier generation. See Connecting to Microsoft Active Directory for information on installing the Oracle password filter.

- You need the CMU configuration database wallet, `cwallet.sso` and the CMU configuration file `dsi.ora` to configure CMU for your Autonomous Database:
  - If you have configured CMU for an on-premise database, you can obtain these configuration files from your on-premise database server.
  - If you have not configured CMU for an on-premise database, you need to create these files. Then you upload the configuration files to the cloud to configure CMU on your Autonomous Database instance. You can validate the wallet and the `dsi.ora` by configuring CMU for an on-premise database and verifying that an Active Directory user can successfully log on to the on-premise database with these configuration files.

  For details on the wallet file for CMU, see Create the Wallet for a Secure Connection and Verify the Oracle Wallet.

  For details on the `dsi.ora` file for CMU, see Creating the dsi.ora File.

  For details on configuring Active Directory for CMU and troubleshooting CMU for on-premise databases, see How To Configure Centrally Managed Users For Database Release 18c or Later Releases (Doc ID 2462012.1).
- Port 636 of the Active Directory servers must be open to Autonomous Database in Oracle Cloud Infrastructure. This allows Autonomous Database to access the Active Directory servers.
- When the Active Directory servers are on a public endpoint:
  - The Active Directory servers must be accessible from Autonomous Database through the public internet.
  - You can also extend your on-premise Active Directory to Oracle Cloud Infrastructure where you can set up Read Only Domain Controllers (RODCs) for the on-premise Active Directory. This allows you to use the RODCs in Oracle Cloud Infrastructure to authenticate and authorize on-premise Active Directory users for access to Autonomous Databases.

    See Extend Active Directory integration in Hybrid Cloud for more information.

Configure CMU with Microsoft Active Directory on Autonomous Database

You can configure Autonomous Database to authenticate and authorize Microsoft Active Directory users.

To configure Autonomous Database for CMU to connect to Active Directory:

> **Note:**
>
> When you perform the configuration steps, connect to the database as the ADMIN user.

1. Verify if another external authentication scheme is enabled on your database, and disable it.

   You can continue with CMU-AD configuration on top of Kerberos to provide CMU-AD Kerberos authentication for Microsoft Active Directory users.

   See Kerberos Authentication for CMU with Microsoft Active Directory for more information.

2. Upload the CMU configuration files, including the database wallet file, `cwallet.sso` and the CMU configuration file, `dsi.ora` to your Object Store. This step depends on the Object Store you use.

   The `dsi.ora` configuration file contains the information to find the Active Directory servers.

   If you are using Oracle Cloud Infrastructure Object Store, see Putting Data into Object Storage for details on uploading files.

3. Run `DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION` procedure and pass in a location URI with the `params` JSON argument. You must place the configuration files `cwallet.sso` and `dsi.ora` in the Object Storage location specified in the `location_uri` parameter.

   For example:

   ```
   BEGIN
      DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
          type     => 'CMU',
          params   => JSON_OBJECT('location_uri' value 'https://
   objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o',
                                   'credential_name' value
   'my_credential_name')
      );
   END;
   /
   ```

   Oracle recommends that you store the CMU configuration files in a private bucket in your Object Store.

   In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

   The `credential_name` you use in this step is the credentials to access the Object Store.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   If the `location_uri` is a pre-authenticated URL or a pre-signed URL, then supplying a `credential_name` is not required.

   The procedure creates a directory object named `CMU_WALLET_DIR` in your database and copies the CMU configuration files from the Object Store location to the directory object. This procedure also sets the database property `CMU_WALLET` to the value `'CMU_WALLET_DIR'` and sets the `LDAP_DIRECTORY_ACCESS` parameter value to the value `PASSWORD` to enable access from the Autonomous Database instance to Active Directory.

4. After you enable CMU authentication, remove the CMU configuration files including the database wallet `cwallet.sso` and the CMU configuration file `dsi.ora` from Object Store. You can use local Object Store methods to remove these files or use `DBMS_CLOUD.DELETE_OBJECT` to delete the files from Object Store.

5. When Active Directory servers are on a private endpoint, perform additional configuration steps to provide access to the private endpoint.

   a. Set the database property `ROUTE_OUTBOUND_CONNECTIONS` to the value `'PRIVATE_ENDPOINT'`.

See Enhanced Security for Outbound Connections with Private Endpoints for more information.

b. Validate that the CMU-AD configuration file `dsi.ora` includes host names. When `ROUTE_OUTBOUND_CONNECTIONS` is set to `'PRIVATE_TARGET'`, IP addresses cannot be specified in `dsi.ora`.

Note for CMU with Active Directory on Autonomous Database:

- Only "password authentication" or Kerberos authentication are supported for CMU with Autonomous Database. When you are using CMU authentication with Autonomous Database, other CMU authentication methods such as Azure AD, OCI IAM, and PKI are not supported.

See Disable Active Directory Access on Autonomous Database for instructions to disable the access from Autonomous Database to Active Directory.

See ENABLE_EXTERNAL_AUTHENTICATION Procedure for information on `DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION`.

See Configuring Centrally Managed Users with Microsoft Active Directory for more information on configuring CMU with Microsoft Active Directory.

Kerberos Authentication for CMU with Microsoft Active Directory

You can configure Autonomous Database to use Kerberos authentication for CMU with Microsoft Active Directory users. This configuration allows CMU Active Directory (CMU-AD) users to access an Autonomous Database instance using Kerberos credentials.

Kerberos can be configured with or without CMU-AD. Just configuring Kerberos requires you to create and maintain a database user for every Kerberos user. Configuring Kerberos with CMU allows you to map an Active Directory group of Kerberos users to a single database user, shared schema, so database access can be controlled by Active Directory group membership. See Configure Kerberos Authentication with Autonomous Database for details on configuring Kerberos without CMU-AD.

> **Note:**
>
> When implementing both the Kerberos authentication and CMU-AD for authorization, Oracle recommends implementing Kerberos authentication first, and then adding CMU-AD authorization.

1. Enable Kerberos in your Autonomous Database instance using Microsoft Active Directory Kerberos server.

   Only Microsoft Active Directory Kerberos servers are supported for Kerberos when you configure Kerberos authentication with CMU-AD.

   a. To enable Kerberos authentication for your Autonomous Database, you must obtain the Kerberos configuration files: `krb.conf` and the service key table file `v5srvtab`.

      To generate these files when you configure Kerberos authentication with CMU-AD you need the server host name. You can obtain the value of the server host from the attribute `PUBLIC_DOMAIN_NAME` in the `CLOUD_IDENTITY` column of `V$PDBS`. This value is different from the Fully Qualified Domain Name (FQDN) for a database on a private endpoint.

Use the following command to obtain the server host name:

```
SELECT guid ||'/'|| json_value(cloud_identity, '$.PUBLIC_DOMAIN_NAME')
    "KSERVICE/KINSTANCE" FROM v$pdbs;
```

You can use a command such as the following to generate the service key table file:

```
ktpass -princ ORACLE/
DATABASE_SERVER_HOST_NAME.DATABASE_SERVER_HOST_DOMAIN@ACTIVE_DIRECTORY_D
EFAULT_DOMAIN
                -pass ACTIVE_DIRECTORY_PASSWORD
                -mapuser DATABASE_SERVER_HOST_NAME
                -crypto ALL
                -ptype KRB5_NT_PRINCIPAL
                -out database.keytab
```

For example:

```
ktpass -princ ORACLE/user.example.com@example.com
                -pass password -mapuser dbexamplekrb
                -crypto ALL -ptype KRB5_NT_PRINCIPAL -out
database.keytab
```

For more information on these files and steps required to obtain them, see Configuring Kerberos Authentication.

b. Copy the Kerberos configuration files `krb.conf` and `v5srvtab` to a bucket in your Object Store.

   This step differs depending on the Object Store you use.

   If you are using Oracle Cloud Infrastructure Object Store, see Putting Data into Object Storage for details on uploading files.

c. Run `DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION` to enable Kerberos external authentication.

   For example:

```
BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
       type     => 'KERBEROS',
       params   => JSON_OBJECT('location_uri' value 'https://
objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/
bucketname/o',
                                'credential_name' value
'my_credential_name')
   );
END;
/
```

> **Note:**
>
> Oracle recommends that you store the Kerberos configuration files in a private bucket in your Object Store.

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

The `credential_name` you use in this step is the credentials for the Object Store.

See Enable Kerberos Authentication on Autonomous Database for more information.

d. Confirm that Kerberos is configured and enabled.

```
SELECT property_value FROM database_properties
      WHERE property_name='KERBEROS_DIRECTORY';
```

2. Enable and configure CMU-AD on Autonomous Database.

a. Upload the CMU configuration files, including the database wallet file, `cwallet.sso` and the CMU configuration file, `dsi.ora` to your Object Store.

You upload the `cwallet.sso` so that the CMU-AD configuration has the credentials for the Autonomous Database instance to connect to the Active Directory service account.

The `dsi.ora` configuration file contains the information to find the Active Directory servers.

This step differs depending on the Object Store you use.

If you are using Oracle Cloud Infrastructure Object Store, see Putting Data into Object Storage for details on uploading files.

b. Run the `DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION` procedure and pass in a location URI with the `params` JSON argument. You must place the configuration files `cwallet.sso` and `dsi.ora` in the Object Storage location specified in the `location_uri` parameter.

For example:

```
BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
       type     => 'CMU',
       params   => JSON_OBJECT('location_uri' value 'https://
objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/
bucketname/o',
                                'credential_name' value
'my_credential_name')
   );
END;
/
```

Oracle recommends that you store the CMU configuration files in a private bucket in your Object Store.

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

The `credential_name` you use in this step is the credentials to access the Object Store.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

If the `location_uri` is a pre-authenticated URL or a pre-signed URL, then supplying a `credential_name` is not required.

See Prerequisites to Configure CMU with Microsoft Active Directory on Autonomous Database for more information.

c. Confirm that CMU-AD is configured and enabled.

```
SELECT property_value FROM database_properties
      WHERE property_name='CMU_WALLET';
```

3. After completing Step 1 and Step 2, verify that the configuration of Kerberos authentication with CMU-AD is complete.

   a. Login to the Autonomous Database instance as an Active Directory user so that `SYS_CONTEXT` information populated in your `USERENV`.

   b. Query the `SYS_CONTEXT USERENV`.

```
SELECT SYS_CONTEXT('USERENV','AUTHENTICATION_METHOD') FROM DUAL;

SYS_CONTEXT('USERENV','AUTHENTICATION_METHOD')

--------------------------------------------------------------------------------
--------
KERBEROS_GLOBAL
```

When you have Kerberos authentication configured and enabled without CMU-AD, this query returns: `KERBEROS`. See Configure Kerberos Authentication with Autonomous Database for more information.

When you have CMU-AD authentication configured without Kerberos, this query returns: `PASSWORD_GLOBAL`. See Prerequisites to Configure CMU with Microsoft Active Directory on Autonomous Database for more information.

Notes for using Kerberos authentication with CMU-AD:

- You do not need to add the password filter when using Kerberos authentication with CMU-AD. See Prerequisites to Configure CMU with Microsoft Active Directory on Autonomous Database for more information.
- Adding or removing Active Directory users is supported, in the same manner as with CMU with Active Directory when you are using password authentication. See Add Microsoft Active Directory Users on Autonomous Database for more information.
- The existing restrictions about authenticating against the Autonomous Database Built-in Tools with CMU with Active Directory password also apply to CMU with Active Directory with Kerberos authentication. See Tools Restrictions with Active Directory on Autonomous Database for more information.

- Use `DBMS_CLOUD_ADMIN.DISABLE_EXTERNAL_AUTHENTICATION` to disable CMU-AD with Kerberos authentication. See DISABLE_EXTERNAL_AUTHENTICATION Procedure for more information.
- When the CMU-AD servers are on a private endpoint, to use CMU-AD with Kerberos authentication the server host name used for generating the key tab must be set to the value of attribute `PUBLIC_DOMAIN_NAME` in the `CLOUD_IDENTITY` column of `V$PDBS`. This value is different from the FQDN for a private endpoint database.

Add Microsoft Active Directory Roles on Autonomous Database

To add Active Directory roles, map the database global roles to Active Directory groups with `CREATE ROLE` or `ALTER ROLE` statements (and include the `IDENTIFIED GLOBALLY AS` clause).

To add global roles for Active Directory groups on Autonomous Database:

1. Log in as the ADMIN user to the database that is configured to use Active Directory (the ADMIN user has the `CREATE ROLE` and `ALTER ROLE` system privileges that you need for these steps).
2. Set the database authorization for Autonomous Database roles with `CREATE ROLE` or `ALTER ROLE` statement. Include the `IDENTIFIED GLOBALLY AS` clause and specify the DN of an Active Directory group.

   Use the following syntax to map a directory user group to a database global role:

   ```
   CREATE ROLE global_role IDENTIFIED GLOBALLY AS
        'DN_of_an_AD_GROUP_of_WHICH_the_AD_USER_IS_a_MEMBER';
   ```

   For example:

   ```
   CREATE ROLE widget_sales_role IDENTIFIED GLOBALLY AS
        'CN=widget_sales_group,OU=sales,DC=production,DC=example,DC=com';
   ```

   In this example all members of the `widget_sales_group` are authorized with the database role `widget_sales_role` when they log in to the database.
3. Use `GRANT` statements to grant the required privileges or other roles to the global role.

   For example:

   ```
   GRANT CREATE SESSION TO WIDGET_SALES_ROLE;
   GRANT DWROLE TO WIDGET_SALES_ROLE;
   ```

   `DWROLE` is a predefined role that has common privileges defined. See Manage User Privileges on Autonomous Database - Connecting with a Client Tool for information on setting common privileges for Autonomous Database users.
4. If you want to make an existing database role to be associated with an Active Directory group, then use `ALTER ROLE` statement to alter the existing database role to map the role to an Active Directory group.

Use the following syntax to alter an existing database role to map it to an Active Directory group:

```
ALTER ROLE existing_database_role
   IDENTIFIED GLOBALLY AS
'DN_of_an_AD_GROUP_of_WHICH_the_AD_USER_IS_a_MEMBER';
```

5. If you want to create additional global role mappings for other Active Directory groups, follow these steps for each Active Directory group.

For more information on configuring roles with Microsoft Active Directory, see *Configuring Authorization for Centrally Managed Users* in Oracle Database 19c Security Guide or Oracle Database 23ai Security Guide.

Add Microsoft Active Directory Users on Autonomous Database

To add Active Directory users to access a database, map database global users to Active Directory groups or users with `CREATE USER` or `ALTER USER` statements (with `IDENTIFIED GLOBALLY AS` clause).

The integration of Autonomous Database with Active Directory works by mapping Microsoft Active Directory users and groups directly to Oracle database global users and global roles.

To add global users for Active Directory groups or users on Autonomous Database:

1. Log in as the ADMIN user to the database that is configured to use Active Directory (the ADMIN user has the required `CREATE USER` and `ALTER USER` system privileges that you need for these steps).
2. Set database authorization for Autonomous Database users with `CREATE USER` or `ALTER USER` statements and include the `IDENTIFIED GLOBALLY AS` clause, specifying the DN of an Active Directory user or group.

   Use the following syntax to map a directory user to a database global user:

   ```
   CREATE USER global_user IDENTIFIED GLOBALLY AS 'DN_of_an_AD_USER';
   ```

   Use the following syntax to map a directory group to a database global user:

   ```
   CREATE USER global_user IDENTIFIED GLOBALLY AS
       'DN_of_an_AD_GROUP_of_WHICH_the_AD_USER_IS_a_MEMBER';
   ```

   For example, to map a directory group named `widget_sales_group` in the `sales` organization unit of the `production.example.com` domain to a shared database global user named `WIDGET_SALES`:

   ```
   CREATE USER widget_sales IDENTIFIED GLOBALLY AS
        'CN=widget_sales_group,OU=sales,DC=production,DC=example,DC=com';
   ```

   This creates a shared global user mapping. The mapping, with global user `widget_sales`, is effective for all users in the Active Directory group. Thus, anyone in the `widget_sales_group` can log in to the database using their Active Directory credentials (through the shared mapping of the `widget_sales` global user).

3. If you want Active Directory users to use an existing database user, own its schema, and own its existing data, then use `ALTER USER` to alter an existing database user to map the user to an Active Directory group or user.

   - Use the following syntax to alter an existing database user to map it to an Active Directory user:

     ```
     ALTER USER existing_database_user IDENTIFIED GLOBALLY AS
     'DN_of_an_AD_USER';
     ```

   - Use the following syntax to alter an existing database user to map it to an Active Directory group:

     ```
     ALTER USER existing_database_user
          IDENTIFIED GLOBALLY AS
     'DN_of_an_AD_GROUP_of_WHICH_the_AD_USER_IS_a_MEMBER';
     ```

4. If you want to create additional global user mappings for other Active Directory groups or users, follow these steps for each Active Directory group or user.

For more information on configuring roles with Microsoft Active Directory, see *Configuring Authorization for Centrally Managed Users* in Oracle Database 19c Security Guide or Oracle Database 23ai Security Guide.

Tools Restrictions with Active Directory on Autonomous Database

Notes for using Autonomous Database tools with Active Directory:

- Oracle APEX is not supported for Active Directory users with Autonomous Database. See Create Oracle APEX Workspaces in Autonomous Database for information on using regular database users with Autonomous Database.
- Database Actions is not supported for Active Directory users with Autonomous Database. See Provide Database Actions Access to Database Users for information on using regular database users with Autonomous Database.
- Oracle Machine Learning Notebooks are not supported for Active Directory users with Autonomous Database. See Add Existing Database User Account to Oracle Machine Learning Components for information on using regular database users with Autonomous Database.

Connect to Autonomous Database with Active Directory User Credentials

After the ADMIN user completes the CMU Active Directory configuration steps and creates global roles and global users, users log in to the database using their Active Directory username and password.

> **Note:**
>
> Do not log in using a Global User name. Global User names do not have a password and connecting with a Global User name will not be successful. You must have a global user mapping in your Autonomous Database in order to log in to the database. You cannot log in to the database with only global role mappings.

- To log in to the database using an Active Directory username and password, connect as follows:

  ```
  CONNECT "AD_DOMAIN\AD_USERNAME"/
  AD_USER_PASSWORD@TNS_ALIAS_OF_THE_AUTONOMOUS_DATABASE;
  ```

  For example:

  ```
  CONNECT "production\pfitch"/password@adbname_medium;
  ```

  You need to include double quotes when the Active Directory domain is included along with the username, as with this example: `"production\pfitch"`.

  In this example, the Active Directory username is `pfitch` in domain `production`. The Active Directory user is a member of `widget_sales_group` group which is identified by its DN `'CN=widget_sales_group,OU=sales,DC=production,DC=example,DC=com'`.

After configuring CMU with Active Directory on Autonomous Database and setting up Active Directory authorization, with global roles and global users, you can connect to your database using any of the connection methods described in Connect to Autonomous Database. When you connect, if you want to use an Active Directory user then use Active Directory user credentials. For example, provide a username in this form, "*AD_DOMAIN\AD_USERNAME*" (double quotes must be included), and use your *AD_USER_PASSWORD* for the password.

If your Autonomous Database instance is in Restricted Mode, this mode only allows users with the `RESTRICTED SESSION` privilege to connect to the database. The ADMIN user has this privilege. You can use restricted access mode to perform administrative tasks such as indexing, data loads, or other planned activities. See Change Autonomous Database Operation Mode to Read/Write Read-Only or Restricted for more information.

Verify Active Directory User Connection Information with Autonomous Database

When users log in to the database using their Active Directory username and password, you can verify and audit the user activity.

For example, when the user `pfitch` logs in:

```
CONNECT "production\pfitch"/password@exampleadb_medium;
```

The Active Directory user's log on username (samAccountName) is `pfitch` and `widget_sales_group` is the Active Directory Group name, and `widget_sales` is the database global user.

After `pfitch` logs in to the database, the command `SHOW USER` shows the global user name:

```
SHOW USER;

USER is "WIDGET_SALES"
```

The following command shows the DN (Distinguished Name) of the Active Directory user:

```
SELECT SYS_CONTEXT('USERENV', 'ENTERPRISE_IDENTITY') FROM DUAL;
```

For example you can verify this centrally managed user's enterprise identity:

```
SQL> SELECT SYS_CONTEXT('USERENV', 'ENTERPRISE_IDENTITY') FROM DUAL;

SYS_CONTEXT('USERENV','ENTERPRISE_IDENTITY')
--------------------------------------------------------------------------------
cn=Peter Fitch,ou=sales,dc=production,dc=examplecorp,dc=com
```

The following command shows the "`AD_DOMAIN\AD_USERNAME`":

```
SELECT SYS_CONTEXT('USERENV', 'AUTHENTICATED_IDENTITY') FROM DUAL;
```

For example, the Active Directory authenticated user identity is captured and audited when the user logs on to the database:

```
SQL> SELECT SYS_CONTEXT('USERENV', 'AUTHENTICATED_IDENTITY') FROM DUAL;

SYS_CONTEXT('USERENV','AUTHENTICATED_IDENTITY')
--------------------------------------------------------------------------------
production\pfitch
```

See *Verifying the Centrally Managed User Logon Information* in Oracle Database 19c Security Guide or Oracle Database 23ai Security Guide for more information.

Remove Active Directory Users and Roles on Autonomous Database

To remove Active Directory users and roles from Autonomous Databases, use standard database commands. This does not remove the related Active Directory users or groups that were mapped from the dropped database users or roles.

To remove users or roles from Autonomous Database:

1. Log in to the database that is configured to use Active Directory as a user who has been granted the `DROP USER` or `DROP ROLE` system privilege.
2. Drop the global users or the global roles that are mapped to Active Directory groups or users with `DROP USER` or `DROP ROLE` statement.

   See Remove Users on Autonomous Database for more information.

Disable Active Directory Access on Autonomous Database

Describes the steps to remove the CMU configuration from your Autonomous Database (and disable the LDAP access from your Autonomous Database to Active Directory).

After you configure your Autonomous Database instance to access CMU Active Directory, you can disable the access as follows:

1. Connect to the Autonomous Database as the ADMIN user.
2. Use the `DBMS_CLOUD_ADMIN.DISABLE_EXTERNAL_AUTHENTICATION` to disable CMU authentication.

> **Note:**
>
> To run this procedure you must be logged in as ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

For example:

```
BEGIN
   DBMS_CLOUD_ADMIN.DISABLE_EXTERNAL_AUTHENTICATION;
END;
/
```

This disables CMU authentication on your Autonomous Database instance.

See DISABLE_EXTERNAL_AUTHENTICATION Procedure for more information.

Configure Kerberos Authentication with Autonomous Database

Describes how to configure Kerberos to authenticate Oracle Autonomous Database users.

- About Kerberos Authentication
  You can configure Oracle Autonomous Database to use Kerberos network authentication protocol to authenticate database users. Kerberos is a strong network authentication protocol. It uses secret-key cryptography to enable strong authentication by providing user-to-server authentication.
- Components of the Kerberos Authentication System
  Provides an overview of the Kerberos authentication system.
- Enable Kerberos Authentication on Autonomous Database
  Shows the steps to enable Kerberos authentication on your Autonomous Database instance.
- Disable Kerberos Authentication on Autonomous Database
  Shows the steps to disable Kerberos authentication for your Autonomous Database instance.
- Notes for Kerberos Authentication on Autonomous Database
  Provides notes on using Kerberos Authentication for Autonomous Database.

About Kerberos Authentication

You can configure Oracle Autonomous Database to use Kerberos network authentication protocol to authenticate database users. Kerberos is a strong network authentication protocol. It uses secret-key cryptography to enable strong authentication by providing user-to-server authentication.

- Oracle Autonomous Database support for Kerberos provides the benefits of single sign-on and centralized authentication of Oracle users. Kerberos is a trusted third-party authentication system that relies on shared secrets. It presumes that the third party is secure, and provides single sign-on capabilities, centralized password storage, database link authentication, and enhanced PC security. It does this through a Kerberos authentication server.

- The Kerberos system revolves around the concept of a ticket. A ticket is a set of electronic information that identifies a user or a service. A ticket identifies you and your network access privileges.
- In Kerberos-based authentication, you transparently send a request for a ticket to a Key Distribution Center (KDC). The Key Distribution Center authenticates you and grants you a ticket to access the database.

Components of the Kerberos Authentication System

Provides an overview of the Kerberos authentication system.

- A realm establishes an authentication administrative domain. Each realm has its own Kerberos database which contains the users and services for that particular administrative domain.
- Tickets are issued by the Key Distribution Center (KDC). Clients present tickets to the Database Server to demonstrate the authenticity of their identity. Each ticket has expiration and a renewal time.
- Keytabs stores long-term keys for one or more principals. A keytab file is generated by invoking the tool `kadmin.local` (for MIT Key Distribution Center) or `ktpass` (for Active Directory Key Distribution Center).
- Principals are the entries in the Key Distribution Center database. Each user, host or service is given a principal. A principal is a unique identity to which the Key Distribution Center can assign tickets.
- Kerberos support in Autonomous Database uses these values for various components that make up a service principal's name:

Component of Service Principal	Value in Autonomous Database
`kinstance`	You can obtain this value from the attribute `PUBLIC_DOMAIN_NAME` in the `CLOUD_IDENTITY` column of `V$PDBS`. This value is different from the Fully Qualified Domain Name (FQDN) for a database on a private endpoint. Use the following query to obtain the `kinstance`: `SELECT json_value(cloud_identity, '$.PUBLIC_DOMAIN_NAME') "KINSTANCE" FROM v$pdbs;` **Note:** This will be the value of the `host` parameter found in the TNS connect string.

Component of Service Principal	Value in Autonomous Database

kservice	On Autonomous Database you have two options for the kservice value:
	• Use the database GUID: If you do not provide a Kerberos service name with DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION, the default service name used is the GUID of the Autonomous Database instance. In this case, when you create the keytab file, use the GUID as the value for the service name.
	Because in the default case the Keytab file uses a service name that is a GUID, which is instance specific, when you use the default service name you must generate different Keytab files for each Autonomous Database instance.
	Use the following command to obtain the GUID (case is significant):
	`SELECT GUID FROM v$pdbs;`
	• Use a custom name: Set the service name when you want to use the same Keytab files on multiple Autonomous Database instances. When you use a custom name you do not need to create and upload different Keytab files for each Autonomous Database instance. When you use a custom name you must specify the params kerberos_service_name parameter with DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION. Specifying this parameter is not required when you use the GUID for the service name.
	After Kerberos is enabled on your Autonomous Database instance, use the following query to view the Kerberos service name:
	`SELECT SYS_CONTEXT('USERENV', 'KERBEROS_SERVICE_NAME') FROM DUAL;`

REALM	Any realm supported by your KDC. REALM must always be in uppercase.

To enable Kerberos authentication for your Autonomous Database, you must keep your Kerberos configuration files (krb.conf) and service key table file (v5srvtab) ready. For more information on these files and steps to obtain them, please see Configuring Kerberos Authentication.

Enable Kerberos Authentication on Autonomous Database

Shows the steps to enable Kerberos authentication on your Autonomous Database instance.

To run DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION you must be logged in as ADMIN user or have the EXECUTE privilege on DBMS_CLOUD_ADMIN.

To use DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION to enable Kerberos authentication:

To enable Kerberos authentication for your Autonomous Database, you must obtain the Kerberos configuration files: krb.conf and the service key table file v5srvtab. For more information on these files and steps required to obtain them, see Configuring Kerberos Authentication .

1. Copy the Kerberos configuration files krb.conf and v5srvtab to a bucket in your Object Store.

   If you are using Oracle Cloud Infrastructure Object Store, see Putting Data into Object Storage for details on uploading files.

2. Run DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION procedure and pass in a location URI with the params JSON argument. You must place the configuration files

`krb.conf` and `v5srvtab` in the Object Storage location specified in the `location_uri` parameter.

For example:

```
BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
       type     => 'KERBEROS',
       params   => JSON_OBJECT(
               'location_uri' value 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o',
               'credential_name' value 'my_credential_name'));
END;
/
```

> **Note:**
>
> Oracle recommends that you store the Kerberos configuration files in a private bucket in your Object Store.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

The `credential_name` you use in this step is the credentials for the Object Store.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

If the `location_uri` is a pre-authenticated URL then supplying a `credential_name` is not required.

This creates a directory object named `KERBEROS_DIR` in your database and uses the credential to download the Kerberos configuration files from the Object Store location to the directory object.

You can specify the `params kerberos_service_name` parameter to specify a Kerberos service name. For example:

```
BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_EXTERNAL_AUTHENTICATION(
       type     => 'KERBEROS',
       params   => JSON_OBJECT(
               'location_uri' value 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o',
               'credential_name' value 'my_credential_name'
               'kerberos_service_name' value 'oracle' ));
END;
/
```

3. After you enable Kerberos authentication, remove the configuration `krb.conf` and `v5srvtab` from Object Store. You can use local Object Store methods to remove these files or use `DBMS_CLOUD.DELETE_OBJECT` to delete the files from Object Store.

See Navigate to Oracle Cloud Infrastructure Object Storage and Create Bucket for more information on Object Storage.

See ENABLE_EXTERNAL_AUTHENTICATION Procedure for more information.

Disable Kerberos Authentication on Autonomous Database

Shows the steps to disable Kerberos authentication for your Autonomous Database instance.

- Run `DBMS_CLOUD_ADMIN.DISABLE_EXTERNAL_AUTHENTICATION` procedure to disable Kerberos authentication. To run the procedure, you must be logged in as ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

  ```
  BEGIN
     DBMS_CLOUD_ADMIN.DISABLE_EXTERNAL_AUTHENTICATION;
  END;
  /
  ```

  This disables the Kerberos authentication (or any external authentication scheme specified) for Oracle Autonomous Database.

  See DISABLE_EXTERNAL_AUTHENTICATION Procedure for more information.

Notes for Kerberos Authentication on Autonomous Database

Provides notes on using Kerberos Authentication for Autonomous Database.

- If you enable Kerberos authentication for your Autonomous Database, you can still use password-based database authentication for your database.
- Kerberos authentication is not supported for these tools:
  - Oracle Database API for MongoDB
  - Oracle REST Data Services
  - Oracle Machine Learning
  - APEX
  - Oracle Graph Studio
  - Oracle Database Actions
- You can enable Kerberos authentication to authenticate the ADMIN user. You can use the Reset Password functionality on the Oracle Cloud Infrastructure Console to reset the ADMIN user's password and regain access if a corrupted keytab file causes ADMIN user's authentication to fail.
- The default value for the maximum **clock skew** in Autonomous Database is 300 seconds (5 minutes). You cannot change the default **clock skew** value.

Manage Credentials or Configure Policies and Roles to Access Resources

Describes the methods in which Autonomous Database connects to other resources, either with credentials, or by configuring policies and roles for access.

- Manage Credentials
  You can create credentials, list credentials, or delete credentials in your Autonomous Database.
- Use Vault Secret Credentials
- Configure Policies and Roles to Access Resources
  You may use the following methods to access cloud resources securely without storing user credentials: Oracle Cloud Infrastructure Resource Principals, AWS Amazon Resource Names (ARN)s, Azure service principal, or Google service accounts.

Manage Credentials

You can create credentials, list credentials, or delete credentials in your Autonomous Database.

- Create Credentials to Access Cloud Services
  To access services in the Cloud, such as Cloud Object Store, you first need to create credentials in your Autonomous Database.
- Create Credentials to Access Cloud Services in Cloud Shell
  Use Cloud Shell to run a script that creates OCI Native Credentials and Auth Token in your Autonomous Database.
- List Credentials
  `DBMS_CLOUD` provides the ability to store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. You can list credentials from the view `ALL_CREDENTIALS`.
- Delete Credentials
  `DBMS_CLOUD` provides the ability to store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. You can remove credentials with `DBMS_CLOUD.DROP_CREDENTIAL`.

Create Credentials to Access Cloud Services

To access services in the Cloud, such as Cloud Object Store, you first need to create credentials in your Autonomous Database.

1. Create and store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. For example:

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
    password => 'password',
    comments => 'credential to access object store'
  );
END;
/
```

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. After you store the credentials you can then use the same credential name for all data loads.

   For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

> **Note:**
>
> Some tools like SQL*Plus and SQL Developer use the ampersand character (`&`) as a special character. If you have the ampersand character in your password use the `SET DEFINE OFF` command in those tools as shown in the example to disable the special character and get the credential created properly.

2. With the credential you created in Step 1, you can access Object Store or other cloud resources from Autonomous Database using a procedure such as `DBMS_CLOUD.COPY_DATA`, `DBMS_CLOUD.EXPORT_DATA`, `DBMS_CLOUD_PIPELINE` if you are using a Data Pipeline, or other procedures that require `DBMS_CLOUD` credentials.

Create Credentials to Access Cloud Services in Cloud Shell

Use Cloud Shell to run a script that creates OCI Native Credentials and Auth Token in your Autonomous Database.

To create credentials using the `DBMS_CLOUD` package, see Create Credentials to Access Cloud Services and CREATE_CREDENTIAL Procedure.

- About the Create Credential Cloud Shell Script
  Run the Create Credential Cloud Shell script in the Cloud Shell developer tool to generate credential scripts to run in your Autonomous Database.
- Example: Create OCI Native Credentials
  This example uses Cloud Shell to run the Create Credential script to create OCI Native Credential scripts.
- Example: Create OCI Native Credentials and Run in Autonomous Database
  This example uses the Create Credential script to create an OCI Native Credential script that is run in your Autonomous Database.
- Create Auth Token Used for Swift Credential
  If you want to create an Auth Token/Swift credential, though Oracle recommends the use of OCI Native Credentials, include the `--all` argument when running the script to generate OCI Native Credentials and the Auth Token/Swift credential.

About the Create Credential Cloud Shell Script

Run the Create Credential Cloud Shell script in the Cloud Shell developer tool to generate credential scripts to run in your Autonomous Database.

Use the Create Credential script, `adb-create-cred.sh`, to create new or to reuse existing OCI Native Credentials, including an RSA key pair with a fingerprint. The credentials are provided to the user in the form of scripts, `oci_native_credential.sql` and `oci_native_credential.json`, that can be run in your Autonomous Database. Existing credentials are backed up if new credentials are created.

Use the `adb-create-cred.sh` script to run the generated credential scripts in your Autonomous Database or exit the program and run the scripts in your database with a SQL or JSON compatible tool or utility of your choice. See Example: Create OCI Native Credentials and Example: Create OCI Native Credentials and Run in Autonomous Database for more information and examples.

Optionally, `adb-create-cred.sh` is used to create Auth Token/Swift credentials. Oracle recommends the use of OCI Native Credentials. However, if you want to create an Auth Token/ Swift credential, it is supported by this shell script. See Create Auth Token Used for Swift Credential for details.

> **Note:**
>
> If for you do not have access to the Cloud Shell developer tool, create OCI Native Credentials without using the `adb-create-cred.sh` script. See Create Oracle Cloud Infrastructure Native Credentials for details.

Example: Create OCI Native Credentials

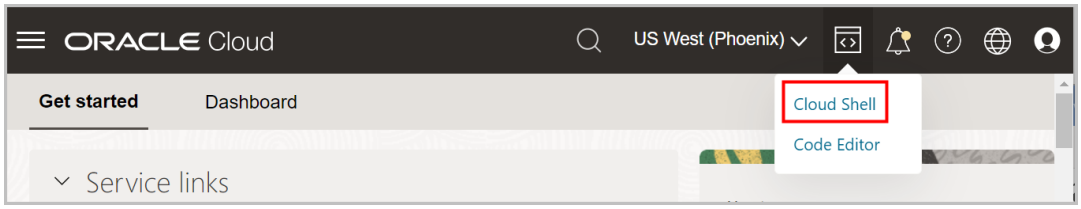
This example uses Cloud Shell to run the Create Credential script to create OCI Native Credential scripts.

Run `adb-create-cred.sh` to generate credential scripts, `oci_native_cred.sql` and `oci_native_cred.json`. The `adb-create-cred.sh` script searches for existing credentials, if found you are asked if you want to reuse them or if you want new credentials created. Depending on your decision, the generated credential scripts include new or existing credentials. Download the OCI Native Credential script or copy it to run it directly in your database using any SQL or JSON tool or utility.

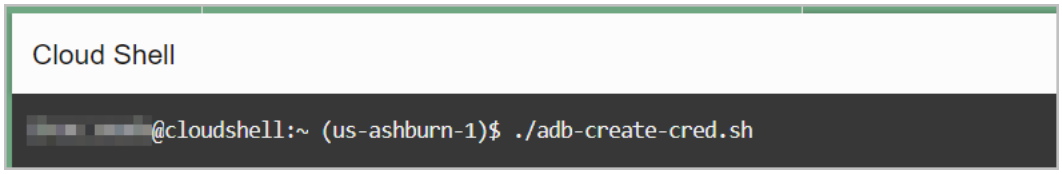
> **Note:**
>
> For a list of arguments supported by the Create Credential script, enter `adb-create-cred.sh --help`.

In this example, OCI Native Credential scripts are generated for your tenancy without running them in your database. See Example: Create OCI Native Credentials and Run in Autonomous Database, for an example of running the OCI Native Credential script in your database.

1. Sign into your Tenancy, select the **Developer Tools** icon and click **Cloud Shell** from the drop down list.



2. Run the **`adb-create-cred.sh`** script.



3. Enter **y** to reuse existing credentials in the generated OCI Native Credential script.

```
################################################################################
# This initial step ensures your OCI API Keys and Fingerprint are setup properly.  #
################################################################################

You have an existing API Key and Fingerprint! Do you want to try to reuse them? (y/n): y
```

If you choose to create new credentials, and decide after overwriting the credentials that you want to use the overwritten credentials, go back to the directory where the backup is and reuse them. The backup file name or folder has a suffix with this syntax: `_bkp_YYYYMMDD_abc`. For example, this backup file was created on June 06, 2024: `_bkp_20240603_woT`.

4. Enter **n** to exit the script without running the OCI Native Credential script in your database.

```
Your API Key was NOT removed, it was found in your OCI Profile. Let's use it!

Your Native Credential SQL file [$HOME/oci_native_credential.sql] was created.

Your Native Credential JSON file [$HOME/oci_native_credential.json] was created.

################################################################################

Proceed to run the Credential Scripts on your Autonomous Database? (y/n):
```

5. The program exits and displays the name of the OCI Native Credential and the command to view it.

```
Exiting...

To view PL/SQL script for creating credentials,

        execute: cat $HOME/oci_native_credential.sql

[redacted]@cloudshell:~ (us-ashburn-1)$
```

Download the OCI Native Credential script or copy it and run it directly in your database using any SQL tool.

Example: Create OCI Native Credentials and Run in Autonomous Database

This example uses the Create Credential script to create an OCI Native Credential script that is run in your Autonomous Database.

Before running the script, consider the following:

- (Optional) Provide the database region, compartment and database name, to avoid having the script search for the database. Although these options are not required, they can save processing time, especially on tenancies spanning a multitude of compartments and Autonomous Databases.

- The script assumes the database is in your home region. If it is in a different region, you must pass in the region name argument, `--region`, when running the script.
- If you don't provide the compartment (--compartment), or database name (--database), the script searches for possible candidates and prompts you to make a selection from lists of possible compartments and databases.
- To list available options, enter `-h` or `--help`.

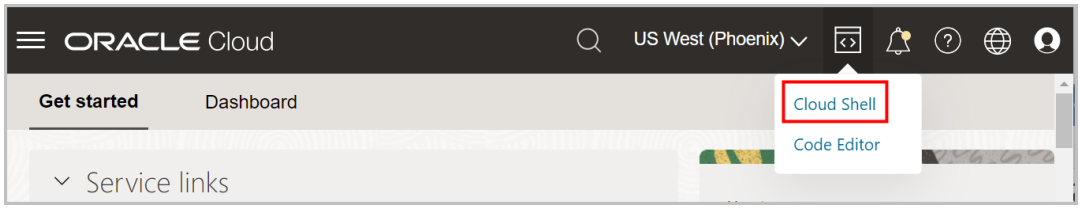
In the following example, the Create OCI Native Credential script, `adb-create-cred.sh`, is used to generate a credential script with existing credentials and run the script in a specified database.

The database region, compartment, and name are passed as arguments to the script. The `--database` option requires both `--region` and `--compartment`. If you specify only `--database` without these, then the option is ignored.

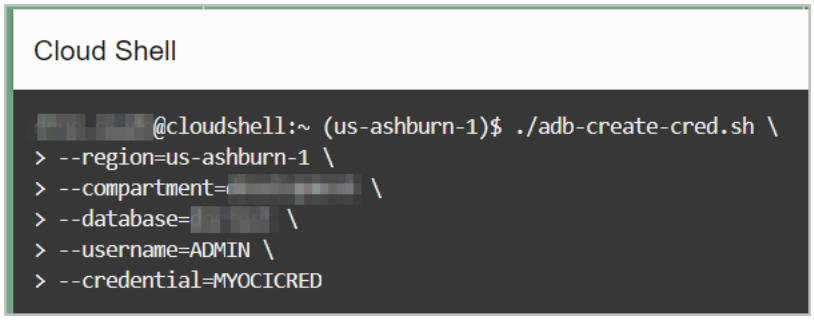
The username used to connect to the database is also provided along with a name for the created credential.

> **Note:**
>
> For a list of arguments supported by the Create Credential script, enter `adb-create-cred.sh --help`.

1. Sign into your Tenancy, select the **Developer Tools** icon and click **Cloud Shell** from the drop down list.



2. Run the **`adb-create-cred.sh`** script, including arguments used to locate the database, connect to the database and a user specified credential name.



3. Existing API keys and fingerprint were found. Enter **y** to reuse them in the generated credential scripts.

```
You specified the Region [us-ashburn-1]

You specified the Compartment [ ]

You named the OCI Native Credential [MYOCICRED]

You specified the Database [ ]

#################################################################################
# This initial step ensures your OCI API Keys and Fingerprint are setup properly.  #
#################################################################################

You have an existing API Key and Fingerprint! Do you want to try to reuse them? (y/n):
```

If you choose to create new credentials, and decide after overwriting the credentials that you want to use the overwritten credentials, you can go back to the directory where the backup is and reuse them. The backup file name or folder has a suffix with this syntax: `_bkp_YYYYMMDD_abc`. For example, this backup file was created on June 06, 2024: `_bkp_20240603_woT`.

4. Enter **y** to run the created credential script, `oci_native_credential.sql`, in the database you specified with the region, compartment and database arguments.

```
Your API Key was NOT removed, it was found in your OCI Profile. Let's use it!

Your Native Credential SQL file [$HOME/oci_native_credential.sql] was created.

Your Native Credential JSON file [$HOME/oci_native_credential.json] was created.

#################################################################################

Proceed to run the Credential Scripts on your Autonomous Database? (y/n): y
```

5. A Wallet File was not found, so it was set up. If a Wallet File was found, you are asked if you want to reuse it or set up a new one. Enter the ***password*** for the ADMIN username you provided. The username and password are used to connect to the database.

```
You do not have a Wallet File. Let's set it up for you.

Fixing path in [ _wallet/sqlnet.ora] to that of your Wallet File.

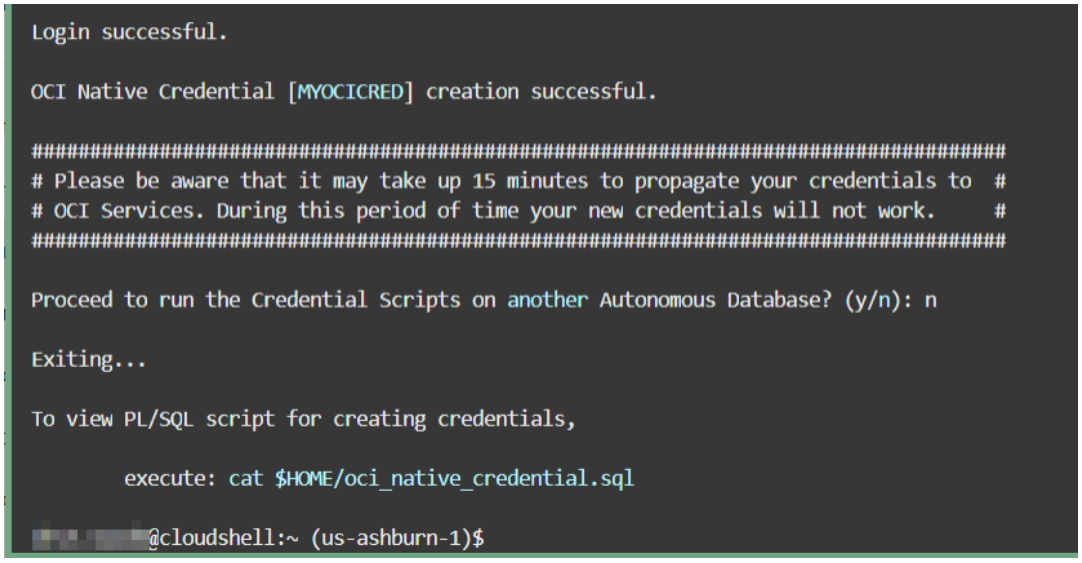
#################################################################################
# We setup your credentials, generated SQL scripts to add the credentials, we   #
# also setup your Autonomous Database connection, and are now connecting you to #
# your Autonomous Database so you can execute the credential scripts.           #
#################################################################################

You specified the Database Username [ADMIN]

Enter Autonomous Database password:
```

> **Note:**
>
> If you have an Autonomous Database private endpoint in a Virtual Cloud Network, the `adb-create-cred.sh` script generates the SQL and JSON scripts. However, it does not perform the steps required to access the Autonomous Database private end point. Instead, it prompts you to execute `cat ~/oci_native_credential.sql` to copy the SQL into whatever SQL tool you have access to via a Bastion or Jump Host.

6. The login was successful and the `MYOCICRED` credential is created in the specified database. The existing credentials are dropped and the new credentials are created. Enter **n** to not run credentials in another database. The script exists and provides the path for the created `oci_native_credential.sql` script.



> **Note:**
>
> If the connection to the Autonomous Database is unsuccessful, you can run `cat ~/oci_native_credential.sql`, and copy the SQL to run it directly in your database using any SQL tool.

Create Auth Token Used for Swift Credential

If you want to create an Auth Token/Swift credential, though Oracle recommends the use of OCI Native Credentials, include the `--all` argument when running the script to generate OCI Native Credentials and the Auth Token/Swift credential.

For example:

```
adb-create-cred.sh --all
```

When this flag is used, the script asks if you want to include an Auth Token. By answering **y**, your Auth Token key is generated and uploaded to your OCI profile, and the `oci_auth_token_credential.sql` and `auth_token.tok` scripts are created.

There are 2 options you can use to view the Auth Token key:

- Run the `oci_auth_token_credential.sql` script from the Cloud Shell, to create the Auth Token key in your database. The Auth Token key is the value of the `password` parameter for `DBMS_CLOUD_CREATE_CREDENTIAL`.
- View `auth_token.tok` from the Cloud Shell. Your Auth Token is the value of `token`.

List Credentials

`DBMS_CLOUD` provides the ability to store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. You can list credentials from the view `ALL_CREDENTIALS`.

For example, to list credentials, run the following command:

```
SELECT credential_name, username, comments FROM all_credentials;

CREDENTIAL_NAME                                                 USERNAME
--------------------------------------------------------------  --------------------
COMMENTS
--------------------------------------------------------------  --------------------
ADB_TOKEN                                                       user_name@example.com
{"comments":"Created via DBMS_CLOUD.create_credential"}
DEF_CRED_NAME                                                   user_name@example.com
{"comments":"Created via DBMS_CLOUD.create_credential"}
```

See ALL_CREDENTIALS for more information.

Delete Credentials

`DBMS_CLOUD` provides the ability to store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. You can remove credentials with `DBMS_CLOUD.DROP_CREDENTIAL`.

For example, to remove the credential named `DEF_CRED_NAME`, run the following command:

```
BEGIN
   DBMS_CLOUD.DROP_CREDENTIAL('DEF_CRED_NAME');
END;
```

For more information about the `DBMS_CLOUD` procedures and parameters, see DBMS_CLOUD Subprograms and REST APIs.

Use Vault Secret Credentials

Describes using vault secret credentials, where the credentials secret (password) is stored as a secret in a vault. You can then use vault secret credentials to access cloud resources or to access other databases (use anywhere that username/password type credentials are required).
You can create vault secret credentials with secrets stored in any of the supported vaults:

- Oracle Cloud Infrastructure Vault
- Azure Key Vault
- AWS Secrets Manager
- GCP Secret Manager

For example, some possible uses cases for vault secret credentials:

- You can avoid duplicating secrets (passwords) when you access cloud resources from an Autonomous Database instance. In this case, you store secrets in a vault and Autonomous Database accesses the vault. This allows you to rotate secrets without updating the credentials you create to access cloud resources.
- You can use vault secret credentials with database links. In this case, you can create routines that access another database and you don't need to expose passwords in your code.
- You can use vault secret credentials with DBMS_DATAPUMP APIs.

> **Note:**
>
> Operations that use Oracle Data Pump support vault secret credentials (for example `impdp` and `expdp`). Oracle Data Pump support with vault secret credentials is limited to Oracle Cloud Infrastructure Swift URIs and Oracle Cloud Infrastructure Native URIs. See DBMS_CLOUD URI Formats for more information.

Use Vault Secret Credentials with Oracle Cloud Infrastructure Vault

Describes using vault secret credentials, where the secret (password) is stored as a secret in Oracle Cloud Infrastructure Vault.

You can use vault secret credentials to access cloud resources, to access other databases with database links, or use anywhere that username/password type credentials are required.

- Prerequisites to Create Vault Secret Credentials with Oracle Cloud Infrastructure Vault

- Create Vault Secret Credentials with Oracle Cloud Infrastructure Vault

Prerequisites to Create Vault Secret Credentials with Oracle Cloud Infrastructure Vault

Describes the required prerequisite steps to use vault secret credentials with Oracle Cloud Infrastructure Vault secrets.

To create vault secret credentials where the secret is stored in Oracle Cloud Infrastructure Vault, first perform the required prerequisites.

1. Create a vault and create a secret in the vault with Oracle Cloud Infrastructure Vault.

   For more information, see the instructions for creating a vault and a secret, Managing Vaults and Overview of Key Management.

2. Set up a dynamic group to provide access to the secret in the Oracle Cloud Infrastructure Vault.

   Create a dynamic group for the Autonomous Database instance where you want to create a vault secret credential:

   a. In the Oracle Cloud Infrastructure console click **Identity & Security**.

   b. Under **Identity** click **Domains** and select an identity domain (or create a new identity domain).

   c. Under Identity domain, click **Dynamic groups**.

   d. Click **Create dynamic group** and enter a **Name**, a **Description**, and a rule.

      - **Create Dynamic Group for an existing database:**

        You can specify that an Autonomous Database instance is part of the dynamic group. The dynamic group in the following example includes only the Autonomous Database whose OCID is specified in the `resource.id` parameter:

        ```
        resource.id = 'your_Autonomous_Database_instance_OCID'
        ```

      - **Create a Dynamic Group for a database that has not been provisioned yet:**

        When you are creating the dynamic group before you provision or clone an Autonomous Database instance, the OCID for the new database is not yet available. For this case, create a dynamic group that specifies the resources in a given compartment:

        ```
        resource.compartment.id = 'your_Compartment_OCID'
        ```

   e. Click **Create**.

3. Write policy statements for the dynamic group to enable access to Oracle Cloud Infrastructure resources (secrets).

   a. In the Oracle Cloud Infrastructure Console click **Identity and Security** and click **Policies**.

   b. To write policies for the dynamic group you created in the previous step, click **Create Policy**, and enter a **Name** and a **Description**.

   c. Use the **show manual editor** option of **Policy Builder** to create a policy.

For example, to allow access to the dynamic group to read a specific secret in a compartment:

```
Allow dynamic-group dynamic_group_name to read secret-bundles in
compartment compartment_name
   where target.secret.id='secret_OCID'
```

For example, to allow access to the dynamic group to read all secrets in a compartment:

```
Allow dynamic-group dynamic_group_name to read secret-bundles in
compartment compartment_name
```

See Details for the Vault Service for more information.

d. Select the group or dynamic group and select the location.

e. Click **Create**.

Create Vault Secret Credentials with Oracle Cloud Infrastructure Vault

Describes the steps to use an Oracle Cloud Infrastructure Vault secret with credentials.

This allows you to store a secret in Oracle Cloud Infrastructure Vault and use the secret with the credential you create to access cloud resources or to access other databases.

To create vault secret credentials where the secret is stored in Oracle Cloud Infrastructure Vault:

1. Enable resource principal authentication to provide access to a secret in the Oracle Cloud Infrastructure Vault.

   See Enable Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

2. Create a dynamic group and define policies to allow your Autonomous Database to access secrets in an Oracle Cloud Infrastructure Vault.

   See Prerequisites to Create Vault Secret Credentials with Oracle Cloud Infrastructure Vault for more information.

3. Use `DBMS_CLOUD.CREATE_CREDENTIAL` to create a vault secret credential.

   For example:

```
BEGIN DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name   => 'OCI_SECRET_CRED',
    params            => JSON_OBJECT(
        'username'   value 'SCOTT',
        'secret_id'  value
'ocid1.vaultsecret.oc1.iad.example..aaaaaaaauq5ok5nq3bf2vwetkpqsoa' ));
END;
/
```

   Where:

   - `username`: is the username of the original credential. It can be the username of any type of username/password credential such as the username of an OCI Swift user, the username required to access a database with a database link, and so on.

- `secret_id`: is the vault secret ID. For example, when you store the password *mysecret* in a secret in Oracle Cloud Infrastructure Vault, the `secret_id` value is the vault secret OCID.

To create a vault secret credential you must have `EXECUTE` privilege on the `DBMS_CLOUD` package.

See CREATE_CREDENTIAL Procedure for more information.

4. Use the credential to access a cloud resource.

   For example:

```
SELECT count(*) FROM DBMS_CLOUD.LIST_OBJECTS(
    'OCI_SECRET_CRED',
    'https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-
string/b/bucketname/o/' );
```

> **Note:**
>
> Every 12 hours the secret (password) is refreshed from the content in the Oracle Cloud Infrastructure Vault. If you change the secret value in the Oracle Cloud Infrastructure Vault, it can take up to 12 hours for the Autonomous Database instance to pick up the latest secret value.

Run `DBMS_CLOUD.REFRESH_VAULT_CREDENTIAL` to immediately refresh a vault secret credential. This procedure gets the latest version of the vault secret from Oracle Cloud Infrastructure Vault. See REFRESH_VAULT_CREDENTIAL Procedure for more information.

Use Vault Secret Credential with Azure Key Vault

Describes using vault secret credentials, where the credential secret (password) is stored in Azure Key Vault.

You can use vault secret credentials to access cloud resources, to access other databases with database links, or use anywhere that username/password type credentials are required.

- Prerequisites to Create Vault Secret Credential with Azure Key Vault
  Describes the required prerequisites to use vault secret credentials with Azure Key Vault.
- Create Vault Secret Credential with Azure Key Vault
  Describes the steps to use an Azure Key Vault with vault secret credentials.

Prerequisites to Create Vault Secret Credential with Azure Key Vault

Describes the required prerequisites to use vault secret credentials with Azure Key Vault.

To create vault secret credentials where the secret is stored in Azure Key Vault, first perform the required prerequisites.

1. Enable Azure service principal authentication to provide access to the key (password) in the Azure Key Vault.

   See Enable Azure Service Principal for more information.

2. Create an Azure Key Vault and create a secret (password) in the vault.

   See About Azure Key Vault for more information.

3. Set up and enable Azure Service Principal to provide access to the secret in the Azure Key Vault.

   In the Azure portal you must grant read access for a service principal to access the secret.

   a. In the Azure portal, navigate to the "Key Vault" resource that contains the secret you created.

   b. Select "Access policies", then select **Create**.

   c. Under Permissions, select the **Get** permission in the **Secret permissions** section.

   d. Under Principal, enter the name of the service principal in the search field and select the appropriate result.

   e. Click **Next**.

   f. Under Review + create, review the access policy changes and click **Create** to save the access policy.

   g. Back on the Access policies page, verify that your access policy is listed.

   See Assign a Key Vault access policy for more information.

Create Vault Secret Credential with Azure Key Vault

Describes the steps to use an Azure Key Vault with vault secret credentials.

This allows you to store a secret in Azure Key Vault and use the secret with the credentials you create to access cloud resources or to access other databases.

To create vault secret credentials where the secret is stored in Azure Key Vault:

1. Create the Azure Key Vault, the secret, and the access policies to allow your Autonomous Database to access secrets in an Azure Key Vault.

   See Prerequisites to Create Vault Secret Credential with Azure Key Vault for more information.

2. Use `DBMS_CLOUD.CREATE_CREDENTIAL` to create a vault secret credential.

   For example:

```
BEGIN DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name  => 'AZURE_SECRET_CRED',
    params  => JSON_OBJECT(
      'username'          value 'azure_user',
      'secret_id'         value 'sales-secret',
      'azure_vault_name'  value 'azure_keyvault_name' ));
END;
/
```

   Where:

   - `username`: is the username of the original credential. It can be the username of any type of username/password credential.
   - `secret_id`: is the secret name.
   - `azure_vault_name`: is the name of the vault where the secret is located.

   To create a vault secret credential you must have `EXECUTE` privilege on the `DBMS_CLOUD` package.

   See CREATE_CREDENTIAL Procedure for more information.

3. Use the credential to access a cloud resource.

   For example:

```
SELECT count(*) FROM DBMS_CLOUD.LIST_OBJECTS(
     'AZURE_SECRET_CRED',
     'https://adb_user.blob.core.windows.net/adb/' );
```

> **Note:**
>
> Every 12 hours the secret (password) is refreshed from the content in the Azure Key Vault. If you change the secret value in the Azure Key Vault, it can take up to 12 hours for the Autonomous Database instance to pick up the latest secret value.

Run `DBMS_CLOUD.REFRESH_VAULT_CREDENTIAL` to immediately refresh a vault secret credential. This procedure gets the latest version of the vault secret from Azure Key Vault. See REFRESH_VAULT_CREDENTIAL Procedure for more information.

Use Vault Secret Credential with AWS Secrets Manager

Describes using vault secret credentials, where the credential secret (password) is stored in AWS Secrets Manager.

You can use vault secret credentials to access cloud resources, to access other databases with database links, or use anywhere that username/password type credentials are required.

- Prerequisites to Create Vault Secret Credential with AWS Secrets Manager
  Describes the required prerequisites to use vault secret credentials with AWS Secrets Manager.
- Create Vault Secret Credential with AWS Secrets Manager
  Describes the steps to use an AWS Secrets Manager secret with credentials.

Prerequisites to Create Vault Secret Credential with AWS Secrets Manager

Describes the required prerequisites to use vault secret credentials with AWS Secrets Manager.

To create vault secret credentials where the secret is stored in AWS Secrets Manager, first perform the required prerequisites.

1. Create a secret with AWS Secrets Manager and copy the AWS secret ARN.

   See AWS Secrets Manager for more information.

2. Perform AWS management prerequisites to use Amazon Resource Names (ARNs).

   See Perform AWS Management Prerequisites to Use Amazon Resource Names (ARNs) for more information.

3. Enable AWS principal authentication to provide access to the secret in AWS Secrets Manager.

   For example, on the Autonomous Database instance run:

```
BEGIN

DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
```

```
          provider => 'AWS',
          params =>
             JSON_OBJECT(
                'aws_role_arn' value 'arn:aws:iam::123456:role/
AWS_ROLE_ARN'));
END;
/
```

See ENABLE_PRINCIPAL_AUTH Procedure and About Using Amazon Resource Names (ARNs) to Access AWS Resources for more information.

4. Set up AWS to provide permissions for Amazon Resource Names (ARNs) to access the secret in AWS Secrets Manager.

   On the AWS console, you must grant read access to the secret to the principal authentication credential.

   a. In the AWS console, navigate to the IAM and select **Roles** in Access Management.
   b. Select the role.
   c. In the Permission tab, click **Add permissions** → **create inline policy**.
   d. In the Service section, select **secret manager** as the service.
   e. In the Action section, select **Read** access level.
   f. In the Resources section, click **Add ARN**, specify ARN for secret and click **Add** → click **Review the policy** → give a policy name → click **create policy**.
   g. Back to the Permission tab, verify that the inline policy is attached.

   See Use Amazon Resource Names (ARNs) to Access AWS Resources and Permissions policy examples for AWS Secrets Manager for more information.

Create Vault Secret Credential with AWS Secrets Manager

Describes the steps to use an AWS Secrets Manager secret with credentials.

This allows you to store a secret in AWS Secrets Manager and use the secret with the credentials you create to access cloud resources or to access other databases.

To create vault secret credentials where the secret is stored in AWS Secrets Manager:

1. Create a secret in AWS Secrets Manager and create an inline policy to allow your Autonomous Database to access secrets in AWS Secrets Manager.

   See Prerequisites to Create Vault Secret Credential with AWS Secrets Manager for more information.

2. Use `DBMS_CLOUD.CREATE_CREDENTIAL` to create a vault secret credential to access the AWS Secrets Manager secret.

   For example:

```
BEGIN DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name      => 'AWS_SECRET_CRED',
    params               => JSON_OBJECT(
         'username'   value 'access_key',
         'secret_id'  value 'arn:aws:secretsmanager:region:account-
ID:secret:secret_name' ));
```

```
END;
/
```

Where:

- `username`: is the username of the original credential. It can be the username of any type of username/password credential.
- `secret_id`: is the vault secret AWS ARN.

To create a vault secret credential you must have `EXECUTE` privilege on the `DBMS_CLOUD` package.

See CREATE_CREDENTIAL Procedure for more information.

3. Use the credential to access a cloud resource.

   For example:

```
SELECT count(*) FROM DBMS_CLOUD.LIST_OBJECTS(
     'AWS_SECRET_CRED',
     'https://s3-us-west-2.amazonaws.com/adb/' );
```

> **Note:**
>
> Every 12 hours the secret (password) is refreshed from the content in the AWS Secrets Manager. If you change the secret value in the AWS Secrets Manager, it can take up to 12 hours for the Autonomous Database instance to pick up the latest secret value.

Run `DBMS_CLOUD.REFRESH_VAULT_CREDENTIAL` to immediately refresh a vault secret credential. This procedure gets the latest version of the vault secret from AWS Secrets Manager. See REFRESH_VAULT_CREDENTIAL Procedure for more information.

Use Vault Secret Credential with GCP Secret Manager

Describes using vault secret credentials, where the credentials secret (password) are stored as a secret in GCP Secret Manager.

You can use vault secret credentials to access cloud resources, to access other databases with database links, or use anywhere that username/password type credentials are required.

- Prerequisites to Create Vault Secret Credential with GCP Secret Manager
  Describes the required prerequisites to use vault secret credentials with GCP Secret Manager.
- Create Vault Secret Credential with GCP Secret Manager
  Describes the steps to use an GCP Secret Manager secret to store secrets for use with the credentials you use to access cloud resources.

Prerequisites to Create Vault Secret Credential with GCP Secret Manager

Describes the required prerequisites to use vault secret credentials with GCP Secret Manager.

To create vault secret credentials where the secret is stored in GCP Secret Manager, first perform the required prerequisites.

1. Create a secret in GCP Secret Manager.

   See Secret Manager and Create and access a secret using Secret Manager for more information.

2. Enable Google Service Account authentication to provide access to GCP Secret Manager.

   On the Google Cloud console you must grant read access to the secret to the principal authentication credential.

   a. Go to the **Secret Manager** page in the Google Cloud console.

   b. On the **Secret Manager** page, click the checkbox next to the name of the secret.

   c. If it is not already open, click **Show Info Panel** to open the panel.

   d. In the info panel, click **Add Principal**.

   e. In the **New principals** text area, enter the service account name to add.

   f. In the **Select a role** dropdown, choose **Secret Manager** and then **Secret Manager Secret Accessor**.

   See Enable Google Service Account and Find the GCP Service Account Name and Manage access to secrets for more information.

Create Vault Secret Credential with GCP Secret Manager

Describes the steps to use an GCP Secret Manager secret to store secrets for use with the credentials you use to access cloud resources.

This allows you to store a secret in GCP Secret Manager and use the secret with the credentials you create to access cloud resources or to access other databases.

To create vault secret credentials where the secret is stored in GCP Secret Manager:

1. Create a secret manager secret accessor to allow your Autonomous Database principal to access secrets in GCP Secret Manager.

   See Prerequisites to Create Vault Secret Credential with GCP Secret Manager for more information.

2. Enable Google service account based authentication to provide access to the secret in the GCP Secret Manager.

   See Enable Google Service Account and Find the GCP Service Account Name for more information.

3. Use `DBMS_CLOUD.CREATE_CREDENTIAL` to create a vault secret credential to access the GCP Secret Manager secret.

   For example:

```
BEGIN DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name      => 'GCP_SECRET_CRED',
    params               => JSON_OBJECT(
          'username'   value 'gcp_user1',
          'secret_id'  value 'my-secret',
          'gcp_project_id' value 'my-sample-project-191923' ));
END;
/
```

   Where:

- `username`: is the username of the original credential. It can be the username of any type of username/password credential.
- `secret_id`: is the secret name. When you store the password *mysecret* in the vault, use the secret name as the value of the `secret_id` parameter.
- `gcp_project_id`: is the ID of the project where the secret is located.

See CREATE_CREDENTIAL Procedure for more information.

4. Use the credential to access a cloud resource.

   For example:

```
SELECT count(*) FROM DBMS_CLOUD.LIST_OBJECTS(
           'GCP_SECRET_CRED',
           'https://bucketname.storage.googleapis.com/' );
```

> **Note:**
>
> Every 12 hours the secret (password) is refreshed from the content in the GCP Secret Manager. If you change the secret value in the GCP Secret Manager, it can take up to 12 hours for the Autonomous Database instance to pick up the latest secret value.

Run `DBMS_CLOUD.REFRESH_VAULT_CREDENTIAL` to immediately refresh a vault secret credential. This procedure gets the latest version of the vault secret from GCP Secret Manager. See REFRESH_VAULT_CREDENTIAL Procedure for more information.

Refresh Vault Secret Credentials

Describes how vault secret credentials can be refreshed from the latest value in the vault.

To refresh vault secret credentials, you have two choices:

- Wait for automatic refresh: Every 12 hours the secret (password) is refreshed from the content in the vault. If you change the secret value in the vault, it can take up to 12 hours for the Autonomous Database instance to pick up the latest secret value.
- Run `DBMS_CLOUD.REFRESH_VAULT_CREDENTIAL` to immediately refresh a vault secret credential. This procedure gets the latest version of the vault secret from Oracle Cloud Infrastructure Vault.

  For example:

```
BEGIN
  DBMS_CLOUD.REFRESH_VAULT_CREDENTIAL(
     credential_name => 'VAULT_SECRET_CRED');
END;
/
```

  See REFRESH_VAULT_CREDENTIAL Procedure for more information.

Update Vault Secret Credentials

Describes the steps to update vault secret credential attributes.

To update vault secret credential attributes:

1. Use `DBMS_CLOUD.UPDATE_CREDENTIAL` to update a vault secret credential attribute.

   For example:

   ```
   BEGIN DBMS_CLOUD.UPDATE_CREDENTIAL(
       credential_name   => 'VAULT_SECRET_CRED',
       attribute         => 'secret_id',
       value             => 'new_secret_id'
     );
   END;
   /
   ```

   To update a vault secret credential you must have `EXECUTE` privilege on the `DBMS_CLOUD` package.

   See UPDATE_CREDENTIAL Procedure for more information.

2. Use the updated credential to access a cloud resource.

   For example:

   ```
   SELECT count(*) FROM DBMS_CLOUD.LIST_OBJECTS(
       'VAULT_SECRET_CRED',
       'https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-
   string/b/bucketname/o/' );
   ```

Configure Policies and Roles to Access Resources

You may use the following methods to access cloud resources securely without storing user credentials: Oracle Cloud Infrastructure Resource Principals, AWS Amazon Resource Names (ARN)s, Azure service principal, or Google service accounts.

- Use Resource Principal to Access Oracle Cloud Infrastructure Resources
  You can use an Oracle Cloud Infrastructure resource principal with Autonomous Database. You or your tenancy administrator define the Oracle Cloud Infrastructure policies and a dynamic group that allows you to access Oracle Cloud Infrastructure resources with a resource principal. You do not need to create a credential object and Autonomous Database creates and secures the resource principal credentials you use to access the specified Oracle Cloud Infrastructure resources.
- Use Amazon Resource Names (ARNs) to Access AWS Resources
  You can use Amazon Resource Names (ARNs) to access AWS resources with Autonomous Database.
- Use Azure Service Principal to Access Azure Resources
  You can use an Azure service principal with Autonomous Database to access Azure resources without having to create and store your own credential objects in the database.
- Use Google Service Account to Access Google Cloud Platform Resources
  You can use a Google service account to access Google Cloud Platform (GCP) resources from an Autonomous Database instance.

Use Resource Principal to Access Oracle Cloud Infrastructure Resources

You can use an Oracle Cloud Infrastructure resource principal with Autonomous Database. You or your tenancy administrator define the Oracle Cloud Infrastructure policies and a dynamic group that allows you to access Oracle Cloud Infrastructure resources with a resource principal. You do not need to create a credential object and Autonomous Database creates and secures the resource principal credentials you use to access the specified Oracle Cloud Infrastructure resources.

- About Using Resource Principal to Access Oracle Cloud Infrastructure Resources
  You can use a resource principal to authenticate and access Oracle Cloud Infrastructure resources.
- Perform Prerequisites to Use Resource Principal with Autonomous Database
  Prior to making a call to an Oracle Cloud Infrastructure resource using a resource principal, an Oracle Cloud Infrastructure tenancy administrator must create Oracle Cloud Infrastructure policies, dynamic groups, and rules that define the resource principal privileges.
- Enable Resource Principal to Access Oracle Cloud Infrastructure Resources
  Perform the following steps to enable resource principal on Autonomous Database.
- Disable Resource Principal on Autonomous Database
  Shows the steps to disable resource principal for all Autonomous Database users or for a specified user.
- Use Resource Principal with DBMS_CLOUD
  When you specify resource principal credentials with `DBMS_CLOUD` calls, the database authenticates the Oracle Cloud Infrastructure requests for you and the database provides the credentials to access Oracle Cloud Infrastructure resources.

About Using Resource Principal to Access Oracle Cloud Infrastructure Resources

You can use a resource principal to authenticate and access Oracle Cloud Infrastructure resources.

A resource principal consists of a temporary session token and secure credentials that enable the database to authenticate itself to other Oracle Cloud Infrastructure services. Using a resource principal to access services, the token stored with the credentials on Autonomous Database is only valid for the resources to which the dynamic group has been granted access.

To use Resource Principal, you or your tenancy administrator define the Oracle Cloud Infrastructure policies and a dynamic group that allows you to access Oracle Cloud Infrastructure resources with a resource principal. You do not need to create a credential object and Autonomous Database creates and secures the resource principal credentials you use to access the specified Oracle Cloud Infrastructure resources.

For example, while using Autonomous Database you might want to use Oracle Cloud Infrastructure resources to do the following:

- Access data from an Object Storage bucket, perform some operation on the data, and then write the modified data back to the Object Storage bucket.
- Access your vaults, keys, or secrets.
- List work requests or list work request errors.

When you are working with the database, you authenticate and access the database as a database user. An Autonomous Database user does not have an Oracle Cloud Infrastructure Identity and Access Management (IAM) identity, so as an Autonomous Database user you

cannot use your database credentials to access Oracle Cloud Infrastructure services. Without a resource principal you must obtain credentials to access Oracle Cloud Infrastructure resources and create a credential object to access a resource from Autonomous Database.

A resource principal enables resources to be authorized to perform actions on Oracle Cloud Infrastructure services. Each resource has its own identity, and the resource authenticates using the certificates that are added to it. These certificates are automatically created, assigned to resources, and rotated, avoiding the need for you to create and manage your own credentials to access the resource.

Autonomous Database lets you use a resource principal to authenticate to Oracle Cloud Infrastructure APIs using the following interfaces:

- `DBMS_CLOUD` procedures and functions that take a credential argument
- Oracle Cloud Infrastructure PL/SQL SDK APIs

When you authenticate using a resource principal, Autonomous Database provides a secure method to access Oracle Cloud Infrastructure resources.

There are several steps required to set up a resource principal on Autonomous Database:

- You must create an define Oracle Cloud Infrastructure Infrastructure Identity and Access Management (IAM) policies. See Perform Prerequisites to Use Resource Principal with Autonomous Database for more information.
- You must enable the resource principal for the ADMIN user, and optionally enable the resource principal for a database user. See Enable Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

When you authenticate using a resource principal, you do not need to create and manage credentials to access Oracle Cloud Infrastructure resources. Autonomous Database makes the resource principal available to you and secures the resource principal for you.

Perform Prerequisites to Use Resource Principal with Autonomous Database

Prior to making a call to an Oracle Cloud Infrastructure resource using a resource principal, an Oracle Cloud Infrastructure tenancy administrator must create Oracle Cloud Infrastructure policies, dynamic groups, and rules that define the resource principal privileges.

Perform the following steps before you use a resource principal with Autonomous Database:

1. Create an Oracle Cloud Infrastructure dynamic group.
   a. In the Oracle Cloud Infrastructure console click **Identity and Security** and click **Dynamic Groups**
   b. Click **Create Dynamic Group** and enter a **Name**, a **Description**, and a rule or use the **Rule Builder** to add a rule.
   c. Click **Create**.

   Resources that meet the rule criteria are members of the dynamic group. When you define a rule for a dynamic group, consider what resource is going to be given access to other resources.

   For example, consider the following examples:

   - Allow a specific Autonomous Database instance to access a resource.

     The Autonomous Database is specified in the `resource.id` parameter with an OCID:

     ```
     resource.id = 'your_Autonomous_Database_instance_OCID'
     ```

You need to add a Domain Name when the tenancy uses an Identity Domain. For example:

```
resource.id = 'identity_domain_name/
your_Autonomous_Database_instance_OCID'
```

- Allow all Autonomous Databases in a compartment.

  The Autonomous Databases are specified in the `resource.type` parameter and the compartment is identified by a specified OCID in the `resource.compartment.id` parameter:

  ```
  ALL {resource.type = 'autonomousdatabase', resource.compartment.id =
  'your_Compartment_OCID'}
  ```

- Allow all resources in the compartment

  The resource type identified by the OCID, specified in the `resource.compartment.id` parameter:

  ```
  ALL
          {resource.compartment.id='your_Compartment_OCID'}
  ```

See Managing Dynamic Groups for more information on creating a dynamic group and creating rules to add resources to the group.

2. Write policy statements for the dynamic group to enable access to Oracle Cloud Infrastructure resources.
   a. In the Oracle Cloud Infrastructure console click **Identity and Security** and click **Policies**.
   b. To write policies for a dynamic group, click **Create Policy**, and enter a **Name** and a **Description**.
   c. Use the **Policy Builder** to create a policy.

      For example to create a policy to allow access to Oracle Cloud Infrastructure Object Store to manage buckets and objects in the Object Store in a tenancy:

      ```
      Allow dynamic-group Example5 to manage buckets in tenancy
      Allow dynamic-group Example5 to manage objects in tenancy
      ```

      You need to add a Domain Name when the tenancy uses an Identity Domain. For example:

      ```
      Allow dynamic-group identity_domain_name/Example5 to manage buckets in
      tenancy
      Allow dynamic-group identity_domain_name/Example5 to manage objects in
      tenancy
      ```

   d. Click **Create**.

> **Note:**
>
> The resource principal token is cached for two hours. Therefore, if you change the policy or the dynamic group, you have to wait for two hours to see the effect of your changes.

See How Policies Work and Managing Policies for more information on policies.

Enable Resource Principal to Access Oracle Cloud Infrastructure Resources

Perform the following steps to enable resource principal on Autonomous Database.

As a prerequisite, configure dynamic groups and policies. See Perform Prerequisites to Use Resource Principal with Autonomous Database for more information.

To enable a resource principal on Autonomous Database:

1. As the ADMIN user, enable resource principal for the Autonomous Database instance.

   For example:

   ```
   EXEC DBMS_CLOUD_ADMIN.ENABLE_RESOURCE_PRINCIPAL();

   PL/SQL procedure successfully completed.
   ```

   See ENABLE_RESOURCE_PRINCIPAL Procedure for more information.

   This creates the credential `OCI$RESOURCE_PRINCIPAL`.

2. (Optional) This step is only required if you want to grant access to the resource principal credential to a database user other than the ADMIN user. As the ADMIN user, enable resource principal for a specified database user.

   For example:

   ```
   EXEC DBMS_CLOUD_ADMIN.ENABLE_RESOURCE_PRINCIPAL(username => 'adb_user');

   PL/SQL procedure successfully completed.
   ```

   This grants the user `adb_user` access to the credential `OCI$RESOURCE_PRINCIPAL`.

   If you want the specified user to have privileges to enable resource principal for other users, set the `grant_option` parameter to `TRUE`.

   For example:

   ```
   BEGIN
   DBMS_CLOUD_ADMIN.ENABLE_RESOURCE_PRINCIPAL(
        username => 'adb_user',
        grant_option => TRUE);
   END;
   /
   ```

After you run this command, `adb_user` can enable resource principal for another user. For example, if you connect as `adb_user`, you can run the following command:

```
EXEC DBMS_CLOUD_ADMIN.ENABLE_RESOURCE_PRINCIPAL(username => 'adb_user2');
```

See ENABLE_RESOURCE_PRINCIPAL Procedure for more information.

3. Verify that the resource principal credential is enabled.

   For example, as the ADMIN user query the view `DBA_CREDENTIALS`:

```
SELECT owner, credential_name FROM dba_credentials
        WHERE credential_name = 'OCI$RESOURCE_PRINCIPAL' AND owner =
'ADMIN';

OWNER  CREDENTIAL_NAME
-----  ----------------------
ADMIN  OCI$RESOURCE_PRINCIPAL
```

   For example, as a non-ADMIN user query the view `ALL_TAB_PRIVS`:

```
SELECT grantee, table_name, grantor FROM ALL_TAB_PRIVS
   WHERE grantee = 'ADB_USER'
        AND table_name = 'OCI$RESOURCE_PRINCIPAL'
        AND table_schema = 'ADMIN';

GRANTEE   TABLE_NAME               GRANTOR
--------- -----------------------  -------------
ADB_USER  OCI$RESOURCE_PRINCIPAL   ADMIN
```

Enabling the resource principal on an Autonomous Database instance is one-time operation. You do not need to enable the resource principal again, unless you run `DBMS_CLOUD_ADMIN.DISABLE_RESOURCE_PRINCIPAL` to disable the resource principal.

Disable Resource Principal on Autonomous Database

Shows the steps to disable resource principal for all Autonomous Database users or for a specified user.

1. To disable resource principal for all users, as the ADMIN user, run the following command:

```
EXEC DBMS_CLOUD_ADMIN.DISABLE_RESOURCE_PRINCIPAL();
```

   This removes the credential `OCI$RESOURCE_PRINCIPAL`.

2. Verify that the resource principal credential is disabled.

   For example:

```
SELECT owner, credential_name FROM dba_credentials
        WHERE credential_name = 'OCI$RESOURCE_PRINCIPAL' AND owner =
'ADMIN';

No rows selected
```

To remove access to the resource principal credential for a specified database user, include the `username` parameter. This denies the specified user access to the `OCI$RESOURCE_PRINCIPAL` credential.

For example:

```
EXEC DBMS_CLOUD_ADMIN.DISABLE_RESOURCE_PRINCIPAL(username => 'ADB_USER');
```

See DISABLE_RESOURCE_PRINCIPAL Procedure for more information.

Use Resource Principal with DBMS_CLOUD

When you specify resource principal credentials with `DBMS_CLOUD` calls, the database authenticates the Oracle Cloud Infrastructure requests for you and the database provides the credentials to access Oracle Cloud Infrastructure resources.

If you have not already done so, perform the required prerequisite steps:

- Access to Oracle Cloud Infrastructure resources depends on the dynamic group rules and the policies you set in Oracle Cloud Infrastructure policies and dynamic groups. See Perform Prerequisites to Use Resource Principal with Autonomous Database for more information.
- After you define the dynamic group and policies, enable the ADMIN schema or another schema to use a resource principal. See Enable Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

To use a `DBMS_CLOUD` procedure with resource principal credentials:

- Use a `DBMS_CLOUD` procedure or function and specify `OCI$RESOURCE_PRINCIPAL` as the credential name.

  For example, you can access Oracle Cloud Infrastructure Object Storage using a resource principal:

```
CREATE TABLE CHANNELS
   (channel_id CHAR(1),
    channel_desc VARCHAR2(20),
    channel_class VARCHAR2(20)
   );
/

BEGIN
 DBMS_CLOUD.COPY_DATA(
    table_name =>'CHANNELS',
    credential_name =>'OCI$RESOURCE_PRINCIPAL',
    file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/channels.txt',
    format => json_object('delimiter' value ',')
 );
END;
/
```

If you compare the steps required to access Object Storage as shown in Create Credentials and Copy Data into an Existing Table, notice that Step 1, creating credentials is not required when you use resource principal because you are using the system defined `OCI$RESOURCE_PRINCIPAL` credential.

Use Amazon Resource Names (ARNs) to Access AWS Resources

You can use Amazon Resource Names (ARNs) to access AWS resources with Autonomous Database.

- About Using Amazon Resource Names (ARNs) to Access AWS Resources
  When you use ARN role based authentication with Autonomous Database, you can securely access AWS resources without creating and saving credentials based on long-term AWS IAM access keys.
- Perform AWS Management Prerequisites to Use Amazon Resource Names (ARNs)
  Using the AWS Management Console or using the APIs, create an AWS user, role, policies, and trust relationship. You perform these steps before you use with `DBMS_CLOUD.CREATE_CREDENTIAL` to create a credential with an ARN parameter on Autonomous Database.
- Perform Autonomous Database Prerequisites to Use Amazon ARNs
  Prior to using an AWS resource with `DBMS_CLOUD.CREATE_CREDENTIAL` with an ARN parameter, the ADMIN user must enable ARN on the Autonomous Database instance.
- Create Credentials with ARN Parameters to Access AWS Resources
  After ARN usage is enabled for the Autonomous Database instance and the ARN is configured by the AWS administrator, on Autonomous Database you can create a credential object with ARN parameters.
- Update Credentials with ARN Parameters for AWS Resources
  The ARN credentials you use on Autonomous Database work with the AWS token service that enables you to use temporary role based credentials to access to AWS resources from Autonomous Database.

About Using Amazon Resource Names (ARNs) to Access AWS Resources

When you use ARN role based authentication with Autonomous Database, you can securely access AWS resources without creating and saving credentials based on long-term AWS IAM access keys.

For example, you may want to load data from an AWS S3 bucket into your Autonomous Database, perform some operation on the data, and then write the modified data back to the S3 bucket. You can do this without using an ARN if you have AWS user credentials to access the S3 bucket. However, using role-based ARNs to access AWS resources from Autonomous Database has the following benefits:

- You can create role-based access, with different policies for different users or schemas that need access to AWS resources from an Autonomous Database instance. This allows you to set a policy to limit access to AWS resources by role. For example, setting a policy limiting to read-only access, by role, to an S3 bucket.
- ARN based credentials provide better security as you do not need to provide long-term AWS user credentials in code to access AWS resources. Autonomous Database manages the temporary credentials generated from the AWS Assume Role Operation.

Steps to Configure ARN Usage with Autonomous Database

Before creating a credential using an ARN in Autonomous Database, in AWS, your account administrator must define a policy that allows you to access AWS resources, such as an S3 bucket. By default, ARN credential services are not enabled on Autonomous Database. The ADMIN user enables ARN credentials for the necessary user which allows them to create and use ARN credentials on the Autonomous Database instance.

In AWS, the role ARN is the identifier for the provided access and can be viewed on the AWS console. For added security, when the AWS administrator configures the role, policies, and trust relationship for the AWS account, they must also configure an External ID in the role's trust relationship.

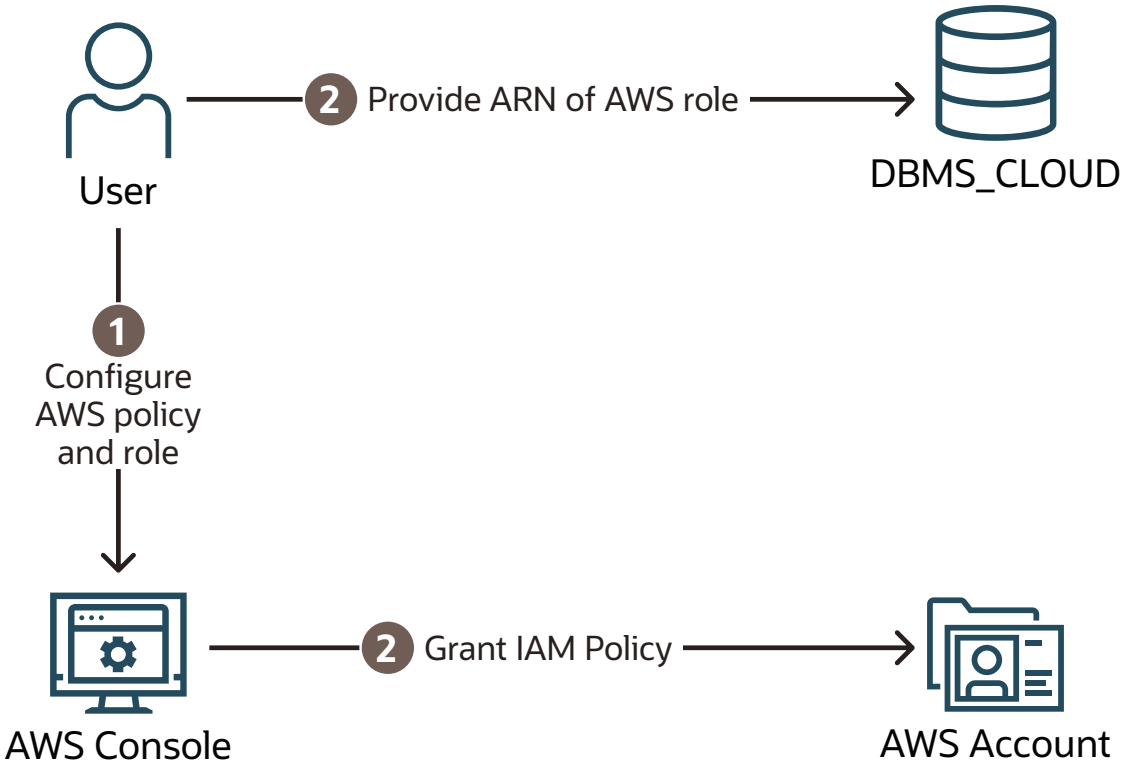
The External ID provides additional protection for assuming roles. The AWS administrator configures configure the External ID as one of the following, based on the Autonomous Database instance:

- The compartment OCID
- The database OCID
- The tenancy OCID

On AWS, the role can only be assumed by trusted users that are identified by the External ID included in the request URL, where the supplied External ID in the request matches the External ID configured in the role's trust relationship.

> **Note:**
>
> Setting the External ID is required for security.

The following figure outlines the configuration steps:



Steps to Use ARNs with DBMS_CLOUD

Each AWS resource has its own identity, and the resource authenticates with the Autonomous Database instance using a `DBMS_CLOUD` credential that you create with parameters that identify the ARN. Autonomous Database creates and secures the principal credentials you use to access AWS resources.

To create a credential with ARN parameters to access AWS resources:

1. Perform prerequisite steps in the AWS Account: In your AWS account, from the AWS Management Console or using the CLI, create the roles and policies for the ARN that you use with Autonomous Database and update the trust relationship for the role. The Oracle user ARN is configured when the trust relationship for the role is updated.

   See Perform AWS Management Prerequisites to Use Amazon Resource Names (ARNs) for more information.

2. Perform prerequisite steps on Autonomous Database: On Autonomous Database you must enable the ADMIN user or another user to use credentials with ARN parameters to access AWS resources.

   See Perform Autonomous Database Prerequisites to Use Amazon ARNs for more information.

3. Create credentials with `DBMS_CLOUD.CREATE_CREDENTIAL` and supply the parameters that identify an AWS role. Using the credential object, Autonomous Database can access AWS resources as specified in the policies defined for the role in the AWS account.

   See Create Credentials with ARN Parameters to Access AWS Resources for details on these steps.

4. Use the credential object you created in the previous step with a `DBMS_CLOUD` procedure or function that takes a credential parameter, such as `DBMS_CLOUD.COPY_DATA` or `DBMS_CLOUD.LIST_OBJECTS`.

Perform AWS Management Prerequisites to Use Amazon Resource Names (ARNs)

Using the AWS Management Console or using the APIs, create an AWS user, role, policies, and trust relationship. You perform these steps before you use with `DBMS_CLOUD.CREATE_CREDENTIAL` to create a credential with an ARN parameter on Autonomous Database.

To use an ARN to access AWS resources your AWS administrator defines the policies and a principal that allows you to access AWS resources. For example, while using Autonomous Database you might want to access data from an S3 bucket, perform some operation on the data, and then write the modified data back to the S3 bucket.

> **Note:**
>
> Depending on your existing AWS configuration and the External ID you use, you do not need to create a new role and policy for each Autonomous Database instance. If you already have an AWS role containing the necessary policy to access a resource, for example to access S3 cloud storage, you can modify the trust relationship to include the details in Step 3. Likewise, if you already have a role with the necessary trust relationship, you can use that role to access all of your databases in an OCI compartment or tenancy if you use an external ID that specifies the compartment OCID or tenancy OCID.

From the AWS Management Console or using the APIs, an AWS administrator performs the following steps:

1. Create a policy. In the policy you specify permissions for accessing AWS resources such as S3 buckets.

   See Creating an IAM policy to access Amazon S3 resources for more information.

2. Create a role and attach the policy to the role.
   a. Access the AWS Management Console and choose Identity and Access Management (IAM).
   b. Click **Create role**.

   c. Select **Another AWS account**.

   d. Enter your **Account ID**.

      You use this as a temporary value. Later you replace this with the Account ID you use to access AWS resources.

   e. In the **Options** area select **Require external ID** and enter a temporary external ID, such as `0000`. Later you replace this external ID with a valid value.
   f. Click **Next Permissions** to attach the Policies you created in Step 1 or other policies you want to apply to the role.
   g. Click **Next Tags** and apply or create tags as needed for the role.
   h. Click **Next Review** and add a **Role Name** and **Role Description**.
   i. Click **Create Role**.

You use the role's ARN with `DBMS_CLOUD.CREATE_CREDENTIAL` to create credential objects with ARN parameters to access AWS resources.

See Creating a role to delegate permissions to an IAM user for more information.

3. Specify a Trust Relationship for the role.
   a. From the Roles list, under **Role name**, select the role you created.
   b. On the roles Summary page for the selected role, select the **Trust relationships** tab.

   c. In the trust relationship, click **Edit trust relationship**.

   d. Edit the trust relationship to specify the Principal parameter **AWS**.

      This AWS user ARN is available in the CLOUD_INTEGRATIONS view. See Perform Autonomous Database Prerequisites to Use Amazon ARNs for more information.

   e. Edit the trust relationship to specify the External ID.

      On Autonomous Database when you create an AWS ARN credential with `DBMS_CLOUD.CREATE_CREDENTIAL` or when you enable AWS ARN with `DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH`, by default the `external_id_type` parameter value is `database_ocid`. Optionally you can set the `external_id_type` value to one of the supported values: `database_ocid`, `compartment_ocid`, or `tenant_ocid`.

      When you use the database OCID as the External ID, the policy's trust relationship only trusts the Autonomous Database instance specified with the OCID. If you use a compartment OCID, the policy's trust relationship trusts all the Autonomous Database instances in the compartment and you can use the same role ARN to grant access to AWS resources to any Autonomous Database in the specified compartment. Likewise,

if you use the tenancy OCID, you can use the same role ARN to grant access to AWS resources to any Autonomous Database in the specified tenancy.

Previously in Step 2 you set the trust relationship External ID to the temporary value `0000`.

On AWS you configure the trust relationship External ID value to match one of the following:

- When the `external_id_type` type is `database_ocid`, on AWS you configure the role's trust relationship External ID to be the Database OCID.

  The Database OCID is available by running the following query:

  ```
  SELECT cloud_identity FROM v$pdbs;
  ```

  See Obtain Tenancy Details for more information.

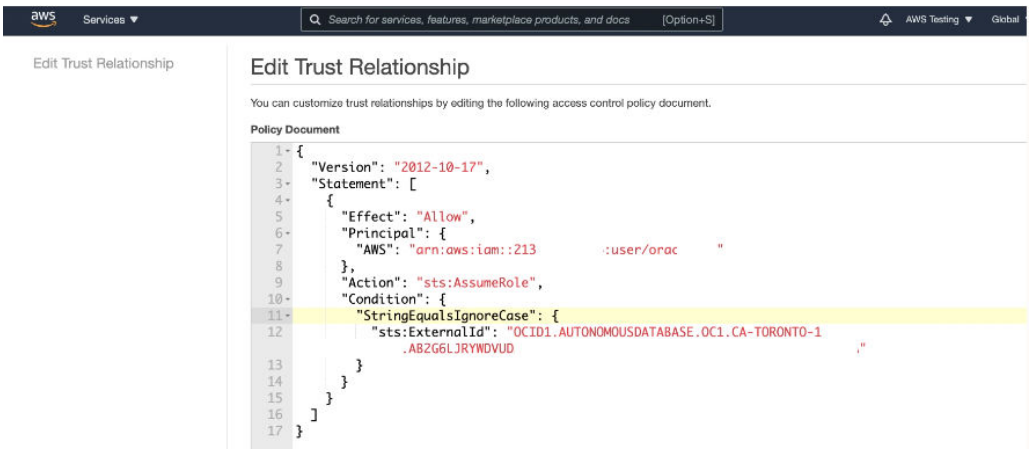
- When the `external_id_type` type is `compartment_ocid`, on AWS you configure the role's trust relationship External ID to be the Compartment OCID.

  The Compartment OCID is available on the Compartment details page from the Oracle Cloud Infrastructure Console. To find the Compartment details page, from the Oracle Cloud Infrastructure left navigation menu click **Identity & and Security** and then select **Compartments**. Select the compartment that contains the Autonomous Database instance to see the Compartment ID.

- When the `external_id_type` type is `tenant_ocid`, on AWS you configure the role's trust relationship External ID to be the Tenancy OCID.

  The Tenancy OCID is available on the Tenancy details page from the Oracle Cloud Infrastructure Console. To find the Tenancy details page, from the Oracle Cloud Infrastructure left navigation menu click **Governance & Administration** and then select **Tenancy Details**. The Tenancy Information tab shows the Tenancy OCID.

- When you set the value for ExternalID, by default the OCID value must be in upper case. If you want to supply the OCID in lower case, set the condition "`StringEqualsIgnoreCase`" instead of "`StringEquals`" in the JSON when you edit the trust relationship.



See How to use trust policies with IAM role and How to use an external ID when granting access to your AWS resources to a third party for more information.

After the ARN role configuration is finished, you can enable ARN on the instance. See Perform Autonomous Database Prerequisites to Use Amazon ARNs for more information.

Perform Autonomous Database Prerequisites to Use Amazon ARNs

Prior to using an AWS resource with `DBMS_CLOUD.CREATE_CREDENTIAL` with an ARN parameter, the ADMIN user must enable ARN on the Autonomous Database instance.

By default, ARN credential services are not enabled on Autonomous Database. The ADMIN user runs the procedure `DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH` to enable the ADMIN user or other users to create credentials with ARN parameters.

1. Enable the use of ARN credentials on the Autonomous Database instance.

```
BEGIN
    DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
        username => 'adb_user',
        params => JSON_OBJECT(
                'aws_role_arn' value 'arn:aws:iam::123456:role/
AWS_ROLE_ARN'));
END;
/
```

If you want the specified user to have privileges to enable ARN credentials for other users, set the `params` parameter `grant_option` to `TRUE`.

For example:

```
BEGIN
DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
     username => 'adb_user',
     params => JSON_OBJECT(
                    'aws_role_arn' value 'arn:aws:iam::123456:role/
AWS_ROLE_ARN',
                    'grant_option' value TRUE ));
END;
/
```

After you run this command, `adb_user` has privileges to enable ARN credentials for other users.

For example, if you connect as `adb_user`, you can run the following command:

```
BEGIN
    DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
        username => 'adb_user2');
END;
/
```

See ENABLE_PRINCIPAL_AUTH Procedure for more information.

2. Query the `CLOUD_INTEGRATIONS` view to obtain Oracle's AWS user ARN.

```
SELECT param_value FROM CLOUD_INTEGRATIONS
        WHERE param_name = 'aws_user_arn';

PARAM_VALUE
```

```
-----------------------------------------
arn:aws:iam::account-ID:user/username
```

The view `CLOUD_INTEGRATIONS` is available to the ADMIN user or to a user with `DWROLE` privileges.

The AWS administrator uses the `aws_user_arn` value when configuring the AWS role's trust relationship with the role and policies on the AWS system. Providing this value grants permission on the AWS side for `DBMS_CLOUD` to access AWS resources.

After you enable ARN on the Autonomous Database instance by running `DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH`, the credential named `AWS$ARN` is available to use with any `DBMS_CLOUD` API that takes a credential as the input. Except for the credential named `AWS$ARN`, you can also create additional credentials with ARN parameters to access AWS resources. See Create Credentials with ARN Parameters to Access AWS Resources for more information.

Create Credentials with ARN Parameters to Access AWS Resources

After ARN usage is enabled for the Autonomous Database instance and the ARN is configured by the AWS administrator, on Autonomous Database you can create a credential object with ARN parameters.

Autonomous Database creates and secures the principal credentials you use to access the Amazon resources when you supply the credential object with `DBMS_CLOUD` procedures and functions.

To use Amazon resources with Autonomous Database, do the following:

1. Create credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL` with the `params` parameter to specify the ARN value. For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_ARN',
    params =>
        JSON_OBJECT('aws_role_arn' value 'arn:aws:iam::123456:role/
AWS_ROLE_ARN',
                    'external_id_type' value 'database_ocid')
  );
END;
/
```

This operation creates the credentials in the database in an encrypted format. You can use any name for the credential name.

For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

2. Use a `DBMS_CLOUD` procedure to access an Amazon resource with the ARN credentials.

For example, use `DBMS_CLOUD.LIST_OBJECTS`.

```
SELECT object_name FROM DBMS_CLOUD.LIST_OBJECTS(
           credential_name => 'DEF_CRED_ARN',
           location_uri    => 'https://my-bucket.s3.us-
west-2.amazonaws.com/');
```

Update Credentials with ARN Parameters for AWS Resources

The ARN credentials you use on Autonomous Database work with the AWS token service that enables you to use temporary role based credentials to access to AWS resources from Autonomous Database.

When an AWS Administrator revokes the policies, roles, or trust relationship, you need to either update the credentials or create new credentials to access the AWS resources.

Perform the following steps to update credentials:

1. Use `DBMS_CLOUD.UPDATE_CREDENTIAL` to update an ARN based credential to supply a new ARN value.

```
BEGIN
  DBMS_CLOUD.UPDATE_CREDENTIAL(
     credential_name => 'DEF_CRED_ARN',
     attribute => 'aws_role_arn',
     value => 'new_ARN_value');
END;
/
```

   This updates the `aws_role_arn` attribute to the new value *`new_ARN_value`* for the credential named DEF_CRED_ARN.

2. Use `DBMS_CLOUD.UPDATE_CREDENTIAL` to update an ARN based credential to update the attribute `external_id_type` value.

```
BEGIN
  DBMS_CLOUD.UPDATE_CREDENTIAL(
     credential_name => 'DEF_CRED_ARN',
     attribute => 'external_id_type',
     value => 'compartment_ocid');
END;
/
```

   This updates the `external_id_type` attribute value to the value `compartment_ocid`.

See UPDATE_CREDENTIAL Procedure and CREATE_CREDENTIAL Procedure for more information.

Use Azure Service Principal to Access Azure Resources

You can use an Azure service principal with Autonomous Database to access Azure resources without having to create and store your own credential objects in the database.

- Enable Azure Service Principal
  Enable Azure service principal authentication to allow Autonomous Database to access Azure services without providing long-term credentials.
- Provide Azure Application Consent and Assign Roles
  To access Azure resources from Autonomous Database with Azure service principal authentication you must consent the Azure application and assign roles to allow access to your Azure resources.

- Use Azure Service Principal with DBMS_CLOUD
  When you make `DBMS_CLOUD` calls to access Azure resources and specify the credential name as `AZURE$PA`, the authentication on the Azure side happens using the Azure service principal.
- Disable Azure Service Principal
  To disable access to Azure resources from Autonomous Database with Azure service principal, use `DBMS_CLOUD_ADMIN.DISABLE_PRINCIPAL_AUTH`.
- Notes for Azure Service Principal
  Notes for using Azure service principal.

Enable Azure Service Principal

Enable Azure service principal authentication to allow Autonomous Database to access Azure services without providing long-term credentials.

> **Note:**
>
> To use Autonomous Database with Azure service principal authentication you need a Microsoft Azure account. See Microsoft Azure for details.

To enable Azure service principal authentication on Autonomous Database:

1. Obtain your Microsoft Azure Active Directory tenant ID.

   See How to find your Azure Active Directory tenant ID for more information.

2. Enable Azure service principal with `DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH`.

   For example:

```
BEGIN
    DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
        provider => 'AZURE',
        username => 'adb_user',
        params   => JSON_OBJECT('azure_tenantid' value 'azure_tenantID'));
END;
/
```

   This enables Azure service principal authentication and creates an Azure application on Autonomous Database.

   If you want the specified user to have privileges to enable Azure service principal for other users, set the `params` parameter `grant_option` to `TRUE`.

   For example:

```
BEGIN
    DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
        provider => 'AZURE',
        username => 'adb_user',
        params   => JSON_OBJECT('grant_option' value TRUE,
                                'azure_tenantid' value 'azure_tenantID'));
END;
/
```

After you run this command, `adb_user` can enable Azure service principal for another user. For example, if you connect as `adb_user`, you can run the following command:

```
BEGIN
    DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
        provider => 'AZURE',
        username => 'adb_user2');
END;
/
```

See ENABLE_PRINCIPAL_AUTH Procedure for more information.

Provide Azure Application Consent and Assign Roles

To access Azure resources from Autonomous Database with Azure service principal authentication you must consent the Azure application and assign roles to allow access to your Azure resources.

To provide Azure application consent and assign roles, perform the following steps:

1. On Autonomous Database query `CLOUD_INTEGRATIONS`.

   For example:

   ```
   SELECT param_name, param_value FROM CLOUD_INTEGRATIONS;

   PARAM_NAME        PARAM_VALUE
   ---------------
   ------------------------------------------------------------------------
   ------------------------------------------------------------------
   azure_tenantid    29981886-6fb3-44e3-82ab-d870b0e8e7eb
   azure_consent_url https://login.microsoftonline.com/f8cdef31-91255a/oauth2/
   v2.0/authorize?
   client_id=d66f1b5-1250d5445c0b&response_type=code&scope=User.read
   azure_app_name
   ADBS_APP_OCID1.AUTONOMOUSDATABASE.REGION1.SEA.ANZWKLJSZLYNB3AAWLYL3JVC4ICEX
   LB3ZG6WTCX735JSSY2NRHOBU4DZOOVA
   ```

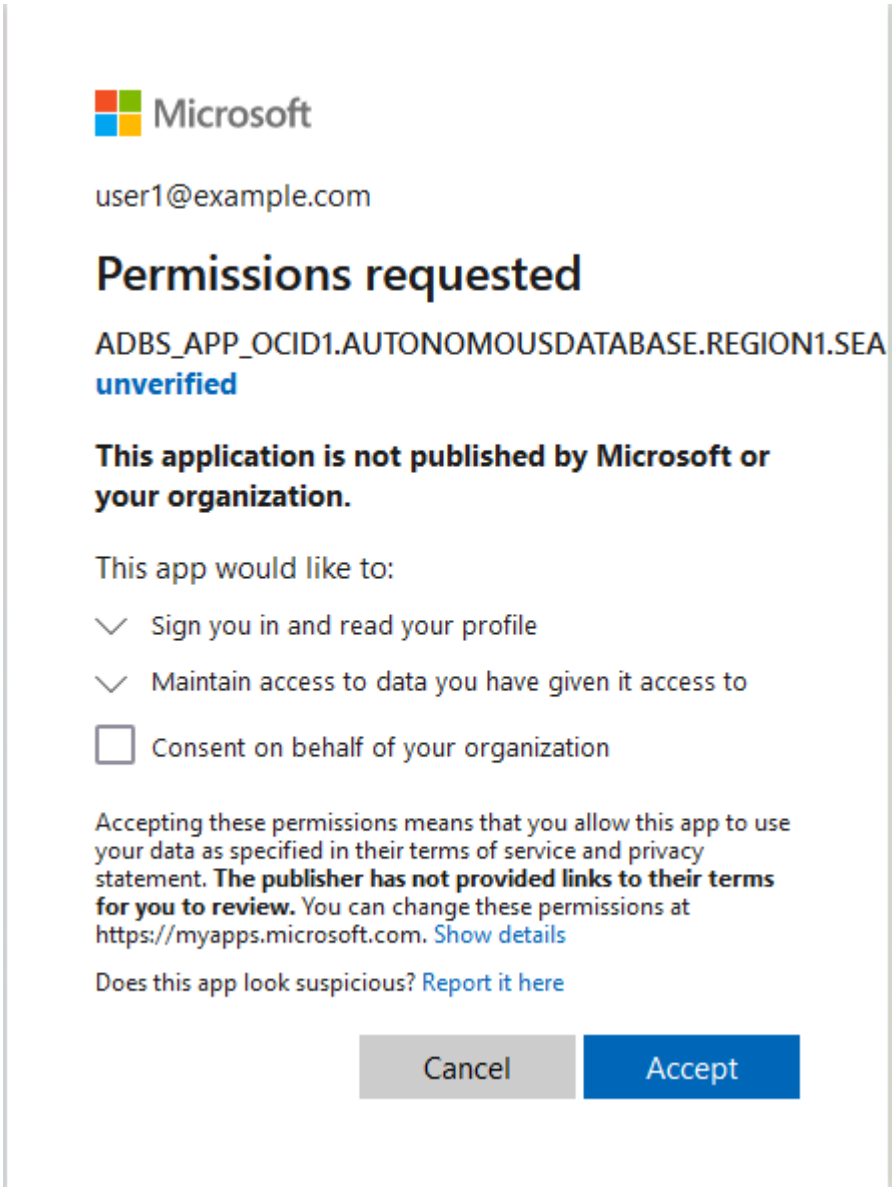
   The view `CLOUD_INTEGRATIONS` is available to the `ADMIN` user or to a user with `DWROLE` role.

2. In a browser, open the Azure consent URL, specified by the `azure_consent_url` parameter.

   For example, copy and enter the URL in your browser:

   ```
   https://login.microsoftonline.com/f8cdef31-91255a/oauth2/v2.0/authorize?
   client_id=d66f1b5-1250d5445c0b&response_type=code&scope=User.read
   ```

   The **Permissions requested** page opens and shows a consent request, similar to the following:



3. To provide consent click **Accept**.
4. On the Microsoft Azure console, assign the roles you want to grant to allow access to the specified Azure resources.

   For example, if you want to access Azure Blob Storage from Autonomous Database, assign roles so that the Azure application (the service principal) has access to Azure Blob Storage.

> **Note:**
>
> To work with Azure Blob Storage, you need an Azure storage account. If you do not have an Azure storage account, create a storage account. See Create a storage account for more information.

   a. On the Microsoft Azure console, under **Azure services**, select **Storage accounts**.

b. Under **Storage accounts**, click the storage account you want to grant service principal access to.

c. On the left, click **Access Control (IAM)**.

d. From the top area, click **+ Add → Add role assignment**.

e. In the search area enter text to narrow the list of roles that you see. For example, enter **Storage Blob** to show the available roles that contain **Storage Blob**.

f. Select one or more roles as appropriate for the access you want to grant. For example, select **Storage Blob Data Contributor**.

g. Click **Next**.

h. In the **Add role assignment**, under **Members** click **+ Select members**.

i. Under **Select members**, in the select field, enter the `azure_app_name` listed in Step 1 (the `param_value` column of the `CLOUD_INTEGRATIONS` view).

j. Select the application.

For example, click `ADBS_APP_OCID1.AUTONOMOUSDATABASE.REGION1.SEA.ANZWKLJSZLYNB3AAWLYL3JVC4ICEXLB3ZG6WTCX735JSSY2NRHOBU4DZOOVA`

k. Click **Select**.

l. Click **Review + assign**.

5. Click **Review + Assign** again.

After assigning a role you need to wait, as role assignments may take up to five minutes to propagate in Azure.

This example shows steps to grant roles for accessing Azure Blob Storage. If you want to provide access for other Azure services you need to perform equivalent steps for the additional Azure services to allow the Azure application (the service principal) to access the Azure service.

Use Azure Service Principal with DBMS_CLOUD

When you make `DBMS_CLOUD` calls to access Azure resources and specify the credential name as `AZURE$PA`, the authentication on the Azure side happens using the Azure service principal.

If you have not already done so, perform the required prerequisite steps:

- Enable the ADMIN schema or another schema to use Azure service principal authentication. See Enable Azure Service Principal for more information.
- Consent the application and perform the Azure role assignment grants. See Provide Azure Application Consent and Assign Roles for more information.

To use a `DBMS_CLOUD` procedure or function with Azure service principal, specify `AZURE$PA` as the credential name. For example, you can access Azure Blob Storage using Azure service principal credentials as follows:

```
SELECT * FROM DBMS_CLOUD.LIST_OBJECTS('AZURE$PA', 'https://
treedata.blob.core.windows.net/treetypes/');

OBJECT_NAME BYTES CHECKSUM                CREATED
LAST_MODIFIED
----------- ----- ----------------------- --------------------
--------------------
```

```
trees.txt      58 aCB1qMOPVobDLCXG+2fcvg== 2022-04-07T23:03:01Z
2022-04-07T23:03:01Z
```

If you compare the steps required to access object storage, as shown in Create Credentials and Copy Data into an Existing Table, notice that Step 1, creating credentials is not required because you are using an Azure service principal called `AZURE$PA`.

Disable Azure Service Principal

To disable access to Azure resources from Autonomous Database with Azure service principal, use `DBMS_CLOUD_ADMIN.DISABLE_PRINCIPAL_AUTH`.

To disable Azure service principal on Autonomous Database:

```
BEGIN
    DBMS_CLOUD_ADMIN.DISABLE_PRINCIPAL_AUTH(
        provider => 'AZURE',
        username => 'adb_user');
END;
/
```

When the `provider` value is `AZURE` and the `username` is a user other than the `ADMIN` user, the procedure revokes the privileges from the specified user. In this case, the `ADMIN` user and other users can continue to use `ADMIN.AZURE$PA` and the application that is created for the Autonomous Database instance remains on the instance.

When the `provider` value is `AZURE` and the `username` is `ADMIN`, the procedure disables Azure service principal based authentication and deletes the Azure service principal application on the Autonomous Database instance. In this case, if you want to enable Azure service principal you must perform all the steps required to use Azure service principal again, including the following:

- Enable the `ADMIN` schema or another schema to use Azure service principal authentication. See Enable Azure Service Principal for more information.
- Consent the application and perform the Azure role assignment grants. See Provide Azure Application Consent and Assign Roles for more information.

See DISABLE_PRINCIPAL_AUTH Procedure for more information.

Notes for Azure Service Principal

Notes for using Azure service principal.

- **Cloning an Autonomous Database instance with Azure service principal**: When you clone an instance with Azure service principal enabled, the Azure service principal configuration is not carried over to the clone. Perform the steps to enable Azure service principal on the clone if you want to enable Azure service principal on a cloned instance.

Use Google Service Account to Access Google Cloud Platform Resources

You can use a Google service account to access Google Cloud Platform (GCP) resources from an Autonomous Database instance.

- About Using a Google Service Account to Access Google Cloud Resources
  When you use Google service account based authentication with Autonomous Database, an application can securely access Google Cloud Platform (GCP) resources without

creating and saving credentials based on long-term IAM access keys for the GCP resources.

- Enable Google Service Account and Find the GCP Service Account Name
  Prior to using a Google Cloud Platform (GCP) resource with a Google service account you need to enable GCP access for your Autonomous Database instance.
- Assign Roles to the Google Service Account and Provide Access for GCP Resources
  To use Google Cloud Platform (GCP) resources from an Autonomous Database instance, you or a Google Cloud Administrator must assign roles and privileges to the Google service account that your application accesses. In addition to assigning roles for the Google service account, for any GCP resources you want to use a Google Cloud administrator must add Google IAM principals.
- Use Google Service Account with DBMS_CLOUD
  When you make `DBMS_CLOUD` calls to access Google Cloud Platform (GCP) resources and specify the credential name as `GCP$PA`, the authentication on the Google Cloud Platform side happens using a Google service account.
- Disable Google Service Account
  To disable Google service account access to Google Cloud Platform (GCP) resources, use `DBMS_CLOUD_ADMIN.DISABLE_PRINCIPAL_AUTH`.
- Google Service Account Notes
  Notes for using Google service account.

About Using a Google Service Account to Access Google Cloud Resources

When you use Google service account based authentication with Autonomous Database, an application can securely access Google Cloud Platform (GCP) resources without creating and saving credentials based on long-term IAM access keys for the GCP resources.

A Google service account is a special kind of GCP account used by an application. You can use a Google service account to make authorized GCP REST API calls from an application (after the service account is given access permissions through IAM role configuration). When an application makes calls with GCP service account based authentication, the initial call generates a temporary access token through OAuth2.0. The OAuth2.0 access token is valid for one hour. Subsequent requests within the hour use the OAuth2.0 access token to make authorized GCP REST API calls.

For example, you may want to load data from Google Cloud Storage into your Autonomous Database, perform some operation on the data, and then write the modified data back to Google Cloud Storage. You can do this without using a service account if you have GCP user credentials to access Google Cloud Storage. However, using a role-based Google service account to access GCP resources from Autonomous Database has the following benefits:

- You can create role-based access, with different policies for different users or schemas that need access to GCP resources from an Autonomous Database instance. This allows you to set a policy to limit access to resources by role. For example, setting a policy that is limited to read-only access, by role, to a Google Cloud Storage bucket.
- Google service account based credentials provide better security, as you do not need to provide long-term user credentials in code when your application accesses GCP resources. Autonomous Database manages the temporary credentials for the Google service account and does not need to store GCP resource user credentials in the database.

See Service accounts for information on Google service accounts.

Enable Google Service Account and Find the GCP Service Account Name

Prior to using a Google Cloud Platform (GCP) resource with a Google service account you need to enable GCP access for your Autonomous Database instance.

1. Enable Google service account authentication with `DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH`.

   For example, to enable Google service account authentication for the `ADMIN` user:

   ```
   BEGIN
       DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
           provider => 'GCP' );
   END;
   /
   ```

   Enable Google service account authentication for a non-`ADMIN` user, `adb_user` as follows:

   ```
   BEGIN
       DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
           provider => 'GCP',
           username => 'adb_user');
   END;
   /
   ```

   If you want the specified user to have privileges to enable Google service account authentication for other users, set the `params` parameter `grant_option` to `TRUE`.

   ```
   BEGIN
       DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
           provider => 'GCP',
           username => 'adb_user',
           params   => JSON_OBJECT('grant_option' value TRUE));
   END;
   /
   ```

   After you run `DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH` with `grant_option` set to `TRUE`, `adb_user` can enable Google service account authentication for another user. For example, if you connect as `adb_user`, you can run the following command to enable GCP service account access for `adb_user2`:

   ```
   BEGIN
       DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH(
           provider => 'GCP',
           username => 'adb_user2');
   END;
   /
   ```

2. When `DBMS_CLOUD_ADMIN.ENABLE_PRINCIPAL_AUTH` runs it creates a Google service account. Query `CLOUD_INTEGRATIONS` to obtain the service account details for your Autonomous Database instance.

```
SELECT * FROM CLOUD_INTEGRATIONS WHERE param_name = 'gcp_service_account';

PARAM_NAME           PARAM_VALUE
-------------------------------------------------------------------------
gcp_service_account  GCP-SA-22222-32222@gcp-example.iam.gserviceaccount.com
```

3. Note the `gcp_service_account` parameter value as you must supply this value when you configure GCP resources.

See ENABLE_PRINCIPAL_AUTH Procedure for more information.

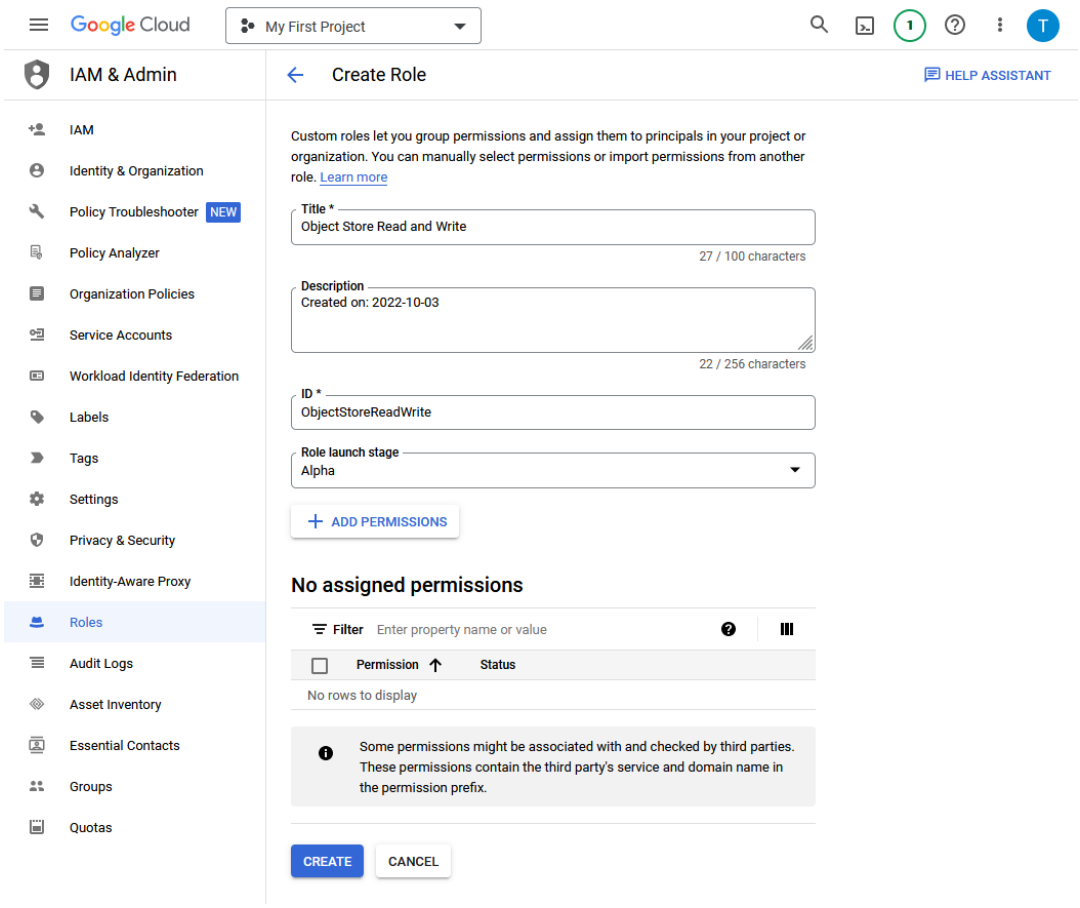
Assign Roles to the Google Service Account and Provide Access for GCP Resources

To use Google Cloud Platform (GCP) resources from an Autonomous Database instance, you or a Google Cloud Administrator must assign roles and privileges to the Google service account that your application accesses. In addition to assigning roles for the Google service account, for any GCP resources you want to use a Google Cloud administrator must add Google IAM principals.

As a prerequisite, first enable the Google service account on your Autonomous Database instance. See Enable Google Service Account and Find the GCP Service Account Name for more information.

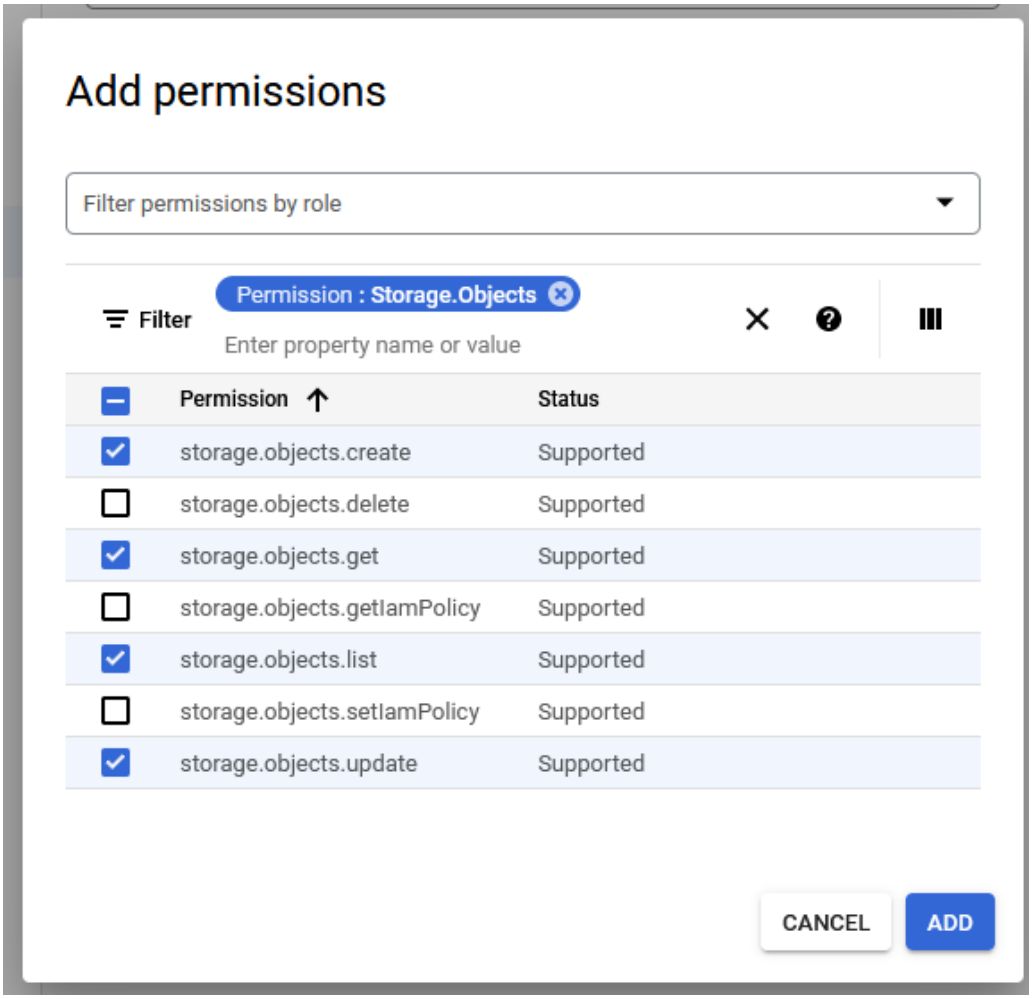
1. Open the Google Cloud Console for your account.
2. Create roles with the specified permissions.
   a. From the navigation menu, select **IAM & Admin**.
   b. From the IAM & Admin navigator, select **Roles**.
   c. On the Roles page, click More Actions and select **+ CREATE ROLE**.

   For example, you can create a role **Object Store Read and Write** to control the use of an Object Store bucket.



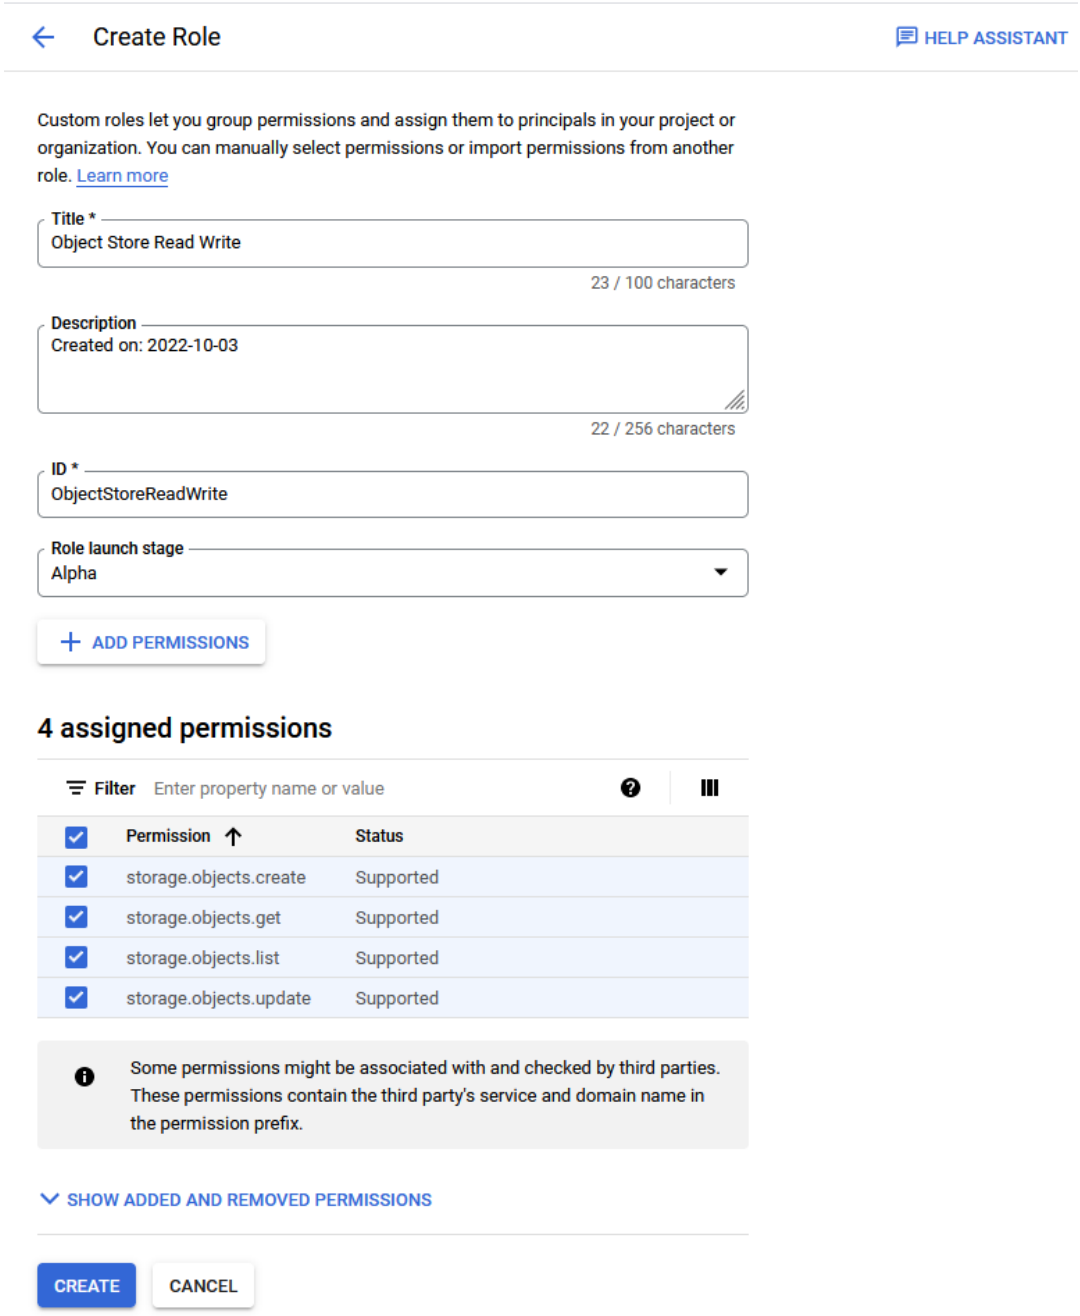
3. On the Create Role page, click **+ ADD PERMISSIONS**.
   a. Select filters to limit the list of permissions.

      For example, enter the filter **Permission: Storage.Objects** to show only the Object Store permissions.



b. On the Add permissions dialog, click **ADD**.

4. On the Create Role page, click **CREATE**.



5. Add roles and principals for the resource you want to access.

   For example, if you want to access Google Cloud Storage using the role you just created, **Object Store Read Write**:

   a. From the navigator, select **Cloud Storage** and select **Buckets**.

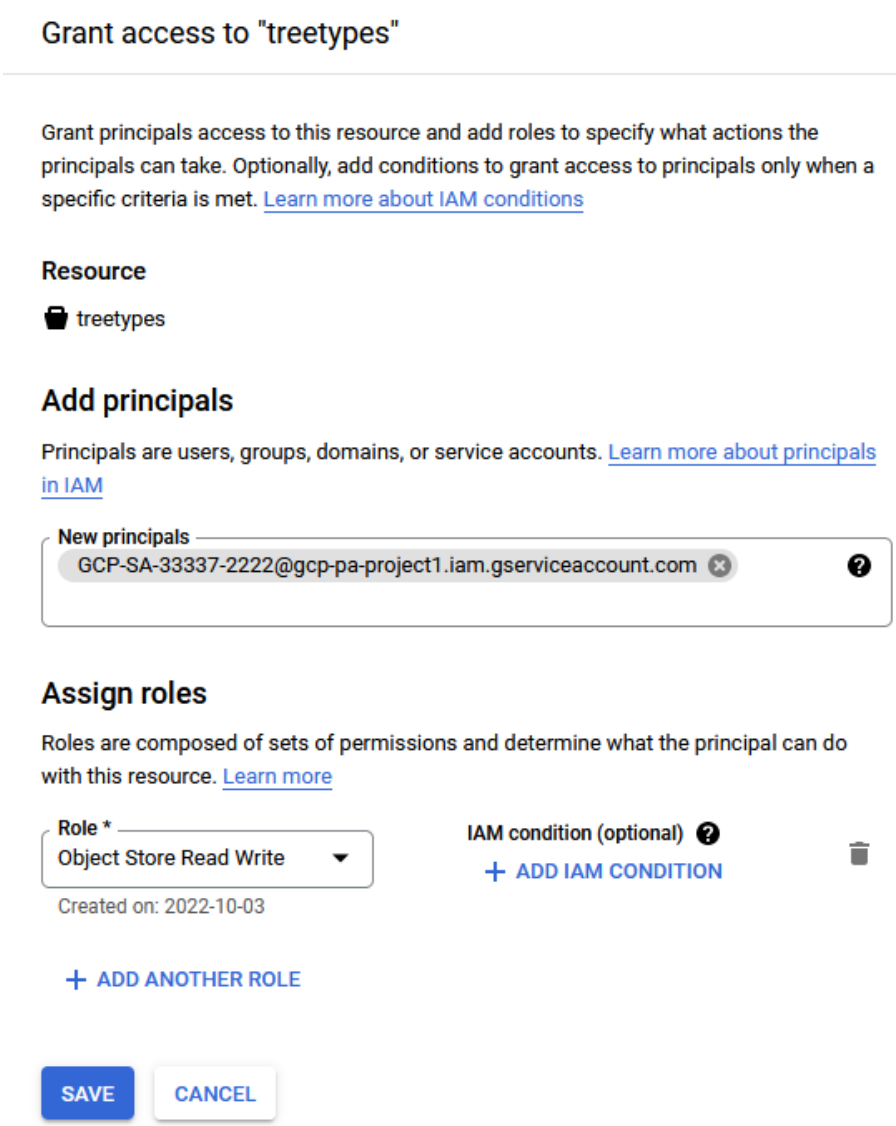
   b. Select the bucket you want to use, and click **PERMISSIONS**.

   c. Click **+ ADD PRINCIPAL**.

6. On the Grant access to "*bucketname*" dialog, add roles and a principals for the selected resource.

   a. Under **Add principals** add the value of the `gcp_service_account` parameter from your Autonomous Database instance.

b. On the Grant access to "*bucketname*" dialog, enter roles under **Assign Roles** and then click **SAVE**.



After you complete these steps the roles and principals are assigned. This allows your application running on the Autonomous Database instance to access the GCP resource with a Google service account.

Use Google Service Account with DBMS_CLOUD

When you make `DBMS_CLOUD` calls to access Google Cloud Platform (GCP) resources and specify the credential name as `GCP$PA`, the authentication on the Google Cloud Platform side happens using a Google service account.

If you have not already done so, perform the prerequisite steps:

- Enable the ADMIN schema or another schema to use Google service account authentication. See Enable Google Service Account and Find the GCP Service Account Name for more information.

- Perform the Google Cloud Platform role assignments for the resources you want to access. See Assign Roles to the Google Service Account and Provide Access for GCP Resources for more information.

To use a `DBMS_CLOUD` procedure or function with Google service account authentication:

1. Use `GCP$PA` as the credential name.
2. Construct the URI to access the GCP resource using virtual hosted-style:

   `https://BUCKET_NAME.storage.googleapis.com/OBJECT_NAME`

   For example, you can access Google Cloud Storage using Google service account credentials as follows:

```
SELECT * FROM DBMS_CLOUD.LIST_OBJECTS('GCP$PA', 'https://
treetypes.storage.googleapis.com/' );

OBJECT_NAME BYTES CHECKSUM                          CREATED LAST_MODIFIED
----------- ----- -------------------------------- -------
------------------------
trees.txt      58 682075a8c38f5686c32c25c6fb67dcbe
2022-10-05T20:03:55.253Z
```

See the following for more information:

- See Request endpoints for more information on GCP virtual hosted-style requests.
- See LIST_OBJECTS Function.

Disable Google Service Account

To disable Google service account access to Google Cloud Platform (GCP) resources, use `DBMS_CLOUD_ADMIN.DISABLE_PRINCIPAL_AUTH`.

When the `provider` value is `GCP` and the `username` is a user other than the `ADMIN` user, the procedure revokes the privileges from the specified user. In this case, the `ADMIN` user and other users can continue to use `GCP$PA`.

For example, to revoke privileges for `adb_user`:

```
BEGIN
    DBMS_CLOUD_ADMIN.DISABLE_PRINCIPAL_AUTH(
        provider => 'GCP',
        username => 'adb_user');
END;
/
```

When the `provider` value is `GCP` and the `username` is `ADMIN`, the procedure disables Google service account access on the Autonomous Database instance. The default value for `username` is `ADMIN`.

For example:

```
BEGIN
    DBMS_CLOUD_ADMIN.DISABLE_PRINCIPAL_AUTH(
        provider => 'GCP' );
```

```
END;
/
```

See DISABLE_PRINCIPAL_AUTH Procedure for more information.

Google Service Account Notes

Notes for using Google service account.

- **Google Cloud Platform (GCP) character restriction**: `DBMS_CLOUD` does not support a URI containing an "_" to access a Google Cloud Storage bucket name. If your Google Cloud Storage bucket name contains an "_", you might see the following error:

  ```
  SELECT * FROM DBMS_CLOUD.LIST_OBJECTS('GCP$PA', 'https://
  app_bucket.storage.googleapis.com/');

  ORA-20006: Unsupported object store URI - https://
  app_bucket.storage.googleapis.com/
  ORA-06512: at "C##CLOUD$SERVICE.DBMS_CLOUD", line 1306
  ```

- **Cloning an Autonomous Database instance with a Google service account**: When you clone an instance with a Google service account enabled, the Google service account configuration is not carried over to the clone. Perform the steps to enable the Google service account on the clone if you want to enable Google service account on a cloned instance.

Load Data into Autonomous Database

Describes packages and tools to load data with Autonomous Database.

- About Data Loading
  Autonomous Database provides many different options to load data into your database.
- Load Data with Oracle Database Actions
  Oracle Database Actions provides a web-based interface with development tools, data tool, administration, and monitoring features and lets you load or access data from local files, from cloud storage, or from remote databases.
- Load Data from Files in the Cloud
  The PL/SQL package `DBMS_CLOUD` provides support for loading data from text, ORC, Parquet, and Avro files in the Cloud to your tables in Autonomous Database. In addition, using `DBMS_CLOUD` you can load Data Pump dump files in the Cloud to your tables in Autonomous Database.
- Import Data Using Oracle Data Pump on Autonomous Database
  Oracle Data Pump offers very fast bulk data and metadata movement between Oracle databases and Autonomous Databases.
- Load Data from Local Files with Oracle Database Actions
  Using Oracle Database Actions, from the Worksheet page, you can load data from local files into an existing table.
- Load Data or Query Data from Files in a Directory
  You can use `DBMS_CLOUD` procedures to load data from files in a directory, including directories created on attached network file systems. You can also use these procedures to create external tables that you can use to query data.

- Load Data from Local Files Using SQL*Loader
  Instead of using SQL*Loader Oracle recommends loading data from the Cloud Object Storage for better performance and enhanced functionality.
- Using Data Pipelines for Continuous Load and Export
  Data pipelines allow you to repeatedly load data from object store or export data to object store. Load pipelines provide continuous incremental data loading from external sources (as data arrives on object store it is loaded to a database table). Export pipelines provide continuous incremental data exporting to object store (as new data appears in a database table it is exported to object store).
- The Data Load Page
  Use the Data Load page to make more data available to your Oracle Autonomous Database. You can load data from files or databases, from links to external databases or cloud storage files, or from a live feed of data from cloud storage.
- Augment Data using Table AI Assist Tool
  The Data Studio suite of tools now features an AI-powered Table Assist Tool to effortlessly enhance your local data tables with the power of AI. You can use natural language prompts to augment and correct your information with this tool.
- Transform Data Using Data Studio
  Data Transforms is an easy-to-use graphical user interface that you can use to design graphical data transformations for data integration with Autonomous Database.
- Data Marketplace
  Data Marketplace provides an innovative platform to access and share datasets effortlessly with Autonomous Database.
- View Data Pump Jobs and Import Data with Data Pump
  Use the Data Pump page to view Data Pump jobs and use the wizard to quickly create and run Data Pump import jobs.

About Data Loading

Autonomous Database provides many different options to load data into your database.

You can load data using any of the following methods:

- You can load data using Oracle Database Actions.
- You can load data using Oracle Database tools and Oracle or other 3rd party data integration tools.
- On transaction processing systems you traditionally ingest data through routine transactions or with DML operations.
- You can load data using `DBMS_CLOUD` procedures.

In general you load data from files local to your client computer or from files stored in a cloud-based object store, or in connected file systems. To load data from files in the cloud, use either Oracle Database Actions or use the Autonomous Database PL/SQL package `DBMS_CLOUD` to load files from the cloud, in connected file systems, or the local file system. `DBMS_CLOUD` provides parallel execution procedures for bulk file upload, download, copy, and transfer activities, which streamlines the user experience and delivers optimal performance for bulk file operations.

For the fastest data loading experience Oracle recommends uploading the source files to a cloud-based object store, such as Oracle Cloud Infrastructure Object Storage, before loading the data into your database. Oracle provides support for loading files that are located locally in

your data center, but when using this method of data loading you should factor in the transmission speeds across the Internet which may be significantly slower.

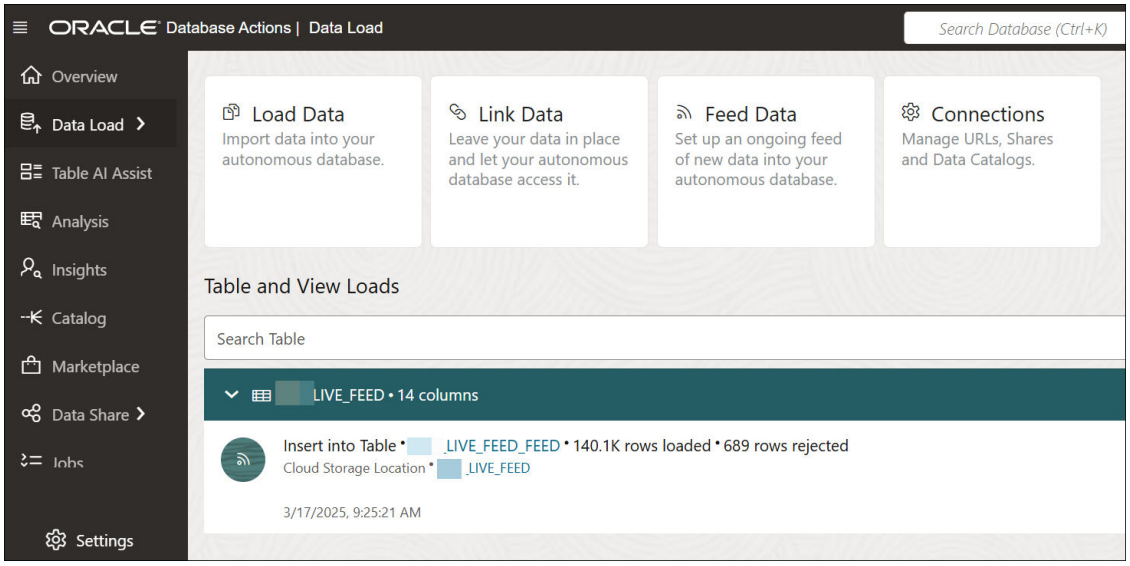
For more information on Oracle Cloud Infrastructure Object Storage, see Putting Data into Object Storage and Overview of Object Storage.

> **Note:**
>
> If you are not using `ADMIN` user, ensure the user has the necessary privileges for the operations the user needs to perform. See Manage User Privileges on Autonomous Database - Connecting with a Client Tool for more information.

Load Data with Oracle Database Actions

Oracle Database Actions provides a web-based interface with development tools, data tool, administration, and monitoring features and lets you load or access data from local files, from cloud storage, or from remote databases.

On the Database Actions Data Load page you can choose to load data from a file on your local device, from cloud storage, or from a database. You can also choose to explore the data in your Oracle Autonomous Database. See The Data Load Page for detailed information and the steps for loading data using Database Actions.



See Connect with Built-In Oracle Database Actions for information on accessing Oracle Database Actions.

Load Data from Files in the Cloud

The PL/SQL package `DBMS_CLOUD` provides support for loading data from text, ORC, Parquet, and Avro files in the Cloud to your tables in Autonomous Database. In addition, using `DBMS_CLOUD` you can load Data Pump dump files in the Cloud to your tables in Autonomous Database.

The package `DBMS_CLOUD` supports loading files from the following cloud services:

- Oracle Cloud Infrastructure Object Storage
- Azure Blob Storage or Azure Data Lake Storage
- Amazon S3
- Amazon S3-Compatible, including: Wasabi Hot Cloud Storage
- GitHub Repository
- Google Cloud Storage

See DBMS_CLOUD URI Formats for more information.

- Create Credentials and Copy Data into an Existing Table
  For data loading from files in the Cloud, you need to first store your object storage credentials in your Autonomous Database and then use the procedure `DBMS_CLOUD.COPY_DATA` to load data.
- Create Credentials and Load Data Pump Dump Files into an Existing Table
  For data loading you can also use Oracle Data Pump dump files as source files.
- Load JSON on Autonomous Database
  The PL/SQL procedure `DBMS_CLOUD.COPY_COLLECTION` provides support for loading JSON documents into SODA collections. The procedure `DBMS_CLOUD.COPY_DATA` provides support for loading JSON data into an existing table in Autonomous Database.
- Monitor and Troubleshoot Loads
  All data load operations done using the PL/SQL package `DBMS_CLOUD` are logged in the tables `dba_load_operations` and `user_load_operations`:
- Examples for Loading Data into Autonomous Database
  Provides examples for loading data in various formats and from different Cloud Storage providers into Autonomous Database.

Create Credentials and Copy Data into an Existing Table

For data loading from files in the Cloud, you need to first store your object storage credentials in your Autonomous Database and then use the procedure `DBMS_CLOUD.COPY_DATA` to load data.

The source file in this example, `channels.txt`, has the following data:

```
S,Direct Sales,Direct
T,Tele Sales,Direct
C,Catalog,Indirect
I,Internet,Indirect
P,Partners,Others
```

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. For example:

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
    password => 'password'
  );
END;
/
```

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for all data loads.

For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

> **Note:**
>
> Some tools like SQL*Plus and SQL Developer use the ampersand character (`&`) as a special character. If you have the ampersand character in your password use the `SET DEFINE OFF` command in those tools as shown in the example to disable the special character and get the credential created properly.

2. Load data into an existing table using the procedure `DBMS_CLOUD.COPY_DATA`. For example:

```
CREATE TABLE CHANNELS
   (channel_id CHAR(1),
    channel_desc VARCHAR2(20),
    channel_class VARCHAR2(20)
   );
/

BEGIN
 DBMS_CLOUD.COPY_DATA(
    table_name =>'CHANNELS',
    credential_name =>'DEF_CRED_NAME',
    file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/channels.txt',
    format => json_object('delimiter' value ',')
 );
END;
/
```

The parameters are:

- `table_name`: is the target table's name.
- `credential_name`: is the name of the credential created in the previous step. The `credential_name` parameter must conform to Oracle object naming conventions. See Database Object Naming Rules for more information.
- `file_uri_list`: is a comma delimited list of the source files you want to load.
- `format`: defines the options you can specify to describe the format of the source file, including whether the file is of type text, ORC, Parquet, or Avro.

  If the data in your source files is encrypted, decrypt the data by specifying the `format` parameter with the `encryption` option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

> **Note:**
>
> Autonomous Database supports a variety of source file formats, including compressed data formats. See DBMS_CLOUD Package Format Options and the DBMS_CLOUD compression format option to see the supported compression types.

For detailed information about the parameters, see COPY_DATA Procedure and COPY_DATA Procedure for Avro, ORC, or Parquet Files.

Create Credentials and Load Data Pump Dump Files into an Existing Table

For data loading you can also use Oracle Data Pump dump files as source files.

The source files for this load type must be exported from the source system using the ORACLE_DATAPUMP access driver in External Tables. See Unloading and Loading Data with the ORACLE_DATAPUMP Access Driver for details on exporting using the ORACLE_DATAPUMP access driver.

To load the data you first move the dump files that were exported using the ORACLE_DATAPUMP access driver to your Object Store and then use DBMS_CLOUD.COPY_DATA to load the dump files to an existing table in your database.

The source files in this example are the Oracle Data Pump dump files, exp01.dmp and exp02.dmp.

1. Store your object store credentials using the procedure DBMS_CLOUD.CREATE_CREDENTIAL. For example:

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
    password => 'password'
  );
END;
/
```

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for all data loads.

For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

> **Note:**
>
> Some tools like SQL*Plus and SQL Developer use the ampersand character (`&`) as a special character. If you have the ampersand character in your password use the `SET DEFINE OFF` command in those tools as shown in the example to disable the special character and get the credential created properly.

2. Load data into an existing table using the procedure `DBMS_CLOUD.COPY_DATA`. For example:

```
CREATE TABLE CHANNELS
   (channel_id CHAR(1),
    channel_desc VARCHAR2(20),
    channel_class VARCHAR2(20)
   );
/

BEGIN
 DBMS_CLOUD.COPY_DATA(
    table_name =>'CHANNELS',
    credential_name =>'DEF_CRED_NAME',
    file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/exp01.dmp,
                      https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/exp02.dmp',
    format => json_object('type' value 'datapump')
 );
END;
/
```

The parameters are:

- `table_name`: is the target table's name.
- `credential_name`: is the name of the credential created in the previous step. The `credential_name` parameter must conform to Oracle object naming conventions. See Database Object Naming Rules for more information.
- `file_uri_list`: is a comma delimited list of the Data Pump dump files you want to load.
- `format`: defines the options you can specify to describe the format of the source file. When you specify the `type` as `'datapump'`, the only other valid format parameter is `'rejectlimit'`.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

For detailed information about the parameters, see COPY_DATA Procedure and COPY_DATA Procedure for Avro, ORC, or Parquet Files.

Load JSON on Autonomous Database

The PL/SQL procedure `DBMS_CLOUD.COPY_COLLECTION` provides support for loading JSON documents into SODA collections. The procedure `DBMS_CLOUD.COPY_DATA` provides support for loading JSON data into an existing table in Autonomous Database.

- About Loading JSON Documents
  You load SODA collections into Autonomous Database using the PL/SQL procedure `DBMS_CLOUD.COPY_COLLECTION` and you load JSON data into a table using `DBMS_CLOUD.COPY_DATA`.
- Load a JSON File of Line-Delimited Documents into a Collection
  For loading data from collections in the Cloud, you must first store your object storage credentials in your Autonomous Database and then use the procedure `DBMS_CLOUD.COPY_COLLECTION` to load documents into a collection.
- Load an Array of JSON Documents into a Collection
  To load data from collections in the Cloud, you first store your object storage credentials in your Autonomous Database and then use PL/SQL procedure `DBMS_CLOUD.COPY_COLLECTION` to load documents into a collection. This topic explains how to load documents to your database from a JSON array in a file.
- Monitor and Troubleshoot COPY_COLLECTION Loads
  All data load operations you perform using the PL/SQL package `DBMS_CLOUD` are logged in the tables `dba_load_operations` and `user_load_operations`. Use these tables to monitor loading with `DBMS_CLOUD.COPY_COLLECTION`.
- Textual JSON Objects That Represent Extended Scalar Values
  Native binary JSON data (OSON format) extends the JSON language by adding scalar types, such as date, that correspond to SQL types and are not part of the JSON standard. Oracle Database also supports the use of textual JSON *objects* that *represent* JSON scalar values, including such nonstandard values.
- Create Credentials and Copy JSON Data into an Existing Table
  Use `DBMS_CLOUD.COPY_DATA` to load JSON data in the cloud into a table.

About Loading JSON Documents

You load SODA collections into Autonomous Database using the PL/SQL procedure `DBMS_CLOUD.COPY_COLLECTION` and you load JSON data into a table using `DBMS_CLOUD.COPY_DATA`.

- `DBMS_CLOUD.COPY_COLLECTION` supports the following typical document loading procedures:
  - Loading line-delimited JSON into a collection. See Load a JSON File of Line-Delimited Documents into a Collection for this procedure.
  - Loading an array of JSON documents into a collection. See Load an Array of JSON Documents into a Collection for this procedure.
- `DBMS_CLOUD.COPY_DATA` supports the following for loading from JSON data in Object Store:
  - Create Credentials and Copy JSON Data into an Existing Table

Load a JSON File of Line-Delimited Documents into a Collection

For loading data from collections in the Cloud, you must first store your object storage credentials in your Autonomous Database and then use the procedure `DBMS_CLOUD.COPY_COLLECTION` to load documents into a collection.

This example loads JSON values from a line-delimited file and uses the JSON file `myCollection.json`. Each value, each line, is loaded into a collection on your database as a single document.

Here's an example of such a file. It has three lines, with one object per line. Each of those objects gets loaded as a separate JSON document.

```
{ "name" : "apple", "count": 20 }
{ "name" : "orange", "count": 42 }
{ "name" : "pear", "count": 10 }
```

Before loading the data from `myCollection.json` into your database, copy the file to your object store:

- Create a bucket in the object store. For example, create an Oracle Cloud Infrastructure Object Storage bucket from the Oracle Cloud Infrastructure Object Storage link, and then in your selected compartment click **Create Bucket**, or use a command such as the following OCI CLI command to create a bucket:

  ```
  oci os bucket create --name fruit_bucket -c <compartment id>
  ```

- Copy the JSON file to your object store bucket. For example use the following OCI CLI command to copy the JSON file to the `fruit_bucket` on Oracle Cloud Infrastructure Object Storage:

  ```
  oci os object put --bucket-name fruit_bucket \
                    --file "myCollection.json"
  ```

Load the JSON file from object store into a collection named `fruit` on your database as follows:

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`, as shown in the following example:

   ```
   SET DEFINE OFF
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password'
     );
   END;
   /
   ```

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials, you can use the same credential name for loading all documents.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   See CREATE_CREDENTIAL Procedure for detailed information about the parameters.

> **Note:**
>
> Some tools like SQL*Plus and SQL Developer use the ampersand character (`&`) as a special character. If you have the ampersand character in your password, then use the `SET DEFINE OFF` command in those tools as shown in the example to disable the special character, and get the credential created properly.

2. Load the data into a collection using the procedure `DBMS_CLOUD.COPY_COLLECTION`.

```
BEGIN
 DBMS_CLOUD.COPY_COLLECTION(
    collection_name => 'fruit',
    credential_name => 'DEF_CRED_NAME',
    file_uri_list   =>
      'https://objectstorage.us-ashburn-1.oraclecloud.com/n/namespace-string/b/
fruit_bucket/o/myCollection.json',
    format          =>
      JSON_OBJECT('recorddelimiter' value '''\n''')  );
END;
/
```

The parameters are:

- `collection_name`: is the name of the target collection.
- `credential_name`: is the name of the credential created in the previous step. The `credential_name` parameter must conform to Oracle object naming conventions. See Database Object Naming Rules for more information.
- `file_uri_list`: is a comma delimited list of the source files that you want to load.
- `format`: defines the options that you can specify to describe the format of the source file. The format options `characterset, compression, encryption, ignoreblanklines, jsonpath, maxdocsize, recorddelimiter, rejectlimit, type, unpackarrays` are supported while loading JSON data. Any other formats specified will result in an error.

  If the data in your source files is encrypted, decrypt the data by specifying the `format` parameter with the `encryption` option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.

  See DBMS_CLOUD Package Format Options for more information.

Where *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and `fruit_bucket` is the bucket name. See Understanding Object Storage Namespaces and Overview of Object Storage for more information.

For detailed information about the parameters, see COPY_COLLECTION Procedure.

The collection `fruit` on your database now contains one document for each line in the file `myCollection.json`.

Load an Array of JSON Documents into a Collection

To load data from collections in the Cloud, you first store your object storage credentials in your Autonomous Database and then use PL/SQL procedure `DBMS_CLOUD.COPY_COLLECTION` to load

documents into a collection. This topic explains how to load documents to your database from a JSON array in a file.

> **Note:**
>
> You can also load documents from a JSON array in a file into a collection using SODA for REST. See Load Purchase-Order Sample Data Using SODA for REST.

This example uses the JSON file `fruit_array.json`. The following shows the contents of the file `fruit_array.json`:

```
[{"name" : "apple", "count": 20 },
 {"name" : "orange", "count": 42 },
 {"name" : "pear", "count": 10 }]
```

Before loading data into Autonomous Database, copy the data to your object store as follows:

- Create a bucket in the object store. For example, create an Oracle Cloud Infrastructure Object Store bucket from the Oracle Cloud Infrastructure Object Storage link, in your selected Compartment, by clicking **Create Bucket**, or use a command line tool such as the following OCI CLI command:

  ```
  oci os bucket create -name json_bucket -c <compartment id>
  ```

- Copy the JSON file to the object store. For example, the following OCI CLI command copies the JSON file `fruit_array.json` to the object store:

  ```
  oci os object put --bucket-name json_bucket --file "fruit_array.json"
  ```

Load the JSON file from object store into a SODA collection named `fruit2` on your database:

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`, as shown in the following example:

   ```
   SET DEFINE OFF
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password'
     );
   END;
   /
   ```

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials, you can use the same credential name for loading all documents.

   See CREATE_CREDENTIAL Procedure for detailed information about the parameters.

> **Note:**
>
> Some tools like SQL*Plus and SQL Developer use the ampersand character (`&`) as a special character. If you have the ampersand character in your password, then use the `SET DEFINE OFF` command in those tools as shown in the example to disable the special character, and get the credential created properly.

2. Load the data into a collection using the procedure `DBMS_CLOUD.COPY_COLLECTION`.

```
BEGIN
  DBMS_CLOUD.COPY_COLLECTION(
    collection_name => 'fruit2',
    credential_name => 'DEF_CRED_NAME',
    file_uri_list => 'https://objectstorage.us-ashburn-1.oraclecloud.com/n/
namespace-string/b/json/o/fruit_array.json',
    format => '{"recorddelimiter" : "0x''01''", "unpackarrays" : "TRUE",
"maxdocsize" : "10240000"}'
  );
END;
/
```

In this example you load a single JSON value which occupies the whole file, so there is no need to specify a record delimiter. To indicate that there is no record delimiter, you can use a character that does not occur in the input file. For this example, to indicate that there is no delimiter, the control character 0x01 (SOH) is set to load the JSON documents into a collection,. Thus, you specify a value for the `recorddelimiter` that does not occur in the JSON file. For example, you can use value `"0x''01''"` because this character does not occur directly in JSON text.

When `unpackarrays` parameter for format value is set to `TRUE`, the array of documents is loaded as individual documents rather than as an entire array. The unpacking of array elements is however limited to single level. If there are nested arrays in the documents, those arrays are not unpacked.

The parameters are:

- `collection_name`: is the name of the target collection.
- `credential_name`: is the name of the credential created in the previous step. The `credential_name` parameter must conform to Oracle object naming conventions. See Database Object Naming Rules for more information.
- `file_uri_list`: is a comma delimited list of the source files that you want to load.
- `format`: defines the options that you can specify to describe the format of the source file. The format options `characterset`, `compression`, `encryption`, `ignoreblanklines`, `jsonpath`, `maxdocsize`, `recorddelimiter`, `rejectlimit`, `type`, `unpackarrays` are supported for loading JSON data. Any other formats specified will result in an error.

  If the data in your source files is encrypted, decrypt the data by specifying the `format` parameter with the `encryption` option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.

  See DBMS_CLOUD Package Format Options for more information.

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

For detailed information about the parameters, see COPY_COLLECTION Procedure.

The load of `fruit_array.json`, with `DBMS_CLOUD.COPY_COLLECTION` using the format option `unpackarrays` recognizes array values in the source and instead of loading the data as a single document, as it would by default, the data is loaded in the collection `fruit2` with each value in the array as a single document.

Monitor and Troubleshoot COPY_COLLECTION Loads

All data load operations you perform using the PL/SQL package `DBMS_CLOUD` are logged in the tables `dba_load_operations` and `user_load_operations`. Use these tables to monitor loading with `DBMS_CLOUD.COPY_COLLECTION`.

- `dba_load_operations` shows all load operations
- `user_load_operations` shows the load operations in your schema

You can query these tables to see information about ongoing and completed data loads. For example, the following `SELECT` statement with a `WHERE` clause predicate on the `TYPE` column shows load operations of the type `COPY`:

```
SELECT table_name, owner_name, type, status, start_time, update_time,
logfile_table, badfile_table
   FROM user_load_operations WHERE type = 'COPY';
TABLE_NAME  OWNER_NAME   TYPE    STATUS     START_TIME
UPDATE_TIME           LOGFILE_TABLE   BADFILE_TABLE
FRUIT       ADMIN        COPY    COMPLETED  2020-04-23 22:27:37    2020-04-23
22:27:38   ""             ""
FRUIT       ADMIN        COPY    FAILED     2020-04-23 22:28:36    2020-04-23
22:28:37   COPY$2_LOG      COPY$2_BAD
```

The `LOGFILE_TABLE` column shows the name of the table you can query to look at the log of a load operation. For example, the following query shows the log of the load operation with status `FAILED` and timestamp `2020-04-23 22:28:36`:

```
SELECT * FROM COPY$2_LOG;
```

The column `BADFILE_TABLE` shows the name of the table you can query to review information for the rows reporting errors during loading. For example, the following query shows the rejected records for the load operation:

```
SELECT * FROM COPY$2_BAD;
```

Depending on the errors shown in the log and the rows shown in the `BADFILE_TABLE` table, you might be able to correct errors by specifying different format options with `DBMS_CLOUD.COPY_COLLECTION`.

> **Note:**
>
> The `LOGFILE_TABLE` and `BADFILE_TABLE` tables are stored for two days for each load operation and then removed automatically.

See DELETE_ALL_OPERATIONS Procedure for information on clearing the `user_load_operations` table.

Textual JSON Objects That Represent Extended Scalar Values

Native binary JSON data (OSON format) extends the JSON language by adding scalar types, such as date, that correspond to SQL types and are not part of the JSON standard. Oracle Database also supports the use of textual JSON *objects* that *represent* JSON scalar values, including such nonstandard values.

When you create native binary JSON data from textual JSON data that contains such **extended objects**, they can optionally be *replaced* with corresponding (native binary) JSON scalar values.

An example of an extended object is `{"$numberDecimal":31}`. It represents a JSON scalar value of the nonstandard type *decimal number*, and when interpreted as such it is replaced by a decimal number in native binary format.

For example, when you use the JSON data type constructor, `JSON`, if you use keyword `EXTENDED` then recognized extended objects in the textual input are replaced with corresponding scalar values in the native binary JSON result. If you do not include keyword `EXTENDED` then no such replacement occurs; the textual extended JSON objects are simply converted as-is to JSON objects in the native binary format.

In the opposite direction, when you use SQL/JSON function `json_serialize` to serialize binary JSON data as textual JSON data (`VARCHAR2`, `CLOB`, or `BLOB`), you can use keyword `EXTENDED` to replace (native binary) JSON scalar values with corresponding textual extended JSON objects.

> **Note:**
>
> If the database you use is an Oracle Autonomous Database then you can use PL/SQL procedure `DBMS_CLOUD.copy_collection` to create a JSON document collection from a file of JSON data such as that produced by common NoSQL databases, including Oracle NoSQL Database.
>
> If you use **`ejson`** as the value of the `type` parameter of the procedure, then recognized extended JSON objects in the input file are replaced with corresponding scalar values in the resulting native binary JSON collection. In the other direction, you can use function `json_serialize` with keyword `EXTENDED` to replace scalar values with extended JSON objects in the resulting textual JSON data.

These are the two main use cases for extended objects:

- *Exchange* (import/export):
  - Ingest existing JSON data (from somewhere) that contains extended objects.
  - Serialize native binary JSON data as textual JSON data with extended objects, for some use outside the database.

- *Inspection* of native binary JSON data: see what you have by looking at corresponding extended objects.

For exchange purposes, you can ingest JSON data from a file produced by common NoSQL databases, including Oracle NoSQL Database, converting extended objects to native binary JSON scalars. In the other direction, you can export native binary JSON data as textual data, replacing Oracle-specific scalar JSON values with corresponding textual extended JSON objects.

> **Tip:**
>
> As an example of inspection, consider an object such as `{"dob" : "2000-01-02T00:00:00"}` as the result of serializing native JSON data. Is `"2000-01-02T00:00:00"` the result of serializing a native binary value of type date, or is the native binary value just a string? Using `json_serialize` with keyword `EXTENDED` lets you know.

The mapping of extended object fields to scalar JSON types is, in general, many-to-one: more than one kind of extended JSON object can be mapped to a given scalar value. For example, the extended JSON objects `{"$numberDecimal":"31"}` and `{"$numberLong:"31"}` are both translated as the value 31 of JSON-language scalar type number, and item method `type()` returns `"number"` for each of those JSON scalars.

Item method `type()` reports the JSON-language scalar type of its targeted value (as a JSON string). Some scalar values are distinguishable internally, even when they have the same scalar type. This generally allows function `json_serialize` (with keyword `EXTENDED`) to reconstruct the original extended JSON object. Such scalar values are distinguished internally either by using *different SQL types* to implement them or by *tagging them with the kind of extended JSON object* from which they were derived.

When `json_serialize` reconstructs the original extended JSON object the result is not always *textually* identical to the original, but it is always *semantically* equivalent. For example, `{"$numberDecimal":"31"}` and `{"$numberDecimal":31}` are semantically equivalent, even though the field values differ in type (string and number). They are translated to the same internal value, and each is tagged as being derived from a `$numberDecimal` extended object (same tag). But when serialized, the *result for both* is `{"$numberDecimal":31}`. Oracle always uses the most directly relevant type for the field value, which in this case is the JSON-language value `31`, of scalar type number.

Table 3-1 presents correspondences among the various types used. It maps across (1) types of extended objects used as input, (2) types reported by item method `type()`, (3) SQL types used internally, (4) standard JSON-language types used as output by function `json_serialize`, and (5) types of extended objects output by `json_serialize` when keyword `EXTENDED` is specified.

Table 3-1 Extended JSON Object Type Relations

Extended Object Type (Input)	Oracle JSON Scalar Type (Reported by type())	SQL Scalar Type	Standard JSON Scalar Type (Output)	Extended Object Type (Output)
`$numberDouble` with value a JSON number, a string representing the number, or one of these strings: `"Infinity"`, `"-Infinity"`, `"Inf"`, `"-Inf"`, `"Nan"`[1]	double	`BINARY_DOUBLE`	number	`$numberDouble` with value a JSON number or one of these strings: `"Inf"`, `"-Inf"`, `"Nan"`[2]
`$numberFloat` with value the same as for `$numberDouble`	float	`BINARY_FLOAT`	number	`$numberFloat` with value the same as for `$numberDouble`
`$numberDecimal` with value the same as for `$numberDouble`	number	`NUMBER`	number	`$numberDecimal` with value the same as for `$numberDouble`
`$numberInt` with value a signed 32-bit integer or a string representing the number	number	`NUMBER`	number	`$numberInt` with value the same as for `$numberDouble`
`$numberLong` with value a JSON number or a string representing the number	number	`NUMBER`	number	`$numberLong` with value the same as for `$numberDouble`
`$binary` with value one of these: • a string of base-64 characters • An object with fields `base64` and `subType`, whose values are a string of base-64 characters and the number `0` (arbitrary binary) or `4` (UUID), respectively When the value is a string of base-64 characters, the extended object can also have field `$subtype` with value 0 or 4, expressed as a one-byte integer (0-255) or a 2-character hexadecimal string. representing such an integer	binary	`BLOB` or `RAW`	string Conversion is equivalent to the use of SQL function `rawtohex`.	One of the following: • `$binary` with value a string of base-64 characters • `$rawid` with value a string of 32 hexadecimal characters, if input had a `subType` value of `4` (UUID)
`$oid` with value a string of 24 hexadecimal characters	binary	`RAW(12)`	string Conversion is equivalent to the use of SQL function `rawtohex`.	`$rawid` with value a string of 24 hexadecimal characters
`$rawhex` with value a string with an even number of hexadecimal characters	binary	`RAW`	string Conversion is equivalent to the use of SQL function `rawtohex`.	`$binary` with value a string of base-64 characters, right-padded with = characters

Table 3-1 (Cont.) Extended JSON Object Type Relations

Extended Object Type (Input)	Oracle JSON Scalar Type (Reported by type())	SQL Scalar Type	Standard JSON Scalar Type (Output)	Extended Object Type (Output)
`$rawid` with value a string of 24 or 32 hexadecimal characters	binary	`RAW`	string Conversion is equivalent to the use of SQL function `rawtohex`.	`$rawid`
`$oracleDate` with value an ISO 8601 date string	date	`DATE`	string	`$oracleDate` with value an ISO 8601 date string
`$oracleTimestamp` with value an ISO 8601 timestamp string	timestamp	`TIMESTAMP`	string	`$oracleTimestamp` with value an ISO 8601 timestamp string
`$oracleTimestampTZ` with value an ISO 8601 timestamp string with a numeric time zone offset or with `Z`	timestamp with time zone	`TIMESTAMP WITH TIME ZONE`	string	`$oracleTimestampTZ` with value an ISO 8601 timestamp string with a numeric time zone offset or with `Z`
`$date` with value one of the following: • An integer millisecond count since January 1, 1990 • An ISO 8601 timestamp string • An object with field `numberLong` with value an integer millisecond count since January 1, 1990	timestamp with time zone	`TIMESTAMP WITH TIME ZONE`	string	`$oracleTimestampTZ` with value an ISO 8601 timestamp string with a numeric time zone offset or with `Z`
`$intervalDaySecond` with value an ISO 8601 interval string as specified for SQL function `to_dsinterval`	daysecondInterval	`INTERVAL DAY TO SECOND`	string	`$intervalDaySecond` with value an ISO 8601 interval string as specified for SQL function `to_dsinterval`
`$intervalYearMonth` with value an ISO 8601 interval string as specified for SQL function `to_yminterval`	yearmonthInterval	`INTERVAL YEAR TO MONTH`	string	`$intervalYearMonth` with value an ISO 8601 interval string as specified for SQL function `to_yminterval`
Two fields: • Field `$vector` with value an array whose elements are numbers or the strings `"Nan"`, `"Inf"`, and `"-Inf"` (representing not-a-number and infinite values). • Field `$vectorElementType` with string value either`"float32"` or `"float64"`. These correspond to IEEE 32-bit and IEEE 64-bit numbers, respectively.	vector	`VECTOR`	array of numbers	Two fields: • Field `$vector` with value an array whose elements are numbers or the strings `"Nan"`, `"Inf"`, and `"-Inf"` (representing not-a-number and infinite values). • Field `$vectorElementType` with string value either`"float32"` or `"float64"`.

1 The string values are interpreted case-insensitively. For example, `"NAN"` `"nan"`, and `"nAn"` are accepted and equivalent, and similarly `"INF"`, `"inFinity"`, and `"iNf"`. Infinitely large (`"Infinity"` or `"Inf"`) and small (`"-Infinity"` or `"-Inf"`) numbers are accepted with either the full word or the abbreviation.

2 On output, only these string values are used — no full-word *Infinity* or letter-case variants.

> **See Also:**
>
> IEEE Standard for Floating-Point Arithmetic (IEEE 754)

Create Credentials and Copy JSON Data into an Existing Table

Use `DBMS_CLOUD.COPY_DATA` to load JSON data in the cloud into a table.

The source file in this example is a JSON data file.

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`. For example:

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
    password => 'password'
  );
END;
/
```

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for all data loads.

   For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

2. Load JSON data into an existing table using the procedure `DBMS_CLOUD.COPY_DATA`.

   For example:

```
CREATE TABLE WEATHER2
    (WEATHER_STATION_ID VARCHAR2(20),
     WEATHER_STATION_NAME VARCHAR2(50));
/

BEGIN
  DBMS_CLOUD.COPY_DATA(
      table_name      => 'WEATHER2',
      credential_name => 'DEF_CRED_NAME',
      file_uri_list   => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/jsonfiles*',
      format          =>  JSON_OBJECT('type' value 'json', 'columnpath'
value '["$.WEATHER_STATION_ID",
          "$.WEATHER_STATION_NAME"]')
    );
```

```
END;
/
```

The parameters are:

- `table_name`: is the target table's name.
- `credential_name`: is the name of the credential created in the previous step.
- `file_uri_list`: is a comma delimited list of the source files you want to load. You can use wildcards in the file names in your URIs. The character "*" can be used as the wildcard for multiple characters, the character "?" can be used as the wildcard for a single character.
- `format`: for `DBMS_CLOUD.COPY_DATA` with JSON data, the `type` is `json`. Specify other format values to define the options to describe the format of the JSON source file. See DBMS_CLOUD Package Format Options for more information.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

For detailed information about the parameters, see COPY_DATA Procedure.

Monitor and Troubleshoot Loads

All data load operations done using the PL/SQL package `DBMS_CLOUD` are logged in the tables `dba_load_operations` and `user_load_operations`:

- `dba_load_operations`: shows all load operations.
- `user_load_operations`: shows the load operations in your schema.

Query these tables to see information about ongoing and completed data loads. Use a `SELECT` statement with a `WHERE` clause predicate on the `TYPE` column to show load operations with the type `COPY`.

For example:

```
SELECT table_name, owner_name, type, status, start_time, update_time, logfile_table,
badfile_table
   FROM user_load_operations WHERE type = 'COPY';

TABLE_NAME OWNER_NAME TYPE STATUS    START_TIME               UPDATE_TIME
LOGFILE_TABLE BADFILE_TABLE
---------- ---------- ---- --------- ------------------------ ------------------------
------------- -------------
TREEDATA   ADMIN      COPY COMPLETED 2022-10-20T23:15:19.990Z 2022-10-20T23:15:24.238Z
COPY$1_LOG    COPY$1_BAD
```

The `LOGFILE_TABLE` column shows the name of the table you can query to look at the log of a load operation. For example, the following query shows the log for this load operation:

```
SELECT * FROM COPY$1_LOG;
```

The column `BADFILE_TABLE` shows the name of the table you can query to look at the rows with errors during loading. For example, the following query shows the rejected records for the load

operation. If there are not any rejected rows in the operation, the query does not show any rejected rows.

```
SELECT * FROM COPY$1_BAD;
```

Depending on the errors shown in the log and the rows shown in the `BADFILE_TABLE` file you can correct the error by specifying the correct format options in `DBMS_CLOUD.COPY_DATA`.

When the format `type` is "`datapump`", any rows rejected up to the specified `rejectlimit` are logged in the log file, but a `BADFILE_TABLE` is not generated.

By default the `LOGFILE_TABLE` and `BADFILE_TABLE` files are retained for two days and then automatically removed. You can change the number of retention days with the `logretention` option for the `format` parameter.

See DBMS_CLOUD Package Format Options for information on the `enablelogs`, `logdir`, `logprefix`, and `logretention` options for the `format` parameter.

See DELETE_ALL_OPERATIONS Procedure for information on clearing the log files.

See Track DBMS_CLOUD Load Operations for information on the `dba_load_operations` and `user_load_operations` views.

Monitor and Troubleshoot Bulk File Operations

See Monitor and Troubleshoot Bulk File Loads for information on monitoring and troubleshooting for bulk file operations.

Monitor and Troubleshoot ORC, Parquet, or Avro File Loading

As with other data files, ORC, Parquet, and Avro data loads generate logs that are viewable in the tables `dba_load_operations` and `user_load_operations`. Each load operation adds a record to `dba`[*user*]`_load_operations` that indicates the table containing the logs.

The log table provides summary information about the load.

> **Note:**
>
> For ORC, Parquet, or Avro files, when the `format` parameter `type` is set to the value `orc`, `parquet` or `avro` the `BADFILE_TABLE` table is always empty.
>
> - `PRIMARY KEY` constraint errors throw an `ORA` error.
> - If data for a column encounters a conversion error, for example, the target column is not large enough to hold the converted value, the value for the column is set to `NULL`. This does not produce a rejected record.

Examples for Loading Data into Autonomous Database

Provides examples for loading data in various formats and from different Cloud Storage providers into Autonomous Database.

- Load Data into Autonomous Database from Oracle Cloud Infrastructure Object Storage
  This example shows you how to load data from Oracle Cloud Infrastructure Object Storage to Autonomous Database using SQL commands.

- Load Data into Autonomous Database from AWS S3
  This example shows you how to load data from Amazon S3 object storage to Autonomous Database.
- Load Data into Autonomous Database from Azure Blob Storage or Azure Data Lake Storage
  This example shows you how to load data from Azure Blob Storage or Azure Data Lake Storage to Autonomous Database.
- Load Data into Autonomous Database from Google Cloud Storage
  This example shows how to load data from Google Cloud Storage to Autonomous Database.
- Load a Fixed-Width File into a New Table
  This provides an example using `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` to load data from a fixed-width source file to an external table.

Load Data into Autonomous Database from Oracle Cloud Infrastructure Object Storage

This example shows you how to load data from Oracle Cloud Infrastructure Object Storage to Autonomous Database using SQL commands.

You have various options to perform data loading into Autonomous Database, such as:

- Using UI options: You can use the Data Studio Load tool user interface to create credentials for the cloud store location, select files containing data, and run data load jobs.

  See Loading Data from Cloud Storage
- Using Rest Data Services APIs: You can use the Data Studio Load tool APIs to create links to the cloud store location and run data load jobs.

  See Using Data Studio Data Load APIs in PL/SQL
- Using SQL commands as explained in this example.

All these methods use the same PL/SQL package `DBMS_CLOUD` for loading data. However, Data Studio provides additional benefits over SQL commands. It not only helps to analyze the source and create table definitions but also performs validation checks.

You require Oracle Cloud Infrastructure access credentials for user account authentication and an object URL for accessing the object in your Oracle Cloud Infrastructure Object Storage bucket.

To load data from Oracle Cloud Infrastructure Object Storage:

1. Create credentials for Oracle Cloud Infrastructure user account in the Autonomous Database.
2. Copy data from Oracle Cloud Infrastructure Object Storage to the database.

Topics

- Prepare for Loading Data from Oracle Cloud Infrastructure
  Verify the prerequisites and prepare for loading data from Oracle Cloud Infrastructure Object Storage.
- Steps for Loading Data from Oracle Cloud Infrastructure
  Run these steps to load data from Oracle Cloud Infrastructure Object Storage to Autonomous Database.

Prepare for Loading Data from Oracle Cloud Infrastructure

Verify the prerequisites and prepare for loading data from Oracle Cloud Infrastructure Object Storage.

Prerequisites

A data file, for example, `oci-data.txt` exists in the Oracle Cloud Infrastructure bucket that you can import. The sample file in this example has the following contents:

```
1,OCI Direct Sales
2,OCI Tele Sales
3,OCI Catalog
4,OCI Internet
5,OCI Partners
```

On the Oracle Cloud Infrastructure side, log in to your Oracle Cloud Infrastructure account and do the following:

1. Obtain an Auth token for the Oracle Cloud Infrastructure account.

   For more information, see Getting an Auth Token.

2. From the Object Details page, obtain the object URL for the data file stored in the Oracle Cloud Infrastructure Object Storage bucket.

   For more information, see Getting an Object Storage Object's Details.

Steps for Loading Data from Oracle Cloud Infrastructure

Run these steps to load data from Oracle Cloud Infrastructure Object Storage to Autonomous Database.

1. Store the Oracle Cloud Infrastructure account credentials in your Autonomous Database and specify a credential name. This enables the database to authenticate with your Oracle Cloud Infrastructure account and access the items in the Oracle Cloud Infrastructure Object Storage bucket.

   ```
   SET DEFINE OFF
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'OCI_CRED_NAME',
       username => 'username',
       password => 'password'
     );
   END;
   /
   ```

   > **Note:**
   >
   > Here, the *username* is your Oracle Cloud Infrastructure user name and the *password* is your user Auth token.

   For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

Optionally, you can test the access to Oracle Cloud Infrastructure as shown in this example.

```
SELECT * FROM DBMS_CLOUD.LIST_OBJECTS('OCI_CRED_NAME', 'https://
objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/
bucketname/o/');
```

2. Create a table in your database where you want to load the data.

```
CREATE TABLE myocitable (id NUMBER, name VARCHAR2(64));
```

3. Import data from the Oracle Cloud Infrastructure bucket to your Autonomous Database.

   Specify the table name and the Oracle Cloud Infrastructure credential name followed by the Oracle Cloud Infrastructure object URL.

```
BEGIN
      DBMS_CLOUD.COPY_DATA(
          table_name => 'myocitable',
          credential_name => 'OCI_CRED_NAME',
          file_uri_list => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/oci-data.txt',
          format => json_object('delimiter' value ',')
      );
END;
/
```

   In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

   For detailed information about the parameters, see COPY_DATA Procedure.

You have successfully imported data from Oracle Cloud Infrastructure Object Storage to your Autonomous Database. You can run this statement and verify the data in your table.

```
SELECT * FROM myocitable;

ID  NAME
--  --------------
 1  OCI Direct Sales
 2  OCI Tele Sales
 3  OCI Catalog
 4  OCI Internet
 5  OCI Partners
```

For more information about loading data, see Load Data from Files in the Cloud.

Load Data into Autonomous Database from AWS S3

This example shows you how to load data from Amazon S3 object storage to Autonomous Database.

You have various options to perform data loading into Autonomous Database, such as:

- Using UI options: You can use the Data Studio Load tool user interface to create credentials for the cloud store location, select files containing data, and run data load jobs.

  See Loading Data from Cloud Storage
- Using Rest Data Services APIs: You can use the Data Studio Load tool APIs to create links to the cloud store location and run data load jobs.

  See Using Data Studio Data Load APIs in PL/SQL
- Using SQL commands as explained in this example.

All these methods use the same PL/SQL package `DBMS_CLOUD` for loading data. However, Data Studio provides additional benefits over SQL commands. It not only helps to analyze the source and create table definitions but also performs validation checks.

You require AWS access credentials for user account authentication and an object URL for accessing the object in Amazon S3 bucket.

To load data from an Amazon S3 bucket:

1. Create credentials for AWS user account in the Autonomous Database.
2. Copy data from the Amazon S3 bucket to the database.

Topics

- Prepare for Loading Data from AWS S3
  Verify the prerequisites and prepare for loading data from Amazon S3.
- Steps for Loading Data from AWS S3
  Run these steps to load data from Amazon S3 to Autonomous Database.

Prepare for Loading Data from AWS S3

Verify the prerequisites and prepare for loading data from Amazon S3.

Prerequisites

A data file, for example, `data.txt` exists in the Amazon S3 bucket that you can import. The sample file in this example has the following contents:

```
1,Direct Sales
2,Tele Sales
3,Catalog
4,Internet
5,Partners
```

On the AWS side, log in to your AWS account and do the following:

1. Grant access privileges to the AWS IAM user for the Amazon S3 bucket.

   For more information, see Controlling access to a bucket with user policies.
2. Create an access key for the user.

For more information, see Managing access keys for IAM users.

3. Obtain an object URL for the data file stored in the Amazon S3 bucket.

   For more information, see Accessing and listing an Amazon S3 bucket.

Steps for Loading Data from AWS S3

Run these steps to load data from Amazon S3 to Autonomous Database.

1. Store the AWS access credentials in your Autonomous Database and specify a credential name. This enables the database to authenticate with your AWS user account and access the items in the S3 bucket.

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'AWS_CRED_NAME',
    username => 'username',
    password => 'password'
  );
END;
/
```

> **Note:**
>
> Here, the *username* is your AWS Access key ID and the *password* is your user access key.

   For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

   Creating a credential to access AWS resources is not required if you enable Amazon Resource Names (ARNs). See Use Amazon Resource Names (ARNs) to Access AWS Resources for more information.

   Optionally, you can test the access to S3 bucket as shown in this example.

```
SELECT * FROM DBMS_CLOUD.LIST_OBJECTS('AWS_CRED_NAME', ' https://aws-
bucket-01.s3.amazonaws.com/');
```

2. Create a table in your database where you want to load the data.

```
CREATE TABLE mytable (id NUMBER, name VARCHAR2(64));
```

3. Import data from the Amazon S3 bucket to your Autonomous Database.

   Specify the table name and the AWS credential name followed by the S3 object URL.

```
BEGIN
      DBMS_CLOUD.COPY_DATA(
          table_name => 'mytable',
          credential_name => 'AWS_CRED_NAME',
          file_uri_list => https://aws-bucket-01.s3.amazonaws.com/
data.txt',
          format => json_object('delimiter' value ',')
      );
```

```
END;
/
```

For detailed information about the parameters, see COPY_DATA Procedure.

You have successfully imported data from Amazon S3 to your Autonomous Database. You can run this statement and verify the data in your table.

```
SELECT * FROM mytable;

ID  NAME
--  --------------
 1  Direct Sales
 2  Tele Sales
 3  Catalog
 4  Internet
 5  Partners
```

For more information about loading data, see Load Data from Files in the Cloud.

Load Data into Autonomous Database from Azure Blob Storage or Azure Data Lake Storage

This example shows you how to load data from Azure Blob Storage or Azure Data Lake Storage to Autonomous Database.

You have various options to perform data loading into Autonomous Database, such as:

- Using UI options: You can use the Data Studio Load tool user interface to create credentials for the cloud store location, select files containing data, and run data load jobs.

  See Loading Data from Cloud Storage
- Using Rest Data Services APIs: You can use the Data Studio Load tool APIs to create links to the cloud store location and run data load jobs.

  See Using Data Studio Data Load APIs in PL/SQL
- Using SQL commands as explained in this example.

All these methods use the same PL/SQL package `DBMS_CLOUD` for loading data. However, Data Studio provides additional benefits over SQL commands. It not only helps to analyze the source and create table definitions but also performs validation checks.

You require Azure access credentials for user account authentication and an object URL for accessing the object in your Azure Storage account container.

To load data from Azure Blob Storage or Azure Data Lake Storage:

1. Create credentials for Azure user account in the Autonomous Database.
2. Copy data from Azure Blob Storage or Azure Data Lake Storage to the database.

Topics

- Prepare for Loading Data from Azure Blob Storage or Azure Data Lake Storage
  Verify the prerequisites and prepare for loading data from Azure Blob Storage or Azure Data Lake Storage.

- Steps for Loading Data from Azure Blob Storage or Azure Data Lake Storage
  Run these steps to load data from Azure Blob Storage or Azure Data Lake Storage to Autonomous Database.

Prepare for Loading Data from Azure Blob Storage or Azure Data Lake Storage

Verify the prerequisites and prepare for loading data from Azure Blob Storage or Azure Data Lake Storage.

Prerequisites

A data file, for example, `azure-data.txt` exists in the Azure Storage account container that you can import. The sample file in this example has the following contents:

```
1,Azure Direct Sales
2,Azure Tele Sales
3,Azure Catalog
4,Azure Internet
5,Azure Partners
```

On the Azure side, log in to your Azure Storage account and do the following:

1. Grant the required role, for example Storage Blob Data Contributor, to your Azure Storage account.

   For more information, see Assign Azure roles using the Azure portal.
2. Obtain an access key for the Azure Storage account.

   For more information, see View account access keys.
3. Obtain the object URL for the data file stored in the Azure Storage account container.

Steps for Loading Data from Azure Blob Storage or Azure Data Lake Storage

Run these steps to load data from Azure Blob Storage or Azure Data Lake Storage to Autonomous Database.

1. Store the Azure Storage account credentials in your Autonomous Database and specify a credential name. This enables the database to authenticate with your Azure Storage account and access the items in the Azure Storage account container.

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'AZURE_CRED_NAME',
    username => 'username',
    password => 'password'
  );
END;
/
```

> **Note:**
>
> Here, the *username* is your Azure Storage account name and the *password* is your user access key.

For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

Creating a credential to access Azure Blob Storage or Azure Data Lake Storage is not required if you enable Azure service principal. See Use Azure Service Principal to Access Azure Resources for more information.

Optionally, you can test the access to Azure Blob Storage or Azure Data Lake Storage as shown in this example.

```
SELECT * FROM DBMS_CLOUD.LIST_OBJECTS('AZURE_CRED_NAME', 'https://
dbazure.blob.core.windows.net/my-azure-container/');
```

2. Create a table in your database where you want to load the data.

```
CREATE TABLE myazuretable (id NUMBER, name VARCHAR2(64));
```

3. Import data from the Azure Blob Storage or Azure Data Lake Storage container to your Autonomous Database.

   Specify the table name and the Azure credential name followed by the Azure Blob Storage or Azure Data Lake Storage object URL.

```
BEGIN
      DBMS_CLOUD.COPY_DATA(
          table_name => 'myazuretable',
          credential_name => 'AZURE_CRED_NAME',
          file_uri_list => 'https://dbazure.blob.core.windows.net/my-azure-
container/azure-data.txt',
          format => json_object('delimiter' value ',')
      );
END;
/
```

   For detailed information about the parameters, see COPY_DATA Procedure.

You have successfully imported data from Azure Blob Storage or Azure Data Lake Storage to your Autonomous Database. You can run this statement and verify the data in your table.

```
SELECT * FROM myazuretable;

ID  NAME
--  --------------
 1  Azure Direct Sales
 2  Azure Tele Sales
 3  Azure Catalog
 4  Azure Internet
 5  Azure Partners
```

For more information about loading data, see Load Data from Files in the Cloud.

Load Data into Autonomous Database from Google Cloud Storage

This example shows how to load data from Google Cloud Storage to Autonomous Database.

You have various options to perform data loading into Autonomous Database, such as:

- Using UI options: You can use the Data Studio Load tool user interface to create credentials for the cloud store location, select files containing data, and run data load jobs.

  See Loading Data from Cloud Storage

- Using Rest Data Services APIs: You can use the Data Studio Load tool APIs to create links to the cloud store location and run data load jobs.

  See Using Data Studio Data Load APIs in PL/SQL

- Using SQL commands as explained in this example.

All these methods use the same PL/SQL package `DBMS_CLOUD` for loading data. However, Data Studio provides additional benefits over SQL commands. It not only helps to analyze the source and create table definitions but also performs validation checks.

You require Google Cloud Platform (GCP) access credentials for user account authentication and an object URL for accessing the object in Google Cloud Storage bucket.

To load data from a Google Cloud Storage bucket:

1. Create credentials for GCP user account in the Autonomous Database.
2. Copy data from the Google Cloud Storage bucket to the database.

Topics

- Prepare for Loading Data from Google Cloud Storage
  Verify the prerequisites and prepare for loading data from Google Cloud Storage.
- Steps for Loading Data from Google Cloud Storage
  Run these steps to load data from Google Cloud Storage to Autonomous Database.

Prepare for Loading Data from Google Cloud Storage

Verify the prerequisites and prepare for loading data from Google Cloud Storage.

Prerequisites

A data file, for example, `gcp-data.txt` exists in the Google Cloud Storage bucket that you can import. The sample file in this example has the following contents:

```
1,GCP Direct Sales
2,GCP Tele Sales
3,GCP Catalog
4,GCP Internet
5,GCP Partners
```

On the Google side, log in to your Google Cloud Platform (GCP) account and do the following:

1. Create an access key for the user.

   For more information, see HMAC keys.

2. Obtain an object URL for the data file stored in the Google Cloud Storage bucket.

   For more information, see Request endpoints.

Steps for Loading Data from Google Cloud Storage

Run these steps to load data from Google Cloud Storage to Autonomous Database.

1. Store the Google Cloud Platform (GCP) access credentials in your Autonomous Database and specify a credential name. This enables the database to authenticate with your GCP user account and access the items in the Google Cloud Storage bucket.

```
SET DEFINE OFF
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'GOOGLE_CRED_NAME',
    username => 'username',
    password => 'password'
  );
END;
/
```

> **Note:**
>
> Here, the *username* is your Google account access key and the *password* is your access key secret.

For detailed information about the parameters, see CREATE_CREDENTIAL Procedure.

Creating a credential to access Google Cloud Platform (GCP) is not required if you enable Google service account. See Use Google Service Account to Access Google Cloud Platform Resources for more information.

Optionally, you can test the access to Google Cloud Storage bucket as shown in this example.

```
SELECT * FROM DBMS_CLOUD.LIST_OBJECTS('GOOGLE_CRED_NAME', 'https://
bucketname.storage.googleapis.com/');
```

2. Create a table in your database where you want to load the data.

```
CREATE TABLE mygoogletable (id NUMBER, name VARCHAR2(64));
```

3. Import data from the Google Cloud Storage bucket to your Autonomous Database.

   Specify the table name and the GCP credential name followed by the Google Cloud Storage object URL.

```
BEGIN
      DBMS_CLOUD.COPY_DATA(
          table_name => 'mygoogletable',
          credential_name => 'GOOGLE_CRED_NAME',
          file_uri_list => 'https://bucketname.storage.googleapis.com/gcp-
data.txt',
          format => json_object('delimiter' value ',')
      );
END;
/
```

For detailed information about the parameters, see COPY_DATA Procedure.

You have successfully imported data from Google Cloud Storage to your Autonomous Database. You can run this statement and verify the data in your table.

```
SELECT * FROM mygoogletable;

ID  NAME
--  --------------
 1  GCP Direct Sales
 2  GCP Tele Sales
 3  GCP Catalog
 4  GCP Internet
 5  GCP Partners
```

For more information about loading data, see Load Data from Files in the Cloud.

Load a Fixed-Width File into a New Table

This provides an example using `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` to load data from a fixed-width source file to an external table.

For this example, the fixed-width source file has the following data:

```
  0INDEX01    INDEX                  2001272020012720200127VALID
  1INDEX02    INDEX                  2001272020012720200127VALID
  2INDEX03    INDEX                  2001272020012720200127VALID
  3INDEX04    INDEX                  2001272020012720200127VALID
  4TABLE01    TABLE                  2001272020012720200918VALID
  5TABLE02    TABLE                  2001272020012720200918VALID
  6CLUSTER01  CLUSTER                2001272020012720200127VALID
  7INDEX05    INDEX                  2001272020012720200127VALID
  8INDEX06    INDEX                  2001272020012720200127VALID
  9INDEX07    INDEX                  2001272020012720200127VALID
 10INDEX08    INDEX                  2001272020012720200127VALID
 11TABLE03    TABLE                  2001272020012720200127VALID
 12INDEX09    INDEX                  2001272020012720200127VALID
 13INDEX10    INDEX                  2001272020012720200127VALID
 14TABLE04    TABLE                  2001272020012720200127VALID
 15INDEX11    INDEX                  2001272020012720200127VALID
```

1. From the console, select the compartment for your Autonomous Database, and then select the link to your Autonomous Database to open the console.

   > **Note:**
   >
   > These steps are shown using **Database Actions** to execute the PL/SQL code, and query the data. These actions can be performed from any SQL connection, connecting to the Autonomous Database as a user with the proper privileges.

2. On the Autonomous Database Details page select **Database Actions** and in the list click **SQL**.

   As an alternative, select **Database Actions** and click **View all database actions** to access the Database Actions Launchpad. From the **Development** section of the **Database Actions Launchpad**, select **SQL**.

3. Within the SQL Worksheet, enter and execute the following code:

```
BEGIN DBMS_CLOUD.CREATE_EXTERNAL_TABLE(
             table_name      => '<YOUR_TABLE_NAME>'
,            credential_name => '<YOUR_CREDENTIAL_NAME>'
,            file_uri_list   => '<YOUR_ORACLE_OBJECT_STORE_URL>'
,            format          => json_object('trimspaces' value
'rtrim','skipheaders' value '1', 'dateformat' value 'YYYYMMDD')
,            field_list      => 'object_id      (1:3)   char
                               , object_name    (4:14)  char
                               , object_type    (15:39)  char
                               , created_date1  (40:45)  date mask "YYMMDD"
                               , created_date2  (46:53)  date
                               , last_ddl_time  (54:61)  date
                               , status         (62:71)'
,            column_list     => 'object_id      number
                               , object_name    varchar2(30)
                               , object_type    varchar2(25)
                               , status         varchar2(10)
                               , created_date1  date
                               , created_date2  date
                               , last_ddl_time  date');
END;
/
```

Import Data Using Oracle Data Pump on Autonomous Database

Oracle Data Pump offers very fast bulk data and metadata movement between Oracle databases and Autonomous Databases.

Data Pump Import lets you import data from Data Pump files residing on Oracle Cloud Infrastructure Object Storage, Microsoft Azure, AWS S3, and Oracle Cloud Infrastructure Object Storage Classic. You can save your data to your Cloud Object Store and use Oracle Data Pump to load data to Autonomous Database.

> **Note:**
>
> When a load or import operation results in the following timezone related error, you need to upgrade your timezone file to the latest version available for your database:
>
> ```
> ORA-39405: Oracle Data Pump does not support importing from a source
> database with TSTZ version n+1
> into a target database with TSTZ version n.
> ```
>
> See Manage Time Zone File Updates on Autonomous Database for more information on this timezone related error.

Topics

- Export Your Existing Oracle Database to Import into Autonomous Database
  Use Oracle Data Pump to export your existing Oracle Database as the first step to migrate to Autonomous Database.

- Import Data with Oracle Data Pump Latest Version or an Older Version
  The steps to import data to Autonomous Database with Oracle Data Pump differ depending on the Oracle Data Pump version.
- Access Log Files for Data Pump Import
  The log files for Data Pump Import operations are stored in the directory you specify with the data pump `impdp` *directory* parameter.
- Oracle Data Pump Import and Table Compression
  Provides notes for using Oracle Data Pump import on Autonomous Database.
- Notes for Importing with Oracle Data Pump
  Lists notes for importing with Oracle Data Pump.

Export Your Existing Oracle Database to Import into Autonomous Database

Use Oracle Data Pump to export your existing Oracle Database as the first step to migrate to Autonomous Database.

Oracle recommends using Oracle Data Pump schema mode to migrate your database to Autonomous Database. You can list the schemas you want to export by using the `schemas` parameter.

For a faster migration, export your schemas into multiple Data Pump files and use parallelism. You can specify the dump file name format you want to use with the `dumpfile` parameter. Set the `parallel` parameter to at least the number of CPUs you have in your database.

You can use other Data Pump Export parameters, such as `compression`, depending on your requirements. For more information on Oracle Data Pump Export see *Oracle Database Utilities*.

You have two options to export data with Data Pump, depending on the Data Pump version and whether you include the `CREDENTIAL` parameter:

- Export Your Existing Oracle Database to a Local Database File (Export without Credential Parameter)
  Use Oracle Data Pump to export your existing Oracle Database and specify an optional directory object and file name in `directory-object-name:file-name` format, as the first step to migrate to Autonomous Database.
- Export Your Existing Oracle Database Directly to Cloud Object Storage (Export with Credential Parameter)
  Use Oracle Data Pump to export your existing Oracle Database directly to Cloud Object Storage, as the first step to migrate to Autonomous Database.

Export Your Existing Oracle Database to a Local Database File (Export without Credential Parameter)

Use Oracle Data Pump to export your existing Oracle Database and specify an optional directory object and file name in `directory-object-name:file-name` format, as the first step to migrate to Autonomous Database.

Oracle recommends using the following Data Pump parameters for faster and easier migration to Autonomous Database:

```
exclude=cluster,indextype,db_link
parallel=n
schemas=schema_name
dumpfile=export%l.dmp
```

The `exclude` parameters ensure that these object types are not exported.

With `encryption_pwd_prompt=yes` Oracle Data Pump export prompts for an encryption password to encrypt the dump files.

The following example exports the SH schema from a source Oracle Database for migration to a database with 16 CPUs:

```
expdp sh/sh@orcl \
exclude=cluster,indextype,db_link \
parallel=16 \
schemas=sh \
dumpfile=export%l.dmp \
encryption_pwd_prompt=yes
```

After you create the dumpfile(s), upload the dumpfile(s) to Cloud Object Storage. For example use `DBMS_CLOUD.PUT_OBJECT` to upload the dumpfiles.

See PUT_OBJECT Procedure for more information.

Notes for Data Pump parameters:

- If during the export with `expdp` you use the `encryption_pwd_prompt=yes` parameter, also use `encryption_pwd_prompt=yes` with your import and input the same password at the `impdp` prompt to decrypt the dump files (remember the password you supply during export). The maximum length of the encryption password is 128 bytes.
- The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.

  Use the legacy `%U` or `%u` wildcard for exports from Oracle Database prior to Release 12.2. If you use this option and more than 99 dump files are needed, you must specify multiple dumpfile names, each with the `%U` or `%u` parameter.

Export Your Existing Oracle Database Directly to Cloud Object Storage (Export with Credential Parameter)

Use Oracle Data Pump to export your existing Oracle Database directly to Cloud Object Storage, as the first step to migrate to Autonomous Database.

> **Note:**
>
> This option is supported for Oracle Data Pump Export 19.9 or later versions.

Oracle recommends using the following Data Pump parameters for faster and easier migration to Autonomous Database:

```
exclude=cluster,indextype,db_link
parallel=n
schemas=schema_name
dumpfile=https://objectstorage.example.com/schema_name.dmp
credential=credential_name
```

The `exclude` parameters ensure that these object types are not exported.

The following example exports the SH schema from a source Oracle Database for migration to a database with 16 CPUs:

```
expdp sh/sh@orcl \
exclude=cluster,indextype,db_link \
parallel=16 \
schemas=sh \
dumpfile=https://objectstorage.example.com/%l.dmp \
credential=sales-dept
```

Notes for Data Pump parameters:

- If during the export with `expdp` you use the `encryption_pwd_prompt=yes` parameter, also use `encryption_pwd_prompt=yes` with your import and input the same password at the `impdp` prompt to decrypt the dump files (remember the password you supply during export). The maximum length of the encryption password is 128 bytes.
- The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.

  Use the legacy `%U` or `%u` wildcard for exports from Oracle Database prior to Release 12.2. If you use this option and more than 99 dump files are needed, you must specify multiple dumpfile names, each with the `%U` or `%u` parameter.
- Data Pump Export does not support using an Oracle Cloud Infrastructure Object Storage pre-authenticated URL (PAR URL) for the `dumpfile` parameter.
- The `credential` parameter can be one of the following supported credential types:
  - Data Pump export supports Oracle Cloud Infrastructure Auth Token based credentials and Oracle Cloud Infrastructure Signing Key based credentials.
  - Data Pump export supports using a resource principal credential with `expdp`.

  See CREATE_CREDENTIAL Procedure for more information on the credential types for Oracle Cloud Infrastructure Cloud Object Storage.

Import Data with Oracle Data Pump Latest Version or an Older Version

The steps to import data to Autonomous Database with Oracle Data Pump differ depending on the Oracle Data Pump version.

- Import Data Using Oracle Data Pump Version 18.3 or Later
  Oracle recommends using the latest Oracle Data Pump version for importing data from Data Pump files into your Autonomous Database, as it contains enhancements and fixes for a better experience.
- Import Data Using Oracle Data Pump Version 18.3 or Later with OCI Resource Principal
  Oracle Data Pump supports importing data pump files into your Autonomous Database using an Oracle Cloud Infrastructure resource principal as a credential object.
- Import Data Using Oracle Data Pump Version 12.2 and Earlier
  You can import data from Data Pump files into your Autonomous Database using Data Pump client versions 12.2.0.1 and earlier by setting the `default_credential` parameter.
- Use Oracle Data Pump Import with a Pre-Authenticated URL
  Provides the steps to use a pre-authenticated URL (PAR URL) with Oracle Data Pump Import.

Import Data Using Oracle Data Pump Version 18.3 or Later

Oracle recommends using the latest Oracle Data Pump version for importing data from Data Pump files into your Autonomous Database, as it contains enhancements and fixes for a better experience.

Download the latest version of Oracle Instant Client, which includes Oracle Data Pump, for your platform from Oracle Instant Client Downloads. See the installation instructions on the platform install download page for the installation steps required after you download Oracle Instant Client.

In Oracle Data Pump version 18.3 and later, the `credential` argument authenticates Data Pump to the Cloud Object Storage service you are using for your source files. The `dumpfile` argument is a comma delimited list of URLs for your Data Pump files.

In Oracle Data Pump, if your source files reside on Oracle Cloud Infrastructure Object Storage you can use Oracle Cloud Infrastructure native URIs or Swift URIs. See DBMS_CLOUD URI Formats for details on these file URI formats.

To load an Oracle Data Pump dumpfile from Cloud Object Storage, run Oracle Data Pump Import and include the `credential` parameter:

1. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example, to create Oracle Cloud Infrastructure Auth Token credentials with the default Identity domain:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password'
     );
   END;
   /
   ```

   For OCI Object Storage the `username` parameter value must include the Identity domain and the user name from your profile. You can find the Identity domain associated with a user in the Oracle Cloud Infrastructure Console. For example, with the `oracleidentitycloudservice` Identity domain, this would be:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'oracleidentitycloudservice/adb_user@example.com',
       password => 'password'
     );
   END;
   /
   ```

   For more information on Oracle Cloud Infrastructure Auth Token authentication see CREATE_CREDENTIAL Procedure.

For example, to create Oracle Cloud Infrastructure Signing Key based credentials:

```
BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'DEF_CRED_NAME',
       user_ocid       =>
'ocid1.user.oc1..aaaaaaaauq54mi7zdyfhw33ozkwuontjceel7fok5nq3bf2vwetkpqsoa'
,
       tenancy_ocid    =>
'ocid1.tenancy.oc1..aabbbbbbaafcue47pqmrf4vigneebgbcmmoy5r7xvoypicjqqge32ew
nrcyx2a',
       private_key     =>
'MIIEogIBAAKCAQEAtUnxbmrekwgVac6FdWeRzoXvIpA9+0r1.....wtnNpESQQQ0QLGPD8NM//
JEBg=',
       fingerprint     =>
'f2:db:f9:18:a4:aa:fc:94:f4:f6:6c:39:96:16:aa:27');
END;
/
```

For more information on Oracle Cloud Infrastructure Signing Key based credentials see CREATE_CREDENTIAL Procedure.

Supported credential types:

- Data Pump Import supports Oracle Cloud Infrastructure Auth Token based credentials and Oracle Cloud Infrastructure Signing Key based credentials.

  For more information on the credential types for Oracle Cloud Infrastructure Cloud Object Storage, see CREATE_CREDENTIAL Procedure.

- Data Pump supports using an Oracle Cloud Infrastructure Object Storage pre-authenticated URL for the `dumpfile` parameter. When you use a pre-authenticated URL, providing the `credential` parameter is required and the `credential` value can be `NULL`. See Using Pre-Authenticated Requests for more information.

- Data Pump supports using a resource principal credential with `impdp`. See Import Data Using Oracle Data Pump Version 18.3 or Later with OCI Resource Principal for more information.

2. Run Data Pump Import with the *dumpfile* parameter set to the list of file URLs on your Cloud Object Storage and the *credential* parameter set to the name of the credential you created in the previous step. For example:

```
impdp admin/password@db2022adb_high \
     directory=data_pump_dir \
     credential=def_cred_name \
     dumpfile= https://namespace-string.objectstorage.us-ashburn-1.oci.customer-
oci.com/n/namespace-string/b/bucketname/o/export%l.dmp \
     parallel=16 \
     encryption_pwd_prompt=yes \
     exclude=cluster,indextype,db_link
```

Notes for Data Pump parameters:

- If during the export with `expdp` you used the `encryption_pwd_prompt=yes` parameter then use `encryption_pwd_prompt=yes` and input the same password at the `impdp` prompt that you specified during the export.

- The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for

exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.

Use the legacy `%U` or `%u` wildcard for exports from Oracle Database prior to Release 12.2. If you use this option and more than 99 dump files are needed, you must specify multiple dumpfile names, each with the `%U` or `%u` parameter.

- If your bucket and data do not reside in a commercial (OC1) realm, where OCI Dedicated Endpoints are not supported, use the following URI format for `dumpfile`:

  `https://objectstorage.`*`region`*`.oraclecloud.com/n/`*`namespace-string`*`/b/`*`bucketname`*`/o/`*`filename`*

- The `credential` parameter cannot be an Azure service principal, Amazon Resource Name (ARN), or a Google service account. See Configure Policies and Roles to Access Resources for more information on resource principal based authentication.
- When you specify the `dumpfile` value as a pre-authenticated URL, the `credential` parameter is required and the value can be `NULL`.

  See Use Oracle Data Pump Import with a Pre-Authenticated URL for details on the steps required to use a pre-authenticated URL.

For `dumpfile`, this example uses the recommended URI format using OCI Dedicated Endpoints for commercial realm (OC1). The *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Object Storage Dedicated Endpoints, Regions and Availability Domains, and Understanding Object Storage Namespaces for more information.
For the dump file URL format for different Cloud Object Storage services, see DBMS_CLOUD URI Formats.

In this example the following are excluded during the Data Pump Import:

- Clusters
- Indextypes
- Database links

To perform a full import or to import objects that are owned by other users, you need the `DATAPUMP_CLOUD_IMP` role.

For information on disallowed objects in Autonomous Database, see SQL Commands.

See Notes for Importing with Oracle Data Pump for additional notes for using Oracle Data Pump Import.

See Oracle Data Pump Import and Table Compression for details on table compression using Oracle Data Pump import on Autonomous Database.

For detailed information on Oracle Data Pump Import parameters see *Oracle Database Utilities*.

Import Data Using Oracle Data Pump Version 18.3 or Later with OCI Resource Principal

Oracle Data Pump supports importing data pump files into your Autonomous Database using an Oracle Cloud Infrastructure resource principal as a credential object.

If you use Oracle Data Pump `expdp` to export directly to Object Store then you must use the same credential that was used to export when you import with `impdp`. In this case, Oracle Data Pump import does not support Oracle Cloud Infrastructure resource principal credentials. Other

methods for uploading are supported for using `impdp` using resource principal credentials. For example, if you upload Oracle Data Pump files on Object Store using `DBMS_CLOUD.PUT_OBJECT`, you can import the files using Oracle Data pump `impdp` using resource principal credentials. Likewise, when you use the Oracle Cloud Infrastructure Console to upload data pump files to Object Store, you can use resource principal credentials to import into an Autonomous Database instance with Oracle Data pump `impdp`.

In Oracle Data Pump, if your source files reside on Oracle Cloud Infrastructure Object Storage you can use Oracle Cloud Infrastructure native URIs or Swift URIs. See DBMS_CLOUD URI Formats for details on these file URI formats.

1. Configure the dynamic groups and policies and enable Oracle Cloud Infrastructure resource principal to access the Object Store location where the data pump files you want to import reside.

   See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

2. Run Data Pump Import with the *dumpfile* parameter set to the list of file URLs on your Cloud Object Storage and the *credential* parameter set to `OCI$RESOURCE_PRINCIPAL`.

   For example:

   ```
   impdp admin/password@db2022adb_high \
        directory=data_pump_dir \
        credential= 'OCI$RESOURCE_PRINCIPAL' \
        dumpfile= https://namespace-string.objectstorage.us-ashburn-1.oci.customer-
   oci.com/n/namespace-string/b/bucketname/o/export%l.dmp \
        parallel=16 \
        encryption_pwd_prompt=yes \
        exclude=cluster,indextype,db_link
   ```

   Notes for Data Pump parameters:

   - If during the export with `expdp` you used the `encryption_pwd_prompt=yes` parameter, also use `encryption_pwd_prompt=yes` and input the same password at the `impdp` prompt that you specified during the export.
   - The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.

     Use the legacy `%U` or `%u` wildcard for exports from Oracle Database prior to Release 12.2. If you use this option and more than 99 dump files are needed, you must specify multiple dumpfile names, each with the `%U` or `%u` parameter.
   - If your bucket and data do not reside in a commercial (OC1) realm, where OCI Dedicated Endpoints are not supported, use the following URI format for `dumpfile`:

     `https://objectstorage.region.oraclecloud.com/n/namespace-string/b/bucketname/o/filename`
   - When you specify the `dumpfile` value as a pre-authenticated URL, the `credential` parameter is required and the value can be `NULL`.

     See Use Oracle Data Pump Import with a Pre-Authenticated URL for details on the steps required to use a pre-authenticated URL.

For `dumpfile`, this example uses the recommended URI format using OCI Dedicated Endpoints for commercial realm (OC1). The *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Object Storage Dedicated Endpoints, Regions and Availability Domains, and Understanding Object Storage Namespaces for more information.
For the dump file URL format for different Cloud Object Storage services, see DBMS_CLOUD URI Formats.

In this example the following are excluded during the Data Pump Import:

- Clusters
- Indextypes
- Database links

To perform a full import or to import objects that are owned by other users, you need the `DATAPUMP_CLOUD_IMP` role.

For information on disallowed objects in Autonomous Database, see SQL Commands.

See Notes for Importing with Oracle Data Pump for additional notes for using Oracle Data Pump Import.

For detailed information on Oracle Data Pump Import parameters see *Oracle Database Utilities*.

Import Data Using Oracle Data Pump Version 12.2 and Earlier

You can import data from Data Pump files into your Autonomous Database using Data Pump client versions 12.2.0.1 and earlier by setting the `default_credential` parameter.

Data Pump Import versions 12.2.0.1 and earlier do not have the *credential* parameter. If you are using an older version of Data Pump Import you need to define a default credential property for Autonomous Database and use the `default_credential` keyword in the `dumpfile` parameter.

In Oracle Data Pump, if your source files reside on Oracle Cloud Infrastructure Object Storage you can use the Oracle Cloud Infrastructure native URIs, or Swift URIs. See DBMS_CLOUD URI Formats for details on these file URI formats.

Importing with Older Oracle Data Pump Versions and Setting `default_credential`

1. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example, to create Oracle Cloud Infrastructure Auth Token credentials:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password'
     );
   END;
   /
   ```

   For more information on Oracle Cloud Infrastructure Auth Token authentication see CREATE_CREDENTIAL Procedure.

For example, to create Oracle Cloud Infrastructure Signing Key based credentials:

```
BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'DEF_CRED_NAME',
       user_ocid       =>
'ocid1.user.oc1..aaaaaaaauq54mi7zdyfhw33ozkwuontjceel7fok5nq3bf2vwetkpqsoa'
,
       tenancy_ocid    =>
'ocid1.tenancy.oc1..aabbbbbbaafcue47pqmrf4vigneebgbcmmoy5r7xvoypicjqqge32ew
nrcyx2a',
       private_key     =>
'MIIEogIBAAKCAQEAtUnxbmrekwgVac6FdWeRzoXvIpA9+0r1.....wtnNpESQQQ0QLGPD8NM//
JEBg=',
       fingerprint     =>
'f2:db:f9:18:a4:aa:fc:94:f4:f6:6c:39:96:16:aa:27');
END;
/
```

For more information on Oracle Cloud Infrastructure Signing Key based credentials see CREATE_CREDENTIAL Procedure.

Supported credential types:

- Data Pump import supports Oracle Cloud Infrastructure Auth Token based credentials and Oracle Cloud Infrastructure Signing Key based credentials.

  For more information on the credential types for Oracle Cloud Infrastructure Cloud Object Storage, see CREATE_CREDENTIAL Procedure.
- Data Pump supports using an Oracle Cloud Infrastructure Object Storage pre-authenticated URL for the `dumpfile`. When you use a pre-authenticated URL, setting the `DEFAULT_CREDENTIAL` is required and the `DEFAULT_CREDENTIAL` value can be `NULL`. See Using Pre-Authenticated Requests for more information.
- Data Pump supports using a resource principal credential with `impdp`.

2. Set the credential as the default credential for your Autonomous Database, as the ADMIN user. For example:

```
ALTER DATABASE PROPERTY SET DEFAULT_CREDENTIAL = 'ADMIN.DEF_CRED_NAME'
```

The `DEFAULT_CREDENTIAL` can be an OCI Resource Principal. For example:

```
ALTER DATABASE PROPERTY SET DEFAULT_CREDENTIAL = 'OCI$RESOURCE_PRINCIPAL'
```

See Configure Policies and Roles to Access Resources for more information on resource principal based authentication.

> **Note:**
>
> The `DEFAULT_CREDENTIAL` value cannot be an Azure service principal, Amazon Resource Name (ARN), or a Google service account.

The `DEFAULT_CREDENTIAL` value can be set to `NULL` if you are using a pre-authenticated URL.

3. Run Data Pump Import with the `dumpfile` parameter set to the list of file URLs on your Cloud Object Storage, and set the `default_credential` keyword. For example:

```
impdp admin/password@db2022adb_high \
     directory=data_pump_dir \
     dumpfile=default_credential:https://namespace-string.objectstorage.us-
ashburn-1.oci.customer-oci.com/n/namespace-string/b/bucketname/o/export%l.dmp \
     parallel=16 \
     encryption_pwd_prompt=yes \
     exclude=cluster,indextype,db_link
```

Notes for the Data Pump parameters:

- If during the export with `expdp` you used the `encryption_pwd_prompt=yes` parameter then use `encryption_pwd_prompt=yes` and input the same password at the `impdp` prompt that you specified during the export.
- The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.

  Use the legacy `%U` or `%u` wildcard for exports from Oracle Database prior to Release 12.2. If you use this option and more than 99 dump files are needed, you must specify multiple dumpfile names, each with the `%U` or `%u` parameter.
- If your bucket and data do not reside in a commercial (OC1) realm, where OCI Dedicated Endpoints are not supported, use the following URI format for `dumpfile`:

  `https://objectstorage.region.oraclecloud.com/n/namespace-string/b/bucketname/o/filename`
- When you specify the `dumpfile` value as a pre-authenticated URL, setting the `default_credential` parameter is required and the value can be `NULL`.

  See Use Oracle Data Pump Import with a Pre-Authenticated URL for details on the steps required to use a pre-authenticated URL.

For `dumpfile`, this example uses the recommended URI format using OCI Dedicated Endpoints for commercial realm (OC1). The *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Object Storage Dedicated Endpoints, Regions and Availability Domains, and Understanding Object Storage Namespaces for more information.
For the dump file URL format for different Cloud Object Storage services, see DBMS_CLOUD URI Formats.

In this example the following are excluded during the Data Pump Import:

- Clusters
- Indextypes
- Database links

> **Note:**
>
> To perform a full import or to import objects that are owned by other users, you need the `DATAPUMP_CLOUD_IMP` role.

For information on disallowed objects in Autonomous Database, see SQL Commands.

See Notes for Importing with Oracle Data Pump for additional notes for using Oracle Data Pump Import.

See Oracle Data Pump Import and Table Compression for details on table compression using Oracle Data Pump import on Autonomous Database.

For detailed information on Oracle Data Pump Import parameters see *Oracle Database Utilities*.

Use Oracle Data Pump Import with a Pre-Authenticated URL

Provides the steps to use a pre-authenticated URL (PAR URL) with Oracle Data Pump Import.

1. Use Oracle Data Pump `expdp` and export to local storage.

   See Export Your Existing Oracle Database to a Local Database File (Export without Credential Parameter) for more information.

2. Upload the dumpfile(s) to Oracle Cloud Infrastructure Object Storage.

   For example use `DBMS_CLOUD.PUT_OBJECT` to upload the dumpfiles.

3. Create a pre-authenticated URL on Oracle Cloud Infrastructure Object Storage, either on the object store bucket if there are multiple dumpfiles or on the dumpfile, if there is only one file.

   See Object Storage Pre-Authenticated Requests for more information.

4. Import the dumpfile(s) with the `dumpfile` parameter value set to the pre-authenticated URL.

   See Import Data Using Oracle Data Pump Version 18.3 or Later for more information.

Access Log Files for Data Pump Import

The log files for Data Pump Import operations are stored in the directory you specify with the data pump `impdp` *directory* parameter.

To access the log file you need to move the log file to your Cloud Object Storage using the procedure `DBMS_CLOUD.PUT_OBJECT`. For example, the following PL/SQL block moves the file `import.log` to your Cloud Object Storage:

```
BEGIN
  DBMS_CLOUD.PUT_OBJECT(
    credential_name => 'DEF_CRED_NAME',
    object_uri => 'https://objectstorage.us-ashburn-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/import.log',
    directory_name  => 'DATA_PUMP_DIR',
    file_name => 'import.log');
END;
/
```

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

For more information, see DBMS_CLOUD Subprograms and REST APIs.

Oracle Data Pump Import and Table Compression

Provides notes for using Oracle Data Pump import on Autonomous Database.

By default the Oracle Data Pump Import utility imports data with the same compression type as specified for tables on the source database (the database where you exported your data from). If you want to leave compression to Autonomous Database, specify the following parameter when you import your data:

```
TRANSFORM=TABLE_COMPRESSION_CLAUSE:NONE
```

The `TRANSFORM` parameter with this option specifies that Oracle Data Pump Import should ignore the compression type of your source tables. Using this option, Oracle Data Pump imports the tables into Autonomous Database using the default compression type, where the default compression type depends on the Autonomous Database workload type:

- **Data Warehouse**: The default table compression is Hybrid Columnar Compression.

  Oracle recommends using this default if your application primarily uses bulk load operations on your tables, as the loads will compress the data. Query performance on these tables will benefit from compression as queries need to do less IO.

  If you have staging tables replicated from other systems using Oracle GoldenGate or other replication tools, or your application primarily uses row-by-row DML operations on tables, Oracle recommends keeping the tables uncompressed or using Advanced Row Compression.
- **Transaction Processing**: The default table compression is no compression.
- **JSON Database**: The default table compression is no compression.
- **APEX**: The default table compression is no compression.

See TRANSFORM for more information on the Oracle Data Pump Import `TRANSFORM` parameter.

See About Table Compression for more information.

Notes for Importing with Oracle Data Pump

Lists notes for importing with Oracle Data Pump.

- For the best import performance use the `HIGH` database service for your import connection and set the `parallel` parameter to one quarter the number of ECPUs (.25 x **ECPU count**). If you are using OCPU compute model, set the parallel parameter to the number of OCPUs (1 x **OCPU count**).

  See Manage Concurrency and Priorities on Autonomous Database for information on database service names.

- You can also use Data Pump Import to import SODA collections on Autonomous Database. See Import SODA Collection Data Using Oracle Data Pump Version 19.6 or Later for more information.
- When you perform Oracle Data Pump export to Object Storage with a Swift URI, you must use Swift credentials to import with Oracle Data Pump import. See Oracle Cloud Infrastructure Object Storage Swift URI Format for more information on Swift URIs.

  See Export Your Existing Oracle Database Directly to Cloud Object Storage (Export with Credential Parameter) for more information.
- When you perform Oracle Data Pump export to Object Storage with a native URI, you can import using either Swift credentials or Signing Key based Credentials. See Oracle Cloud Infrastructure Object Storage Native URI Format for more information on Native URIs.

  See Export Your Existing Oracle Database Directly to Cloud Object Storage (Export with Credential Parameter) for more information.
- You must use a multiple step process to export with Oracle Data Pump Export if you want to use Oracle Data Pump Import with a PAR URL. See Use Oracle Data Pump Import with a Pre-Authenticated URL for details.

Load Data from Local Files with Oracle Database Actions

Using Oracle Database Actions, from the Worksheet page, you can load data from local files into an existing table.

- Load Data into Existing Autonomous Database Table with Oracle Database Actions
  You can load data into an existing table in Autonomous Database with the Database Actions import from file feature.

Load Data into Existing Autonomous Database Table with Oracle Database Actions

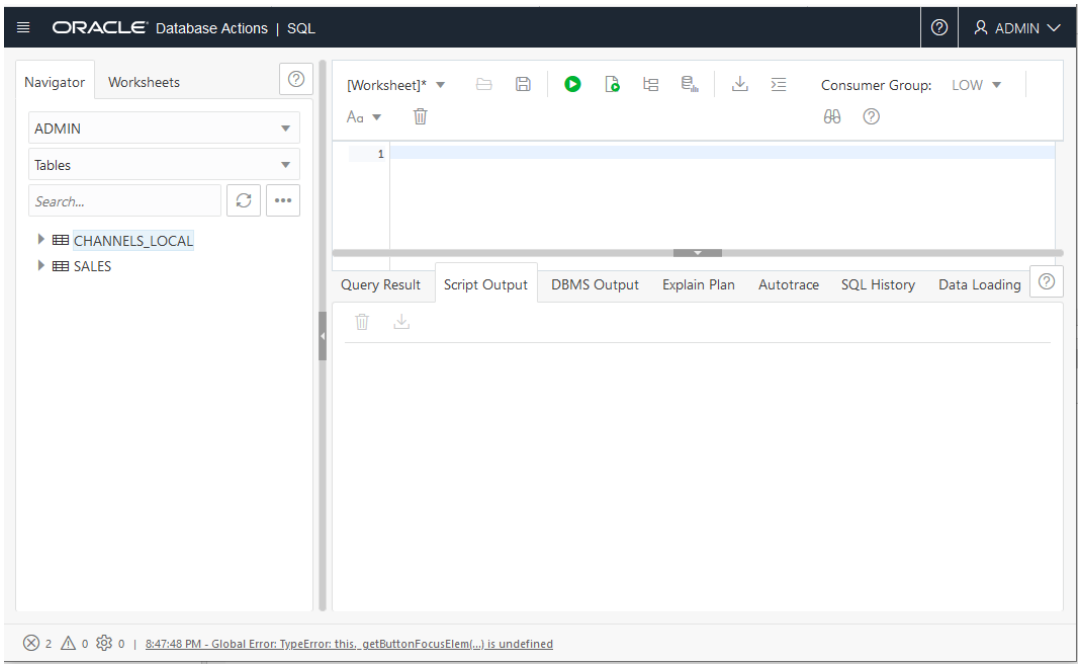
You can load data into an existing table in Autonomous Database with the Database Actions import from file feature.

Before you load data, create the table in Autonomous Database. The file formats that you can upload with the Database Actions upload feature are CSV, XLS, XLSX, TSV and TXT.

To upload data from local files to an existing table with Database Actions, do the following:

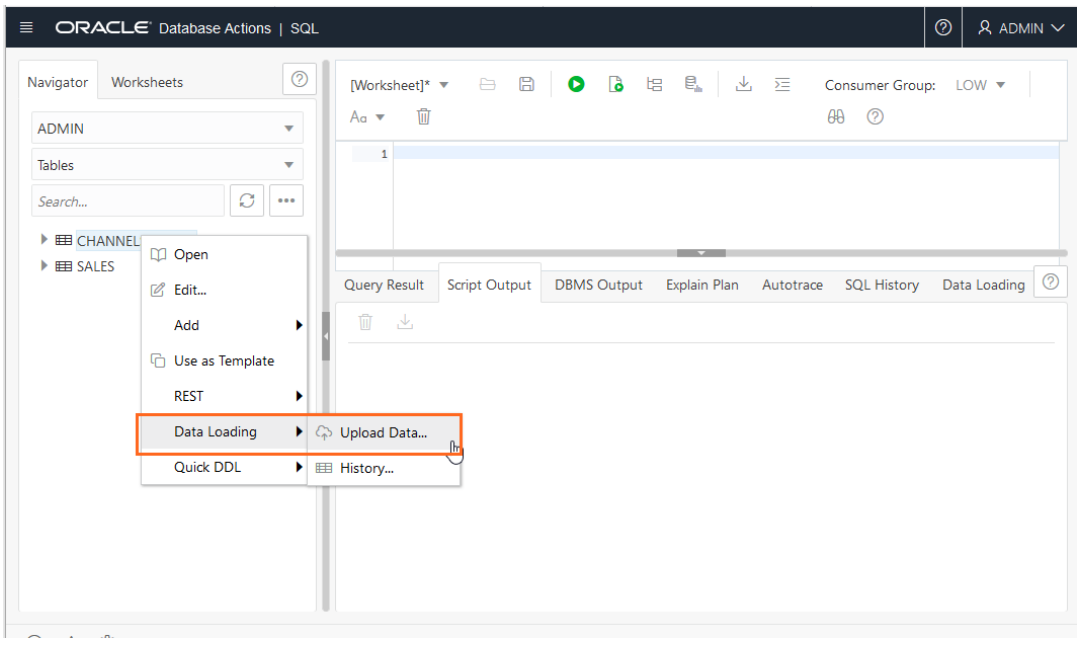
1. Access Database Actions from the Oracle Cloud Infrastructure Console or with the Database Actions link provided to you.
2. To import data, in Database Actions, under Development click **SQL**.

   This shows an SQL worksheet.

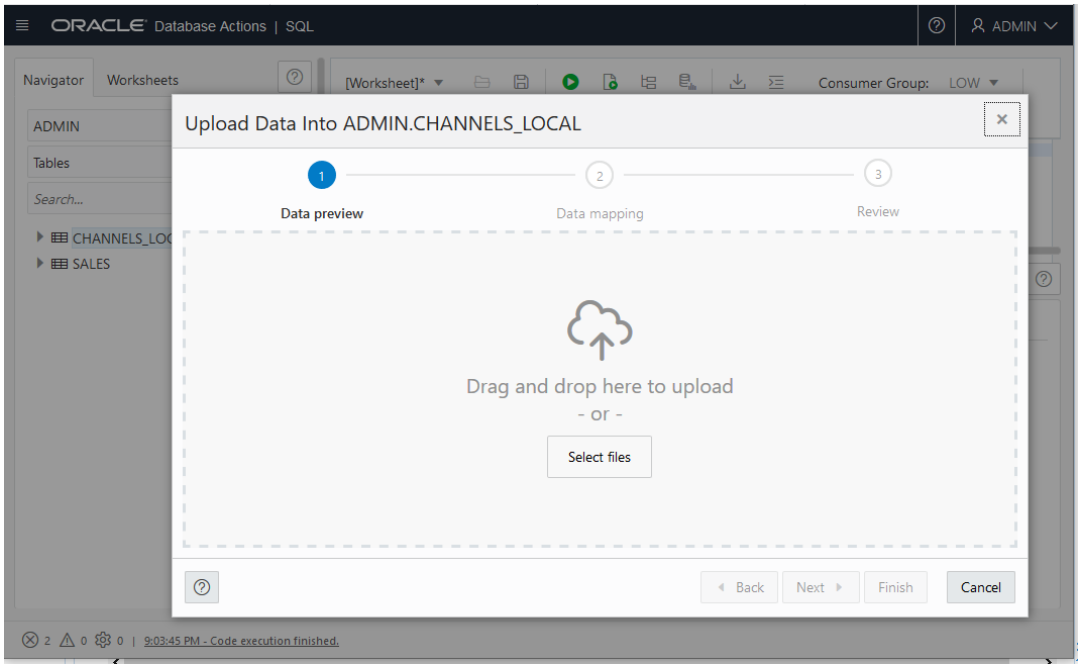


3. In the **Navigator**, right-click the table where you want to load data.
4. In the menu select **Data loading → Upload Data...**

   For example, select the `SALES` table, right-click, and select **Data loading → Upload Data...**



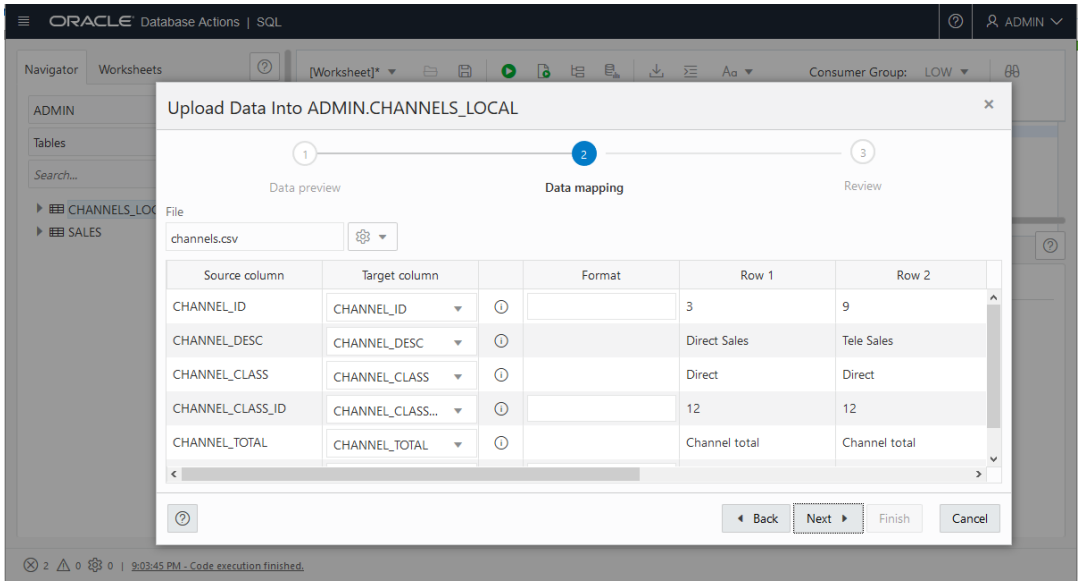
This shows the Import data dialog:



5. In the Import data dialog you can either drag and drop files or click **Select files** to show a browser to select the files to import.
6. Complete the mapping for the columns you are importing. There are a number of options for column mapping. Click (Show/Hide options) icon to show the data import and format options to change column names, skip rows, rows to load, and various other options.

   Click **Apply** to apply the options you select.
7. When you finish selecting format and mapping options, click **Next** to preview the column mapping.

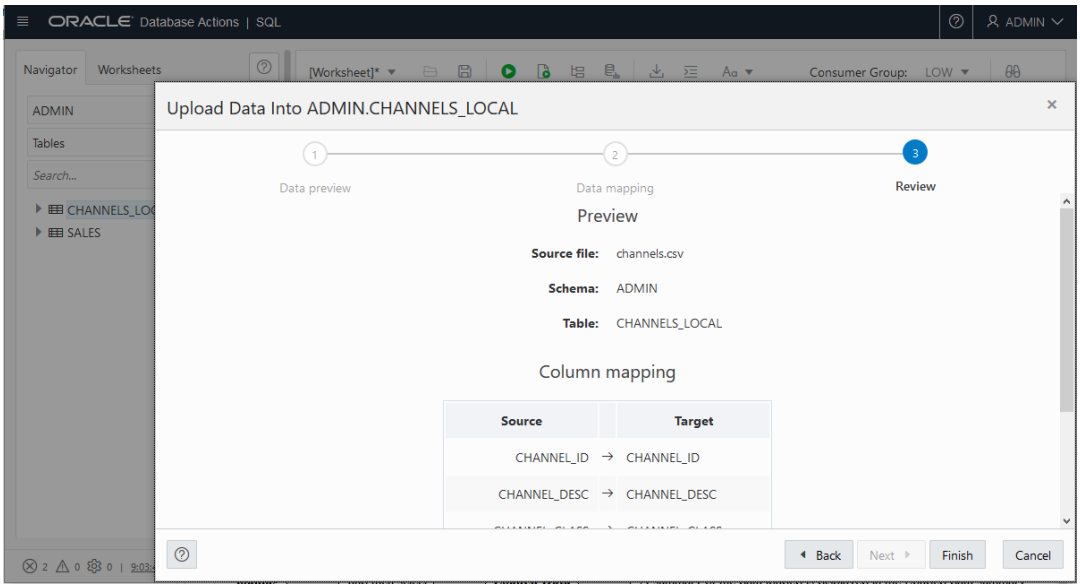
   If there is a problem at this stage, information shows with more details, such as: **2 pending actions**. This means you need to correct or fix the source file data before you import.



8. Click **Next**.

9. Click **Next** to review the column mapping.

   This shows the **Review** page to review the source columns and target columns for the import:



10. Click **Finish**.

11. Click **OK** to confirm the import.

    Depending on the size of the data file you are importing, the import may take some time.

Database Actions provides history to show the status of the import and to allow you to review the results or errors associated with the import operation.

For a detailed summary of the upload process, right-click the table in the **Navigator** tab, select **Data loading**, and then select **Loaded Data**. A summary of the data loaded is displayed in the Loaded data summary dialog.

If any data failed to load, you can view the number of rows in the Failed Rows column. Click the column and a dialog is displayed showing the failed rows.

In the Loaded data summary dialog, you can also search for files loaded by schema name, table name, or file name. To remove the loaded files, click the Delete icon.

See Uploading Data from Local Files for more information on using Database Actions to upload data.

Load Data or Query Data from Files in a Directory

You can use `DBMS_CLOUD` procedures to load data from files in a directory, including directories created on attached network file systems. You can also use these procedures to create external tables that you can use to query data.

The following `DBMS_CLOUD` procedures support loading data into the database from a directory:

- `DBMS_CLOUD.COPY_COLLECTION`
- `DBMS_CLOUD.COPY_DATA`

In addition, the following `DBMS_CLOUD` procedures support creating external tables from data in files in a directory.

- DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE
- DBMS_CLOUD.CREATE_EXTERNAL_TABLE
- DBMS_CLOUD.CREATE_HYBRID_PART_TABLE

Depending on the procedure, use either the file_uri_list parameter or the partitioning_clause parameter to specify files in one or more directories.

To load data from a directory, you do not need to include the credential_name parameter, but you need READ object privileges on the directory.

For example, you can load data into an existing table using DBMS_CLOUD.COPY_DATA:

1. Use an existing directory, create a directory, or attach a network file system for the source files.

   See Create Directory in Autonomous Database for information on creating a local directory on your Autonomous Database instance.

   See Attach Network File System to Autonomous Database for information on attaching a network file system that contains the data you want to load.

2. Load data with a DBMS_CLOUD procedure.

   For example:

```
CREATE TABLE CHANNELS
   (channel_id CHAR(1),
    channel_desc VARCHAR2(20),
    channel_class VARCHAR2(20)
   );
/

BEGIN
 DBMS_CLOUD.COPY_DATA(
    table_name => 'CHANNELS',
    file_uri_list => 'MY_DIR:channels.txt',
    format => json_object('delimiter' value ',')
 );
END;
/
```

   The parameters are:

   - table_name: is the target table's name.
   - file_uri_list: is a directory and file names specification for the source files you want to load.

     You can specify one directory and one or more file names or use a comma separated list of directories and file names. The format to specify a directory is:'*MY_DIR*:*filename.ext*'. By default the directory name *MY_DIR* is a database object and is case-insensitive. The file name is case sensitive.

     See Load Data from Directories in Autonomous Database for more details and example of specifying files in a directory. This also shows information on quoting the directory name to make the directory name case sensitive, and for information on using wildcards.

   - format: defines the options you can specify to describe the format of the source file, including whether the file is of type text, ORC, Parquet, or Avro.

See COPY_DATA Procedure for more information.

See Attach Network File System to Autonomous Database for information on attaching network file systems.

Load Data from Local Files Using SQL*Loader

Instead of using SQL*Loader Oracle recommends loading data from the Cloud Object Storage for better performance and enhanced functionality.

For information on loading from Cloud Object Store, see Load Data from Files in the Cloud.

Depending on your workload type, note the following:

- **Data Warehouse:** If you use SQL*Loader to load data, note that Autonomous Database does not gather optimizer statistics for your load and you need to gather optimizer statistics manually as explained in Manage Optimizer Statistics on Autonomous Database. Autonomous Database gathers optimizer statistics automatically for tables loaded with direct path operations issued in SQL (direct path load operations that bypass the SQL data processing, such as SQL*Loader direct path, do not collect statistics).
- **Transaction Processing** or **JSON Database**: If you use SQL*Loader to load data, note that Autonomous Database does not gather optimizer statistics for your load and you need to gather optimizer statistics manually as explained in in Manage Optimizer Statistics on Autonomous Database or wait for the automatic statistic gathering task to kick in.

For detailed information on SQL*Loader see, Oracle Database Utilities.

Using Data Pipelines for Continuous Load and Export

Data pipelines allow you to repeatedly load data from object store or export data to object store. Load pipelines provide continuous incremental data loading from external sources (as data arrives on object store it is loaded to a database table). Export pipelines provide continuous incremental data exporting to object store (as new data appears in a database table it is exported to object store).

- About Data Pipelines on Autonomous Database
- Create and Configure Pipelines
  You can create one or more load or export pipelines. When you create a pipeline, you use parameters and set pipeline attributes to configure the pipeline.
- Test Pipelines
- Control Pipelines (Start, Stop, Drop, or Reset a Pipeline)
  After you create and test a pipeline, you control a pipeline by starting, stopping, or dropping the pipeline. You can also reset a pipeline.
- Monitor and Troubleshoot Pipelines
  All pipelines that are created are logged in the `DBMS_CLOUD_PIPELINE` views.
- Use Oracle Maintained Pipelines
  Autonomous Database provides built-in pipelines. These pipelines are preconfigured and can be started by the ADMIN user. Oracle Maintained pipelines are owned by ADMIN user.

About Data Pipelines on Autonomous Database

Autonomous Database data pipelines are either load pipelines or export pipelines.

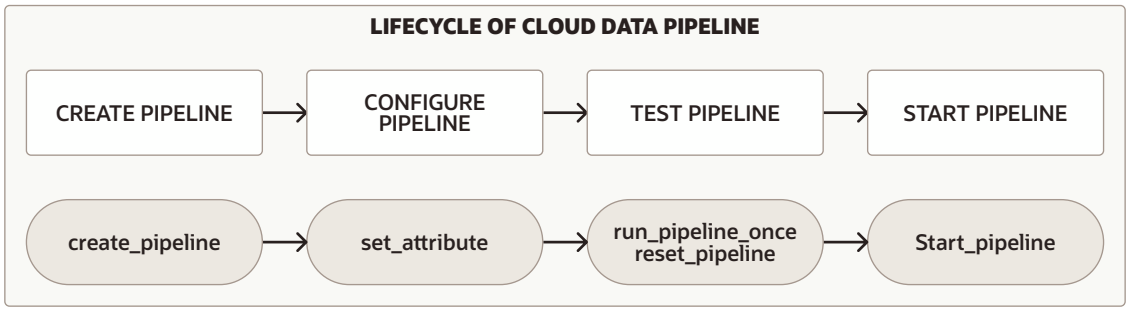
Load pipelines provide continuous incremental data loading from external sources (as data arrives on object store it is loaded to a database table). Export pipelines provide continuous incremental data exporting to object store (as new data appears in a database table it is exported to object store). Pipelines use database scheduler to continuously load or export incremental data.

Autonomous Database data pipelines provide the following:

- **Unified Operations**: Pipelines allow you to quickly and easily load or export data and repeat these operations at regular intervals for new data. The `DBMS_CLOUD_PIPELINE` package provides a unified set of PL/SQL procedures for pipeline configuration and for creating and starting a scheduled job for load or export operations.
- **Scheduled Data Processing**: Pipelines monitor their data source and periodically load or export the data as new data arrives.
- **High Performance**: Pipelines scale data transfer operations with the available resources on your Autonomous Database. Pipelines by default use parallelism for all load or export operations, and scale based on the CPU resources available on your Autonomous Database, or based on a configurable priority attribute.
- **Atomicity and Recovery**: Pipelines guarantee atomicity such that files in object store are loaded exactly once for a load pipeline.
- **Monitoring and Troubleshooting**: Pipelines provide detailed log and status tables that allow you to monitor and debug pipeline operations.
- **Multicloud Compatible**: Pipelines on Autonomous Database support easy switching between cloud providers without application changes. Pipelines support all the credential and object store URI formats that Autonomous Database supports (Oracle Cloud Infrastructure Object Storage, Amazon S3, Azure Blob Storage or Azure Data Lake Storage, Google Cloud Storage, and Amazon S3-Compatible object stores).
- About the Data Pipeline Lifecycle on Autonomous Database
  The `DBMS_CLOUD_PIPELINE` package provides procedures for creating, configuring, testing, and starting a pipeline. The pipeline lifecycle and procedures are the same for both load and export pipelines.
- About Load Pipelines on Autonomous Database
- About Export Pipelines on Autonomous Database
  Use an export pipeline for continuous incremental export of data from the database to object store. An export pipeline periodically identifies candidate data and uploads the data to object store.
- About Oracle Maintained Pipelines
  Autonomous Database provides built-in pipelines for exporting logs to object store. These pipelines are preconfigured and can be started by the ADMIN user.

About the Data Pipeline Lifecycle on Autonomous Database

The `DBMS_CLOUD_PIPELINE` package provides procedures for creating, configuring, testing, and starting a pipeline. The pipeline lifecycle and procedures are the same for both load and export pipelines.



For either pipeline type you perform the following steps to create and use a pipeline:

1. Create and configure the pipeline. See Create and Configure Pipelines for more information.
2. Test a new pipeline. See Test Pipelines for more information.
3. Start a pipeline. See Start a Pipeline for more information.

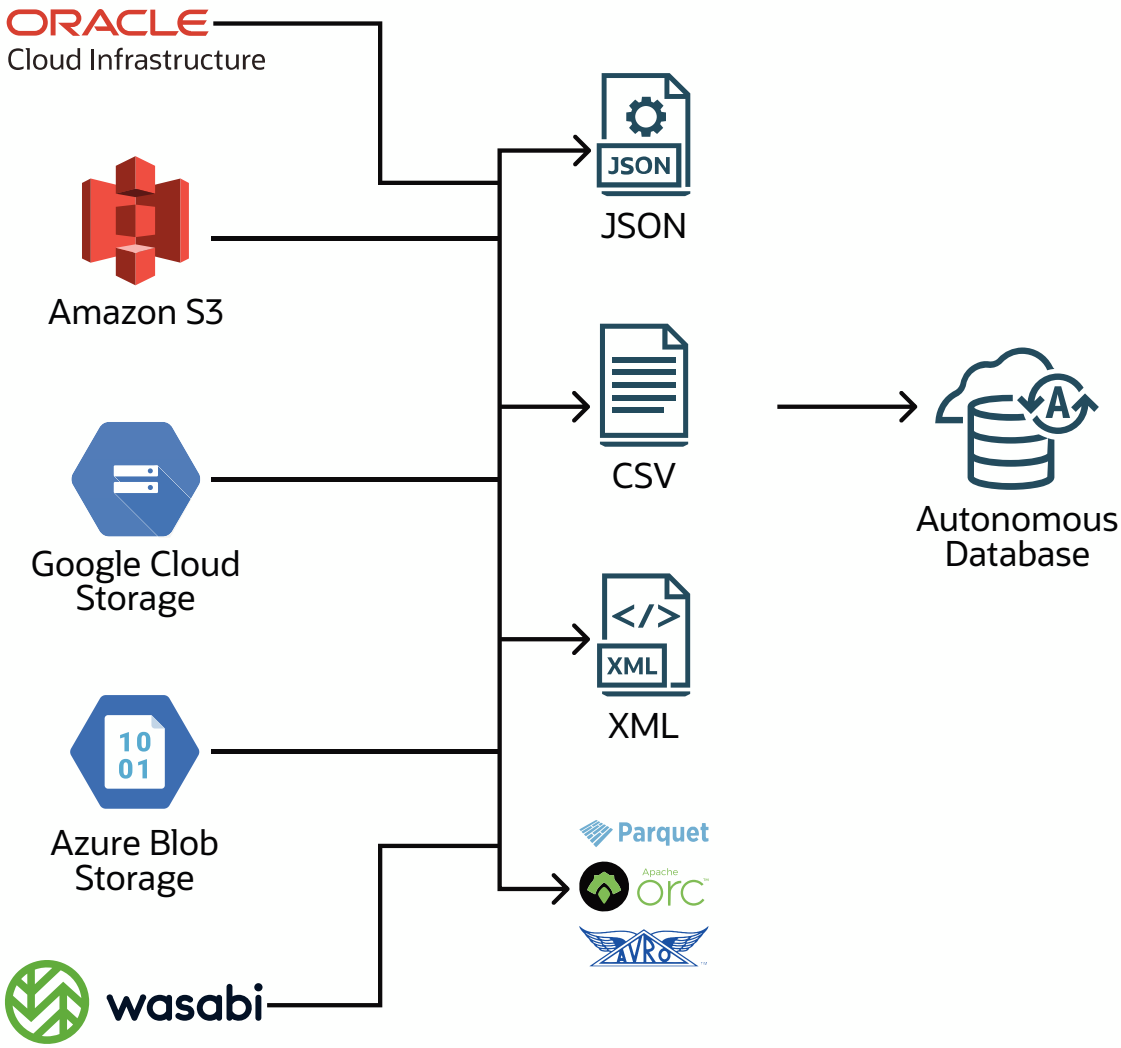
In addition, you can monitor, stop, or drop pipelines:

- While a pipeline is running, either during testing or during regular use after you start the pipeline, you can monitor the pipeline. See Monitor and Troubleshoot Pipelines for more information.
- You can stop a pipeline and later start it again, or drop a pipeline when you are finished using the pipeline. See Stop a Pipeline and Drop a Pipeline for more information.

About Load Pipelines on Autonomous Database

Use a load pipeline for continuous incremental data loading from external files in object store into a database table. A load pipeline periodically identifies new files in object store and loads the new data into the database table.
A load pipeline operates as follows (some of these features are configurable using pipeline attributes):

- Object store files are loaded in parallel into a database table.
  - A load Pipeline uses the object store file name to uniquely identify and load newer files.
  - Once a file in object store has been loaded in the database table, if the file content changes in object store, it will not be loaded again.
  - If the object store file is deleted, it does not impact the data in the database table.
- If failures are encountered, a load pipeline automatically retries the operation. Retries are attempted on every subsequent run of the pipeline's scheduled job.
- In cases where the data in a file does not comply with the database table, it is marked as `FAILED` and can be reviewed to debug and troubleshoot the issue.
  - If any file fails to load, the pipeline does not stop and continues to load the other files.
- Load pipelines support multiple input file formats, including: JSON, CSV, XML, Avro, ORC, and Parquet.



Migration from non-Oracle databases is one possible use case for a load pipeline. When you need to migrate your data from a non-Oracle database to Oracle Autonomous Database, you can extract the data and load it into Autonomous Database (Oracle Data Pump format cannot be used for migrations from non-Oracle databases). By using a generic file format such as CSV to export data from a non-Oracle database, you can save your data to files and upload the files to object store. Next, create a pipeline to load the data to Autonomous Database. Using a load pipeline to load a large set of CSV files provides important benefits such as fault tolerance, and resume and retry operations. For a migration with a large data set you can create multiple pipelines, one per table for the non-Oracle database files, to load data into Autonomous Database.

About Export Pipelines on Autonomous Database

Use an export pipeline for continuous incremental export of data from the database to object store. An export pipeline periodically identifies candidate data and uploads the data to object store.

There are three export pipeline options (the export options are configurable using pipeline attributes):

- Export incremental results of a query to object store using a date or timestamp column as key for tracking newer data.

- Export incremental data of a table to object store using a date or timestamp column as key for tracking newer data.
- Export data of a table to object store using a query to select data without a reference to a date or timestamp column (so that the pipeline exports all the data that the query selects for each scheduler run).

Export pipelines have the following features (some of these are configurable using pipeline attributes):

- Results are exported in parallel to object store.
- In case of any failures, a subsequent pipeline job repeats the export operation.
- Export pipelines support multiple export file formats, including: CSV, JSON, Parquet, or XML.

About Oracle Maintained Pipelines

Autonomous Database provides built-in pipelines for exporting logs to object store. These pipelines are preconfigured and can be started by the ADMIN user.

The Oracle Maintained pipelines are:

- `ORA$AUDIT_EXPORT`: This pipeline exports the database audit logs to object store in JSON format and runs every 15 minutes after starting the pipeline (based on the `interval` attribute value).
- `ORA$APEX_ACTIVITY_EXPORT`: This pipeline exports the Oracle APEX workspace activity log to object store in JSON format. This pipeline is preconfigured with the SQL query for retrieving APEX activity records and runs every 15 minutes after starting the pipeline (based on the `interval` attribute value).

The Oracle Maintained pipelines are owned by the ADMIN user and attributes of Oracle Maintained Pipelines can be modified by the ADMIN user.

By default the Oracle Maintained Pipelines use `OCI$RESOURCE_PRINCIPAL` as the `credential_name`.

See Use Oracle Maintained Pipelines for more information.

Create and Configure Pipelines

You can create one or more load or export pipelines. When you create a pipeline, you use parameters and set pipeline attributes to configure the pipeline.

The options to create and configure a pipeline follow:

- **Load Pipeline**:
  - See Create and Configure a Pipeline for Loading Data.
- **Export Pipeline**:
  - Export incremental results of a query to object store using a date or timestamp column as key for tracking newer data. See Create and Configure a Pipeline for Export with Timestamp Column.
  - Export incremental data of a table to object store using a date or timestamp column as key for tracking newer data. See Create and Configure a Pipeline for Export with Timestamp Column.

  - Export data of a table to object store using a query to select data without a reference to a date or timestamp column (so that the pipeline exports all the data that the query selects for each scheduler run). See Create and Configure a Pipeline to Export Query Results (Without a Timestamp).

- Create and Configure a Pipeline for Loading Data
  You can create a pipeline to load data from external files in object store to tables in Autonomous Database.
- Create and Configure a Pipeline for Export with Timestamp Column
- Create and Configure a Pipeline to Export Query Results (Without a Timestamp)
  You can create an export pipeline to automatically export data from your Autonomous Database to object store. Using this export pipeline option you specify a SQL query that the pipeline runs periodically to export data to object store. You can use this export option to share the latest data from your Autonomous Database to object store for other applications to consume the data.

Create and Configure a Pipeline for Loading Data

You can create a pipeline to load data from external files in object store to tables in Autonomous Database.

A load pipeline consumes data placed on object store and loads it to a table in Autonomous Database. When you create a load pipeline, the pipeline runs at regular intervals to consume data placed on object store, when new data files arrive the pipeline loads the new data. You can also use a pipeline to reliably copy files, with resume and retry capabilities, from object store to a table on your database.

With a load pipeline, the pipeline package uses `DBMS_CLOUD.COPY_DATA` to load data.

On your Autonomous Database, either use an existing table or create the database table where you are loading data. For example:

```
CREATE TABLE EMPLOYEE
            (name     VARCHAR2(128),
             age      NUMBER,
             salary   NUMBER);
```

1. Create a pipeline to load data from object store.

   ```
   BEGIN
        DBMS_CLOUD_PIPELINE.CREATE_PIPELINE(
           pipeline_name => 'MY_PIPE1',
           pipeline_type => 'LOAD',
           description   => 'Load metrics from object store into a table'
     );
   END;
   /
   ```

   See CREATE_PIPELINE Procedure for more information.

2. Create a credential object to access the object store that contains the files you are loading.

   You specify the credential for the pipeline source location with the attribute `credential_name`. If you do not supply a `credential_name` in the next step, the `credential_name` value is set to `NULL`. You can use the default `NULL` value when the `location` attribute is a public or pre-authenticated URL.

See CREATE_CREDENTIAL Procedure for more information.

3. Set the pipeline attributes, including the required attributes: `location`, `table_name`, and `format`.

```
BEGIN
     DBMS_CLOUD_PIPELINE.SET_ATTRIBUTE(
       pipeline_name => 'MY_PIPE1',
       attributes    => JSON_OBJECT(
            'credential_name' VALUE 'OBJECT_STORE_CRED',
            'location' VALUE 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/',
            'table_name' VALUE 'employee',
            'format' VALUE '{"type":"json", "columnpath":["$.NAME",
"$.AGE", "$.SALARY"]}',
            'priority' VALUE 'HIGH',
            'interval' VALUE '20')
  );
END;
/
```

The following attributes must be set to run a load pipeline:

- `location`: Specifies the source file location on object store.
- `table_name`: Specifies the table in your database where you are loading data. The `location` you specify is for one `table_name` per pipeline.
- `format`: Describes the format of the data you are loading.

  See DBMS_CLOUD Package Format Options for more information.

The `credential_name` is the credential you created in the previous step.

The `priority` value determines the number of files loaded in parallel. A pipeline with a higher priority consumes more database resources and completes each run faster, as compared to running at a lower priority.

The `interval` value specifies the time interval in minutes between consecutive runs of a pipeline job. The default `interval` is 15 minutes.

See DBMS_CLOUD_PIPELINE Attributes for details on the pipeline attributes.

After you create a pipeline you can test the pipeline or start the pipeline:

- Test Pipelines
- Start a Pipeline

As an alternative, to set the format for JSON, you could use the following format:

```
BEGIN
    DBMS_CLOUD_PIPELINE.SET_ATTRIBUTE(
        pipeline_name   => 'MY_PIPE1',
        attribute_name  => 'format',
        attribute_value => JSON_OBJECT('type' value 'json', 'columnpath'
value '["$.NAME", "$.AGE", "$.SALARY"]')
    );
END;
/
```

Create and Configure a Pipeline for Export with Timestamp Column

You can create an export pipeline to automatically export time-series data from your Autonomous Database to object store.

Using this export pipeline option you specify a table or SQL query and a column with a timestamp that the pipeline uses to keep track of the time of the last upload. You can use an export pipeline to share data for consumption by other applications or to save data to object store.

With an export pipeline, the pipeline package uses `DBMS_CLOUD.EXPORT_DATA` to export data.

An export pipeline exports data from your Autonomous Database to object store. When you create an export pipeline, the pipeline runs at regular intervals and places data on object store.

1. Create a pipeline to export data to object store.

```
BEGIN
     DBMS_CLOUD_PIPELINE.CREATE_PIPELINE(
        pipeline_name=>'EXP_PIPE1',
        pipeline_type=>'EXPORT',
        description=>'Export time series metrics to object store');
END;
/
```

   See CREATE_PIPELINE Procedure for more information.

2. Create a credential object to access the destination object store location where you are exporting data files.

   You specify the credential for the pipeline destination location with the attribute `credential_name`. If you do not supply a `credential_name` in the next step, the `credential_name` value is set to `NULL`. You can use the default `NULL` value when the `location` attribute is a public or pre-authenticated URL.

   See CREATE_CREDENTIAL Procedure for more information.

3. Set the export pipeline attributes.

   When you specify a `table_name` parameter, table rows are exported to object store. When you specify a `query` parameter, the query specifies a `SELECT` statement so that only the required data is exported to object store.

   - Using using a `table_name` parameter:

```
BEGIN
     DBMS_CLOUD_PIPELINE.SET_ATTRIBUTE(
       pipeline_name => 'EXP_PIPE1',
       attributes    => JSON_OBJECT('credential_name' VALUE
'OBJECT_STORE_CRED',
          'location' VALUE 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/',
          'table_name' VALUE 'metric_table',
          'key_column' VALUE 'metric_time',
          'format' VALUE '{"type": "json"}',
          'priority' VALUE 'MEDIUM',
          'interval' VALUE '20')
  );
```

```
END;
/
```

- Using a `query` parameter:

```
BEGIN
     DBMS_CLOUD_PIPELINE.SET_ATTRIBUTE(
       pipeline_name => 'EXP_PIPE1',
       attributes    => JSON_OBJECT('credential_name' VALUE
'OBJECT_STORE_CRED',
           'location' VALUE 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/',
           'query' VALUE 'SELECT * from metrics_table',
           'key_column' VALUE 'metric_time',
           'format' VALUE '{"type": "json"}',
           'priority' VALUE 'MEDIUM',
           'interval' VALUE '20')
  );
END;
/
```

Where the `credential_name` is the credential you created in the previous step.

The following attributes must be set to run an export pipeline:

- `location`: Specifies the destination object store location. The `location` you specify is for one `table_name` per pipeline.
- `table_name`: Specifies the table in your database that contains the data you are exporting (either the `table_name` parameter or the `query` parameter is required).
- `query`: Specifies the query to run in your database that provides the data you are exporting (either the `table_name` parameter or the `query` parameter is required).
- `format`: Describes the format of the data you are exporting.

  See DBMS_CLOUD Package Format Options for EXPORT_DATA for more information.

The `priority` value determines the degree of parallelism for fetching data from the database.

The `interval` value specifies the time interval in minutes between consecutive runs of a pipeline job. The default `interval` is 15 minutes.

See DBMS_CLOUD_PIPELINE Attributes for details on the pipeline attributes.

After you create a pipeline you can test the pipeline or start the pipeline:

- Test Pipelines
- Start a Pipeline

Create and Configure a Pipeline to Export Query Results (Without a Timestamp)

You can create an export pipeline to automatically export data from your Autonomous Database to object store. Using this export pipeline option you specify a SQL query that the pipeline runs periodically to export data to object store. You can use this export option to share

the latest data from your Autonomous Database to object store for other applications to consume the data.

An export pipeline exports data from your Autonomous Database to object store. When you create an export pipeline, the pipeline runs at regular intervals and places data on object store.

1. Create a pipeline to export data to object store.

```
BEGIN
     DBMS_CLOUD_PIPELINE.CREATE_PIPELINE(
        pipeline_name=>'EXP_PIPE2',
        pipeline_type=>'EXPORT',
        description=>'Export query results to object store.');
END;
/
```

   See CREATE_PIPELINE Procedure for more information.

2. Create a credential object to access the destination object store location where you are exporting data files.

   You specify the credential for the pipeline destination location with the attribute `credential_name`. If you do not supply a `credential_name` in the next step, the `credential_name` value is set to `NULL`. You can use the default `NULL` value when the `location` attribute is a public or pre-authenticated URL.

   See CREATE_CREDENTIAL Procedure for more information.

3. Set the export pipeline attributes.

```
BEGIN
     DBMS_CLOUD_PIPELINE.SET_ATTRIBUTE(
       pipeline_name => 'EXP_PIPE2',
       attributes    => JSON_OBJECT(
          'credential_name' VALUE 'OBJECT_STORE_CRED',
          'location' VALUE 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/',
          'query' VALUE 'SELECT * FROM table_name',
          'format' VALUE '{"type": "json"}',
          'priority' VALUE 'MEDIUM',
          'interval' VALUE '20')
  );
END;
/
```

   Where the `credential_name` is the credential you created in the previous step.

   The following attributes must be set to run an export pipeline:

   - `location`: Specifies the destination object store location.
   - `query`: Specifies the query to run in your database that provides the data you are exporting.
   - `format`: Describes the format of the data you are exporting.

     See DBMS_CLOUD Package Format Options for EXPORT_DATA for more information.

The `priority` value determines the degree of parallelism for fetching data from the database.

The `interval` value specifies the time interval in minutes between consecutive runs of a pipeline job. The default `interval` is 15 minutes.

See DBMS_CLOUD_PIPELINE Attributes for details on the pipeline attributes.

After you create a pipeline you can test the pipeline or start the pipeline:

- Test Pipelines
- Start a Pipeline

Test Pipelines

Use `RUN_PIPELINE_ONCE` to run a pipeline once on-demand without creating a scheduled job.

`RUN_PIPELINE_ONCE` is useful for testing a pipeline before you start the pipeline. After you run a pipeline once to test the pipeline and check that it is working as expected, use `RESET_PIPELINE` to reset the pipeline's state (to the state before you ran `RUN_PIPELINE_ONCE`).

1. Create a pipeline.

   See Create and Configure Pipelines for more information.

2. Run a pipeline once to test the pipeline.

```
BEGIN
    DBMS_CLOUD_PIPELINE.RUN_PIPELINE_ONCE(
        pipeline_name => 'MY_PIPE1'
);
END;
/
```

   See RUN_PIPELINE_ONCE Procedure for more information.

3. Perform any required checks to verify the pipeline is operating as expected.

   See Monitor and Troubleshoot Pipelines for more information.

4. Reset the pipeline.

```
BEGIN
   DBMS_CLOUD_PIPELINE.RESET_PIPELINE(
     pipeline_name => 'MY_PIPE1',
     purge_data => TRUE
);
END;
/
```

   See RESET_PIPELINE Procedure for more information.

Control Pipelines (Start, Stop, Drop, or Reset a Pipeline)

After you create and test a pipeline, you control a pipeline by starting, stopping, or dropping the pipeline. You can also reset a pipeline.

- Start a Pipeline

- Stop a Pipeline
- Drop a Pipeline
- Reset a Pipeline

Start a Pipeline

After you create a pipeline, you can start the pipeline.

When a pipeline is started the pipeline runs continuously in a scheduled job. The pipeline's scheduled job repeats, either by default every 15 minutes or at the interval you set with the `interval` attribute.

1. Start a pipeline.

```
BEGIN
  DBMS_CLOUD_PIPELINE.START_PIPELINE(
      pipeline_name => 'EMPLOYEE_PIPELINE'
  );
END;
/
```

   By default, a pipeline job begins immediately, as soon as the pipeline is started. To start a pipeline job at a later time, specify a valid future date or timestamp using the `start_date` parameter.

   See START_PIPELINE Procedure for more information.

2. Verify that the pipeline is started.

   For example:

```
SELECT pipeline_name, status from USER_CLOUD_PIPELINES
   WHERE pipeline_name = 'EMPLOYEE_PIPELINE';

PIPELINE_NAME            STATUS
------------------------ -------
EMPLOYEE_PIPELINE        STARTED
```

Stop a Pipeline

Use `STOP_PIPELINE` to stop a pipeline. When a pipeline is stopped, no future jobs are scheduled for the pipeline.

By default currently running jobs complete when you stop a pipeline. Set the `force` parameter to `TRUE` to terminate any running jobs and stop the pipeline immediately.

1. Stop a pipeline.

```
BEGIN
  DBMS_CLOUD_PIPELINE.STOP_PIPELINE(
      pipeline_name => 'EMPLOYEE_PIPELINE'
  );
END;
/
```

See STOP_PIPELINE Procedure for more information.

2. Verify that the pipeline is stopped.

```
SELECT pipeline_name, status from USER_CLOUD_PIPELINES
   WHERE pipeline_name = 'EMPLOYEE_PIPELINE';

PIPELINE_NAME            STATUS
------------------------ -------
EMPLOYEE_PIPELINE        STOPPED
```

See STOP_PIPELINE Procedure for more information.

Drop a Pipeline

The procedure `DROP_PIPELINE` drops an existing pipeline.

If a pipeline has been started, it must be stopped before the pipeline can be dropped. See STOP_PIPELINE Procedure for more information.

In order to drop a pipeline that is started, set the `force` parameter to `TRUE` to terminate any running jobs and drop the pipeline immediately

1. Drop a pipeline.

```
BEGIN
  DBMS_CLOUD_PIPELINE.DROP_PIPELINE(
      pipeline_name => 'EMPLOYEE_PIPELINE'
  );
END;
/
```

2. Verify the pipeline is dropped.

```
SELECT pipeline_name, status from USER_CLOUD_PIPELINES
   WHERE pipeline_name = 'EMPLOYEE_PIPELINE';

No rows selected
```

See DROP_PIPELINE Procedure for more information.

Reset a Pipeline

Use the reset pipeline operation to clear the record of the pipeline to the initial state.

> **Note:**
>
> You can optionally use reset pipeline to purge data in the database table associated with a load pipeline or to remove files in object store for an export pipeline. Usually this option is used when you are testing a pipeline during pipeline development.

Reset pipeline operates as follows:

- **Load Pipeline**: For a load pipeline, resetting the pipeline clears the record of the files being loaded by the pipeline. When you call either `START_PIPELINE` or `RUN_PIPELINE_ONCE` after resetting a load pipeline, the pipeline repeats the data load and includes all the files present in the object store location.

  When `purge_data` is set to `TRUE`, the procedure truncates the data in the database table.

- **Export Pipeline**: For an export pipeline, resetting the pipeline clears the last tracked data in the database table. When you call either `START_PIPELINE` or `RUN_PIPELINE_ONCE` after resetting an export pipeline, the pipeline repeats exporting data from the table or query.

  When `purge_data` set to `TRUE`, the procedure deletes existing files in the object store location specified with the `location` attribute.

To reset a pipeline:

1. Stop the pipeline you want to reset.

   A data pipeline must be in stopped state to reset it. See STOP_PIPELINE Procedure for more information.

2. Reset the pipeline.

```
BEGIN
     DBMS_CLOUD_PIPELINE.RESET_PIPELINE(
        pipeline_name => 'EMPLOYEE_PIPELINE',
        purge_data => TRUE);
END;
/
```

   Only use the `purge_data` parameter with value `TRUE` if you want to clear data in your database table, for a load pipeline, or clear files in object store for an export pipeline. Usually this option is used when you are testing a pipeline during pipeline development.

   See RESET_PIPELINE Procedure for more information.

Monitor and Troubleshoot Pipelines

All pipelines that are created are logged in the `DBMS_CLOUD_PIPELINE` views.

View Pipeline Status Information

Check pipeline status and obtain other pipeline information using the `USER_CLOUD_PIPELINES` or `DBA_CLOUD_PIPELINES` views. For example, the following `SELECT` statement with a `WHERE` clause predicate on the `pipeline_name` shows that `MY_TREE_DATA` is a load pipeline and the pipeline is started:

```
SELECT pipeline_name, pipeline_type, status FROM USER_CLOUD_PIPELINES
   WHERE pipeline_name = 'MY_TREE_DATA';

PIPELINE_NAME PIPELINE_TYPE STATUS
------------- ------------- -------
MY_TREE_DATA  LOAD          STARTED
```

See DBMS_CLOUD_PIPELINE Views for more information.

View Pipeline Attributes

The pipeline attributes can be monitored by querying the `USER_CLOUD_PIPELINE_ATTRIBUTES` or `DBA_CLOUD_PIPELINE_ATTRIBUTES` views. Query these views to see pipeline attribute information.

For example:

```
SELECT pipeline_name, attribute_name, attribute_value FROM
user_cloud_pipeline_attributes
     WHERE pipeline_name = 'MY_TREE_DATA';

PIPELINE_NAME ATTRIBUTE_NAME
ATTRIBUTE_VALUE

------------- ---------------
--------------------------------------------------------------------------------
---
MY_TREE_DATA  credential_name
DEF_CRED_OBJ_STORE

MY_TREE_DATA  format          {"type":
"csv"}
MY_TREE_DATA  interval
20

MY_TREE_DATA  location        https://objectstorage.us-
ashburn-1.oraclecloud.com/n/namespace/b/treetypes/o/
MY_TREE_DATA  priority
high

MY_TREE_DATA  table_name      TREES
```

See DBMS_CLOUD_PIPELINE Views for more information.

View Pipeline History

The `USER_CLOUD_PIPELINE_HISTORY` and `DBA_CLOUD_PIPELINE_HISTORY` views show the state of running jobs. Use the pipeline history views to help you monitor the health of a pipeline and detect failures in a running pipeline.

For example:

```
SELECT pipeline_id, pipeline_name, status, error_message  FROM
user_cloud_pipeline_history
     WHERE pipeline_name = 'MY_TREE_DATA';

PIPELINE_ID PIPELINE_NAME STATUS    ERROR_MESSAGE
----------- ------------- --------- -------------
          7  MY_TREE_DATA SUCCEEDED
```

See DBMS_CLOUD_PIPELINE Views for more information.

Pipeline Status Table: Additional Monitoring for Load Pipelines

The pipeline status table shows each file name and its status for a load pipeline. The `STATUS_TABLE` column in `DBA_CLOUD_PIPELINES` and `USER_CLOUD_PIPELINES` shows the status table name.

For example, the following `SELECT` statement with a `WHERE` clause predicate on the `pipeline_name` shows the status table name for a pipeline:

```
SELECT pipeline_name, status_table FROM user_cloud_pipelines
   WHERE pipeline_name = 'MY_TREE_DATA';

PIPELINE_NAME STATUS_TABLE
------------- --------------------
MY_TREE_DATA  PIPELINE$9$41_STATUS
```

View the status table to see information about the pipeline, including the following:

- The relevant error number and error message are recorded in the status table if an operation on a specific file fails.
- For completed pipeline operations, the time needed for each operation can be calculated using the reported `START_TIME` and `END_TIME`.

For example the following shows that the load operation for two files failed and one completed:

```
SELECT id, name, status, error_code, error_message, sid FROM
PIPELINE$9$41_STATUS;

ID NAME       STATUS    ERROR_CODE ERROR_MESSAGE                       SID
-- ---------- --------- ---------- ------------------------------ -----
 1 trees1.txt FAILED         30653 ORA-30653: reject limit reached  18070
 2 trees2.txt FAILED         30653 ORA-30653: reject limit reached  18070
 3 trees3.txt COMPLETED                                             18070
```

Pipelines for loading data, where the `pipeline_type` is `'LOAD'`, reserve an `ID` that is shown in `USER_LOAD_OPERATIONS` and in `DBA_LOAD_OPERATIONS`. The `ID` value in these views maps to the pipeline's `OPERATION_ID` in `USER_CLOUD_PIPELINES` and `DBA_CLOUD_PIPELINES`.

To obtain more information for a load pipeline, query the pipeline's `OPERATION_ID`:

```
SELECT PIPELINE_NAME, OPERATION_ID FROM USER_CLOUD_PIPELINES
     WHERE PIPELINE_NAME = 'MY_TREE_DATA';

PIPELINE_NAME OPERATION_ID
------------- ------------
MY_TREE_DATA            41
```

Next, query either `USER_LOAD_OPERATIONS` or `DBA_LOAD_OPERATIONS` with a `WHERE` clause predicate on the `ID` column (using the `OPERATION_ID` value).

For example:

```
SELECT ID, TYPE, LOGFILE_TABLE, BADFILE_TABLE, STATUS_TABLE FROM
USER_LOAD_OPERATIONS
```

```
     WHERE ID = 41;

ID TYPE     LOGFILE_TABLE     BADFILE_TABLE     STATUS_TABLE
-- -------- ----------------- ----------------- --------------------
41 PIPELINE PIPELINE$9$41_LOG PIPELINE$9$41_BAD PIPELINE$9$41_STATUS
```

This query shows `ID`, `TYPE`, `LOGFILE_TABLE`, `BADFILE_TABLE` if it exists, and the `STATUS_TABLE`. You can view these tables for additional pipeline load information.

Pipeline Status Table Details

Column	Datatype	Description
`ID`	`NUMBER`	Unique number assigned to the pipeline.
`NAME`	`VARCHAR2(4000)`	Name of the pipeline.
`BYTES`	`NUMBER`	Bytes
`CHECKSUM`	`VARCHAR2(128)`	Checksum
`LAST_MODIFIED`	`TIMESTAMP(6) WITH TIME ZONE`	Last modification time for the pipeline.
`STATUS`	`VARCHAR2(30)`	The `STATUS` value is one of: • `COMPLETED`: The file operation completed successfully. • `FAILED`: The file operation failed, a retry may be attempted two times. • `PENDING`: The file operation has not yet started. • `RUNNING`: The file operation is currently in progress. • `SKIPPED`: The file operation skipped.
`ERROR_CODE`	`NUMBER`	Error code
`ERROR_MESSAGE`	`VARCHAR2(4000)`	Error message
`START_TIME`	`TIMESTAMP(6) WITH TIME ZONE`	Start time for the pipeline.
`END_TIME`	`TIMESTAMP(6) WITH TIME ZONE`	End time for the pipeline.
`SID`	`NUMBER`	The session `SID` and`SERIAL#` indicate the job session that was running the pipeline load operation.
`SERIAL#`	`NUMBER`	The session `SID` and`SERIAL#` indicate the job session that was running the pipeline load operation.
`ROWS_LOADED`	`NUMBER`	Number of rows loaded.
`OPERATION_ID`	`NUMBER`	Reserved for future use.

Pipeline Log File and Bad File Tables

To obtain the log file and bad file names for a load pipeline, query the pipeline's `OPERATION_ID`. For example:

```
SELECT PIPELINE_NAME, OPERATION_ID FROM USER_CLOUD_PIPELINES
     WHERE PIPELINE_NAME = 'MY_TREE_DATA';
```

```
PIPELINE_NAME OPERATION_ID
------------- ------------
MY_TREE_DATA            41
```

Next, query either `USER_LOAD_OPERATIONS` or `DBA_LOAD_OPERATIONS` with a `WHERE` clause predicate on the `ID` column (using the `OPERATION_ID` value).

For example:

```
SELECT ID, TYPE, LOGFILE_TABLE, BADFILE_TABLE, STATUS_TABLE FROM
USER_LOAD_OPERATIONS
     WHERE ID = 41;

ID TYPE     LOGFILE_TABLE     BADFILE_TABLE     STATUS_TABLE
-- -------- ----------------- ----------------- --------------------
41 PIPELINE PIPELINE$9$41_LOG PIPELINE$9$41_BAD PIPELINE$9$41_STATUS
```

This query shows `ID`, `TYPE`, `LOGFILE_TABLE`, `BADFILE_TABLE` if it exists, and the `STATUS_TABLE`. You can view these tables for additional pipeline load information.

View the pipeline log file table to see a complete log of the pipeline's load operations.

For example:

```
SELECT * FROM PIPELINE$9$41_LOG;
```

View the pipeline bad file table to see details on input format records with errors. The bad file table show information for the rows reporting errors during loading. Depending on the errors shown in the log file table and the rows shown in the pipeline's bad file table, you might be able to correct the errors either by modifying the pipeline `format` attribute options, or by modifying the data in the file you are loading.

For example:

```
SELECT * FROM PIPELINE$9$41_BAD;
```

See Monitor and Troubleshoot Loads for more information.

Use Oracle Maintained Pipelines

Autonomous Database provides built-in pipelines. These pipelines are preconfigured and can be started by the ADMIN user. Oracle Maintained pipelines are owned by ADMIN user.

The Oracle Maintained pipelines are:

- `ORA$AUDIT_EXPORT`: This pipeline exports the database audit logs to object store in JSON format and runs every 15 minutes after starting the pipeline (based on the `interval` attribute value).
- `ORA$APEX_ACTIVITY_EXPORT`: This pipeline exports the Oracle APEX workspace activity log to object store in JSON format. This pipeline is preconfigured with the SQL query for retrieving APEX activity records and runs every 15 minutes after starting the pipeline (based on the `interval` attribute value).

To configure and start an Oracle Managed pipeline:

1. Determine the Oracle Managed Pipeline you want to use: `ORA$AUDIT_EXPORT` or `ORA$APEX_ACTIVITY_EXPORT`.
2. Set the `credential_name` and `location` attributes.

   For example:

```
BEGIN
  DBMS_CLOUD_PIPELINE.SET_ATTRIBUTE(
    pipeline_name => 'ORA$AUDIT_EXPORT',
    attribute_name => 'credential_name',
    attribute_value => 'DEF_CRED_OBJ_STORE'
  );
  DBMS_CLOUD_PIPELINE.SET_ATTRIBUTE(
    pipeline_name => 'ORA$AUDIT_EXPORT',
    attribute_name => 'location',
    attribute_value => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/'
  );
END;
/
```

   The log data from database is exported to the object store location you specify.

   See SET_ATTRIBUTE Procedure for more information.

   By default the Oracle Maintained Pipelines use `OCI$RESOURCE_PRINCIPAL` as the `credential_name`. See Enable Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.
3. Optionally, set the `interval`, `format`, or `priority` attributes.

   See SET_ATTRIBUTE Procedure for more information.
4. Start the pipeline.

   See START_PIPELINE Procedure for more information.

The Data Load Page

Use the Data Load page to make more data available to your Oracle Autonomous Database. You can load data from files or databases, from links to external databases or cloud storage files, or from a live feed of data from cloud storage.

See The Data Load Page for more information.

- The Data Load Page
  Use the Data Load dashboard page to make more data available to your Oracle Autonomous Database. You can load data from files or databases, from links to external databases or cloud storage files, or from a live feed of data from cloud storage.

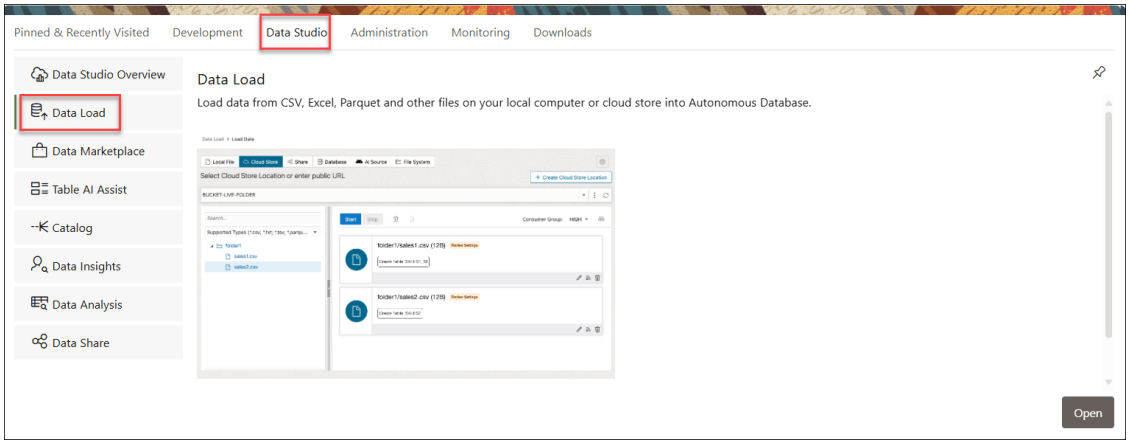
The Data Load Page

Use the Data Load dashboard page to make more data available to your Oracle Autonomous Database. You can load data from files or databases, from links to external databases or cloud storage files, or from a live feed of data from cloud storage.

From the Data Load page, you can also explore the data in your autonomous database and manage your cloud storage locations.

> **Note:**
>
> If you do not see the Data Load card then your database user is missing the required DWROLE role.

To reach the Data Load page, click the **Data Studio** tab in the Database Actions page and select the **Data Load** pane.



You can alternatively click the Selector icon and select **Data Load** from the Data Studio menu in the navigation pane.

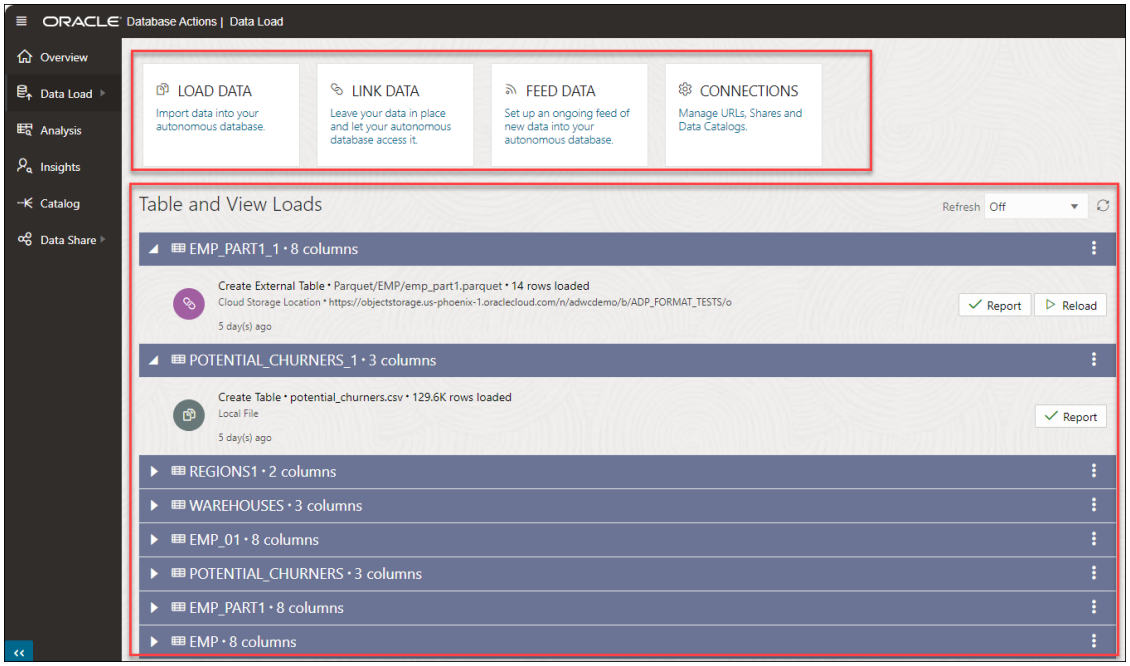
The Data Load Dashboard provides a central location for all data load and live feed tasks. The various icons on the dashboard, provide access to loading data, linking data, setting up an ongoing feed, checking data load jobs, and managing connections.

You can view the following tiles on the top section of the dashboard:

- Load Data
- Link Data
- Feed Data
- Connections

The bottom section of the dashboard displays the tables, views, and life feed you load into the tool.

The following image illustrates the **Data Load Dashboard**.



After drilling down onto a table, in the **Table and View Loads** section, you can view the details of the table load such as the name of the table, the number of rows and columns in the table, and the time you load the table.

Tables which are not active for last 7 days are collapsed.

You can also view the source location of the data you load. Click the location to view objects in the location.

Click the **Actions** icon beside the table name and select **Table** to view the following properties of the table:

- View Details
- Gather Statistics
- Register to Cloud Link
- Publish Listings to Marketplace
- Create Analytic View
- The Table AI Assist Tool
- Export Data to Cloud
- The Data Analysis Tool
- Edit
- **Drop** : Select **Drop** to delete the table.

Select **Report** to view a report of total rows processed successfully and failed for the selected table.

Select **Reload** to reload the source of the data load job. Clicking Reload takes you to the **Link Data** page where you can link your data source to the Autonomous Database.

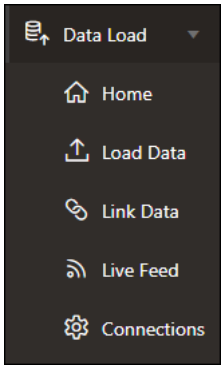
> **Note:**
>
> For tables you load via Cloud Store, you can view **Create Live Feed** icon. See Create Live Feed from Data Load. After the creation of live feed is successful, you will view a Live Feed badge besides the table load header.

In case of errors, you can reload data with suggested fixes.

To load or create links to data or create live table feeds, on the Data Load dashboard, select a combination of an operation and a data source location. The following table lists the operations and the source locations that support those operations.

Operation	Source Location	Description
Load data	Local file Database Cloud storage Directory Share AI Sources	Load data from files on your local device, from remote databases, or from cloud storage into tables in your Oracle Autonomous Database.
Link data	Database Objects in Oracle Cloud Infrastructure (OCI) Catalog	Create external tables or views in your Oracle Autonomous Database that link to data in cloud storage or remote databases. Changes to the source data automatically appear in the target objects.
Feed data	Cloud storage	Set up a feed of data from a cloud storage bucket into a table. Changes to the source data load into the target table as scheduled or on demand.
Connections	Cloud storage Data Catalog links Share Providers	Create a cloud storage location. Subscribe to Share Provider and Register Data Catalog. You can manage cloud storage locations, Data Catalog and Shares.

The left navigation pane of the Data Load Dashboard provides links to the Data Load features and pages. When you select a link from the left navigation pane, the corresponding page appears in the target content area.



Topics:

- Data Studio Settings
  This topic explains the Data Studio settings on the Data Studio tool.
- Managing Connections
  Connections that are established from the Data Studio to the cloud, catalogs and shares are listed on this page.
- Loading Data
  You can load data from files on your local device, from remote databases, or from cloud storage buckets from directories and share providers. The file formats that you can load are CSV, XLS, XLSX, TSV, TXT, XML, JSON, GEOJSON, AVRO, PARQUET, GZ, GZIP, ZIP, PDF, PNG, JPG, JPEG and TIFF.
- Linking Data
  You can link to data in remote databases or in cloud storage buckets.
- Feeding Data
  You can run a live table feed on demand, on a schedule, or as the result of a notification.
- DBMS_LIVE_FEED Package Reference
  This chapter provides information about the packages you use with the Data Load Tool in Data Studio. The `DBMS_LIVE_FEED` topic also covers the procedures included in the `DBMS_LIVE_FEED` package.

Data Studio Settings

This topic explains the Data Studio settings on the Data Studio tool.

This settings on the **Data Studio** navigation menu and the Data studio overview page enables you to use the associated Cloud Service, configure AI profile and configure SMTP.

This helps in defining the data during the load. This setting sets a variety of general preferences like setting default credentials to define the data you load, configure SMTP for data sharing, configure AI profile and configure Marketplace cloud link access.

To set the Data Studio Settings, on the **General** tab of the wizard, specify the email address to configure your profile for Marketplace and Sharing.

On the **Cloud Services** tab of the wizard, under **Cloud Object Store Access**, specify the following field values:

- **OCI Credential**: Selecting an OCI credential enables you to discover the OCI buckets. Click **+** to create OCI Credentials.

- **OCI Compartment**: This drop-down field lists the buckets present in your compartment for loading and linking from Oracle cloud services. If you select any other cloud service provider apart from Oracle, this field displays **None** by default.
- **AWS Credential**: Selecting an AWS credential in Data Studio Settings enables you to discover the S3 buckets. Click **+** to create credentials for Amazon S3 cloud storage.
- **Azure Credential**: Selecting an Azure credential in preferences enables you to discover the Azure BLOB storage. Click **+** to create credentials for Microsoft Azure BLOB storage and Azure Data Lake Storage.
  Click **Check Object Store Access** to check if you have access to the object store. You will view a Policy Check wizard with the following bucket lists:
  - OCI list buckets
  - AWS list buckets
  - Azure list buckets

  The Object Storage Listing Policy checker evaluates if you have access to the buckets. If yes, the checker box is highlighted in green with a check sign, else the checker box displays the policy highlighted in red with a red cross.

Under **Cloud Service Provider for AI**: Select any of the following options from the drop-drown field:

- Oracle Cloud Interface (OCI)
- Amazon Web Services (AWS)

Click **Check Cloud Service Access**.

You will view the following options in the Cloud Services Policy Checker dialog box. The AI cloud policies listed below must be checked against the listed policies and approved by the Cloud Service vendors for support. The Data Studio tool will test these services and inform you if the data you load in the tool is able to access the services.

- **Language**- Checks if the Data Studio tool has accessed the Cloud's language processing abilities. See Use OCI Language Service Capabilities in Data Studio for more information on this service.
- **Document Understanding**- Checks if the data you load into the Data Studio tool has accessed the Cloud's Document Understanding AI ability. See Use OCI Document Understanding to extract Tables from Images for more information on this service.
- **Translation**- Checks if the Data Studio tool accesses the OCI Translation feature. See Perform Text Translation for more information on this service.

On the **AI Profile** tab of the Data Studio Settings wizard, you can configure your AI preferences.

1. Select **AI Profile (Experimental)** from the drop-down use this AI profile for facilitating and configuring the translation of natural language prompts to SQL statements.
   - To utilize the AI services in Data Studio, you must have either an **OCI AI** or **OpenAI** or **Cohere** or **Azure OpenAI service** account.
   - You must also have access to `DBMS_CLOUD_AI` package to set your AI profile.
   - If you have Select AI set up using either **OpenAI** or **Cohere** or **Azure OpenAI** service, you can enhance your data by loading small reference data tables that are generated by large language models. Try out the suggested prompts or come up with your own to generate data to load into the autonomous database.
     You can also use this AI profile to generate Marketplace dataset description and tags. This AI profile is used to generate table description in Catalog App.

See Use DBMS_CLOUD_AI to Configure AI Profiles to create and configure your AI profile.

2. Click **Check AI Access**.

   The AI Policy checker checks for the following service:

   - **Generative AI**- The Data Studio tool checks if it has access to the Generative AI service.

3. Click **View Profile** to view the details related to the AI profile you use. You can view the **AI Provider**, **AI Model** and the **Credential** you use to create the AI profile.
4. Click **Create Profile** to create a new AI profile. Specify the following field values:
   - **Profile Name**: Enter the name of the AI profile. For example, *OCI AI*.
   - **AI Provider**: Select any of the following providers from the drop-down field:
     - *OCI AI*
     - *AI Azure*
     - *Cohere*
   - **Model**: Select any of the following models from the drop-down field:
     - *Llama*
     - *Cohere*
   - **Credential**: Select any of the credentials from the drop-down to create an AI profile.
   - Click **Show Code** to view the equivalent PL/SQL code to create AI profile.

     ```
     BEGIN
         C##CLOUD$SERVICE.DBMS_CLOUD_AI.CREATE_PROFILE(
             PROFILE_NAME => 'new_profile',
             ATTRIBUTES =>
     '{"credential_name":"my_credential_name","model":"","provider":""}');
     END;
     /
     ```

   Click **Create AI Profile**.

You have successfully set and configured your AI profile in the Data Studio Settings wizard.

On the SMTP tab of the Data Studio Preferences wizard, you can configure email service like a local email client on your system (e.g., Thunderbird).

> **Note:**
>
> You must configure SMTP only once and then the system uses the saved configuration from that point forward.

Specify the following field values in the SMTP tab of the wizard:

1. **Server host**: Enter the endpoint used to send the email. For example, *internal-mailrouter.oracle.com*.
2. **Server port**: Enter the SMTP port used to accept an email. Email Delivery supports TLS on port 25. Sender:
3. Enter the email address of the sender. For example, *oaapgens_us@oracle.com*.

4. **Server Encryption**: This field indicates if TLS, the standard means of performing encryption in transit for emails, is being used. Providers must encrypt emails while it's in transit to the Oracle Cloud Infrastructure Email Delivery service. Encrypted emails are protected from being read during transit. If there is no encryption, enter, *None*.
5. Select credential to use for SMTP connection from the drop-down. If there is no available credential in the drop-down, you can create credential by clicking Create Credential icon.

Click **Save** to save your changes and **Test** the test the ongoing process of setting preferences.

On the **Marketplace** tab, you can set the configurations you require for the Data Marketplace tool.

Access to data in Data Marketplace is restricted based on user authorizations. As non admin users you have permission to access the Data Marketplace tool based on the Data Studio Settings configuration. You can view the following options:

- **Restricted, Requires Authorization**:
  Selecting this option enables you to publish restricted cloud links and, consequently, restricted marketplace listings. You will have the ability to grant and revoke access to these listings to specific OCIDs.

- **Publish**:
  This option specifies who and from where you are allowed to access the registered table.

  You can choose from any of the following available options:

  – **TENANCY**: You can grant remote data access to any resource, tenancy, compartment, or database in the tenancy of the Autonomous Database instance that is registering the data set. This scope is more restrictive than the **REGION** scope.

  – **COMPARTMENT**: You can grant remote data access to any resource, compartment, or database in the compartment of the Autonomous Database instance that is registering the data set.

  – **REGION**: You can grant remote data access via cloud links to other tenancies in the Autonomous Database instance that is registering the data set.

  > **Note:**
  >
  > Marketplace listing currently can only be published up to the compartment level. The tool does not allow you to publish a marketplace listing to entire region for security reasons.

  – **None**: You do not have access to any resource.

- **Read**:
  This option allows **READ** access for the specific user to access the registered table.

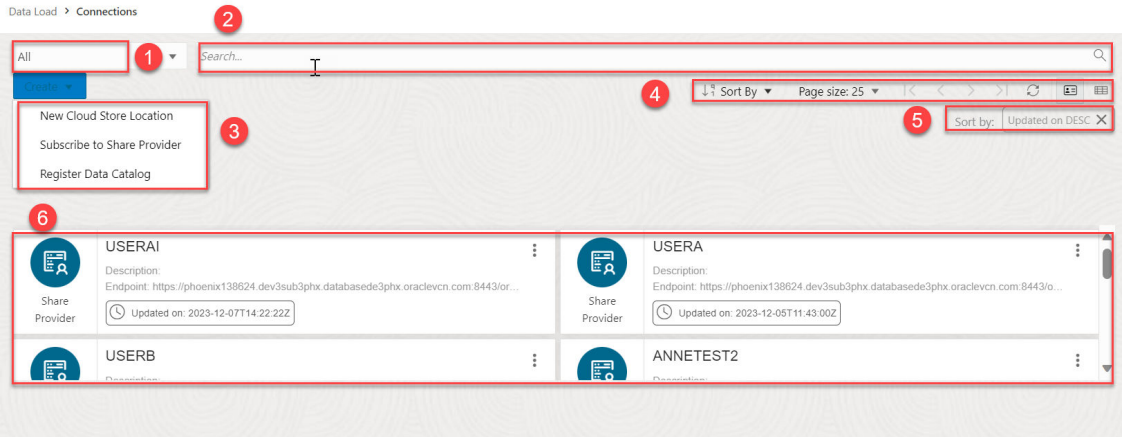
Select **Apply Changes** to save and apply the configuration you made in the Marketplace tab of the Data Settings dialog.

You have successfully set and configured your preferences in the Data Studio Settings wizard.

Managing Connections

Connections that are established from the Data Studio to the cloud, catalogs and shares are listed on this page.

The Connections page contains the Search for entities such as Cloud Storage Links, Data Catalog Links, and Share Providers, and a list of entity cards. You can enter the entity you are looking for in the field or click one of the entity card from the list. You can register the cloud store you want to use from this page. You can also register data catalogs and subscribe to a share provider.



The Connections page consists of the following:

1. **Entity Selector**: You can Use the drop-down lists to select the entity from which the connection is created. You can select from Cloud Storage Links, Data Catalog Links, Share Provider or all.
2. **Search field**: Searches for entities in the field by name. The search functionality is not case-sensitive, retrieves all matching entries, and does not require the use of wild card characters.
3. **Create drop-down**: The options available in the Create drop-down are:
   - **New Cloud Store Location**: Before you can load data from a cloud store, you must establish a connection to the cloud store you want to use. You can select cloud store location from the cloud store locations field. A cloud storage link is a connection to a bucket in a cloud store. You can view the existing cloud storage links and add new ones. Refer to the Create Credentials to add a cloud store location.
   - **Subscribe to a Share Provider**: Upload the JSON profile file and create a share provider description To subscribe, you need to use the information contained in the uploaded JSON profile you received from the share provider. From the Consume Share feature of the Data Share tool, you upload the JSON profile and follow the subscribe wizard. Refer to the Consume Versioned Share for more details.
   - **Register Data Catalogs**: You can create a connection by registering a data source as a data asset in your data catalog. You can view, delete and rename the data catalogs. Refer to the Register Data Catalog chapter.
4. The toolbar consists of the following buttons:
   - **Sort By**

     To select sorting values, click the **Sort By** button to open the list of options. Then click the **Ascending** or **Descending** icon next to one or more of the sorting values. For example, if you select the **Ascending** icon next to **Entity name** and the **Descending** icon next to **Entity type**, the entities will be sorted in alphabetical order by entity name and then in reverse alphabetical order by entity type.

     Click **Reset** in the list to clear the choices in the list.

- **Page size**

  By default, up to 25 entities are displayed on the page. If you want more entities on a page, select a number from this list.

- **Previous** and **Next**

  If the search results are displayed on multiple pages, click these buttons to navigate through the pages.

- **Refresh**

  Click to refresh the data load jobs shown on the page, based on the current search field.

5. The sorting values you choose are listed next to the **Sort by** label beneath the toolbar. Click the **X** icon on a sorting value to remove it.
6. Display area: The area below the Create drop-down field displays the entity carts returned by a search.

View Entity Details

- To view details about the existing entities, click **Actions**.
- For a Share Provider, refer to the View Share Provider Entity detail.
- For a Cloud Storage Link, click **Actions** to perform the following operations:
  - Select **View Details** to view details about the table.
  - Select **Objects** to view objects available in the selected storage link. You can click a file on the navigator pane to view it on the display area.
  - Selecting **Link Tables** opens the Link Data page on the Data Load tool with the selected cloud storage link on the Cloud Location URL field. You can link data present in the cloud storage to the Autonomous Database. See Linking to Objects in Cloud Storage.
  - Selecting **Load Tables** opens the Load Data page on the Data Load tool with the selected cloud storage link on the Cloud Location URL field. You can load data present in the cloud storage to the Autonomous Database. See Loading Data from Cloud Storage.
  - Selecting **Create Live Table Feed** opens the Create Live Table feed wizard with he selected cloud storage link on the Cloud Location URL field. See Feeding Data to view more details.
  - Select **Edit** to update any details on the cloud storage location. See Create Credentials to view details on creation of cloud storage location.
  - Select **Rename** to rename the cloud store location to a different name.
  - Select **Delete** to delete the cloud store location.
- Register Data Catalog
  You can register data catalogs you want to use with registering the data catalog.
- Create Credentials
  The procedure for creating a credential varies depending on the cloud storage provider. If your source files reside in a cloud store provided by one of the following, see the example for that provider.
- Create Oracle Cloud Infrastructure Native Credentials
  To establish cloud storage connection from Data Studio to Oracle Cloud Infrastructure (OCI) Object storage service, you must configure the cloud storage location with your OCI

authentication details. You can create Oracle Cloud Infrastructure (OCI) Native Credentials by using the CREATE_CREDENTIAL procedure of DBMS_CLOUD package.

- Create Amazon Web Services (AWS) Credentials
  To access AWS Glue Catalog you must have AWS credentials that you can create via the Create Credential wizard. This wizard stores cloud service credentials in the Autonomous Database.
- Manage Resource Principal with DBMS_CLOUD
  The Oracle Cloud Infrastructure (OCI) Resource Principal allows applications and services running within the OCI to access an Autonomous Database without the need for traditional database credentials (e.g., username and password).

Create Credentials

The procedure for creating a credential varies depending on the cloud storage provider. If your source files reside in a cloud store provided by one of the following, see the example for that provider.

- **Oracle Cloud Infrastructure (OCI)**, see Create an OCI Cloud Store Location.
- **Amazon S3**, or you are calling an AWS API, see Create an Amazon S3 Cloud Store Location.
- **Microsoft Azure Blob Storage** or you are calling an Azure API, see Create a Microsoft Azure Cloud Store Location.
- **Google Cloud Storage**, see Create a Google Cloud Storage Location.
- **Other (Swift compatible)** cloud storage, see Create an Other (Swift Compatible) Cloud Store Location.
- **OCI cloud storage** by using native OCI credentials, see the subsequent section.

> **Note:**
>
> This method is suggested if you need to use the OCI REST APIs. You need to use the Native OCI credentials if you want to use the OCI REST APIs. To create an OCI cloud storage location using Oracle Cloud Infrastructure Signing Keys, you must first Create Oracle Cloud Infrastructure Native Credentials.

- **OCI Cloud Shell**, see Create Credentials using OCI Cloud Shell.

Create an OCI Cloud Store Location

1. On the **Connections** page, click **Create** and select **Create New Cloud Store Location**. This opens the Add Cloud Store Location wizard.
2. In the Storage Settings tab of the Add Cloud Store Location box, enter a name for the cloud storage link. For example:

   ```
   My_Cloud_Store
   ```

3. (Optional) In the **Description** field, enter a description for the link. For example:

   ```
   My cloud storage link.
   ```

4. Click **Select Credential** and **Create Credential** to create a credential. This opens a Create Credential wizard.

In the Credentials section, select **Cloud Username and Password**.

5. From the **Cloud Store** drop-down list, select **Oracle**.
6. Enter a name in the **Credential Name** field. The name must conform to Oracle object naming conventions. For example:

   ```
   my_credential
   ```

7. For an OCI cloud store, in the **Oracle Cloud Infrastructure User Name** field, enter your OCI user name. You must use Oracle Cloud Infrastructure User Name from your profile in the OCI console. For example:

   ```
   oracleidentitycloudservice/foo@example.com
   ```

   or

   ```
   default/foo@example.com
   ```

8. For an OCI cloud store, in the **Auth Token** field, enter your auth token. For example:

   ```
   LPB>Ktk(1M1SD+a]+r
   ```

9. In the **Bucket URI** field, enter the URI and bucket for your OCI instance bucket.
   a. To get the URI and bucket, go to the bucket in the Object Storage compartment in your Oracle Cloud Instance.
   b. In the Objects group, click the Actions (three vertical dots) icon for a file in the bucket, then click **View Object Details**.
   c. Copy all of the URL Path (URI) except for the file name. Be sure to include the trailing slash. For example, for the file `https://objectstorage.us-phoenix-1.oraclecloud.com/n/myoci/b/my_bucket/o/MyFile.csv`, select the following:

      ```
      https://objectstorage.us-phoenix-1.oraclecloud.com/n/myoci/b/
      my_bucket/o/
      ```

   d. Paste the string into the **URI + Bucket** field.
10. Click **Next**.
    The dialog box progresses to the Cloud Data tab. This tab lists the objects available on this cloud storage location in the display area.

    > **Note:**
    >
    > The display area is blank when we create a new cloud storage location.

11. Click **Create** create the cloud storage location.

Create an Amazon S3 Cloud Store Location

1. On the **Connections** page, click **Create** and select **Create New Cloud Store Location**. This opens the Add Cloud Store Location wizard.

2. In the Storage Settings tab of the Add Cloud Store Location box, enter a name for the cloud storage link. For example:

   ```
   My_Cloud_Store
   ```

3. (Optional) In the **Description** field, enter a description for the link. For example:

   ```
   My cloud storage link.
   ```

4. Click **Select Credential** and **Create Credential** to create a credential. This opens a Create Credential wizard.
   In the Credentials section, select **Cloud Username and Password**.
5. From the **Cloud Store** drop-down list, select **Oracle**.
6. Enter a name in the **Credential Name** field. The name must conform to Oracle object naming conventions. For example:

   ```
   my_credential
   ```

7. From the **Cloud Store** drop-down list, select **Amazon S3**.
8. Enter a name in the **Credential Name** field. The name must conform to Oracle object naming conventions. For example:

   ```
   my_credential
   ```

9. In the **AWS Access Key ID** field, enter your AWS access key ID. For example:myAccessKeyID
10. In the **AWS Secret Access Key** field, enter your AWS secret access key. For information on AWS access keys, see Managing access keys for IAM users.
11. In the **Bucket URI** field, enter the URI and bucket for your Amazon S3 bucket. For example:

    ```
    https://s3.us-west-2.amazonaws.com/my_bucket
    ```

12. Click **Next**.
    The dialog box progresses to the Cloud Data tab. This tab lists the objects available on this cloud storage location in the display area.

    > **Note:**
    >
    > The display area is blank when we create a new cloud storage location.

13. Click **Create** create the cloud storage location.

Create an Microsoft Azure Cloud Store Location

1. On the **Connections** page, click **Create** and select **Create New Cloud Store Location**. This opens the Add Cloud Store Location wizard.
2. In the Storage Settings tab of the Add Cloud Store Location box, enter a name for the cloud storage link. For example:

   ```
   My_Cloud_Store
   ```

3. (Optional) In the **Description** field, enter a description for the link. For example:

   ```
   My cloud storage link.
   ```

4. Click **Select Credential** and **Create Credential** to create a credential. This opens a Create Credential wizard.
   In the Credentials section, select **Cloud Username and Password**.
5. From the Cloud Store drop-down list, select **Microsoft Azure**.
6. Enter a name in the **Credential Name** field. The name must conform to Oracle object naming conventions. For example:

   ```
   my_credential
   ```

7. In the **Azure Storage Account Name** field, enter the name of your Azure storage account. For example:

   ```
   myaccount
   ```

8. In the **Azure Storage Account Access Key** field, enter your Azure access key.
   For information on Azure storage accounts, see Create a storage account.
9. In the **Bucket URI** field, enter the URI and bucket for your Microsoft Azure bucket. For example:

   ```
   https://myaccount.blob.core.windows.net/mycontainer
   ```

10. Click **Next**.
    The dialog box progresses to the Cloud Data tab. This tab lists the objects available on this cloud storage location in the display area.

    > **Note:**
    >
    > The display area is blank when we create a new cloud storage location.

11. Click **Create** to create the cloud storage location.

Create an Microsoft Azure Cloud Store Location

1. On the **Connections** page, click **Create** and select **Create New Cloud Store Location**. This opens the Add Cloud Store Location wizard.
2. In the Storage Settings tab of the Add Cloud Store Location box, enter a name for the cloud storage link. For example:

   ```
   My_Cloud_Store
   ```

3. (Optional) In the **Description** field, enter a description for the link. For example:

   ```
   My cloud storage link.
   ```

4. Click **Select Credential** and **Create Credential** to create a credential. This opens a Create Credential wizard.
   In the Credentials section, select **Cloud Username and Password**.
5. From the Cloud Store drop-down list, select **Microsoft Azure**.

6. Enter a name in the **Credential Name** field. The name must conform to Oracle object naming conventions. For example:

   ```
   my_credential
   ```

7. In the **Azure Storage Account Name** field, enter the name of your Azure storage account. For example:

   ```
   myaccount
   ```

8. In the **Azure Storage Account Access Key** field, enter your Azure access key.
   For information on Azure storage accounts, see Create a storage account.
9. In the **Bucket URI** field, enter the URI and bucket for your Microsoft Azure bucket. For example:

   ```
   https://myaccount.blob.core.windows.net/mycontainer
   ```

10. Click **Next**.
    The dialog box progresses to the Cloud Data tab. This tab lists the objects available on this cloud storage location in the display area.

    > **Note:**
    >
    > The display area is blank when we create a new cloud storage location.

11. Click **Create** to create the cloud storage location.

Create a Google Cloud Store Location

1. On the **Connections** page, click **Create** and select **Create New Cloud Store Location**. This opens the Add Cloud Store Location wizard.
2. In the Storage Settings tab of the Add Cloud Store Location box, enter a name for the cloud storage link. For example:

   ```
   My_Cloud_Store
   ```

3. (Optional) In the **Description** field, enter a description for the link. For example:

   ```
   My cloud storage link.
   ```

4. Click **Select Credential** and **Create Credential** to create a credential. This opens a Create Credential wizard.
   In the Credentials section, select **Cloud Username and Password**.
5. Enter a name in the **Credential Name** field. The name must conform to Oracle object naming conventions. For example:

   ```
   my_credential
   ```

6. From the **Cloud Store** drop-down list, select **Google**.

7. In the **HMAC Access Key** field, enter your HMAC access ID. For example:

   ```
   GOOGTS1C3LPB3KTKSDMB2BFD
   ```

8. In the **HMAC Access Secret** field, enter your HMAC secret. For information on HMAC keys, see HMAC Keys.
9. In the Storage Settings tab of the Add Cloud Store dialog box, enter a name for the cloud storage link. For example:

   ```
   My_Cloud_Store
   ```

10. (Optional) In the **Description** field, enter a description for the link. For example:

    ```
    My cloud storage link.
    ```

11. In the **Bucket URI** field, enter the bucket and URI for your Google bucket. For example:

    ```
    https://my_bucket.storage.googleapis.com
    ```

12. Click **Next**.
    The dialog box progresses to the Cloud Data tab. This tab lists the objects available on this cloud storage location in the display area.

    > **Note:**
    >
    > The display area is blank when we create a new cloud storage location.

13. Click **Create** to create the cloud storage location.

Create an Other (Swift Compatible) Cloud Store Location

1. On the **Connections** page, click **Create** and select **Create New Cloud Store Location**. This opens the Add Cloud Store Location wizard.
2. In the Storage Settings tab of the Add Cloud Store Location box, enter a name for the cloud storage link. For example:

   ```
   My_Cloud_Store
   ```

3. (Optional) In the **Description** field, enter a description for the link. For example:

   ```
   My cloud storage link.
   ```

4. Click **Select Credential** and **Create Credential** to create a credential. This opens a Create Credential wizard.
   In the Credentials section, select **Cloud Username and Password**.

> **Note:**
>
> If you have the user OCID, tenancy OCID, private key and fingerprint, select **Oracle Cloud Infrastructure Signing Keys** and refer to the *Create an OCI Cloud storage location using Oracle Cloud Infrastructure Signing Keys* section of this topic.

5. From the Cloud Store drop-down list, select **Other (Swift Compatible)**.
6. Enter a name in the **Credential Name** field. The name must conform to Oracle object naming conventions. For example:

   ```
   my_credential
   ```

7. In the **Access User Name** field, enter your access user name. For example:

   ```
   OTHER_KEY123...
   ```

8. In the **Access Key** field, enter your access key.
9. In the **Bucket URI** field, enter the URI and bucket for your cloud store bucket. For example:

   ```
   https://someswiftcompatibleprovider.com/my_bucket
   ```

10. Click **Next**.The dialog box progresses to the Cloud Data tab. This tab lists the objects available on this cloud storage location in the display area. The display area is blank when we create a new cloud storage location.
11. Click **Create** to create the cloud storage location.

Create an OCI Cloud storage location using Oracle Cloud Infrastructure Signing Keys

To create an OCI Cloud storage location using Oracle Cloud Infrastructure Signing Keys:

1. On the **Connections** page, click **Create** and select **Create New Cloud Store Location**. This opens the Add Cloud Store Location wizard.
2. In the Storage Settings tab of the Add Cloud Store Location box, enter a name for the cloud storage link. For example:

   ```
   My_Cloud_Store
   ```

3. (Optional) In the **Description** field, enter a description for the link. For example:

   ```
   My cloud storage link.
   ```

4. Click **Select Credential** and **Create Credential** to create a credential. This opens a Create Credential wizard.
   If you have the user OCID, tenancy OCID, private key and fingerprint, select **Oracle Cloud Infrastructure Signing Keys**.

> **Note:**
>
> If you only have a username and password select **Cloud Username and Password** in this step and refer to the *Create an Other (Swift Compatible) Cloud Store Location* section of this topic.

5. Specify the following information about your OCI account:

   Credential Name: Specify a name to identify the credentials. See Create an OCI Credential Object to enter the Credential name to specify the credential name.

6. **Fingerprint:** The fingerprint of the RSA key pair. See Create an OCI Credential Object to enter the Credential name to enter the fingerprint.

7. **Private Key:** The unencrypted private key in the RSA key pair. This should not be encrypted by using any passphrase. See Create an OCI Credential Object to enter the Credential name to enter the private key.

8. **Oracle Cloud Infrastructure Tenancy:** The OCID of the tenant. See Where to Get the Tenancy's OCID and User's OCID for details on obtaining the Tenancy's OCID.

9. **Oracle Cloud Infrastructure User Name:** The OCID of the user. See Where to Get the Tenancy's OCID and User's OCID for details on obtaining the User's OCID.

10. Select **Create Credential**.

11. In the **Bucket URI** field, enter the URI and bucket for your cloud store bucket. For example:

    ```
    https://objectstorage.<region>.oraclecloud.com/n/<namespace>/b/<bucket>/
    ```

12. Click **Next**.

13. The dialog box progresses to the Cloud Data tab. This tab lists the objects available on this cloud storage location in the display area.

> **Note:**
>
> The display area is blank when we create a new cloud storage location.

14. Click **Create**.

You will receive a notification that the cloud storage location is created successfully.

Create Credentials using OCI Cloud Shell

You can create OCI native credentials using a Cloud Shell script.

To create credentials using OCI Cloud shell, you must run `adb-create-cred.sh` to generate credential scripts. The `adb-create-cred.sh` script searches for existing credentials, if found you are asked if you want to reuse them or if you want new credentials created. Depending on your decision, the generated credential scripts include new or existing credentials. Download the OCI Native Credential script or copy it to run it directly in your database using any SQL or JSON tool or utility.

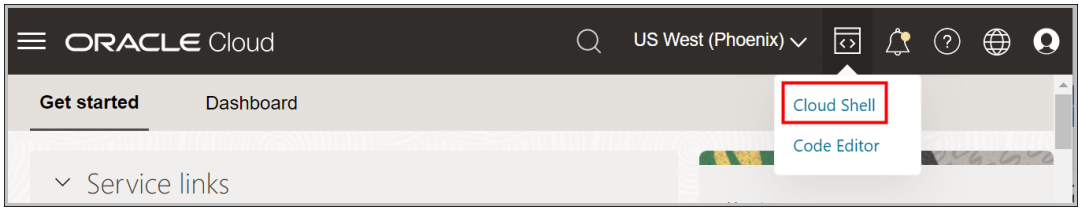
> **Note:**
>
> For a list of arguments supported by the Create Credential script, enter `adb-create-cred.sh --help`.

In this example, OCI Native Credential scripts are generated in the script area for your tenancy without running them in your database.

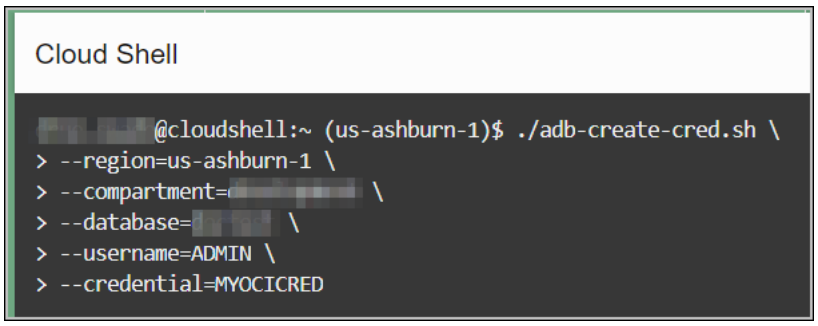
1. On the **Connections** page, click **Create** and select **New Cloud Store Location**. You need to know the Name and Cloud Store Location of the Credential to create a new one.
2. Select **Create Credential**.
3. On the Create Credential wizard, select **Create using OCI Cloud Shell**. You will view a script in the script editor field.

   > **Note:**
   >
   > - If you are in your home region and the Autonomous Database is in your home region, run the script without the region argument. The script assumes the Autonomous Database is in your home region and will not prompt for an alternate region.
   > - If you are in your home region and your Autonomous Database is in an alternate region, then you must pass in the --region argument when running the script.

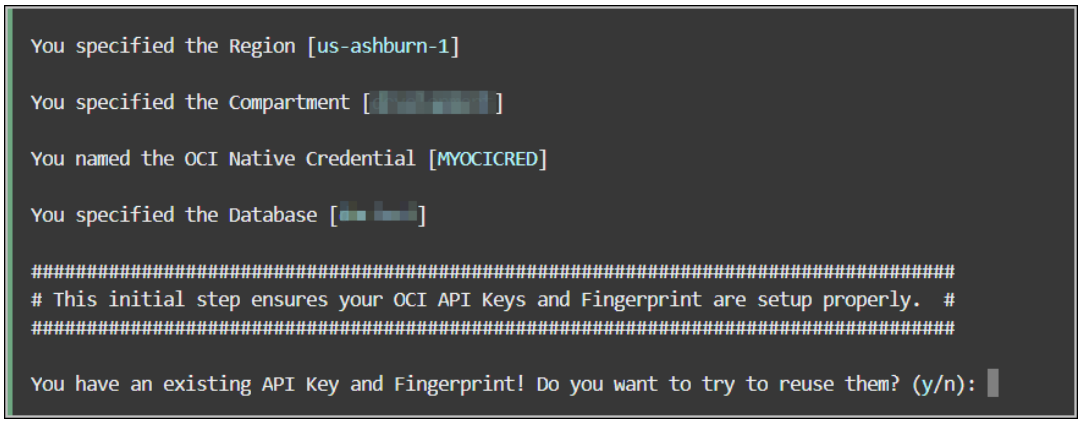
4. Click **Copy Script**.
5. Sign into your OCI Tenancy, select the **Developer Tools** icon and click **Cloud Shell** from the drop down list.



6. Paste the **`adb-create-cred.sh`** script you copied in the previous step that includes arguments the tool uses to locate the database, connect to the database and the credential name you provide in the **Credential Name** field.

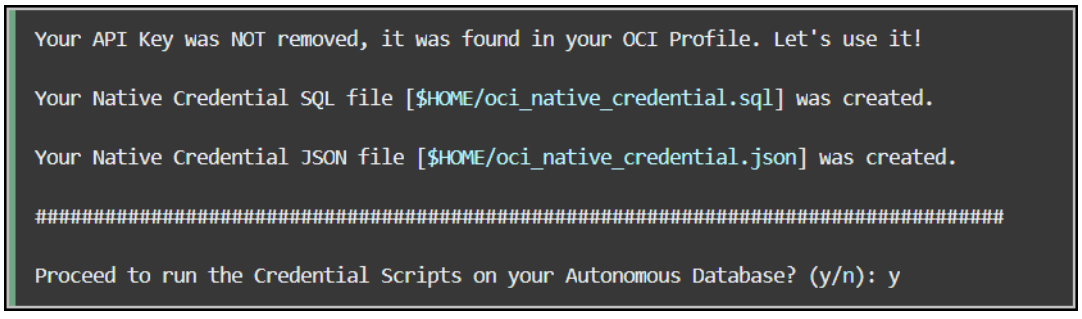


7. The Cloud Shell script informs you of existing OCI API Keys and Fingerprint and if you want to reuse them. Enter `y` to reuse the existing keys and fingerprint.



If you choose to create new credentials, and decide after overwriting the credentials that you want to use the overwritten credentials, you can go back to the directory where the backup is and reuse them. The backup file name or folder has a suffix with this syntax: `_bkp_YYYYMMDD_abc`. For example, this backup file was created on June 06, 2024: `_bkp_20240603_woT`.

8. The Cloud Shell script window displays if you want to run the credential scripts on your Autonomous Database. Enter `y` to run the credential script in the database with the region, compartment and database arguments.



9. You can view a notification that informs you that you do not have a wallet file. The script creates a wallet file. You must specify the ADMIN password you use to connect to the database. In case the script detects the wallet file, the script prompts you to either reuse it or set up a new one.

```
You do not have a Wallet File. Let's set it up for you.

Fixing path in [~ _wallet/sqlnet.ora] to that of your Wallet File.

#########################################################################################
# We setup your credentials, generated SQL scripts to add the credentials, we      #
# also setup your Autonomous Database connection, and are now connecting you to    #
# your Autonomous Database so you can execute the credential scripts.              #
#########################################################################################

You specified the Database Username [ADMIN]

Enter Autonomous Database password:
```

> **Note:**
>
> If you have an Autonomous Database private endpoint in a Virtual Cloud Network, the `adb-create-cred.sh` script generates the SQL and JSON scripts. However, it does not perform the steps required to access the Autonomous Database private end point. Instead, it prompts you to execute `cat ~/oci_native_credential.sql` to copy the SQL into whatever SQL tool you have access to via a Bastion or Jump Host.

10. The Cloud Shell script displays a notification of successful login and creation of credentials in the specific database.
    The script prompts you if you want to run it on **another** database. Enter `n` to not run credentials in another database.

    The script exits and displays the path to run the `oci_native_credential.sql` script to create a credential.

```
Login successful.

OCI Native Credential [MYOCICRED] creation successful.

#########################################################################################
# Please be aware that it may take up 15 minutes to propagate your credentials to  #
# OCI Services. During this period of time your new credentials will not work.     #
#########################################################################################

Proceed to run the Credential Scripts on another Autonomous Database? (y/n): n

Exiting...

To view PL/SQL script for creating credentials,

        execute: cat $HOME/oci_native_credential.sql

 @cloudshell:~ (us-ashburn-1)$
```

> **Note:**
>
> If the connection to the Autonomous Database is unsuccessful, you can run `cat ~/oci_native_credential.sql`, and copy the SQL to run it directly in your database using any SQL tool.

Create Oracle Cloud Infrastructure Native Credentials

To establish cloud storage connection from Data Studio to Oracle Cloud Infrastructure (OCI) Object storage service, you must configure the cloud storage location with your OCI authentication details. You can create Oracle Cloud Infrastructure (OCI) Native Credentials by using the CREATE_CREDENTIAL procedure of DBMS_CLOUD package.

Create an Oracle Cloud Infrastructure (OCI) Credential Object

To access Object Storage, you must have credentials that you can create via the CREATE_CREDENTIAL procedure of DBMS_CLOUD package. DBMS_CLOUD supports creation of credential objects that contains OCI native authentication. The DBMS_CLOUD procedure stores cloud service credentials in Autonomous Database.

The DBMS_CLOUD.CREATE_CREDENTIAL procedure is overloaded with the Oracle Cloud Infrastructure-related parameters, including: user_ocid, tenancy_ocid, private_key, and fingerprint. This is for using Oracle Cloud Infrastructure Signing Keys authentication.

Let us create an OCI native authentication credential when creating an object store credential object. In the OCI native authentication, the DBMS_CLOUD.CREATE_CREDENTIAL procedure includes the following parameters:

Table 3-2 DBMS_CLOUD.CREATE_CREDENTIAL parameter descriptions

Parameter	Description
`credential_name`	The `credential_name` parameter must conform to Oracle object naming conventions.
`user_ocid`	Specifies the user's OCID. See Where to Get the Tenancy's OCID and User's OCID for details on obtaining the User's OCID.
`tenancy_ocid`	Specifies the tenancy's OCID. See Where to Get the Tenancy's OCID and User's OCID for details on obtaining the Tenancy's OCID.
`private_key`	Specifies the generated private key. Private keys generated with a passphrase are not supported. You need to generate the private key without a passphrase. See How to Generate an API Signing Key for details on generating a key pair in PEM format.
`fingerprint`	Specifies a fingerprint. After a generated public key is uploaded to the user's account the fingerprint is displayed in the console. Use the displayed fingerprint for this argument. See How to Get the Key's Fingerprint and How to Generate an API Signing Key for more details.

Here is the syntax of the DBMS_CLOUD.CREATE_CREDENTIAL procedure:

```
DBMS_CLOUD.CREATE_CREDENTIAL (
    credential_name IN VARCHAR2,
    user_ocid       IN VARCHAR2,
    tenancy_ocid    IN VARCHAR2,
    private_key     IN VARCHAR2,
    fingerprint     IN VARCHAR2);
```

Once you obtain all the necessary inputs and generate your private key, here is a sample of your CREATE_CREDENTIAL procedure:

```
BEGIN  DBMS_CLOUD.CREATE_CREDENTIAL (    credential_name =>
      'OCI_NATIVE_CRED',    user_ocid              =>

'ocid1.user.oc1..aaaaaaaatfn77fe3fxux3o5lego7glqjejrzjsqsrs64f4jsjrhbsk5qzndq'
,    tenancy_ocid           =>

'ocid1.tenancy.oc1..aaaaaaaapwkfqz3upqklvmelbm3j77nn3y7uqmlsod75rea5zmtmbl574v
e6a',    private_key            =>

'MIIEogIBAAKCAQEAsbNPOYEkxM5h0DF+qXmie6ddo95BhlSMSIxRRSO1JEMPeSta0C7WEg7g8SOSz

    PL/SQL procedure successfully completed.
```

You can now retrieve the new credentials with the following query:

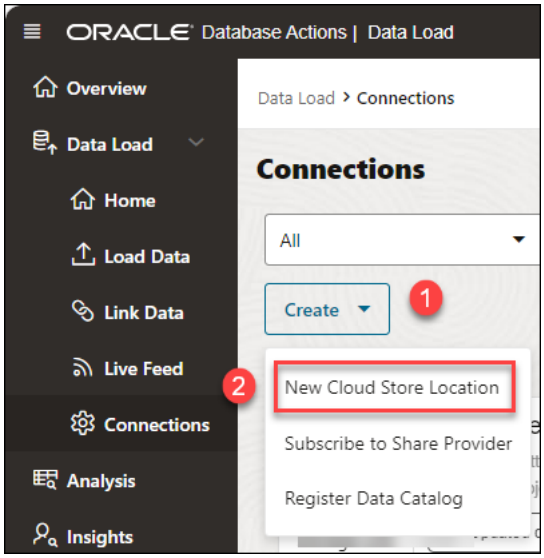
```
SELECT owner, credential_name FROM dba_credentials WHERE credential_name LIKE
'%NATIVE%';  OWNER CREDENTIAL_NAME----- ---------------
    ADMIN OCI_NATIVE_CRED
```

Create Amazon Web Services (AWS) Credentials

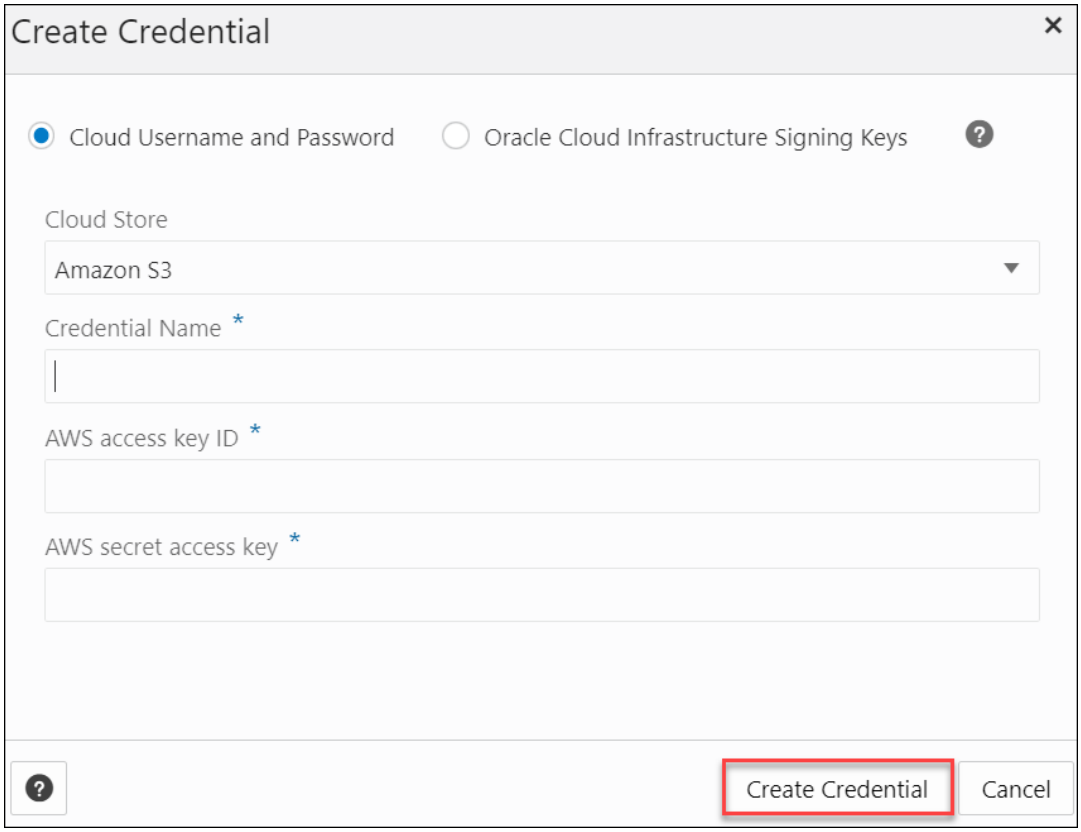
To access AWS Glue Catalog you must have AWS credentials that you can create via the Create Credential wizard. This wizard stores cloud service credentials in the Autonomous Database.

Use the `CREATE CREDENTIAL` wizard depending on where your source files reside. To create AWS credentials:

1. On the **Connections** page, click **Create** and select **New Cloud Store Location**.



2. Select **Create Credential** from **Add Cloud Store Location** wizard.



3. Select **Cloud Username and Password**.
4. Select **Amazon S3** from the Cloud Store drop-down.
5. Enter a name in the Credential Name field. The name must conform to Oracle object naming conventions. For example, `MY_AWS_CRED`.
6. In the **AWS Access Key ID** field, enter your AWS access key ID. For example: `myAccessKeyID`, see Managing access keys for IAM users.
7. In the **AWS Secret Access Key** field, enter your AWS secret access key. For information on AWS access keys, see Managing access keys for IAM users.
8. Click **Create Credential** to create AWS credentials.

Manage Resource Principal with DBMS_CLOUD

The Oracle Cloud Infrastructure (OCI) Resource Principal allows applications and services running within the OCI to access an Autonomous Database without the need for traditional database credentials (e.g., username and password).

You do not need to create a credential object when you use a resource principal. The Autonomous Database creates and secures the resource principal credentials you use to access the specified Oracle Cloud Infrastructure resources. A resource principal consists of a temporary session token and secure credentials that enable the database to authenticate itself to other Oracle Cloud Infrastructure services.

Prerequisites to Use Resource Principal with Autonomous Database:

- There are several steps required to set up a resource principal on an Autonomous Database: You must create and define Oracle Cloud Infrastructure Identity and Access

Management (IAM) policies. See Perform Prerequisites to Use Resource Principal with Autonomous Database for more information.

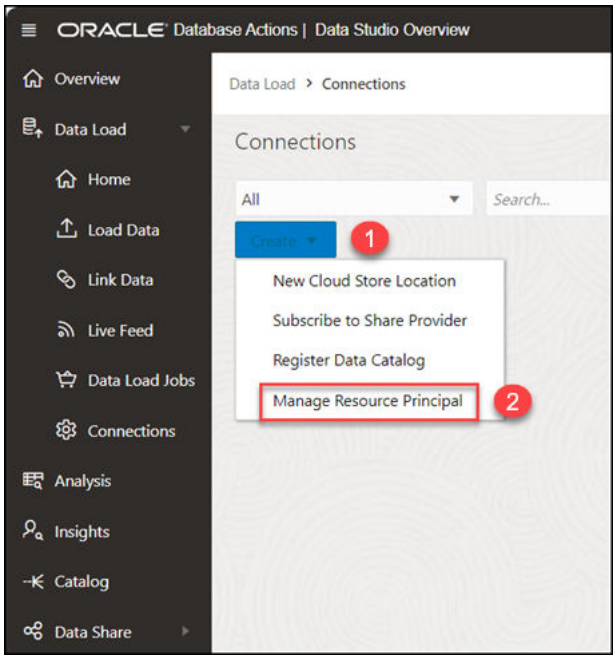
- Enable the resource principal for the ADMIN user, and optionally enable the resource principal for a database user. See Enable Resource Principal to access OCI Resources.

When you authenticate using a resource principal, you do not need to create and manage credentials to access OCI resources. The Autonomous Database makes the resource principal available to you and secures the resource principal for you.

Manage Resource Principal using Data Studio

You can also enable Resource Principal using Data Studio.

1. From the Database Actions Launchpad, select the **Data Load** tile.
2. Click **Connections** This opens the Connections page.
3. On the **Connections** page, click **Create** and select **Manage Resource Principal.**



This opens the Manage Resource Principal dialog.

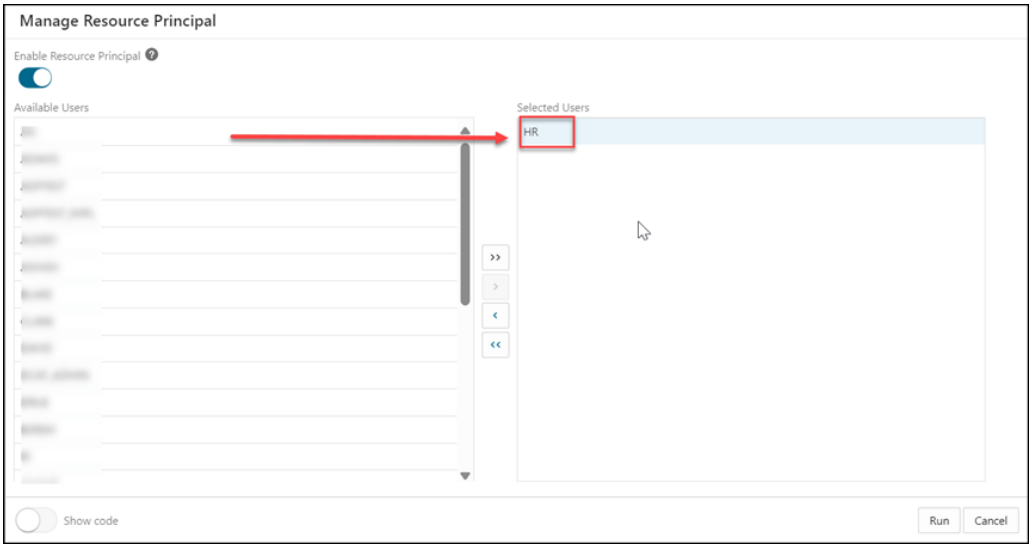
4. Select the user or users you want to add from the **Available Users** list to the **Selected Users** list to enable their resource principal.
Choose any of the available options:

   - **>**: This option enables you to move the user to **Selected Users**.

     <: To remove the selected user from **Selected Users**, select this option.

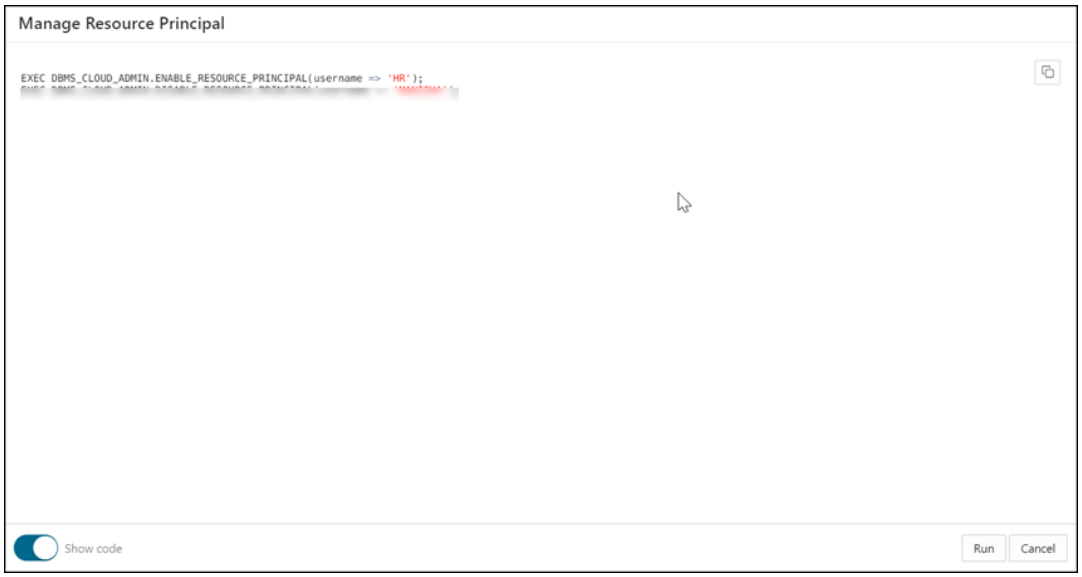
     >>: This option allows you to move all the tables to the **Selected Users** list.

     <<: To remove all the selected users from **Selected Users**, select this option.



> **Note:**
>
> You can grant access to the resource principal credential to a database user only if the ADMIN user has enabled the resource principal credential.

5. Select the **Show Code** option to view the PL/SQL code equivalent of the Manage Resource Principal dialog box. You can copy and execute this PL/SQL code in the worksheet to perform the same action that occurs when you click **Enable Resource Principal** in the Manage Resource Principal dialog box.



6. Click **Run** to complete the process of enabling the resource principal of the selected users. A confirmation notification is displayed that confirms that the resource principal of selected users is enabled.
7. Select a user from Selected Users to Available Users to **disable** the resource principal for the selected user. This removes the credential `OCI$RESOURCE_PRINCIPAL`. Refer to Disable Resource Principal on Autonomous Database for more information on this topic.

Register Data Catalog

You can register data catalogs you want to use with registering the data catalog.

Register OCI Data Catalog

To register a data catalog you need to specify the details of the credentials you want to register your data source. A credential object manages a data catalog instance. In OCI native authentication, the DBMS_CLOUD.CREATE_CREDENTIAL procedure includes these parameters: `credential_name`, `user_ocid`, `tenancy_ocid`, `private_key`, and `fingerprint`.

See REF DBMS_DCAT Package to refer to the procedures to add custom parameters such as region and data catalog ID to the Data Catalog. The Data Catalog ID is a unique Oracle cloud Identifier for data catalog instance and region is the data catalog region.

To register Data catalog:

1. From Connections page, click **Create** and select **Register Data Catalog**. This opens Register Data Catalog wizard.
2. In the Catalog Settings tab, specify the following details:
   - **Catalog Name:** `Test`. Enter a name of your choice.
   - **Description:** Specify a description. This is an optional field.
   - Under Data Catalog details, fill in the following field values:

- **Credential for Data Catalog Connection:** Select a value from the drop-down. The drop-down lists the values of the credentials you create. If you do not have credentials, you can create one. Refer to Create Credentials for more information.
- **Region:** `us-ashburn-1`. Enter the region name you use while you create the credentials using the DBMS_DCAT package.
- **Data Catalog ID:** `ocid1.datacatalog.oc1.iad.amaaaaaa7ratcziayxh7uzll24cp3uwzsugfj7qlubak77toiehidpsqsygq`. Enter the data catalog ID from the DBMS_DCAT package.
- Select the **Register Data Catalog Connection** button to register the data catalog within the autonomous database. You can view this option when you select **OCI Data Catalog** from Catalog Type.
- Select the **Use separate credential** for object Storage to select the database credentials from the drop-down. You can view this option when you select **OCI Data Catalog** from Catalog Type.

3. Click **Next** to progress to the Register Assets tab. This tab creates a connection with the source Data Catalog objects you select from the list of objects.
4. After successful registering of the data catalog objects, click **Create**.
5. You will receive a notification that the data catalog is created successfully.
   After successful creation of the data catalog, you can view the data catalog entity in the list of entities in the **Connections** page.

Register AWS Glue Catalog

You can integrate Oracle Data Catalog with Amazon's Glue data catalog.

To access the AWS Glue Catalog, register the catalog on the **Connections** page.

This enables you to synchronize Data Catalog metadata with AWS Glue and query data stored in S3 from an Autonomous Database without manually deriving the schema for the external data sources and creating external tables.

Refer to Query External Data with Glue Data CatalogQuery External Data with Glue Data Catalog for more details.

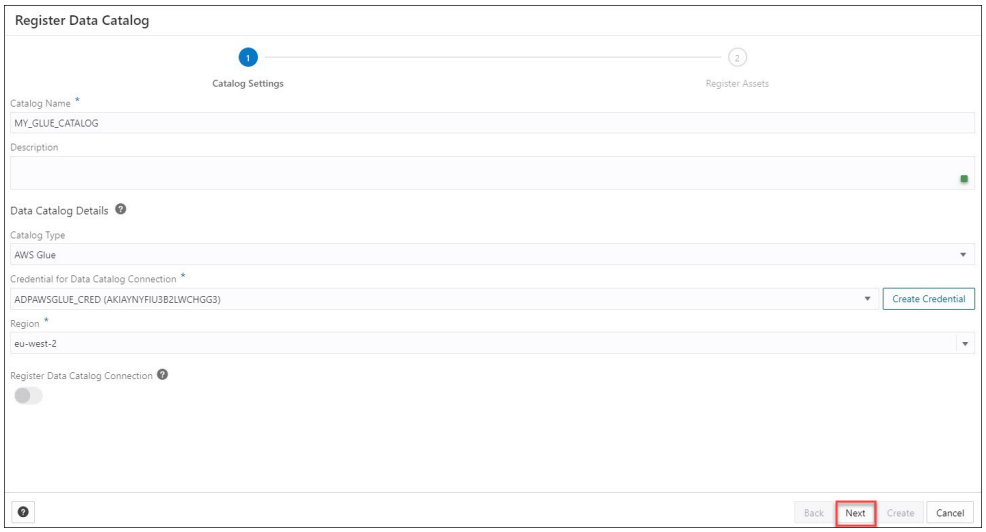
You also need an AWS Credential to be associated with the AWS Glue Catalog. The tool initiates the connection by specifying the following field values:

- Cloud Store
- Credential Name
- AWS access key ID
- AWS Secret Access Key

To register the Data Catalog:

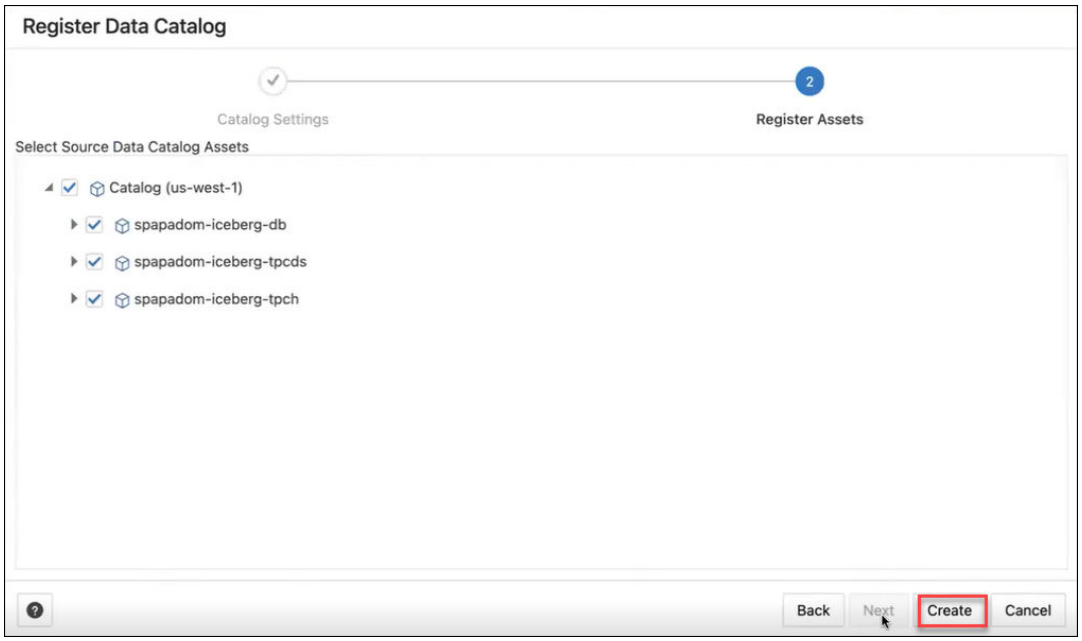
1. From the Connections page, click **Create** and select **Register Data Catalog**. This opens the Register Data Catalog wizard.
2. In the Catalog Settings tab, specify the following details:
   - **Catalog Name**: `MY_GLUE_CATALOG`
   - **Description**: Specify a description. This is an optional field.
   - Under Data Catalog Details, fill in the following field values:
     - **Catalog Type**: Select AWS Catalog from the drop-down.

- **Credential for Data Catalog Connection**: Select a credential value from the drop down. The drop-down lists the values of the credentials you create. If you do not have credentials, you can create one. Refer to Create Amazon Web Services (AWS) Credentials for more information.
- **Region**: `eu-west-2`. Enter the region name you use while you create the AWS credentials.



The **Register Data Catalog Connection** field will be greyed out since you selected AWS Catalog. You can select this field only if you want to register data catalog connection within the Autonomous Database (i.e., when you select OCI Data Catalog).

3. Click **Next** to progress to the Register Assets tab. The Register Assets tab creates a connection with the source data catalog objects you select from the list of objects.
4. After successfully registering the data catalog objects, click **Create**.



5. You will receive a notification that the data catalog has been created successfully. After the successful creation of the data catalog, you can view the data catalog entity in the list of entities on the **Connections** page.

Loading Data

You can load data from files on your local device, from remote databases, or from cloud storage buckets from directories and share providers. The file formats that you can load are CSV, XLS, XLSX, TSV, TXT, XML, JSON, GEOJSON, AVRO, PARQUET, GZ, GZIP, ZIP, PDF, PNG, JPG, JPEG and TIFF.

The Data Load tool supports the loading of source files with boolean format. The data type boolean has the truth values `TRUE` and `FALSE`. If there is no `NOT NULL` constraint, the boolean data type also supports the truth value `UNKNOWN` as the null value. You can use the boolean data type wherever the datatype appears in Oracle SQL syntax.

It also supports the `VECTOR` data type, which allows you to store vector embeddings directly within Oracle Database tables.

- Use OCI Language Service Capabilities in Data Studio
  You can utilize OCI Language Service Capabilities such as Sentiment Analysis, Key Phrase Extraction and Language Detection to analyze data without machine learning (ML) or artificial intelligence (AI) expertise.
- Use OCI Document Understanding to extract Tables from Images
  You can utilize Oracle Cloud Infrastructure(OCI) Document Understanding Capabilities such as Table Extraction to detect tables from the data you load.
- Use GeoJSON in Data Load
  A GeoJSON object accommodates information about the specific geometry (e.g. Point, Line, Polygon, etc.) along with optional metadata (e.g. ID, etc.).
- Loading Data From Local Files
  To load data from local files into your Oracle Autonomous Database, on the Data Load page, select **LOAD DATA** and **LOCAL FILE**.
- Loading Data from Other Databases
  To load data from tables in another database into your Oracle Autonomous Database, on the Data Load page, select **LOAD DATA** and **DATABASE**. Select a database link from the drop-down list. Drag one or more tables from the list of database tables and drop them in the Data Load Cart.
- Loading Data from Cloud Storage
  You can load data from a cloud store to a table in your Autonomous Database.
- Load Apache Iceberg Tables
  Data Studio supports loading and linking Iceberg tables from the object store.
- Loading Data from File System
  You can load files from file system directories to your Autonomous Database.
- Loading Data from AI Source
  You can use Data Studio tools to load data from AI source.
- Loading Data from Share
  You can select tables from a Share. You need to subscribe and access provided data share.
- Create Live Feed from Data Load
  The Data load tool loads the data from folders in cloud object stores and enables it to schedule repeated data loads in real time. This is the creation of Live Feed from a data load job.

Use OCI Language Service Capabilities in Data Studio

You can utilize OCI Language Service Capabilities such as Sentiment Analysis, Key Phrase Extraction and Language Detection to analyze data without machine learning (ML) or artificial intelligence (AI) expertise.

For example, you can use it for feedback on a product. A phone manufacturer has launched a new phone model and they want to know what the customer sentiment is on their product. If a large percentage of sentiment is negative it could signal a potential fault with the camera which wasn't detected in Quality Control (QC).

- Overview of Sentiment Analysis, Key Phrase Extraction and Language Detection
  Sentiment Analysis, Key Phrase Extraction, Language Detection and Text Translation are currently supported in loading data from local files and loading data from cloud storage.
- Parameters to Analyze Data
  When you invoke an **Add Expression** from the Settings tab, you must configure the model using parameters.
- Perform Sentiment Analysis
  To determine the Sentiments of input data:
- Perform Key Phrase Extraction
  To extract Key Phrase information from input data:
- Perform Language Detection
  The Data Studio supports the detection of multiple languages.
- Perform Text Translation
  The Data Studio supports the translation of multiple languages supported by OCI Language Service.

Overview of Sentiment Analysis, Key Phrase Extraction and Language Detection

Sentiment Analysis, Key Phrase Extraction, Language Detection and Text Translation are currently supported in loading data from local files and loading data from cloud storage.

Sentiment Analysis

Sentiment Analysis analyses the text to define your sentiment on a topic or product. The Language service sentiment analysis uses natural language processing (NLP). The Data Studio tool uses the Oracle Cloud Infrastructure (OCI) Language service to analyze and understand the input data. The Data Studio tool dynamically adds new columns to the data load that contains the output of the OCI Language service. You can detect the sentiments of any column of the source data. For example, when searching through a column containing reviews for an application, assume that you want a general opinion about the application. The Data Studio tool performs sentiment analysis on the input data and creates a new expression column defined in the target table that consists of the sentiment.

For more details, refer to Sentiment Analysis in OCI.

Key Phrase Extraction

Key phrase extraction identifies the main concepts in a text. Keyword extraction is the automated process of extracting the words with the most relevance, and expressions from the input text. It helps summarize the content and recognizes the main topics. A word cloud can be generated with key phrases to help visualize key concepts in text comments or feedback. For example, a Movie review could generate a word cloud based on key phrases identified in their comments and might see that people are commenting most frequently about the direction, acting, and cinematography staff.

For more details, refer to Key Phrase Extraction in OCI.

Language Detection

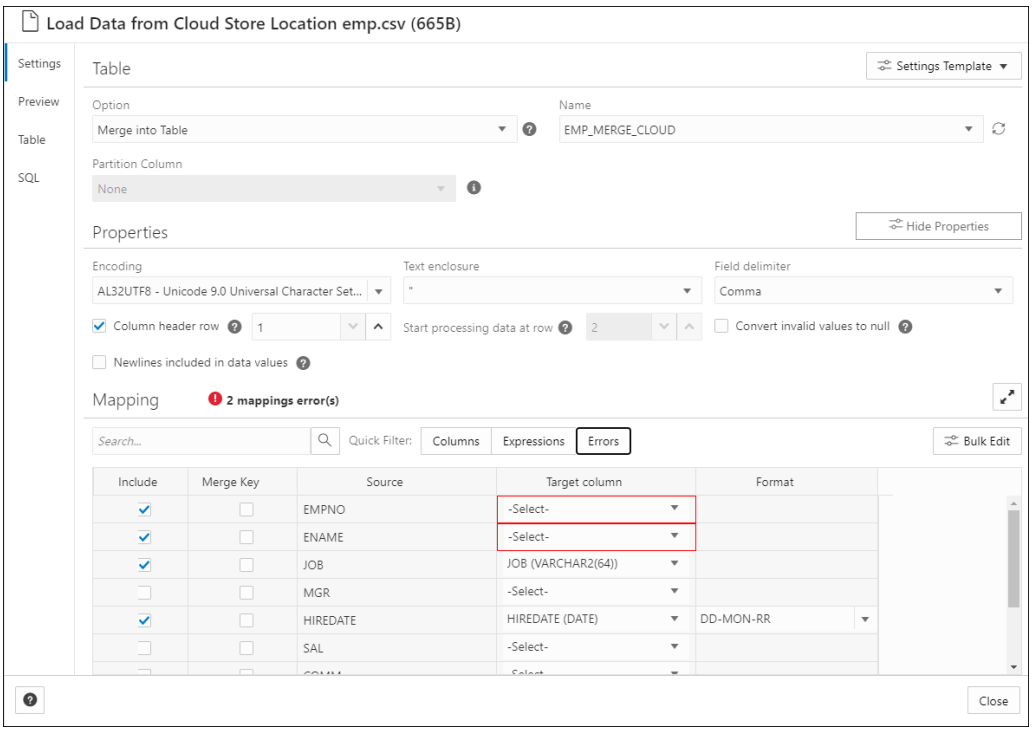
You can utilize OCI Language Service Capabilities such as Language Detection to detect the language of the input text. It returns which natural language the text is in. You can use it to overcome language barriers thus improving communication with people from other countries. You can determine the language of the input text and translate content to different languages. For more details refer to Language Extraction in OCI.

Text Translation

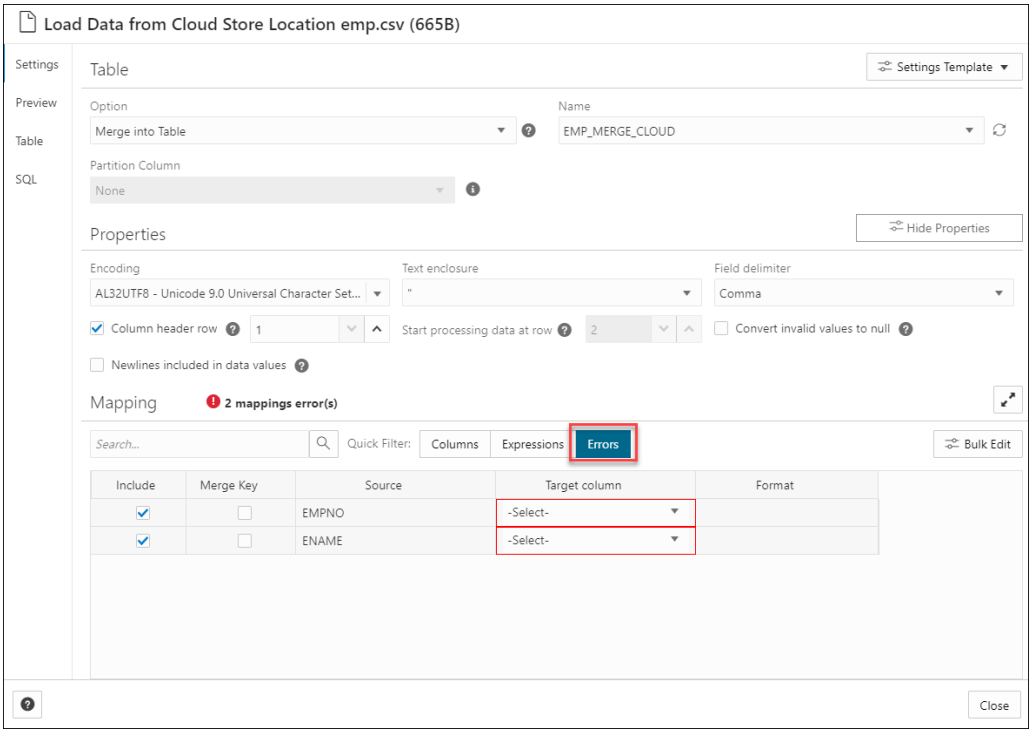
The Text Translation translates input text into any one of the OCI Language service-supported target languages. The Data Studio tool uses the Oracle Cloud Infrastructure (OCI) Language service to analyze and understand the input data. The Data Studio tool dynamically adds new column to the data load that contains the translated input source column. For example, when you need to know what customers are saying about your product in the local market language – French. The Data Studio tool performs language translation on the input data and creates a new expression column defined in the target table that consists of the translated source language in the column.

Before you start:

- **Load Data from Local Files or Cloud storage:** Load the data you wish to analyze into your Oracle Autonomous Database from Local files or Cloud storage. Make sure the data is loaded to the data load cart without any errors. You can view and fix mapping errors from the **Errors** quick filter in the **Load Data from Cloud Store Location**. After you load data into the Data load tool,
  - Click the **Settings** icon on the Data Load job cart to review the settings.
  - On the Settings pane of the **Load Data from Cloud Store Location** wizard, if there is a mapping error, the mapping grid cell will be highlighted with red to indicate an invalid value that must be fixed.



– Click the **Errors** quick filter, it shows only the columns with errors.



- The tools perform sentiment analysis, Key Phrase extraction and Language Detection while you specify settings for the data load job.

Parameters to Analyze Data

When you invoke an **Add Expression** from the Settings tab, you must configure the model using parameters.

Table 3-3 Parameters for Sentiment Analysis, Key Phase Extraction, and Language Detection

Parameter	Description
Expression Type	Select any one of the following operations you wish to perform on the input text: Sentiment Analysis, Key Phrase Extraction, and Language Detection.
Input Column	Select the column which you wish to analyze. The input column drop-down only contains columns that Sentiment Analysis, Key Phrase Extraction, and Language Detection support. For Sentiment Analysis, only VARCHAR2, NVARCHAR2, CLOB, or NCLOB target columns will be displayed in the input drop-down.

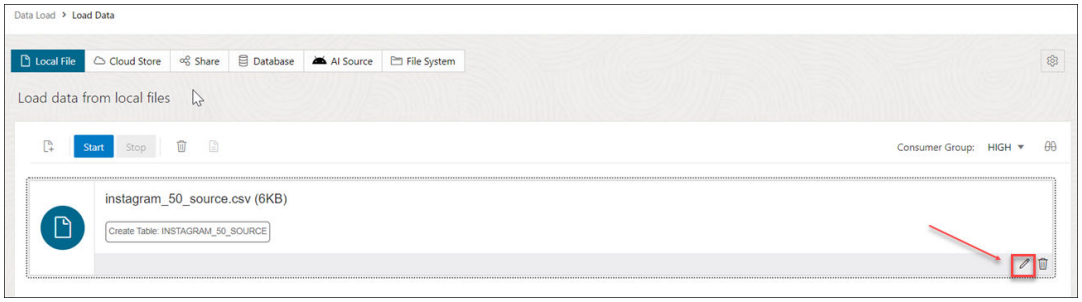
Table 3-3 (Cont.) Parameters for Sentiment Analysis, Key Phase Extraction, and Language Detection

Parameter	Description
Target Column	• Enter the name of the newly created expression column defined in the target table. • For Sentiment Analysis, this column displays the sentiment of the input column. The different types of sentiments the tool identifies are: – Positive – Neutral – Mixed – Negative If the tool cannot determine the sentiment of the input column, it returns `NULL` in the expression column. • For Key Phrase Extraction, this column displays the key phrases of the input column you select. • For Language Detection, this column displays the language of the input column you select.

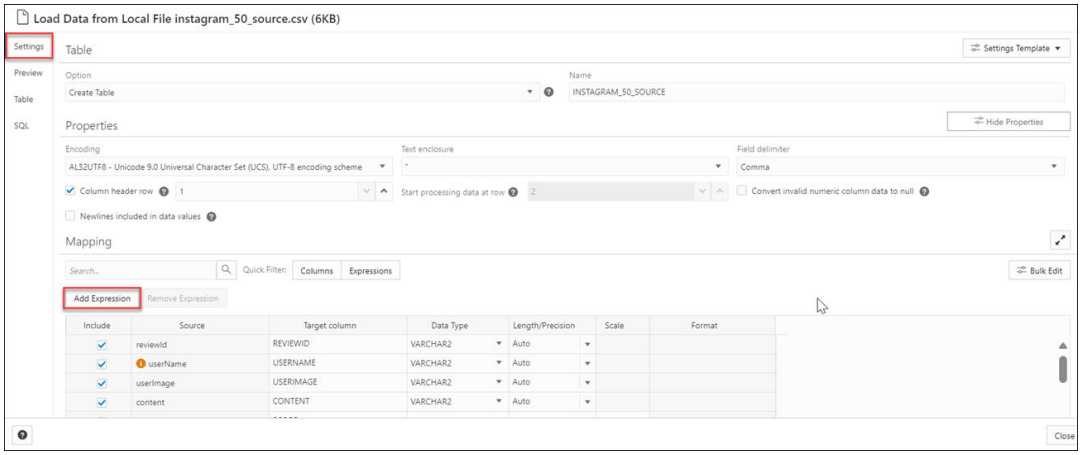
Perform Sentiment Analysis

To determine the Sentiments of input data:

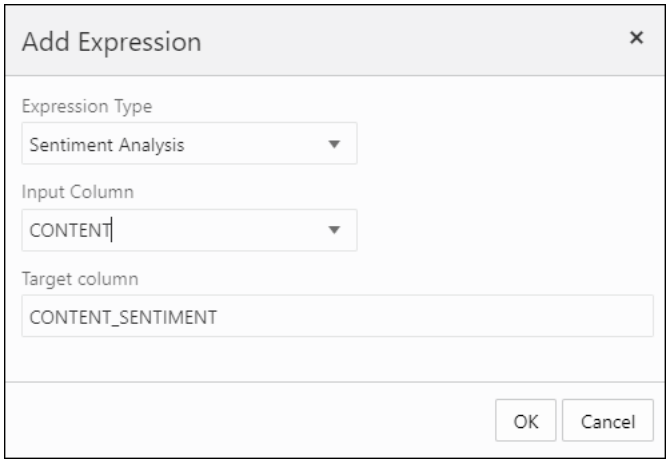
1. After you load data into the Data Load cart from local files or cloud storage, you can view the file in the cart. Click the **settings** icon.



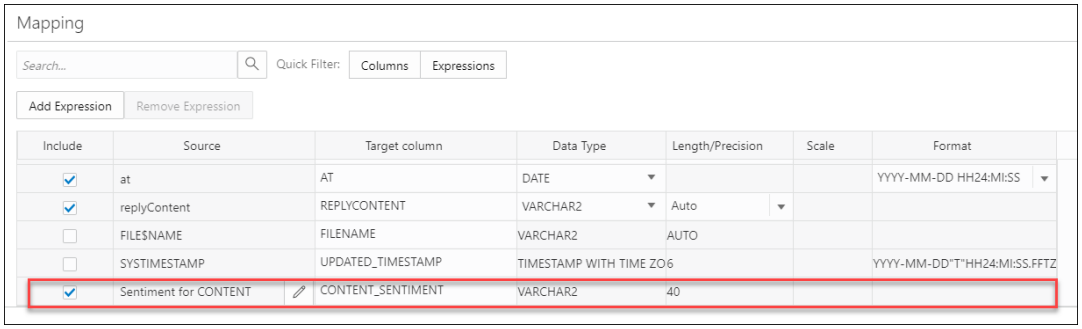
2. Clicking the Setting icon opens a **Load Data from Local File** wizard. In this example, we have loaded data from a local file.
3. On the Settings tab of the wizard, click **Add Expression** under the Mapping section.



This opens the **Add Expression** dialog box.



4. On the **Add Expression** dialog, specify the following fields:
   - **Expression Type:** From the Expression Type drop-down, select **Sentiment Analysis**.
   - **Input Column:** Select the column from the drop-down that you wish to analyze. For example, *CONTENT*.
   - **Target column:** Enter the name of the newly created expression column. For example, *CONTENT_SENTIMENT.*
     Refer to the Parameters to Analyze Data for more details.
5. Click **OK**. You will see a new row added to the mapping grid. This row determines the output expression column generated by the OCI Language service.



6. Click **Close**.
7. Click **Start** in the Data Load menu cart to load data from local files. You will view a confirmation message asking if you wish to start the load from local files.
8. Click **Run** to confirm.

When the data load job completes, the **Table and View Loads** of the Data Load page display the details of the source table that is loaded into the tool. It displays the number of rows and columns and when the upload was complete.

- Output Data Generated from OCI Sentiment Analysis
  When you analyze columns using OCI Language Service model, the Data Studio generates a new expression column and saves the result in the updated table.

Output Data Generated from OCI Sentiment Analysis

When you analyze columns using OCI Language Service model, the Data Studio generates a new expression column and saves the result in the updated table.

To locate the generated expression column, from the Database Actions Launchpad, navigate to **Data Load**. Select the table you load under the **Table and View Loads** section.

Click the three vertical dots beside the load name, and click **Table** then select **View Details**.

This opens the Preview tab of the data load which displays the updated source file. For example, here is an output dataset from sentiment analysis of the Instagram application. Here, `CONTENT` is the target column, and `CONTENT_SENTIMENT` is the sentiment analysis of the input column. This column displays one of the following values such as positive, neutral, mixed, or negative It displays **Null** when the tool is unable to determine the sentiment.

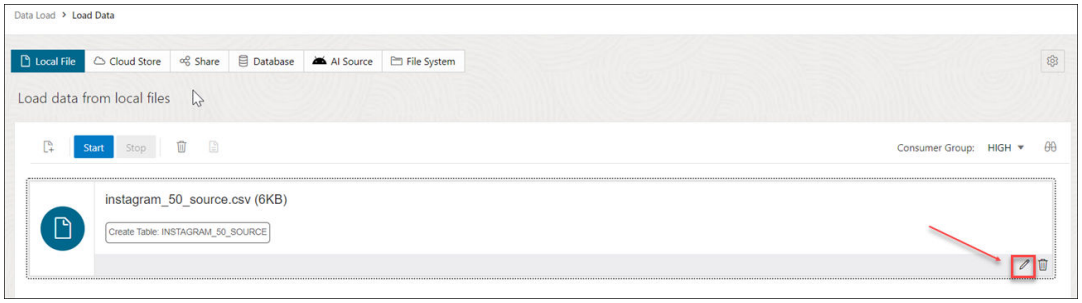
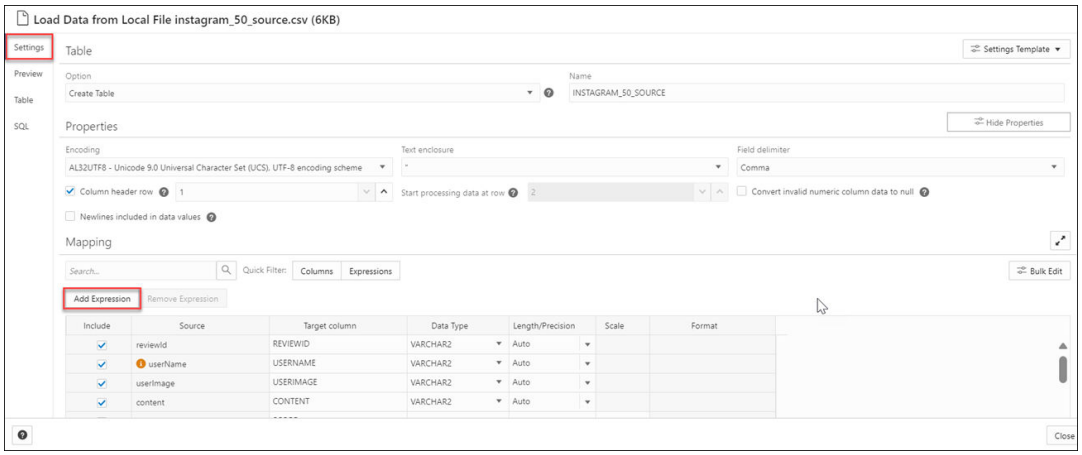
Perform Key Phrase Extraction

To extract Key Phrase information from input data:

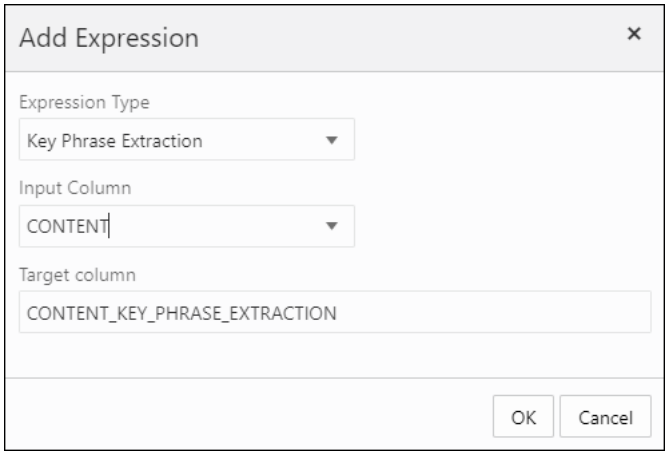
1. After you load data into the Data Load cart from local files or cloud storage, you can view the file in the cart. Click the **settings** icon.



2. Clicking the Setting icon opens a **Load Data from Local File** wizard. In this example, we have loaded data from a local file.
3. On the Settings tab of the wizard, click **Add Expression** under the Mapping section.



This opens the Add Expression dialog box.

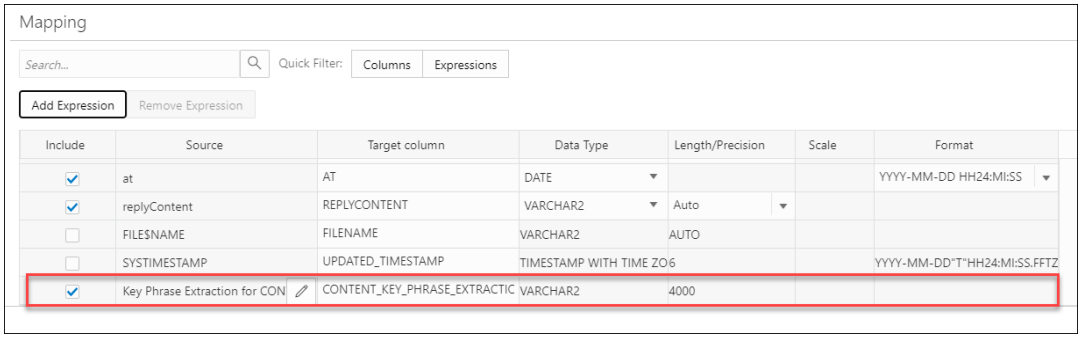


4. On the Add Expression dialog, specify the following fields:
   - **Expression Type:** From the Expression Type drop-down, select Key Phrase Extraction.
   - **Input Column:** Select the column from the drop-down that you wish to analyze. For example, *CONTENT*.

- **Target column:** Enter the name of the newly created expression column. For example, *CONTENT_KEY_PHRASE_EXTRACTION.*

Refer to the Parameters to Analyze Data for more details.

5. Click **OK**. You will see a new row added to the mapping grid .This row determines the output expression column generated by the OCI Language service.



6. Click **Close**.
7. Click **Start** in the Data Load menu cart to load data from local files. You will view a confirmation message asking if you wish to start the load from local files.
8. Click **Run** to confirm.

When the data load job completes, the **Table and View Loads** of the Data Load page display the details of the source table that is loaded into the tool. It displays the number of rows and columns and when the upload was complete.

- Output Data Generated from OCI Key Phrase Extraction
  When you analyze columns using OCI Language Service model, the Data Studio generates a new expression column and saves the result in the updated table.

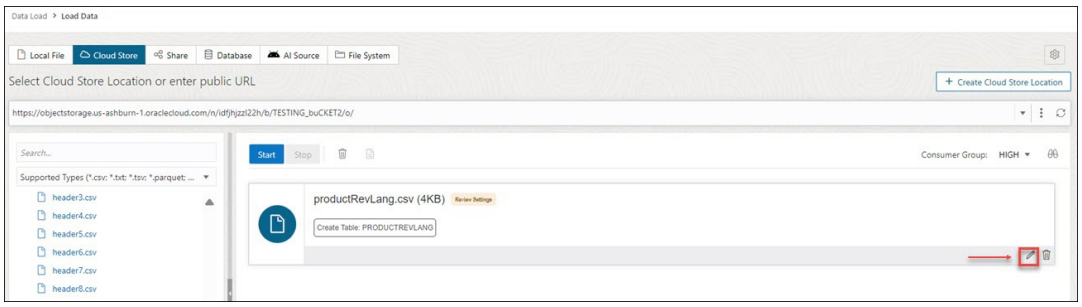
Perform Language Detection

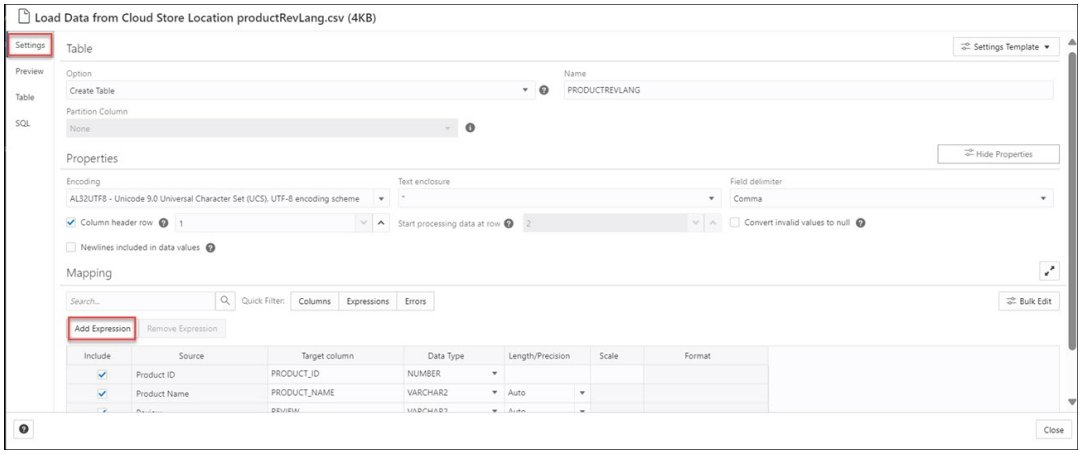
The Data Studio supports the detection of multiple languages.

To determine the language of the input text:

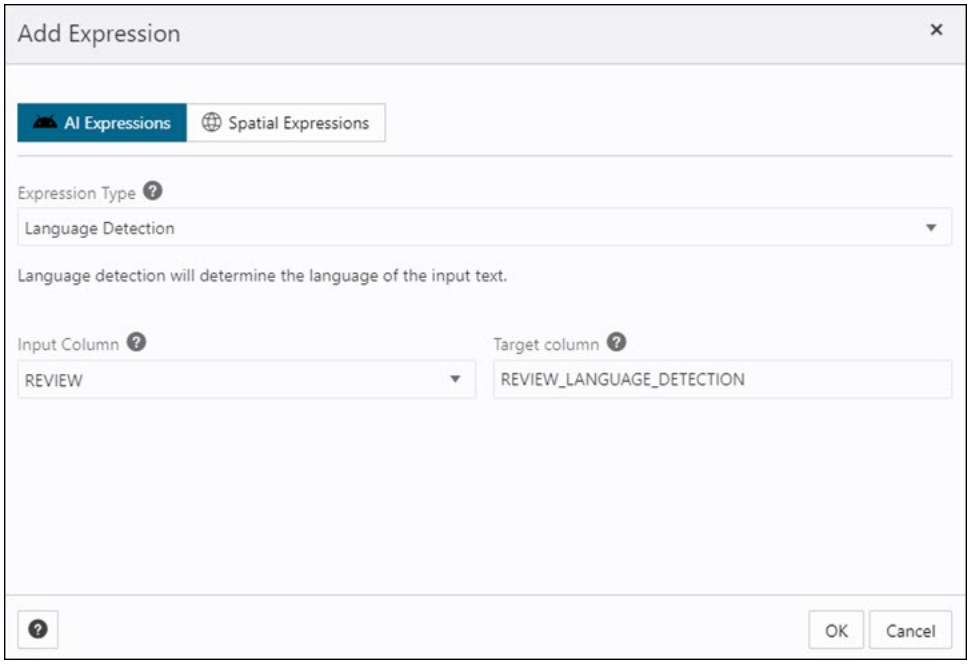
1. After you load data into the Data Load cart from cloud storage, you can view the file in the cart. Click the **Settings** icon.



2. Clicking the Setting icon opens a Load Data from Cloud Store Location wizard.
3. On the Settings tab of the wizard, click **Add Expression** under the Mapping section.

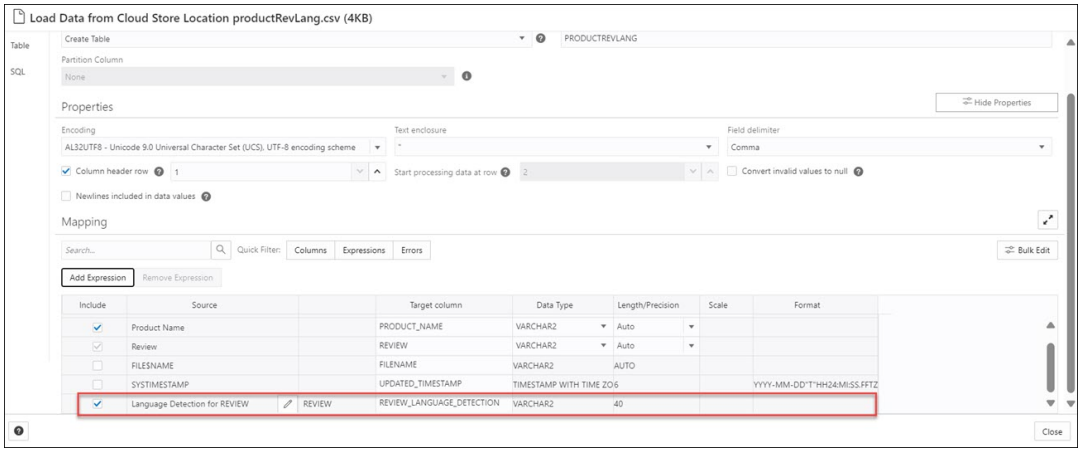


This opens the **Add Expression** dialog box. Select **AI Expressions**.



4. On the Add Expression dialog, specify the following fields:
   - **Expression Type:** From the Expression Type drop-down, select Language Detection.
   - **Input Column:** Select the column from the drop-down that you wish to analyze. In this case, we need to detect the language of the Review column. For example, *REVIEW*.
   - **Target column:** Enter the name of the newly created expression column. For example, *REVIEW_LANGUAGE_DETECTION.*

   Refer to the Parameters to Analyze Data for more details.
5. Click **OK**. You will see a new row added to the mapping grid .This row determines the output expression column generated by the OCI Language service.



6. Click **Close**.
7. Click **Start** in the Data Load menu cart to load data from local files. You will view a confirmation message asking if you wish to start the load from local files.
8. Click **Run** to confirm.

When the data load job completes, the **Table and View Loads** of the Data Load page display the details of the source table that is loaded into the tool. It displays the number of rows and columns and when the upload was complete.

- Output Data Generated from OCI Language Detection
  When you analyze columns using OCI Language Service model, the Data Studio generates a new expression column and saves the result in the updated table.

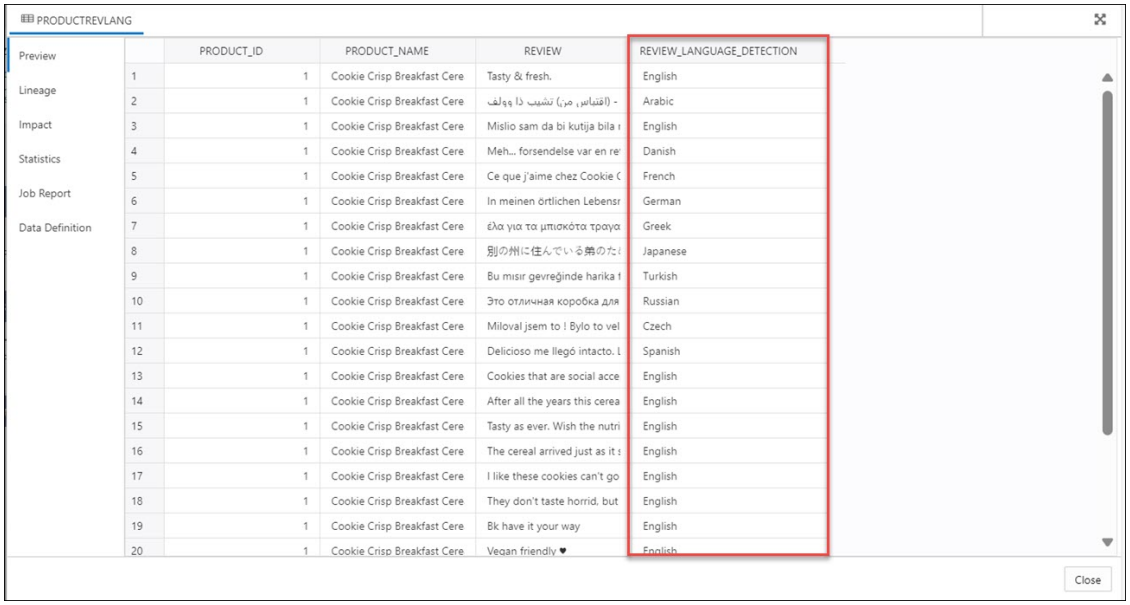
Output Data Generated from OCI Language Detection

When you analyze columns using OCI Language Service model, the Data Studio generates a new expression column and saves the result in the updated table.

To locate the generated expression column, from the Database Actions Launchpad, navigate to **Data Load**. Select the table you load under the **Table and View Loads** section.

Click the three vertical dots beside the load name, and click **Table** then select **View Details**.

For example, here's an output dataset from language detection of the Review column. Here, `REVIEW` is the target column, and `REVIEW_LANGUAGE_DETECTION` column displays the language detected from the input column.

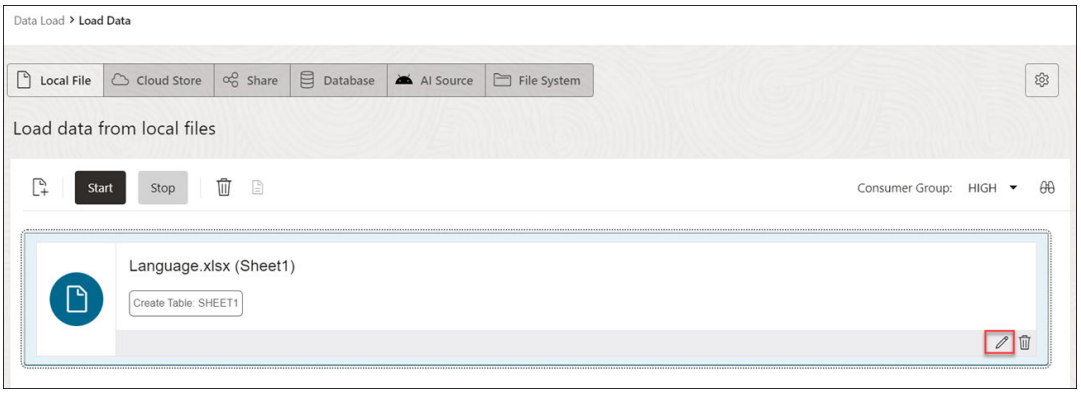


Perform Text Translation

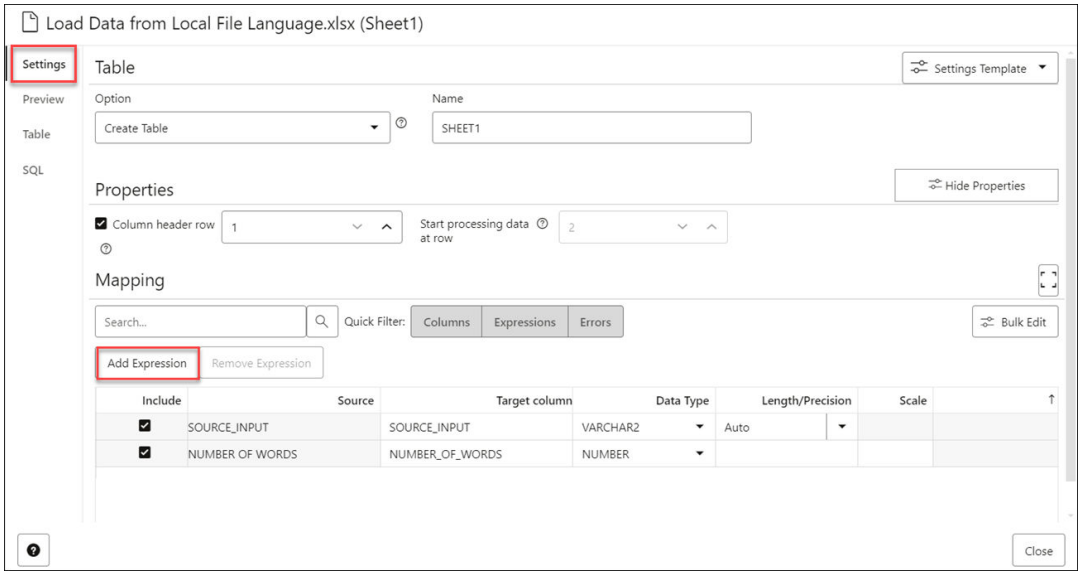
The Data Studio supports the translation of multiple languages supported by OCI Language Service.

To determine the translated input text:

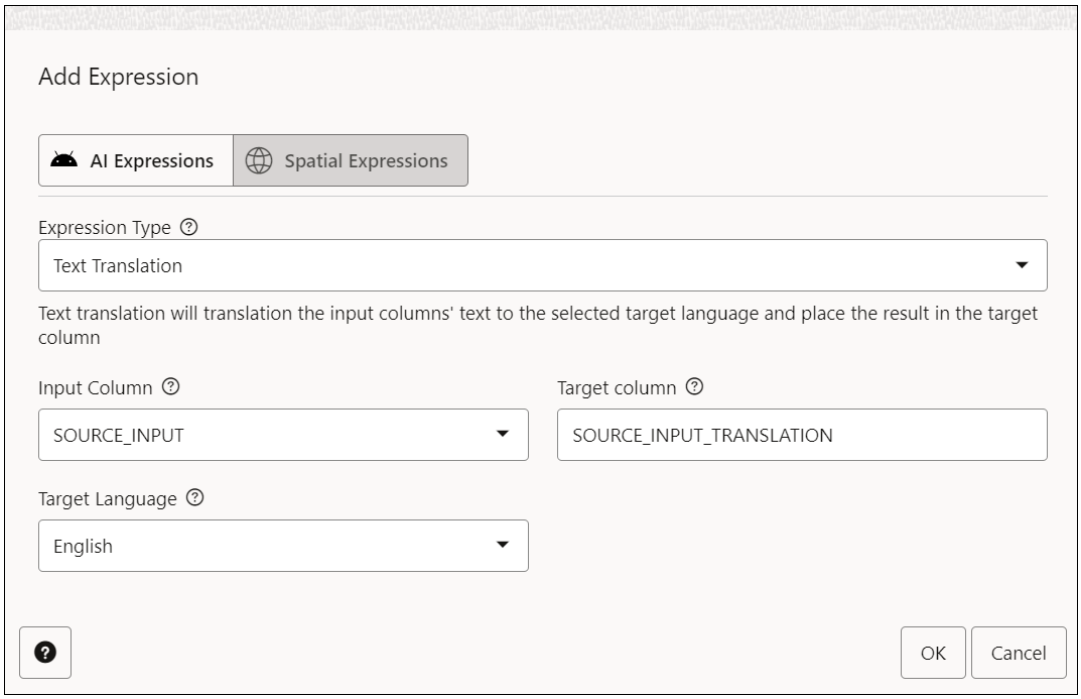
1. After you load data into the Data Load cart from local files, you can view the file in the cart. Click the **settings** icon.



2. Clicking the **Setting** icon opens a Load Data from Local File wizard.
3. On the Settings tab of the wizard, click **Add Expression** under the Mapping section.



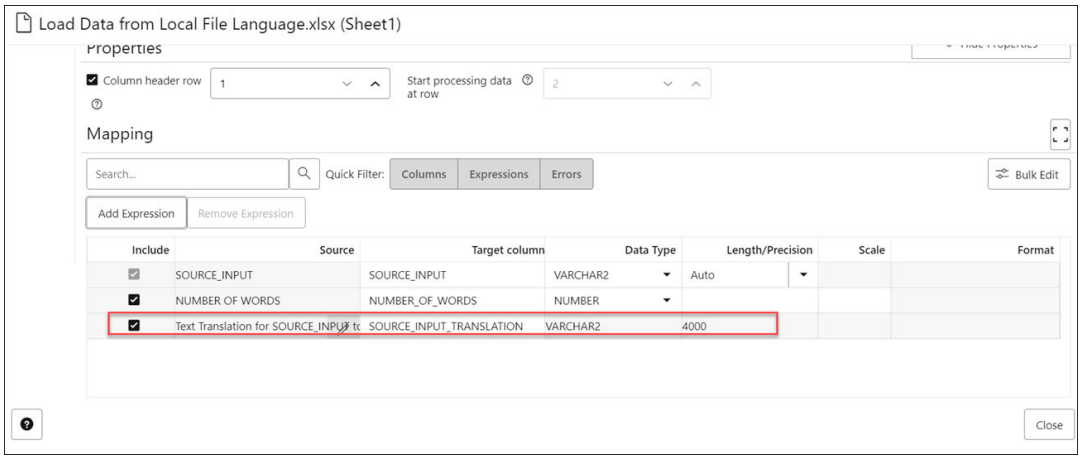
This opens the **Add Expression** dialog box. Select **AI Expressions**.



4. On the **Add Expression** dialog, specify the following fields:
   - **Expression Type:** From the Expression Type drop-down, select **Text Translation**.
   - **Input Column:** Select the column from the drop-down that you wish to analyze. In this case, we need to translate the text of the *SOURCE_INPUT* column.
   - **Target column:** Enter the name of the newly created expression column. For example, *SOURCE_INPUT_TRANSLATION.*
   - **Target Language:** Select the language of the text the tool translates from the drop-down. For example, *English*.

Refer to the Parameters to Analyze Data for more details.

5. Click **OK**. You will see a new row added to the mapping grid .This row determines the output expression column generated by the OCI Language service.



6. Click **Close**.
7. Click **Start** in the Data Load menu cart to load data from local files. You will view a confirmation message asking if you wish to start the load from local files.
8. Click **Run** to confirm.

When the data load job completes, the **Table and View Loads** of the Data Load page display the details of the source table that is loaded into the tool. It displays the number of rows and columns and when the upload was complete.

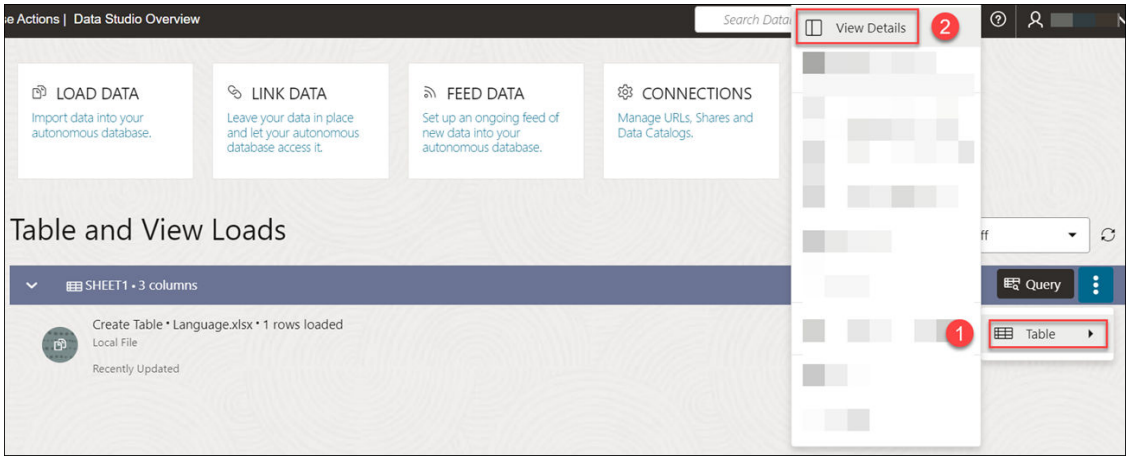
- Output Data Generated from OCI Text Translation
  When you analyze columns using OCI Language Service model, the Data Studio generates a new expression column and saves the result in the updated table.

Output Data Generated from OCI Text Translation

When you analyze columns using OCI Language Service model, the Data Studio generates a new expression column and saves the result in the updated table.

To locate the generated expression column, from the Database Actions Launchpad, navigate to **Data Load**. Select the table you load under the **Table and View Loads** section.

Click the three vertical dots beside the load name, and click **Table** then select **View Details**.



Use OCI Document Understanding to extract Tables from Images

You can utilize Oracle Cloud Infrastructure(OCI) Document Understanding Capabilities such as Table Extraction to detect tables from the data you load.

The supported file formats to use this feature are PDF, JPEG, JPG, PNG and Tag Image File Format (TIFF) formats.

For example, if a PDF document consists of all the employee details including their hiring date and salary, document understanding will identify the table and extract the table structure. It will extract the content of the table while maintaining the row and column relationship of cells.

- Overview of Table Extraction
  The Load Data tool supports Table Extraction in loading data from local files and loading data from cloud storage.
- Perform Table Extraction from Image
  Let us perform table extraction with a sample PDF.

Overview of Table Extraction

The Load Data tool supports Table Extraction in loading data from local files and loading data from cloud storage.

Table Extraction

OCI Document Understanding service allows customers to uncover insights in unstructured documents powered by deep learning models. It enables you to extract text, tables and identify document types among other great capabilities. Table Extraction identifies all the tables in a document and extracts the content in tabular format maintaining the row/column relationship.

> **Note:**
>
> This service is available for source data in English Language only.

For more details, see Table Extraction.

Perform Table Extraction from Image

Let us perform table extraction with a sample PDF.

You can see a table in the PDF below.

	NAME	COLUMN 2	VALUE	RECORD	VALUE_2	VALUE_3	VALUE_4	COLUM
1	EMPNO	ENAME	JOB	MGR	HIREDATE SAL	COMM	(null)	DEPTN

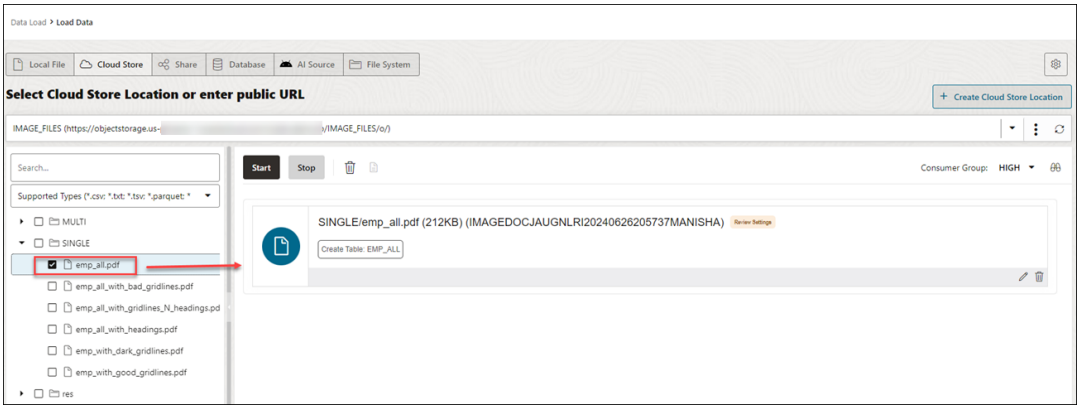
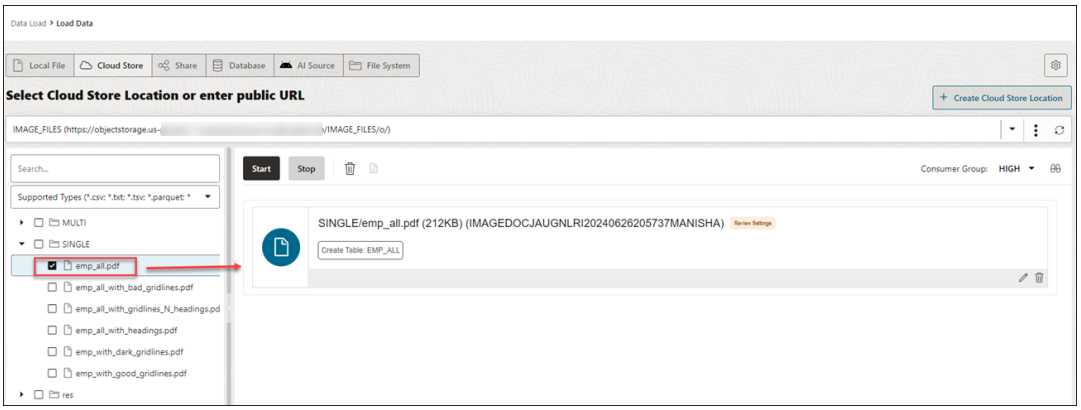
To extract a table from the PDF located in the cloud storage location:

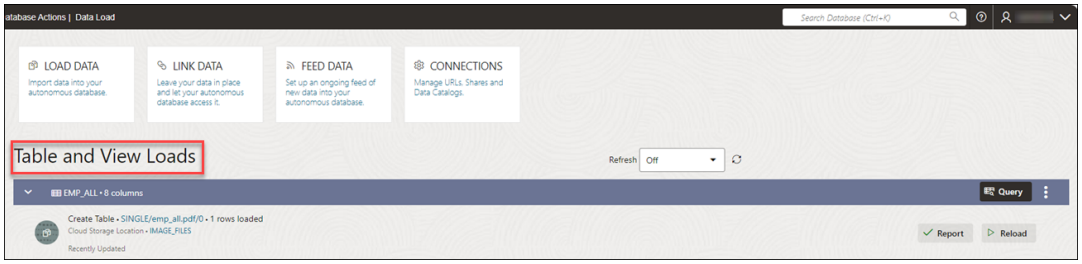
1. Load the PDF file into the Data Load cart from the cloud storage. You can drag and drop the file from the navigator to the cart.



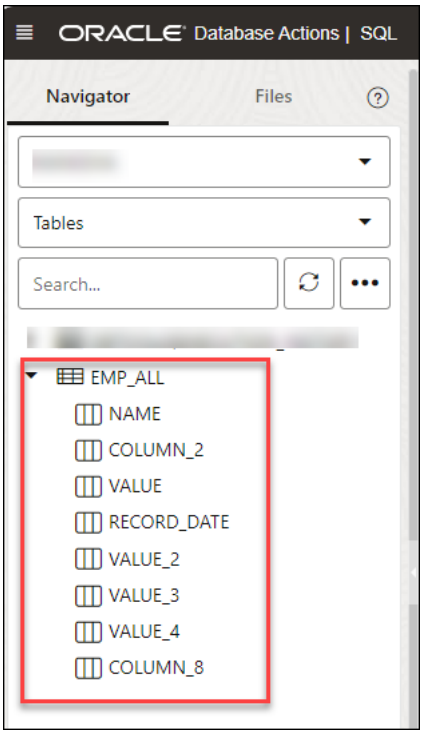
2. Click **Start** to load the data. You will receive a notification that confirms if you wish to start loading the data. Click **Run** to continue.



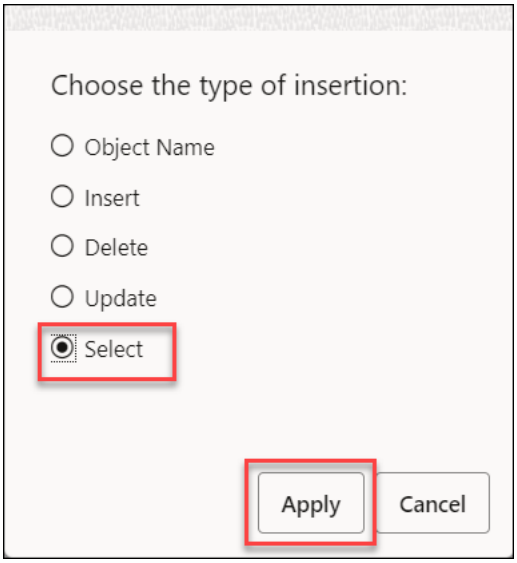
3. After the loading is complete, you can view the loaded file under Table and View Loads in the Data Load dashboard.



4. Extract the table from the PDF you loaded in the autonomous database:
   - Click **Database Actions** in the breadcrumb.
   - Select **Development**, then click **SQL**.
   - Select **Tables**, on the left Navigator, from the object drop-down. From the list of available tables, drag and drop the `EMP_ALL` table to the worksheet.

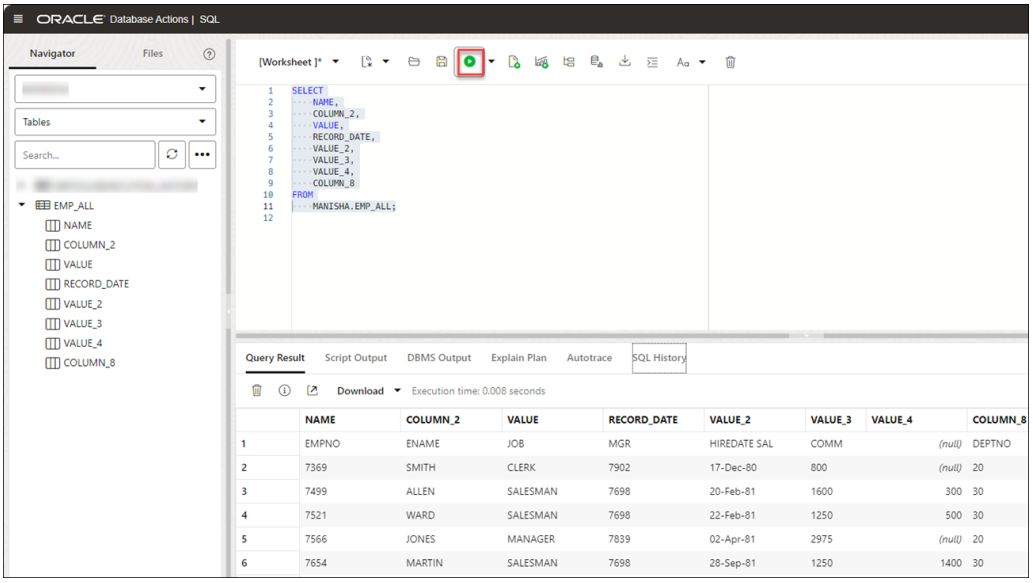


A dialog displays offering the types of available insertions.



Click **Select**, then **Apply**.

- Click **Run** (the arrow icon at the top of the worksheet). The tool displays the extracted table under the Query Results tab.



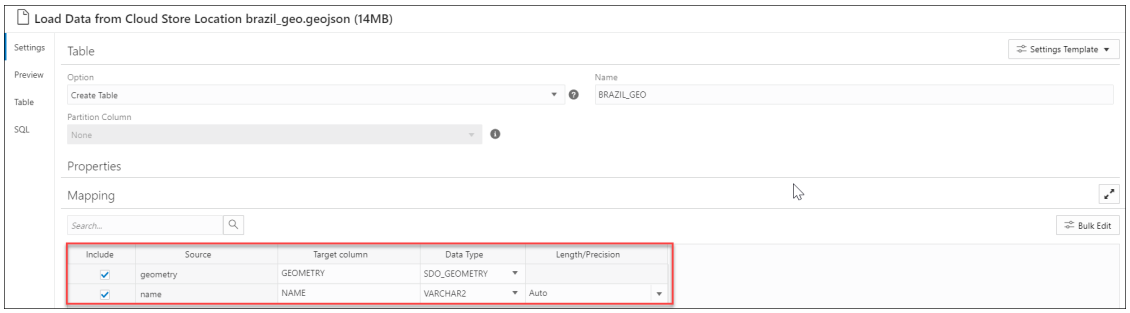
Use GeoJSON in Data Load

A GeoJSON object accommodates information about the specific geometry (e.g. Point, Line, Polygon, etc.) along with optional metadata (e.g. ID, etc.).

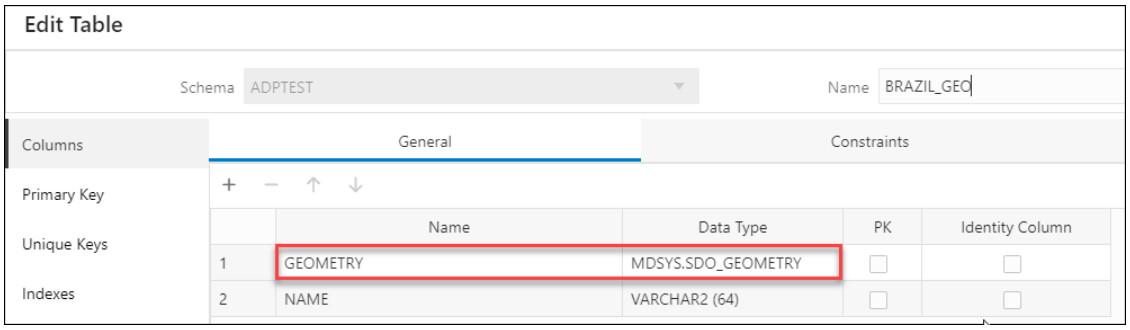
The extension for a GeoJSON file is *.`geojson`. You can load GeoJSON data into the Autonomous Database using the Data Load in Data Studio. If the table contains GeoJSON data, then the data is loaded in a column that projects GeoJSON data from the document set of SQL data type `SDO_GEOMETRY`.

Load a table with GeoJSON Data

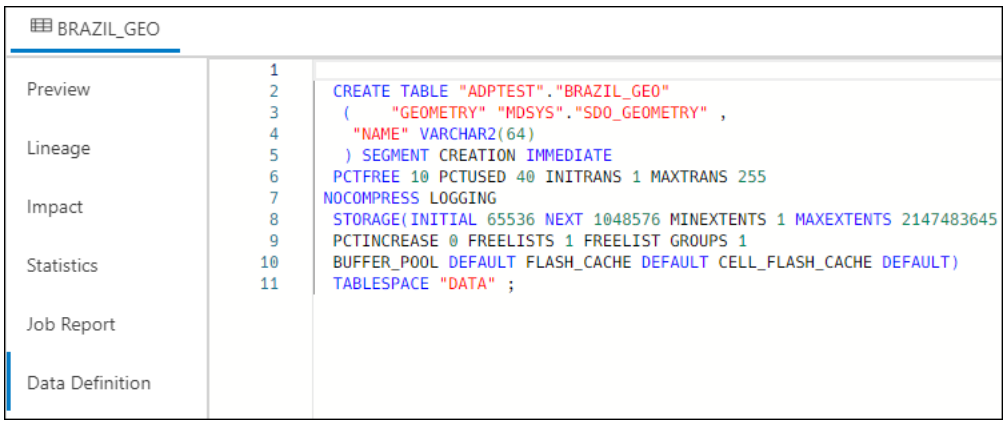
When you load a table in Data Studio with GeoJSON data and review its settings, you will see that it creates table `Brazil_Geo`, which has a column `geometry` of GeoJSON data.



After you load `BRAZIL_GEO` you will view that the tool loads GeoJSON object into a new column `geometry` with the data type `SDO_GEOMETRY`.



You can also view the same in the **Data Definition** tab when you **View Details** of the Table load after it is run.



- Add Spatial Expression for GeoJSON columns
  Oracle Spatial is designed to make spatial data management easier and more natural to users of location-enabled applications and geographic information system (GIS) applications.

- Parameters for Spatial Data Analysis
  When you invoke an **Add Expression** and select **Spatial Expressions** from the **Add Expression** wizard, you must configure the model using parameters.
- Perform Spatial Analysis
  You can load Spatial data using the Data Load tool from local files or cloud storage.
- Output Data Generated from Spatial Analysis
  When you analyze columns using Spatial Expressions, the Data Studio generates a new expression column and saves the result in the updated table.

Add Spatial Expression for GeoJSON columns

Oracle Spatial is designed to make spatial data management easier and more natural to users of location-enabled applications and geographic information system (GIS) applications.

Once spatial data is stored in an Oracle database, it can be easily manipulated, retrieved, and related to all other data stored in the database.

The spatial data model in Oracle Spatial is a hierarchical structure consisting of elements, geometries, and layers. Layers are composed of geometries, which in turn are made up of elements.

Tolerance is used to associate a level of precision with spatial data. **Tolerance** reflects the distance that two points can be apart and still be considered the same (for example, to accommodate rounding errors). The tolerance value must be a positive number greater than zero. See Tolerance in Spatial Data for more information.

Parameters for Spatial Data Analysis

When you invoke an **Add Expression** and select **Spatial Expressions** from the **Add Expression** wizard, you must configure the model using parameters.

Table 3-4 Parameters for Spatial Data Analysis

Parameter	Description
Expression Type	Select any one of the following spatial attributes such as **Length** or **Area**: • **Length**: Selecting this attribute returns and stores the perimeter of a two-dimensional polygon in the mapping table with a target column of type `GEOMETRY_LENGTH`. • **Area**: Selecting this attribute returns and stores the area of a two-dimensional polygon in the mapping table with a target column of type `GEOMETRY_AREA`.
Input Column	Select the column which you wish to analyze for Spatial Data: You will by default view a `GEOMETRY` column in Source mapped to the `SDO_GEOMETRY` column value. This also means that the table is spatially enabled.

Table 3-4 (Cont.) Parameters for Spatial Data Analysis

Parameter	Description
Target Column	This is the newly created expression column defined in the target table which stores the result of the Spatial Expression and depends on the expression type value you select: • `GEOMETRY_LENGTH`: If you select Length as your Expression type, you can view the target column of type `GEOMETRY_LENGTH` which displays the geometry's length value. • `GEOMETRY_AREA`:If you select Area as your Expression type, you can view the target column of type `GEOMETRY_AREA` which displays the geometry's area value.

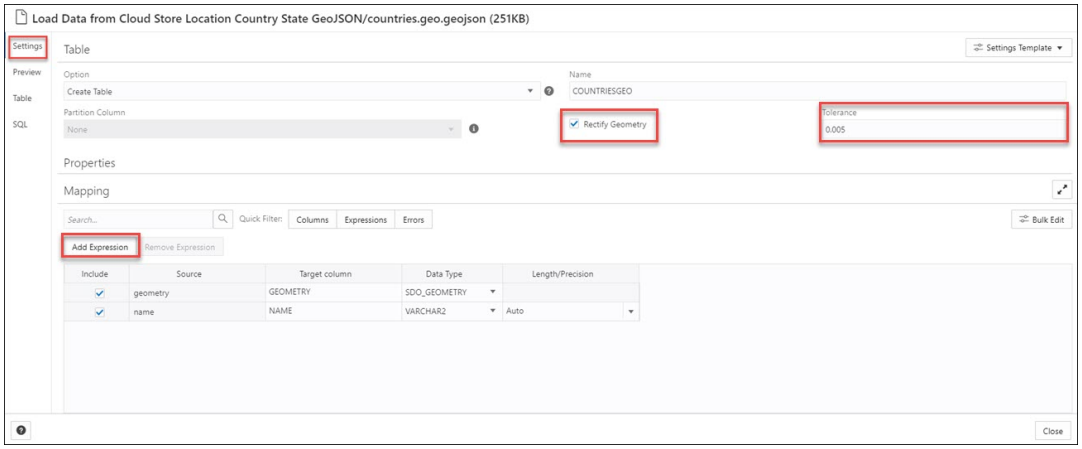
Perform Spatial Analysis

You can load Spatial data using the Data Load tool from local files or cloud storage.

To perform Spatial Analysis on GeoJSON data:

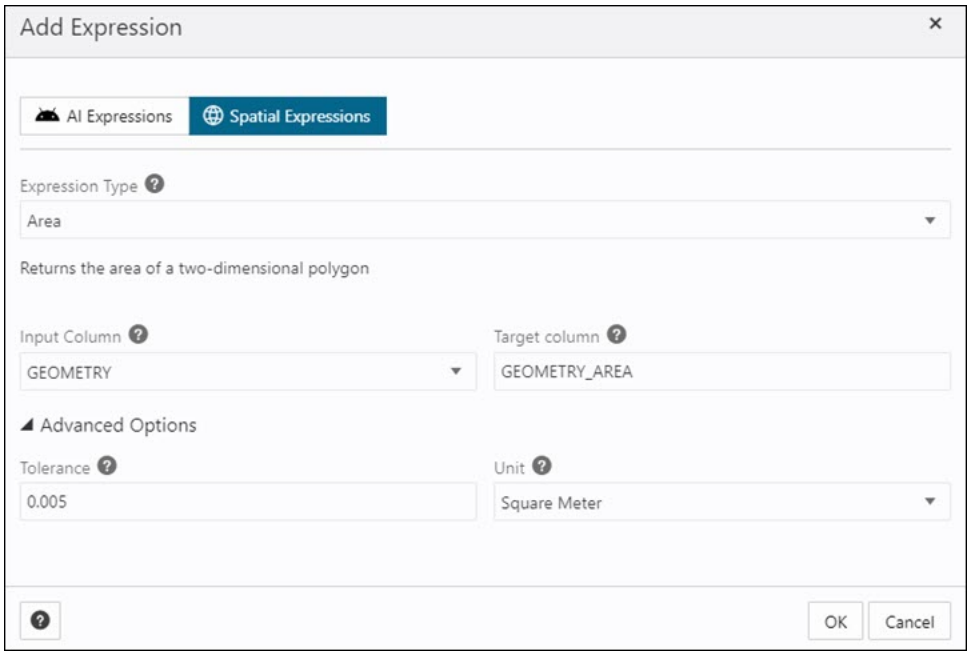
1. After you load data into the Data Load cart from local files or cloud storage, you can view the file in the cart. Click the **Settings** icon.

2. On the Settings tab of the wizard, select **Rectify Geometry** to fix invalid geometries. This icon corrects the most common errors such as duplicate points, polygon orientation errors, polygon construction errors etc. If it detects any uncorrectable error, it fails with an `ORA-13199: the given geometry cannot be rectified` exception.



> **Note:**
>
> You cannot fix geometries having wrong orientation with the. **Rectify Geometry** icon.

3. Specify the **Tolerance** value. In the above example, we specify 0.005 as tolerance, i.e., 5mm.
4. Click **Add Expression** under the Mapping section and select **Spatial Expressions**.



On the **Add Expression** dialog, specify the following fields:

- **Expression Type**: From the Expression Type drop-down, select **Area** to display the area of a two-dimensional polygon. You can also select **Length** to display the perimeter of a two-dimensional polygon.
- **Input Column**: You will view a `GEOMETRY` column by default. This source column stores the area of the geometry. In case you select **Length** as an expression type, this source column stores the length of the geometry.
- **Target column**: Specifies the name of the newly created special expression column. For example, `GEOMETRY_AREA` for **Area** type expression parameter and `GEOMETRY_LENGTH` for **Length** type expression parameter.

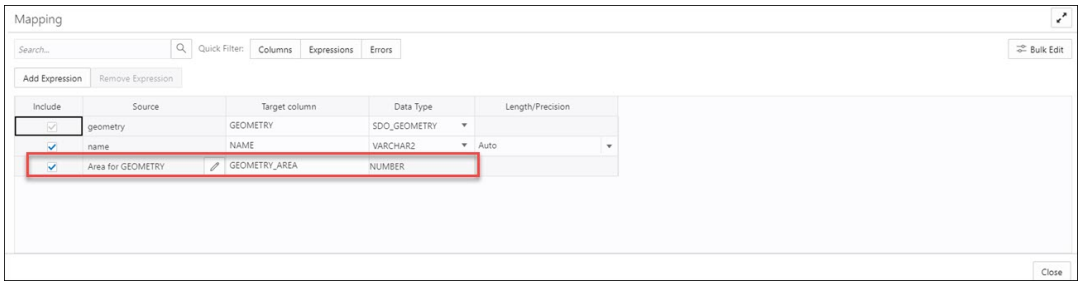
Under the Advanced Options section, specify the following field values:

- **Tolerance**: Enter the tolerance value. For example, `0.005`.
- **Unit**: Select a unit of measure of the tolerance from the drop-down. For example, `Square meter`.

> **Note:**
>
> If the file you load does not contain spatial data, you will view the following error on the **Add Expression** wizard "`No input columns have the SDO_GEOMETRY data type for the currently selected expression type of Area`".

Refer to the Parameters for Spatial Data Analysis for more details.

5. Click **OK**. You will see a new row added to the mapping grid. This row determines the output spatial expression column generated by the OCI Language service. In this example, you can view a new `GEOMETRY_AREA` will be created in the target table after we load the table.



For more information on Oracle Spatial, refer to Oracle Spatial Developer's Guide.

When the data load job completes, the **Table and View Loads** of the Data Load page display the details of the source table that is loaded into the tool. It displays the number of rows and columns and when the upload was complete.

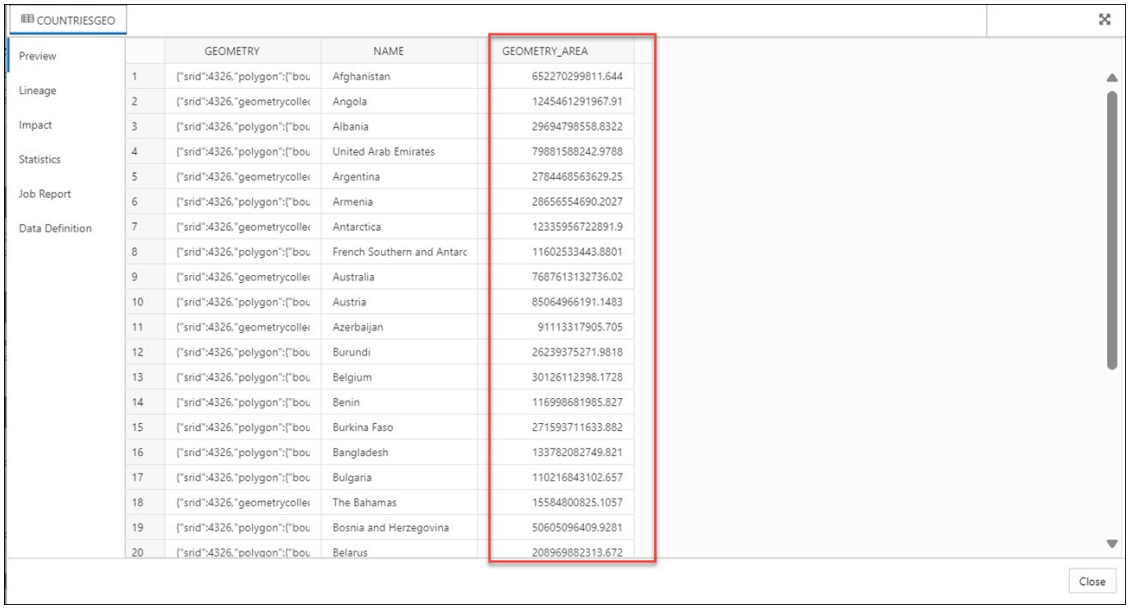
Output Data Generated from Spatial Analysis

When you analyze columns using Spatial Expressions, the Data Studio generates a new expression column and saves the result in the updated table.

To locate the generated expression column, from the Database Actions Launchpad, navigate to **Data Load**. Select the table you load under the **Table and View Loads** section.

Click the three vertical dots beside the load name, and click **Table** then select **View Details**.

This opens the Preview tab of the data load which displays the updated source file. For example, here is an output dataset from spatial analysis of the `COUNTRIESGEO.GeoJSON` file. Here, `GEOMETRY_AREA` is the spatial analysis of the input column. This column displays the area of the two-dimensional polygons.

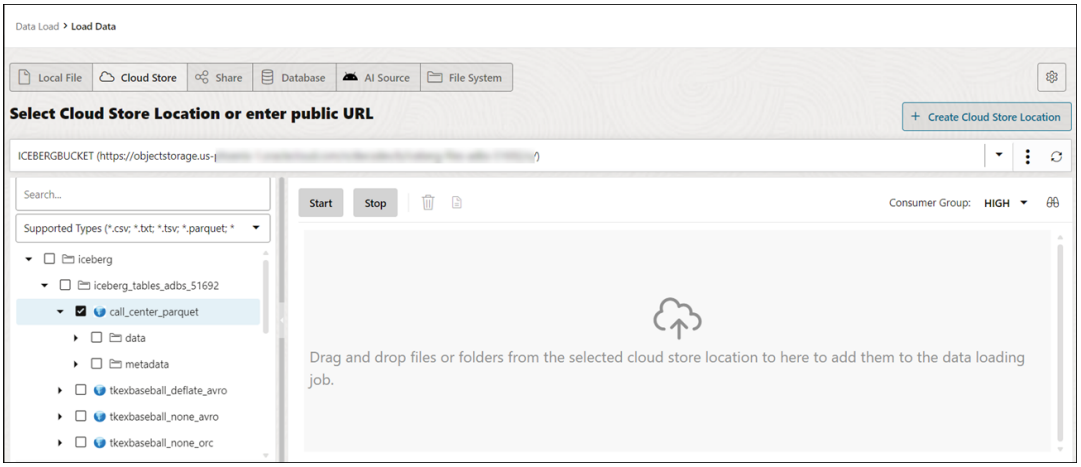


Load Apache Iceberg Tables

Data Studio supports loading and linking Iceberg tables from the object store.

The tool can load multiple versions of the same file.

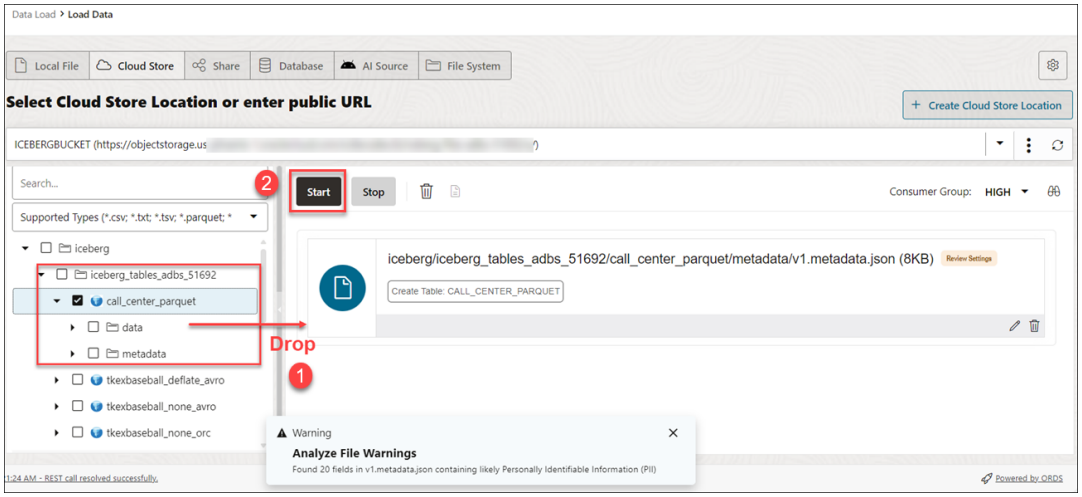
1. Select the Cloud Store Location that has iceberg tables defined. In this example, we will select the `ICEBERGBUCKET` stored in OCI.



You can detect the Iceberg files with the Iceberg symbol

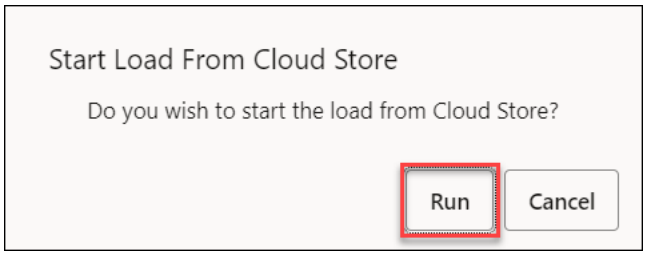
beside its name.

2. Drag the folder to the file navigator on the left and drop it into the cart on the right. The folder also consists of the metadata JSON file that keeps track of the table snapshots, partitioning scheme, and schema information.
When you add the folder to the cart, a warning about the number of files consisting of a Personal Identifiable Information (PII) prompt is displayed.



> **Note:**
>
> : If you load multiple files instead of a folder, the tool asks if you want to load all the objects from the multiple source files into a single target table. Click **OK** to continue or Escape to cancel.

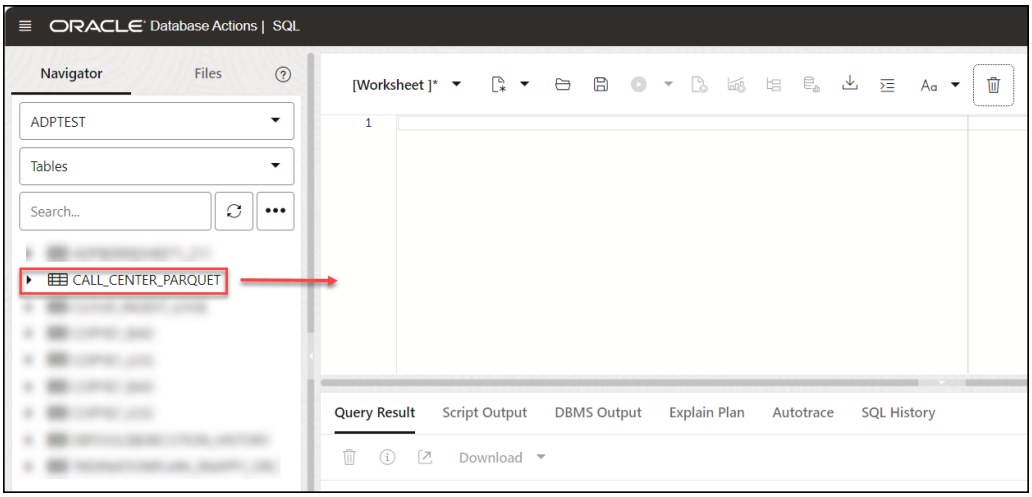
3. Click **Start** in the data link cart menu bar. You will view a notification that says if you wish to start the load from the cloud store. Select **Run** to continue.



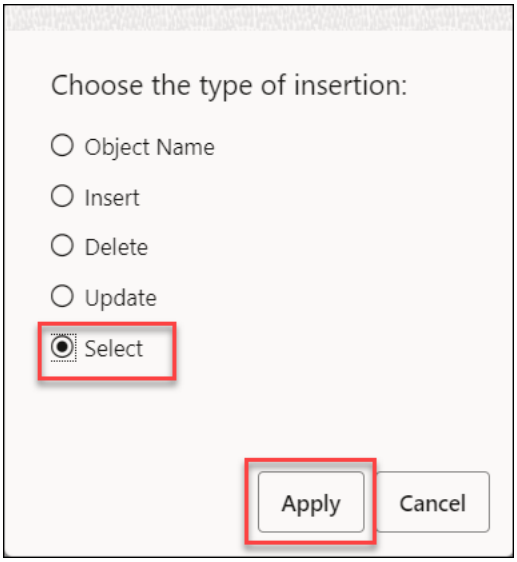
4. You will view the loading progress under Table and View Loads. After loading, you will view the Report and Reload icons on the table load.

5. Query Iceberg tables you loaded in the Autonomous Database:
   - Click **Database Actions** in the breadcrumb.

- Select **Development**, then click **SQL**.
- Select **Tables**, on the left Navigator, from the object drop-down. From the list of available views, drag and drop the **CALL_CENTER_PARQUET** table to the worksheet.

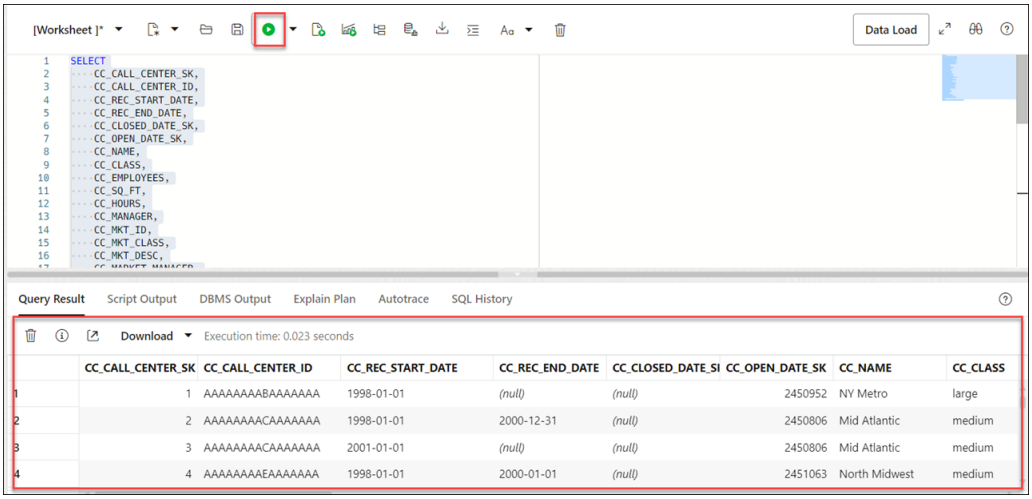


- A dialog displays offering the types of available insertions.



Click **Select**, then **Apply**.

- Click **Run** (the arrow icon at the top of the worksheet). The tool displays the iceberg data under Query Results.



Loading Data from File System

You can load files from file system directories to your Autonomous Database.

You can set filters on the data for a table to load only the specified data. For example, to limit the files to only those that are CSV files, enter *.CSV in the file extension filter.

Configure and run a data load job from the Load Cloud Object page. To open that page:

1. On the Data Studio tab and select **Data Load**. You will view the Data Load dashboard.
2. Click **LOAD DATA** and select the **File System** option.

On the top of the page you need to select the directory from where you need to load the files. On the left side of the page is a navigator pane, where you choose the files in the directory containing the data. On the right of the page is the data load cart, where you stage the files and folders for the data load job. You can set options for the data load job before running it. The Autonomous Database comes with predefined CPU/IO shares assigned to different consumer groups. You can set the consumer group to either low, medium or high while executing a data load job depending on your workload. To load files from a directory into your database, do the following:

1. Prepare the Data Load Job: Refer to the Prepare the Data Load Job section for more details.
2. Add Files or Folders for the Data Load Job: Refer to the Add Files or Folders for the Data Load Job section for more details.
3. Enter Details for the Data Load Job: Refer to the Enter Details for the Data Load Job for more details.
4. Run the Data Load Job: Refer to the Run the Data Load Job section for more details.
5. View Details About the Data Load Job After It Is Run: Refer to the View Details About the Data Load Job After It Is Run section for more details.
6. View the Table Resulting from the Data Load Job: Refer to the View the Table Resulting from the Data Load Job section for more details.

- Create Directories in Database Actions
  In the Autonomous Database, there is a preconfigured `data_pump_dir` where you can store files. You can also create directories, drop directories, and attach network file systems.

Create Directories in Database Actions

In the Autonomous Database, there is a preconfigured `data_pump_dir` where you can store files. You can also create directories, drop directories, and attach network file systems.

For example, you can use the `CREATE DIRECTORY` command to create additional directories. Use the database `DROP DIRECTORY` command to drop directories and use `DBMS_CLOUD.LIST_FILES` to list the contents of a directory.

Create a Directory

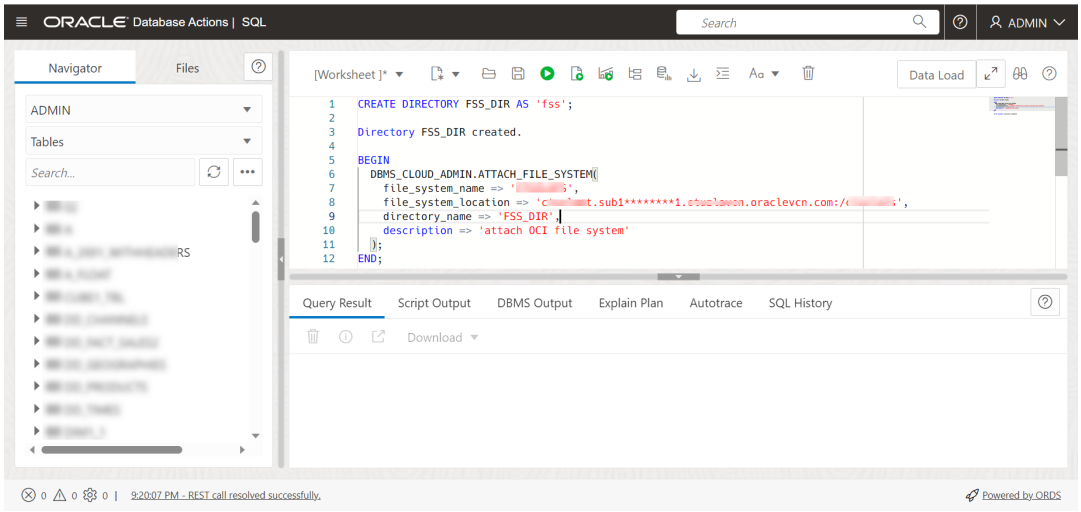
To add a directory, you must have the `CREATE ANY DIRECTORY` system privilege. The ADMIN user is granted the `CREATE ANY DIRECTORY` system privilege. The ADMIN user can grant `CREATE ANY DIRECTORY` system privileges to other users.

See CREATE DIRECTORY for more information.

> **Note:**
>
> - `CREATE DIRECTORY` creates the database directory object in the database and also creates the file system directory. For example the directory path could be:
>
>   ```
>   /u03/dbfs/7C149E35BB1000A45FD/data/stage
>   ```
>
> - You can create a directory in the root file system to see all the files with the following commands:
>
>   ```
>   CREATE OR REPLACE DIRECTORY ROOT_DIR AS '';
>   ```
>
>   After you create the `ROOT_DIR` directory, use the following command to list all files:
>
>   ```
>   SELECT * FROM DBMS_CLOUD.list_files('ROOT_DIR');
>   ```
>
> - To run `DBMS_CLOUD.LIST_FILES` with a user other than ADMIN you need to grant read privileges on the directory to that user.

Let us demonstrate how to create a directory and access it from Data Studio:

- **Create a directory in Database Actions:**
  Login to your Database Actions instance and select the SQL card under **Development**. You can view the SQL worksheet. Now create a directory and attach a file system name of your choice to the directory you create. In the below given example, `FSS_DIR` is the name of the directory.



Run the above command. The above command gives the following output:

```
PL/SQL procedure successfully completed.
```

- **Attach the file system**
  Attach your file system with the name of your choice to the `FSS_DIR` directory via the DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM procedure.

```
BEGIN
  DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM(
    file_system_name => '********',
    file_system_location => '*******.sub1********1.********.oraclevcn.com:/
********',
    directory_name => 'FSS_DIR',
    description => 'attach OCI file system'
  );
END;
/
```

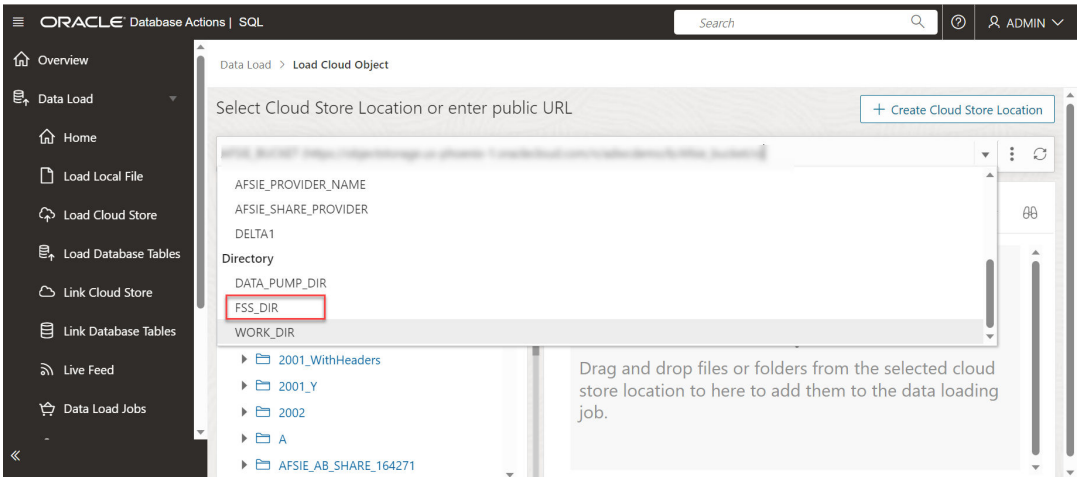
Run the above command to view the following output:

```
PL/SQL procedure successfully completed.
```

- To view the attached file system, run the following command:
  `SELECT file_system_name, file_system_location, directory_path FROM dba_cloud_file_systems;`

  You will view the file system name, file system location and directory path.
- You can view the new directory along with the files attached to it by navigating to Load Cloud Object under Data Load menu of the Data Studio tool. Click the **Select Cloud Store**

location drop-down.

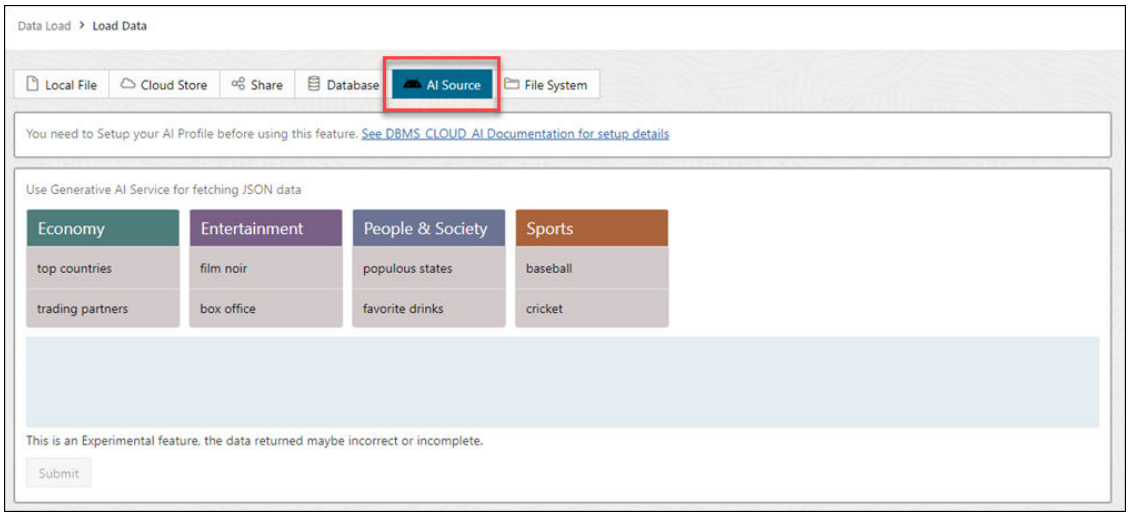


You can view the newly created directory `FSS_DIR`. You can load data from the file system directories to the autonomous database using the Data Load tool. See Loading Data from File System.

Loading Data from AI Source

You can use Data Studio tools to load data from AI source.

On the Data Load dashboard, click **Load Data** card, and select **AI Source**.



You need to perform a pre-requisite of setting up your AI profile before using this feature. See Configure DBMS_CLOUD_AI Package for details on the setup of this feature.

To set an AI profile, you must have:

- An OpenAI account, or a Cohere account, or Azure OpenAI service
- An access to `DBMS_CLOUD_AI` package.

Follow the steps in Use DBMS_CLOUD_AI to Configure AI Profiles section to create and configure your AI profile and utilize this feature.

Loading Data from Share

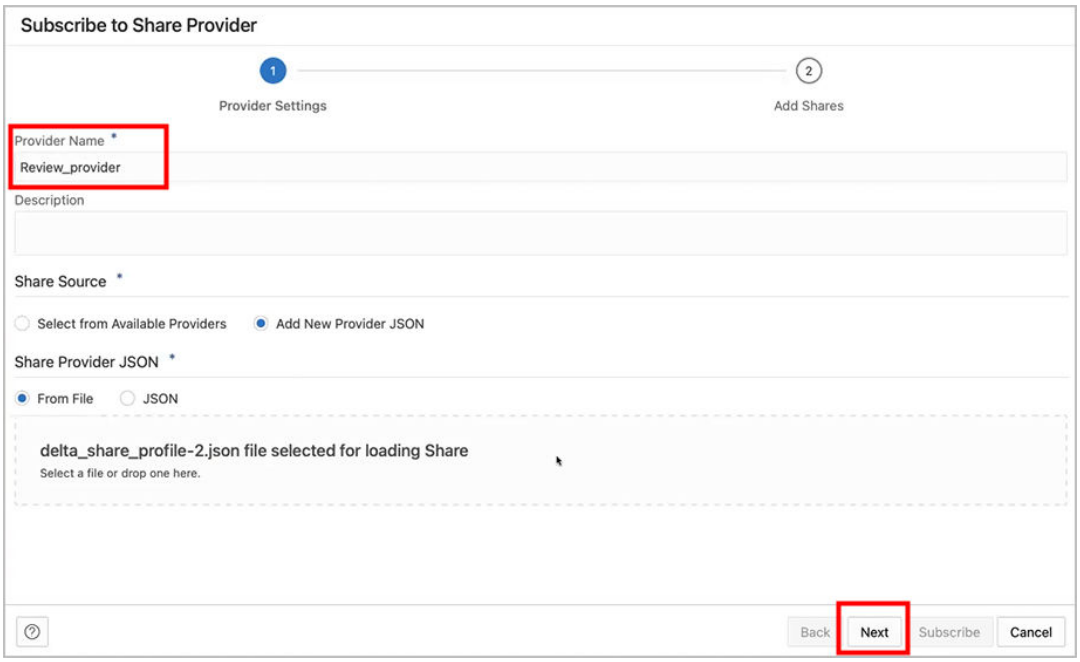
You can select tables from a Share. You need to subscribe and access provided data share.

To load tables from a share, click **Load Data** on the Data Load Dashboard. Click **Share** on the Load Data page. Click **+ Subscribe to Share Provider** to subscribe to a Share Provider.

Subscribe to the Data Share Provider

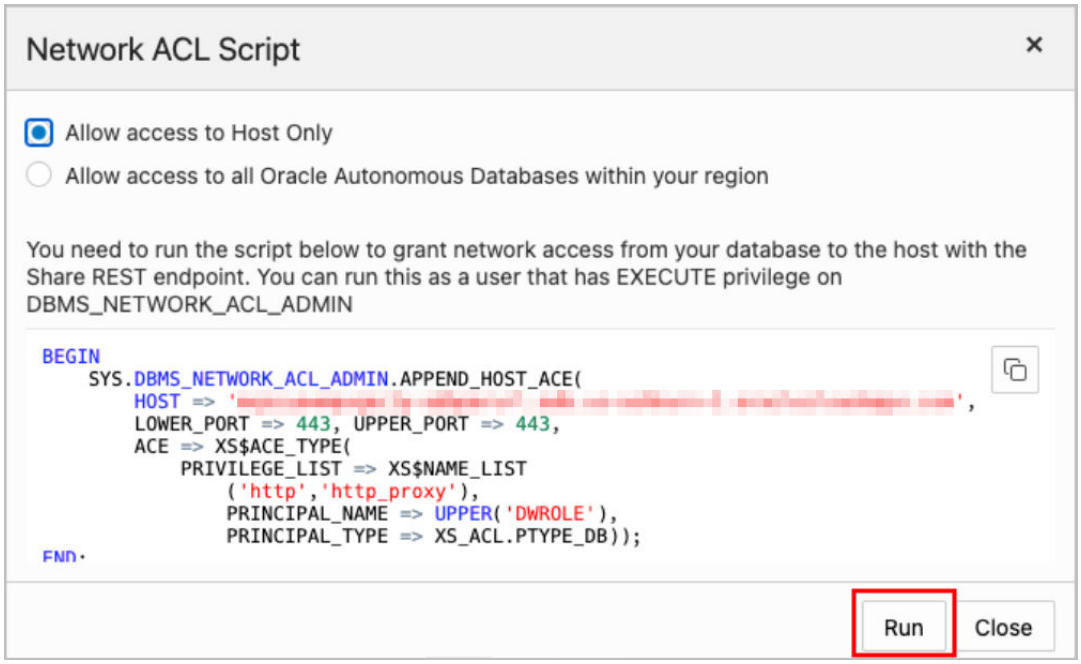
To subscribe, you need to use the information contained in the uploaded JSON profile you received from the share provider.

1. On the Subscribe to Data Share Provider, enter the **Provider Name**.

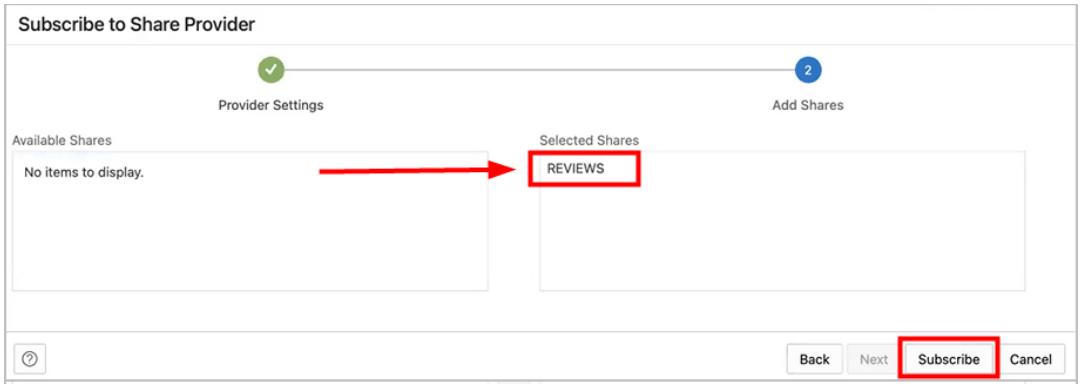


2. Select Add New Provider JSON and click on the Delta Share Profile JSON to drag and drop the JSON profile.
3. Click **Next** to progress to the Add Shares tab.
4. Select the level of network access you want to allow from your database to the host with the Share REST endpoint, and click **Run**. In this example, **Allow access to Host Only** is

selected.



5. To register the shares available to you, move shares from **Available Shares** to **Selected Shares** and click **Subscribe**.
   The screenshot below shows the **REVIEWS** share moved from **Available Share**s to **Selected Shares** before clicking **Subscribe**.

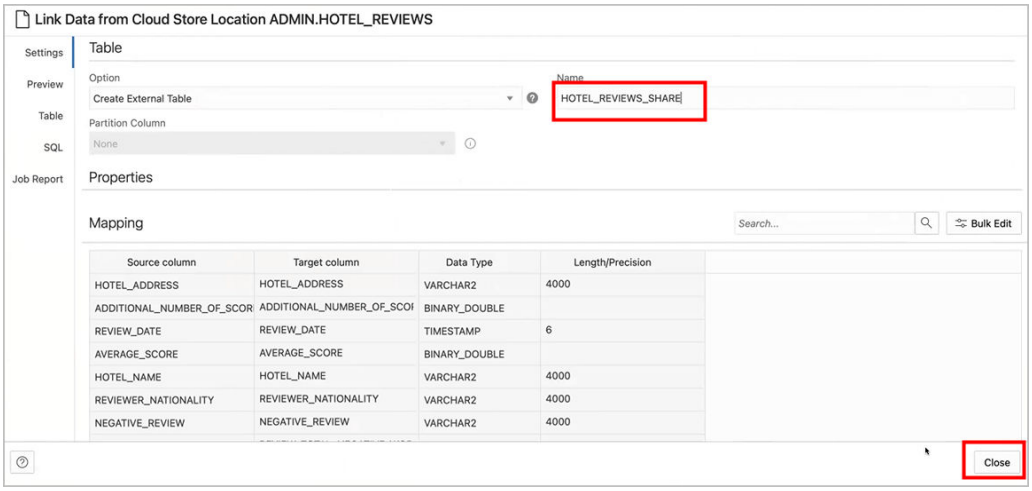


6. Create external tables derived from tables selected from the data share.

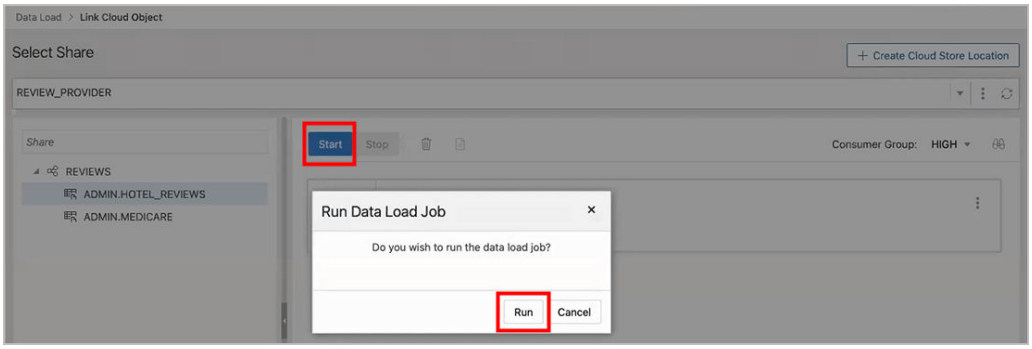
   a. Drag and drop tables from the selected share. You can optionally click **settings** to view the table details.
      In this example, the only table selected is **HOTEL_REVIEWS**.

   b. You can optionally change the name of your table and click **Close**.

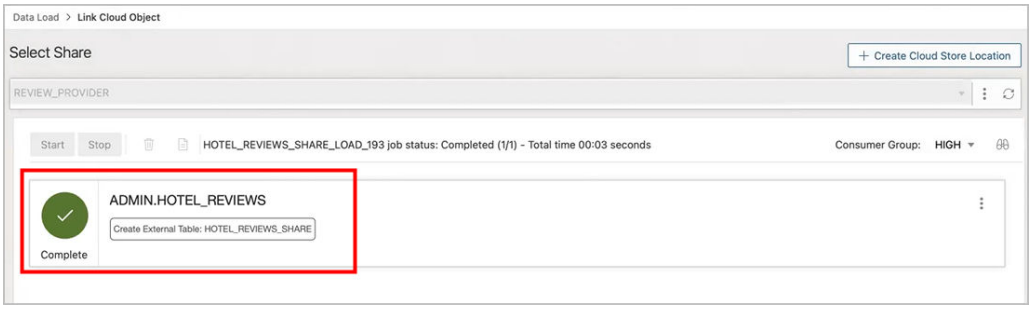
In this example, the name is changed from **HOTEL_REVIEWS** to **HOTEL_REVIEWS_SHARE**.



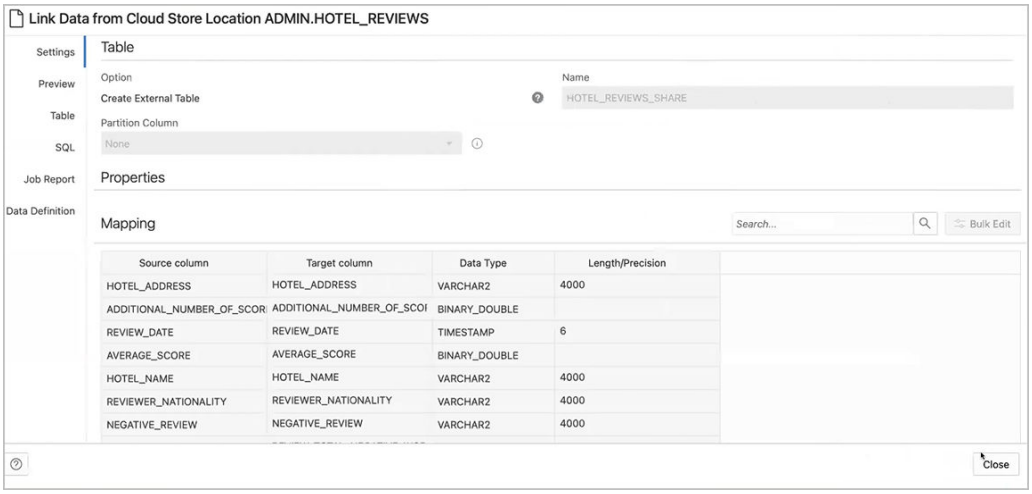
c. Create the external table by clicking **Start**, on the Select Share page, and then clicking **Run** on the Run Data Load Job dialog.



d. When the external tables are created the Complete message is displayed.



e. Click on the external table name to view the table details.

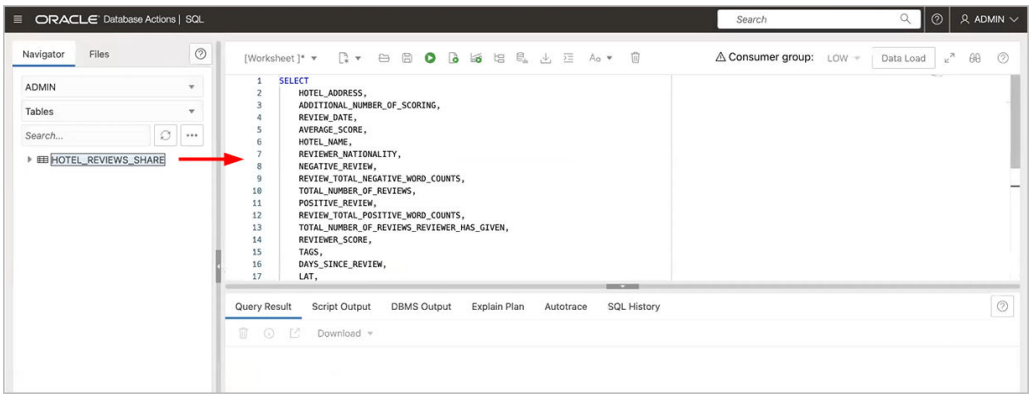


7. View the created tables from Database Actions.

   a. Click on **Database Actions**, in the breadcrumb, to go back to the Database Actions launchpad.

   b. Click on the **SQL** tile.

   c. Select the external table, drag and drop it into the worksheet.
   The SQL Select statement for the table appears. This SQL statement can be run to consume the shared data.



8. Drag and drop tables from selected share

Create Live Feed from Data Load

The Data load tool loads the data from folders in cloud object stores and enables it to schedule repeated data loads in real time. This is the creation of Live Feed from a data load job.

Once the data load is complete, you can create a Live Feed from a cart item that loaded an object store folder using the Create Table or Drop Table and Create New Table options.

To create a live feed from Data Load:

1. Click **Selector** to display the navigation menu. Under Data Studio, select **Data Load**.
2. Select the **Load Data** tile to load data from various sources such as local files, databases, cloud store, directories, and Shares.
3. Click **Cloud Stores**to load objects from URLs or Cloud store links.

4. Select the cloud store location from the drop-down. If are not able to view the cloud store location, select **Create Cloud Store Location** to create a new cloud store location. Follow the steps described in the Create Oracle Cloud Infrastructure Native Credentials if you do not have a cloud location available.
5. After you select the cloud store location, you can view the list of folders and files present in the cloud storage. Add files from the cloud store to the data load cart, where you can edit the details of the load job.

> **Note:**
>
> The Data load tool does not support the creation of a live feed from a loaded cart item that consists of a single file in CSV, XLS, XLSX, TSV, TXT, XML, JSON, and AVRO format or of a folder that contains a file in XLSX format.

6. To add the folders, drag a folder from the file navigator on the left and drop them into the cart on the right. When you add the folder to the cart, a prompt is displayed that asks if you want to load all the objects from the multiple source files into a single target table. Click **Yes** to continue or **No** to cancel. You can add multiple folders to the cart, the data represented by each card will be loaded into a separate table, but all the items in the cart will be processed as part of the same data load job.
7. Select **Settings** (pencil icon) from the data load cart to enter the details about the data load job.
8. In the **Settings** tab of the Load Data from the Cloud Store Location, you can select **Create Table** or **Drop Table and Create New Table** from the **Option** drop-down.

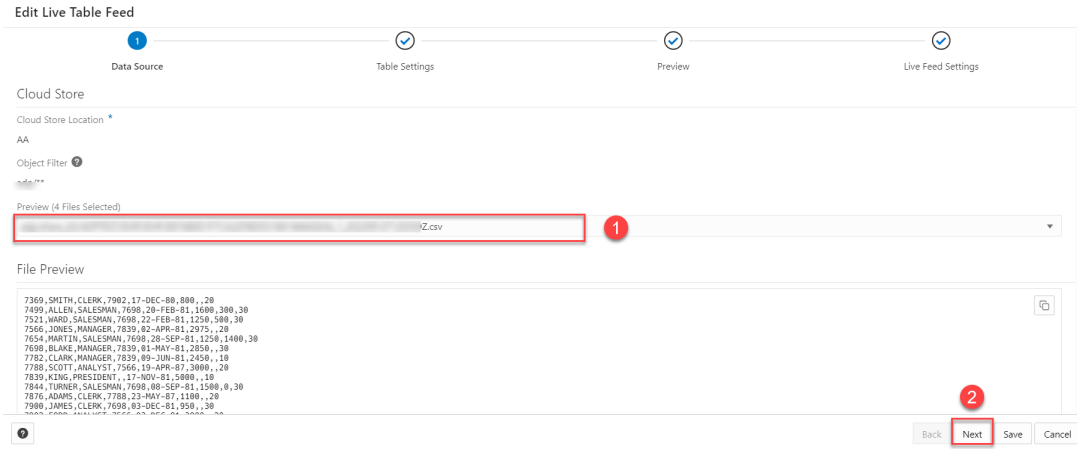
> **Note:**
>
> The Live feed tool works with the Data load job only if you create a table and insert the data into a new table or drop the existing table and insert the data into a new table.

9. Enter the other details for the data load job. For more information on entering the details, refer to the Enter Details for the Data Load Job topic.
10. Once you have added data sources to the data load cart and entered details about the data load job, select **Start** to run the job.
11. After the data load job is run, the data load cart displays a green check mark

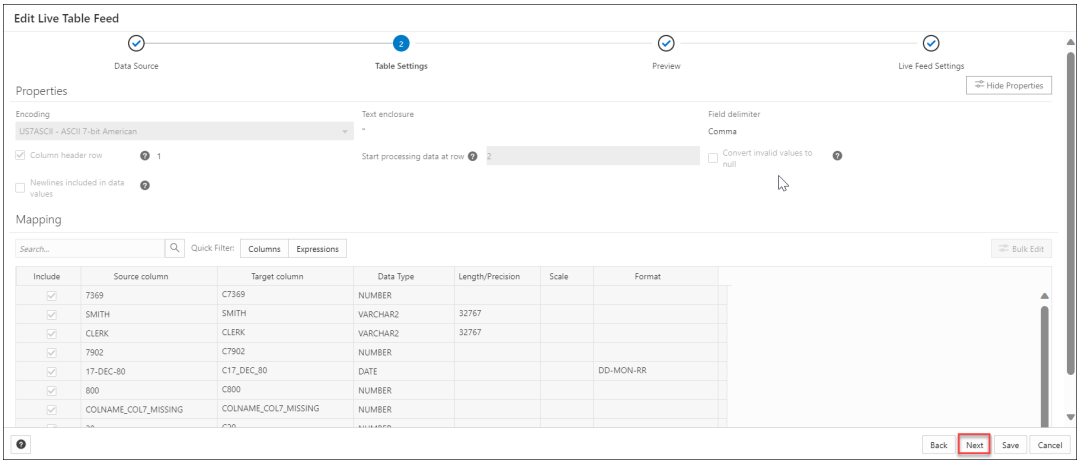
which indicates that the data load job is complete.

12. Click **Create Live Table Feed** on the data load cart to create a Live table feed from the data load job. You will view a successful message that says the creation of Live Table feed is successful and if you wish to edit the live table feed. Click **Yes** to continue and **No** to cancel. Selecting **Yes** opens an Edit Live Table Feed wizard.

13. On the Edit Live Table Feed wizard, you can view the **Cloud Store Location** of the source folder and the **Object Filter** applied to the data.
Select any file whose data you want to preview from the Preview drop-down in the Data Source tab: The field shows the total number of files present in the cloud store folder you loaded. A preview of the data is displayed.



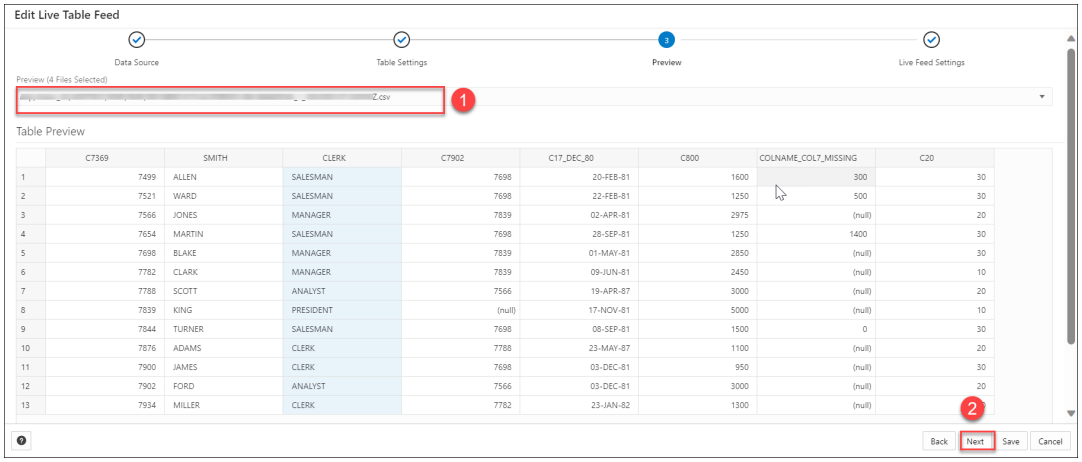
14. Click **Next** to progress to the Table Settings tab.



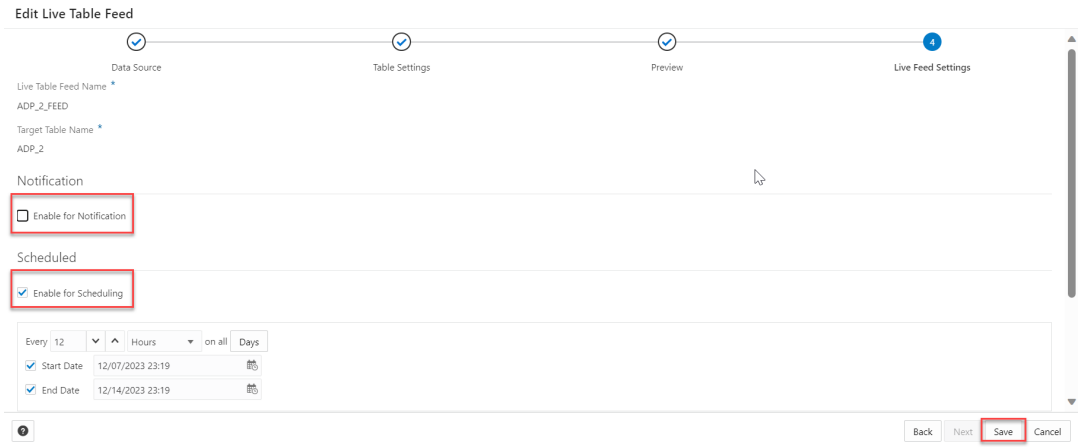
You can view the Properties and Mapping details of the data load job on the Table Settings tab.

> **Note:**
>
> You cannot select or edit any of the details of this tab.

15. Click **Next** to progress to the Preview tab of the wizard.
Select any file from the Preview drop-down to view the file. The Table Preview displays the preview of the file you select from the drop-down.



16. Click **Next** to view the Live Feed Settings tab of the wizard. On the Live Feed Settings tab, specify the following values in the field:



- **Enable for Notification**: Select this option so that new or changed data in the data source will be loaded based on an Oracle Cloud Infrastructure notification. When you select this option, you can avoid delays that might occur when polling is initiated on a schedule (that is, if you selected the live table feed Scheduled option.

  When you select the Enable for Notification option, you must also configure your object store bucket to emit notifications

- **Enable For Scheduling**: Select this option to set up a schedule for data feed. In the time interval fields, enter a number, and select a time type and the days on which to poll the bucket for new or changed files. For example, to poll every two hours on Monday, Wednesday, and Friday, enter **2**, select **Hours**, and then select **Monday**, **Wednesday**, and **Friday** in the appropriate fields. You can select **All Days**, **Monday to Friday**, **Sunday to Thursday**, or **Custom** from the Week Days drop-down. The Custom field enables you to select **Monday**,**Tuesday**, **Wednesday**, **Thursday** and **Friday** .

Select a start and end date. If you don't select a start date, the current time and date will be used as the start date. The end date is optional. However, without an end date, the feed will continue to poll.

The rest of the fields displayed in the wizard such as the **Live Table Feed Name**, **Target Table Name** , and **Consumer Group** are greyed out and disabled for selecting or editing.

Click **Save** to save and create a Live Table Feed from a data load cart.

Loading Data From Local Files

To load data from local files into your Oracle Autonomous Database, on the Data Load page, select **LOAD DATA** and **LOCAL FILE**.

Drag one or more files from your local file system navigator and drop them in the Data Load Cart. You can also click **Select Files** or the Select Files icon, select one or more files from the file system navigator, and then click **Open**.

You can add files in these file formats: AVRO, CSV, JSON, GeoJSON, TSV, delimited TXT, XLS, XLSX, XML, PNG, JPEG and PDF. For information on supported file formats, see Format Specifications for JSON, AVRO, and XML Files.

An item for each file appears in the cart. For an XLS or XLSX spreadsheet, the worksheets of the spreadsheet appear as individual items. The item shows the name of the source file or worksheet and its size, and the name of the table that is the target for the data load. The Data Load tool supports loading tables from only the first worksheet of a multi-worksheet XLSX file when the file is in an object store.

You can add more files to the cart by clicking the Select Files icon. You can add any number of files to the cart and load data from all of them in a single data load job.

To remove a source file from the Data Load Cart, click the Remove (trash can) icon for the source item. To remove all source files from the cart, click the Remove All (trash can) icon in the Data Load Cart menu bar.

To return to the Data Load page, click **Data Load** above the Data Load Cart menu bar.

Specify Processing Options

To specify settings for the data load job or preview the data in the source or the target, select the Settings (pencil) icon for the item in the Data Load Cart.

In the settings pane, on the **Settings** tab, you can view the name and size of the file in the title of the Load Data dialog box.

The **Name** field specifies the name of the target table. The value in the field varies depending on the selection in the **Options** field. If the option is **Create Table**, then the default target value is the name of source file or worksheet.

To specify a different name for the target table, enter it in the **Name** field. For the other target table choices in the **Options** field, the default value is <None>. Expand the drop-down list and select an existing table as the target.

In the **Options** field select **Create Table**, **Insert into Table**, **Replace Data**, **Drop Table and Create New Table**, or **Merge into Table**. Point to the question mark icon to see a brief description of the selected option.

Select a different schema from the **Schema** drop-down to create your target table in another schema.

> **Note:**
>
> The **Schema** drop-down is available only if you have `PDB_DBA` role grant to you. To grant yourself a `PDB_DBA` role, you must log into your Database Actions instance and enter the following command in the **SQL** worksheet area displayed in the **SQL** tab under **Development** tools present in the Launchpad.
>
> ```
> Grant PDB_DBA to Username;
> ```
>
> This drop-down is available for **Create Table** and **Drop Table and Create New Table** options.

The **Source column name** option specifies whether to get the source and target column names from the file or to specify the column names manually. Getting the column names from the header of the source file is the default. If you select the **Column header** option, then the first row in the file is processed as column names. If you deselect the option, then the first row is processed as data. To specify column names manually, enter a name for each target column in the **Mapping** section. You can also select a data type for the column.

The **Start processing data at row** field specifies how many rows to skip when loading the source data into the target. If you have selected the **Column header** option, and if you enter a number greater than 0 in the **Start processing data at row** field, then that number of rows after the first row are not loaded into the target. If you have deselected the **Column header** option, and if you enter a number greater than 0 in the **Start processing data at row** field, that number of rows including the first row are not loaded into the target.

To change the character set encoding for the contents of the file, select a value from the **Encoding** drop-down list.

To specify the characters that enclose text, select the double-quotes or single-quote character or `None` from the **Text enclosure** drop-down list.

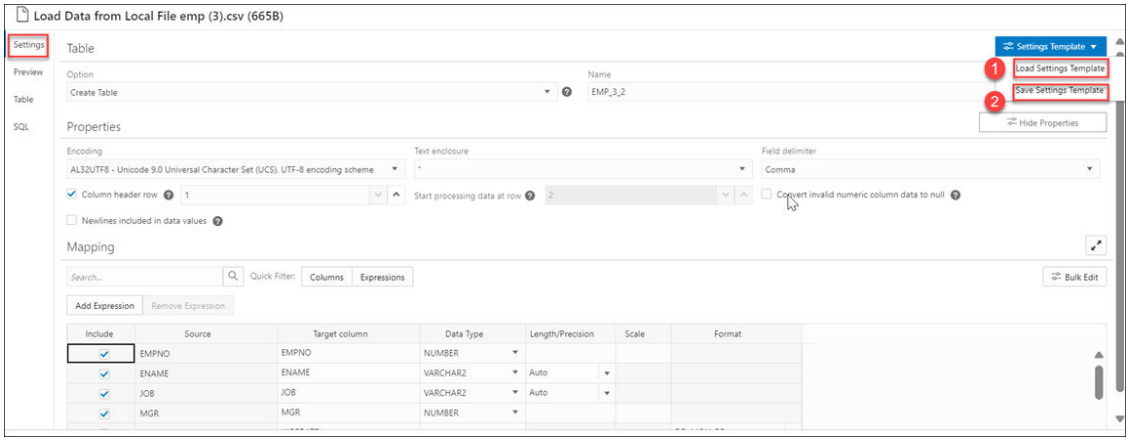
To change the delimiter character that separates columns in the source, expand the **Field delimiter** drop-down list and select a character. For example, if the file has columns delimited by semicolons, change the delimiter from the default comma delimiter to a semicolon.

To convert any invalid value in a numeric source column to a null value in the target column, select the Numeric column **Convert invalid data to null** option.

Settings Template

The save settings feature saves the configuration set in the Cart settings in the form of a JSON file. When opening the Settings template, you have the following options:

1. **Load Settings Template**: Loads a settings template from your local system.
2. **Save Settings Template**: Saves the current existing settings template.



You can use the **Load Settings Template** if you want to use an existing customized template present in your local.

1. From the Settings Template in the Settings tab of the Load Data page, select **Load Settings Template**.
2. You will see a Load Settings Template wizard, click the Settings Template JSON to load a JSON file from your system.
3. Clicking the Settings template JSON will open your local system. Click **OK** to load the JSON file.
4. After you load the JSON file, you can view the updates applied automatically to the settings tab which matches the JSON settings template you load from your local.

You can use the **Save Settings Template** to save the existing current Settings template.

1. From the Settings Template in the Settings tab of the Load Data page, select **Save Settings Template**.
2. The Template file editor appears. Click the Template File name and name the new template.
3. Click **OK** to finish saving the new name of the existing template.
4. You can test the configuration of the new template.

Bulk Edit Settings

You can use the Bulk edit settings to update all the columns at once from the mapping table. Use it to apply changes to the selection currently displayed in the results pane. You can search for the values of the column you want to edit in the search field and click the magnifier icon. The mapping table will display the results of the search. Select the Bulk Edit setting to update the column. The Bulk Edit setting allows you to:

- Update values of all the fields in a group.
- Find and replace, Add Prefix and Add suffix to target column name.
- Include the column(s) for loading data to the target table.
- Exclude the column(s) for loading data to the target table.

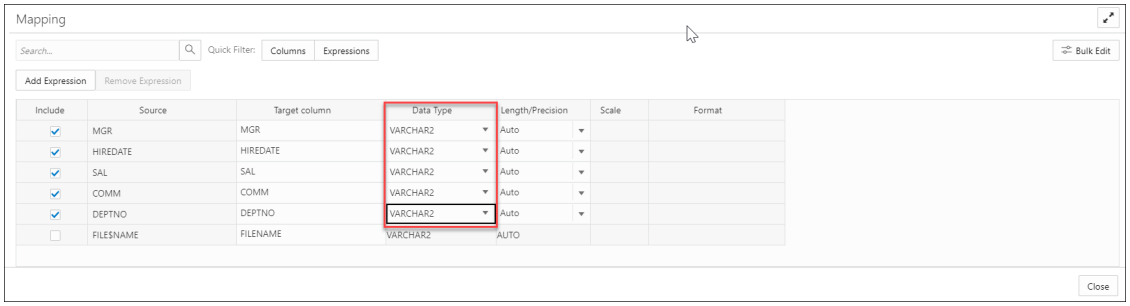
Searching the Column

The Bulk Edit setting updates the columns returned by the search field. The search box besides the Bulk Edit setting icon filters the list of columns you wish to update in a bulk. As soon as you start typing in the search field, the tool returns the field values which contains the letters you type. You can remove the filter by deleting all the content from the search box and clicking the magnifier icon that appears next to the search box.

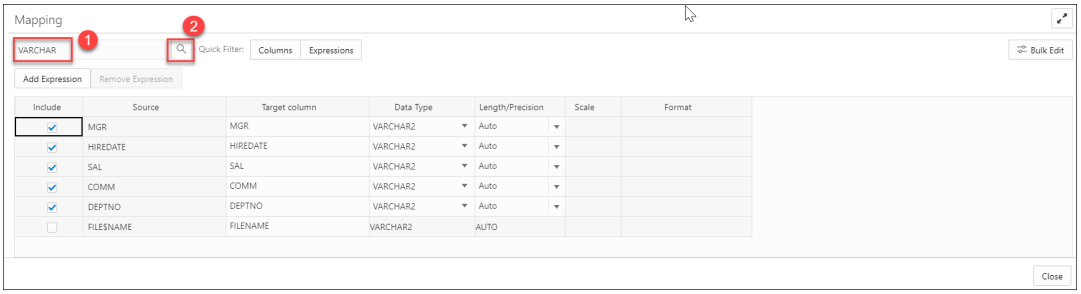
The Bulk Edit setting enables you to update the values of the following columns for all the searches returned by the search field:

- Data Type
- Target Column name
- Include Columns for loading
- Exclude columns for loading

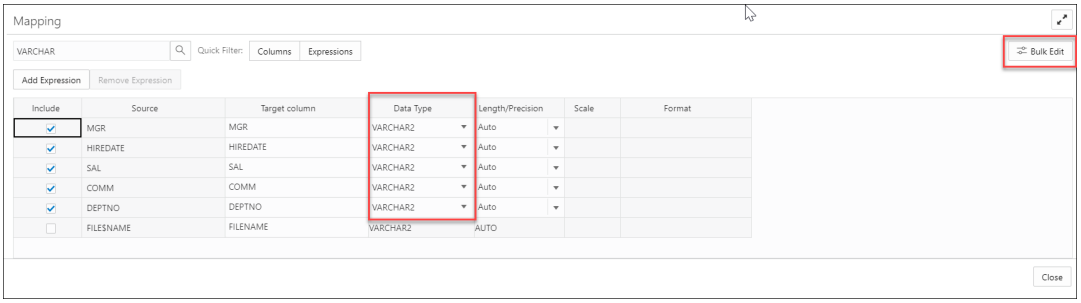
Consider changing the Data Type of first to fifth rows from VARCHAR to NUMBER in the mapping table.



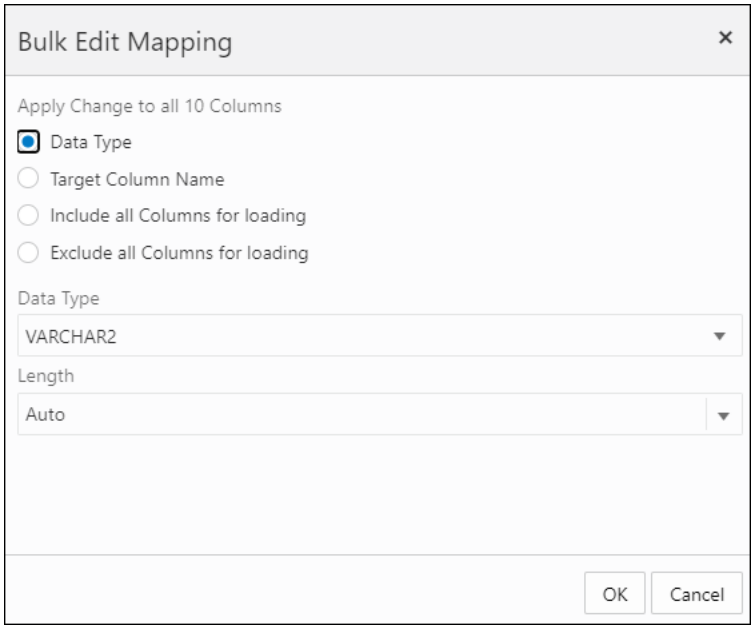
- Type `VARCHAR` in the search field and click on the magnifier icon besides the search field.



- The search will return the rows having `VARCHAR` as the Data Type. Select the **Bulk Edit** icon besides the magnifier icon.

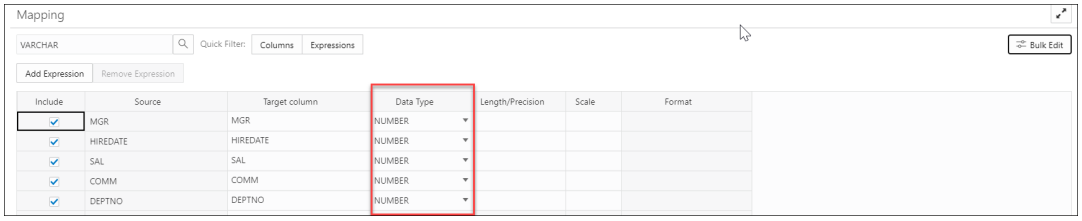


- Selecting the Bulk Edit icon opens the Bulk Edit Mapping dialog box.

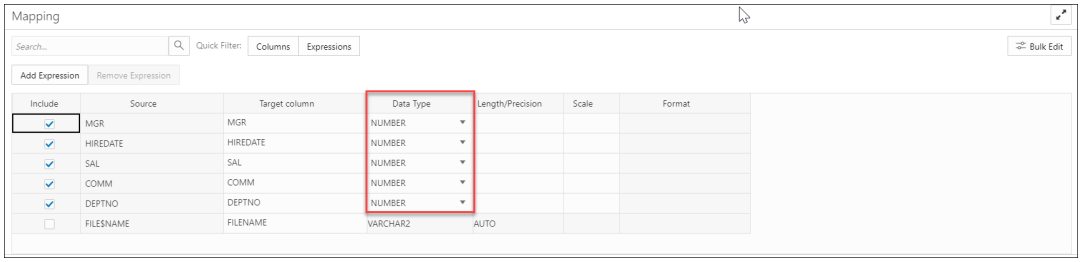


- Click **Data Type** and select `NUMBER` from the Data Type drop-down. Click **OK**.

- The Data Type of the selected rows changes from `VARCHAR` to `NUMBER`.



- Clear the content from the search field and click the magnifier icon to view the bulk edit updates in the Mapping table.



Specify Mappings

You can filter the results in the mapping table with Quick Filter field that enables you to filter out **Columns** or **Expressions**.

Select **Add Expression** to perform **Sentiment Analysis** or **Key Phrase extraction** with the source data. See Use OCI Language Service Capabilities in Data Studio for more details.

If you select the **Create Table** or **Drop Table and Create New Table** option and you are getting the source column names from the file header, then in the **Mapping** section either accept the default values for the target columns and data types or specify different values. To specify different values, in the target column, enter a name for the column. In the Data Type column, select a data type from the drop-down list. If you are not getting the source column names from the file header, then for each source column specify a name for the target column and select a data type from the Data Type drop-down list. For the Date data type, select a date format from the Format drop-down list.

> **Note:**
>
> You will receive a tooltip error message with the exact reason for the error message when you complete editing a cell. The mapping grid cell will be highlighted with red to indicate an invalid value that must be fixed. The highlight is removed after you fix the invalid value. For example, you can view the following tooltip error message when the target column name is not filled in.
>
> >

For the **Merge into Table** option, for each source column, select a target column form the drop-down list. You must specify at least one column as a key column. To specify a column as a key column, select the **Merge Key** check box for the column. Merge keys are one or more columns that uniquely identify each row in the table. Merge keys must not contain any null values. For loading tables with primary keys, this option automatically enables the selection of primary key columns as the merge keys.

For the **Insert into Table** or **Replace Data** options, for each source column, select a target column from the drop-down list of existing columns.

Preview Source Data

To view a selection of data in the source file, select the **Preview** tab. The Preview tab displays a File menu which displays the data in tabular format with it's values. You can copy the table. The **Load Preview** tab displays the source data.

Any modifications you make in the source preview do not affect the loading of data from the file.

Preview Target Data

For all options except **Create Table**, to view the existing data in the target table, select the **Load Preview** tab. The load preview displays the data in the target table before you run the data load job.

To close the settings pane, click **Close**.

Run the Data Load Job

When you have added all of the sources for the job and specified the settings for each source, to run the job click the Start icon in the Data Load Cart menu bar. In the Run Data Load Job dialog box, click **Start**. To stop the data load job, click the Stop icon.

Once the data load job starts, you can view the progress of the job in the Data Load dashboard. See The Data Load Page for more details.

When the data load job completes, the Data Load dashboard page displays the results of the job. At the top of the header of the table load, you can view the name of the table along with the total columns present in the table.

Click **Report** to view the total number of rows processed successfully and the count of rejected rows. You can also view the Start time. The SQL pane of the Report displays the equivalent SQL code of the job.

To view information about an item in the job, click the **Actions** icon on the Table Load.

To view a log of the load operation, click the Logging icon. You can save the log, clear it, or refresh it. Click **OK** to dismiss the log.

The list of tables on the Data Load page contains any new tables created. The target tables for the **Insert into Table**, **Replace Data**, **Drop Table and Create New Table**, and **Merge into Table** options contain the loaded data.

Fixing a data load job

After your data load job, you might see errors that you want to correct, or upon inspection, realize that you wanted to name a column differently. In such cases, you will view a warning sign on the Table load. Click the **Reload** icon to reload source with suggested fixes. Click **Actions** icon on the Table load and select **Edit** to make any changes to the data load job (i.e., change a column name).

Click **Apply** to apply any changes. Click **Close** to return to the Database Actions page.

Loading Data from Other Databases

To load data from tables in another database into your Oracle Autonomous Database, on the Data Load page, select **LOAD DATA** and **DATABASE**. Select a database link from the drop-down list. Drag one or more tables from the list of database tables and drop them in the Data Load Cart.

Each table appears as an item in the Data Load Cart. The item shows the name of the table and the number of rows in it, and the name of the table that is the target for the data load.

To remove a table from the Data Load Cart, click the Remove (trash can) icon for the item. To remove all tables from the cart, click the Remove All (trash can) icon in the Data Load Cart menu bar.

To add a remote database to the list of database links, create a database link to the remote database. For information on creating a database link, see Database Links in *Oracle Database Administrator's Guide*.

The databases available to you appear in the drop-down list of the database navigation pane of the Load Tables page.

You can filter the tables displayed in the navigation pane by entering a case-sensitive value in the search field at the top of the navigation tree and pressing Enter. To display all of the tables again, clear the search field and press Enter.

You can add any number of tables from the navigation pane to the Data Load Cart and load data from all of them in a single data loading job. You can set filters on the data for a table to load only the specified data.

Specify Processing Options

To specify settings for the data load job, preview the data in the source or the target, and see statistics about the data, click the Settings (pencil) icon for the item in the Data Load Cart.

In the settings pane, on the Settings tab, you can view the name and size of the file in the title of the Load Data dialog box.

The **Table** field specifies the name of the target table. The value in the field varies depending on the selection in the **Options** field. If the option is **Create Table**, then the default target value is the name of source table. To specify a different name for the target, enter it in the **Name** field. For the other options, the default value is <None>. Expand the drop-down list and select a table as the target.

In the **Options** field for the source, select **Create Table**, **Insert into Table**, **Replace Data**, **Drop Table and Create New Table**, or **Merge into Table**. Point to the question mark icon to see a brief description of the selected option.

Select a different schema from the **Schema** drop-down to create your target table in another schema.

> **Note:**
>
> The **Schema** drop-down is available only if you have `PDB_DBA` role grant to you.
>
> To grant yourself a `PDB_DBA` role, you must log into your Database Actions instance and enter the following command in the **SQL** worksheet area displayed in the **SQL** tab under **Development** tools present in the Launchpad.
>
> ```
> Grant PDB_DBA to Username;
> ```
>
> This drop-down is available for **Create Table** and **Drop Table and Create New Table** options.

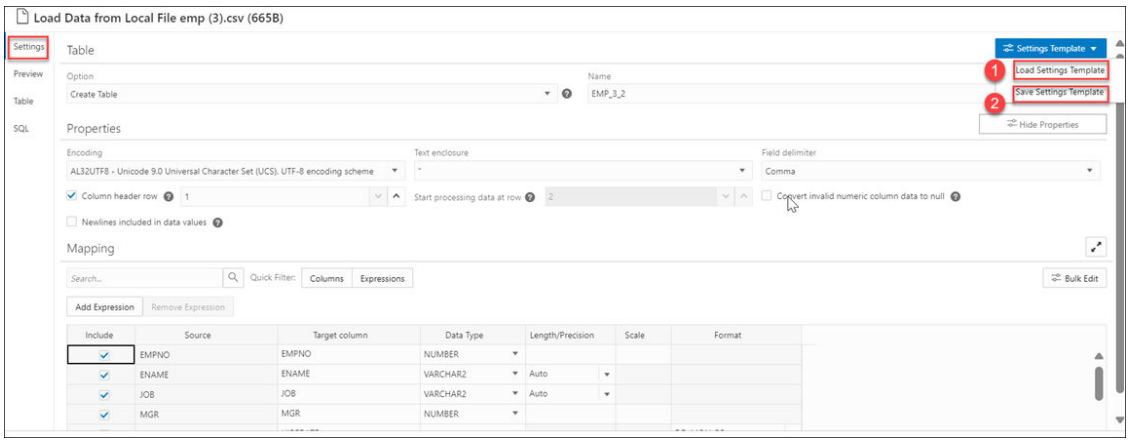
If you select **Create Table**, then in the **Name** field accept the default name, which is the name of the source table, or enter a different name.

If you select one of the other options, then expand the drop-down list of the **Name** field and select a table as the target.

Settings Template

The save settings feature saves the configuration set in the Cart settings in the form of a JSON file. When opening the Settings template, you have the following options:

1. **Load Settings Template**: Loads a settings template from your local system.
2. **Save Settings Template**: Saves the current existing settings template.



You can use the **Load Settings Template** if you want to use an existing customized template present in your local.

1. From the Settings Template in the Settings tab of the Load Data page, select **Load Settings Template**.
2. You will see a Load Settings Template wizard, click the Settings Template JSON to load a JSON file from your system.
3. Clicking the Settings template JSON will open your local system. Click **OK** to load the JSON file.
4. After you load the JSON file, you can view the updates applied automatically to the settings tab which matches the JSON settings template you load from your local.

You can use the **Save Settings Template** to save the existing current Settings template.

1. From the Settings Template in the Settings tab of the Load Data page, select **Save Settings Template**.
2. The Template file editor appears. Click the Template File name and name the new template.
3. Click **OK** to finish saving the new name of the existing template.
4. You can test the configuration of the new template.

Bulk Edit Settings

You can use the Bulk edit settings to update all the columns at once from the mapping table. Use it to apply changes to the selection currently displayed in the results pane. You can search for the values of the column you want to edit in the search field and click the magnifier icon. The mapping table will display the results of the search. Select the Bulk Edit setting to update the column. The Bulk Edit setting allows you to:

- Update values of all the fields in a group.
- Find and replace, Add Prefix and Add suffix to target column name.
- Include the column(s) for loading data to the target table.

- Exclude the column(s) for loading data to the target table.

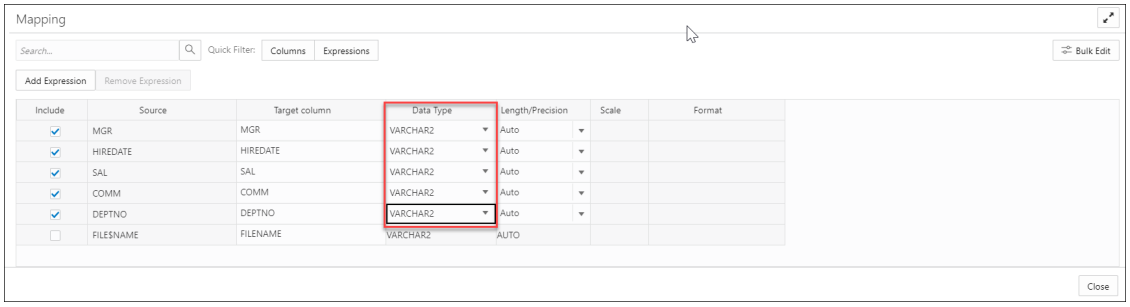
Searching the Column

The Bulk Edit setting updates the columns returned by the search field. The search box besides the Bulk Edit setting icon filters the list of columns you wish to update in a bulk. As soon as you start typing in the search field, the tool returns the field values which contains the letters you type. You can remove the filter by deleting all the content from the search box and clicking the magnifier icon that appears next to the search box.

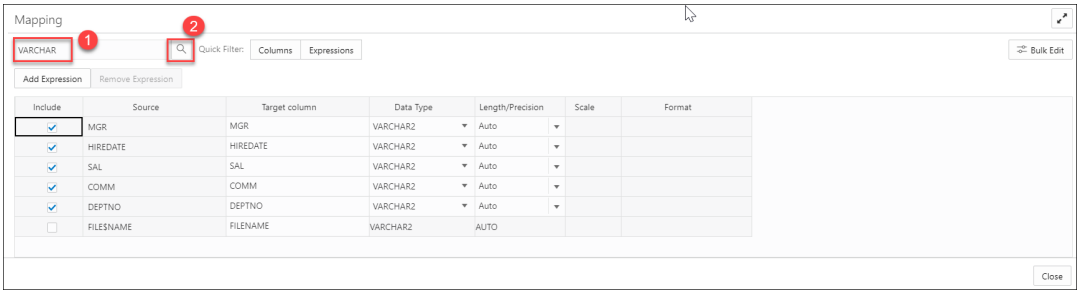
The Bulk Edit setting enables you to update the values of the following columns for all the searches returned by the search field:

- Data Type
- Target Column name
- Include Columns for loading
- Exclude columns for loading

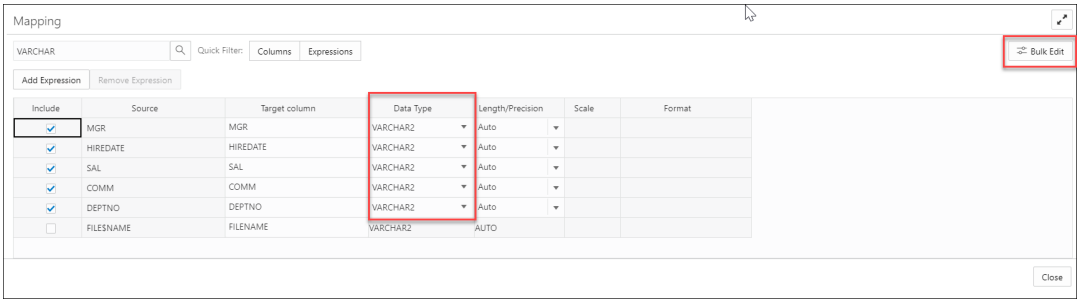
Consider changing the Data Type of first five rows from VARCHAR to NUMBER in the mapping table.



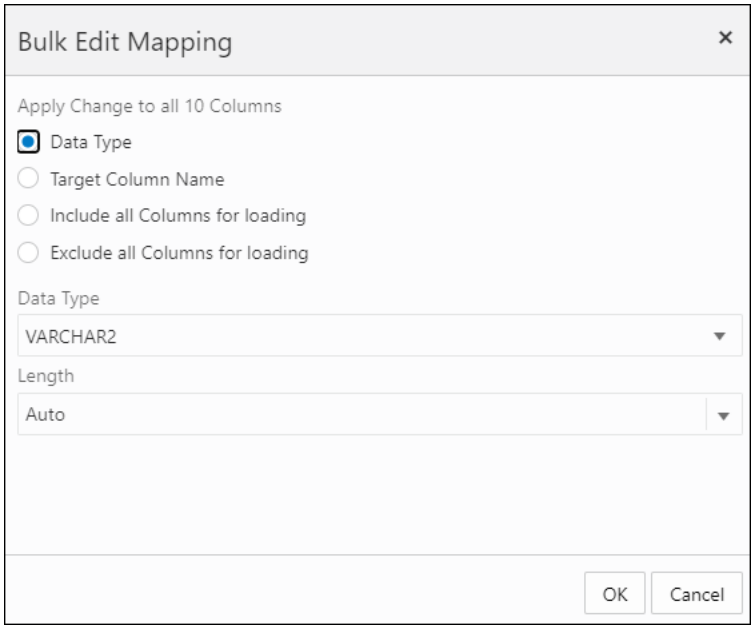
- Type `VARCHAR` in the search field and click on the magnifier icon besides the search field.



- The search will return the rows having `VARCHAR` as the Data Type. Select the **Bulk Edit** icon besides the magnifier icon.

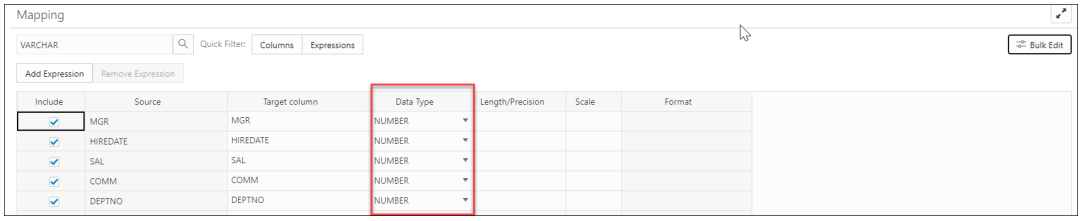


- Selecting the Bulk Edit icon opens the Bulk Edit Mapping dialog box.

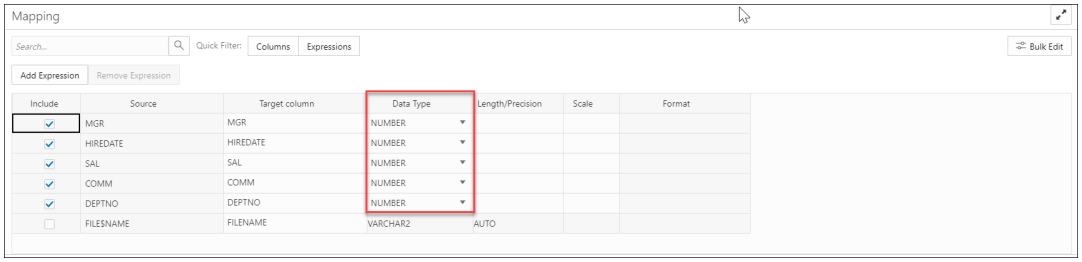


- Click **Data Type** and select `NUMBER` from the Data Type drop-down. Click **OK**.

- The Data Type of the selected rows changes from `VARCHAR` to `NUMBER`.



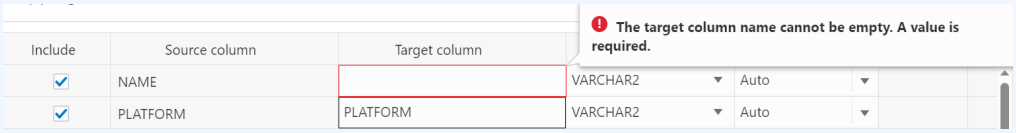
- Clear the content from the search field and click the magnifier icon to view the bulk edit updates in the Mapping table.



Specify Mappings

If you select the **Create Table** or the **Drop Table and Create New Table** option, then in the **Mapping** section either accept the default values for the target columns or specify different values. For the target column, enter a name for the column.

> **Note:**
>
> You will receive a tooltip error message with the exact reason for the error message when you complete editing a cell. The mapping grid cell will be highlighted with red to indicate an invalid value that must be fixed. The highlight is removed after you fix the invalid value. For example, you can view the following tooltip error message when the target column name is not filled in.



For the **Insert into Table** or **Replace Data** options, select a target column from the drop-down list of existing columns.

For the **Merge into Table** option, for each source column, select a target column form the drop-down list. You must specify at least one column as a key column. To specify a column as a key column, select the **Merge Key** check box for the column. Merge keys are one or more columns that uniquely identify each row in the table. Merge keys must not contain any null values. For loading tables with primary keys, this option automatically enables the selection of primary key columns as the merge keys.

Preview

To view the data in the source table, in the settings pane select the **Source Table** tab. The source preview displays the data in the table.

Table

For all options except **Create Table**, to view the existing data in the target table, in the settings pane select the **Target Table** tab. The target preview displays the data in the table before you run the data load job.

SQL

The SQL tab displays the SQL commands that will be run to complete this data load job.

> **Note:**
>
> You can see the SQL code even before the table is created.

Run the Data Load Job

When you have added all of the source tables for the job and specified the settings for each table, to run the job click the Start icon in the Data Load Cart menu bar. To stop the data load job, click the Stop icon.

Once the data load job starts, you can view the progress of the job in the Data Load dashboard.

When the data load job completes, the Data Load dashboard page displays the results of the job. At the top of the header of the table load, you can view the name of the table along with the total columns present in the table.

Click **Report** to view a report of the total rows loaded and failed for a specific table.You can view the name of the table, the time the table was loaded and the time taken to process the load.

At the header of the Table Load, you can view the name of the table with total number of columns loaded. When you expand the Table Load you can view the options you used to load the source data with the count of rows loaded.

To view information about an item in the job, click the Settings icon in the item. The settings pane has the same **Settings**, **Source**, **Table**, **SQL**, **Job Report** and **Data Definition** tabs as the settings pane before running the job, except that the target preview now contains the data loaded by the data load job. To close the settings pane, click **Close**.

To view a log of the load operation, click the Log icon. You can save the log, clear it, or refresh it. Click **OK** to dismiss the log.

The list of tables on the Data Load / Explore page contains any new tables created. The target tables for the **Insert into Table**, **Replace Data**, **Drop Table and Create New Table**, and **Merge into Table** options contain the loaded data.

Fixing a data load job

After your data load job, you might see errors that you want to correct, or upon inspection, realize that you wanted to name a column differently. In such cases, you will view a warning sign on the Table load. Click the **Reload** icon to reload source with suggested fixes. Click **Actions** icon on the Table load and select **Edit** to make any changes to the data load job (i.e., change a column name).

Click **Apply** to apply any changes. Click **Close** to return to the Database Actions page.

- Load Data from Oracle and Non-Oracle Databases using Database Links
  This section of the document describes how to create database links and then transfer data from various non-Oracle databases into your Autonomous Database using Data Studio.

Load Data from Oracle and Non-Oracle Databases using Database Links

This section of the document describes how to create database links and then transfer data from various non-Oracle databases into your Autonomous Database using Data Studio.

To load data from Oracle and Non-Oracle Databases using Database Links, you must first create a Database Link.

Run the following steps to load data from Oracle databases, or non-Oracle databases into Autonomous Database using Database Links:

1. Log in to your Database Actions instance. On the **Development** menu, click **SQL**. You can view the SQL Worksheet.
2. **Create Credentials and Database Links to access the Autonomous Database.**

   You will use the `DBMS_CLOUD.CREATE_CREDENTIAL` procedure to create credentials where the `username` and `password` values you specify are the credentials for the target database.

   The `DBMS_CLOUD.CREATE_CREDENTIAL` procedure stores the credentials in an encrypted format.

   After you create credentials, you will create database links to load data in Data Studio from non-Oracle Databases using the Data Load tool.

   Following are the sample codes you will run to create credentials and then use the same credentials to create the database links:

   a. **Create Database Links from MySQL**:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'MYSQLPE_CRED',
    username => 'admin',
    password => <enter password here> );

  DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
    db_link_name => 'MYSQLPE_DBLINK',
    hostname => 'scottmysql.scottprivate.com',
    port => '3306',
    service_name => 'scott',
    ssl_server_cert_dn => NULL,
    credential_name => 'MYSQLPE_CRED',
    private_target => TRUE,
    gateway_params => JSON_OBJECT('db_type' value 'MYSQL'));
END;
/
```

   b. **Create Database Links from Microsoft Azure**:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'AZURE_CRED',
    username => 'oracle',
    password => <enter password here> );

  DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
    db_link_name => 'AZURE_DBLINK',
    hostname => 'scott-server.database.windows.net',
    port => '1433',
    service_name => 'scottdb',
    ssl_server_cert_dn => NULL,
    credential_name => 'AZURE_CRED',
    gateway_params => JSON_OBJECT('db_type' value 'AZURE'));
```

```
END;
/
```

c. Create Database Links from Snowflake:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'SNOWFLAKE_CRED',
    username => 'SCOTT',
    password => <enter password here> );

  DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
    db_link_name => 'SNOWFLAKE_DBLINK',
    hostname => 'https://abcdefg-hij12345.snowflakecomputing.com',
    port => '443',
    service_name => 'SCOTTDB',
    credential_name => 'SNOWFLAKE_CRED',
    gateway_params => JSON_OBJECT('db_type' value 'SNOWFLAKE'),
    directory_name => NULL,
    ssl_server_cert_dn => NULL);
END;
/
```

d. Create Database Links from Oracle Cloud Object Storage using Native OCI Credentials

```
BEGIN
  DBMS_CLOUD.GET_OBJECT(
    object_uri => 'https://objectstorage.us-ashburn-1.oraclecloud.com/n/
abcdefgh12ij/b/scott-bucket/o/cwallet.sso',
    credential_name => 'OCI_NATIVE_CRED',
    directory_name => 'REG_WALLET_DIR');

  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'ADBS_CRED',
    username => 'ADMIN',
    password => <enter password here> );

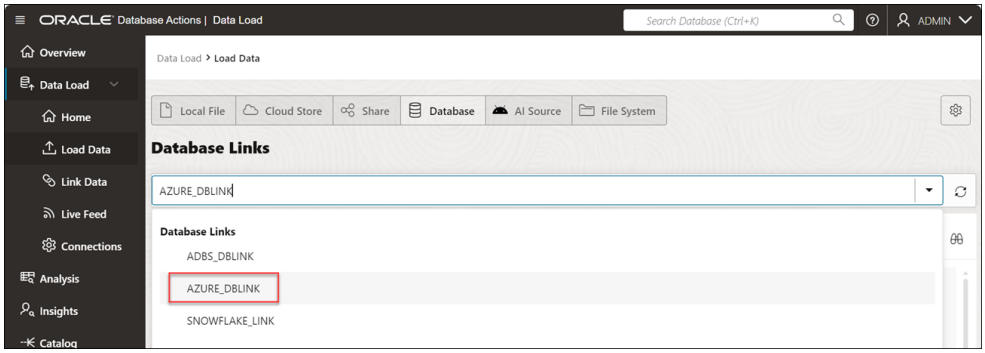
  DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
    db_link_name => 'ADBS_DBLINK',
    hostname => 'adb.us-ashburn-1.oraclecloud.com',
    port => '1522',
    service_name =>
'ab1cdefgh2i3jkl_scottadbs_high.adb.oraclecloud.com',
    credential_name => 'ADBS_CRED',
    directory_name => 'REG_WALLET_DIR');
END;
/
```

For more details on the parameters and their values, see the Create_Database_Link procedure.

> **Note:**
>
> - You require `ADMIN` privileges to run the `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` procedure.
> - You can use a vault secret credential for the target database credential in a database link. See Use Vault Secret Credentials for more information.

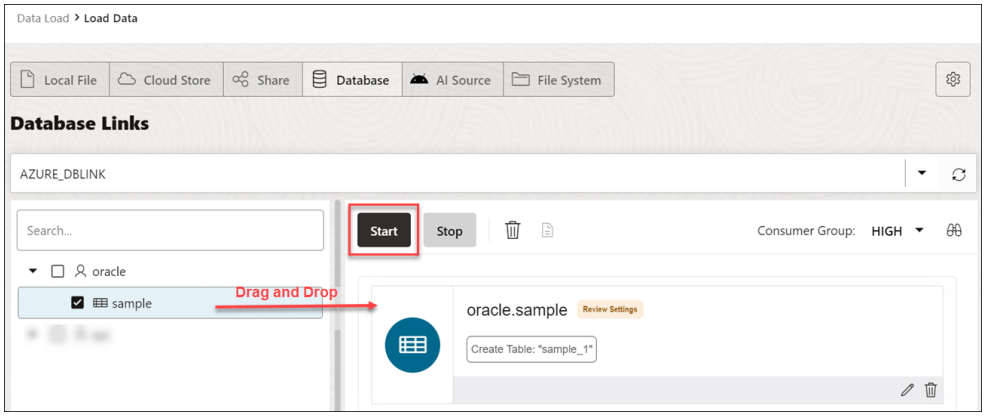
3. a. **Use the Data Load tool to LOAD data from Oracle and non-Oracle Databases:** You can use the database link you created to load access data on Data Studio. After you create the database links, you can view and use the list of database links you created in the Data Load tool and access data from Oracle and non-Oracle databases.

   - Click **Data Load** under the Data Studio suite of tools and select the **Load Data** card.
   - Click the **Database** tab and select the database link from the list of available database links you created. In this example, we will use `AZURE_DBLINK`.

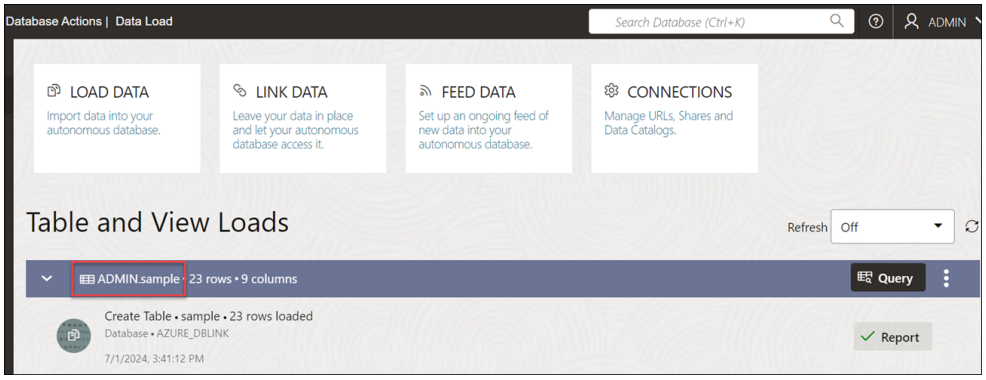


> **Note:**
>
> You cannot view the database link you create from **MySQL** since it resides within a Virtual Cloud Network (VCN), and the Autonomous Database would need to be either located in or connected to the Private Subnet within that VCN.

   - Drag the `sample` table from the database and drop it in the data load cart to load the data in your autonomous database.

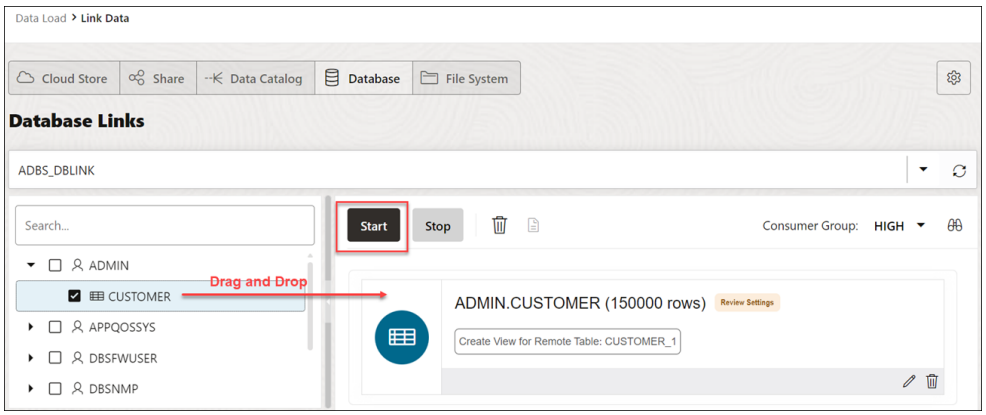


- Click **Start** to start the loading process.
- After the table is loaded in the tool, you can view the result in the Data Load Dashboard under the **Table and View Loads** section.

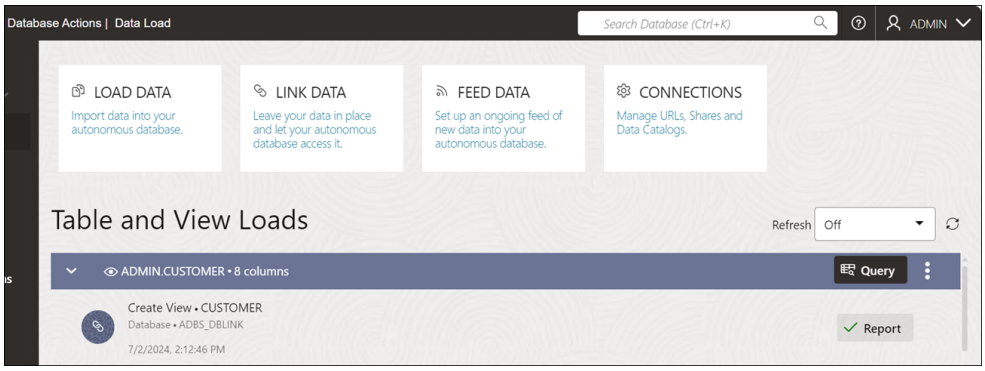


b. Use the Data Load tool to LINK data from Oracle and non-Oracle Databases: Alternatively, you can use the Data Load to link data that creates a view of the data by directly accessing cloud databases via the Database Link.

- From the **Data Load** menu under Data Studio, select **Link Data**.
- Click the **Database** tab. In this example, we will use the `ADBS_DBLINK` link.
- Drag the `customer` table from the database and drop it in the data link cart to link the data in your autonomous database.



- Click **Start** to start linking the data in Data Studio.
- After the data is linked, you will view the results of the data link job in the Data Load dashboard under the **Table and View Loads** section.



You have successfully loaded the data from Oracle and non-Oracle databases using Database Links in Data Studio.

Loading Data from Cloud Storage

You can load data from a cloud store to a table in your Autonomous Database.

You can load files in these file formats: AVRO, CSV, JSON, GeoJSON, ORC, Delimited TXT, XLSX, PRQ, GZ, GNU ZIP and Tab-Separated Values. For information on supported file formats, see Format Specifications for JSON and AVRO Files. The Data Load tool supports loading tables from multiple worksheets XLSX files when the file is in a cloud store.

You can set filters on the data for a table to load only the specified data. For example, to limit the files to only those that are CSV files, enter *.CSV in the file extension filter.

Configure and run a data load job from the Load Cloud Object page. To open that page:

1. Open the Database Actions and select **Data Load**.
2. Select **LOAD DATA** and **Cloud Store** .

On the left side of the page is a *navigator pane*, where you choose a cloud store connection and the folders or files containing the data. On the right of the page is the data load *cart*, where you stage the files and folders for the data load job. You can set options for the data load job before running it. The Autonomous Database comes with predefined CPU/IO shares assigned to different consumer groups. You can set the consumer group to either low, medium or high while executing a data load job depending on your workload.

- Manage Cloud Storage Links for Data Load Jobs
  Before you can load data from a cloud store, you must establish a connection to the cloud store you want to use. You can select cloud store location from the cloud store locations field.
- Prepare the Data Load Job
- Add Files or Folders for the Data Load Job
- Enter Details for the Data Load Job
  Enter the details about the data load job in the Load Data from Cloud Storage pane.

- Run the Data Load Job
  Once you've added data sources to the data load cart and entered details about the data load job, you can run the job.
- View Details About the Data Load Job After It Is Run
- View the Table Resulting from the Data Load Job

Manage Cloud Storage Links for Data Load Jobs

Before you can load data from a cloud store, you must establish a connection to the cloud store you want to use. You can select cloud store location from the cloud store locations field.

On the Load Data page when you select Cloud Store:

1. Click the **Create Cloud Store locations** menu besides the cloud store locations text field. This opens an Add Cloud Store Location dialog box. See Managing Connections to add cloud store location.

See Managing Connections.

To return to the Load Cloud Object page, click **Data Load** in the breadcrumbs at the top of the page and then navigate back to the page.

Prepare the Data Load Job

As you'll see below in Enter Details for the Data Load Job, the first decision you'll make when configuring a data load job is how to load the source data into a new or existing table in the database. The choices are:

- Create a table and insert data loaded from the source into the new table.
- Insert data loaded from the source into an existing table.
- Delete all data in an existing table and then insert new data from the source into the table.
- Drop a table, create a new table, and then insert data loaded from the source into the new table.
- Merge data from the source into a table by updating existing rows in the table and inserting new rows into the table.

You may have to adjust your source data or your target table so that the source data loads correctly into the external target table. The number, order, and data types of columns in the source must match those in the target. Consider:

- If you're creating a new table or if the columns in your source exactly match the columns in an existing target, you don't have to do any special preparation.
- If the columns in your source don't match the columns in an existing target, you must edit your source files or target table so they do match.
- If you're loading multiple files, you must make sure that:
  - All the source files are of the same type, for example, CSV, JSON, etc.
  - The number, order, and data types of the columns in all the source files match (and that they match the target, if you're loading into an existing table).
- If you want to partition by date:
  - The source file must contain data where the data type is date or timestamp.
  - You must load a folder containing two or more data sources.
  - The names of the files in the folder must indicate a date or dates, for example, `MAR-1999.csv` or `2017-04-21.xlsx`.

Add Files or Folders for the Data Load Job

Add files from the cloud store to the data load cart, where you can edit the details of the data load job. To add the files:

1. From the list at the top of the navigator pane on the left, select the bucket from the drop-down with your source data.

   The list shows links that were established on the Manage Cloud Storage page. If you haven't yet registered the cloud store you want to use, click the **Create Cloud Store Location** button at the top of the page and register a connection. See Manage Cloud Storage Links for Data Load Jobs, above.

2. Drag one or more items from the file navigator on the left and drop them into the cart on the right.

   - You can add files, folders, or both. A card is added to the cart for each file or folder you drag into it. The card lists the name of the source file or folder and a proposed name for the target table.
   - If you add a folder that contains multiple files, all the files must be of the same type, that is, CSV, TXT, etc.

     When you add the folder to the cart, a prompt is displayed that asks if you want to load all the objects from the multiple source files into a single target table. Click **Yes** to continue or **No** to cancel.
   - When you add multiple individual files or multiple folders to the cart, the data represented by each card will be loaded into a separate table, but all the items in the cart will be processed as part of the same data load job. The multiple files you load must have same file extension.
   - You can add files or folders from a different bucket, but if you do that, you're prompted to remove all files that are already in the cart before proceeding. To select files from a different bucket, select the bucket from the drop-down list in the navigator pane on the left and then add the file(s), as described above.
   - You can drop files or folders into the data load cart and then navigate away from the Data Load Object page. When you return to the page, those items remain on the page.

You can remove items from the cart before running the data load job:

- To remove an item from the cart, click the **Remove** icon on the card for the item.
- To remove all items from the cart, click **Remove All** in the data link cart menu bar at the top of the pane besides the **Start** and **Stop** icon.

Enter Details for the Data Load Job

Enter the details about the data load job in the Load Data from Cloud Storage pane.

On the card in the data link cart, click the **Actions** icon and select the **Settings** to open the Load Data from Cloud Storage pane for that job. The pane contains:

- Settings Tab - Table Section
- Settings Tab - Properties Section
- Settings Tab - Mapping Section
- Preview Tab
- Table Tab
- Close Button - Save and Close the Pane

Settings Tab - Table Section

Set details about the target table in the **Table** section.

- **Option:** Select an item from the **Option** list to specify how the data should be loaded into a new or existing table. The processing options are:
  - **Create Table**: Creates a table and inserts the data into the new table. When you select this option, the **Name** field on the **Settings** tab is filled with a default name, based on the name of the source file or folder. You can change it if you want.
  - **Insert into Table**: Inserts data loaded from the source into an existing table. When you select this option, the **Name** field on the **Settings** tab presents a list of the tables in the current schema. Select the table into which you want to insert the data.
  - **Replace Data**: Deletes all data in the existing table and then inserts new data from the source into the table. When you select this option, the **Name** field on the **Settings** tab presents a list of the tables in the current schema. Select the table you want to use.
  - **Drop Table and Create New Table**: Drops the table (if it already exists), creates a new table, and then inserts the new data into the table. When you select this option, the **Name** field on the **Settings** tab presents a list of the tables in the current schema. Select the table you want to use.
  - **Merge into Table**: Updates existing rows and inserts new rows in the table. When you select this option, the **Name** field on the **Settings** tab presents a list of the tables in the current schema. Select the table you want to use.
- Select a different schema from the **Schema** drop-down to create your target table in another schema.

> **Note:**
>
> The **Schema** drop-down is available only if you have `PDB_DBA` role grant to you.
>
> To grant yourself a `PDB_DBA` role, you must log into your Database Actions instance and enter the following command in the **SQL** worksheet area displayed in the **SQL** tab under **Development** tools present in the Launchpad:
>
> ```
> Grant PDB_DBA to USER;
> ```
>
> You can now view the **Schema** drop-down. It is only available for **Create Table** and **Drop Table and Create New Table** options.

- **Name:** The name of the target table.
- **Partition Column:**

  List Partitions and Date-based partitions are the different types of partitions available in data loading.

  List partitioning is required when you specifically want to map rows to partitions based on discrete values.

  To partition according to a specific column, click the **Partition Column** drop-down list and select the column you want to use for the partitioning.

  You will have N files per partition value, all partitioned by the partition column you select.

> **Note:**
>
> – For linked files (from external tables) there is also a requirement that for each file, the list partitioning column can contain only a single distinct value across all of the rows.
>
> – If a file is list partitioned, the partitioning key can only consist of a single column of the table.

Date-based partitioning is available when you load a folder containing two or more data sources that contain date or timestamp data.

To partition according to date, click the **Partition Column** drop-down list and select the **DATE** or **TIMESTAMP** column you want to use for the partitioning.

Settings Tab - Properties Section

Specify options to control how the source data is interpreted, previewed, and processed. These options vary, depending on the type of source data.

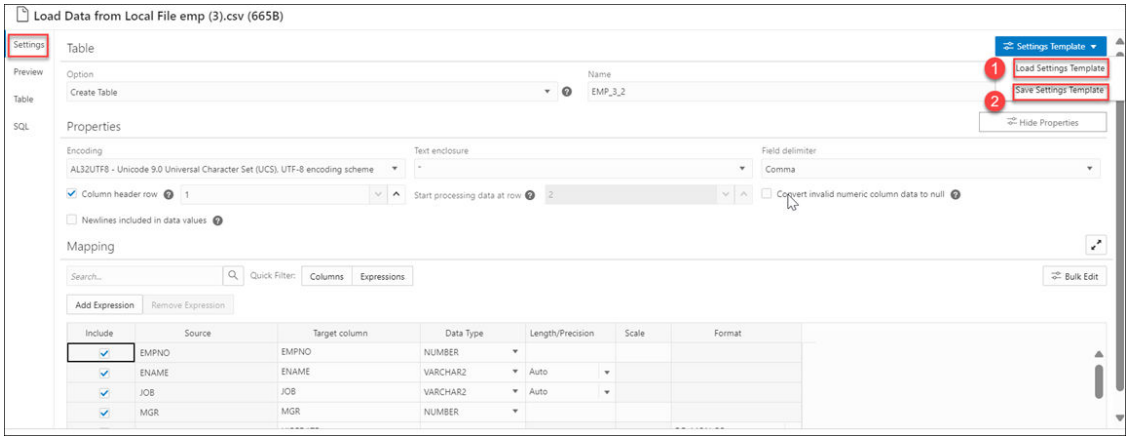
- **Encoding:** Select a character encoding type from the list. This option is available when the loaded file is in plain text format (CSV, TSV, or TXT). The default encoding type is UTF-8.
- **Text enclosure:** Select the character for enclosing text: **"** (double-quote character), **'** (single-quote character) or **None**. This option is visible only when the selected file is in plain text format (CSV, TSV, or TXT).
- **Field delimiter:** Select the delimiter character used to separate columns in the source. For example, if the source file uses semicolons to delimit the columns, select **Semicolon** from this list. The default is **Comma**. This option is visible only when the selected file is in plain text format (CSV, TSV, or TXT).
- **Column header row**: Select the **Column header row** checkbox to use the column names form the source table in the target table.
  - By selecting this option you can indicate what row in the file contains column names. The rows in the **Mapping** section, below, are filled with those names (and with the existing data types, unless you change them).
  - If you deselect this option, the first row is processed as data. To specify column names manually, enter a name for each target column in the **Mapping** section. (You will also have to enter data types.)
- **Start processing data at row**: Specifies the number of rows to skip when loading the source data into the target:
  - If you select the **Column header row** option under **Source column name** (see below) and if you enter a number greater than 0 in the **Start processing data at row** field, then that number of rows after the first row are not loaded into the target.
  - If you deselect the **Column header row** option under **Source column name**, and if you enter a number greater than 0 in the **Start processing data at row** field, then that number of rows including the first row are not loaded into the target.
- **Numeric column**: Select the **Convert invalid data to null** checkbox to convert an invalid numeric column value into a null value.
- **Newlines included in data values**: Select this option if there are newline characters or returns to the beginning of the current line without advancing downward in the data fields.

Selecting this option will increase the time taken to process the load. If you do not select this option when loading the data, the rows with newlines in the fields will be rejected. You can view the rejected row in the Job Report panel.

Settings Template

The save settings feature saves the configuration set in the Cart settings in the form of a JSON file. When opening the Settings template, you have the following options:

1. **Load Settings Template**: Loads a settings template from your local system.
2. **Save Settings Template**: Saves the current existing settings template.



You can use the **Load Settings Template** if you want to use an existing customized template present in your local.

1. From the Settings Template in the Settings tab of the Load Data page, select **Load Settings Template**.
2. You will see a Load Settings Template wizard, click the Settings Template JSON to load a JSON file from your system.
3. Clicking the Settings template JSON will open your local system. Click **OK** to load the JSON file.
4. After you load the JSON file, you can view the updates applied automatically to the settings tab which matches the JSON settings template you load from your local.

You can use the **Save Settings Template** to save the existing current Settings template.

1. From the Settings Template in the Settings tab of the Load Data page, select **Save Settings Template**.
2. The Template file editor appears. Click the Template File name and name the new template.
3. Click **OK** to finish saving the new name of the existing template.
4. You can test the configuration of the new template.

Bulk Edit Settings

You can use the Bulk edit settings to update all the columns at once from the mapping table. Use it to apply changes to the selection currently displayed in the results pane. You can search for the values of the column you want to edit in the search field and click the magnifier icon. The mapping table will display the results of the search. Select the Bulk Edit setting to update the column. The Bulk Edit setting allows you to:

- Update values of all the fields in a group.

- Find and replace, Add Prefix and Add suffix to target column name.
- Include the column(s) for loading data to the target table.
- Exclude the column(s) for loading data to the target table.

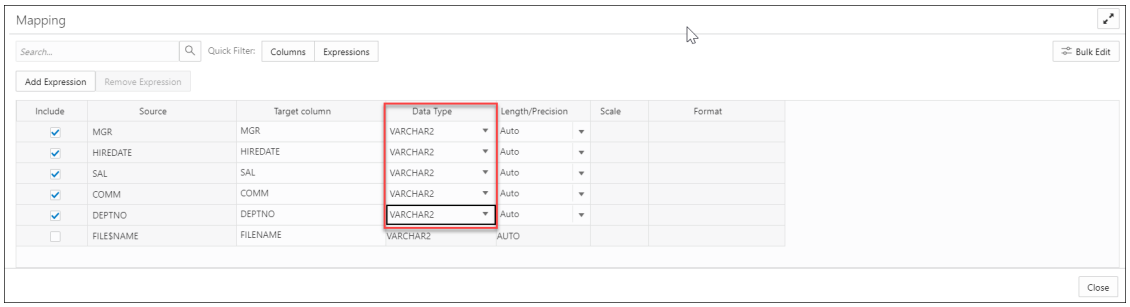
Searching the Column

The Bulk Edit setting updates the columns returned by the search field. The search box besides the Bulk Edit setting icon filters the list of columns you wish to update in a bulk. As soon as you start typing in the search field, the tool returns the field values which contains the letters you type. You can remove the filter by deleting all the content from the search box and clicking the magnifier icon that appears next to the search box.

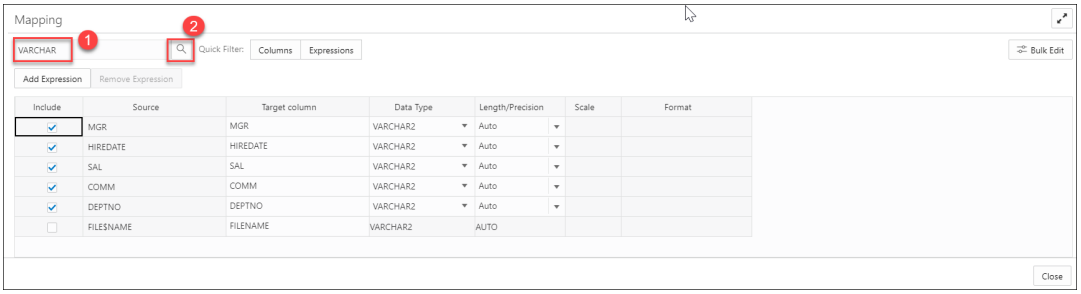
The Bulk Edit setting enables you to update the values of the following columns for all the searches returned by the search field:

- Data Type
- Target Column name
- Include Columns for loading
- Exclude columns for loading

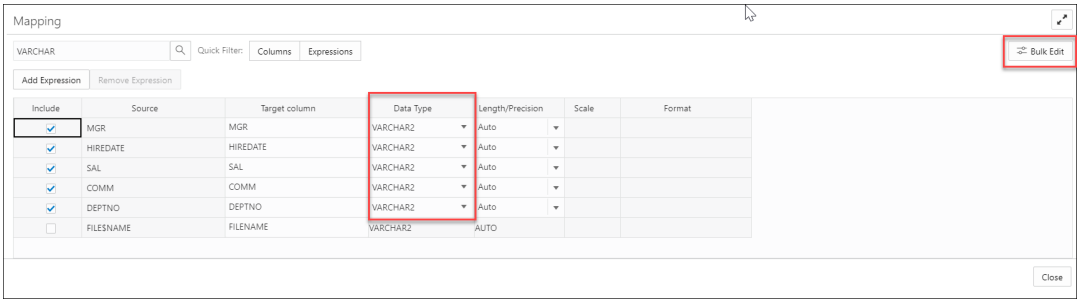
Consider changing the Data Type of first five rows from VARCHAR to NUMBER in the mapping table.



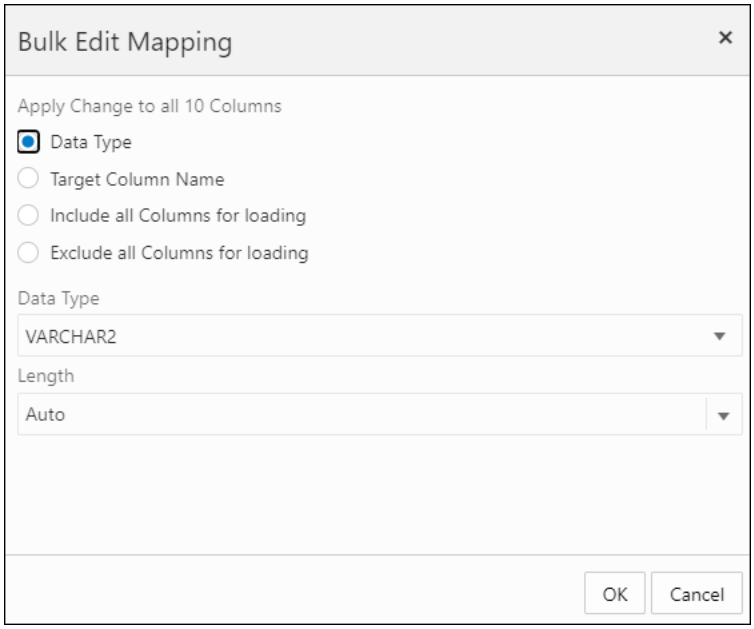
- Type `VARCHAR` in the search field and click on the magnifier icon besides the search field.



- The search will return the rows having `VARCHAR` as the Data Type. Select the **Bulk Edit** icon besides the magnifier icon.

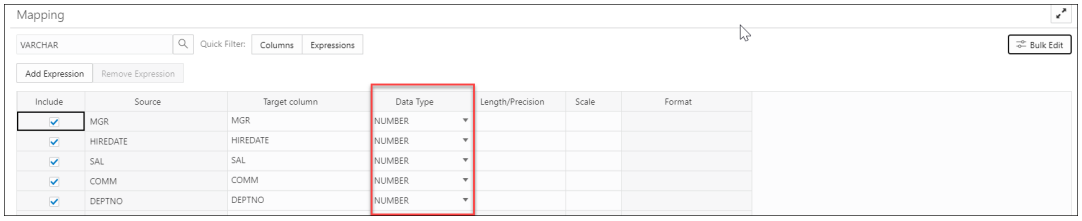


- Selecting the Bulk Edit icon opens the Bulk Edit Mapping dialog box.

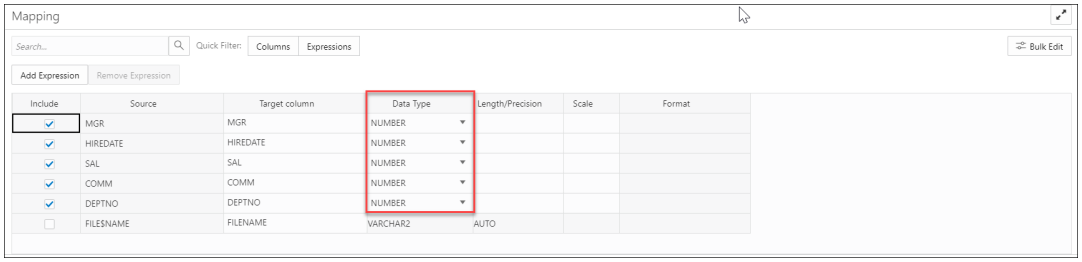


- Click **Data Type** and select `NUMBER` from the Data Type drop-down. Click **OK**.

- The Data Type of the selected rows changes from `VARCHAR` to `NUMBER`.



- Clear the content from the search field and click the magnifier icon to view the bulk edit updates in the Mapping table.



Settings Tab - Mapping Section

The settings in the **Mapping** section control how data from the source files are loaded into the rows of the target database table. For each row, the data from the column listed under **Source column** will be loaded into the column listed under **Target column**.

As mentioned above, the contents of the **Mapping** table change according to what processing option you chose in the **Table** section and which properties you set in the **Properties** section.

You can filter the results in the mapping table with **Quick Filter** field that enables you to filter out **Columns** or **Expressions**.

Select **Add Expression** to perform **Sentiment Analysis** or **Key Phrase extraction** with the source data. See Use OCI Language Service Capabilities in Data Studio for more details.

- **Include**: This check box ensures that the row you select is loaded from the source column to the target column.
- **Source column**: Lists the columns from the source file.

  If the **Column header row** option under **Properties** is selected, **Source column** shows the names of the columns in the source file. If the **Column header row** option is not selected, generic names like **COLUMN_1**, **COLUMN_2**, etc., are used. This field is always read only.

  You can view two source columns `FILE$NAME` and `SYSTIMESTAMP`. The `FILE$NAME` column enables you to locate the source file containing a particular data record. For example, you load a source file that contains a list of files. The file names in the file list refer to the department names across the organization. For instance, a *finance.txt* file contains data from the Finance department. In the mapping, you can use string data types to extract the department name from the output of the file name column. You can use the extracted department name to process data differently for each department.

  The `SYSTIMESTAMP` column allows us to view the current timestamp in the database.

> **Note:**
>
> – `FILE$NAME` and `SYSTIMESTAMP` source columns are not included by default. You must check the **Include** check box and run the load for the target table to display these two columns.
>
> – When you are creating a livefeed, the `FILE$NAME` and `SYSTIMESTAMP` source columns appear in the Mapping table by default.

- **Target column:** Lists the columns in the target table. Accept, select, or enter a column in the target table. You need to make sure that the target column is not empty. The target

column name cannot have duplicate name as another target column. The target column length must not be beyond 128 bytes. 128 byte limit is a database limit.

The contents of this column differ, depending on what you selected for the table processing **Option** and whether you selected for the **Column header row** option.

- If (1) the processing option is **Create Table** or **Drop Table and Create New Table** and (2) the **Column header row** option *is* selected, then the **Target column** uses the names of the columns in the source file. You can change the name of a target column by replacing the provided name with a new one.
- If (1) the processing option is **Create Table** or **Drop Table and Create New Table** and (2) the **Column header row** option is *not* selected, then generic names like **COLUMN_1**, **COLUMN_2**, etc., are used. You can change the name of a target column by replacing the provided name with a new one.
- If (1) the processing option is **Insert into Table**, **Replace Data**, or **Merge Into Table** and (2) the **Column header row** option *is* selected, then the **Target column** has a drop-down list of all the columns in the target table, with their data types. By default, the column with the name corresponding to the source column is selected, but you can select a different one from the list.
- If (1) the processing option is **Insert into Table**, **Replace Data**, or **Merge Into Table** and (2) the **Column header row** option is *not* selected, then the **Target column** has a drop-down list of all the columns in the target table, with their data types. Select a column from the list to use as the target column.

> **Note:**
>
> If you're loading multiple files from a folder in a single data load job, only the first file will be shown in the **Mapping** section. However, as long as the column names and data types match, the data from all source files will be loaded.

- **Data Type:** Lists the data type to use for data in that column. This column is displayed only for **Create Table** or **Drop Table and Create New Table**. The contents change depending on whether the **Get from file header** option is selected.
  - If the **Get from file header** option *is* selected, **Data type** shows the data types of the columns in the source file (for **Create Table**) or in the existing table (for **Drop Table and Create New Table**). If you want to change the data type for the target, click the name and select a different one from the list.
  - If the **Column header row** option is *not* selected, **Data type** shows all available data types. Select the data type to use for the target column from the list.
- **Length/Precision** (Optional): For columns where the **Data Type** is **NUMBER**, enter the length/precision for the numbers in the column. Precision is the number of significant digits in a number. Precision can range from 1 to 38.

  For columns where Data Type is VARCHAR2, the **Auto** value in **Length/Precision** field enables the Auto Size feature.

  With the Auto-Size column Width feature, you can automatically size any column to fit the largest value in the column. Select **Auto** from the **Length/Precision** drop-down values or pick a value from the drop-down list.
- **Scale** (Optional): For columns where the **Data Type** is **NUMBER**, enter the scale for the numbers in the column. Scale is the number of digits to the right (positive) or left (negative) of the decimal point. Scale can range from ranges from -84 to 127.

- **Format:** If the data type in the **Data type** column is **DATE** or one of the **TIMESTAMP** types, select a format for that type from the from the **Format** drop-down list.
- **Merge Key:** This option is used only for the processing option **Merge into Table**.

  For the **Merge into Table** option, you must specify at least one column to use as a key column. Merge keys are one or more columns that uniquely identify each row in the table. To specify a key column, select the **Merge Key** checkbox for the column. Merge keys must not contain any null values. For loading tables with primary keys, this option automatically enables the selection of primary key columns as the merge keys.

Preview Tab

The **Preview** tab displays the source data in tabular form in the **Load Preview** menu. The display reflects the settings you chose in the **Properties** section.

The **File** menu in the **Preview** tab displays the source data with all the columns with their names. You can copy the text.

Table Tab

The **Table** tab displays what the target table is expected to look like after the data has been loaded. If you chose the **Create Table** processing option, no table is shown.

SQL Tab

The **SQL** tab displays the SQL commands that will be run to complete this data load job.

> **Note:**
>
> You can see the SQL code even before the table is created.

Close Button - Save and Close the Pane

After entering all the details for the data load job, click **Close** at the bottom of the page. This saves the details you entered and returns you to the Load Data from Cloud Storage pane. To close the page without saving your entries, press **Escape**.

Run the Data Load Job

Once you've added data sources to the data load cart and entered details about the data load job, you can run the job.

To run the job:

1. If you haven't already done so, click the **Close** button in the **Load Data from Cloud Storage** pane to save your settings and close the pane. If any of the settings are invalid, an error message reports the problem. Fix the problem and click **Close**.
2. Click **Start** in the data load cart menu bar. To stop the data load job, click **Stop**.

   When you have added all of the sources for the job and specified the settings for each source, to run the job click the Start icon in the Data Load Cart menu bar. In the Run Data Load Job dialog box, click **Start**. To stop the data load job, click the Stop icon.

   Once the data load job starts, you can view the progress of the job in the Data Load dashboard.

When the data load job completes, the Data Load dashboard page displays the results of the job. At the top of the header of the table load, you can view the name of the table along with the total columns present in the table.

Click **Job Report** to view the total number of rows processed successfully and the count of rejected rows. You can also view the Start time. The SQL pane of the Job Report displays the equivalent SQL code of the job.

To view information about an item in the job, click the **Actions** icon on the Table Load.

To view a log of the load operation, click the Logging icon. You can save the log, clear it, or refresh it. Click **OK** to dismiss the log.

View Details About the Data Load Job After It Is Run

To view details about the data load job after it is run, click the **Actions** icon on the **Table and View Loads** section of the Data Load dashboard.

You can view Table details, Gather Statistics, Register to Cloud Link, Create Analytic View, Export Data to Cloud, Edit Table and delete the table.

When the data load job completes, the Data Load dashboard page displays the results of the job. At the top of the header of the table load, you can view the name of the table along with the total columns present in the table.

Click **Report** to view the total number of rows processed successfully and the count of rejected rows. You can also view the Start time. The SQL pane of the Report displays the equivalent SQL code of the job.

After your data load job, you might see errors that you want to correct, or upon inspection, realize that you wanted to name a column differently. In such cases, you will view a warning sign on the Table load. Click the **Reload** icon to reload source with suggested fixes. Click **Actions** icon on the Table load and select **Edit** to make any changes to the data load job (i.e., change a column name).

View the Table Resulting from the Data Load Job

To view the new tables or tables modified by the data load job, you can:

1. Fix your data load job. After your data load job, you might see errors that you want to correct, or upon inspection, realize that you wanted to name a column differently. In such cases, click the **Reload** option on the selected Table Load to reload cards from your recent cart and edit them as you did before your first attempt. The Reload icon reloads the source data with the fixes suggested by the tool. Click the **Actions** icon on the Table header, click **Table** and select **Edit** to make any changes to the data load job (i.e., change a column name).
2. You can use the **Edit** icon as mentioned in the above paragraph to review the table.

Linking Data

You can link to data in remote databases or in cloud storage buckets.

When you link to data in a remote database or in cloud storage, the target object produced is an external table or a view. When you select that target table or view on the Data Load Jobs page, the source preview for the object shows the current data in the source object.

Linking to columns in a remote database or to files in cloud storage can be useful when the source data is being continually updated. For example, if you have a database table with columns that are updated for each new sales transaction, and you have run a data load job that links columns of the source table to targets in your Oracle Autonomous Database, then those targets have the new sales data as it is updated in the source.

- Linking to Other Databases
  To link to data in tables in another database from your Oracle Autonomous Database, on the Data Load Dashboard, click **LINK DATA**, then click **Database**. Select a database link from the drop-down list. Drag one or more tables from the list of database tables and drop them in the Data Load Cart.
- Linking to Objects in Cloud Storage
  When you create a link to files in a cloud store bucket from you Oracle Autonomous database, you create an external table that links to the files in the cloud store.
- Linking to File System
  You can link to file system directories from your Autonomous Database.
- Linking to Share
  You can subscribe to a Share Provider for linking data.
- Linking to Data Catalog
  You can link your Data Catalogs to Autonomous Database.

Linking to File System

You can link to file system directories from your Autonomous Database.

On the Data Load dashboard page, click **Link Data** and select **File System**. On the left side of the page is a navigator pane, where you choose a directory with the folders or files containing the data. On the right of the page is the data link cart, where you stage the files and folders for the data link job. You can set options for the data link job before running it. The Autonomous Database comes with predefined CPU/IO shares assigned to different consumer groups. You can set the consumer group to either low, medium or high while executing a data load job depending on your workload.

Drag and drop the files or folders from the directory you select to add them to linking job.

Enter Details for the Data Link Job

Enter the details about the data link job in the Link Data from Directory dialog box. For more details, refer to the Linking to Objects in Cloud Storage chapter.

Linking to Share

You can subscribe to a Share Provider for linking data.

On the Data Load Dashboard page, click **Link Data** and select **Share**. For more details, refer to the Loading data from a Share chapter.

Linking to Data Catalog

You can link your Data Catalogs to Autonomous Database.

Click **OCI Data Catalog** in the Link Data page under the Data Load menu to register a Data Catalog for linking data. Refer to the Register Data Catalog chapter for more details on this.

Linking to Other Databases

To link to data in tables in another database from your Oracle Autonomous Database, on the Data Load Dashboard, click **LINK DATA**, then click **Database**. Select a database link from the drop-down list. Drag one or more tables from the list of database tables and drop them in the Data Load Cart.

Each table appears as an item in the Data Load Cart. The item shows the name of the table and the number of rows in it, and the name of the table that is the target for the data load.

To remove a table from the Data Load Cart, select the Remove (trash can) icon for the item. To remove all tables from the cart, click the Remove All (trash can) icon in the Data Load Cart menu bar.

To add a remote database to the list of databases, create a database link to the remote database. For information on creating a database link, see Database Links in *Oracle® Database Database Administrator's Guide*.

The databases available to you appear in the drop-down list of the database navigation pane of the Link Tables page.

Specify the Target, Create Filters, and View Mappings

To specify settings for the data load job, preview the data in the source or the target, and see statistics about the data, click the Settings (pencil) icon for the item in the Data Load Cart.

In the settings pane, on the Settings tab, the **Source** field displays the name of the table and the number of rows in the table.

Preview Source Data

To view the data in the source table, in the settings pane select the **Source Preview** tab. The source preview displays the data in the table.

View Statistics

To view statistics about the source table, in the settings pane select the **Statistics** tab. It may take a moment for the statistics to appear. The statistics include the size of the table, the number of rows and columns, the column names, data types, number of distinct values, and other information. Below the details about the columns is a bar graph that displays the top unique values for the selected column.

Preview Target Data

To view the data in the target view, in the settings pane select the **Target Preview** tab. The target preview displays the data in the target view. If the view does not yet exist, then the target data is the same as the source data, regardless of any filters set for the data load job.

Run the Data Load Job

When you have added all of the source tables for the job and specified the settings for each table, to run the job click the Start icon in the Data Load Cart menu bar. In the Run Data Load Job dialog box, click **Start**. To stop the data load job, click the Stop icon.

At the top of the page, the **Status** shows the number of items for which the load has completed over the number of items in the job, and the total time elapsed for the job. When the data load job completes, the Link Tables page displays the results of the job.

To view information about an item in the job, click the Settings (circled i) icon in the item. The settings pane has the same **Settings**, **Preview**, and **Target Preview** tabs as the settings pane before running the job, except that the **Target Preview** now contains the data loaded by the data load job. To close the settings pane, click **Close**.

To view a log of the load operation, click the Logging icon. You can save the log, clear it, or refresh it. Click **OK** to dismiss the log.

The list of views on the Data Load page contains any new views created. A preexisting view that was the target for the data load job now contains the loaded data.

On the Database links page, click the **Reload Cart** button. Clicking the button enables you to add the data sources to the data load the cart again.

Click **Done** to return to the Database Actions page.

Linking to Objects in Cloud Storage

When you create a link to files in a cloud store bucket from you Oracle Autonomous database, you create an external table that links to the files in the cloud store.

You can link to files in these file formats: AVRO, CSV, JSON, GeoJSON, Parquet, ORC, Delimited TXT. For information on supported file formats, see Format Specifications for JSON, AVRO, and XML Files.

Configure and run a data link job from the Link Cloud Object page. To open that page:

1. Open the Database Actions launchpad , click **Data Studio** tab and select the **Data Load** menu. See, The Data Load Page.
2. Select **LINK DATA** and **CLOUD STORE**.

On the left side of the page is a *navigator pane*, where you choose a cloud store connection and the folders or files containing the data. On the right of the page is the data load *cart*, where you stage the files and folders for the data link job. You can set options for the data link job before running it. The Autonomous Database comes with predefined CPU/IO shares assigned to different consumer groups. You can set the consumer group to either low, medium or high while executing a data load job depending on your workload.

- Manage Cloud Storage Links for Data Link Jobs
  Before you can link to data in a cloud store, you must establish a connection to the cloud store you want to use.
- Prepare the Data Link Job
- Add Files or Folders for the Data Link Job
- Enter Details for the Data Link Job
  Enter the details about the data link job in the Link Data from Cloud Storage pane.
- Run the Data Link Job
  Once you've added data sources to the data link cart and entered details about the data link job, you can run the job.
- View Details About the Data Link Job After It Is Run
  You can view the progress of the job on the Data Load dashboard.
- View the Table Resulting from the Data Link Job
  After running a data link job, you can view the table created by the data link job on the Data Load dashboard.

Manage Cloud Storage Links for Data Link Jobs

Before you can link to data in a cloud store, you must establish a connection to the cloud store you want to use.

On the Link Cloud Object page:

1. Click the Manage cloud store icon besides the field where you enter the cloud store location. Select **+ Create Cloud Store Location**.
2. Enter your information in the **Add Cloud Store Location** pane. See to add cloud storage location.

See Managing Connections.

To return to the Link Cloud Object page, click **Data Load** in the breadcrumbs at the top of the page and then navigate back to the page.

Prepare the Data Link Job

You may have to adjust your source data or your target table so that the source data links correctly to the external target table. Consider:

- If you're linking to multiple files, you must make sure that:
  - All the source files are of the same type, for example, CSV, JSON, etc.
  - The number, order, and data types of the columns in all the source files match.
- If you want to partition by date:
  - The source file must contain data where the data type is date or timestamp.
  - You must load a folder containing two or more data sources.
  - The names of the files in the folder must indicate a date or dates, for example, `MAR-1999.csv` or `2017-04-21.xlsx`.

Add Files or Folders for the Data Link Job

Add files from the cloud store to the data link cart, where you can edit the details of the data link job. To add the files:

1. From the list at the top of the navigator pane on the left, select the bucket with your source data.

   The list shows links that were established on the Manage Cloud Storage page. If you haven't yet registered the cloud store you want to use, click the **Connections** button under the Data Load menu in Data Studio suite of tools and register a connection.

2. Drag one or more items from the file navigator on the left and drop them into the cart on the right.
   - You can add files, folders, or both. A card is added to the cart for each file or folder you drag into it. The card lists the name of the source file or folder and a proposed name for the target table.
   - If you add a folder that contains multiple files, all the files must be of the same type, that is, CSV, TXT, etc.

     When you add the folder to the cart, a prompt is displayed that asks if you want to load all the objects from the multiple source files into a single target table. Click **Yes** to continue or **No** to cancel.
   - When you add multiple individual files or multiple folders to the cart, the data represented by each card will be loaded into a separate table, but all the items in the cart will be processed as part of the same data load job.
   - You can add files or folders from a different bucket, but if you do that, you're prompted to remove all files that are already in the cart before proceeding. To select files from a different bucket, select the bucket from the drop-down list in the navigator pane on the left and then add the file(s), as described above.
   - You can drop files or folders into the data load cart and then navigate away from the Data Link Object page. When you return to the page, those items remain on the page, but you may receive a message, "Remove All Data Link Items. Changing to another Cloud storage location requires all items to be removed from the data load job. Do you wish to continue?" Click **Yes** to remove the items from the cart. Click **No** to keep the items in the cart. Then you can continue to work.

You can remove items from the cart before running the data link job:

- To remove an item from the cart, select **Remove** on the card for the item Data Link cart menu bar at the top of the pane.

- To remove all items from the cart, click **Remove All** in the data link cart menu bar at the top of the pane.

Enter Details for the Data Link Job

Enter the details about the data link job in the Link Data from Cloud Storage pane.

On the card in the data link cart, click **Settings** to open the Link Data from Cloud Storage pane for that job. The pane contains:

- Settings Tab - Table Section
- Settings Tab - Properties Section
- Settings Tab - Mapping Section
- File Tab
- Table Tab
- SQL Tab
- Close Button - Save and Close the Pane

Settings Tab - Table Section

Set details about the target table in the **Table** section.

- **Name:** The name of the target table.
- **Partition Column:**

  List Partitions and Date-based partitions are the different types of partitions available in data linking.

  List partitioning is required when you specifically want to map rows to partitions based on discrete values.

  To partition according to a specific column, click the **Partition Column** drop-down list and select the column you want to use for the partitioning.

  You will have N files per partition value, all partitioned by the partition column you select.

  > **Note:**
  >
  > – For linked files (from external tables) there is also a requirement that for each file, the list partitioning column can contain only a single distinct value across all of the rows.
  >
  > – If a file is list partitioned, the partitioning key can only consist of a single column of the table.

  Date-based partitioning is available when you link a folder containing two or more data sources that have columns that contain date or timestamp data.

  To partition according to date, click the **Partition Column** drop-down list and select the **DATE** or **TIMESTAMP** column you want to use for the partitioning.

- **Validation Type:** Validation examines the source files, optional partitioning information, and report rows that do not match the format options specified. Select **None** for no validation; select **Sample** to perform validation based on a sample of the data; or select **Full** to perform validation based on all the data.

- **Use Wildcard:** This check box enables use of wildcard characters in search condition to retrieve specific group of files that matches the filter criteria.
  You can use a wildcard character, such as an asterisk (*) that searches, filters, and specifies groups of files that detect and add new files to the external table.

  For example, if you enter file*, then file01, file02, file03, and so on are considered to match the keyword. The asterisk (*) matches zero or more characters of the possibilities, to the keyword.

> **Note:**
>
> The wildcard support is incompatible with partitioning. The validation of source file fails if you use wildcards with partitioned data.

Settings Tab - Properties Section

Specify options to control how the source data is interpreted, previewed, and processed. These options vary, depending on the type of source data.

- **Encoding:** Select a character encoding type from the list. This option is available when the linked file is in plain text format (CSV, TSV, or TXT). The default encoding type is UTF-8.
- **Text enclosure:** Select the character for enclosing text: **"** (double-quote character), **'** (single-quote character) or **None**. This option is visible only when the selected file is in plain text format (CSV, TSV, or TXT).
- **Field delimiter:** Select the delimiter character used to separate columns in the source. For example, if the source file uses semicolons to delimit the columns, select **Semicolon** from this list. The default is **Comma**. This option is visible only when the selected file is in plain text format (CSV, TSV, or TXT).
- **Start processing data at row:** Specifies the number of rows to skip when linking the source data to the target external table:
  - If you select the **Column header row** option under **Source column name** (see below) and if you enter a number greater than 0 in the **Start processing data at row** field, then that number of rows after the first row are not linked to the target.
  - If you deselect the **Column header row** option under **Source column name**, and if you enter a number greater than 0 in the **Start processing data at row** field, then that number of rows including the first row are not linked to the target.
- **Source column name:** Select the **Column header row** checkbox to use the column names form the source table in the target table.
  - If you select this option, the first row in the file is processed as column names. The rows in the **Mapping** section, below, are filled with those names (and with the existing data types, unless you change them).
  - If you deselect this option, the first row is processed as data. To specify column names manually, enter a name for each target column in the **Mapping** section. (You will also have to enter data types.)
- **Numeric column**: Select the **Convert invalid data to null** checkbox to convert an invalid numeric column value into a null value.
- **Newlines included in data values**: Select this option if there are newline characters or returns to the beginning of the current line without advancing downward in the data fields. Selecting this option will increase the time taken to process the load. If you do not select

this option when loading the data, the rows with newlines in the fields will be rejected. You can view the rejected row in the Job Report panel.

Settings Tab - Mapping Section

The settings in the **Mapping** section control how data from the source files are linked to the rows of the target external table. For each row, the data from the column listed under **Source column** will be linked to the column listed under **Target column**.

- **Source column**: Lists the columns from the source file.

  If the **Column header row** option under **Properties** is selected, **Source column** shows the names of the columns in the source file. If the **Column header row** option is not selected, generic names like **COLUMN_1**, **COLUMN_2**, etc., are used. This field is always read only.

  You can view two source columns `FILE$NAME` and `SYSTIMESTAMP`. The `FILE$NAME` column enables you to locate the source file containing a particular data record. For example, you load a source file that contains a list of files. The file names in the file list refer to the department names across the organization. For instance, a *finance.txt* file contains data from the Finance department. In the mapping, you can use string data types to extract the department name from the output of the file name column. You can use the extracted department name to process data differently for each department.

  The `SYSTIMESTAMP` column allows us to view the current timestamp in the database.

  > **Note:**
  >
  > – `FILE$NAME` and `SYSTIMESTAMP` source columns are not included by default. You must check the **Include** check box and run the load for the target table to display these two columns.
  >
  > – When you are creating a livefeed, the `FILE$NAME` and `SYSTIMESTAMP` source columns appear in the Mapping table by default.

- **Target column:** Lists the columns in the target table.
  – If the **Column header row** option *is* selected, then the **Target column** uses the names of the columns in the source file. You can change the name of a target column by replacing the provided name with a new one. You need to make sure that the target column is not empty. Target column name must not be a duplicate of another target column. The target column name cannot have duplicate name as another target column. The target column length must not be beyond 128 bytes. 128 byte limit is a database limit.
  – If the **Column header row** option is *not* selected, then generic names like **COLUMN_1**, **COLUMN_2**, etc., are used. You can change the name of a target column by replacing the provided name with a new one.

  > **Note:**
  >
  > If you're linking multiple files from a folder in a single data link job, only the first file will be shown in the **Mapping** section. However, as long as the column names and data types match, the data from all source files will be linked.

- **Data Type:** Lists the data type to use for data in that column. The contents change depending on whether the **Get from file header** option is selected.
  - If the **Column header row** option *is* selected, **Data type** shows the data types of the columns in the source file. If you want to change the data type for the target, click the name and select a different one from the list.
  - If the **Column header row** option is *not* selected, **Data type** shows all available data types. Select the data type to use for the target column from the list.
- **Length/Precision** (Optional): For columns where the **Data Type** is **NUMBER**, enter the length/precision for the numbers in the column. Precision is the number of significant digits in a number. Precision can range from 1 to 38.

  For columns where Data Type is VARCHAR2, the **Auto** value in **Length/Precision** field enables the Auto Size feature.

  With the Auto-Size column Width feature, you can automatically size any column to fit the largest value in the column. Select **Auto** from the **Length/Precision** drop-down values or pick a value from the drop-down list.
- **Scale** (Optional): For columns where the **Data Type** is **NUMBER**, enter the scale for the numbers in the column. Scale is the number of digits to the right (positive) or left (negative) of the decimal point. Scale can range from ranges from -84 to 127.
- **Format:** If the data type in the **Data type** column is **DATE** or one of the **TIMESTAMP** types, select a format for that type from the from the **Format** drop-down list.

Preview Tab

The **Load Preview** menu in the **Preview** tab displays the source data in tabular form. The display reflects the settings you chose in the **Properties** section. The **File** menu displays source data with the column names.

If you dragged a folder containing multiple files into the data link cart and then clicked **Settings** for that card, the **Preview** pane includes a **Preview Object (File)** drop-down list at the top of the pane that lists all the files in the folder. Select the source file you want to preview from that list.

Table Tab

The **Table** tab displays what the target table is expected to look like after the data has been linked.

SQL Tab

The **SQL** tab displays the SQL commands that will be run to complete this data link job.

> **Note:**
>
> You can see the SQL code even before the table is created.

Close Button - Save and Close the Pane

After entering all the details for the data link job, click **Close** at the bottom of the page. This saves the details you entered and returns you to the Link Data from Cloud Storage pane.

Run the Data Link Job

Once you've added data sources to the data link cart and entered details about the data link job, you can run the job.

To run the job:

1. If you haven't already done so, click the **Close** button in the **Link Data from Cloud Storage** pane to save your settings and close the pane. If any of the settings are invalid, an error message reports the problem. Fix the problem and click **Close**.

2. Click **Start** in the data link cart menu bar. To stop the data link job, click **Stop**.

   When the data link job completes, the **Data Load Dashboard** page displays the results of the job under **Table and View Loads** section.

   Once the data link job starts, you can view the progress of the job in the Data Load dashboard.

View Details About the Data Link Job After It Is Run

You can view the progress of the job on the Data Load dashboard.

When the data load job completes, the Data Load dashboard page displays the results of the job. At the top of the header of the table load, you can view the name of the table along with the total columns present in the table.

Click **Job Report** to view the total number of rows processed successfully and the count of rejected rows. You can also view the Start time. The SQL pane of the Job Report displays the equivalent SQL code of the job.

To view information about an item in the job, click the **Actions** icon on the Table Load.

To view a log of the load operation, click the Logging icon. You can save the log, clear it, or refresh it. Click **OK** to dismiss the log.

View the Table Resulting from the Data Link Job

After running a data link job, you can view the table created by the data link job on the Data Load dashboard.

Fix your data load job. After your data load job, you might see errors that you want to correct, or upon inspection, realize that you wanted to name a column differently. In such cases, click the **Reload** option on the selected Table Load to reload cards from your recent cart and edit them as you did before your first attempt. The Reload icon reloads the source data with the fixes suggested by the tool. Click the **Actions** icon on the Table header, click **Table** and select **Edit** to make any changes to the data load job (i.e., change a column name).

Feeding Data

You can run a live table feed on demand, on a schedule, or as the result of a notification.

A Live Table Feed automates loading of data into a table in your database. Files automatically load as they appear in object storage and the Live Table Feed system ensures that files are only loaded once. The loading can happen manually, by a schedule, or even by notifications delivered directly from Object Storage.

The bucket can contain files in these formats: AVRO, CSV, JSON, GeoJSON, Parquet, ORC, Delimited TXT. All of the files must have the same column signature.

About the Live Feed Page

On the Database Actions - Data Load Dashboard page select **FEED DATA** to display the Live Feed page. On this page, you can:

- Manage Cloud Storage Connections for Live Table Feeds
- Create a Live Table Feed Object
- List, Filter, and Sort Live Table Feed Objects
- Find and View Live Table Feed Objects
- Run a Live Table Feed
- Delete a Live Table Feed

Manage Cloud Storage Connections for Live Table Feeds

Before you create a live table feed, you must establish a connection to the cloud store you want to use:

1. Click **Connections** under the Data Load menu. For instructions, see Managing Connections.

Create a Live Table Feed Object

To create a live table feed object,

1. On the Live Feed page, click the **+ Create Live Table Feed** button to display the Live Feed Settings pane. Enter information on the Data Source tab as follows:
   - **Cloud Store Location**: Select the Cloud Store Location from the drop-down. Select the cloud connection for the bucket containing the file you want to use for feeding data.

     On the **Basic** mode, you can view the following options:
   - **Folders**:
     Select the folder containing the file(s) you want to use for feeding data on the object store. Select **Entire Bucket** to load all the files in your bucket into your table. The folders are listed and organized in the drop-down based on how you create folders or directories and store your files. For example, you can create a sales folder to store *sales1.csv* and *sales2.csv* files.
   - **Extensions**:
     Enter an extension to limit the live table feed to only those files in the bucket that match the extension. For example, to limit the files to only those that are CSV files, select **CSV**.

     On the **Advanced** mode, you can view the following options:
   - **Object Filter (glob):** Enter a file glob to limit the live table feed to only those files in the bucket that match the glob. For example, to limit the files to only those that are CSV files, enter ***.CSV**.
   - Under the Live Feed File Preview section, you can view a preview of the file you select in the previous step.

   Click **Next** to progress to the **Table Settings** tab.

   On the **Option** field, select any of the two available options:
   - **Load Table**: This option appends the feed into the target table. It adds new rows to your table for every file it views.
   - **Merge into Table**: This option merges live feed data into the target table. Click **Merge Key** in the Mapping section when the row already exists, and the loaded key matches the newly added feed. This avoids insertion of a new row.
   - **Load Collection**: You can define your livefeed over JSON files with this option. By selecting this option, you will not view the mapping section and Add Expression

section. The tool loads the source data into a JSON collection which you can extract later.

Target Table Name: Accept the default name or enter a different name. This is the name of the target table that data from the live feed will be loaded into in your Autonomous Database instance. If the table does not exist, Live Feed will attempt to guess the correct columns. You can pre-create the table in which you wish the Live Feed to load into. This is for higher accuracy.

The Table Settings tab specifies options to control how the source data is interpreted, previewed, and processed. These options vary, depending on the type of source data.

- **Encoding:** Select a character encoding type from the list. This option is available when the linked file is in plain text format (CSV, TSV, or TXT). The default encoding type is UTF-8.
- **Text enclosure:** Select the character for enclosing text: **"** (double-quote character),**'** (single-quote ch **None**. This option is visible only when the selected file is in plain text format (CSV, TSV, or TXT).
- **Field delimiter:** Select the delimiter character used to separate columns in the source. For example, if the source file uses semicolons to delimit the columns, select **Semicolon** from this list. The default is **Comma**. This option is visible only when the selected file is in plain text format (CSV, TSV, or TXT).
- **Start processing data at row:** Specifies the number of rows to skip when linking the source data to the target external table:
  If you select the **Column header row** option under **Source column name** (see below) and if you enter a number greater than 0 in the **Start processing data at row**field, then that number of rows after the first row are not linked to the target.

  If you deselect the **Column header row** option under **Source column name**, and if you enter a number greater than 0 in the **Start processing data at row** field, then that number of rows including the first row are not linked to the target.

  Column header row: Select the **Column header row** checkbox to use the column names form the source table in the target table.

  If you select this option, the first row in the file is processed as column names. The rows in the **Mapping** section, below, are filled with those names (and with the existing data types, unless you change them).

  If you deselect this option, the first row is processed as data. To specify column names manually, enter a name for each target column in the **Mapping** section. (You will also have to enter data types).

  Select the **Convert invalid data to null** checkbox to convert an invalid numeric column value into a null value.

  Newlines included in data values: Select this option if there are newline characters or returns to the beginning of the current line without advancing downward in the data fields. Selecting this option will increase the time taken to process the load. If you do not select this option when loading the data, the rows with newlines in the fields will be rejected. You can view the rejected row in the Job Report panel.
- Edit or update the table settings in the **Mapping** section: In this pane, the mapping of the source to target columns is displayed.
  The contents of the **Mapping** table change according to what processing option you chose in the **Table** section and which properties you set in the **Properties** section.

  You can filter the results in the mapping table with **Quick Filter** field that enables you to filter out **Columns** or **Expressions**.

Select **Add Expression** to perform **Sentiment Analysis** or **Key Phrase extraction** or **Language Detection** or **Text Translation**with the source data. See Use OCI Language Service Capabilities in Data Studio for more details.

- Select the Include check box at the beginning of a row to add the column to the target table.
- Select or enter values for column attributes such as Target Column Name, Column Type, Precision, Scale, Default, Primary Key and Nullable.
- You need to review the suggested data type and if needed, modify it by entering the data type directly into the target cell.
  Review the generated mapping table code based on the selections made in the previous screens.

  Click **Merge Key** in the Mapping section when the row already exists, and the loaded key matches the newly added feed. This avoids insertion of a new row. This option shows up when you select the **Merge into Table** option.

Click **Next** to progress to the Preview tab.

- The Preview Pane displays the changes you make to the table.
- Click **Next** to progress to the Live Feed Settings tab.

On the Live Feed Settings tab, specify the following field values:

- **Live Table Feed Name**: Accept the default name or enter a different name to identify this live table feed.
- **Enable for Notification**: Select this option so that new or changed data in the data source will be loaded based on an Oracle Cloud Infrastructure *notification*. When you select this option, you can avoid delays that might occur when polling is initiated on a schedule (that is, if you selected the live table feed **Scheduled** option).

  When you select the **Enable for Notification** option, you must also:

  - Configure your object store bucket to emit notifications
  - Create a Notifications service subscription topic
  - Create an Events service rule
  - Copy the notification URL
  - Create a Notifications service subscription
  - Confirm that notifications are allowed

  For complete instructions, see Creating a Notification-Based Live Table Feed.
- **Enable for Scheduling:** Select this option to set up a schedule for running the live table feed object; that is, to poll the data source on a regular basis:
  - In the time interval fields, enter a number, and select a time type and the days on which to poll the bucket for new or changed files. For example, to poll every two hours on Monday, Wednesday, and Friday, enter **2**, select **Hours**. You can select **All Days**, **Monday to Friday**, **Sunday to Thursday**, or **Custom** from **Week Days** drop-down. The Custom field enables you to select **Monday**, **Tuesday**, **Wednesday**, **Thursday** and **Friday** in the appropriate fields.
  - Select a start and end date with start and end time. If you don't select a start date, the current time and date are used as the start date. The end date is optional. However, without an end date, the live feed will continue to poll.

Select a consumer group from the drop-down, namely, low, medium and high.

2. Click **Create** to create the Live Table feed object.

   Show code: Select this option to view the PL/SQL code equivalent of the Create Live Table Feed wizard. You can copy and execute this PL/SQL code in the worksheet to perform the same action that occurs when you click **Create** in the Create Live Table Feed wizard.

List, Filter, and Sort Live Table Feed Objects

When you open the Live Feed page, existing live table feed objects are displayed as cards on the page. They are identified as LIVE_TABLE_FEED entities.

To filter live table feed objects:

1. Click the search field at the top of the page to display filter options. By default, the live table feed objects from the current user's schema are shown. As soon as you start typing in the search field, the feed tool returns the values which contain the letters you type. You can remove the filter by deleting the content from search box and clicking the cross icon that appears next to the search box.
2. To include objects from other schemas, select the drop-down next to the search field, under **Schema**. To remove a schema from the filter list, deselect the box next to its name.
3. To show objects from all available schemas, select **All** from the **Schema** drop-down.

To sort live table feed objects

1. Click the **Sort by** button at the top right of the page.
2. Select a sorting option. To sort ascending, click the icon with the up arrow. To sort descending, click the icon with the down arrow.

Find and View Live Table Feed Objects

To search for available live table feed entities in the selected schemas, enter a value in the search field at the top of the page and press **Enter**. The display then includes only the entities whose names contain the characters in the search field. To clear the search field, click the Clear search results (X) icon in the search field.

To remove a schema or sorting value from the selected filters, deselect the schema or sorting value in the filter panel, or click the Remove filter (X) icon for the schema or sorting value above the display of live table feed objects. To close the filter panel, click the Hide filter panel (X) icon in the panel.

To refresh the display of live table feeds, click the Refresh icon at the top of the page.

Edit a Live Table Feed Object

To edit details of a live table feed object,

1. On the Live Feed page, find the card for the live table feed whose details you want to edit.
2. Click the Actions icon (three dots) on the card and select **Edit Live Table Feed**. You can edit the following options:
   - Enter information on the Data Source tab as follows:
   - **Cloud Store Location**: Select the Cloud Store Location from the drop-down. Select the cloud connection for the bucket containing the file you want to use for feeding data.
     - On the **Basic** mode, you can view the following options:
     - **Folders**:

Select the folder containing the file you want to use for feeding data on the object store. Select **Entire Bucket** to upload all the files to your bucket. The folders are listed and organized in the drop-down based on how you create folders or directories and store your files. For example, you can create a sales folder to store *sales1.csv* and *sales2.csv* files.

- **Extensions**:
  Enter an extension to limit the live table feed to only those files in the bucket that match the extension. For example, to limit the files to only those that are CSV files, select **CSV**.

  On the **Advanced** mode, you can view the following options:

- **Object Filter (glob):** Enter a file glob to limit the live table feed to only those files in the bucket that match the glob. For example, to limit the files to only those that are CSV files, enter ***.CSV**.

- On the **Live Feed Settings** tab, edit the following fields:
- **Enable for Notification**: Select this option so that new or changed data in the data source will be loaded based on an Oracle Cloud Infrastructure *notification*. When you select this option, you can prevent any delays that might occur when polling is initiated on a schedule (that is, the live table feed **Scheduled** option).

  When you select the **Enable for Notification** option, you must also:

  - Copy the live table feeds notification URL
  - Configure your cloud store to emit notifications
  - Configure Oracle Cloud Infrastructure to route events to the endpoint used for the live table feed.
  - Create a rule.
  - Create a subscription.
  - Confirm that notifications are allowed at the live feed service.

  For complete instructions, see Creating a Notification-Based Live Table Feed.

- **Scheduled:** Select this option to set up a schedule for running the live table feed object; that is, to poll the data source on a regular bases:

  - In the time interval fields, enter a number, and select a time type and the days on which to poll the bucket for new or changed files. For example, to poll every two hours on Monday, Wednesday, and Friday, enter `2`, select **Hours**. You can select **All Days**, **Monday to Friday**, **Sunday to Thursday**, or **Custom** from **Week Days** drop-down. The Custom field enables you to select **Monday**, **Tuesday**, **Wednesday**, **Thursday** and **Friday** in the appropriate fields.
  - Select a start and end date with start and end time.

3. Click **Save**.

Run a Live Table Feed

You can run a live table feed on demand, on a schedule, or as the result of a notification.

To run a live table feed on demand:

1. On the Live Feed page, find the card for the live table feed you want to run.
2. Click the Actions icon (three dots) on the card and select **Run Live Table Feed Immediately (Once)**.

To run a live table feed on a schedule:

You can set a schedule for running live table feeds on the **Create Live Table Feed** pane (when creating a new table feed) or the **Edit Live Table Feed** pane (when editing an existing table feed). See Create a Live Table Feed Object or Edit a Live Table Feed Object.

To run a live table feed as the result of a notification:

See Creating a Notification-Based Live Table Feed.

Select the **Scheduled** check box to display the schedule options and then set the schedule by selecting the options you want.

To view live table feed run details:

1. On the Live Feed page, find the card for the live table feed whose run details you want to see.
2. Click the Actions icon (three dots) on the card and select **Live Table Feed Run Details**. The **Objects** tab on the Live Table Feed Run Details pane displays information about the jobs, such as when the run occurred, the objects involved in the run, the table owner, the table Name, status of the live feed, the rows loaded and the rows rejected, and other details. Click the **All** tab to view more details, such as the event type.

Delete a Live Table Feed

1. On the Live Feed page, find the card for the live table feed job you want to delete.
2. Click the Actions icon (three dots) on the card and select **Delete Live Table Feed**.

- Creating a Notification-Based Live Table Feed
  You can load data through a live table feed based on an Oracle Cloud Infrastructure *notification*.
- Creating a Notification-Based Live Table Feed using Amazon Simple Storage Service (S3)
  You can integrate Amazon Simple Storage Service (S3) and Oracle Cloud Infrastructure (OCI) to automate the process of live feed notifications when storage objects it is observing have updates. The following section provides instructions for creating event notifications in your Amazon S3 bucket where your data files are stored.
- Creating a Notification-Based Live Table Feed using Microsoft Azure
  A notification-based Live Table Feed is an interface between Oracle Cloud Infrastructure and a third-party cloud message queuing service such as Azure Event Grid.
- Send Email using Live Feed Tool
  You can configure the Live Feed tool to send you email notifications when certain specific live feed events occur.

Creating a Notification-Based Live Table Feed

You can load data through a live table feed based on an Oracle Cloud Infrastructure *notification*.

In addition to being able to run a live table feed on demand or on a schedule, as described in Feeding Data, you can also run a feed as the result of a notification. When data in the source bucket is changed, a notification is sent which triggers a run of the table feed. With a notification-based live table feed, you can avoid any delay that might come from running on-demand or scheduled live table feed jobs.

> **Note:**
>
> - Notification-based live table feeds aren't available on the Oracle Cloud Infrastructure free tier. You must be on a paid tenancy with appropriate permissions on your account to use this feature.
> - Notification-based live table feeds aren't available on Oracle Autonomous Data Warehouse Databases (ADW) that are configured using a private endpoint.

To create a notification-based live table feed:

- Step 1: Configure your object store bucket to emit notifications
- Step 2: Create a Notifications service subscription topic
- Step 3: Create an Events service rule
- Step 4: Create and configure a live table feed to use notifications, and copy the notification URL
- Step 5: Create a Notifications service subscription
- Step 6: Confirm that the endpoint can receive notifications

> **Tip:**
>
> To complete those steps, you will alternate between Oracle Cloud Infrastructure Console pages and Oracle Database Actions pages. You may find it convenient to open the Cloud Console in one browser page or tab and Database Actions in another, so it's easy to move back and forth.

Step 1: Configure your object store bucket to emit notifications

Where: Oracle Cloud Infrastructure Console: Object Storage & Archive Storage - Buckets page

Configure the bucket containing your source data so that it will emit notifications when the data changes. You can set this option when you create a bucket or you can set it in an existing bucket.

1. Open the Cloud Console navigation menu and click **Storage**. Under **Object Storage and Archive Storage**, click **Buckets**.
2. **If you're creating a new bucket:**
   a. On the Buckets page, click the **Create Bucket** button to create a new bucket, as described in Managing Buckets. In the **Create Bucket** wizard, select the **Emit Object Events** option, along with the other options for your new bucket.
   b. Click **Create**.

   If you're using an existing bucket:
   a. On the Buckets page, click the name of the bucket you want to use, as described in Managing Buckets.
   b. On the Bucket Details page, click the **Edit** link next to **Emit Object Events**.
   c. Select the **Emit Objects Events** check box, and then click **Save Changes**.

Step 2: Create a Notifications service subscription topic

Where: Oracle Cloud Infrastructure Console: Notifications - Topics page

1. Open the Cloud Console navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.
2. Click **Create Topic**, enter a name and optional description, and then click **Create**.

Step 3: Create an Events service rule

Where: Oracle Cloud Infrastructure Console: Events - Rules page

1. Open the Cloud Console navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Click **Create Rule**, and fill out the Create Rule page as described in Managing Rules for Events.
   - Under **Rule Conditions**, select:
     - **Condition:** Event Type
     - **Service Name:** Object Storage
     - **Event Type:** Object - Create
   - Under **Actions**, select:
     - **Action Type:** Notifications
     - **Notifications Compartment:** Select the compartment to use for the notifications.
     - **Topic:** Select the name of the topic you created above, in Step 2: Create a Notifications service subscription topic.
3. Click **Create Rule**.

Step 4: Create and configure a live table feed to use notifications, and copy the notification URL

Where: Database Actions: Live Feeds page

You can configure a new or an existing live table feed to use notifications:

1. Go to the Database Actions Live Feeds page, as described in Feeding Data.
2. Create or edit a live table feed object, as described in Create a Live Table Feed Object or Edit a Live Table Feed Object. Select the **Enable for Notification** option
3. Click **Create** or **Save**.
4. Click the Actions (three vertical dots) icon on the card for your live feed, and select **Show Confirmation URL**.
5. In the **Notification URL** dialog box, click the **Copy** icon to copy the URL to the clipboard. You may want to copy it to a temporary file, so you can retrieve it later. You'll use this URL in the next step, Step 5: Create a Notifications service subscription.

Step 5: Create a Notifications service subscription

Where: Oracle Cloud Infrastructure Console: Notifications - Subscriptions page

1. Return to the Oracle Cloud Infrastructure Console. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.

2. On the Notifications page, click the **Subscriptions** tab (on the left side of the page), the status will be **Active**.
3. Click **Create Subscription** and fill in the **Create Subscription** page:
   - **Subscription topic:** Select the subscription topic you created in Step 2: Create a Notifications service subscription topic.
   - **Protocol:** HTTPS (Custom URL)
   - **URL:** Paste in the URL you copied in Step 4: Create and configure a live table feed to use notifications, and copy the notification URL.
   - Click **Create**. The subscription will be listed in the **Subscriptions** table in a state of "Pending."

Step 6: Confirm that the endpoint can receive notifications

Where: Database Actions: Live Feeds page

1. Return to the Database Actions Live Feeds page and find the card for the live table feed you are configuring for a notification-based feed.
2. You will view the live feed card in an Active status.

You will receive email notifications when certain specific live feed events occur.

See Send Email using Live Feed Tool for more details.

Once you finish the above steps, any new files uploaded to the bucket will automatically be loaded into the live table feed table.

Creating a Notification-Based Live Table Feed using Amazon Simple Storage Service (S3)

You can integrate Amazon Simple Storage Service (S3) and Oracle Cloud Infrastructure (OCI) to automate the process of live feed notifications when storage objects it is observing have updates. The following section provides instructions for creating event notifications in your Amazon S3 bucket where your data files are stored.

> **Tip:**
>
> To complete these steps, you will need to alternate between Amazon Web Services (AWS) Management console and Oracle Database Actions pages. You may find it convenient to open the Amazon Web Services in one browser page or tab and Database Actions in another, so it is easy to move back and forth.

To create a notification- based live feed with Amazon S3 as cloud storage you must:

- Step 1: Create your object store bucket in Amazon S3
- Step 2: Create Access Keys
- Step 3: Add an OCI Cloud Storage using Amazon S3
- Step 4: Create and configure a live table feed to use notifications and copy the notification URL
- Step 5: Create a notifications service subscription topic
- Step 6: Enable and configure event notifications using the Amazon S3 console
- Step 7: Create a notifications service subscription

- Step 8: Confirm that the endpoint can receive notifications

Step 1: Create your object store bucket in Amazon S3

Where: Amazon Web Services (AWS) Management console

Configure and create your bucket containing source data so that it emits notifications when the data changes.

1. Log in to AWS Management console and open the Amazon S3 console.
2. On the home page click the **Create Bucket** icon.
3. In **Bucket name**, enter a valid name for your bucket. For example: testbucket. After you create the bucket, you cannot change its name.
4. In **Region**, select the Amazon Web Services (AWS) Region from the dropdown. For example: us-west-2
5. In Bucket settings for Block Public Access, select the **Block Public Access** settings that you want to apply to the bucket. It is recommended to keep all settings enabled unless you know that you need to turn any of them off.
6. Select **Advanced settings**, and accept all the default options if you want to enable S3 Object Lock. This step is optional.
7. Select **Create bucket**.

Step 2: Create Access Keys

Where: AWS Management console

To access Amazon Simple Notification Service (SNS), you must have credentials that Amazon Web Services (AWS) can use to validate your requests. These credentials must have permissions to access Amazon SNS topics. The following steps provide you details on steps to create access keys using AWS Identity and Access Management (IAM) for security purposes.

1. Log in to AWS Management console and open Amazon Identity and Access Management (IAM) console.
2. On the navigation menu, select **Users**.
3. Select your **user name**.
4. In the Security Credentials tab, select **Create access key**.
5. Copy the **Access key ID** and **Secret access key** in the display. Paste them in a clipboard.
6. To download the keys, select **Download.csv file** icon. This way you can store the file in a secure location.

Step 3: Add an Amazon S3 Cloud Storage Link

Where: Database Actions: Manage Cloud page

Before you create a live table feed, you must establish a connection to the cloud store you want to use.

1. Click the **Manage Cloud Store** button at the top of the page to go to the Manage Cloud page. For further instructions on adding source files residing in cloud storage provided by Amazon S3, refer to *Create an Amazon S3 Cloud Storage Link* topic in Managing Connections.

> **Note:**
>
> Paste the Access key ID and Secret access key generated in the previous step (Step 2: Create Access Keys) to their respective text fields in the **Add Cloud Storage** page.

Step 4: Create and configure a live table feed to use notifications, and copy the notification URL

Where: Database Actions: Live Feeds page

Creating a live table feed enables you to load data in real time from external storage sources to your table in ADB. External storage you use include as Oracle Object Store, AWS S3 or Microsoft Azure containers.

You can configure a new or an existing live table feed to use notifications:

1. Go to the Database Actions Live Feeds page, as described in Feeding Data.
2. Create or edit a live table feed object, as described in Create a Live Table Feed Object or Edit a Live Table Feed Object. Select the **Enable for Notification** option
3. Click **Create** or **Save**.
4. Click the **Actions** (three vertical dots) icon on the card for your live feed, and select **Show Notification URL**.
5. In the **Notification URL** dialog box, click the **Copy** icon to copy the URL to the clipboard. You may want to copy it to a temporary file, so you can retrieve it later. You will use this URL in the subsequent step (Step 7: Create a notifications service subscription).

Step 5: Create a notifications service subscription topic

Where: Amazon Simple Notification Service (SNS) console

You receive Amazon S3 notifications using Amazon Simple Notification Service (Amazon SNS) topic. You need to add a notification configuration to your bucket using an Amazon SNS topic. SNS topics are shared locations which are used to send notifications of various events that happen in AWS buckets.

During creation, you select a topic name and topic type. After creating a topic, you cannot change the topic type or name. All other configuration choices are optional during topic creation, which you can edit later.

To access any AWS service, you must first create an AWS account.

Navigate to the AWS Management console, and then select **Create an AWS Account**.

Follow the instructions as provided in the Amazon SNS link to create your first IAM administrator user and group. Now you can log in to any of the AWS services as an IAM user.

1. Log in to Amazon SNS console as an IAM user.
2. On the **Topics** page, select **Create topic**.
3. Specify the following fields on the **Create topic** page, in the **Details** section.
   - **Type:**Standard (Standard or FIFO)
   - **Name:** notify-topic. For a FIFO topic, add fifo to the end of the name.
   - **Display Name:** This field is optional.

4. Expand the **Encryption** section and select **Disable encryption**.
5. Expand the **Access policy** section and configure additional access permissions, if required. By default, only the topic owner can publish or subscribe to the topic. This step is optional. Edit the JSON format of the policy based on the topic details you enter. Here is a sample of Access policy in JSON format.

```
{ "Version": "2008-10-17",
"Id": "__default_policy_ID",
"Statement":[
{"Sid": "__default_statement_ID",
"Effect": "Allow",
"Principal": {"AWS": "*"
},"Action": [
        "SNS:Publish",
        "SNS:RemovePermission",
        "SNS:SetTopicAttributes",
        "SNS:DeleteTopic",
        "SNS:ListSubscriptionsByTopic",
        "SNS:GetTopicAttributes",
        "SNS:AddPermission",
        "SNS:Subscribe"
      ],
      "Resource": "arn:aws:sns:us-west-2:555555555555:notify-topic", //us-
west-2 is the region
      "Condition": {
        "StringEquals": {
          "AWS:SourceOwner": "555555555555"
        }
      }
    },
    {
      "Sid": "s3_policy", //This field accepts string values
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": [
        "SNS:Publish"
      ],
      "Resource": "arn:aws:sns:us-west-2:555555555555:notify-topic", //
notify-topic is the topic name
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "555555555555" //This is the Account ID
        },
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:*:*:testbucket /*testbucket is the
s3 bucket name. You will get notifications only when file is uploaded to
this
    bucket.*/
"
        }
      }
    }
```

```
    ]
}
```

6. Expand the **Delivery retry policy (HTTP/S)** section to configure how Amazon SNS retries failed message delivery attempts. This step is optional.
7. Expand the **Delivery status logging** section to configure how Amazon SNS logs the delivery of messages to CloudWatch. This step is optional.
8. Expand **Tags** section to add metadata tags to the topic. This step is optional.
9. Select **Create topic**.
10. The topic's Name, ARN (Amazon Resource Name), and Topic owner's AWS account ID are displayed in the Details section.
11. Copy the topic ARN to the clipboard.

Step 6: Enable and configure event notifications using the Amazon S3 console

Where: Amazon S3 Management console

You can enable Amazon S3 bucket events to send a notification message to a destination whenever those events occur. You configure event notifications for your S3 bucket to notify OCI when there is an update or new data available to load. The following steps explain the procedure to be followed in Amazon S3 console to enable event notifications.

1. Log in to Amazon S3 Management console and sign in as an IAM (Amazon Identity and Access Management) user.
2. In the **Buckets** list, select the name of the bucket i.e. testbucket. This is the bucket that you had created in Step 1: Create your object store bucket in Amazon S3.
3. Select **Properties** icon.
4. Navigate to the **Event Notifications** section and select **Create event notification** icon.
5. In the **General configuration** section, specify the following values for event notification.
   - **Event name:** bucket-notification
   - **Prefix:** This value is to filter event notifications by prefix. It is an optional value. This is added to filter event activity.
   - **Suffix:** This value is to filter event notifications by suffix. It is an optional value. This is added to filter event activity.
6. In the **Event types** section, select one or more event types that you want to receive notifications for. If you are unsure of what event types to pick, then select the **All object create events** option.
7. In the **Destination** section, select **SNS Topic** as the event notification destination.

> **Note:**
>
> Before you can publish event notifications, you must grant the Amazon S3 the necessary permissions to call the relevant API. This is so that it can publish notifications to a Lambda function or an SNS topic.

8. After you select SNS topic as the event notification destination, select the SNS topic i.e. notify-topic from dropdown. This is the topic you created in Step 5: Create a notifications service subscription topic.

9. Select **Save changes**.

Step 7: Create a notifications service subscription

Where: Amazon SNS console

Every Amazon SNS topic has a set of subscriptions. Once a message is published to a topic, SNS handles distributing the message to all its subscribers. The subscribers can be AWS Lambda functions, HTTP(S) endpoints, email addresses and mobile phone numbers capable of receiving SMS messages.

Amazon SNS matches the topic to a list of subscribers who have subscribed to that topic and delivers the message to each of those subscribers.

1. Log in to Amazon SNS console.
2. In the left navigation pane, select **Subscriptions**.
3. Select **Create subscription** on the subscriptions page.
4. In the **Details** section of the **Create subscription** page, specify the following values.
   - **Topic ARN:** Paste the ARN value copied from previous step (Step 5: Create a notifications service subscription topic).
   - **Protocol:** HTTPS
   - **Endpoint:** Paste the endpoint value you copied while creating the live table feed in previous step (Step 4: Create and configure a live table feed to use notifications and copy the notification URL).
5. Expand the **Subscription filter policy** section to configure a filter policy. This step is optional.
6. Expand the **Redrive policy (dead-letter queue)** section to configure a dead-letter queue for the subscription. This step is optional.
7. Select **Create subscription**.

> **Note:**
>
> HTTP(S) endpoints, email addresses, and AWS resources in other AWS accounts require confirmation of the subscription before they can receive messages.

Step 8: Confirm that the endpoint can receive notifications

Where: Database Actions: Live Feeds page

1. Return to the Database Actions Live Feeds page and find the card for the live table feed you are configuring for a notification-based feed.
2. Click the **Actions** (three vertical dots) icon on the card, and select **Show Confirmation URL**.
3. In the **Confirmation URL** dialog box, click the link to confirm the URL. This does not close this dialog box. If the link is successful, a message is displayed that confirms the subscription is active.
4. Return to the **Confirmation URL** dialog box and select the Check only when the cloud store confirmation process is complete check box, and click **OK**.

Once you finish the above steps, any new files uploaded to the bucket will automatically be loaded into the live table feed table.

For more information on how to enable and configure event notifications using the Amazon S3 console, refer Enabling and configuring event notifications using the Amazon S3 console.

Creating a Notification-Based Live Table Feed using Microsoft Azure

A notification-based Live Table Feed is an interface between Oracle Cloud Infrastructure and a third-party cloud message queuing service such as Azure Event Grid.

The following section explains the procedure to generate automatic live feed messages using Microsoft (MS) Azure as the cloud storage. When there is an update in the container and the notification conditions are met, a log message is generated and displayed in the live feed in Oracle Cloud Infrastructure.

To create a notification-based live feed with Microsoft Azure as cloud storage you must:

- Step 1: Create a resource group in Microsoft Azure
- Step 2: Create a storage account in Microsoft Azure
- Step 3: Create Access Keys
- Step 4: Create a container
- Step 5: Add cloud storage using Microsoft Azure cloud store
- Step 6: Create and configure a live table feed to use notifications and copy the notification URL
- Step 7: Enable Event Resource Provider
- Step 8: Create Event subscription
- Step 9: Confirm that the endpoint can receive notifications

> **Tip:**
>
> To complete the steps above, you will need to alternate between Microsoft Azure portal and Oracle Database Actions pages. You may find it convenient to open the Microsoft Azure portal in one browser page or tab and Database Actions in another, so it is easy to move back and forth.

Step 1: Create a resource group in Microsoft Azure

Where: Microsoft Azure Portal

Resource groups are logical containers where you can manage Azure resources like storage accounts. Resource groups are created so you can deploy, update and delete them as a group. You can create a resource group by following these steps:

1. On the Azure portal, click the **Resource groups** button.
2. Select **Add**.
3. Enter the following values:
   - **Subscription:** Select your Azure subscription, such as Microsoft Azure Enterprise.
   - **Resource group:** Enter a new resource group name, such as resource-group.
   - **Region:** Select your location, such as US west.

4. Click **Review+create**.
5. Click **Create**. It takes a few seconds to create a resource group.

Step 2: Create a storage account in Microsoft Azure

Where: Microsoft Azure Portal

An Azure storage account contains all your storage data objects like blobs, tables, disks etc. You can create a storage account inside the resource group. It provides a unique namespace for your data. To create a storage account, do the following:

1. From the left portal menu, select **Storage accounts** to display a list of your storage accounts.
2. On the Storage accounts page, click the **Create** icon.
3. On the Basic tab, provide the following information for your storage account.
   - **Subscription:** Microsoft Azure Enterprise
   - **Resource group:** resource-group
   - **Storage account name:** teststorage
   - **Region:** Select your location, such as US west.
   - **Redundancy:** Locally-redundant storage (LRS)
4. You can select **Review+create** to accept the default options and proceed to validate the account.
5. After the validation passes, you can proceed to click on **Create storage** account. In case the validation fails, the portal indicates which settings must be modified.

Step 3: Create access Keys

Where: Microsoft Azure Portal

You must grant Microsoft Azure the permissions necessary to obtain access keys on your storage locations. The access keys specific to the storage account are generated automatically after the storage account is created in the previous step. The following steps describes the procedure to create access keys.

1. In **Security+Networking** , select **Access keys**. Your account access keys appear with the complete connection string for each key.
2. Select **Show keys** to show your access keys and connection string for each key and to copy values.
3. Copy the connection string value under key1. This value will be pasted in **Azure storage account access key** text field of next step (Step 5: Add cloud storage using Microsoft Azure cloud store).
4. Copy the storage account name i.e. teststorage and paste it in **Azure storage account name** text field of next step (Step 5: Add cloud storage using Microsoft Azure cloud store).
5. Test the credentials to see if it works or not.

Step 4: Create a container

Where: Microsoft Azure Portal

A container is a location (also known as buckets in Amazon S3 and OCI) which holds Azure Blob (Binary large object) storage. Follow these steps to create a container.

1. Navigate to your new storage account in the Azure portal.
2. In the left menu for the storage account, scroll to the **Data storage** section, then select **Containers**.
3. Click the **+Container** icon.
4. Enter the name for your new container. The container name must be lowercase, must start with a letter or number, and can include only letters, numbers, and the dash character.
5. Set the level of **Public Access Level** to Private. The default level is Private.
6. Select **Create** to create the container.

Step 5: Add cloud storage using Microsoft Azure cloud store

Where: Database Actions: Manage Cloud page

1. Click the **Manage Cloud Store** button at the top of the page to go to the Manage Cloud page. For further instructions on adding source files residing in cloud storage provided by Microsoft Azure cloud storage, refer to *Create an Microsoft Azure Cloud Storage Link* topic in Managing Connections section.

> **Note:**
>
> Paste the connection string value under key 1 of previous step Step 3: Create Access Keys in **Azure storage account access key** text field of **Add Cloud Storage** page. Also paste the storage account name generated in the previous step Step 3: Create Access Keys in **Azure storage account name** text field of **Add Cloud Storage** page.

Step 6: Create and configure a live table feed to use notifications and copy the notification URL

Where: Database Actions: Live Feeds page

The Live table feed object enables data to be loaded from Microsoft Azure cloud storage with no polling delay. This object creates an integration between Oracle Cloud Interface and Microsoft Azure.

You can configure a new or an existing live table feed to use notifications:

1. Go to the Database Actions Live Feeds page, as described in Feeding Data.
2. Create or edit a live table feed object, as described in Create a Live Table Feed Object or Edit a Live Table Feed Object. Select the **Enable for Notification** option
3. Click **Create** or **Save**.
4. Click the **Actions** (three vertical dots) icon on the card for your live feed, and select **Show Confirmation URL**.
5. In the **Notification URL** dialog box, click the **Copy** icon to copy the URL to the clipboard. You may want to copy it to a temporary file, so you can retrieve it later. You will use this URL in the subsequent step, (Step 8: Create Event subscription).

Step 7: Enable Event Resource Provider

Where: Microsoft Azure Portal

If this is the first time you are using Event Grid, you must enable Event Grid resource provider.

1. Select **Subscriptions** on the left menu.
2. Select the subscription you are using for Event Grid i.e. Microsoft Azure Enterprise.
3. On the left menu, under Settings, select **Resource Providers**.
4. Search **Microsoft.EventGrid**.
5. Select **Register**.

It takes a minute for the registration to finish.

Step 8: Create Event subscription

Where: Microsoft Azure Portal

You create an Event Subscription by configuring the subscription and specifying the endpoint that will receive the notifications.

1. Select the storage account you created in Step 2: Create a storage account in Microsoft Azure.
2. Select the **Events** icon in the left navigation pane.
3. Click on **+Event Subscription**.

The **Create Event Subscription** window appears.

1. Specify the following fields in **Event Subscription** details section:
   - **Name:** Eventssub. This is the name of the Event Subscription we create.
   - **Event Schema:** Event Grid Schema
2. Specify the following fields in **Topic Details** section:
   - **Topic Type:** Storage account
   - **System Topic Name:** eventtopic.
3. Specify the following fields in **Event Types** section:
   - **Event Type:** MicrosoftStorage.BlobCreated
4. Specify the following fields in **Endpoint Details** section:
   - **Endpoint Type:** Web Hook
   - **Endpoint:** Paste the Notification URL copied in Step 6: Create and configure a live table feed to use notifications and copy the notification URL.
5. Select **Create**.

This way Microsoft Azure creates a system topic first and then the Event Subscription for the topic.

Step 9: Confirm that the endpoint can receive notifications

Where: Database Actions: Live Feeds page

1. Return to the Database Actions Live Feeds page and find the card for the live table feed you are configuring for a notification-based feed as created in Step 6: Create and configure a live table feed to use notifications and copy the notification URL.
2. Click the **Actions** (three vertical dots) icon on the card, and select **Show Confirmation URL**.

3. In the **Confirmation URL** dialog box, click the link to confirm the URL. This does not close this dialog box. If the link is successful, a message is displayed that confirms the subscription is active.

> **Note:**
>
> The **Confirmation URL** link expires after a few minutes. You must make sure that you click the link before it expires.

4. Return to the **Confirmation URL** dialog box and select the **Check only when the cloud store confirmation process is complete** check box, and click **OK**.

Once you finish the above steps, upload a new file to the Microsoft Azure container you created in Step 4: Create a container.

1. Navigate to the container you created.
2. Select the **Container** to show a list of blobs it contains.
3. Select **Upload** button to open your local repository and browse the file you need to upload as a block blob.
4. Select the **Upload** button to upload the blob.
5. You can now view the new blob listed within the container.
6. Return to the Database Actions Live Feeds page and find the card for the live table feed you are configuring for a notification-based feed.
7. Click the **Actions** (three vertical dots) icon on the card, and select **Live table feed Run Details**.

You should be able to view logs for the blob uploaded to the Live Feed table from the Microsoft Azure storage in **Live table feed Run Details** window.

For more details on how to create a topic and subscription in Azure portal, refer to Azure Event Grid Notifications.

Send Email using Live Feed Tool

You can configure the Live Feed tool to send you email notifications when certain specific live feed events occur.

Prerequisite

1. Before subscribing to notifications, make sure that you have first created a live feed.
2. **Configure the mail service**:
   For the live feed tool to send notifications, you need to configure the Simple Mail Transfer Protocol (SMTP) Settings in the Data Studio Settings.

   Refer to the Send Email on Autonomous Database chapter for more details.

> **Note:**
>
> The Live Feed tool uses the UTL_SMTP package in the back end to provide an interface. While UTL_SMTP itself does not inherently support encryption like OAuth2, which is required by some providers (e.g., Microsoft 365), using a secure connection (SSL/TLS) can encrypt the communication between your application and the SMTP server. However, UTL_SMTP does not natively support OAuth2, which is becoming increasingly common for authentication with large email providers.

The following rules apply while configuration:

- The SMTP server port must be 25 or higher. The only ports likely to be used here are 587 (most common for modern setups, typically with StartTLS), 465 (Secure Sockets Layer) or 25 (no encryption).
- The SMTP server host name must not be blank.
- The E-mail address field must not be blank.
- Typically, clients will need to provide authentication credentials to access their SMTP server. Additionally, most setups will likely use StartTLS for encryption. However, the specific requirements can vary depending on how the company or provider has configured their system.

You can configure the email notifications in the following locations:

Livefeed page

Data Load Dashboard

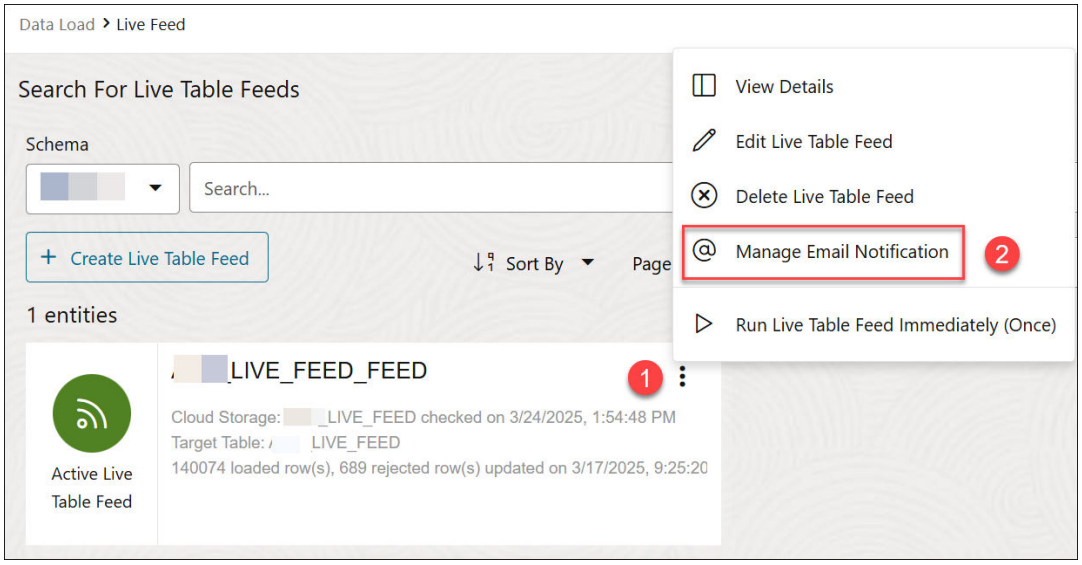
Catalog page

Configure Email Notifications on the Live Feed tool

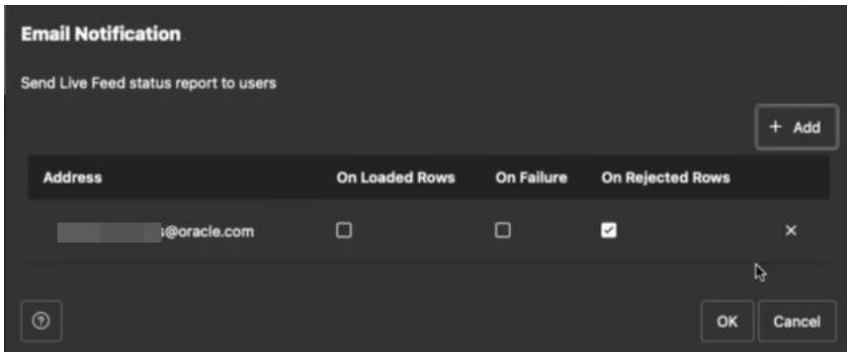
After you have created a Live Table Feed using the Live Feed tool, navigate to the Live Feed tool .

You will view the Live Table Feed card on the Live Feed tool page.

1. Click the **Actions** icon on the card and select **Manage Email Notification**.



2. On the Email Notification dialog, select **+Add** to add your email address where you will receive the notification.

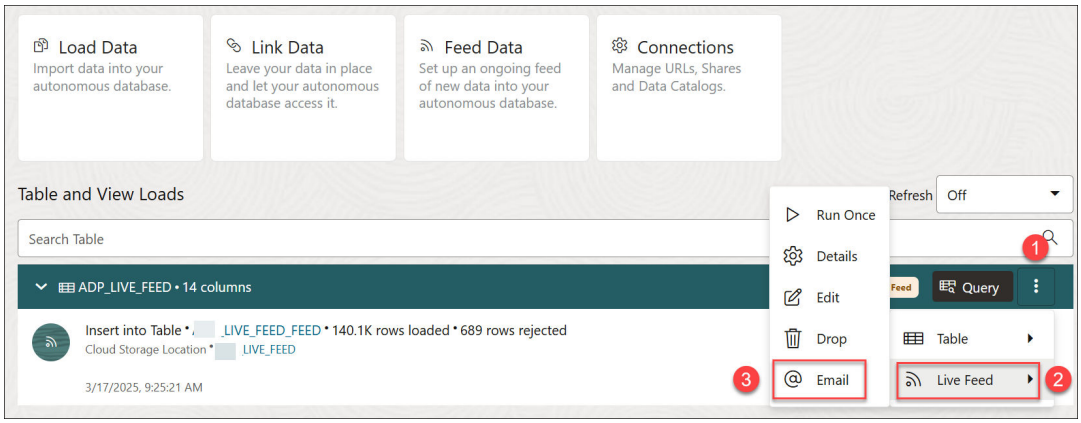


3. Enter the email address.
4. Select any of the available options to receive email notifications based on the following conditions:
   - **On Loaded Rows**: Select this option if you want to be notified in case the Live Feed successfully imports new data into your table.
   - **On Failure**: Select this option if you want to be notified in case the Live Feed fails to run due to an error. For example, if the storage location for your files is missing, or your access credentials are no longer valid.
   - **On Rejected Rows**: Select this option if you want to be notified in case the Live Feed encounters and rejects incorrect data. For instance, when there is a data type mismatch, such as attempting to import the word `Blue` into a column that must consist of only numbers.
5. Click **OK**.

Configure Email Notifications on the Data Load Dashboard

Once you have created a Live Feed, you will view the status of the feed on the Data Load Dashboard.

1. Click the **Actions** menu on the table header, click **Live Feed** and select **Email**.



2. On the Email Notification dialog, select **+Add** to add your email address where you will receive the notification.
3. Enter the email address.
4. Click **OK**.

Configure Email Notifications on the Catalog Tool

You can view the Live Feed entity on the Catalog page after you create it.

1. Select **Manage Email Notifications** the Live Feed entity.
2. **Continue with the wizard**: Progress to the next steps in the **Manage Email Notifications** wizard by following the same process you used previously.

After you have configured the email notifications, the subscriber with the email address specified in the Email Management notification dialog will now receive notifications according to the settings you configure during the live feed creation process.

DBMS_LIVE_FEED Package Reference

This chapter provides information about the packages you use with the Data Load Tool in Data Studio. The `DBMS_LIVE_FEED` topic also covers the procedures included in the `DBMS_LIVE_FEED` package.

Topics:

Summary of `DBMS_LIVE_FEED` Subprograms

- `DBMS_LIVE_FEED` Procedures
- Summary of DBMS_LIVE_FEED Subprograms
  The `DBMS_LIVE_FEED` package simplifies common operations like running a live table feed on demand, on a schedule, or as the result of a notification driven updates to a table based on new objects in object store buckets.

Summary of DBMS_LIVE_FEED Subprograms

The `DBMS_LIVE_FEED` package simplifies common operations like running a live table feed on demand, on a schedule, or as the result of a notification driven updates to a table based on new objects in object store buckets.

The following table lists the `DBMS_LIVE_FEED` subprograms and briefly describes them.

DBMS_LIVE_FEED Package Subprograms

Subprogram	Description
create_for_storage_link	This procedure creates a live feed for storage link.
create_for_directory	This procedure creates a live feed for directory.
create_for_url	This procedure creates a live feed from URL.
modify_live_feed	This procedure modifies a live feed.
drop_live_feed	This procedure drops a live feed.
load_new_content	This procedure loads new content in an existing Live Feed.
get_notification_key	This procedure retrieves Notification Key from a Live Feed.
get_confirmation_url	This procedure receives confirmation URL from a Live feed.
get_notification_state	This procedure receives notification state from a Live Feed.

Create For Storage Link Procedure

This procedure creates a live table feed from a cloud storage link. A cloud storage link is a named association between an OCI bucket URI, and a local credential name.

Syntax

```
procedure create_for_storage_link(live_feed_name     IN VARCHAR2,
                                  table_name         IN VARCHAR2,
                                  storage_link_name  IN VARCHAR2,
                                  schema             IN VARCHAR2
DEFAULT NULL,
                                  table_schema       IN VARCHAR2
DEFAULT NULL,
                                  column_list        IN CLOB
DEFAULT NULL,
                                  object_type        IN VARCHAR2
DEFAULT NULL,
                                  object_format      IN VARCHAR2
DEFAULT NULL,
                                  object_filter      IN VARCHAR2
DEFAULT NULL,
                                  object_filter_type IN VARCHAR2
DEFAULT NULL,
                                  scheduled          IN BOOLEAN
DEFAULT NULL,
                                  scheduler_interval IN VARCHAR2
DEFAULT NULL,
                                  notifications      IN BOOLEAN
DEFAULT NULL,
                                  job_class          IN VARCHAR2
```

```
DEFAULT NULL,
                                                start_date          IN TIMESTAMP
WITH TIME ZONE DEFAULT NULL,
                                                end_date            IN TIMESTAMP
WITH TIME ZONE DEFAULT NULL);
```

DBMS_ LIVE_FEED Parameters

If you are accessing `DBMS_LIVE_FEED` procedures, use the following parameters.

Parameter	Description
`live_feed_name`	The name of the Live feed which you want to create.
`storage_link_name`	The name of the cloud storage link. The name of the link should follow standard Oracle naming conventions.
`table_name`	The name of the Autonomous Database target table into which the live feed will load data from Cloud Object Storage.
`Object_filter`	The name of the target table that data from the live feed will be loaded into in your Autonomous Database instance to access the Cloud Object Storage.
`object_filter_type`	The regular expression to limit the live table feed to only those files in the bucket that match the expression. . It could be a regular expression or a glob, depending on the `object_filter_type` parameter.
`scheduled`	The default is `TRUE`. If `TRUE`, you can set up a schedule for running the live table feed object.
`notifications`	The default is `FALSE`. When `TRUE`, the Live Feed tool allows your livefeed to be notified by object storage that there are new files to be loaded.
`schema`	The name of the schema. The name of the schema of the livefeed. Only the current schema is supported at the moment.
`table_schema`	The schema of the target table.
`object_type`	The type of the object. The type of files you can load are CSV, JSON and Parquet.
`object_format`	This is one of the SQL Loader options. It accepts format received by `DBMS_CLOUD.COPY_DATA` procedure.
`scheduler_interval`	This parameter displays the interval at which the livefeed runs using the `DBMS_SCHEDULER` syntax.
`job_class`	The Scheduler job class. The values are `TPURGENT`, `TP`, `HIGH`, `MEDIUM` and `LOW`.
`start_date`	The starting date for the live feed job.
`end_date`	The ending date of the Live feed job.

> **Note:**
>
> The parameters of all the procedures described below are listed in the above table.

Example

In this example, a live feed named `MYLIVEFEED` is created on the given URL.

```
SQL> BEGIN
   dbms_live_feed.create_for_storage_link(
     live_feed_name => 'MYLIVEFEED',
     storage_link_name => 'DATATOOLS_LF_BUCKET',
     table_name => 'MALTESE',
     object_filter => 'fndcalday?.csv',
     object_filter_type => 'GLOB',
     scheduled => false,
     notifications => false);
end;
/;
PL/SQL procedure successfully completed.
```

Create For Directory Procedure

This procedure creates a live table feed from a directory.

Syntax

```
procedure create_for_directory(live_feed_name     IN VARCHAR2,
                               table_name         IN VARCHAR2,
                               directory_name     IN VARCHAR2,
                               schema             IN VARCHAR2 DEFAULT NULL,
                               table_schema       IN VARCHAR2 DEFAULT NULL,
                               column_list        IN CLOB     DEFAULT NULL,
                               object_type        IN VARCHAR2 DEFAULT NULL,
                               object_format      IN VARCHAR2 DEFAULT NULL,
                               object_filter      IN VARCHAR2 DEFAULT NULL,
                               object_filter_type IN VARCHAR2 DEFAULT NULL,
                               scheduled          IN BOOLEAN  DEFAULT NULL,
                               scheduler_interval IN VARCHAR2 DEFAULT NULL,
                               notifications      IN BOOLEAN  DEFAULT NULL,
                               job_class          IN VARCHAR2 DEFAULT NULL,
                               start_date         IN TIMESTAMP WITH TIME
ZONE DEFAULT NULL,
                               end_date           IN TIMESTAMP WITH TIME
ZONE DEFAULT NULL);
```

Create For URL Procedure

This procedure creates a live table feed from a URL.

Syntax

```
 procedure create_for_url(live_feed_name     IN VARCHAR2,
                          table_name         IN VARCHAR2,
                          url                IN VARCHAR2,
                          credential_name    IN VARCHAR2,
                          schema             IN VARCHAR2 DEFAULT NULL,
                          table_schema       IN VARCHAR2 DEFAULT NULL,
                          column_list        IN CLOB     DEFAULT NULL,
```

```
                            object_type        IN VARCHAR2 DEFAULT NULL,
                            object_format      IN VARCHAR2 DEFAULT NULL,
                            object_filter      IN VARCHAR2 DEFAULT NULL,
                            object_filter_type IN VARCHAR2 DEFAULT NULL,
                            scheduled          IN BOOLEAN  DEFAULT NULL,
                            scheduler_interval IN VARCHAR2 DEFAULT NULL,
                            notifications      IN BOOLEAN  DEFAULT NULL,
                            job_class          IN VARCHAR2 DEFAULT NULL,
                            start_date         IN TIMESTAMP WITH TIME ZONE
DEFAULT NULL,
                            end_date           IN TIMESTAMP WITH TIME ZONE
DEFAULT NULL);
```

Modify Live Feed Procedure

This procedure modifies a live table feed.

Syntax

```
procedure modify_live_feed(live_feed_name     IN VARCHAR2,
                           schema               IN VARCHAR2 DEFAULT NULL,
                           scheduled            IN BOOLEAN  DEFAULT NULL,
                           scheduler_interval IN VARCHAR2 DEFAULT NULL,
                           notifications      IN BOOLEAN  DEFAULT NULL,
                           job_class          IN VARCHAR2 DEFAULT NULL,
                           start_date         IN TIMESTAMP WITH TIME ZONE
DEFAULT NULL,
                           end_date           IN TIMESTAMP WITH TIME ZONE
DEFAULT NULL);
```

Example

In this example, a live feed named `MYLIVEFEED` is modified.

```
begin
   dbms_live_feed.modify_live_feed(
     live_feed_name => 'MYLIVEFEED',
     scheduled => true,
     scheduler_interval => 'FREQ=daily;INTERVAL=1',
     notifications => true);
end;
/
```

Drop Live Feed Procedure

This procedure drops a live table feed.

Syntax

```
procedure drop_live_feed(live_feed_name     IN VARCHAR2,
                                 schema             IN VARCHAR2 DEFAULT
NULL);
```

Example

In this example, a live feed named `MYLIVEFEED` is dropped.

```
begin
   dbms_live_feed.drop_live_feed(live_feed_name => 'MYLIVEFEED');
end;
/
```

Load New Content Procedure

This procedure loads new content in the feed.

Syntax

```
 procedure load_new_content(live_feed_name IN VARCHAR2,
                                    schema         IN VARCHAR2 DEFAULT NULL);
```

Get Notification Key Procedure

This procedure receives Live Table Feed Notification Key. It is used for a live feed with notifications enabled to construct a notification URL to provide a cloud service. Follow the instructions in the Creating a Notification-Based Live Table Feed chapter to create a notification based live feed.

Syntax

```
function get_notification_key(live_feed_name IN VARCHAR2,
                                      schema         IN VARCHAR2 DEFAULT
NULL)
    return VARCHAR2;
```

Get Confirmation URL

This procedure receives confirmation URL which verifies that the endpoint can receive notifications.

You must visit this URL to enable notifications you receive from a cloud service. It is not possible to confirm the enabling of notifications automatically due to database firewall restrictions. Click this URL to enable notifications else you will not receive any notifications.

Syntax

```
function get_confirmation_url(live_feed_name IN VARCHAR2,
                                      schema         IN VARCHAR2 DEFAULT
NULL)
    return VARCHAR2;
```

Get Notification State

This procedure receives the state of notification of the Live Feed job execution.

Syntax

```
 function get_notification_state(live_feed_name IN VARCHAR2,
                                        schema         IN VARCHAR2 DEFAULT
```

```
NULL)
    return VARCHAR2;
```

Augment Data using Table AI Assist Tool

The Data Studio suite of tools now features an AI-powered Table Assist Tool to effortlessly enhance your local data tables with the power of AI. You can use natural language prompts to augment and correct your information with this tool.

Topic

- The Table AI Assist Tool
  The **Table AI Assist Tool** enables you to add, remove, and rename columns in a table using AI assistance. It enables you to augment or correct data found in tables in your local schema using natural language AI prompts. For example, prepare data for analytics by adding columns for days of the week or reporting quarters or deriving the distance between two sets of geographical co-ordinates, and more.

The Table AI Assist Tool

The **Table AI Assist Tool** enables you to add, remove, and rename columns in a table using AI assistance. It enables you to augment or correct data found in tables in your local schema using natural language AI prompts. For example, prepare data for analytics by adding columns for days of the week or reporting quarters or deriving the distance between two sets of geographical co-ordinates, and more.

You can add columns for day, month, quarter and year using data in a date column or add a distance column from two columns with geographical co-ordinates.

The **Table AI Assist** tool enables you to prepare and enhance data for analytics, for example by deriving separate columns from a single date column for time-based reporting, or by calculating the distance between two geographical co-ordinates and adding that as a new column. The Table AI Assist tool works by using your configured AI profile to generate SQL to prepare your data. The output of the tool can then be a new view on top of your source table, or a new table.

Prerequisite:

See Data Studio Settings to set and configure your AI profile.

The following topics describe the **Table AI Assist** page and how to use it:

- Prepare Data Using Table AI Assist Tool
  Data Augmentation helps you to add data to your source tables from your target tables. The Table AI Assist allows you to add, rename, and remove columns in a table using natural language prompts.
- View Table Entity Details
  You can view the entity details of the selected entity by just clicking the **Actions** icon on the entity. This displays a list of icons that lets you view the entity's details. The icons vary from entity to entity.

Prepare Data Using Table AI Assist Tool

Data Augmentation helps you to add data to your source tables from your target tables. The Table AI Assist allows you to add, rename, and remove columns in a table using natural language prompts.

The **Table AI Assist** tool uses an AI service to generate SQL. You can choose to use the generated SQL to alter the table, create a view, or create a SELECT statement. It enables you to try suggested prompts generated by Artificial Intelligence (AI) and receive a query that is run where you can preview the data.

What is a Recipe?

A recipe is a set of steps. Each step lets you add, replace, remove and rename columns without making any changes to your base table. You add as many steps as you want to a recipe. You can save a recipe to your schema or export it as JSON to a file. You can return back to your saved recipe and keep working on it.

Different modes of Recipe
The following are different modes of a recipe:

- Create or Replace View
- Create a new table
- Alter table

Once you are satisfied with a recipe you can use it to Create or replace a View, Create a new Table or Alter the Table.

You can choose how to use the recipe at any time. The choices are different modes of recipe.

Let's say you have a table with four columns, and then add two new columns that are derived from the original data. The **Table AI Assist** tool can then:

- Alter the table to add the two new columns.
- Create either a new table, or a view on the table, with any of the four original columns and the two new columns.

Consider a table with `EMP` details. The table contains columns such as `HIREDATE`, `ENAME`, `JOB`, `MGR`, `SAL`, `COMM` and `DEPTNO`.

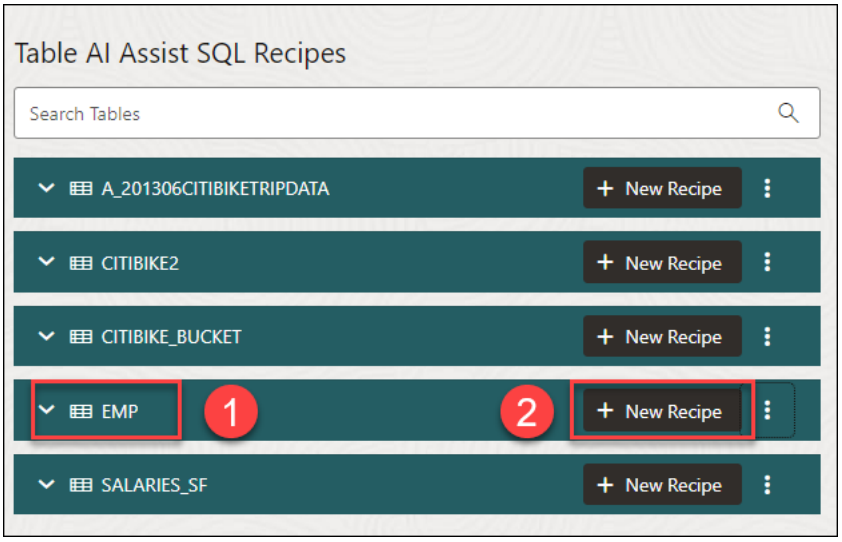
Using Table AI Assist, you can use natural prompts such as:

- add month in format year-month from `order_date`
- add year from `order_date`

The **Table AI Assist** tool generates SQL expressions for each prompt and gathers all changes into a recipe.

The following article demonstrates augmenting data using the **Table AI Assist** menu.

1. **Select the table to be modified.**
   a. From Launchpad, select Table AI Assist menu from the Data Studio suite of tools.
   b. On the **Table AI Assist** page, you can either search for the existing table from the search field at the top of the page or view it on the list of tables. In this example, let us select the ***EMP*** table.
2. **Create a new Recipe.**
   a. Click **+ New Recipe** to create a new recipe.



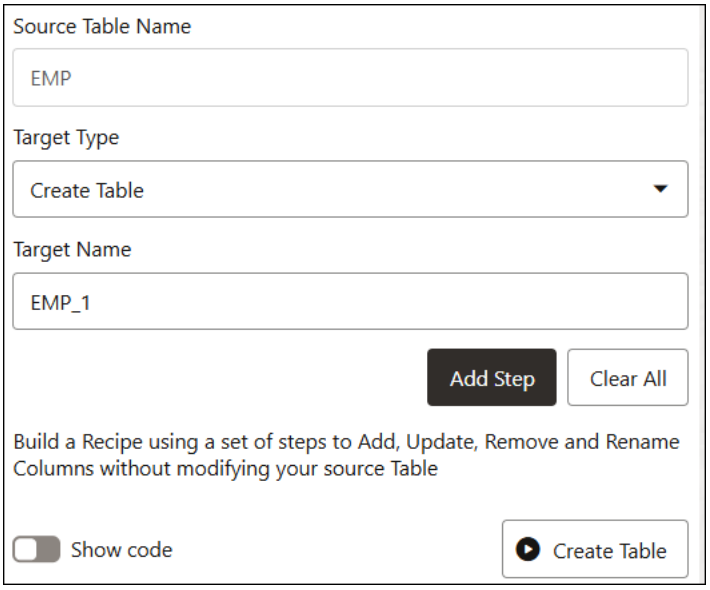
You can build a Recipe using a set of steps to Add, Update, Remove and Rename Columns without modifying your source Table.

b. **Select the Target Type and Target Name for viewing the changes you make to the source data.**
On the right panel of the Table AI Assist page, specify the following field values:

- **Source Table Name**: This is the name of the source table. In this example, it is *EMP*.
- **Target Type**: You can select one of the following options:
  - **Create View**: This option creates a view using steps in the recipe and updates the column values using column expressions in the view. Views contain only selected columns and expressions. Views do not store data.
  - **Create Table**: This option creates a new table using steps in the recipe. Data is stored in all columns, including columns added by using the recipe. It stores the updated column values.
  - **Alter Table**: This option adds, removes, and renames columns in the source table and stores the updated column values using steps in the recipe. The new columns are added as virtual columns using expressions (they do not store data).
  - **Query**: This option creates a query using steps in the recipe.

  In this example, you will **Create Table**.
- **Target Name**: Enter the name of the newly created table or view. It is a table or a view depends on the selection in **Target Type** drop-down field.

  In this example, you will view *EMP_1*.



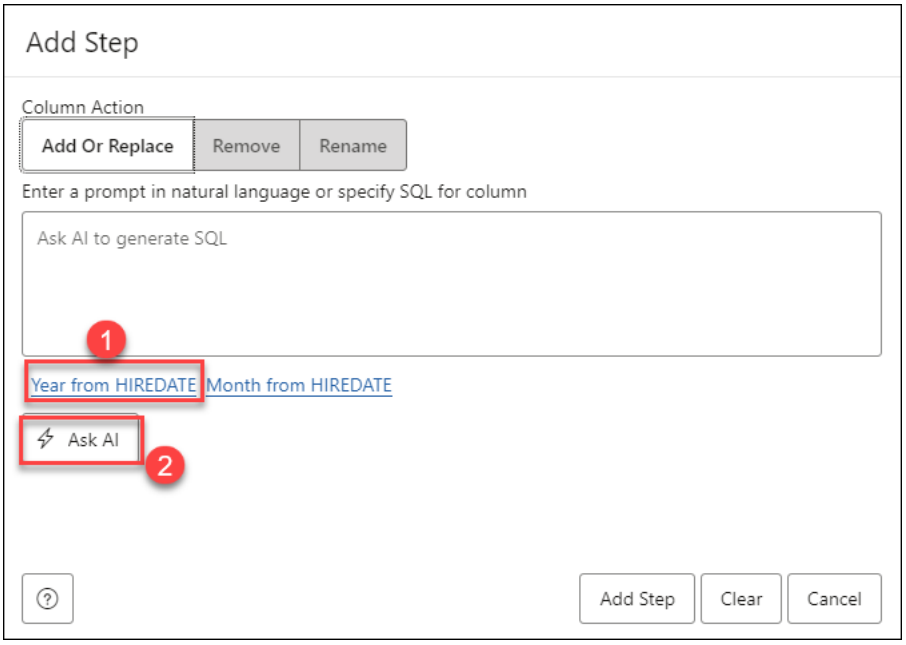
3. **Add Steps to build the recipe that is comprised of various column actions.**

   a. Click **Add Step** to update the source tabular data.

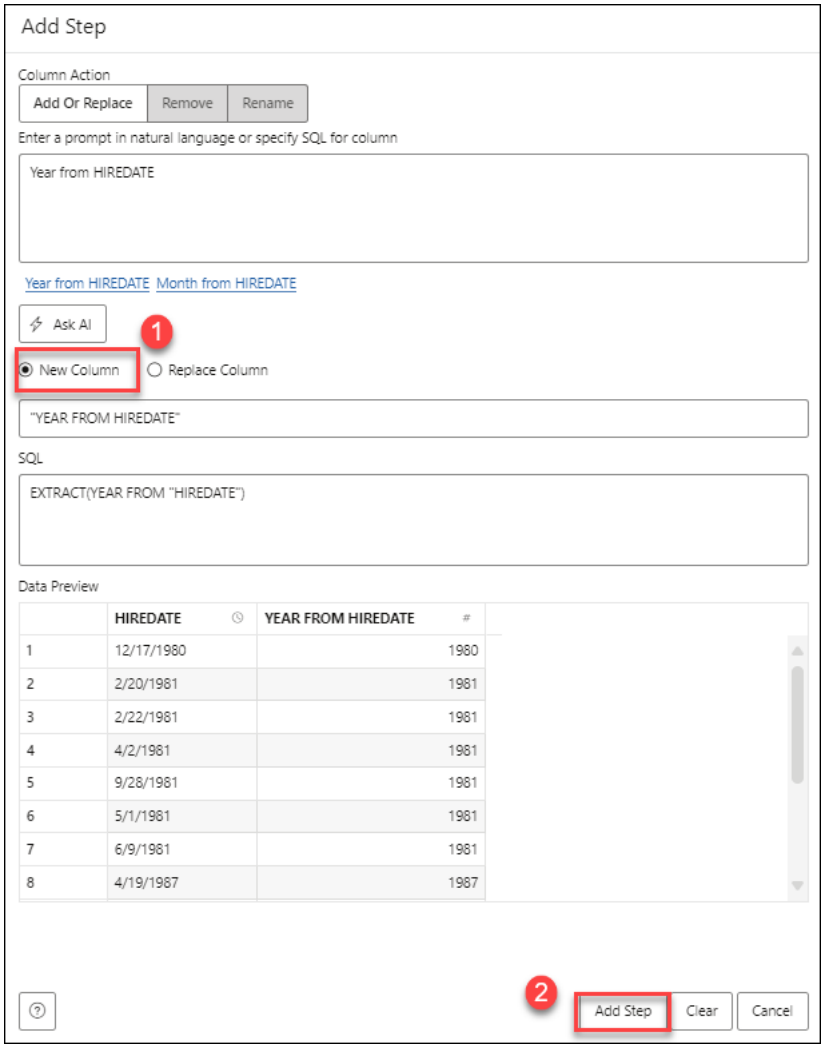
   b. Specify the following fields in the Add Step dialog box:
   On the Column Action, you can select one of the following available actions:

   - **Add or Replace**: You can add or replace the data in the source column based on the SQL code the tool generates in the prompt field. See Add a Column or Replace a Column. For example, if you replace `SALES_DATE` with `YEAR`, (assume `SALES_DATE` as a date data type) with prompt such, you will get a `SALE_DATE` column with years.
   - **Remove**: You can remove a column from the source data. See Remove a Column.
   - **Rename**: You can rename a source column. See Rename a Column.

   The fields generated when you add steps varies on the column action you select.



- Select **Year from `HIREDATE`**.
- Click **Ask AI**.
- Click **New Column** to create a new column and store the **Year from `HIREDATE`** value.

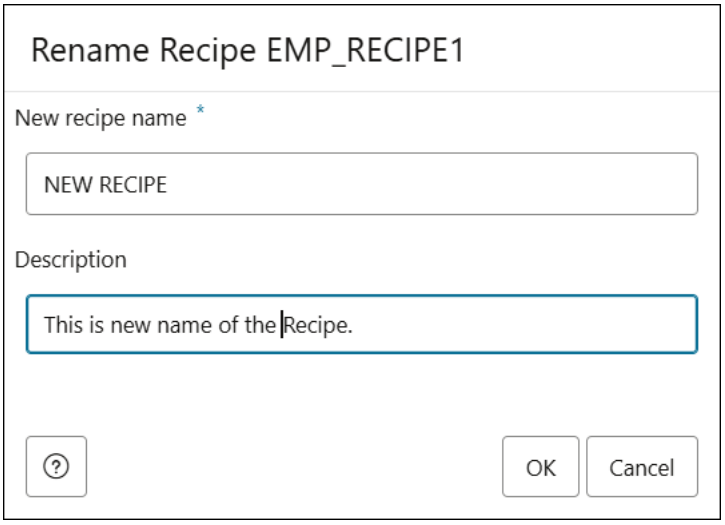


- Click **Add Step** to create a recipe.

4. **Save Recipe**.

   a. Click **Save Recipe** on the left panel of the Table AI assist page to save this recipe.

   b. Click the default Recipe name besides the **Save Recipe** to rename the Recipe. On clicking the Recipe name, you will view a **Rename Recipe** dialog.



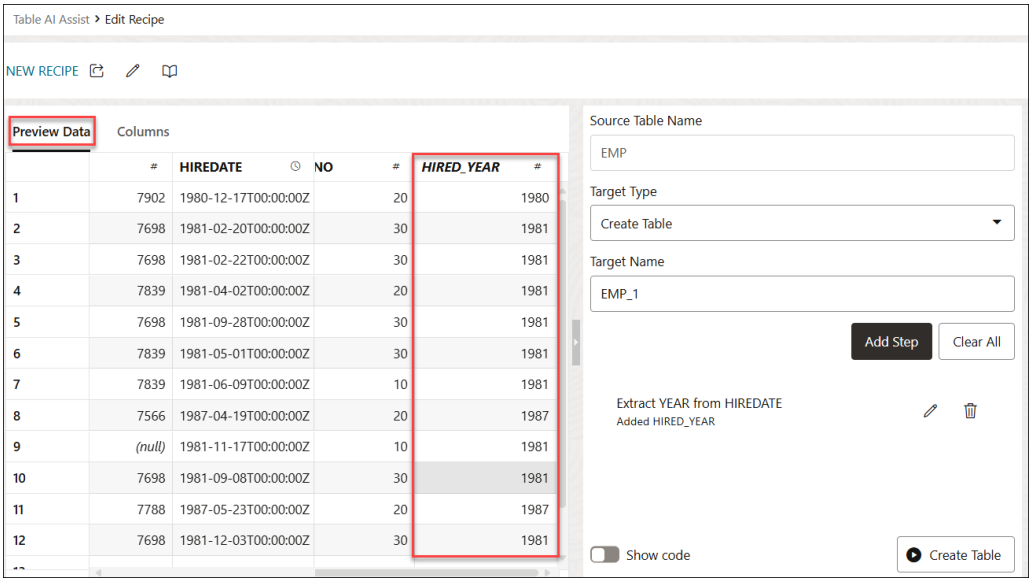
Specify the following field values on the **Rename Recipe** dialog:

- **New recipe name**: Enter the recipe's name that you created. For example, *NEW RECIPE*.
- **Description**: Enter any description. This field is optional.

5. **View the results**

   a. You can view the newly added recipe in the main recipe panel on the Table AI Assist page.

   b. You can progressively keep adding steps, modifying the source data, storing it on the target table or target view and view the updated data in the **Preview Data** tab.



You can view the newly added column header in *italics*.

6. **Create a new target table, a new target view or Alter the target table with modified column source data.**

   a. After you have modified the source data, you can create a new table, create a new view or Alter table based on the option you select in the **Target Type** drop-down.

b. Select **Create Table**, **Create View** or **Alter Table** on the side panel of the Table AI Assist page based on the **Target Type** you select.
The tool creates the target data upon confirmation.

c. You will receive a successful notification message that says the creation of the target type is successful.

After you have created the recipe, you can view it under the **Table AI Assist SQL Recipes** on the Table AI Assist page.

Edit Recipe

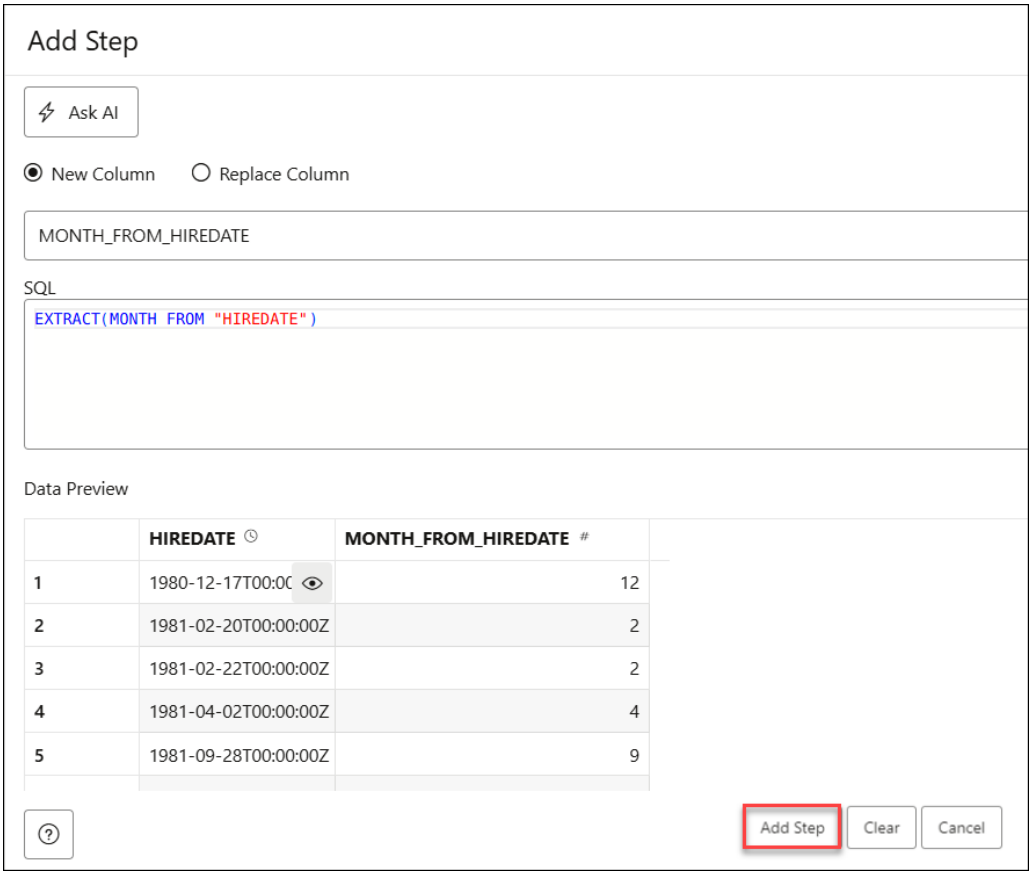
You can edit an existing recipe from the Table AI Assist tool.

1. On the Table AI Assist page, click on the **Edit Recipe** (pencil) icon besides the recipe name. This opens the Edit Recipe page.
2. You can add steps or delete the existing steps to edit the existing recipe.
Let's perform another operation of adding a new column that consists of "month" extracted from the hire date.
   - Click **Add Step**. In the **Enter a prompt in natural language or specify SQL for column** text field, provide some natural language prompt of what you want to do such as

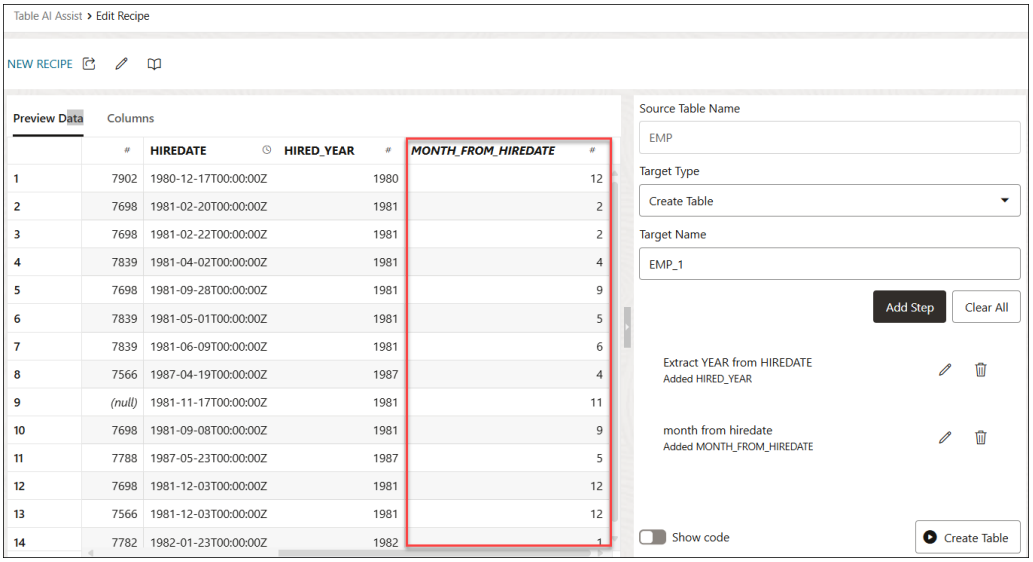
     ```
     month from hiredate
     ```

   - Click **Ask AI**.

   - The SQL expression that was used to create this column is displayed in the **SQL** field.



Scroll to the right of the table to view the newly added ***MONTH_FROM_HIREDATE*** column is displayed in the **Preview Data** section.



3. Click **Save Recipe** to save the updated recipe.

Export Recipe

You can export the specific recipe.

1. On the **Edit Recipe** page.
2. Click the Export Recipe icon besides the Recipe name.
3. Select the **Export** icon on the to generate the JSON file for download.

Load or Import Recipe

You can load or import recipe.

1. Click **Load Recipe** on the Edit Recipe page. Selecting Load Recipe opens a **Load Recipe** Dialog which displays the following options:
   - Load
     - Select **Load** to load an existing recipe.

     - Specify the following field values:
       * **Table**: Select the table from the drop-down field you want to load the recipe from.
       * **Recipe**: Select the recipe you want to load from the drop-down.
       * Under Steps, you can view the Steps involved in creating the recipe.
       * Click **OK** to load the recipe.

- Import
  - Select **Import** to import a recipe file you download. This file is in JSON format.

  - Drop an existing Table AI Assist Recipe file (in JSON format) you have exported.

  - Click **OK** to import the recipe. Click **Cancel** to cancel the ongoing process of loading or importing.

  You can share a recipe with another user by importing it. For example, if you and another user both load the same table, and you use the Table AI Assist tool to set up a bunch of new and interesting columns, you can import and share the recipe with the other user so they can view the modified data.

- Add a Column
  You can view the following fields when you select **Add or Replace** from Column Action.
- Replace a Column
  You can view the following fields when you select **Add or Replace** from Column Action.
- Remove a Column
  You can view the following fields when you select **Remove** from the Column Action field.

- Rename a Column
  You can view the following fields when you select **Rename** from the Column Action field.
- View Statistical Details about the Table you Load after you Create a Recipe
  After you have created a recipe using the Table AI Assist tool, you can view additional information such as statistics about the table you create. You can generate statistics that measure the data distribution and storage characteristics of the table.

Add a Column

You can view the following fields when you select **Add or Replace** from Column Action.

1. **Enter a prompt in natural language or specify SQL for column**: Select any one of the prompts suggested by the tool.

   > **Note:**
   >
   > The Data Studio suite of tools uses a Large Language Model (LLM) when using prompts to generate SQL.

2. Click **Ask AI**.
   The **Ask AI** button sends the prompt, along with the table metadata (not data) to the Large Language Model (LLM) that is selected in your Data Studio settings. The LLM then attempts to generate SQL that will perform the request of the prompt.
3. Select **New Column** to create a new column that consists of the updated new column. After you select **New Column**, you can view a text box where you specify the name of the new column.

   The SQL textbox displays the SQL code the tool generates to display the action performed by the column action you selected in the previous step.
4. Under **Data Preview**, you can view the existing old column and the generated new column.

After you have decided the column action, click **Add Step** to add this step in the main recipe panel.

Clicking **Add Step** closes the Add Step dialog and opens the Table AI assist page.

Replace a Column

You can view the following fields when you select **Add or Replace** from Column Action.

1. **Enter a prompt in natural language or specify SQL for column**: Select any one of the prompts suggested by the tool.
2. Click **Ask AI**.
   The **Ask AI** button to send the prompt with table metadata and asks the Large Language Model (LLM) to generate a SQL.
3. Click **Replace Column**.
   Select a column you want to replace from the **Column Name to Replace** drop-down field.

   The SQL textbox displays the equivalent SQL code the tool generates to display the action performed by the column action you selected in the previous step.
4. Under **Data Preview**, you can view the existing old column and the updated new column.
5. Save the newly created recipe.

> **Note:**
>
> By default, the **Table AI Assist** tool does not replace the original source table. It only affects the new view or table that is generated by the **Table AI Assist** tool.

After you have decided the column action, click **Add Step** to add this step in the main recipe panel.

Clicking **Add Step** closes the Add Step dialog and opens the Table AI assist page.

Remove a Column

You can view the following fields when you select **Remove** from the Column Action field.

Select the column which you want to remove from the **Column Name** to remove drop-down.

After you have decided the column action, click **Add Step** to add this step in the main recipe panel.

Clicking **Add Step** closes the Add Step dialog and opens the Table AI assist page.

> **Note:**
>
> By default, the **Table AI Assist** tool does not replace the original source table. It only affects the new view or table that is generated by the **Table AI Assist** tool.

Rename a Column

You can view the following fields when you select **Rename** from the Column Action field.

1. Select the column name you want to change the name of from the **Source Column Name** drop-down.
2. Enter the new name for the column you want to use.
3. After you have decided the column action, click **Add Step** to add this step in the main recipe panel.
4. Clicking **Add Step** closes the Add Step dialog and opens the Table AI assist page.

View Statistical Details about the Table you Load after you Create a Recipe

After you have created a recipe using the Table AI Assist tool, you can view additional information such as statistics about the table you create. You can generate statistics that measure the data distribution and storage characteristics of the table.

1. Select the table whose details you want to view.
   a. On the Table AI Assist page, you can either search for the existing table from the search field at the top of the page or view it on the list of tables.
   b. Click **Edit Recipe** on any of the recipes that were generated from the table.
2. View information about the tabular data
   a. You can preview the tabular data.
   b. Click **Columns** tab to view the following information about the table:

- **Table Size (Bytes)**: Specifies the size of the table in bytes.
- **Number of Rows**: Displays the number of rows in the table.
- **Number of Columns**: Displays the number of columns in the table.
- **Compressed Size**: Displays the size of compressed table in bytes.
- **Statistics Gathered on**: Displays date and time of last statistics gathered.

c. Click **Gather Statistics** to collect statistics periodically for tables where the statistics become stale over time because of changing data volumes or changes in column values.

3. **Column Statistics**:

- Number of distinct values (NDV) in column
- Number of nulls in column
- Data distribution (histogram)

The above information is displayed in the statistics details of the table.

View Table Entity Details

You can view the entity details of the selected entity by just clicking the **Actions** icon on the entity. This displays a list of icons that lets you view the entity's details. The icons vary from entity to entity.

On the **Table AI Assist** page, click the Action icon on the table header to view the details of a table. You can view the following options:

- **View Details**: Select **View Details** to view details about the table. Refer to Viewing Entity Details for more detailed information.
- **Gather Statistics**: Select this option to display new statistics after you modify the table's structure. Refer to Gathering Statistics for Tables for more detailed information.
- **Add to Share**: Select this option to share the table. Refer to Provide Share for more detailed information.
- **Register to Cloud Link**: Select this option to register the table for remote access for a selected audience you define. See Registering Cloud Links to Access Data section for more information.
- **Publish to Marketplace**: Select this option to publish the selected table to Data Marketplace. Refer to Publish Listings to Marketplace for more detailed information.
- **Create Analytic View**: Select this option to create an Analytic View from the selected associated table. See Creating Analytic Views.
- **Query**: Select this option to analyze the selected table. See The Data Analysis Tool for more detailed information.
- **Export Data to Cloud**: Select Export Data to Cloud to export data to a cloud object store.
- **Edit**: Select **Edit** to edit the properties of the table. Refer to Editing Tables for more information.
- **Drop**: Select **Drop** to delete the table.

Transform Data Using Data Studio

Data Transforms is an easy-to-use graphical user interface that you can use to design graphical data transformations for data integration with Autonomous Database.

- The Data Transforms Page
  Data Transforms allows you to design data transformations in the form of data loads, data flows, and workflows, without requiring you to write any code.

The Data Transforms Page

Data Transforms allows you to design data transformations in the form of data loads, data flows, and workflows, without requiring you to write any code.

Data loads provide a convenient way of loading data into Autonomous Database, data flows define how the data is moved and transformed between different systems, while the workflows define the sequence in which the data flows are executed.

After your data flows and workflows are ready, you can execute the mappings immediately or schedule to execute them at a later time. Oracle Data Transforms run-time agent orchestrates the execution of jobs. On execution, Oracle Data Transforms generates the code for you.

You can launch Data Transforms in any of the following ways:

- **Oracle Cloud Marketplace:** Create a Data Transforms instance from Oracle Cloud Marketplace. Data Transforms is available as a separate listing on Marketplace called Data Integrator: Web Edition.
- **Database Actions Data Studio:** Navigate to Database Actions Data Studio Page, and click **Data Transforms** in the Database Actions page.
  If you have already registered a Data Transforms instance from OCI Marketplace with the Autonomous Database, the **Data Transforms** card on the Database Actions page will continue to take you to your Marketplace instance.

> **Note:**
>
> If you do not see the Data Transforms card then your database user is missing the required DATA_TRANSFORM_USER role.

Access to the standard set of Data Transforms features may depend on where you launch Data Transforms from. In this documentation, certain topics could include any of the following badges to indicate features that may or may not be available for use:

- APPLIES TO: ● Data Transforms that is available as a separate listing on Marketplace called Data Integrator: Web Edition.
- APPLIES TO: ● Data Transforms instance that is registered with Autonomous Database.
- APPLIES TO: ● Data Transforms that is part of the suite of data tools built into Oracle Autonomous Database.

Topics

- Access Oracle Data Transforms From Data Studio
- Data Transforms Notes
- Work with Connections
  Connections help you to connect Data Transforms to various technologies reachable from your OCI network.
- Create and Run Data Loads
  A data load allows you to load multiple data entities from a source connection to a target connection.

- Work with Data Entities
  A Data Entity is a tabular representation of a data structure.
- Work with Projects
  A project is the top-level container, which can include multiple folders to organize your data flows or work flows into logical groups.
- About Data Flows
  A data flow defines how the data is moved and transformed between different systems.
- Schedule Data Flows or Workflows
  You can schedule workflows and data flows to run at specified time interval.
- Monitor Status of Data Loads, Data Flows, and Workflows
  When you run a data load, data flow, or workflow Oracle Data Transforms runs jobs in the background to complete the request. You can view the status of the job in the panel on the bottom right of the Data Load Details, the Data Flow Editor, and the Workflow Editor page.
- Introduction to Workflows
  A workflow is made up of multiple flows organized in a sequence in which they must be executed.
- Create and Use Variables
  A variable is an object that stores a single value, which can be a string, a number or a date.
- Use Machine Learning (ML) Models
  Data Transforms supports the use of ML Model in a data flow. Learn how to create and use Machine Learning (ML) Models in data flows.
- Create and Manage Jobs
  When you execute a data load, data flow or workflow Oracle Data Transforms creates a job to complete the process in the background.
- Export and Import Objects
  You can move Data Transforms objects between environments. You require an Object Storage connection to store the exported file. You then need to use the same Object Storage connection to import the objects.
- Reference
  Get additional information about using Oracle Data Tranforms on an Autonomous Database.

Access Oracle Data Transforms From Data Studio

APPLIES TO: ✔ Data Transforms that is part of the suite of data tools built into Oracle Autonomous Database.

Data Transforms combines all the elements of data integration - data movement, data synchronization, data quality, and data management to ensure that information is timely, accurate, and consistent across complex systems.

To use the Data Transforms tool you must access Database Actions as the ADMIN user or have the DATA_TRANSFORM_USER role assigned. See Manage User Profiles with Autonomous Database for information on granting roles.

To access the Data Transforms tool:

1. Login as an ADMIN user or a user with the DATA_TRANSFORM_USER role assigned.
2. Click **Data Transforms** in the Database Actions page, or click the Selector icon and select **Data Transforms** from the Data Studio menu in the navigation pane.

> **Note:**
>
> Data Transforms is also available as a separate listing on OCI Marketplace. If you have already registered a Data Transforms instance from OCI Marketplace with the Autonomous Database, the Data Transforms card on the Database Actions page will continue to take you to your Marketplace instance. If you wish to use the embedded Data Transforms, then you must unregister the Marketplace instance. See Unregister the ODI Instance from Autonomous Database.

3. When you login to the Data Transforms tool for the first time, you need to provide the database user credentials to sign in.
   It takes approximately 1-2 minutes for the Data Transforms service to start. After the service starts, the Data Transforms home page opens.
4. From the left pane of the Home page, click the **Connections** tab to view the newly created Autonomous Database connection.
   4. Click the **Actions** icon next to the connection and select **Edit**.
5. In the **Update Connection** page, enter the database username and password to use the connection. Click **Update** to save the changes.

Data Transforms Notes

APPLIES TO: Data Transforms that is part of the suite of data tools built into Oracle Autonomous Database.

Notes for using Data Transforms.

- **Enable access to private data sources from Autonomous Database**: If your Autonomous Database is configured to use a Private Endpoint, then you can only access private data sources from clients in the same Virtual Cloud Network (VCN). See Enable Access to Private Data Sources from Autonomous Database for more information.

  Data Transforms jobs stuck in the Running status: If there are any Data Transforms jobs that are stuck in the Running status for an interminably long time, either stop the job immediately or delete the job and then rerun it. You may want to do this to avoid unwanted usage of resources for your tenancy. If the issue persists, file a service request at Oracle Cloud Support or contact your support representative.

Work with Connections

Connections help you to connect Data Transforms to various technologies reachable from your OCI network.

This section describes the generic steps to create a connection. The displayed connection detail options may vary depending on the selected connection type.

Apart from the connection types listed in Supported Connection Types you can create custom connectors, which you can use to connect Data Transforms to any JDBC supported data sources. See Create Custom Connectors.

To create a new connection:

1. From the left pane of the Home page, click the **Connections** tab.
   Connections page appears.
2. Click **Create Connection**.
   The **Create Connection** page slides in.

3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the type of connection that you wish to create.
     - Databases - Allows you to configure any connection type for supported database types.
     - Applications - Allows you to configure any connection type for supported applications.
     - Services - Allows you to configure any connection type for supported services.
4. After selecting the required connection type, click **Next**.
   The **Connection Name** field is pre-populated with a default name. You can edit this value.
5. For **Connection Details**, provide the connection details for the selected type such as:
   - Connection -
     - JDBC URL - The URL to connect to the data server. For example:
       `jdbc:weblogic:sqlserver://hostname:port[;property=value[;...]]`

       > **Note:**
       >
       > If you are accessing Data Transforms from an Autonomous Database on a public endpoint, then the allowed port numbers are 2484, 1521-1525, 1708, 3306, 80.

       For connectors that use an autoREST driver that provides the model files along with the driver, specify the servername and other properties required to connect to that datasource. For example:

       `jdbc:weblogic:autorest://servername;[property=value[;...]]`
     - User - The user name, if required, for connecting to the server.
     - Password - The password for connecting to server.
   - Advanced Options
     - Array Fetch Size - When reading large volumes of data from a data server, Oracle Data Transforms fetches successive batches of records. This value is the number of rows (records read) requested by Oracle Data Transforms on each communication with the data server.
     - Batch Update Size - When writing large volumes of data into a data server, Oracle Data Transforms pushes successive batches of records. This value is the number of rows (records written) in a single Oracle Data Transforms INSERT command.

       > **Note:**
       >
       > Set Batch Update Size to 1000 or less for loading tables with BLOB data type columns.

     - Degree of Parallelism for Target - This value indicates the number of threads allowed for a loading task. The default value is 1. The maximum number of threads allowed is 99.

> **Note:**
>
> Connection details are specific and the above options vary based on the selected connection type. For the default connection that is created during provisioning, only the User and Password fields are editable. All the other fields are disabled.

6. After providing all the required connection details, click **Test Connection** to test the connection.
   If the test connection fails, do one of the following:
   - Check whether the Autonomous Database from where you are accessing Data Transforms is configured to use a private endpoint.
     See Enable Access to Private Data Sources from Autonomous Database for more information.
   - If a connection between Autonomous Databases on a Private Endpoint fails with a "Mismatch with server cert DN" error, check whether you have specified the `ssl_server_dn_match=yes` property in the JDBC URL. See Troubleshoot Mismatch with Server Cert DN Error for more information.
7. Click **Create**.
   The new connection is created.

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit** to edit the provided connection details.
- Select **Test Connection** to test the created connection.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema** to delete schemas.
- Select **Delete Connection** to delete the created connection.

You can also search for the required connection to know its details based on the following filters:

- **Name** of the connection.
- **Technology** associated with the created connection.

Topics

- Supported Connection Types
  This topic lists the connection types that are supported for connecting to Data Transforms.
- Create Custom Connectors
- Create a Data Transforms Connection for Remote Data Load
  You can connect to an existing Data Transforms instance and run a data load remotely.
- Create an Apache Iceberg Connection
  Apache Iceberg is an open standard table format that is optimized to manage large analytic datasets. Data Transforms supports the use of Apache Iceberg as a target to load data from any SQL-based data sources.

- Create a Delta Share Connection
  Databricks Delta Share is an open protocol for secure data sharing. Oracle Data Transforms integrates with Delta Share to load data to Oracle Autonomous Database. You can use the Delta Share connection to load data from Databricks or Oracle Data Share.
- Create an Oracle Business Intelligence Cloud Connector Connection
  Oracle Business Intelligence Cloud Connector (BICC) allows you to extract business data from a data source and load it into Autonomous Database.
- Create and use an Oracle Cloud Infrastructure Generative AI Connection
  Oracle Cloud Infrastructure (OCI) Generative AI enables organizations to automate text summarization and dynamic content generation. Data Transforms integrates with OCI Generative AI to support the use of embedding vectors in a data flow.
- Create an Oracle Enterprise Resource Planning Cloud Connection
- Create an Oracle Financials Cloud Connection
  You can fetch real time transactional data from Oracle Financials Cloud REST endpoints, import the data entities into Data Transforms, and use them as a source in a data flow.
- Create and Use an Oracle NetSuite Connection
  You can use the Oracle NetSuite JDBC Driver or OAuth 2.0 authentication to connect to the Oracle NetSuite application. For Oracle NetSuite connections, Data Transforms allows you to load pre-built dataflows and workflows that you can run to transfer data from NetSuite to your target schema.
- Create an Oracle Object Storage Connection
  You can use Data Transforms to upload data from Oracle Object Storage to Autonomous Database.
- Create a REST Server Connection

Supported Connection Types

This topic lists the connection types that are supported for connecting to Data Transforms.

Government cloud regions are required to support FIPS compliance standards for data protection. Data Transforms in Government realms is FIPS 140-2 Level 1 compliant. Make sure the connections sources are FIPS compliant to ensure secure communication between the servers.

> **Note:**
>
> APPLIES TO: Data Transforms that is available as a separate listing on Marketplace called Data Integrator: Web Edition.
>
> - For the connectors that require driver installation, you need to copy the jar files to the `/u01/oracle/transforms_home/userlibs` directory before you add the connection.
> - Apart from the connection types listed here you can create custom connectors, which you can use to connect Data Transforms to any JDBC supported data sources. See Create Custom Connectors.

Name	Type	Supported in Data Integrator: Web Edition	Supported in Data Transforms built into Autonomous Data Base	Supported in Data Transforms built into OCI Golden Gate	Supports Write Operation	Authentication Mode: Connection URL Example	Notes
Aha!	Application	Yes	Yes	Yes	No	**OAuth2**: `jdbc:weblogic:autorest:servername=https://{yourdomain}.aha.io; AuthenticationMethod=OAuth2; clientid=**********;clientsecret=**********; authuri=https://{yourdomain}.aha.io/oauth/authorize; tokenuri=https://{yourdomain}.aha.io/oauth/token; redirectUri=http://localhost;`

Create Custom Connectors

APPLIES TO: Data Transforms that is available as a separate listing on Marketplace called Data Integrator: Web Edition.

The Custom Connections page of the Administration tab of Oracle Data Transforms helps you to create custom connectors that point to any JDBC supported data sources.

The custom connectors will be listed in the Create Connection page where you can use them to connect data sources to Data Transforms. See Work with Connections for more information. To create a new connector:

1. In the left pane, click **Administration**.
   A warning message appears.

2. Click **Continue**.
3. In the left pane, click **Custom Connections**.
   Custom Connections screen appears.
4. Click **Create Connection Type**.
   The Create Connection Type page appears.
5. From the **Category** drop-down select the type of connection that you wish to create whether database, application, or service.
6. Enter a name for the connection.
7. Enter the name of the JDBC Driver of the source connection. For example, `oracle.jdbc.OracleDriver`.

> **Note:**
>
> For connectors that require driver installation, you need to copy the jar files to the `/u01/oracle/transforms_home/userlibs` directory before you add the connection.

8. Click **OK**.

The newly created custom connection appears in the list and are available in the Create Connection page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit**, to edit the provided connection details.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete**, to delete the created connection.

> **Note:**
>
> You cannot delete custom connectors that have existing connections.

Create a Data Transforms Connection for Remote Data Load

You can connect to an existing Data Transforms instance and run a data load remotely.

To create this connection, you need to specify the URL of the Data Transforms instance along with the name of the ODI rest API from where you want to run the data load.

To define a Data Transforms connection:

1. From the left pane of the Home page, click the **Connections** tab.

   Connections page appears.
2. Click **Create Connection**.

   Create Connection page slides in.
3. For **Select Type**,
   - In the **Name** field, enter the name of the newly created connection

- Select **Services** as the type of connection that you wish to create.

4. In the **Endpoint URL** textbox, enter the URL of the ODI rest API from where you want to run the data load. Enter the URL in the format `http://<host-ip-address>:<port>/odi-rest`.
5. In the **User** text box enter SUPERVISOR as the user name.
6. In the **Password** text box enter the ODI Supervisor password.
7. After providing all the required connection details, click **Test Connection** to test the established connection.
8. Click **Create**.

   The new connection is created.

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit** to edit the provided connection details.
- Select **Test Connection** to test the created connection.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema** to delete schemas.
- Select **Delete Connection** to delete the created connection.

You can also search for the required connection to know its details based on the following filters:

- **Name** of the Connection.
- **Technology** associated with the created Connection.

Create an Apache Iceberg Connection

Apache Iceberg is an open standard table format that is optimized to manage large analytic datasets. Data Transforms supports the use of Apache Iceberg as a target to load data from any SQL-based data sources.

Data Transforms supports Oracle Object Storage (S3 compatibility) and AWS S3 storage services to store the parquet files for the Apache Iceberg tables.

The Data Transforms Apache Iceberg Connector requires that a REST Catalog already exists. This REST Catalog is setup based on Apache Gravitino (external link) with Iceberg Open API specification.

> **Note:**
>
> Data Transforms supports the use of Apache Gravitino version 0.7.0-incubating or lower to bring up the REST service.

This topic has the following sections:

- Creating an Apache Iceberg Connection
- Creating and Running an Apache Iceberg Data Load

Creating an Apache Iceberg Connection

You can configure an Apache Iceberg connection with the Iceberg REST Catalog by providing the REST URL and authentication details such as the username and password. You can also use the more secure OAuth 2.0 authentication to create the connection.

To create an Apache Iceberg connection:

1. From the left pane of the Home page, click the **Connections** tab.
   Connections page appears.
2. Click **Create Connection**.
   Create Connection page slides in.
3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Databases** tab.
4. Select **Apache Iceberg** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. In the **Catalog Name** textbox, enter a name.
8. In the **Rest URL** textbox, enter the URL of the REST server. Enter the value in the `<host>:<port>/<ServiceName>/iceberg` format.
9. From the **Authentication** drop-down section, do one of the following:
   - Select **None**.
   - Select **Simple** and enter the **Rest User** and **Rest Password**.
   - Select **OAuth** and enter the following details:
     - **Warehouse Location**: The location where you want to store the data. For example, `s3://my-bucket/my/table/location`
     - **Token URI**: The URL to obtain the OAuth Token in the format `http://<host>:<port>`
     - **Token Path**: The path to the OAuth token. For example, `/oauth2/token`.
     - **Client ID**: The OAuth Client ID.
     - **Client Secret**: The OAuth Client secret.
     - **Auth Scope**: The permissions granted to a client when accessing the Gravitino server. For example, a `test` Auth Scope value might indicate that the client is authorized to access resources related to the test" scope within Gravitino. [Optional]
     - **Grant Type**: The method that the authorization server should use to issue the access token. For example, `client_credentials` and `authorization_code`. [Optional]
10. Click **Test Connection**, to test the established connection.
11. After providing all the required connection details, click **Create**.
    The Apache Iceberg connection is configured with REST Catalog, which stores the Iceberg data in Oracle Object Storage.

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit**, to edit the provided connection details.
- Select **Test Connection**, to test the created connection.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema**, to delete schemas.
- Select **Delete Connection**, to delete the created connection.

You can also search for the required Connection to know its details based on the following filters:

- **Name** of the Connection.
- **Technology** associated with the created Connection.

Creating and Running an Apache Iceberg Data Load

You can create a data load for any SQL-based source data source, such as Oracle, to load data into Apache Iceberg target tables. To use Apache Iceberg as a target data source, you need to provide the name of the connection and the namespace. A namespace in Apache Iceberg is similar to schema in relational databases.

After you create the data load, all the tables in the source schema are listed on the Data Load Detail page along with options to incrementally load, append, and merge the data for each of the selected source tables. When the data load run completes, you can read the data from the Iceberg tables. You can add the data load as a step in a workflow and create a schedule to run the workflows at a predefined time interval. See Create a New Workflow.

To create and run an Apache Iceberg Data Load:

1. Do one of the following:
   - On the Home page, click **Load Data**. The Create Data Load wizard appears.
     In the Create Data Load tab, enter a name if you want to replace the default value, add a description, and select a project from the drop-down.
   - On the Home page, click **Projects**, and then the required project tile. In the left pane, click **Data Loads**, and then click **Create Data Load**. The Create Data Load wizard appears.
2. Enter a name if you want to replace the default value and add a description.
3. For Load Processing do one of the following:
   - Select the **Internal** radio button and from the **Deployment Type** drop-down select **Data Transforms (Batch)**.
   - Select the **Delegate** radio button and from the **Deployment Type** drop-down select OCI GoldenGate. From the GoldenGate Deployment Connection select a connection.
4. Click **Next**.
5. In the Source Connection tab,
   a. From the **Connection Type** drop-down, select a SQL-based data source.
   b. from the **Connection** drop-down, select the required connection from which you wish to add the data entities.
   c. Click **Next**.

6. In the Target Connection tab,
   a. From the **Connection Type** drop-down, select **Apache Iceberg** as the connection type.
   b. From the **Connection** drop-down, select the connection you want to use to load the data into.
   c. Specify the **Namespace**. You can either select from existing namespaces or create a new namespace.
   d. Click **Save**.

   The Data Load Detail page appears listing all the source tables.
7. Select the required tables to load and the corresponding data load operation. The data load options you can use are Incremental Merge, Incremental Append, Append, and Do Not Load.
8. Click to save the changes. A green checkmark ( ) in the row indicates that the changes are saved.
9. Click to run the data load.
   A confirmation prompt appears when the data load starts successfully.

To check the status of the data load, see the Data Load Status panel on the right below the Target Schema details. For details about the panel, see Monitor Status of Data Loads, Data Flows, and Workflows. This panel shows links to the jobs that execute to run this data load. Click the link to monitor the progress on the Job Details page. For more information about jobs, see Create and Manage Jobs.

All the loaded tables along with their details are listed in the Data Entities page. To view the statistics of the data entities, click the **Actions** icon ( ) next to the data entity, click **Preview**, and then select the **Statistics** tab. See View Statistics of Data Entities for information.

Create a Delta Share Connection

Databricks Delta Share is an open protocol for secure data sharing. Oracle Data Transforms integrates with Delta Share to load data to Oracle Autonomous Database. You can use the Delta Share connection to load data from Databricks or Oracle Data Share.

To use Databricks as a source, you need to specify the URL of the Delta Sharing server along with the bearer token that lets you access the Delta Lake share server. To use Oracle Data Share as a source, you need to specify the URL for the token end point along with a client ID and the secret key.

This topic has the following sections:

- Creating the Delta Share Connection
- Creating and Running a Delta Share Data Load

Creating the Delta Share Connection

To define a Delta Share connection:

1. From the left pane of the Home page, click the **Connections** tab.
   Connections page appears.
2. Click **Create Connection**.
   Create Connection page slides in.

3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Databases** tab.
4. Select **Delta Share** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. In the **Share Endpoint URL** textbox, enter the URL of the Delta Sharing server. Enter the value in the `<host>:<port>/<shareEndpoint>/` format.
8. In the Connection section, do one of the following:
   - Select **Oracle Data Share** and provide the **Token Endpoint URL**, **Client ID**, and **Client Secret** for accessing the share.
     You can get this information from the Delta Share Profile JSON document that you will need to download from supplied to you by the Share Provider. (This is also where they get the Share Endpoint URL from)

     You can get this information from the Delta Share Profile JSON document that you can download from the activation link that is provided by the Data Share provider to access their share.
   - Select **Databricks** and in the **Bearer Token** text box enter the token for connecting to the Delta Sharing server.
9. If you need to use a proxy to access the Delta Share Server or Delta Share Storage configure the following settings:
   - In the **Proxy Host** textbox, enter the host name of the proxy server to be used for the connection.
   - In the **Proxy Port** textbox, enter the port number of the proxy server.
   - Select the following checkboxes depending on where the proxy is required:
     - **Use Proxy to access Delta Share Server**
     - **Use Proxy to access Delta Share Storage**
10. Click **Test Connection**, to test the established connection.
11. After providing all the required connection details, click **Create**.
    The new connection is created.

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit**, to edit the provided connection details.
- Select **Test Connection**, to test the created connection.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema**, to delete schemas.
- Select **Delete Connection**, to delete the created connection.

You can also search for the required Connection to know its details based on the following filters:

- **Name** of the Connection.

- **Technology** associated with the created Connection.

Creating and Running a Delta Share Data Load

To load data from Delta Share into Oracle Autonomous Database, the Oracle connection user must be an Admin user. Admin privileges are required so that the Oracle user can create and insert data into tables in another schema.

When you run the data load, Data Transforms loads the data onto a corresponding table in the target schema. The data load runs incrementally. The very first time you run a data load, Data Transforms copies all the data into new tables. For every subsequent data load run, it only uploads the changes. Any additions or deletions in the records will reflect in the target tables. Note that if there is any metadata change in the table, for example a column is added, Data Transforms creates a new table to load the data on to the target server. You could create a workflow, add the data load as a step, create a schedule to run the workflows at a predefined time interval. See Create a New Workflow.

To create and run a Delta Share data load:

1. Do one of the following:
   - On the Home page, click **Load Data**. The Create Data Load wizard appears.
     In the Create Data Load tab, enter a name if you want to replace the default value, add a description, and select a project from the drop-down.
   - On the Home page, click **Projects**, and then the required project tile. In the left pane, click **Data Loads**, and then click **Create Data Load**. The Create Data Load wizard appears.
     In the Create Data Load tab, enter a name if you want to replace the default value and add a description.
2. Click **Next**.
3. In the Source Connection tab,
   a. From the **Connection Type** drop-down, select **Delta Share**.
   b. from the **Connection** drop-down, select the required connection from which you wish to add the data entities.
   c. Select the share that you want to load tables from the **Share** drop-down. The drop-down lists all the shares for the selected connection.
   d. Click **Next**.
4. In the Target Connection tab,
   a. From the **Connection Type** drop-down, select **Oracle** as the connection type.

      > **Note:**
      > This drop-down lists only JDBC type connections.

   b. From the **Connection** drop-down, select the required connection from to you wish to load the data entities.
   c. Enter a unique name in the **Schema** textbox.
   d. Click **Save**.

   The Data Load Detail page appears listing all the tables in the selected share with their schema names.

> **Note:**
>
> For Delta Share data loads the Data Load Detail page only includes the option. You cannot apply different actions - incremental merge, incremental append, recreate, truncate, append - on the data entities before loading it to the target schema. This is to make sure that the data is consistent between the Delta Sharing server and the target schema.

5. Click to run the data load.
   A confirmation prompt appears when the data load starts successfully.

To check the status of the data load, see the Status panel on the right below the Target Schema details. For details about the Status panel, see Monitor Status of Data Loads, Data Flows, and Workflows. This panel shows links to the jobs that execute to run this data load. Click the link to monitor the progress on the Job Details page. For more information about jobs, see Create and Manage Jobs.

All the loaded data entities along with their details are listed in the Data Entities page. To view the statistics of the data entities, click the **Actions** icon ( ) next to the data entity, click **Preview**, and then select the **Statistics** tab. See View Statistics of Data Entities for information.

Create an Oracle Business Intelligence Cloud Connector Connection

Oracle Business Intelligence Cloud Connector (BICC) allows you to extract business data from a data source and load it into Autonomous Database.

To create an Oracle BICC connection you need to first configure external storage using the OCI Object Storage Connection tab in the BICC Console. You need to specify these connection details when you define the connection in Oracle Data Transforms.

You can use the BICC connection to choose the offerings whose data stores you want to extract. Data Transforms uses an Oracle Object Storage Data Server used by Oracle BICC to stage the extracted files, which you can then use as a source for mapping. Note that you cannot use an Oracle BICC connection as a target for mapping.

To define an Oracle BICC connection,

1. From the left pane of the Home page, click the **Connections** tab.

   Connections page appears.
2. Click **Create Connection**.

   Create Connection page slides in.
3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Applications** tab.
4. Select **Oracle BI Cloud Connector** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. Enter the URL in the **BI Cloud Connector Service URL** textbox.

8. In the **Connection** section, enter the following details:
   - In the **User** text box enter the user name configured in the Oracle BI Cloud Connector Console.
   - In the **Password** text box enter the password configured in the Oracle BI Cloud Connector Console.
9. In the **Storage** section, enter the following details:
   - In the **External Storage BICC Name** text box enter the name of the external storage as it appears in the Oracle BI Cloud Connector Console.
   - In the **External Storage Bucket** text box specify the bucket into which extracts are uploaded. Bucket names are obtained in the OCI Console.
   - In the **External Storage Name Space** text box specify the namespace. Namespace is obtained in the OCI Console.
   - In the **External Storage Region** text box enter the OCI Object Storage region.
   - In the **External Storage User** text box enter your Oracle Cloud Infrastructure username.
   - In the **External Storage Token** text box enter the auth token.
10. Click **Test Connection** to test the established connection.
11. Click **Create**.

    The new connection is created.

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit**, to edit the provided connection details.
- Select **Test Connection**, to test the created connection.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema**, to delete schemas.
- Select **Delete Connection**, to delete the created connection.

You can also search for the required Connection to know its details based on the following filters:

- **Name** of the Connection.
- **Technology** associated with the created Connection.

Create and use an Oracle Cloud Infrastructure Generative AI Connection

Oracle Cloud Infrastructure (OCI) Generative AI enables organizations to automate text summarization and dynamic content generation. Data Transforms integrates with OCI Generative AI to support the use of embedding vectors in a data flow.

Before you create an OCI Generative AI connection you create an Oracle Database 23ai connection. Data Transforms will use this connection to test the OCI Generative AI connection. To create the OCI Generative AI connection you need to specify details such as the OCI URL, User OCID, Tenancy OCID, Compartment OCID, Private Key, and Fingerprint information.

See Use Text Embedding Vector in a Data Flow for information on how you will use this connection to add vector embedding in a data flow.

To define Oracle Cloud Infrastructure Generative AI Connection:

1. From the left pane of the Home page, click the **Connections** tab.
   Connections page appears.
2. Click **Create Connection**.
   Create Connection page slides in.
3. For **Select Type**,
   - In the **Name** field, enter the name of the newly created connection.
   - Select **Services** as the type of connection.
4. Select **OCI Generative AI**, and **Next**.
5. For **Connection Details**, provide the following details:
   - **OCI URL** - The endpoint URL of the OCI Generative AI service.
   - **User OCID** - The user OCID from the Oracle Cloud Infrastructure Console.
   - **Tenancy OCID** - The tenancy OCID from the Oracle Cloud Infrastructure Console.
   - **Compartment OCID** - The compartment OCID from the Oracle Cloud Infrastructure Console.
   - **Private Key** - The private key in the PEM format. Specify the path to your downloaded private key file.
   - **Fingerprint** - The fingerprint of the key that was just added.
6. After proving all the required connection details, click **Create**.
   The new connection is created.
7. Click **Test Connection**, to test the established connection.
   A pop-up appears listing the Oracle Database 23ai connections that you have configured. Select the option you want to use to test this connection.

> **Note:**
>
> If test connection fails see Troubleshooting OCI Generative AI connection issues for instructions to fix the issue.

The newly created connection is displayed in the Connections page.

Troubleshooting OCI Generative AI connection issues

If **Test Connection** fails for an OCI Generative AI connection, do the following to troubleshoot the issue:

1. Make sure that you have entered all the connection information correctly. For example,
   - OCI URL sample: `https://inference.generativeai.us-chicago-1.oci.oraclecloud.com/20231130/actions/embedText`
   - Private Key sample: `MIIEvg.....beE/`
2. When you click **Test Connection**, you will be asked to choose an Oracle Connection. Make sure that it is an Oracle 23ai connection.

3. Log into that Oracle 23ai database as admin and run the following query to make sure the statuses are valid:

```
SELECT object_name, object_type, status
FROM dba_objects
WHERE object_name = 'DBMS_VECTOR_CHAIN' AND owner = 'CTXSYS';
```

4. Check whether the following plsql block works in your database. Data Transforms uses the plsql block to run the **Test Connection**.

```
exec dbms_vector_chain.drop_credential('OCI_CRED');
declare
  jo json_object_t;
begin
  -- create an OCI credential
  jo := json_object_t();
  jo.put('user_ocid', '<your user ocid>');
  jo.put('tenancy_ocid', '<your tenancy ocid');
  jo.put('compartment_ocid', '<your compartment ocid');
  jo.put('private_key', '<your private key');
  jo.put('fingerprint', '<your fingerprint>');
  dbms_output.put_line(jo.to_string);
  dbms_vector_chain.create_credential(
    credential_name => 'OCI_CRED',
    params => json(jo.to_string));
end;

select dbms_vector_chain.utl_to_embedding('hello', JSON('{"provider":
"ocigenai","credential_name" : "OCI_CRED", "url": "https://
inference.generativeai.us-chicago-1.oci.oraclecloud.com/20231130/actions/
embedText","model": "cohere.embed-english-light-v2.0"}')) from dual;
```

If you get an `HTTP request failed` error when running the plsql block query, try to grant network access to your user:

```
BEGIN
    DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
        host => '*',
        ace => xs$ace_type(privilege_list => xs$name_list('connect'),
                           principal_name => '<your username>',
                           principal_type => xs_acl.ptype_db));
END;
```

Create an Oracle Enterprise Resource Planning Cloud Connection

Oracle Enterprise Resource Planning (ERP) Cloud is a cloud based end-to-end Software as a service (SaaS) suite to manage functions such as accounting, financial management, project management, procurement, and risk management. The Data Transforms Oracle ERP Cloud connector allows you to extract report data from an ERP Cloud server and load it into Autonomous Database.

To use an Oracle ERP Cloud connection in Data Transforms you need the URL of the BI Publisher web service used for the Oracle ERP Cloud instance and BI Publisher report file that is output in the Data (CSV) format.

Note the following:

- You cannot use an Oracle ERP Cloud connection as a target for mapping.
- Data load is not supported for Oracle ERP Cloud connections.

This topic has the following sections:

- Creating an Oracle ERP Cloud Server Connection
- Importing Data Entity Definitions from an Oracle ERP Cloud Server

Creating an Oracle ERP Cloud Server Connection

To create this connection, you need to specify the WSDL URL of the Report service and the username and password to connect to the ERP Cloud instance.

To define an Oracle ERP Cloud Server Connection:

1. From the left pane of the Home page, click the **Connections** tab.
   Connections page appears.
2. Click **Create Connection**.
   Create Connection page slides in.
3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Applications** tab.
4. Select **Oracle ERP Cloud** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. In the **WSDL URL** textbox, enter the URL of the BI Publisher web service used for the Oracle ERP Cloud instance. The format of the URL is `BI Publisher Hostname/xmlpserver/services/PublicReportWSSService?wsdl`.
   For example: `https://fa-eudu-saasfademo1.ds-fa.oraclepdemos.com/xmlpserver/services/PublicReportWSSService?wsdl`.
8. In the **Proxy Host** textbox, enter the host name of the proxy server to be used for the connection.
9. In the **Proxy Port** textbox, enter the port number of the proxy server.
10. In the **User** text box enter the user name for connecting to the Oracle ERP Cloud instance.
11. In the **Password** text box enter the password for connecting to the Oracle ERP Cloud instance.
12. After providing all the required connection details, click **Test Connection** to test the connection.
13. Click **Create**.
    The newly created connection is displayed in the **Connections** page.

    Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:
    - Select **Edit** to edit the provided connection details.
    - Select **Test Connection** to test the created connection.
    - Click **Export** to export the connection. See Export Objects.

- Select **Delete Schema** to delete schemas.
- Select **Delete Connection** to delete the created connection.

You can also search for the required connection to know its details based on the following filters:

- **Name** of the connection.
- **Technology** associated with the created connection.

Importing Data Entity Definitions from an Oracle ERP Cloud Server

For Oracle ERP Cloud connections, the Import Data Entities page requires input in key/value pairs. To import data, you need to specify the `BIPReportLocation` key, which refers to the location of the BI publisher report on the BI server. You can find this information on the BI server when the corresponding report is open.

To import data entities from Oracle ERP Cloud:

1. From the left pane of the Home page, click the **Data Entities** tab.
   Data Entities page appears.
2. Click **Import Data Entities**. The Import Data Entities page slides-in.
3. In the **Connection** drop-down, select the Oracle ERP Cloud connection that you created in Creating an Oracle ERP Cloud Server Connection. The options on the page change to display only the **Entity Name** field.
4. In the **Entity Name** field enter a name for the data entity.
5. Enter `BIPReportLocation` in the **Key** field.
6. Enter the location of the BI Publisher report file in the **Value** field corresponding to the key. Specify the path till the name of the *`ReportFile`*`.xdo` file.
7. Click **Start**.
   A Job is created, and the corresponding Job ID is displayed for you to track the session. Click the Job ID to view the details of the job. Upon successful execution of the job, the data entity is displayed on the Data Entities page.
8. Click the **Actions** icon (⋮) next to the selected Data Entity and select **Edit**.
   The **Edit Data Entity** page appears that displays a table with the following information:
   - Name
   - Data Type
   - Length
   - Scale
   - Not Null

   Verify the data type and length for the imported entities. Oracle Data Transforms determines the data types and length from the first record of the file, but may set default values (for example, 50 for the string field length) or incorrect data types. In case of an empty field, data type is set to String with length 50.
9. Click **Save**.

Create an Oracle Financials Cloud Connection

You can fetch real time transactional data from Oracle Financials Cloud REST endpoints, import the data entities into Data Transforms, and use them as a source in a data flow.

To create an Oracle Financials Cloud connection you need to choose a temporary schema where Data Transforms can create data entities after the reverse-engineering operation.

To define an Oracle Financials Cloud connection,

1. From the left pane of the Home page, click the **Connections** tab.

   Connections page appears.
2. Click **Create Connection**.

   Create Connection page slides in.
3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Applications** tab.
4. Select **Oracle Financials Cloud** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. In the **REST Service URL** textbox, enter the URL of the endpoint that services the REST resources.
8. In the **Proxy Host** textbox, enter the host name of the proxy server to be used for the connection.
9. In the **Proxy Port** textbox, enter the port number of the proxy server.
10. In the **User** text box enter the user name for connecting to the REST endpoint.
11. In the **Password** text box enter the password for connecting to the REST endpoint.
12. Choose a connection from the **Staging Connection** drop-down list. The list displays only existing Autonomous Database connections. To use a different connection, create the connection before you reach this page.
13. After providing all the required connection details, click **Create**.

    The new connection is created.
14. Click **Test Connection**, to test the established connection.

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit**, to edit the provided connection details.
- Select **Test Connection**, to test the created connection.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema**, to delete schemas.
- Select **Delete Connection**, to delete the created connection.

You can also search for the required Connection to know its details based on the following filters:

- **Name** of the Connection.
- **Technology** associated with the created Connection.

Create and Use an Oracle NetSuite Connection

You can use the Oracle NetSuite JDBC Driver or OAuth 2.0 authentication to connect to the Oracle NetSuite application. For Oracle NetSuite connections, Data Transforms allows you to load pre-built dataflows and workflows that you can run to transfer data from NetSuite to your target schema.

This topic has the following sections:

- Configuring Access Permissions Required for Building Data Warehouse
- Creating the Oracle NetSuite Connection
- Using the Build Data Warehouse Wizard
- Running the Pre-Built Workflows to Load Data into the Target Schema

Configuring Access Permissions Required for Building Data Warehouse

Before you create a NetSuite connection or use the Build Data Warehouse Wizard in Data Transforms, you need to login to NetSuite as an administrator, enable SuiteAnalytics Connect, create a custom role, and set the access permissions that are required to build the NetSuite Data Warehouse.

To configure the access permissions:

1. Log in to NetSuite as an administrator using the following URL:
   https://system.netsuite.com/pages/customerlogin.jsp
2. Check whether the SUITEANALYTICS CONNECT feature is enabled.
   Go to *Setup* > *Company* > *Enable Features*. Click the **Analytics** tab and verify that the **SuiteAnalytics Connect** box is checked.
3. Add a custom role.
   Go to *Setup* > *Users/Roles* > *User Management* > *Manage Roles*. Click **New Role**, add the required details, and click **Save** to create a custom role.
4. Assign the required permissions to the custom role.
   Go to *Setup* > *Users/Roles* > *User Management* > *Manage Roles*. Click **Customize** next to the name of the custom role for which you would like to add the SuiteAnalytics Connect permission.

   Click the **Transactions** tab under the **Permissions** tab and assign the following permissions:

   - Account Detail
   - Accounting Lists
   - Accounting Management
   - Accounts
   - Accounts Payable
   - Accounts Payable Graphing
   - Accounts Payable Register

- Accounts Receivable
- Accounts Receivable Graphing

5. Add the **SuiteAnalytics Connect – Read All** permission.
   Click the **Setup** tab under the **Permissions** tab, select **SuiteAnalytics Connect – Read All** from the drop-down, and click **Add**.
6. Click **Save** to apply these permissions to the custom role.
7. Assign the custom role to a user. When you create a connection to NetSuite from Data Transforms, you will need to enter the credentials of this user to connect to the data server. See Creating the Oracle NetSuite Connection for information about creating the connection.
   To assign the custom role to the user, go to *Setup* > *Users / Roles* > *Manage Users*. Click **Edit** next to the name of the user, assign the custom role, and click **Save**.
8. To verify the access permissions, log in as the user that has the custom role assigned. Go to *Analytics* > *Datasets*. Click **New Dataset**. This page will list all the tables and record types that the user has access to. Search for “transaction” table, for example, to verify whether the user has access to the transaction table.

Creating the Oracle NetSuite Connection

You can create an Oracle NetSuite connection using JDBC connectivity or OAuth 2.0 authentication.

To define an Oracle NetSuite connection:

1. From the left pane of the Home page, click the **Connections** tab.
   Connections page appears.
2. Click **Create Connection**.
   Create Connection page slides in.
3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Applications** tab.
4. Select **Oracle NetSuite** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. To specify the connection details, do one of the following:
   - To use JDBC connectivity, specify the following details:
     - **JDBC URL** - Enter the URL of the SuiteAnalytics Connect server to be used for the connection.
     - **User** - Enter the user name for connecting to the data server.
     - In the **Password** textbox enter the password for connecting to the data server.
     - In the **Account ID** textbox, enter the account ID for connecting to the data server.
     - In the **Role ID** textbox, enter the role ID for connecting to the data server.
   - To use OAuth 2.0 authentication, click the **OAuth 2.0** switch and then specify the following details:
     - **Username** - Enter the name of the user who has role access to login to NetSuite using OAuth 2.0 connection. This is the user you have assigned the custom role to in Configuring Access Permissions Required for Building Data Warehouse.

- **Account ID** - Enter the account ID for connecting to the data server. You can get this information by logging into the NetSuite account and viewing the SuiteAnalytics connect information.
- **Role ID** - Enter the role ID for connecting to the data server. You can get this information by logging into the NetSuite account and viewing the SuiteAnalytics connect information.
- **Client ID** - Enter the client ID for connecting to the data server.
  To obtain the client ID, create an Integration record in NetSuite by enabling OAuth 2.0 Client Credentials Flow. Copy and save the Client ID that is displayed when the Integration Record is successfully created.

  > **Note:**
  >
  > NetSuite no longer supports the RSA PKCSv1.5 scheme for token signing for NetSuite OAuth 2.0 client credentials flow. Any integrations that rely on the RSA PKCSv1.5 scheme will need to be updated to use the RSA-PSS scheme. Refer to the Oracle NetSuite documentation for more information.

- **Public Certificate** and **Private Key** - Use the OpenSSL commands to generate the key pair in the required PEM format. For example,
  ```
  openssl req -new -x509 -newkey rsa:4096 -keyout private.pem -sigopt rsa_padding_mode:pss -sha256 -sigopt rsa_pss_saltlen:64 -out public.pem -nodes -days 365
  ```
  Paste the contents of `public.pem` in the Public Certificate field. Paste the contents of `private.pem` in the Private Key field.
- **Certificate ID** - Enter the Certificate ID for connecting to the data server.
  To get the certificate ID, use the NetSuite OAuth 2.0 Client Credentials (M2M) Setup to add the public certificate file (`auth-cert.pem`) to the certificate key list and copy the generated Certificate ID.

8. If the source that you want to use for mapping is a saved search, you need to also specify the following details in **Saved Search Extraction**:
   - **Application ID**: Enter the NetSuite Application ID for Data Transforms.
   - **Version**: Enter the NetSuite version number.
9. Select the checkbox in **Build Data Model** to install pre-built dataflows and workflows that you can run to extract data from NetSuite and move it to your Oracle target schema using the Build Data Warehouse wizard.
10. Click **Test Connection**, to test the established connection.
11. After providing all the required connection details, click **Create**.
    The new connection is created.

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit**, to edit the provided connection details.
- Select **Test Connection**, to test the created connection.

- Select **Build Data Warehouse**, to select the functional areas and create the NetSuite Data Warehouse in the target schema. See Using the Build Data Warehouse Wizard for more information.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema**, to delete schema.
- Select **Delete Connection**, to delete the created connection.

You can also search for the required Connection to know its details based on the following filters:

- **Name** of the Connection.
- **Technology** associated with the created Connection.

Using the Build Data Warehouse Wizard

Data in your NetSuite account is grouped into business or subject areas in the Analytics Warehouse. The Build Data Warehouse wizard allows you to select the areas that you want to include in the newly created Data Warehouse.

To use the Build Data Warehouse Wizard:

1. On the Home page, click the **Connections** tab. The **Connections** page appears.
2. Click the Actions icon (⋮) next to the Oracle NetSuite connection that you want to use to build the data warehouse and click **Build Data Warehouse**.
   The Build Data Warehouse wizard opens.
3. From the **Connection** drop-down list, choose the Autonomous Database connection where your target schema resides.
4. From the **Staging Schema** drop-down, all schema corresponding to the selected connection are listed in two groups:
   - Existing Schema (ones that you've imported into Oracle Data Transforms) and
   - New Database Schema (ones that you've not yet imported).

   Select the schema that you want to use from the drop-down.
5. Similarly select the **Target Schema**.
6. Click **Next**.
7. Select the **NetSuite Business Areas** that you want to use to transfer data from the NetSuite Data Warehouse to the target schema.
8. Click **Save**.
   Data Transforms starts the process to build the data warehouse. Click **Jobs** on the left pane of the Home page to monitor the progress of the process. When the job completes successfully, Data Transforms creates a Project folder that includes all the pre-built workflows and dataflows, which you can run to transfer data from the NetSuite connection to your target schema. See Running the Pre-Built Workflows to Load Data into the Target Schema for more information.

Running the Pre-Built Workflows to Load Data into the Target Schema

When the Build Data Warehouse wizard completes successfully, Data Transforms creates a project that includes all the pre-built data flows and workflows that you can run to extract data from a NetSuite connection and load it into your target schema.

To view and run the pre-built workflows:

1. Click **Projects** on the left pane of the Home page and select the newly created NetSuite project.
2. Click **Workflows** in the left pane. The following pre-built workflows are listed in the Project Details page:
   - Stage NetSuite Source to SDS
   - Extract Transaction Primary Keys
   - Load SDS to Warehouse
   - Apply Deletes
   - All Workflows
3. Click the Actions icon (⋮) next to the workflow you want to run and click **Start**. Oracle recommends that you run **All Workflows** to execute all the pre-built workflows.

   To see the status of the workflow, click **Jobs** from the left pane in the current project. When the job completes successfully, all the data from the NetSuite connection is loaded into the target schema.

Create an Oracle Object Storage Connection

You can use Data Transforms to upload data from Oracle Object Storage to Autonomous Database.

The OCI Object Storage dedicated endpoints feature allows OCI customers to securely access the storage buckets. See Object Storage Dedicated Endpoints for more information. You need to use the new URL format when you create Object Storage connections in Data Transforms. For users that already have an Object Storage connection, the existing URL is automatically updated to the new URL format.

To create an Oracle Object Storage connection you need to have an Oracle Cloud Infrastructure username and an auth token. See Getting an Auth Token for information about how to generate the auth token. You need to specify these details when you define the connection in Oracle Data Transforms.

Note the following:

- To use an Oracle Object Storage connection to import data into Data Transforms, you must use a public IP address to access the compute node. If you want to use a private IP address to access the Object Storage service, make sure that you have access to the Internet.
- The supported file format for loading data from Oracle Object Storage to Autonomous Database and vice versa is CSV.
- The supported data types are Numeric, Double, String, and Date.
- Data load is not supported for Oracle Object Storage connections.
- To create a mapping to Object Storage, the source technology must support the `DBMS_CLOUD` package. Otherwise, the mapping will fail.
- Data Transforms does not support cross-realm connectivity for Object Storage. For example, you cannot connect from Data Transforms configured in a Government Cloud region to Object Storage that is in a commercial realm.

To define an Oracle Object Storage connection,

1. From the left pane of the Home page, click the **Connections** tab.

Connections page appears.

2. Click **Create Connection**.

   Create Connection page slides in.

3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Databases** tab.
4. Select **Oracle Object Storage** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. Enter the URL in the **Object Storage URL** textbox. You can enter the URL in either of the following formats:
   - URL with fully qualified domain name.
     For example,

     ```
     https://<namespace>.swiftobjectstorage.<your-region>.oci.customer-
     oci.com/v1/<your-namespace>/<your-bucket>
     ```

     ```
     https://<namespace>.objectstorage.<your-region>.oci.customer-oci.com/n/
     <your-namespace>/b/<your-bucket>/o
     ```

   - If you want to use the URL provided by the OCI Console, specify the URL only till the name of the bucket.
     For example,

     ```
     https://<namespace>.swiftobjectstorage.<your-region>.oci.customer-
     oci.com/v1/<your-namespace>/<your-bucket>
     ```

     ```
     https://<namespace>.objectstorage.<your-region>.oci.customer-oci.com/n/
     <your-namespace>/b/<your-bucket>/o
     ```

   - If you choose **Credential** as the **Connection Mode** (see step 6), specify the URL till *bucketname*/o
     For example,

     ```
     https://<namespace>.objectstorage.<your-region>.oci.customer-oci.com/n/
     <your-namespace>/b/<your-bucket>/o/
     ```

     > **Note:**
     >
     > Credential mode is available only to Data Transforms that is available as a separate listing on Marketplace called Data Integrator: Web Edition.

   The values for Region, Namespace and Bucket are auto-populated based on the URL provided.
8. To select the **Connection Mode** do one of the following:
   - Select **Swift Connectivity**, and provide the following details:

  - In the **User Name** text box enter your Oracle Cloud Infrastructure username. For tenancies that support identity domains, specify the domain name along with the username. For example, *<identity-domain-name>/<username>*.
  - In the **Token** text box enter the auth token.
- (This is applicable only to Data Transforms that is available as a separate listing on Marketplace called Data Integrator: Web Edition.) Select **Credential** and provide the ODI credential in the **Enter Credential** text box.
  You must create the credential in the repository and in the Autonomous Database that you created during instance creation. When you create a data flow to map data from Object Storage to Autonomous Database you need to create the ODI credential in the target schema as well. Before you run the mapping, make sure that you select the step and in the Properties panel, set the **Create credential** KM option to `false`. Otherwise, the credential-based connection will fail.

  To create the credential, execute the following script:

```
begin DBMS_CLOUD.create_credential( credential_name => '<Credential
name>',
      username => '<oci username>', password => '<auth token>' ); end;
```

9. Click **Create**.

   The new connection is created.

10. Click **Test Connection**, to test the established connection.

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit**, to edit the provided connection details.
- Select **Test Connection**, to test the created connection.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema**, to delete schemas.
- Select **Delete Connection**, to delete the created connection.

You can also search for the required Connection to know its details based on the following filters:

- **Name** of the Connection.
- **Technology** associated with the created Connection.

Create a REST Server Connection

You can connect to any REST service endpoint, import the data entities into Data Transforms, and use them as source in a data flow.

To create a generic REST connector, you need to provide the JDBC URL, username, and password to connect to the endpoint. You can also create and upload a config file that contains information such as the authentication methods, endpoints, and tables that you want to import data entities from.

The **Application** tab on the **Create Connection** page includes two connection options to create a generic REST connection - Generic REST and Generic REST Config. This topic has the following sections:

- Creating a Generic REST Connection
- Creating a Generic Rest Connection Using a Config File

The newly created connections are displayed in the **Connections** page.

Click the **Actions** icon (⋮) next to the selected connection to perform the following operations:

- Select **Edit** to edit the provided connection details.
- Select **Test Connection** to test the created connection.
- Click **Export** to export the connection. See Export Objects.
- Select **Delete Schema** to delete schemas.
- Select **Delete Connection** to delete the created connection.

You can also search for the required connection to know its details based on the following filters:

- **Name** of the connection.
- **Technology** associated with the created connection.

Creating a Generic REST Connection

To create this connection you need to specify the REST service URL and choose a temporary schema where Data Transforms can create data entities after the reverse-engineering operation.

To define a REST server connection:

1. From the left pane of the Home page, click the **Connections** tab.
   Connections page appears.
2. Click **Create Connection**.
   Create Connection page slides in.
3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Applications** tab.
4. Select **Generic Rest** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. In the **REST Service URL** textbox, enter the URL of the endpoint that services the REST resources.
8. In the **Proxy Host** textbox, enter the host name of the proxy server to be used for the connection.
9. In the **Proxy Port** textbox, enter the port number of the proxy server.
10. In the **User** text box enter the user name for connecting to the REST endpoint.
11. In the **Password** text box enter the password for connecting to the REST endpoint.
12. Choose a connection from the **Staging Connection** drop-down list. The list displays only existing Autonomous Database connections. To use a different connection, create the connection before you reach this page.

13. After providing all the required connection details, click **Test Connection** to test the connection.
14. Click **Create**.
    The new connection is created.

Creating a Generic Rest Connection Using a Config File

APPLIES TO: Data Transforms that is available as a separate listing on Marketplace called Data Integrator: Web Edition.

To create a generic REST connector, you need the JDBC URL, username, password, and a config file. The config file is a model file with the *file_name.rest* naming convention that you need to upload when you create a REST Server connection. You need to specify the endpoints, table mappings, and the authentication methods to create the config file. You can create the config file using any text editor.

To define a REST server connection using a config file:

1. From the left pane of the Home page, click the **Connections** tab.
   Connections page appears.
2. Click **Create Connection**.
   Create Connection page slides in.
3. Do one of the following:
   - In the **Select Type** field, enter the name or part of the name of the connection type.
   - Select the **Applications** tab.
4. Select **Generic Rest Config** as the connection type.
5. Click **Next**.
6. The **Connection Name** field is pre-populated with a default name. You can edit this value.
7. Use the **Config File** text box to upload the config file that you want to use.
8. In the **JDBC URL** textbox, enter the URL to connect to the server.
9. In the **User** and **Password** text boxes enter the user name and password for connecting to the REST endpoint. You may leave these fields blank if these values are not applicable or are already mentioned in the JDBC URL.
10. After providing all the required connection details, click **Test Connection** to test the connection.
11. Click **Create**.
    The new connection is created.

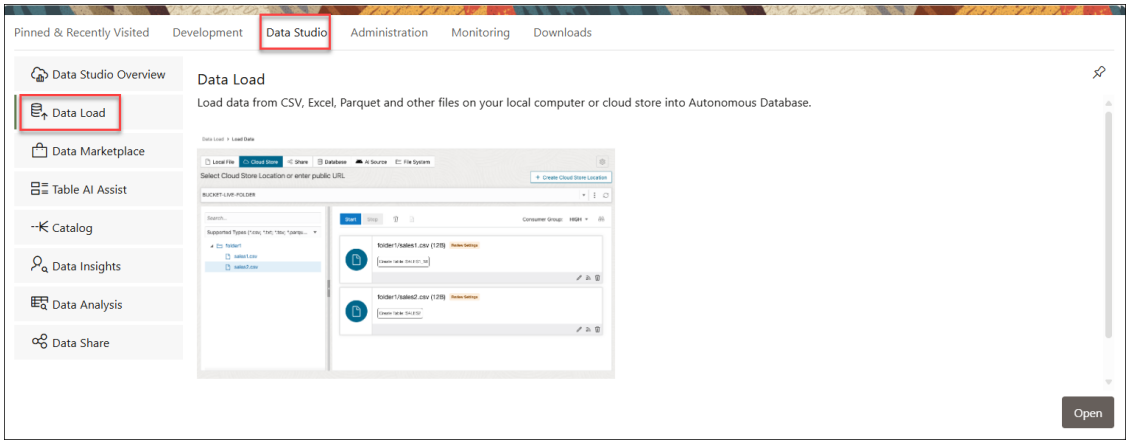
The Data Load Page

Use the Data Load dashboard page to make more data available to your Oracle Autonomous Database. You can load data from files or databases, from links to external databases or cloud storage files, or from a live feed of data from cloud storage.

From the Data Load page, you can also explore the data in your autonomous database and manage your cloud storage locations.

> **Note:**
>
> If you do not see the Data Load card then your database user is missing the required DWROLE role.

To reach the Data Load page, click the **Data Studio** tab in the Database Actions page and select the **Data Load** pane.



You can alternatively click the Selector icon and select **Data Load** from the Data Studio menu in the navigation pane.

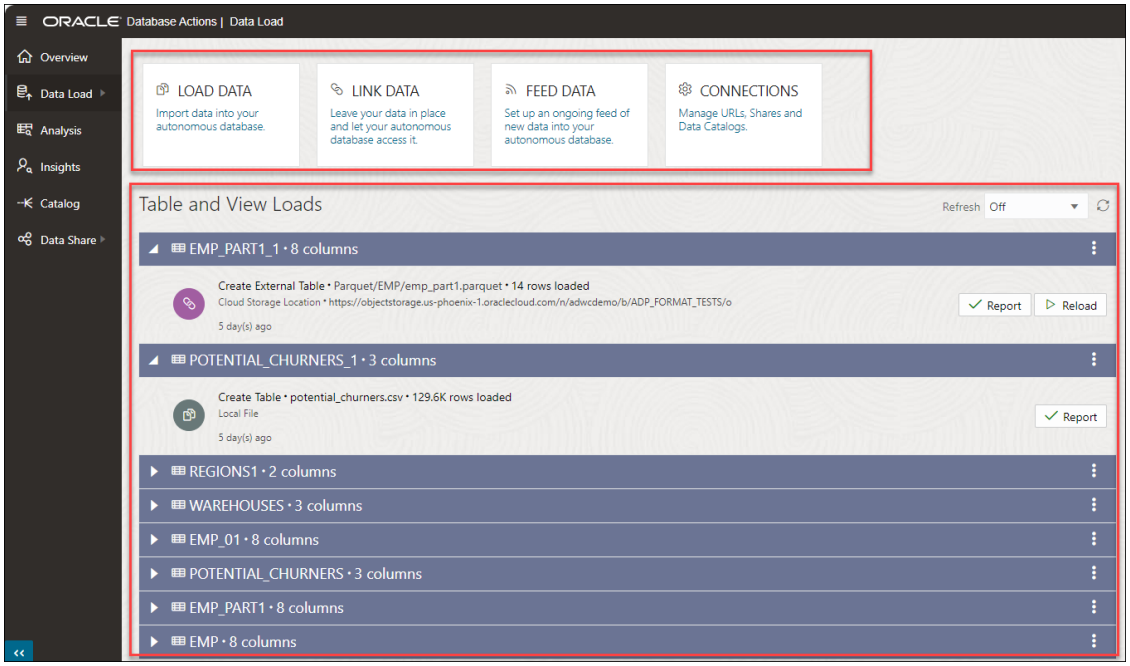
The Data Load Dashboard provides a central location for all data load and live feed tasks. The various icons on the dashboard, provide access to loading data, linking data, setting up an ongoing feed, checking data load jobs, and managing connections.

You can view the following tiles on the top section of the dashboard:

- Load Data
- Link Data
- Feed Data
- Connections

The bottom section of the dashboard displays the tables, views, and life feed you load into the tool.

The following image illustrates the **Data Load Dashboard**.



After drilling down onto a table, in the **Table and View Loads** section, you can view the details of the table load such as the name of the table, the number of rows and columns in the table, and the time you load the table.

Tables which are not active for last 7 days are collapsed.

You can also view the source location of the data you load. Click the location to view objects in the location.

Click the **Actions** icon beside the table name and select **Table** to view the following properties of the table:

- View Details
- Gather Statistics
- Register to Cloud Link
- Publish Listings to Marketplace
- Create Analytic View
- The Table AI Assist Tool
- Export Data to Cloud
- The Data Analysis Tool
- Edit
- **Drop** : Select **Drop** to delete the table.

Select **Report** to view a report of total rows processed successfully and failed for the selected table.

Select **Reload** to reload the source of the data load job. Clicking Reload takes you to the **Link Data** page where you can link your data source to the Autonomous Database.

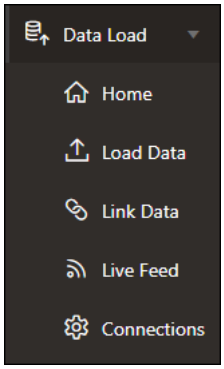
> **Note:**
>
> For tables you load via Cloud Store, you can view **Create Live Feed** icon. See Create Live Feed from Data Load. After the creation of live feed is successful, you will view a Live Feed badge besides the table load header.

In case of errors, you can reload data with suggested fixes.

To load or create links to data or create live table feeds, on the Data Load dashboard, select a combination of an operation and a data source location. The following table lists the operations and the source locations that support those operations.

Operation	Source Location	Description
Load data	Local file Database Cloud storage Directory Share AI Sources	Load data from files on your local device, from remote databases, or from cloud storage into tables in your Oracle Autonomous Database.
Link data	Database Objects in Oracle Cloud Infrastructure (OCI) Catalog	Create external tables or views in your Oracle Autonomous Database that link to data in cloud storage or remote databases. Changes to the source data automatically appear in the target objects.
Feed data	Cloud storage	Set up a feed of data from a cloud storage bucket into a table. Changes to the source data load into the target table as scheduled or on demand.
Connections	Cloud storage Data Catalog links Share Providers	Create a cloud storage location. Subscribe to Share Provider and Register Data Catalog. You can manage cloud storage locations, Data Catalog and Shares.

The left navigation pane of the Data Load Dashboard provides links to the Data Load features and pages. When you select a link from the left navigation pane, the corresponding page appears in the target content area.



Topics:

- Data Studio Settings
  This topic explains the Data Studio settings on the Data Studio tool.
- Managing Connections
  Connections that are established from the Data Studio to the cloud, catalogs and shares are listed on this page.
- Loading Data
  You can load data from files on your local device, from remote databases, or from cloud storage buckets from directories and share providers. The file formats that you can load are CSV, XLS, XLSX, TSV, TXT, XML, JSON, GEOJSON, AVRO, PARQUET, GZ, GZIP, ZIP, PDF, PNG, JPG, JPEG and TIFF.
- Linking Data
  You can link to data in remote databases or in cloud storage buckets.
- Feeding Data
  You can run a live table feed on demand, on a schedule, or as the result of a notification.
- DBMS_LIVE_FEED Package Reference
  This chapter provides information about the packages you use with the Data Load Tool in Data Studio. The `DBMS_LIVE_FEED` topic also covers the procedures included in the `DBMS_LIVE_FEED` package.

Create and Run Data Loads

A data load allows you to load multiple data entities from a source connection to a target connection.

Topics

- Create a Data Load
  Use the Create Data Load wizard to define the source connection and the target connection for the data load.
- Run a Data Load
  After you create the data load, you are taken to the Data Load Detail page that displays the details that you need to run a data load.

Create a Data Load

Use the Create Data Load wizard to define the source connection and the target connection for the data load.

> **Note:**
>
> Data load is not supported for Oracle Object Storage connections.

The wizard also allows you to choose the load processing option based on the deployment type. The newly created data load is displayed in the Data Loads page of the associated project. Click the Actions icon (⋮) next to the selected data load to edit, rename, start, export, or delete it.

To create a data load from the Home page:

1. Do one of the following:
   - On the Home page, click **Load Data**. The Create Data Load wizard appears.
     In the Create Data Load tab, enter a name if you want to replace the default value, add a description, and select a project from the drop-down.
   - On the Home page, click **Projects**, and then the required project tile. In the left pane, click **Data Loads**, and then click **Create Data Load**.

   The Create Data Load wizard appears.
2. In the Name field, enter a name for the data load. The field is pre-populated with a default name. You can edit this value.
3. Add a description. This is optional.
4. If you have opened the Create Data Load wizard from the Home page, then you need to select a project name from the drop-down. If this your first time here, click the + icon to create a project. If you have logged in as SUPERVISOR, the default project name is `Home`. For other users, the default project name is in the format `<username>_Home`. You can edit the default value. See Work with Projects for more information about projects.
5. For **Load Processing** do one of the following:
   - Select the **Internal** radio button and from the **Deployment Type** drop-down select **Data Transforms (Batch)**.
   - Select the **Delegate** radio button and from the **Deployment Type** drop-down select OCI GoldenGate. From the GoldenGate Deployment Connection drop down select a connection.
6. Click **Next**.
7. To define your source connection, from the **Connection** drop-down, select the required connection from which you wish to add the data entities. Alternatively, click the + icon to create a new connection. See Work with Connections for more details about connections.
8. In the **Schema** drop-down, all schema corresponding to the selected connection are listed in two groups:
   - Existing Schema (ones that you've imported into Oracle Data Transforms) and
   - New Database Schema (ones that you've not yet imported).

   Select the schema that you want to use from the drop down.

> **Note:**
>
> If there is missing information such as user name or password not specified, wallet missing, and so on, the list may fail to populate with a “This connection has missing information.” error. Click the Edit icon ( ) to open the Update Connection page where you can fill in the missing details.

9. Click **Next**.
10. Similarly, define the target connection. If you plan to use an Apache Iceberg connection as a target to load data, see Creating and Running an Apache Iceberg Data Load for specific instructions.
11. Click **Save**.
    The Data Load Detail page appears listing all the loaded data entities.

Run a Data Load

After you create the data load, you are taken to the Data Load Detail page that displays the details that you need to run a data load.

It includes the details of the source schema, the data entities that are loaded from the source schema, and the details of the target schema. You can choose the action that you want to apply on each data entity – recreate, truncate, append - and load tables in bulk to the target schema. When you run a data load, multiple jobs run in the background to complete the request.

You can run a data load in either of the following ways:

- Using the Data Load Detail Page.
- Running a Data Load from the Workflow Details Page.

> **Note:**
>
> Data load is not supported for Oracle Object Storage connections.

Running a Data Load from the Data Load Detail Page

The Data Load Detail page displays the information that you need to run a data load. You can apply different actions - incremental merge, incremental append, recreate, truncate, append - on the data entities before loading it to the target schema.

> **Note:**
>
> APPLIES TO: Data Transforms that is available as a separate listing on Marketplace called Data Integrator: Web Edition.
> If the data load is huge, you might want to increase the memory of the ODI Agent to avoid any issues. Follow the instructions in Increase the Memory of ODI Agent before you start to run the data load.

To run a data load from the Data Load Detail Page:

1. In the Data Load Detail page, select the data entities that you want to move to the target schema.
   To filter the list, you can do one of the following:
   - Enter the name or part of the name in the **Name** text box. This search returns data entities that include the specified string in the name. For example, the search string AD returns results such as ADMIN, ADDRESS, BADGE, UPGRADE, WORKLOAD, and so on.
   - Turn on the **Use Regular Expression** toggle to use pattern matching to search for particular strings of characters. For example, the search string CO.* returns results such as CONTACT, COUNT, COUNTRY and so on.

   You can select multiple data entities and load them to the target schema. You can also sort the displayed list using the following options:
   - All - Displays all the data entities that match the search criteria.
   - Selected - Displays all the rows that you selected.
   - Unselected - Displays all the unselected rows.
   - Invalid – Displays all the invalid rows.

   > **Note:**
   >
   > These options display the list of data entities based on the search criteria. To view the list of all data entities, clear any applied filters.

2. Click on the required icon to choose any of the following actions:
   - Incremental Merge - Updates the data in the selected column by comparing the source table with the target table based on the specified merge key. To use this option, select the column that you want to merge and then select the merge key. To use this option, select the column that you want to merge and then select the merge key. Click the Validate icon (✓) to validate the selected values.

     > **Note:**
     >
     > – The last update values for the Incremental Column are stored in the Data Load. If you create a new data load with the same table, this option acts like Append, Truncate, and Recreate the first time you run it.
     >
     > – If the target table is not truncated, do not start the Data Load using the Append, Truncate, or Recreate mode and then switch the action to Incremental Merge. This will cause every existing row in the target table to be updated. Oracle recommends that you start the Data Load using the Incremental Merge action.

   - Incremental Append - Updates data in the selected column in the target schema. To use this option, select the column that you want to update and click the Validate icon (✓) to validate the selection.
     The first time you run the Data Load, this option works in the same way as the Append, Truncate, and Recreate options, meaning all rows are inserted into the target. On all subsequent Data Load runs, the Incremental Column is used to filter only new rows to append data to avoid the same rows from being loaded more than once.

> **Note:**
>
> – The last update values for the Incremental Column are stored in the Data Load. If you create a new data load with the same table, this option acts like Append, Truncate, and Recreate the first time you run it.
>
> – If the target table is not truncated, do not start the Data Load using the Append, Truncate, or Recreate mode and then switch the action to Incremental Append. Oracle recommends that you start the Data Load using the Incremental Append action.

- Recreate – If the table is already present in the target schema, drops the existing table and recreates it.

> **Note:**
>
> This option is not available for data entities that are loaded using OCI GoldenGate.

- Truncate – If the table is already present in the target schema, deletes all the data from the selected table. Nothing is dropped.

> **Note:**
>
> For Delta Share data loads the Data Load Detail page only includes the option. You cannot apply different actions - incremental merge, incremental append, recreate, truncate, append - on the data entities before loading it to the target schema. This is to make sure that the data is consistent between the Delta Sharing server and the target schema.

- Append – Inserts all rows in the Dataset into the target. If the Dataset contains records that already exist in the target, there will be duplicate records. Use Append if the source dataset is expected to have only new records or duplicate rows in the target are not a concern.
- Do Not Load – Skips the selected data entity from the data load job. After you click **Save**, these data entities are no longer available for future data load jobs.

You can select multiple data entities and apply different actions. The unsaved rows are highlighted in bold.

> **Note:**
>
> These options are not available for Delta Share connections.

3. To specify how you want to store the source column names in the target tables, click **Settings**, which is on the right side of the Data Load Detail page. Choose one of the following:
   - **Retain original names by enclosing all names with delimiters** - Creates column names with the same names as is from the source tables in the target table.

- **Use no delimiters** - This is the default selection. Converts all the column names to upper case and replaces spaces and special characters with underscores.
  The following options are applicable to reserved words such as `Date`, `Timestamp`, `Start`, and so on.
  - **Enclose with delimiters** - This is the default selection. Encloses column names that are reserved words with delimiters (not all column names).
  - **Use a prefix** - Adds the specified prefix to column names that are reserved words (not all column names).

  For column names that have the same name after conversion, the names are suffixed with a numeric value to maintain uniqueness. For example column names

  `Date, date, DATE, Item_@Code, Item$$Code, Item%%Code`

  are created in the target table as

  `DATE, DATE_0, DATE_1, ITEM__CODE, ITEM__CODE_0, ITEM__CODE_1.`

> **Note:**
>
> Once the data load is run, the selected options are applied and retained for all subsequent runs. You cannot change the configuration.

4. Click to save the changes. A green checkmark ( ) in the row indicates that the changes are saved.
5. To start the data load,
   - Click .
   - For GoldenGate data loads, click .

   A confirmation prompt appears when the data load starts successfully.

To check the status of the data load, see the Status panel on the right below the Target Schema details. For details about the Status panel, see Monitor Status of Data Loads, Data Flows, and Workflows. This panel shows links to the jobs that execute to run this data load. Click the link to monitor the progress on the Job Details page. For more information about jobs, see Create and Manage Jobs.

Running a Data Load from the Workflow Details Page

You can add multiple data loads to a workflow along with data flows or workflows and run them as separate steps. The left panel of the Workflow Details page lists the data flows, workflows, and data loads that are available for use.

For data loads, the left panel lists the following two folders:

- **Data Loads** - This folder lists all the data loads that you have created in the local Data Transforms instance. When you select a step in the workflow that is a local data load, the Properties Panel available on the right side of the design canvas displays the Type as `Data Load` and the Linked Object as Home>`<nameofDataLoad>`.
- **Remote Data Loads** - This folder lists all the data loads that you have created in a remote Data Transforms instance. See Create a Data Transforms Connection for Remote Data Load. When you select a step in the workflow that is a remote data load, the Properties Panel available on the right side of the design canvas displays the Type as `Remote Data`

`Load` and the Linked Object as `Name of the Data Transforms connection` > `<nameofDataLoad>`.

After you have added the data loads to the workflow, click to execute them.

Work with Data Entities

A Data Entity is a tabular representation of a data structure.

It includes Database Tables or Views that can be used in a mapping as a source or target. They are simply the metadata for sources and targets. They are used in creating data flows.

You can add Data Entities to your newly created project in one of the following two ways:

- Importing Data Entities
- Creating Data Entities

All the newly created or imported Data Entities along with their details are displayed in the **Data Entities** page. The details include:

- **Name** of the Data Entity
- **Connection** for which the Data Entity was created
- **Schema** to which the Data Entity is associated
- Click the **Actions** icon (⋮) next to the selected Data Entity to perform the following operations:
  - Select **Edit**, to edit the existing details.
  - Select **Preview**, to preview the selected Data Entity. If the data entity belongs to an Oracle database, you can also view statistics of the table. See View Statistics of Data Entities for more details.
  - Select **Delete**, to delete the selected Data Entity.
- To delete the Data Entities in bulk, in the Data Entities page, select the check boxes of the respective Data Entities and click **Delete**.
- You can also search for the required Data Entity to know its details based on the following filters:
  - **Name** of the Data Entity
  - **Connection** for which the Data Entity was created
  - **Schema** to which the Data Entity is associated
  - **Tag** that is associated with the Data Entity

Topics

- Import Data Entities
  The easiest and most common way to create a Data Entity is by importing its structure from the connection type (for example, Oracle database).
- Create Data Entities
  You can manually create or update the Data Entities through the Oracle Data Transforms interface.
- Create Data Entities within the Data Flow editor
  If you have already created or imported your target data entity, then you would drag the data entity onto the Design Canvas and complete the column mappings and options.

- View Statistics of Data Entities
  The Preview tab displays detailed statistics of each data entity.

Import Data Entities

The easiest and most common way to create a Data Entity is by importing its structure from the connection type (for example, Oracle database).

To import existing Data Entities:

1. From the left pane of the Home page, click the **Data Entities** tab.
   Data Entities page appears.
2. Click **Import Data Entities**, to import the existing data entities.
   Import Data Entities page slides-in. If you plan to use an Oracle ERP Cloud Server connection for the import, see Importing Data Entity Definitions from an Oracle ERP Cloud Server.
3. Select the **Connection** followed by **Schema** and then finally select the **Type of Objects** you want to import.
   For Oracle Object Storage connections, the Schema drop-down lists the name of the bucket that you specified in the URL when you created the connection.
4. [For Oracle Business Intelligence Cloud Connector (BICC) connections only] From the **Offerings to import for collection**, choose the offerings whose data stores you want to import. You must select at least one offering to import the BICC public view objects (PVO).

   > **Note:**
   >
   > The import of BICC PVOs can take a long time depending on the number of selected objects. To improve performance, Oracle recommends that you use a mask to filter and limit the number of PVOs that you want to import.

5. Choose a **Mask**/filter if you don't want to import every object in the schema.
   Depending on the Connection Type, you will be presented with further options for importing.

   > **Note:**
   >
   > For Oracle Object Storage connections, this value is case-sensitive. If **Batch similar files** is set to `True`, all the files that match the mask and have the same structure are grouped together into a single data entity.

6. [For Oracle Financials Cloud connections only] From the list in the **Resources** section, select the items that you want to import. When the import process completes, a table is created for each selected resource.
7. [For REST server connections only] In the **Resources** section, do the following:
   - In the **Resource URI** field, enter the URL of the REST service you want to import resources from.
   - Click the + icon.
   - In the **Name** column enter an identifier for the resource.
   - In the **Operation URI** column enter the URI of the resource.
   - Click **Test Resource** to check whether the entries are valid.

8. Click **Start**.
   A Job is created and the corresponding Job ID is displayed for you to track the session. Click the Job ID to view the details of the job.

   Upon successful execution of the job, all the selected Data Entities are imported. Click the Refresh icon present at the right corner of the Data Entities page, to see the new imported Data Entities.

Create Data Entities

You can manually create or update the Data Entities through the Oracle Data Transforms interface.

Data entities should possess the corresponding objects in the source connection to be used as a source in a data flow. Usually the import process makes sure that these objects are in coordination. However, whenever you manually create or update Data Entities always make sure to check if both the definitions are in coordination with each other.

When you use a Data Entity as a target then it doesn't have to exist previously in the target connection and can be created as a part of Data Flow execution.

To create a new Data Entity:

1. From the left pane of the Home page, click the **Data Entities** tab.
   Data Entities page appears.
2. Click **Create Data Entity**, to create a new data entity.
   Create Data Entity page appears.
3. In the Name text box, enter the name of the new Data Entity that you are creating.
4. From the **Connection** drop-down, select the required connection from which you wish to add the newly created Data Entity.

   > **Note:**
   >
   > Oracle Financials Cloud connections are not listed here because you cannot manually create data entities for such connections. You can only import data entities from Oracle Financials Cloud REST endpoints using the Import Data Entities page. See Import Data Entities.

5. In the **Schema** drop-down, all schema corresponding to the selected connection are listed in two groups.
   - New Database Schema (ones that you've not imported from before) and
   - Existing Database Schema (ones that you've imported from before and are potentially replacing data entities).

   From the **Schema** drop-down, select the required schema.

   > **Note:**
   >
   > For Oracle Object Storage connections, the Schema drop-down lists the name of the bucket that you specified in the URL when you created the connection.

6. From the **Type** drop-down, select the data entity type.

- **Table**: To define the table structure for the newly created Data Entity, click the + icon to add columns. For each column, you can specify parameters such as Name, Data Type, Length, Scale, Not Null. Double click on the cell to configure the value.
  Click the 'x' icon, to delete a row. Click the Up and Down arrows to sort the table rows.
- **Inline View**: To create the data entity using inline code, enter the Select statement in the **Query** tab. For example, `SELECT * FROM CUSTOMER`. Click **Validate**.
  The **Columns** tab displays a read-only list of the columns that the query returns. Click the **Preview** tab to see the column data.

7. In the **Tags** text box, enter a tag of your choice. You can use tags to filter the Data Entities displayed in the Data Entity Page.
8. For Oracle Object Storage connections, this page displays the following options:
   - **Contents** – Select the CSV file that contains the data you want to import. The metadata displayed in the preview table, such as the data type and length of columns, is based on the first row of the CSV file. Make sure that the CSV file has a header line. The header should contain only alphanumeric characters and no special characters.
   - **Group Files** – Select this check box if you want to group data from multiple CSV files into one data entity. For example, say you want to merge data from Employee_Data1.csv, Employee_Data2.csv, and Employee_Data3.csv into a single data entity.
     If you want to upload the CSV files using Windows, make sure that you first convert the files to Unix format to avoid character encoding issues during grouping.
   - **Resource Name** – Use this option along with **Group Files**. Enter the value you want to use to identify the files. The resource name should be a regular expression. You can use only an asterisk (*) as a wildcard character in the resource name. For example, `Employee_Data*.csv`.
9. For Oracle database connections, you can mark the data entities as a feature group. Expand **Advanced Options** and click the **Treat as Feature Group** checkbox.
10. Click **Save**.
    The new Data Entity is created.

Create Data Entities within the Data Flow editor

If you have already created or imported your target data entity, then you would drag the data entity onto the Design Canvas and complete the column mappings and options.

To create the definition of an entity while in the Data Flow editor,

1. Drag the data entity onto the Design Canvas.
2. Select the component and click the Add Data Entity icon present on the top right corner of the target component.
3. **Add Data Entity** page appears allowing you to configure the following details of the target component:
   General tab
   - In the **Name** text box, enter the name of the newly created Data Entity.
   - From the **Entity Type** drop-down, select the data entity type.
     - **Table**
     - **ML Model**
       When you select this entity type the user interface changes as follows:

    * The **Connection Type** drop-down only lists **Oracle** as the option. Consequently, the **Connection** drop down only lists the Oracle connections that you have created.
    * The Add Data Entity wizard displays the **Properties** tab where you can select the Type of Learning, Function, Algorithm, and configure parameters to define the ML Model. See Use Machine Learning (ML) Models for detailed information about creating and using an ML Model data entity.

- From the **Connection Type** drop-down, select the required connection from which you wish to add the newly created Data Entity. The Connection drop-down is populated with the connections you have created with the associated connection type.
- From the **Connection** drop-down, select the server name from which you wish to add the newly created Data Entity.
- In the **Schema** drop-down, all schema corresponding to the selected connection are listed in two groups.
  – New Database Schema (ones that you've not imported from before) and
  – Existing Database Schema (ones that you've imported from before and are potentially replacing data entities).

  From the **Schema** drop-down, select the required schema.

  > **Note:**
  >
  > For Oracle Object Storage connections, the Schema drop-down lists the name of the bucket that you specified in the URL when you created the connection.

- In the **Tags** text box, enter a tag of your choice. You can use tags to filter the Data Entities displayed in the Data Entity Page.
- For Oracle database connections, you can mark the data entities as a feature group. Expand **Advanced Options** and click the **Treat as Feature Group** checkbox.
- Click **Next**.

Columns tab

- Click the Add Columns icon, to add new columns to the newly created Data Entity.
  A new column is added to the displayed table.
- The table displays the following columns:
  – Name
  – Data Type - Click the cell to configure the required Data Type.
  – Scale
  – Length
  – Actions - Click the cross icon to delete the created column.
- To delete the columns in bulk, select the columns and click the Delete icon.

- To search for the required column details, in the Search text box enter the required column name and click enter. The details of the required column are displayed.
- Click **Next**.

Preview Data Entity tab

It displays a preview of all the created columns and their configured details. If the data entity belongs to an Oracle database, you can also view statistics of the table. See View Statistics of Data Entities for more information.

4. Click **Save**.
The new target Data Entity is created.
5. Expand the **Properties Panel** in the right pane to view the following settings of the created components:
   - General - Displays the Name of the component along with its Connection and Schema details.
   - Attributes - Displays the details of all the attributes associated to the component.
   - Column Mapping - Click Auto Map to map all the columns automatically.
   - Preview - Click to have a preview of the component.
   - Options - Change the options as appropriate.

View Statistics of Data Entities

The Preview tab displays detailed statistics of each data entity.

> **Note:**
>
> This feature is available for Oracle database tables only.

You can view the statistics of a selected data entity in one of following ways:

- In the Data Entities list, click the **Actions** icon (⋮) next to the Data Entity and click **Preview**. Select the **Statistics** tab to view the statistics of the selected data entity.
- On any data flow click on any source or target data entity, and expand the properties panel in the right pane. Click **Preview**.

The statistical data is presented as follows:

- The total number of rows and columns in the data entity is displayed at the top.
- The statistics panel displays the thumbnail graphs for each column with information about the Min, Max, Distinct, and Null values.
- Two types of thumbnail representations are displayed based on the histogram:
  - A bar chart represents data for frequency and top-frequency histograms. The bar chart show the first top 10 values for the number of rows in the table.
  - A table lists data for Hybrid and Height-Balanced histograms. The table displays the entire data and is scrollable. The table displays the range for the values and the percentage of rows in each range.
- You can click each thumbnail to view the statistics of the column in a new browser tab.
- The detailed view of each chart also shows the type of histogram.

Work with Projects

A project is the top-level container, which can include multiple folders to organize your data flows or work flows into logical groups.

The Projects page displays all the existing projects, which includes projects created by all users not just the logged in user.

You can perform the following operations on a Project folder:

- View Details
- Edit the name
- Export the Project. See Export Objects.
- Delete

Creating a Project

To create a new project:

1. Click **Create Project** on the Projects page.
2. On the **Create Project** page, provide a project name.
3. Click **Create**.
   After creating the project, you're redirected to the **Projects** page.

Viewing Project Details

On the Projects page, select a project and click **View Details** from the project's **Actions** icon (⋮) or select a project to open its details page. The left panel displays all the resources associated with the selected project such as data loads, data flows, workflows, variables, schedules, and jobs.

Deleting a Project

When you delete a project, you also delete the resources it contains. Once you delete a project, it cannot be restored.

> **Note:**
>
> Be sure to review all contained resources before you delete the project.

To delete a project, on the Projects page, select Delete from the **Actions** icon (⋮) for the project you want to delete or select a project to open its details page, and then click **Delete**.

In the **Delete Project** dialog, click **Delete** to confirm the delete operation.

About Data Flows

A data flow defines how the data is moved and transformed between different systems.

A data flow in Data Transforms connects sources to targets through a flow of components such as Join, Filter, Aggregate, Set, Split, and so on. See Supported Database Functions for more information.
When you run a data flow, Data Transforms uses the joins, filters, mappings, and constraints to transform source data and load it to target tables. Note that you can run only one execution flow at a time. You cannot put multiple flows on a Data Flow and a flow cannot diverge into multiple flows.

Topics

- Create a Data Flow
  Create data flows to load data from a source connection, run transformations, and move the data to a target database.
- About Data Flow Editor
  The Data flow editor is divided into five parts, the Data Entity Panel, the Database Functions Toolbar, the Design Canvas, the Properties Panel, and the Status Panel.
- Supported Database Functions
  Oracle Data Transforms supports various database functions that you can drag and drop on the Design Canvas to connect components within a data flow.
- Add Components
  Add the data entities and database functions to the Design Canvas, and connect them in a logical order to complete your data flows.
- Use Text Embedding Vector in a Data Flow
  Data Transforms supports the use of vector datatype and embedding vectors in a data flow. Currently, Data Transforms integrates with OCI Generative AI service to convert input text into vector embeddings that you can use for data analysis and searches.
- Component Properties
  The Properties Panel displays various settings for components selected in the Design Canvas.
- Map Data Columns
  When you connect the source data entity with the target data entity, the column names are automatically mapped by the column names. You have a choice to map the columns by Position or by Name or map the columns manually using the Expression Editor.
- Validate and Execute a Data Flow
  After your mappings are ready, you can proceed to validate and execute the data flow.

Create a Data Flow

Create data flows to load data from a source connection, run transformations, and move the data to a target database.

You can create data flows in any of the following ways:

- From the Projects page
- From the Data Flows page within a project
- From the Home page

The newly created data flow is displayed in the Data Flows page of the associated project.

Click the Actions icon (⋮) next to the selected data flow to edit, rename, copy, change folder, start, export, or delete it.

From the Projects page

To create a data flow from the Projects page,

1. On the Projects page, click **Create Data Flow**.
   Create Data Flow page appears:
2. In the **Name** field, enter a name for the new data flow.
3. Select **Create New Project**, if you wish to create new project folder for the newly created data flow.
4. Else, click **Add to Existing Projects**, if you wish to add the newly created data flow to an existing project folder.
5. If you have selected **Create New Project** for the previous option, in the **Project Name** field, enter the name of the newly created project.
6. Else, if you have selected **Add to Existing Projects** for the previous option, select the required project from the **Project Name** drop-down arrow.
7. In the **Description** field, enter a description for the newly created data flow.
8. Click **Create**.

From the Data Flows page within a project

To create a data flow from the Data Flows page within a project,

1. On the Projects page click the project tile you wish to create a new data flow for. The **Project Details** page appears.
2. In the **Data Flows** page, click **Create Data Flow**.
3. Provide the **Name** and **Description** of the new data flow.
4. Click **Next**.
5. To define your source connection, from the **Connection** drop-down, select the required connection from which you wish to add the data entities.
6. In the Schema drop-down, all schema corresponding to the selected connection are listed in two groups:
   - Existing Schema (ones that you've imported into Oracle Data Transforms) and
   - New Database Schema (ones that you've not yet imported).

   Select the schema that you want to use from the drop down. For Oracle Object Storage connections, the Schema drop-down lists the name of the bucket that you specified in the URL when you created the connection.
7. Click Save.
   The Data Flow Editor appears that allows you to create a new data flow.

From the Home page

To create a data flow from the Home page,

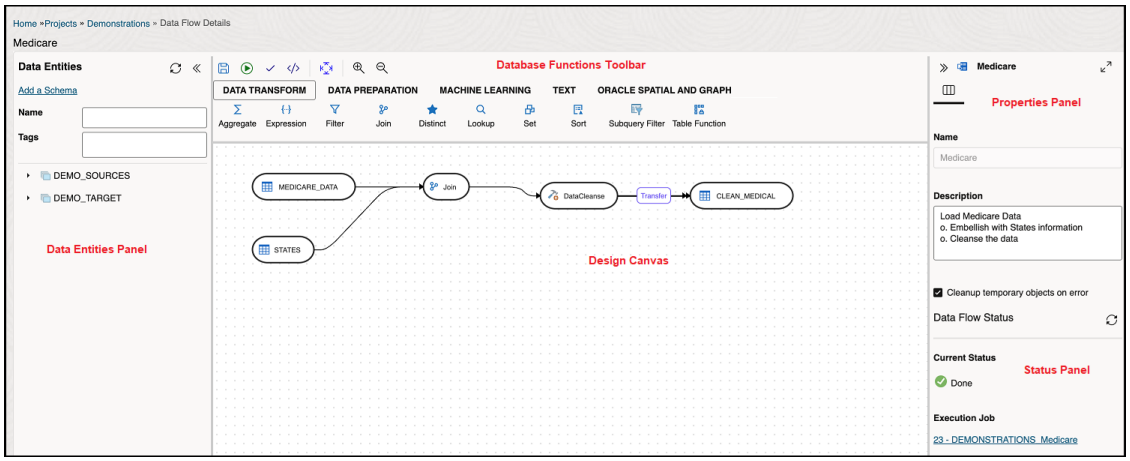
1. On the Home page, click **Transform Data**. The Create Data Flow page appears.
2. Provide the **Name** and **Description** of the new data flow.

3. Select a project name from the drop-down. Alternatively, click the + icon to create a project.
4. Click **Next**.
5. From the **Connection** drop-down, select the required connection from which you wish to add the data entities. Alternatively, click the + icon to create a new connection.
6. In the Schema drop-down, all schema corresponding to the selected connection are listed in two groups:
   - Existing Schema (ones that you've imported into Oracle Data Transforms) and
   - New Database Schema (ones that you've not yet imported).

   Select the schema that you want to use from the drop down.
7. Click **Save**.

About Data Flow Editor

The Data flow editor is divided into five parts, the Data Entity Panel, the Database Functions Toolbar, the Design Canvas, the Properties Panel, and the Status Panel.



- **Data Entities Panel**: The data entity panel displays the Data Entities that are available to use in your Data flows. The displayed list can be filtered using the Name and Tags fields. The panel includes options that let you add schemas, import data entities, remove any of the schemas that are associated with the data flow, and refresh data entities. See Add Components for information about how to use these options.
- **Database Functions Toolbar**: The Database Functions toolbar display the database functions that can be used in your data flows. Just like Data Entities, you can drag and drop the Database tools you want to use on the design canvas. See Supported Database Functions for more information.
- **Design Canvas**: The design canvas is where you build your transformation logic. After adding the Data Entities and Database Functions to the design canvas, you can connect them in a logical order to complete your data flows.
- **Properties Panel**: The properties panel displays the properties of the selected object on the design canvas. The Properties Panel is grouped into four Tabs. **General**, **Attributes**, **Preview Data**, **Column Mapping**, and **Options**. Not all tabs are available as they vary based on the selected object. See Component Properties to know more about these options.

- **Status Panel**: When you run a data flow, the Status Panel shows the status of the job that is running in the background to complete the request. You can see the status of the job that is currently running or the status of the last job. For more information about the Status panel, see Monitor Status of Data Loads, Data Flows, and Workflows.

After designing the required data flow,

- Click , to save the created/designed data flow.
- Click , to align the nodes of the designed data flow.
- Click , to execute the created data flow.
- Click , to validate the created data flow.
- Click , to maximize or minimize the created data flow diagram in the design canvas.

Supported Database Functions

Oracle Data Transforms supports various database functions that you can drag and drop on the Design Canvas to connect components within a data flow.

The Database Functions toolbar in the Data Flow editor includes the following database functions that can be used in your data flows. See Oracle Database SQL Language Reference for information about the database functions.

1. **Data Transformation**
   It contains the following components:
   - Aggregate
   - Expression
   - Filter
   - Join
   - Distinct
   - Lookup
   - Set
   - Sort
   - Subquery Filter
   - Table Function
2. **Data Preparation**
   It contains the following components:
   - Data Cleanse
   - Substitution
   - Equi_Width Binning
   - Quantile Binning
   - Lead
   - Lag
   - Replace

3. **Machine Learning**
   It contains the following components:
   - Prediction
   - Predition Model
   - Outlier Detection
   - Text Embedding Vector
4. **Text**
   It contains the following components:
   - REGEXP COUNT
   - REGEXP INSTR
   - REGEXP SUBSTR
   - REGEXP REPLACE
   - Edit Distance Similarity
   - Contains
5. **Oracle Spatial and Graph**
   It contains the following components:
   - Buffer Dim
   - Buffer Tol
   - Distance Dim
   - Distance Tol
   - Nearest
   - Simplify
   - Point
   - Geocode Tools:

     > **Note:**
     >
     > The following Geocode Tools work only in non-Autonomous Database environment.

     - Geocode As Geometry
     - Geocode
     - Geocode Addr
     - Geocode All
     - Geocode Addr All
     - Reverse Geocode

> **Note:**
>
> The following Geocode Tool works only in an Autonomous Database environment.

  - Geocode Cloud
- Spatial Join

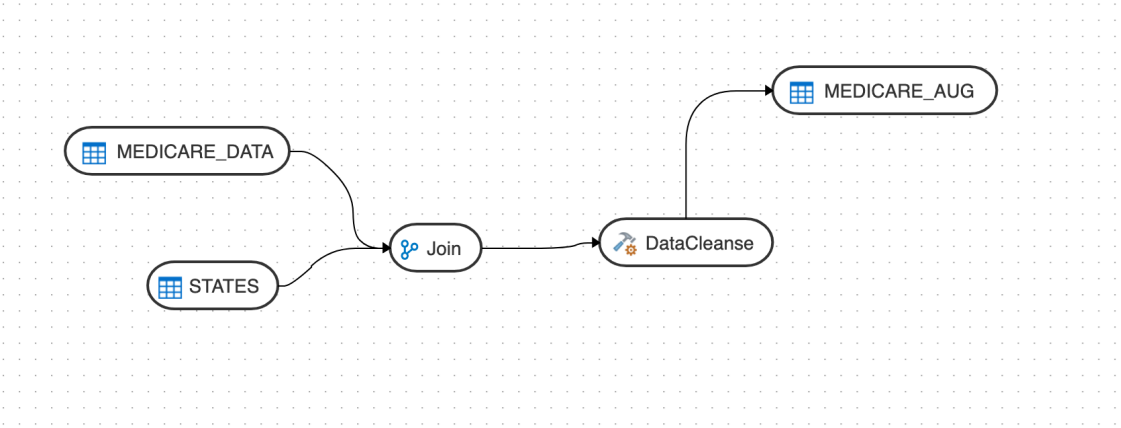
Add Components

Add the data entities and database functions to the Design Canvas, and connect them in a logical order to complete your data flows.

To add components to your data flow:

1. In the Data Entities panel, click **Add a Schema** to add schemas that contain the data entities that you want to use in the data flow.
2. In the Add a Schema page, select the connection and schema name.
3. Click **Import**.
4. In the Import Data Entities page, select the Type of Objects you want to import. Choose a Mask/filter if you don't want to import every object in the schema and click **Start**.
5. The Data Entities panel lists the imported data entities. The panel includes various options that let you do the following:
   - Refresh Data Entities – Click the Refresh icon to refresh the displayed list.
   - **Name** - Search for data entities by name.
   - **Tags** - Filter the data entities by the name of the tag used.
   - **Import Data Entities** - Right-click the schema to see this option. Use this option to import the data entities.
   - **Remove Schema** - Right-click the data entity to see this option. Use this option to remove the schema from the list. Note that this option does not delete the schema, it only removes the association of the schema with this data flow.
6. Similarly add more schemas to the Data Flow, if required.
7. Drag the required Data Entities that you want to use in the data flow and drop them on the design canvas.
8. From the **Database Functions** toolbar, drag the transformation component that you want to use in the data flow and drop them on the design canvas. You can use variables in the data flow. See Use Variables in a Data Flow for more information.
9. Select an object on the design canvas, and drag the **Connector** icon ( ) next to it to connect the components.
10. After saving the data flow, there may be a Transfer icon overlaid on one or more of the component connections. This indicates that ODI has detected an additional step and it is required to move the data between data servers. You can click on this Icon to view properties associated with this step.

For example:



Use Text Embedding Vector in a Data Flow

Data Transforms supports the use of vector datatype and embedding vectors in a data flow. Currently, Data Transforms integrates with OCI Generative AI service to convert input text into vector embeddings that you can use for data analysis and searches.

For text embedding Data Transforms supports both the text stored in a column and from the http links stored in a column. Before you use embedding vectors in a data flow, you need to do the following:

- Create an Oracle Database 23ai connection. See Work with Connections for generic instructions on how to create a connection in Data Transforms.
- Create an Oracle Cloud Infrastructure (OCI) Generative AI connection. See Create and use an Oracle Cloud Infrastructure Generative AI Connection.

To use vector embeddings in a data flow:

1. Follow the instructions in Create a Data Flow to create a new data flow.
2. In the Data Flow Editor click **Add a Schema** to define your source connection. From the **Connection** drop-down, select the Oracle Database 23ai connection and the schema that you want to use from the drop down. Click **OK**.
3. Drag the tables that you want to use as a source in the data flow and drop them on the design canvas.
4. From the Database Functions toolbar, click **Machine Learning** and drag the **Text Embedding Vector** transformation component drop it on the design canvas.
5. Click the **Text Embedding Vector** transformation component to view its properties.
6. In the **General** tab, specify the following:
   - **AI Service** - Select **OCI Generative AI** from the drop-down.
   - **Connection** - The drop-down lists all the available connections for the selected AI Service. Select the connection that you want to use.
   - **AI Model** - The drop-down lists all the available models for the selected AI Service and Connection. The following models are listed:
     - "cohere.embed-english-light-v2.0"
     - "cohere.embed-english-light-v3.0"
     - "cohere.embed-english-v3.0"

  - "cohere.embed-multilingual-light-v3.0"
  - "cohere.embed-multilingual-v3.0"

  You can also type in the model name.

7. In the **Column Mapping** tab, map the source column that you want to embed to the INPUT attribute of the operator. The only column available in the column mappings is `input_text`. Drag a text column from the available columns to the Expression column. This is the data that the vectors will be built on.
8. Drag the table that you want to use as a target in the data flow and drop it on the design canvas.
9. Save and execute the data flow.
   Data Transforms will build vectors for each of the rows in the source table and write that to the target table.

Component Properties

The Properties Panel displays various settings for components selected in the Design Canvas.

Depending on the component selected, you may see any of the following icons:

- General ( ) - Displays the name of the component along with its connection and schema details. You can edit some of these properties.
- Attributes ( ) - Displays the details of all the attributes associated with the component.
- Column Mapping ( ) - Allows you to map all the columns automatically. See Map Data Columns for more information.
- Preview ( ) - Displays a preview of the component. For Oracle tables, you can also view the statistics of the selected data entity. See View Statistics of Data Entities for details about the statistical information available.
- Options ( ) - Displays options such as
  - Truncate Table - Replaces any existing target table content with new data.
  - Append - Inserts records from the flow into the target. Existing records are not updated.
  - Incremental - Integrates data in the target table by comparing the records of the flow with existing records and updating the records when their associated data is not the same. Those that don't yet exist in the target are inserted.
    The option includes an Auto compression feature that is set to `True` by default. For data flow jobs that use the Incremental Update mode to load data onto a compressed Oracle target partition, the Auto compression feature recompresses the modified target partitions after the load completes successfully. For table partitions that are not originally compressed, the compression is skipped irrespective of whether Auto compression is set to true.

> **Note:**
>
> The Auto compression option is available to the ADMIN user or to a user with the DWROLE role. For data flows that have schema users other than ADMIN you need to either assign the DWROLE to the user or disable Auto compression to avoid execution errors.

Map Data Columns

When you connect the source data entity with the target data entity, the column names are automatically mapped by the column names. You have a choice to map the columns by Position or by Name or map the columns manually using the Expression Editor.

To map columns by Position or by Name:

1. Select the target Data Entity.
2. Click the arrow icon present on the top right corner to expand the Properties Panel. This will give you more space to work with.
3. In the **Properties Panel**, click the **Column Mapping** icon ( ).
4. To map the columns by Position or by Name, from the **Auto Map** drop-down menu, select **By Position** or **By Name**.

To map the columns manually:

1. From the **Auto Map** drop-down menu, select **Clear** to clear the existing mappings.
2. Drag and drop the attributes from the tree on the left to map with the Expression column.
3. To edit an expression, click the **Edit** icon of the respective column. The **Expression Editor** appears allowing you to perform the required changes (for example, you can just add an expression-"UPPER" or open the Expression Editor to edit the expression).

> **Note:**
>
> Use the expression editor only if you have complex expressions for a particular column.

4. Click **OK**.

Validate and Execute a Data Flow

After your mappings are ready, you can proceed to validate and execute the data flow.

Do the following:

1. Click Save.
   After saving, if data needs to be staged before transforming, Transfer button is added to one or more links. You can click these buttons to set more options, if available.
2. Click the **Code Simulation** icon ( ) if you want to check the code that will run to complete the tasks that are performed when you execute the data flow job. The source and target details are displayed in different colors for ease of reference. This is handy if you want to check if the mapping is correct before you run the job or if the job fails. Note that

the code cannot be used for debugging. For detailed information about the job, see the Job Details page.

3. Click the **Validate** icon ( ) in the toolbar above the design canvas to validate the data flow.

4. After a successful validation, click the **Execute** icon ( ) next to the **Validate** icon to execute the data flow.
If you have added variables to the data flow, the **Variable values** page appears that displays the list of variables that you have added to the data flow. You can choose to use the current value, the default value, or set a custom value for each variable. Note that the custom value is applied only to the current run of the data flow. The custom value does not persist for any subsequent sessions.

   A message appears that displays the execution Job ID and name. To check the status of the data flow, see the Status panel on the right below the Properties Panel. For details about the Status panel, see Monitor Status of Data Loads, Data Flows, and Workflows. This panel also shows the link to the Job ID that you can click to monitor the progress on the Jobs page. For more information, see Create and Manage Jobs.

   For data flows created using Oracle Object Storage connections, the data from the source CSV file is loaded into the target Oracle Autonomous Database. You can also export data from an Oracle Autonomous Database table to a CSV file in Oracle Object Storage.

Schedule Data Flows or Workflows

You can schedule workflows and data flows to run at specified time interval.

Each schedule allows you to specify a start date and time, and execution frequency.

To schedule a data flow or a workflow:

1. In the left pane, click **Schedules**.
2. Click **Create Schedule**.
3. From the **Resource** drop-down menu, select **Data Flow** or **Workflow** as appropriate.
4. From the **Resource Name** drop-down list, select a data flow or workflow that you want to schedule.
5. From the **Frequency** drop-down list, select the time frame in which you wish to execute the created schedule. You can schedule it On Startup, Simple, Daily, Hourly, Weekly, Monthly or Yearly. Based on the selected frequency, **Time** field appears allowing you to schedule the selected Data Flow or Workflow. For detailed information refer to the below table:

Frequency	Time Values
On Startup	NIL
Simple	Click Select Date Time icon next to **Date and Time** field, to select the required date and time in `MM/DD/YY` and `HH:mm` format.
Daily	Click the clock icon next to **Time** field, to select the required time in `HH:mm` format.
Hourly	Click up and down arrows next to **Time** field, to select the required time in `Minutes:Seconds` format.

Frequency	Time Values
Weekly	• **Run Every** parameter appears with check-boxes for all the days of the week. • Click the clock icon next to **Time** field, to select the required time in `HH:mm` format.
Monthly (day of the month)	• Select the required date from the **Monthly Date** drop-down box. • Click the clock icon next to **Time** field, to select the required time in `HH:mm` format.
Monthly (week day)	• From the **Monthly date** drop down box select the required value. • From the **Week day** drop-down box, select the required weekday in which you wish to schedule the job.
Yearly	• From the **Month** drop down box, select the required month in which you wish to schedule the job. • From the **Monthly date** drop down box, select the required date in which you wish to schedule the job. • Click the clock icon next to **Time** field, to select the required time in `HH:mm` format.

6. In the **Number of Attempts on Failure** text box, enter the required value or click the up or down arrows next to the text box, to select the required value. This value denotes the number of retry attempts that should happen after the schedule failure.
7. **Stop Execution After** field denotes the time after which the schedule has to stop after executing it. It can be in **Hours**, **Minutes** or **Seconds**. Select the value and its unit.
8. Select the status of the scheduled Data Flow or Workflow from the **Status** options. It can be **Active**, **Inactive** or **Active for Period**. Through **Active for Period** option you can configure the exact time frame of the created schedule. It's Starting and Ending Date with time, time interval in which you wish to run the schedule and exceptions, if any.
9. After configuring the above details, click **Save**.
   The created schedules get listed in the **Schedules** page along with the following details:
   - Resource
   - Status
   - Frequency
   - Valid or Invalid

   Click the Actions menu (⋮) of the respective schedule to perform the following operations:
   - Click **Edit** to edit the details of the created schedule.
   - Click **Disable** to disable the created schedule. The status of a schedule becomes inactive when you disable it and gets displayed in the Scheduled list. Select the schedule and click **Enable**, to enable it whenever required. You can enable it again for a specific period, through **Enable for Period** option.
   - Click **Validate** to validate the created schedule.
   - Click **Export** to export the schedule. See Export Objects.

- Click **Delete** to delete the created schedule. Upon confirmation the created schedule is deleted.

To schedule a data flow or a workflow specific to a project:

- Click the Project title displayed on the **Projects** page.
  Project Details page appears.
- In the left pane, click **Schedules**.
  Schedules page appears. It displays all the schedules pertaining to the selected project.

> **Note:**
>
> This page is project specific and displays only the Data Flows and Workflows pertaining to the selected project.

- To create a new schedule, click **Create Schedule**.
- Enter all the required details and click **Save**.
  The new schedule is created and is added to the existing list of schedules for the project.

Monitor Status of Data Loads, Data Flows, and Workflows

When you run a data load, data flow, or workflow Oracle Data Transforms runs jobs in the background to complete the request. You can view the status of the job in the panel on the bottom right of the Data Load Details, the Data Flow Editor, and the Workflow Editor page.

This panel includes the following:

- A Refresh icon ( ) to refresh the displayed status.
- The current status. You can see any of the following statuses:
  - Not Started – If no data load, data flow, or workflow has been executed yet.
  - Running – When the job starts.
  - Done – When the job completes.
    The status of the last job run persists in this panel till you run a new data load, data flow, or workflow.

> **Note:**
>
> For data loads created using OCI GoldenGate, the status panel shows the link to the GoldenGate Deployment Console and the status of the Extract and Replicat processes.

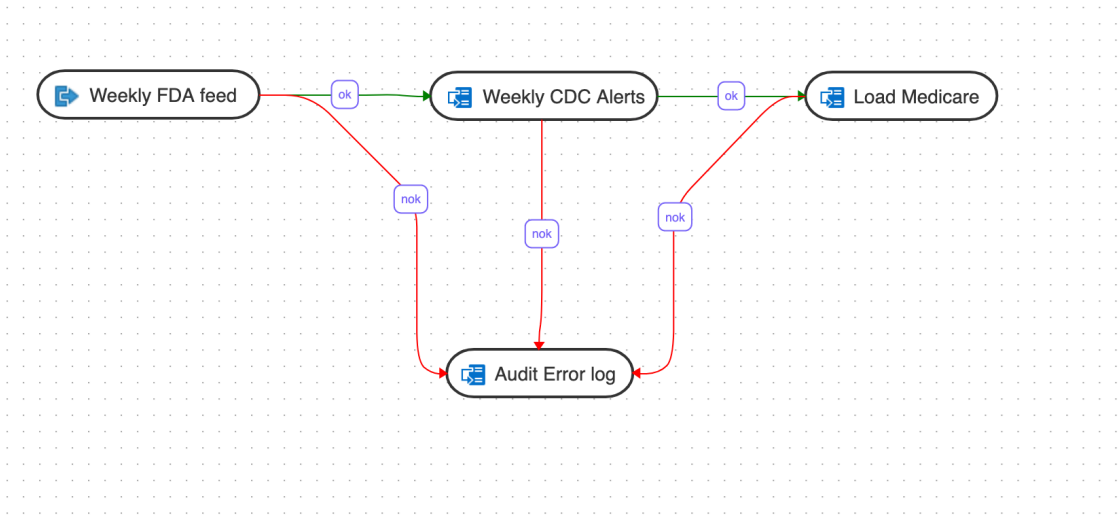
- The name of the job and a link that takes you to the Jobs Details page where you can see detailed information about the job and monitor the execution status. For more information, see Create and Manage Jobs.
  When you run a data load, multiple jobs run in the background to complete the request. This panel shows a link for each job that executes when running a data load.

Introduction to Workflows

A workflow is made up of multiple flows organized in a sequence in which they must be executed.

Each data flow is executed as a step. You can also add workflows, SQL queries, data loads, as well as variables as steps within a workflow. When you execute a workflow, a step either succeeds or fails. Depending on whether the first step succeeds or fails, you can choose the next step that must be executed.

Here is an example of a workflow:



In this example, the workflow performs the following actions:

1. Execute the "Weekly FDA feed" data flow.
2. If the "Weekly FDA feed" data flow execution is successful, execute the "Weekly CDC alerts" data flow.
3. If the "Weekly CDC alerts" data flow execution is successful, execute the "Load Medicare" data flow.
4. If any of the above data flow fails, then execute the "Audit_error_log" data flow.

Topics

- Create a New Workflow
  You can add data flows, workflows, variables, or data loads in a workflow.

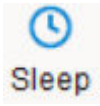
Create a New Workflow

You can add data flows, workflows, variables, or data loads in a workflow.

To create a new workflow for your project:

1. On the **Home** page, click the required Project title.
   You are navigated to the **Project Details** page.
2. In the left pane, click **Workflows**.
   The Workflow page appears.
3. On the **Workflow** page, click **Create Workflow**.
   The **Create Workflow** page appears.
4. In the **Name** field provide a name for the new workflow and click **Create**.
   The new workflow is created and listed in the **Workflow** page with its **Name** and **Folder** details. Click the Actions icon (⋮) next to the workflow to edit, rename, copy, change folder, start, export, or delete it.

5. Click the Workflow to configure the **Workflow Details**.
6. From the left panel drag the data flows, workflows, variables, or data loads that you want to run in the workflow. To use variables in the workflow, see Use Variables in a Workflow for more information.
   If you have connected to any other Data Transforms instance, you can also add data loads that you have created in that Data Transforms instance. See Create a Data Transforms Connection for Remote Data Load and Run a Data Load for more information.
7. Select either the ok (green arrow) icon, the not ok (red arrow) or the ok/not ok (black arrow) in the toolbar.
   This defines the mode that subsequent links drawn on the canvas will be set to.
   - ok (green) defines the success path.
   - not ok (red) defines the failure path.
   - ok/not ok (black) defines a path that is followed on success or failure.
8. Use the Sleep icon (

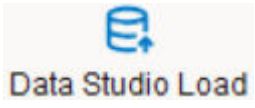
   


) to add a delay in the workflow. Drag the Sleep icon on the canvas and connect it in the flow with either the ok (green), not ok (red) or ok/not ok (black) links. This will add a delay at that point in the flow.
9. If you wan to add a SQL or PL/SQL query as a step in the workflow, do the following:
   - Drag the SQL icon ( ) on the canvas.

   - Double click the SQL step in the editor to open the step properties page.
   - Select the **Attributes** tab.
   - From the **Connection** drop-down select the connection you want to run the query on.

     > **Note:**
     >
     > The drop-down lists only Oracle database connections.

   - In the **SQL** textbox add the query that you want to run.
10. If you want to add a Data Studio Data Load as a step in the workflow, use the Data Studio Load icon (

) on the canvas. See Define a Data Studio Data Load in a Work Flow for detailed instructions on how to use a Data Studio Data Load to load data to Autonomous Database.

11. Select the step and click the **Connector** icon ( ) next to it to connect it with the next step.
12. After defining all the required Workflow details,

    - Click , to save the created/designed workflow.
    - Click , to align the nodes of the designed workflow.
    - Click , to execute the created workflow.
      If you have added variables to the workflow, the **Variable values** page appears that displays the list of variables that you have added to the workflow. You can choose to use the current value, the default value, or set a custom value for each variable. Note that the custom value is applied only to the current run of the workflow. The custom value does not persist for any subsequent sessions.
    - Select a single step in the canvas and click the **Execute Step** icon ( ), to execute only the selected data flow or workflow.
      To check the status of the workflow, see the Status panel on the right below the Properties Panel. For details about the Status panel, see Monitor Status of Data Loads, Data Flows, and Workflows. This panel shows the link to the Job ID that you can click to monitor the execution status on the Jobs page. For more information about jobs see Create and Manage Jobs.
    - Click , to maximize or minimize the created workflow diagram in the design canvas.
      The newly created workflows get listed in the Project Details page. The following details are displayed:
      – Name of the Workflow
      – Folder corresponding to the workflow - Default Folder

      To view the details of a workflow, click the name of the workflow and you are navigated to the Workflow Details page.

    In the left pane, you can search for the required Data Flow or Workflow using the Name filter. In the **Name** text box, enter the name of the required Data Flow or Workflow.

    Select a step in the canvas and check the **Properties Panel** available at the right side of the design canvas to know the following properties of the selected step in a created Data Flow or Workflow:

    - Name
    - Linked Object

      > **Note:**
      > You cannot edit this field.

    - Step -
      – First Step - Select the **First Step** check-box, to execute the selected step as the first step for execution in a Data Flow or Workflow.

> **Note:**
>
> You can select only a single step as a first step for execution in a Data Flow or Workflow.

- Number of attempts on Failure
- Time between attempts in seconds(s)
- Log steps in journal - Select any of the following options from the drop-down box:
  - Always
  - Never
  - Error

- Define a Data Studio Data Load in a Work Flow
  You can add a Data Studio Data Load as a step in a workflow and run the data load at scheduled intervals.

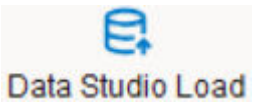
Define a Data Studio Data Load in a Work Flow

You can add a Data Studio Data Load as a step in a workflow and run the data load at scheduled intervals.

To do this, you need to create a connection, import data entities, create a data flow and then schedule the data load run.

To define and run a Data Studio Data Load within a workflow:

1. On the **Home** page, click the required Project title.
   You are navigated to the **Project Details** page.
2. In the left pane, click **Workflows**.
   The Workflow page appears.
3. On the **Workflow** page, click **Create Workflow**.
   The **Create Workflow** page appears.
4. In the **Name** field provide a name for the new workflow and click **Create**.
   The new workflow is created and listed in the **Workflow** page with its **Name** and **Folder** details. Click the Actions icon (⋮) next to the workflow to edit, rename, copy, change folder, start, export, or delete it.
5. Click the Workflow to configure the **Workflow Details**.
6. To add a Data Studio Data Load as a step in the workflow, drag the Data Studio Load icon (

) on the canvas.
7. Double click the Data Studio Load step in the editor to open the step properties page.
8. Select the **Attributes** tab.
9. From the **Connection** drop-down select the connection you want to load the data from.

> **Note:**
>
> The drop-down lists only Oracle database connections.

10. Select a Data Studio Load from the drop down.
11. Click , to save the created/designed workflow.
12. Click , to execute the created workflow.
13. To check the status of the workflow, see the Status panel on the right below the Properties Panel. For details about the Status panel, see Monitor Status of Data Loads, Data Flows, and Workflows. This panel shows the link to the Job ID that you can click to monitor the execution status on the Jobs page. For more information about jobs see Create and Manage Jobs.
    The newly created workflows get listed in the Project Details page.

Create and Use Variables

A variable is an object that stores a single value, which can be a string, a number or a date.

Topics

- Create a Variable
  You can specify the value of the variables when you create the variable or set the value using a query expression.
- Use Variables in a Data Flow
  You can use variables in a data flow by using them as a filter definition. You can refer to variables in a data flow using the format `#<variable_name>`. During execution the variable is substituted by the value.
- Use Variables in a Workflow
  The left panel of the Workflow Details page lists the variables that you can use as steps within a workflow.

Create a Variable

You can specify the value of the variables when you create the variable or set the value using a query expression.

The Variables page lists all the existing variables. Click the **Actions** icon ( ) of a variable to edit, refresh, or delete it. All the available variables are also listed in the left panel of the Workflow Details page. You can use variables as steps in data flows and workflows.

To create a variable:

1. On the **Home** page, click the required Project title. You are navigated to the **Project Details** page.
2. In the left pane, click **Variables**. The Create Variable page appears.
3. Enter a name for the variable.
4. From the **Data Type** drop down, select one of the following:
    - **Short text** - The value can be alphanumeric, can contain special characters, and cannot exceed 255 characters.

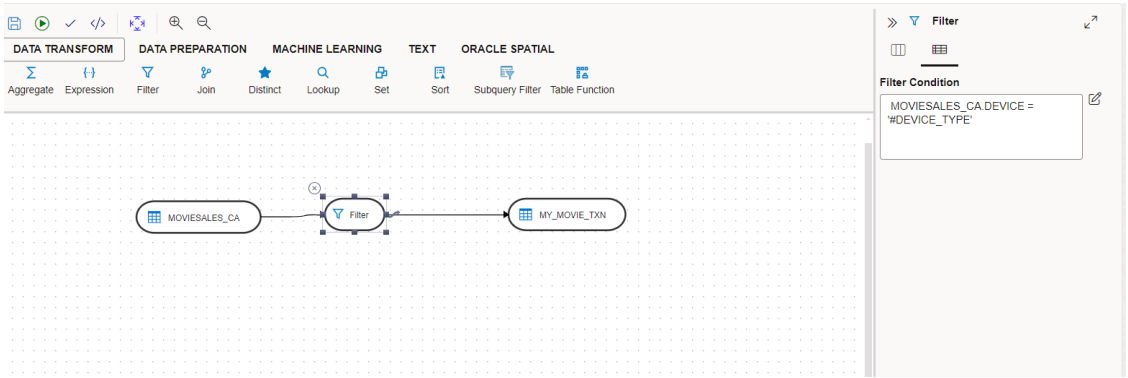
- **Long text** - The value can be alphanumeric, can contain special characters, and cannot exceed 64000 characters.
- **Numeric** - The value can be a numeric value and can be preceded by a minus (-) sign. The value cannot exceed 10 digits. Possible value range is -999999999 to 9999999999.
- **Date** - The value is a date format.

5. In the **Default Value** field enter the value you want to assign to the variable. The allowed value depends on the **Data Type** you select.
6. For variables that you modify, you can click the Actions menu next to the variable to open the Refresh Variable page to update the value. From the **Keep History** drop down select how you want the variable value to be displayed in the Refresh Variable page:
   - **All Values** - You can see the history of all the values held by this variable.
   - **Latest Value** - You can see only the latest value specified for the variable.
   - **No History** - Data Transforms does not keep the history of the values held by this variable.
   - **Secure Value** - This is useful when the variable contains passwords or other sensitive data. The value is not displayed in the Refresh Variable page.
7. Enter a description for the variable.
8. If you want the variable value to be set by a query, click the **Refresh** tab. Select the connection type and schema where you want to execute the command. Enter the query and click **Validate** to check the syntax of your expression.
9. Click **Save**.
   The newly created variable is listed in the Variables page as well as in the Variables node in the left panel of the Workflow Details page.

Use Variables in a Data Flow

You can use variables in a data flow by using them as a filter definition. You can refer to variables in a data flow using the format `#<variable_name>`. During execution the variable is substituted by the value.

When you execute the data flow, the **Variable values** page appears that displays the list of variables that you have added to the data flow. You can choose to use the current value, the default value, or set a custom value for each variable. Note that the custom value is applied only to the current run of the data flow. The custom value does not persist for any subsequent sessions.
Here is an example of the use of a variable in a data flow:



In this example, the data flow uses the variable DEVICE_TYPE as a step with the filter condition set as follows:

```
MOVIESALES_CA.DEVICE = '#DEVICE_TYPE'
```

The variable is quoted because the substituted value needs to be quoted. Since the variable value is substituted during execution, you can use it for many use cases such as in the transformation expression in the mapping.

Use Variables in a Workflow

The left panel of the Workflow Details page lists the variables that you can use as steps within a workflow.

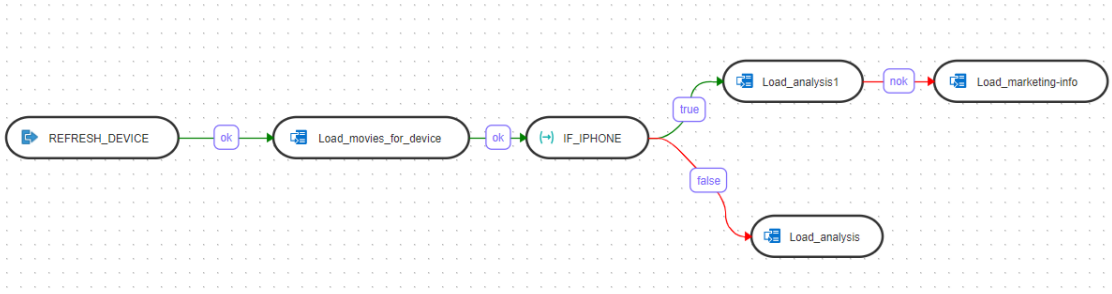
You can drag and drop the variables you want to use in the workflow on the design canvas. The Properties Panel available on the right side of the design canvas displays various details about the step such as the following.

- **Name**, **Type**, and the **Step** sequence number. These are non-editable values.
- Click the link under **Linked Object** to view and update the details about the variable.
- **Operation**: Select any one from the following:
  - **Set Variable** - There are two functions for this step:
    Update sets the current value of a variable.

    Increment increases or decreases a numeric value by the specified amount.
  - **Refresh Variable** - This variable step refreshes the variable by running the query specified in the variable definition.
  - **Evaluate Variable**: This variable step type compares the value of the variable with a given value according to an operator. If the condition is met, then the evaluation step is true, otherwise it is false.
- **Number of attempts on Failure**
- **Time between attempts in seconds(s)**
- **Log steps in journal** - You can select from Always, Never, or Error.

When you execute the workflow, the **Variable values** page appears that displays the list of variables that you have added to the workflow. You can choose to use the current value, the default value, or set a custom value for each variable. Note that the custom value is applied only to the current run of the workflow. The custom value does not persist for any subsequent sessions.

Here is an example of the use of a variable in a workflow:



In this example, a variable called DEVICE _TYPE with the value "iphone" is used as a step in the workflow. The workflow performs the following actions:

1. Execute the "REFRESH_DEVICE data flow.
2. If the "REFRESH_DEVICE" data flow execution is successful, execute the "Load_movies_for_device" data flow.
3. If the "Load_movies_for_device" data flow execution is successful, execute the "IF_IPHONE" variable evaluation step.
4. If the variable value is equal to ‘iphone’, execute path for “true”.
5. If the variable value is not equal to ‘iphone’, execute path for “false”.

Use Machine Learning (ML) Models

Data Transforms supports the use of ML Model in a data flow. Learn how to create and use Machine Learning (ML) Models in data flows.

Topics

- Create an ML Model Data Entity in the Data Flow editor
  To use ML models in Data Transforms you need to create two data flows. You need to first build the ML model data entity using the Data Flow editor, and then you can use the data entity in a data flow to mine data from a source connection and load it into a target server.
- ML Model Data Entity Properties
  The **Properties** tab of the **Add Data Entity** wizard provides data mining options that you can use to define the ML Model data entity.
- Use ML Model in a Data Flow
  You can use the **Prediction Model** database function to run ML Model algorithms on source data and load the output to a target database.

Create an ML Model Data Entity in the Data Flow editor

To use ML models in Data Transforms you need to create two data flows. You need to first build the ML model data entity using the Data Flow editor, and then you can use the data entity in a data flow to mine data from a source connection and load it into a target server.

To build an ML Model data entity in the Data Flow editor,

1. Drag the data entity that you want to build the ML Model on onto the Design Canvas.
2. Select the component and click the Add Data Entity icon present on the top right corner of the target component.
3. **Add Data Entity** page appears allowing you to configure the following details of the target component:
   General tab
   - In the **Name** text box, enter the name of the newly created Data Entity.
   - From the **Entity Type** drop-down, select **ML Model** as the data entity type.
     When you select this entity type the user interface changes as follows:
     – The **Connection** drop down only lists the Oracle connections that you have created.
     – The Add Data Entity wizard displays the **Properties** tab where you can select the Type of Learning, Function, Algorithm, and configure parameters to define the ML Model. See ML Model Data Entity Properties for more information.

- From the **Connection Type** drop-down, select the required connection from which you wish to add the newly created Data Entity. For ML Model data entities, the **Connection Type** drop-down only lists **Oracle** as the option.
- The Connection drop-down is populated with the connections you have created with the associated connection type. From the **Connection** drop-down, select the server name where you wish to keep the ML model data entity.
- In the **Schema** drop-down, all schema corresponding to the selected connection are listed in two groups.
  - New Database Schema (ones that you've not imported from before) and
  - Existing Database Schema (ones that you've imported from before and are potentially replacing data entities).

  From the **Schema** drop-down, select the required schema.
- In the **Tags** text box, enter a tag of your choice. You can use tags to filter the Data Entities displayed in the Data Entity Page.
- If you want to mark this data entity as a feature group, expand **Advanced Options** and click the **Treat as Feature Group** checkbox.
- Click **Next**.

Properties tab

- Select the **Type of Learning**, **Function**, and **Algorithm** you want to use to build this data entity. For more information about the options, see ML Model Data Entity Properties.
- Based on the options selected, the **Parameters** section is populated with the list of parameters that are marked as "Importance" and "High". You can add other required parameters using the icon.
  You must specify a value for each parameter so that the data flow can run successfully.

Columns tab

- Click the Add Columns icon, to add new columns to the newly created Data Entity.
  A new column is added to the displayed table.
- The table displays the following columns:
  - Name
  - Data Type - Click the cell to configure the required Data Type.
  - Scale
  - Length
  - Actions - Click the cross icon to delete the created column.
- To delete the columns in bulk, select the columns and click the Delete icon.
- To search for the required column details, in the Search text box enter the required column name and click enter. The details of the required column are displayed.

- Click **Next**.

Preview Data Entity tab

It displays a preview of all the created columns and their configured details. If the data entity belongs to an Oracle database, you can also view statistics of the table. See View Statistics of Data Entities for more information.

4. Click **Save** to save the configuration and exit the wizard.
5. Save and execute the data flow.
The new Data Entity is created. displayed in the Data Entities page.

ML Model Data Entity Properties

The **Properties** tab of the **Add Data Entity** wizard provides data mining options that you can use to define the ML Model data entity.

This topic assumes prior knowledge of Oracle Machine Learning concepts such as data mining functions and algorithms. For more information, see Oracle Machine Learning for SQL API Guide.

Type of Learning	Function	Algorithm
Supervised	Classification	Decision Tree
		Explicit Semantic Analysis
		Generalized Linear Models
		Naive Bayes
		Random Forest
		Neural Network
		Support Vector Machines
	Regression	Generalized Linear Models
		Neural Network
		Support Vector Machines
	Time Series	Exponential Smoothing
	Attribute Importance	Minimum Description Length
Unsupervised	Association	Apriori
	Attribute Importance	CUR matrix decomposition
	Anomaly Detection	One Class Support Vector Machines
	Clustering	Expectation Maximization
		k-Means
		Orthogonal Partitioning Clustering
	Feature Extraction	Explicit Semantic Analysis
		Non-Negative Matrix Factorization
		Singular Value Decomposition

Use ML Model in a Data Flow

You can use the **Prediction Model** database function to run ML Model algorithms on source data and load the output to a target database.

Before you use an ML Model in a data flow, you need build the ML Model. For instructions on how to create an ML model, see Create an ML Model Data Entity in the Data Flow editor.

To use an ML Model in a data flow:

1. Follow the instructions in Create a Data Flow to create a new data flow.
2. In the Data Flow Editor, drag the tables that you want to use as a source in the data flow and drop them on the design canvas.
3. From the Database Functions toolbar, click **Machine Learning** and drag the **Prediction Model** transformation component drop it on the design canvas.
4. Click the **Prediction Model** transformation component to view its properties.
5. In the **General** tab, specify the following:
   - **Connection** - The drop-down lists all the available Oracle connections. Select the Oracle connection that you want to use.
   - **Schema** - Select the schema.
   - **ML Model** - The drop-down lists all the available ML models. See Create an ML Model Data Entity in the Data Flow editor for instructions on how to build an ML Model.
6. In the **Column Mapping** tab, map the source column that you want to embed to the INPUT attribute of the operator. The only column available in the column mappings is `prediction parameters`. Drag a text column from the available columns to the Expression column.
7. Drag the table that you want to use as a target in the data flow and drop it on the design canvas.
8. Save and execute the data flow.
   Data Transforms will run the prediction model on the source data and write the output to the target table.

Create and Manage Jobs

When you execute a data load, data flow or workflow Oracle Data Transforms creates a job to complete the process in the background.

A job is made up of multiple steps that corresponds to an execution task.

The **Jobs** page by default, lists the execution job sessions that are running and completed for the present day as `Date` parameter is set to `Today` by default. You can click on any of the instance IDs from the list to see its details.

To work with jobs in Data Transforms, you can do the following:

- Create a Job from the Home page
- Create a Job from the Projects page
- View and Delete a Job
- Configure Purge Interval for Jobs
- Search for a Job

Create a Job from the Home page

To create a new job,

- On the Home page, click **Jobs** on the left pane to access the Jobs page.
- Click **Create Job**.
  The **Create Job** page slides-in.

- From the **Resource Type** drop-down, select the type of resource for which you wish to create a new job. It can be - Data Flow, Workflow or Schema.
- All the resources associated with the selected Resource Type get listed in the **Resource** field. From the **Resource** drop-down, select the required resource for which you wish to create a new job.
- Click **Create**.

A new job is created and is added to the existing list of jobs in the Jobs page.

For each session, you can see the Job Session **ID**, **Name**, **Status**, **Start Time** and **End Time** for each of the jobs that are executed.

Create a Job from the Projects page

To view the job sessions pertaining to a specific project:

- Click the Project tile displayed in the Projects page.
  Project Details page appears.
- In the left pane, click **Jobs**.
  Jobs page appears. It displays all the jobs and their details pertaining to the selected project.

> **Note:**
>
> This page is project specific and displays only the jobs pertaining to the selected project.

- To create a new job, click **Create Job**.
- Enter all the required details and click **Create**.
  A new job is created and is added to the existing list of jobs for the project.

View and Delete a Job

Click the Actions menu (⋮) to **View Details** of the jobs, **Delete** and **Rerun** the jobs, if required. If any of the steps failed, you can click on them to see the error details.

To delete a job, select the check box of the respective job session and click **Delete**. Upon confirmation the selected job gets deleted.

Configure Purge Interval for Jobs

You can configure the interval to purge older jobs to reduce the load on the sessions table. The default time interval is 30 days, which means that all jobs that are older than 30 days will be purged periodically. Note that only an ADMIN user (odiadmin) can configure the purge interval.

To configure the purge interval for jobs, click the gear icon (⚙) on the Jobs page. In the **Configurations** dialog box, set the required value in the **Delete jobs before (days)** field and click **Save**.

Search for a Job

You can also search for the required job session to know its details based on filters such as:

- **Name** - Name of the Job

- **Status** - Select the required session status from the list - All, Done, Error, Queued, Running, Waiting and Warning. Note that to use the Queued and Waiting filter options in the drop-down you must enable the **Show Queued/Waiting** Jobs option.
- **Show Queued/Waiting Jobs** – Enable this option to include the queued or waiting jobs in the list on the Jobs page. When this option is enabled, the **Status** drop-down includes the Queued and Waiting options that you can use to filter the list.
- **Date** - Select the date in which the required job session was executed - All, Today, Yesterday, Last Week, Last Month and Custom Range, which allows you to select specific From and To dates.

Export and Import Objects

You can move Data Transforms objects between environments. You require an Object Storage connection to store the exported file. You then need to use the same Object Storage connection to import the objects.

Topics

- Export Objects
  You can export Data Transforms artifacts such as projects, connections, data loads, data flows, workflows, and schedules from one environment and import them to another.
- Import Objects
  To import objects you need to provide the same Object Storage connection that you had used for the export operation.

Export Objects

You can export Data Transforms artifacts such as projects, connections, data loads, data flows, workflows, and schedules from one environment and import them to another.

The Export and Import options in Data Transforms allow you to do the following:

- Move code from development environments to production environments.
- Share code between development environments.
- Backup and restore objects.

To export objects from a Development environment you need to provide an Object Storage connection as an input. You need to use the same Object Storage connection when you want to run the import process in another environment. See Import Objects. The export operation exports all the metadata of the repository objects along with all its dependent parent and child objects, and stores the information in an XML format in the Object Storage bucket.

You can use the Export wizard to export the entire project or export individual objects at the following levels:

- Projects
- Connections
- Data Load
- Data Flow
- Workflow
- Schedule

When you export an individual object, all the dependent objects are automatically included in the export.

> **Note:**
>
> Individual variables export is not currently supported. However, when you export a Project, the variables within that project are also exported.

To export objects using the Export wizard:

1. From the left pane, click the Home tab. Click **Export**.
   The **Export** wizard appears.
2. In the **Export File Name** field, enter a name for the file. The exported data will be stored in the ZIP format with the *filename_timestamp*_DTR file naming convention.
3. Select an Object Storage connection from the drop-down to store the exported file. Note that you need to select the same Object Storage connection during the import operation.
4. Click **Next**.
5. Select the objects that you want to export. You can choose to export a single, multiple, or all the objects that are listed on the page.
6. Click **Next**.
7. Select the connections that you want to export.
   You may choose not to make any selection on this page. The connections that are associated with the objects that you selected in the previous screen are automatically included during the export operation.
8. Click **Next** to preview your selections.
9. Click **Export** to start the export operation.
   A confirmation prompt appears when the export operation starts. Click the link that is displayed in the prompt to monitor the progress of the export operation on the Job Details page.

To export individual objects:

1. Click the **Actions** menu of the project, connection, dataload, dataflow, workflow, or schedule that you want to export, and click **Export**.
2. In the **Export File Name** field, enter a name for the file. The exported data will be stored in the ZIP format with the *filename_timestamp*_DTR file naming convention.
3. Select an Object Storage connection from the drop-down to store the exported file. You need to select the same Object Storage connection during the import operation.
4. Click **Export** to start the export operation.
   A confirmation prompt appears when the export operation starts. Click the link that is displayed in the prompt to monitor the progress of the export operation on the Job Details page.

Import Objects

To import objects you need to provide the same Object Storage connection that you had used for the export operation.

Note the following about the import process:

- **Projects** - To import projects, you can choose whether you want to overwrite the data in the repository or merge the matching container objects with the objects that are being imported.

  - **Overwrite** - If there is a match in the repository, all the dependent child objects will be overwritten by default.
    If there is no match, the project along with the child objects will be copied into the repository.
  - **Merge** - If the project exists in the repository, but the dependent child objects have no match, all the child objects in the repository will be merged with the new child objects that are coming through the import process.
    If the project exists in the repository, and the dependent child objects have a match, all the child objects in the repository will be overwritten with the new child objects that are coming through the import process.

    If the project does not exist in the repository, the project along with the child objects will be copied into the repository.

- **Connections** - For connections that have a match in the repository, the import process updates only the advanced properties of the connection in the repository along with the connection name. Credentials such as the schema name, passwords, and connection URL are persisted as is in the new environment. You can use such connections without any modification in the target repository.
  For connections that have no match in the repository, credentials such as the schema name, passwords, and connection URL are not carried over during the import operation. Post import, you need to update the credential information for such connections. You also need to make sure that you create a schema user in the database along with the required tables created for the schema user, which you may use as a data entity in dataloads, dataflows, workflows, and schedules.
- **Data Loads**, **Data Flows**, and **Workflows** - For these objects if there is a match in the repository, all the objects will be overwritten by default.
- **Schedule** - The status for schedules that have no match in the repository are set to Inactive. You need to update the connection information that is associated with the schedule, and then set the status of the schedule to Active.

To import objects:

1. From the left pane, click the Home tab. Click **Import**.
   The **Import** dialog box appears.
2. From the **Object Storage Connection** drop-down, select the connection that you had used for the export operation. See Export Objects.
3. From the **Import File Name** drop-down, select the exported file.
4. Choose one of the following import options:
   - **Merge** - Choose this to merge the objects that are already in the repository with the objects that are coming through the import process. This option is only available for container objects such as Projects.
   - **Overwrite** - Choose this to replace the objects that are already in the repository with the objects that are coming through the import process.
5. Click **Import** to start the import operation.
   A confirmation prompt appears when the import operation starts. Click the link that is displayed in the prompt to monitor the progress of the import operation on the Job Details page.

Reference

Topics:

- Enable Access to Private Data Sources from Autonomous Database
- Troubleshoot Mismatch with Server Cert DN Error
- Increase the Memory of ODI Agent

Enable Access to Private Data Sources from Autonomous Database

APPLIES TO: Data Transforms that is part of the suite of data tools built into Oracle Autonomous Database.

The Autonomous Database from where you are accessing Data Transforms should be configured to use a private endpoint to be able to communicate with private database sources. Otherwise when you try to create and test such a connection, you might get a "failed to connect" error.

If your Autonomous Database is configured to use a Private Endpoint, then you can only access private data sources from clients in the same Virtual Cloud Network (VCN). See Configuring Network Access with Private Endpoints for detailed instructions.

After you have configured network access using private endpoints, you need to do the following additional configurations for Oracle Data Transforms to communicate with private data sources. This chapter includes the following topics:

- Configuring DNS and Traffic Management
- Configuring RCE Proxy on the Private Endpoint

Configuring DNS and Traffic Management

You need to set up a fully qualified domain name (FQDN) and specify this FQDN in the connection host field when you create the connection. Refer to https://docs.oracle.com/en-us/iaas/Content/DNS/Concepts/views.htm for more information.

The VCN DNS resolver should know about the FQDN and be able to resolve it to a Type A IP address.

If you are not able to test a connection in Data Transforms on an Autonomous Database that is configured to use private endpoints, then do the following:

- Check whether the query to set the `ROUTE_OUTBOUND_CONNECTIONS` database property to `PRIVATE_ENDPOINT` is run. See Enhanced Security for Outbound Connections with Private Endpoints for more information.
- Make sure that the FQDN is used as the host so that the framework resolves the FQDN to the required IP address.
  Ensure that the data source VM has the FQDN set up with the required security rules.

If test connection fails even after using an FQDN, then do the following:

- From the OCI services menu, click **DNS Management** under **Networking**. Configure private DNS zones views and resolvers.
- Create and publish a record using the FQDN and the private IP (Type A) of the target database.

> **Note:**
>
> Do not use `*.oraclecloud.com` as the domain name when you set up the FQDN because it is a reserved domain name.

- Retry test connection.
  The test connection operation should complete successfully.

Configuring RCE Proxy on the Private Endpoint

For Autonomous Databases that are configured to use a private endpoint, the Autonomous Database service supports RCE to access resources in the customer subnet through a private route.

If you encounter a "failed to connect" error when you try to test a connection, contact your database administrator to check whether the database is RCE-enabled.

Note that RCE proxy can forward the reverse traffic only to the default OCI DNS resolver. If there is any overridden resolver, then connectivity will fail.

Troubleshoot Mismatch with Server Cert DN Error

APPLIES TO: Data Transforms that is part of the suite of data tools built into Oracle Autonomous Database.

For a connection on an Autonomous Database that is configured to use private endpoints, you must specify the distinguished name (DN) of the database server in the JDBC URL so that the Oracle Connection Manager (CMAN) can accept the request. Otherwise when you try to create and test such a connection, you might get a "Mismatch with Server Cert DN" error.

First, specify `ssl_server_dn_match=yes` in the JDBC URL for the CMAN to accept the request. Next, use the `ssl_server_cert_dn` parameter to specify the DN of the database server. Note that the order in which the keys are placed in `ssl_server_cert_dn` is important. The sequence should be `CN`, `O`, `L`, `ST`, `C`.

For example:

```
jdbc:oracle:thin:@(description= (retry_count=20)(retry_delay=3)
(address=(protocol=tcps)(port=1521)(host=xxxxx.adb.us-phoenix-1.oraclevcn.com))
(connect_data=(service_name=xxxxx.adb.oraclecloud.com))
(security=(ssl_server_dn_match=yes)(ssl_server_cert_dn="CN=adwc.uscom-
east-1.oraclecloud.com, O=Oracle Corporation, L=Redwood City, ST=California,
C=US")))
```

To get the values for `ssl_server_cert_dn`:

1. Login to the VM that is in the same subnet where your Autonomous Database lies.
2. Type the following command:
   `openssl s_client -connect xxxxx.adb.us-phoenix-1.oraclevcn.com:1521 -showcerts`

   You will find the values for the following under Server Certificate details:

   CN, O, L, ST, C

   For example, `"CN=adwc.uscom-east-1.oraclecloud.com, O=Oracle Corporation, L=Redwood City, ST=California, C=US"`

Increase the Memory of ODI Agent

APPLIES TO: Data Transforms that is available as a separate listing on Marketplace called Data Integrator: Web Edition.

If the data that you are loading from the source schema is huge, then you may want to increase the memory of the ODI Agent to avoid OutOfMemory exception errors.

To increase the memory of the ODI Agent:

1. Edit the `/u01/oracle/transforms_home/common/scripts/jettyServer.sh` file.
2. Add the `java -Xms1024m -Xmx4096m` parameter.
3. Restart the jetty server. Log in as OPC user and execute the following commands:

```
ssh -i <path to id_rsa> opc@<Instance IP>
sudo su
systemctl stop|start jettyserver.service
exit
```

Data Marketplace

Data Marketplace provides an innovative platform to access and share datasets effortlessly with Autonomous Database.

The Data Marketplace is a part of the Data Studio suite of tools that provides data scientists and business users with access to load and query datasets for their organizational requirements. You can access and discover data sets curated by data providers. You can integrate the shared data with the existing data, augmenting the data using AI capabilities.

This allows you as a producer to share data in the marketplace, which users of the system, either in the same tenancy or in a different tenancy, can then load the data locally in their database and consume it.

With the Data Marketplace, you can:

- Publish listings as a producer that enables you to access provide data to the intended audience based on how you configure the publishing. You can also view the statistical profile of your dataset.
- Load, analyze, and query the data as a consumer and leverage the AI capabilities of the Data Studio, like language detection, sentiment analysis, and key phrase extraction. You can also browse the datasets you can access based on your profile.

Topics

- The Data Marketplace Tool
  Data Marketplace provides an innovative platform to access and share datasets effortlessly.

The Data Marketplace Tool

Data Marketplace provides an innovative platform to access and share datasets effortlessly.

The Data Marketplace is a part of the Data Studio suite of tools that provides data scientists and business users with access to load, and query datasets for their organizational requirements. You can access and discover data sets curated by data providers. You can integrate the shared data with the existing data, augmenting the data using AI capabilities.

This allows you as a producer to *share* data in the marketplace, which users of the system (either in the same tenancy or different, depending on how you list your table) can then load the data locally in their database and *consume* it.

With the Data Marketplace, you can:

- Publish listings as a *producer* that enables you to access provide data to the intended audience based on how you configure the publishing. You can also view the statistical profile of your dataset.

- Load, analyze, and query the data as a *consumer* and leverage the AI capabilities of the Data Studio, like language detection, sentiment analysis, and key phrase extraction. You can also browse the datasets you can access based on your profile.

Data Marketplace Terminology

- **Dataset**: A unit of data you share in the Autonomous Database Marketplace as a producer. As a producer, you can create a dataset that supports tables and views.
- **Listings**: A list of tables available for consumption in the Data Marketplace. As a producer, you can publish a listing, specify the description, add a namespace, add tags, add links to documentation, and specify with whom you intend to share the data. Upon creation, the listings are displayed as cards on the Data Marketplace page.
- Access Data Marketplace Tool
  You can access shared datasets using the Data Marketplace tool, navigate to the Data Studio and launch the Data Marketplace tool.
- Publish Listings to Marketplace
  As a producer, you can create listings, configure the listing to prepare it for publishing, submit the listing for publishing to publish a table to Marketplace.
- Consume Dataset
  Depending on how you have made your listing available, consumers can access your dataset available on the Data Marketplace page.
- DBMS_DATAMART Package Reference
  This chapter provides information about the packages you use with the Data Marketplace Tool in Data Studio. The `DBMS_DATAMART` topic also covers the procedures included in the `DBMS_DATAMART` package. The `DBMS_DATAMART` package provides APIs to support common operations with Data Marketplace.

Access Data Marketplace Tool

You can access shared datasets using the Data Marketplace tool, navigate to the Data Studio and launch the Data Marketplace tool.

Prerequisites

You must run the following code as an `ADMIN` user to enable the Data Marketplace tool:

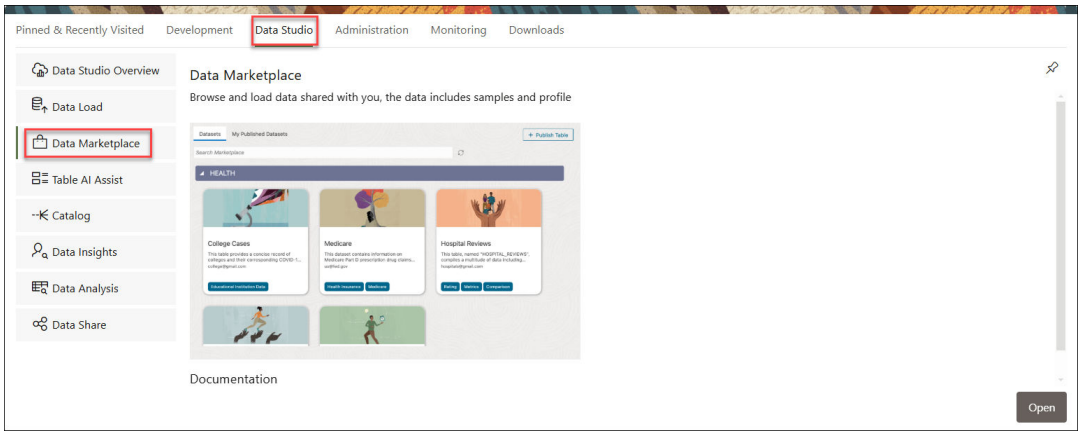
```
BEGIN
  DBMS_CLOUD_LINK_ADMIN.GRANT_READ( username =>'USER_NAME');
END;
```

> **Note:**
>
> - You must have the Data Marketplace tool enabled to view the listings. Otherwise, you will view an empty Marketplace page.
> - You can enable the Data Marketplace tool by running the above command or go to the Marketplace tab of the Data Studio Settings.

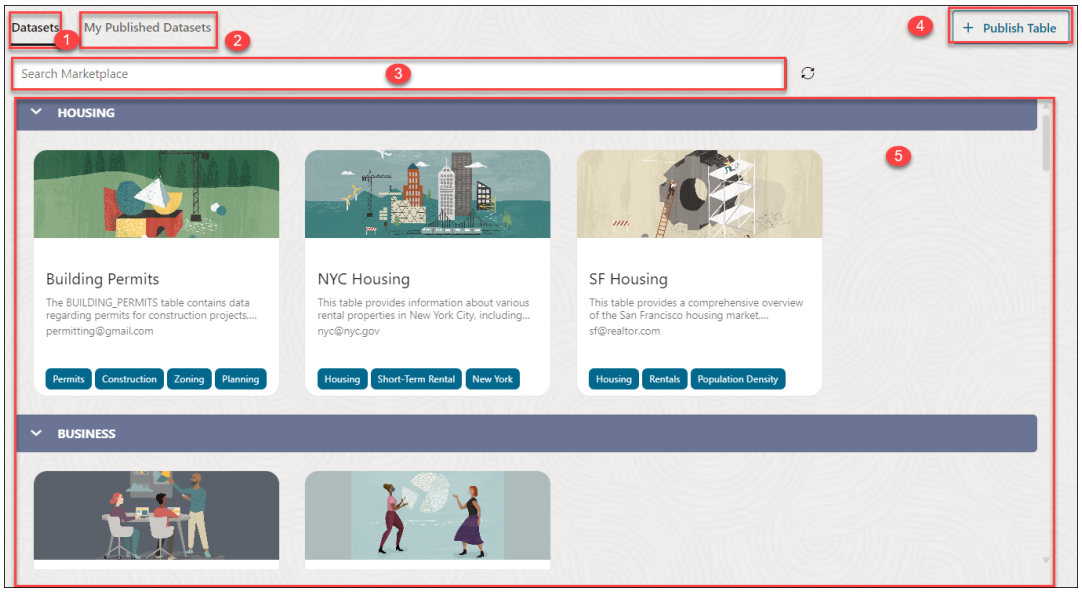
Follow these steps:

1. Navigate to the **Launchpad** on your Database Actions instance.

2. Click the **Data Studio** tab and select the **Data Marketplace** pane.



3. Clicking the Data Marketplace tab opens the Data Marketplace page.



You can view the following components on the Data Marketplace page:

- **Datasets tab**: This is the default tab selected when you open the Data Marketplace tool. You can view all the datasets shared with you available on this page.
- **My Published Datasets**: The datasets you publish are visible on this tab under the namespace or category you specify while publishing. You can **unregister** the listing by clicking any of the published datasets and selecting **Unregister**.
- **Search Marketplace Field**: You can search for the datasets from this field.

  Click the search field and enter the name of the Dataset you wish to view. You can also browse the datasets by the tags of the dataset. After you type the name and click enter, you can view the result in the display area. Click **Refresh** at the right end of the search field to refresh the page. Remove the search suggestion and click refresh to switch the view to its default view.

- **+Publish Table** icon: You can publish datasets using this icon. See Publish Listings to Marketplace for more details.
- **Display area:** The area below the search marketplace field displays the datasets returned by the search. You can expand the header which consists of the name of the category. It consists of the Dataset card with its name, description, and tags. Click the dataset card to view its details. See **Consume Dataset** for more information.

Publish Listings to Marketplace

As a producer, you can create listings, configure the listing to prepare it for publishing, submit the listing for publishing to publish a table to Marketplace.

Prerequisites

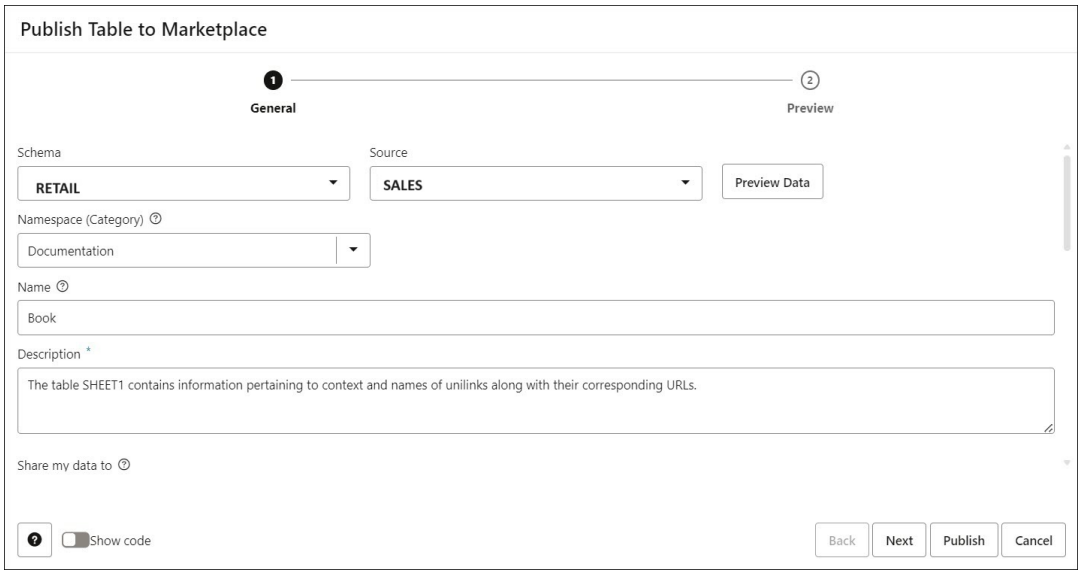
You must run the following code as an `ADMIN` user to publish datasets for a given region:

```
BEGIN
DBMS_CLOUD_LINK_ADMIN.GRANT_REGISTER( username =>'USER_NAME', scope =>
'MY$REGION');
END;
```

> **Note:**
>
> If you do not run the above command, the tool will raise an exception.

This topic describes how to publish listings to the Marketplace.

1. On the Data Marketplace page, select **+Publish Table**. You can view a **Publish Table to Marketplace** wizard.
2. On the **General** tab, specify the following details:



- **Schema**: Select the schema from the drop-down. For example, *RETAIL*.

- **Source**: You can view the source tables you load in the Autonomous Database using the Data Load tool. For example, *SALES*.

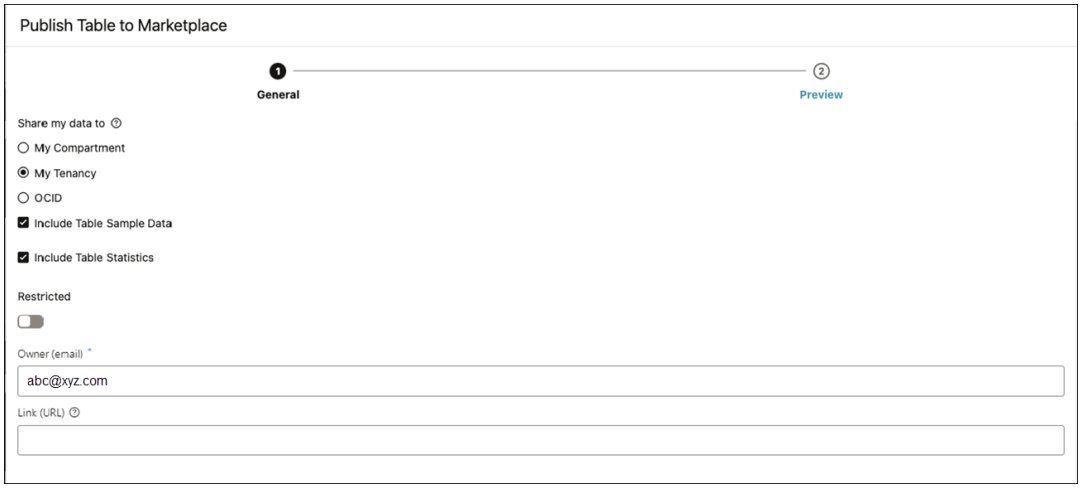
  > **Note:**
  >
  > *Note: If you have not loaded a table, the drop-down will be empty and the option will be greyed out. Make sure you have source data.*

  Click **Preview Data** to view the preview of the loaded table. You can also view the statistics of the table.

  See View Statistics of Data Entities for more information.

- **Namespace:** Specify the category of the data set you wish to group your data sets under. For example, *Documentation*.
- **Name:** Specify the name of the dataset. This should fall under the Namespace category. For example, *Book*.
- **Description:** This field is Auto filled using the AI capabilities of the Marketplace feature. It displays the description of the dataset shared in the listing. The description helps consumers understand the content of your dataset.

  > **Note:**
  >
  > – You can view the auto filled description only after you have configured and set AI profile using the Use DBMS_CLOUD_AI to Configure AI Profiles procedure.
  >
  > – After you have configured and set your AI profile, you must set the Data Studio Settings wizard on the Connections page.



- **Share my data to**: Specifies who and from where you are allowed to access the registered table.

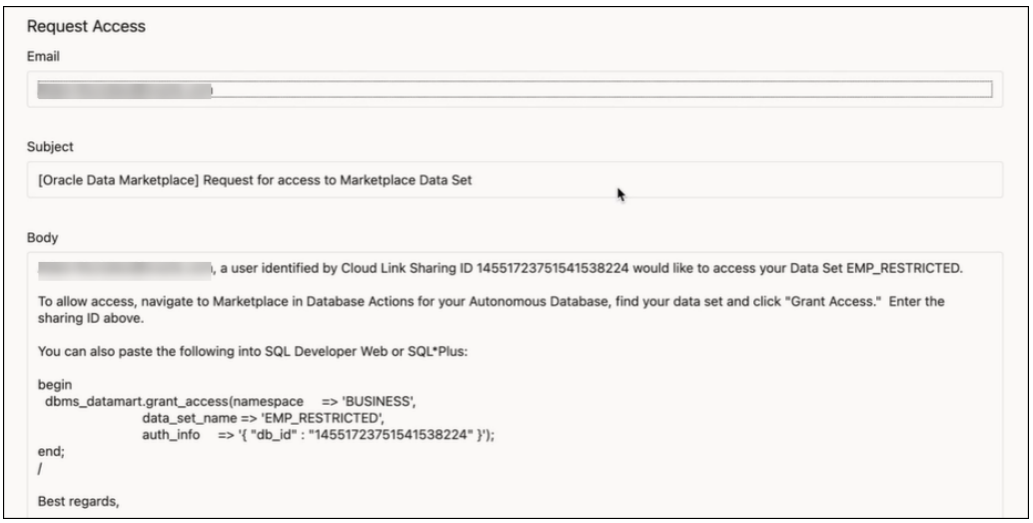
  You can choose from any of the following available options:

- **MY TENANCY**: You can grant remote data access to any resource, tenancy, compartment, or database in the tenancy of the Autonomous Database instance that is registering the data set.
- **MY COMPARTMENT**: You can grant remote data access to any resource, compartment, or database in the compartment of the Autonomous Database instance that is registering the data set.
- **OCID**: Access to the data set is allowed for the specific Autonomous Database instances identified by OCID.

> **Note:**
>
> Follow the steps provided in GET SHARING ID to obtain the OCID. It is alternatively known as `SHARING_ID`.

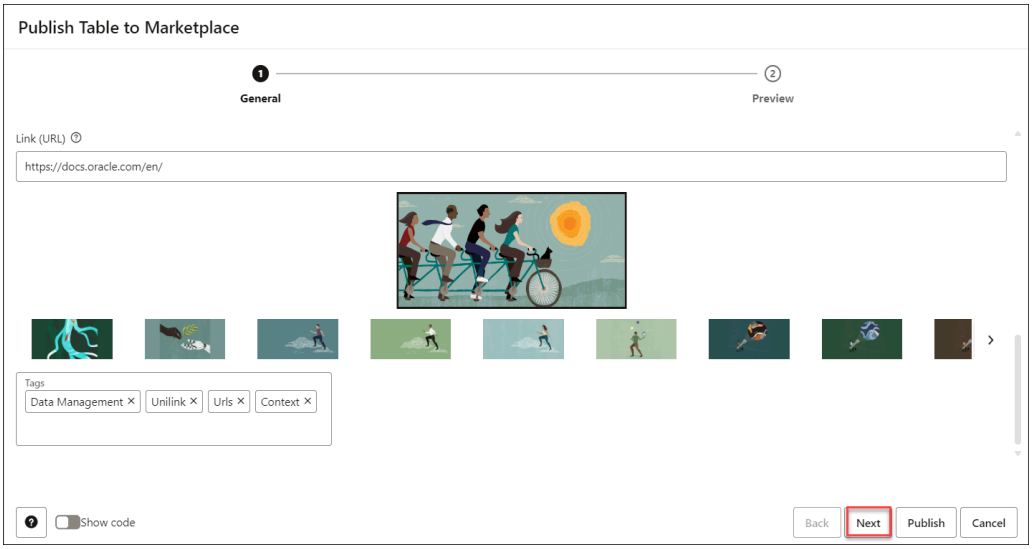
You can also include to share the Sample Data and Statistics of the table you select.

Restricted: When you publish a listing as restricted, the producer will receive an email notification with the Database ID for your listing.

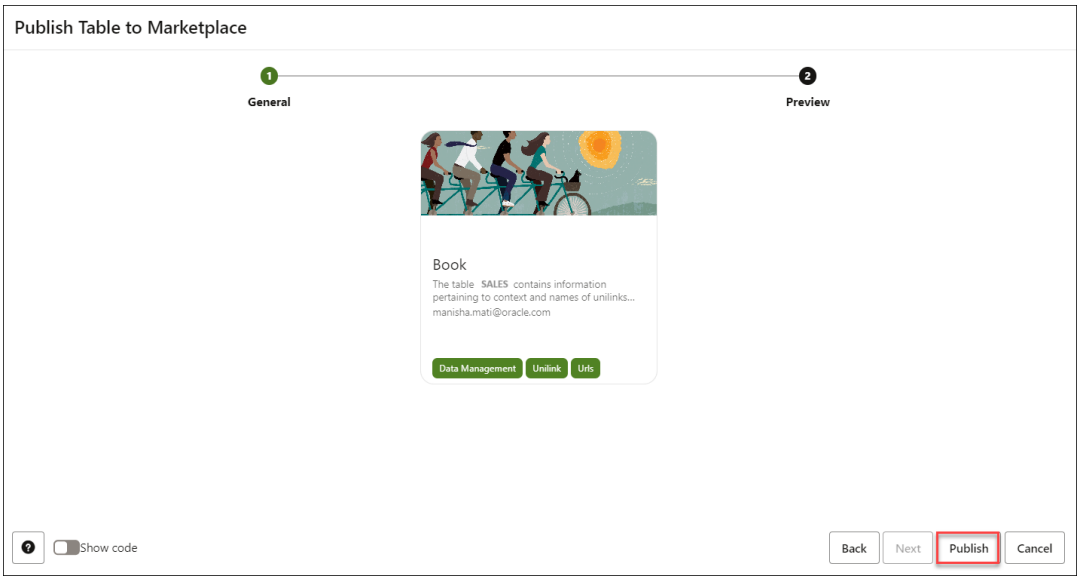


The producer shall grant access to the dataset for the consumer to consume the dataset by specifying the Database ID shared in the email.

- **Owner (email)**: Specify the email address of the producer, for example, *abc@xyz.com*.
- **Link (URL)**: Specify a URL that you can browse to discover more details on the data the provider shares. This field is optional.
- **Tags:** In the **Tags** text box, enter the tags of your choice. You can use tags to filter the Datasets on the search field.



3. Click **Next** to progress to the **Preview** tab. The preview tab displays the preview of the dataset card that will be displayed as a result of this publish.



4. Click **Publish** to publish the table to the Marketplace.

   You can view the published dataset in the **My Published Dataset** tab of the Data Marketplace page.

Consume Dataset

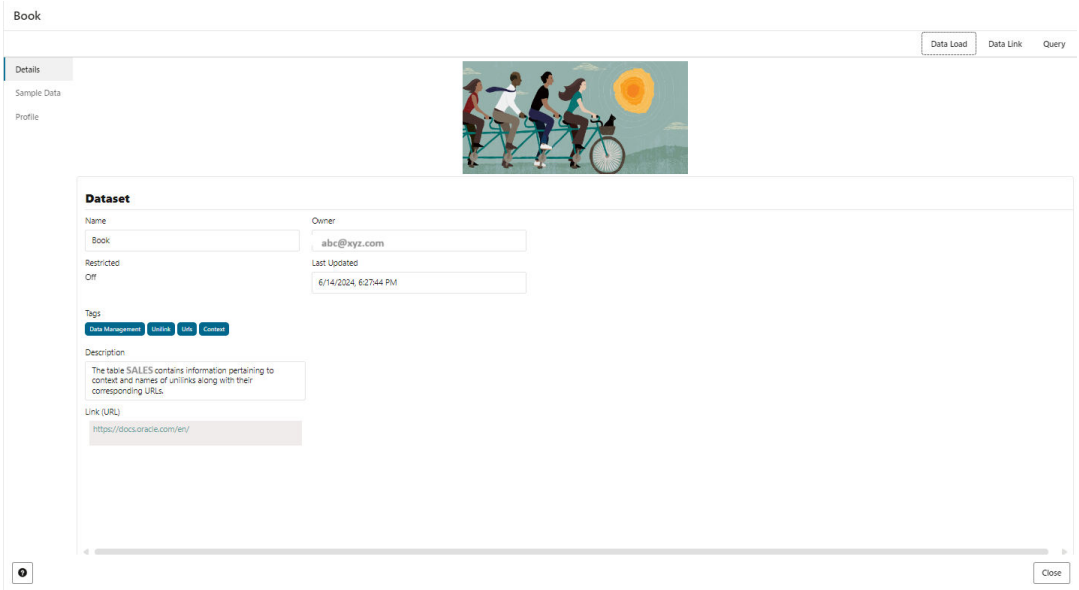
Depending on how you have made your listing available, consumers can access your dataset available on the Data Marketplace page.

As consumers you can view and consume the data in the dataset by following these steps:

1. On the Data Marketplace page select the listing whose data you wish to view.

   This opens the listing card.

2. You can view the following details of the Dataset:

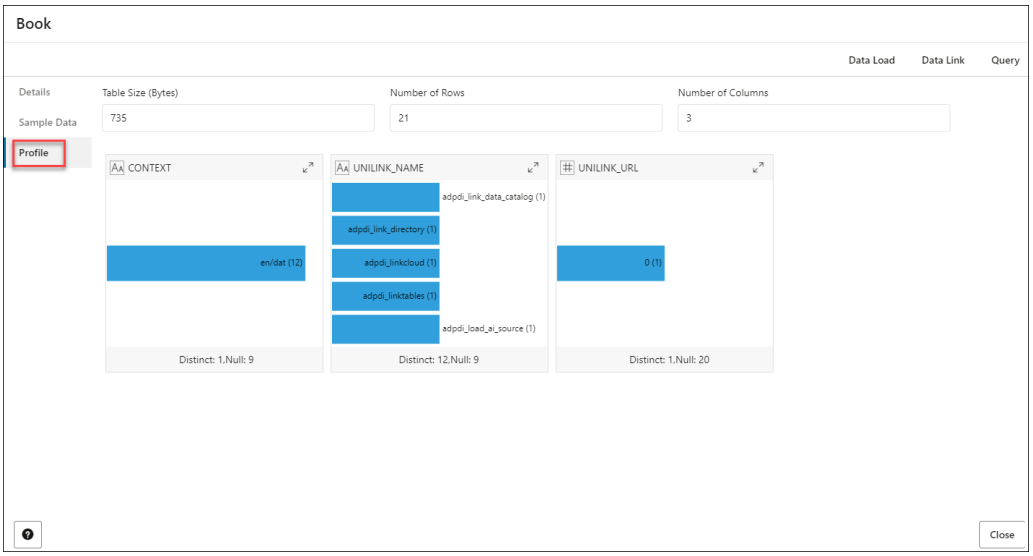


You can view the following fields on the Details tab:

- **Name:** Displays the name of the dataset.
- **Owner**: Displays the email address of the provider.
- **Restricted:** Specifies if the dataset shared is restricted or not.
- **Tags:** Displays the tags you selected while configuring the listing.
- **Description**: Displays description of the dataset shared in the listing.
- **Link(URL)**: Displays the URL the producer specifies during configuring the listing for publishing which displays more details on the data they share.

3. The Sample Data tab displays the preview of all the columns of the table selected in the dataset.

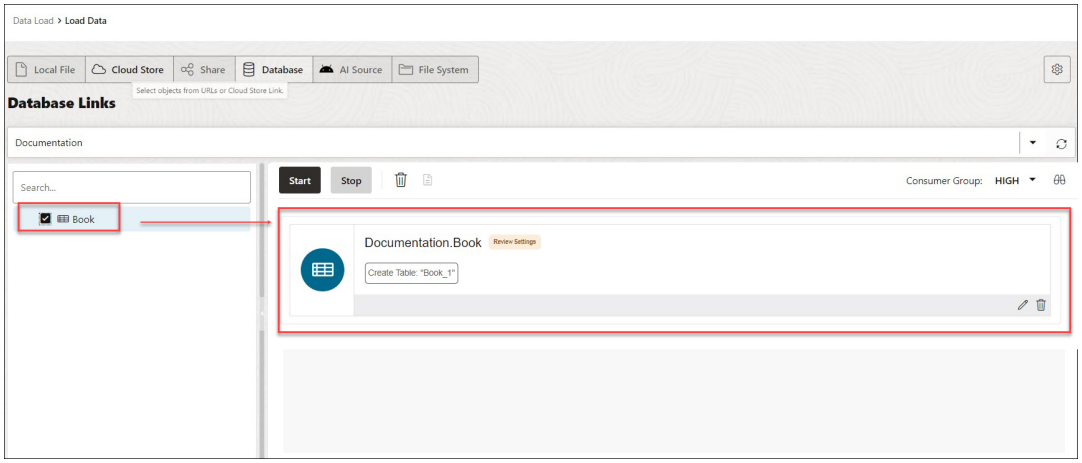
4. The Profile tab displays the statistical data of the dataset. You can view:
   - The total number of rows and columns in the data entity is displayed at the top.
   - The statistics panel displays the thumbnail graphs for each column with information about the Min, Max, Distinct, and Null values.
   - Two types of thumbnail representations are displayed based on the histogram:
     - A bar chart represents data for frequency and top-frequency histograms. The bar chart shows the first top 10 values for the number of rows in the table.
     - A table lists data for Hybrid and Height-Balanced histograms. The table displays the entire data and is scrollable. The table displays the range for the values and the percentage of rows in each range.
   - You can click expand thumbnail to view the statistics of the column in a new tab.
   - The detailed view of each chart also shows the type of histogram.



5. On the top header of the listing card details you can view the following icons:

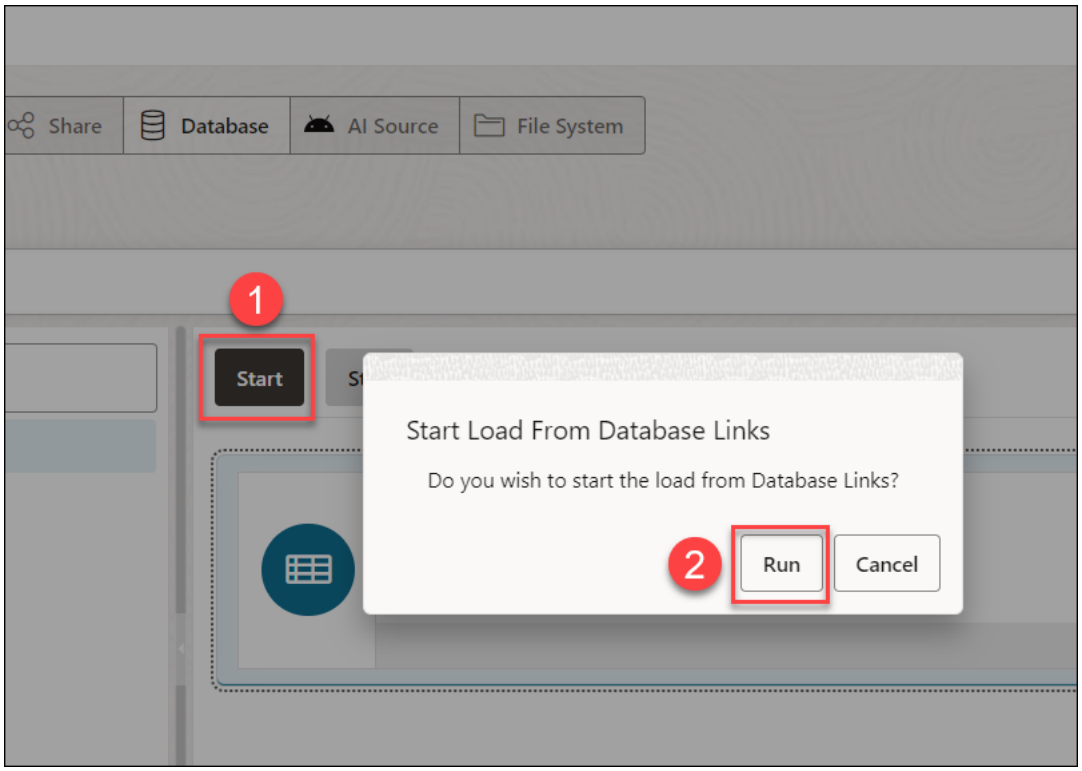
   Data Load: Selecting this option takes you to the Data Load page. You can create external tables derived from tables selected from the dataset.

   Drag and drop tables from the selected dataset.

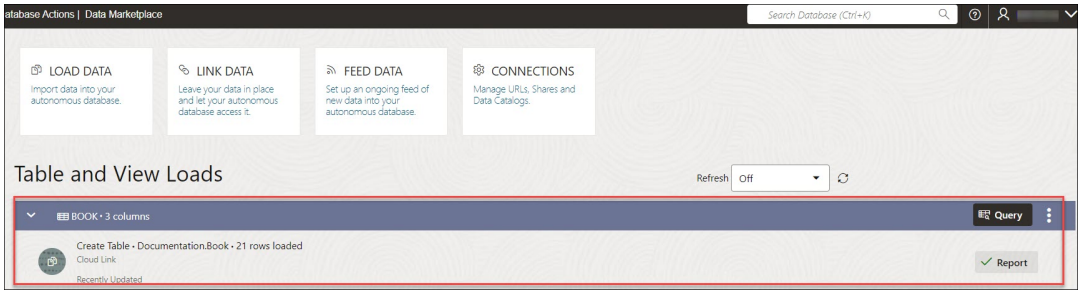


In this example, the only table selected is *BOOK*.

Create the external table by clicking **Start**, on the Load Data page, and then clicking **Run** on the Run Data Load Job dialog.



You can view the external table on the Dashboard under **Table and View Loads**.



- **Data Link**: Selecting this icon opens the Data Link page which is similar to the above operation of selecting the Data Load icon.
- **Query:** Selecting this icon opens the The Data Analysis Tool with the associated table as source input. This icon helps you analyze the data in the dataset and perform queries with the associated table. You can also create analytic views from the associated table in the dataset. See Data Analysis tool for more information.

DBMS_DATAMART Package Reference

This chapter provides information about the packages you use with the Data Marketplace Tool in Data Studio. The `DBMS_DATAMART` topic also covers the procedures included in the `DBMS_DATAMART` package. The `DBMS_DATAMART` package provides APIs to support common operations with Data Marketplace.

- Summary of DBMS_DATAMART Subprograms
  You can use Oracle Data Marketplace APIs to register and access datasets.

Summary of DBMS_DATAMART Subprograms

You can use Oracle Data Marketplace APIs to register and access datasets.

The `DBMS_DATAMART` package simplifies common operations with Oracle Data Marketplace, such as registering objects, requesting access, granting access, revoking access, unregistering and listing datasets.

The following table lists the `DBMS_DATAMART` subprograms and briefly describes them.

DBMS_DATAMART Package Subprograms

Subprogram	Description
register_object	This procedure registers datasets.
request_access	This procedure requests access to a specific dataset.
grant_access	This procedure grants access to a specific dataset.
revoke_access	This procedure revokes access to a specific dataset.
unregister	This procedure unregisters a dataset.
list_data_sets	This procedure returns the list of datasets.
get_stock_image_urls	This procedure returns the URL base from which you can select images.
get_reserved_namespaces	This procedure displays a JSON array of namespaces which are reserved by the system and cannot be used by you.
update_registration	This procedure updates an existing registration.

Register Object Procedure

This procedure registers datasets.

Syntax

```
procedure register_object(schema_name         in varchar2,
                          object_name         in varchar2,
                          namespace           in varchar2,
                          data_set_name       in varchar2,
                          scope               in clob default null,
                          thumbnail           in blob default null,
                          thumbnail_url       in varchar2 default null,
                          thumbnail_mime_type in varchar2 default null,
                          parameters          in clob default null);
```

Register Object Parameters

If you are accessing `Register Object` procedures, use the following parameters.

Parameter	Description
`schema_name`	The name of the schema.
`object_name`	The name of the object.
`namespace`	The namespace for the object.
`data_set_name`	The name of the dataset.
`scope`	This parameter indicates who can remotely access the data. The scope can be set to various levels, including to the region where the database resides, to individual tenancies, or to compartments. `MY$REGION` is not supported.
`thumbnail`	The image the tool displays in the cover of a dataset. You cannot use this parameter.
`thumbnail_url`	You cannot specify your own `thumbnail_url`. Oracle provides this parameter.
`thumbnail_mime_type`	It specifies Multipurpose Internet Mail Extensions (MIME) type of thumbnail.
`Parameters`	It specifies JSON parameters such as `tags`, `description`, `data_set_owner`, `authorization_required`, `offload_targets`, `offload_targets` and `store_sample`.

Request Access Procedure

This procedure requests access to the specified dataset.

Syntax

```
procedure request_access(namespace     in  varchar2,
                         data_set_name in  varchar2,
                         auth_info     out clob);
```

Request Access Parameters

If you are accessing `Request Access` procedure, use the following parameters.

Parameter	Description
`Namespace`	The namespace for the object.
`Dataset name`	The name of the dataset.
`Auth Info`	This parameter is generated populated as JSON on return. If the dataset provider has provided an email address and the requesting user has set up their Data Studio SMTP settings, the request will be submitted via email and this parameter will be generated with the `delivery` field set to smtp. Otherwise, the `delivery` field will be set to `browser` and you must use the rest of the metadata to submit their own request over email.

Grant Access Procedure

This procedure grants access to the specified dataset. The auth info parameter must contain the Sharing ID.

Syntax

```
procedure grant_access(namespace     in varchar2,
                       data_set_name in varchar2,
                       auth_info     in clob);
```

Revoke Access Procedure

This procedure revokes access to the specified dataset. The auth info parameter must contain the Sharing ID.

Syntax

```
procedure revoke_access(namespace     in varchar2,
                        data_set_name in varchar2,
                        auth_info     in clob);
```

Unregister Procedure

This procedure revokes access to the specified dataset. The auth info parameter must contain the Sharing ID.

Syntax

```
procedure unregister(namespace     in varchar2,
                     data_set_name in varchar2);
```

List Dataset Procedure

This procedure displays a list of datasets.

Syntax

```
function list_data_sets(registrations in boolean default false)
  return clob;
```

If `registrations` is `true`, it returns the list of datasets you register. If `false`, it returns the available data sets.

Get Stock Image URL Procedure

This procedure displays the URL from which you can select images.

Syntax

```
function get_stock_image_url return varchar2;
```

Get Reserved Namespaces Procedure

This procedure displays JSON array of namespaces that are reserved by the system. You cannot use these namespaces.

Syntax

```
function get_reserved_namespaces return clob;
```

Update Registration Procedure

This procedure updates an existing registration.

Syntax

```
procedure update_registration(namespace           in varchar2,
                              data_set_name       in varchar,
                              scope               in clob default null,
                              thumbnail           in blob default null,
                              thumbnail_url       in varchar2 default null,
                              thumbnail_mime_type in varchar2 default null,
                              parameters          in clob default null);
```

The parameters of this procedure are already described above.

View Data Pump Jobs and Import Data with Data Pump

Use the Data Pump page to view Data Pump jobs and use the wizard to quickly create and run Data Pump import jobs.

See The Data Pump Page for more information.

Link Data

You can link to data in remote databases, in cloud storage, or in connected file systems or the local file system. You can also use Database Links to access objects on another database.

When you link to data in a remote database or in cloud storage or in connected file systems or the local file system, the target object produced is an external table or a view. When you select

that target table or view on the Data Load, explore page in Database Actions, the source preview for the object shows the current data in the source object.

Linking to columns in a remote database, to files in cloud storage, or in connected file systems or the local file system can be useful when the source data is being continually updated. For example, if you have a database table with columns that are updated for each new sales transaction, and you have run a data load job that links columns of the source table to targets in your Oracle Autonomous Database, then those targets have the new sales data as it is updated in the source.

In addition, you can use Database Links to access objects on another database. Using Database Links, the other database need not be an Oracle Database system.

- Query External Data with Autonomous Database
  Describes packages and tools to query and validate data with Autonomous Database.
- Use Database Links with Autonomous Database
  You can create database links from an Autonomous Database to another Autonomous Database, to other Oracle databases, or to non-Oracle databases. In addition, you can create database links from other databases to an Autonomous Database.

Query External Data with Autonomous Database

Describes packages and tools to query and validate data with Autonomous Database.

External data is not managed by the database; however, you can use `DBMS_CLOUD` procedures to query your external data. Although queries on external data will not be as fast as queries on database tables, you can use this approach to quickly start running queries on your external source files and external data. Depending on the type of external table, you can validate external data using the `DBMS_CLOUD` validation procedures. The data validation procedures let you validate the source files for an external table so that you can identify problems and either correct the data in the external table or exclude invalid data before you use the data.

> **Note:**
>
> If you are not using `ADMIN` user, ensure the user has the necessary privileges for the operations the user needs to perform. See Manage User Privileges on Autonomous Database - Connecting with a Client Tool for more information.

- Query External Data
- Query External Data with ORC, Parquet, or Avro Source Files
  Autonomous Database makes it easy to access ORC, Parquet, or Avro data stored in object store using external tables. ORC, Parquet, and Avro sources have metadata embedded in them and the `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` procedure can utilize this metadata to simplify the creation of external tables.
- Query External Tables with Implicit Partitioning
  On Autonomous Database you can create implicit partitioned external tables from Hive style partitioned data or from simple folder partitioned data stored on your Cloud Object Store.
- Query External Tables with Partitioning Specified in Source Files
  If you want to query multiple data files in the Object Store as a single external table and the files can be represented as multiple logical partitions, it is highly recommended to use an external partitioned table. Using an external partitioned table preserves the logical partitioning of your data files for query access.

- Query External Partitioned Data (with Partitioning Clause)
  If you want to query multiple data files in the Object Store as a single external table and the files can be represented as multiple logical partitions, then it is highly recommended to use an external partitioned table. Using an external partitioned table preserves the logical partitioning of your data files for query access. Use the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` to create an external partitioned table.
- Query Data that Uses Table Hyperlink Source
  You can create an external table over an Autonomous Database Table Hyperlink.
- Query Hybrid Partitioned Data
  If you want to query internal data and multiple data files in the Object Store as single logical table you can use a hybrid partitioned table to represent the data as single object. Use the procedure `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` to create a hybrid partitioned table.
- Query External Data Pump Dump Files
  You can also query Oracle Data Pump dump files in the Cloud by creating an external table using `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`.
- Query Big Data Service Hadoop (HDFS) Data from Autonomous Database
  You can create database links to Oracle Big Data Service from Autonomous Database.
- Query External Data with Data Catalog
  Oracle Cloud Infrastructure Data Catalog is the metadata management service for Oracle Cloud that helps you discover data and support data governance. It provides an inventory of assets, a business glossary, and a common metastore for data lakes.
- Query External Data with AWS Glue Data Catalog
  Autonomous Database supports a system for synchronizing with an Amazon AWS Glue Data Catalog instance.
- Query Apache Iceberg Tables
  Autonomous Database supports querying Apache Iceberg tables.
- Validate External Data
  To validate any external table, you can use the procedure `DBMS_CLOUD.VALIDATE_EXTERNAL_TABLE`.
- Validate External Partitioned Data
  To validate an external partitioned table, you can use the procedure `DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE`. This procedure includes a parameter that lets you specify a specific partition to validate.
- Validate Hybrid Partitioned Data
  To validate a hybrid partitioned table, you can use the procedure `DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE`. This procedure includes a parameter that lets you specify a specific partition to validate.
- View Logs for Data Validation
  To validate an external table, use the procedures `DBMS_CLOUD.VALIDATE_EXTERNAL_TABLE`, `DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE`, and `DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE`.

Query External Data

To query data in files in the Cloud, you need to first store your object storage credentials in your Autonomous Database, and then create an external table using the PL/SQL procedure `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`.

You can also use the procedure DBMS_CLOUD.CREATE_EXTERNAL_TABLE to query external data in attached file systems or in the local file system.

The procedure DBMS_CLOUD.CREATE_EXTERNAL_TABLE supports external files in the supported cloud object storage services, including:

- Oracle Cloud Infrastructure Object Storage
- Azure Blob Storage or Azure Data Lake Storage
- Amazon S3
- Amazon S3-Compatible, including: Oracle Cloud Infrastructure Object Storage, Google Cloud Storage, and Wasabi Hot Cloud Storage.
- GitHub Repository

The source file in this example, channels.txt, has the following data:

```
S,Direct Sales,Direct
T,Tele Sales,Direct
C,Catalog,Indirect
I,Internet,Indirect
P,Partners,Others
```

1. Store your object store credentials using the procedure DBMS_CLOUD.CREATE_CREDENTIAL.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password' );
   END;
   /
   ```

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

   See CREATE_CREDENTIAL Procedure for information about the username and password parameters for different object storage services.

2. Create an external table on top of your source files using the procedure DBMS_CLOUD.CREATE_EXTERNAL_TABLE.

   The procedure DBMS_CLOUD.CREATE_EXTERNAL_TABLE supports external files in the supported cloud object storage services. The credential is a table level property; therefore, the external files must be on the same object store.

   For example:

   ```
   BEGIN
      DBMS_CLOUD.CREATE_EXTERNAL_TABLE(
       table_name =>'CHANNELS_EXT',
       credential_name =>'DEF_CRED_NAME',
   ```

```
    file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/channels.txt',
    format => json_object('delimiter' value ','),
    column_list => 'CHANNEL_ID VARCHAR2(2), CHANNEL_DESC VARCHAR2(20),
CHANNEL_CLASS VARCHAR2(20)' );
END;
/
```

The parameters are:

- `table_name`: is the external table name.
- `credential_name`: is the name of the credential created in the previous step. The `credential_name` parameter must conform to Oracle object naming conventions. See Database Object Naming Rules for more information.

  The `credential_name` parameter is not used when you specify a directory or a Table Hyperlink URL with `file_uri_list`. See Creating and Managing Directories on Autonomous Database and About Table Hyperlinks on Autonomous Database for more information.
- `file_uri_list`: is a comma delimited list of the source files you want to query.
- `format`: defines the options you can specify to describe the format of the source file.

  If the data in your source files is encrypted, decrypt the data by specifying the `format` parameter with the `encryption` option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.
- `column_list`: is a comma delimited list of the column definitions in the source files.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

> **Note:**
>
> Autonomous Database supports a variety of source file formats, including compressed data formats. See DBMS_CLOUD Package Format Options and the `DBMS_CLOUD compression` format option to see the supported compression types.

You can now run queries on the external table you created in the previous step. For example:

```
SELECT count(*) FROM channels_ext;
```

By default the database expects all rows in the external data file to be valid and match both the target data type definitions as well as the format definition of the files. If there are any rows in the source files that do not match the format options you specified, the query reports an error. You can use `DBMS_CLOUD` parameters, like *rejectlimit,* to suppress these errors. As an alternative, you can also validate the external table you created to see the error messages and the rejected rows so that you can change your format options accordingly. See Validate External Data for more information.

For detailed information about the parameters, see CREATE_EXTERNAL_TABLE Procedure.

See DBMS_CLOUD URI Formats for more information on the supported cloud object storage services.

- External Table Metadata Columns
  The external table metadata helps you determine where data is coming from when you perform a query.

External Table Metadata Columns

The external table metadata helps you determine where data is coming from when you perform a query.

The external tables you create with `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`, `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`, or `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` include two invisible columns `file$path` and `file$name`. These columns help identify which file a record is coming from.

- `file$path`: Specifies the file path text up to the beginning of the object name.
- `file$name`: Specifies the object name, including all the text that follows the final "`/`".

For example:

```
SELECT genre_id, name, file$name, file$path FROM ext_genre
     WHERE rownum <= 2;

genre_id      name        file$name     file$path
--------      ---------   -----------   ----------------------
1             Action      genre.csv     https://objectstorage.us-
ashburn-1.oraclecloud.com/n/namespace-string/b/moviestream_gold/o/genre
2             Adventure   genre.csv     https://objectstorage.us-
ashburn-1.oraclecloud.com/n/namespace-string/b/moviestream_gold/o/genre
```

See Invisible Columns for more information on invisible columns.

Query External Data with ORC, Parquet, or Avro Source Files

Autonomous Database makes it easy to access ORC, Parquet, or Avro data stored in object store using external tables. ORC, Parquet, and Avro sources have metadata embedded in them and the `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` procedure can utilize this metadata to simplify the creation of external tables.

You don't need to know the structure of the data, `DBMS_CLOUD` can examine the file and convert ORC, Parquet, or Avro contents into the equivalent Oracle columns and data types. You only need to know the location of the data in object store, specify its type, ORC, Parquet, or Avro, and have credentials to access the source file on your object store.

> **Note:**
>
> The steps to use external tables are very similar for ORC, Parquet, and Avro. These steps show working with a Parquet format source file.

The source file in this example, `sales_extended.parquet`, contains Parquet format data. To query this file in Autonomous Database, do the following:

1. Store your object store credentials, to access the object store, using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
    password => 'password' );
END;
/
```

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

   See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create an external table for ORC, Parquet, or Avro on top of your source files using the procedure `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`.

   The procedure `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` supports external files in the supported cloud object storage services, including: Oracle Cloud Infrastructure Object Storage, Azure Blob Storage or Azure Data Lake Storage, Amazon S3, and Amazon S3-Compatible, including: Oracle Cloud Infrastructure Object Storage, Google Cloud Storage, and Wasabi Hot Cloud Storage. The credential is a table level property; therefore, the external files must be on the same object store.

   By default, the columns created in the external table automatically map their data types to Oracle data types for the fields found in the source files and the external table column names match the source field names.

```
BEGIN
   DBMS_CLOUD.CREATE_EXTERNAL_TABLE(
    table_name =>'sales_extended_ext',
    credential_name =>'DEF_CRED_NAME',
    file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-
string/b/bucketname/o/sales_extended.parquet',
    format =>  '{"type":"parquet", "schema": "first"}'
 );
END;
/
```

   The parameters are:

   - `table_name`: is the external table name.
   - `credential_name`: is the name of the credential created in the previous step. The `credential_name` parameter must conform to Oracle object naming conventions. See Database Object Naming Rules for more information.
   - `file_uri_list`: is a comma delimited list of the source files you want to query. The URI format for Dedicated Endpoints is supported in commercial (OC1) realms. See

Object Storage Dedicated Endpoints, and DBMS_CLOUD URI Formats for more information.

- `format`: defines the options to describe the format of the source file. For a Parquet file, use the `format` parameter to specify the `type parquet`. For an Avro file use the `format` parameter to specify the `type avro`. For an ORC file use the `format` parameter to specify the `type orc`.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

By default the `format schema` parameter is set and the columns and data types are derived automatically and the fields in the source match the external table columns by name. Source data types are converted to the external table column Oracle data types according to the `DBMS_CLOUD` mapping for ORC, Parquet, or Avro data types. The valid `schema` parameter values are:

- `first`: Analyze the schema of the first ORC, Parquet, or Avro file that `DBMS_CLOUD` finds in the specified `file_uri_list` (`first` is the default value for `schema`).
- `all`: Analyze all the schemas for all the ORC, Parquet, or Avro files found in the `file_uri_list`. Because these are simply files captured in an object store, there is no guarantee that each file's metadata is the same. For example, File1 may contain a field called "address", while File2 may be missing that field. Examining each file to derive the columns is a bit more expensive but may be required if the first file does not contain all the required fields.

> **Note:**
>
> If the `column_list` parameter is specified, then you provide the column names and data types for the external table and the `schema` value, if specified is ignored. Using `column_list` you can limit the columns in the external table. If `column_list` is not specified then the `schema` default value is `first`.

3. You can now run queries on the external table you created in the previous step:

```
DESC sales_extended_ext;
Name           Null? Type
-------------- ----- --------------
PROD_ID              NUMBER(10)
CUST_ID              NUMBER(10)
TIME_ID              VARCHAR2(32767)
CHANNEL_ID           NUMBER(10)
PROMO_ID             NUMBER(10)
QUANTITY_SOLD        NUMBER(10)
AMOUNT_SOLD          NUMBER(10,2)
GENDER               VARCHAR2(32767)
CITY                 VARCHAR2(32767)
STATE_PROVINCE       VARCHAR2(32767)
INCOME_LEVEL         VARCHAR2(32767)
```

```
SELECT prod_id, quantity_sold, gender, city, income_level
     FROM sales_extended_ext
     WHERE ROWNUM < 8;
```

```
     PROD_ID     QUANTITY_SOLD     GENDER    CITY              INCOME_LEVEL
1    13          1                 M         Adelaide          K: 250,000 - 299,999
2    13          1                 M         Dolores           L: 300,000 and above
3    13          1                 M         Cayuga            F: 110,000 - 129,999
4    13          1                 F         Bergen op Zoom    C: 50,000 - 69,999
5    13          1                 F         Neuss             J: 190,000 - 249,999
6    13          1                 F         Darwin            F: 110,000 - 129,999
7    13          1                 M         Sabadell          K:250,000 - 299,999
```

This query shows values for rows in the external table. If you want to query this data frequently, after examining the data you can load it into a table with `DBMS_CLOUD.COPY_DATA`.

See CREATE_EXTERNAL_TABLE Procedure for Avro, ORC, or Parquet Files and COPY_DATA Procedure for Avro, ORC, or Parquet Files for more information.

See DBMS_CLOUD URI Formats for information on supported cloud object storage services.

- Query External Data with ORC, Parquet, or Avro Source Files and Explicitly Set the Text Column Size
  When you access ORC, Parquet, or Avro data stored in object store using external tables on Autonomous Database, you can either automatically or explicitly set the maximum size of text columns.

Query External Data with ORC, Parquet, or Avro Source Files and Explicitly Set the Text Column Size

When you access ORC, Parquet, or Avro data stored in object store using external tables on Autonomous Database, you can either automatically or explicitly set the maximum size of text columns.

By default the text column size is set based on the value of `MAX_STRING_SIZE`.

The source file in this example, `sales_extended.parquet`, contains Parquet format data. To query this file in Autonomous Database and set the maximum text column size, do the following:

1. Store your object store credentials, to access the object store, using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
    password => 'password' );
END;
/
```

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create an external table for ORC, Parquet, or Avro on top of your source files using the procedure `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` and specify the `maxvarchar` format parameter.

   The procedure `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` supports external files in the supported cloud object storage services, including: Oracle Cloud Infrastructure Object Storage, Azure Blob Storage or Azure Data Lake Storage, Amazon S3, and Amazon S3-Compatible, including: Oracle Cloud Infrastructure Object Storage, Google Cloud Storage, and Wasabi Hot Cloud Storage. The credential is a table level property; therefore, the external files must be on the same object store.

   By default, the columns created in the external table automatically map their data types to Oracle data types for the fields found in the source files and the external table column names match the source field names.

```
BEGIN
   DBMS_CLOUD.CREATE_EXTERNAL_TABLE(
    table_name =>'sales_extended_ext',
    credential_name =>'DEF_CRED_NAME',
    file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-
string/b/bucketname/o/sales_extended.parquet',
    format =>  '{"type":"parquet", "schema": "first", "maxvarchar":"extended"}'
 );
END;
/
```

The parameters are:

- `table_name`: is the external table name.
- `credential_name`: is the name of the credential created in the previous step. The `credential_name` parameter must conform to Oracle object naming conventions. See Database Object Naming Rules for more information.
- `file_uri_list`: is a comma delimited list of the source files you want to query. The URI format for Dedicated Endpoints is supported in commercial (OC1) realms. See Object Storage Dedicated Endpoints, and DBMS_CLOUD URI Formats for more information.
- `format`: defines the options to describe the format of the source file. For a Parquet file, use the `format` parameter to specify the `type parquet`. For an Avro file use the `format` parameter to specify the `type avro`. For an ORC file use the `format` parameter to specify the `type orc`.

  The option `maxvarchar` with value `extended` specifies that text columns are created as `varchar(32767)` on an Autonomous Database instance with extended string size. The possible values are `standard` with `varchar(4000)`, `extended` with `varchar(32767)`, and `auto`. The default `maxvarchar` value is `auto`. With this value, the maximum text size is based on the value of `MAX_STRING_SIZE`.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

By default the `format schema` parameter is set and the columns and data types are derived automatically and the fields in the source match the external table columns by name.

Source data types are converted to the external table column Oracle data types according to the `DBMS_CLOUD` mapping for ORC, Parquet, or Avro data types. The valid `schema` parameter values are:

- `first`: Analyze the schema of the first ORC, Parquet, or Avro file that `DBMS_CLOUD` finds in the specified `file_uri_list` (`first` is the default value for `schema`).
- `all`: Analyze all the schemas for all the ORC, Parquet, or Avro files found in the `file_uri_list`. Because these are simply files captured in an object store, there is no guarantee that each file's metadata is the same. For example, File1 may contain a field called "address", while File2 may be missing that field. Examining each file to derive the columns is a bit more expensive but may be required if the first file does not contain all the required fields.

> **Note:**
>
> If the `column_list` parameter is specified, then you provide the column names and data types for the external table and the `schema` value, if specified is ignored. Using `column_list` you can limit the columns in the external table. If `column_list` is not specified then the `schema` default value is `first`.

3. You can now run queries on the external table you created in the previous step:

```
DESC sales_extended_ext;
Name           Null? Type
-------------- ----- --------------
PROD_ID              NUMBER(10)
CUST_ID              NUMBER(10)
TIME_ID              VARCHAR2(32767)
CHANNEL_ID           NUMBER(10)
PROMO_ID             NUMBER(10)
QUANTITY_SOLD        NUMBER(10)
AMOUNT_SOLD          NUMBER(10,2)
GENDER               VARCHAR2(32767)
CITY                 VARCHAR2(32767)
STATE_PROVINCE       VARCHAR2(32767)
INCOME_LEVEL         VARCHAR2(32767)
```

```
SELECT prod_id, quantity_sold, gender, city, income_level
     FROM sales_extended_ext
     WHERE ROWNUM < 8;

     PROD_ID     QUANTITY_SOLD     GENDER    CITY              INCOME_LEVEL
1    13          1                 M         Adelaide          K: 250,000 - 299,999
2    13          1                 M         Dolores           L: 300,000 and above
3    13          1                 M         Cayuga            F: 110,000 - 129,999
4    13          1                 F         Bergen op Zoom    C: 50,000 - 69,999
5    13          1                 F         Neuss             J: 190,000 - 249,999
6    13          1                 F         Darwin            F: 110,000 - 129,999
7    13          1                 M         Sabadell          K:250,000 - 299,999
```

This query shows values for rows in the external table. If you want to query this data frequently, after examining the data you can load it into a table with `DBMS_CLOUD.COPY_DATA`.

If you specify the `format` option `maxvarchar` as `standard`, the `varchar2()` text columns are created with size `4000`. For example:

```
BEGIN
   DBMS_CLOUD.CREATE_EXTERNAL_TABLE(
    table_name =>'sales_extended_ext',
    credential_name =>'DEF_CRED_NAME',
    file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-
string/b/bucketname/o/sales_extended.parquet',
    format =>  '{"type":"parquet", "schema": "first", "maxvarchar":"standard"}'
 );
END;
/
```

The `format` parameter with the option `maxvarchar` set to the value `standard` specifies that text columns are created as `varchar(4000)`.

```
DESC sales_extended_ext;
Name           Null? Type
-------------- ----- --------------
PROD_ID              NUMBER(10)
CUST_ID              NUMBER(10)
TIME_ID              VARCHAR2(4000)
CHANNEL_ID           NUMBER(10)
PROMO_ID             NUMBER(10)
QUANTITY_SOLD        NUMBER(10)
AMOUNT_SOLD          NUMBER(10,2)
GENDER               VARCHAR2(4000)
CITY                 VARCHAR2(4000)
STATE_PROVINCE       VARCHAR2(4000)
INCOME_LEVEL         VARCHAR2(4000)
```

See CREATE_EXTERNAL_TABLE Procedure for Avro, ORC, or Parquet Files and COPY_DATA Procedure for Avro, ORC, or Parquet Files for more information.

See DBMS_CLOUD URI Formats for information on supported cloud object storage services.

Query External Tables with Implicit Partitioning

On Autonomous Database you can create implicit partitioned external tables from Hive style partitioned data or from simple folder partitioned data stored on your Cloud Object Store.

- About External Tables with Implicit Partitioning
  On Autonomous Database use the `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` procedure to create implicit partitioned external tables from Hive style partitioned data or from simple folder partitioned data stored on your Cloud Object Store.
- Query External Implicit Partitioned Data with Hive Format Source File Organization
  Use the `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` procedure to create an implicit partitioned external table from data in Object Store that was generated from Hive data.

- Query External Implicit Partitioned Non-Hive Style Data
  Use the DBMS_CLOUD.CREATE_EXTERNAL_TABLE procedure to create an implicit partitioned external table from data in object storage that has been generated from non-Hive data.

About External Tables with Implicit Partitioning

On Autonomous Database use the DBMS_CLOUD.CREATE_EXTERNAL_TABLE procedure to create implicit partitioned external tables from Hive style partitioned data or from simple folder partitioned data stored on your Cloud Object Store.

Use the DBMS_CLOUD.CREATE_EXTERNAL_TABLE procedure to create implicit partitioned external tables. By passing the appropriate options to this procedure, the partitions are derived from the source data. The partitioned external tables support runtime discovery of partition columns and their values. Runtime discovery of changes in the underlying object store structure, such as adding or removing objects, simplifies the maintenance process by eliminating the need for additional synchronization procedures required by DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE. This ensures that the data is up to date at query runtime.

With implicit partitioning, Autonomous Database automatically determines the columns a table is "partitioned on" based on the object storage source hierarchical file structure. There is no need to explicitly declare a partitioning scheme. Implicit partitioning provides partition-table-like performance benefits without the need to explicitly define a partitioned external table using the DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE procedure.

Implicit partitioned external tables support the following naming styles for partitioned objects in object store:

- Hive Naming Format: Data in object storage that has been generated from Hive has the following format.

  ```
  OBJBUCKET/<table>/<partcol1>=<value1>/<partcol2>=<value2>/file.parquet
  ```

  For an example, see Query External Implicit Partitioned Data with Hive Format Source File Organization
- Non-Hive "Pathtail" Naming Format: A second format that is often found in data lakes is similar to the hive format, but the folder name does not include the partition columns.

  ```
  OBJBUCKET/<table>/<value1>/<value2>/file.parquet
  ```

  For an example, see Query External Implicit Partitioned Non-Hive Style Data.

For more information on naming formats, see About External Tables with Source File Partitioning.

Using the DBMS_CLOUD.CREATE_EXTERNAL_TABLE procedure, implicit partitioned external tables can be created in the following ways:

- Set the partition type to hive with a given list of partition columns
  In this case, implicit_partition_type is set to hive and implicit_partition_columns provides a list of partition columns.

  For example:

  ```
  DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
     table_name        => 'mysales',
     credential_name   => 'mycredential',
     file_uri_list     => 'https://swiftobjectstorage.us-
  ```

```
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/*.parquet',
   column_list       => 'product varchar2(100), units number, country
varchar2(100),year (number), month varchar2(2)',
   format            => '{"type":"parquet",
                         "implicit_partition_type":"hive",
                         "implicit_partition_columns":
["country","year","month"]}');
```

- Set the partition type to hive without providing a list of partition columns
  In this case, `implicit_partition_type` is set to `hive` and `implicit_partition_columns` is not provided. The partition columns are automatically detected by searching for '=' in the path specified by `file_uri_list`. The `column_name` is to the left of the '=' and the value is on the right side. If a `column_name` is not found in the path, an error is thrown.

  For example:

```
DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
   table_name        => 'mysales',
   credential_name   => 'mycredential',
   file_uri_list     => 'https://swiftobjectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/*.parquet',
   column_list       => 'product varchar2(100), units number, country
varchar2(100),year (number), month varchar2(2)',
   format            => '{"type":"parquet",
"implicit_partition_type":"hive"');
```

- Provide a list of partition columns without specifying the type
  In this case, `implicit_partition_type` is not set and `implicit_partition_columns` provides a list of columns.

  For example:

```
DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
   table_name        => 'mysales',
   credential_name   => 'mycredential',
   file_uri_list     => 'https://swiftobjectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/*.parquet',
   column_list       => 'product varchar2(100), units number, country
varchar2(100),year (number), month varchar2(2)',
   format            => '{"type":"parquet",
                         "implicit_partition_columns":
["country","year","month"]}');
```

See CREATE_EXTERNAL_TABLE Procedure for further information.

Query External Implicit Partitioned Data with Hive Format Source File Organization

Use the `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` procedure to create an implicit partitioned external table from data in Object Store that was generated from Hive data.

The sample source files in the follow example, use this naming format:

```
OBJBUCKET/<table>/<partcol1>=<value1>/<partcol2>=<value2>/file.parquet
```

Consider the following sample source files:

```
OBJBUCKET/sales/country=USA/year=2024/month=01/sales-2024-01.parquet
```

```
OBJBUCKET/sales/country=USA/year=2024/month=02/sales-2024-02.parquet

OBJBUCKET/sales/country=USA/year=2024/month=02/sales-2024-03.parquet
```

To create an implicit partitioned external table with data stored in this sample Hive format, do the following:

1. Store Object Store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password' );
   END;
   /
   ```

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

   See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create an implicit partitioned external table on top of your source files using the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`.

   In this example, since the format option `implicit_partition_columns` is not provided, partition columns are automatically detected and implicit partitioning is enabled by setting the format option `implicit_partition_type` to `hive`.
   However, if a list of columns is given, then those columns are used as partition columns and Autonomous Database doesn't try to discover the columns.

   To detect the partition columns Autonomous Database starts searching from the beginning of the path, specified by `file_uri_list`, for '='. When found, the left part of '=' up to the last '/' is taken as column (e.g. "country") and the right part of '=', until the first '/' as value (e.g. "USA"). The search continues for '=' until after the '/' that follows the first partition value, detecting the second '=' in the path, and so on.

   ```
   DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
      table_name        => 'mysales',
      credential_name   => 'DEF_CRED_NAME',
      file_uri_list     => 'https://swiftobjectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/*.parquet',
      column_list       => 'product varchar2(100), units number, country
   varchar2(100),year (number), month varchar2(2)',
      format            => '{"type":"parquet",
   "implicit_partition_type":"hive"');
   ```

   The parameters are:

- `table_name`: is the external table name.
- `credential_name`: is the name of the credential created in the previous step.
- `file_uri_list`: is a comma-delimited list of source file URIs. There are two options for this list:
  - Specify a comma-delimited list of individual file URIs without wildcarding.
  - Specify a single file URI with wildcards, where the wildcards can only be after the last slash "/". The character "*" can be used as the wildcard for multiple characters, the character "?" can be used as the wildcard for a single character.
- `column_list`: is a comma delimited list of column names and data types for the external table. The list includes the columns inside the data file and those derived from the object name (from names in the file path specified by `file_uri_list`).

  The `column_list` is not required when the data files are structured files (Parquet, Avro, or ORC).
- `format`: defines the options you can specify to describe the format of the source file. The `implicit_partition_type` option specifies the data format type as hive.

  If the data in your source file is encrypted, decrypt the data by specifying the `encryption` format option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.

  See DBMS_CLOUD Package Format Options for more information.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

See CREATE_EXTERNAL_TABLE Procedure for detailed information about the parameters. See DBMS_CLOUD URI Formats for more information on the supported cloud object storage services.

3. You can now run queries on the external partitioned table you created in the previous step.

   Your Autonomous Database takes advantage of the partitioning information of your external partitioned table, ensuring that the query only accesses the relevant data files in Object Store.

   For example:

   ```
   SELECT product, units FROM mysales WHERE year='2024' and month='02'
   ```

   This SQL statement only queries data in the partition for month 02 of year 2024.

Query External Implicit Partitioned Non-Hive Style Data

Use the `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` procedure to create an implicit partitioned external table from data in object storage that has been generated from non-Hive data.

The sample source files in the follow example, use this naming format:

```
OBJBUCKET/<table>/<value1>/<value2>/file.parquet
```

Consider the following sample source files:

```
OBJBUCKET/sales/USA/2024/01/sales-2024-01.parquet

OBJBUCKET/sales/USA/2024/01/sales-2024-02.parquet
```

```
OBJBUCKET/sales/USA/2024/01/sales-2024-03.parquet
```

To create an implicit partitioned external table with data stored in this sample Hive format, do the following:

1. Store Object Store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password' );
   END;
   /
   ```

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

   See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create an implicit partitioned external table on top of your source files using the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`.

   In this example, implicit partitioning is enabled by providing the partition columns with the format option `implicit_partition_columns`. Since the folder name does not include the partition columns, the partition values in the path, specified by `file_uri_list`, can only be discovered if an explicit list of columns is given with the format option `implicit_partition_columns`. In order to detect the respective column values in the path the order of columns must be the same as the order of values.

   The partition columns are automatically detected.

   ```
   DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
      table_name        => 'mysales',
      credential_name   => 'DEF_CRED_NAME',
      file_uri_list     => 'https://swiftobjectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/*.parquet',
      column_list       => 'product varchar2(100), units number, country
   varchar2(100),year (number), month varchar2(2)',
      format            => '{"type":"parquet", "implicit_partition_columns":
   ["country","year","month"]}');
   ```

   The parameters are:

   - `table_name`: is the external table name.
   - `credential_name`: is the name of the credential created in the previous step.
   - `file_uri_list`: is a comma-delimited list of source file URIs. There are two options for this list:

  - Specify a comma-delimited list of individual file URIs without wildcarding.
  - Specify a single file URI with wildcards, where the wildcards can only be after the last slash "/". The character "*" can be used as the wildcard for multiple characters, the character "?" can be used as the wildcard for a single character.

- `column_list`: is a comma delimited list of column names and data types for the external table. The list includes the columns inside the data file and those derived from the object name (from names in the file path specified by `file_uri_list`).

  The `column_list` is not required when the data files are structured files (Parquet, Avro, or ORC).

- `format`: defines the options you can specify to describe the format of the source file. The `implicit_partition_type` option is unset. Since `implicit_partition_columns` is given, the type is automatically detected as non-hive.

  If the data in your source file is encrypted, decrypt the data by specifying the `encryption` format option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.

  See DBMS_CLOUD Package Format Options for more information.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

See CREATE_EXTERNAL_TABLE Procedure for detailed information about the parameters.

See DBMS_CLOUD URI Formats for more information on the supported cloud object storage services.

3. You can now run queries on the external partitioned table you created in the previous step.

   Your Autonomous Database takes advantage of the partitioning information of your external partitioned table, ensuring that the query only accesses the relevant data files in Object Store.

   For example:

```
SELECT product, units FROM mysales WHERE year='2024'
```

   This SQL statement only queries data in the partition for year 2024.

Query External Tables with Partitioning Specified in Source Files

If you want to query multiple data files in the Object Store as a single external table and the files can be represented as multiple logical partitions, it is highly recommended to use an external partitioned table. Using an external partitioned table preserves the logical partitioning of your data files for query access.

Using partitioned external tables has the potential to dramatically improve query performance by only accessing the data required for the query. For example, you may have two years of daily partitions stored in separate objects on Cloud Object Store. When you use partitioned external tables, a query for a single day only needs to access that day's source data. When you use partitioned external tables the database automatically partition prunes, and in this example only needs to scan a very small fraction of the data.

There are two ways to create an external partitioned table with the `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` procedure:

- Using the `file_url_path` value in combination with the `format` parameter: Autonomous Database analyzes Cloud Object Store file path information supplied with this parameter to determine the partition columns and data types (or you can manually specify the partition columns and data types).

  This type of partitioning provides a synchronization routine to handle changes when external partition files are added or removed.

- Using the `partitioning_clause` parameter: Autonomous Database uses the explicit partitioning clause you supply to create an external partitioned table.

  This type of partitioning does not support a synchronization routine.

  See Query External Partitioned Data (with Partitioning Clause) for a description of this type of external table.

- About External Tables with Source File Partitioning
  On Autonomous Database you can create partitioned external tables from Hive style partitioned data or from simple folder partitioned data stored on your Cloud Object Store.
- Query External Partitioned Data with Hive Format Source File Organization
  Use `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` to create an external partitioned table and generate the partitioning information from the Cloud Object Store file path.
- Query External Partitioned Data with Folder Format Source File Organization
  Use `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` to create an external partitioned table and generate the partitioning information from the Cloud Object Store file path.
- Refresh External Partitioned Tables with Updated or Deleted Source Files
  You can use `DBMS_CLOUD.SYNC_EXTERNAL_PART_TABLE` to refresh an external partitioned table. Use this procedure when new partitions are added or when partitions are removed from the object store source.

About External Tables with Source File Partitioning

On Autonomous Database you can create partitioned external tables from Hive style partitioned data or from simple folder partitioned data stored on your Cloud Object Store.

Using source file partitioning, instead of supplying a complete partition specification the procedure derives partitioning information from the file path for certain file patterns. For example, consider the following data file specifications:

- Hive style: for example: `sales/country=USA/year=2020/month=01/file1.csv`
- Simple folder partitioning style: for example: `sales/USA/2020/01/file1.parquet`

Using one of these common partitioning formats greatly simplifies both the creation and management of partitioned external tables. In addition, even though partition columns may not appear in the data file, they can still be queried using SQL. Partitioning data also improves query performance by dramatically reducing the amount of data scanned. In this example, when you query ‘USA’ data, the query can skip scanning the files for other countries.

Hive Format Partitioned Data in Cloud Object Store

Hive offers a standard metadata format for big data processing engines. Partitioned data in Cloud Object Store that is generated in Hive format is represented in a `folder/subfolder` format. For example, on Cloud Object Store a Hive format data file is stored as follows:

*table/partition1=partition1_value/partition2=partition2_value/*data_file.csv

Files saved in Hive partitioned format provide partition information in the data file path name. The data file path name includes information about the object contents, including partition column names and partition column values (the data file does not include the partition columns and their associated values).

For example, consider an external partitioned `SALES` table created from Hive format data on Cloud Object Store:

```
.../sales/country=USA/year=2020/month=01/file1.csv
.../sales/country=USA/year=2020/month=01/file2.csv
.../sales/country=USA/year=2020/month=02/file3.csv
.../sales/country=USA/year=2020/month=03/file1.csv
.../sales/country=FRA/year=2020/month=03/file1.csv
```

The Hive format partition information shows the data files in Cloud Object Store are partitioned by `country`, `year`, and `month` and the values for these partition columns are also specified within the Hive format path name for each data file (the path name includes values for the partitioned columns: `country`, `year`, and `month`).

The column names in the path will be used by the API to simplify the table definition.

Simple Folder Format Partitioned Data in Cloud Object Store

Partitioned data in Cloud Object Store that is generated in folder format is represented in a `folder/subfolder` format, similar to Hive format partitioned data, but the information in the path shows the column values and does not include the column names. Also, with folder format partitioned data the partition order specified in the object name is significant, and must match the order in the table columns.

For example, on Cloud Object Store a folder format data file is stored as follows:

table/partition1_value/partition2_value/.parquet*

The path includes both partition column values, in partition column order, and the data files. Autonomous Database allows you to create an external partitioned table from folder format data and you can perform a query using the specified partitions.

Files saved in folder partitioned format provide the data partition column values in the file name. Unlike Hive, the paths do not include the column name, therefore the column names must be provided. The order of partition columns is important and the order in the file name for column partition names must match the order in the `partition_columns` parameter.

About Querying Partitioned Data in Cloud Object Store

When you query external partitioned data in Hive format, the query engine understands and utilizes the partitioning information from the file path name. For example, consider an external partitioned `SALES` table where the source file, `sales/country=USA/year=2020/month=02/file3.csv` on Object Store includes the following sales data:

```
tents, 291
canoes, 22
backpacks, 378
```

The `country` values in the path name, and the time period values for `month` and `year` are not specified as columns within the data file. The partition column values are specified only in the path name with values shown: USA, 2020, and 02. After you create an external partitioned

table with this data file you can use the partition columns and their values when you run a query on the external partitioned table.

For example:

```
SELECT year, month, product, units
     FROM SALES WHERE year='2020' AND month='02' AND country='USA'
```

The benefit of creating an external partitioned table with data generated as Hive format partitioned data is that the query engine is optimized to partition prune the data to select the correct partition and the query only selects data from one partition and only needs to search a single data file. Thus, the query would only require a scan of the `file3.csv` file (`/sales/country=USA/year=2020/month=02/file3.csv`). For large amounts of data, such partition pruning can provide significant performance improvements.

Using standard Oracle Database external tables, the partition column must be available as a column within the data file to use it for queries or partition definitions. Without the special handling that is available with external partitioned tables on Autonomous Database, this would be a problem if you want to use data stored in Hive format on Cloud Object Store, as you would need to regenerate the data files to include the partition as a column in the data file.

About Creating Partitioned External Tables

When you use unstructured data stored in Hive format on Cloud Object Store and you create an external partitioned table, the columns and their types cannot be derived from the source file. Thus, the columns and their data types must be specified with the `column_list` parameter. To create the partitioned external tables, use the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` to specify the partition columns and their types as follows:

- The root for the file list is specified in the path name with the `file_uri_list` parameter. For example, `http://.../sales/*`
- The column names and data types are specified with the `column_list` parameter.
- The option `partition_columns` in the `format` parameter specifies the partition columns.
- The generated DLL includes the columns specified in the path name.

For this example, when the external table is created the `country`, `year`, and `month` columns are added in the `column_list` parameter. The external table is created with the `country`, `year`, and `month` columns, which are not in the data files, and list partitions are created enabling partition pruning.

When you use structured data, such as Parquet, Avro, or ORC files stored in folder format on Cloud Object Store, the columns and their data types are known. and you do not need to specify the column list as is required with unstructured data. To create the partitioned external tables, use the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` to specify the partition columns and their types as follows:

- The root for the file list is specified in the path name with the `file_uri_list` parameter. For example, `http://.../sales/*`
- The `column_list` parameter is not required for structured files. If you do not specify the column list, you must define the partition columns and their data types when you create the external partitioned table. Use the option `partition_columns` in the `format` parameter to specify the partition columns and their data types.
- The generated DLL includes the columns specified in the path name.

See Query External Partitioned Data with Hive Format Source File Organization and Query External Partitioned Data with Folder Format Source File Organization for complete examples.

- External Partitioning: CSV Source Files with Hive-style Folders
  Shows how to create external partitioned tables with CSV source files stored on Cloud Object Store in Hive-style folders.
- External Partitioning: CSV Source Files with Simple Folders
  Shows how to create external partitioned tables with CSV source files stored on Cloud Object Store in simple folder format.
- External Partitioning: Parquet Source Files with Hive-style Folders
  Shows how to create external partitioned tables with Parquet source files stored on Cloud Object Store in Hive-style folders.
- External Partitioning: Parquet with Simple Folders
  Shows how to create external partitioned tables with Parquet source files stored on Cloud Object Store in simple folder format.

External Partitioning: CSV Source Files with Hive-style Folders

Shows how to create external partitioned tables with CSV source files stored on Cloud Object Store in Hive-style folders.

Source file list:

```
.../sales/country=USA/year=2020/month=01/file1.csv
.../sales/country=USA/year=2020/month=01/file2.csv
.../sales/country=USA/year=2020/month=02/file3.csv
.../sales/country=USA/year=2020/month=03/file1.csv
.../sales/country=FRA/year=2020/month=03/file1.csv
```

API:

```
DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE (
   table_name        => 'mysales',
   credential_name   => 'mycredential',
   file_uri_list     => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/.../sales/*.csv',
   column_list       => 'product varchar2(100), units number, country
varchar2(100), year number, month varchar2(2)',
   field_list        => 'product, units', --[Because country, year and month
are not in the file, they are not listed in the field list]
   format            => '{"type":"csv","partition_columns":["country",
"year", "month"]}');
```

> **Note:**
>
> The `partition_columns` in the `format` parameter must match the column names found in the path (for example, the `country` column matches "`country=…`")

External Partitioning: CSV Source Files with Simple Folders

Shows how to create external partitioned tables with CSV source files stored on Cloud Object Store in simple folder format.

Source file list:

```
.../sales/USA/2020/01/file1.csv
.../sales/USA/2020/01/file2.csv
.../sales/USA/2020/02/file3.csv
.../sales/USA/2020/03/file1.csv
.../sales/FRA/2020/03/file1.csv
```

API:

```
DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE(
   table_name        => 'mysales',
   credential_name   => 'mycredential',
   file_uri_list     =>  'https://objectstorage.us-
phoenix-1.oraclecloud.com/.../sales/*.csv',
   column_list       => 'product varchar2(100), units number, country
varchar2(100), year number, month varchar2(2)',
   field_list        => 'product, units', --[Because country, year and month
are not in the file, they are not listed in the field list]
   format            => '{"type":"csv","partition_columns":["country",
"year", "month"]}');
```

> **Note:**
>
> The API call is the same as in the previous example, but the order of the `partition_columns` in the `format` parameter is significant because the column name is not in the file path.

External Partitioning: Parquet Source Files with Hive-style Folders

Shows how to create external partitioned tables with Parquet source files stored on Cloud Object Store in Hive-style folders.

Source file list:

```
.../sales/USA/2020/01/file1.parquet
.../sales/USA/2020/01/file2.parquet
.../sales/USA/2020/02/file3.parquet
.../sales/USA/2020/03/file1.parquet
.../sales/FRA/2020/03/file1.parquet
```

API:

```
DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE (
   table_name            => 'mysales',
     credential_name     => 'mycredential',
     file_uri_list       => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/.../sales/*.parquet',
     format              =>
         json_object(    'type' value 'parquet',
               'schema' value 'first',
               'partition_columns' value
```

```
                  json_array(
                      json_object('name' value 'country', 'type' value
'varchar2(100)'),
                      json_object('name' value 'year', 'type' value 'number'),
                      json_object('name' value 'month', 'type' value
'varchar2(2)')
                  )
          )

);
```

> **Note:**
>
> The `column_list` parameter is not specified. As shown, for each partition column specify both the name and data type in the `format` parameter `partition_columns`.

External Partitioning: Parquet with Simple Folders

Shows how to create external partitioned tables with Parquet source files stored on Cloud Object Store in simple folder format.

Source file list:

```
.../sales/USA/2020/01/file1.parquet
.../sales/USA/2020/01/file2.parquet
.../sales/USA/2020/02/file3.parquet
.../sales/USA/2020/03/file1.parquet
.../sales/FRA/2020/03/file1.parquet
```

API:

```
DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE (
   table_name        => 'mysales',
   credential_name   => 'mycredential',
   file_uri_list     => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/.../sales/*.parquet',
   format            =>
     json_object(    'type' value 'parquet',
                  'schema' value 'first',
           'partition_columns' value
             json_array(
                json_object('name' value 'country', 'type' value
'varchar2(100)'),
                json_object('name' value 'year', 'type' value 'number'),
                json_object('name' value 'month', 'type' value 'varchar2(2)')
             )
          )

);
```

> **Note:**
>
> The `column_list` parameter is not specified. You must include both the name and data type for the partition columns. In addition, the order of the `partition_columns` in the format clause matters because the column name is not in the file path.

Query External Partitioned Data with Hive Format Source File Organization

Use `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` to create an external partitioned table and generate the partitioning information from the Cloud Object Store file path.

Consider the following sample source files in Object Store:

```
custsales/month=2019-01/custsales-2019-01.csv

custsales/month=2019-02/custsales-2019-02.csv

custsales/month=2019-03/custsales-2019-03.csv
```

With this naming, the values for `month` are captured within the object name.

To create a partitioned external table with data stored in this sample Hive format, do the following:

1. Store Object Store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password' );
   END;
   /
   ```

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

   See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create an external partitioned table on top of your source files using the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`.

   The procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` supports external partitioned files in the supported cloud object storage services. The credential is a table level property; therefore, the external files must all be on the same cloud object store.

For example:

```
BEGIN
    DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE(
        TABLE_NAME => 'sales_sample',
        CREDENTIAL_NAME => 'DEF_CRED_NAME',
        FILE_URI_LIST => 'https://objectstorage.us-
ashburn-1.oraclecloud.com/n/namespace-string/b/moviestream_landing/o/
sales_sample/*.parquet',
        FORMAT => '{"type":"parquet", "schema":
"first","partition_columns":[{"name":"month","type":"varchar2(100)"}]}');
END;
/
```

The parameters are:

- `table_name`: is the external table name.
- `credential_name`: is the name of the credential created in the previous step.
- `file_uri_list`: is a comma-delimited list of source file URIs. There are two options for this list:
  - Specify a comma-delimited list of individual file URIs without wildcarding.
  - Specify a single file URI with wildcards, where the wildcards can only be after the last slash "/". The character "*" can be used as the wildcard for multiple characters, the character "?" can be used as the wildcard for a single character.
- `column_list`: is a comma delimited list of column names and data types for the external table. The list includes the columns inside the data file and those derived from the object name (from names in the file path).

  The `column_list` is not required when the data files are structured files (Parquet, Avro, or ORC).
- `format`: defines the options you can specify to describe the format of the source file. The `partition_columns format` parameter specifies the names of the partition columns.

  If the data in your source file is encrypted, decrypt the data by specifying the `encryption` format option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.

  See DBMS_CLOUD Package Format Options for more information.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

The `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` call would result in the following table definition:

```
CREATE TABLE "ADMIN"."SALES_SAMPLE"
   ( "DAY_ID" TIMESTAMP (6),
     "GENRE_ID" NUMBER(19,0),
     "MOVIE_ID" NUMBER(19,0),
     "CUST_ID" NUMBER(19,0),
     "APP" VARCHAR2(4000 BYTE) COLLATE "USING_NLS_COMP",
     "DEVICE" VARCHAR2(4000 BYTE) COLLATE "USING_NLS_COMP",
     "OS" VARCHAR2(4000 BYTE) COLLATE "USING_NLS_COMP",
```

```
      "PAYMENT_METHOD" VARCHAR2(4000 BYTE) COLLATE "USING_NLS_COMP",
      "LIST_PRICE" BINARY_DOUBLE,
      "DISCOUNT_TYPE" VARCHAR2(4000 BYTE) COLLATE "USING_NLS_COMP",
      "DISCOUNT_PERCENT" BINARY_DOUBLE,
      "ACTUAL_PRICE" BINARY_DOUBLE,
      "MONTH" VARCHAR2(100 BYTE) COLLATE "USING_NLS_COMP"
   ) DEFAULT COLLATION "USING_NLS_COMP"
   ORGANIZATION EXTERNAL
    ( TYPE ORACLE_BIGDATA
      DEFAULT DIRECTORY "DATA_PUMP_DIR"
      ACCESS PARAMETERS
      ( com.oracle.bigdata.fileformat=parquet
com.oracle.bigdata.filename.columns=["month"]
com.oracle.bigdata.file_uri_list="https://objectstorage.us-
ashburn-1.oraclecloud.com/n/namespace-string/b/moviestream_landing/o/
sales_sample/*.parquet"
com.oracle.bigdata.credential.schema="ADMIN"
com.oracle.bigdata.credential.name=CRED_OCI
com.oracle.bigdata.trimspaces=notrim
  )
    )
   REJECT LIMIT 0
  PARTITION BY LIST ("MONTH")
 (PARTITION "P1" VALUES (('2019-01'))
      LOCATION
       ( 'https://objectstorage.us-ashburn-1.oraclecloud.com/n/namespace-
string/b/moviestream_landing/o/sales_sample/month=2019-01/*.parquet'
       ),
 PARTITION "P2" VALUES (('2019-02'))
      LOCATION
       ( 'https://objectstorage.us-ashburn-1.oraclecloud.com/n/namespace-
string/b/moviestream_landing/o/sales_sample/month=2019-02/*.parquet'
       ))
  PARALLEL ;
```

See CREATE_EXTERNAL_PART_TABLE Procedure for detailed information about the parameters.

See DBMS_CLOUD URI Formats for more information on the supported cloud object storage services.

3. You can now run queries on the external partitioned table you created in the previous step.

   Your Autonomous Database takes advantage of the partitioning information of your external partitioned table, ensuring that the query only accesses the relevant data files in the Object Store.

   For example:

   ```
   SELECT movie_id, month FROM sales WHERE month='2019-02'
   ```

   The external partitioned tables you create with `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` include two invisible columns `file$path` and `file$name`. These columns help identify which file a record is coming from. See External Table Metadata Columns for more information.

If there are any rows in the source files that do not match the format options you specified, the query reports an error. You can use `DBMS_CLOUD` parameters, like *rejectlimit,* to suppress these errors. As an alternative, you can also validate the external partitioned table you created to see the error messages and the rejected rows so that you can change your format options accordingly. See Validate External Data and Validate External Partitioned Data for more information.

Query External Partitioned Data with Folder Format Source File Organization

Use `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` to create an external partitioned table and generate the partitioning information from the Cloud Object Store file path.

When you create an external table with folder format data files, you have two options for specifying the types of the partition columns:

- You can manually specify the columns and their data types with `column_list` parameter. See Query External Partitioned Data with Hive Format Source File Organization for an example using the `column_list` parameter.
- You can let `DBMS_CLOUD` derive the data file columns and their types from information in structured data files such as Avro, ORC, and Parquet data files. In this case, you use the `partition_columns` option with the `format` parameter to supply the column names and their data types for the partition columns and you do not need to supply the `column_list` or the `field_list` parameters.

Consider the following sample source files in Object Store:

```
.../sales/USA/2020/01/sales1.parquet

.../sales/USA/2020/02/sales2.parquet
```

To create a partitioned external table with the Cloud Object Store file path defining the partitions from files with this sample folder format, do the following:

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password' );
   END;
   /
   ```

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

   See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create an external partitioned table on top of your source files using the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`.

The procedure DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE supports external partitioned files in the supported cloud object storage services. The credential is a table level property; therefore, the external files must all be on the same cloud object store.

For example:

```
BEGIN DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE(
    table_name => 'MYSALES',
    credential_name => 'DEF_CRED_NAME',
    file_uri_list => 'https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-
string/b/bucketname/o/sales/*.parquet',
    format =>
        json_object('type' value 'parquet', 'schema' value 'first',
                    'partition_columns' value
                          json_array(
                                json_object('name' value 'country', 'type' value
'varchar2(100)'),
                                json_object('name' value 'year', 'type' value 'number'),
                                json_object('name' value 'month', 'type' value
'varchar2(2)')
                          )
         )
    );
END;
/
```

The DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE parameters for structured data files, such as for a Parquet data file does not require the column_list or the field_list parameters. The column names and data types are derived for the columns from the first parquet file that the procedure scans (and therefore all files must have the same shape). The generated column list includes the columns derived from the object name and these column have the data types specified with the partition_columns format parameter.

The parameters are:

- table_name: is the external table name.
- credential_name: is the name of the credential created in the previous step.
- file_uri_list: is a comma-delimited list of source file URIs. There are two options for this list:
  - Specify a comma-delimited list of individual file URIs without wildcarding.
  - Specify a single file URI with wildcards, where the wildcards can only be after the last slash "/". The character "*" can be used as the wildcard for multiple characters, the character "?" can be used as the wildcard for a single character.
- column_list: is a comma delimited list of column names and data types for the external table. The list includes the columns that are inside the file as well as those derived from the object name.

  The column_list is not required when the data files are structured files (Parquet, Avro, or ORC).
- field_list: Identifies the fields in the source files and their data types. The default value is NULL meaning the fields and their data types are determined by the column_list parameter.

The `field_list` is not required when the data files are structured files (Parquet, Avro, or ORC).

- `format`: defines the options you can specify to describe the format of the source file. The `partition_columns format` parameter specifies the names of the partition columns. See DBMS_CLOUD Package Format Options for more information.

  If the data in your source file is encrypted, decrypt the data by specifying the `encryption` format option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

See CREATE_EXTERNAL_PART_TABLE Procedure for detailed information about the parameters.

See DBMS_CLOUD URI Formats for more information on the supported cloud object storage services.

If there are any rows in the source files that do not match the format options you specified, the query reports an error. You can use `DBMS_CLOUD` parameters, like `rejectlimit` to suppress these errors. As an alternative, you can also validate the external partitioned table you created to see the error messages and the rejected rows so that you can change your format options accordingly. See Validate External Data and Validate External Partitioned Data for more information.

3. You can now run queries on the external partitioned table you created in the previous step.

   Your Autonomous Database takes advantage of the partitioning information of your external partitioned table, ensuring that the query only accesses the relevant data files in the Object Store. For example, the following query only reads data files from one partition.

   For example:

   ```
   SELECT year, month, product, units
   FROM SALES WHERE year='2020' AND month='02' AND country='USA'
   ```

   The external partitioned tables you create with `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` include two invisible columns `file$path` and `file$name`. These columns help identify which file a record is coming from. See External Table Metadata Columns for more information.

Refresh External Partitioned Tables with Updated or Deleted Source Files

You can use `DBMS_CLOUD.SYNC_EXTERNAL_PART_TABLE` to refresh an external partitioned table. Use this procedure when new partitions are added or when partitions are removed from the object store source.

> **Note:**
>
> Only use `DBMS_CLOUD.SYNC_EXTERNAL_PART_TABLE` when the partitioned external table is created with `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` and the `file_url_path` parameter.

To refresh a partitioned external table:

1. Refresh an external partitioned table on top of your Cloud Object Store source files using the procedure `DBMS_CLOUD.SYNC_EXTERNAL_PART_TABLE`.

   For example:

```
BEGIN
   DBMS_CLOUD.SYNC_EXTERNAL_PART_TABLE(table_name => 'MYSALES');
END;
/
```

   `DBMS_CLOUD.SYNC_EXTERNAL_PART_TABLE` uses the credential information from the corresponding `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` with the specified `table_name` to access Cloud Object Store.

   See SYNC_EXTERNAL_PART_TABLE Procedure for detailed information about the parameter.

2. The partition information is now refreshed and you can run queries on the updated external partitioned table. with new partitions available or with partitions that were removed no longer available in the external partitioned table.

Query External Partitioned Data (with Partitioning Clause)

If you want to query multiple data files in the Object Store as a single external table and the files can be represented as multiple logical partitions, then it is highly recommended to use an external partitioned table. Using an external partitioned table preserves the logical partitioning of your data files for query access. Use the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` to create an external partitioned table.

There are two ways to create an external partitioned table on Autonomous Database:

- The first version is for. See Query External Partitioned Data with Hive Format Source File Organization for information on this type of external partitioned table usage.
- The second version is for. When you a create a partitioned external table in this way you include a partitioning clause in the `partitioning_clause` parameter. The partitioning clause that you include depends upon the data files in the Cloud and the type of partitioning you use. This section describes this type of external partitioned table usage.

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL (
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
    password => 'password' );
END;
/
```

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your

object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create an external partitioned table on top of your source files using the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`.

   The procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` supports external partitioned files in the supported cloud object storage services. The credential is a table level property; therefore, the external files must be on the same object store.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE(
      table_name =>'PET1',
      credential_name =>'DEF_CRED_NAME',
      format => json_object('delimiter' value ',', 'recorddelimiter' value 'newline',
'characterset' value 'us7ascii'),
      column_list => 'col1 number, col2 number, col3 number',
      partitioning_clause => 'partition by range (col1)
         (partition p1 values less than (1000) location
             ( ''https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/
bucketname/o/file_11.txt''),
          partition p2 values less than (2000) location
             ( ''https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/
bucketname/o/file_21.txt''),
          partition p3 values less than (3000) location
             ( ''https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/
bucketname/o/file_31.txt'') )'
     );
END;
/
```

   The parameters are:

   - `table_name`: is the external table name.
   - `credential_name`: is the name of the credential created in the previous step.
   - `partitioning_clause`: is the complete partitioning clause, including the location information for individual partitions.
   - `format`: defines the options you can specify to describe the format of the source file. format: defines the options you can specify to describe the format of the source file.

     If the data in your source files is encrypted, decrypt the data by specifying the `format` parameter with the `encryption` option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.
   - `column_list`: is a comma delimited list of the column definitions in the source files.

   In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

   You can now run queries on the external partitioned table you created in the previous step. Your Autonomous Database takes advantage of the partitioning information of your

external partitioned table, ensuring that the query only accesses the relevant data files in the Object Store. For example, the following query only reads data files from partition P1:

```
SELECT * FROM pet1 WHERE col1 < 750;
```

The external partitioned tables you create with `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` include two invisible columns `file$path` and `file$name`. These columns help identify which file a record is coming from. See External Table Metadata Columns for more information.

If there are any rows in the source files that do not match the format options you specified, the query reports an error. You can use `DBMS_CLOUD` parameters, like *rejectlimit,* to suppress these errors. As an alternative, you can also validate the external partitioned table you created to see the error messages and the rejected rows so that you can change your format options accordingly. See Validate External Data and Validate External Partitioned Data for more information.

See CREATE_EXTERNAL_PART_TABLE Procedure for detailed information about the parameters.

See DBMS_CLOUD URI Formats for more information on the supported cloud object storage services.

Query Data that Uses Table Hyperlink Source

You can create an external table over an Autonomous Database Table Hyperlink.

Consider creating external tables over an Autonomous Database Table Hyperlink in the following scenarios:

- When you need to use a REST client to create an external table and then utilize the SQL API to perform analytics on the datasets. This may include running SQL queries to analyze the data or aggregating results based on your requirements.
- When you need to query data from databases across regions.

There are two ways to create an external table in an Autonomous Database using a Table Hyperlink:

- Use a single Autonomous Database Table Hyperlink to create an external table. After the table is created, you can read data from the table using the `SELECT` statement. You can also apply filters and clauses when retrieving data from the table. For example, you can filter the data with the `WHERE` clause or sort it using the `ORDER BY` clause.

  Example to create an external table over a single Table Hyperlink:

```
DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
   table_name => 'ext_tab_parurl',
   file_uri_list => 'https://dataaccess.adb.us-
chicago-1.oraclecloudapps.com/adb/p/K6XExample/data'
);
END;
/
```

After the table is created, you can query the table using the `SELECT` statement, and you can also filter or sort the output. Example to read data from the `ext_tab_parurl` table in descending order:

```
SELECT * FROM ext_tab_parurl
   ORDER BY height DESC;

COUNTY    SPECIES      HEIGHT
------    ----------   -------
First     Chestnut      51
Main      Alder         45
Main      Douglas-fir   34
Main      Pine          29
Main      Cedar         21
```

- Use a comma-delimited list of Autonomous Database Table Hyperlink URLs, you must ensure that all included Table Hyperlinks must have the same column names, column order, and column data types in the same schema.

  Example to create an external table over a list of Table Hyperlinks:

  ```
  DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
     table_name => 'ext_tab_parurl_1',
     file_uri_list => 'https://dataaccess.adb.us-
  chicago-1.oraclecloudapps.com/adb/p/K6XExample/data',
                      'https://dataaccess.adb.us-
  chicago-1.oraclecloudapps.com/adb/p/K7XExample/data'
  );
  END;
  /
  ```

  Query the table using the `SELECT` statement:

  ```
  SELECT * FROM ext_tab_parurl_1;

  COUNTY   SPECIES      HEIGHT
  ------   ----------   -------
  First     Chestnut      51
  Main      Alder         45
  Main      Douglas-fir   34
  Main      Pine          29
  Main      Cedar         21
  Main      Aspen         35
  First     Maple         16
  ```

The parameters are:

- `table_name`: is the external table name.
- `file_uri_list`: is either a single Table Hyperlinks or a comma-delimited list of Table Hyperlinks.

See CREATE_EXTERNAL_TABLE Procedure for more information.

Query Hybrid Partitioned Data

If you want to query internal data and multiple data files in the Object Store as single logical table you can use a hybrid partitioned table to represent the data as single object. Use the procedure `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` to create a hybrid partitioned table.

If your data, internal or external, can be represented in finer granularity as multiple logical partitions then it is highly recommended to create a hybrid partitioned table with multiple internal and external partitions, preserving the logical partitioning of your data for query access.

When you a create a hybrid partitioned table, you include a partitioning clause in the `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` statement. The partitioning clause that you include depends upon your data files and the type of partitioning you use. See Creating Hybrid Partitioned Tables for more information.

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL (
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password' );
   END;
   /
   ```

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating hybrid partitioned tables.

   See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create a hybrid partitioned table on top of your source files using the procedure `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE`.

   The procedure `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` supports external partitioned files in the supported cloud object storage services. The credential is a table level property; therefore, the external files must be on the same object store.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_HYBRID_PART_TABLE(
      table_name =>'HPT1',
      credential_name =>'DEF_CRED_NAME',
      format => json_object('delimiter' value ',', 'recorddelimiter' value 'newline',
'characterset' value 'us7ascii'),
      column_list => 'col1 number, col2 number, col3 number',
      partitioning_clause => 'partition by range (col1)
           (partition p1 values less than (1000) external location
              ( ''https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/
```

```
bucketname/o/file_11.txt'') ,
            partition p2 values less than (2000) external location
              ( ''https://objectstorage.us-phoenix-1.oraclecloud.com/n/namespace-string/b/
bucketname/o/file_21.txt'') ,
            partition p3 values less than (3000) )'
     );
END;
/
```

The parameters are:

- `table_name`: is the hybrid partitioned table name.
- `credential_name`: is the name of the credential created in the previous step.
- `partitioning_clause`: is the complete partitioning clause, including the location information for individual partitions.
- `format`: defines the options you can specify to describe the format of the source file.

  If the data in your source files is encrypted, decrypt the data by specifying the `format` parameter with the `encryption` option. See Decrypt Data While Importing from Object Storage for more information on decrypting data.
- `column_list`: is a comma delimited list of the column definitions in the source files.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

You can now run queries on the hybrid partitioned table you created in the previous step. Your Autonomous Database takes advantage of the partitioning information of your hybrid partitioned table, ensuring that the query only accesses relevant data files in the Object Store. For example, the following query only reads data files from partition P1:

```
SELECT * FROM hpt1 WHERE col1 < 750;
```

The hybrid partitioned tables you create with `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` include two invisible columns `file$path` and `file$name`. These columns help identify which file a record is coming from. See External Table Metadata Columns for more information.

If there are any rows in the source files that do not match the format options you specified, the query reports an error. You can use `DBMS_CLOUD` parameters, like *rejectlimit,* to suppress these errors. As an alternative, you can also validate the hybrid partitioned table you created to see the error messages and the rejected rows so that you can change your format options accordingly. See Validate External Data and Validate Hybrid Partitioned Data for more information.

See CREATE_HYBRID_PART_TABLE Procedure detailed information about the parameters.

See DBMS_CLOUD URI Formats for more information on the supported cloud object storage services.

Query External Data Pump Dump Files

You can also query Oracle Data Pump dump files in the Cloud by creating an external table using `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`.

The source files to create this type of external table must be exported from the source system using the `ORACLE_DATAPUMP` access driver in External Tables. See Unloading and Loading Data with the ORACLE_DATAPUMP Access Driver for details on exporting using the `ORACLE_DATAPUMP` access driver.

To create an external table you first move the Oracle Data Pump dump files that were exported using the `ORACLE_DATAPUMP` access driver to your Object Store and then use `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` to create the external table.

The source files in this example are the Oracle Data Pump dump files, `exp01.dmp` and `exp02.dmp`.

1. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password' );
   END;
   /
   ```

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name for creating external tables.

   See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

2. Create an external table on top of your source files using the procedure `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`.

   For example:

   ```
   BEGIN
      DBMS_CLOUD.CREATE_EXTERNAL_TABLE(
       table_name =>'CHANNELS_EXT',
       credential_name =>'DEF_CRED_NAME',
       file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
   namespace-string/b/bucketname/o/exp01.dmp,
                        https://objectstorage.us-phoenix-1.oraclecloud.com/n/
   namespace-string/b/bucketname/o/exp02.dmp'
       format => json_object('type' value 'datapump', 'rejectlimit' value
   '1'),
       column_list => 'CHANNEL_ID NUMBER, CHANNEL_DESC VARCHAR2(20),
   CHANNEL_CLASS VARCHAR2(20)' );
   END;
   /
   ```

The parameters are:

- `table_name`: is the external table name.
- `credential_name`: is the name of the credential created in the previous step.
- `file_uri_list`: is a comma delimited list of the Data Pump dump files you want to query.
- `format`: defines the options you can specify to describe the format of the source file defines the options you can specify to describe the format of the source file. When you specify the type `'datapump'`, the only other valid format parameter is `'rejectlimit'`.
- `column_list`: is a comma delimited list of the column definitions in the source files.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

You can now run queries on the external table you created in the previous step. For example:

```
SELECT count(*) FROM channels_ext;
```

By default the database expects all rows in the external data file to be valid and match both the target data type definitions as well as the format definition of the files. As part of validation, `DBMS_CLOUD` makes sure all the necessary dump file parts are there and also checks that the dump files are valid and not corrupt (for example `exp01.dmp`, `exp02.dmp`, and so on). You can use the `DBMS_CLOUD` format option `rejectlimit` to suppress these errors. As an alternative, you can also validate the external table you created to see the error messages and the rejected rows. See Validate External Data for more information.

For detailed information about the parameters, see CREATE_EXTERNAL_TABLE Procedure.

See DBMS_CLOUD URI Formats for more information on the supported cloud object storage services.

Query Big Data Service Hadoop (HDFS) Data from Autonomous Database

You can create database links to Oracle Big Data Service from Autonomous Database.

Big Data Service provides enterprise-grade Hadoop as a service, with end-to-end security, high performance, and ease of management and upgradeability. After deploying the Oracle Cloud SQL Query Server to Big Data Service, you can easily query data available on Hadoop clusters at scale from Autonomous Database using SQL. This allows you to blend data coming from your data lake with data in your Autonomous Database.

Oracle Cloud SQL Query Server is an Oracle SQL engine that can be accessed using database links in Autonomous Database. You create links to Big Data Service using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`. See Integrating Cloud SQL with Autonomous Database for more information.

Query External Data with Data Catalog

Oracle Cloud Infrastructure Data Catalog is the metadata management service for Oracle Cloud that helps you discover data and support data governance. It provides an inventory of assets, a business glossary, and a common metastore for data lakes.

Autonomous Database can leverage this metadata to dramatically simplify management for access to your data lake's object store. Instead of manually defining external tables to access your data lake, use the external tables that are defined and managed automatically. These tables will be found in Autonomous Database protected schemas that are kept up to date with changes in Data Catalog.

For more information about Data Catalog, please refer to Data Catalog documentation.

- About Querying with Data Catalog
  By synchronizing with Data Catalog metadata, Autonomous Database automatically creates external tables for each logical entity harvested by Data Catalog. These external tables are defined in database schemas that are fully managed by the metadata synchronization process. Users can immediately query data without having to manually derive the schema (columns and data types) for external data sources and manually create external tables.
- Concepts Related to Querying with Data Catalog
  An understanding of the following concepts is necessary for querying with Data Catalog.
- Synchronization Mapping
  The synchronization process creates and updates Autonomous Database schemas and external tables based on Data Catalog data assets, folders, logical entities, attributes and relevant custom overrides.
- Typical Workflow with Data Catalog
  There is a typical workflow of actions performed by users who want to query with Data Catalog.
- Example: MovieStream Scenario
  In this scenario, Moviestream is capturing data in a landing zone on object storage. Much of this data, but not necessarily all, is then used to feed an Autonomous Database. Prior to feeding Autonomous Database, the data is transformed, cleansed and subsequently stored in the "gold" area.
- Example: Partitioned Data Scenario
  This scenario illustrates how to create external tables in Autonomous Database that are based on Data Catalog logical entities harvested from partitioned data in Object Store.

About Querying with Data Catalog

By synchronizing with Data Catalog metadata, Autonomous Database automatically creates external tables for each logical entity harvested by Data Catalog. These external tables are defined in database schemas that are fully managed by the metadata synchronization process. Users can immediately query data without having to manually derive the schema (columns and data types) for external data sources and manually create external tables.

Synchronization is dynamic, keeping the Autonomous Database up-do-date with respect to changes to the underlying data, reducing administration cost as it automatically maintains hundreds to thousands of tables. It also allows multiple Autonomous Database instances to share the same Data Catalog, further reducing management costs and providing a common set of business definitions.

The Data Catalog folders/buckets are containers that sync with Autonomous Database schemas. Logical entities within those folders/buckets map to Autonomous Database external tables. These schemas and external tables are automatically generated and maintained through the sync process:

- Folders/Buckets map to database schemas that are for organizational purposes only.
- The organization is meant to be consistent with the data lake and minimize confusion when accessing data thru different paths.

- Data Catalog is the source of truth for the tables contained within schemas. Changes made in the Data Catalog update the schema's tables during a subsequent sync.

To use this capability, a Database Data Catalog Administrator initiates a connection to a Data Catalog instance, selects which data assets and logical entities to synchronize, and runs the sync. The sync process creates schemas and external tables based on the selected Data Catalog harvested data assets and logical entities. As soon as the external tables are created, Data Analysts can start querying their data without having to manually derive the schema for external data sources and create external tables.

> **Note:**
>
> The `DBMS_DCAT` Package is available for performing the tasks required to query Data Catalog object store data assets. See DBMS_DCAT Package.

Concepts Related to Querying with Data Catalog

An understanding of the following concepts is necessary for querying with Data Catalog.

Data Catalog
Data Catalog harvests data assets that point to the object store data sources you want to query with Autonomous Database. From Data Catalog you can specify how the data is organized during harvesting, supporting different file organization patterns. As part of the Data Catalog harvesting process, you can select the buckets and files you want to manage within the asset. For further information, see Data Catalog Overview.

Object Stores
Object Stores have buckets containing a variety of objects. Some common types of objects found in these buckets include: CSV, parquet, avro, json, and ORC files. Buckets generally have a structure or a design pattern to the objects they contain. There are many different ways to structure data and many different ways of interpreting these patterns.
For example, a typical design pattern uses top-level folders that represent tables. Files within a given folder share the same schema and contain data for that table. Subfolders are often used to represent table partitions (for example, a subfolder for each day). Data Catalog refers to each top-level folder as a logical entity, and this logical entity maps to an Autonomous Database external table.

Connection
A connection is an Autonomous Database connection to a Data Catalog instance. For each Autonomous Database instance there can be connections to multiple Data Catalog instances. The Autonomous Database credential must have rights to access Data Catalog assets that have been harvested from object storage.

Harvest
A Data Catalog process that scans object storage and generates the logical entities from your data sets.

Data Asset
A data asset in Data Catalog represents a data source, which includes databases, Oracle Object Storage, Kafka, and more. Autonomous Database leverages Oracle Object Storage assets for metadata synchronization.

Data Entity
A data entity in Data Catalog is a collection of data such as a database table or view, or a single file and normally has many attributes that describe its data.

Logical Entity
In Data Lakes, numerous files typically comprise a single logical entity. For example, you may have daily clickstream files, and these files share the same schema and file type.
A Data Catalog logical entity is a group of Object Storage files that are derived during harvesting by applying filename patterns that have been created and assigned to a data asset.

Data Object
A data object in Data Catalog refers to data assets and data entities.

Filename Pattern
In a data lake, data may be organized in different ways. Typically, folders capture files of the same schema and type. You must register to Data Catalog how your data is organized. Filename patterns are used to identify how your data is organized. In Data Catalog, you can define filename patterns using regular expressions. When Data Catalog harvests a data asset with an assigned filename pattern, logical entities are created based on the filename pattern. By defining and assigning these patterns to data assets, multiple files can be grouped as logical entities based on the filename pattern.

Synchronize (Sync)
Autonomous Database performs synchronizations with Data Catalog to automatically keep its database up-to-date with respect to changes to the underlying data. Synchronization can be performed manually, or on a schedule.
The sync process creates schemas and external tables based on the Data Catalog data assets and logical entities. These schemas are protected, which means their metadata is managed by Data Catalog. If you want to alter the metadata, you must make the changes in Data Catalog. The Autonomous Database schemas will reflect any changes after the next sync is run. For further details, see Synchronization Mapping.

Synchronization Mapping

The synchronization process creates and updates Autonomous Database schemas and external tables based on Data Catalog data assets, folders, logical entities, attributes and relevant custom overrides.

Data Catalog	Autonomous Database	Mapping Description
Data asset and folder (object storage bucket)	Schema name	**Default values**: By default, the generated schema name in Autonomous Database has the following format: `DCAT$<dcat-con-id>_<data-asset-name>_<folder-name>` • `dcat-con-id` is the unique Data Catalog connection identifier. For details on specifying this identifier, see the `dcat_con_id` parameter in the DBMS_DCAT RUN_SYNC Procedure. • `data-asset-name` is the name of the Data Catalog data asset's name. • `folder-name` is the Data Catalog folder name. This folder maps to an object storage bucket. **Customizations**: The default `data-asset-name` and `folder-name` can be customized by defining custom properties, business names and display names to override these default names. • `data-asset-name` can be overidden by defining the `oracle-db-schema-prefix` custom property for the data asset in Data Catalog. • `folder-name` can be overidden by defining the `oracle-db-schema` custom property for the folder in Data Catalog, a business name or display name. The following attributes are used in order of precedence for generating the `folder-name`: 1. `oracle-db-schema` custom property 2. Business Name 3. Display Name **Examples**: • If the connection id is `DataModels`, the asset name is `ObjectStorage`, the folder name is `HR` and there are no custom property overrides, the derived schema name is: `DCAT$DATAMODELS_OBJECTSTORAGE_HR` • If the data asset name is MYASSET, the folder name is MYFOLDER, and there are no custom property overrides, the schema name is: `DCAT$MYASSET_MYFOLDER` • If the data asset has `oracle-db-prefix = FIRSTASSET`, and the folder has `oracle-db-schema = FIRSTFOLDER`, then the schema name is: `DCAT$FIRSTASSET_FIRSTFOLDER`

Data Catalog	Autonomous Database	Mapping Description
Logical entity	External table	Logical entities are mapped to external tables. If the logical entity has a partitioned attribute, it is mapped to a partitioned external table. The external table name is derived from the corresponding logical entity's Display Name, or Business Name. If `oracle-db-schema` is set, then its value overrides all the names and custom properties of the corresponding folders and data assets. For example, if `oracle-db-schema` for an entity is set to `EntitySchema`, then the table is created in schema `DCAT$ENTITYSCHEMA`.
Logical entity's attributes	External table columns	**Column names**: The external table column names are derived from the corresponding logical entity's attribute display names, or business names. For logical entities derived from Parquet, Avro, and ORC files, the column name is always the display name of the attribute as it represents the field name derived from the source files. For attributes corresponding to a logical entity derived from CSV files, the following attribute fields are used in order of precedence for generating the column name: 1. `oracle-db-column-name` 2. Business Name 3. Display Name **Column type**: The `oracle-db-column-type` custom property overrides the default column type that was derived by Data Catalog. For attributes corresponding to a logical entity derived from Avro files with `TIME_MICROS`, `TIME_MILLIS`, `TIMESTAMP_MICROS` or `TIMESTAMP_MILLIS` data types, you must set the `oracle-db-column-type` of the corresponding attribute in Data Catalog. **Column length**: The `oracle-db-column-length` custom property overrides the default column length for a string field that was derived by Data Catalog. **Column precision**: The `oracle-db-column-precision` custom property overrides the default precision for a number that was derived by Data Catalog. For attributes corresponding to a logical entity derived from Avro files with `TIME_MICROS`, `TIME_MILLIS`, `TIMESTAMP_MICROS` or `TIMESTAMP_MILLIS` data types, you must set the `oracle-db-column-precision` of the corresponding attribute in Data Catalog. **Column scale**: The `oracle-db-column-scale` custom property overrides the default scale for a number that was derived by Data Catalog.

Typical Workflow with Data Catalog

There is a typical workflow of actions performed by users who want to query with Data Catalog.

The Database Data Catalog Admin creates a connection between the Autonomous Database instance and a Data Catalog instance, then configures and runs a synchronization (sync) between the Data Catalog and Autonomous Database. The sync creates external tables and schemas in the Autonomous Database instance based on the synced Data Catalog contents. The Database Data Catalog Query Admin or Database Admin grants READ access to the generated external tables so that Data Analysts and other database users can browse and query the external tables.

The table below describes each action in detail. For a description of the different user types included in this table, see Data Catalog Users and Roles.

> **Note:**
>
> The `DBMS_DCAT` Package is available for performing the tasks required to query Data Catalog object store data assets. See DBMS_DCAT Package.

Action	Who is the user	Description
Create policies	Database Data Catalog Administrator	The Autonomous Database resource principal or Autonomous Database user credential must have the appropriate permissions to manage Data Catalog and to read from object storage. **More information**: Required Credentials and IAM Policies.
Create credentials	Database Data Catalog Administrator	Ensure database credentials are in place to access Data Catalog and to query object store. The user calls `DBMS_CLOUD.CREATE_CREDENTIAL` to create user credentials and/or `DBMS_CLOUD_ADMIN.ENABLE_RESOURCE_PRINCIPAL` to enable resource principals. **More information**: DBMS_CLOUD CREATE_CREDENTIAL Procedure, Use Resource Principal with DBMS_CLOUD.

Action	Who is the user	Description
Create connections to Data Catalog	Database Data Catalog Administrator	To initiate a connection between an Autonomous Database instance and a Data Catalog instance the user calls `DBMS_DCAT.SET_DATA_CATALOG_CONN` to specify the target Data Catalog instance. Connections from an Autonomous Database instance to multiple Data Catalog instances is supported. The connection to the Data Catalog instance must use a database credential object with sufficient Oracle Cloud Infrastructure (OCI) privileges. For example, the Resource Principal Service Token for the Autonomous Database instance or an OCI user with sufficient privileges can be used. Once the connection has been made, the Data Catalog instance is updated with the `DBMS_DCAT` namespace and custom properties (if they do not already exist). The user can run a query to see the new connection including all current connections: `select * from all_dcat_connections;` **More information**: SET_DATA_CATALOG_CONN Procedure, UNSET_DATA_CATALOG_CONN Procedure.
Create a selective sync	Database Data Catalog Administrator	Create a sync job by selecting the Data Catalog objects to sync. The user can: • Select data assets/folders to sync. • Select individual logical entities to sync. • Preview the resulting external tables before syncing. • Change external tables (for example, the name) by modifying custom properties on Data Catalog. **More information**: See CREATE_SYNC_JOB Procedure, DROP_SYNC_JOB Procedure, Synchronization Mapping
Sync with Data Catalog	Database Data Catalog Administrator	The user initiates a sync operation. The sync is initiated manually through the `DBMS_DCAT.RUN_SYNC` procedure call, or automatically as part of a scheduled sync job. The sync operation creates, modifies and drops external tables and schemas according to the Data Catalog contents and sync selections. Manual configuration is applied using Data Catalog Custom Properties. **More information**: See RUN_SYNC Procedure, CREATE_SYNC_JOB Procedure, Synchronization Mapping
Monitor sync and view logs	Database Data Catalog Administrator	The user can view the sync status by querying the `USER_LOAD_OPERATIONS` view. After the sync process has completed, the user can view a log of the sync results, including details about the mappings of logical entities to external tables. **More information**: Monitoring and Troubleshooting Loads
Grant privileges	Database Data Catalog Query Administrator, Database Administrator	The database Data Catalog Query Administrator or database Administrator must grant READ on generated external tables to data analyst users. This allows the data analysts to query the generated external tables.

Action	Who is the user	Description
Browse and query external tables	Data Analyst	Data analysts are able to query the external tables through any tool or application that supports Oracle SQL. Data Analysts can review the synced schemas and tables in the DCAT$* schemas, and query the tables using Oracle SQL. **More information**: Synchronization Mapping
Terminate connections to Data Catalog	Database Data Catalog Administrator	To remove an existing Data Catalog association, the user calls the UNSET_DATA_CATALOG_CONN procedure. This action is only done when you no longer plan on using Data Catalog and the external tables that are derived from the catalog. This action deletes Data Catalog metadata, and drops synced external tables from the Autonomous Database instance. The custom properties on Data Catalog and OCI policies are not affected. **More information**: UNSET_DATA_CATALOG_CONN Procedure

Example: MovieStream Scenario

In this scenario, Moviestream is capturing data in a landing zone on object storage. Much of this data, but not necessarily all, is then used to feed an Autonomous Database. Prior to feeding Autonomous Database, the data is transformed, cleansed and subsequently stored in the "gold" area.

Data Catalog is used to harvest these sources and then provide a business context to the data. Data Catalog metadata is shared with Autonomous Database, allowing Autonomous Database users to query those data sources using Oracle SQL. This data may be loaded into Autonomous Database or queried dynamically using external tables.

For more information on using Data Catalog, see Data Catalog Documentation.

1. Object Store - Review buckets, folders and files
   a. Review the buckets in your object store.

      For example, below are the landing (`moviestream_landing`) and gold zone (`moviestream_gold`) buckets in object storage:

   b. Review the folders and files in the object store buckets.

      For example, below are the folders in the landing bucket (`moviestream_landing`) in object storage:
2. Data Catalog - Create filename patterns
   a. Inform Data Catalog how your data is organized using filename patterns. These are regular expressions used to categorize files. The filename patterns are used by the Data Catalog harvester to derive logical entities. The following two filename patterns are used to harvest the buckets in the MovieStream example. See Harvesting Object Storage Files as Logical Data Entities for further details on creating filename patterns.

Hive-style	Folder-style
`{bucketName:.*}/{logicalEntity:[^/]+}.db/{logicalEntity:[^/]+}/.*`	`{bucketName:[\w]+}/{logicalEntity:[^/]+}(?<!.db)/.*$`

Hive-style	Folder-style
• Creates logical entities for sources that contain ".db" as the first part of the object name. • To ensure uniqueness within the bucket, the resulting name is (db-name).(folder name)	• Creates a logical entity based on the folder name off of the root • To prevent duplication with Hive, object names that have ".db" in them are skipped.

b. To create filename patterns, go to the **Filename Patterns** tab for your Data Catalog and click **Create Filename Pattern**. For example, the following is the **Create Filename Pattern** tab for the `moviestream` Data Catalog:

3. Data Catalog - Data Asset Creation

   a. Create a data asset that is used to harvest data from your object store.

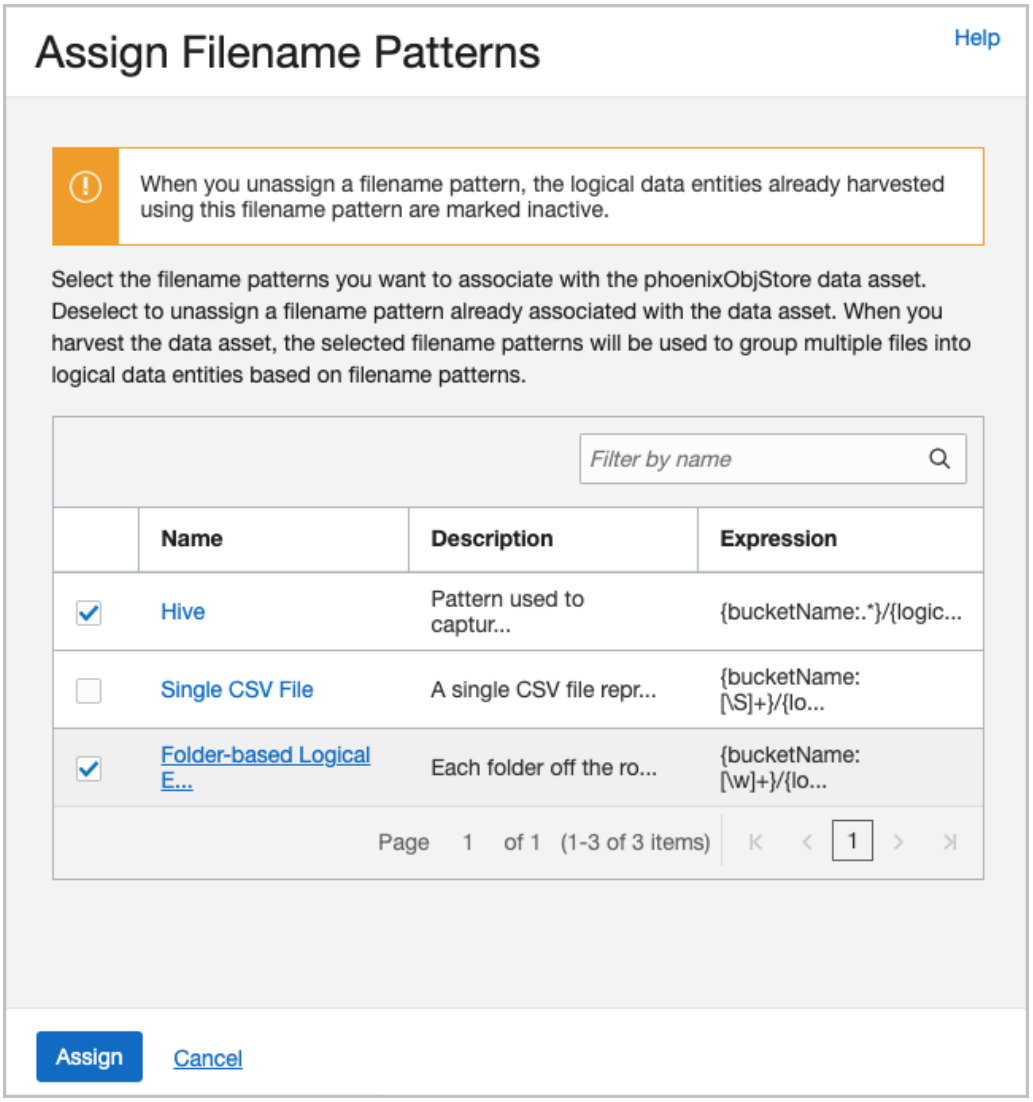
      For example, a data asset named `phoenixObjStore` is created in the `moviestream` Data Catalog:

   b. Add a connection to your data asset.

      In this example, the data asset connects to the compartment for the `moviestream` object storage resource.

   c. Now, associate your filename patterns with your data asset. Select **Assign Filename Patterns**, check the patterns you want and click **Assign**.

For example, here are the patterns assigned to the `phoenixObjStore` data asset:



4. Data Catalog - Harvest data from object store

   a. Harvest the Data Catalog data asset. Select the object store buckets containing the source data.

      In this example, the `moviestream_gold` and `moviestream_landing` buckets from object store are selected for harvesting.

   b. After running the job, you see the logical entities. Use the **Browse Data Assets** to review them.

      In this example, you are looking at the `customer-extension` logical entity and its attributes.
      If you have a glossary, Data Catalog recommends categories and terms to associate with the entity and its attributes. This provides a business context for the items. Schemas, tables and columns are oftentimes not self-explanatory.

      In our example, we want to differentiate between the different types of buckets and the meaning of their content:

      - what is a landing zone?
      - how accurate is the data?

- when was it last updated?
- what is the definition of a logical entity or its attribute

5. Autonomous Database - Connect to Data Catalog

   Connect Autonomous Database to Data Catalog. You need to ensure that the credential used to make that connection is using an OCI principal that is authorized to access the Data Catalog asset. For further information, see Data Catalog Policies and Access Cloud Resources by Configuring Policies and Roles.

   a. Connect to Data Catalog

```
-- Variables are used to simplify usage later
define oci_credential = 'OCI$RESOURCE_PRINCIPAL'
define dcat_ocid = 'ocid1.datacatalog.oc1.iad.aaaaaaaardp66bg....twiq'
define dcat_region='us-ashburn-1'
define uri_root =    'https://objectstorage.us-
ashburn-1.oraclecloud.com/n/mytenancy/b/landing/o'
define uri_private = 'https://objectstorage.us-
ashburn-1.oraclecloud.com/n/mytenancy/b/private_data/o'

-- Run as admin
-------
-- Enable resource principal support
-------
exec dbms_cloud_admin.enable_resource_principal();

-- Test to make sure credential was created. Returns a row if it was
successful
select *
from dba_credentials
where credential_name = 'OCI$RESOURCE_PRINCIPAL' and owner = 'ADMIN';

-- Query a private bucket to test the principal and privileges.
select *
from dbms_cloud.list_objects('&oci_credential', '&uri_private/');

--------
-- Set the credentials to use for object store and data catalog
-- Connect to Data Catalog
-- Review connection
---------
-- Set credentials
exec dbms_dcat.set_data_catalog_credential(credential_name =>
'&oci_credential');
exec dbms_dcat.set_object_store_credential(credential_name =>
'&oci_credential');

-- Connect to Data Catalog
begin
   dbms_dcat.set_data_catalog_conn (
     region => '&dcat_region',
     catalog_id => '&dcat_ocid');
end;
/
```

```
-- Review the connection
select * from all_dcat_connections;
```

b. Sync Data Catalog with Autonomous Database. Here, we'll sync all the object storage assets:

```
-- Sync Data Catalog with Autonomous Database
---- Let's sync all of the assets.
begin
 dbms_dcat.run_sync('{"asset_list":["*"]}');
end;
/

-- View log
select type, start_time, status, logfile_table from
user_load_operations;  -- Logfile_Table will have the name of the table
containing the full log.
select * from dbms_dcat$1_log;

-- View the new external tables
select * from dcat_entities;
select * from dcat_attributes;
```

c. Autonomous Database - Now start running queries against object store.

```
-- Query the Data !
select *from dcat$phoenixobjstore_moviestream_gold.genre
;
```

6. Change schemas for objects

   The default schema names are rather complicated. Let's simplify them by specifying both the asset and the folder's `Oracle-Db-Schema` custom attribute in Data Catalog. Change the data asset to `PHX` and the folders to `landing` and `gold` respectively. The schema is a concatenation of the two.

   a. From Data Catalog, navigate to the `moviestream_landing` bucket and change the asset to `landing` and `gold` respectively.

      Before change:

      After change:

   b. Run another sync.

Example: Partitioned Data Scenario

This scenario illustrates how to create external tables in Autonomous Database that are based on Data Catalog logical entities harvested from partitioned data in Object Store.

The following example is based on Example: MovieStream Scenario and has been adapted to demonstrate integrating with partitioned data. Data Catalog is used to harvest these sources and then provide a business context to the data. For further details about this example, see Example: MovieStream Scenario .

For more information on using Data Catalog, see Data Catalog Documentation.

1. Object Store - Review buckets, folders and files
   a. Review the buckets in your object store.

      For example, below are the landing (`moviestream_landing`) and gold zone (`moviestream_gold`) buckets in object storage:

   b. Review the folders and files in the object store buckets.

      For example, below are the folders in the landing bucket (`moviestream_landing`) in object storage:

2. Data Catalog - Create filename patterns
   a. Inform Data Catalog how your data is organized using filename patterns. These are folder prefixes or regular expressions used to categorize files. The filename patterns are used by the Data Catalog harvester to derive logical entities. When a folder prefix is specified, the Data Catalog automatically generates logical entities from the specified folder prefix in the object store. The following filename pattern is used to harvest the buckets in the MovieStream example. See Harvesting Object Storage Files as Logical Data Entities for further details on creating filename patterns.

Folder prefix	Description
`workshop.db/`	Creates logical entities for sources that contain "workshop.db" path in the object store.

   b. To create filename patterns, go to the **Filename Patterns** tab for your Data Catalog and click **Create Filename Pattern**. For example, the following is the **Create Filename Pattern** tab for the `moviestream` Data Catalog:

3. Data Catalog - Data Asset Creation
   a. Create a data asset that is used to harvest data from your object store.

      For example, a data asset named `amsterdamObjStore` is created in the `moviestream` Data Catalog:

   b. Add a connection to your data asset.

      In this example, the data asset connects to the compartment for the `moviestream` object storage resource.

   c. Now, associate your filename patterns with your data asset. Select **Assign Filename Patterns**, check the patterns you want and click **Assign**.

      For example, here are the patterns assigned to the `amsterdamObjStore` data asset:

4. Data Catalog - Harvest data from object store
   a. Harvest the Data Catalog data asset. Select the object store buckets containing the source data.

      In this example, the `moviestream_gold` and `moviestream_landing` buckets from object store are selected for harvesting.

   b. After running the job, you see the logical entities. Use the **Browse Data Assets** to review them.

      In this example, you are looking at the `sales_sample_parquet` logical entity and its attributes. Note that Data Catalog has identified the `month` attribute as partitioned.

5. Autonomous Database - Connect to Data Catalog

   Connect Autonomous Database to Data Catalog. You need to ensure that the credential used to make that connection is using an OCI principal that is authorized to access the

Data Catalog asset. For further information, see Data Catalog Policies and Access Cloud Resources by Configuring Policies and Roles.

a. Connect to Data Catalog

```
-- Variables are used to simplify usage later
define oci_credential = 'OCI$RESOURCE_PRINCIPAL'
define dcat_ocid = 'ocid1.datacatalog.oc1.eu-
amsterdam-1....leguurn3dmqa'
define dcat_region='eu-amsterdam-1'
define uri_root =    'https://objectstorage.us-
ashburn-1.oraclecloud.com/n/mytenancy/b/landing/o'
define uri_private = 'https://objectstorage.us-
ashburn-1.oraclecloud.com/n/mytenancy/b/private_data/o'

-- Run as admin
-------
-- Enable resource principal support
-------
exec dbms_cloud_admin.enable_resource_principal();

-- Test to make sure credential was created. Returns a row if it was
successful
select *
from dba_credentials
where credential_name = 'OCI$RESOURCE_PRINCIPAL' and owner = 'ADMIN';

-- Query a private bucket to test the principal and privileges.
select *
from dbms_cloud.list_objects('&oci_credential', '&uri_private/');

--------
-- Set the credentials to use for object store and data catalog
-- Connect to Data Catalog
-- Review connection
---------
-- Set credentials
exec dbms_dcat.set_data_catalog_credential(credential_name =>
'&oci_credential');
exec dbms_dcat.set_object_store_credential(credential_name =>
'&oci_credential');

-- Connect to Data Catalog
begin
   dbms_dcat.set_data_catalog_conn (
     region => '&dcat_region',
     catalog_id => '&dcat_ocid');
end;
/
-- Review the connection
select * from all_dcat_connections;
```

b. Sync Data Catalog with Autonomous Database. Here, we'll sync all the object storage assets:

```
-- Sync Data Catalog with Autonomous Database
---- Let's sync all of the assets.
begin
 dbms_dcat.run_sync('{"asset_list":["*"]}');
end;
/

-- View log
select type, start_time, status, logfile_table from
user_load_operations;  -- Logfile_Table will have the name of the table
containing the full log.
select * from dbms_dcat$1_log;

-- View the new external tables
select * from dcat_entities;
select * from dcat_attributes;
```

c. Autonomous Database - Now start running queries against object store.

```
-- Query the Data !
select count(*) from
DCAT$AMSTERDAMOBJSTORE_MOVIESTREAM_LANDING.SALES_SAMPLE_PARQUET;

-- Examine the generated partitioned table
select
dbms_metadata.get_ddl('TABLE','SALES_SAMPLE_PARQUET','DCAT$AMSTERDAMOBJS
TORE_MOVIESTREAM_LANDING') from dual;

CREATE TABLE

sales_sample_parquet/month=2020-12/*'))
PARALLEL
```

6. Change schemas for objects

   The default schema names are rather complicated. Let's simplify them by specifying both the asset and the folder's `Oracle-Db-Schema` custom attribute in Data Catalog. Change the data asset to `PHX` and the folders to `landing` and `gold` respectively. The schema is a concatenation of the two.

   a. From Data Catalog, navigate to the `moviestream_landing` bucket and change the asset to `landing` and `gold` respectively.

      Before change:

      After change:

   b. Run another sync.

Query External Data with AWS Glue Data Catalog

Autonomous Database supports a system for synchronizing with an Amazon AWS Glue Data Catalog instance.

- About Querying with AWS Glue Data Catalog
  Autonomous Database allows you to synchronize with Amazon Web Service (AWS) Glue Data Catalog metadata. A database external table is automatically created by Autonomous Database for every table harvested by AWS Glue about data stored in Amazon Simple Storage Service (S3). Users can query data stored in S3 from Autonomous Database without having to manually derive the schema for the external data sources and create external tables.
- Concepts Related to Querying with AWS Glue Data Catalog
  An understanding of the following concepts is necessary for querying with Amazon Web Service (AWS) Glue data catalogs.
- Mapping Between Autonomous Database and AWS Glue
  During the synchronization process, external tables are created in Autonomous Database derived from the AWS Glue Data Catalog databases and tables over Amazon S3.
- User Workflow for Querying with AWS Glue Data Catalog
  The basic user workflow for querying AWS S3 data with AWS Glue Data Catalog involves connecting to AWS Glue Data Catalog, synchronizing with Autonomous Database to automatically create external tables, and then querying the S3 data.
- Example: Query with AWS Glue Data Catalog
  This example steps you through the process of running queries over datasets stored in Amazon Simple Storage Service (Amazon S3) using an AWS Glue Data Catalog.

About Querying with AWS Glue Data Catalog

Autonomous Database allows you to synchronize with Amazon Web Service (AWS) Glue Data Catalog metadata. A database external table is automatically created by Autonomous Database for every table harvested by AWS Glue about data stored in Amazon Simple Storage Service (S3). Users can query data stored in S3 from Autonomous Database without having to manually derive the schema for the external data sources and create external tables.

Amazon AWS Glue Data Catalog is a centralized metadata management service that helps data professionals discover data and supports data governance in AWS cloud. An Autonomous Database instance has the ability to synchronize automatically data catalog metadata with AWS Glue Data Catalog allowing database users to immediately use Autonomous Database to query data stored in the AWS cloud.

Synchronizing with AWS Glue Data Catalog has the same properties as synchronizing with OCI Data Catalog. Synchronization is dynamic, keeping the database up-do-date with respect to changes to the underlying data, reducing administration cost as it automatically maintains hundreds to thousands of tables.

Concepts Related to Querying with AWS Glue Data Catalog

An understanding of the following concepts is necessary for querying with Amazon Web Service (AWS) Glue data catalogs.

AWS Glue Data Catalog: Database
An AWS Glue database represents a collection of relational table definitions, organized in a logical group. Each AWS Glue data catalog instance manages multiple databases.

AWS Glue Data Catalog: Table
An AWS Glue table represents a relational table over data stored in the AWS cloud. An AWS Glue table defines the schema of the underlying data and consists of column information, partition information, serialization information, storage information, statistics, user-defined metadata and other metadata. Tables in AWS Glue data catalog can be created manually, or automatically using an AWS Glue crawler.

Glue Data Catalog: Crawler
You can use a crawler to populate the AWS Glue data catalog with tables. This is the primary method used by most AWS Glue users. A crawler can crawl multiple data stores in a single run. Upon completion, the crawler creates or updates one or more tables in your data catalog. Extract, transform, and load (ETL) jobs that you define in AWS Glue use these data catalog tables as sources and targets. The ETL job reads from and writes to the data stores that are specified in the source and target data catalog tables.
AWS Glue tables can be created manually by the user or automatically using a predefined or a custom crawler. Crawlers connect to the underlying data stores (for example, Amazon S3), invoke classifiers for deriving the schema of the data, and create AWS Glue tables for storing the inferred metadata. AWS Glue provides classifiers for common file types, such as CSV, JSON, Parquet, and AVRO.

Mapping Between Autonomous Database and AWS Glue

During the synchronization process, external tables are created in Autonomous Database derived from the AWS Glue Data Catalog databases and tables over Amazon S3.

AWS Glue organizes collected metadata in databases and tables. An AWS Glue database is a collection of relational table definitions. AWS Glue tables that describe the common schema and properties of the files associated with the table.

AWS Glue follows the relational model for representing attributes. For mapping hierarchical schemas to relational schemas, AWS Glue infers the schema of the semi-structured data and flattens the data to a relational schema using an ETL process.

The following table represents the mapping between OCI Data Catalog concepts and AWS Glue Data Catalog Concepts.

Table 3-5 OCI Data Catalog to AWS Glue Data Catalog Mapping

OCI Data Catalog	AWS Glue Data Catalog	Oracle Database
Data Asset	Database	Schema
Folder	(Bucket)	Schema
Logical Entity	Table	Table

User Workflow for Querying with AWS Glue Data Catalog

The basic user workflow for querying AWS S3 data with AWS Glue Data Catalog involves connecting to AWS Glue Data Catalog, synchronizing with Autonomous Database to automatically create external tables, and then querying the S3 data.

The Database Data Catalog Administrator creates a connection between the Autonomous Database instance and an AWS Glue Data Catalog instance, then configures and runs a synchronization (sync) between the AWS Glue Data Catalog and Autonomous Database. Autonomous Database automatically creates an external table for tables harvested by AWS Glue about data stored in S3.
The Database Data Catalog Query Admin or Database Admin grants READ access to the generated external tables so that Data Analysts and other database users can browse and query Autonomous Database without having to manually derive the schema for the external data sources and create external tables.

Users

The table below describes the different types of users that perform the user workflow actions.

User	Description
Database Data Catalog Administrator	Database user with `DCAT_SYNC` role.
Database Data Catalog Query Administrator	Database user able to grant access on automatically created external tables to other users.
Data Analyst	Database user on Autonomous Database querying data in AWS S3 either by querying automatically created external tables or by interacting directly with AWS Glue Data Catalog.
AWS Glue Data Catalog User	AWS user with access to an AWS Glue Data Catalog.
AWS S3 Object Storage User	AWS user with access to data stored in AWS S3

User Workflow

The table below describes each action included in the workflow and what type of user can perform the action.

> **Note:**
>
> The `DBMS_DCAT` package is available for performing the tasks required to query AWS S3 object storage using AWS Glue Data Catalog. See DBMS_DCAT Package.

Action	Who is the user	Description
Create policies	Database Data Catalog Administrator	The Autonomous Database user credential must have the appropriate permissions to access AWS Glue Data Catalog and to read from S3 object storage. **More information**: Required Credentials and IAM Policies.
Create credentials	Database Data Catalog Administrator	Ensure database credentials are in place to access AWS Glue Data Catalog and to query S3 object storage. The user calls `DBMS_CLOUD.CREATE_CREDENTIAL` to create user credentials. **Note:** Only Amazon Web Services (AWS) credentials are supported. AWS Amazon Resource Names (ARN) credentials are not supported. **More information**: DBMS_CLOUD CREATE_CREDENTIAL Procedure
Connect	Database Data Catalog Administrator	Establish a connection between an Autonomous Database instance and an AWS Glue Data Catalog instance. The connection uses the privileges of the AWS Glue Data Catalog User. Connections from an Autonomous Database instance to multiple AWS Glue Data Catalog instances is supported. To initiate a connection between an Autonomous Database instance and an AWS Glue Data Catalog instance the user: 1. Calls `DBMS_DCAT.SET_DATA_CATALOG_CREDENTIAL` using an AWS credential (CREATE_CREDENTIAL Procedure) to specify the target AWS Glue Data Catalog instance. 2. Calls the `DBMS_DCAT.SET_OBJECT_STORE_CREDENTIAL` using an AWS credential (CREATE_CREDENTIAL Procedure) to access the AWS S3 object storage. 3. Calls `DBMS_DCAT.SET_DATA_CATALOG_CONN` using an AWS Glue service endpoint Once the connection has been made, Autonomous Database stores the associated metadata, such as the AWS Glue catalog id, region, endpoint, and credential objects. **More information**: SET_DATA_CATALOG_CONN Procedure, UNSET_DATA_CATALOG_CONN Procedure, SET_DATA_CATALOG_CREDENTIAL Procedure, SET_OBJECT_STORE_CREDENTIAL Procedure.

Action	Who is the user	Description
Synchronize	Database Data Catalog Administrator	The user can manually start a synchronization with connected AWS Glue Data Catalogs using `DBMS_DCAT.RUN_SYNC` or create automatic synchronizations using `DBMS_DCAT.CREATE_SYNC_JOB`. Synchronization does the following: • Creates external tables in Autonomous Database that are derived from the connected AWS Glue Data Catalog. • Allows users to preview metadata for AWS Glue databases and tables. • Modifies or drops existing synchronized external tables if AWS Glue metadata has changed. **More information**: See RUN_SYNC Procedure, CREATE_SYNC_JOB Procedure, DROP_SYNC_JOB Procedure, Synchronization Mapping
Monitor Synchronization	Database Data Catalog Administrator	The user can view the sync status by querying the `USER_LOAD_OPERATIONS` view. After the sync process has completed, the user can view a log of the sync results, including details about the mappings to external tables. **More information**: Monitoring and Troubleshooting Loads
Grant privileges	Database Data Catalog Query Administrator, Database Administrator	The database Data Catalog Query Administrator or Database Administrator must grant READ privileges on generated external tables to data analyst users. This allows the data analysts to query the generated external tables.
Query	Data Analyst	Data analysts are able to review the synced schemas and tables in the GLUE$* schemas and query the external tables through any tool or application that supports Oracle SQL. Data in S3 is accessed using the privileges of the AWS S3 object storage user. **More information**: Example: Query with AWS Glue Data Catalog
Terminate connections	Database Data Catalog Administrator	To remove an existing Data Catalog association, the user calls the `UNSET_DATA_CATALOG_CONN` procedure. This action is only done when you no longer plan on using the connected AWS Glue Data Catalog and the external tables that are derived from the catalog. This action deletes AWS Glue Data Catalog metadata, and drops synced external tables from the Autonomous Database instance. **More information**: UNSET_DATA_CATALOG_CONN Procedure

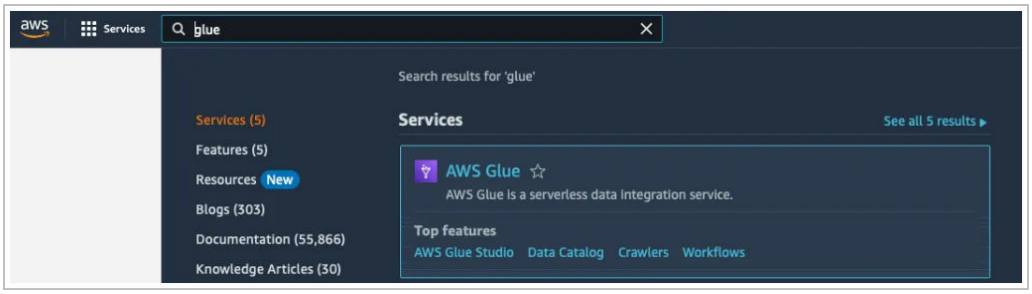
Example: Query with AWS Glue Data Catalog

This example steps you through the process of running queries over datasets stored in Amazon Simple Storage Service (Amazon S3) using an AWS Glue Data Catalog.

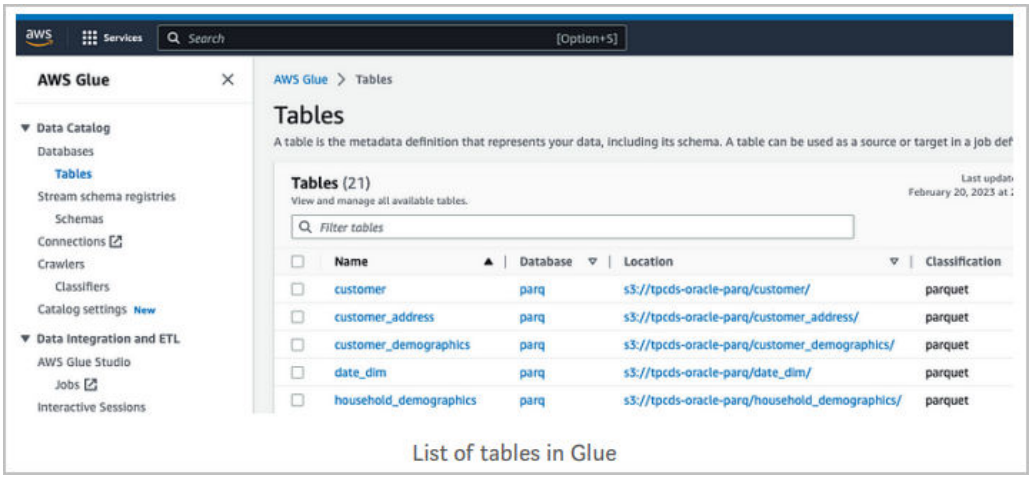
In this example, metadata in an AWS Glue Data Catalog is inspected to see what Amazon S3 objects have been previously crawled and exist in the data catalog. Autonomous Database is then associated with the AWS Glue Data Catalog and Amazon S3. The data catalog is synchronized with Autonomous Database to create external tables over the datasets stored in Amazon S3. The external tables are used to query the datasets in Amazon S3.

1. Inspect metadata in AWS Glue Data Catalog.

a. Launch the AWS Glue console.



b. Navigate to the data catalog, databases and tables to find existing objects.
In this example, some objects exist in Amazon S3 that AWS Glue has previously crawled and created tables for as shown below:



List of tables in Glue

2. Associate AWS Glue with Autonomous Database.

a. Create credentials in Autonomous Database.
The following procedure call includes the access ID and secret key to provide Autonomous Database with access to the underlying data in Amazon S3.

```
exec dbms_cloud.create_credential('CRED_AWS','<access id>', '<access
key>');
```

b. Associate the credentials with the AWS Glue Data Catalog and Amazon S3 object storage.
These procedure calls associate the data catalog and object storage, respectively, with the credentials.

```
exec dbms_dcat.set_data_catalog_credential('CRED_AWS');
exec dbms_dcat.set_object_store_credential('CRED_AWS');
```

c. Set up an AWS region where Glue is running.

```
exec dbms_dcat.set_data_catalog_conn(region => 'us-west-2',
catalog_type=>'AWS_GLUE');
```

3. Synchronize metadata to create external tables in Autonomous Database derived from AWS Glue databases and tables.

a. Now that the association is done, use the `all_glue_databases` view to find what databases are inside an AWS Glue Data Catalog.

```
select * from all_glue_databases order by name;
```

b. Use the `all_glue_tables` view to get a list of tables available for sync.

```
select * from all_glue_tables order by database_name, name;
```

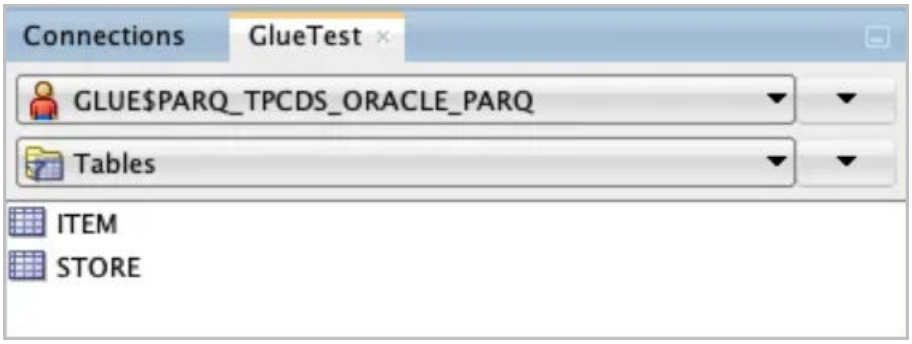
CATALO...	DATA...	NAME	TABLE_TYPE	CLASSIFICATION	DESCRIPTION	OWNER	CREATED_BY
221152...	parq	customer	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	customer_address	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	customer_demographics	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	date_dim	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	household_demographics	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	income_band	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	inventory	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	item	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	promotion	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	reason	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	ship_mode	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	store	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	store_returns	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	store_sales	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	test_glue	EXTERNAL_TABLE	(null)	(null)	221152299178	arn:aws:iam::22115...
221152...	parq	time_dim	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...
221152...	parq	warehouse	EXTERNAL_TABLE	parquet	(null)	owner	arn:aws:sts::22115...

c. Synchronize Autonomous Database with two tables, `store` and `item`, found in the `parq` database.

```
begin
dbms_dcat.run_sync(
    synced_objects => '
        {
            "database_list": [
                {
                "database": "parq",
                "table_list": ["store","item"]
                }
             ]
         }',
error_semantics => 'STOP_ON_ERROR');
end;
/
```

4. Inspect new objects in Autonomous Database and run a query on top of S3.

a. Use SQL Developer to view new objects created by the previous sync operation. The `GLUE$PARQ_TPCDS_ORACLE_PARQ` schema was generated and named automatically by the `dbms_dcat.run_sync` procedure call.



b. Run a SQL query over datasets stores in Amazon S3.

```
SELECT * FROM glue$parq_tpcds_oracle_parq.store;
```

Query Apache Iceberg Tables

Autonomous Database supports querying Apache Iceberg tables.

- About Querying Apache Iceberg Tables
  Autonomous Database supports querying of Apache Iceberg tables stored in Amazon Web Services (AWS) or in Oracle Cloud Infrastructure (OCI) Object Storage.
- Concepts Related to Querying Apache Iceberg Tables
  An understanding of the following concepts is helpful for querying Apache Iceberg tables.
- Examples: Querying Apache Iceberg Tables
  These examples show how to query Apache Iceberg tables on Amazon Web Services (AWS) and Oracle Cloud Infrastructure (OCI), using a data catalog and using direct URLs for the root manifest file.

About Querying Apache Iceberg Tables

Autonomous Database supports querying of Apache Iceberg tables stored in Amazon Web Services (AWS) or in Oracle Cloud Infrastructure (OCI) Object Storage.

Supported Configurations

These specific configurations are supported:

- Iceberg tables on AWS:
  - Iceberg tables registered with AWS Glue Data Catalog, created with Spark or Athena. For more information see Use the AWS Glue connector to read and write Apache Iceberg tables with ACID transactions and perform time travel and Using Iceberg tables.
  - Iceberg tables stored on AWS S3 by directly providing the URL for the root metadata file.
- Iceberg tables on OCI:
  - Iceberg tables generated with OCI Data Flow using a Hadoop Catalog.
    For more information, see Oracle Data Flow Examples and Using a Hadoop Catalog.
  - Iceberg tables stored on OCI Object Storage by directly providing the URL for the root metadata file.

Restrictions

- Partitioned Iceberg tables
  Oracle does not support Iceberg partitioned tables.
- Row-level updates of Iceberg tables
  Oracle does not support merge-on-read for Iceberg table updates. Queries encountering deleted files in the Iceberg metadata will fail. For more information about merge-on-read, see Enum RowLevelOperationMode.
- Schema evolution
  The schema for Oracle external tables is fixed and reflects the Iceberg schema version at external table creation time. Queries fail if the Iceberg metadata points to a different schema version compared to the one used to create the Iceberg table. If the Iceberg schema changes after the external table has been created, it is recommended that the external table be recreated.

Concepts Related to Querying Apache Iceberg Tables

An understanding of the following concepts is helpful for querying Apache Iceberg tables.

Iceberg Catalog

The Iceberg catalog is a service that manages table metadata, such table snapshots, the table schema and partitioning information. In order to query the latest snapshot for an Iceberg table, query engines must first access the catalog and obtain the location of the most recent metadata file. There are already a number of available catalog implementations, including AWS Glue, Hive, Nessie, and Hadoop. Autonomous Database supports the AWS Glue catalog and the HadoopCatalog implementation used by Spark.

For more information, see Optimistic Concurrency.

Metadata Files

The metadata file is a JSON document that keeps track of the table snapshots, partitioning scheme and schema information. The metadata file is the entry point to a hierarchy of manifest lists and manifest files. The manifests track the table's data files along with information including partitioning and column statistics. See the Iceberg Table Specification, for more information.

Transactions

Iceberg supports row-level updates to tables using either copy-on-write or merge-on-read. Copy-on-write generates new data files that reflect the updated rows, while merge-on-read generates new "delete files" that must be merged with the data files during reading. Oracle supports copy-on-write. Queries on iceberg tables fail if they encounter a delete file. For more information, see RowLevelOperationMode.

Schema Evolution

Iceberg supports schema evolution. Schema changes are reflected in the Iceberg metadata using a schema ID. Note that Oracle external tables have a fixed schema, determined by the most current schema version at table creation time. Iceberg queries fail when the queried metadata points to a different schema version compared to the one used at table creation time. For more information, see Schema Evolution.

Partitioning

Iceberg supports advanced partitioning options such as hidden partitioning and partition evolution that rely on processing/altering the table's metadata without costly data layout changes.

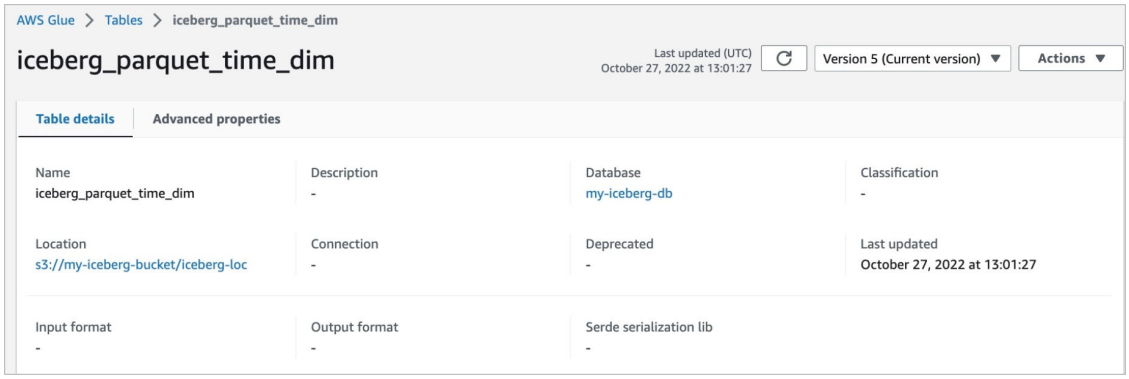
Examples: Querying Apache Iceberg Tables

These examples show how to query Apache Iceberg tables on Amazon Web Services (AWS) and Oracle Cloud Infrastructure (OCI), using a data catalog and using direct URLs for the root manifest file.

For detailed information on creating external tables for Apache Iceberg, see CREATE_EXTERNAL_TABLE Procedure for Apache Iceberg.

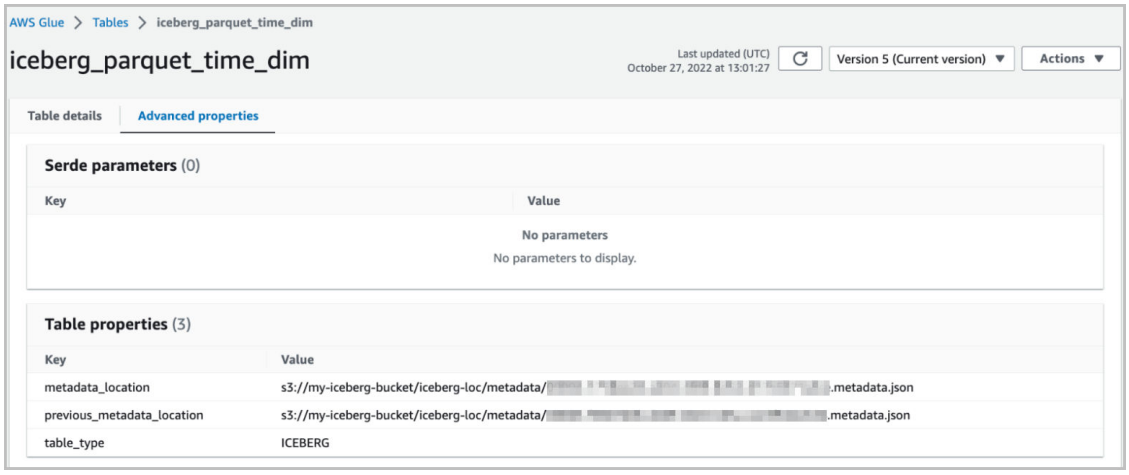
Query an Iceberg table on AWS using a Glue Data Catalog

In this example, we query the Iceberg table `iceberg_parquet_time_dim`.



The table belongs to Glue database `my-iceberg-db` and is stored in folder `s3://my-iceberg-bucket/iceberg-loc`.

The table details for `iceberg_parquet_time_dim` are shown here:



We can create an external table for `iceberg_parquet_time_dim` as follows:

```
BEGIN
DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
    table_name       => 'iceberg_parquet_time_dim',
    credential_name  => 'AWS_CRED',
```

```
    file_uri_list    => '',
    format           =>
      '{"access_protocol":
        {
         "protocol_type": "iceberg",
         "protocol_config":
          {
           "iceberg_catalog_type": "aws_glue",
           "iceberg_glue_region": "us-west-1",
           "iceberg_table_path": "my-iceberg-db.iceberg_parquet_time_dim"
          }
        }
      }'
  );
END;
/
```

In the protocol_config section we specify that the table uses AWS Glue as the catalog type, and set the catalog's region to `us-west-1`.

The credential `AWS_CRED` is created using `dbms_cloud.create_credential` with an AWS API key. The Glue Data Catalog instance is determined by the account ID associated with `AWS_CRED` for region `us-west-1`, as there is a single Glue Data Catalog region for each account. The `iceberg_table_path` element in the `protocol_config` section uses a `$database_name.$table_name` path to specify the Glue table name and database name. Finally, the `column_list` and `field_list` parameters are left null because the table's schema is automatically derived from the Iceberg metadata.

For further information on creating the credential, see CREATE_CREDENTIAL Procedure. For information on AWS Glue resources, see Specifying AWS Glue resource ARNs.

Query an Iceberg table on AWS using the location of the root metadata file

If we know the location of the metadata file for an Iceberg table, we can create an external table without specifying a catalog, as follows:

```
BEGIN
DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
    table_name       => 'iceberg_parquet_time_dim',
    credential_name  => 'AWS_CRED',
    file_uri_list    => 'https://my-iceberg-bucket.s3.us-west-1.amazonaws.com/
iceberg-loc/metadata/00004-1758ee2d-a204-4fd9-8d52-
d17e5371a5ce.metadata.json',
    format           =>'{"access_protocol":{"protocol_type":"iceberg"}}');
END;
/
```

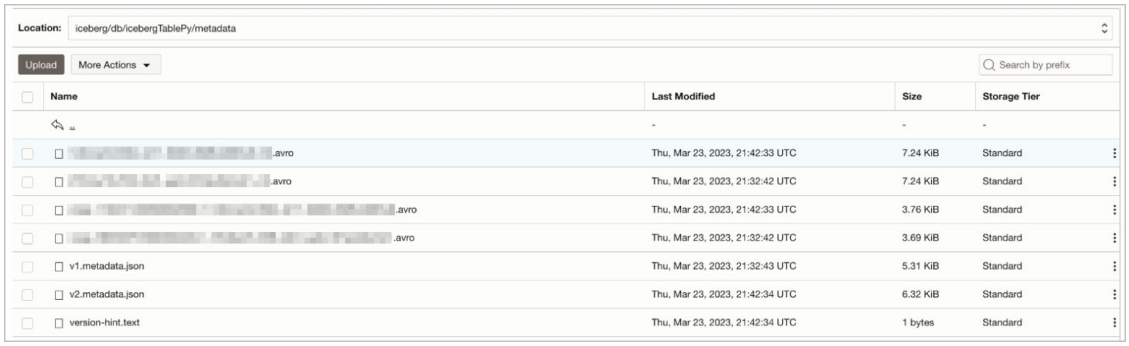
We use the `file_uri_list` parameter to specify the location of the metadata file in AWS S3 virtual-hosted-style URL format. For information on this format, see Methods for accessing an AWS S3 bucket.

In this example, the database accesses the metadata file directly, so there is no need to provide a `protocol_config` section in the `format` parameter. When using the metadata file location to create an external table, the database queries the most recent snapshot referenced by the metadata file. Subsequent updates to the Iceberg table, that create new snapshots and new metadata files, will not be visible to the database.

Query an Iceberg table that uses Hadoop Catalog on OCI

In this example, we query the Iceberg table `icebergTablePy`, created using OCI Data Flow, where Spark uses the HadoopCatalog implementation for the Iceberg catalog. HadoopCatalog uses a `warehouse` directory and puts the Iceberg metadata in a `$database_name/$table_name` subfolder under this directory. It also uses a `version-hint.text` file that contains the version number for the most recent metadata file version. See Iceberg Support on OCI Data Flow for the example on Github.

The sample table `db.icebergTablePy` was created using a `warehouse` folder, named `iceberg`, in OCI bucket `my-iceberg-bucket`. The storage layout on OCI for table `icebergTablePy` is shown below:



Create an external table for table `db.icebergTablePy` as follows:

```
BEGIN
DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
    table_name       => 'iceberg_parquet_time_dim3',
    credential_name  => 'OCI_CRED',
    file_uri_list    => '',
    format           =>'{"access_protocol":{"protocol_type":"iceberg",
        "protocol_config":{"iceberg_catalog_type": "hadoop",
        "iceberg_warehouse":"https://objectstorage.uk-
cardiff-1.oraclecloud.com/n/my-tenancy/b/my-iceberg-bucket/o/iceberg",
        "iceberg_table_path": "db.icebergTablePy"}}}');
END;
/
```

Query an Iceberg table on OCI using the location of the root metadata file

We can query the Iceberg table described in the previous section by directly using the URL for the metadata file, as follows:

```
BEGIN
DBMS_CLOUD.CREATE_EXTERNAL_TABLE (
    table_name       => 'iceberg_parquet_time_dim4',
    credential_name  => 'OCI_CRED',
    file_uri_list    => 'https://objectstorage.uk-
cardiff-1.oraclecloud.com/n/my-tenancy/b/my-iceberg-bucket/o/iceberg/db/
icebergTablePy/metadata/v2.metadata.json',
    format           =>'{"access_protocol":{"protocol_type":"iceberg"}}'
    );
  END;
/
```

In this example, we use the `file_uri_list` parameter to specify the URI for the metadata file using the native OCI URI format. When using the metadata file URI, the external table always queries the latest snapshot stored in the specific file. Subsequent updates that generate new snapshots and new metadata files are not accessible to the query.

For more information on the native OCI URI format, see Cloud Object Storage URI Formats.

Validate External Data

To validate any external table, you can use the procedure `DBMS_CLOUD.VALIDATE_EXTERNAL_TABLE`.

To validate a partitioned external table, see Validate External Partitioned Data. This procedure includes a parameter that lets you specify a specific partition to validate.

To validate a hybrid partitioned table, see Validate Hybrid Partitioned Data. This procedure includes a parameter that lets you specify a specific partition to validate.

Before validating an external table you need to create the external table. To create an external table use the procedure for your table type, either `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`. For example:

```
BEGIN
  DBMS_CLOUD.VALIDATE_EXTERNAL_TABLE (
    table_name => 'CHANNELS_EXT' );
END;
/
```

This procedure scans your source files and validates them using the format options specified when you create the external table.

The validate operation, by default, scans all the rows in your source files and stops when a row is rejected. If you want to validate only a subset of the rows, use the `rowcount` parameter. When the `rowcount` parameter is set the validate operation scans rows and stops either when a row is rejected or when the specified number of rows are validated without errors.

For example, the following validate operation scans 100 rows and stops when a row is rejected or when 100 rows are validated without errors:

```
BEGIN
  DBMS_CLOUD.VALIDATE_EXTERNAL_TABLE (
     table_name => 'CHANNELS_EXT',
     rowcount => 100 );
END;
/
```

If you do not want the validate to stop when a row is rejected and you want to see all rejected rows, set the `stop_on_error` parameter to `FALSE`. In this case `VALIDATE_EXTERNAL_TABLE` scans all rows and reports all rejected rows.

If you want to validate only a subset of rows use the `rowcount` parameter. When `rowcount` is set and `stop_on_error` is set to `FALSE`, the validate operation scans rows and stops either when the specified number of rows are rejected or when the specified number of rows are

validated without errors. For example, the following example scans 100 rows and stops when 100 rows are rejected or when 100 rows are validated without errors:

```
BEGIN
  DBMS_CLOUD.VALIDATE_EXTERNAL_TABLE (
     table_name => 'CHANNELS_EXT',
     rowcount => 100
     stop_on_error => FALSE );
END;
/
```

See VALIDATE_EXTERNAL_TABLE Procedure for detailed information about `DBMS_CLOUD.VALIDATE_EXTERNAL_TABLE` parameters.

See View Logs for Data Validation to see the results of validate operations in the tables `dba_load_operations` and `user_load_operations`.

Validate External Partitioned Data

To validate an external partitioned table, you can use the procedure `DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE`. This procedure includes a parameter that lets you specify a specific partition to validate.

Before validating an external partitioned table you need to create the external partitioned table. To create an external partitioned table use the procedure `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` (see Query External Partitioned Data (with Partitioning Clause) for more details):

```
BEGIN
  DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE (
    table_name => 'PET1',
    partition_name => 'P1');
END;
/
```

This procedure scans your source files for partition P1 and validates them using the format options specified when you create the external partitioned table.

The validation of a partitioned table by default validates all the partitions sequentially until `rowcount` is reached. If you specify a `partition_name` then only a specific partition is validated.

The validate operation, by default, scans all the rows in your source files and stops when a row is rejected. If you want to validate only a subset of the rows, use the `rowcount` parameter. When the `rowcount` parameter is set the validate operation scans rows and stops either when a row is rejected or when the specified `rowcount` number of rows are validated without errors.

For example, the following validate operation scans 100 rows and stops when a row is rejected or when 100 rows are validated without errors:

```
BEGIN
  DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE (
     table_name => 'PET1',
     rowcount => 100 );
END;
/
```

If you do not want the validate to stop when a row is rejected and you want to see all rejected rows, set the `stop_on_error` parameter to `FALSE`. In this case `DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE` scans all rows and reports all rejected rows.

If you want to validate only a subset of rows use the `rowcount` parameter. When `rowcount` is set and `stop_on_error` is set to `FALSE`, the validate operation scans rows and stops either when the specified number of rows are rejected or when the specified number of rows are validated without errors. For example, the following example scans 100 rows and stops when 100 rows are rejected or when 100 rows are validated without errors:

```
BEGIN
  DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE (
     table_name => 'PET1',
     rowcount => 100
     stop_on_error => FALSE );
END;
/
```

See VALIDATE_EXTERNAL_PART_TABLE Procedure for more information on `DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE`.

See View Logs for Data Validation to see the results of validate operations in the tables `dba_load_operations` and `user_load_operations`.

Validate Hybrid Partitioned Data

To validate a hybrid partitioned table, you can use the procedure `DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE`. This procedure includes a parameter that lets you specify a specific partition to validate.

Before validating a hybrid partitioned table you need to create the table. To create a hybrid partitioned table use the procedure `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE` (see Query Hybrid Partitioned Data for more details):

```
BEGIN
 DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE(
    table_name => 'HPT1',
    partition_name => 'P1');
END;
/
```

This procedure scans your source files for partition P1 and validates them using the format options specified when you create the hybrid partitioned table.

The validation of a hybrid partitioned table by default validates all the external partitions sequentially until `rowcount` is reached. If you specify a `partition_name` then only that specific partition is validated.

The validate operation, by default, scans all the rows in your source files and stops when a row is rejected. If you want to validate only a subset of the rows, use the `rowcount` parameter. When the `rowcount` parameter is set the validate operation scans rows and stops either when a row is rejected or when the specified `rowcount` number of rows are validated without errors.

For example, the following validate operation scans 100 rows and stops when a row is rejected or when 100 rows are validated without errors:

```
BEGIN
  DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE (
     table_name => 'HPT1',
     rowcount=>100 );
END;
/
```

If you do not want the validate to stop when a row is rejected and you want to see all rejected rows, set the `stop_on_error` parameter to `FALSE`. In this case `DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE` scans all rows and reports all rejected rows.

If you want to validate only a subset of rows use the `rowcount` parameter. When `rowcount` is set and `stop_on_error` is set to `FALSE`, the validate operation scans rows and stops either when the specified number of rows are rejected or when the specified number of rows are validated without errors. For example, the following example scans 100 rows and stops when 100 rows are rejected or when 100 rows are validated without errors:

```
BEGIN
  DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE (
     table_name => 'HPT1',
     rowcount => 100
     stop_on_error => FALSE );
END;
/
```

For detailed information about `DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE` parameters see VALIDATE_HYBRID_PART_TABLE Procedure.

See View Logs for Data Validation to see the results of validate operations in the tables `dba_load_operations` and `user_load_operations`.

View Logs for Data Validation

To validate an external table, use the procedures `DBMS_CLOUD.VALIDATE_EXTERNAL_TABLE`, `DBMS_CLOUD.VALIDATE_EXTERNAL_PART_TABLE`, and `DBMS_CLOUD.VALIDATE_HYBRID_PART_TABLE`.

After you validate your source files you can see the result of the validate operation by querying a load operations table:

- `dba_load_operations`: shows all validate operations.
- `user_load_operations`: shows the validate operations in your schema.

You can use these files to view load validation information. For example use this select operation to query `user_load_operations`:

```
SELECT table_name, owner_name, type, status, start_time, update_time, logfile_table,
badfile_table
FROM user_load_operations
WHERE type = 'VALIDATE';

TABLE_NAME    OWNER_NAME  TYPE       STATUS     START_TIME     UPDATE_TIME
LOGFILE_TABLE    BADFILE_TABLE
```

```
------------ ----------  ---------- ---------- -------------- -------------
---------------  ---------------
CHANNELS_EXT  SH          VALIDATE   COMPLETED  13-NOV-17...   13-NOV-17...
VALIDATE$21_LOG  VALIDATE$21_BAD
```

Using this SQL statement with the `WHERE` clause on the `TYPE` column displays all of the load operations with type `VALIDATE`.

The `LOGFILE_TABLE` column shows the name of the table you can query to look at the log of a validate operation. For example, the following query shows the log for this validate operation:

```
SELECT * FROM VALIDATE$21_LOG;
```

The column `BADFILE_TABLE` shows the name of the table you can query to look at the rows where there were errors during validation. For example, the following query shows the rejected records for the above validate operation:

```
SELECT * FROM VALIDATE$21_BAD;
```

Depending on the errors shown in the log and the rows shown in the `BADFILE_TABLE`, you can correct the error by dropping the external table using the `DROP TABLE` command and recreating it by specifying the correct format options in `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`, `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE` or `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE`.

> **Note:**
>
> The `LOGFILE_TABLE` and `BADFILE_TABLE` tables are stored for two days for each validate operation and then removed automatically.

Use Database Links with Autonomous Database

You can create database links from an Autonomous Database to another Autonomous Database, to other Oracle databases, or to non-Oracle databases. In addition, you can create database links from other databases to an Autonomous Database.

- Create Database Links from Autonomous Database to Another Autonomous Database
  You can create database links from Autonomous Database to another Autonomous Database that is on a private endpoint or on a public endpoint (publicly accessible).
- Create Database Links to an Oracle Database that is not an Autonomous Database
  You can create database links from an Autonomous Database to an Oracle database that is on a private endpoint or on a public endpoint (publicly accessible).
- Create Database Links to Non-Oracle Databases
  You can create database links from Autonomous Database to Non-Oracle databases.
- Create Database Links from Other Databases to Autonomous Database
  You can create database links to an Autonomous Database from an Oracle database that is not an Autonomous Database. For example from an on-premise Oracle database to an Autonomous Database
- Drop Database Links
  After you create a database link you can drop the database link.

Create Database Links from Autonomous Database to Another Autonomous Database

You can create database links from Autonomous Database to another Autonomous Database that is on a private endpoint or on a public endpoint (publicly accessible).

> **Note:**
>
> See Create Database Links to an Oracle Database that is not an Autonomous Database if the target for your database link is an Oracle Database that is not an Autonomous Database.

- Create Database Links from Autonomous Database to a Publicly Accessible Autonomous Database
  You can create database links from an Autonomous Database to a target Autonomous Database that is on a public endpoint.
- Create Database Links from Autonomous Database to an Autonomous Database on a Private Endpoint
  You can create database links from an Autonomous Database to a target Autonomous Database that is on a private endpoint.
- Database Link Notes with a Target that is an Autonomous Database
  Provides notes for creating database links to a target that is another Autonomous Database.

Create Database Links from Autonomous Database to a Publicly Accessible Autonomous Database

You can create database links from an Autonomous Database to a target Autonomous Database that is on a public endpoint.

See How to Create a Database Link from Your Autonomous Database to a Database Cloud Service Instance for more information.

- Create Database Links from Autonomous Database to a Publicly Accessible Autonomous Database without a Wallet (TLS)
  You can create database links from an Autonomous Database to a publicly accessible Autonomous Database without a wallet (TLS).
- Create Database Links from Autonomous Database to a Publicly Accessible Autonomous Database with a Wallet (mTLS)
  You can to create database links from an Autonomous Database to a publicly accessible Autonomous Database with a wallet (mTLS).

Create Database Links from Autonomous Database to a Publicly Accessible Autonomous Database without a Wallet (TLS)

You can create database links from an Autonomous Database to a publicly accessible Autonomous Database without a wallet (TLS).

To create database links to a public target, the target database must be accessible. Some databases, including Autonomous Databases, may limit access (for example, using Access Control Lists). Make sure you enable your target database to allow access from your source

database for the database link to work. If you limit access with Access Control Lists (ACLs), you can find the outbound IP address of your source Autonomous Database and allow that IP address to connect to your target database. When the target database is another Autonomous Database, you can add the outbound IP address of the source database to the ACL of the target database.

See Obtain Tenancy Details for information on finding the outbound IP address.

To create a database link to a target Autonomous Database without a wallet (TLS):

1. If you have not already done so, enable TLS connections on your Autonomous Database instance.

   See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for details.

2. On the Autonomous Database instance where you are creating the database link, create credentials to access the target Autonomous Database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database (you use these credentials to create the database link).

   > **Note:**
   >
   > Supplying the `credential_name` parameter is required.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
           credential_name => 'DB_LINK_CRED',
           username => 'NICK',
           password => 'password' );
   END;
   /
   ```

   The characters in the `username` parameter must be all uppercase letters.

   > **Note:**
   >
   > You can use a vault secret credential for the target database credential in a database link. See Use Vault Secret Credentials for more information.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

3. Create a database link to the target Autonomous Database instance using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example:

   ```
   BEGIN
       DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
           db_link_name => 'SALESLINK',
           hostname => 'adb.eu-frankfurt-1.oraclecloud.com',
   ```

```
        port => '1521',
        service_name => 'example_medium.adb.example.oraclecloud.com',
        credential_name => 'DB_LINK_CRED',
        directory_name => NULL);
END;
/
```

To create a database link with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` to a target Autonomous Database on a public endpoint using a secure TCP connection without a wallet, the `directory_name` parameter must be `NULL`.

The `ssl_server_cert_dn` parameter can either be omitted or if included, specify a `NULL` value.

Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

4. Use the database link you created to access data on the target database.

   For example:

   ```
   SELECT * FROM employees@SALESLINK;
   ```

For the credentials you create in Step 1, the target database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:

```
BEGIN
    DBMS_CLOUD.UPDATE_CREDENTIAL (
          credential_name => 'DB_LINK_CRED',
          attribute => 'PASSWORD',
          value => 'password' );
END;
/
```

Where *password* is the new password.

After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

> **Note:**
>
> You can create links to Big Data Service using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`. See Query Big Data Service Hadoop (HDFS) Data from Autonomous Database for more information.

For additional information, see:

- CREATE_DATABASE_LINK Procedure
- UPDATE_CREDENTIAL Procedure

Create Database Links from Autonomous Database to a Publicly Accessible Autonomous Database with a Wallet (mTLS)

You can to create database links from an Autonomous Database to a publicly accessible Autonomous Database with a wallet (mTLS).

To create database links to a public target, the target database must be accessible. Some databases, including Autonomous Databases, may limit access (for example, using Access Control Lists). Make sure you enable your target database to allow access from your source database for the database link to work. If you limit access with Access Control Lists (ACLs), you can find the outbound IP address of your source Autonomous Database and allow that IP address to connect to your target database. For example, if the target database is another Autonomous Database, you can add the outbound IP address of the source database to the ACL of the target database.

See Obtain Tenancy Details for information on finding the outbound IP address.

To create database links to a target Autonomous Database with a wallet (mTLS):

1. Copy your target database wallet, `cwallet.sso`, containing the certificates for the target database to Object Store.

   Note the following for the wallet file:

   - The wallet file, along with the Database user ID and password provide access to data in the target Oracle Database. Store wallet files in a secure location. Share wallet files only with authorized users.
   - Do not rename the wallet file. The wallet file in Object Storage must be named `cwallet.sso`.

2. Create credentials to access your Object Store where you store the wallet file `cwallet.sso`. See CREATE_CREDENTIAL Procedure for information about the username and password parameters for different object storage services.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Create a directory on Autonomous Database for the wallet file `cwallet.sso`.

   For example:

   ```
   CREATE DIRECTORY dblink_wallet_dir AS 'directory_path_of_your_choice';
   ```

   See Create Directory in Autonomous Database for information on creating directories.

4. Use `DBMS_CLOUD.GET_OBJECT` to upload the target database wallet to the directory you created in the previous step, *DBLINK_WALLET_DIR*.

   For example:

   ```
   BEGIN
       DBMS_CLOUD.GET_OBJECT(
           credential_name => 'DEF_CRED_NAME',
           object_uri => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
           directory_name => 'DBLINK_WALLET_DIR');
   ```

```
END;
/
```

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

> **Note:**
>
> The `credential_name` you use in this step is the credentials for the Object Store. In the next step you create the credentials to access the target database.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

5. On the Autonomous Database instance, create credentials to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database that you use to create the database link.

> **Note:**
>
> Supplying the `credential_name` parameter is required.

For example:

```
BEGIN
    DBMS_CLOUD.CREATE_CREDENTIAL(
        credential_name => 'DB_LINK_CRED',
        username => 'NICK',
        password => 'password');
END;
/
```

The characters in the `username` parameter must be all uppercase letters.

> **Note:**
>
> You can use a vault secret credential for the target database credential in a database link. See Use Vault Secret Credentials for more information.

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

6. Create the database link to the target database using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

For example:

```
BEGIN
    DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
        db_link_name => 'SALESLINK',
        hostname => 'adb.eu-frankfurt-1.oraclecloud.com',
        port => '1522',
        service_name => 'example_medium.adb.example.oraclecloud.com',
        ssl_server_cert_dn => 'CN=adb.example.oraclecloud.com,OU=Oracle
BMCS FRANKFURT,O=Oracle Corporation,L=Redwood City,ST=California,C=US',
        credential_name => 'DB_LINK_CRED',
        directory_name => 'DBLINK_WALLET_DIR');
END;
/
```

Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

If the wallet file in the directory specified with `directory_name` is not `cwallet.sso`, the procedure reports an error such as: `ORA-28759: failure to open file`.

7. Use the database link you created to access data on the target database.

   For example:

   ```
   SELECT * FROM employees@SALESLINK;
   ```

For the credentials you create in Step 5, the target database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:

```
BEGIN
    DBMS_CLOUD.UPDATE_CREDENTIAL (
        credential_name => 'DB_LINK_CRED',
        attribute => 'PASSWORD',
        value => 'password' );
END;
/
```

Where *password* is the new password.

After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

> **Note:**
>
> You can create links to Big Data Service using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`. See Query Big Data Service Hadoop (HDFS) Data from Autonomous Database for more information.

For additional information, see:

- CREATE_DATABASE_LINK Procedure

- GET_OBJECT Procedure and Function
- UPDATE_CREDENTIAL Procedure

Create Database Links from Autonomous Database to an Autonomous Database on a Private Endpoint

You can create database links from an Autonomous Database to a target Autonomous Database that is on a private endpoint.

Depending on configuration of the target Autonomous Database, you have these options:

- Create Database Links to a Target Autonomous Database on a Private Endpoint without a Wallet (TLS)
- Create Database Links to a Target Autonomous Database on a Private Endpoint with a Wallet (mTLS)

See How to Create a Database Link from Your Autonomous Database to a Database Cloud Service Instance for more information.

Topics

- Prerequisites for Database Links from Autonomous Database to a Target Autonomous Database on a Private Endpoint
  Lists the prerequisites to create database links to a target Autonomous Database that is on a private endpoint.
- Create Database Links to a Target Autonomous Database on a Private Endpoint without a Wallet (TLS)
  You can create database links from an Autonomous Database to a target Autonomous Database that is on a private endpoint and connect without a wallet (TLS).
- Create Database Links to a Target Autonomous Database on a Private Endpoint with a Wallet (mTLS)
  You can create database links from an Autonomous Database to a target Autonomous Database that is on a private endpoint (mTLS).

Prerequisites for Database Links from Autonomous Database to a Target Autonomous Database on a Private Endpoint

Lists the prerequisites to create database links to a target Autonomous Database that is on a private endpoint.

To create a database link to a target Autonomous Database on a private endpoint:

- The target database must be accessible from the source database's Oracle Cloud Infrastructure VCN. For example, you can connect to the target database when:
  - The target database is on a private endpoint.
  - Both the source database and the target database are in the same Oracle Cloud Infrastructure VCN.
  - The source database and the target database are in different Oracle Cloud Infrastructure VCNs that are paired.
  - The target database is connected to the source database's Oracle Cloud Infrastructure VCN using FastConnect or VPN.

- For a target on a private endpoint, `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` supports specifying a single hostname with the `hostname` parameter. On a private endpoint, using an IP address, SCAN IP, or a SCAN hostname is not supported (when the target is on a public endpoint, `CREATE_DATABASE_LINK` supports using an IP address, a SCAN IP, or a SCAN hostname).
- `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` does not support a value of `localhost` for the `hostname` parameter.
- The following ingress and egress rules must be defined for the private endpoint:
  - Define an egress rule in the source database's subnet security list or network security group such that the traffic over TCP is allowed to the target database's IP address and port number.
  - Define an ingress rule in the target database's subnet security list or network security group such that the traffic over TCP is allowed from the source database IP address to the destination port.

  See Configure Network Access with Private Endpoints for information on configuring private endpoints with ingress and egress rules.

> **Note:**
>
> When your Autonomous Database instance is configured with a private endpoint, set the `ROUTE_OUTBOUND_CONNECTIONS` database property to '`PRIVATE_ENDPOINT`' to specify that all outgoing database links are subject to the Autonomous Database instance private endpoint VCN's egress rules. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

Create Database Links to a Target Autonomous Database on a Private Endpoint without a Wallet (TLS)

You can create database links from an Autonomous Database to a target Autonomous Database that is on a private endpoint and connect without a wallet (TLS).

Perform the prerequisite steps, as required. See Prerequisites for Database Links from Autonomous Database to a Target Autonomous Database on a Private Endpoint for details.

To create a database link to a target Autonomous Database on a private endpoint without a wallet:

1. If you have not already done so, enable TLS connections on your Autonomous Database instance.

   See Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication for details.

2. Create credentials to access the target Autonomous Database instance. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database used within the database link, (where the target database is accessed through the VCN).

   For example:

```
BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
         credential_name => 'PRIVATE_ENDPOINT_CRED',
```

```
        username => 'NICK',
        password => 'password'
        );
END;
/
```

The characters in the `username` parameter must be all uppercase letters.

> **Note:**
>
> You can use a vault secret credential for the target database credential in a database link. See Use Vault Secret Credentials for more information.

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

3. Create the database link to the target database using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example:

```
BEGIN
     DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
         db_link_name => 'PRIVATE_ENDPOINT_LINK',
         hostname => 'exampleHostname',
         port => '1521',
         service_name => 'example_high.adb.oraclecloud.com',
         credential_name => 'PRIVATE_ENDPOINT_CRED',
         directory_name => NULL,
         private_target => TRUE);
END;
/
```

   For a target on a private endpoint, `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` supports specifying a single hostname with the `hostname` parameter. On a private endpoint, using an IP address, SCAN IP, or a SCAN hostname is not supported (when the target is on a public endpoint, `CREATE_DATABASE_LINK` supports using an IP address, a SCAN IP, or a SCAN hostname).

   Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   As shown in the example, to create a database link with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` to a target database on a private endpoint without a wallet, all of the following are required:

   - The `directory_name` parameter must be `NULL`.
   - The `ssl_server_cert_dn` parameter can either be omitted or if included, specify a `NULL` value.
   - The `private_target` parameter must be `TRUE`.

> **Note:**
>
> If you set `ROUTE_OUTBOUND_CONNECTIONS` to `PRIVATE_ENDPOINT`, setting the `private_target` parameter to `TRUE` is not required in this API. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

4. Use the database link you created to access data in the target database.

   For example:

```
SELECT * FROM employees@PRIVATE_ENDPOINT_LINK;
```

> **Note:**
>
> For the credentials you create in Step 1, the Oracle Database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:
>
> ```
> BEGIN
>      DBMS_CLOUD.UPDATE_CREDENTIAL (
>          credential_name => 'DB_LINK_CRED',
>          attribute => 'PASSWORD',
>          value => 'password');
> END;
> /
> ```
>
> Where *password* is the new password.
>
> After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

See CREATE_DATABASE_LINK Procedure for additional information.

Create Database Links to a Target Autonomous Database on a Private Endpoint with a Wallet (mTLS)

You can create database links from an Autonomous Database to a target Autonomous Database that is on a private endpoint (mTLS).

Perform the prerequisite steps, as required. See Prerequisites for Database Links from Autonomous Database to a Target Autonomous Database on a Private Endpoint for details.

To create a database link to a target Autonomous Database on a private endpoint, with a wallet:

1. Copy your target database wallet, `cwallet.sso`, containing the certificates for the target database to Object Store.

> **Note:**
>
> The wallet file, along with the Database user ID and password provide access to data in the target Oracle database. Store wallet files in a secure location. Share wallet files only with authorized users.

2. Create credentials to access your Object Store where you store the `cwallet.sso`. See CREATE_CREDENTIAL Procedure for information about the username and password parameters for different object storage services.
3. Create a directory on Autonomous Database for the wallet file `cwallet.sso`.

   For example:

   ```
   CREATE DIRECTORY wallet_dir AS 'directory_path_of_your_choice';
   ```

   See Create Directory in Autonomous Database for information on creating directories.
4. Use `DBMS_CLOUD.GET_OBJECT` to upload the target database wallet to the directory you created in the previous step, *WALLET_DIR*.

   For example:

   ```
   BEGIN
       DBMS_CLOUD.GET_OBJECT(
           credential_name => 'DEF_CRED_NAME',
           object_uri => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
           directory_name => 'WALLET_DIR');
   END;
   /
   ```

   In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

   > **Note:**
   >
   > The `credential_name` you use in this step is the credentials for the Object Store. In the next step you create the credentials to access the target database.

5. On Autonomous Database create credentials to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database used within the database link, (where the target database is accessed through the VCN).

   > **Note:**
   >
   > Supplying the `credential_name` parameter is required.

For example:

```
BEGIN
    DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DB_LINK_CRED',
       username => 'NICK',
       password => 'password');
END;
/
```

The characters in the `username` parameter must be all uppercase letters.

> **Note:**
>
> You can use a vault secret credential for the target database credential in a database link. See Use Vault Secret Credentials for more information.

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

6. Create the database link to the target database using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example:

```
BEGIN
    DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
        db_link_name => 'PEDBLINK1',
        hostname => 'example1.adb.ap-osaka-1.oraclecloud.com',
        port => '1522',
        service_name => 'example_high.adb.oraclecloud.com',
        ssl_server_cert_dn => 'ssl_server_cert_dn',
        credential_name => 'DB_LINK_CRED',
        directory_name => 'WALLET_DIR',
        private_target => TRUE);
END;
/
```

> **Note:**
>
> If you set `ROUTE_OUTBOUND_CONNECTIONS` to `PRIVATE_ENDPOINT`, setting the `private_target` parameter to `TRUE` is not required in this API. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

For a target on a private endpoint, `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` supports specifying a single hostname with the `hostname` parameter. On a private endpoint, using an IP address, SCAN IP, or a SCAN hostname is not supported (when the target is on a public endpoint, `CREATE_DATABASE_LINK` supports using an IP address, a SCAN IP, or a SCAN hostname).

`DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` does not support a value of `localhost` for the `hostname` parameter.

Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

7. Use the database link you created to access data in the target database.

   For example:

   ```
   SELECT * FROM employees@PEDBLINK1;
   ```

> **Note:**
>
> For the credentials you create in Step 5, the Oracle Database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:
>
> ```
> BEGIN
>     DBMS_CLOUD.UPDATE_CREDENTIAL (
>         credential_name => 'DB_LINK_CRED',

Database Link Notes with a Target that is an Autonomous Database

Provides notes for creating database links to a target that is another Autonomous Database.

Notes for database links to another Autonomous Database:

- Only one wallet file is valid per directory for use with database links. You can only upload one `cwallet.sso` at a time to the directory you choose for wallet files (for example *DBLINK_WALLET_DIR*). This means with a `cwallet.sso` in *DBLINK_WALLET_DIR* you can only create database links to the databases for which the wallet in that directory is valid. To use multiple `cwallet.sso` files with database links you need to create additional directories and put each `cwallet.sso` in a different directory. When you create database links with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`, specify the directory that contains the wallet with the `directory_name` parameter.

  See Create Directory in Autonomous Database for information on creating directories.
- To list the database links, use the `ALL_DB_LINKS` view. See ALL_DB_LINKS for more information.
- The wallet file, along with the Database user ID and password provide access to data in the target Autonomous Database. Store wallet files in a secure location. Share wallet files only with authorized users.

Create Database Links to an Oracle Database that is not an Autonomous Database

You can create database links from an Autonomous Database to an Oracle database that is on a private endpoint or on a public endpoint (publicly accessible).

> **Note:**
>
> See Create Database Links from Autonomous Database to Another Autonomous Database if the target for your database link is another Autonomous Database.

- Create Database Links from Autonomous Database to a Publicly Accessible Oracle Database with a Wallet (mTLS)
  You can create database links from an Autonomous Database to a target Oracle database that is on a public endpoint.
- Create Database Links from Autonomous Database to an Oracle Database on a Private Endpoint
  You can create database links from an Autonomous Database to a target Oracle Database that is on a private endpoint.
- Database Link Notes with a Target Oracle Database
  Provides notes for creating database links to a target Oracle database (when the target is not an Autonomous Database)

Create Database Links from Autonomous Database to a Publicly Accessible Oracle Database with a Wallet (mTLS)

You can create database links from an Autonomous Database to a target Oracle database that is on a public endpoint.

To use database links with Autonomous Database the target database must be configured to use TCP/IP with SSL (TCPS) authentication. Autonomous Databases use TCP/IP with SSL (TCPS) authentication by default, so you do not need to do any additional configuration in your target database to link to another Autonomous Database. Other Oracle databases must be configured to use TCP/IP with SSL (TCPS) authentication. See Configuring Secure Sockets Layer Authentication for more information.

To create database links to a public target, the target Oracle Database must be accessible. Some databases may limit access (for example, using Access Control Lists). Make sure you enable your target database to allow access from your source database for the database link to work. If you limit access with Access Control Lists (ACLs), you can find the outbound IP address of your source Autonomous Database and allow that IP address to connect to your target database.

See How to Create a Database Link from Your Autonomous Database to a Database Cloud Service Instance for more information.

To create database links to a target Oracle database with a wallet (mTLS):

1. Copy your target database wallet, `cwallet.sso`, containing the certificates for the target database to Object Store.

   Note the following for the wallet file:

- The wallet file, along with the Database user ID and password provide access to data in the target Oracle Database. Store wallet files in a secure location. Share wallet files only with authorized users.
- Do not rename the wallet file. The wallet file in Object Storage must be named `cwallet.sso`.

2. Create credentials to access your Object Store where you store the wallet file `cwallet.sso`. See CREATE_CREDENTIAL Procedure for information about the username and password parameters for different object storage services.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Create a directory on Autonomous Database for the wallet file `cwallet.sso`.

   For example:

   ```
   CREATE DIRECTORY dblink_wallet_dir AS 'directory_path_of_your_choice';
   ```

   See Create Directory in Autonomous Database for information on creating directories.

4. Use `DBMS_CLOUD.GET_OBJECT` to upload the target database wallet to the directory you created in the previous step, *DBLINK_WALLET_DIR*.

   For example:

   ```
   BEGIN
       DBMS_CLOUD.GET_OBJECT(
           credential_name => 'DEF_CRED_NAME',
           object_uri => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
           directory_name => 'DBLINK_WALLET_DIR');
   END;
   /
   ```

   In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

   > **Note:**
   >
   > The `credential_name` you use in this step is the credentials for the Object Store. In the next step you create the credentials to access the target database.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

5. On the Autonomous Database instance, create credentials to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database that you use to create the database link.

> **Note:**
>
> Supplying the `credential_name` parameter is required.

For example:

```
BEGIN
    DBMS_CLOUD.CREATE_CREDENTIAL(
        credential_name => 'DB_LINK_CRED',
        username => 'NICK',
        password => 'password');
END;
/
```

The characters in the `username` parameter must be all uppercase letters.

> **Note:**
>
> You can use a vault secret credential for the target database credential in a database link. See Use Vault Secret Credentials for more information.

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

6. Create the database link to the target database using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example:

```
BEGIN
    DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
        db_link_name => 'SALESLINK',
        hostname => 'adb.eu-frankfurt-1.oraclecloud.com',
        port => '1522',
        service_name => 'example_medium.adb.example.oraclecloud.com',
        ssl_server_cert_dn => 'CN=adb.example.oraclecloud.com,OU=Oracle
BMCS FRANKFURT,O=Oracle Corporation,L=Redwood City,ST=California,C=US',
        credential_name => 'DB_LINK_CRED',
        directory_name => 'DBLINK_WALLET_DIR');
END;
/
```

   Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   If the wallet file in the directory specified with `directory_name` is not `cwallet.sso`, the procedure reports an error such as: `ORA-28759: failure to open file`.

7. Use the database link you created to access data on the target database.

For example:

```
SELECT * FROM employees@SALESLINK;
```

For the credentials you create in Step 5, the target database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:

```
BEGIN
    DBMS_CLOUD.UPDATE_CREDENTIAL (
        credential_name => 'DB_LINK_CRED',
        attribute => 'PASSWORD',
        value => 'password' );
END;
/
```

Where *password* is the new password.

After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

> **Note:**
>
> You can create links to Big Data Service using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`. See Query Big Data Service Hadoop (HDFS) Data from Autonomous Database for more information.

For additional information, see:

- CREATE_DATABASE_LINK Procedure
- GET_OBJECT Procedure and Function
- UPDATE_CREDENTIAL Procedure

Create Database Links from Autonomous Database to an Oracle Database on a Private Endpoint

You can create database links from an Autonomous Database to a target Oracle Database that is on a private endpoint.

Depending on the type and the configuration of the target Oracle database:

- **Another Oracle Database, such as on-premises or a Database Cloud Service database, on a private endpoint that is configured for SSL (TCPS)**: In this case you can create the database link with a wallet, and the database link communicates with TCPS. See Create Database Links from Autonomous Database to Oracle Databases on a Private Endpoint with a Wallet (mTLS) for details:
- **Oracle Database, such as on-premises or a Database Cloud Service database, on a private endpoint that is configured for TCP**: In this case you create the database link without a wallet and the database link communicates with TCP. See Create Database Links to Oracle Databases on a Private Endpoint without a Wallet for details

See How to Create a Database Link from Your Autonomous Database to a Database Cloud Service Instance for more information.

Topics

- Prerequisites for Database Links from Autonomous Database to Oracle Databases on a Private Endpoint
  Lists the prerequisites to create database links from an Autonomous Database to a target Oracle database that is on a private endpoint.
- Create Database Links to Oracle Databases on a Private Endpoint without a Wallet
  Use `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` to create database links from an Autonomous Database to a target Oracle database that is on a private endpoint and connect without a wallet (TCP).
- Create Database Links from Autonomous Database to Oracle Databases on a Private Endpoint with a Wallet (mTLS)
  You can create database links from an Autonomous Database to a target Oracle database that is on a private endpoint.

Prerequisites for Database Links from Autonomous Database to Oracle Databases on a Private Endpoint

Lists the prerequisites to create database links from an Autonomous Database to a target Oracle database that is on a private endpoint.

To create a database link to a target Oracle database on a private endpoint:

- The target database must be accessible from the source database's Oracle Cloud Infrastructure VCN. For example, you can connect to the target database when:
  - The target database is on a private endpoint.
  - Both the source database and the target database are in the same Oracle Cloud Infrastructure VCN.
  - The source database and the target database are in different Oracle Cloud Infrastructure VCNs that are paired.
  - The target database is an on-premises database that is connected to the source database's Oracle Cloud Infrastructure VCN using FastConnect or VPN.
- There are two options to specify the target database, use the `hostname` parameter or the `rac_hostnames` parameter:
  - For a target on a private endpoint, `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` supports specifying a single hostname with the `hostname` parameter. On a private endpoint, using an IP address, SCAN IP, or a SCAN hostname is not supported (when the target is on a public endpoint, `CREATE_DATABASE_LINK` supports using an IP address, a SCAN IP, or a SCAN hostname).
  - When the target is an Oracle RAC database, use the `rac_hostnames` parameter to specify one or more hostnames with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`. This allows you to take advantage of the high availability capabilities of Oracle RAC. Using an IP address, a SCAN IP, or a SCAN hostname in the `rac_hostnames` value is not supported.

    When you specify a list of host names in the `rac_hostnames` parameter, `CREATE_DATABASE_LINK` uses all of the specified host names as addresses in the connect string. If one of the specified hosts is not available on the target Oracle RAC database, Autonomous Database automatically attempts to connect using another host name from the list.

- The following ingress and egress rules must be defined for the private endpoint:
  - Define an egress rule in the source database's subnet security list or network security group such that the traffic over TCP is allowed to the target database's IP address and port number.
  - Define an ingress rule in the target database's subnet security list or network security group such that the traffic over TCP is allowed from the source database IP address to the destination port.

  See Configure Network Access with Private Endpoints for information on configuring private endpoints with ingress and egress rules.

> **Note:**
>
> When your Autonomous Database instance is configured with a private endpoint, set the `ROUTE_OUTBOUND_CONNECTIONS` database parameter to '`PRIVATE_ENDPOINT`' to specify that all outgoing database links are subject to the Autonomous Database instance private endpoint VCN's egress rules. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

Create Database Links to Oracle Databases on a Private Endpoint without a Wallet

Use `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` to create database links from an Autonomous Database to a target Oracle database that is on a private endpoint and connect without a wallet (TCP).

> **Note:**
>
> This option is for target Oracle databases that are on a private endpoint and do not have SSL/TCPS configured.

Perform the prerequisite steps, as required. See Prerequisites for Database Links from Autonomous Database to a Target Autonomous Database on a Private Endpoint for details.

To create a database link to a target database on a private endpoint using a secure TCP connection without a wallet:

1. On Autonomous Database create credentials to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database used within the database link, (where the target database is accessed through the VCN).

   For example:

```
BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
         credential_name => 'PRIVATE_ENDPOINT_CRED',
         username => 'NICK',
         password => 'password'
         );
END;
/
```

The characters in the `username` parameter must be all uppercase letters.

> **Note:**
>
> You can use a vault secret credential for the target database credential in a database link. See Use Vault Secret Credentials for more information.

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

2. Create the database link to the target database using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example:

```
BEGIN
     DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
         db_link_name => 'PRIVATE_ENDPOINT_LINK',
         hostname => 'exampleHostname',
         port => '1522',
         service_name => 'exampleServiceName',
         ssl_server_cert_dn => NULL,
         credential_name => 'PRIVATE_ENDPOINT_CRED',
         directory_name => NULL,
         private_target => TRUE);
END;
/
```

   For a target on a private endpoint, `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` supports specifying a single hostname with the `hostname` parameter. On a private endpoint, using an IP address, SCAN IP, or a SCAN hostname is not supported (when the target is on a public endpoint, `CREATE_DATABASE_LINK` supports using an IP address, a SCAN IP, or a SCAN hostname).

   When the target is an Oracle RAC database, use the `rac_hostnames` parameter to specify one or more hostnames with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`. This allows you to take advantage of the high availability capabilities of Oracle RAC. Using an IP address, a SCAN IP, or a SCAN hostname in the `rac_hostnames` value is not supported.

   For example, with a target Oracle RAC database use the `rac_hostnames` parameter:

```
BEGIN
     DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
         db_link_name => 'PRIVATE_ENDPOINT_LINK',
         rac_hostnames => '["sales1-svr1.example.adb.us-
ashburn-1.oraclecloud.com",
                           "sales1-svr2.example.adb.us-
ashburn-1.oraclecloud.com",
                           "sales1-svr3.example.adb.us-
ashburn-1.oraclecloud.com"]',
         port => '1522',
         service_name => 'exampleServiceName',
         ssl_server_cert_dn => NULL,
         credential_name => 'PRIVATE_ENDPOINT_CRED',
         directory_name => NULL,
```

```
        private_target => TRUE);
END;
/
```

`DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` does not support a value of `localhost` for the `hostname` or in the `rac_hostnames` parameter.

Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

As shown in the example, to create a database link with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` to a target database on a private endpoint using a secure TCP connection without a wallet, all of the following are required:

- The `directory_name` parameter must be `NULL`.
- The `ssl_server_cert_dn` parameter must be `NULL`.
- The `private_target` parameter must be `TRUE`.

> **Note:**
>
> If you set `ROUTE_OUTBOUND_CONNECTIONS` to `PRIVATE_ENDPOINT`, setting the `private_target` parameter to `TRUE` is not required in this API. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

3. Use the database link you created to access data in the target database.

   For example:

```
SELECT * FROM employees@PRIVATE_ENDPOINT_LINK;
```

> **Note:**
>
> For the credentials you create in Step 1, the Oracle Database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:
>
> ```
> BEGIN
>      DBMS_CLOUD.UPDATE_CREDENTIAL (
>          credential_name => 'DB_LINK_CRED',
>          attribute => 'PASSWORD',
>          value => 'password');
> END;
> /
> ```
>
> Where *password* is the new password.
>
> After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

See CREATE_DATABASE_LINK Procedure for additional information.

Create Database Links from Autonomous Database to Oracle Databases on a Private Endpoint with a Wallet (mTLS)

You can create database links from an Autonomous Database to a target Oracle database that is on a private endpoint.

> **Note:**
>
> This option is for target Oracle databases that have SSL/TCPS configured and that are on a private endpoint.

If the target Oracle database does not have SSL/TCPS configured, you have two options:

- You can configure the target Oracle database to use TCP/IP with SSL (TCPS) authentication. See Configuring Transport Layer Security Authentication for information on configuring SSL/TCPS.
- You can connect to the target Oracle database with TCP. See Create Database Links to Oracle Databases on a Private Endpoint without a Wallet for details.

Perform the prerequisite steps, as required. See Prerequisites for Database Links from Autonomous Database to a Target Autonomous Database on a Private Endpoint for details.

To create a database link to a target Oracle database on a private endpoint using TCP/IP with SSL (TCPS) authentication:

1. Copy your target database wallet, `cwallet.sso`, containing the certificates for the target database to Object Store.

   > **Note:**
   >
   > The wallet file, along with the Database user ID and password provide access to data in the target Oracle database. Store wallet files in a secure location. Share wallet files only with authorized users.

2. Create credentials to access your Object Store where you store the `cwallet.sso`. See CREATE_CREDENTIAL Procedure for information about the username and password parameters for different object storage services.
3. Create a directory on Autonomous Database for the wallet file `cwallet.sso`.

   For example:

   ```
   CREATE DIRECTORY wallet_dir AS 'directory_path_of_your_choice';
   ```

   See Create Directory in Autonomous Database for information on creating directories.
4. Use `DBMS_CLOUD.GET_OBJECT` to upload the target database wallet to the directory you created in the previous step, *WALLET_DIR*.

For example:

```
BEGIN
    DBMS_CLOUD.GET_OBJECT(
        credential_name => 'DEF_CRED_NAME',
        object_uri => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
        directory_name => 'WALLET_DIR');
END;
/
```

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

> **Note:**
>
> The `credential_name` you use in this step is the credentials for the Object Store. In the next step you create the credentials to access the target database.

5. On Autonomous Database create credentials to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database used within the database link, (where the target database is accessed through the VCN).

> **Note:**
>
> Supplying the `credential_name` parameter is required.

For example:

```
BEGIN
   DBMS_CLOUD.CREATE_CREDENTIAL(
      credential_name => 'DB_LINK_CRED',
      username => 'NICK',
      password => 'password');
END;
/
```

The characters in the `username` parameter must be all uppercase letters.

> **Note:**
>
> You can use a vault secret credential for the target database credential in a database link. See Use Vault Secret Credentials for more information.

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

6. Create the database link to the target database using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example:

```
BEGIN
    DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
        db_link_name => 'PEDBLINK1',
        hostname => 'example1.adb.ap-osaka-1.oraclecloud.com',
        port => '1522',
        service_name => 'example_high.adb.oraclecloud.com',
        ssl_server_cert_dn => 'ssl_server_cert_dn',
        credential_name => 'DB_LINK_CRED',
        directory_name => 'WALLET_DIR',
        private_target => TRUE);
END;
/
```

> **Note:**
>
> If you set `ROUTE_OUTBOUND_CONNECTIONS` to `PRIVATE_ENDPOINT`, setting the `private_target` parameter to `TRUE` is not required in this API. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

For a target on a private endpoint, `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` supports specifying a single hostname with the `hostname` parameter. On a private endpoint, using an IP address, SCAN IP, or a SCAN hostname is not supported (when the target is on a public endpoint, `CREATE_DATABASE_LINK` supports using an IP address, a SCAN IP, or a SCAN hostname).

When the target is an Oracle RAC database, use the `rac_hostnames` parameter to specify one or more hostnames with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`. This allows you to take advantage of the high availability capabilities of Oracle RAC. Using an IP address, a SCAN IP, or a SCAN hostname in the `rac_hostnames` value is not supported.

For example, with a target Oracle RAC database use the `rac_hostnames` parameter:

```
BEGIN
    DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
        db_link_name => 'PEDBLINK1',
        rac_hostnames => '["sales1-svr1.example.adb.us-
ashburn-1.oraclecloud.com",
                          "sales1-svr2.example.adb.us-
ashburn-1.oraclecloud.com",
                          "sales1-svr3.example.adb.us-
ashburn-1.oraclecloud.com"]',
        port => '1522',
        service_name => 'example_high.adb.oraclecloud.com',
        ssl_server_cert_dn => 'ssl_server_cert_dn',
        credential_name => 'DB_LINK_CRED',
        directory_name => 'WALLET_DIR',
        private_target => TRUE);
END;
/
```

`DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` does not support a value of `localhost` for the `hostname` or in the `rac_hostnames` parameter.

Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

7. Use the database link you created to access data in the target database.

   For example:

```
SELECT * FROM employees@PEDBLINK1;
```

> **Note:**
>
> For the credentials you create in Step 5, the Oracle Database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:
>
> ```
> BEGIN
>     DBMS_CLOUD.UPDATE_CREDENTIAL (
>         credential_name => 'DB_LINK_CRED',
>         attribute => 'PASSWORD',
>         value => 'password');
> END;
> /
> ```
>
> Where *password* is the new password.
>
> After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

See CREATE_DATABASE_LINK Procedure for additional information.

Database Link Notes with a Target Oracle Database

Provides notes for creating database links to a target Oracle database (when the target is not an Autonomous Database)

Notes for database links to other Oracle databases:

- If you are using database links between Autonomous Database and other Oracle Databases, you might need to apply Patch 33843368 on the Oracle Database that is not an Autonomous Database. This applies to cases where the Autonomous Database instance is either the source or the target of the database link.

  See My Oracle Support Knowledge Base: Patch Requirement For Database Links Between ADB-S And Other Oracle Databases(Doc ID 2874244.1) for further details.

- Only one wallet file is valid per directory for use with database links. You can only upload one `cwallet.sso` at a time to the directory you choose for wallet files (for example *DBLINK_WALLET_DIR*). This means with a `cwallet.sso` in *DBLINK_WALLET_DIR* you can only create database links to the databases for which the wallet in that directory is valid. To use multiple `cwallet.sso` files with database links you need to create additional directories and put each `cwallet.sso` in a different directory. When you create database

links with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`, specify the directory that contains the wallet with the `directory_name` parameter.

See Create Directory in Autonomous Database for information on creating directories.

- Supported target Oracle database versions for database links to another Oracle Database are: 19c, 12.2.0, and 12.1.0.

> **Note:**
>
> For complete information on supported versions, see Client Server Interoperability Support Matrix for Different Oracle Versions (Doc ID 207303.1)

- Autonomous Database sets the `SEC_CASE_SENSITIVE_LOGON` parameter to `true` and this value cannot be changed. If your target database is not an Autonomous Database, then you must set `SEC_CASE_SENSITIVE_LOGON` parameter to `true` on the target database. If `SEC_CASE_SENSITIVE_LOGON` is set to `false` on the target database, then error `ORA-28040: No matching authentication protocol` is raised.
- To list the database links, use the `ALL_DB_LINKS` view. See ALL_DB_LINKS for more information.
- The wallet file, along with the Database user ID and password provide access to data in the target Oracle database. Store wallet files in a secure location. Share wallet files only with authorized users.
- When the Autonomous Database instance is on a private endpoint, there are two options to specify the target database: use either the `hostname` parameter or the `rac_hostnames` parameter:
  - For a target on a private endpoint, `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` supports specifying a single hostname with the `hostname` parameter. On a private endpoint, using an IP address, SCAN IP, or a SCAN hostname is not supported (when the target is on a public endpoint, `CREATE_DATABASE_LINK` supports using an IP address, a SCAN IP, or a SCAN hostname).
  - When the target is an Oracle RAC database, use the `rac_hostnames` parameter to specify one or more hostnames with `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`. This allows you to take advantage of the high availability capabilities of Oracle RAC. Using an IP address, a SCAN IP, or a SCAN hostname in the `rac_hostnames` value is not supported.

    When you specify a list of host names in the `rac_hostnames` parameter, `CREATE_DATABASE_LINK` uses all of the specified host names as addresses in the connect string. If one of the specified hosts is not available on the target Oracle RAC database, Autonomous Database automatically attempts to connect using another host name from the list.
  - `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` does not support a value of `localhost` for the `hostname` or in the `rac_hostnames` parameter.

Create Database Links to Non-Oracle Databases

You can create database links from Autonomous Database to Non-Oracle databases.

- Create Database Links to Non-Oracle Databases with Oracle-Managed Heterogeneous Connectivity
  Autonomous Database support for Oracle-managed heterogeneous connectivity makes it easy to create database links to non-Oracle databases.
- Create Database Links to Non-Oracle Databases with Customer-Managed Heterogeneous Connectivity
  Use `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` to create database links from an Autonomous Database to an Oracle Database Gateway to access Non-Oracle databases.

Create Database Links to Non-Oracle Databases with Oracle-Managed Heterogeneous Connectivity

Autonomous Database support for Oracle-managed heterogeneous connectivity makes it easy to create database links to non-Oracle databases.

When you use database links with Oracle-managed heterogeneous connectivity, Autonomous Database configures and sets up the connection to the non-Oracle database.

> **Note:**
>
> With Oracle-managed heterogeneous connectivity the support is for query-only connections on the remote database. That is, updates are not supported when using Oracle-managed heterogeneous connectivity.

The following is a prerequisite to use Oracle-managed heterogeneous connectivity with Autonomous Database:

- When the target database is on a public endpoint, database must be configured to allow incoming SSL/TLS connections with CA signed certificates.

  Oracle-managed heterogeneous connectivity supports connections to target database services on private endpoints (for example you can connect to Oracle MySQL Database Service when the service is on a private endpoint). When you connect to a non-oracle database with Oracle-managed heterogeneous connectivity on a private endpoint, the connection uses TCP protocol and it does not require SSL/TLS to be configured on the target database.

  See Create Database Links to Oracle MySQL on a Private Endpoint with Oracle-Managed Heterogeneous Connectivity for more information.

To create database links to a non-Oracle database using Oracle-managed heterogeneous connectivity, do the following:

1. On Autonomous Database create credentials to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database used within the database link.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'AWS_REDSHIFT_LINK_CRED',
       username => 'nick',
       password => 'password'
     );
   ```

```
END;
/
```

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Supplying the `credential_name` parameter is required.

To access Google Analytics, Google BigQuery, Google Drive, Youtube, ServiceNow, or Microsoft SharePoint with OAuth2, the credential must include the `params` parameter with the value `gcp_oauth2`.

For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'SERVICENOW_OAUTH',
    params => JSON_OBJECT(
                'gcp_oauth2' value JSON_OBJECT(
                       'client_id' value 'CLIENT_ID',
                       'client_secret' value 'CLIENT_SECRET',
                       'refresh_token' value 'Refresh_Token')));
END;
/
```

See CREATE_CREDENTIAL Procedure for more information.

2. Create the database link to the target database using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example, to create a database link to AWS Redshift:

```
BEGIN
     DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
          db_link_name => 'AWSREDSHIFT_LINK',
          hostname => 'example.com',
          port => '5439',
          service_name => 'example_service_name',
          credential_name => 'AWS_REDSHIFT_LINK_CRED',
          gateway_params => JSON_OBJECT('db_type'  value 'awsredshift'),
          ssl_server_cert_dn => NULL);
END;
/
```

The `service_name` is the database name of the non-Oracle database.

The `gateway_params db_type` value that you supply must be one of the supported values:

db_type Value	Database Type
awsredshift	Amazon Redshift
azure	Microsoft SQL Server Azure SQL Azure Synapse Analytics
db2	IBM Db2
google_analytics	Google Analytics

db_type Value	Database Type
google_bigquery	Google BigQuery
google_drive	Google Drive
hive	Apache Hive
mongodb	MongoDB
mysql	MySQL
mysql_community	MySQL Community Edition
postgres	PostgreSQL
salesforce	Salesforce
servicenow	ServiceNow
sharepoint	Microsoft SharePoint
snowflake	Snowflake
youtube	YouTube

Autonomous Database automatically configures and handles the secure connection to a target database and your connections are end-to-end encrypted. Oracle-managed heterogeneous connectivity is preconfigured with a wallet that contains most of the common trusted root and intermediate SSL certificates. Thus, `NULL` must be provided as the value for the `ssl_server_cert_dn` parameter.

To ensure security when using database links with Oracle-managed heterogeneous connectivity, the connection port is restricted and must have SSL/TLS enabled. You specify the target database port with the `port` parameter.

See Oracle-Managed Heterogeneous Connectivity Database Types and Ports for the list of supported non-Oracle database types.

The `HETEROGENEOUS_CONNECTIVITY_INFO` view provides information on supported Oracle Heterogeneous Connectivity types and shows a PL/SQL code sample for each supported type. See Access Heterogeneous Connectivity Information and Samples for more information.

When you specify the `gateway_params` parameter, for some `db_type` values, additional `gateway_params` parameters are supported:

db_type Value	Supported Gateway Parameters with Specified db_type
azure	When the `db_type` value is `azure` there are two optional parameters, `auth_method` and `domain` to support NTLM/AD authentication. When NTLMv2 is configured, set `auth_method=10` and set `domain` to the Windows domain value. To use an Azure Active Directory password, set `auth_method=13`. Do not use `auth_method=13` to access an Oracle on-premises Database. See Microsoft SQL Server Authentication Method for more information.
google_analytics	When the `db_type` value is `google_analytics` the `hostname` is not used and you can provide value such as `example.com`. For `db_type google_analytics`, the credential must be an OAuth type credential using the `params` parameter with `gcp_oauth2` values specified (`client_id`, `client_secret`, and `refresh_token`). See CREATE_CREDENTIAL Procedure for more information.

db_type Value	Supported Gateway Parameters with Specified db_type
google_bigquery	When db_type is google_bigquery, the parameter project is valid. This parameter specifies the project name on google_bigquery and is required. When the db_type value is google_bigquery the hostname is not used and you can provide value such as example.com. For db_type google_bigquery, the credential must be an OAuth type credential using the params parameter with gcp_oauth2 values specified (client_id, client_secret, and refresh_token). See CREATE_CREDENTIAL Procedure for more information.

google_drive	For db_type google_drive, the credential you supply with DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK must be an OAuth type credential using the params parameter with gcp_oauth2 values specified (client_id, client_secret, and refresh_token).
	To connect to Google Drive and get data you must supply the gateway parameters directory_name and file_name. These parameters specify a model file (auto REST file) that maps the JSON response to the relational model. The model file specifies the endpoints, table mapping, and HTTP response code for processing the JSON response. See Model file syntax and Example Model file for more information.
	When you use gateway_params parameter with db_type google_drive you must supply the gateway_params parameter db_type with the value 'google_drive' and the directory_name and file_name parameters, along with OAuth type credentials:
	The directory_name parameter specifies the directory with the REST config file. You could create this directory as follows:
	`create or replace directory google_drive_dir as 'GOOGLE_DRIVE_DIR';`
	Obtain and download the auto REST file to the specified directory. For example:
	`exec DBMS_CLOUD.get_object('google_drive_dir_cred', 'https://objectstorage.<...>/ google_drive.rest','GOOGLE_DRIVE_DIR');`
	Set the file_name value to the name of the auto REST file you downloaded, "google_drive.rest". Then you can use the REST config file with OAuth 2.0.

hive	When db_type is hive, the parameter http_path is valid. This parameter specifies the HttpPath value, if required, to connect to the Hive instance.

db_type Value	Supported Gateway Parameters with Specified db_type
salesforce	When you use gateway_params parameter with db_type salesforce, you must supply the security_token option. The security token is a case-sensitive alphanumeric code. See Reset Your Security Token for more information. When you use gateway_params parameter with db_type salesforce, you must supply the correct hostname parameter. Salesforce provides two forms of URLs for the Salesforce service account: • *xxxx*.develop.lightning.force.com form of URL • *xxxx*my.salesforce.com form of URL as shown under the **View profile** tab. Oracle-Managed Heterogeneous Connectivity only supports the *xxxx*my.salesforce.com form of URL for the hostname parameter value.

servicenow	To connect to ServiceNow and get data you must supply the gateway parameters directory_name and file_name. These parameters specify a model file (REST config file) that maps the JSON response to the relational model. The model file specifies the endpoints, table mapping, and HTTP response code for processing the JSON response. See Model file syntax and Example Model file for more information.
	When you use gateway_params parameter with db_type servicenow there are two supported options:
	• Basic Authentication: you must supply the gateway_params parameter db_type with the value 'servicenow', and supply the directory_name and file_name parameters along with username/password type credentials.
	• OAuth 2.0 Authentication: you must supply the gateway_params parameter db_type with the value 'servicenow', and the directory_name, file_name, and token_uri parameters, along with OAuth type credentials.
	For OAuth 2.0 authentication with db_type servicenow, the credential must be an OAuth type credential using the params parameter with gcp_oauth2 values specified specified (client_id, client_secret, and refresh_token). See CREATE_CREDENTIAL Procedure for more information.
	The directory_name parameter specifies the directory with the ServiceNow REST config file. You could create this directory as follows:
	`create or replace directory servicenow_dir as 'SERVICENOW_DIR';`
	Obtain and download the ServiceNow REST config file to the specified directory. For example:
	`exec DBMS_CLOUD.get_object('servicenow_dir_cred', 'https://objectstorage.<...>/ servicenow.rest','SERVICENOW_DIR');`
	Set the file_name value to the name of the REST config file you downloaded, "servicenow.rest".
	Then you can use the ServiceNow REST config file with either basic authentication or OAuth2.0. See HETEROGENEOUS_CONNECTIVITY_INFO View for samples.

db_type Value	Supported Gateway Parameters with Specified db_type
sharepoint	When you use gateway_params parameter with db_type sharepoint, also specify values for auth_uri, scope, service_url, and token_uri. For db_type sharepoint, the credential you supply with DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK must be an OAuth type credential using the params parameter with gcp_oauth2 values specified (client_id, client_secret, and refresh_token). See CREATE_CREDENTIAL Procedure for more information. Generate the refresh_token for *tenant_id*.sharepoint.com/.default offline_access. See the following for more information: Determine the scope and OAuth 2.0 authentication. Set values for gateway_params for db_type sharepoint: • auth_uri: Set the auth_uri from Azure. See Obtain application client information and endpoints for more information. • scope: Set the scope. See Connection option descriptions for more information. • service_url: Set the service_url. See Service URL for more information. • token_uri: Get the token_uri from Azure. See Obtain application client information and endpoints for more information.
snowflake	When you use gateway_params parameter with db_type snowflake, use the Snowflake account identifier as the hostname parameter. In this case, the driver adds snowflakecomupting.com, so you do not pass this part of the hostname explicitly. To find your Snowflake account identifier, see Account Identifier Formats by Cloud Platform and Region. For example: for the Snowflake account: https://example-marketing_test_account.snowflakecomputing.com Set the hostname value to "example-marketing_test_account". When the db_type is SNOWFLAKE, the optional parameters: role, schema, and warehouse are valid. These values specify a different schema, role, or warehouse value, other than the default. For example: gateway_params => JSON_OBJECT('db_type' value 'snowflake', 'role' value 'ADMIN', 'schema' value 'PUBLIC', 'warehouse' value 'TEST')

db_type Value	Supported Gateway Parameters with Specified db_type

youtube	To connect to YouTube and get data, you must supply the parameters directory_name and file_name. These parameters specify a model file (REST config file) that maps the JSON response to the relational model. The model file specifies the endpoints, table mapping, and HTTP response code for processing the JSON response. See Model file syntax and Example Model file for more information.
	For db_type youtube, the credential must be an OAuth type credential using the params parameter with gcp_oauth2 values specified (client_id, client_secret, and refresh_token). See CREATE_CREDENTIAL Procedure for more information.
	The directory_name parameter specifies the directory with the youtube REST config file.
	For example, to create this directory and add the required contents:
	a. Create a directory on the Autonomous Database instance:
	`create or replace directory youtube_dir as 'YOUTUBE_DIR';`
	b. Obtain and download the auto rest REST config file to the specified directory. For example:
	`exec DBMS_CLOUD.get_object('youtube_dir_cred', 'https://objectstorage.<...>/youtube.rest','YOUTUBE_DIR');`
	c. Set the file_name value to the name of the REST config file you downloaded, 'youtube.rest'.
	Then you can use the REST config file with OAuth2.0. See HETEROGENEOUS_CONNECTIVITY_INFO View for samples.

See CREATE_DATABASE_LINK Procedure for more information.

3. Use the database link to access data on the target database.

   For example:

```
SELECT count(*) FROM sales@AWSREDSHIFT_LINK
```

   The table name you specify when you use SELECT with Google BigQuery must be in quotes. For example:

```
SELECT count(*) FROM "sales"@GOOGLE_BIGQUERY_LINK
```

> **Note:**
>
> For the credentials you create in Step 1, the target database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:
>
> ```
> BEGIN
>     DBMS_CLOUD.UPDATE_CREDENTIAL (
>        credential_name => 'AWS_REDSHIFT_LINK_CRED',
>        attribute => 'PASSWORD',
>        value => 'password');
> END;
> /
> ```
>
> Where *password* is the new password.
>
> After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

For additional information, see:

- Supported SQL Syntax and Functions in *Oracle Database Gateway for ODBC User's Guide*
- CREATE_DATABASE_LINK Procedure
- UPDATE_CREDENTIAL Procedure
- Create Database Links to Oracle MySQL on a Private Endpoint with Oracle-Managed Heterogeneous Connectivity
  Autonomous Database support for Oracle-managed heterogeneous connectivity makes it easy to create database links to Oracle MySQL Database Service on a private endpoint. When you use database links with Oracle-managed heterogeneous connectivity, Autonomous Database configures and sets up the connection to the Oracle MySQL Database Service.
- Oracle-Managed Heterogeneous Connectivity Database Types and Ports
  Shows the non-Oracle databases that you can connect to from Autonomous Database with Oracle-managed heterogeneous connectivity, and lists the supported port value for each database type. Also provides a link where you can see the supported database versions for each database type.
- Access Heterogeneous Connectivity Information and Samples
  Oracle Autonomous Database provides heterogeneous connectivity information for database links to non-Oracle databases.

Create Database Links to Oracle MySQL on a Private Endpoint with Oracle-Managed Heterogeneous Connectivity

Autonomous Database support for Oracle-managed heterogeneous connectivity makes it easy to create database links to Oracle MySQL Database Service on a private endpoint. When you use database links with Oracle-managed heterogeneous connectivity, Autonomous Database configures and sets up the connection to the Oracle MySQL Database Service.

The following are prerequisites to use Oracle-managed heterogeneous connectivity with Oracle MySQL Database Service on a private endpoint:

- Create a DNS name using private DNS Zone pointing to private IP of your Oracle MySQL Database Service in your VCN. See Private DNS.
- Create an Autonomous Database with a Private Endpoint on same subnet.
- Configure the VCN for the Oracle MySQL Database Service to allow incoming connections on port 3306.

To create database links to a Oracle MySQL Database Service on a private endpoint using Oracle-managed heterogeneous connectivity, do the following:

1. On Autonomous Database create credentials to access the Oracle MySQL Database Service. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the Oracle MySQL Database Service used within the database link.

   > **Note:**
   >
   > Supplying the `credential_name` parameter is required.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'MYSQL_LINK_CRED',
       username => 'NICK',
       password => 'password'
     );
   END;
   /
   ```

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

2. Create the database link to the Oracle MySQL Database Service using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example, to create a database link:

   ```
   BEGIN
        DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
             db_link_name => 'MYSQL_LINK',
             hostname => 'mysql.example.com',
             port => '3306',
             service_name => 'mysql.example_service_name',
             ssl_server_cert_dn => NULL,
             credential_name => 'MYSQL_LINK_CRED',
             private_target => TRUE,
             gateway_params => JSON_OBJECT('db_type' value 'mysql'));
   END;
   /
   ```

3. Use the database link to access data on the target database.

   For example:

   ```
   SELECT count(*) FROM sales@MYSQL_LINK
   ```

> **Note:**
>
> For the credentials you create in Step 1, the target database credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:
>
> ```
> BEGIN
>     DBMS_CLOUD.UPDATE_CREDENTIAL (
>        credential_name => 'MYSQL_LINK_CRED',
>        attribute => 'PASSWORD',
>        value => 'password');
> END;
> /
> ```
>
> Where *password* is the new password.
>
> After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

For additional information, see:

- Supported SQL Syntax and Functions in *Oracle Database Gateway for ODBC User's Guide*
- CREATE_DATABASE_LINK Procedure
- UPDATE_CREDENTIAL Procedure

Oracle-Managed Heterogeneous Connectivity Database Types and Ports

Shows the non-Oracle databases that you can connect to from Autonomous Database with Oracle-managed heterogeneous connectivity, and lists the supported port value for each database type. Also provides a link where you can see the supported database versions for each database type.

> **Note:**
>
> Oracle uses Progress DataDirect connectors. The Database Support column provides links to the Progress website where you can find the supported database versions for each database type.

Database Type	db_type Value	Required Port	Database Support
Amazon Redshift	`awsredshift`	5439	Amazon Redshift Supported Versions
Azure SQL Microsoft SQL Server Azure Synapse Analytics	`azure`	1433	Azure SQL Supported Versions Azure Synapse Analytics Supported Versions
Apache Hive	`hive`	443	Hive Supported Versions
Google Analytics	`google_analytics`	443	Google Analytics Supported Versions

Database Type	db_type Value	Required Port	Database Support
Google BigQuery	`google_bigquery`	443	Google BigQuery Supported Versions
Google Drive	`google_drive`	443	Google Drive Supported Versions
Apache Hive	`hive`	443	Hive Supported Versions
IBM Db2 11.5.6 or greater IBM Db2 11.5.5 or less	`db2`	25000 50000	IBM Db2 Supported Versions
Microsoft SharePoint	`sharepoint`	443	Microsoft SharePoint Supported Versions
MongoDB	`mongodb`	27017	MongoDB Supported Versions
MySQL	`mysql`	3306	MySQL Supported Versions
MySQL Community Edition	`mysql_community`	3306	
PostgreSQL	`postgres`	5432	PostgreSQL Supported Versions
Salesforce	`salesforce`	19937	Salesforce Supported Versions
ServiceNow	`servicenow`	443	ServiceNow Supported Versions
Snowflake	`snowflake`	443	Snowflake Supported Versions
Youtube	`youtube`	443	Youtube Supported Versions

Access Heterogeneous Connectivity Information and Samples

Oracle Autonomous Database provides heterogeneous connectivity information for database links to non-Oracle databases.

The `HETEROGENEOUS_CONNECTIVITY_INFO` view provides information on supported Oracle Heterogeneous Connectivity types and shows a PL/SQL code sample for each supported type.

For example:

```
SELECT * FROM HETEROGENEOUS_CONNECTIVITY_INFO WHERE DATABASE_TYPE = 'hive';
```

- HETEROGENEOUS_CONNECTIVITY_INFO View
  The `HETEROGENEOUS_CONNECTIVITY_INFO` view lists connectivity information and examples for connecting with PL/SQL using database links and Oracle Managed Heterogeneous Connectivity.

HETEROGENEOUS_CONNECTIVITY_INFO View

The `HETEROGENEOUS_CONNECTIVITY_INFO` view lists connectivity information and examples for connecting with PL/SQL using database links and Oracle Managed Heterogeneous Connectivity.

Column	Datatype	Description
`DATABASE_TYPE`	`VARCHAR2(32)`	Database type value used with `gateway_params` parameter.

Column	Datatype	Description
REQUIRED_PORT	NUMBER	Supported port values for the database type.
DESCRIPTION	CLOB	Specifies a description for the DATABASE_TYPE.
OPTIONAL_PARAMETERS	VARCHAR2(1024)	Specifies the valid optional parameters for the DATABASE_TYPE.
SAMPLE_USAGE	CLOB	Shows sample PL/SQL usage for the DATABASE_TYPE.

Create Database Links to Non-Oracle Databases with Customer-Managed Heterogeneous Connectivity

Use DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK to create database links from an Autonomous Database to an Oracle Database Gateway to access Non-Oracle databases.

Topics

- Prerequisites to Create Database Links to Non-Oracle Databases with Customer-Managed Heterogeneous Connectivity
  Use DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK to create database links from an Autonomous Database to an Oracle Database Gateway to access Non-Oracle databases.
- Create Database Links with Customer-Managed Heterogeneous Connectivity to Publicly Accessible Non-Oracle Databases
  Use DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK to create database links from an Autonomous Database instance on a public endpoint to an Oracle Database Gateway to access Non-Oracle databases.
- Create Database Links with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases on a Private Endpoint
  You can create database links from an Autonomous Database to an Oracle Database Gateway to access Non-Oracle databases that are on a private endpoint.

Prerequisites to Create Database Links to Non-Oracle Databases with Customer-Managed Heterogeneous Connectivity

Use DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK to create database links from an Autonomous Database to an Oracle Database Gateway to access Non-Oracle databases.

An Oracle Database Gateway is a gateway that is designed for accessing a specific non-Oracle system. Using an Oracle Database Gateway, you can access data anywhere in a distributed database system without knowing either the location of the data or how it is stored. Using database links on Autonomous Database with Oracle Database Gateway supports heterogeneous environments and eliminates the need to customize your applications to access data from non-Oracle systems.

Before you create database links to a target gateway, do the following:

1. Configure the Oracle Database Gateway to access a non-Oracle database.
2. Configure Oracle Net Listener to handle incoming requests on the Oracle Database Gateway.
3. Create a self signed wallet on the Oracle Database Gateway.

For more information on Oracle Database Gateway, see Oracle Database Gateways in *Oracle Database Heterogeneous Connectivity User's Guide*. Also see the Installation and Configuration Guide and the Gateway User's Guide for the database you want to connect to. For example, for Oracle Database Gateway for SQL Server see:

- Installing and Configuring Oracle Database Gateway for SQL Server
- Introduction to the Oracle Database Gateway for SQL Server in *Oracle Database Gateway for SQL Server User's Guide*.
- Configure Oracle Net for the Gateway

Create Database Links with Customer-Managed Heterogeneous Connectivity to Publicly Accessible Non-Oracle Databases

Use `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` to create database links from an Autonomous Database instance on a public endpoint to an Oracle Database Gateway to access Non-Oracle databases.

To use database links from an Autonomous Database instance on a public endpoint, the target an Oracle Database Gateway must be configured to use TCP/IP with SSL (TCPS) authentication. See Configuring Secure Sockets Layer Authentication for more information.

To create database links from an Autonomous Database instance on a public endpoint to a target Oracle Database Gateway:

1. Copy the target Oracle Database Gateway self-signed wallet to Object Store. For example, copy `cwallet.sso`, containing the certificates for the Oracle Database Gateway, to Object Store.

   > **Note:**
   >
   > The wallet file, along with the Database user ID and password provide access to data available through the target Oracle Database Gateway. Store wallet files in a secure location. Share wallet files only with authorized users.

2. Create credentials to access the Object Store where you store the `cwallet.sso`. See CREATE_CREDENTIAL Procedure for information about the username and password parameters for different object storage services.
3. Create a directory on your Autonomous Database instance for the wallet file `cwallet.sso`.

   For example:

   ```
   CREATE DIRECTORY dblink_wallet_dir AS 'directory_path_of_your_choice';
   ```

   See Create Directory in Autonomous Database for information on creating directories.
4. Use `DBMS_CLOUD.GET_OBJECT` to upload the target gateway self signed wallet to the directory you created in the previous step, *DBLINK_WALLET_DIR*.

   For example:

   ```
   BEGIN
        DBMS_CLOUD.GET_OBJECT(
           credential_name => 'DEF_CRED_NAME',
           object_uri => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
   ```

```
        directory_name => 'DBLINK_WALLET_DIR');
END;
/
```

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

The `credential_name` you use in this step is the credentials for the Object Store. In the next step you create the credentials to access the target gateway.

5. On your Autonomous Database instance create a credential to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database to be used when you create the database link, (where the target database is accessed through the Oracle Database Gateway).

   Supplying the `credential_name` parameter is required.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DB_LINK_CRED',
       username => 'NICK',
       password => 'password'
     );
   END;
   /
   ```

   The characters in the `username` parameter must be all uppercase letters.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

6. Create a database link to access the target gateway using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example:

   ```
   BEGIN
        DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
             db_link_name =>       'SALESLINK',
             hostname =>           'example.com',
             port =>               '1522',
             service_name =>       'example_service_name',
             ssl_server_cert_dn => 'ssl_server_cert_dn',
             credential_name =>    'DB_LINK_CRED',
             directory_name =>     'DBLINK_WALLET_DIR',
             gateway_link =>        TRUE);
   END;
   /
   ```

   Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

7. Use the database link to access data on the target gateway.

For example:

```
SELECT * FROM employees@SALESLINK;
```

For the credentials you create in Step 5, the Oracle Database Gateway credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:

```
BEGIN
    DBMS_CLOUD.UPDATE_CREDENTIAL (
       credential_name => 'DB_LINK_CRED',
       attribute => 'PASSWORD',
       value => 'password');
END;
/
```

Where *password* is the new password.

After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

See the following for an example that shows you how to create a database link to an Oracle Database Gateway to access a Microsoft SQL Server database:

How to Access Non-Oracle Databases from Autonomous Database using Oracle Database Gateway

For additional information, see:

- CREATE_DATABASE_LINK Procedure
- GET_OBJECT Procedure and Function
- UPDATE_CREDENTIAL Procedure

Create Database Links with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases on a Private Endpoint

You can create database links from an Autonomous Database to an Oracle Database Gateway to access Non-Oracle databases that are on a private endpoint.

This section covers the steps for using database links to connect from Autonomous Database to a non-Oracle Database that through an Oracle Database Gateway, where the non-Oracle Database is on a private endpoint.

- Prerequisites to Create Database Links with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases on a Private Endpoint
  Lists the prerequisites to create database links from an Autonomous Database with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases that are on a Private Endpoint.
- Create Database Links with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases on a Private Endpoint (without a wallet)
  You can create database links from an Autonomous Database instance to an Oracle Database Gateway to access Non-Oracle databases that are on a private endpoint, connecting either with a wallet (TCPS) or without a wallet (TLS).

- Create Database Links with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases on a Private Endpoint (with a Wallet)
  You can create database links from an Autonomous Database instance to an Oracle Database Gateway to access Non-Oracle databases that are on a private endpoint, connecting either with a wallet (TCPS) or without a wallet (TLS).

Prerequisites to Create Database Links with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases on a Private Endpoint

Lists the prerequisites to create database links from an Autonomous Database with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases that are on a Private Endpoint.

To create a database link with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases that are on a Private Endpoint:

- The target database must be accessible from the source database's Oracle Cloud Infrastructure VCN. For example, you can connect to the target database when:
  - The target database is on a private endpoint.
  - Both the source database and the target database are in the same Oracle Cloud Infrastructure VCN.
  - The source database and the target database are in different Oracle Cloud Infrastructure VCNs that are paired.
  - For a target on a private endpoint, `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK` supports specifying a single hostname with the `hostname` parameter. On a private endpoint, using an IP address, SCAN IP, or a SCAN hostname is not supported (when the target is on a public endpoint, `CREATE_DATABASE_LINK` supports using an IP address, a SCAN IP, or a SCAN hostname).
- The following ingress and egress rules must be defined for the private endpoint:
  - Define an egress rule in the source database's subnet security list or network security group such that the traffic over TCP is allowed to the target database's IP address and port number.
  - Define an ingress rule in the target database's subnet security list or network security group such that the traffic over TCP is allowed from the source database IP address to the destination port.

  See Configure Network Access with Private Endpoints for information on configuring private endpoints with ingress and egress rules.

> **Note:**
>
> When your Autonomous Database instance is configured with a private endpoint, set the `ROUTE_OUTBOUND_CONNECTIONS` database parameter to '`PRIVATE_ENDPOINT`' to specify that all outgoing database links are subject to the Autonomous Database instance private endpoint VCN's egress rules. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

Create Database Links with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases on a Private Endpoint (without a wallet)

You can create database links from an Autonomous Database instance to an Oracle Database Gateway to access Non-Oracle databases that are on a private endpoint, connecting either with a wallet (TCPS) or without a wallet (TLS).

To create database links from an Autonomous Database instance on a private endpoint to a target Oracle Database Gateway, connecting without a wallet (TLS):

1. On Autonomous Database create credentials to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database used within the database link, (where the target database is accessed through the Oracle Database Gateway).

   Supplying the `credential_name` parameter is required.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DB_LINK_CRED',
       username => 'NICK',
       password => 'password'
     );
   END;
   /
   ```

   The characters in the `username` parameter must be all uppercase letters.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

2. Create the database link to the target gateway using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

   For example:

   ```
   BEGIN
        DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
             db_link_name =>       'SALESLINK',
             hostname =>           'example.com',
             port =>               '1522',
             service_name =>       'example_service_name',
             ssl_server_cert_dn => 'ssl_server_cert_dn',
             credential_name =>    'DB_LINK_CRED',
             directory_name =>      NULL,
             gateway_link =>        TRUE,
             private_target =>      TRUE,
             gateway_params =>      NULL);
   END;
   /
   ```

   The `ssl_server_cert_dn` parameter is optional if the connection is created as a TCP based database link (without a wallet).

   When the `directory_name` is `NULL`, the connection is created as a TCP based database link (without a wallet).

   The `private_target` parameter must be set to `TRUE` when the target non-Oracle Database is on a private endpoint (that is, the database link accesses a hostname that needs to be

resolved in a VCN DNS server). When `private_target` is `TRUE`, the `hostname` parameter must be a single hostname (on a private endpoint, using an IP address, a SCAN IP, or a SCAN hostname is not supported).

When `gateway_link` is `TRUE` and `gateway_params` is `NULL`, this specifies that the database link is to a customer-managed Oracle gateway.

Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

3. Use the database link you created to access data on the target gateway.

   For example:

   ```
   SELECT * FROM employees@SALESLINK;
   ```

For the credentials you create in Step 1, the Oracle Database Gateway credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:

```
BEGIN
    DBMS_CLOUD.UPDATE_CREDENTIAL (
       credential_name => 'DB_LINK_CRED',
       attribute => 'PASSWORD',
       value => 'password');
END;
/
```

Where *password* is the new password.

After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

For additional information, see:

- CREATE_DATABASE_LINK Procedure
- UPDATE_CREDENTIAL Procedure

Create Database Links with Customer-Managed Heterogeneous Connectivity to Non-Oracle Databases on a Private Endpoint (with a Wallet)

You can create database links from an Autonomous Database instance to an Oracle Database Gateway to access Non-Oracle databases that are on a private endpoint, connecting either with a wallet (TCPS) or without a wallet (TLS).

To create database links from an Autonomous Database instance on a private endpoint to a target Oracle Database Gateway, and connect without a wallet:

1. Copy the target Oracle Database Gateway self-signed wallet to Object Store. For example, copy `cwallet.sso`, containing the certificates for the Oracle Database Gateway, to Object Store.

   The wallet file, along with the Database user ID and password provide access to data available through the target gateway. Store wallet files in a secure location. Share wallet files only with authorized users.

2. Create credentials to access the Object Store where you store the `cwallet.sso`. See CREATE_CREDENTIAL Procedure for information about the username and password parameters for different object storage services.

3. Create a directory on Autonomous Database for the wallet file `cwallet.sso`.

For example:

```
CREATE DIRECTORY dblink_wallet_dir AS 'directory_path_of_your_choice';
```

See Create Directory in Autonomous Database for information on creating directories.

4. Use `DBMS_CLOUD.GET_OBJECT` to upload the target gateway self signed wallet to the directory you created in the previous step, *DBLINK_WALLET_DIR*.

   For example:

```
BEGIN
     DBMS_CLOUD.GET_OBJECT(
        credential_name => 'DEF_CRED_NAME',
        object_uri => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/cwallet.sso',
        directory_name => 'DBLINK_WALLET_DIR');
END;
/
```

   In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

> **Note:**
>
> The `credential_name` you use in this step is the credentials for the Object Store. In the next step you create the credentials to access the target gateway.

5. On Autonomous Database create credentials to access the target database. The `username` and `password` you specify with `DBMS_CLOUD.CREATE_CREDENTIAL` are the credentials for the target database used within the database link, (where the target database is accessed through the Oracle Database Gateway).

   Supplying the `credential_name` parameter is required.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DB_LINK_CRED',
    username => 'NICK',
    password => 'password'
  );
END;
/
```

   The characters in the `username` parameter must be all uppercase letters.

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name.

6. Create the database link to the target gateway using `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

For example:

```
BEGIN
     DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK(
          db_link_name =>       'SALESLINK',
          hostname =>           'example.com',
          port =>               '1522',
          service_name =>       'example_service_name',
          ssl_server_cert_dn => 'ssl_server_cert_dn',
          credential_name =>    'DB_LINK_CRED',
          directory_name =>     'DBLINK_WALLET_DIR',
          gateway_link =>        TRUE,
          private_target =>      TRUE,
          gateway_params =>      NULL);
END;
/
```

If `directory_name` is not `NULL`, a TCPS-based database link is created.

The `private_target` parameter must be set to `TRUE` when the target non-Oracle Database is on a private endpoint (that is, the database link accesses a hostname that needs to be resolved in a VCN DNS server). When `private_target` is `TRUE`, the `hostname` parameter must be a single hostname (on a private endpoint, using an IP address, a SCAN IP, or a SCAN hostname is not supported).

When `gateway_link` is `TRUE` and `gateway_params` is `NULL`, this specifies that the database link is to a customer-managed Oracle gateway.

Users other than ADMIN require privileges to run `DBMS_CLOUD_ADMIN.CREATE_DATABASE_LINK`.

7. Use the database link you created to access data on the target gateway.

   For example:

   ```
   SELECT * FROM employees@SALESLINK;
   ```

For the credentials you create in Step 5, the Oracle Database Gateway credentials, if the password of the target user changes you can update the credential that contains the target user's credentials as follows:

```
BEGIN
    DBMS_CLOUD.UPDATE_CREDENTIAL (
       credential_name => 'DB_LINK_CRED',
       attribute => 'PASSWORD',
       value => 'password');
END;
/
```

Where *password* is the new password.

After this operation, the existing database links that use this credential continue to work without having to drop and recreate the database links.

For additional information, see:

- CREATE_DATABASE_LINK Procedure

- GET_OBJECT Procedure and Function
- UPDATE_CREDENTIAL Procedure

Create Database Links from Other Databases to Autonomous Database

You can create database links to an Autonomous Database from an Oracle database that is not an Autonomous Database. For example from an on-premise Oracle database to an Autonomous Database

- Supported Oracle Database versions for database links where the source is an Oracle Database and the target is an Autonomous Database instance are: 19.2 (or later), 21 (base release or later).
- If you are using database links between Autonomous Database and other Oracle Databases, you might need to apply Patch 33843368 on the Oracle Database that is not an Autonomous Database. This applies to cases where the Autonomous Database instance is either the source or the target of the database link.

  See My Oracle Support Knowledge Base: Patch Requirement For Database Links Between ADB-S And Other Oracle Databases(Doc ID 2874244.1) for further details.

To create database links to an Autonomous Database do the following:

1. Download your Autonomous Database wallet. See Download Client Credentials (Wallets) for more information.
2. Upload the wallet to the database instance where you want to create the link to the Autonomous Database.
3. Unzip the Autonomous Database wallet:

> **Note:**
>
> The wallet file, along with the Database user ID and password provide access to data in your Autonomous Database. Store wallet files in a secure location. Share wallet files only with authorized users.

```
[oracle@sys1 ~]$ cd/u01/targetwallet
[oracle@sys1 targetwallet]$ unzip Wallet_name1.zip
        Archive: Wallet_name1.zip
          inflating: cwallet.sso
          inflating: tnsnames.ora
          inflating: truststore.jks
          inflating: ojdbc.properties
          inflating: sqlnet.ora
          inflating: ewallet.p12
          inflating: keystore.jks
```

4. Set `GLOBAL_NAMES` to `FALSE`.

```
SQL> ALTER SYSTEM SET GLOBAL_NAMES = FALSE;

System altered.

SQL> SHOW PARAMETER GLOBAL_NAMES
NAME                    TYPE        VALUE
```

```
----------------------   ----------- -----------
global_names             boolean     FALSE
```

Set `GLOBAL_NAMES` to `FALSE` to use a database link name without checking that the name is different than the remote database name.When `GLOBAL_NAMES`, is set to `TRUE`, the database requires the database link to have the same name as the database to which it connects. See GLOBAL_NAMES for more information.

5. Create the database link to the target Autonomous Database. Note that the `security` path includes `my_wallet_directory`; the path where you unzip the Autonomous Database wallet.

```
CREATE DATABASE LINK ADBLINK
   CONNECT TO NAME1 IDENTIFIED BY ************
   USING
'(description=(retry_count=20)(retry_delay=3)
     (address=(protocol=tcps)(port=1522)
(host=example1.oraclecloud.com))
     (connect_data=(service_name=example2_high.adb.oraclecloud.com))
     (security=(my_wallet_directory=/u01/targetwallet)
        (ssl_server_dn_match=true)))';

Database link created.
```

6. Use the database link you created to access data on the target database (your Autonomous Database instance in this case):

   For example:

```
SELECT * FROM employees@ADBLINK;
```

To list the database links, use the `ALL_DB_LINKS` view. See ALL_DB_LINKS for more information.

For additional information, see:

- See CREATE DATABASE LINK for details on the procedure.
- See Create Database Links from Autonomous Database to a Publicly Accessible Autonomous Database with a Wallet (mTLS)

Drop Database Links

After you create a database link you can drop the database link.

1. Drop a database link to a target database using `DBMS_CLOUD_ADMIN.DROP_DATABASE_LINK`.

   For example:

```
BEGIN
     DBMS_CLOUD_ADMIN.DROP_DATABASE_LINK(
          db_link_name => 'SALESLINK' );
END;
/
```

2. Include the `public_link` parameter when the database link is a public database link.

For example:

```
BEGIN
     DBMS_CLOUD_ADMIN.DROP_DATABASE_LINK(
          db_link_name => 'SALESLINK'
          public_link => TRUE);
END;
/
```

To run `DBMS_CLOUD_ADMIN.DROP_DATABASE_LINK` with `public_link` set to `TRUE`, you must have the `DROP PUBLIC DATABASE LINK` system privilege.

See DROP_DATABASE_LINK Procedure for detailed information about the procedure.

Call Web Services from Autonomous Database

Describes options for calling Web Services from Autonomous Database.

There are a number of options for calling Web Services from Autonomous Database, including the following:

- Use `DBMS_CLOUD` REST APIs: The `DBMS_CLOUD.SEND_REQUEST` function begins an HTTP request, gets the response, and ends the response. This function provides a workflow for sending a cloud REST API request with arguments and the function returns a response code and payload. See SEND_REQUEST Function and Procedure for more information.
- Use Oracle APEX: You can interact with both SOAP and RESTful style web services from APEX in your Autonomous Database instance. See Use Web Services with Oracle APEX for more information.
- Use `UTL_HTTP` to submit a request to a public site: See Submit an HTTP Request to a Public Host for more information.
- Use `UTL_HTTP` to submit a request to a private site: See Submit an HTTP Request to a Private Host for more information.

  When your Autonomous Database instance is on a private endpoint you can use a customer-managed wallet with procedures in `UTL_HTTP`, `DBMS_LDAP`, `UTL_SMTP`, or `UTL_TCP`. See Make External Calls Using a Customer-Managed Wallet for more information.

See PL/SQL Package Notes for Autonomous Database for information on restrictions for `UTL_HTTP` on Autonomous Database.

Topics

- Submit an HTTP Request to a Public Host
  Provides details for using `UTL_HTTP` to submit an HTTP request on a public host.
- Submit an HTTP Request to a Private Host
  Describes the steps to use `UTL_HTTP` to submit an HTTP request on a private host.
- Submit an HTTP Request to Private Site with a Proxy
  When your Autonomous Database instance is on a private endpoint you can use a proxy to submit HTTP requests with `UTL_HTTP`.
- Use Credential Objects to Set HTTP Authentication
  Describes how to pass a credential objects to `UTL_HTTP.SET_CREDENTIAL` procedure.

- Notes for Submitting HTTP Requests with Oracle APEX or Database Actions
  When you use Oracle APEX SQL Commands or Database Actions SQL worksheet to run multiple sequential SQL commands, the commands can run in different database sessions that do not save the state of a previous statement. This behavior differs from desktop SQL clients such as SQL*Plus and SQL Developer that maintain a persistent connection to the database.

Submit an HTTP Request to a Public Host

Provides details for using `UTL_HTTP` to submit an HTTP request on a public host.

For example, to submit an HTTP request for a public host www.example.com, create an Access Control List for the host:

```
BEGIN
   DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => 'www.example.com',
         ace =>  xs$ace_type( privilege_list => xs$name_list('http'),
                              principal_name => 'ADMIN',
                              principal_type => xs_acl.ptype_db));
END;
```

Then submit the HTTP request:

```
SELECT UTL_HTTP.REQUEST(url => 'https://www.example.com/') FROM dual;
```

> **Note:**
>
> If your Autonomous Database instance is on a private endpoint and you want your `UTL_HTTP` calls to public hosts to be subject to your private endpoint VCN's egress rules, set the `ROUTE_OUTBOUND_CONNECTIONS` database property to `PRIVATE_ENDPOINT`. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

See PL/SQL Package Notes for Autonomous Database for information on restrictions for `UTL_HTTP` on Autonomous Database.

Submit an HTTP Request to a Private Host

Describes the steps to use `UTL_HTTP` to submit an HTTP request on a private host.

To submit a request to a target host on a private endpoint, the target host must be accessible from the source database's Oracle Cloud Infrastructure VCN. For example, you can connect to the target host when:

- Both the source database and the target host are in the same Oracle Cloud Infrastructure VCN.
- The source database and the target host are in different Oracle Cloud Infrastructure VCNs that are paired.
- The target host is an on-premises network that is connected to the source database's Oracle Cloud Infrastructure VCN using FastConnect or VPN.

You can also make UTL_HTTP calls with a customer-managed wallet when your Autonomous Database is on a private endpoint. See Make External Calls Using a Customer-Managed Wallet for more information.

To make a UTL_HTTP request to a target on a private endpoint:

1. Create an Access Control List for the host.

   For example:

```
BEGIN
   DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
         host => 'www.example.com',
         ace => xs$ace_type( privilege_list => xs$name_list('http'),
                             principal_name => 'ADMIN',
                             principal_type => xs_acl.ptype_db),
                             private_target => TRUE);
END;
/
```

   As shown in this example, when you create an Access Control List for the host specify the private_target parameter with the value TRUE.

> **Note:**
>
> If you set ROUTE_OUTBOUND_CONNECTIONS to PRIVATE_ENDPOINT, setting the private_target parameter to TRUE is not required in this API. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

2. Submit the HTTP request:

```
SELECT UTL_HTTP.REQUEST(
               url => 'https://www.example.com/',
               https_host => 'www.example.com')
            FROM dual;
```

See PL/SQL Package Notes for Autonomous Database for information on restrictions for UTL_HTTP on Autonomous Database.

Submit an HTTP Request to Private Site with a Proxy

When your Autonomous Database instance is on a private endpoint you can use a proxy to submit HTTP requests with UTL_HTTP.

When your Autonomous Database instance is on a private endpoint, to use UTL_HTTP with a target proxy the target proxy must be accessible from the source database's Oracle Cloud Infrastructure VCN.

For example, you can connect using a proxy when:

- Both the source database and the proxy server are in the same Oracle Cloud Infrastructure VCN.
- The source database and the proxy server are in different Oracle Cloud Infrastructure VCNs that are paired.

- The proxy server is an on-premises network that is connected to the source database's Oracle Cloud Infrastructure VCN using FastConnect or VPN.

You can also make `UTL_HTTP` calls using a customer-managed wallet. See Make External Calls Using a Customer-Managed Wallet for more information.

To use a proxy server with `UTL_HTTP`:

1. Set the HTTP_PROXY ACL on the proxy server.

   For example:

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
       host =>'www-proxy-example.com',
       ace  => xs$ace_type(privilege_list => xs$name_list('HTTP_PROXY'),
                           principal_name => 'APPUSER1',
                           principal_type => xs_acl.ptype_db),
                           private_target => TRUE);
END;
/
```

   As shown in this example, when you create an Access Control List for the proxy server specify the `private_target` parameter with the value `TRUE`.

> **Note:**
>
> If you set `ROUTE_OUTBOUND_CONNECTIONS` to `PRIVATE_ENDPOINT`, setting the `private_target` parameter to `TRUE` is not required in this API. See Enhanced Security for Outbound Connections with Private Endpoints for more information.

2. Set the HTTP ACL on the remote Web Server.

   For example:

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
        host =>'example.com',
        ace => xs$ace_type( privilege_list => xs$name_list('HTTP'),
                            principal_name => 'APPUSER1',
                            principal_type => xs_acl.ptype_db)
END;
/
```

3. Set the wallet and the proxy for `UTL_HTTP`.

   For example:

```
BEGIN
   UTL_HTTP.SET_WALLET('');
   UTL_HTTP.SET_PROXY('www-proxy-example:80');
END;
/
```

4. Submit an HTTP request:

```
SELECT UTL_HTTP.REQUEST(
                    url         => 'https://www.example.com/',
                    https_host  => 'www.example.com')
               FROM dual;
```

Notes for setting a proxy server with `UTL_HTTP.SET_PROXY`:

- `DBMS_CLOUD` requests do not honor the proxy server you set with `UTL_HTTP.SET_PROXY`. This includes `DBMS_CLOUD.SEND_REQUEST` and all object storage access for `DBMS_CLOUD` external tables that you define with `DBMS_CLOUD.CREATE_EXTERNAL_TABLE`, `DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE`, or `DBMS_CLOUD.CREATE_HYBRID_PART_TABLE`.
- `APEX_WEB_SERVICE` requests do not honor the proxy server you set with `UTL_HTTP.SET_PROXY`.

See PL/SQL Package Notes for Autonomous Database for information on restrictions for `UTL_HTTP` on Autonomous Database.

Use Credential Objects to Set HTTP Authentication

Describes how to pass a credential objects to `UTL_HTTP.SET_CREDENTIAL` procedure.

The `UTL_HTTP.SET_CREDENTIAL` procedure sets HTTP authentication information in the HTTP request header. The Web server needs this information to authorize the request.

The `UTL_HTTP.SET_CREDENTIAL` procedure enables you to pass credential objects to set HTTP authentication. Credential objects are schema objects, hence they can be accessed only by privileged users and enable you to configure schema-level privileges to access control the credentials. Passing credential objects is an appropriate and secure way to store and manage username/password/keys to be used for authentication.

The `UTL_HTTP.SET_CREDENTIAL` procedure is a secure and convenient alternative to `UTL_HTTP.SET_AUTHENTICATION` procedure.

Example

```
...
UTL_HTTP.SET_AUTHENTICATION (l_http_request, 'web_app_user', 'xxxxxxxxxxxx');
...
```

As shown in the example above, when you invoke `SET_AUTHENTICATION` procedure, you must pass the username/password in clear text as part of PL/SQL formal parameters. You might need to embed the username/password into various PL/SQL automation or cron scripts. Passing clear text passwords is a compliance issue that is addressed in `UTL_HTTP.SET_CREDENTIAL` procedure.

See SET_AUTHENTICATION Procedure and SET_AUTHENTICATION_FROM_WALLET Procedure for more information.

`UTL_HTTP.SET_CREDENTIAL` Syntax

```
UTL_HTTP.SET_CREDENTIAL (
    r          IN OUT NOCOPY req,
    credential IN VARCHAR2,
```

```
    scheme      IN VARCHAR2 DEFAULT 'Basic',
    for_proxy   IN BOOLEAN  DEFAULT FALSE);
```

Example to pass a credential object in the `SET_CREDENTIAL` procedure:

- Create a credential object:

  ```
  BEGIN DBMS_CLOUD.CREATE_CREDENTIAL (
      credential_name => 'HTTP_CRED',
      username        => 'web_app_user',
      password        => '<password>' );
  END;
  ```

  This creates a credential object which creates a stored username/password pair.

  See CREATE_CREDENTIAL Procedure for more information.

  See Specifying Scheduler Job Credentials for more information.

- Invoke `UTL_HTTP.SET_CREDENTIAL` procedure:

  ```
  DECLARE
        l_http_request  UTL_HTTP.REQ;
      BEGIN
        l_http_request := UTL_HTTP.BEGIN_REQUEST('https://www.example.com/v1/
  dwcsdev/NAME/dwcs_small_xt1.csv');
        UTL_HTTP.SET_CREDENTIAL (l_http_request, 'HTTP_CRED','BASIC');
        ...
  END;
  ```

  This example first creates a request by invoking the `BEGIN_REQUEST` procedure and sets HTTP authentication information in the HTTP request header by invoking the `SET_CREDENTIAL` procedure. The Web server needs this information to authorize the request. The value `l_http_request` is the HTTP request, `HTTP_CRED` is the credentials name and `BASIC` is the HTTP authentication scheme.

See UTL_HTTP for more information.

See PL/SQL Package Notes for Autonomous Database for information on restrictions for `UTL_HTTP` on Autonomous Database.

Notes for Submitting HTTP Requests with Oracle APEX or Database Actions

When you use Oracle APEX SQL Commands or Database Actions SQL worksheet to run multiple sequential SQL commands, the commands can run in different database sessions that do not save the state of a previous statement. This behavior differs from desktop SQL clients such as SQL*Plus and SQL Developer that maintain a persistent connection to the database.

Oracle APEX SQL Commands and Database Actions SQL worksheet submissions to an Autonomous Database instance are stateless. This means running individual SQL and PL/SQL statements may save state in database memory, for example when you submit a command to use a wallet, but the state might be cleared before you run the next statement.

View the following table for the steps to keep the database memory state between statement executions for SQL commands you submit to Autonomous Database.

SQL Command Tool	Submit Statements as a Block
Database Actions SQL Worksheet	• Select all statements and click **Run Statement** • Select nothing and click **Run as SQL script**
Oracle APEX SQL Commands	APEX SQL Commands only supports running individual statements. When you want to run multiple statements you must wrap the statements in a single PL/SQL anonymous block. To run the block with APEX SQL Commands, click **Run**.

For example, use the following code block to run a `utl_http.request()` command that makes use of a Customer-Managed Wallet:

```
SELECT utl_http.request(url => 'https://api.example.com/', wallet_path =>
'file:path_to_wallet', wallet_password => 'password' ) FROM DUAL";
```

Compare this to running with two consecutive statements that might fail if the `utl_http.set_wallet()` command and the `utl_http.request()` statement run individually, rather than as a single code block:

```
EXEC utl_http.set_wallet('file:WALLET_DIR/wallet.sso', 'password');
SELECT utl_http.request('https://api.example.com/') FROM DUAL;
```

Move Files

Describes how to create directories and copy files to Autonomous Database.

- Creating and Managing Directories on Autonomous Database
- Copy Files Between Object Store and a Directory in Autonomous Database
  Use the procedure `DBMS_CLOUD.PUT_OBJECT` to copy a file from a directory to Object Store. Use the procedure `DBMS_CLOUD.GET_OBJECT` to copy a file from Object Store to a directory.
- Bulk Operations for Files in the Cloud
  The PL/SQL package `DBMS_CLOUD` offers parallel execution support for bulk file upload, download, copy, and transfer activities, which streamlines the user experience and delivers optimal performance for bulk file operations.

Creating and Managing Directories on Autonomous Database

Autonomous Database includes a predefined `data_pump_dir` directory in the database where you can place files. You can also create directories, drop directories, and attach network file systems.

For example you can use the `data_pump_dir` directory for Data Pump import and export operations. To create additional directories use the database `CREATE DIRECTORY` command. Use the database `DROP DIRECTORY` command to drop directories, and use `DBMS_CLOUD.LIST_FILES` to list the contents of a directory. You can attach a Network File System to a directory location in your Autonomous Database with the `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM` procedure.

- Create Directory in Autonomous Database
  To create directories use the database `CREATE DIRECTORY` command. Using `CREATE DIRECTORY` you specify the path as a relative path for the new directory.

- Drop Directory in Autonomous Database
  Use the database `DROP DIRECTORY` command to drop a directory object.
- List Contents of Directory in Autonomous Database
  Use the function `DBMS_CLOUD.LIST_FILES` to list the contents of a directory.
- Access Network File System from Autonomous Database
  You can attach a Network File System to a directory location in your Autonomous Database.
- Load Data from Directories in Autonomous Database
  As an alternative to an object store location URI, you can specify a directory with `DBMS_CLOUD` procedures to load or unload data from files in a local directory, including directories created on attached network file systems.

Create Directory in Autonomous Database

To create directories use the database `CREATE DIRECTORY` command. Using `CREATE DIRECTORY` you specify the path as a relative path for the new directory.

`CREATE DIRECTORY` creates the database directory object and also creates the file system directory if it does not already exist. If the file system directory exists then `CREATE DIRECTORY` only creates the database directory object. For example, the following command creates the database directory named `staging` and creates the file system directory `stage`:

```
CREATE DIRECTORY staging AS 'stage';
```

You can also create subdirectories. For example, the following command creates the database directory object `sales_staging` and the file system directory `stage/sales`:

```
CREATE DIRECTORY sales_staging AS 'stage/sales';
```

When you create subdirectories you do not have to create the initial file system directory. For example, in the previous example if the directory `stage` does not exist then the `CREATE DIRECTORY` command creates both directories `stage` and `stage/sales`.

To add a directory, you must have the `CREATE ANY DIRECTORY` system privilege. The ADMIN user is granted the `CREATE ANY DIRECTORY` system privilege. The ADMIN user can grant `CREATE ANY DIRECTORY` system privilege to other users.

See CREATE DIRECTORY for more information.

Notes:

- `CREATE DIRECTORY` creates the database directory object in the database and also creates the file system directory. For example the directory path could be:

  ```
  /u03/dbfs/7C149E35BB1000A45FD/data/stage
  ```

- You can create a directory in the root file system to see all the files with the following commands:

  ```
  CREATE OR REPLACE DIRECTORY ROOT_DIR AS '';
  ```

  After you create the `ROOT_DIR` directory, use the following command to list all files:

  ```
  SELECT * FROM DBMS_CLOUD.list_files('ROOT_DIR');
  ```

  To run `DBMS_CLOUD.LIST_FILES` with a user other than ADMIN you need to grant read privileges on the directory to that user. See LIST_FILES Function for more information.
- Space in the file system allocated for the directories you create and their contents is part of your storage allocation. See Database Dashboard Overview to view the total space allocated.

Drop Directory in Autonomous Database

Use the database `DROP DIRECTORY` command to drop a directory object.

For example, the following command drops the database directory object `staging`:

```
DROP DIRECTORY staging;
```

The `DROP DIRECTORY` command does not delete files in the directory. If you want to delete the directory and the files in the directory, first use the procedure `DBMS_CLOUD.DELETE_FILE` to delete the files. See DELETE_FILE Procedure for more information.

To drop a directory, you must have the `DROP ANY DIRECTORY` system privilege. The ADMIN user is granted the `DROP ANY DIRECTORY` system privilege. The ADMIN user can grant `DROP ANY DIRECTORY` system privilege to other users.

See DROP DIRECTORY for more information.

Notes:

- You are not allowed to drop the predefined directories: `data_pump_dir` or `sql_tcb_dir`
- If you just want to drop the directory and you do not remove the files in the directory, after you drop the directory you can view all the files in the file system, including any files that were in the directory you dropped, as follows:

  ```
  CREATE OR REPLACE DIRECTORY ROOT_DIR AS '';
  ```

  Then list the contents of `ROOT_DIR` with the following command:

  ```
  SELECT * FROM DBMS_CLOUD.list_files('ROOT_DIR');
  ```

  To run `DBMS_CLOUD.LIST_FILES` with a user other than ADMIN you need to grant read privileges on the directory to that user. See LIST_FILES Function for more information.
- The `DROP DIRECTORY` command does not remove the underlying file system directory. Autonomous Database manages the underlying file system directory; users do not remove the file system directory.

List Contents of Directory in Autonomous Database

Use the function `DBMS_CLOUD.LIST_FILES` to list the contents of a directory.

For example, to list the contents of the `staging` directory, run the following query:

```
SELECT * FROM DBMS_CLOUD.LIST_FILES('STAGING');
```

To run `DBMS_CLOUD.LIST_FILES` with a user other than ADMIN you need to grant read privileges on the directory to that user. See LIST_FILES Function for more information.

Access Network File System from Autonomous Database

You can attach a Network File System to a directory location in your Autonomous Database.

This allows you to load data from Oracle Cloud Infrastructure File Storage in your Virtual Cloud Network (VCN) or from any other Network File System in on-premises data centers. Depending on the version of the Network File System you want to access, both NFSv3 and NFSv4 are supported.

Supporting Network File System allows you to do the following:

- Connect to an Autonomous Database instance from a legacy application and use the file system to load and unload data.
- Analyze data from different sources in an Autonomous Database.
- Secure access to data in an Autonomous Database from the file systems in an on-premises data center or Private Virtual Cloud Networks (VCNs).

Topics

- Attach Network File System to Autonomous Database
  Use `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM` to attach a file system to a directory in your Autonomous Database.
- Detach Network File System from Autonomous Database
  Use the `DBMS_CLOUD_ADMIN.DETACH_FILE_SYSTEM` procedure to detach a file system from a directory in your Autonomous Database.
- Example: Set Up an NFSv4 Server on Oracle Cloud Compute
  Provides an example for setting up an NSFv4 server for use with Autonomous Database.
- DBA_CLOUD_FILE_SYSTEMS View
  The `DBA_CLOUD_FILE_SYSTEMS` view lists information about the network file system attached to a directory location in the database.

Attach Network File System to Autonomous Database

Use `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM` to attach a file system to a directory in your Autonomous Database.

With an attached file system you can load data from any of the following:

- Oracle Cloud Infrastructure File Storage in your Virtual Cloud Network (VCN).

  See How to Attach a File System to your Autonomous Database for details on setting up Oracle Cloud Infrastructure File Storage with Autonomous Database.
- From a Network File System in an on-premises data center. Depending on the version of the Network File System you want to access, both NFSv3 and NFSv4 are supported.

  See Example: Set Up an NFSv4 Server on Oracle Cloud Compute for a configuration example with an NFSv4 Network File System.

> **Note:**
>
> The `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM` procedure can only attach a private File Storage Service when the Autonomous Database instance is on a private endpoint.

To access data in an Autonomous Database from the file systems in an on-premises data center you must set up FastConnect or a Site-to-Site VPN to connect to the on-premises data center. See FastConnect and Site-to-Site VPN for more information.

1. Create a directory or use an existing directory to attach a Network File System in your Autonomous Database. You must have `WRITE` privilege on the directory object on your Autonomous Database instance to attach a file system to a directory location in the database.

   For example, the following command creates the database directory named `FSS_DIR` and creates the file system directory `fss`:

   ```
   CREATE DIRECTORY FSS_DIR AS 'fss';
   ```

   See Create Directory in Autonomous Database for more information.

2. Run `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM` to attach a file system to a directory in your Autonomous Database. To run this procedure, you must be logged in as the ADMIN user or have `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

   - By default `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM` uses NFSv3:

     ```
     BEGIN
        DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM(
         file_system_name      => 'FSS',
         file_system_location  => 'myhost.sub000445.myvcn.oraclevcn.com:/
     results',
         directory_name        => 'FSS_DIR',
         description           => 'Source NFS for sales data'
     );
     END;
     /
     ```

     Optionally you can use the `params` parameter and specify the `nfs_version` with value 3 to specify NFSv3.

   - To use NFSv4, include the `params` parameter with `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM` and specify the `nfs_version` with value 4 to specify NFSv4:

     ```
     BEGIN
        DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM(
         file_system_name      => 'FSS',
         file_system_location  => 'myhost.sub000445.myvcn.oraclevcn.com:/
     results',
         directory_name        => 'FSS_DIR',
         description           => 'Source NFS for sales data',
         params                => JSON_OBJECT('nfs_version' value 4)
     );
     END;
     /
     ```

   These examples attach the network file system specified in the `file_system_name` parameter to the Autonomous Database.

   The `file_system_location` parameter specifies the location of the file system. The value you supply with `file_system_location` consists of a Fully Qualified Domain Name (FQDN) and a file path in the form: *FQDN*:*file_path*.

   For example:

   - FQDN: `myhost.sub000445.myvcn.oraclevcn.com`

     For Oracle Cloud Infrastructure File Storage set the FQDN in **Show Advanced Options** when you create a file system. See Creating File Systems for more information.

   - File Path: `/results`

   The `directory_name` parameter specifies the directory name in the Autonomous Database where you want to attach the file system. This is the directory you created in Step 1, or another directory you previously created.

   The `description` parameter specifies the description for the task.

The `params` parameter is a JSON value that specifies an additional attribute `nfs_version`, whose value can be either 3 or 4 (NFSv3 or NFSv4).

After you attach a file system you can query the `DBA_CLOUD_FILE_SYSTEMS` view to retrieve information about the attached file system.

For example:

```
SELECT file_system_name, file_system_location,
directory_path
   FROM dba_cloud_file_systems
   WHERE file_system_name = 'FSS';
```

This query returns details for the `FSS` file system name.

See DBA_CLOUD_FILE_SYSTEMS View for more information.

With an attached file system you can read and write to files on an attached file system using any PL/SQL API that accepts a directory name. For example, you can use any of the following methods to work with an attached NFS directory:

- The `UTL_FILE` package.
- Data Pump Export and Import utilities.
- The `DBMS_CLOUD` APIs that work with directories such as `DBMS_CLOUD.LIST_FILES` and `DBMS_CLOUD.PUT_OBJECT`.

Example showing a write a file on an attached file system using `UTL_FILE`:

```
DECLARE
  l_file         UTL_FILE.FILE_TYPE;
  l_location     VARCHAR2(100) := 'FSS_DIR';
  l_filename     VARCHAR2(100) := 'test.csv';
BEGIN
  -- Open the file.
  l_file := UTL_FILE.FOPEN(l_location, l_filename, 'w');

  UTL_FILE.PUT(l_file, 'Scott, male, 1000');

  -- Close the file.
  UTL_FILE.FCLOSE(l_file);
END;
/
```

Example showing a read a file on an attached file system using `UTL_FILE`:

```
DECLARE
  l_file         UTL_FILE.FILE_TYPE;
  l_location     VARCHAR2(100) := 'FSS_DIR';
  l_filename     VARCHAR2(100) := 'test.csv';
  l_text         VARCHAR2(32767);
BEGIN
  -- Open the file.
  l_file := UTL_FILE.FOPEN(l_location, l_filename, 'r');

  UTL_FILE.GET_LINE(l_file, l_text, 32767);
```

```
  -- Close the file.
  UTL_FILE.FCLOSE(l_file);
END;
/
```

Example showing list files on an attached file system using `DBMS_CLOUD.LIST_FILES`:

```
SELECT object_name FROM DBMS_CLOUD.LIST_FILES('FSS_DIR');
```

Notes for using `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM`:

- Oracle Cloud Infrastructure File Storage uses NFSv3 to share. See Overview of File Storage for more information.
- If you attach to non-Oracle Cloud Infrastructure File Storage systems, the procedure supports NFSv3 and NFSv4.
- If you have an attached NFS server that uses NFSv3 and the NFS version is updated to NFSv4 in the NFS server, you must run `DBMS_CLOUD_ADMIN.DETACH_FILE_SYSTEM` and then `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM` (using the `params` parameter with `nfs_version` set to 4). This attaches NFS with the matching protocol so that Autonomous Database can access the NFSv4 Server. Without detaching and then reattaching, the NFS server will be inaccessible and you may see an error such as: `"Protocol not supported"`.

See the following for more information:

- UTL_FILE
- LIST_FILES Function
- OCI File Storage Service
- ATTACH_FILE_SYSTEM Procedure

Detach Network File System from Autonomous Database

Use the `DBMS_CLOUD_ADMIN.DETACH_FILE_SYSTEM` procedure to detach a file system from a directory in your Autonomous Database.

> **Note:**
>
> The `DBMS_CLOUD_ADMIN.DETACH_FILE_SYSTEM` procedure can only detach a private File Storage Service from databases that are on private endpoints.

You must have `WRITE` privilege on the directory object to detach a file system from a directory location.

Run `DBMS_CLOUD_ADMIN.DETACH_FILE_SYSTEM` procedure to detach a file system from a directory location in your Autonomous Database. To run this procedure, you must be logged in as the ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD_ADMIN`.

For example:

```
BEGIN
   DBMS_CLOUD_ADMIN.DETACH_FILE_SYSTEM (
    file_system_name      => 'FSS'
```

```
  );
END;
/
```

This example detaches the network file system specified in the `file_system_name` parameter from the Autonomous Database. You must provide a value for this parameter.

The information about this file system is removed from the `DBA_CLOUD_FILE_SYSTEMS` view.

See the following for more information:

- OCI File Storage Service
- Creating and Managing Directories on Autonomous Database
- DETACH_FILE_SYSTEM Procedure

Example: Set Up an NFSv4 Server on Oracle Cloud Compute

Provides an example for setting up an NSFv4 server for use with Autonomous Database.

1. Set up a private endpoint for the Autonomous Database instance.

   See Configuring Network Access with Private Endpoints for more information.

   The following ingress and egress rules need to be set for your VCN's security list so that Autonomous Database and the NFSv4 server can talk to each other

   - Stateful ingress from ALL ports in source CIDR block to TCP port 2049.
   - Stateful egress from TCP ALL ports to port 2049 in destination CIDR block.

2. Set up the NFS server on an Oracle Cloud VM with Oracle Linux 8 in the private subnet, which can connect to the Autonomous Database instance.

```
Compute Instance Image: Oracle-Linux-8.8-2023.09.26-0
$ sudo su -
$ mkdir /exports
$ chown nobody /exports
$ chgrp nobody /exports

# If the VM is using Linux 7, "data" directory may need having the
privilege 777 so that ADB can have access to NFS.
uname -a
chmod 777 /exports/data

$ mkdir /exports/data
$ chown nobody /exports/data
$ chgrp nobody /exports/data

# Either the private IP or the private FQDN can be used in "/etc/exports".
# Both can be found in the information of the autonomous database on the
OCI console.
$ tee -a /etc/exports <<'EOF'
  /exports/data *(rw,insecure)
  /exports/data example.adb.us-phoenix-1.oraclecloud.com(rw,insecure)
  EOF

$ systemctl start nfs-server
$ systemctl enable nfs-server
```

```
# Configure the firewall to allow NFS connections. "public" is the default
zone on Oracle Cloud VM.
$ firewall-cmd --get-default-zone
public

$ firewall-cmd --zone=public --add-service=nfs
$ firewall-cmd --permanent --zone=public --add-service=nfs

$ firewall-cmd --reload

# Display a list of the exported file systems.
$ showmount -e

# Displays all of the current clients and all of the file systems that the
clients have mounted.
$ showmount -a
```

3. Mount the NFSv4 file system with `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM`.

   See Attach Network File System to Autonomous Database for more information.

DBA_CLOUD_FILE_SYSTEMS View

The `DBA_CLOUD_FILE_SYSTEMS` view lists information about the network file system attached to a directory location in the database.

Column	Data Type	Description
`FILE_SYSTEM_NAME`	`VARCHAR2(128)`	File system name
`FILE_SYSTEM_LOCATION`	`VARCHAR2(4000)`	File system location
`DIRECTORY_NAME`	`VARCHAR2(128)`	Attached directory name
`DIRECTORY_PATH`	`VARCHAR2(4000)`	Attached directory path
`NFS_VERSION`	`NUMBER`	The NFS version.
`DESCRIPTION`	`VARCHAR2(4000)`	The value provided for the description parameter when you run `DBMS_CLOUD_ADMIN.ATTACH_FILE_SYSTEM`
`CREATION_TIME`	`TIMESTAMP(6) WITH TIME ZONE`	Creation timestamp
`UPDATE_TIME`	`TIMESTAMP(6) WITH TIME ZONE`	Update timestamp

Load Data from Directories in Autonomous Database

As an alternative to an object store location URI, you can specify a directory with `DBMS_CLOUD` procedures to load or unload data from files in a local directory, including directories created on attached network file systems.

The following procedures support specifying files in a directory with the `file_uri_list` parameter:

- `DBMS_CLOUD.COPY_COLLECTION`
- `DBMS_CLOUD.COPY_DATA`

- DBMS_CLOUD.CREATE_EXTERNAL_TABLE

The following procedures support specifying files in a directory with the partitioning_clause parameter:

- DBMS_CLOUD.CREATE_EXTERNAL_TABLE
- DBMS_CLOUD.CREATE_HYBRID_PART_TABLE

You can specify one directory and one or more file names or use a comma separated list of directories and file names. The format to specify a directory is:'*MY_DIR*:*filename.ext*'. By default the directory name *MY_DIR* is a database object and is case-insensitive. The file name is case sensitive.

When you use the file_uri_list parameter to specify a directory you do not need to include the credential_name parameter, but you need READ object privileges on the directory.

For example, with a call to DBMS_CLOUD.COPY_DATA, use the file_uri_list parameter to specify files in a directory:

```
BEGIN
  DBMS_CLOUD.COPY_DATA(
     table_name => 'HRDATA1',
     file_uri_list => 'HR_DIR:test.csv',
     format => JSON_OBJECT('type' value 'csv')  );
END;
/
```

This example copies the data from test.csv in the local directory HR_DIR to the table HRDATA1.

Regular expressions are not supported when specifying the file names in a directory. You can only use wildcards to specify file names in a directory. The character "*" can be used as the wildcard for multiple characters, and the character "?" can be used as the wildcard for a single character. For example:'*MY_DIR*:*" or '*MY_DIR*:test?'

To specify multiple directories, use a comma separated list of directories: For example:'*MY_DIR1*:*, *MY_DIR2*:test?'

Use double quotes to specify a case-sensitive directory name. For example:'"*my_dir1*":*, "*my_dir2*":Test?'

To include a quote character, use two quotes. For example:'*MY_DIR*:''filename.ext'. This specifies the filename starts with a quote (').

See Attach Network File System to Autonomous Database for information on attaching network file systems.

Notes for Using Directories with DBMS_CLOUD Procedures

Note the following when you use DBMS_CLOUD procedures and specify a directory with the file_uri_list parameter:

- Compression options for files such as GZIP are not supported for directory files. See the compression format option in DBMS_CLOUD Package Format Options for more information.
- Special characters such as colon (:), single quote('), and comma(,) are not supported in the directory name.

Copy Files Between Object Store and a Directory in Autonomous Database

Use the procedure `DBMS_CLOUD.PUT_OBJECT` to copy a file from a directory to Object Store. Use the procedure `DBMS_CLOUD.GET_OBJECT` to copy a file from Object Store to a directory.

For example, to copy a file from Object Store to the `stage` directory, run the following command:

```
BEGIN
   DBMS_CLOUD.GET_OBJECT(
   credential_name => 'DEF_CRED_NAME',
   object_uri => 'https://objectstorage.usphoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/cwallet.sso',
   directory_name => 'STAGE');
END;
/
```

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

To run `DBMS_CLOUD.GET_OBJECT` with a user other than ADMIN you need to grant write privileges on the directory to that user.

To run `DBMS_CLOUD.PUT_OBJECT` with a user other than ADMIN you need to grant read privileges on the directory to that user.

See GET_OBJECT Procedure and Function and PUT_OBJECT Procedure for more information.

Bulk Operations for Files in the Cloud

The PL/SQL package `DBMS_CLOUD` offers parallel execution support for bulk file upload, download, copy, and transfer activities, which streamlines the user experience and delivers optimal performance for bulk file operations.

The package `DBMS_CLOUD` supports loading and unloading files into the following cloud services:

- Oracle Cloud Infrastructure Object Storage
- Azure Blob Storage or Azure Data Lake Storage
- Amazon S3
- Amazon S3-Compatible, including Wasabi Hot Cloud Storage
- Google Cloud Storage

See DBMS_CLOUD Package File URI Formats for more information.

- About Bulk File Operations

- Bulk Copy Files in Cloud Object Storage
  Use the `DBMS_CLOUD.BULK_COPY` procedure to bulk copy files from one Object Store bucket or folder to another bucket or folder.
- Bulk Move Files Across Cloud Object Storage
- Bulk Download Files from Cloud Object Storage
  Use the `DBMS_CLOUD.BULK_DOWNLOAD` procedure to bulk download files from the Cloud Object Store location to the directory object in an Autonomous Database.
- Bulk Upload Files to Cloud Object Storage
  Use the `DBMS_CLOUD.BULK_UPLOAD` procedure to bulk upload files from a directory object in database to a Cloud Object Store location.
- Bulk Delete Files from Cloud Object Storage
  Use the `DBMS_CLOUD.BULK_DELETE` procedure to bulk delete files from Cloud Object Storage.
- Monitor and Troubleshoot Bulk File Loads
  All `DBMS_CLOUD` data load operations are logged in the `dba_load_operations` and `user_load_operations` views.
- Notes for Bulk File Operations
  Provides notes for the credentials you use with bulk file operations.

About Bulk File Operations

`DBMS_CLOUD` bulk file operations support downloading and uploading files on Autonomous Database, including support for copying, moving, and deleting files across Cloud Object Stores, either within the same Object Store provider or between Object Store providers. The bulk file operations support parallelism and provide optimal performance for uploading, downloading, copying, and moving files. Parallelism for bulk file operations is handled by specifying a priority for an operation. The supported priorities are:

- `HIGH`: Use the Autonomous Database instance CPU compute count to determine the number of parallel files processed.
- `MEDIUM`: Use the concurrency limit for Medium service to determine the parallelism.
- `LOW`: Process files in serial order (no concurrency).

Running bulk operations with a higher priority uses more database resources and operations complete faster when parallelism can speed up the operation. A lower priority consumes less database resources and operations take longer to complete when parallelism can speed up the operation. When bulk operations involve small numbers of files that contain little data, specifying higher priority may not change the performance.

To increase parallelism for bulk file operations use `HIGH` priority and increase the number of CPUs assigned to your Autonomous Database instance. The maximum supported concurrent file operations is limited to 64 for bulk file operations.

The default priority is `MEDIUM`, which specifies that bulk file operations use the concurrency limit defined for the MEDIUM consumer group. See Manage Concurrency and Priorities on Autonomous Database for more information.

See DBMS_CLOUD for Bulk File Management for details on using the `format` parameter to specify the `priority` with bulk file operations.

Bulk Copy Files in Cloud Object Storage

Use the `DBMS_CLOUD.BULK_COPY` procedure to bulk copy files from one Object Store bucket or folder to another bucket or folder.

1. Create a credential object to access the source location.

   The source credential name, as specified with the `source_credential_name` parameter is by default also used as the credential for the target location.

   See CREATE_CREDENTIAL Procedure for more information.

2. When the source and target are in distinct Object Stores or have different accounts with the same cloud provider, create a credential to access the target location and include the `target_credential_name` parameter.

3. Run `DBMS_CLOUD.BULK_COPY` procedure to copy files in parallel from one Object Store bucket or folder to another bucket or folder which can be across cloud provider, accounts, and buckets. To run the procedure, you must be logged in as the ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD`.

   ```
   BEGIN
   DBMS_CLOUD.BULK_COPY (
         source_credential_name => 'OCI_CRED',
         source_location_uri    => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname1/o',
         target_location_uri    => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname2/o',
         format                 => JSON_OBJECT ('logretention' value 7,
   'logprefix' value 'BULKOP')
   );
   END;
   /
   ```

   This example bulk copies files from one Oracle Cloud Infrastructure Object Storage bucket to another.

   See BULK_COPY Procedure for more information.

   See DBMS_CLOUD URI Formats for more information.

For example, use `DBMS_CLOUD.BULK_COPY` to copy files from Amazon S3 to Oracle Cloud Infrastructure Object Storage.

```
BEGIN
DBMS_CLOUD.BULK_COPY(
      source_credential_name  => 'AWS_CRED',
      source_location_uri     => 'https://bucketname.s3-us-
west-2.amazonaws.com/',
      target_credential_name  => 'OCI_CRED',
      target_location_uri     => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname2/o',
      format                  =>  JSON_OBJECT ('logretention' value 7,
'logprefix' value 'BULKOP')
);
END;
/
```

Bulk Move Files Across Cloud Object Storage

Use the `DBMS_CLOUD.BULK_MOVE` procedure to bulk move files from one Cloud Object Storage location to another.

The first step in moving files is copying them to the target location. After the files are successfully copied, they are deleted from the source location.

The files are renamed rather than copied if Object Store allows renaming operations between source and target locations.

1. Create a credential object to access the source location.

   The source credential name, as specified with the `source_credential_name` parameter is by default also used as the credential for the target location.

   See CREATE_CREDENTIAL Procedure for more information.

2. When the source and target are in distinct Object Stores or have different accounts with the same cloud provider, create a credential to access the target location and include the `target_credential_name` parameter.

3. Run `DBMS_CLOUD.BULK_MOVE` procedure to bulk move files from one Cloud Object Storage location to another. To run the procedure, you must be logged in as the ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD`.

   ```
   BEGIN
   DBMS_CLOUD.BULK_MOVE (
        source_credential_name => 'OCI_CRED',
        source_location_uri    => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname1/o',
        target_location_uri    => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname2/o',
        format                 => JSON_OBJECT ('logretention' value 7,
   'logprefix' value 'BULKMOVE')
   );
   END;
   /
   ```

   This example bulk moves files from one Oracle Cloud Infrastructure Object Storage location to another.

   See BULK_MOVE Procedure for more information.

   See DBMS_CLOUD URI Formats for more information.

For example, use `DBMS_CLOUD.BULK_MOVE` to move files from Amazon S3 to Oracle Cloud Infrastructure Object Storage.

```
BEGIN
DBMS_CLOUD.BULK_MOVE(
      source_credential_name  => 'AWS_CRED',
      source_location_uri     => 'https://bucketname.s3-us-
west-2.amazonaws.com/',
      target_credential_name  => 'OCI_CRED',
      target_location_uri     => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname2/o',
      format                  =>  JSON_OBJECT ('logretention' value 7,
```

```
'logprefix' value 'BULKOP')
);
END;
/
```

Bulk Download Files from Cloud Object Storage

Use the `DBMS_CLOUD.BULK_DOWNLOAD` procedure to bulk download files from the Cloud Object Store location to the directory object in an Autonomous Database.

1. Create a credential to access your Cloud Object Storage.

   The credential name, is specified with the `credential_name` parameter.

   See CREATE_CREDENTIAL Procedure for more information.

2. Run `DBMS_CLOUD.BULK_DOWNLOAD` procedure to download files into an Autonomous Database directory from Cloud Object Storage. To run the procedure, you must be logged in as the ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD`.

   ```
   BEGIN
   DBMS_CLOUD.BULK_DOWNLOAD (
        credential_name => 'OCI_CRED',
        location_uri    => 'https://objectstorage.us-
   phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o',
        directory_name  => 'BULK_TEST',
        format          => JSON_OBJECT ('logretention' value 7, 'logprefix'
   value 'BULKOP')
    );
   END;
   /
   ```

   This example bulk downloads files from the Oracle Cloud Infrastructure Object Store location URI to the directory object in an Autonomous Database.

   > **Note:**
   >
   > To write the files in the target directory object, you must have the `WRITE` privilege on the directory object.

   See BULK_DOWNLOAD Procedure for more information.

   See DBMS_CLOUD URI Formats for more information.

Bulk Upload Files to Cloud Object Storage

Use the `DBMS_CLOUD.BULK_UPLOAD` procedure to bulk upload files from a directory object in database to a Cloud Object Store location.

1. Create a credential to access your Cloud Object Storage.

   The credential name, is specified with the `credential_name` parameter.

   See CREATE_CREDENTIAL Procedure for more information.

2. Run `DBMS_CLOUD.BULK_UPLOAD` procedure to copy files into Cloud Object Storage from a database directory on your Autonomous Database instance. To run the procedure, you must be logged in as the ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD`.

```
BEGIN
DBMS_CLOUD.BULK_UPLOAD (
     credential_name => 'OCI_CRED',
     location_uri    => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o',
     directory_name  => 'BULK_TEST',
     format          => JSON_OBJECT ('logretention' value 5, 'logprefix'
value 'BULKUPLOAD')
 );
END;
/
```

This example bulk uploads files from a directory object, as specified with the `directory_name` parameter to the Oracle Cloud Infrastructure Object Store location URI.

> **Note:**
>
> To read the source files in the directory object, you must have the `READ` privilege on the directory object.

See BULK_UPLOAD Procedure for more information.

Bulk Delete Files from Cloud Object Storage

Use the `DBMS_CLOUD.BULK_DELETE` procedure to bulk delete files from Cloud Object Storage.

1. Create a credential to access your Cloud Object Storage.

   The credential name, is specified with the `credential_name` parameter.

   The `credential_name` can be `NULL` for public or Pre-authenticated or Pre-signed bucket URI.

   See CREATE_CREDENTIAL Procedure for more information.

2. Run `DBMS_CLOUD.BULK_DELETE` procedure to delete files from the Cloud Object Store. To run the procedure, you must be logged in as the ADMIN user or have the `EXECUTE` privilege on `DBMS_CLOUD`.

```
BEGIN
DBMS_CLOUD.BULK_DELETE (
     credential_name => 'OCI_CRED',
     location_uri    => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o',
     format          => JSON_OBJECT ('logretention' value 5, 'logprefix'
value 'BULKDEL')
);
END;
/
```

This example bulk deletes files from the Oracle Cloud Infrastructure Object Store.

See BULK_DELETE Procedure for more information.

See DBMS_CLOUD URI Formats for more information.

Monitor and Troubleshoot Bulk File Loads

All `DBMS_CLOUD` data load operations are logged in the `dba_load_operations` and `user_load_operations` views.

You can use the following views to monitor and troubleshoot bulk file loads:

- `dba_load_operations`: shows all load operations.
- `user_load_operations`: shows the load operations in your schema.

Query these views to see information about ongoing and completed bulk file operations. For example, the following `SELECT` statement with a `WHERE` clause predicate on the `TYPE` shows `DOWNLOAD` operations:

```
SELECT owner_name, type, status, start_time, update_time, status_table, rows_loaded
   FROM user_load_operations WHERE type = 'DOWNLOAD';

OWNER_NAME TYPE     STATUS    START_TIME               UPDATE_TIME              STATUS_TABLE
ROWS_LOADED
---------- -------- --------- ------------------------ ------------------------ ------------
-----------
"ADMIN"    DOWNLOAD COMPLETED 2022-10-17T20:42:19.498Z 2022-10-17T20:42:21.054Z
DWN$2_STATUS           4
"ADMIN"    DOWNLOAD FAILED    2022-10-17T20:40:54.348Z 2022-10-17T20:40:55.679Z
DWN$1_STATUS
```

The `STATUS_TABLE` column shows the name of the table you can query to look at detailed logging information for the bulk download operation. For example:

```
DESCRIBE DWN$2_STATUS
Name          Null?    Type
------------- -------- ---------------------------
ID            NOT NULL NUMBER
NAME                   VARCHAR2(4000)
BYTES                  NUMBER
CHECKSUM               VARCHAR2(128)
LAST_MODIFIED          TIMESTAMP(6) WITH TIME ZONE
STATUS                 VARCHAR2(30)
ERROR_CODE             NUMBER
ERROR_MESSAGE          VARCHAR2(4000)
START_TIME             TIMESTAMP(6) WITH TIME ZONE
END_TIME               TIMESTAMP(6) WITH TIME ZONE
SID                    NUMBER
SERIAL#                NUMBER
ROWS_LOADED            NUMBER

SELECT id, name, bytes, status, error_message, start_time, end_time FROM
DWN$2_STATUS;
ID NAME       BYTES STATUS    ERROR_MESSAGE START_TIME
```

```
END_TIME
-- ---------- ----- --------- ------------ ------------------------
------------------------
 1 trees.txt     58 COMPLETED               2022-10-17T20:42:19.998Z
2022-10-17T20:42:20.421Z
 2 trees1.txt    58 COMPLETED               2022-10-17T20:42:20.425Z
2022-10-17T20:42:20.533Z
 3 trees2.txt    58 COMPLETED               2022-10-17T20:42:20.535Z
2022-10-17T20:42:20.894Z
 4 trees3.txt    58 COMPLETED               2022-10-17T20:42:20.896Z
2022-10-17T20:42:21.043Z
```

The status table shows each file name and its status for the bulk operation.

The relevant error number and message are recorded in the status table if an operation on a specific file fails.

For completed operations, the time needed for each operation can be calculated using the reported `START_TIME` and `END_TIME` time.

The file operation `STATUS` column can have one of the following values:

File Status	Description
`COMPLETED`	File operation completed successfully.
`FAILED`	File operation failed, a retry may be attempted for two times.
`PENDING`	The file operation has not yet started.
`RUNNING`	File operation is currently in progress.
`SKIPPED`	File operation skipped.

If any file operation fails after two retry attempts, then the bulk operation is marked as failed and an error is raised. For example:

```
ORA-20003: Operation failed, please query table DOWNLOAD$2_STATUS for error details
```

When you use a `DBMS_CLOUD` bulk file operation there are `format` parameter options that control status tables:

- `logretention`: Specifies an integer value that determines the duration in days that the status table is retained. The default value is 2 days.
- `logprefix`: Specifies a string value that determines the bulk operation status table's name prefix.

  Each bulk operation has its own default value for the `logprefix` option:

Procedure	Default Value for `logprefix`
`DBMS_CLOUD.BULK_COPY`	`COPYOBJ`
`DBMS_CLOUD.BULK_DELETE`	`DELETE`
`DBMS_CLOUD.BULK_DOWNLOAD`	`DOWNLOAD`
`DBMS_CLOUD.BULK_MOVE`	`MOVE`
`DBMS_CLOUD.BULK_UPLOAD`	`UPLOAD`

See DELETE_ALL_OPERATIONS Procedure for information on clearing the `user_load_operations` table.

Notes for Bulk File Operations

Provides notes for the credentials you use with bulk file operations.

- You may specify principals as the `credential_name`, `source_credential_name` or `target_credential_name` parameter to access cloud resources securely without storing user credentials. The supported principals are:
  - Oracle Cloud Infrastructure Resource Principals
  - AWS Amazon Resource Names (ARN)s
  - Azure service principal
  - Google Service Account

  See Configure Policies and Roles to Access Resources for more information.
- The `credential_name`, `source_credential_name` or the `target_credential_name` can be `NULL` for public, Pre-authenticated, or Pre-signed bucket URI.

Replicate Data

Describes using Oracle GoldenGate to replicate data between an Autonomous Database instance and to any target database or platform that Oracle GoldenGate supports.

- Use Oracle GoldenGate to Replicate Data to Autonomous Database
  You can replicate data to Autonomous Database using Oracle GoldenGate.

Use Oracle GoldenGate to Replicate Data to Autonomous Database

You can replicate data to Autonomous Database using Oracle GoldenGate.

Oracle GoldenGate Capture for Oracle Autonomous Database supports the following:

- Replication for different use cases: Report Offloading, Active-Active, Cloud to Cloud, and Cloud to on-premise.
- Inter-region and cross-region replication: Replicate data between different Oracle Cloud data centers around the world.
- Replicate between targets: Replicate from an Autonomous Database to any target database or platform that Oracle GoldenGate supports, including to other Oracle Autonomous Database environments.

The following are not available for Always Free Autonomous Databases:

- Supplemental logging
- Oracle GoldenGate Extract

See Supplemental Logging for more information.

See Configure Replicat to Apply to Autonomous Databases for more information.

Exporting Data from Autonomous Database to Object Store or to Other Oracle Databases

To export data from an Autonomous Database, use one of the following methods:

- Export to Cloud Object Store:
  - Use the procedure `DBMS_CLOUD.EXPORT_DATA` to export data to your Cloud Object Store as text, by specifying a query. This export method supports exporting data as CSV, JSON, Parquet, or XML files.

    This export method supports all the Cloud Object Stores supported by Autonomous Database.
  - Use Oracle Data Pump to export data to a directory on your database, and then move the data from the directory to Cloud Object Storage.
  - Use Oracle Data Pump to export the data to Cloud Object Storage directly. This method is only supported with Oracle Cloud Infrastructure Object Storage and Oracle Cloud Infrastructure Object Storage Classic.
  - Use the procedure `DBMS_CLOUD.EXPORT_DATA` to export data to your Cloud Object Store as Oracle Data Pump dump files, by specifying a query. This method is only supported with Oracle Cloud Infrastructure Object Storage and Oracle Cloud Infrastructure Object Storage Classic.
- Export to a directory:
  - Use the procedure `DBMS_CLOUD.EXPORT_DATA` to export data to a directory as text by specifying a query. This export method supports exporting data as CSV, JSON, Parquet, or XML files.
  - Use Oracle Data Pump to export data to a directory.
- Use Oracle GoldenGate Capture for Oracle Autonomous Database.

Topics

- Export Data to Object Store as Text
- Export Data to a Directory
- Move Data with Data Pump Export to an Autonomous Database Directory
  Oracle Data Pump offers very fast bulk data and metadata movement between Autonomous Database and other Oracle databases. To move data from an Autonomous Database to another Oracle database, use Oracle Data Pump to export to a directory on your Autonomous Database.
- Move Data with Data Pump Export to Object Store
  To move data from Autonomous Databases to other Oracle databases you can use Oracle Data Pump. Using this export method you use Oracle Data Pump to directly export data to your object store. This export method is supported with Oracle Cloud Infrastructure Object Storage and Oracle Cloud Infrastructure Object Storage Classic.
- Move Data to Object Store as Oracle Data Pump Files Using EXPORT_DATA
  You can export data to Oracle Data Pump dump files by specifying a query.

- Download Dump Files, Run Data Pump Import, and Clean Up Object Store
  If required, download the dump files from Cloud Object Store and use Oracle Data Pump Import to import the dump file set to the target database. Then perform any required clean up.
- Access Log Files for Data Pump Export
  The log files for Data Pump Export operations are stored in the directory you specify with the data pump `directory` parameter.
- Oracle GoldenGate Capture for Oracle Autonomous Database
  Using Oracle GoldenGate you can capture changes from an Oracle Autonomous Database and replicate to any target database or platform that Oracle GoldenGate supports, including another Oracle Autonomous Database.

Export Data to Object Store as Text

Use `DBMS_CLOUD.EXPORT_DATA` to export data as text from an Autonomous Database to cloud Object Store. The text format export options are CSV, JSON, Parquet, or XML.

See Move Data to Object Store as Oracle Data Pump Files Using EXPORT_DATA for details on exporting to cloud Object Store in Oracle Data Pump dump format.

- Export JSON Data to Cloud Object Storage
  Shows the steps to export table data from your Autonomous Database to Cloud Object Storage as JSON data by specifying a query.
- Export Data as CSV to Cloud Object Storage
  Shows the steps to export table data from your Autonomous Database to Cloud Object Storage as CSV data by specifying a query.
- Export Data as Parquet to Cloud Object Storage
  Shows the steps to export table data from your Autonomous Database to Cloud Object Storage as Parquet data by specifying a query.
- Export Data as XML to Cloud Object Storage
  Shows the steps to export table data from your Autonomous Database to Cloud Object Storage as XML data by specifying a query.
- File Naming for Text Output (CSV, JSON, Parquet, or XML)
  Describes the output file naming using `DBMS_CLOUD.EXPORT_DATA` with CSV, JSON, Parquet, or XML text file output.

Export JSON Data to Cloud Object Storage

Shows the steps to export table data from your Autonomous Database to Cloud Object Storage as JSON data by specifying a query.

This export method supports all the Cloud Object Stores supported by Autonomous Database, and you can use an Oracle Cloud Infrastructure resource principal to access your Oracle Cloud Infrastructure Object Store, Amazon Resource Names (ARNs) to access AWS Simple Storage Service (S3), an Azure service principal to access Azure BLOB storage or Azure Data Lake Storage, or a Google service account to access Google Cloud Platform (GCP) resources.

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.
2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'user1@example.com',
    password => 'password'
  );
END;
/
```

The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Run `DBMS_CLOUD.EXPORT_DATA` and specify the `format` parameter `type` with the value `json` to export the results as JSON files on Cloud Object Storage.

   To generate the JSON output files there are two options for the `file_uri_list` parameter:

   - Set the `file_uri_list` value to the URL for an existing bucket on your Cloud Object Storage.
   - Set the `file_uri_list` value to the URL for an existing bucket on your Cloud Object Storage and include a file name prefix to use when generating the file names for the exported JSON.

   If you do not include the file name prefix in the `file_uri_list`, `DBMS_CLOUD.EXPORT_DATA` supplies a file name prefix. See File Naming for Text Output (CSV, JSON, Parquet, or XML) for details.

   For example, the following shows `DBMS_CLOUD.EXPORT_DATA` with a file name prefix specified in `file_uri_list`:

```
BEGIN
  DBMS_CLOUD.EXPORT_DATA(
    credential_name => 'DEF_CRED_NAME',
    file_uri_list   => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/dept_export',
    query           => 'SELECT * FROM DEPT',
    format          => JSON_OBJECT('type' value 'json'));
END;
/
```

   In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

   When record delimiters include escape characters, such as \r\n or \t, enclose the record delimiters in double quotes. For example, to use the record delimiter `\r\n`, enclose the value in double quotes:`"\r\n"`.

```
BEGIN
  DBMS_CLOUD.EXPORT_DATA(
    credential_name => 'DEF_CRED_NAME',
```

```
    file_uri_list   => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/dept_export',
    query => 'SELECT * FROM DEPT',
    format => JSON_OBJECT('type' value 'json', 'recorddelimiter' value
'"\r\n"' format json));
END;
/
```

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

For detailed information about the parameters, see EXPORT_DATA Procedure.

For detailed information about the available `format` parameters you can use with `DBMS_CLOUD.EXPORT_DATA`, see DBMS_CLOUD Package Format Options for EXPORT_DATA.

Notes for exporting with `DBMS_CLOUD.EXPORT_DATA`:

- The `query` parameter that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- Specify the `format` parameter with the `compression` option to compress the output files.
- Specify the `format` parameter with the `encryption` option to encrypt data while exporting. See Encrypt Data While Exporting to Object Storage for more information.
- When you no longer need the files that you export, use the procedure `DBMS_CLOUD.DELETE_OBJECT` or use native Cloud Object Storage commands to delete the files.

Export Data as CSV to Cloud Object Storage

Shows the steps to export table data from your Autonomous Database to Cloud Object Storage as CSV data by specifying a query.

This export method supports all the Cloud Object Stores supported by Autonomous Database, and you can use an Oracle Cloud Infrastructure resource principal to access your Oracle Cloud Infrastructure Object Store, Amazon Resource Names (ARNs) to access AWS Simple Storage Service (S3), an Azure service principal to access Azure BLOB storage or Azure Data Lake Storage, or a Google service account to access Google Cloud Platform (GCP) resources.

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'user1@example.com',
    password => 'password'
  );
END;
/
```

The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Run `DBMS_CLOUD.EXPORT_DATA` and specify the `format` parameter `type` with the value `csv` to export the results as CSV files on Cloud Object Storage.

   To generate the CSV output files there are two options for the `file_uri_list` parameter:

   - Set the `file_uri_list` value to the URL for an existing bucket on your Cloud Object Storage.
   - Set the `file_uri_list` value to the URL for an existing bucket on your Cloud Object Storage and include a file name prefix to use when generating the file names for the exported CSV files.

   If you do not include the file name prefix in the `file_uri_list`, `DBMS_CLOUD.EXPORT_DATA` supplies a file name prefix. See File Naming for Text Output (CSV, JSON, Parquet, or XML) for details.

   For example, the following shows `DBMS_CLOUD.EXPORT_DATA` with a file name prefix specified in `file_uri_list`:

```
BEGIN
  DBMS_CLOUD.EXPORT_DATA(
    credential_name => 'DEF_CRED_NAME',
    file_uri_list   => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/dept_export',
    query           => 'SELECT * FROM DEPT',
    format          => JSON_OBJECT('type' value 'csv', 'delimiter' value
'|', 'compression' value 'gzip'));
END;
/
```

   In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

   For detailed information about the parameters, see EXPORT_DATA Procedure.

   For detailed information about the available `format` parameters you can use with `DBMS_CLOUD.EXPORT_DATA`, see DBMS_CLOUD Package Format Options for EXPORT_DATA.

Notes for exporting with `DBMS_CLOUD.EXPORT_DATA`:

- The `query` parameter that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- Specify the `format` parameter with the `compression` option to compress the output files.
- Specify the `format` parameter with the `encryption` option to encrypt data while exporting. See Encrypt Data While Exporting to Object Storage for more information.
- When you no longer need the files that you export, use the procedure `DBMS_CLOUD.DELETE_OBJECT` or use native Cloud Object Storage commands to delete the files.

Export Data as Parquet to Cloud Object Storage

Shows the steps to export table data from your Autonomous Database to Cloud Object Storage as Parquet data by specifying a query.

This export method supports all the Cloud Object Stores supported by Autonomous Database, and you can use an Oracle Cloud Infrastructure resource principal to access your Oracle Cloud Infrastructure Object Store, Amazon Resource Names (ARNs) to access AWS Simple Storage Service (S3), an Azure service principal to access Azure BLOB storage or Azure Data Lake Storage, or a Google service account to access Google Cloud Platform (GCP) resources.

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'user1@example.com',
       password => 'password'
     );
   END;
   /
   ```

   The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Run `DBMS_CLOUD.EXPORT_DATA` and specify the `format` parameter `type` with the value `parquet` to export the results as parquet files on Cloud Object Storage.

   To generate the parquet output files there are two options for the `file_uri_list` parameter:

   - Set the `file_uri_list` value to the URL for an existing bucket on your Cloud Object Storage.
   - Set the `file_uri_list` value to the URL for an existing bucket on your Cloud Object Storage and include a file name prefix to use when generating the file names for the exported parquet files.

   If you do not include the file name prefix in the `file_uri_list`, `DBMS_CLOUD.EXPORT_DATA` supplies a file name prefix. See File Naming for Text Output (CSV, JSON, Parquet, or XML) for details.

   For example, the following shows `DBMS_CLOUD.EXPORT_DATA` with a file name prefix specified in `file_uri_list`:

   ```
   BEGIN
     DBMS_CLOUD.EXPORT_DATA(
       credential_name => 'DEF_CRED_NAME',
       file_uri_list   => 'https://objectstorage.us-
   ```

```
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/dept_export',
    query           => 'SELECT * FROM DEPT',
    format          => JSON_OBJECT('type' value 'parquet', 'compression'
value 'snappy'));
END;
/
```

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

For detailed information about the parameters, see EXPORT_DATA Procedure.

For detailed information about the available `format` parameters you can use with `DBMS_CLOUD.EXPORT_DATA`, see DBMS_CLOUD Package Format Options for EXPORT_DATA.

Notes for exporting with `DBMS_CLOUD.EXPORT_DATA`:

- The `query` parameter that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- Specify the `format` parameter with the `compression` option to compress the output files. The default `compression` for `type parquet` is `snappy`.
- When you no longer need the files that you export, use the procedure `DBMS_CLOUD.DELETE_OBJECT` or use native Cloud Object Storage commands to delete the files.
- See DBMS_CLOUD Package Oracle Data Type to Parquet Mapping for details on Oracle Type to Parquet Type mapping.

  The following types are not supported or have limitations on their support for exporting Parquet with `DBMS_CLOUD.EXPORT_DATA`:

Oracle Type	Notes
`BFILE`	Not supported
`BLOB`	Not supported
`DATE`	Supported with the following limitation: `DATE` format supports only date, month and year. Hour, minute and seconds are not supported. See DBMS_CLOUD Package Oracle Data Type to Parquet Mapping for details on NLS format limitations for exporting `DATE` to Parquet.
`INTERVAL DAY TO SECOND`	Supported and is treated as string internally
`INTERVAL YEAR TO MONTH`	Supported and is treated as string internally
`LONG`	Not supported
`LONG RAW`	Not supported

Oracle Type	Notes
NUMBER	Supported with the following limitations: – Can have maximum precision of 38 and scale equal to less than precision. – If no precision and scale is provided for the column NUMBER type, by default precision of 38 and scale of 20 is used. – Negative scale is not supported for NUMBER types.
Object Types	Not supported
TIMESTAMP	Supported with the following limitations: – If there are multiple columns with different precision, highest precision will be taken. – TIMESTAMP WITH TIME ZONE Oracle datatype will use the timestamp only. See DBMS_CLOUD Package Oracle Data Type to Parquet Mapping for details on NLS format limitations for exporting TIMESTAMP to Parquet.

Export Data as XML to Cloud Object Storage

Shows the steps to export table data from your Autonomous Database to Cloud Object Storage as XML data by specifying a query.

This export method supports all the Cloud Object Stores supported by Autonomous Database, and you can use an Oracle Cloud Infrastructure resource principal to access your Oracle Cloud Infrastructure Object Store, Amazon Resource Names (ARNs) to access AWS Simple Storage Service (S3), an Azure service principal to access Azure BLOB storage or Azure Data Lake Storage, or a Google service account to access Google Cloud Platform (GCP) resources.

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Store your Cloud Object Storage credential using DBMS_CLOUD.CREATE_CREDENTIAL.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'user1@example.com',
    password => 'password'
  );
END;
/
```

   The values you provide for username and password depend on the Cloud Object Storage service you are using.

   Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

3. Run DBMS_CLOUD.EXPORT_DATA and specify the format parameter type with the value xml to export the results as XML files on Cloud Object Storage.

To generate the XML output files there are two options for the `file_uri_list` parameter:

- Set the `file_uri_list` value to the URL for an existing bucket on your Cloud Object Storage.
- Set the `file_uri_list` value to the URL for an existing bucket on your Cloud Object Storage and include a file name prefix to use when generating the file names for the exported JSON.

If you do not include the file name prefix in the `file_uri_list`, `DBMS_CLOUD.EXPORT_DATA` supplies a file name prefix. See File Naming for Text Output (CSV, JSON, Parquet, or XML) for details.

For example, the following shows `DBMS_CLOUD.EXPORT_DATA` with a file name prefix specified in `file_uri_list`:

```
BEGIN
  DBMS_CLOUD.EXPORT_DATA(
    credential_name => 'DEF_CRED_NAME',
    file_uri_list   => 'https://objectstorage.us-
phoenix-1.oraclecloud.com/n/namespace-string/b/bucketname/o/dept_export',
    query           => 'SELECT * FROM DEPT',
    format          => JSON_OBJECT('type' value 'xml', 'compression' value
'gzip'));
END;
/
```

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

For detailed information about the parameters, see EXPORT_DATA Procedure.

For detailed information about the available `format` parameters you can use with `DBMS_CLOUD.EXPORT_DATA`, see DBMS_CLOUD Package Format Options for EXPORT_DATA.

Notes for exporting with `DBMS_CLOUD.EXPORT_DATA`:

- The `query` parameter that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- Specify the `format` parameter with the `compression` option to compress the output files.
- Specify the `format` parameter with the `encryption` option to encrypt data while exporting. See Encrypt Data While Exporting to Object Storage for more information.
- When you no longer need the files that you export, use the procedure `DBMS_CLOUD.DELETE_OBJECT` or use native Cloud Object Storage commands to delete the files.

File Naming for Text Output (CSV, JSON, Parquet, or XML)

Describes the output file naming using `DBMS_CLOUD.EXPORT_DATA` with CSV, JSON, Parquet, or XML text file output.

`DBMS_CLOUD.EXPORT_DATA` performs the query specified with the `query` parameter and sends the results to text files either in the Cloud Object Store bucket or to a directory. The output format depends on the `format` parameter `type` you specify (one of CSV, JSON, Parquet, or XML).

To speed up the procedure and to generate the output as fast as possible, `DBMS_CLOUD.EXPORT_DATA` divides its work. This means that, depending on system resources, when you run `DBMS_CLOUD.EXPORT_DATA` the procedure creates multiple output files either in the Cloud Object Store bucket or in the directory.

The format for each generated file is:

[*FileNamePrefix* | *client_info_module_action*]*_sequenceNum_timestamp.format_extension.*[*compression_extension*]

- *FileNamePrefix*: (optional) If a *FileNamePrefix* is supplied, `DBMS_CLOUD.EXPORT_DATA` uses the file name prefix to generate file names for the results. The *FileNamePrefix* is specified using the text supplied after the bucket or directory name in the `file_uri_list` parameter value.

  You cannot provide multiple values for the *FileNamePrefix* in the `file_uri_list`.

- *client_info_module_action*: If a file name prefix is not supplied with the `file_uri_list` parameter, `DBMS_CLOUD.EXPORT_DATA` uses the combination of *client_info*, application *module* and *action* as the file name prefix (when this information is available). The procedure obtains these names from the application information for the database session that runs the query. See DBMS_APPLICATION_INFO for information on *client_info*, *module* name, and *action* name.

  If a file name prefix is not supplied with the `file_uri_list` and the database session attributes are not available, `DBMS_CLOUD.EXPORT_DATA` uses the file name prefix "`data`".

- *sequenceNum*: The sequence number associated with the `DBMS_CLOUD.EXPORT_DATA` query. Depending on the query, the database service, and the number of ECPUs (OCPUs if your database uses OCPUs) there are one or more *sequenceNum*s. Also, depending on the size of the results, there are one or more output files for each *sequenceNum*.

  See Manage Concurrency and Priorities on Autonomous Database for information on database services.

- *timestamp*: Timestamp when the file is uploaded.

- *format_extension*: The default value depends on the `format type` value:

  - CSV format: `.csv`
  - JSON format: `.json`
  - PARQUET format `.parquet`
  - XML format: `.xml`

  For more information, see the description for `format` option `fileextension` in DBMS_CLOUD Package Format Options for EXPORT_DATA.

- *compression_extension*: When you include the `format` parameter with the `compression` option with the value `gzip`, this is "`gz`".

  When the `format type` is `parquet`, the `compression` value `snappy` is also supported and is the default.

For example, the file name prefix in the following `DBMS_CLOUD.EXPORT_DATA` procedure is specified in the `file_uri_list` parameter, as `dept_export`. The example generates the output to the provided Object Store in the specified format.

```
BEGIN
  DBMS_CLOUD.EXPORT_DATA(
    credential_name => 'DEF_CRED_NAME',
```

```
    file_uri_list   => 'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/dept_export',
    query           => 'SELECT * FROM DEPT',
    format          => JSON_OBJECT('type' value 'json'));
END;
/
```

When you specify a file name prefix the generated output files include the file name prefix, similar to the following:

```
dept_export_1_20210809T173033Z.json
dept_export_2_20210809T173034Z.json
dept_export_3_20210809T173041Z.json
dept_export_4_20210809T173035Z.json
```

The number of generated output files depends on the size of the results, the database service, and the number of ECPUs (OCPUs if your database uses OCPUs) in the Autonomous Database instance.

In the following example the `file_uri_list` parameter does not include a file name prefix and the `compression` parameter is supplied, with value `gzip`:

```
BEGIN
  DBMS_CLOUD.EXPORT_DATA(
    credential_name => 'DEF_CRED_NAME',
    file_uri_list   => 'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/',
    query           => 'SELECT * FROM DEPT',
    format          => json_object('type' value 'json', 'compression' value
'gzip'));
END;
/
```

When a file name prefix is not in the `file_uri_list` parameter, `DBMS_CLOUD.EXPORT_DATA` uses a file name prefix of the form: *client_info_module_action*. For this example the generated output files include the file name prefix that `DBMS_CLOUD.EXPORT_DATA` supplies and the files are compressed with gzip and the file extension `.gz` is added, as follows:

```
Client1_Module1_Action1_1_20210809T173033Z.json.gz
Client1_Module1_Action1_2_20210809T173034Z.json.gz
Client1_Module1_Action1_3_20210809T173041Z.json.gz
Client1_Module1_Action1_4_20210809T173035Z.json.gz
```

If the *client_info_module_action* session information is not available when you run `DBMS_CLOUD.EXPORT_DATA`, the file name prefix is set to `data`. For example:

```
data_1_20210809T173033Z.json.gz
data_2_20210809T173034Z.json.gz
data_3_20210809T173041Z.json.gz
data_4_20210809T173035Z.json.gz
```

For example, the file name prefix in the following `DBMS_CLOUD.EXPORT_DATA` procedure is specified in the `file_uri_list` parameter, as `dept_export`. The example generates the output to the provided directory in the specified format.

```
BEGIN
  DBMS_CLOUD.EXPORT_DATA(
    file_uri_list   => 'DATA_PUMP_DIR:sales.json',
    query           => 'SELECT * FROM SALES',
    format          => JSON_OBJECT('type' value 'json'));
END;
/
```

When you specify a file name prefix the generated output file include the file name prefix, similar to the following:

```
sales_1_20230705T124523275915Z.csv
```

Notes for file naming with `DBMS_CLOUD.EXPORT_DATA`:

- `DBMS_CLOUD.EXPORT_DATA` does not create buckets or directories.
- The number of files that `DBMS_CLOUD.EXPORT_DATA` generates is determined by the number of ECPUs (OCPUs if your database uses OCPUs), the database service, and the size of the result data.
- The following applies when providing a directory object name in the `file_uri_list` parameter:
  - The provided directory must exist and you must have `WRITE` access to the directory.
  - The directory name is case-sensitive when enclosed in double quotes.
  - The credential name parameter must not be provided.
- For CSV, JSON, or XML output, by default when a generated file contains 10MB of data a new output file is created. However, if you have less than 10MB of result data you may have multiple output files, depending on the database service and the number of ECPUs (OCPUs if your database uses OCPUs) for the Autonomous Database instance.

  The default output file chunk size is 10MB for CSV, JSON, or XML. You can change this value with the `format` parameter `maxfilesize` option. See DBMS_CLOUD Package Format Options for EXPORT_DATA for more information.
- For Parquet output, each generated file is less than 128MB and multiple output files may be generated. However, if you have less than 128MB of result data, you may have multiple output files depending on the database service and the number of ECPUs (OCPUs if your database uses OCPUs) for the Autonomous Database instance.

  The `format` parameter `maxfilesize` option does not apply for Parquet files.

Export Data to a Directory

Use `DBMS_CLOUD.EXPORT_DATA` to export files to a directory.

The directory you export files to can be in the Autonomous Database file system or an attached Network File System. See Creating and Managing Directories on Autonomous Database for more information.

- Export Data as CSV to a Directory
  Shows the steps to export table data from your Autonomous Database to a directory as CSV data by specifying a query.
- Export Data as JSON a Directory
  Shows the steps to export table data from your Autonomous Database to a directory as JSON data by specifying a query.
- Export Data as Parquet to a Directory
  Shows the steps to export table data from your Autonomous Database to a directory as Parquet data by specifying a query.
- Export Data as XML to a Directory
  Shows the steps to export table data from your Autonomous Database to Directory as XML data by specifying a query.
- Export Data to a Directory as Oracle Data Pump Files
  You can export data to a directory as Oracle Data Pump dump files by specifying a query.

Export Data as CSV to a Directory

Shows the steps to export table data from your Autonomous Database to a directory as CSV data by specifying a query.

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Create a directory.

   For example:

   ```
   CREATE DIRECTORY export_dir AS 'export_dir';
   ```

   See Create Directory in Autonomous Database for more information.

3. Run `DBMS_CLOUD.EXPORT_DATA` and specify the `format` parameter `type` with the value `json` to export the results as CSV files to a directory. Do not include the `credential` parameter when sending output to a directory.

   ```
   BEGIN
    DBMS_CLOUD.EXPORT_DATA(
       file_uri_list => 'export_dir:sales.csv',
       format => JSON_OBJECT('type' value 'csv'),
       query => 'SELECT * FROM sales'
    );
   END;
   /
   ```

   When record delimiters include escape characters, such as \r\n or \t, enclose the record delimiters in double quotes. For example, to use the record delimiter `\r\n`, enclose the value in double quotes:`"\r\n"`.

   ```
   BEGIN
     DBMS_CLOUD.EXPORT_DATA(
       file_uri_list => 'export_dir:sales.csv',
       query => 'SELECT * FROM sales',
       format => JSON_OBJECT('type' value 'json', 'recorddelimiter' value
   ```

```
'"\r\n"' format json));
END;
/
```

The directory name is case-sensitive when the directory name is enclosed in double quotes. For example:

```
BEGIN
 DBMS_CLOUD.EXPORT_DATA(
    file_uri_list => '"export_dir":sales.csv',
    format => JSON_OBJECT('type' value 'csv'),
    query => 'SELECT * FROM sales'
 );
END;
/
```

For detailed information about the parameters, see EXPORT_DATA Procedure.

For detailed information about the available `format` parameters you can use with `DBMS_CLOUD.EXPORT_DATA`, see DBMS_CLOUD Package Format Options for EXPORT_DATA.

The parameters are:

- `file_uri_list`: is a comma delimited list of the export file(s). Use of wildcard and substitution characters is not supported in the `file_uri_list`.
- `format`: specifies the required `type` parameter. The valid values are `datapump`, `json`, `xml`, `csv` and `parquet` and it also optionally defines the options you can specify for the export with the `ORACLE_DATAPUMP` Access Driver.
- `query`: specifies a `SELECT` statement so that only the required data is exported. The query determines the contents of the dump file(s).

> **Note:**
>
> The `DBMS_CLOUD.EXPORT_DATA` procedure creates the dump file(s) that you specify in the `file_uri_list`. The procedure does not overwrite files. If a dump file in the `file_uri_list` exists, `DBMS_CLOUD.EXPORT_DATA` generates another file with a unique name. `DBMS_CLOUD.EXPORT_DATA` does not create directories.

For detailed information about the parameters, see EXPORT_DATA Procedure.

Notes for exporting with `DBMS_CLOUD.EXPORT_DATA`:

- The `query` parameter that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- Specify the `format` parameter with the `compression` option to compress the output files.

Export Data as JSON a Directory

Shows the steps to export table data from your Autonomous Database to a directory as JSON data by specifying a query.

1. Connect to your Autonomous Database instance.

See Connect to Autonomous Database for more information.

2. Create a directory.

   For example:

   ```
   CREATE DIRECTORY export_dir AS 'export_dir';
   ```

   See Create Directory in Autonomous Database for more information.

3. Run `DBMS_CLOUD.EXPORT_DATA` and specify the `format` parameter `type` with the value `json` to export the results as JSON files to a directory. Do not include the `credential` parameter when sending output to a directory.

   ```
   BEGIN
    DBMS_CLOUD.EXPORT_DATA(
       file_uri_list => 'export_dir:sales.dmp',
       format => json_object('type' value 'json'),
       query => 'SELECT * FROM sales'
    );
   END;
   /
   ```

   When record delimiters include escape characters, such as \r\n or \t, enclose the record delimiters in double quotes. For example, to use the record delimiter `\r\n`, enclose the value in double quotes:`"\r\n"`.

   ```
   BEGIN
     DBMS_CLOUD.EXPORT_DATA(
       file_uri_list => 'export_dir:sales.dmp',
       query => 'SELECT * FROM sales',
       format => JSON_OBJECT('type' value 'json', 'recorddelimiter' value
   '"\r\n"' format json));
   END;
   /
   ```

   The directory name is case-sensitive when the directory name is enclosed in double quotes. For example:

   ```
   BEGIN
    DBMS_CLOUD.EXPORT_DATA(
       file_uri_list => '"export_dir":sales.dmp',
       format => json_object('type' value 'json'),
       query => 'SELECT * FROM sales'
    );
   END;
   /
   ```

   For detailed information about the parameters, see EXPORT_DATA Procedure.

   For detailed information about the available `format` parameters you can use with `DBMS_CLOUD.EXPORT_DATA`, see DBMS_CLOUD Package Format Options for EXPORT_DATA.

   The parameters are:

- `file_uri_list`: is a comma delimited list of the export file(s). Use of wildcard and substitution characters is not supported in the `file_uri_list`.
- `format`: specifies the required `type` parameter. The valid values are `datapump`, `json`, `xml`, `csv` and `parquet` and it also optionally defines the options you can specify for the export with the `ORACLE_DATAPUMP` Access Driver.
- `query`: specifies a `SELECT` statement so that only the required data is exported. The query determines the contents of the dump file(s).

> **Note:**
>
> The `DBMS_CLOUD.EXPORT_DATA` procedure creates the dump file(s) that you specify in the `file_uri_list`. The procedure does not overwrite files. If a dump file in the `file_uri_list` exists, `DBMS_CLOUD.EXPORT_DATA` generates another file with a unique name. `DBMS_CLOUD.EXPORT_DATA` does not create directories.

For detailed information about the parameters, see EXPORT_DATA Procedure.

Notes for exporting with `DBMS_CLOUD.EXPORT_DATA`:

- The `query` parameter that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- Specify the `format` parameter with the `compression` option to compress the output files.

Export Data as Parquet to a Directory

Shows the steps to export table data from your Autonomous Database to a directory as Parquet data by specifying a query.

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Create a directory.

   For example:

   ```
   CREATE DIRECTORY export_dir AS 'export_dir';
   ```

   See Create Directory in Autonomous Database for more information.

3. Run `DBMS_CLOUD.EXPORT_DATA` and specify the `format` parameter `type` with the value `json` to export the results as Parquet files to a directory. Do not include the `credential` parameter when sending output to a directory.

   ```
   BEGIN
    DBMS_CLOUD.EXPORT_DATA(
       file_uri_list => 'export_dir:sales.parquet',
       format => JSON_OBJECT('type' value 'parquet'),
       query => 'SELECT * FROM sales'
    );
   END;
   /
   ```

The directory name is case-sensitive when the directory name is enclosed in double quotes. For example:

```
BEGIN
 DBMS_CLOUD.EXPORT_DATA(
    file_uri_list => '"export_dir":sales.parquet',
    format => JSON_OBJECT('type' value 'parquet'),
    query => 'SELECT * FROM sales'
 );
END;
/
```

For detailed information about the parameters, see EXPORT_DATA Procedure.

For detailed information about the available `format` parameters you can use with `DBMS_CLOUD.EXPORT_DATA`, see DBMS_CLOUD Package Format Options for EXPORT_DATA.

The parameters are:

- `file_uri_list`: is a comma delimited list of the export file(s). Use of wildcard and substitution characters is not supported in the `file_uri_list`.
- `format`: specifies the required `type` parameter. The valid values are `datapump`, `json`, `xml`, `csv` and `parquet` and it also optionally defines the options you can specify for the export with the `ORACLE_DATAPUMP` Access Driver.
- `query`: specifies a `SELECT` statement so that only the required data is exported. The query determines the contents of the dump file(s).

For detailed information about the parameters, see EXPORT_DATA Procedure.

Notes for exporting with `DBMS_CLOUD.EXPORT_DATA`:

- The `query` parameter that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- Specify the `format` parameter with the `compression` option to compress the output files.
- See DBMS_CLOUD Package Oracle Data Type to Parquet Mapping for details on Oracle Type to Parquet Type mapping.

  The following types are not supported or have limitations on their support for exporting Parquet with `DBMS_CLOUD.EXPORT_DATA`:

Oracle Type	Notes
`BFILE`	Not supported
`BLOB`	Not supported
`DATE`	Supported with the following limitation: `DATE` format supports only date, month and year. Hour, minute and seconds are not supported. See DBMS_CLOUD Package Oracle Data Type to Parquet Mapping for details on NLS format limitations for exporting `DATE` to Parquet.
`INTERVAL DAY TO SECOND`	Supported and is treated as string internally
`INTERVAL YEAR TO MONTH`	Supported and is treated as string internally
`LONG`	Not supported

Oracle Type	Notes
LONG RAW	Not supported
NUMBER	Supported with the following limitations: – Can have maximum precision of 38 and scale equal to less than precision. – If no precision and scale is provided for the column NUMBER type, by default precision of 38 and scale of 20 is used. – Negative scale is not supported for NUMBER types.
Object Types	Not supported
TIMESTAMP	Supported with the following limitations: – If there are multiple columns with different precision, highest precision will be taken. – TIMESTAMP WITH TIME ZONE Oracle datatype will use the timestamp only. See DBMS_CLOUD Package Oracle Data Type to Parquet Mapping for details on NLS format limitations for exporting TIMESTAMP to Parquet.

Export Data as XML to a Directory

Shows the steps to export table data from your Autonomous Database to Directory as XML data by specifying a query.

1. Connect to your Autonomous Database instance.

   See Connect to Autonomous Database for more information.

2. Create a directory.

   For example:

   ```
   CREATE DIRECTORY export_dir AS 'export_dir';
   ```

   See Create Directory in Autonomous Database for more information.

3. Run DBMS_CLOUD.EXPORT_DATA and specify the format parameter type with the value json to export the results as XML files to a directory. Do not include the credential parameter when sending output to a directory.

   ```
   BEGIN
    DBMS_CLOUD.EXPORT_DATA(
       file_uri_list => 'export_dir:sales.csv',
       format => JSON_OBJECT('type' value 'csv'),
       query => 'SELECT * FROM sales'
    );
   END;
   /
   ```

   The directory name is case-sensitive when the directory name is enclosed in double quotes. For example:

   ```
   BEGIN
    DBMS_CLOUD.EXPORT_DATA(
   ```

```
    file_uri_list => '"export_dir":sales.xml',
    format => JSON_OBJECT('type' value 'xml'),
    query => 'SELECT * FROM sales'
 );
END;
/
```

For detailed information about the parameters, see EXPORT_DATA Procedure.

For detailed information about the available `format` parameters you can use with `DBMS_CLOUD.EXPORT_DATA`, see DBMS_CLOUD Package Format Options for EXPORT_DATA.

The parameters are:

- `file_uri_list`: is a comma delimited list of the export file(s). Use of wildcard and substitution characters is not supported in the `file_uri_list`.
- `format`: specifies the required `type` parameter. The valid values are `datapump`, `json`, `xml`, `csv` and `parquet` and it also optionally defines the options you can specify for the export with the `ORACLE_DATAPUMP` Access Driver.
- `query`: specifies a `SELECT` statement so that only the required data is exported. The query determines the contents of the dump file(s).

> **Note:**
>
> The `DBMS_CLOUD.EXPORT_DATA` procedure creates the dump file(s) that you specify in the `file_uri_list`. The procedure does not overwrite files. If a dump file in the `file_uri_list` exists, `DBMS_CLOUD.EXPORT_DATA` generates another file with a unique name. `DBMS_CLOUD.EXPORT_DATA` does not create directories.

For detailed information about the parameters, see EXPORT_DATA Procedure.

Notes for exporting with `DBMS_CLOUD.EXPORT_DATA`:

- The `query` parameter that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- Specify the `format` parameter with the `compression` option to compress the output files.

Export Data to a Directory as Oracle Data Pump Files

You can export data to a directory as Oracle Data Pump dump files by specifying a query.

With this export method you use the `DBMS_CLOUD.EXPORT_DATA` procedure to specify a query to select the data to export as a dump file to a directory.

1. Connect to your Autonomous Database instance.
2. Create a directory.

   For example:

   ```
   CREATE DIRECTORY export_dir AS 'export_dir';
   ```

   See Create Directory in Autonomous Database for more information.

3. Export data from Autonomous Database to your directory as Oracle Data Pump dump file(s) with `DBMS_CLOUD.EXPORT_DATA` and specify the `format` parameter `type` as `datapump`. For example:

```
BEGIN
 DBMS_CLOUD.EXPORT_DATA(
    file_uri_list => 'export_dir:sales.dmp',
    format => json_object('type' value 'datapump'),
    query => 'SELECT * FROM sales'
 );
END;
/
```

Example to export data as multiple Data Pump files to a directory:

```
BEGIN
 DBMS_CLOUD.EXPORT_DATA(
    file_uri_list => 'export_dir:sales1.dmp, export_dir:sales2.dmp',
    format => json_object('type' value 'datapump'),
    query => 'SELECT * FROM sales'
 );
END;
/
```

The parameters are:

- `file_uri_list`: is a comma delimited list of the export file(s). Use of wildcard and substitution characters is not supported in the `file_uri_list`.
- `format`: specifies the required `type` parameter. The valid values are `datapump`, `json`, `xml`, `csv` and `parquet` and it also optionally defines the options you can specify for the export with the `ORACLE_DATAPUMP` Access Driver.
- `query`: specifies a `SELECT` statement so that only the required data is exported. The query determines the contents of the dump file(s).

> **Note:**
>
> The `DBMS_CLOUD.EXPORT_DATA` procedure creates the dump file(s) that you specify in the `file_uri_list`.

For detailed information about the parameters, see EXPORT_DATA Procedure.

Notes for exporting data with `DBMS_CLOUD.EXPORT_DATA`:

- The provided directory must exist and you must be logged in as the `ADMIN` user or have `WRITE` access to the directory.
- The procedure does not overwrite files. If a dump file in the `file_uri_list` exists, `DBMS_CLOUD.EXPORT_DATA` reports an error such as:

```
ORA-31641: unable to create dump file  "/u02/exports/123.dmp"
ORA-27038: created file already exists
```

- `DBMS_CLOUD.EXPORT_DATA` does not create directories.
- The directory name is case-sensitive when enclosed in double quotes.
- The number of dump files that `DBMS_CLOUD.EXPORT_DATA` generates is determined when the procedure runs. The number of dump files that are generated depends on the number of file names you provide in the `file_uri_list` parameter, as well as on the number of ECPUs available to the instance, the service level, and the size of the data.

  For example, if you use a 2 ECPU Autonomous Database instance or the `low` service, then a single dump file is exported with no parallelism, even if you provide multiple file names. If you use an 8 ECPU Autonomous Database instance with the `medium` or `high` service, then the jobs can run in parallel and multiple dump files are exported if you provide multiple file names.
- The `query` parameter value that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.
- The dump files you create with `DBMS_CLOUD.EXPORT_DATA` cannot be imported using Oracle Data Pump `impdp`. Depending on the database, you can use these files as follows:
  - On an Autonomous Database, you can use the dump files with the `DBMS_CLOUD` procedures that support the `format` parameter `type` with the value '`datapump`'. You can import the dump files using `DBMS_CLOUD.COPY_DATA` or you can call `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` to create an external table.
  - On any other Oracle Database, such as Oracle Database 19c on-premise, you can import the dump files created with the procedure `DBMS_CLOUD.EXPORT_DATA` using the `ORACLE_DATAPUMP` access driver. See Unloading and Loading Data with the ORACLE_DATAPUMP Access Driver for more information.

Move Data with Data Pump Export to an Autonomous Database Directory

Oracle Data Pump offers very fast bulk data and metadata movement between Autonomous Database and other Oracle databases. To move data from an Autonomous Database to another Oracle database, use Oracle Data Pump to export to a directory on your Autonomous Database.

This export method is supported on all of the object stores that Autonomous Database supports:

- Oracle Cloud Infrastructure Object Storage
- Oracle Cloud Infrastructure Object Storage Classic
- Azure Blob Storage or Azure Data Lake Storage
- Amazon S3

> **Note:**
>
> If you are using Oracle Cloud Infrastructure Object Storage or Oracle Cloud Infrastructure Object Storage Classic, then you can use the alternative methods to export directly to object store. See Move Data with Data Pump Export to Object Store and Move Data to Object Store as Oracle Data Pump Files Using EXPORT_DATA for more information.

This export method includes the following steps:

1. Use Data Pump Export to save a dump file set to a directory on your database.

   See Use Data Pump to Create a Dump File Set on Autonomous Database for details.

2. Move the dump file set from the directory on your database to your cloud object store.

   See Move Dump File Set from Autonomous Database to Your Cloud Object Store for details.

3. Download the dump file set from the cloud object store, run Data Pump Import, and then perform any required clean up such as removing the dump file set from your cloud object store.

   See Download Dump Files, Run Data Pump Import, and Clean Up Object Store for details.

Topics

- Use Data Pump to Create a Dump File Set on Autonomous Database
  Shows the steps to export data from your Autonomous Database to a directory with Oracle Data Pump.
- Move Dump File Set from Autonomous Database to Your Cloud Object Store
  To move the dump file set to your Cloud Object Store, upload the files from the database directory to your Cloud Object Store.

Use Data Pump to Create a Dump File Set on Autonomous Database

Shows the steps to export data from your Autonomous Database to a directory with Oracle Data Pump.

Oracle recommends using the latest Oracle Data Pump version for exporting data from Autonomous Database to other Oracle databases, as it contains enhancements and fixes for a better experience. Download the latest version of Oracle Instant Client and download the Tools Package, which includes Oracle Data Pump, for your platform. See the installation instructions on the platform install download page for the installation steps required after you download Oracle Instant Client and the Tools Package. See Oracle Instant Client Downloads for details.

> **Note:**
>
> Database Actions provides a link for Oracle Instant Client. To access this link from Database Actions, under **Downloads**, click **Download Oracle Instant Client**.

1. Run Data Pump Export with the *dumpfile* parameter set, the *filesize* parameter set to less than 5G, and the *directory* parameter set. For example, the following shows how to export a schema named `SALES` in an Autonomous Database named `DB2022ADB` with 16 ECPUs:

```
expdp sales/password@db2022adb_high
directory=data_pump_dir
dumpfile=exp%L.dmp
parallel=4
encryption_pwd_prompt=yes
filesize=1G
logfile=export.log
```

   Notes for Data Pump parameters:

- If during the export with `expdp` you use the `encryption_pwd_prompt=yes` parameter then use `encryption_pwd_prompt=yes` with your import and input the same password at the `impdp` prompt to decrypt the dump files (remember the password you supply with export). The maximum length of the encryption password is 128 bytes.
- The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.

For the best export performance use the `HIGH` database service for your export connection and set the `parallel` parameter to one quarter the number of ECPUs (.25 x **ECPU count**). If you are using OCPU compute model, set the parallel parameter to the number of OCPUs (1 x **OCPU count**). For information on which database service name to connect to run Data Pump Export, see Manage Concurrency and Priorities on Autonomous Database.

After the export is finished you can see the generated dump files by running the following query:

```
SELECT * FROM DBMS_CLOUD.LIST_FILES('DATA_PUMP_DIR');
```

For example, the output from this query shows the generated dump files and the export log file:

```
OBJECT_NAME                    BYTES  CHECKSUM                    CREATED
LAST_MODIFIED
---------------------- ---------- --------- ------------------------------
--------------------
exp01.dmp                      12288               12-NOV-19 06.10.47.0 PM GMT       12-
NOV-19...
exp02.dmp                       8192               12-NOV-19 06.10.48.0 PM GMT       12-
NOV-19...
exp03.dmp                    1171456               12-NOV-19 06.10.48.0 PM GMT       12-
NOV-19...
exp04.dmp                     348160               12-NOV-19 06.10.48.0 PM GMT       12-
NOV-19...
export.log                      1663               12-NOV-19 06.10.50.0 PM GMT       12-
NOV-19...
```

2. Move the dump file set to your cloud object store. See Move Dump File Set from Autonomous Database to Your Cloud Object Store for details.

Notes:

- To perform a full export or to export objects that are owned by other users, you need the `DATAPUMP_CLOUD_EXP` role.
- The `DATA_PUMP_DIR` is the only predefined directory. You can specify a different directory as the *directory* argument if you previously created the directory and you have write privileges on the directory. See Create Directory in Autonomous Database for information on creating directories.
- The API you use to move the dump files to Cloud Object Storage has a maximum file transfer size, so make sure you use a *filesize* argument that is less than or equal to the maximum supported size for your Cloud Object Storage service. See PUT_OBJECT Procedure for the Cloud Object Storage Service file transfer size limits.
- For more information on Oracle Data Pump Export see *Oracle Database Utilities*.

Move Dump File Set from Autonomous Database to Your Cloud Object Store

To move the dump file set to your Cloud Object Store, upload the files from the database directory to your Cloud Object Store.

1. Connect to your database.
2. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

   ```
   BEGIN
     DBMS_CLOUD.CREATE_CREDENTIAL(
       credential_name => 'DEF_CRED_NAME',
       username => 'adb_user@example.com',
       password => 'password'
     );
   END;
   /
   ```

   This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name.

   See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.
3. Move the dump files from the database to your Cloud Object Store by calling `DBMS_CLOUD.PUT_OBJECT`.

   For example:

   ```
   BEGIN
      DBMS_CLOUD.PUT_OBJECT(credential_name => 'DEF_CRED_NAME',
        object_uri => 'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
   namespace-string/b/bucketname/o/exp01.dmp',
        directory_name => 'DATA_PUMP_DIR',
   ```

```
      file_name => 'exp01.dmp');
   DBMS_CLOUD.PUT_OBJECT(credential_name => 'DEF_CRED_NAME',
      object_uri => 'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/exp02.dmp',
      directory_name => 'DATA_PUMP_DIR',
      file_name => 'exp02.dmp');
   DBMS_CLOUD.PUT_OBJECT(credential_name => 'DEF_CRED_NAME',
      object_uri => 'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/exp03.dmp',
      directory_name => 'DATA_PUMP_DIR',
      file_name => 'exp03.dmp');
   DBMS_CLOUD.PUT_OBJECT(credential_name => 'DEF_CRED_NAME',
      object_uri => 'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/exp04.dmp',
      directory_name => 'DATA_PUMP_DIR',
      file_name => 'exp04.dmp');
END;
/
```

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

See PUT_OBJECT Procedure for information on `PUT_OBJECT`.

4. Perform the required steps to use Oracle Data Pump import and clean up. See Download Dump Files, Run Data Pump Import, and Clean Up Object Store for more details.

Move Data with Data Pump Export to Object Store

To move data from Autonomous Databases to other Oracle databases you can use Oracle Data Pump. Using this export method you use Oracle Data Pump to directly export data to your object store. This export method is supported with Oracle Cloud Infrastructure Object Storage and Oracle Cloud Infrastructure Object Storage Classic.

See Move Data with Data Pump Export to an Autonomous Database Directory for details on the alternative export method to use with other supported cloud object stores.

To export data from Autonomous Databases to other Oracle databases, do the following:

1. Use Data Pump Export to export from your database to Object Storage.

   You have two options for setting the credential to access Object Store, depending on your Oracle Data Pump version:

   - Using Oracle Data Pump version 19.9 (or later) use the `CREDENTIAL` parameter to set the credential or set the database property `DEFAULT_CREDENTIAL`, both options are supported. See Use Oracle Data Pump to Export Data to Object Store Using CREDENTIAL Parameter (Version 19.9 or Later) for details.
   - For Oracle Data Pump versions before 19.9 the `CREDENTIAL` parameter is not supported. Use the `DEFAULT_CREDENTIAL` database property to set the credential to use to access your Object Store. See Use Oracle Data Pump to Export Data to Object Store Setting DEFAULT_CREDENTIAL Property for details.

2. Download the dump files from the Object Storage service, run Data Pump Import with the dump files, and perform any required clean up such as removing the dump file set from Object Storage.

See Download Dump Files, Run Data Pump Import, and Clean Up Object Store for details.

Topics

- Use Oracle Data Pump to Export Data to Object Store Using CREDENTIAL Parameter (Version 19.9 or Later)
  Shows the steps to export data from your Autonomous Database to Cloud Object Storage with Oracle Data Pump Export using the `credential` parameter.
- Use Oracle Data Pump to Export Data to Object Store Setting DEFAULT_CREDENTIAL Property
  Shows the steps to export data from your Autonomous Database to Cloud Object Storage with Oracle Data Pump Export and setting the `DEFAULT_CREDENTIAL` property.

Use Oracle Data Pump to Export Data to Object Store Using CREDENTIAL Parameter (Version 19.9 or Later)

Shows the steps to export data from your Autonomous Database to Cloud Object Storage with Oracle Data Pump Export using the `credential` parameter.

Oracle recommends using the latest Oracle Data Pump version for exporting data from Autonomous Database to other Oracle databases, as it contains enhancements and fixes for a better experience. Download the latest version of Oracle Instant Client and download the Tools Package, which includes Oracle Data Pump, for your platform from Oracle Instant Client Downloads. See the installation instructions on the platform install download page for the installation steps required after you download Oracle Instant Client and the Tools Package.

> **Note:**
>
> Database Actions provides a link for Oracle Instant Client. To access this link from Database Actions, under **Downloads**, click **Download Oracle Instant Client**.

If you are using Oracle Data Pump Version 19.9 or later, then you can use the `credential` parameter as shown in these steps. For instructions for using Oracle Data Pump Versions 19.8 and earlier, see Use Oracle Data Pump to Export Data to Object Store Setting DEFAULT_CREDENTIAL Property.

1. Connect to your database.
2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`. For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'user1@example.com',
    password => 'password'
  );
END;
/
```

The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

If you are exporting to Oracle Cloud Infrastructure Object Storage, you can use the Oracle Cloud Infrastructure native URIs or Swift URIs, but the credentials must be auth tokens. See CREATE_CREDENTIAL Procedure for more information.

3. Run Data Pump Export with the `dumpfile` parameter set to the URL for an existing bucket on your Cloud Object Storage, ending with a file name or a file name with a substitution variable, such as `exp%L.dmp`, and with the `credential` parameter set to the name of the credential you created in the previous step. For example:

```
expdp admin/password@db2022adb_high \
     filesize=5GB \
     credential=def_cred_name \
     dumpfile=https://namespace-string.objectstorage.us-ashburn-1.oci.customer-
oci.com/n/namespace-string/b/bucketname/o/exp%L.dmp \
     parallel=16 \
     encryption_pwd_prompt=yes \
     logfile=export.log \
     directory=data_pump_dir
```

Notes for Oracle Data Pump parameters:

- If during the export with `expdp` you used the `encryption_pwd_prompt=yes` parameter then use `encryption_pwd_prompt=yes` and input the same password at the `impdp` prompt that you specified during the export.
- The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.
- If your bucket and data do not reside in a commercial (OC1) realm, where OCI Dedicated Endpoints are not supported, use the following URI format for `dumpfile`:

  `https://objectstorage.region.oraclecloud.com/n/namespace-string/b/bucketname/o/filename`

For `dumpfile`, this example uses the recommended URI format using OCI Dedicated Endpoints for commercial realm (OC1). The *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Object Storage Dedicated Endpoints, Regions and Availability Domains, and Understanding Object Storage Namespaces for more information.
The `credential` parameter cannot be an OCI resource principal, Azure service principal, Amazon Resource Name (ARN), or a Google service account. See Accessing Cloud Resources by Configuring Policies and Roles for more information on resource principal based authentication.

For the best export performance use the `HIGH` database service for your export connection and set the `parallel` parameter to one quarter the number of ECPUs (.25 x **ECPU count**). If you are using OCPU compute model, set the parallel parameter to the number of OCPUs (1 x **OCPU count**).

For information on which database service name to connect to run Data Pump Export, see Database Service Names for Autonomous Database.

For the dump file URL format for different Cloud Object Storage services, see DBMS_CLOUD URI Formats.

This example shows the recommended parameters for exporting from Autonomous Database. For these `expdp` parameters, note the following:

- The maximum `filesize` parameter value is 10000MB for Oracle Cloud Infrastructure Object Storage exports.
- The maximum `filesize` parameter value is 20GB for Oracle Cloud Infrastructure Object Storage Classic exports.
- If the specified `filesize` is too large, the export shows the error message:

  ```
  ORA-17500: ODM err:ODM HTTP Request Entity Too Large
  ```

- The `directory` parameter specifies the directory `data_pump_dir` for the specified log file, `export.log`. See Access Log Files for Data Pump Export for more information.

Oracle Data Pump divides each dump file part into smaller chunks for faster uploads. The Oracle Cloud Infrastructure Object Storage console shows multiple files for each dump file part that you export. The size of the actual dump files will be displayed as zero (0) and its related file chunks as 10mb or less. For example:

```
exp100.dmp
exp100.dmp_aaaaaa
exp101.dmp
exp101.dmp_aaaaaa
```

Downloading the zero byte dump file from the Oracle Cloud Infrastructure console or using the Oracle Cloud Infrastructure CLI will not give you the full dump files. To download the full dump files from the Object Store, use a tool that supports Swift such as curl, and provide your user login and Swift auth token. For example:

```
curl -O -v -X GET -u 'user1@example.com:auth_token' \
   https://swiftobjectstorage.us-ashburn-1.oraclecloud.com/v1/namespace-
string/bucketname/exp100.dmp
```

If you import a file with the `DBMS_CLOUD` procedures that support the `format` parameter `type` with the value '`datapump`', you only need to provide the primary file name. The procedures that support the '`datapump`' format type automatically discover and download the chunks.

When you use `DBMS_CLOUD.DELETE_OBJECT`, the procedure automatically discovers and deletes the chunks when the procedure deletes the primary file.

4. Perform the required steps to use Oracle Data Pump import and clean up.

   See Download Dump Files, Run Data Pump Import, and Clean Up Object Store for details.

> **Note:**
>
> To perform a full export or to export objects that are owned by other users, you need the `DATAPUMP_CLOUD_EXP` role.

For detailed information on Oracle Data Pump Export parameters see *Oracle Database Utilities*.

Use Oracle Data Pump to Export Data to Object Store Setting DEFAULT_CREDENTIAL Property

Shows the steps to export data from your Autonomous Database to Cloud Object Storage with Oracle Data Pump Export and setting the `DEFAULT_CREDENTIAL` property.

Oracle recommends using the latest Oracle Data Pump version for exporting data from Autonomous Database to other Oracle databases, as it contains enhancements and fixes for a better experience. Download the latest version of Oracle Instant Client and download the Tools Package, which includes Oracle Data Pump, for your platform from Oracle Instant Client Downloads. See the installation instructions on the platform install download page for the installation steps required after you download Oracle Instant Client and the Tools Package.

> **Note:**
>
> Database Actions provides a link for Oracle Instant Client. To access this link from Database Actions, under **Downloads**, click **Download Oracle Instant Client**.

1. Connect to your Autonomous Database.
2. Store your Cloud Object Storage credential using `DBMS_CLOUD.CREATE_CREDENTIAL`. For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
    credential_name => 'DEF_CRED_NAME',
    username => 'user1@example.com',
    password => 'password'
  );
END;
/
```

   The values you provide for `username` and `password` depend on the Cloud Object Storage service you are using.

   If you are exporting to Oracle Cloud Infrastructure Object Storage, you can use the Oracle Cloud Infrastructure native URIs or Swift URIs, but the credentials must be auth tokens. See CREATE_CREDENTIAL Procedure for more information.
3. As the ADMIN user, set the credential you defined in step 2 as the default credential for your database. For example:

```
ALTER DATABASE PROPERTY SET DEFAULT_CREDENTIAL = 'ADMIN.DEF_CRED_NAME'
```

   The `DEFAULT_CREDENTIAL` value cannot be an OCI resource principal, Azure service principal, Amazon Resource Name (ARN), or a Google service account. See Configure Policies and Roles to Access Resources for more information on resource principal based authentication.
4. Run Data Pump Export with the `dumpfile` parameter set to the URL for an existing bucket on your Cloud Object Storage (ending with a file name or a file name with a substitution variable, such as `exp%L.dmp`). For example:

```
expdp admin/password@db2022adb_high \
     filesize=5GB \
     dumpfile=default_credential:https://namespace-string.objectstorage.us-
ashburn-1.oci.customer-oci.com/n/namespace-string/b/bucketname/o/exp%L.dmp \
     parallel=16 \
     encryption_pwd_prompt=yes \
     logfile=export.log \
     directory=data_pump_dir
```

Notes for Data Pump parameters:

- If during the export with `expdp` you used the `encryption_pwd_prompt=yes` parameter then use `encryption_pwd_prompt=yes` and input the same password at the `impdp` prompt that you specified during the export.
- The `dumpfile` parameter supports the `%L` and `%l` wildcards in addition to the legacy `%U` and `%u` wildcards. For example, `dumpfile=export%L.dmp`. Use the `%L` or `%l` wildcard for exports from Oracle Database Release 12.2 and higher. This wildcard expands the dumpfile file name into a 3-digit to 10-digit, variable-width incrementing integer, starting at 100 and ending at 2147483646.
- If your bucket and data do not reside in a commercial (OC1) realm, where OCI Dedicated Endpoints are not supported, use the following URI format for `dumpfile`:

  ```
  https://objectstorage.region.oraclecloud.com/n/namespace-string/b/
  bucketname/o/filename
  ```

For `dumpfile`, this example uses the recommended URI format using OCI Dedicated Endpoints for commercial realm (OC1). The *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Object Storage Dedicated Endpoints, Regions and Availability Domains, and Understanding Object Storage Namespaces for more information.
The `default_credential` keyword in the `dumpfile` parameter is required.

For the best export performance use the `HIGH` database service for your export connection and set the `parallel` parameter to one quarter the number of ECPUs (.25 x **ECPU count**). If you are using OCPU compute model, set the parallel parameter to the number of OCPUs (1 x **OCPU count**).

For information on which database service name to connect to run Data Pump Export, see Manage Concurrency and Priorities on Autonomous Database.

For the dump file URL format for different Cloud Object Storage services, see DBMS_CLOUD URI Formats.

This example shows the recommended parameters for exporting from Autonomous Database. For these `expdp` parameters, note the following:

- The maximum `filesize` parameter value is 10000MB for Oracle Cloud Infrastructure Object Storage exports.
- The maximum `filesize` parameter value is 20GB for Oracle Cloud Infrastructure Object Storage Classic exports.
- If the specified `filesize` is too large, the export shows the error message:

  ```
  ORA-17500: ODM err:ODM HTTP Request Entity Too Large
  ```

- The `directory` parameter specifies the directory `data_pump_dir` for the specified log file, `export.log`. See Access Log Files for Data Pump Export for more information.

Oracle Data Pump divides each dump file part into smaller chunks for faster uploads. The Oracle Cloud Infrastructure Object Storage console shows multiple files for each dump file part that you export. The size of the actual dump files will be displayed as zero (0) and its related file chunks as 10mb or less. For example:

```
exp100.dmp
exp100.dmp_aaaaaa
exp101.dmp
exp101.dmp_aaaaaa
```

Downloading the zero byte dump file from the Oracle Cloud Infrastructure console or using the Oracle Cloud Infrastructure CLI will not give you the full dump files. To download the full dump files from the Object Store, use a tool that supports Swift such as curl, and provide your user login and Swift auth token. For example:

```
curl -O -v -X GET -u 'user1@example.com:auth_token' \
   https://swiftobjectstorage.us-ashburn-1.oraclecloud.com/v1/namespace-
string/bucketname/exp100.dmp
```

If you import a file with the `DBMS_CLOUD` procedures that support the `format` parameter `type` with the value '`datapump`', you only need to provide the primary file name. The procedures that support the '`datapump`' format type automatically discover and download the chunks.

When you use `DBMS_CLOUD.DELETE_OBJECT`, the procedure automatically discovers and deletes the chunks when the procedure deletes the primary file.

5. Perform the required steps to use Oracle Data Pump import and clean up.

   See Download Dump Files, Run Data Pump Import, and Clean Up Object Store for details.

> **Note:**
>
> To perform a full export or to export objects that are owned by other users, you need the `DATAPUMP_CLOUD_EXP` role.

For detailed information on Oracle Data Pump Export parameters see *Oracle Database Utilities*.

Move Data to Object Store as Oracle Data Pump Files Using EXPORT_DATA

You can export data to Oracle Data Pump dump files by specifying a query.

With this export method you use the `DBMS_CLOUD.EXPORT_DATA` procedure to specify a query to select the data to export, as follows:

1. Connect to your database.
2. Store your object store credentials using the procedure `DBMS_CLOUD.CREATE_CREDENTIAL`.

   For example:

```
BEGIN
  DBMS_CLOUD.CREATE_CREDENTIAL(
```

```
    credential_name => 'DEF_CRED_NAME',
    username => 'adb_user@example.com',
    password => 'password'
  );
END;
/
```

Creating a credential to access Oracle Cloud Infrastructure Object Store is not required if you enable resource principal credentials. See Use Resource Principal to Access Oracle Cloud Infrastructure Resources for more information.

This operation stores the credentials in the database in an encrypted format. You can use any name for the credential name. Note that this step is required only once unless your object store credentials change. Once you store the credentials you can then use the same credential name.

See CREATE_CREDENTIAL Procedure for information about the `username` and `password` parameters for different object storage services.

3. Export data from Autonomous Database to your Cloud Object Store as Oracle Data Pump dump file(s) by calling `DBMS_CLOUD.EXPORT_DATA` with the `format` parameter `type` set to value `datapump`. For example:

```
BEGIN
 DBMS_CLOUD.EXPORT_DATA(
    credential_name =>'DEF_CRED_NAME',
    file_uri_list =>'https://objectstorage.us-phoenix-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/exp01.dmp',
    format => json_object('type' value 'datapump'),
    query => 'SELECT warehouse_id, quantity FROM inventories'
 );
END;
/
```

The parameters are:

- `credential_name`: is the name of the credential created in the previous step.
- `file_uri_list`: is a comma delimited list of the export file(s). Use of wildcard and substitution characters is not supported in the `file_uri_list`.
- `format`: specifies the required `type` parameter with the value `datapump`, and optionally defines the options you can specify for the export with the `ORACLE_DATAPUMP` Access Driver.
- `query`: specifies a `SELECT` statement so that only the required data is exported. The query determines the contents of the dump file(s).

In this example, *`namespace-string`* is the Oracle Cloud Infrastructure object storage namespace and *`bucketname`* is the bucket name. See Understanding Object Storage Namespaces for more information.

> **Note:**
>
> The `DBMS_CLOUD.EXPORT_DATA` procedure creates the dump file(s) that you specify in the `file_uri_list`. The procedure does not overwrite files. If a dump file in the `file_uri_list` exists, `DBMS_CLOUD.EXPORT_DATA` reports an error. `DBMS_CLOUD.EXPORT_DATA` does not create buckets.

For detailed information about the parameters, see EXPORT_DATA Procedure.

4. Perform the required steps to use Oracle Data Pump import and clean up. See Download Dump Files, Run Data Pump Import, and Clean Up Object Store for more details.

Notes for exporting data with `DBMS_CLOUD.EXPORT_DATA`:

- The dump files you create with `DBMS_CLOUD.EXPORT_DATA` cannot be imported using Oracle Data Pump `impdp`. Depending on the database, you can use these files as follows:
  - On an Autonomous Database, you can use the dump files with the `DBMS_CLOUD` procedures that support the `format` parameter `type` with the value '`datapump`'. You can import the dump files using `DBMS_CLOUD.COPY_DATA` or you can call `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` to create an external table.
  - On any other Oracle Database, such as Oracle Database 19c on-premise, you can import the dump files created with the procedure `DBMS_CLOUD.EXPORT_DATA` using the `ORACLE_DATAPUMP` access driver. See Unloading and Loading Data with the ORACLE_DATAPUMP Access Driver for more information.
- The number of dump files that `DBMS_CLOUD.EXPORT_DATA` generates is determined when the procedure runs. The number of dump files that are generated depends on the number of file names you provide in the `file_uri_list` parameter, as well as on the number of ECPUs available to the instance, the service level, and the size of the data.

  For example, if you use a 2 ECPU Autonomous Database instance or the `low` service, then a single dump file is exported with no parallelism, even if you provide multiple file names. If you use an 8 ECPU Autonomous Database instance with the `medium` or `high` service, then the jobs can run in parallel and multiple dump files are exported if you provide multiple file names.
- The `query` parameter value that you supply can be an advanced query, if required, such as a query that includes joins or subqueries.

Download Dump Files, Run Data Pump Import, and Clean Up Object Store

If required, download the dump files from Cloud Object Store and use Oracle Data Pump Import to import the dump file set to the target database. Then perform any required clean up.

1. Download the dump files from Cloud Object Store.

> **Note:**
>
> This step is not needed if you are importing the data to an Autonomous Data Warehouse database, to an Autonomous Transaction Processing database, or to Autonomous JSON Database.

If you export directly to Object Store using Oracle Data Pump, as shown in Move Data with Data Pump Export to Object Store, then the dump files on Object Store show size 0. Oracle Data Pump divides each dump file part into smaller chunks for faster uploads. The Oracle Cloud Infrastructure Object Storage console shows multiple files for each dump file part that you export. The size of the actual dump files will be displayed as zero (0) and its related file chunks as 10mb or less. For example:

```
exp01.dmp
exp01.dmp_aaaaaa
exp02.dmp
exp02.dmp_aaaaaa
```

Downloading the zero byte dump file from the Oracle Cloud Infrastructure console or using the Oracle Cloud Infrastructure CLI will not give you the full dump files. To download the full dump files from the Object Store, use a tool that supports Swift such as curl, and provide your user login and Swift auth token.

```
curl -O -v -X GET -u 'user1@example.com:auth_token' \
   https://swiftobjectstorage.us-ashburn-1.oraclecloud.com/v1/namespace-
string/bucketname/exp01.dmp
```

The cURL command does not support wildcards or substitution characters in its URL. You need to use multiple cURL commands to download the dump file set from your Object Store. Alternatively, you can use a script that supports substitution characters to download all the dump files from your Object Store in a single command. See How To: Download all files from an export to object store job in Autonomous Database using cURL for an example.

2. Run Data Pump Import to import the dump file set to the target database.

   If you are importing the data to another Autonomous Database, see Import Data Using Oracle Data Pump on Autonomous Database.

3. Perform post import clean up tasks. If you are done importing the dump files to your target database then drop the bucket containing the data or remove the dump files from the Cloud Object Store bucket, and remove the dump files from the location where you downloaded the dump files to run Data Pump Import.

For detailed information on Oracle Data Pump Import parameters see *Oracle Database Utilities*.

Access Log Files for Data Pump Export

The log files for Data Pump Export operations are stored in the directory you specify with the data pump `directory` parameter.

To access the log file you need to move the log file to your Cloud Object Storage using the procedure `DBMS_CLOUD.PUT_OBJECT`. For example, the following PL/SQL block moves the file `export.log` to your Cloud Object Storage:

```
BEGIN
  DBMS_CLOUD.PUT_OBJECT(
    credential_name => 'DEF_CRED_NAME',
    object_uri => 'https://objectstorage.us-ashburn-1.oraclecloud.com/n/
namespace-string/b/bucketname/o/import.log',
    directory_name  => 'DATA_PUMP_DIR',
```

```
    file_name => 'export.log');
END;
/
```

In this example, *namespace-string* is the Oracle Cloud Infrastructure object storage namespace and *bucketname* is the bucket name. See Understanding Object Storage Namespaces for more information.

See PUT_OBJECT Procedure for more information.

Oracle GoldenGate Capture for Oracle Autonomous Database

Using Oracle GoldenGate you can capture changes from an Oracle Autonomous Database and replicate to any target database or platform that Oracle GoldenGate supports, including another Oracle Autonomous Database.

Oracle GoldenGate Capture for Oracle Autonomous Database supports the following:

- Replication for different use cases: Report Offloading, Active-Active, Cloud to Cloud, and Cloud to on-premise.
- Inter-region and cross-region replication: Replicate data between different Oracle Cloud data centers around the world
- Replicate between targets: Replicate from an Autonomous Database to any target database or platform that Oracle GoldenGate supports, including to other Oracle Autonomous Database environments.

See Configure Replicat to Apply to an Autonomous Databases for more information.

Data Sharing

Share data on Autonomous Database

- Use Cloud Links for Read Only Data Access on Autonomous Database
  Cloud Links provide a cloud-based method to remotely access read only data on an Autonomous Database instance.
- Use Table Hyperlinks for Read Only Data Access on Autonomous Database
  You can generate and manage Table Hyperlinks to access data on Autonomous Database.
- Share Data with Data Studio
  The Data Share tool enables you to share data and metadata with other users. The Data Share page displays information about the different types of shares available in the Oracle Autonomous Database.

Use Cloud Links for Read Only Data Access on Autonomous Database

Cloud Links provide a cloud-based method to remotely access read only data on an Autonomous Database instance.

- About Cloud Links on Autonomous Database
  With Cloud Links a data owner registers a table or view for remote access for a selected audience as defined by the data owner, and the data is then accessible to those with access granted at registration time. No further actions are required to set up Cloud Links and whoever is supposed to see and access your data is able to discover and work with the data.

- Grant Cloud Links Access for Database Users
  The ADMIN user grants privileges to database users to register data sets. The ADMIN user also grants privileges to database users to access registered data sets.
- Register a Data Set
  Describes the options and steps to register a table or view you own as a registered data set to share with Cloud Links.
- Find Data Sets and Use Cloud Links
  A user who is granted access to read Cloud Links can search for data sets available to an Autonomous Database instance and can access and use registered data sets with their queries.
- Use Cloud Links Consumer Options
  You can set the service name mapping to use to access data from a consumer database and you can enable caching on a data set consumer for the results of a query or for a query fragment that accesses Cloud Link data.
- Monitor and View Cloud Links Information
  Autonomous Database provides views that allow you to monitor and audit Cloud Links.
- Define a Virtual Private Database Policy to Secure a Registered Data Set
- Notes for Cloud Links
  Provides notes and restrictions for using Cloud Links.

About Cloud Links on Autonomous Database

With Cloud Links a data owner registers a table or view for remote access for a selected audience as defined by the data owner, and the data is then accessible to those with access granted at registration time. No further actions are required to set up Cloud Links and whoever is supposed to see and access your data is able to discover and work with the data.

The Cloud Links implementation leverages Oracle Cloud Infrastructure access mechanisms to make data accessible within a specific scope. Scope indicates who can remotely access the data. Scope can be set to various levels, including to the region where the database resides, to individual tenancies, or to compartments. In addition, you can specify that authorization to access a data set is limited to one or more Autonomous Database instances.

By creating one or more cross-region refreshable clones from the source (data set owner's) Autonomous Database instance, you can use Cloud Links to share data across multiple regions.

Cloud Links greatly simplify the sharing of tables or views across Autonomous Database instances, as compared to traditional database linking mechanisms. With Cloud Links you can discover data without requiring a complex database link setup. Autonomous Database provides transparent access using SQL, and implements privilege enforcement with the Cloud Links scope and by granting authorization to individual Autonomous Database instances.

Cloud Links introduce the concepts of regional namespaces and names for data that is made remotely accessible. This is similar to existing Oracle tables where there is a table, for example `"EMP"` that resides in a namespace (schema), for example `"LWARD"`. There can only be one `LWARD.EMP` in your database. Cloud Links provide a similar namespace and name on a regional level, that is not tied to a single database but applies across many Autonomous Database instances as specified with the scope and optionally with database authorization.

For example, you can register a data set under the namespace `FOREST` and for security purposes or for naming convenience, you can provide a namespace and a name other than the original schema and object names. In this example, `TREE_DATA` is the visible name of the registered data set and this name is not required to be the name of the source table. In

addition to the namespace and the name, the `cloud$link` keyword indicates to the database that it must resolve the source as a Cloud Link.

To access a registered data set, include the namespace, the name, and the `cloud$link` keyword in the `FROM` clause of a `SELECT` statement:

```
SELECT county, species, height FROM FOREST.TREE_DATA@cloud$link;
```

Optionally, you can specify that access to a data set from one or more databases is offloaded to a refreshable clone. When a consumer Autonomous Database is listed in a data set's offload list, access to the data set is directed to the refreshable clone.

> **Note:**
>
> Cloud Links provide read only access to remote objects on an Autonomous Database instance. If you want to use database links with other Oracle databases or with non-Oracle databases, or if you want to use your remote data with DML operations, you need to use database links. See Use Database Links with Autonomous Database for more information.

Cloud Links support private and public synonyms. For example, you can define and use a synonym for `FOREST.TREE_DATA@cloud$link`:

```
CREATE SYNONYM S1 for FOREST.TREE_DATA@cloud$link;
SELECT county, species, height FROM S1;

CREATE PUBLIC SYNONYM S2 for FOREST.TREE_DATA@cloud$link;
SELECT * FROM S2;
```

See Overview of Synonyms for more information on synonyms.

Cloud Links Terms

There are several concepts and terms to use when you work with Cloud Links:

- **Registered Data Set (Data Set)**: Identifies a table or view that has been enabled for remote access in an Autonomous Database. A registered data set also indicates who is allowed to access the data set (its scope). Data set registration defines a namespace and a name for use with Cloud Links. After data set registration, these values together specify the Fully Qualified Name (FQN) for remote access, and allow Cloud Links to manage accessibility for the data set.
- **Data Set Owner**: Specify a data set owner to provide a point of contact for questions about a data set.
- **Scope**: Specifies who and from where a user is allowed to access a registered data set. See Data Set Scope, Access Control, and Authorization for more details on scope.
- **OCID** (Oracle Cloud Identifier): Identifies a specific Tenancy, Compartment, or Database. The scope for a registered data set can be expressed in terms of OCIDs. See Resource Identifiers for more information.
- **Data Registration**: With data registration a user makes a table or view available for remote access, subject to the access restrictions imposed by scope, and optionally subject to an additional authorization step. You can allow remote access with Cloud Links on a table or view stored in the database or on data stored in Object Store.

- **Data Discovery**: A registered data set can be discovered using textual queries from the database. The discovery only shows a data set if there is a privilege to access the data set. You can search to find a registered data set by name or by description.
- **Data Describe**: Allows a user to retrieve a description or metadata for a table or view made available as a registered data set.
- **Offload Targets**: Optionally, you can specify one or more offload targets. Offload targets are refreshable clones that provide Cloud Links data sets to specified Autonomous Database instances. By specifying an offload target, you can dedicate an Autonomous Database instance to provide data sets to separate production from development, for performance, to assure security, or for other reasons. See Use Refreshable Clones with Autonomous Database for more information.

Cloud Links Auditing

Any access to a registered data set using Cloud Links is logged for audit purposes. The log includes the tenancy, compartment, or database that accessed the data set, the amount of data accessed, and additional information. The V$CLOUD_LINK_ACCESS_STATS and GV$CLOUD_LINK_ACCESS_STATS Views show audit information.

Data Set Metadata and Audit Views

Each Autonomous Database instance provides views that expose data set metadata and that allow you to monitor and audit data usage. See Monitor and View Cloud Links Information for more information.

- Data Set Scope, Access Control, and Authorization

Data Set Scope, Access Control, and Authorization

Cloud Links leverage Oracle Cloud Infrastructure access mechanisms to make registered data sets accessible, and to protect your data with access restrictions.
Autonomous Database determines the accessibility of registered data sets as follows:

- The ADMIN user specifies a scope for a user that allows the user to register data sets based on the scope provided.
- A user who has been granted privileges to register data sets specifies a scope when they register a data set.
- Optionally, when you register a data set, a user who has been granted authorization privileges can specify that an authorization step required to access a data set. This authorization step is in addition to scope level access authorization.

Data Set Scope

The ADMIN sets a user's scope with `DBMS_CLOUD_LINK_ADMIN.GRANT_REGISTER` to be one of:

- `'MY$REGION'`
- `'MY$TENANCY'`
- `'MY$COMPARTMENT'`

A user's scope is hierarchical, meaning a user who is granted one of these scopes can allow access as follows:

- `MY$REGION`: A user can grant remote data access to other tenancies in the region of the Autonomous Database instance that is registering the data set. This is the least restrictive scope.

- `MY$TENANCY`: A user can grant remote data access to any resource, tenancy, compartment, or database in the tenancy of the Autonomous Database instance that is registering the data set. This scope is more restrictive than `MY$REGION` scope.
- `MY$COMPARTMENT`: A user can grant remote data access to any resource, compartment, or database in the compartment of the Autonomous Database instance that is registering the data set. This is the most restrictive scope you can set for a user with `GRANT_REGISTER`.

Next, the scope you set when you register a data set determines from where users are allowed to access the data set. The `DBMS_CLOUD_LINK.REGISTER scope` is a comma separated list consisting of one or more of the following:

- **Database OCID**: Access to the data set is allowed for the specific Autonomous Database instances identified by OCID.
- **Compartment OCID**: Access to the data set is allowed for databases in the compartments identified by compartment OCID.
- **Tenancy OCID**: Access to the data set is allowed for databases in the tenancies identified by tenancy OCID.
- **Region name**: Access to the data set is allowed for databases in the region identified by the named region. In all cases, Cloud Links access is limited to within a single region and is not cross-region.
- **`MY$COMPARTMENT`**: Access to the data set is allowed for databases in the same compartment as the data set owner.
- **`MY$TENANCY`**: Access to the data set is allowed for databases in the same tenancy as the data set owner.
- **`MY$REGION`**: Access to the data set is allowed for databases in the same region as the data set owner.

The scope values, `MY$REGION`, `MY$TENANCY`, and `MY$COMPARTMENT` are variables that act as convenience macros and resolve to OCIDs.

> **Note:**
>
> The scope you set when you register a data set is only honored when it matches or is more restrictive than the value set with `DBMS_CLOUD_LINK_ADMIN.GRANT_REGISTER`. For example, assume the ADMIN granted the scope `'MY$TENANCY'` with `GRANT_REGISTER`, and the user specifies `'MY$REGION'` when they register a data set with `DBMS_CLOUD_LINK.REGISTER`. In this case they would see an error such as the following:
>
> ```
> ORA-20001: Share privileges are not enabled for current user or it is
> enabled but not for scope MY$REGION
> ```

You can also use an additional access control mechanism based on a `SYS_CONTEXT` value. This mechanism uses the function `DBMS_CLOUD_LINK.GET_DATABASE_ID` that returns an identifier that is available as a `SYS_CONTEXT` value.

When you register a data set with `DBMS_CLOUD_LINK.REGISTER` you can use the `SYS_CONTEXT` value in Oracle Virtual Private Database (VPD) security policies to control database access to further restrict and control what specific data can be accessed by individual Autonomous Database instances.

See Define a Virtual Private Database Policy to Secure a Registered Data Set for more information on using VPD policies.

The database ID value is also available in the V$CLOUD_LINK_ACCESS_STATS and GV$CLOUD_LINK_ACCESS_STATS Views that tracks access statistics and audit information.

See Using Oracle Virtual Private Database to Control Data Access for more information.

Data Set Authorization

When you register a data set, if you have been granted authorization privileges you can specify that database OCID authorization is required to access a data set. To provide database OCID authorization for a data set, use the `DBMS_CLOUD_LINK.GRANT_AUTHORIZATION` procedure to specify the Autonomous Database instances that are authorized to access the data set. Before you run `DBMS_CLOUD_LINK.GRANT_AUTHORIZATION`, the ADMIN must authorize you to run this procedure with `DBMS_CLOUD_LINK_ADMIN.GRANT_AUTHORIZE`.

Data set registration with authorization required specifies database level access for a data set, in addition to the scope access control specified for the data set, as follows:

- Databases that are within the `SCOPE` specified and have been authorized with `DBMS_CLOUD_LINK.GRANT_AUTHORIZATION` can view rows from the data set.
- Any databases that are within the specified `SCOPE` but have not been authorized with `DBMS_CLOUD_LINK.GRANT_AUTHORIZATION` cannot view data set rows. In this case, consumers without authorization see the data set as empty.
- Databases that are not within the `SCOPE` specified see an error when attempting to access the data set.

Grant Cloud Links Access for Database Users

The ADMIN user grants privileges to database users to register data sets. The ADMIN user also grants privileges to database users to access registered data sets.

When the ADMIN user grants register privileges, they provide a scope that specifies the maximum scope that a user can provide when they register a data set (within the scope hierarchy). The valid `scope` values for use with `DBMS_CLOUD_LINK_ADMIN.GRANT_REGISTER` are:

- `'MY$REGION'`
- `'MY$TENANCY'`
- `'MY$COMPARTMENT'`

See Data Set Scope, Access Control, and Authorization for more information.

1. As the ADMIN user, allow a user to register data sets within a specified scope.

```
BEGIN
DBMS_CLOUD_LINK_ADMIN.GRANT_REGISTER(
   username => 'DB_USER1',
   scope    => 'MY$REGION');
END;
/
```

This specifies that the user `DB_USER1`, has privileges to register data sets within a specified scope, `'MY$REGION'`.

A user can query `SYS_CONTEXT('USERENV', 'CLOUD_LINK_REGISTER_ENABLED')` to check if they are enabled for registering data sets.

For example, the following query:

```
SELECT SYS_CONTEXT('USERENV', 'CLOUD_LINK_REGISTER_ENABLED') FROM DUAL;
```

Returns '`YES`' or '`NO`'.

See GRANT_REGISTER Procedure for more information.

2. As the ADMIN user, allow a user to access registered data sets.

```
EXEC DBMS_CLOUD_LINK_ADMIN.GRANT_READ('LWARD');
```

This allows `LWARD` to access registered data sets that are available to the Autonomous Database instance.

A user can query `SYS_CONTEXT('USERENV', 'CLOUD_LINK_READ_ENABLED')` to check if they are enabled for `READ` access to a data set.

For example, the following query:

```
SELECT SYS_CONTEXT('USERENV', 'CLOUD_LINK_READ_ENABLED') FROM DUAL;
```

Returns '`YES`' or '`NO`'.

See GRANT_READ Procedure for more information.

3. During data registration you can set the authorization required parameter to `TRUE`. When authorization required is `TRUE`, the ADMIN user must run `DBMS_CLOUD_LINK_ADMIN.GRANT_AUTHORIZE` to provide authorization to invoke `DBMS_CLOUD_LINK.GRANT_AUTHORIZATION`. Use `DBMS_CLOUD_LINK.GRANT_AUTHORIZATION` to specify authorization details.

   See Register a Data Set with Authorization Required for more information.

4. When the Autonomous Database instance has Database Vault enabled and the table or view to be registered with Cloud Links is protected by a realm, the owner of the table or view must be authorized to the realm as a realm-owner before registration.

```
BEGIN
     DBMS_MACADM.ADD_AUTH_TO_REALM(
           realm_name    => 'myrealm',
           grantee       => 'object_owner',
           auth_option   => dbms_macutl.g_realm_auth_owner);
END;
/
```

If the realm protecting the table or view is a mandatory realm, the Autonomous Database common schema named `C##DATA$SHARE`, which is used internally as the connecting schema, must be authorized to the realm as a realm-participant.

For example:

```
BEGIN
     DBMS_MACADM.ADD_AUTH_TO_REALM(
           realm_name    => 'myrealm',
```

```
            grantee      => 'C##DATA$SHARE',
            auth_option  => dbms_macutl.g_realm_auth_participant);
END;
/
```

See Use Oracle Database Vault with Autonomous Database for more information.

Notes for granting privileges to database users to register data sets:

- To register data sets or see and access remote data sets, you have to have granted the appropriate privilege for either registering with `DBMS_CLOUD_LINK_ADMIN.GRANT_REGISTER` or for reading data sets with `DBMS_CLOUD_LINK_ADMIN.GRANT_READ`.

  This is true for ADMIN user as well; however the ADMIN user can grant privileges to themself.
- The views `DBA_CLOUD_LINK_PRIVS` and `USER_CLOUD_LINK_PRIVS` provide information on user privileges. See Monitor and View Cloud Links Information for more information.
- A user can run the following query to check if they are enabled for authenticating registered, protected data sets:

  ```
  SELECT SYS_CONTEXT('USERENV', 'CLOUD_LINK_AUTH_ENABLED') FROM DUAL;
  ```

- Revoke Cloud Links Access for Database Users
  The ADMIN user can revoke registration to disallow a user from registering data sets for remote access. The ADMIN user can also revoke privileges or database users to access registered data sets.

Revoke Cloud Links Access for Database Users

The ADMIN user can revoke registration to disallow a user from registering data sets for remote access. The ADMIN user can also revoke privileges or database users to access registered data sets.

1. As the ADMIN user, revoke a user's privileges to register data sets.

   For example:

   ```
   EXEC DBMS_CLOUD_LINK_ADMIN.REVOKE_REGISTER('DB_USER1');
   ```

   This revokes the privileges to register data sets for the user, `DB_USER1`.

   Running `DBMS_CLOUD_LINK_ADMIN.REVOKE_REGISTER` does not affect data sets that are already registered. Use `DBMS_CLOUD_LINK.UNREGISTER` to remove access for a registered data set.

   See REVOKE_REGISTER Procedure and UNREGISTER Procedure for more information.
2. As the ADMIN user, revoke access to registered data sets.

   For example:

   ```
   EXEC DBMS_CLOUD_LINK_ADMIN.REVOKE_READ('LWARD');
   ```

   This revokes access to Cloud Links data sets for the user `LWARD`.

   See REVOKE_READ Procedure for more information.

Register a Data Set

Describes the options and steps to register a table or view you own as a registered data set to share with Cloud Links.

- Register or Unregister a Data Set
  You can register a table or view you own as a registered data set. When you want to remove or replace the data set, you need to unregister it. After you register a data set you can changes the values of a data set's attributes.
- Register or Unregister a Data Set in a Different Region
  You can use Cloud Links in multiple regions, where the source region contains the data set's source database and one or more remote regions contain refreshable clones of the source database.
- Register a Data Set with Authorization Required
  Optionally, when you register a data set, in addition to the scope you can specify that database level authorization is required to access a data set.
- Register a Data Set with Offload Targets for Data Set Access
  Optionally, when you register a data set you can offload access to the data set to one or more Autonomous Database instances that are refreshable clones.
- Update Data Set Registration Attributes
  After you register a data set you can update some data set attributes. You cannot update the schema name, schema object, namespace, or name attributes.

Register or Unregister a Data Set

You can register a table or view you own as a registered data set. When you want to remove or replace the data set, you need to unregister it. After you register a data set you can changes the values of a data set's attributes.

Data set registration defines a namespace and a name for use with Cloud Links. After data set registration, these values together specify the Fully Qualified Name (FQN) for remote access, and allow Cloud Links to manage accessibility for the data set.

To register a data set:

1. Obtain grant register privileges from the ADMIN user.

   See Grant Cloud Links Access for Database Users for more information.

2. Register one ore more data sets.

   For example, assuming there is a schema `CLOUDLINK` on your Autonomous Database instance, you can register two objects, `SALES_VIEW_AGG` and `SALES_ALL` and provide different `scope` parameters to determine how the objects are accessed.

```
BEGIN
   DBMS_CLOUD_LINK.REGISTER(
    schema_name    => 'CLOUDLINK',
    schema_object  => 'SALES_VIEW_AGG',
    namespace      => 'REGIONAL_SALES',
    name           => 'SALES_AGG',
    description    => 'Aggregated regional sales information.',
    scope          => 'MY$TENANCY',
    auth_required  =>  FALSE,
    data_set_owner =>  'amit@example.com' );
```

```
END;
/

BEGIN
   DBMS_CLOUD_LINK.REGISTER(
    schema_name    => 'CLOUDLINK',
    schema_object  => 'SALES_ALL',
    namespace      => 'TRUSTED_COMPARTMENT',
    name           => 'SALES',
    description    => 'Trusted Compartment, only accessible within my
compartment. Early sales data.',
    scope          => 'MY$COMPARTMENT',
    auth_required  =>  FALSE,
    data_set_owner =>  'amit@example.com' );
END;
/
```

The parameters are:

- `schema_name`: is the schema name (the object owner).
- `schema_object`: is the object's name. Valid objects are:
  - Tables (including Heap, External or Hybrid)
  - Views
  - Materialized Views
  - Cloud Tables (see Use Cloud Tables to Store Logging and Diagnostic Information for more information.)

> **Note:**
>
> Other objects such as analytic views or synonyms are not supported.

- `namespace`: is the namespace you provide as a name for access with Cloud Links (one part of the Cloud Link FQN).

  A `NULL` value specifies a system-generated `namespace` value, unique to the Autonomous Database instance.
- `name`: is the name you provide for access with Cloud Links (one part of the Cloud Link FQN).
- `description`: Specifies text to describe the data.
- `scope`: Specifies the scope. You can use one of the variables: `MY$REGION`, `MY$TENANCY`, or `MY$COMPARTMENT` or specify one or more OCIDs.

  See Data Set Scope, Access Control, and Authorization for more information.
- `auth_required`: A Boolean value that specifies if database level authorization is required for the data set, in addition to the scope access control. When this is set to `TRUE`, the data set enforces an additional authorization step. See Register a Data Set with Authorization Required for more information.

- `data_set_owner`: Text value specifies information about the individual responsible for the data set or a contact for questions about the data set. For example, you could supply an email address for the data set owner.

See REGISTER Procedure for more information.

For this example, after the registration completes the scope for the two registered objects are different, based on the scope parameter you supplied with `DBMS_CLOUD_LINK.REGISTER`:

- `MY$TENANCY`: Specifies tenancy level scope for `REGIONAL_SALES.SALES_AGG`.
- `MY$COMPARTMENT`: Specifies the more restrictive compartment level scope within the tenancy for `TRUSTED_COMPARTMENT.SALES`.

You can update some of the values for a data set's attributes after you register a data set. See Update Data Set Registration Attributes for more information.

If you want to revoke remote access to a registered data set, unregister the data set.

For example:

```
BEGIN
   DBMS_CLOUD_LINK.UNREGISTER(
    namespace      => 'TRUSTED_COMPARTMENT',
    name           => 'SALES');
END;
/
```

See UNREGISTER Procedure for more information.

- Notes for Registering or Unregistering a Data Set
  Provides notes for registering a data set with `DBMS_CLOUD_LINK.REGISTER` and unregistering a data set with `DBMS_CLOUD_LINK.UNREGISTER`.

Notes for Registering or Unregistering a Data Set

Provides notes for registering a data set with `DBMS_CLOUD_LINK.REGISTER` and unregistering a data set with `DBMS_CLOUD_LINK.UNREGISTER`.

- After you register an object, users may need to wait up to ten (10) minutes to access the object with Cloud Links.
- When you register a data set and you want consumers in a remote regions to access the data set, you must perform additional steps to make the data set available in a remote region. See Register or Unregister a Data Set in a Different Region for more information.
- Use the procedure `DBMS_CLOUD_LINK.UPDATE_REGISTRATION` to change the attributes for an existing data set.

  The wait time for the update to complete can be up to 10 minutes for a registration change to be propagated and accessible through Cloud Links. This delay can impact the accuracy of the data in the both the `DBA_CLOUD_LINK_REGISTRATIONS` and `DBA_CLOUD_LINK_ACCESS` views.
- You can register a table or view that resides in another user's schema when the you have `READ WITH GRANT OPTION` privileges for the table or view.
- Autonomous Database does not perform hierarchical validity checks at registration time and registrations that are outside the scope will never be visible or accessible.

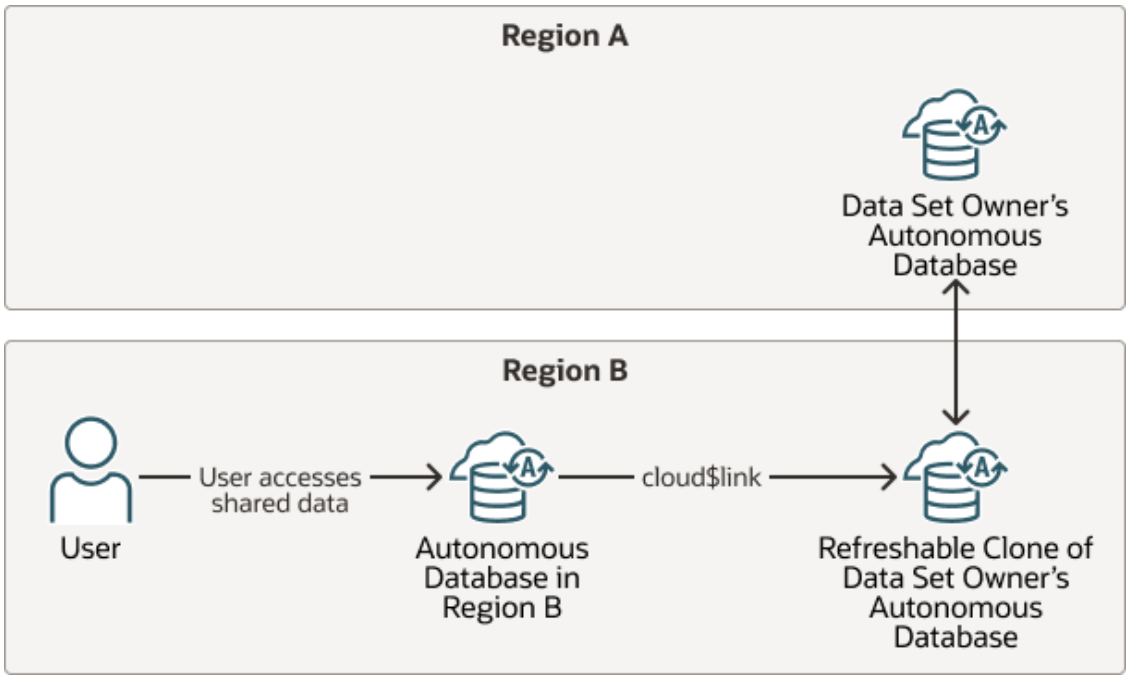
  For example, consider the following sequence:

1. A user with scope `MY$COMPARTMENT` registers an object with a scope that specifies an individual database OCID.
2. When a user requests access to the registered data set, Autonomous Database performs the check to see that the database OCID of the database where the request originates is in the OCID list specified with the `scope` when the data set was registered.
3. After this, the `namespace.name` object will be discoverable, visible, and usable in the database where the request originated.

- `DBMS_CLOUD_LINK.UNREGISTER` may take up to ten (10) minutes to fully propagate, after which the data can longer be accessed remotely.

Register or Unregister a Data Set in a Different Region

You can use Cloud Links in multiple regions, where the source region contains the data set's source database and one or more remote regions contain refreshable clones of the source database.



To use Cloud Links with a data set in a different region:

1. Create a cross-region Refreshable Clone of the source database in a remote region.

   See Create a Cross Tenancy or Cross-Region Refreshable Clone for information on adding a cross-region refreshable clone.

2. On the source database, register the data set.

   See Register or Unregister a Data Set for more information.

3. Refresh the refreshable clone.

   See Refresh a Refreshable Clone on Autonomous Database for more information.

4. On the remote Refreshable Clone register the data set using the same arguments you used to register the data set in the source region.

For example, assuming there is a schema `CLOUDLINK` on your Autonomous Database instance, after you the register `SALES_ALL` on the source database, register `SALES_ALL` on the refreshable clone:

```
BEGIN
   DBMS_CLOUD_LINK.REGISTER(
    schema_name    => 'CLOUDLINK',
    schema_object  => 'SALES_ALL',
    namespace      => 'TRUSTED_COMPARTMENT',
    name           => 'SALES',
    description    => 'Trusted Compartment, only accessible within my
compartment. Early sales data.',
    scope          => 'MY$COMPARTMENT',
    auth_required  =>  FALSE,
    data_set_owner =>  'amit@example.com' );
END;
/
```

The parameters are:

- `schema_name`: is the schema name (the object owner).
- `schema_object`: is the object's name. Valid objects are:
  - Tables (including Heap, External or Hybrid)
  - Views
  - Materialized Views

  > **Note:**
  >
  > Other objects such as analytic views or synonyms are not supported.

- `namespace`: is the namespace you provide as a name for access with Cloud Links (one part of the Cloud Link FQN).

  A `NULL` value specifies a system-generated `namespace` value, unique to the Autonomous Database instance.
- `name`: is the name you provide for access with Cloud Links (one part of the Cloud Link FQN).
- `description`: Specifies text to describe the data.
- `scope`: Specifies the scope. You can use one of the variables: `MY$REGION`, `MY$TENANCY`, or `MY$COMPARTMENT` or specify one or more OCIDs.

  See Data Set Scope, Access Control, and Authorization for more information.
- `auth_required`: A Boolean value that specifies if database level authorization is required for the data set, in addition to the scope access control. When this is set to `TRUE`, the data set enforces an additional authorization step. See Register a Data Set with Authorization Required for more information.
- `data_set_owner`: Text value specifies information about the individual responsible for the data set or a contact for questions about the data set. For example, you could supply an email address for the data set owner.

See REGISTER Procedure for more information.

After the registration completes on the refreshable clone, the scope for the registered object is `MY$COMPARTMENT`: Specifies the more restrictive compartment level scope for my compartment within my tenancy for `TRUSTED_COMPARTMENT.SALES`.

You can unregister a remote data set only in the remote regions, or in both the remote regions and in the source region:

To unregister a data set in a remote region and disable remote access to the data set:

1. On the refreshable clone, unregister the data set.

   For example:

```
BEGIN
   DBMS_CLOUD_LINK.UNREGISTER(
    namespace       => 'TRUSTED_COMPARTMENT',
    name            => 'SALES');
END;
/
```

2. Refresh the refreshable clone.

   See Refresh a Refreshable Clone on Autonomous Database for more information.

To unregister a data set on the source database and unregister the data set on remote region refreshable clones:

1. On the remote refreshable clone if there is only one, or on multiple refreshable clones in remote regions if there are more than one, unregister the data set.

   For example:

```
BEGIN
   DBMS_CLOUD_LINK.UNREGISTER(
    namespace       => 'TRUSTED_COMPARTMENT',
    name            => 'SALES');
END;
/
```

2. On the source database, unregister the data set.

   See Register or Unregister a Data Set for more information.

3. Refresh the refreshable clones.

   See Refresh a Refreshable Clone on Autonomous Database for more information.

- Notes for Registering or Unregistering a Data Set in a Remote Region
  Provides notes for registering a data set in a remote region.

Notes for Registering or Unregistering a Data Set in a Remote Region

Provides notes for registering a data set in a remote region.

- When you register a data set on a refreshable clone in a remote region, the invocation of `DBMS_CLOUD_LINK.REGISTER` on the remote region clone must use the same parameters with the same values as on the source database, with the exception of the `offload_targets` parameter.

  For example, when you run `DBMS_CLOUD_LINK.REGISTER` with scope set to `MY$COMPARTMENT` on the source Autonomous Database instance, run the procedure again on the cross-region refreshable clone with the same scope parameter value (`MY$COMPARTMENT`).

- If you specify the `offload_targets` parameter with `DBMS_CLOUD_LINK.REGISTER` on source, you should omit this parameter when you register the data set on the refreshable clone.
- After you register an object, users may need to wait up to ten (10) minutes to access the object with Cloud Links.
- The following actions require that you refresh the refreshable clone:
  - If you add a VPD policy to the data set in the source, you must refresh the refreshable clone.
  - If you perform a grant or a revoke for the data set on the source database, you must refresh the refreshable clone.

  See Refresh a Refreshable Clone on Autonomous Database for more information.

Register a Data Set with Authorization Required

Optionally, when you register a data set, in addition to the scope you can specify that database level authorization is required to access a data set.

Compared to the previous example where you set `auth_required` to `FALSE`, in this example you set `auth_required` to `TRUE`. When `auth_required` is `TRUE`, additional steps are required to specify one or more databases from which access to the data set is authorized.

> **Note:**
>
> You can only grant authorization, as shown in these steps, if you are authorized. The ADMIN grants authorization privileges with `DBMS_CLOUD_LINK_ADMIN.GRANT_AUTHORIZE`.

1. Use `DBMS_CLOUD_LINK.REGISTER` to register a data with authorization required.

   Assuming there is a schema `CLOUDLINK` on your Autonomous Database instance and you register the object `SALES_VIEW_AGG` and set `auth_required` to `TRUE`, then in addition to defining the scope, you must preform additional steps to determine how the object is accessed.

```
BEGIN
   DBMS_CLOUD_LINK.REGISTER(
    schema_name    => 'CLOUDLINK',
    schema_object  => 'SALES_VIEW_AGG',
    namespace      => 'REGIONAL_SALES',
    name           => 'SALES_AGG',
    description    => 'Aggregated regional sales information.',
    scope          => 'MY$TENANCY',
    auth_required  =>  TRUE,
    data_set_owner =>  'amit@example.com' );
END;
/
```

   The parameters are:

   - `schema_name`: is the schema name (the object owner).
   - `schema_object`: is the object's name. Valid objects are:
     - Tables (including Heap, External or Hybrid)

  - Views
  - Materialized Views

> **Note:**
>
> Other objects such as analytic views or synonyms are not supported.

- `namespace`: is the namespace you provide as a name for access with Cloud Links (one part of the Cloud Link FQN).

  A `NULL` value specifies a system-generated `namespace` value, unique to the Autonomous Database instance.
- `name`: is the name you provide for access with Cloud Links (one part of the Cloud Link FQN).
- `scope`: Specifies the scope. You can use one of the variables: `MY$REGION`, `MY$TENANCY`, or `MY$COMPARTMENT` or specify one or more OCIDs.

  See Data Set Scope, Access Control, and Authorization for more information.
- `auth_required`: A Boolean value that specifies if database level authorization is required for the data set, in addition to the scope access control. When this is set to `TRUE`, the data set enforces an additional authorization step.
- `data_set_owner`: Text value specifies information about the individual responsible for the data set or a contact for questions about the data set. For example, you could supply an email address for the data set owner.

2. Obtain the database ID for the database you want to grant authorization to (to allow the database to access to the data set).

   On the system you want to grant access the data set:

   ```
   SELECT DBMS_CLOUD_LINK.GET_DATABASE_ID FROM DUAL:
   ```

3. Use the database ID you obtained to grant authorization to a specified data set.

   You can only grant authorization, and run `DBMS_CLOUD_LINK.GRANT_AUTHORIZATION`, as shown in this step, if you are authorized. The ADMIN grants authorization with `DBMS_CLOUD_LINK_ADMIN.GRANT_AUTHORIZE`.

   ```
   BEGIN
      DBMS_CLOUD_LINK.GRANT_AUTHORIZATION(
       database_id    => '120xxxxxxx8506029999',
       namespace      => 'TRUSTED_COMPARTMENT',
       name           => 'SALES');
   END;
   /
   ```

   Perform these steps multiple times if you want to authorize additional databases.

You can update the value of the `auth_required` parameter after you register a data set. See Update Data Set Registration Attributes for more information.

If you want to revoke authorization for a database:

```
BEGIN
   DBMS_CLOUD_LINK.REVOKE_AUTHORIZATION(
    database_id    => '120xxxxxxx8506029999',
    namespace      => 'TRUSTED_COMPARTMENT',
    name           => 'SALES');
END;
/
```

See the following for more information:

- REGISTER Procedure
- UPDATE_REGISTRATION Procedure
- GRANT_AUTHORIZE Procedure
- REVOKE_AUTHORIZATION Procedure

Register a Data Set with Offload Targets for Data Set Access

Optionally, when you register a data set you can offload access to the data set to one or more Autonomous Database instances that are refreshable clones.

Use the optional `offload_targets` parameter with `DBMS_CLOUD_LINK.REGISTER` to specify that access is offloaded to refreshable clones. The source database for each refreshable clone is the Autonomous Database instance where you register the data set (data publisher).

The `offload_targets` value is a JSON document that defines one or more `CLOUD_LINK_DATABASE_ID` and `OFFLOAD_TARGET` key value pairs:

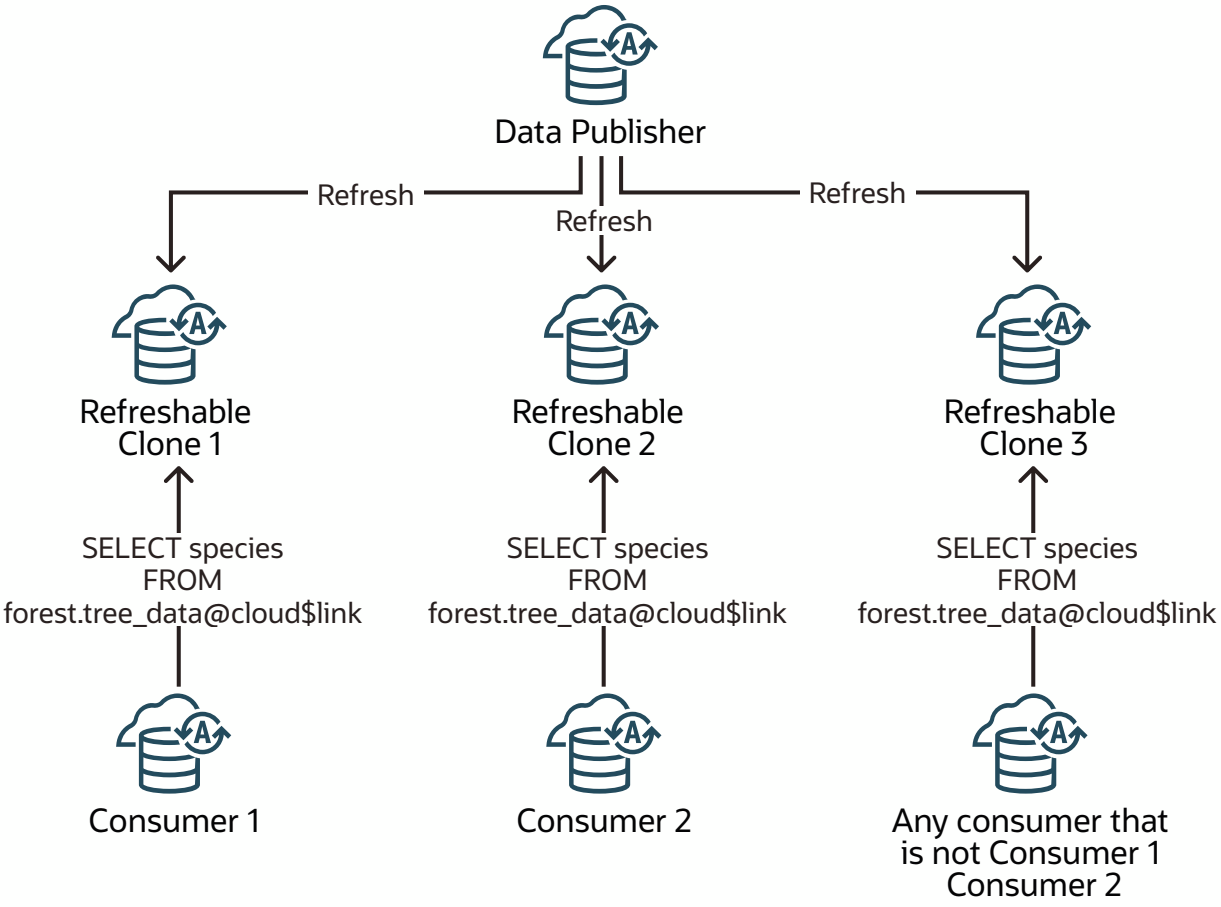
- `CLOUD_LINK_DATABASE_ID` is one of:
  - A database ID: This specifies a database ID for the data set consumer whose request is offloaded to the corresponding refreshable clone specified with the `OFFLOAD_TARGET` value.

    Obtain the database ID by running `DBMS_CLOUD_LINK.GET_DATABASE_ID`. See GET_DATABASE_ID Function for more information.
  - `ANY`: This specifies that any data set consumer's request is offloaded to the corresponding offload target. A consumer's data set request will be routed to the corresponding offload target.

    If you specify `ANY` without specifying database IDs, all data set requests from consumers are offloaded to the refreshable clone specified with the `OFFLOAD_TARGET` value.

    If you specify both database IDs and `ANY`, data set requests from consumers that do not match a database ID are offloaded to the refreshable clone specified with the `OFFLOAD_TARGET` value.
- `OFFLOAD_TARGET` is the OCID for an Autonomous Database instance that is a refreshable clone.

The following figure illustrates using offload targets.



OFFLOAD_TARGETS JSON	
CLOUD LINK DATABASE ID	**OFFLOAD TARGET**
Consumer 1's Database ID	Refreshable Clone 1
Consumer 2's Database ID	Refreshable Clone 2
ANY	Refreshable Clone 3

When a data set consumer requests access to a data set that you register with `offload_targets` and the Autonomous Database instance's database ID matches the value specified in `CLOUD_LINK_DATABASE_ID`, access is offloaded to the refreshable clone identified with `OFFLOAD_TARGET` in the supplied JSON.

For example, the following shows a JSON sample with three `OFFLOAD_TARGET`/ `CLOUD_LINK_DATABASE_ID` value pairs:

```
{
  "OFFLOAD_TARGETS": [
    {
      "CLOUD_LINK_DATABASE_ID": "34xxxxx69708978",
      "OFFLOAD_TARGET":
"ocid1.autonomousdatabase.oc1..xxxxx3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqs
```

```
tifsfabc"
    },
    {
      "CLOUD_LINK_DATABASE_ID": "34xxxxx89898978",
      "OFFLOAD_TARGET":
"ocid1.autonomousdatabase.oc1..xxxxx3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqs
tifsfdef"
    },
    {
      "CLOUD_LINK_DATABASE_ID": "34xxxxx4755680",
      "OFFLOAD_TARGET":
"ocid1.autonomousdatabase.oc1..xxxxx3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqs
tifsfghi"
    }
  ]
}
```

When a data set consumer requests access to a data set that you register with `offload_targets` that includes the `ANY` keyword, access is offloaded to the refreshable clone identified with `OFFLOAD_TARGET` in the supplied JSON (except for requests from consumers that have a matching database ID entry in the supplied JSON).

For example, the following shows a JSON sample with one explicit `OFFLOAD_TARGET`/ `CLOUD_LINK_DATABASE_ID` value pair, and one `ANY` value with a corresponding `OFFLOAD_TARGET`:

```
{
  "OFFLOAD_TARGETS": [
    {
      "CLOUD_LINK_DATABASE_ID": "ANY",
      "OFFLOAD_TARGET":
"ocid1.autonomousdatabase.oc1..xxxxx3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqs
tifsfdef"
    },
    {
      "CLOUD_LINK_DATABASE_ID": "34xxxxx4755680",
      "OFFLOAD_TARGET":
"ocid1.autonomousdatabase.oc1..xxxxx3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr4h25vqs
tifsfghi"
    }
  ]
}
```

To register a data set and specify offload targets, do the following:

1. Obtain the OCID for one or more refreshable clones where you want to offload data set access. Refreshable clone OCIDs are available on the Oracle Cloud Infrastructure Console on a refreshable clone.

> **Note:**
>
> It can take up to 10 minutes after you create a refreshable clone for the refreshable clone to be visible as an offload target. This means you may need to wait up to 10 minutes after you create a refreshable clone for the refreshable clone to be available for Cloud Links offload registration.

2. Obtain the database ID for one or more Autonomous Database instances that you want to access the data set using data provided by the refreshable clone.

   On the system you want to access the data set from a refreshable clone, run the command:

   ```
   SELECT DBMS_CLOUD_LINK.GET_DATABASE_ID FROM DUAL:
   ```

3. Register a data set and specify the `offload_targets` parameter.

   For example, assuming there is a schema `CLOUDLINK` on your Autonomous Database instance, you can register `SALES_VIEW_AGG` and specify the refreshable clones that provide access to the data set:

   ```
   BEGIN
      DBMS_CLOUD_LINK.REGISTER(
       schema_name     => 'CLOUDLINK',
       schema_object   => 'SALES_VIEW_AGG',
       namespace       => 'REGIONAL_SALES',
       name            => 'SALES_AGG',
       description     => 'Aggregated regional sales information.',
       scope           => 'MY$TENANCY',
       auth_required   =>  FALSE,
       data_set_owner  =>  'amit@example.com',
       offload_targets => '{
     "OFFLOAD_TARGETS": [
       {
         "CLOUD_LINK_DATABASE_ID": "34xxxx754755680",
         "OFFLOAD_TARGET":
   "ocid1.autonomousdatabase.oc1..xxxxxaaba3pv6wkcr4jqae5f44n2b2m2yt2j6rx32uzr
   4h25vqstifsfghi"
       }
     ]
   }');
   END;
   /
   ```

   The parameters are:

   - `schema_name`: is the schema name (the object owner).
   - `schema_object`: is the object's name. Valid objects are:
     - Tables (including Heap, External or Hybrid)
     - Views
     - Materialized Views

> **Note:**
>
> Other objects such as analytic views or synonyms are not supported.

- `namespace`: is the namespace you provide as a name for access with Cloud Links (one part of the Cloud Link FQN).

  A `NULL` value specifies a system-generated `namespace` value, unique to the Autonomous Database instance.
- `name`: is the name you provide for access with Cloud Links (one part of the Cloud Link FQN).
- `scope`: Specifies the scope. You can use one of the variables: `MY$REGION`, `MY$TENANCY`, or `MY$COMPARTMENT` or specify one or more OCIDs.

  See Data Set Scope, Access Control, and Authorization for more information.
- `auth_required`: A Boolean value that specifies if database level authorization is required for the data set, in addition to the scope access control. When this is set to `TRUE`, the data set enforces an additional authorization step. See Register a Data Set with Authorization Required for more information.
- `data_set_owner`: Text value specifies information about the individual responsible for the data set or a contact for questions about the data set. For example, you could supply an email address for the data set owner.
- `offload_targets`: Specifies one or more Autonomous Database OCIDs of refreshable clones where access to data sets is offloaded, from the Autonomous Database where the data set is registered.

  For each data set consumer, one of the following can match to offload the request to a refreshable clone:

  – When there is matching the value of the specified `cloud_link_database_id`, that is the values matches the consumer's database ID, access is offloaded to the refreshable clone identified by the OCID specified in `offload_target`.

  – When the `ANY` keyword is specified, if there is not a matching the value of a specified `cloud_link_database_id`, access is offloaded to the refreshable clone identified with the ANY entry by the OCID specified in the corresponding `offload_target`.

See the following for more information:

- REGISTER Procedure
- UPDATE_REGISTRATION Procedure
- Use Refreshable Clones with Autonomous Database

Update Data Set Registration Attributes

After you register a data set you can update some data set attributes. You cannot update the schema name, schema object, namespace, or name attributes.

To update data set attributes:

1. The user who registered a data set can update its attributes with `DBMS_CLOUD_LINK.UPDATE_REGISTRATION`.

If you do not have privileges to update data set attributes, you need to obtain grant register privileges from the ADMIN user.

See Grant Cloud Links Access for Database Users for more information.

2. Update one or more attributes for a data set.

   For example, use `DBMS_CLOUD_LINK.UPDATE_REGISTRATION` to update the `description`, `scope`, and `auth_required` attributes for the data set in the namespace `REGIONAL_SALES` with the name `SALES_AGG`:

```
BEGIN
   DBMS_CLOUD_LINK.UPDATE_REGISTRATION(
    namespace      => 'REGIONAL_SALES',
    name           => 'SALES_AGG',
    description    => 'Updated description for aggregated regional sales
information.',
    scope          => 'MY$COMPARTMENT',
    auth_required  =>  TRUE );
END;
/
```

   The required parameters are:

   - `namespace`: is the data set's namespace you provided when you registered the data set.
   - `name`: is the data set's name you provided when you registered the data set.

   Following is a list of the optional parameters. If `NULL` is passed in for an optional parameter value, the attribute is not modified.

   - `description`: Specifies the updated text to describe the data.
   - `scope`: Specifies the scope. You can use one of the variables: `MY$REGION`, `MY$TENANCY`, or `MY$COMPARTMENT` or specify one or more OCIDs.

     See Data Set Scope, Access Control, and Authorization for more information.
   - `auth_required`: A Boolean value that specifies if database level authorization is required for the data set, in addition to the scope access control. When this is set to `TRUE`, the data set enforces an additional authorization step. See Register a Data Set with Authorization Required for more information.
   - `data_set_owner`: Text value specifies information about the individual responsible for the data set or a contact for questions about the data set. For example, you could supply an email address for the data set owner.
   - `offload_targets`: Specifies one or more Autonomous Database OCIDs of refreshable clones where access to data sets is offloaded, from the Autonomous Database where the data set is registered. See Register a Data Set with Offload Targets for Data Set Access for more information.

   You cannot update the `schema_name` or `schema_object` attributes.

   See UPDATE_REGISTRATION Procedure for more information.

When a data set is registered in one or more cross-region Refreshable Clones, any changes to the registration in the source database should be propagated to the remote regions.

Note the following to propagate changes to cross-region Refreshable Clones:

- If a Producer has N cross-region Refreshable Clones in a region, for example in region A, run `DBMS_CLOUD_LINK.UPDATE_REGISTRATION` on exactly one Refreshable Clone in region A.
- If the same Producer has M cross-region Refreshable Clones in a different remote region, for example in region B, run `DBMS_CLOUD_LINK.UPDATE_REGISTRATION` on exactly one Refreshable Clone in region B.

To update attributes when a data set is registered in one or more cross-region Refreshable Clones:

1. On the source database, update the data set registration.
2. On a remote Refreshable Clone in the remote region if the there is only one remote region, or on a remote Refreshable Clone in each remote region if there are replicated Refreshable Clones in multiple regions, update the data set registration with the same values you used to update the source database, with the exception of the `offload_targets` parameter.

   In any given remote region, you only need to run `DBMS_CLOUD_LINK.UPDATE_REGISTRATION` on exactly one Refreshable Clone in that region (if the region has more than one Refreshable Clone associated with the same data set, you only need to run the procedure once to propagate the changes to all of the Refreshable Clones in an individual remote region).
3. Refresh the refreshable clones.

   See Refresh a Refreshable Clone on Autonomous Database for more information.

Find Data Sets and Use Cloud Links

A user who is granted access to read Cloud Links can search for data sets available to an Autonomous Database instance and can access and use registered data sets with their queries.

After the ADMIN user runs `GRANT_READ`, a user can search for and use Cloud Links.

1. Find the available data sets on your Autonomous Database instance.

   For example, search for all data sets that contain the string, "TREE":

```
DECLARE
   result CLOB DEFAULT NULL;
BEGIN
   DBMS_CLOUD_LINK.FIND('TREE', result);
    DBMS_OUTPUT.PUT_LINE(result);
END;
/

[{"name":"TREE_DATA","namespace":"FOREST","description":"Urban tree data
including county, species and height"}]
```

   The parameters are:

   - `search_string`: The string to search for. The search string is not case sensitive.
   - `search_result`: A JSON document that includes the namespace, name, and description values for the data set.

   See FIND Procedure for more information.

The `DBMS_CLOUD_LINK.FIND` procedure provides the FQN you can use with Cloud Links. In this case, `FOREST.TREE_DATA`.

2. Use the view `DBA_CLOUD_LINK_ACCESS` to list available data sets:

```
SELECT * FROM DBA_CLOUD_LINK_ACCESS;

NAMESPACE            NAME
---------            --------------
FOREST               TREE_DATA
REGIONAL_SALES       SALES_AGG
TRUSTED_COMPARTMENT  SALES
```

3. Use the procedure `DBMS_CLOUD_LINK.DESCRIBE` to find out more details about a registered data set.

```
SELECT DBMS_CLOUD_LINK.DESCRIBE('FOREST','TREE_DATA') FROM DUAL;

DBMS_CLOUD_LINK.DESCRIBE('FOREST','TREE_DATA')
-----------------------------------------------
Urban tree data including county, species and height
```

4. Use the registered data set in a query.

```
SELECT * FROM FOREST.TREE_DATA@cloud$link;
```

> **Note:**
>
> It can take up to 10 minutes after you register a data set with `DBMS_CLOUD_LINK.REGISTER` for the data set to be visible and accessible.

Cloud Links support private and public synonyms. For example, you can define and use a synonym for `FOREST.TREE_DATA@cloud$link`:

```
CREATE SYNONYM S1 for FOREST.TREE_DATA@cloud$link;
CREATE PUBLIC SYNONYM S2 for FOREST.TREE_DATA@cloud$link;

SELECT * FROM S1;

SELECT * FROM S2;
```

See CREATE SYNONYM for more information.

Use Cloud Links Consumer Options

You can set the service name mapping to use to access data from a consumer database and you can enable caching on a data set consumer for the results of a query or for a query fragment that accesses Cloud Link data.

- Set Database Service Name Mapping for Cloud Links Consumers
  You can set the service name mapping to use when Cloud Links consumers access data from a data set owner.

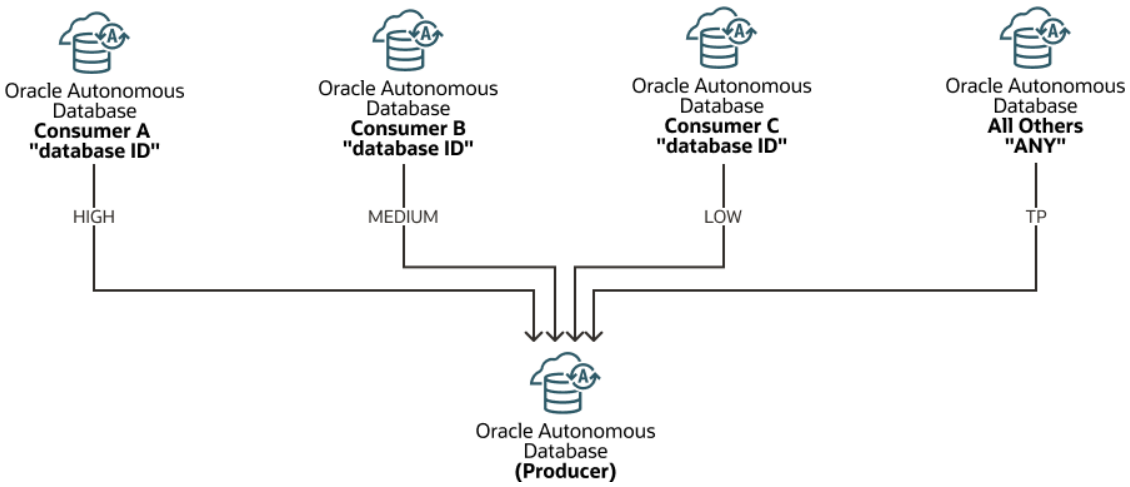
- Enable Caching for a Cloud Link Consumer
  You can enable caching on a data set consumer for the results of a query or for a query fragment that accesses Cloud Link data.

Set Database Service Name Mapping for Cloud Links Consumers

You can set the service name mapping to use when Cloud Links consumers access data from a data set owner.

Cloud Links rely on database resources in the Autonomous Database instance that is the data set producer, or the resources of a refreshable clone, to access shared data. By default remote connectivity for consumers to access Cloud Links data uses the `MEDIUM` database service.

Use `DBMS_CLOUD_LINK_ADMIN.ADD_SERVICE_MAPPING` to set the database service mapping for a consumer. In this procedure you supply either a database ID or the keyword `ANY` to specify the consumer service mapping. For example, the following figure shows a mapping for Consumer A to the HIGH service, Consumer B to the MEDIUM service, Consumer C to the LOW service, and a mapping for ANY to the TP service, meaning all other consumers access Cloud Links using the TP service.



See Database Service Names for Autonomous Database for more information on the characteristics of database services.

Perform the following steps to set the database service to use for a Cloud Links consumer:

1. Obtain the database ID for the database that you want to set a service mapping.

   On the consumer database run `GET_DATABASE_ID` to obtain the consumer's database ID. For example:

   ```
   SELECT DBMS_CLOUD_LINK.GET_DATABASE_ID FROM DUAL:
   ```

   See GET_DATABASE_ID Function for more information.

2. On the data set owner's Autonomous Database instance, specify a service mapping.

   Perform this step on the data set owner's Autonomous Database instance (that is, on the producer database).

   ```
   BEGIN
      DBMS_CLOUD_LINK_ADMIN.ADD_SERVICE_MAPPING(
   ```

```
    database_id      => 'database_id',
    service_name     => 'HIGH');
END;
/
```

Where the *database_id* parameter value is the database ID you obtained in step 1.

Specify the value `ANY` for the `database_id` to use the specified `service_name` with all consumer databases that do not have a `service_name` associated with their `database_id`. That is, any `database_id` whose `service_name` has not been set with `DBMS_CLOUD_LINK_ADMIN.ADD_SERVICE_MAPPING`.

See ADD_SERVICE_MAPPING Procedure for more information.

Only the ADMIN user and schemas with `PDB_DBA` role can run `DBMS_CLOUD_LINK_ADMIN.ADD_SERVICE_MAPPING`.

3. Verify the database IDs and service mapping by listing the Cloud Links service mappings.

   For example:

   ```
   SELECT * FROM  DBA_CLOUD_LINK_SERVICE_MAPPINGS;
   ```

   See DBA_CLOUD_LINK_SERVICE_MAPPINGS View for more information.

Notes for setting and changing service mappings:

- Service mappings take effect at the time connections are established. If a particular consumer's service mappings are changed, the new mappings take effect only for new sessions from the consumer.
- Any service mapping configured in a data set owner for a specific Consumer is honored even if access from the Consumer is offloaded to a Refreshable Clone. The Refreshable Clone must be refreshed to a point in time after the time when service mappings were configured in the data set owner. Note that offload to a Refreshable Clone is configured with the argument `offload_targets` during data set registration.

  See Register a Data Set with Offload Targets for Data Set Access for more information.
- Use the procedure `DBMS_CLOUD_LINK_ADMIN.REMOVE_SERVICE_MAPPING` to remove a service mapping for a specified `database_id`.

  After running `DBMS_CLOUD_LINK_ADMIN.REMOVE_SERVICE_MAPPING` a consumer either uses the default `MEDIUM` database service or the `service_name` you specify if you run `DBMS_CLOUD_LINK_ADMIN.ADD_SERVICE_MAPPING` with the `database_id` value `ANY`. See REMOVE_SERVICE_MAPPING Procedure for more information.
- Set Database Service Name Mapping for Cloud Links Consumers in Remote Region
  A data set that is registered in a source region can be accessed with Cloud Links from a remote region when you create cross-region Refreshable Clone in the remote region.

Set Database Service Name Mapping for Cloud Links Consumers in Remote Region

A data set that is registered in a source region can be accessed with Cloud Links from a remote region when you create cross-region Refreshable Clone in the remote region.

In this case, the service mappings for consumers in the remote region must be added twice, in the source database, and in the refreshable clone in the remote region.

Perform the following steps to set the service mappings for Cloud Links consumers in a remote region.

1. Create a cross-region Refreshable Clone of the source database (the Refreshable Clone is a clone of the Cloud Links data set owner in the remote region).

   See Create a Cross Tenancy or Cross-Region Refreshable Clone for more information.

2. Register the data set.

   See Register a Data Set for more information.

3. Add the service mappings on the data set owner.

   See Set Database Service Name Mapping for Cloud Links Consumers for more information.

4. Refresh the Refreshable Clone.

   See Refresh a Refreshable Clone on Autonomous Database for more information.

5. On the remote Refreshable Clone, register the data set using the same arguments you used to register the data set in the source region (that is, use the same arguments you used in Step 2).

6. On the remote Refreshable Clone, add the service mappings using the same arguments that you used in the source region (that is, use the same arguments you used in Step 3).

When a consumer in the remote region access Cloud Links data, the access will use the same service mappings as you added in source region's data set owner database.

Enable Caching for a Cloud Link Consumer

You can enable caching on a data set consumer for the results of a query or for a query fragment that accesses Cloud Link data.

To enable caching on a data set consumer use the `RESULT_CACHE` hint with the `SHELFLIFE` option. With the `SHELFLIFE` option you supply a value that indicates the duration, in seconds, that a query result is cached. After the `SHELFLIFE` interval has passed, the cached result is marked as invalid. As long as the cached result is valid, a query retrieves the cached data from the cache on the consumer database, which avoids a round trip to the data set owner's database.

Use the `RESULT_CACHE` hint with the `SHELFLIFE` option when the data set is static or when the consumer can tolerate stale results. The value of `SHELFLIFE` allows the Cloud Link data set consumer to control the time, in seconds, when the data in the cache is valid (the acceptable degree of staleness).

If the query result is large and does not fit in memory, you can use the `RESULT_CACHE` hint with the `SHELFLIFE` option and the `TEMP` option to indicate that the result should be written to disk in the temporary tablespace.

To cache Cloud Link data with the `RESULT_CACHE` hint:

1. In a query, specify the `RESULT_CACHE` hint with the `SHELFLIFE` option.

   For example:

   ```
   SELECT /*+ RESULT_CACHE (SHELFLIFE=120) */ * FROM
   FOREST.TREE_DATA@cloud$link;
   ```

   This `RESULT_CACHE` specifies a `SHELFLIFE` value of 120. This indicates that the result should be cached in memory for 120 seconds. After 120 seconds, the cached result is marked as invalid.

The SHELFLIFE value must be a positive integer. The maximum SHELFLIFE value is 4294967295.

2. If the query result is large and does not fit in memory, use both the SHELFLIFE and the TEMP options to indicate that the result should be written to disk in the temporary tablespace.

```
SELECT /*+ RESULT_CACHE (TEMP=true SHELFLIFE=360) */ * FROM
FOREST.TREE_DATA@cloud$link;
```

See RESULT_CACHE_MODE for details on using the result cache with Autonomous Database.

See RESULT_CACHE Hint for more information on RESULT_CACHE with SHELFLIFE.

See DBMS_RESULT_CACHE for information on procedures to manage the result cache and to invalidate objects in the result cache.

Monitor and View Cloud Links Information

Autonomous Database provides views that allow you to monitor and audit Cloud Links.

View	Description
V$CLOUD_LINK_ACCESS_STATS and GV$CLOUD_LINK_ACCESS_STATS Views	Use to track access to each registered data set on the Autonomous Database instance. These views track elapsed time, CPU time, the number of rows retrieved, and additional information about registered data sets. You can use the information in these views to audit Cloud Links data set access and usage.
DBA_CLOUD_LINK_REGISTRATIONS and ALL_CLOUD_LINK_REGISTRATIONS Views	Use to list details of the registered data sets on an Autonomous Database instance.
DBA_CLOUD_LINK_ACCESS and ALL_CLOUD_LINK_ACCESS Views	Use to retrieve details of registered data sets a database is allowed to access.
DBA_CLOUD_LINK_AUTHORIZATIONS View	Provides information about which databases are authorized to access which data sets. This applies to data sets where the auth_required parameter is TRUE.
DBA_CLOUD_LINK_PRIVS and USER_CLOUD_LINK_PRIVS Views	Provides information on the Cloud Link specific privileges, REGISTER, READ, or AUTHORIZE, granted to all users or to the current user.
DBA_CLOUD_LINK_SERVICE_MAPPINGS View	Displays details of all service mappings for Cloud Links consumer databases. Each service mapping consists of a Cloud Link database ID and a database service.

Define a Virtual Private Database Policy to Secure a Registered Data Set

By defining Virtual Private Database (VPD) policies for a registered data set, you can provide fine-grained Cloud Link access control so that only a subset of data (rows) is visible for specific remote sites.

Oracle Virtual Private Database (VPD) is a security feature that lets you control data access dynamically at row level for users and applications by applying filters on the same data set.

Any user who is granted access to read Cloud Links can access and use registered data sets if they are within the scope specified when the data set is registered, and if the extra authorization required parameter is set for the data set, the access is from an authorized

database. Each remote access is done in the context of the remote Autonomous Database instance accessing the registered data set (on the database where the data set was registered).

You use the function `DBMS_CLOUD_LINK.GET_DATABASE_ID` on the remote system to get the database's unique ID. By defining a VPD policy on the database that registered a data set, you now can use the remote database's identifier as `SYS_CONTEXT` rule to provide more fine-grained control. You can define rules for remote databases accessing your registered data set and limit access beyond what is possible by specifying a Cloud Link scope.

Consider an example where `REGIONAL_SALES.SALES_AGG` is made available at the tenancy level. If you want to restrict access to all databases except one specific database, only allowing full access to the specified database, you can add a VPD policy on the registered data set.

For example:

1. Obtain the unique Cloud Link database ID for the Autonomous Database instance where you want to provide full access.

```
DECLARE
     DB_ID NUMBER;
 BEGIN
     DB_ID := DBMS_CLOUD_LINK.GET_DATABASE_ID;
     DBMS_OUTPUT.PUT_LINE('Database ID:' || DB_ID);
 END;
 /
```

2. Create VPD policy on the database that registered the data set by only allowing full access to the one specific database whose identifier you got on the database in question in Step 1.

```
CREATE OR REPLACE FUNCTION vpd_policy_sales(
     owner IN VARCHAR2,
     object IN VARCHAR2)
     RETURN VARCHAR2 IS
BEGIN
  IF SYS_CONTEXT('USERENV', 'CLOUD_LINK_DATABASE_ID')  <>
'12121212163948244901' THEN
    RETURN 'time_id >= trunc(sysdate,''year'')';
  ELSE
    RETURN '';
  END IF;
END;
/
```

   See DBMS_RLS for more information.

3. Register the VPD policy for your registered data set to limit full access to only the database identified in step 1.

```
BEGIN
  DBMS_RLS.ADD_POLICY(object_schema => 'CLOUDLINK',
            object_name => 'SALES_VIEW_AGG',
            policy_name => 'THIS_YEAR',
            function_schema => 'ADMIN',
            policy_function => 'VPD_POLICY_SALES',
```

```
            statement_types => 'SELECT',
            policy_type => DBMS_RLS.SHARED_CONTEXT_SENSITIVE);
END;
/
```

See DBMS_RLS for more information.

See Using Oracle Virtual Private Database to Control Data Access for more information.

Notes for Cloud Links

Provides notes and restrictions for using Cloud Links.

- There is a limit of 4096 on the number of data sets you can register.

  Each Autonomous Database instance can register no more than 4096 data sets. This limit applies to every Autonomous Database instance, regardless of the number of ECPUs (OCPUs if your database uses OCPUs) or the storage size of the instance. The limit is a fixed value and setting the **ECPU count** to a larger value does not allow you to register more data sets.
- You can register an object in another schema if you have `READ WITH GRANT OPTION` privilege on the object.
- To register data sets or see and access remote data sets, you have to have granted the appropriate privilege for either registering or reading data sets. This is true for ADMIN as well; however ADMIN can grant this privilege to themself.
- To use either `DBMS_CLOUD_LINK.REGISTER` or `DBMS_CLOUD_LINK.UPDATE_REGISTRATION`, you must have execute privilege on the `DBMS_CLOUD_LINK` package, in addition to the register privilege assigned with `DBMS_CLOUD_LINK_ADMIN.GRANT_REGISTER`. Only the ADMIN user and schemas with `PDB_DBA` have this privilege by default.
- If you drop and re-create a table that was registered, you need to re-register the table for remote access.
- Only the ADMIN user and users with the role `PDB_DBA` are privileged to access the following views:
  - `DBA_CLOUD_LINK_ACCESS`
  - `DBA_CLOUD_LINK_REGISTRATIONS`
  - `DBA_CLOUD_LINK_AUTHORIZATIONS`
  - `DBA_CLOUD_LINK_PRIVS`

  See DBMS_CLOUD_LINK Views for more information.
- Accessing registered, remote data requires the remote database to be open. If the remote database is closed or in restricted mode, you will not be able to access the data and an Oracle error will be returned.
- There is a limit of a maximum of four open database links per session. Exceeding this limit can lead to `ORA-02020` or `ORA-12545`.
- If result cache is enabled, like the default behavior in Autonomous Database with **Data Warehouse** workload, you need to ensure that result cache is not used when realtime data is required.
- When you update your license type from Free to Paid, you must re-register Cloud Links data sets. See Update Always Free Instance to Paid with Autonomous Database for more information.

- Cloud Links remote connectivity by default uses the `MEDIUM` database service. You can change the default with `DBMS_CLOUD_LINK_ADMIN.ADD_SERVICE_MAPPING` by using `ANY` as the value for `DATABASE_ID`. You can change the database service for a consumer with `DBMS_CLOUD_LINK_ADMIN.ADD_SERVICE_MAPPING` by specifying the consumer's `DATABASE_ID`. See Set Database Service Name Mapping for Cloud Links Consumers for more information.

  You can see the remote connections as user `C##DATA$SHARE` in `V$SESSION` and the Cloud Links views V$CLOUD_LINK_ACCESS_STATS and GV$CLOUD_LINK_ACCESS_STATS Views provide more details about remote connections.
- All interfaces are case-sensitive unless otherwise noted, as follows:
  - Anything you enter that exists in the database, for example user names and table names, case is significant and must be entered with uppercase letters.
  - Predefined variables, for example the predefined scope values must be entered in uppercase letters.
  - Anything that you specify for the setup of Cloud Links, for example namespaces or names of tables in a namespace, must be specified as entered. For example, if you define a namespace as `trees`, you must enclose the namespace in double quotes, as `"trees"`, when accessing it with SQL.
- You can share Cloud Links when a data set resides on an Autonomous Database instance in Read-Only mode. See Use Cloud Links from a Read Only Autonomous Database Instance for more information.
- It can take up to 10 minutes after you create a refreshable clone for the refreshable clone to be visible as an offload target. This means you may need to wait up to 10 minutes after you create a refreshable clone for the refreshable clone to be available for Cloud Links offload registration.

  See Register a Data Set with Offload Targets for Data Set Access and Create a Refreshable Clone for an Autonomous Database Instance for more information.
- Use Cloud Links from a Read Only Autonomous Database Instance
  You can share Cloud Links when a data set resides on a Read-Only Autonomous Database instance.

Use Cloud Links from a Read Only Autonomous Database Instance

You can share Cloud Links when a data set resides on a Read-Only Autonomous Database instance.

To share Cloud Links from an Autonomous Database instance that is in Read-Only mode:

1. Change the database mode to Read/Write mode.

   See Change Autonomous Database Operation Mode to Read/Write Read-Only or Restricted for more information.
2. With the database in Read/Write mode, perform the steps to register a data set.
   a. Grant Cloud Links Access for Database Users
   b. Register or Unregister a Data Set
3. After you register one or more data sets, change the database to read-only mode.

   See Change Autonomous Database Operation Mode to Read/Write Read-Only or Restricted for more information.

Use Table Hyperlinks for Read Only Data Access on Autonomous Database

You can generate and manage Table Hyperlinks to access data on Autonomous Database.

Using a Table Hyperlink allows you to easily retrieve data from the database, without requiring you to provide additional information other than the Table Hyperlink to access the data. Any user can access the data by supplying the Table Hyperlink in a browser or using a REST client, subject to security controls enforced by the database. Users can view the retrieved data in tabular format from a browser by appending a query parameter to the Table Hyperlink.

You can read and access data in a Microsoft Excel sheet using a Table Hyperlink through the Oracle Autonomous Database Add-in for Excel, which allows direct retrieval and viewing of tabular data from the Autonomous Database within Excel. See Read and Access Data Using Table Hyperlinks in Excel Sheet for more information.

- About Table Hyperlinks on Autonomous Database
  Depending on how you generate a Table Hyperlink, a Table Hyperlink provides access to data in tables or views or by running a SQL query.
- Generate, List, Invalidate, and Monitor Table Hyperlinks
  Shows you the steps to generate. list, invalidate, or monitor Table Hyperlinks.
- Use Table Hyperlink to Access Data
  Table Hyperlink data is retrieved and returned in JSON format and is paginated.
- Use Table Hyperlinks to Access Data in Table Format
  Table Hyperlink data can be viewed in tabular format when accessed from a browser. The table format supports scrolling, sorting, filtering, cell colors, and Group By where you select a column name to see column data based on the values in the column.
- Use Table Hyperlinks to Create an External Table
  You can create an external table over an Autonomous Database Table Hyperlink.

About Table Hyperlinks on Autonomous Database

Depending on how you generate a Table Hyperlink, a Table Hyperlink provides access to data in tables or views or by running a SQL query.

When you generate a Table Hyperlink you specify an expiration, either as an expiration time, for example set the Table Hyperlink to expire after 120 minutes, or as an expiration count, for example the Table Hyperlink expires after the Table Hyperlink is used 10 times.

Table Hyperlinks provide the following:

- **Public Access**: Using a Table Hyperlink a data recipient on the public internet can access data when the data resides on an Autonomous Database instance in a private subnet.
- **Access with ACL Checking**: You can generate a Table Hyperlink with ACL checking enabled. When you generate a Table Hyperlink and you enable ACL checking, Table Hyperlink data is only accessible to a consumer database after the incoming request's IP address is validated based on the ACLs defined on the producer database.
- **Expiration**: A data provider specifies expiration for a Table Hyperlink, meaning the Table Hyperlink has a limited time before it expires (up to a maximum of 90 Days).
- **Expiration Use Count Limits**: A data provider can specify a limit on how many times a recipient can use a Table Hyperlink to access data.
- **Endpoint Transparency**: A data provider is able to hide the Autonomous Database name so that it is not visible in a Table Hyperlink.

- **Column Level Options for Tabular Format Features and Grouping**: When you generate a Table Hyperlink you can specify the following options by column: sorting, filtering, allow cell colors, or the group by option where you can select to view data grouped by the values in a specified column.

> **Note:**
>
> There is a limit of 128 active Table Hyperlinks on an Autonomous Database instance.

Table Hyperlink Use Cases

Generating and providing a Table Hyperlink supports the following use cases:

Use Case	Description
Within Organization Collaboration	You can use Table Hyperlinks for emergency data access. In situations where a rapid response is needed, such as during a critical incident investigation, you provide a Table Hyperlink to allow immediate and temporary access to specific data without the need to create new database accounts or modify existing permissions.
BB (Business to Business) Applications	A business partner can easily access data. Using a Table Hyperlink, a business can provide a business partner with a simple way to access data or reports. This can eliminate the need for manual report generation and email distribution.
Third-party Audits and Reviews	When an external auditor or reviewer requires access to specific data for a limited time, a Table Hyperlink can give them the access they need without compromising the overall security of the database.
Data as a Product (Digital Commerce)	Vendors can grant limited or single-use access to purchased content or data using a Table Hyperlink. Once accessed, the URL expires, protecting the product's exclusivity and ensuring efficient, secure delivery.

Security Best Practices for Table Hyperlinks

Following are some best practices for generating and using Table Hyperlinks:

- **Set a Short Expiration Time**: A Table Hyperlink should only be valid for the minimum time required. The shorter the validity period, the lower the risk if the Table Hyperlink is compromised.
- **PAR Invalidation**: Invalidate a Table Hyperlink immediately when it is no longer required.
- **Use Appropriate Permissions**: A Table Hyperlink runs using the privileges granted to the database user who generates the Table Hyperlink. The user that generates a Table Hyperlink should have the minimum privileges required for providing access to the data.
- **Content Security**: To mitigate risk of sharing unintended dynamic data:
  - Create a view on top of the data that you want to share in a Table Hyperlink, and monitor that the view definition is up to date.
  - As needed, create a VPD policy when you generate a Table Hyperlink. You can use VPD policies to restrict the rows visible to the Table Hyperlink users.
  - As needed, enable ACL checking when you generate a Table Hyperlink.
- **Load Monitoring**: Monitor the Table Hyperlink query load using PerfHub and SQL monitoring.

Enable **Compute auto scaling** and make sure that the CPU count is appropriately sized for the data set size and Table Hyperlink query load.

Generate, List, Invalidate, and Monitor Table Hyperlinks

Shows you the steps to generate. list, invalidate, or monitor Table Hyperlinks.

- Generate a Table Hyperlink for a Table or a View
  Shows you the steps to generate a Table Hyperlink that you can use to share access for a schema object (table or view).
- Generate a Table Hyperlink with a Select Statement
  Shows you the steps to generate a Table Hyperlink that provides access to data using a SQL query statement.
- Generate a Table Hyperlink with UI Features Specified on Columns
  When you generate a Table Hyperlink you can use the `column_lists` parameter to specify UI features for specified columns.
- List Table Hyperlinks
  You can list the active Table Hyperlinks that you generated on an Autonomous Database instance and the ADMIN user can list all active Table Hyperlinks.
- Invalidate Table Hyperlinks
  At any time a user with appropriate privileges can invalidate a Table Hyperlink.
- Define a Virtual Private Database Policy to Secure Table Hyperlink Data
- Monitor and View Table Hyperlink Usage
  Autonomous Database provides views that allow you to monitor Table Hyperlink usage.

Generate a Table Hyperlink for a Table or a View

Shows you the steps to generate a Table Hyperlink that you can use to share access for a schema object (table or view).

When a Table Hyperlink runs it uses the privileges granted to the database user who generates the Table Hyperlink. The user that generates a Table Hyperlink should have the minimum privileges required for providing access to the data. To maintain security, Oracle recommends that you do not run `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL` as the ADMIN user.

To use a Table Hyperlink to provide access to data as a schema object (table or view):

1. Identify the table or view that you want to share.

   If there are restrictions on the data you want to make available, use the `application_user_id` parameter when you generate the Table Hyperlink and create a VPD policy to restrict the data that you expose. See Define a Virtual Private Database Policy to Secure Table Hyperlink Data for more information.

2. Run `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL` to generate the Table Hyperlink.

```
DECLARE
   status CLOB;
   BEGIN
      DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL(
          schema_name => 'ADMIN',
          schema_object_name    => 'TREE_DATA',
          expiration_minutes    => 360,
          service_name          => 'HIGH',
          inherit_acl            => FALSE,
```

```
            result                => status);
        dbms_output.put_line(status);
    END;
/
```

Use the optional `service_name` parameter to specify that the generated Table Hyperlink is serviced with a specific service-level guarantee and resources. For example, use the `service_name` parameter to specify that access to the object is mapped to the HIGH service.

Use the optional `inherit_acl` parameter if you want to limit access to Table Hyperlink data. Set this parameter to `TRUE` to inherit the ACL. When inherit ACL is true, an incoming Table Hyperlink consumer's IP address is validated with the ACLs on the producer database before allowing access to data. If the producer database does not have ACLs configured, the `inherit_acl` value is ignored and data access is allowed without any ACL checks.

See Configuring Network Access with Access Control Rules (ACLs) and GET_PREAUTHENTICATED_URL Procedure for more information.

3. Check the result.

   In this example `status` contains the result that includes information about the Table Hyperlink.

```
{
"status":"SUCCESS","id":"wPY0uxyx-gioxOndiKVlqVF585xqJs14CIp9M1qH",
"preauth_url":"https://dataaccess.adb.us-
ashburn-1.oraclecloudapps.com/adb/p/-pPLdrbUTcLUrZLExyzxyzabc_1w/data",
"expiration_ts":"2024-10-22T22:37:18.805Z",
"expiration_count":null
}
```

Notes for generating a Table Hyperlink with `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL`:

- When you generate a Table Hyperlink on an Autonomous Database instance with a private endpoint, the result includes a name `private_preauth_url` with the value of the form: `"https://`*`private-endpoint`*`/adb/p/`*`parurl-token`*`/data"`.

  When you generate a Table Hyperlink on an Autonomous Database instance with a private endpoint and the private endpoint is configured with **Allow public access** enabled, the result includes both the `preauth_url` for the public endpoint and `private_preauth_url`.

  See Configure Private Endpoints and Use a Private Endpoint with Public Access Allowed for more information.

- Use `DBMS_DATA_ACCESS.LIST_ACTIVE_URLS` to show Table Hyperlinks. See List Table Hyperlinks for details.
- Use `DBMS_DATA_ACCESS.EXTEND_URL` to extend the life of a Table Hyperlink. See EXTEND_URL Procedure for more information.

Generate a Table Hyperlink with a Select Statement

Shows you the steps to generate a Table Hyperlink that provides access to data using a SQL query statement.

When a Table Hyperlink runs it uses the privileges granted to the database user who generates the Table Hyperlink. The user that generates a Table Hyperlink should have the minimum

privileges required for providing access to the data. To maintain security, Oracle recommends that you do not run `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL` as the ADMIN user.

To use a Table Hyperlink to provide to access to data as an arbitrary SQL query statement:

1. Identify the table or view that contains the information you want to share, as well as the `SELECT` statement on the table or view that you want to use.

   If there are restrictions on the data you want to make available, use the `application_user_id` parameter when you generate the Table Hyperlink and create a VPD policy to restrict the data that you expose. See Define a Virtual Private Database Policy to Secure Table Hyperlink Data for more information.

2. Run `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL` to generate the Table Hyperlink.

   You have two options, depending on whether you want to include default bind variable values (if you include bind variables in the select statement).

   a. Provide a select statement and do not use the optional `default_bind_values` parameter.

      For example:

```
DECLARE
   status CLOB;
   BEGIN
      DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL(
          sql_statement        => 'SELECT species, height FROM
TREE_DATA',
          expiration_count     => 10,
          service_name         => 'HIGH',
          inherit_acl            => FALSE,
          result               => status);
       dbms_output.put_line(status);
    END;
/
```

      The `sql_statement` value must be a `SELECT` statement. The `SELECT` statement supports bind variables. If bind variables are included in the select statement, the bind variable values must be appended to the generated Table Hyperlink as a query parameter when accessing the data.

   b. Provide a select statement and include the `default_bind_values` parameter.

      For example:

```
DECLARE
   status CLOB;
   BEGIN
      DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL(
          sql_statement => 'select * FROM TREE_DATA WHERE COUNTY
= :countyNAME',
          default_bind_values  => '{"countyNAME" : "First"}',
          expiration_count     => 10,
          service_name         => 'HIGH',
          inherit_acl            => FALSE,
          result               => status);
       dbms_output.put_line(status);
```

```
    END;
/
```

The `sql_statement` parameter must be a `SELECT` statement. The `SELECT` statement supports bind variables.

The `default_bind_values` parameter specifies values for one or more bind variables in the `sql_statement`. When `default_bind_values` is included with `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL`:

- For bind variables specified in `default_bind_values`, you can omit the bind variable values when you access the data. The default value is used for a specified bind variable if an override is not provided in the Table Hyperlink URL as a query parameter when you access the data.
- You can override a default bind variable value specified in `default_bind_values` if you append the bind variable value in the Table Hyperlink URL as a query parameter when you access the data.
- If a bind variable is included in the select statement and a default value for the bind variable is not specified in the `default_bind_values` parameter, you must append a bind variable value to the generated Table Hyperlink URL as a query parameter when you access the data.

Bind variable support is available for `NUMBER` and `VARCHAR2` column types.

In these examples the `expiration_count` parameter specifies that the Table Hyperlink expires and is invalidated after 10 uses. When an `expiration_time` is not specified, the expiration time is set to the default value, 90 days.

Use the optional `service_name` parameter to specify that the generated Table Hyperlink is serviced with a specific service-level guarantee and resources. For example, use the `service_name` parameter to specify access to the SQL statement is mapped to the HIGH service.

Use the optional `inherit_acl` parameter if you want to limit access to Table Hyperlink data. Set this parameter to `TRUE` to inherit ACLs. When inherit ACL is true, an incoming Table Hyperlink consumer's IP address is validated with the ACLs on the producer database before allowing access to data. If the producer database does not have ACLs configured, the `inherit_acl` value is ignored and data access is allowed without any ACL checks.

See Configuring Network Access with Access Control Rules (ACLs) and GET_PREAUTHENTICATED_URL Procedure for more information.

3. Check the result.

   In this example `status` contains the result that includes the Table Hyperlink.

```
{
"status":"SUCCESS","id":"LCvtpALqZgcHGL4Lxyzabcxyza-
QVEFngwh1UGhg8jjuFAHOQJLGFi",
"preauth_url":"https://dataaccess.adb.us-
ashburn-1.oraclecloudapps.com/adb/p/RIabc_xyz7Kw8ZLyZ2JzCXZQXpc/data",
"expiration_ts":"2025-01-20T16:42:49.527Z",
"expiration_count":10}
}
```

Notes for generating a Table Hyperlink with `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL`:

- When you generate a Table Hyperlink on an Autonomous Database instance with a private endpoint, the result includes a name `private_preauth_url` with the value of the form: "`https://`*`private-endpoint`*`/adb/p/`*`parurl-token`*`/data`".

  When you generate a Table Hyperlink on an Autonomous Database instance with a private endpoint and the private endpoint is configured with **Allow public access** enabled, the result includes both the `preauth_url` for the public endpoint and `private_preauth_url`.

  See Configure Private Endpoints and Use a Private Endpoint with Public Access Allowed for more information.
- Use `DBMS_DATA_ACCESS.LIST_ACTIVE_URLS` to show Table Hyperlinks. See List Table Hyperlinks for details.
- Use `DBMS_DATA_ACCESS.EXTEND_URL` to extend the life of a Table Hyperlink. See EXTEND_URL Procedure for more information.

Generate a Table Hyperlink with UI Features Specified on Columns

When you generate a Table Hyperlink you can use the `column_lists` parameter to specify UI features for specified columns.

The `column_lists` parameter is a JSON value that specifies options by column. The supported values in `column_lists` are one or more of the following:

column_lists Value	Description
`order_by_columns`	Specifies the columns that support sorting. The columns are specified in a JSON array.
`filter_columns`	Specifies the columns that support filtering. The columns are specified in a JSON array.
`default_color_columns`	Specifies to only use the default coloring for the specified columns. The columns are specified in a JSON array.
`group_by_columns`	Specifies that group by is allowed for the specified columns (viewing the data by grouping the specified column is allowed). The columns are specified in a JSON array.

To specify table view column level UI features for a Table Hyperlink:

1. Identify the table or view or select statement that you want to share.

   This example generates a Table Hyperlink using the `column_lists` parameter with a table. You can also use this parameter when you generate a Table Hyperlink with a `SELECT` statement.

   See Generate a Table Hyperlink for a Table or a View and Generate a Table Hyperlink with a Select Statement for more information.

2. Run `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL` to generate the Table Hyperlink and specify group by columns option for viewing with a browser:

   For example, to specify group by columns:

```
DECLARE
   status CLOB;
   BEGIN
      DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL(
          schema_name => 'ADMIN',
          schema_object_name    => 'TREE_DATA',
```

```
          expiration_minutes    => 360,
          service_name          => 'HIGH',
          column_lists          => '{ "group_by_columns": ["COUNTY",
"SPECIES"] }',
          result                => status);

       dbms_output.put_line(status);
    END;
/
```

The `column_lists` parameter is JSON that contains a list of JSON arrays of columns defining Table Hyperlink functionality. Use this parameter to specify the columns for one or more of the options: `order_by_columns`, `filter_columns`, `default_color_columns`, or `group_by_columns`.

For example:

```
column_lists => '{
        "group_by_columns":["COUNTY", "SPECIES"],
        "order_by_columns":["COUNTY"] }'
```

See GET_PREAUTHENTICATED_URL Procedure for more information.

3. Check the result.

   In this example `status` contains the result that includes information about the Table Hyperlink.

```
{
"status":"SUCCESS",
"id":"LLUZjJ5Yy8d0txydMiuxCVL_j4abc_xyzV1989GmgRInaBYTw",
"preauth_url":"https://dataaccess.adb.us-
ashburn-1.oraclecloudapps.com/adb/p/Rt_yRfTxbcabc_xyzWlANP5RmM9Y/data",
"expiration_ts":"2024-10-25T02:30:39.810Z",
"expiration_count":null
}
```

   See Use Table Hyperlinks to Access Data with the Group By Option in Table Format for an example showing group by columns usage.

4. Run `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL` to generate the Table Hyperlink and specify a UI format option.

   For example, to set the columns that can be sorted use the `column_lists order_by_columns` option:

```
DECLARE
   status CLOB;
   column_lists CLOB;
   BEGIN
      DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL(
          schema_name => 'ADMIN',
          schema_object_name    => 'TREE_DATA',
          expiration_minutes    => 360,
          service_name          => 'HIGH',
          column_lists          => '{ "order_by_columns": ["COUNTY",
```

```
"SPECIES"] }',
          result                => status);
       dbms_output.put_line(status);
    END;
/
```

The `column_lists` parameter is JSON that contains a list of JSON arrays of columns defining Table Hyperlink functionality. Use this parameter to specify the columns for one or more of the options: `order_by_columns`, `filter_columns`, `default_color_columns`, or `group_by_columns`.

See GET_PREAUTHENTICATED_URL Procedure for more information.

5. Check the result.

   In this example `status` contains the result that includes information about the Table Hyperlink.

```
{
"status":"SUCCESS",
"id":"LLUZjJ5Yy8d0txydMiuxCVL_j4abc_xyzV1989GmgRInaBYTw",
"preauth_url":"https://dataaccess.adb.us-
ashburn-1.oraclecloudapps.com/adb/p/Rt_yRfTxbcabc_xyzk3EmM9Y/data",
"expiration_ts":"2024-10-25T02:30:39.810Z",
"expiration_count":null
}
```

   See Use Table Hyperlinks in Table Format with Column Sorting for an example showing order by columns usage.

You can also:

- Use `DBMS_DATA_ACCESS.LIST_ACTIVE_URLS` to show Table Hyperlinks. See List Table Hyperlinks for details.
- Use `DBMS_DATA_ACCESS.EXTEND_URL` to extend the life of a Table Hyperlink. See EXTEND_URL Procedure for more information.
- Generate Table Hyperlinks that are serviced with different service-level guarantees and resources. For example, access to an object or SQL statement can be mapped to services HIGH or MEDIUM, whereas access to another object or SQL statement can be mapped to the LOW service. See GET_PREAUTHENTICATED_URL Procedure for more information.

List Table Hyperlinks

You can list the active Table Hyperlinks that you generated on an Autonomous Database instance and the ADMIN user can list all active Table Hyperlinks.

Run `DBMS_DATA_ACCESS.LIST_ACTIVE_URLS` to list the active Table Hyperlinks. For example:

```
DECLARE
    result CLOB;
    BEGIN
       result := DBMS_DATA_ACCESS.LIST_ACTIVE_URLS;
       dbms_output.put_line(result);
    END;
/
```

This example shows the following output:

```
[{"id":"pT36lYHFGA4s3UXSNBCRO13v3D4_example1",
"created_by":"SCOTT",
"service_name":"HIGH",
"expiration_time":"2025-07-28T16:38:02.723Z",
"expiration_count":10,
"access_count":0,
"created":"2025-04-29T16:38:02.977Z",
"inherit_acl":true,
"is_group_url":false,
"group_ids":[null],
"sql_statement":"select * FROM TREE_DATA WHERE COUNTY = :county"}]
```

See LIST_ACTIVE_URLS Function for more information.

> **Note:**
>
> The behavior of `DBMS_DATA_ACCESS.LIST_ACTIVE_URLS` is dependent on the invoker. If the invoker is ADMIN or any user with `PDB_DBA` role, the function lists all active Table Hyperlinks, regardless of the user who generated the Table Hyperlink. If the invoker is not the ADMIN user and not a user with `PDB_DBA` role, the list includes only the active Table Hyperlinks generated by the invoker.

Invalidate Table Hyperlinks

At any time a user with appropriate privileges can invalidate a Table Hyperlink.

To invalidate a Table Hyperlink, you need the Table Hyperlink `id`. Use `DBMS_DATA_ACCESS.LIST_ACTIVE_URLS` to list each Table Hyperlinks and its associated `id`.

Use `DBMS_DATA_ACCESS.INVALIDATE_URL` to invalidate a Table Hyperlink. For example:

```
DECLARE
    status CLOB;
    BEGIN
       DBMS_DATA_ACCESS.INVALIDATE_URL(
        id => 'Vd1Px7QWASdqDbnndiuwTAyyEstv82PCHqS_example',
        result => status);
       dbms_output.put_line(status);
    END;
/
```

See INVALIDATE_URL Procedure for more information.

Define a Virtual Private Database Policy to Secure Table Hyperlink Data

By defining Oracle Virtual Private Database (VPD) policies for data that you share with a Table Hyperlink, you can provide fine-grained access control so that only a subset of data, rows, is visible for a specific Table Hyperlink.

Oracle Virtual Private Database (VPD) is a security feature that lets you control data access dynamically at row level for users and applications by applying filters on the same data set.

When a Table Hyperlink is accessed, the value of `application_user_id` specified during Table Hyperlink generation is available through `sys_context('DATA_ACCESS_CONTEXT$', 'USER_IDENTITY')`. You can define VPD Policies that make use of the value of this Application Context to restrict the data, rows, visible to the application user.

Any user who is granted access to read data with a Table Hyperlink can access and use the data (either a table, a view, or the data provided with a select statement). By defining a VPD policy on the database that generated a Table Hyperlink, you can use the `application_user_id` value in a SYS_CONTEXT rule to provide more fine-grained control. Consider an example where data is made available with a Table Hyperlink. If you want to restrict access to some of the data you can add a VPD policy.

For example:

1. Obtain the `application_user_id` value that you specified when you generated the Table Hyperlink.
2. Create VPD policy on the database where you generated the Table Hyperlink.

```
CREATE OR REPLACE FUNCTION limit_sal (v_schema IN VARCHAR2, v_objname IN
VARCHAR2)
  RETURN VARCHAR2 authid current_user AS
BEGIN
     RETURN 'employee_id = SYS_CONTEXT(''DATA_ACCESS_CONTEXT$'',
''USER_IDENTITY'')';
END;
```

   See DBMS_RLS for more information.

3. Register the VPD policy.

```
BEGIN
   DBMS_RLS.ADD_POLICY(
        object_schema        => 'HR',
        object_name          => 'EMPLOYEE',
        policy_name          => 'POL',
        policy_function      => 'LIMIT_SAL');
END;
/
```

   See DBMS_RLS for more information.

See Using Oracle Virtual Private Database to Control Data Access for more information.

Monitor and View Table Hyperlink Usage

Autonomous Database provides views that allow you to monitor Table Hyperlink usage.

Views	Description
V$DATA_ACCESS_URL_STATS and GV$DATA_ACCESS_URL_STATS Views	These views track Table Hyperlink usage, including elapsed time, CPU time, and additional information.

Use Table Hyperlink to Access Data

Table Hyperlink data is retrieved and returned in JSON format and is paginated.

> **Note:**
>
> Table Hyperlink data can be viewed in tabular format when accessed from a browser. See Use Table Hyperlinks to Access Data in Table Format for details.

You can access Table Hyperlink data using a browser or using any REST client. The data returned is paginated to allow you to access a maximum of 100 records at a time, with the total data size in the response limited to 1 MB. You can provide the `limit` query parameter to limit the number of records fetched. Table Hyperlink data retrieval is blocked if Table Hyperlink authentication fails or if the requested Table Hyperlink has expired.

For example, use a Table Hyperlink:

```
curl https://dataaccess.adb.us-chicago-1.oraclecloudapps.com/adb/p/K6XExample/
data
```

The Table Hyperlink response includes links for any previous or next pages, when the data includes more than one page. This allows you to navigate in either direction while fetching data. The JSON also includes a `self` link that points to the current page, as well as a `hasMore` attribute that indicates if there is more data available to fetch.

The following is the response format:

```
{
    "items": [],                <-- Array of records from database
    "hasMore": true OR false,   <-- Indicates if there are more records to
fetch or not
    "limit": Number,            <-- Indicates number of records in the page.
Maximum allowed number is 100.
    "offset": Number,           <-- Offset indicating the start of the
current page
    "count": Number,            <-- Count of records in the current page
    "links": [
        {
            "rel": "self",
            "href": "{Link to table hyperlink url for the current page}"
        },
        {
            "rel": "previous",
            "href": "{Link to table hyperlink url for the previous page}"
        },
        {
            "rel": "next",
            "href": "{Link to table hyperlink url for the next page}"
        }
    ]
}
```

For example, the following is a sample response from a Table Hyperlink (with newlines added for clarity):

```
{"items":[
{"COUNTY":"Main","SPECIES":"Alder","HEIGHT":45},
{"COUNTY":"First","SPECIES":"Chestnut","HEIGHT":51},
{"COUNTY":"Main","SPECIES":"Hemlock","HEIGHT":17},
{"COUNTY":"Main","SPECIES":"Douglas-fir","HEIGHT":34},
{"COUNTY":"First","SPECIES":"Larch","HEIGHT":12},
{"COUNTY":"Main","SPECIES":"Cedar","HEIGHT":21},
{"COUNTY":"First","SPECIES":"Douglas-fir","HEIGHT":10},
{"COUNTY":"Main","SPECIES":"Yew","HEIGHT":11},
{"COUNTY":"First","SPECIES":"Willow","HEIGHT":17},
{"COUNTY":"Main","SPECIES":"Pine","HEIGHT":29},
{"COUNTY":"First","SPECIES":"Pine","HEIGHT":16},
{"COUNTY":"First","SPECIES":"Spruce","HEIGHT":6},
{"COUNTY":"Main","SPECIES":"Spruce","HEIGHT":8},
{"COUNTY":"First","SPECIES":"Hawthorn","HEIGHT":19},
{"COUNTY":"First","SPECIES":"Maple","HEIGHT":16},
{"COUNTY":"Main","SPECIES":"Aspen","HEIGHT":35},
{"COUNTY":"First","SPECIES":"Larch","HEIGHT":27},
{"COUNTY":"First","SPECIES":"Cherry","HEIGHT":20},
{"COUNTY":"Main","SPECIES":"Pine","HEIGHT":37},
{"COUNTY":"Main","SPECIES":"Redwood","HEIGHT":78},
{"COUNTY":"Main","SPECIES":"Alder","HEIGHT":45},
{"COUNTY":"First","SPECIES":"Chestnut","HEIGHT":51},
{"COUNTY":"Main","SPECIES":"Hemlock","HEIGHT":17},
{"COUNTY":"Main","SPECIES":"Douglas-fir","HEIGHT":34},
{"COUNTY":"First","SPECIES":"Larch","HEIGHT":12},
{"COUNTY":"Main","SPECIES":"Cedar","HEIGHT":21},
{"COUNTY":"First","SPECIES":"Douglas-fir","HEIGHT":10},
{"COUNTY":"Main","SPECIES":"Redwood","HEIGHT":78}],

"hasMore":false,
"limit":100,
"offset":0,
"count":30,
"links":
[
{"rel":"self",
"href":"https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/
F5Sn..._example/data"}
]}
```

Use Table Hyperlink to Access Data with Bind Variables

If there is a bind variable in the `SELECT` statement when you generate a Table Hyperlink, you must either use the `default_bind_values` parameter when you generate the Table Hyperlink to specify a default bind variable value or you must pass a bind variable value as a query parameter to access the Table Hyperlink data.

Bind variable support is available for `NUMBER` and `VARCHAR2` column types.

For example, when a Table Hyperlink is generated with the following SQL statement without the `default_bind_values` parameter:

```
sql_statement = 'SELECT * FROM TREE_DATA WHERE COUNTY = :countyName'
```

You must append a bind variable and specify a value as a query parameter to access the data. For example:

```
curl https://dataaccess.adb.us-chicago-1.oraclecloudapps.com/adb/p/
K6X...example/data?countyNAME=MAIN
```

The bind value does not need to be specified in the URL when the `DBMS_DATA_ACCESS.GET_PREAUTHENTICATED_URL` includes the `default_bind_values` parameter:

```
sql_statement = 'SELECT * FROM TREE_DATA WHERE COUNTY = :countyNAME',
default_bind_values => '{"countyNAME" : "First"}',
```

In the case where `default_bind_values` defines a value for a variable you do not need to provide the value as a query parameter (the default value is supplied):

```
curl https://dataaccess.adb.us-chicago-1.oraclecloudapps.com/adb/p/
K6X...example/data

{"items":[
{"COUNTY":"First","SPECIES":"Pine","HEIGHT":16},
{"COUNTY":"First","SPECIES":"Spruce","HEIGHT":6},
{"COUNTY":"First","SPECIES":"Hawthorn","HEIGHT":19},
{"COUNTY":"First","SPECIES":"Cherry","HEIGHT":20},
{"COUNTY":"First","SPECIES":"Chestnut","HEIGHT":51}],
"hasMore":false,
"limit":100,
"offset":0,
"count":6,
"links":
[
{"rel":"self",
"href":"https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/
gTlbq...example/data"}
]}
```

When `default_bind_values` defines a bind variable value you can override the bind variable value by explicitly specifying a value as a query parameter. For example:

```
curl https://dataaccess.adb.us-chicago-1.oraclecloudapps.com/adb/p/
K6X...example/data?countyNAME=MAIN
```

See GET_PREAUTHENTICATED_URL Procedure for more information.

Use Table Hyperlinks to Access Data in Table Format

Table Hyperlink data can be viewed in tabular format when accessed from a browser. The table format supports scrolling, sorting, filtering, cell colors, and Group By where you select a column name to see column data based on the values in the column.

- Use Table Hyperlinks and View Data in Default Table Format
  You can access data with a Table Hyperline from a browser and view the data in table format.
- Use Table Hyperlinks in Table Format with Column Sorting
  You can access data with a Table Hyperlink from a browser and view the data in table format and sort table data.
- Use Table Hyperlinks in Table Format with Column Filtering
  You can access data with a Table Hyperlink from a browser and view the data in table format and filter table data.
- Use Table Hyperlinks to Access Data in Table Format with Colors in Cells
  You can access data with a Table Hyperlink from a browser and view the data in table format and display cell values with color.
- Use Table Hyperlinks to Access Data with the Group By Option in Table Format
  You can access data with a Table Hyperlink from a browser and group the data by the values of cells in a column.

Use Table Hyperlinks and View Data in Default Table Format

You can access data with a Table Hyperline from a browser and view the data in table format.

To return data in table format, append the `?view=table` query parameter to any Table Hyperlink. For example, from a browser use a Table Hyperlink with `?view=table` appended:

```
https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/F5Sn..._example/
data?view=table
```

Here is a sample response to a Table Hyperlink with `?view=table` appended:

COUNTY	SPECIES	HEIGHT
Main	Spruce	8
First	Douglas-fir	10
Main	Yew	11
First	Larch	12
First	Pine	16
First	Maple	16
Main	Hemlock	17
First	Willow	17
First	Hawthorn	19
First	Cherry	20

Column options are configurable when a Table Hyperlink is generated. See Generate a Table Hyperlink with UI Features Specified on Columns for more information.

Use Table Hyperlinks in Table Format with Column Sorting

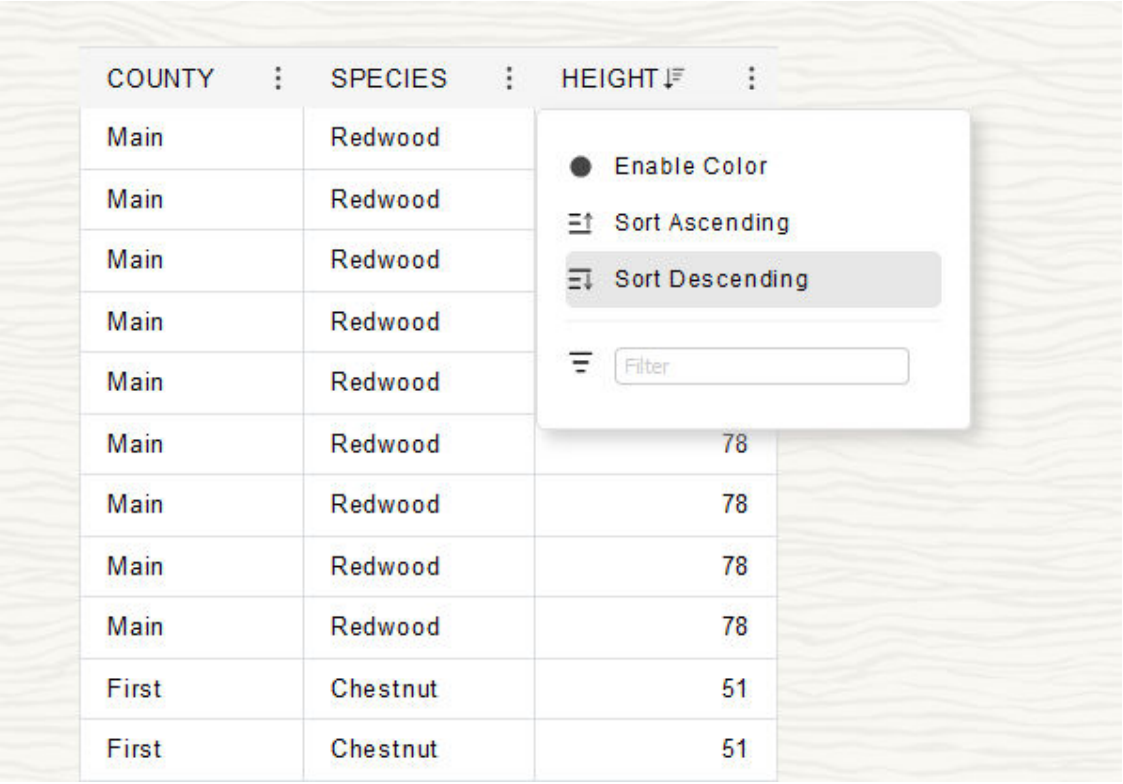
You can access data with a Table Hyperlink from a browser and view the data in table format and sort table data.

To return data in table format, append the `?view=table` query parameter to any Table Hyperlink. For example, from a browser use a Table Hyperlink with `?view=table` appended:

```
https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/F5Sn..._example/
data?view=table
```

In table view you can sort Table Hyperlink columns in ascending or descending order by clicking ⋯ next to a column heading, and then select **Sort Ascending** or **Sort Descending**.

For example:



Column sorting is configurable by column when a Table Hyperlink is generated. See Generate a Table Hyperlink with UI Features Specified on Columns for more information.

Use Table Hyperlinks in Table Format with Column Filtering

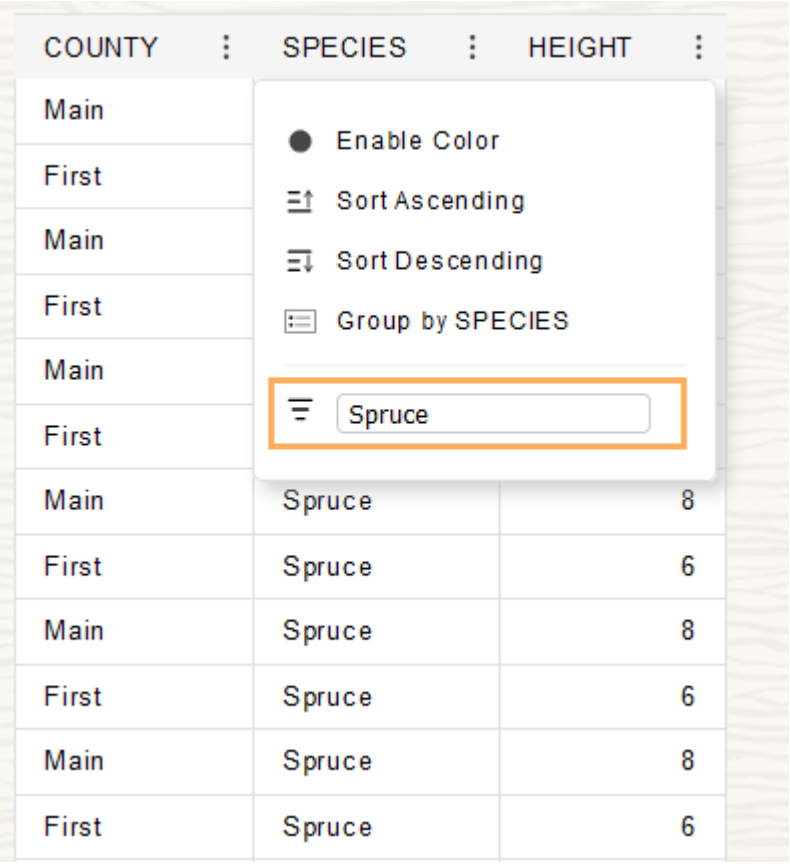
You can access data with a Table Hyperlink from a browser and view the data in table format and filter table data.

To return data in table format, append the `?view=table` query parameter to any Table Hyperlink. For example, from a browser use a Table Hyperlink with `?view=table` appended:

```
https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/F5Sn..._example/
data?view=table
```

You can filter Table Hyperlink columns by clicking ... next to a column heading, and then enter the filter text in the input text box, and type **Enter**.

The following is a screenshot of a sample table with the `SPECIES` column filtered to only display data for Spruce trees:



Column filtering is configurable by column when a Table Hyperlink is generated. See Generate a Table Hyperlink with UI Features Specified on Columns for more information.

Use Table Hyperlinks to Access Data in Table Format with Colors in Cells

You can access data with a Table Hyperlink from a browser and view the data in table format and display cell values with color.

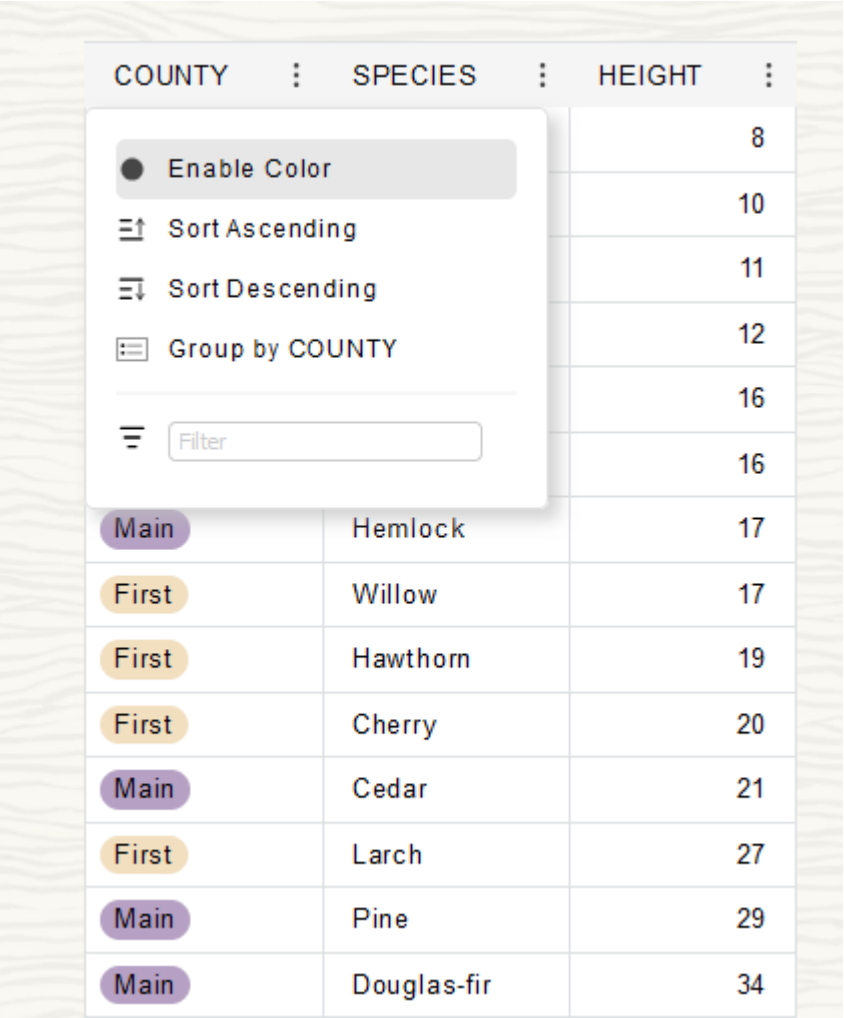
You can access Table Hyperlink data with a browser and view the returned data in database table like format. The table format supports scrolling, sorting, filtering and cell colors.

To return data in table format, append the `?view=table` query parameter to any Table Hyperlink. For example, from a browser use a Table Hyperlink with `?view=table` appended:

```
https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/F5Sn..._example/
data?view=table
```

By default columns do not include coloring for cell values. You can add color to cell values in Table Hyperlink table view by clicking ... next to a column heading, and then select **Enable Color**.

The following is a screenshot of a sample table with the `SPECIES` column showing color with values in cells:

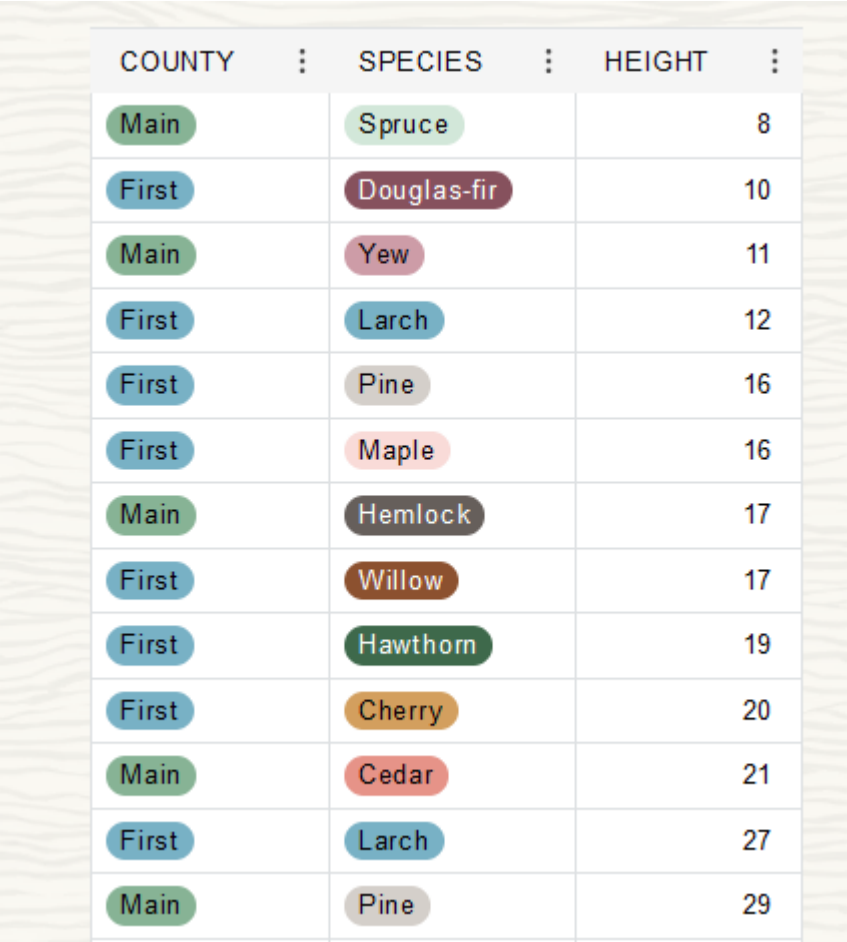


Color Column Data with Query Parameters

You can also use query parameters select the columns you want to add color to. To specify the columns with color, include the column names with the `colored_column_names` query parameter. For example, to color the `COUNTY` and `SPECIES` columns:

```
https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/F5Sn..._example/
data?view=table&colored_column_names=COUNTY,SPECIES
```

The following is a screenshot of a sample table with COUNTY and `SPECIES` columns showing color with cell values:



COUNTY	SPECIES	HEIGHT
Main	Spruce	8
First	Douglas-fir	10
Main	Yew	11
First	Larch	12
First	Pine	16
First	Maple	16
Main	Hemlock	17
First	Willow	17
First	Hawthorn	19
First	Cherry	20
Main	Cedar	21
First	Larch	27
Main	Pine	29

Color Column Data Types with Query Parameter

You can also use query parameter to select a specific column data type to add color in a table by providing the data type with the `colored_column_types` query parameter.

This parameter supports `colored_column_types=VARCHAR` to color all the string (VARCHAR) columns, and `colored_column_types=NONE` to not color any data types.

For example:

```
https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/F5Sn..._example/
data?view=table&colored_column_types=VARCHAR
```

Use Table Hyperlinks to Access Data with the Group By Option in Table Format

You can access data with a Table Hyperlink from a browser and group the data by the values of cells in a column.

The Table Hyperlink generation procedures supports column list options that provides support specifying columns and viewing column values with the group by option.

For example, when group by is specified when a Table Hyperlink is generated, do the following to view data by group:

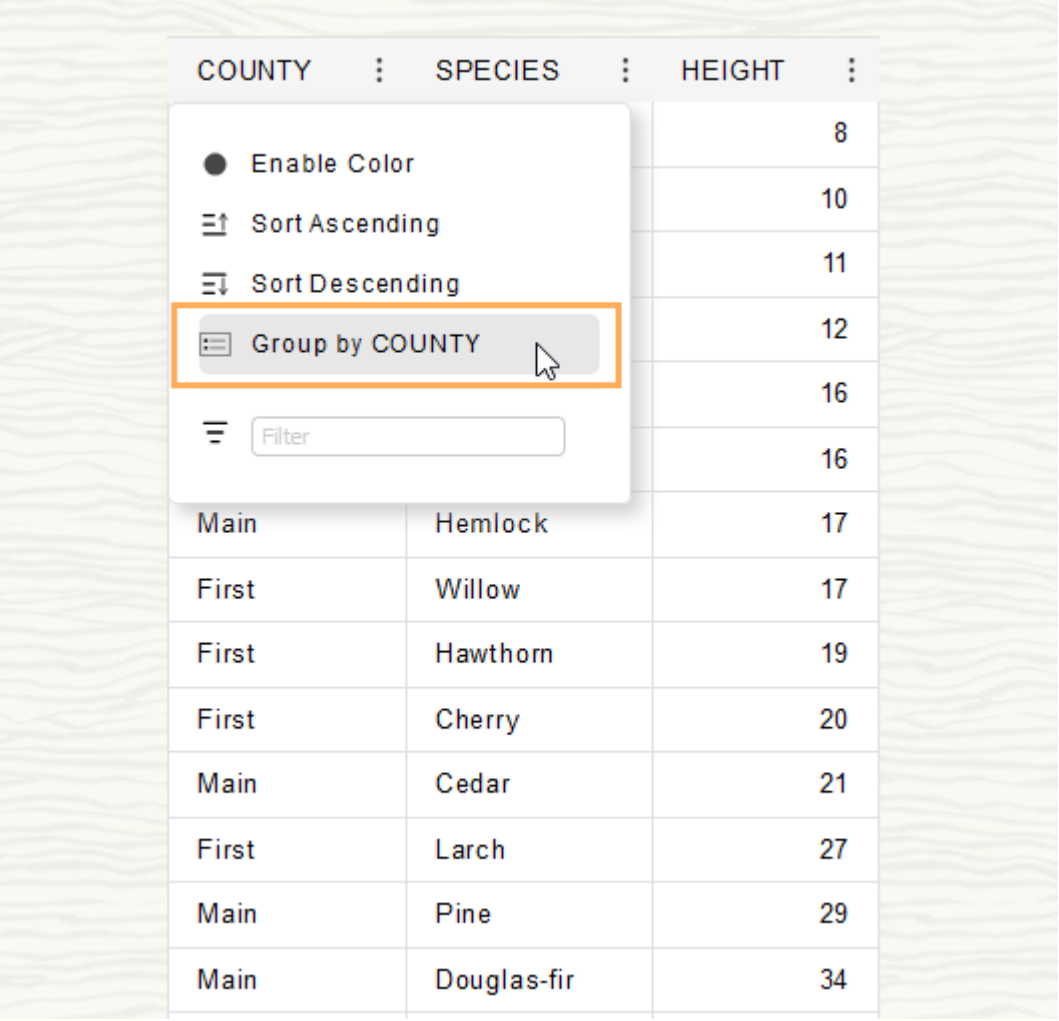
1. From a browser use a Table Hyperlink with `?view=table` appended.

For example:

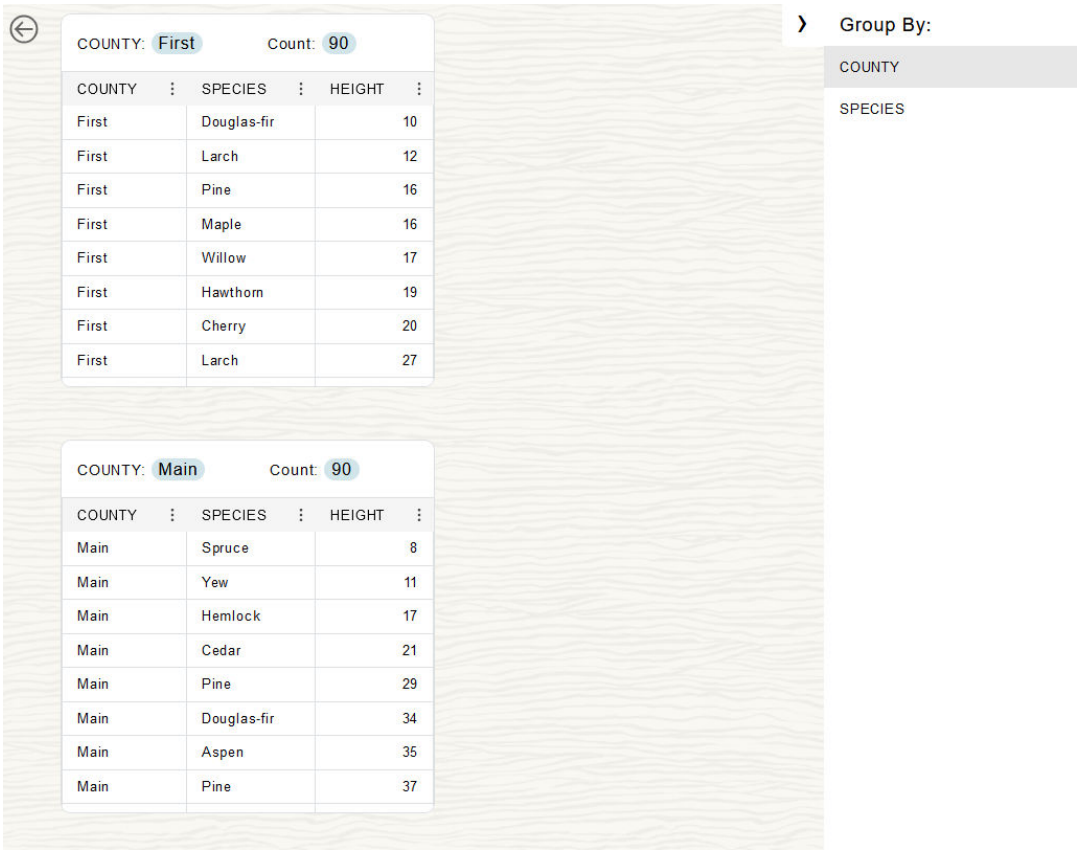
```
https://dataaccess.adb.us-ashburn-1.oraclecloudapps.com/adb/p/
F5Sn..._example/data?view=table
```

2. From a column that shows the group by option, select **Group by**.

   For example:



This shows the Group by display, and allows you to select another column if another column is available for group by display (depending on how the Table Hyperlink was generated).



By default the Table Hyperlink columns do not support group by options. This option is configurable by column when a Table Hyperlink is generated. See Generate a Table Hyperlink with UI Features Specified on Columns for more information.

Use Table Hyperlinks to Create an External Table

You can create an external table over an Autonomous Database Table Hyperlink.

You can use a single Autonomous Database Table Hyperlink or a comma-delimited list of Autonomous Database Table Hyperlinks to create an external table. See Query Data that Uses Table Hyperlink Source for more information.

Share Data with Data Studio

The Data Share tool enables you to share data and metadata with other users. The Data Share page displays information about the different types of shares available in the Oracle Autonomous Database.

See The Data Share Tool for more information.

- The Data Share Tool
  The Data Share tool allows you to share Oracle data and metadata with other databases and non-database tools. The Data Share page displays information about the different types of shares available in the Oracle Autonomous Database.

The Data Share Tool

The Data Share tool allows you to share Oracle data and metadata with other databases and non-database tools. The Data Share page displays information about the different types of shares available in the Oracle Autonomous Database.

- Overview of the Data Share Tool
  Oracle Autonomous Database enables you to create shares using the share tool.
- Access and Enable the Data Share Tool
  To share or consume data using the Data Share tool, navigate to the Data Studio, launch the Data Share tool, and enable sharing.
- Provide Share
  Use the Provide Share page to view the number of shares of the database, and the number of share recipients, search for a share entity, search for a recipient, create a new share, and create a new recipient.
- Consume Share
  Once the providers share the objects, there are a few steps the recipients need to follow to consume the share.
- Data Share Limitations on Autonomous Database
  This section summarizes the limitations of Data Share (both Versioned and Live Share) included in the Oracle Autonomous Database.
- Troubleshooting Errors with the Data Share Tool
  This chapter provides instructions on what issues cause slow performance and how to troubleshoot the issues.
- FAQs on the Data Share Tool
  The following are frequently asked questions on the Data Share tool.

Overview of the Data Share Tool

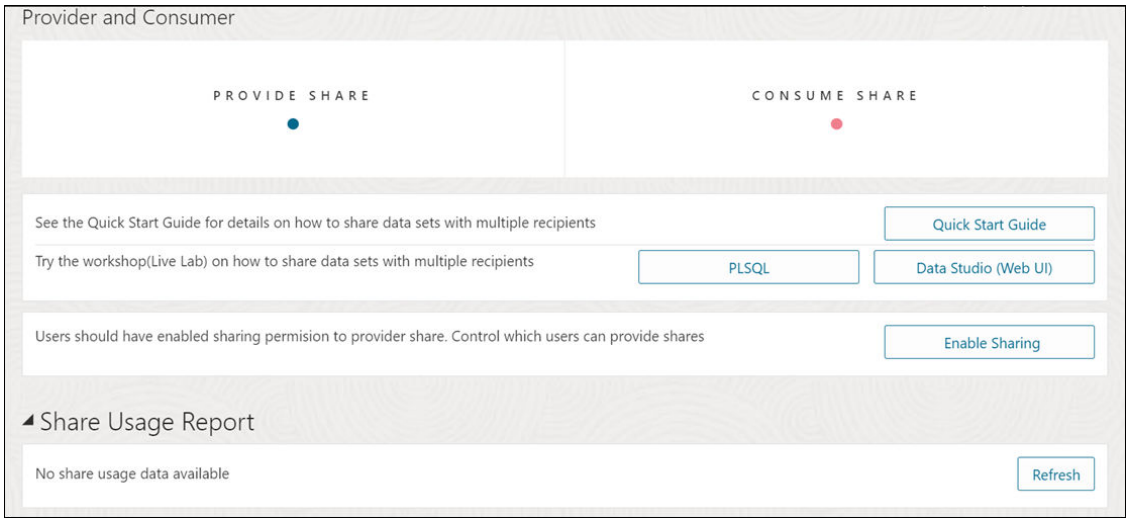
Oracle Autonomous Database enables you to create shares using the share tool.

Sharing objects requires two steps. The Provider provides data share for access and the Consumer role consumes (or receives) access to the published shares. The provider creates a share with the objects to share in the desired cloud object location. The provider also adds the recipient. The recipient accepts and receives the configured shared objects from the provider for consumption.

> **Note:**
>
> You must have the correct privileges to create or consume a data share. In case the Data Share card is disabled, click on the tool tip and follow the steps for the administrator to grant you the required privilege.

Select the **Data Share** menu from the Data Studio suite in the Database Actions homepage to access this tool. This opens the **Data Share** homepage. It consists of widgets that enable you to provide and consume share objects.

> **Note:**
>
> This is the homepage you view after you have enabled sharing and set Provider identification details.



> **Note:**
>
> If you do not see the Data Share tool card then your database user is missing the required DWROLE role.

Click Quick Start Guide to familiarize yourself with the Data Share tool.

Click PLSQL or Data Studio (Web UI) to try Data Sharing with PL/SQL or Data Studio without creating an account on Oracle Cloud tenancy.

Click **Enable Sharing** to grant sharing permission to you as a provider. See Access and Enable the Data Share Tool for more details.

The widgets are defined in the following sections:

- Provide Share
- Consume Share

Share Terminology

Provider: The Autonomous Database Serverless enables the provider to share existing objects. The share can contain a single table, a set of related tables, or a set of tables with some logical grouping. It could be a person, an institution, or a software system that shares the objects.

Example: An institution, such as NASA, that makes a data set available via data.gov.

Recipient: A Share recipient is an entity that associates an individual, an institution or a software system that receives a share from a provider. A recipient can have access to multiple shares. If you remove a recipient, that recipient loses access to all shares it could previously access.

Example: An external system, such as Microsoft Power BI, that supports the Delta Sharing REST API.

Share: A Share is a named entity in the provider's instance. It can be a group of datasets shared as a single entity.

Example: A SALES table that needs to be shared within an organization.

Overview of Providers and Recipients

A Data Share is the logical container that contains objects (such as tables) that share recipients will get access to a share and all tables within this share. A Data Share also implements security mechanisms on a high object level which simplifies the authorization for a set of individual objects. A provider creates and publishes share of a versioned type. The recipient is given access to a share. The provider can modify shares (both data and metadata) after the provider publishes the share to the recipients.

Use Case of Data Share

A marketing agency can share sales information with multiple interested parties. The Data Analysis tool analyses the data, generates insights and then the application shares the information with interested parties.

How the Data Share tool works?

Data is made accessible by the data sharing provider (that is an Oracle Autonomous Database) to the data sharing recipient at query time in parquet format for a versioned share. A live share uses cloud links and can only be consumed in an Oracle database The provider can only share data which they have access to when they log into an autonomous database instance.

As a data provider, you create a share and select other additional entities to share. The Oracle Data Sharing for general recipients is based on the open delta sharing standard protocol, providing a simple REST-based API to share data in parquet format. For near real-time access to shared data, customers can use Live Shares accessed using the consumer's ADB-S instance.

The Autonomous Database Serverless Versioned Sharing protocol works as follows:

- The provider creates and publishes a share that can be shared with one or multiple recipients. Every recipient will get a personal activation link to download their own JSON profile with the necessary information to access their share.
- The versioned share recipient registers with the share server by entering the URL for the end point along with a client ID, secret key and a bearer token.
- The versioned share recipient retrieves data from the share by calling the /shares/../tables/../query endpoint to obtain a list of URLs. The recipient then sends a GET request on these URLs to obtain the parquet files.

The Autonomous Database Serverless Live Sharing protocol works as follows:

- For a Live Share, the intended recipient will copy the sharing ID from the consumer page and publish the share that can be shared with recipients. This is the case when provider shares to only one database.

- A provider can share also share to **ALL_REGIONS**, **ALL_TENANCY**, or **ALL_COMPARTMENTS**.

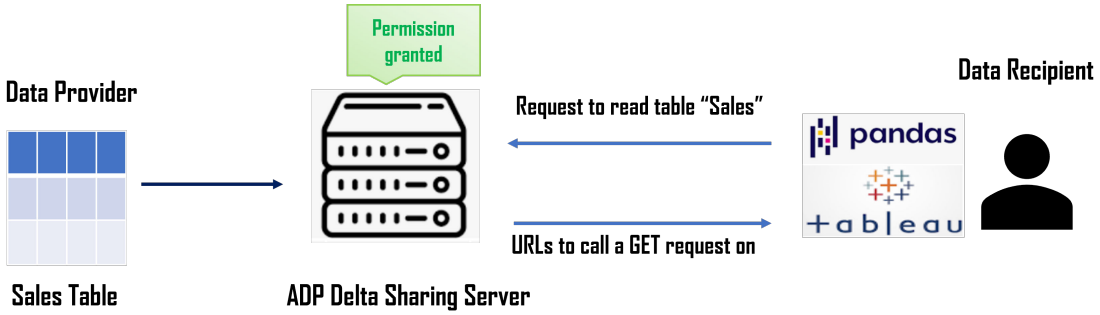
Features of Autonomous Database Serverless Share

With Autonomous Database Share you can:

- Share objects easily across Autonomous Databases and all tools or APIs that support the open delta sharing protocol.
- Share versioned data with many recipients without data replication for all recipients.
- Establish secure and centrally managed data sharing and collaboration within and across organizations.

Share Architecture

The following diagram is a generalized flow diagram of the architecture of the Data Share.



Prerequisites for Share Providers

Here are some prerequisites for a share provider to use the share tool:

- For a versioned share, you must have read and write access to a bucket to store or cache your shares.
- The schema you wish to use to create and publish shares must be enabled by an `ADMIN` user.

Prerequisites for Share Recipients

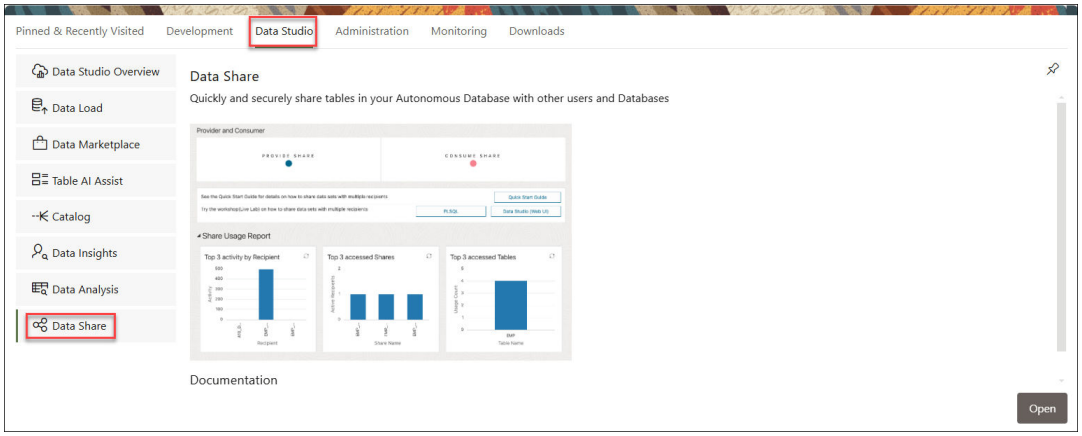
The share recipient must have a valid email address a provider can use to register the recipient to use the share tool. Oracle Data Share allows to share the information about a recipient's activation link by email.

Access and Enable the Data Share Tool

To share or consume data using the Data Share tool, navigate to the Data Studio, launch the Data Share tool, and enable sharing.

Follow these steps:

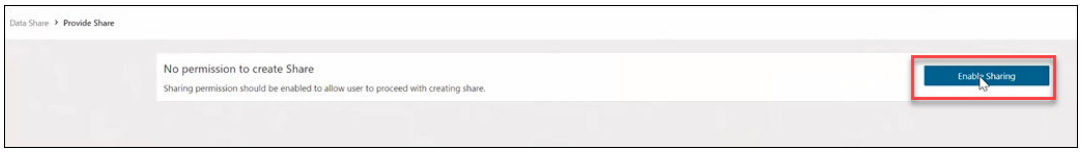
1. Navigate to the **Launchpad** on your Database Actions instance.
2. Click the **Data Studio** tab and select the **Data Share** pane.



3. Clicking the Data Share pane opens a Provider and Consumer page where you can view **Provide Share** and **Consume Share** widgets.

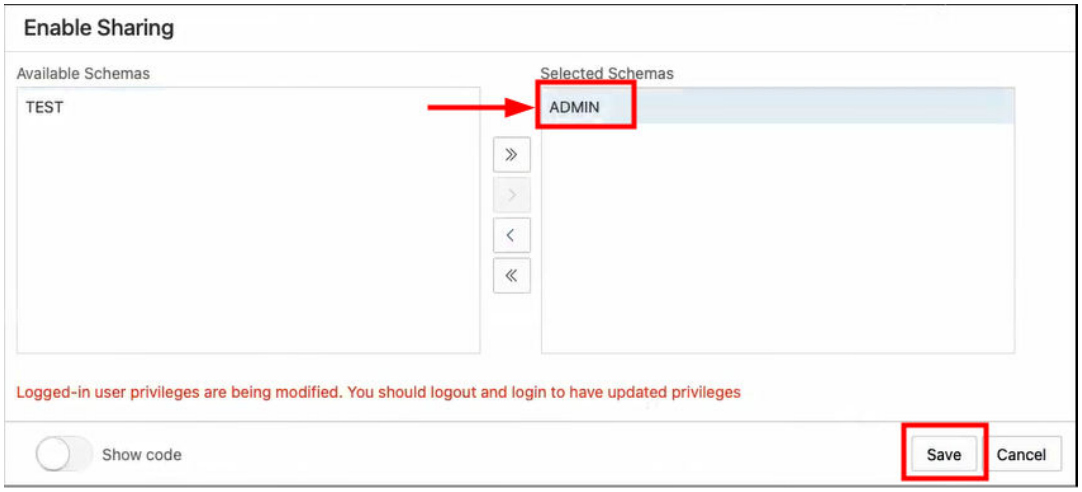
Click **Provide Share**.

4. On the **Provide Share** page, click **Enable Sharing**.



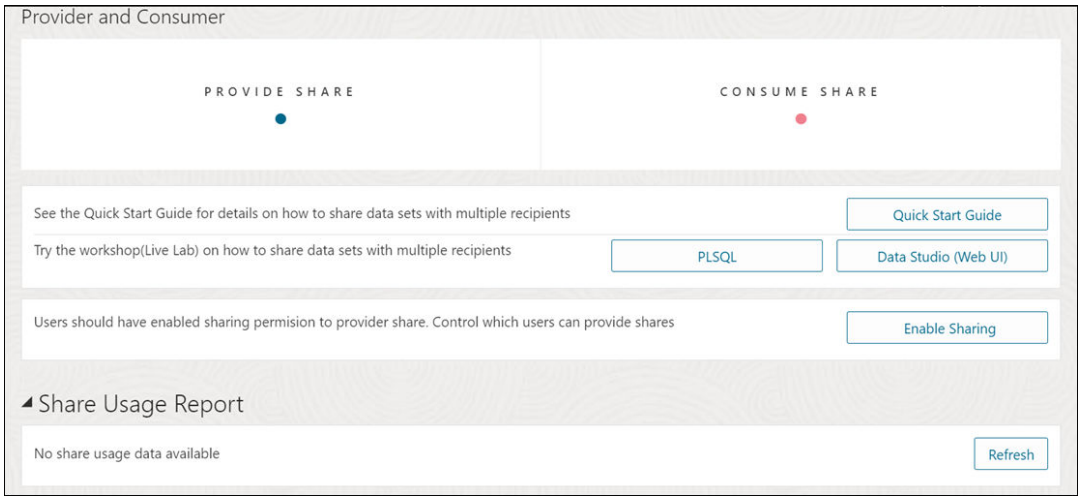
Clicking the **Enable Share** icon takes you to the Enable Sharing screen where you must select the user schema you want to enable and move it from the Available Schemas column to the Selected Schemas column.

5. Click **Save**.



6. Log out and log in again to update privileges.

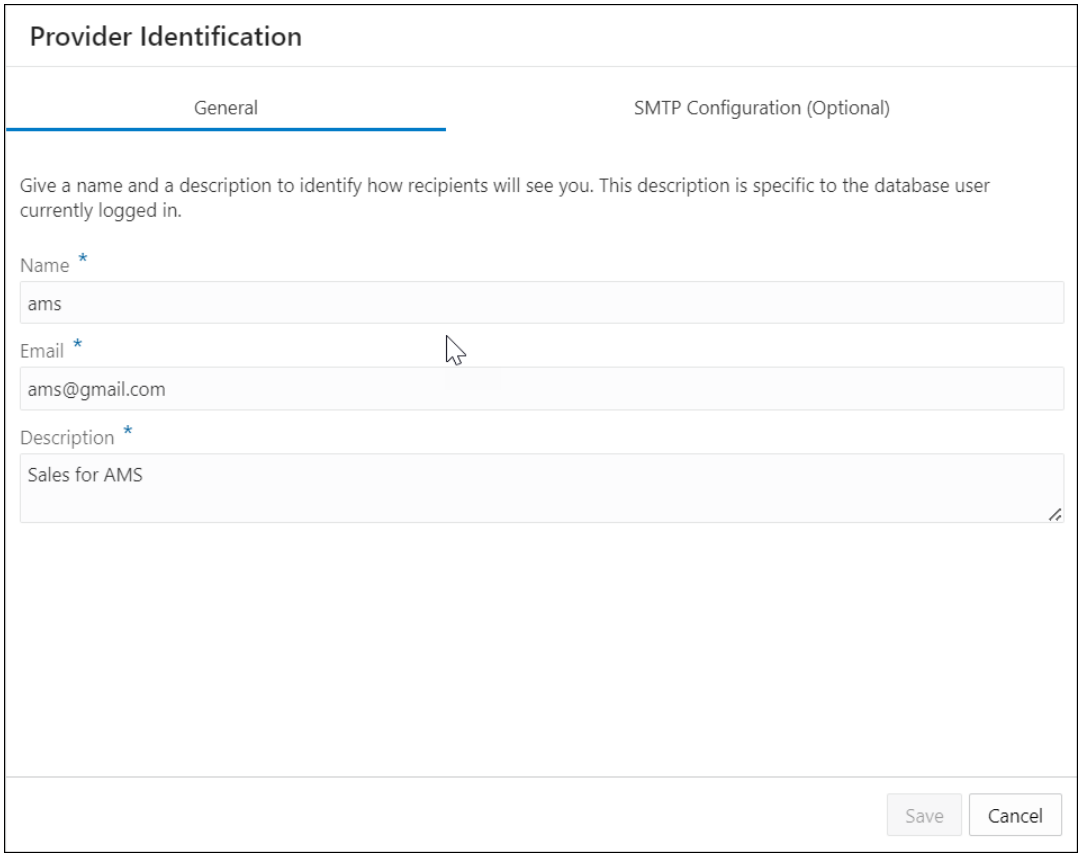
7. You now view the following **Provider** and **Consumer** page.



You have now enabled the share. Click **Provide Share**. On the Provide Share page, click **Provider Identification** to create a Provider ID. This provides information to the recipient on how to identify you.

This field provides the details of the provider before you share the data. The share provider identification will be available to recipients with whom you grant the share.

Selecting this button opens a Provider Identification wizard. Specify the following fields on the General tab of the Provider Identification wizard:



- **Name**: Enter the name of the provider. For example, *ams*.
- **Email**: Enter the email address of the provider. For example, *ams@gmail.com*.
- **Description**: Enter a description of the provider. For example, *AMS sharing stuff*.

Progress to the Simple Mail Transfer Protocol (SMTP) Configuration tab of the wizard. This tab configures email service like a local email client on your system (e.g., Thunderbird).

> **Note:**
>
> You must configure SMTP only once and then the system uses the saved configuration from that point forward.

Specify the following field values in the SMTP Configuration tab of the wizard:

- **Server host**: Enter the endpoint used to send the email. For example, *internal-mailrouter.oracle.com*.
- **Server port**: Enter the SMTP port used to accept an email. Email Delivery supports TLS on port 25. Sender: Enter the email address of the sender. For example, *oaapgens_us@oracle.com*.
- **Server Encryption**: This field indicates if TLS, the standard means of performing encryption in transit for emails, is being used. Providers must encrypt emails while it's in transit to the Oracle Cloud Infrastructure Email Delivery service. Encrypted emails are protected from being read during transit. If there is no encryption, enter, *None*.

Select credential to use for SMTP connection from the drop-down. If there is no available credential in the drop-down, you can create credential by clicking **Create Credential** icon. Refer to Create Oracle Cloud Infrastructure Native Credentials for more details.

Click **Test** to test the SMTP configuration. You will view a screen that asks you to run the ACL script. You can run the script if you have the ADMIN rights. This is just a first time setting. After you receive a successful message of SMTP Test, you can save the SMTP configuration.

You can now start sharing your data.

Provide Share

Use the Provide Share page to view the number of shares of the database, and the number of share recipients, search for a share entity, search for a recipient, create a new share, and create a new recipient.

The Provide Share page consists of widgets Shares and Recipients and icons to create Shares and Recipients. The page is described in the following sections:

- Provide Share Overview
  Use the Provide Share to create and publish shares.
- Provide Versioned Share
  In this type of share, data is shared and published as well-defined, known, as-of-snapshots. At the time of publication, the tool generates and stores the data share as parquet files in the specified bucket. The recipient can directly access the share in the object store.
- Provide Live Share
  In this type of share the recipient accesses data directly from the Oracle table or view. This share gives the recipient the latest data. Live Share works by querying data over a cloud

link, which is implemented on a database link. The database link allows you to query objects over the network on a foreign machine and schema. The advantage of this mode is that the data is up to date as of the time of query.

- View Share Entity Details
  Use the **Actions** icon at the right of the share entity entry to view details about the live share or delta share entity you create.
- Create Share Recipient
  Use the **+ Create Share Recipient** icon on the Provide Share page to create a consumer of the data share. When there is already a recipient created, use the **+ Create Recipient** icon on the Recipients widget of the Provide Share page to create a consumer of the data share.
- View Share Recipient Entity Details
  Use the **Actions** icon at the right of the share recipient entity entry to view details about the live share or delta share recipient entity you create.
- Provide Share Overview
  The Provide Share page enables you to view, create, edit, and access information on the shares and recipients you create from this page.
- Provide Versioned Share
  You can share data as a set of distinct versions, such as at the end of each day. The recipient will only see changes to the data when you publish a new version. As a versioned share Provider, you must create an OCI native credential and associate the bucket's URL with the credential.
- Provide Live Share
  You can share data as of the latest database commit with Autonomous Databases in the same region. The recipient will always see the latest data.
- View Share Entity Details
  To view details about an entity, click the **Actions** icon at the right of the Share entity entry, then click **View Details**.
- Create Share Recipient
  On the Provide Shares page, click the **Recipients** widget and select **+ Create Recipient** to create a new Share Recipient.
- View Share Recipient Entity Details
  Click the **Actions** icon at the right of the Share Recipient entity entry, then click **View Details**.

Provide Share Overview

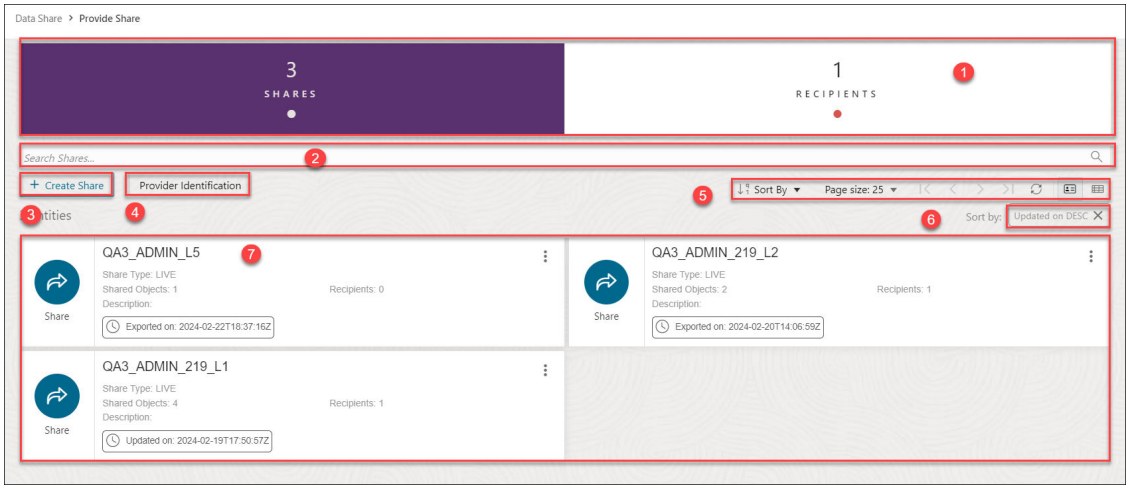
The Provide Share page enables you to view, create, edit, and access information on the shares and recipients you create from this page.

Click the **Provide Share** menu under Data Share in the Data Studio menu to reach the Provide Share page. You can switch the display of the Provide Share screen based on the widget you select from the Shares and Recipients section.

The search field and the display area of the **Provide Share** page varies when you switch between the **SHARES** and **RECIPIENTS** widgets.

Shares Page

The following image displays the Provide Share page when you select the **SHARES** widget.



The Provide Share page when you select the Shares widget consists of the following:

1. The top section of the Provide Share page displays Shares and Recipients section with two widgets. The widgets are defined in the following sections:
   - **SHARES**- Select this widget to view, search and perform actions on the Shares you create.
   - **RECIPIENTS**- Select this widget to view, search and perform actions on the Share Recipients you create.
2. **Search Shares** field
   Selecting Shares widget enables you to search for the share you create. You can click the field and type or paste the name of the share or the recipient you are looking for. Click the magnifier icon to return the search input. Click **X** to clear your searches in the Search Shares field.
3. **+ Create Share** button
   You can use the **Create Share** wizard to define data shares based on object storage data and associate them with recipients. A single data share can consist of multiple shared objects that are shared with one or multiple recipients.

   You can create a new share and a new recipient from this button. Refer to the Provide Live Share, Provide Versioned Share and Create Share Recipients section to explore more on what each button does.
4. **Provider Identification** button : See Access and Enable the Data Share tool to view more about this icon for a first time user. If you have already configured SMTP, you can edit the Provider ID or set SMTP using this button.
5. **Toolbar**
   The toolbar consists of the following buttons:
   - **Sort By**
     To select sorting values, click the **Sort By** button to open the list of options. Then click the **Ascending** or **Descending** icon next to one or more of the sorting values.

     For example, if you select the **Ascending** icon next to **Entity name** and the **Descending** icon next to **Entity type**, the entities will be sorted in alphabetical order by entity name and then in reverse alphabetical order by entity type.

     Click **Reset** in the list to clear the choices in the list.

     The sorting values you choose are listed next to the **Sort by** label beneath the toolbar. Click the **X** icon on a sorting value to remove it.
   - **Page size**

By default, up to 25 entities are displayed on the page. If you want more entities on a page, select a number from this list.

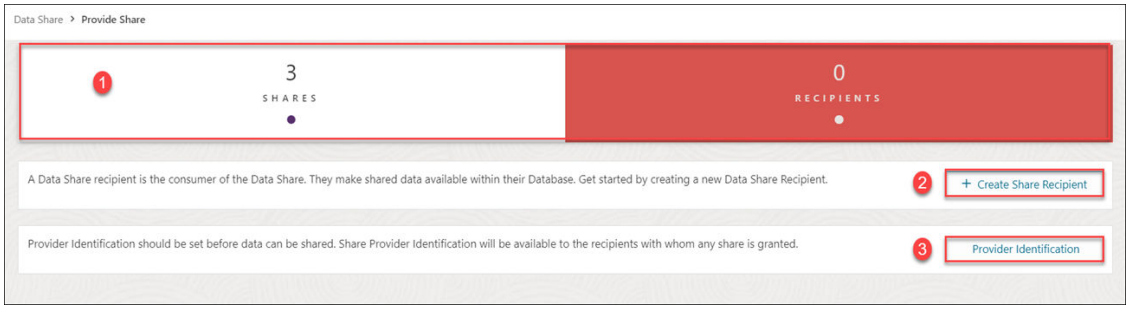
- **Previous** and **Next**
  If the search results are displayed on multiple pages, click these buttons to navigate through the pages.
- **Refresh**
  Click to refresh the entities shown on the page, based on the current search string.
- **Entity view options**
  Choose one of these three options to set how entities are displayed on the page.

  Click **Open Card view** to display entities as card arranged into one or two columns; click **Open Grid View** to display entities as rows in a table; or click **Open List View** to display entities in a single column of panels.

6. **Sort by settings**
   When you set sorting values by using the Sort By control in the toolbar, the settings are displayed in small boxes beneath the toolbar. You can delete a setting by clicking the X icon in the box. Or you can change the settings by returning to the Sort By control in the toolbar.
7. **Display area**
   The area below the Search field displays the entities returned by a search. If you select the Shares widget, you will view the Share entities in the display area. If you select the Recipient widget, you will view the Share Recipient entities in the display area. This area shows all providers you are subscribed to.

Recipients Page

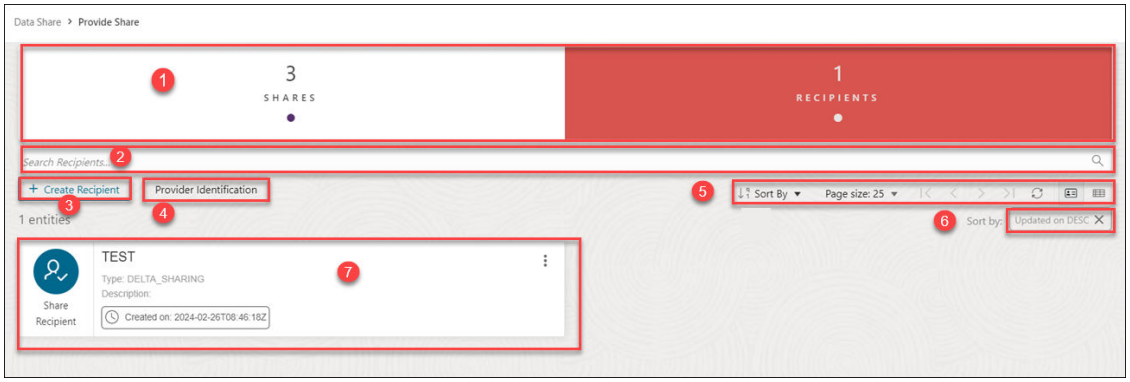
The following image displays the Provide Share page when you select the RECIPIENTS widget and ***there is no RECIPIENT created***



Click **+ Create Share Recipient** to create a share recipient. See Create Share Recipient for more details.

Click **Provider Identification** to specify the name and description to identify how the recipients will view you. You can also configure SMTP settings.

The following image displays the Provide Share page when you select the RECIPIENTS widget and ***there is minimum one RECIPIENT already created***



The Provide Share page consists of the following:

1. The top section of the Provide Share page displays Shares and Recipients section with two widgets. The widgets are defined in the following sections:
   - **SHARES**- Select this widget to view, search and perform actions on the Shares you create.
   - **RECIPIENTS**- Select this widget to view, search and perform actions on the Share Recipients you create.
2. **Search Recipients** field
   Searching for a share or recipient depends on the widget you select from the Shares and Recipients section. If you select the Recipients widget, you can search for the recipients you create. You can click the field and type or paste the name of the share or the recipient you are looking for. Click the magnifier icon to return the search input. Click **X** to clear your searches in the Search Shares or Search Recipients field.
3. **+ Create Recipient** button
   You can create a new share and a new recipient from this button. Refer to the Provide Live Share, Provide Versioned Share and Create Share Recipients section to explore more on what each button does.
4. **Provider Identification** button: See Access and Enable the Data Share tool to view more about this icon for a first time user. If you have already configured SMTP, you can edit the Provider ID or set SMTP using this button.
5. **Toolbar**
   The toolbar consists of the following buttons:
   - **Sort By**
     To select sorting values, click the **Sort By** button to open the list of options. Then click the **Ascending** or **Descending** icon next to one or more of the sorting values.

     For example, if you select the **Ascending** icon next to **Entity name** and the **Descending** icon next to **Entity type**, the entities will be sorted in alphabetical order by entity name and then in reverse alphabetical order by entity type.

     Click **Reset** in the list to clear the choices in the list.

     The sorting values you choose are listed next to the **Sort by** label beneath the toolbar. Click the **X** icon on a sorting value to remove it.
   - **Page size**
     By default, up to 25 entities are displayed on the page. If you want more entities on a page, select a number from this list.
   - **Previous** and **Next**
     If the search results are displayed on multiple pages, click these buttons to navigate through the pages.

- **Refresh**
  Click to refresh the entities shown on the page, based on the current search string.
- **Entity view options**
  Choose one of these three options to set how entities are displayed on the page.

  Click **Open Card view** to display entities as card arranged into one or two columns; click **Open Grid View** to display entities as rows in a table; or click **Open List View** to display entities in a single column of panels.

6. **Sort by settings**
   When you set sorting values by using the Sort By control in the toolbar, the settings are displayed in small boxes beneath the toolbar. You can delete a setting by clicking the **X** icon in the box. Or you can change the settings by returning to the Sort By control in the toolbar.
7. **Display area**
   The area below the Search field displays the entities returned by a search. If you select the Shares widget, you will view the Share entities in the display area. If you select the Recipient widget, you will view the Share Recipient entities in the display area.

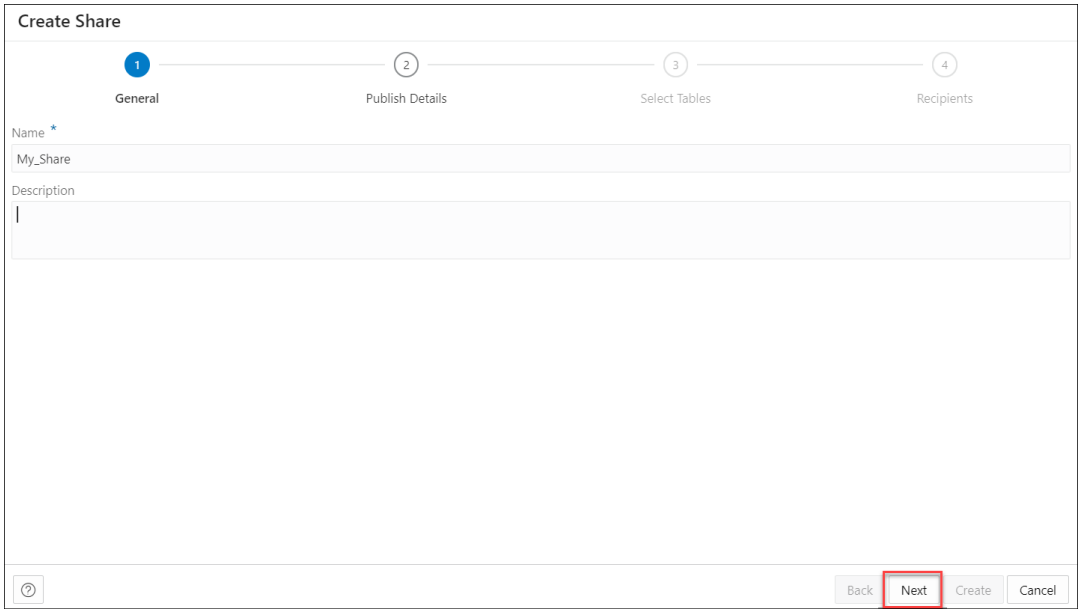
Provide Versioned Share

You can share data as a set of distinct versions, such as at the end of each day. The recipient will only see changes to the data when you publish a new version. As a versioned share Provider, you must create an OCI native credential and associate the bucket's URL with the credential.

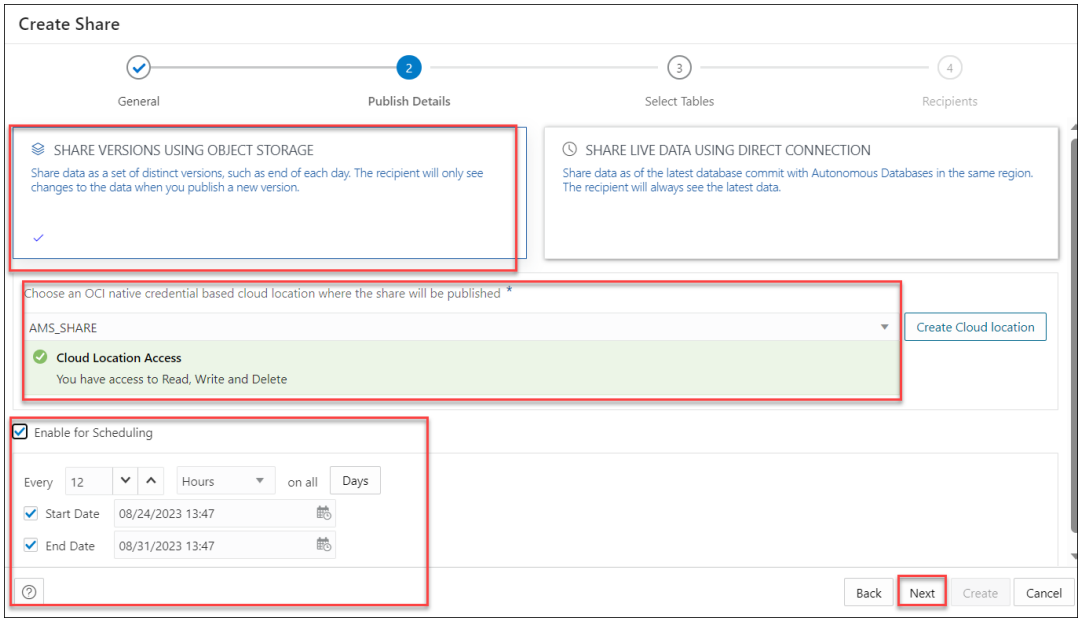
On the Provide Share page, select **+ Create Share** from the Create menu. This brings up the **Create Share** wizard.

1. On the Create Share wizard, in the **Name** field of the General tab, enter a name for the Share. For example: *My_Share*.
   In the **Description** field, enter a description for the link. For example: *Weekly Sales report*.

   Select **Next** to progress to the Publish Details tab of the Create Share wizard. You can alternatively click on the Publish Details tab to progress to the Publish Details screen of the wizard.



2. In the Publish Details Tables tab of the wizard, select **SHARE VERSIONS USING OBJECT STORAGE**.



Select a cloud location where you want the share to be published. If you already have an OCI cloud storage location available, use the **Select Cloud location** drop-down and select any available Cloud location from the drop-down. You will view a successful message if you have access to read, write, or delete in that cloud location.

> **Note:**
>
> Select **Create Cloud location** and follow the steps described in the Create Oracle Cloud Infrastructure Native Credentials if you do not have a cloud location available.

For sharing versioned data, you can enable the schedule for share. Select **Enable For Scheduling** option to set up a schedule for sharing. In the time interval fields, enter a number, and select a time type and the days on which to poll the bucket for new or changed files. For example, to poll every two hours on Monday, Wednesday, and Friday, enter **2**, select **Hours**, and then select **Monday**, **Wednesday**, **Friday** in the appropriate fields. You can select **All Days**, **Monday to Friday**, **Sunday to Thursday**, or **Custom** from the Week Days drop-down. The Custom field enables you to select Monday, Tuesday, Wednesday, Thursday and Friday in the appropriate fields.

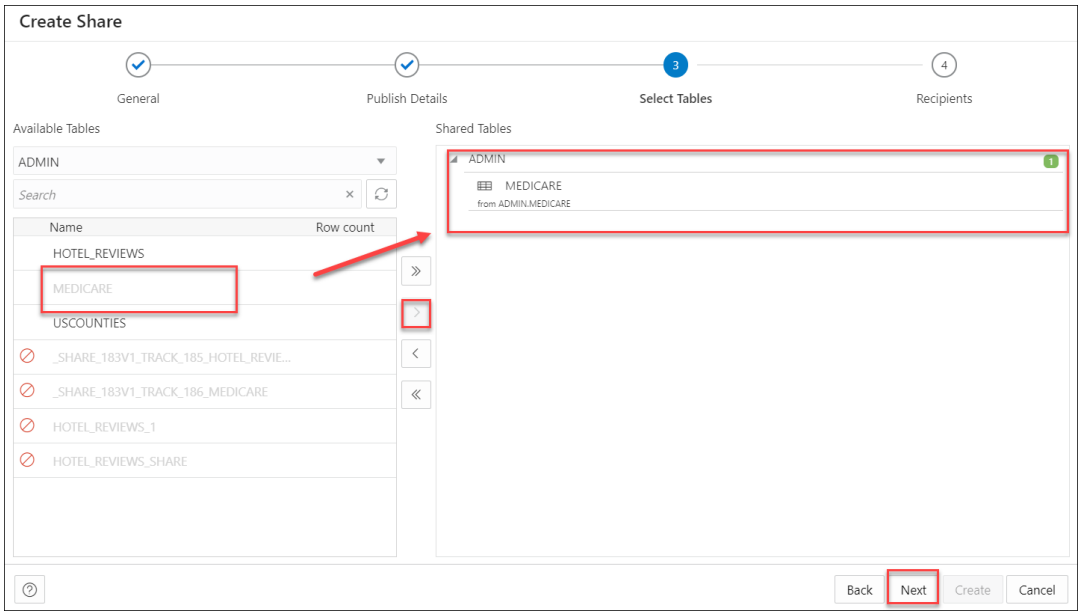
Select a start and end date. If you don't select a start date, the current time and date are used as the start date. The end date is optional. However, without an end date, the share will continue to poll. This is an optional step.

Click **Next** to progress to the Select Tables tab of the Create Share wizard.

3. On the **Select Tables** tab of the wizard, select the schema from the drop-down menu and click the table you wish to share from the Available Tables. Choose any of the available options:

   - **>**: This option enables you to move the table to Shared Tables.
   - **<**: To remove the selected table from Shared Tables select this option.
   - **>>**: This option allows you to move all the tables to the Shared Tables screen.

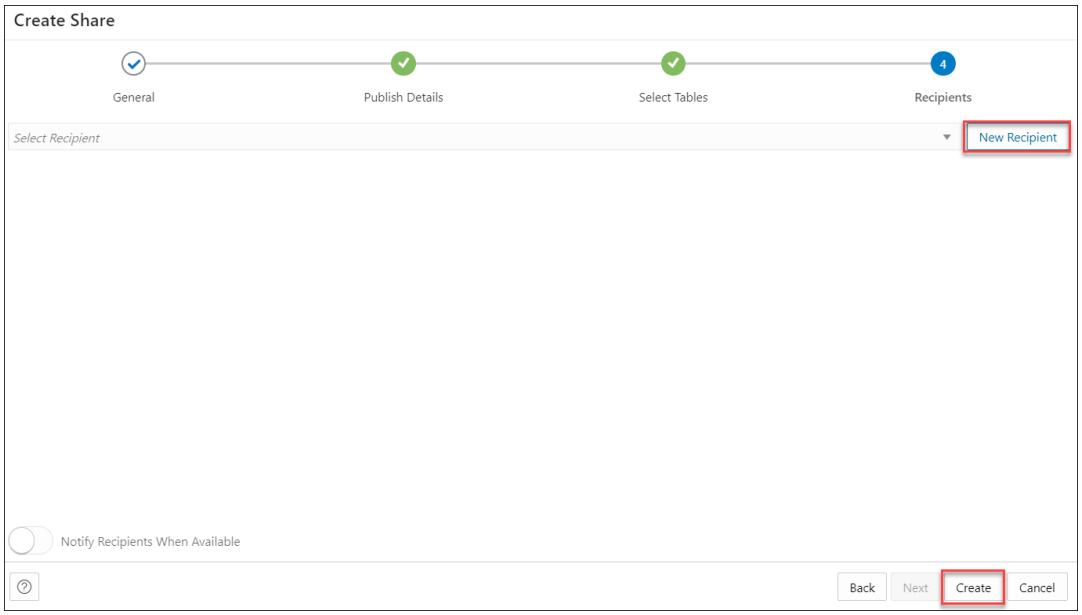
- **<<**: To remove all the selected tables from Shared Tables select this option.



Click **Next** to proceed to the Recipients tab of the Create Share wizard.

> **Note:**
>
> You may find it convenient to click on the specific tab to move back and forth. You can update changes on any screen this way.

4. On the Recipients tab of the Create Share wizard, select available Recipient from the drop-down.



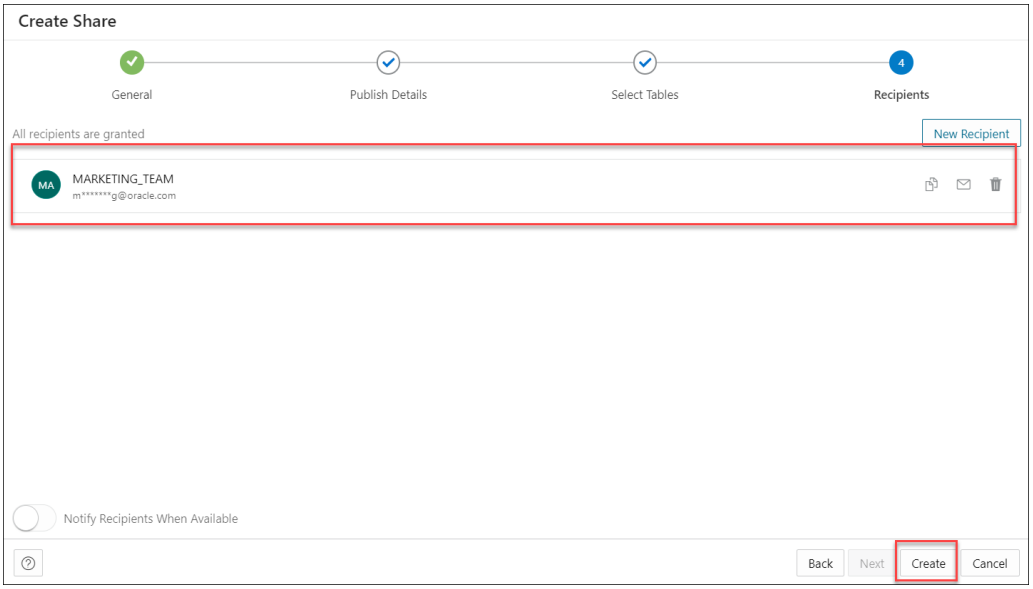
Select **Notify Recipients When Available** when you want to notify the recipients when they are available. This can be enabled when SMTP is configured to send an email notification to the recipient.

5. In case you want to create a new recipient, select **New Recipient**. Selecting New Recipient opens a **Create Share Recipient** wizard. See Create Share Recipient.

> **Note:**
>
> Ensure there are no spaces in the name of the recipient. This field does not support duplicate recipient names. If you try creating a recipient with a duplicate name, the creation of the share fails with the "Name is already used by an existing object" error.

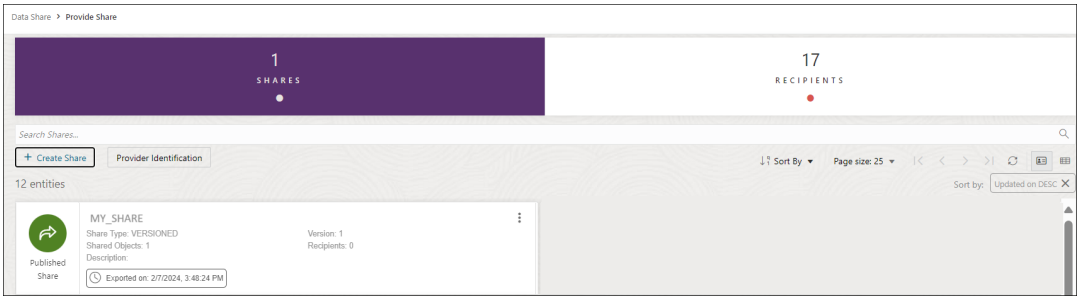
Click **Create** to finish creating the share recipient. The newly added recipient is displayed in the list of recipients. Click **Cancel** to cancel the ongoing process of recipient creation.

6. After you create a new share recipient, in the granted recipient's list you can:
   - Select **copy profile activation link to clipboard** icon to copy the activation link.
   - Select **Email recipient profile download link** icon to mail the profile link to the recipient you select in this step. Once you select it, the Share tool triggers an activation mail with the profile link to the recipient's email address. Click **Send** to share the profile link with the recipient. See *About the Consume Share Page* to know more about the activation mail and how to proceed as a recipient once you receive the activation mail.
   - Click **deselect Recipient** icon to remove the selected recipient.



Select **Create** to create the share. Note that the status of the share changes from unpublished to published depending on the size of the table in the share. You will receive a successful share notification message at the top right of the display that says the share is successful. The Provide Share page displays the share along with its details such as the entity type, owner, shared objects and the recipients.

> **Note:**
>
> The Data Share tool can create only two delta share profiles for the same recipient. If you try to create a third profile, the tool invalidates the first profile, and the newly created profile becomes active.



Note:

A versioned share will show different colors and states depending upon what state the share is in.

Provide Live Share

You can share data as of the latest database commit with Autonomous Databases in the same region. The recipient will always see the latest data.

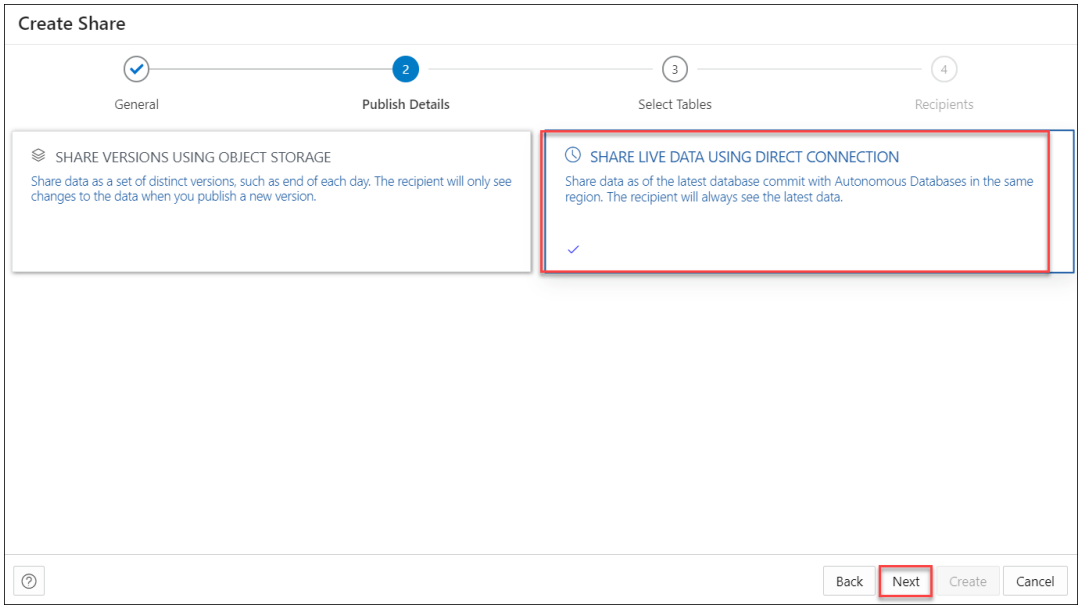
To provide access to live shared data, you must define data shares and grant recipients access to consume them. Use the **Create Share** wizard to create and publish shares for live data.

On the Provide Share page, select **+ Create Share** from the Create menu. This brings up the Create Share wizard.

1. On the Create Share wizard, in the **Name** field of the General tab, enter a name for the Share. For example: *My_Share*.
   In the **Description** field, enter a description for the data you are sharing. For example: *Weekly Sales report*.

   Select **Next** to progress to the Publish Details tab of the Create Share wizard. You can alternatively click on the Publish Details tab to progress to the Publish Details screen of the wizard.

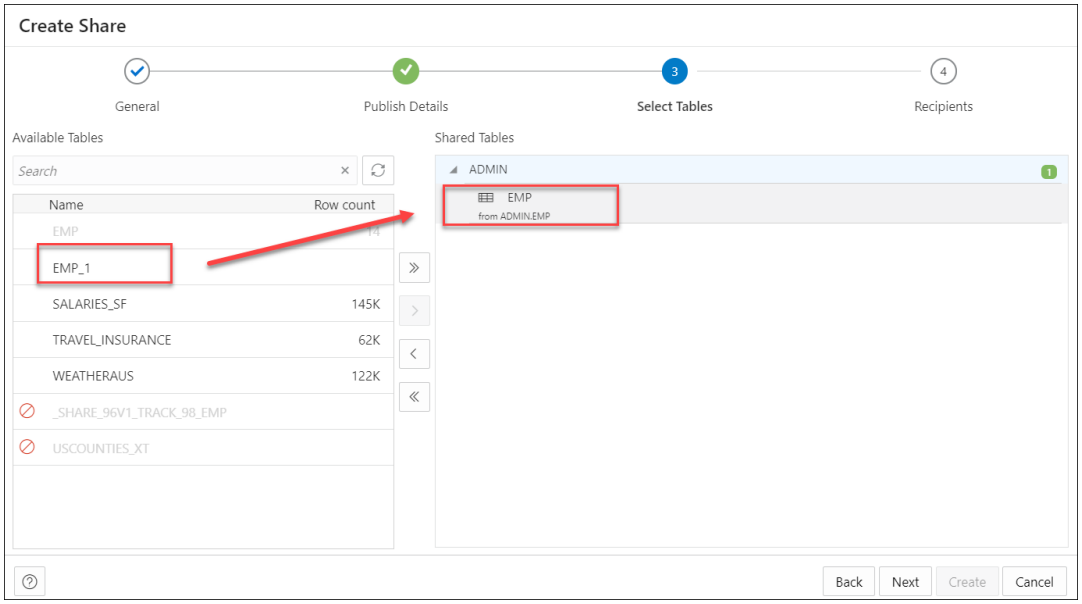
2. In the Publish Details Tables tab of the wizard, select **SHARE LIVE DATA USING DIRECT CONNECTION**.



Click **Next** to progress to the Select Tables tab of the Create Share wizard.

3. On the **Select Tables** tab of the wizard, select the schema from the drop-down menu and click the table you wish to share from the Available Tables. Choose any of the available options:

- **>**: This option enables you to move the table to Shared Tables.
- **<**: To remove the selected table from Shared Tables select this option.
- **>>**: This option allows you to move all the tables to the Shared Tables screen.
- **<<**: To remove all the selected tables from Shared Tables select this option.

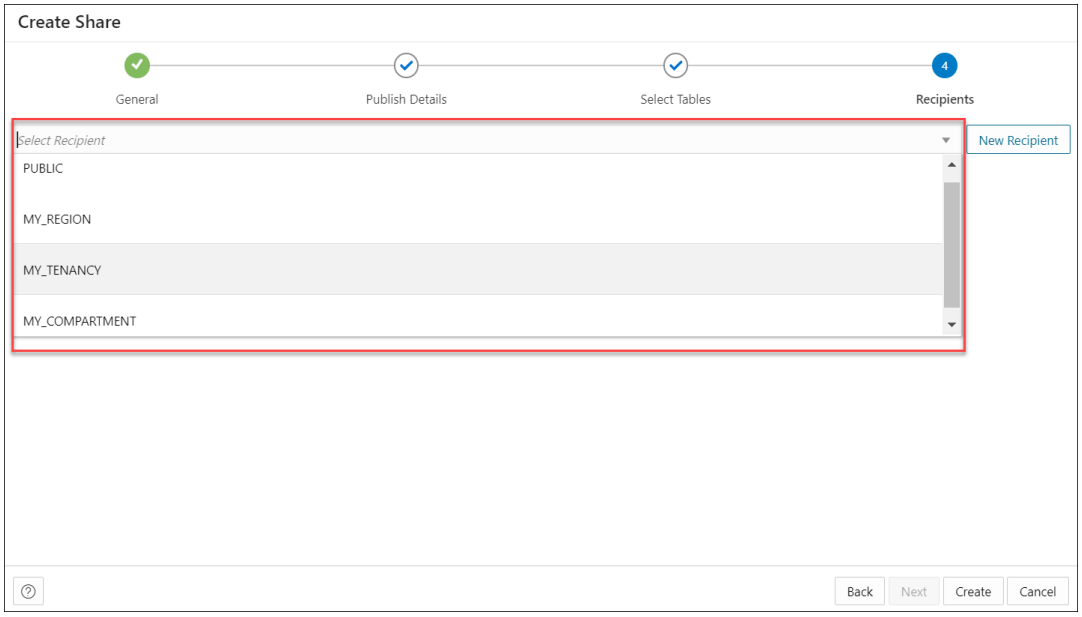


> **Note:**
>
> If a live share data provider is sharing multiple tables which would normally be joined together, it is recommended that the producer create a view that performs the joins and then only shares the view.

Click **Next** to proceed to the Recipients tab of the Create Share wizard.

> **Note:**
>
> You may find it convenient to click on the specific tab to move back and forth. You can update changes on any screen this way.

4. On the Recipients tab of the Create Share wizard, select available Recipients from the drop-down. The list of recipients available in the drop-down depends on the scope of the share. You can select any or all the following values depending on with whom you intend to share the data:
   - **MY_REGION**: Access to the data share is allowed for databases in the same region as the data share provider.
   - **MY_TENANCY**: Access to the data share is allowed for databases in the same tenancy as the data share provider.
   - **MY_COMPARTMENT**: Access to the data share is allowed for databases in the same compartment as the data share provider.

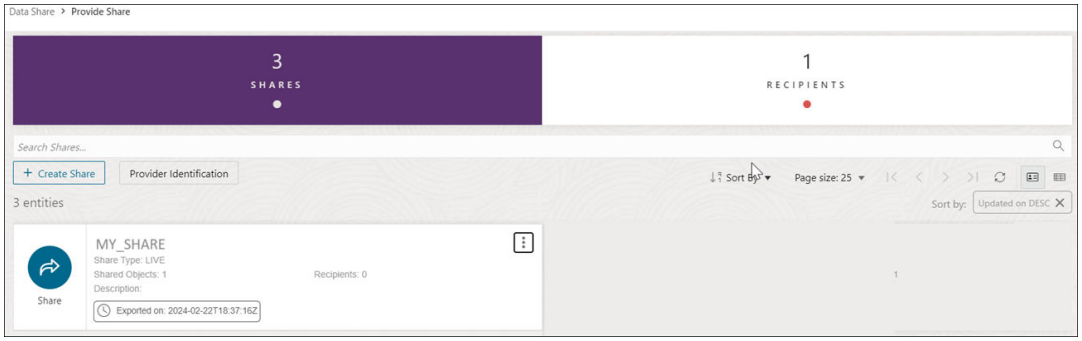


5. In case you want to create a new recipient, select **New Recipient**. Selecting New Recipient opens a **Create Share Recipient** wizard. Enter the recipient's Name, Description (optional), Sharing ID, Email in their respective fields.

> **Note:**
>
> - Ensure there are no spaces in the name of the recipient. This field does not support duplicate recipient names. If you try creating a recipient with a duplicate name, the creation of the share fails with the "Name is already used by an existing object" error.
> - A Sharing ID is a unique provider for your Autonomous Database. The Data Share tool uses it to share data with you. Copy the Sharing ID from the Consume Share page to the clipboard and paste it in the Sharing ID field of the **Create Share Recipient** wizard.

Click **Create** to finish creating the share recipient. The newly added recipient is displayed in the list of recipients. Click **Cancel** to cancel the ongoing process of recipient creation.

6. Select **Create** to create the share. You will receive a successful share notification message at the top right of the display that says the share is successful. The Provide Share page displays the share along with its details such as the entity type, owner, shared objects and the recipients.



Click the name of the entity or click **Action** to view details about the share entity. See View Share Entity Details.

After share is created, you can view the new Share entity in the Provide Share page.

View Share Entity Details

To view details about an entity, click the **Actions** icon at the right of the Share entity entry, then click **View Details**.

For all entities, the details include General, Selected Tables, Publishing details, Recipients, Versions, Log Details, Lineage and Impact sections.

General

The General tab displays the Name and description of the share.

Selected Tables

The Selected Tables tab displays the list of tables you wish to share.

Publishing

This tab displays the publishing details you configure during creation of the share. It displays whether you select live data share or share versioned data.

Recipients

You can review the list of recipients with whom you intend to share objects. It displays the name of the recipient with their mail address.

Jobs

See the Jobs option below to view information about it.

Log Details

You can view the detailed status of the share in this tab. It provides information such as, the time, Status, Log Level, and Details of each activity that takes place during the running of the job, i.e., creation of the share. It also displays if any errors are encountered during the creation of the share.

Lineage

Lineage displays all known information about the dependencies of the entity, and therefore how the entity was created and how it is linked to other entities.

For example, for a share you create in the database, the lineage is just the cloud location. For a share that you create by adding files from cloud storage, the lineage includes the cloud location of the file you share.

Pointing to the name of an item in the lineage displays the share name, the application that creates it, the type of entity, the path to it, and the schema it is in.

Arrows point from an entity to the entity that it derives from. For example, for a share you create, an arrow points from the cloud location to the share. If you point to an arrow, then a Links Information box appears that shows information about the relationship between the two entities.

To view more details about an item, click the **Actions** icon for the item, then click **Expand**. For a cloud location, the files in the location are displayed. Pointing to the name of the file displays the name, application, type, path, and schema of the file. To collapse the display, click the Actions icon, then click Collapse.

Impact

Impact shows all known information about the downstream use of an entity, and therefore how a change in the definition of an entity may affect other entities that depend on it.

For a specific share entity, you can perform the following actions using the Actions context menu:

- **View Details:** See View Share Entity Details.
- **Objects:** Opens Select Tables dialog of the specific share where you can remove tables from the list of Shared Tables list or add tables from the list of Available Tables list to the list of Shared Tables.
- **Recipients and Profiles:** Opens the Recipients and Profiles dialog which enables you to create a new share recipient. You can also revoke the recipient right from the share by clicking X next to the recipient name. The Recipients and Profiles dialog enables you to update the list of recipients, copy profile activation link, send an activation mail to the selected recipient.
- **Jobs:** Opens the Jobs table and displays information related to it. A job is created whenever something needs to happen to a share. This includes the following:
  - PUBLISH VERSIONED SHARE
  - PUBLISH LIVE SHARE
  - DROP SHARE VERSIONS

Only one job can run at a time on a single share. E.g. if the user calls `publish_share` while a `PUBLISH` job is already running, then the second job will have to wait. The `STATUS` column reflects the same.

The `JOB TYPE` column displays the method of parquet files generation (only for a versioned share). It's values can be `ODI` or `DBMS_CLOUD`.

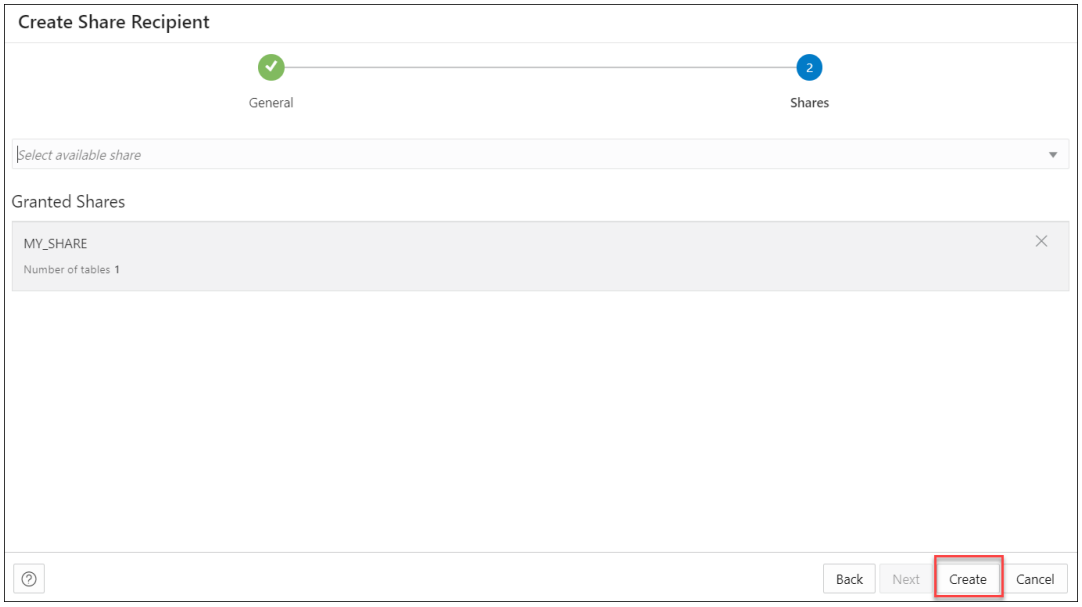
- **Publish:** Select **Publish** to publish the updated share.
- **Unpublish:** Select **Unpublish** to unpublish the share. This option prevents all recipients from accessing a single share, but lets them continue to access any other shares. You can restore access by publishing share again.
- **Delete:** Deletes the Share Provider Entity.

Create Share Recipient

On the Provide Shares page, click the **Recipients** widget and select **+ Create Recipient** to create a new Share Recipient.

Share Recipients are those with whom we intend to share objects with. You can share objects securely with users outside of Oracle workspace. Apart from creating recipients from the Create Share wizard, you can also create a share recipient from the Create Recipient icon on the Provide Share page and verify the details you configure while its creation.

1. On clicking the **+ Create Recipient** icon, a Create Share Recipient dialog box appears.



2. On the General tab, specify the following fields:
   - **Name**: Enter the name of the Share Recipient. For example, *Marketing_team.*

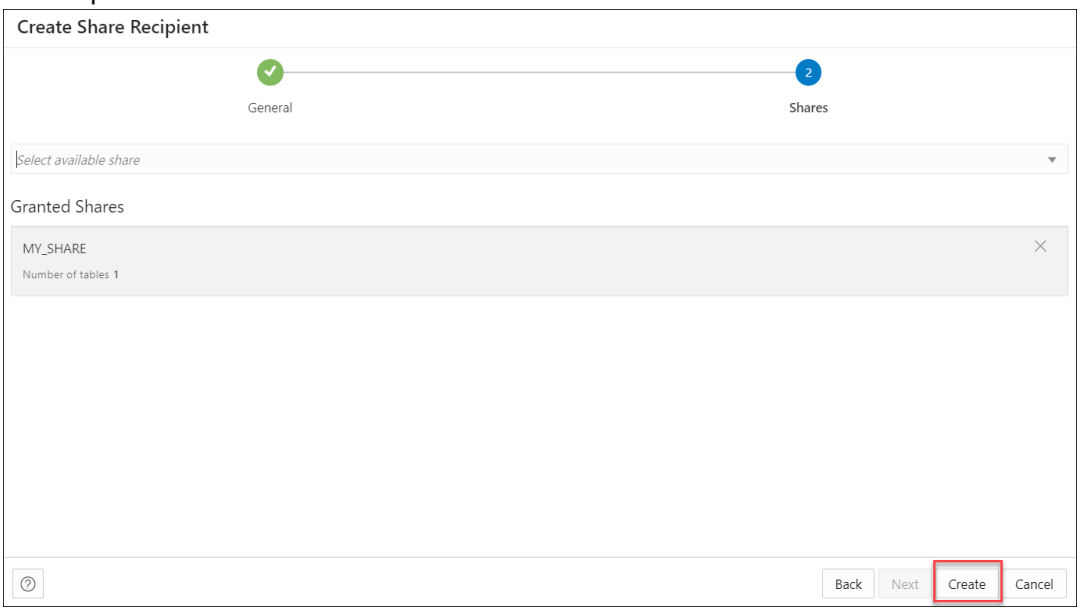
> **Note:**
>
> Ensure there are no spaces in the name of the recipient. This field does not support duplicate recipient names. If you try creating a recipient with a duplicate name, the creation of the share fails with the "Name is already used by an existing object" error.

   - **Email**: Enter the email ID of the recipient. For example, *marketing@oracle.com*.

- **Description**: Add a description. This is optional.
- **Sharing ID**: An intended Recipient should copy this ID from the consumer page and send it to the Producer to be used here. The Share Provider wont have access to the consumer page. **This field is required for Live Share Recipients only**.
  On the User token lifetime section, enter any value in the `TOKEN_LIFETIME` field for the share recipient. This property specifies for how long the generated token will be valid after which the recipient loses access to the data share and must request a new token. Enter 60 in the first text field. Select Minutes from the drop-down menu.

Click **Next** to progress to the Shares tab of the Create Share Recipient dialog box.

3. On the Shares tab, select an available share from the drop-down. As you select the share, it lists under the Granted Shares section. You have the choice to share multiple shares to the recipient.



Select **Create** to create the Share recipient.

Once you have created the Share recipient, you will be able to view the newly created Share Recipient entity in the display area of the Provide Share page. The new recipient card displays details such as the entity type and the owner.

Click the name of the entity or click **Action** to view details about the share recipient entity. See View Share Recipient Entity Details.

View Share Recipient Entity Details

Click the **Actions** icon at the right of the Share Recipient entity entry, then click **View Details**.

For all entities, the details include general details, Log details, Granted Shares, Lineage and Impact.

General

The General tab displays the Name and Email address of the Share Recipient.

Granted Shares

The Granted Shares tab displays the list of shares granted to the recipient.

Log Details

The Log details tab displays the Time, Status, Log Level, Share Name, Request, End Point, Remote address, User Agent and Details of the Recipient.

Lineage

Lineage displays all known information about the dependencies of the entity, and therefore how the entity was created and how it is linked to other entities.

For example, for a share you publish, the lineage includes the files in cloud storage along with the cloud location of the files you share.

To view more details about an item, click the **Actions** icon for the item, then click **Expand**. For a cloud location, the files in the location are displayed. Pointing to the name of the file displays the name, application, type, path, and schema of the file. To collapse the display, click the **Actions** icon, then click **Collapse**.

Impact

Impact shows all known information about the downstream use of an entity, and therefore how a change in the definition of an entity may affect other entities that depend on it.

Click **Actions** in the Share Recipient entity card to open the context menu. The actions available are:

- **View Details:** See View Share Recipient Entity Details.
- **Granted Share:** Opens Manage Granted Shares dialog where you can grant access to a share from list of available shares or you can revoke access from the current selection of share.
- **Get Bearer Token:** Opens an Auth Token dialog to authenticate the recipient. Use this option when your token expires. This enables you to generate a new token. A Bearer Token is part of the JSON file.
- **Send Activation Mail:** Opens the mail with the profile link.
- **Copy Profile Activation Link to Clipboard:** Copies the JSON profile activation link to clipboard.
- **Rename:** Select this option to rename the Recipient.
- **Delete:** Select this option to delete the recipient you created entirely. By doing so, access to all shares will end instantly and any existing delta credentials will become invalid.

Consume Share

Once the providers share the objects, there are a few steps the recipients need to follow to consume the share.

Use the Consume Share page to perform the following operations:

- Consume Share Overview:
  To consume data shares, you need to subscribe to them and create views of tables included in the live share.
- Consume Versioned Share:
  As a recipient, you will need to download your share profile, subscribe to the data share provider, register the shares and create external tables on top of your shares. The Data Share tool authorizes the access using the JSON profile sent to the recipient using the activation mail. After the access is granted, the Data Share tool links the shared objects with the Data link tool where the consumer can run the data link job and access the objects shared by the provider.
- Consume Live Share:
  This lets you as a recipient to consume live data from the database.
- View Share Provider Entity Details:
  Use the **Actions** icon at the right of the live share or delta share provider entity entry to view details about the live share or delta share provider entity you create.
- Consume Share Overview
  The Consume Share provides an overview on the list of share providers, search for share providers and add a share provider.
- Consume Versioned Share
  You must follow these steps to make shared versioned data available to you within Oracle Autonomous Database. Data shared with you through Delta Sharing is not automatically available and discoverable in your Autonomous Database.
- Consume Live Share
  Live data shared with you through data sharing is not automatically available for consumption.
- View Share Provider Entity Details
  To view details about the Share Provider entity, click the **Actions** icon at the right of the Share Provider entity entry, then click **View Details**.

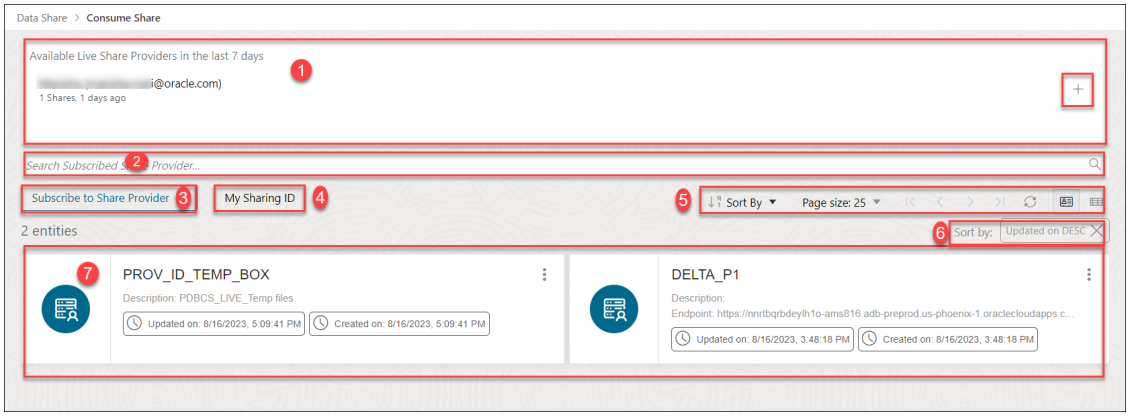
Consume Share Overview

The Consume Share provides an overview on the list of share providers, search for share providers and add a share provider.

To navigate to the Consume Share page, do either of the following:

- On the Data Studio menu, select **Consume Share** under the Data Share menu.
- On the Data Share page, click the **Consume Share** widget present in the Provider and Consumer section.

The Consume Share page contains:



1. **Available Live Share Providers in the last 7 Days**
   This area displays the list of available Live Share Providers you create in the last 7 days. You can update any of the fields as per your wish. You can also subscribe to Live Share using the + sign to the right of Shares listed in **Available shares in the last 7 days**.
2. **Search Subscribed Share Provider** field

   You can search for the Share Recipient you create by entering the name of the Subscribed Share Provider. Enter the name of the Subscribed Share Provider, for example, *REVIEW_PROVIDER* and click the **magnifier** icon to complete the search. The Share tool displays the search results in the display area.
3. Select **+ Subscribe to Share Provider** to subscribe to a new Share Provider. See Subscribe to Share Provider for exploring this icon.
4. **My Sharing ID**
   A Sharing ID is a unique provider for your Autonomous Database. Copy this ID to the clipboard and paste it in the Sharing ID field of the **Create Share Recipient** wizard. This enables a Live Share to be shared with a share provider.
5. **Toolbar**
   The toolbar consists of the sort by, page size, refresh and entity view options.
6. **Sort by settings**
   When you set sorting values by using the Sort By control in the toolbar, the settings are displayed in small boxes beneath the toolbar. You can delete a setting by clicking the **X** icon in the box. Or you can change the settings by returning to the Sort By control in the toolbar.
7. **Display area**

   The area beneath the Search Consumer Share Providers field displays the entities returned by a search and that match the filter criteria set in the Filters panel. You can sort the entities by clicking the **Sort By** button and then setting sort values.

Consume Versioned Share

You must follow these steps to make shared versioned data available to you within Oracle Autonomous Database. Data shared with you through Delta Sharing is not automatically available and discoverable in your Autonomous Database.

You need to perform several basic steps to subscribe and access the provided data shares. Here are the steps you need to perform:

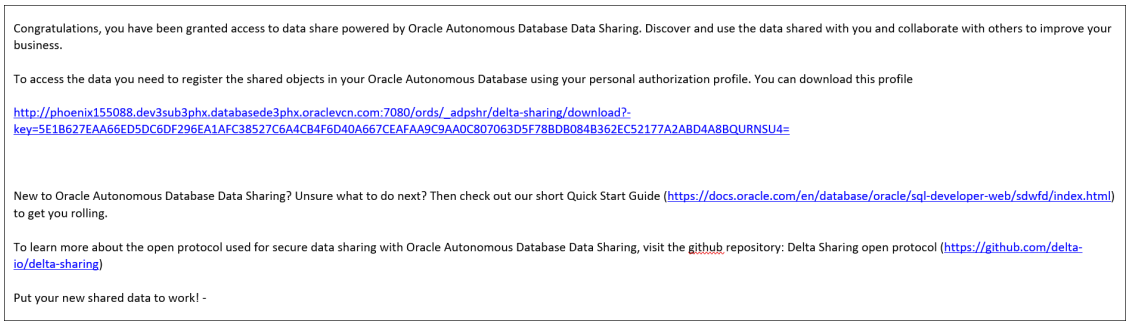
- Download the JSON profile.
- Subscribe to the data share provider.

- Register shares made available to you.
- Create external tables on top of your shares.

About JSON Profile

Profile files are JSON files containing a user's credentials to access a Delta Sharing Server. This enables you to authenticate yourself with the delta sharing server and to discover the data shares you are eligible to access. Download the profile using the URL included in the invitation email sent by the data share provider.

Once the Share tool creates a share object, the recipient receives an activation mail with subject titled *Oracle Autonomous Database Data Share*.



Congratulations, you have been granted access to data share powered by Oracle Autonomous Database Data Sharing. Discover and use the data shared with you and collaborate with others to improve your business.

To access the data you need to register the shared objects in your Oracle Autonomous Database using your personal authorization profile. You can download this profile

http://phoenix155088.dev3sub3phx.databasede3phx.oraclevcn.com:7080/ords/_adpshr/delta-sharing/download?-key=5E1B627EAA66ED5DC6DF296EA1AFC38527C6A4CB4F6D40A667CEAFAA9C9AA0C807063D5F78BDB084B362EC52177A2ABD4A8BQURNSU4=

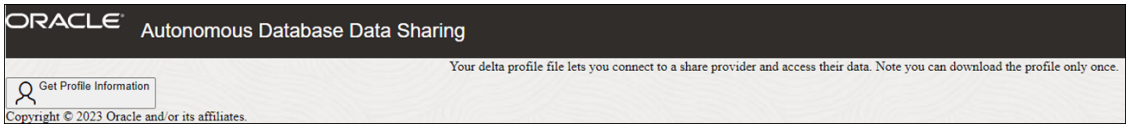
New to Oracle Autonomous Database Data Sharing? Unsure what to do next? Then check out our short Quick Start Guide (https://docs.oracle.com/en/database/oracle/sql-developer-web/sdwfd/index.html) to get you rolling.

To learn more about the open protocol used for secure data sharing with Oracle Autonomous Database Data Sharing, visit the github repository: Delta Sharing open protocol (https://github.com/delta-io/delta-sharing)

Put your new shared data to work! -

To access the share, you need to register the shared objects using personal authorization JSON profile.

You can click on the profile link to download the JSON profile. Clicking the profile link takes you to a new screen in the browser with a **Get Profile Information** button as shown below:



Select **Get Profile Information** to download the JSON profile to connect to the share provider.

> **Note:**
>
> You can click on the **Get Profile Information** button only once and also view the link to the Quick Start Guide. The share tool does not allow you to select **Get Profile Information** twice. Clicking on it twice brings up a screen which displays the list of causes of the failure to download the profile.

The below profile is an example of the JSON profile you download.

```
{  "
        shareCredentialsVersion ": 1,
        "endpoint": "https://myhost.us.example.com/ords/prov/
_delta_sharing/",
        "tokenEndpoint": "http://myhost.us.example.com:1234/ords/pdbdba/oauth/
token",
        "bearerToken": "-xxxxxxxxxxxxxxxxxxxx",
        "expirationTime": "2023-01-13T07:53:11.073Z",
```

```
"clientID": "xxxxxxxxxxxxxxxxxxxxx..",
"clientSecret": "xxxxxxxxxxxxxxxxxxxx.."}
```

The profile stores the credentials in an encrypted format. The parameters with their description are:

- **shareCredentialsVersion:** The version of the share you publish.
- **endpoint:** Specifies the share endpoint.
- **tokenEndpoint:** Specifies the token endpoint. The Share tool client use the token endpoint to refresh the timeout on your bearer token if you are consuming the share using Oracle.
- **bearerToken:** This is a cryptic string which the authentication server generates in response to a login request.
- **expirationTime:** This is the time taken for the authentication to expire.
- **ClientID:** Specifies the public identifier the authentication server generates when you register the instance for authentication.
- **clientSecret:** Specifies a secret identifier the authentication server generates for authorization.

Copy the JSON content of the profile in a notepad. You will need this JSON below to subscribe your share provider.

> **Note:**
>
> Ensure you copy the full JSON content profile, including the left brace and the right brace.

Security enhancements

As a share recipient, you must set up an access control list (ACL) to the share provider's machine by using the `APPEND_HOST_ACE` procedure as an ADMIN user, or another privileged user. This allows you to access the share via the Internet.

> **Note:**
>
> This must be done before using the Add Share Provider Wizard to add an access control entry (ACE) to the access control list (ACL) of the host (i.e. Share provider). You can find the host name from the JSON profile you downloaded in the previous step.

For example, if you wish to allow a database user, A_SHARE_USER to access the endpoints on a host (Share provider) named, here is a sample of PL/SQL procedure you will need to run in the SQL worksheet editor as an admin. As a prerequisite, extract the host name from the endpoint property in the delta sharing JSON profile, as provided in the example above. The hostname from the example is `myhost.us.example.com`.

```
BEGIN
        dbms_network_acl_admin.append_host_ace(
        host =>'myhost.us.example.com',
```

```
lower_port=>443,
upper_port=>443,
ace => xs$ace_type(
privilege_list => xs$name_list('http', 'http_proxy'),
principal_name =>'A_SHARE_USER',
principal_type => xs_acl.ptype_db));
COMMIT;
END;
/
```

Following are the parameters with their description:

- **host**- Specifies the name or the IP address of the host. The host or domain name is not case-sensitive.
- **lower port**- Specifies the lower port of an optional TCP port range.
- **upper port**- Specifies the upper port of an optional TCP port range.
- **ace** – The Access Control Entry.
- **privilege list**- Specifies the list of network privileges to be granted or denied.
- **principal_name**- It is the principal (database user or role) to whom the privilege is granted or denied. It is case-sensitive.
- **principal_type**- Specifies the type of principal you use.

Refer to the PL/SQL Packages and Types Reference document for more details on the `DBMS_NETWORK_ACL_ADMIN` package subprograms.

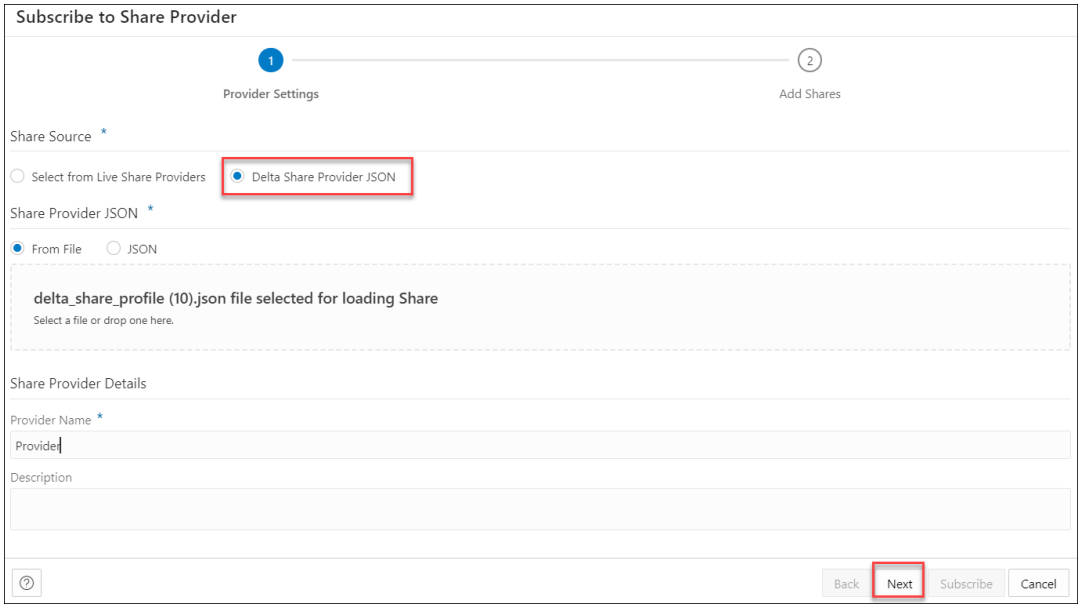
Grant an ACL to the user on the local ORDS endpoint. You will need this to generate bearer tokens on locally created shares.

```
PRIV_ORDS_ACL             CONSTANT PLS_INTEGER := 8;
```

In this process you will load the provider's JSON profile for configuration and credentials to enable access to the recipients.

1. Open the Consume Share page and click **+ Subscribe to Share Provider** to select **Subscribe to Delta Share Provider** from the drop-down. This opens the Subscribe to Share Provider dialog box.

2. On the Provider Settings pane of the Register Share Provider dialog box, specify the following details:



- **Provider Name**: *Provider*.
- **Description**: Add a description. This field is optional.

Under Share Source section, choose **Delta Share Provider JSON**.

Under Share Provider JSON field, you can share the JSON profile in the following ways:

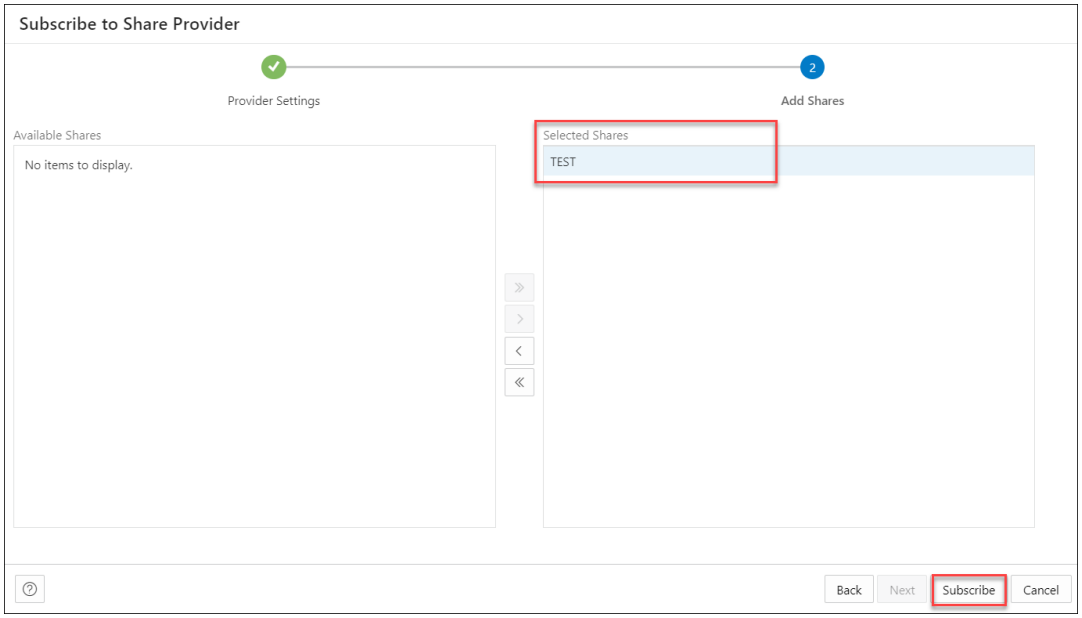
- **From File**: Select this option and click on the drop area titled "Delta Share Profile JSON". Clicking on the area opens your local repository where you can select the JSON profile you had downloaded.
- **JSON**: You can select this option and paste the JSON content of the profile you copy into the notepad.

Upload the JSON profile file and create a share provider subscription.

Click **Next** to progress to the Add Shares tab.

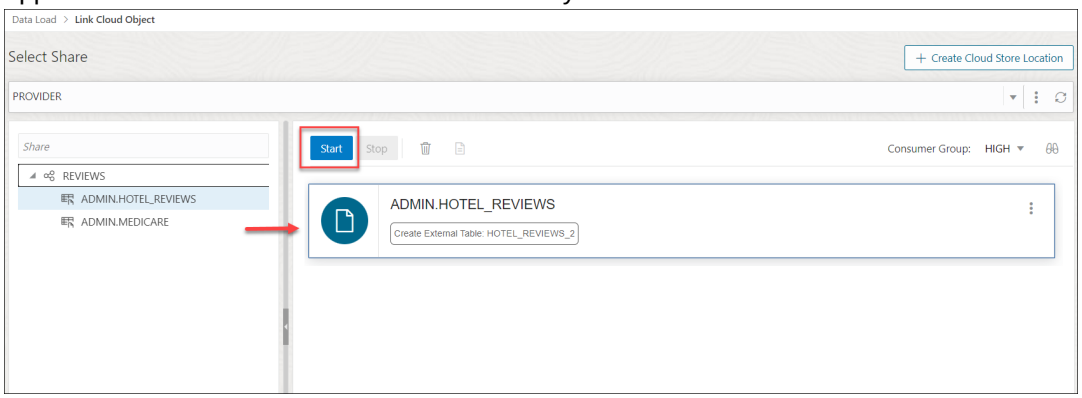
3. On the Add Shares tab of the dialog, you will view the list of available shares. Click the share you wish to consume from the Available Shares and select any of the available

options:



- **>**: This option enables you to move the Available Share to Selected Shares.
- **<**: Select this option to remove the selected share from Selected Shares.
- **>>**: This option allows you to move all the shares to the Selected Shares screen.
- **<<**: Select this option to remove all the selected shares from Selected Shares.

4. Click **Subscribe** to add the share. A confirmation prompt appears when the provider is created successfully. After successful creation of the provider, you will now view the Link Cloud Object screen of the Data Load page.
5. You can view the name of the Share provider in the cloud storage location field. The share appears in the source file location with the files you add to the share.

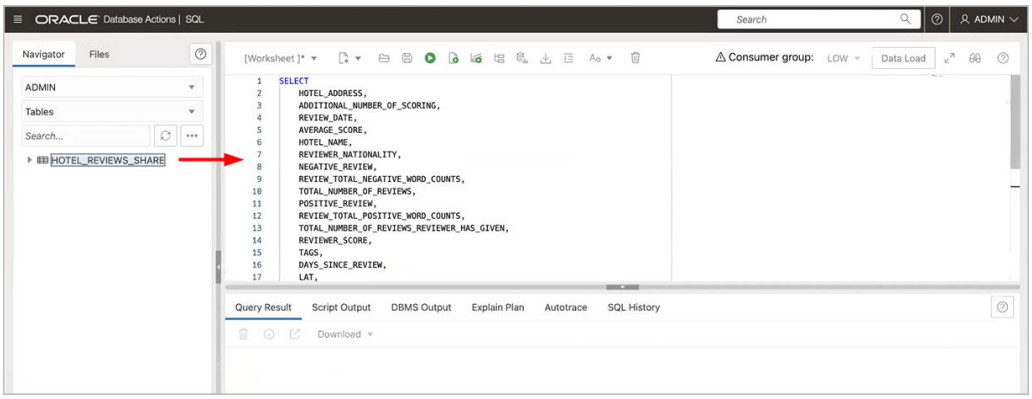


Expand the Share folder cart, drag and drop the file you share from the source to the Data Link cart.

Select **Start** in the Data link cart to run the data link job.

6. View the created tables from Database Actions.
   - Click on Database Actions, in the breadcrumb, to go back to the Database Actions launchpad.
   - Click on the SQL tile.
   - Select the external table, drag and drop it into the worksheet.

The SQL Select statement for the table appears. This SQL statement can be run to consume the shared data.

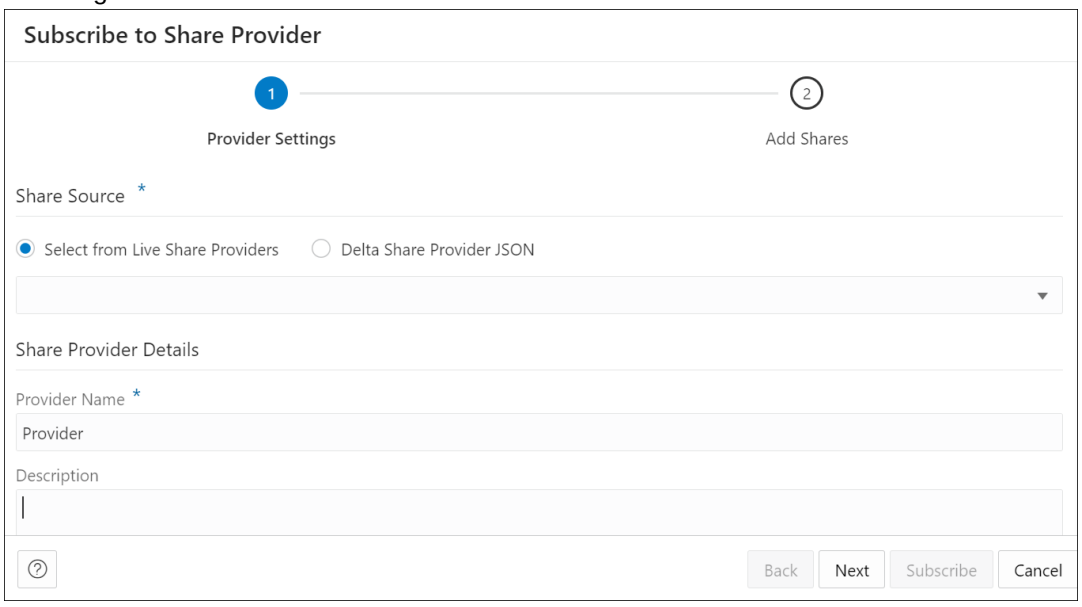


Consume Live Share

Live data shared with you through data sharing is not automatically available for consumption.

To consume live data shares, you need to subscribe to them and create views of tables included in the live share. The views can be queried using SQL scripts.

1. Open the Consume Share page and click **+ Subscribe to Share Provider** to select **Subscribe to Live Share Provider** from the drop-down. This opens the Subscribe to Share Provider dialog box.
2. On the Provider Settings pane of the Subscribe to Share Provider dialog box, specify the following details:



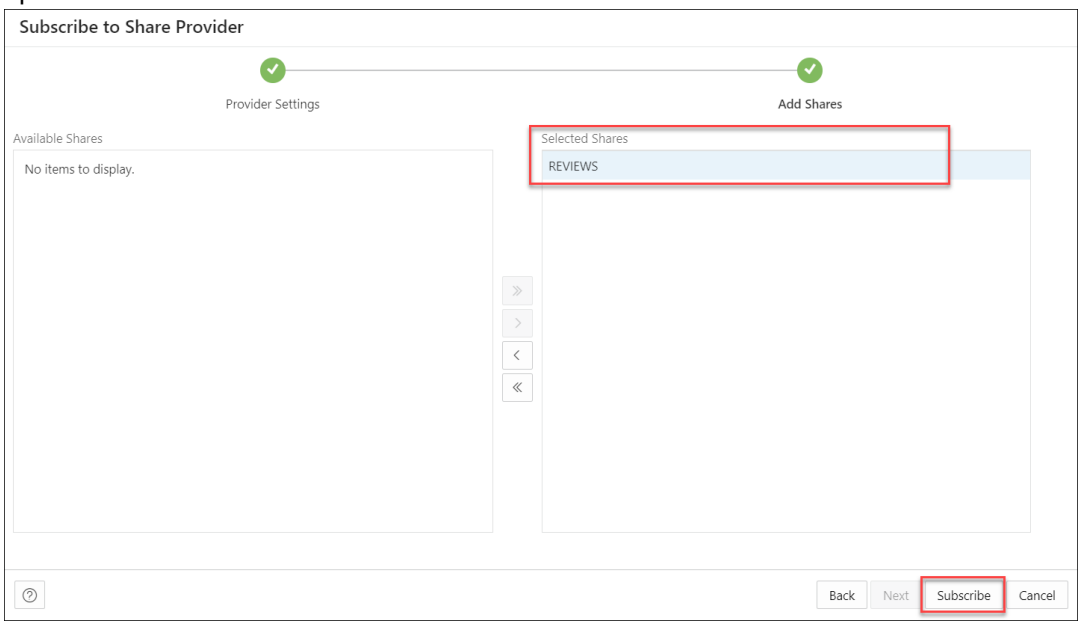
Under Share Source section, choose **Select from Live Share Providers** and select the provider from the drop-down.

Under Share Provider Details field, enter the following:

- **Provider Name**: Specify the name of the provider.
- **Description**: Enter a description of the Provider.

Click **Next** to progress to the Add Shares tab.

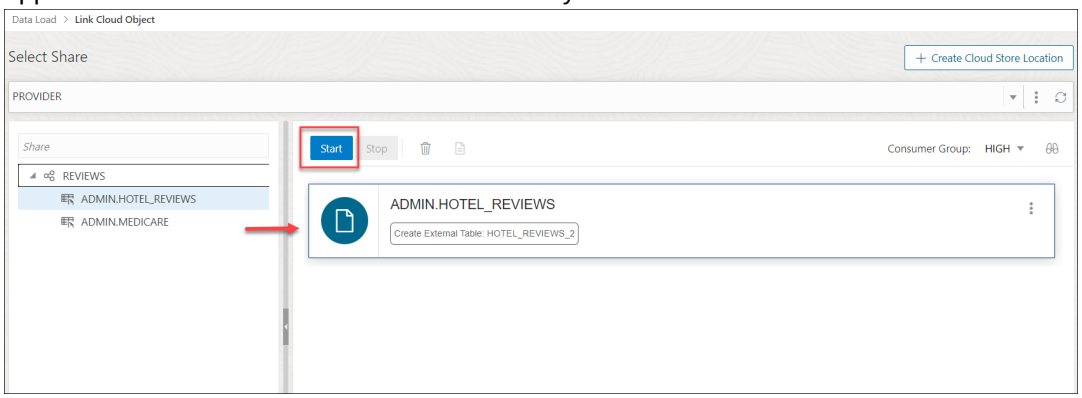
3. On the Add Shares tab of the dialog, you will view the list of available shares. Click the share you wish to consume from the Available Shares and select any of the available options:



- **>**: This option enables you to move the Available Share to Selected Shares.
- **<**: Select this option to remove the selected share from Selected Shares.
- **>>**: This option allows you to move all the shares to the Selected Shares screen.
- **<<**: Select this option to remove all the selected shares from Selected Shares.

Click **Subscribe** to add the share. A confirmation prompt appears when the provider is created successfully. After successful creation of the provider, you will now view the Link Cloud Object screen of the Data Load page.

4. You can view the name of the Share provider in the cloud storage location field. The share appears in the source file location with the files you add to the share.



Expand the Share folder cart, drag and drop the file you share from the source to the Data Link cart.

Select **Start** in the Data link cart to run the data link job.

View Share Provider Entity Details

To view details about the Share Provider entity, click the **Actions** icon at the right of the Share Provider entity entry, then click **View Details**.

For all entities, the details include Lineage and Impact sections.

For a specific Share Provider entity, you can perform the following actions using the **Actions** context menu.

- **View Details:** See View Share Provider Entity Details.
- **Manage Shares:** Opens a Manage Shares for Share provider dialog box. This lists the shares you select to share with the recipient. You can edit the list of shares you wish to share with the recipient. Click **OK** to save any changes or select **Cancel** to discard the process of editing.
- **Rename:** Renames the Provider Name. Select **Yes** to make changes else click **No**.
- **Delete:** Removes the Share Provider Entity.
- **Load Tables:** You are directed to the Load Data page with the Share tab selected.
- **Link Tables:** You are directed to the Link Data page with the Share tab selected to view and run the related link object. Drag and drop the shared data to add it to the data link job.

Data Share Limitations on Autonomous Database

This section summarizes the limitations of Data Share (both Versioned and Live Share) included in the Oracle Autonomous Database.

Oracle Database Release Restriction

Only **Oracle Database 19c** supports both Versioned Share and Live Share. You cannot use Versioned Share and Live Share with any other database version.

Supported Column Types

Only the following list of column types are supported:

- `BINARY_DOUBLE`
- `BINARY_FLOAT`
- `CHAR`
- `CLOB`
- `DATE`
- `FLOAT`
- `INTERVAL DAY TO SECOND`
- `INTERVAL YEAR TO MONTH`
- `NCHAR`
- `NCLOB`
- `NUMBER`
- `NVARCHAR2`
- `TIMESTAMP`
- `VARCHAR2`

Live Share Data Provider

The following are limitations for using the Data Share tool as a Data Share provider:

1. A live share data provider can create shares with a maximum of four objects.

2. If the live share data provider is sharing multiple tables which would normally be joined together, it is recommended that the producer create a view that performs the joins and then only shares the view.

Troubleshooting Errors with the Data Share Tool

This chapter provides instructions on what issues cause slow performance and how to troubleshoot the issues.

With an increase in ECPUs, does the performance of the Live share feature in the Data Share tool improve while running complex queries?

No, it does not. In such cases, you need to configure the **Degree Of Parallelism (DOP)** using Data Studio to improve the performance of complex running queries.

Configure the Degree Of Parallelism (DOP) using Data Studio

When the Live Share feature of the Database Actions instance runs on an increased value of ECPU, by default the performance of the complex running queries does not improve.

You can use the DOP option to improve the performance of the complex running queries. The DOP sets the number of processors employed to run a single statement, for each parallel plan execution. This section describes how to configure the `degree of parallelism` (DOP) configuration option in the Autonomous Database by using the Live Share feature of Data Studio.

In this example, you will use the Live share feature and share tables of an uncompressed size of 1TB.

Before you begin, here are a few things you need to consider:

- The option to configure the value of DOP can only be done by an `admin`.

Prerequisite:

- Log in to your Database Actions instance as an admin and under **Administration**, select **Set Resource Management Rules**.
- Note the default **concurrency value** and **DOP**.

To configure the degree of parallelism using Data Studio to improve the performance of complex running queries, you will:

- Create Share as a provider.
- Consume Share as a consumer and create external queries on top of your shares to record the query execution time.
- Increase the ECPUs to a value greater than the current value as provider and consumer and record the query execution time.
- Configure the `DOP` value for the `MEDIUM` consumer group.
- Consume the same share and record the query execution time of the same table.

> **Note:**
>
> You must configure the `ECPU` count and `DOP` value as a **provider** with `ADMIN` privileges.

On the Database Actions launchpad, click **Selector** and select the **Data Share** tool from the **Data Studio** suite of tools.

1. **Create Share as a provider.**

   a. Click **Provide Shares** and select **+Create Share**.

   b. On the Create Share wizard, in the **Name** field of the General tab, enter a name for the Share. For example: *TEST*.

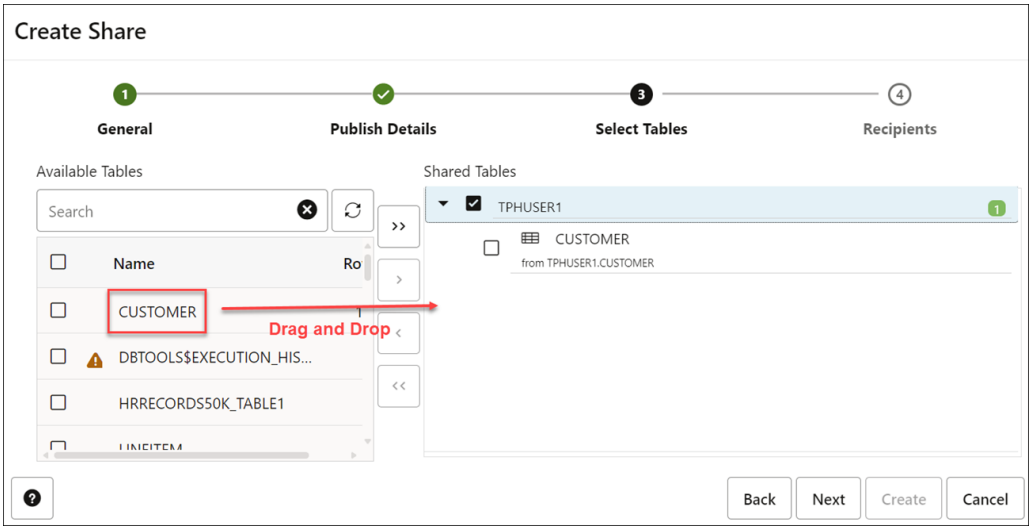
   In the **Description** field, enter a description for the data you share. This field is optional.

   Select **Next** to progress to the Publish Details tab.

   c. In the Publish Details Tables tab of the wizard, select **SHARE LIVE DATA USING DIRECT CONNECTION**.

   Click **Next**.

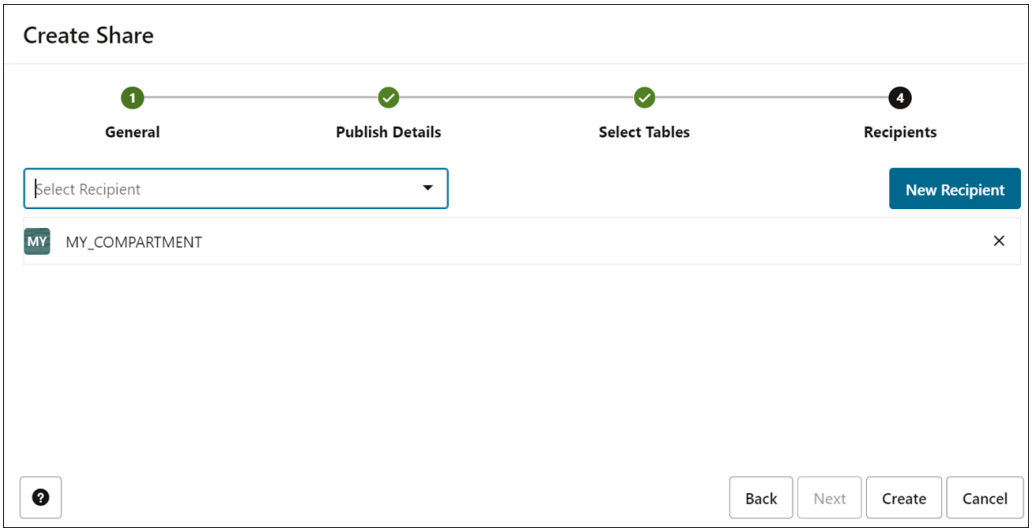
   d. On the **Select Tables** tab of the wizard, select the schema from the drop-down menu, drag and drop the `CUSTOMER` table from the Available Tables.



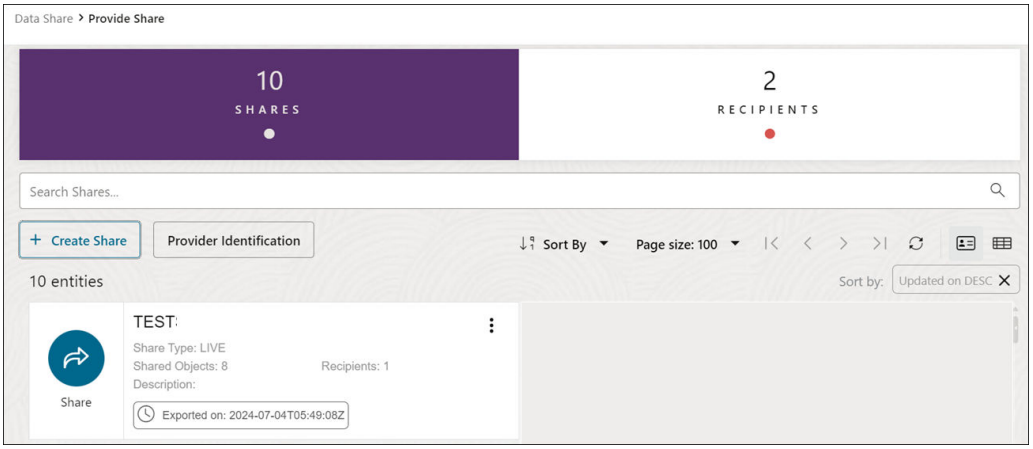
> **Note:**
>
> In this example, we are sharing a single table named `Customer` of large size.

Click **Next** to proceed to the Recipients tab of the Create Share Wizard.

e. On the Recipients tab of the Create Share wizard, select `MY_COMPARTMENT` from the drop-down.



f. Select **Create** to create the share.



2. **Consume Share as a consumer and create external queries on top of your shares to record the query execution time.**

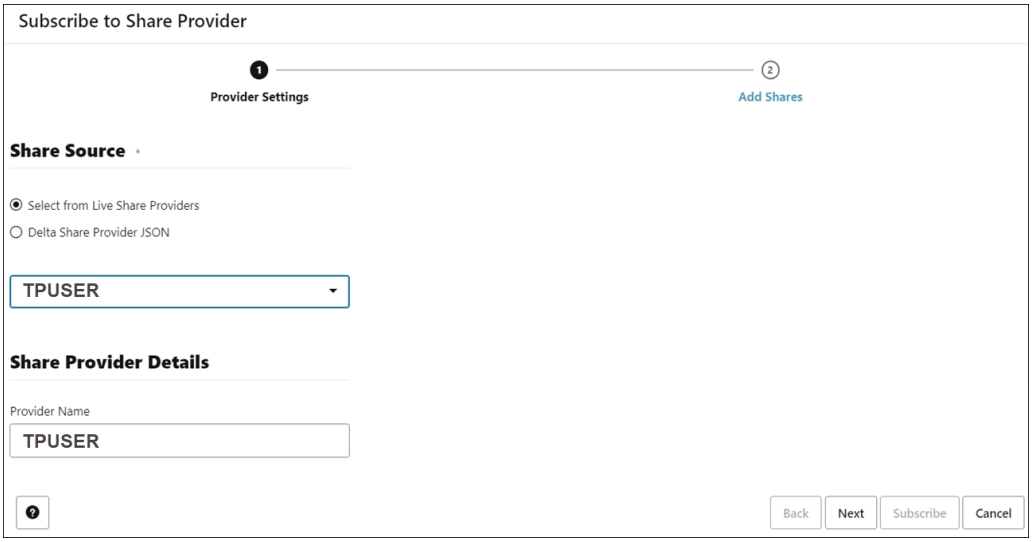
   a. After you have created the share as a provider, you will consume the data shared by the provider.
   See Consume Share for more details.

   b. Log in as a **consumer** to subscribe to the data share provider and access the data in your share.

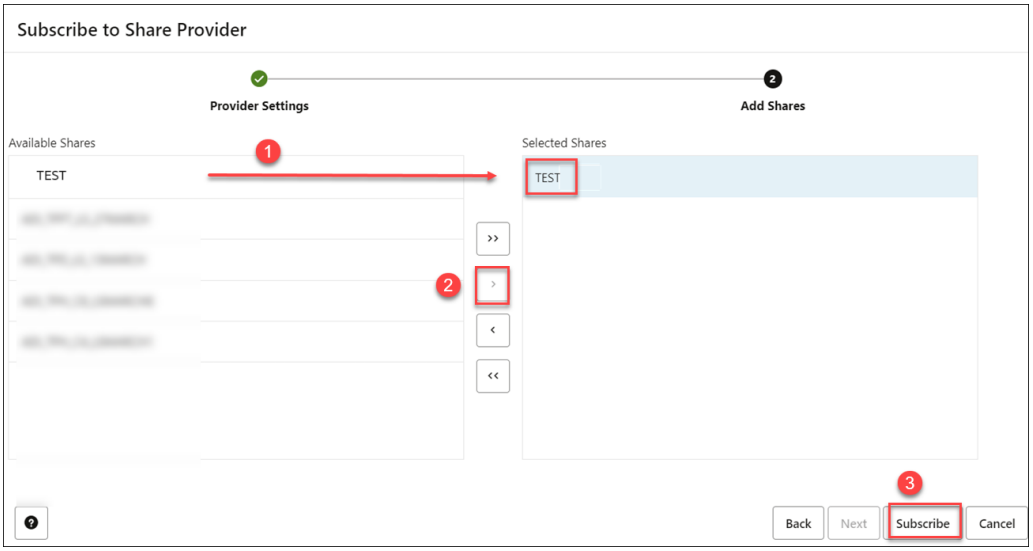
   c. On the **Provider and Consumer** page of the Data Share tool, click the **CONSUME SHARE** tile to display the **Consume Share** page.

   d. Click the **Subscribe to Share Provider** drop-down list, and then click the **Subscribe to Live Share Provider** option.

   e. Under Share Provider Details, select the **Provider Name**. In this example, `TPUSER` is the name of the provider.

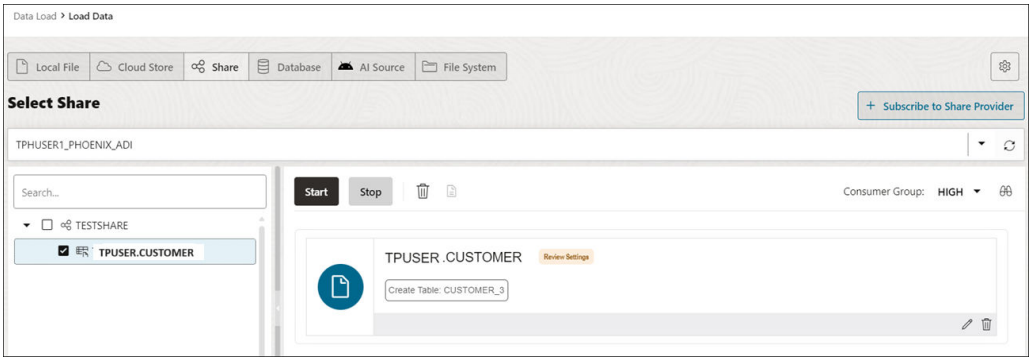


f. On the **Add Shares** panel of the Subscribe to Share **Provider Settings** wizard page, click the **TEST** in the **Available Shares** section, and then click the **(>)** icon.



g. The tool adds the share to the **Selected Shares** section. Click **Subscribe**.

h. A `TPUSER` share provider was created successfully informational message is displayed. You are directed to the **Load Data** page with the **Share** tab selected.

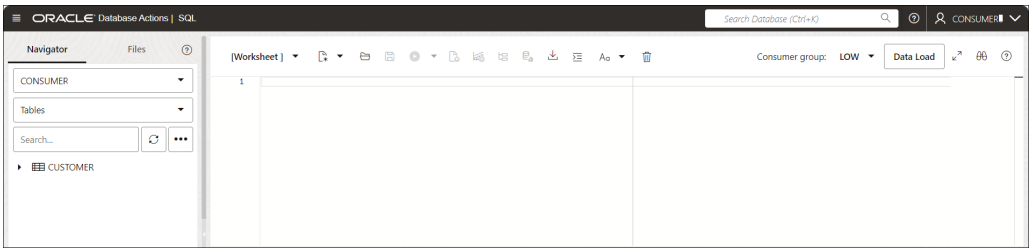


i. Expand the `TESTSHARE` data share node to display the objects in it. Drag and drop the `TPUSER.CUSTOMER` shared table to add it to the data load job.

j. The shared table is added to the data link job. When you run this job, a new `CUSTOMER` view will be created on top of the `CUSTOMER` table that was shared with you.

k. Click **Start**. A **Start Link from Cloud Store** dialog box is displayed. Click **Run**. When the job completes successfully, a link icon is displayed. The `CUSTOMER` view is created.

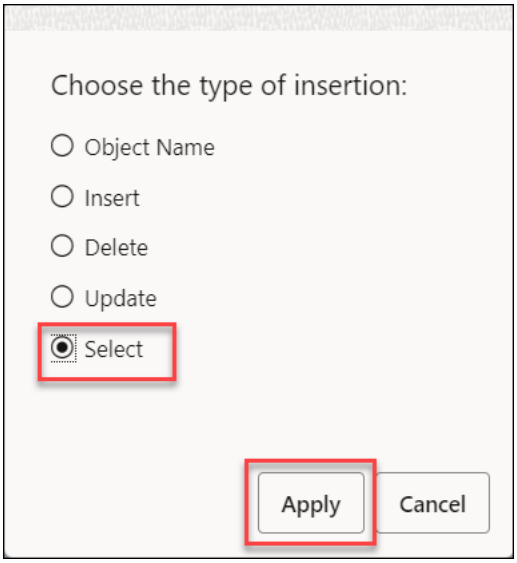
l. Click the **Database Actions | Data Share** banner. On the **Database Actions | Launchpad**, click the **Development** tab, and then click the **SQL** tab to display the SQL Worksheet.

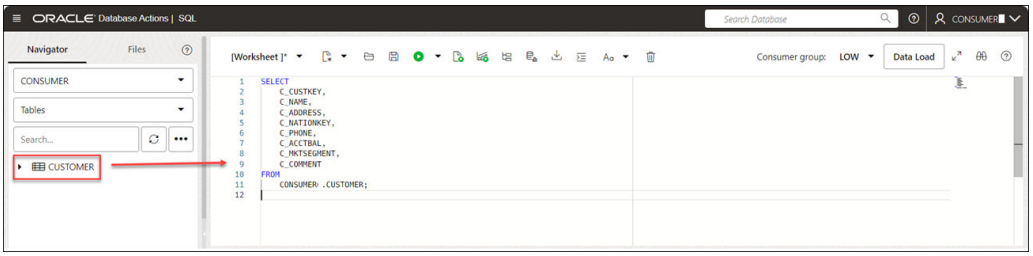


m. Drag and drop the `CUSTOMER` table to the SQL worksheet area.

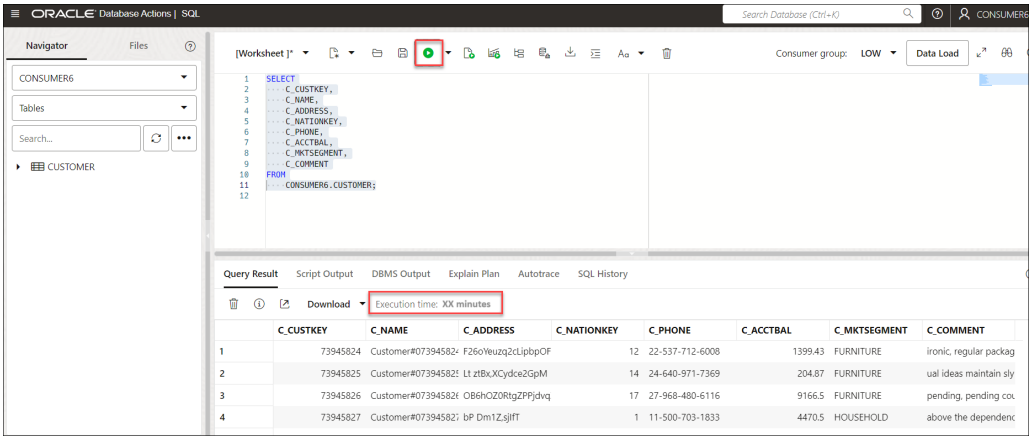
n. A dialog displays offering the types of available insertions.

o. Click **Select**, then **Apply**.





p. Click **Run**. You can view the automatically generated query displayed in the Worksheet.



q. Note the query execution time in the **Execution time** field displayed under Query Result tab.

3. **Increase the ECPUs as provider and consumer and record the query execution time.**

a. Increase the ECPUs of your Autonomous Database instance as a **provider** and a **consumer** from your OCI console. See Add CPU or Storage Resources or Enable Auto Scaling.

> **Note:**
>
> Make sure you have not enabled Auto Scaling.

In this example we have increased the ECPU count to **32**. You can upscale the ECPU count to any value of your choice. For more details on the maximum ECPU count you set and licensing see, View and Update Your License and Oracle Database Edition on Autonomous Database (ECPU Compute Model)

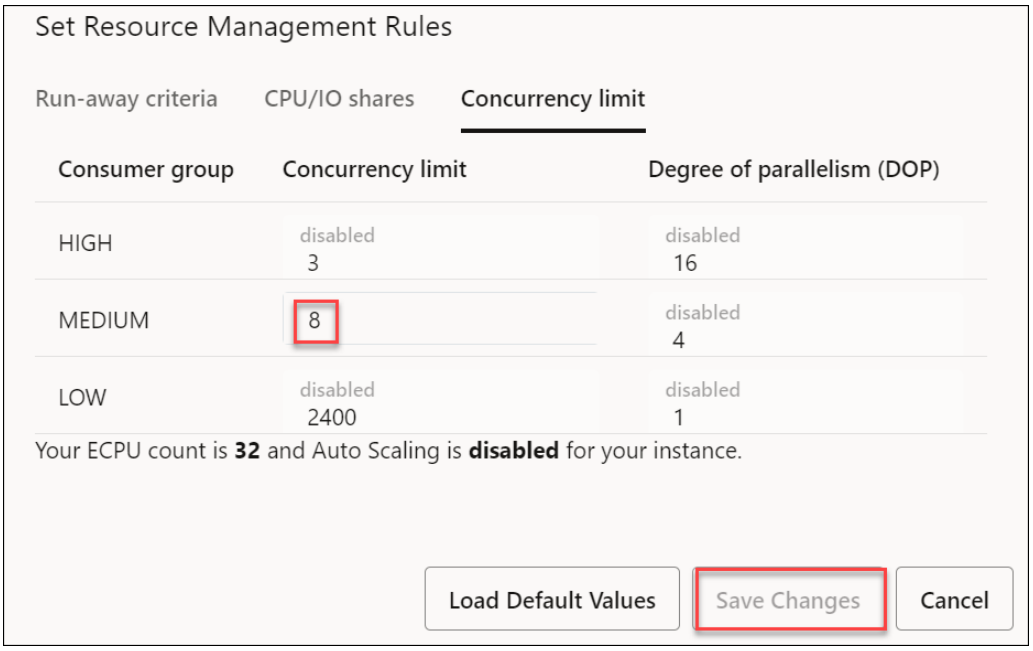
b. Repeat consuming the same `CUSTOMER` share and calculating the query execution time. There will be no change in the time to query the table.

4. **Configure the DOP value for the `MEDIUM` consumer group.**

   a. Log in to your database actions instance as a **consumer** with `ADMIN` privilege.

   b. Click **Selector** and under **Administration**, select **Set Resource Management Rules**.

   c. Decrease the **Concurrency limit** of the `MEDIUM` consumer group to **8** and click **Save Changes**. Decreasing the concurrency limit increases the DOP.



> **Note:**
>
> The concurrency limit you set in this step should be lesser than the default value you noted in the prerequisite.

5. **Follow up step- After you configure the degree of parallelism option, repeat the process of consuming the share, creating external queries on top of your shares to record the query execution time.**
   You will see the value of query execution time has decreased.

The improvement in the performance of the same complex SQL queries happens immediately without restarting the server.

FAQs on the Data Share Tool

The following are frequently asked questions on the Data Share tool.

1. When do recipients receive the Data Definition Language (DDL) updates to the source tables?
   The recipients need to link objects again from the cloud storage location.
   - Navigate to the link cloud Object page from the Data Studio menu.
   - Select the table in the Data Link cart.
   - Click on the **Actions** icon on the table and select Settings.
     This opens the Link Data from Cloud Store Location dialog.
   - Click the **Settings** pane and select "Drop Table and Create New External Table" option from the drop-down.

   You will receive the updated source table.
2. When do recipients receive the Data Manipulation Language (DML) updates to the source tables?
   The provider selects the option to publish versioned data, changes will be reflected if the provider publishes a new version.
3. Does the Data Share tool support object path-based partitioning on the Data Provider end when Oracle Autonomous Database is the consumer?
   No, the Data Share tool does not support object path-based partitioning on the Data Provider end. It supports consumption of only the values that are physically present within a file. The Oracle Autonomous Database consumers will not be able to view the partition values that are based on the file path.

Develop

Describes developer tasks and procedures on Autonomous Database.

- Create Applications with Oracle APEX in Autonomous Database
  You can create applications with Oracle APEX on Autonomous Database.
- Using JSON Documents with Autonomous Database
  Autonomous Database has full support for data represented as JSON documents. In Autonomous Databases, JSON documents can coexist with relational data.
- Developing RESTful Services in Autonomous Database
  You can develop and deploy RESTful Services with native Oracle REST Data Services (ORDS) support on Autonomous Databases. Simple Oracle Document Access (SODA) for REST lets you use a database as a simple JSON document store.
- Using Oracle Database API for MongoDB
  Oracle Database API for MongoDB makes it possible to connect to Oracle Autonomous Database using MongoDB language drivers and tools.
- Send Email and Notifications on Autonomous Database
  There are a number of options for sending email on Autonomous Database. You can also send notifications to a Slack channel, to MSTeams, or to an OCI Notifications topic.
- User Defined Notification Handler for Scheduler Jobs

- Oracle Extensions for IDEs
  Oracle extensions let developers connect to, browse, and manage Autonomous Databases directly from common IDEs.
- Use Oracle Java on Autonomous Database
- Test Workloads with Oracle Real Application Testing
  Oracle Real Application Testing is an extremely cost-effective and easy-to-use proactive performance management solution that enables you to fully assess the outcome of a system change in test or production.
- Manage and Store Files in a Cloud Code Repository with Autonomous Database
  Autonomous Database provides routines to manage and store files in Cloud Code (Git) Repositories. The supported Cloud Code Repositories are: GitHub, AWS CodeCommit, and Azure Repos.
- Invoke User Defined Functions
  You can invoke external functions such as OCI, AWS Lambda, Google Cloud Run functions and Azure remote functions in your Autonomous Database as SQL functions.
- Make External Calls Using a Customer-Managed Wallet
  When your Autonomous Database instance is on a private endpoint you can use a customer-managed wallet with procedures in `UTL_HTTP`, `DBMS_LDAP`, `UTL_SMTP`, or `UTL_TCP`. You can also use a customer-managed wallet when the scheduler sends SMTP email notifications for various events related to scheduler jobs.
- Use Cloud Tables to Store Logging and Diagnostic Information
  You can create Cloud Tables where table data resides on Oracle managed Cloud Storage and the table data does not consume database storage.

Create Applications with Oracle APEX in Autonomous Database

You can create applications with Oracle APEX on Autonomous Database.

- About Oracle APEX
  Oracle APEX is a low-code development platform that enables you to build scalable, secure enterprise applications with world-class features that can be deployed anywhere.
- Access Oracle APEX Administration Services
  Each Autonomous Database instance includes a dedicated instance of Oracle APEX; you can use this instance to create multiple workspaces. A workspace is a shared work area where you can build applications. You create workspaces in Oracle APEX Administration Services.
- Create Oracle APEX Workspaces in Autonomous Database
  An Autonomous Database instance does not have precreated Oracle APEX workspaces. Create a workspace if you have not already done so or use these instructions to create additional workspaces.
- Access Oracle APEX App Builder
  Use App Builder to create and manage Oracle APEX applications and application pages. The App Builder home page displays all installed applications in the current Oracle APEX workspace.
- Create Oracle APEX Developer Accounts
- Load Data from the Cloud into Oracle APEX
  Using Oracle APEX SQL Workshop, you can declaratively load data from Object Store into the database schema associated with your Oracle APEX workspace.

- Use JSON Data with Oracle APEX
  You can use Oracle APEX to create applications with JSON data. You must first create a view to extract the required attributes from the JSON data and maps them into columns of a relational view.
- Use Web Services with Oracle APEX
- Send Email from Oracle APEX
  You can use the `APEX_MAIL` package to send email from Oracle APEX applications deployed in Autonomous Database.
- Control Oracle APEX Upgrades
  Oracle automatically maintains Oracle APEX in your Autonomous Database including the deployment of patches and upgrades. When a new Oracle APEX release becomes available in your region, for example, APEX 24.2.0, you have a choice when to apply this upgrade within the 45-day upgrade window. You can optionally extend this window to 90 days.
- Access Oracle APEX, Oracle REST Data Services, and Developer Tools Using a Vanity URL
  By default you access Oracle APEX apps, REST endpoints, and developer tools on Autonomous Database using the `oraclecloudapps.com` domain name. You can optionally configure a vanity URL or custom domain name that is easy to remember to help promote your brand identity.
- Oracle APEX Limitations on Autonomous Database
  This section summarizes restrictions and limitations of Oracle APEX included in Oracle Autonomous Database and APEX Service.

About Oracle APEX

Oracle APEX is a low-code development platform that enables you to build scalable, secure enterprise applications with world-class features that can be deployed anywhere.

Oracle APEX provides you with an easy-to-use browser-based environment to load data, manage database objects, develop REST interfaces, and build applications which look and run great on both desktop and mobile devices. You can use Oracle APEX to develop a wide variety of solutions: import spreadsheets and develop a single source of truth in minutes, create compelling data visualizations against your existing data, deploy productivity applications to elegantly solve a business need, or build your next mission-critical data management application.

Oracle APEX embraces SQL. Anything you can express with SQL can be easily employed in an Oracle APEX application. Oracle APEX also embodies low code with powerful data management and data visualization components, as well as responsive development out of the box. Instead of writing code by hand, you are able to use intelligent wizards to guide you through the rapid creation of applications and components.

Oracle APEX on Autonomous Database provides a preconfigured, fully managed and secured environment to both build and deploy world-class data-centric applications. There are no limits on the number of developers or end users for your Oracle APEX applications; Autonomous Database can instantly scale compute and storage online as needed, based upon your workload. Additionally, Oracle APEX applications developed on-premise can be easily deployed to Oracle APEX on Autonomous Database, or vice-versa.

Configuration, patching, monitoring, and upgrading of all Oracle APEX components is fully managed by Oracle, leaving you free to focus on developing your solutions and solving your business problems. With Oracle APEX and low code, your organization can be more agile and develop solutions faster, for less cost, and with greater consistency. You can adapt to changing

requirements with ease. And you can empower professional developers and everyone else in your organization to be a part of the solution.

This chapter covers information on Oracle APEX specific to working on Autonomous Database.

For more information on APEX, see the following:

- Oracle APEX Release 24.2
- apex.oracle.com

Access Oracle APEX Administration Services

Each Autonomous Database instance includes a dedicated instance of Oracle APEX; you can use this instance to create multiple workspaces. A workspace is a shared work area where you can build applications. You create workspaces in Oracle APEX Administration Services.

> **Note:**
>
> If your Autonomous Database is configured to use a Private Endpoint, then you can only access Oracle APEX from clients in the same Virtual Cloud Network (VCN). See Configure Network Access with Private Endpoints for more information.

Perform the following prerequisite steps as necessary:

- Open the Oracle Cloud Infrastructure Console by clicking the ☰ next to Cloud.
- From the Oracle Cloud Infrastructure left navigation menu click **Oracle Database** and then click **Autonomous Database**.
- On the Autonomous Databases page select an Autonomous Database from the links under the **Display name** column.

To access Oracle APEX Administration Services you can use the Oracle Cloud Infrastructure Console or Database Actions.

To access Administration Services from Database Actions:

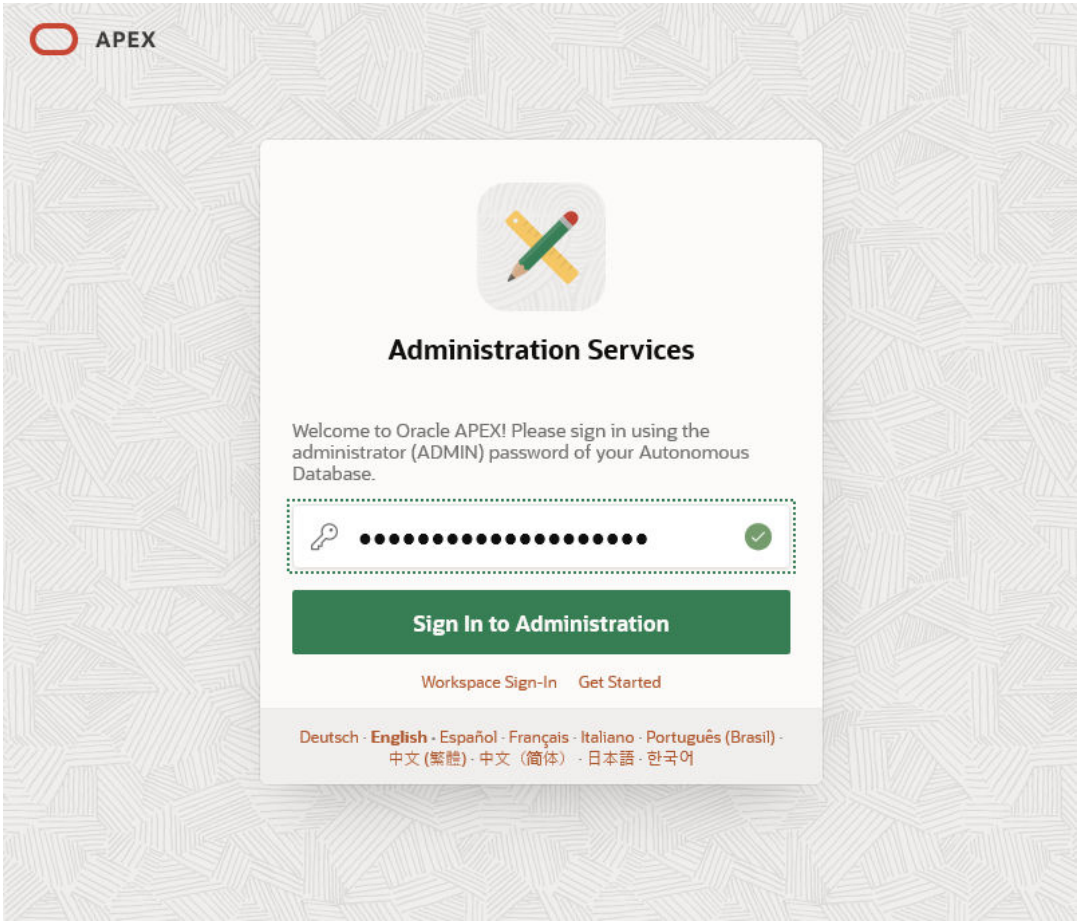
1. On the Autonomous Database details page select **Database Actions** and in the list click **View all database actions**.
2. From the Database Actions Launchpad, under **Development**, click **APEX**.

   The Oracle APEX Administration Services sign-in page appears.

   If you already created a workspace, the APEX workspace sign-in page appears instead. In this case, to open Administration Services, click Administration Services link.
3. In the **Password** field, enter the password for the ADMIN user.

> **Note:**
>
> By default, Administration Services and the Oracle APEX development environment on Autonomous Database use Database Accounts authentication. This authentication method uses the database account user name and password to authenticate users. You can switch to a different authentication method on the Administration Services, Manage Instance, Security page.

See Set the ADMIN Password in Autonomous Database to change the password.



4. Click **Sign In to Administration**.

   When you sign in for the first time, follow the prompts to create an APEX workspace. See Create Oracle APEX Workspaces in Autonomous Database for more information.

To access Administration Services from Oracle Cloud Infrastructure Console:

1. On the Autonomous Database details page click the **Tools** tab.
2. In the **Tools** column, select the Oracle APEX link.

You can also use Administration Services to manage your APEX instance. See Oracle APEX Administration Services in *Oracle APEX Administration Guide* for more information.

Create Oracle APEX Workspaces in Autonomous Database

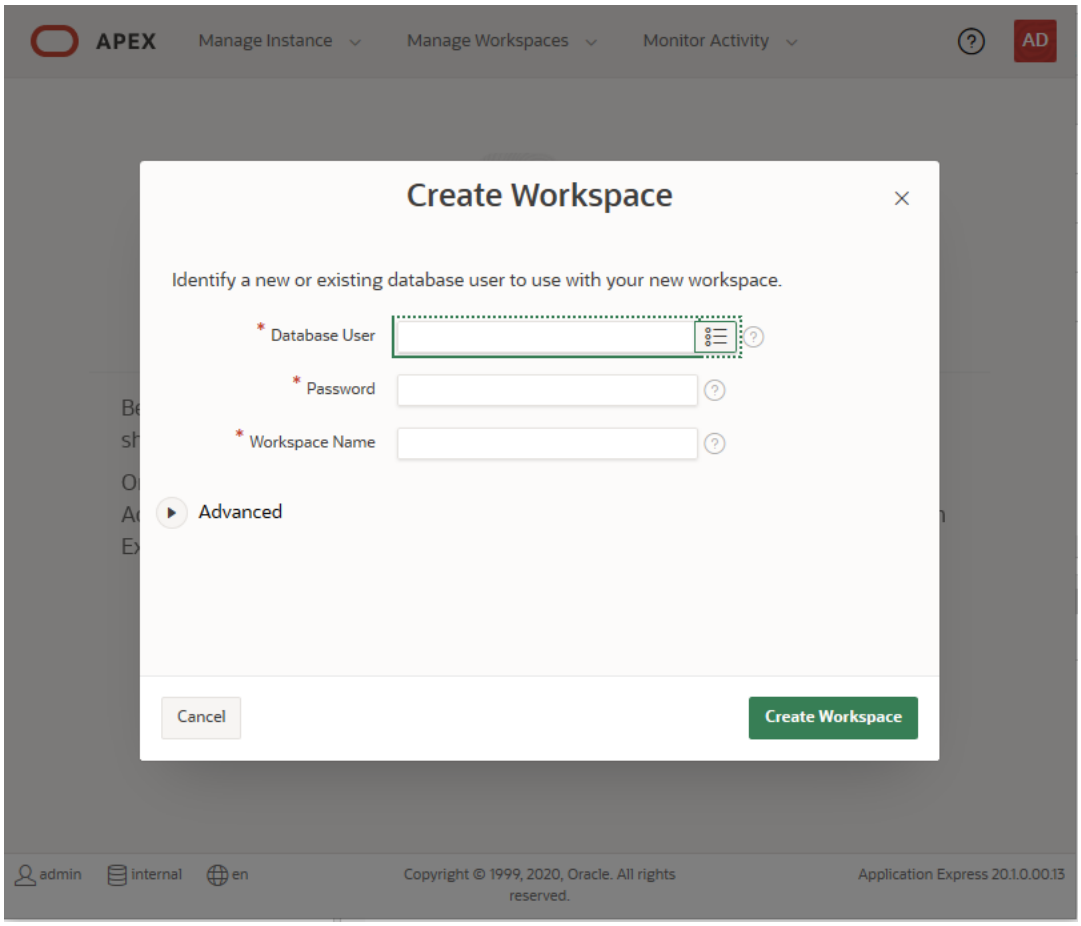
An Autonomous Database instance does not have precreated Oracle APEX workspaces. Create a workspace if you have not already done so or use these instructions to create additional workspaces.

To create an Oracle APEX workspace:

1. Sign in to Oracle APEX Administration Services.

   See Access Oracle APEX Administration Services for more information.

2. Click **Create Workspace**.



3. On the Create Workspace page, in the **Database User** field, enter a new database username or choose an existing user from the list.

   The ADMIN database user cannot be associated with a workspace.

4. In the Password field, provide a strong password if the database user is a new user. If the user is an existing database user you do not enter a password.

   See About User Passwords on Autonomous Database to learn more about the default password complexity rules.

5. (optional) In the **Workspace Name** field, change the name of the workspace that was automatically populated.

6. Click **Create Workspace**.

See Access Oracle APEX App Builder and Create Oracle APEX Developer Accounts to create additional developer accounts.

Access Oracle APEX App Builder

Use App Builder to create and manage Oracle APEX applications and application pages. The App Builder home page displays all installed applications in the current Oracle APEX workspace.

If your Autonomous Database is configured to use a Private Endpoint, you can only access Oracle APEX App Builder from clients in the same Virtual Cloud Network (VCN).

See Configure Network Access with Private Endpoints for more information.

To access Oracle APEX App Builder:

1. Sign in to Oracle APEX using the workspace name, username, and password you specify when you create the workspace.

> **Note:**
>
> Oracle APEX Administration Services and the Oracle APEX development environment on Autonomous Database use Database Accounts authentication. This authentication method uses the database account user name and password to authenticate users.

2. On the Workspace home page, click the App Builder icon.

See Create Oracle APEX Developer Accounts to create developer accounts.

Create Oracle APEX Developer Accounts

Oracle APEX developers need a developer account in each workspace where they wish to build applications.

The initial developer account is created when you create a workspace (this account also has Workspace Administrator privilege). These steps show you how to create additional developer accounts for members of your team or reset their passwords. When you create a developer account, a corresponding database user is automatically created.

To create developer accounts and provide direct access to Oracle APEX:

1. Sign in to Oracle APEX Administration Services.

   See Access Oracle APEX Administration Services for more information.
2. Click **Manage Workspaces**.
3. Under Workspace Actions, click **Manage Developers and Users**.
4. On the Manage Application Developers and Users page, click **Create User**.
5. On the Create/Edit User page, in the **Username** field, enter a username.
6. In the **Email Address** field, enter an email address.
7. (Optional) Use the on-screen and in-line help to fill in additional fields.
8. In the **User is an administrator** field, select **No**.

9. In the **User is a developer** field, select **Yes**.
10. In the **Password** field, enter a strong password.

    See Create Users on Autonomous Database - Connecting with a Client Tool to learn more about the default password complexity rules.
11. In the **Confirm Password** field, confirm the password.
12. At the top of the page, click **Create User**.

    Alternatively, click **Create and Create Another** if you want to create the user and create another user.

To share sign-in details with developers:

1. On the Autonomous Databases page, under the **Display Name** column, select the Autonomous Database instance that contains the user and the user's workspace.
2. On the Autonomous Database Details page select **Database Actions** and click **View all database actions**.
3. In Database Actions Launchpad, under **Development**, right-click **APEX** and choose **Copy URL**.
4. Provide the copied URL, along with the Workspace Name, the Username, and the Password for the developer account you created.

Using this URL developers can access the Oracle APEX environment without having to navigate to the Autonomous Database Oracle Cloud Infrastructure Console.

> **Note:**
>
> Changing the password of Workspace Administrators and Developers through **Manage Developers and Users** page or **Edit Profile** page only affects applications configured with "Oracle APEX Accounts" authentication scheme. To change the password used to access App Builder, use Database Actions or another client to change the password of the corresponding database user.

See Creating User Accounts in *Oracle APEX Administration Guide* for more information.

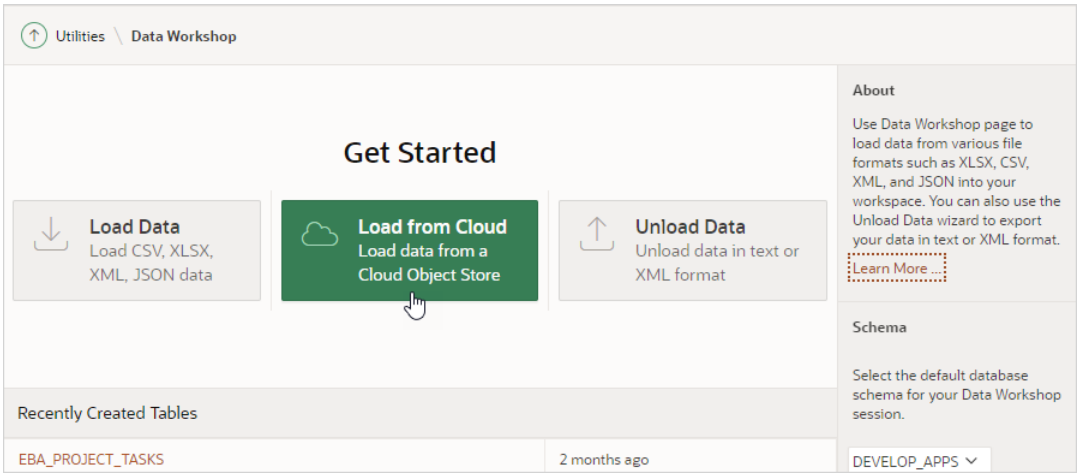
Load Data from the Cloud into Oracle APEX

Using Oracle APEX SQL Workshop, you can declaratively load data from Object Store into the database schema associated with your Oracle APEX workspace.

To load data from the cloud, do the following:

1. Open your Oracle APEX workspace.
2. Select **SQL Workshop**.
3. Select **Utilities**.
4. Select **Data Workshop**.

   This shows the Load from Cloud button.



5. Under Get Started, select **Load from Cloud**.

See Loading Data From the Cloud for more information.

Use JSON Data with Oracle APEX

You can use Oracle APEX to create applications with JSON data. You must first create a view to extract the required attributes from the JSON data and maps them into columns of a relational view.

- Create a View from JSON Data Guide
  Oracle APEX interprets data in relational format. Creating a view extracts required attributes from the JSON data and maps them into columns of a relational view.
- Create a View with JSON_TABLE Function
  You can create views of JSON data using the `json_table` SQL/JSON function.

Create a View from JSON Data Guide

Oracle APEX interprets data in relational format. Creating a view extracts required attributes from the JSON data and maps them into columns of a relational view.

For creating a view of JSON data that is stored in SODA collections, you can use SODA APIs and JSON Data Guide. The following PL/SQL code uses SODA APIs to create a Data Guide view on JSON Data stored in SODA Collections.

Run the following code in Oracle APEX SQL Workshop to create a view named `myview`:

```
-- Fetch the data guide and create a view
DECLARE
    coll  SODA_Collection_T;
    dg    CLOB;
    n     NUMBER;
BEGIN    -- Fetch the data guide from the collection or create one with
hierarchical format
    coll := dbms_soda.open_Collection('mycollection');
    dg := coll.get_Data_Guide;
    dbms_output.put_line(JSON_QUERY(dg, '$' pretty));
    -- User can modify the data guide as needed
    n := coll.create_View_From_DG('myview', dg);
    dbms_output.put_line('Status: ' || n);
```

```
    dbms_lob.freeTemporary(dg);
END;
/
```

Use the following command to check if the view has been created:

```
select count(1) from user_views where view_name = 'myview';
```

Use the following command to see the structure of the view:

```
describe myview;
```

See Create View using JSON Data Guide for more information on creating a view using JSON Data Guide.

Create a View with JSON_TABLE Function

You can create views of JSON data using the `json_table` SQL/JSON function.
