Primary Author: Rajesh Bhatiya, Padmaja Potineni

Contributing Authors: Randy Urbano, Virginia Beecher, Leo Cloutier, Steve Fogel, Chuck Murray

Contributors: A. Agrawal, L. Ashdown, P. Avril, D. Austin, T. Baby, H. Baer, S. Ball, S. Battula, M. Bauer, T. Bednar, E. Belden, J. Byun, L. Carpenter, A. Chaudhry, C. Chang, B. Cheng, H. Chien, T. Chien, G. Christman, C. C. Chui, L. Clarke, D. Colello, C. Colrain, K. Cook, J. Creighton, A. Dadhich, S. Datta, S. Davidson, M. Dilman, S. Doraiswamy, J. Draaijer, M. Fallen, M. Fuller, D. Gagne, A. Ganesh, GP Gongloor, J. Gonzalez, V. Goorah, S. Gopalan, S. Gupta, B. Habeck, S. Hase, W. Hu, P. Huey, K. Inoue, M. Ito, C. Iyer, K. Itikarlapalli, P. Jaganath, S. Jain, C. Jones, S. Joshi, B. Khaladkar, F. Kobylanski, B. Krishnan, V. Krishnaswamy, A. Kruglikov, B. Kuchibhotla, V. Kuhr, R. Kumar, S. Kumar, V. Kumar, H. Lakshmanan, A. Lee, B. Lee, J. Lee, S. K. Lee, T. Lee, C. Lei, B. Leung, Y. Li, I. Listvinsky, B. Llewellyn, H. Lombera, B. Lundhild, S. Lynn, R. Mani, V. Marwah, C. McGregor, J. McDonnell, J. McHugh, B. McGuirk, J. Meeks, K. Mensah, M. Minhas, K. Mohan, H. Mohankumar, A. Munnilimath, G. Mulagund, P. Murguia, P. Murthy, A. Mylavarapu, V. Moore, N. Muthukrishnan, S. Muthulingam, L. Nim, S. Panchumarthy, R. Pang, V. Panteleenko, R. Pingte, K. Rajamani, A. Raghavan, M. Ramacher, R. Ramkissoon, S. Ravindhran, G. Ravipati, A. Ray, W. Ren, K. Rich, J. Rivera, C. A. L. Rueda, R. Rungra, S. Sahu, P. Shanthaveerappa, S. Sonawane, Y. Sarig, M. Savanur, S. Shankar, D. Sharma, A. Shen, B. Sinha, J. Spiller, D. Steiner, J. Stern, M. Stewart, S. Stoian, R. Swonger, M. Subramaniam, N. Sundarappa, M. Susairaj, A. Tran, A. Tsukerman, C. Tuzla, T. Ueda, K. Ummageswaran, D. Utzig, E. Voss, N. Wagner, X. Wang, M. Wei, S. Wertheimer, P. Wheeler, D. Williams, A. Witkowski, S. Wolicki, D. M. Wong, Z. Yang, T. F. Yu, W. Zhang

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software" or "commercial computer software documentation" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Changes in This Release for Oracle Database Administrator's Guide

Changes in Oracle Database 12c Release 2 (12.2.0.1)	lxix
Changes in Oracle Database 12c Release 1 (12.1.0.2)	lxxiii
Changes in Oracle Database 12c Release 1 (12.1.0.1)	lxxvi

Part I Basic Database Administration

1 Getting Started with Database Administration

1.1 Types of Oracle Database Users	1-1
1.1.1 Database Administrators	1-2
1.1.2 Security Officers	1-3
1.1.3 Network Administrators	1-3
1.1.4 Application Developers	1-3
1.1.5 Application Administrators	1-4
1.1.6 Database Users	1-4
1.2 Tasks of a Database Administrator	1-4
1.2.1 Task 1: Evaluate the Database Server Hardware	1-5
1.2.2 Task 2: Install the Oracle Database Software	1-5
1.2.3 Task 3: Plan the Database	1-6
1.2.4 Task 4: Create and Open the Database	1-6
1.2.5 Task 5: Back Up the Database	1-7
1.2.6 Task 6: Enroll System Users	1-7
1.2.7 Task 7: Implement the Database Design	1-7

1.2.8	Task 8: Back Up the Fully Functional Database	1-7
1.2.9	Task 9: Tune Database Performance	1-7
1.2.10	Task 10: Download and Install Patches	1-8
1.2.11	Task 11: Roll Out to Additional Hosts	1-8
1.3	SQL Statements	1-9
1.3.1	Submitting Commands and SQL to the Database	1-9
1.3.2	About SQL*Plus	1-10
1.3.3	Connecting to the Database with SQL*Plus	1-10
1.3.3.1	About Connecting to the Database with SQL*Plus	1-10
1.3.3.2	Step 1: Open a Command Window	1-11
1.3.3.3	Step 2: Set Operating System Environment Variables	1-11
1.3.3.4	Step 3: Start SQL*Plus	1-12
1.3.3.5	Step 4: Submit the SQL*Plus CONNECT Command	1-12
1.4	Identifying Your Oracle Database Software Release	1-17
1.4.1	Release Number Format	1-17
1.4.1.1	Major Database Release Number	1-18
1.4.1.2	Database Maintenance Release Number	1-18
1.4.1.3	Fusion Middleware Release Number	1-18
1.4.1.4	Component-Specific Release Number	1-18
1.4.1.5	Platform-Specific Release Number	1-18
1.4.2	Checking Your Current Release Number	1-18
1.5	About Database Administrator Security and Privileges	1-19
1.5.1	The Database Administrator's Operating System Account	1-19
1.5.2	Administrative User Accounts	1-19
1.5.2.1	About Administrative User Accounts	1-20
1.5.2.2	SYS	1-21
1.5.2.3	SYSTEM	1-21
1.5.2.4	SYSBACKUP, SYSDG, SYSKM, and SYSRAC	1-21
1.5.2.5	The DBA Role	1-22
1.6	Database Administrator Authentication	1-23
1.6.1	Administrative Privileges	1-23
1.6.2	Operations Authorized by Administrative Privileges	1-24
1.6.3	Authentication Methods for Database Administrators	1-27
1.6.3.1	About Authentication Methods for Database Administrators	1-27
1.6.3.2	Nonsecure Remote Connections	1-28
1.6.3.3	Local Connections and Secure Remote Connections	1-29
1.6.4	Using Operating System Authentication	1-29
1.6.4.1	Operating System Groups	1-29
1.6.4.2	Preparing to Use Operating System Authentication	1-31
1.6.4.3	Connecting Using Operating System Authentication	1-31
1.6.5	Using Password File Authentication	1-32

1.6.5.1	Preparing to Use Password File Authentication	1-32
1.6.5.2	Connecting Using Password File Authentication	1-34
1.7	Creating and Maintaining a Database Password File	1-35
1.7.1	ORAPWD Syntax and Command Line Argument Descriptions	1-35
1.7.2	Creating a Database Password File with ORAPWD	1-40
1.7.3	Sharing and Disabling the Database Password File	1-42
1.7.4	Keeping Administrator Passwords Synchronized with the Data Dictionary	1-42
1.7.5	Adding Users to a Database Password File	1-44
1.7.6	Granting and Revoking Administrative Privileges	1-44
1.7.7	Viewing Database Password File Members	1-45
1.7.8	Removing a Database Password File	1-46
1.8	Data Utilities	1-46

2 Creating and Configuring an Oracle Database

2.1	About Creating an Oracle Database	2-2
2.2	Considerations Before Creating the Database	2-3
2.2.1	Planning for Database Creation	2-3
2.2.2	About Selecting a Character Set	2-4
2.2.3	Meeting Creation Prerequisites	2-6
2.3	Creating a Database with DBCA	2-6
2.3.1	About Creating a Database with DBCA	2-7
2.3.2	About Creating a Database with Interactive DBCA	2-7
2.3.3	About Creating a Database with Noninteractive/Silent DBCA	2-7
2.3.3.1	DBCA Examples	2-7
2.4	Creating a Database with the CREATE DATABASE Statement	2-8
2.4.1	About Creating a Database with the CREATE DATABASE Statement	2-9
2.4.2	Step 1: Specify an Instance Identifier (SID)	2-10
2.4.3	Step 2: Ensure That the Required Environment Variables Are Set	2-11
2.4.4	Step 3: Choose a Database Administrator Authentication Method	2-12
2.4.5	Step 4: Create the Initialization Parameter File	2-12
2.4.6	Step 5: (Windows Only) Create an Instance	2-13
2.4.7	Step 6: Connect to the Instance	2-14
2.4.8	Step 7: Create a Server Parameter File	2-15
2.4.9	Step 8: Start the Instance	2-16
2.4.10	Step 9: Issue the CREATE DATABASE Statement	2-16
2.4.11	Step 10: Create Additional Tablespaces	2-20
2.4.12	Step 11: Run Scripts to Build Data Dictionary Views	2-20
2.4.13	Step 12: (Optional) Run Scripts to Install Additional Options	2-21
2.4.14	Step 13: Back Up the Database	2-21
2.4.15	Step 14: (Optional) Enable Automatic Instance Startup	2-21

2.5 Specifying CREATE DATABASE Statement Clauses	2-22
2.5.1 About CREATE DATABASE Statement Clauses	2-23
2.5.2 Protecting Your Database: Specifying Passwords for Users SYS and SYSTEM	2-23
2.5.3 Creating a Locally Managed SYSTEM Tablespace	2-24
2.5.4 Specify Data File Attributes for the SYSAUX Tablespace	2-25
2.5.4.1 About the SYSAUX Tablespace	2-25
2.5.5 Using Automatic Undo Management: Creating an Undo Tablespace	2-26
2.5.6 Creating a Default Permanent Tablespace	2-26
2.5.7 Creating a Default Temporary Tablespace	2-27
2.5.8 Specifying Oracle Managed Files at Database Creation	2-28
2.5.9 Supporting Bigfile Tablespaces During Database Creation	2-29
2.5.9.1 Specifying the Default Tablespace Type	2-30
2.5.9.2 Overriding the Default Tablespace Type	2-30
2.5.10 Specifying the Database Time Zone and Time Zone File	2-31
2.5.10.1 Setting the Database Time Zone	2-31
2.5.10.2 About the Database Time Zone Files	2-31
2.5.10.3 Specifying the Database Time Zone File	2-32
2.5.11 Specifying FORCE LOGGING Mode	2-32
2.5.11.1 Using the FORCE LOGGING Clause	2-33
2.5.11.2 Performance Considerations of FORCE LOGGING Mode	2-33
2.6 Specifying Initialization Parameters	2-34
2.6.1 About Initialization Parameters and Initialization Parameter Files	2-35
2.6.1.1 Sample Initialization Parameter File	2-36
2.6.1.2 Text Initialization Parameter File Format	2-37
2.6.2 Determining the Global Database Name	2-38
2.6.2.1 DB_NAME Initialization Parameter	2-38
2.6.2.2 DB_DOMAIN Initialization Parameter	2-38
2.6.3 Specifying a Fast Recovery Area	2-39
2.6.4 Specifying Control Files	2-40
2.6.5 Specifying Database Block Sizes	2-40
2.6.5.1 DB_BLOCK_SIZE Initialization Parameter	2-41
2.6.5.2 Nonstandard Block Sizes	2-41
2.6.6 Specifying the Maximum Number of Processes	2-42
2.6.7 Specifying the DDL Lock Timeout	2-42
2.6.8 Specifying the Method of Undo Space Management	2-43
2.6.8.1 UNDO_MANAGEMENT Initialization Parameter	2-44
2.6.8.2 UNDO_TABLESPACE Initialization Parameter	2-44
2.6.9 Specifying the Database Compatibility Level	2-44
2.6.9.1 About The COMPATIBLE Initialization Parameter	2-45
2.6.10 Setting the License Parameter	2-46

2.7	Managing Initialization Parameters Using a Server Parameter File	2-46
2.7.1	What Is a Server Parameter File?	2-47
2.7.2	Migrating to a Server Parameter File	2-48
2.7.3	Server Parameter File Default Names and Locations	2-49
2.7.4	Creating a Server Parameter File	2-50
2.7.5	The SPFILE Initialization Parameter	2-50
2.7.6	Changing Initialization Parameter Values	2-51
2.7.6.1	About Changing Initialization Parameter Values	2-51
2.7.6.2	Setting or Changing Initialization Parameter Values	2-51
2.7.7	Clearing Initialization Parameter Values	2-53
2.7.8	Exporting the Server Parameter File	2-54
2.7.9	Backing Up the Server Parameter File	2-55
2.7.10	Recovering a Lost or Damaged Server Parameter File	2-55
2.7.11	Methods for Viewing Parameter Settings	2-56
2.8	Managing Application Workloads with Database Services	2-57
2.8.1	Database Services	2-57
2.8.1.1	About Database Services	2-58
2.8.1.2	Database Services and Performance	2-59
2.8.1.3	Oracle Database Features That Use Database Services	2-59
2.8.1.4	Creating Database Services	2-60
2.8.2	Global Data Services	2-61
2.8.3	Database Service Data Dictionary Views	2-62
2.9	Considerations After Creating a Database	2-62
2.9.1	Some Security Considerations	2-63
2.9.2	Transparent Data Encryption	2-64
2.9.3	A Secure External Password Store	2-65
2.9.4	Transaction Guard and Application Continuity	2-65
2.9.5	File System Server Support in the Database	2-66
2.9.6	The Oracle Database Sample Schemas	2-67
2.10	Cloning a Database with CloneDB	2-67
2.10.1	About Cloning a Database with CloneDB	2-67
2.10.2	Cloning a Database with CloneDB	2-68
2.10.3	After Cloning a Database with CloneDB	2-73
2.11	Dropping a Database	2-74
2.12	Database Data Dictionary Views	2-74
2.13	Database Configuration Assistant Command Reference for Silent Mode	2-75
2.13.1	DBCA Command-Line Syntax Overview	2-75
2.13.2	About DBCA Templates	2-77
2.13.3	Database User Authentication in DBCA Commands Using Oracle Wallet	2-77
2.13.4	DBCA Silent Mode Commands	2-79

2.13.4.1	createDatabase	2-80
2.13.4.2	createDuplicateDB	2-87
2.13.4.3	configureDatabase	2-89
2.13.4.4	createTemplateFromDB	2-91
2.13.4.5	createCloneTemplate	2-92
2.13.4.6	generateScripts	2-94
2.13.4.7	deleteDatabase	2-101
2.13.4.8	createPluggableDatabase	2-103
2.13.4.9	unplugDatabase	2-108
2.13.4.10	deletePluggableDatabase	2-109
2.13.4.11	configurePluggableDatabase	2-110
2.13.4.12	addInstance	2-112
2.13.4.13	deleteInstance	2-113
2.13.4.14	executePrereqs	2-114

3 Starting Up and Shutting Down

3.1	Starting Up a Database	3-1
3.1.1	About Database Startup Options	3-2
3.1.1.1	Starting Up a Database Using SQL*Plus	3-3
3.1.1.2	Starting Up a Database Using Recovery Manager	3-3
3.1.1.3	Starting Up a Database Using Cloud Control	3-3
3.1.1.4	Starting Up a Database Using SRVCTL	3-3
3.1.2	Specifying Initialization Parameters at Startup	3-4
3.1.2.1	About Initialization Parameter Files and Startup	3-4
3.1.2.2	Starting Up with SQL*Plus with a Nondefault Server Parameter File	3-6
3.1.2.3	Starting Up with SRVCTL with a Nondefault Server Parameter File	3-6
3.1.3	About Automatic Startup of Database Services	3-7
3.1.4	Preparing to Start Up an Instance	3-7
3.1.5	Starting Up an Instance	3-8
3.1.5.1	About Starting Up an Instance	3-9
3.1.5.2	Starting an Instance, and Mounting and Opening a Database	3-10
3.1.5.3	Starting an Instance Without Mounting a Database	3-10
3.1.5.4	Starting an Instance and Mounting a Database	3-11
3.1.5.5	Restricting Access to an Instance at Startup	3-11
3.1.5.6	Forcing an Instance to Start	3-12
3.1.5.7	Starting an Instance, Mounting a Database, and Starting Complete Media Recovery	3-13
3.1.5.8	Automatic Database Startup at Operating System Start	3-13
3.1.5.9	Starting Remote Instances	3-13

3.2	Altering Database Availability	3-13
3.2.1	Mounting a Database to an Instance	3-14
3.2.2	Opening a Closed Database	3-14
3.2.3	Opening a Database in Read-Only Mode	3-14
3.2.4	Restricting Access to an Open Database	3-16
3.3	Shutting Down a Database	3-16
3.3.1	About Shutting Down the Database	3-17
3.3.2	Shutting Down with the Normal Mode	3-17
3.3.3	Shutting Down with the Immediate Mode	3-18
3.3.4	Shutting Down with the Transactional Mode	3-18
3.3.5	Shutting Down with the Abort Mode	3-19
3.3.6	Shutdown Timeout	3-20
3.4	Quiescing a Database	3-20
3.4.1	About Quiescing a Database	3-20
3.4.2	Placing a Database into a Quiesced State	3-21
3.4.3	Restoring the System to Normal Operation	3-22
3.4.4	Viewing the Quiesce State of an Instance	3-23
3.5	Suspending and Resuming a Database	3-23
3.6	Delaying Instance Abort	3-24

4 Configuring Automatic Restart of an Oracle Database

4.1	About Oracle Restart	4-1
4.1.1	Oracle Restart Overview	4-2
4.1.2	About Startup Dependencies	4-3
4.1.3	About Starting and Stopping Components with Oracle Restart	4-3
4.1.4	About Starting and Stopping Oracle Restart	4-4
4.1.5	Oracle Restart Configuration	4-4
4.1.6	Oracle Restart Integration with Oracle Data Guard	4-6
4.1.7	Fast Application Notification with Oracle Restart	4-7
4.1.7.1	Overview of Fast Application Notification	4-7
4.1.7.2	Application High Availability with Services and FAN	4-8
4.2	Configuring Oracle Restart	4-12
4.2.1	About Configuring Oracle Restart	4-13
4.2.2	Preparing to Run SRVCTL	4-14
4.2.3	Obtaining Help for SRVCTL	4-15
4.2.4	Adding Components to the Oracle Restart Configuration	4-15
4.2.5	Removing Components from the Oracle Restart Configuration	4-17
4.2.6	Disabling and Enabling Oracle Restart Management for a Component	4-18
4.2.7	Viewing Component Status	4-19
4.2.8	Viewing the Oracle Restart Configuration for a Component	4-19

4.2.9	Modifying the Oracle Restart Configuration for a Component	4-20
4.2.10	Managing Environment Variables in the Oracle Restart Configuration	4-21
4.2.10.1	About Environment Variables in the Oracle Restart Configuration	4-21
4.2.10.2	Setting and Unsetting Environment Variables	4-22
4.2.10.3	Viewing Environment Variables	4-22
4.2.11	Creating and Deleting Database Services with SRVCTL	4-23
4.2.12	Enabling FAN Events in an Oracle Restart Environment	4-24
4.2.13	Automating the Failover of Connections Between Primary and Standby Databases	4-25
4.2.14	Enabling Clients for Fast Connection Failover	4-26
4.2.14.1	About Enabling Clients for Fast Connection Failover	4-26
4.2.14.2	Enabling Fast Connection Failover for JDBC Clients	4-27
4.2.14.3	Enabling Fast Connection Failover for Oracle Call Interface Clients	4-28
4.2.14.4	Enabling Fast Connection Failover for ODP.NET Clients	4-29
4.3	Starting and Stopping Components Managed by Oracle Restart	4-30
4.4	Stopping and Restarting Oracle Restart for Maintenance Operations	4-33
4.5	SRVCTL Command Reference for Oracle Restart	4-34
4.5.1	add	4-37
4.5.1.1	srvctl add asm	4-38
4.5.1.2	srvctl add database	4-39
4.5.1.3	srvctl add listener	4-41
4.5.1.4	srvctl add ons	4-42
4.5.1.5	srvctl add service	4-43
4.5.2	config	4-47
4.5.2.1	srvctl config asm	4-48
4.5.2.2	srvctl config database	4-48
4.5.2.3	srvctl config listener	4-49
4.5.2.4	srvctl config ons	4-50
4.5.2.5	srvctl config service	4-50
4.5.3	disable	4-51
4.5.3.1	srvctl disable asm	4-52
4.5.3.2	srvctl disable database	4-52
4.5.3.3	srvctl disable diskgroup	4-52
4.5.3.4	srvctl disable listener	4-53
4.5.3.5	srvctl disable ons	4-53
4.5.3.6	srvctl disable service	4-54
4.5.4	downgrade	4-54
4.5.4.1	srvctl downgrade database	4-55
4.5.5	enable	4-55
4.5.5.1	srvctl enable asm	4-56
4.5.5.2	srvctl enable database	4-56

4.5.5.3	srvctl enable diskgroup	4-57
4.5.5.4	srvctl enable listener	4-57
4.5.5.5	srvctl enable ons	4-58
4.5.5.6	srvctl enable service	4-58
4.5.6	getenv	4-59
4.5.6.1	srvctl getenv asm	4-59
4.5.6.2	srvctl getenv database	4-60
4.5.6.3	srvctl getenv listener	4-60
4.5.7	modify	4-61
4.5.7.1	srvctl modify asm	4-61
4.5.7.2	srvctl modify database	4-62
4.5.7.3	srvctl modify listener	4-63
4.5.7.4	srvctl modify ons	4-64
4.5.7.5	srvctl modify service	4-64
4.5.8	remove	4-69
4.5.8.1	srvctl remove asm	4-69
4.5.8.2	srvctl remove database	4-70
4.5.8.3	srvctl remove diskgroup	4-71
4.5.8.4	srvctl remove listener	4-71
4.5.8.5	srvctl remove ons	4-72
4.5.8.6	srvctl remove service	4-72
4.5.9	setenv	4-73
4.5.9.1	srvctl setenv asm	4-74
4.5.9.2	srvctl setenv database	4-74
4.5.9.3	srvctl setenv listener	4-75
4.5.10	start	4-76
4.5.10.1	srvctl start asm	4-76
4.5.10.2	srvctl start database	4-77
4.5.10.3	srvctl start diskgroup	4-78
4.5.10.4	srvctl start home	4-78
4.5.10.5	srvctl start listener	4-79
4.5.10.6	srvctl start ons	4-80
4.5.10.7	srvctl start service	4-80
4.5.11	status	4-81
4.5.11.1	srvctl status asm	4-81
4.5.11.2	srvctl status database	4-82
4.5.11.3	srvctl status diskgroup	4-83
4.5.11.4	srvctl status home	4-83
4.5.11.5	srvctl status listener	4-84
4.5.11.6	srvctl status ons	4-84
4.5.11.7	srvctl status service	4-85

4.5.12 stop	4-85
4.5.12.1 srvctl stop asm	4-86
4.5.12.2 srvctl stop database	4-87
4.5.12.3 srvctl stop diskgroup	4-88
4.5.12.4 srvctl stop home	4-89
4.5.12.5 srvctl stop listener	4-89
4.5.12.6 srvctl stop ons	4-90
4.5.12.7 srvctl stop service	4-90
4.5.13 unsetenv	4-92
4.5.13.1 srvctl unsetenv asm	4-92
4.5.13.2 srvctl unsetenv database	4-93
4.5.13.3 srvctl unsetenv listener	4-93
4.5.14 update	4-94
4.5.14.1 srvctl update database	4-94
4.5.15 upgrade	4-95
4.5.15.1 srvctl upgrade database	4-95
4.6 CRSCTL Command Reference	4-95
4.6.1 check	4-96

5 Managing Processes

5.1 About Dedicated and Shared Server Processes	5-2
5.1.1 Dedicated Server Processes	5-2
5.1.2 Shared Server Processes	5-3
5.2 About Database Resident Connection Pooling	5-5
5.2.1 Comparing DRCP to Dedicated Server and Shared Server	5-7
5.3 Configuring Oracle Database for Shared Server	5-8
5.3.1 Initialization Parameters for Shared Server	5-8
5.3.2 Memory Management for Shared Server	5-9
5.3.3 Enabling Shared Server	5-9
5.3.3.1 About Determining a Value for SHARED_SERVERS	5-11
5.3.3.2 Decreasing the Number of Shared Server Processes	5-11
5.3.3.3 Limiting the Number of Shared Server Processes	5-12
5.3.3.4 Limiting the Number of Shared Server Sessions	5-12
5.3.3.5 Protecting Shared Memory	5-13
5.3.4 Configuring Dispatchers	5-13

5.3.4.1	DISPATCHERS Initialization Parameter Attributes	5-14
5.3.4.2	Determining the Number of Dispatchers	5-15
5.3.4.3	Setting the Initial Number of Dispatchers	5-16
5.3.4.4	Altering the Number of Dispatchers	5-17
5.3.4.5	Shutting Down Specific Dispatcher Processes	5-18
5.3.5	Disabling Shared Server	5-19
5.3.6	Shared Server Data Dictionary Views	5-19
5.4	Configuring Database Resident Connection Pooling	5-20
5.4.1	Enabling Database Resident Connection Pooling	5-21
5.4.2	Configuring the Connection Pool for Database Resident Connection Pooling	5-22
5.4.2.1	Configuration Parameters for Database Resident Connection Pooling	5-23
5.4.3	Data Dictionary Views for Database Resident Connection Pooling	5-25
5.4.4	Determining the States of Connections in the Connection Pool	5-25
5.5	About Oracle Database Background Processes	5-26
5.6	Managing Prespawned Processes	5-28
5.6.1	About Managing Prespawned Processes	5-28
5.6.2	Managing Pools for Prespawned Processes	5-28
5.7	Managing Processes for Parallel SQL Execution	5-30
5.7.1	About Parallel Execution Servers	5-30
5.7.2	Altering Parallel Execution for a Session	5-31
5.7.2.1	Disabling Parallel SQL Execution	5-32
5.7.2.2	Enabling Parallel SQL Execution	5-32
5.7.2.3	Forcing Parallel SQL Execution	5-32
5.8	Managing Processes for External Procedures	5-33
5.8.1	About External Procedures	5-33
5.8.2	DBA Tasks to Enable External Procedure Calls	5-33
5.9	Terminating Sessions	5-35
5.9.1	About Terminating Sessions	5-35
5.9.2	Identifying Which Session to Terminate	5-35
5.9.3	Terminating an Active Session	5-36
5.9.4	Terminating an Inactive Session	5-37
5.10	Process and Session Data Dictionary Views	5-38

6 Managing Memory

6.1	About Memory Management	6-2
6.2	Memory Architecture Overview	6-3
6.3	Using Automatic Memory Management	6-5
6.3.1	About Automatic Memory Management	6-5
6.3.2	Enabling Automatic Memory Management	6-6

6.3.3	Monitoring and Tuning Automatic Memory Management	6-9
6.4	Configuring Memory Manually	6-10
6.4.1	About Manual Memory Management	6-10
6.4.2	Using Automatic Shared Memory Management	6-11
6.4.2.1	About Automatic Shared Memory Management	6-12
6.4.2.2	Components and Granules in the SGA	6-12
6.4.2.3	Setting Maximum SGA Size	6-13
6.4.2.4	Setting SGA Target Size	6-13
6.4.2.5	Enabling Automatic Shared Memory Management	6-16
6.4.2.6	Setting Minimums for Automatically Sized SGA Components	6-17
6.4.2.7	Dynamic Modification of SGA_TARGET	6-18
6.4.2.8	Modifying Parameters for Automatically Sized Components	6-19
6.4.2.9	Modifying Parameters for Manually Sized Components	6-20
6.4.3	Using Manual Shared Memory Management	6-20
6.4.3.1	About Manual Shared Memory Management	6-21
6.4.3.2	Enabling Manual Shared Memory Management	6-21
6.4.3.3	Setting the Buffer Cache Initialization Parameters	6-22
6.4.3.4	Specifying the Shared Pool Size	6-24
6.4.3.5	Specifying the Large Pool Size	6-25
6.4.3.6	Specifying the Java Pool Size	6-25
6.4.3.7	Specifying the Streams Pool Size	6-26
6.4.3.8	Specifying the Result Cache Maximum Size	6-26
6.4.3.9	Specifying Miscellaneous SGA Initialization Parameters	6-27
6.4.4	Using Automatic PGA Memory Management	6-28
6.4.5	Using Manual PGA Memory Management	6-29
6.5	Using Force Full Database Caching Mode	6-30
6.5.1	About Force Full Database Caching Mode	6-30
6.5.2	Before Enabling Force Full Database Caching Mode	6-31
6.5.3	Enabling Force Full Database Caching Mode	6-32
6.5.4	Disabling Force Full Database Caching Mode	6-32
6.6	Configuring Database Smart Flash Cache	6-33
6.6.1	When to Configure Database Smart Flash Cache	6-33
6.6.2	Sizing Database Smart Flash Cache	6-34
6.6.3	Tuning Memory for Database Smart Flash Cache	6-34
6.6.4	Database Smart Flash Cache Initialization Parameters	6-35
6.6.5	Database Smart Flash Cache in an Oracle Real Applications Clusters Environment	6-36
6.7	Improving Query Performance with the In-Memory Column Store	6-36
6.8	Memory Management Reference	6-37
6.8.1	Platforms That Support Automatic Memory Management	6-37

7 Managing Users and Securing the Database

7.1	The Importance of Establishing a Security Policy for Your Database	7-1
7.2	Managing Users and Resources	7-1
7.3	User Privileges and Roles	7-2
7.4	Auditing Database Activity	7-2
7.5	Predefined User Accounts	7-3

8 Monitoring the Database

8.1	Monitoring Errors and Alerts	8-1
8.1.1	Monitoring Errors with Trace Files and the Alert Log	8-1
8.1.1.1	About Monitoring Errors with Trace Files and the Alert Log	8-2
8.1.1.2	Controlling the Size of an Alert Log	8-3
8.1.1.3	Controlling the Size of Trace Files	8-3
8.1.1.4	Controlling When Oracle Database Writes to Trace Files	8-5
8.1.1.5	Reading the Trace File for Shared Server Sessions	8-6
8.1.2	Monitoring a Database with Server-Generated Alerts	8-6
8.1.2.1	About Monitoring a Database with Server-Generated Alerts	8-6
8.1.2.2	Setting and Retrieving Thresholds for Server-Generated Alerts	8-7
8.1.2.3	Viewing Server-Generated Alerts	8-9
8.1.2.4	Server-Generated Alerts Data Dictionary Views	8-10
8.2	Monitoring Performance	8-10
8.2.1	Monitoring Locks	8-11
8.2.2	About Monitoring Wait Events	8-11
8.2.3	Performance Monitoring Data Dictionary Views	8-12
8.3	Monitoring Quarantined Objects	8-12
8.3.1	About Object Quarantine	8-13
8.3.2	Viewing Quarantined Objects	8-13

9 Managing Diagnostic Data

9.1	About the Oracle Database Fault Diagnosability Infrastructure	9-2
9.1.1	Fault Diagnosability Infrastructure Overview	9-2
9.1.2	Incidents and Problems	9-3
9.1.2.1	About Incidents and Problems	9-4
9.1.2.2	Incident Flood Control	9-5
9.1.2.3	Related Problems Across the Topology	9-5
9.1.3	Fault Diagnosability Infrastructure Components	9-6
9.1.3.1	Automatic Diagnostic Repository (ADR)	9-6

9.1.3.2	Alert Log	9-7
9.1.3.3	Trace Files, Dumps, and Core Files	9-8
9.1.3.4	DDL Log	9-9
9.1.3.5	Debug Log	9-9
9.1.3.6	Other ADR Contents	9-10
9.1.3.7	Enterprise Manager Support Workbench	9-10
9.1.3.8	ADRCI Command-Line Utility	9-10
9.1.4	Structure, Contents, and Location of the Automatic Diagnostic Repository	9-11
9.2	Investigating, Reporting, and Resolving a Problem	9-15
9.2.1	Roadmap—Investigating, Reporting, and Resolving a Problem	9-16
9.2.2	Task 1: View Critical Error Alerts in Cloud Control	9-18
9.2.3	Task 2: View Problem Details	9-19
9.2.4	Task 3: (Optional) Gather Additional Diagnostic Information	9-20
9.2.5	Task 4: (Optional) Create a Service Request	9-20
9.2.6	Task 5: Package and Upload Diagnostic Data to Oracle Support	9-20
9.2.7	Task 6: Track the Service Request and Implement Any Repairs	9-22
9.3	Viewing Problems with the Support Workbench	9-23
9.4	Adding Problems Manually to the Automatic Diagnostic Repository	9-25
9.5	Viewing the Alert Log	9-26
9.6	Finding Trace Files	9-27
9.7	Running Health Checks with Health Monitor	9-27
9.7.1	About Health Monitor	9-28
9.7.1.1	About Health Monitor Checks	9-28
9.7.1.2	Types of Health Checks	9-29
9.7.2	Running Health Checks Manually	9-30
9.7.2.1	Running Health Checks Using the DBMS_HM PL/SQL Package	9-30
9.7.2.2	Running Health Checks Using Cloud Control	9-31
9.7.3	Viewing Checker Reports	9-31
9.7.3.1	About Viewing Checker Reports	9-31
9.7.3.2	Viewing Reports Using Cloud Control	9-32
9.7.3.3	Viewing Reports Using DBMS_HM	9-32
9.7.3.4	Viewing Reports Using the ADRCI Utility	9-33
9.7.4	Health Monitor Views	9-34
9.7.5	Health Check Parameters Reference	9-35
9.8	Repairing SQL Failures with the SQL Repair Advisor	9-36
9.8.1	About the SQL Repair Advisor	9-36
9.8.2	Running the SQL Repair Advisor	9-37
9.8.3	Viewing, Disabling, or Removing a SQL Patch	9-38
9.9	Repairing Data Corruptions with the Data Recovery Advisor	9-39
9.10	Creating, Editing, and Uploading Custom Incident Packages	9-40

9.10.1	Incident Packages	9-41
9.10.1.1	About Incident Packages	9-41
9.10.1.2	About Correlated Diagnostic Data in Incident Packages	9-42
9.10.1.3	About Quick Packaging and Custom Packaging	9-43
9.10.1.4	About Correlated Packages	9-44
9.10.2	Packaging and Uploading Problems with Custom Packaging	9-44
9.10.3	Viewing and Modifying Incident Packages	9-49
9.10.3.1	Viewing Package Details	9-49
9.10.3.2	Accessing the Customize Package Page	9-50
9.10.3.3	Editing Incident Package Files (Copying Out and In)	9-50
9.10.3.4	Adding an External File to an Incident Package	9-51
9.10.3.5	Removing Incident Package Files	9-52
9.10.3.6	Viewing and Updating the Incident Package Activity Log	9-52
9.10.4	Creating, Editing, and Uploading Correlated Packages	9-53
9.10.5	Deleting Correlated Packages	9-54
9.10.6	Setting Incident Packaging Preferences	9-55

Part II Oracle Database Structure and Storage

10 Managing Control Files

10.1	What Is a Control File?	10-1
10.2	Guidelines for Control Files	10-2
10.2.1	Provide File Names for the Control Files	10-2
10.2.2	Multiplex Control Files on Different Disks	10-3
10.2.3	Back Up Control Files	10-3
10.2.4	Manage the Size of Control Files	10-4
10.3	Creating Control Files	10-4
10.3.1	Creating Initial Control Files	10-4
10.3.2	Creating Additional Copies, Renaming, and Relocating Control Files	10-5
10.3.3	Creating New Control Files	10-5
10.3.3.1	When to Create New Control Files	10-6
10.3.3.2	The CREATE CONTROLFILE Statement	10-6
10.3.3.3	Creating New Control Files	10-7
10.4	Troubleshooting After Creating Control Files	10-8
10.4.1	Checking for Missing or Extra Files	10-9
10.4.2	Handling Errors During CREATE CONTROLFILE	10-9
10.5	Backing Up Control Files	10-9
10.6	Recovering a Control File Using a Current Copy	10-10
10.6.1	Recovering from Control File Corruption Using a Control File Copy	10-10
10.6.2	Recovering from Permanent Media Failure Using a Control File Copy	10-10

10.7	Dropping Control Files	10-11
10.8	Control Files Data Dictionary Views	10-11

11 Managing the Redo Log

11.1	What Is the Redo Log?	11-2
11.1.1	Redo Threads	11-2
11.1.2	Redo Log Contents	11-2
11.1.3	How Oracle Database Writes to the Redo Log	11-3
11.1.3.1	Active (Current) and Inactive Redo Log Files	11-4
11.1.3.2	Log Switches and Log Sequence Numbers	11-5
11.2	Planning the Redo Log	11-5
11.2.1	Multiplexing Redo Log Files	11-6
11.2.1.1	Responding to Redo Log Failure	11-7
11.2.1.2	Legal and Illegal Configurations	11-8
11.2.2	Placing Redo Log Members on Different Disks	11-9
11.2.3	Planning the Size of Redo Log Files	11-10
11.2.4	Planning the Block Size of Redo Log Files	11-10
11.2.5	Choosing the Number of Redo Log Files	11-11
11.2.6	Controlling Archive Lag	11-12
11.2.6.1	Setting the ARCHIVE_LAG_TARGET Initialization Parameter	11-12
11.2.6.2	Factors Affecting the Setting of ARCHIVE_LAG_TARGET	11-13
11.3	Creating Redo Log Groups and Members	11-14
11.3.1	Creating Redo Log Groups	11-14
11.3.2	Creating Redo Log Members	11-15
11.4	Relocating and Renaming Redo Log Members	11-16
11.5	Dropping Redo Log Groups and Members	11-17
11.5.1	Dropping Log Groups	11-17
11.5.2	Dropping Redo Log Members	11-18
11.6	Forcing Log Switches	11-19
11.7	Verifying Blocks in Redo Log Files	11-19
11.8	Clearing a Redo Log File	11-20
11.9	Precedence of FORCE LOGGING Settings	11-21
11.10	Redo Log Data Dictionary Views	11-22

12 Managing Archived Redo Log Files

12.1	What Is the Archived Redo Log?	12-2
12.2	Choosing Between NOARCHIVELOG and ARCHIVELOG Mode	12-2
12.2.1	Running a Database in NOARCHIVELOG Mode	12-3
12.2.2	Running a Database in ARCHIVELOG Mode	12-3

12.3	Controlling Archiving	12-4
12.3.1	Setting the Initial Database Archiving Mode	12-5
12.3.2	Changing the Database Archiving Mode	12-5
12.3.3	Performing Manual Archiving	12-6
12.3.4	Adjusting the Number of Archiver Processes	12-7
12.4	Specifying Archive Destinations	12-7
12.4.1	Setting Initialization Parameters for Archive Destinations	12-8
12.4.1.1	Method 1: Using the LOG_ARCHIVE_DEST_n Parameter	12-9
12.4.1.2	Method 2: Using LOG_ARCHIVE_DEST and LOG_ARCHIVE_DUPLEX_DEST	12-10
12.4.2	Expanding Alternate Destinations with Log Archive Destination Groups	12-11
12.4.2.1	About Log Archive Destination Groups	12-12
12.4.2.2	Specifying Log Archive Destination Groups	12-13
12.4.3	Understanding Archive Destination Status	12-14
12.4.4	Specifying Alternate Destinations	12-15
12.5	About Log Transmission Modes	12-15
12.5.1	Normal Transmission Mode	12-15
12.5.2	Standby Transmission Mode	12-15
12.6	Managing Archive Destination Failure	12-16
12.6.1	Specifying the Minimum Number of Successful Destinations	12-16
12.6.1.1	Specifying Mandatory and Optional Destinations	12-17
12.6.1.2	Specifying the Number of Successful Destinations: Scenarios	12-17
12.6.2	Rearchiving to a Failed Destination	12-19
12.7	Controlling Trace Output Generated by the Archivelog Process	12-19
12.8	Viewing Information About the Archived Redo Log	12-20
12.8.1	Archived Redo Log Files Views	12-20
12.8.2	Using the ARCHIVE LOG LIST Command	12-21

13 Managing Tablespaces

13.1	Guidelines for Managing Tablespaces	13-2
13.1.1	Use Multiple Tablespaces	13-2
13.1.2	Assign Tablespace Quotas to Users	13-3
13.2	Creating Tablespaces	13-3
13.2.1	About Creating Tablespaces	13-4
13.2.2	Locally Managed Tablespaces	13-5
13.2.2.1	About Locally Managed Tablespaces	13-5
13.2.2.2	Creating a Locally Managed Tablespace	13-6
13.2.2.3	Specifying Segment Space Management in Locally Managed Tablespaces	13-7
13.2.3	Bigfile Tablespaces	13-8
13.2.3.1	About Bigfile Tablespaces	13-9

13.2.3.2	Creating a Bigfile Tablespace	13-9
13.2.3.3	Identifying a Bigfile Tablespace	13-10
13.2.4	Tablespaces with Default Compression Attributes	13-10
13.2.4.1	About Tablespaces with Default Compression Attributes	13-11
13.2.4.2	Creating Tablespaces with Default Compression Attributes	13-11
13.2.5	Encrypted Tablespaces	13-11
13.2.5.1	About Encrypted Tablespaces	13-12
13.2.5.2	Creating Encrypted Tablespaces	13-14
13.2.5.3	Viewing Information About Encrypted Tablespaces	13-14
13.2.6	Temporary Tablespaces	13-15
13.2.6.1	About Temporary Tablespaces	13-15
13.2.6.2	Creating a Locally Managed Temporary Tablespace	13-17
13.2.6.3	Creating a Bigfile Temporary Tablespace	13-18
13.2.6.4	Viewing Space Usage for Temporary Tablespaces	13-18
13.2.7	Temporary Tablespace Groups	13-18
13.2.7.1	Multiple Temporary Tablespaces: Using Tablespace Groups	13-19
13.2.7.2	Creating a Tablespace Group	13-19
13.2.7.3	Changing Members of a Tablespace Group	13-20
13.2.7.4	Assigning a Tablespace Group as the Default Temporary Tablespace	13-20
13.3	Consider Storing Tablespaces in the In-Memory Column Store	13-20
13.4	Specifying Nonstandard Block Sizes for Tablespaces	13-21
13.5	Controlling the Writing of Redo Records	13-22
13.6	Altering Tablespace Availability	13-23
13.6.1	Taking Tablespaces Offline	13-23
13.6.2	Bringing Tablespaces Online	13-25
13.7	Using Read-Only Tablespaces	13-25
13.7.1	About Read-Only Tablespaces	13-26
13.7.2	Making a Tablespace Read-Only	13-26
13.7.3	Making a Read-Only Tablespace Writable	13-28
13.7.4	Creating a Read-Only Tablespace on a WORM Device	13-29
13.7.5	Delaying the Opening of Data Files in Read-Only Tablespaces	13-29
13.8	Altering and Maintaining Tablespaces	13-30
13.8.1	Increasing the Size of a Tablespace	13-30
13.8.2	Altering a Locally Managed Tablespace	13-30
13.8.3	Altering a Bigfile Tablespace	13-31
13.8.4	Altering a Locally Managed Temporary Tablespace	13-32
13.8.5	Shrinking a Locally Managed Temporary Tablespace	13-33
13.9	Renaming Tablespaces	13-33
13.10	Dropping Tablespaces	13-34
13.11	Managing the SYSAUX Tablespace	13-35

13.11.1	Monitoring Occupants of the SYSAUX Tablespace	13-36
13.11.2	Moving Occupants Out Of or Into the SYSAUX Tablespace	13-36
13.11.3	Controlling the Size of the SYSAUX Tablespace	13-36
13.12	Correcting Problems with Locally Managed Tablespaces	13-37
13.12.1	Diagnosing and Repairing Locally Managed Tablespace Problems	13-38
13.12.2	Scenario 1: Fixing Bitmap When Allocated Blocks are Marked Free (No Overlap)	13-40
13.12.3	Scenario 2: Dropping a Corrupted Segment	13-40
13.12.4	Scenario 3: Fixing Bitmap Where Overlap is Reported	13-40
13.12.5	Scenario 4: Correcting Media Corruption of Bitmap Blocks	13-41
13.12.6	Scenario 5: Migrating from a Dictionary-Managed to a Locally Managed Tablespace	13-41
13.13	Migrating the SYSTEM Tablespace to a Locally Managed Tablespace	13-41
13.14	Viewing Information About Tablespaces	13-42
13.14.1	Tablespace Data Dictionary Views	13-42
13.14.2	Example 1: Listing Tablespaces and Default Storage Parameters	13-43
13.14.3	Example 2: Listing the Data Files and Associated Tablespaces of a Database	13-44
13.14.4	Example 3: Displaying Statistics for Free Space (Extents) of Each Tablespace	13-44

14 Managing Data Files and Temp Files

14.1	Guidelines for Managing Data Files	14-2
14.1.1	About Data Files	14-2
14.1.2	Determine the Number of Data Files	14-3
14.1.2.1	About Determining the Number of Data Files	14-3
14.1.2.2	Determine a Value for the DB_FILES Initialization Parameter	14-4
14.1.2.3	Consider Possible Limitations When Adding Data Files to a Tablespace	14-4
14.1.2.4	Consider the Performance Impact of the Number of Data Files	14-5
14.1.3	Determine the Size of Data Files	14-5
14.1.4	Place Data Files Appropriately	14-5
14.1.5	Store Data Files Separate from Redo Log Files	14-6
14.2	Creating Data Files and Adding Data Files to a Tablespace	14-6
14.3	Changing Data File Size	14-7
14.3.1	Enabling and Disabling Automatic Extension for a Data File	14-7
14.3.2	Manually Resizing a Data File	14-8
14.4	Altering Data File Availability	14-8
14.4.1	About Altering Data File Availability	14-9
14.4.2	Bringing Data Files Online or Taking Offline in ARCHIVELOG Mode	14-10
14.4.3	Taking Data Files Offline in NOARCHIVELOG Mode	14-10
14.4.4	Altering the Availability of All Data Files or Temp Files in a Tablespace	14-11

14.5 Renaming and Relocating Data Files	14-11
14.5.1 Renaming and Relocating Online Data Files	14-11
14.5.2 Renaming and Relocating Offline Data Files	14-14
14.5.2.1 Procedures for Renaming and Relocating Offline Data Files in a Single Tablespace	14-14
14.5.2.2 Renaming and Relocating Offline Data Files in Multiple Tablespaces	14-16
14.6 Dropping Data Files	14-17
14.7 Verifying Data Blocks in Data Files	14-18
14.8 Copying Files Using the Database Server	14-19
14.8.1 About Copying Files Using the Database Server	14-19
14.8.2 Copying a File on a Local File System	14-20
14.8.3 Third-Party File Transfer	14-21
14.8.4 Advanced File Transfer Mechanisms	14-22
14.8.5 File Transfer and the DBMS_SCHEDULER Package	14-22
14.9 Mapping Files to Physical Devices	14-23
14.9.1 Overview of Oracle Database File Mapping Interface	14-24
14.9.2 How the Oracle Database File Mapping Interface Works	14-24
14.9.2.1 Components of File Mapping	14-25
14.9.2.2 Mapping Structures	14-26
14.9.2.3 Example of Mapping Structures	14-27
14.9.2.4 Configuration ID	14-28
14.9.3 Using the Oracle Database File Mapping Interface	14-28
14.9.3.1 Enabling File Mapping	14-29
14.9.3.2 Using the DBMS_STORAGE_MAP Package	14-30
14.9.3.3 Obtaining Information from the File Mapping Views	14-31
14.9.4 File Mapping Examples	14-32
14.9.4.1 Example 1: Map All Database Files that Span a Device	14-32
14.9.4.2 Example 2: Map a File Into Its Corresponding Devices	14-33
14.9.4.3 Example 3: Map a Database Object	14-33
14.10 Data Files Data Dictionary Views	14-34

15 Transporting Data

15.1 About Transporting Data	15-1
15.1.1 Purpose of Transporting Data	15-2
15.1.2 Transporting Data: Scenarios	15-2
15.1.2.1 Scenarios for Full Transportable Export/import	15-2
15.1.2.2 Scenarios for Transportable Tablespaces or Transportable Tables	15-4
15.1.3 Transporting Data Across Platforms	15-8
15.1.4 General Limitations on Transporting Data	15-10

15.1.5	Compatibility Considerations for Transporting Data	15-12
15.2	Transporting Databases	15-13
15.2.1	Introduction to Full Transportable Export/Import	15-14
15.2.2	Limitations on Full Transportable Export/import	15-14
15.2.3	Transporting a Database Using an Export Dump File	15-15
15.2.4	Transporting a Database Over the Network	15-21
15.3	Transporting Tablespaces Between Databases	15-26
15.3.1	Introduction to Transportable Tablespaces	15-27
15.3.2	Limitations on Transportable Tablespaces	15-28
15.3.3	Transporting Tablespaces Between Databases	15-28
15.3.3.1	Task 1: Pick a Self-Contained Set of Tablespaces	15-30
15.3.3.2	Task 2: Generate a Transportable Tablespace Set	15-31
15.3.3.3	Task 3: Transport the Export Dump File	15-33
15.3.3.4	Task 4: Transport the Tablespace Set	15-34
15.3.3.5	Task 5: (Optional) Restore Tablespaces to Read/Write Mode	15-35
15.3.3.6	Task 6: Import the Tablespace Set	15-35
15.4	Transporting Tables, Partitions, or Subpartitions Between Databases	15-37
15.4.1	Introduction to Transportable Tables	15-37
15.4.2	Limitations on Transportable Tables	15-38
15.4.3	Transporting Tables, Partitions, or Subpartitions Using an Export Dump File	15-38
15.4.4	Transporting Tables, Partitions, or Subpartitions Over the Network	15-44
15.5	Converting Data Between Platforms	15-48
15.5.1	Converting Data Between Platforms Using the DBMS_FILE_TRANSFER Package	15-49
15.5.2	Converting Data Between Platforms Using RMAN	15-51
15.5.2.1	Converting Tablespaces on the Source System After Export	15-52
15.5.2.2	Converting Data Files on the Target System Before Import	15-53
15.6	Guidelines for Transferring Data Files	15-54

16 Managing Undo

16.1	What Is Undo?	16-2
16.2	Introduction to Automatic Undo Management	16-2
16.2.1	Overview of Automatic Undo Management	16-3
16.2.2	The Undo Retention Period	16-4
16.2.2.1	About the Undo Retention Period	16-4
16.2.2.2	Automatic Tuning of Undo Retention	16-5
16.2.2.3	Retention Guarantee	16-6
16.2.2.4	Undo Retention Tuning and Alert Thresholds	16-6
16.2.2.5	Tracking the Tuned Undo Retention Period	16-7
16.3	Setting the Minimum Undo Retention Period	16-7

16.4	Sizing a Fixed-Size Undo Tablespace	16-8
16.4.1	Activating the Undo Advisor PL/SQL Interface	16-9
16.5	Managing Undo Tablespaces	16-10
16.5.1	Creating an Undo Tablespace	16-10
16.5.1.1	About Creating an Undo Tablespace	16-11
16.5.1.2	Using CREATE DATABASE to Create an Undo Tablespace	16-11
16.5.1.3	Using the CREATE UNDO TABLESPACE Statement	16-12
16.5.2	Altering an Undo Tablespace	16-12
16.5.3	Dropping an Undo Tablespace	16-13
16.5.4	Switching Undo Tablespaces	16-13
16.5.5	Establishing User Quotas for Undo Space	16-14
16.5.6	Managing Space Threshold Alerts for the Undo Tablespace	16-15
16.6	Migrating to Automatic Undo Management	16-15
16.7	Managing Temporary Undo	16-15
16.7.1	About Managing Temporary Undo	16-15
16.7.2	Enabling and Disabling Temporary Undo	16-17
16.8	Undo Space Data Dictionary Views	16-18

17 Using Oracle Managed Files

17.1	About Oracle Managed Files	17-1
17.1.1	What Is Oracle Managed Files?	17-2
17.1.2	Who Can Use Oracle Managed Files?	17-2
17.1.3	What Is a Logical Volume Manager?	17-3
17.1.4	What Is a File System?	17-3
17.1.5	Benefits of Using Oracle Managed Files	17-3
17.1.6	Oracle Managed Files and Existing Functionality	17-4
17.2	Enabling the Creation and Use of Oracle Managed Files	17-4
17.2.1	Initialization Parameters That Enable Oracle Managed Files	17-5
17.2.2	Setting the DB_CREATE_FILE_DEST Initialization Parameter	17-6
17.2.3	Setting the DB_RECOVERY_FILE_DEST Parameter	17-6
17.2.4	Setting the DB_CREATE_ONLINE_LOG_DEST_n Initialization Parameters	17-6
17.3	Creating Oracle Managed Files	17-7
17.3.1	When Oracle Database Creates Oracle Managed Files	17-8
17.3.2	How Oracle Managed Files Are Named	17-8
17.3.3	Creating Oracle Managed Files at Database Creation	17-9
17.3.3.1	Specifying Control Files at Database Creation	17-10
17.3.3.2	Specifying Redo Log Files at Database Creation	17-11
17.3.3.3	Specifying the SYSTEM and SYSAUX Tablespace Data Files at Database Creation	17-12
17.3.3.4	Specifying the Undo Tablespace Data File at Database Creation	17-13

17.3.3.5	Specifying the Default Temporary Tablespace Temp File at Database Creation	17-13
17.3.3.6	CREATE DATABASE Statement Using Oracle Managed Files: Examples	17-13
17.3.4	Creating Data Files for Tablespaces Using Oracle Managed Files	17-16
17.3.4.1	About Creating Data Files for Tablespaces Using Oracle Managed Files	17-16
17.3.4.2	CREATE TABLESPACE: Examples	17-17
17.3.4.3	CREATE UNDO TABLESPACE: Example	17-18
17.3.4.4	ALTER TABLESPACE: Example	17-18
17.3.5	Creating Temp Files for Temporary Tablespaces Using Oracle Managed Files	17-19
17.3.5.1	About Creating Temp Files for Temporary Tablespaces Using Oracle Managed Files	17-19
17.3.5.2	CREATE TEMPORARY TABLESPACE: Example	17-20
17.3.5.3	ALTER TABLESPACE... ADD TEMPFILE: Example	17-20
17.3.6	Creating Control Files Using Oracle Managed Files	17-20
17.3.6.1	About Creating Control Files Using Oracle Managed Files	17-21
17.3.6.2	CREATE CONTROLFILE Using NORESETLOGS Keyword: Example	17-22
17.3.6.3	CREATE CONTROLFILE Using RESETLOGS Keyword: Example	17-22
17.3.7	Creating Redo Log Files Using Oracle Managed Files	17-23
17.3.7.1	Using the ALTER DATABASE ADD LOGFILE Statement	17-23
17.3.7.2	Using the ALTER DATABASE OPEN RESETLOGS Statement	17-24
17.3.8	Creating Archived Logs Using Oracle Managed Files	17-24
17.4	Operation of Oracle Managed Files	17-24
17.4.1	Dropping Data Files and Temp Files	17-25
17.4.2	Dropping Redo Log Files	17-25
17.4.3	Renaming Files	17-26
17.4.4	Managing Standby Databases	17-26
17.5	Scenarios for Using Oracle Managed Files	17-26
17.5.1	Scenario 1: Create and Manage a Database with Multiplexed Redo Logs	17-27
17.5.2	Scenario 2: Create and Manage a Database with Database and Fast Recovery Areas	17-30
17.5.3	Scenario 3: Adding Oracle Managed Files to an Existing Database	17-31

Part III Schema Objects

18 Managing Schema Objects

18.1	Creating Multiple Tables and Views in a Single Operation	18-2
18.2	Analyzing Tables, Indexes, and Clusters	18-2
18.2.1	About Analyzing Tables, Indexes, and Clusters	18-3
18.2.2	Using DBMS_STATS to Collect Table and Index Statistics	18-4
18.2.3	Validating Tables, Indexes, Clusters, and Materialized Views	18-4
18.2.4	Cross Validation of a Table and an Index with a Query	18-5
18.2.5	Listing Chained Rows of Tables and Clusters	18-6
18.2.5.1	Creating a CHAINED_ROWS Table	18-6
18.2.5.2	Eliminating Migrated or Chained Rows in a Table	18-7
18.3	Truncating Tables and Clusters	18-8
18.3.1	Using DELETE to Truncate a Table	18-8
18.3.2	Using DROP and CREATE to Truncate a Table	18-9
18.3.3	Using TRUNCATE	18-9
18.4	Enabling and Disabling Triggers	18-10
18.4.1	About Enabling and Disabling Triggers	18-11
18.4.2	Enabling Triggers	18-12
18.4.3	Disabling Triggers	18-12
18.5	Managing Integrity Constraints	18-12
18.5.1	Integrity Constraint States	18-13
18.5.1.1	About Integrity Constraint States	18-14
18.5.1.2	About Disabling Constraints	18-14
18.5.1.3	About Enabling Constraints	18-15
18.5.1.4	About the Enable NVALIDATE Constraint State	18-15
18.5.1.5	Efficient Use of Integrity Constraints: A Procedure	18-15
18.5.2	Setting Integrity Constraints Upon Definition	18-16
18.5.2.1	Disabling Constraints Upon Definition	18-16
18.5.2.2	Enabling Constraints Upon Definition	18-16
18.5.3	Modifying, Renaming, or Dropping Existing Integrity Constraints	18-17
18.5.3.1	Disabling and Enabling Constraints	18-17
18.5.3.2	Renaming Constraints	18-18
18.5.3.3	Dropping Constraints	18-18
18.5.4	Deferring Constraint Checks	18-19
18.5.4.1	Set All Constraints Deferred	18-19
18.5.4.2	Check the Commit (Optional)	18-20
18.5.5	Reporting Constraint Exceptions	18-20
18.5.6	Viewing Constraint Information	18-21
18.6	Renaming Schema Objects	18-22
18.7	Managing Object Dependencies	18-23
18.7.1	About Object Dependencies and Object Invalidation	18-23

18.7.2	Manually Recompiling Invalid Objects with DDL	18-25
18.7.3	Manually Recompiling Invalid Objects with PL/SQL Package Procedures	18-25
18.8	Managing Object Name Resolution	18-26
18.9	Switching to a Different Schema	18-28
18.10	Managing Editions	18-28
18.10.1	About Editions and Edition-Based Redefinition	18-29
18.10.2	DBA Tasks for Edition-Based Redefinition	18-29
18.10.3	Setting the Database Default Edition	18-30
18.10.4	Querying the Database Default Edition	18-30
18.10.5	Setting the Edition Attribute of a Database Service	18-30
18.10.5.1	About Setting the Edition Attribute of a Database Service	18-31
18.10.5.2	Setting the Edition Attribute During Database Service Creation	18-31
18.10.5.3	Setting the Edition Attribute of an Existing Database Service	18-32
18.10.6	Using an Edition	18-32
18.10.7	Editions Data Dictionary Views	18-33
18.11	Displaying Information About Schema Objects	18-33
18.11.1	Using a PL/SQL Package to Display Information About Schema Objects	18-33
18.11.2	Schema Objects Data Dictionary Views	18-34
18.11.2.1	Example 1: Displaying Schema Objects By Type	18-35
18.11.2.2	Example 2: Displaying Dependencies of Views and Synonyms	18-35

19 Managing Space for Schema Objects

19.1	Managing Tablespace Alerts	19-1
19.1.1	About Managing Tablespace Alerts	19-2
19.1.2	Setting Alert Thresholds	19-3
19.1.3	Viewing Alerts	19-5
19.1.4	Limitations	19-5
19.2	Managing Resumable Space Allocation	19-6
19.2.1	Resumable Space Allocation Overview	19-7
19.2.1.1	How Resumable Space Allocation Works	19-7
19.2.1.2	What Operations are Resumable?	19-8
19.2.1.3	What Errors are Correctable?	19-9
19.2.1.4	Resumable Space Allocation and Distributed Operations	19-9
19.2.1.5	Parallel Execution and Resumable Space Allocation	19-9
19.2.2	Enabling and Disabling Resumable Space Allocation	19-10
19.2.2.1	About Enabling and Disabling Resumable Space Allocation	19-10
19.2.2.2	Setting the RESUMABLE_TIMEOUT Initialization Parameter	19-11
19.2.2.3	Using ALTER SESSION to Enable and Disable Resumable Space Allocation	19-11

19.2.3	Using a LOGON Trigger to Set Default Resumable Mode	19-13
19.2.4	Detecting Suspended Statements	19-13
19.2.4.1	Notifying Users: The AFTER SUSPEND System Event and Trigger	19-13
19.2.4.2	Using Views to Obtain Information About Suspended Statements	19-14
19.2.4.3	Using the DBMS_RESUMABLE Package	19-14
19.2.5	Operation-Suspended Alert	19-15
19.2.6	Resumable Space Allocation Example: Registering an AFTER SUSPEND Trigger	19-15
19.3	Reclaiming Unused Space	19-17
19.3.1	About Reclaimable Unused Space	19-17
19.3.2	The Segment Advisor	19-18
19.3.2.1	About the Segment Advisor	19-18
19.3.2.2	Using the Segment Advisor	19-19
19.3.2.3	Automatic Segment Advisor	19-19
19.3.2.4	Running the Segment Advisor Manually	19-20
19.3.2.5	Viewing Segment Advisor Results	19-25
19.3.2.6	Configuring the Automatic Segment Advisor	19-31
19.3.2.7	Viewing Automatic Segment Advisor Information	19-32
19.3.3	Shrinking Database Segments Online	19-33
19.3.4	Deallocating Unused Space	19-35
19.4	Dropping Unused Object Storage	19-36
19.5	Understanding Space Usage of Data Types	19-37
19.6	Displaying Information About Space Usage for Schema Objects	19-37
19.6.1	Using PL/SQL Packages to Display Information About Schema Object Space Usage	19-37
19.6.2	Schema Objects Space Usage Data Dictionary Views	19-38
19.6.2.1	Example 1: Displaying Segment Information	19-39
19.6.2.2	Example 2: Displaying Extent Information	19-40
19.6.2.3	Example 3: Displaying the Free Space (Extents) in a Tablespace	19-40
19.7	Capacity Planning for Database Objects	19-41
19.7.1	Estimating the Space Use of a Table	19-41
19.7.2	Estimating the Space Use of an Index	19-42
19.7.3	Obtaining Object Growth Trends	19-42

20 Managing Tables

20.1	About Tables	20-2
20.2	Guidelines for Managing Tables	20-3
20.2.1	Design Tables Before Creating Them	20-4
20.2.2	Specify the Type of Table to Create	20-5

20.2.3	Specify the Location of Each Table	20-6
20.2.4	Consider Parallelizing Table Creation	20-6
20.2.5	Consider Using NOLOGGING When Creating Tables	20-6
20.2.6	Consider Using Table Compression	20-7
20.2.6.1	About Table Compression	20-8
20.2.6.2	Examples Related to Table Compression	20-11
20.2.6.3	Compression and Partitioned Tables	20-12
20.2.6.4	Determining If a Table Is Compressed	20-13
20.2.6.5	Determining Which Rows Are Compressed	20-13
20.2.6.6	Changing the Compression Level	20-14
20.2.6.7	Adding and Dropping Columns in Compressed Tables	20-15
20.2.6.8	Exporting and Importing Hybrid Columnar Compression Tables	20-15
20.2.6.9	Restoring a Hybrid Columnar Compression Table	20-16
20.2.6.10	Notes and Restrictions for Compressed Tables	20-17
20.2.6.11	Packing Compressed Tables	20-17
20.2.7	Managing Table Compression Using Enterprise Manager Cloud Control	20-18
20.2.7.1	Table Compression and Enterprise Manager Cloud Control	20-18
20.2.7.2	Viewing the Compression Summary at the Database Level	20-19
20.2.7.3	Viewing the Compression Summary at the Tablespace Level	20-19
20.2.7.4	Estimating the Compression Ratio	20-20
20.2.7.5	Compressing an Object	20-21
20.2.7.6	Viewing Compression Advice	20-21
20.2.7.7	Initiating Automatic Data Optimization on an Object	20-21
20.2.8	Consider Using Segment-Level and Row-Level Compression Tiering	20-22
20.2.9	Consider Using Attribute-Clustered Tables	20-23
20.2.10	Consider Using Zone Maps	20-24
20.2.11	Consider Storing Tables in the In-Memory Column Store	20-25
20.2.12	Consider Using Invisible Columns	20-26
20.2.12.1	Understand Invisible Columns	20-26
20.2.12.2	Invisible Columns and Column Ordering	20-27
20.2.13	Consider Encrypting Columns That Contain Sensitive Data	20-29
20.2.14	Understand Deferred Segment Creation	20-30
20.2.15	Materializing Segments	20-32
20.2.16	Estimate Table Size and Plan Accordingly	20-33
20.2.17	Restrictions to Consider When Creating Tables	20-33
20.3	Creating Tables	20-34
20.3.1	Example: Creating a Table	20-34
20.3.2	Creating a Temporary Table	20-36
20.3.3	Parallelizing Table Creation	20-38
20.4	Loading Tables	20-38

20.4.1	Methods for Loading Tables	20-39
20.4.2	Improving INSERT Performance with Direct-Path INSERT	20-40
20.4.2.1	About Direct-Path INSERT	20-41
20.4.2.2	How Direct-Path INSERT Works	20-42
20.4.2.3	Loading Data with Direct-Path INSERT	20-43
20.4.2.4	Logging Modes for Direct-Path INSERT	20-44
20.4.2.5	Additional Considerations for Direct-Path INSERT	20-46
20.4.3	Using Conventional Inserts to Load Tables	20-47
20.4.4	Avoiding Bulk INSERT Failures with DML Error Logging	20-48
20.4.4.1	Inserting Data with DML Error Logging	20-48
20.4.4.2	Error Logging Table Format	20-49
20.4.4.3	Creating an Error Logging Table	20-51
20.4.4.4	Error Logging Restrictions and Caveats	20-51
20.5	Optimizing the Performance of Bulk Updates	20-52
20.6	Automatically Collecting Statistics on Tables	20-54
20.7	Altering Tables	20-55
20.7.1	Reasons for Using the ALTER TABLE Statement	20-56
20.7.2	Altering Physical Attributes of a Table	20-57
20.7.3	Moving a Table to a New Segment or Tablespace	20-57
20.7.3.1	About Moving a Table to a New Segment or Tablespace	20-57
20.7.3.2	Moving a Table	20-58
20.7.3.3	Moving a Table Partition or Subpartition Online	20-59
20.7.4	Manually Allocating Storage for a Table	20-60
20.7.5	Modifying an Existing Column Definition	20-61
20.7.6	Adding Table Columns	20-61
20.7.7	Renaming Table Columns	20-62
20.7.8	Dropping Table Columns	20-63
20.7.8.1	Removing Columns from Tables	20-64
20.7.8.2	Marking Columns Unused	20-64
20.7.8.3	Removing Unused Columns	20-65
20.7.8.4	Dropping Columns in Compressed Tables	20-65
20.7.9	Placing a Table in Read-Only Mode	20-66
20.8	Redefining Tables Online	20-67
20.8.1	About Redefining Tables Online	20-68
20.8.2	Features of Online Table Redefinition	20-69
20.8.3	Privileges Required for the DBMS_REDEFINITION Package	20-71
20.8.4	Restrictions for Online Redefinition of Tables	20-71
20.8.5	Performing Online Redefinition with the REDEF_TABLE Procedure	20-73
20.8.6	Redefining Tables Online with Multiple Procedures in DBMS_REDEFINITION	20-74
20.8.6.1	Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION	20-74

20.8.6.2	Constructing a Column Mapping String	20-77
20.8.6.3	Handling Virtual Private Database (VPD) Policies During Online Redefinition	20-78
20.8.6.4	Creating Dependent Objects Automatically	20-79
20.8.6.5	Creating Dependent Objects Manually	20-80
20.8.7	Results of the Redefinition Process	20-81
20.8.8	Performing Intermediate Synchronization	20-82
20.8.9	Refreshing Dependent Materialized Views During Online Table Redefinition	20-82
20.8.10	Monitoring Online Table Redefinition Progress	20-86
20.8.11	Restarting Online Table Redefinition After a Failure	20-89
20.8.12	Rolling Back Online Table Redefinition	20-93
20.8.12.1	About Online Table Redefinition Rollback	20-93
20.8.12.2	Performing Online Table Redefinition Rollback	20-94
20.8.13	Aborting Online Table Redefinition and Cleaning Up After Errors	20-97
20.8.14	Online Redefinition of One or More Partitions	20-97
20.8.14.1	Rules for Online Redefinition of a Single Partition	20-98
20.8.15	Online Table Redefinition Examples	20-99
20.9	Researching and Reversing Erroneous Table Changes	20-120
20.10	Recovering Tables Using Oracle Flashback Table	20-121
20.11	Dropping Tables	20-122
20.12	Using Flashback Drop and Managing the Recycle Bin	20-123
20.12.1	What Is the Recycle Bin?	20-124
20.12.2	Enabling and Disabling the Recycle Bin	20-125
20.12.3	Viewing and Querying Objects in the Recycle Bin	20-126
20.12.4	Purging Objects in the Recycle Bin	20-126
20.12.5	Restoring Tables from the Recycle Bin	20-127
20.13	Managing Index-Organized Tables	20-129
20.13.1	What Are Index-Organized Tables?	20-129
20.13.2	Creating Index-Organized Tables	20-130
20.13.2.1	About Creating Index-Organized Tables	20-131
20.13.2.2	Example: Creating an Index-Organized Table	20-131
20.13.2.3	Restrictions for Index-Organized Tables	20-132
20.13.2.4	Creating Index-Organized Tables That Contain Object Types	20-133
20.13.2.5	Choosing and Monitoring a Threshold Value	20-134
20.13.2.6	Using the INCLUDING Clause	20-134
20.13.2.7	Parallelizing Index-Organized Table Creation	20-135
20.13.2.8	Using Prefix Compression	20-135
20.13.3	Maintaining Index-Organized Tables	20-136
20.13.3.1	Altering Index-Organized Tables	20-136
20.13.3.2	Moving (Rebuilding) Index-Organized Tables	20-137
20.13.4	Creating Secondary Indexes on Index-Organized Tables	20-138

20.13.4.1	About Secondary Indexes on Index-Organized Tables	20-138
20.13.4.2	Creating a Secondary Index on an Index-Organized Table	20-139
20.13.4.3	Maintaining Physical Guesses in Logical Rowids	20-139
20.13.4.4	Specifying Bitmap Indexes on Index-Organized Tables	20-139
20.13.5	Analyzing Index-Organized Tables	20-140
20.13.5.1	Collecting Optimizer Statistics for Index-Organized Tables	20-140
20.13.5.2	Validating the Structure of Index-Organized Tables	20-141
20.13.6	Using the ORDER BY Clause with Index-Organized Tables	20-141
20.13.7	Converting Index-Organized Tables to Regular Tables	20-141
20.14	Managing External Tables	20-142
20.14.1	About External Tables	20-143
20.14.2	Creating External Tables	20-144
20.14.3	Altering External Tables	20-147
20.14.4	Preprocessing External Tables	20-149
20.14.5	Overriding Parameters for External Tables in a Query	20-150
20.14.6	Partitioning External Tables	20-151
20.14.6.1	About Partitioning External Tables	20-151
20.14.6.2	Restrictions for Partitioned External Tables	20-153
20.14.6.3	Creating a Partitioned External Table	20-154
20.14.6.4	Altering a Partitioned External Table	20-158
20.14.7	Dropping External Tables	20-159
20.14.8	System and Object Privileges for External Tables	20-159
20.15	Tables Data Dictionary Views	20-159

21 Managing Indexes

21.1	About Indexes	21-1
21.2	Guidelines for Managing Indexes	21-2
21.2.1	Create Indexes After Inserting Table Data	21-3
21.2.2	Index the Correct Tables and Columns	21-4
21.2.3	Order Index Columns for Performance	21-5
21.2.4	Limit the Number of Indexes for Each Table	21-5
21.2.5	Drop Indexes That Are No Longer Required	21-6
21.2.6	Indexes and Deferred Segment Creation	21-6
21.2.7	Estimate Index Size and Set Storage Parameters	21-6
21.2.8	Specify the Tablespace for Each Index	21-7
21.2.9	Consider Parallelizing Index Creation	21-7
21.2.10	Consider Creating Indexes with NOLOGGING	21-8
21.2.11	Understand When to Use Unusable or Invisible Indexes	21-8
21.2.12	Understand When to Create Multiple Indexes on the Same Set of Columns	21-10
21.2.13	Consider Costs and Benefits of Coalescing or Rebuilding Indexes	21-11

21.2.14	Consider Cost Before Disabling or Dropping Constraints	21-12
21.2.15	Consider Using the In-Memory Column Store to Reduce the Number of Indexes	21-12
21.3	Creating Indexes	21-13
21.3.1	Prerequisites for Creating Indexes	21-14
21.3.2	Creating an Index Explicitly	21-14
21.3.3	Creating a Unique Index Explicitly	21-15
21.3.4	Creating an Index Associated with a Constraint	21-15
21.3.4.1	About Creating an Index Associated with a Constraint	21-16
21.3.4.2	Specifying Storage Options for an Index Associated with a Constraint	21-16
21.3.4.3	Specifying the Index Associated with a Constraint	21-16
21.3.5	Creating a Large Index	21-17
21.3.6	Creating an Index Online	21-18
21.3.7	Creating a Function-Based Index	21-18
21.3.8	Creating a Compressed Index	21-19
21.3.8.1	Creating an Index Using Prefix Compression	21-20
21.3.8.2	Creating an Index Using Advanced Index Compression	21-21
21.3.9	Creating an Unusable Index	21-22
21.3.10	Creating an Invisible Index	21-24
21.3.11	Creating Multiple Indexes on the Same Set of Columns	21-25
21.4	Altering Indexes	21-26
21.4.1	About Altering Indexes	21-26
21.4.2	Altering Storage Characteristics of an Index	21-27
21.4.3	Rebuilding an Existing Index	21-27
21.4.4	Making an Index Unusable	21-28
21.4.5	Making an Index Invisible or Visible	21-30
21.4.6	Renaming an Index	21-31
21.4.7	Monitoring Index Usage	21-31
21.5	Monitoring Space Use of Indexes	21-32
21.6	Dropping Indexes	21-32
21.7	Indexes Data Dictionary Views	21-33

22 Managing Clusters

22.1	About Clusters	22-1
22.2	Guidelines for Managing Clusters	22-3
22.2.1	Choose Appropriate Tables for the Cluster	22-3
22.2.2	Choose Appropriate Columns for the Cluster Key	22-4
22.2.3	Specify the Space Required by an Average Cluster Key and Its Associated Rows	22-4
22.2.4	Specify the Location of Each Cluster and Cluster Index Rows	22-5

22.2.5	Estimate Cluster Size and Set Storage Parameters	22-5
22.3	Creating Clusters and Objects That Use Them	22-5
22.3.1	Creating Clusters	22-6
22.3.2	Creating Clustered Tables	22-6
22.3.3	Creating Cluster Indexes	22-7
22.4	Altering Clusters and Objects That Use Them	22-8
22.4.1	Altering Clusters	22-8
22.4.2	Altering Clustered Tables	22-9
22.4.3	Altering Cluster Indexes	22-9
22.5	Dropping Clusters and Objects That Use Them	22-9
22.5.1	Dropping Clusters	22-10
22.5.2	Dropping Clustered Tables	22-11
22.5.3	Dropping Cluster Indexes	22-11
22.6	Clusters Data Dictionary Views	22-11

23 Managing Hash Clusters

23.1	About Hash Clusters	23-1
23.2	When to Use Hash Clusters	23-2
23.2.1	Situations Where Hashing Is Useful	23-2
23.2.2	Situations Where Hashing Is Not Advantageous	23-3
23.3	Creating Different Types of Hash Clusters	23-3
23.3.1	Creating Hash Clusters	23-4
23.3.2	Creating a Sorted Hash Cluster	23-4
23.3.3	Creating Single-Table Hash Clusters	23-7
23.3.4	Controlling Space Use Within a Hash Cluster	23-7
23.3.4.1	Choosing the Key	23-8
23.3.4.2	Setting HASH IS	23-8
23.3.4.3	Setting SIZE	23-8
23.3.4.4	Setting HASHKEYS	23-9
23.3.4.5	Controlling Space in Hash Clusters	23-9
23.3.5	Estimating Size Required by Hash Clusters	23-10
23.4	Altering Hash Clusters	23-11
23.5	Dropping Hash Clusters	23-11
23.6	Hash Clusters Data Dictionary Views	23-12

24 Managing Views, Sequences, and Synonyms

24.1	Managing Views	24-1
24.1.1	About Views	24-2
24.1.2	Creating Views and Join Views	24-2

24.1.2.1	Creating Views	24-3
24.1.2.2	Creating Join Views	24-4
24.1.2.3	Expansion of Defining Queries at View Creation Time	24-4
24.1.2.4	Creating Views with Errors	24-5
24.1.3	Replacing Views	24-5
24.1.4	Using Views in Queries	24-6
24.1.5	DML Statements and Join Views	24-7
24.1.5.1	Updating a Join View	24-8
24.1.5.2	Key-Preserved Tables	24-9
24.1.5.3	Rules for DML Statements and Join Views	24-10
24.1.5.4	Updating Views That Involve Outer Joins	24-13
24.1.5.5	Using the UPDATABLE_COLUMNS Views	24-14
24.1.6	Altering Views	24-15
24.1.7	Dropping Views	24-16
24.2	Managing Sequences	24-16
24.2.1	About Sequences	24-16
24.2.2	Creating Sequences	24-17
24.2.3	Altering Sequences	24-18
24.2.4	Using Sequences	24-18
24.2.4.1	Referencing a Sequence	24-19
24.2.4.2	Caching Sequence Numbers	24-21
24.2.5	Dropping Sequences	24-22
24.3	Managing Synonyms	24-23
24.3.1	About Synonyms	24-23
24.3.2	Creating Synonyms	24-23
24.3.3	Using Synonyms in DML Statements	24-24
24.3.4	Dropping Synonyms	24-25
24.4	Views, Synonyms, and Sequences Data Dictionary Views	24-25

25 Repairing Corrupted Data

25.1	Options for Repairing Data Block Corruption	25-1
25.2	About the DBMS_REPAIR Package	25-2
25.2.1	DBMS_REPAIR Procedures	25-2
25.2.2	Limitations and Restrictions for DBMS_REPAIR Procedures	25-3
25.3	Using the DBMS_REPAIR Package	25-3
25.3.1	Task 1: Detect and Report Corruptions	25-4
25.3.1.1	About Detecting and Reporting Corruptions	25-4
25.3.1.2	DBMS_REPAIR: Using the CHECK_OBJECT and ADMIN_TABLES Procedures	25-5
25.3.1.3	DB_VERIFY: Performing an Offline Database Check	25-5
25.3.1.4	ANALYZE: Reporting Corruption	25-5

25.3.1.5	DB_BLOCK_CHECKING Initialization Parameter	25-6
25.3.2	Task 2: Evaluate the Costs and Benefits of Using DBMS_REPAIR	25-6
25.3.3	Task 3: Make Objects Usable	25-7
25.3.3.1	Corruption Repair: Using the FIX_CORRUPT_BLOCKS and SKIP_CORRUPT_BLOCKS Procedures	25-7
25.3.3.2	Implications When Skipping Corrupt Blocks	25-7
25.3.4	Task 4: Repair Corruptions and Rebuild Lost Data	25-7
25.3.4.1	Recover Data Using the DUMP_ORPHAN_KEYS Procedures	25-8
25.3.4.2	Fix Segment Bitmaps Using the SEGMENT_FIX_STATUS Procedure	25-8
25.4	DBMS_REPAIR Examples	25-8
25.4.1	Examples: Building a Repair Table or Orphan Key Table	25-8
25.4.1.1	About Repair Tables or Orphan Key Tables	25-9
25.4.1.2	Example: Creating a Repair Table	25-9
25.4.1.3	Example: Creating an Orphan Key Table	25-10
25.4.2	Example: Detecting Corruption	25-10
25.4.3	Example: Fixing Corrupt Blocks	25-11
25.4.4	Example: Finding Index Entries Pointing to Corrupt Data Blocks	25-12
25.4.5	Example: Skipping Corrupt Blocks	25-13

Part IV Database Resource Management and Task Scheduling

26 Managing Automated Database Maintenance Tasks

26.1	About Automated Maintenance Tasks	26-2
26.2	About Maintenance Windows	26-3
26.3	Configuring Automated Maintenance Tasks	26-4
26.3.1	Enabling and Disabling Maintenance Tasks for all Maintenance Windows	26-4
26.3.2	Enabling and Disabling Maintenance Tasks for Specific Maintenance Windows	26-5
26.4	Configuring Maintenance Windows	26-5
26.4.1	Modifying a Maintenance Window	26-5
26.4.2	Creating a New Maintenance Window	26-6
26.4.3	Removing a Maintenance Window	26-7
26.5	Configuring Resource Allocations for Automated Maintenance Tasks	26-7
26.5.1	About Resource Allocations for Automated Maintenance Tasks	26-8
26.5.2	Changing Resource Allocations for Automated Maintenance Tasks	26-9
26.6	Automated Maintenance Tasks Reference	26-9
26.6.1	Predefined Maintenance Windows	26-9

27 Managing Resources with Oracle Database Resource Manager

27.1 About Oracle Database Resource Manager	27-2
27.1.1 What Solutions Does the Resource Manager Provide for Workload Management?	27-2
27.1.2 The Elements of Resource Manager	27-4
27.1.2.1 About the Elements of Resource Manager	27-5
27.1.2.2 About Resource Consumer Groups	27-5
27.1.2.3 About Resource Plan Directives	27-6
27.1.2.4 About Resource Plans	27-6
27.1.2.5 Example: A Simple Resource Plan	27-7
27.1.2.6 About Subplans	27-8
27.1.2.7 Example: A Resource Plan with Subplans	27-8
27.1.3 About Resource Manager Administration Privileges	27-9
27.2 Assigning Sessions to Resource Consumer Groups	27-10
27.2.1 Overview of Assigning Sessions to Resource Consumer Groups	27-11
27.2.2 Assigning an Initial Resource Consumer Group	27-11
27.2.3 Specifying Session-to-Consumer Group Mapping Rules	27-12
27.2.3.1 About Session-to-Consumer Group Mapping Rules	27-12
27.2.3.2 Creating Consumer Group Mapping Rules	27-13
27.2.3.3 Modifying and Deleting Consumer Group Mapping Rules	27-15
27.2.3.4 Creating Mapping Rule Priorities	27-15
27.2.4 Switching Resource Consumer Groups	27-16
27.2.4.1 Manually Switching Resource Consumer Groups	27-17
27.2.4.2 Enabling Users or Applications to Manually Switch Consumer Groups	27-18
27.2.5 Specifying Automatic Consumer Group Switching	27-19
27.2.5.1 Specifying Automatic Switching with Mapping Rules	27-19
27.2.5.2 Specifying Automatic Switching by Setting Resource Limits	27-20
27.2.6 Granting and Revoking the Switch Privilege	27-23
27.2.6.1 About Granting and Revoking the Switch Privilege	27-23
27.2.6.2 Granting the Switch Privilege	27-24
27.2.6.3 Revoking Switch Privileges	27-24
27.3 The Types of Resources Managed by the Resource Manager	27-25
27.3.1 CPU	27-26
27.3.1.1 Management Attributes	27-26
27.3.1.2 Utilization Limit	27-27
27.3.2 Exadata I/O	27-28
27.3.3 Parallel Execution Servers	27-29
27.3.3.1 Degree of Parallelism Limit	27-29

27.3.3.2	Parallel Server Limit	27-29
27.3.3.3	Parallel Queue Timeout	27-31
27.3.4	Program Global Area (PGA)	27-32
27.3.5	Runaway Queries	27-33
27.3.5.1	Automatic Consumer Group Switching	27-34
27.3.5.2	Cancelling SQL and Terminating Sessions	27-34
27.3.5.3	Execution Time Limit	27-34
27.3.6	Active Session Pool with Queuing	27-34
27.3.7	Undo Pool	27-35
27.3.8	Idle Time Limit	27-35
27.4	Creating a Simple Resource Plan	27-35
27.5	Creating a Complex Resource Plan	27-37
27.5.1	About the Pending Area	27-38
27.5.2	Creating a Pending Area	27-39
27.5.3	Creating Resource Consumer Groups	27-39
27.5.4	Mapping Sessions to Consumer Groups	27-40
27.5.5	Creating a Resource Plan	27-40
27.5.5.1	About the RATIO CPU Allocation Method	27-41
27.5.6	Creating Resource Plan Directives	27-42
27.5.6.1	Conflicting Resource Plan Directives	27-47
27.5.7	Validating the Pending Area	27-47
27.5.8	Submitting the Pending Area	27-48
27.5.9	Clearing the Pending Area	27-49
27.6	Enabling Oracle Database Resource Manager and Switching Plans	27-49
27.7	Putting It All Together: Oracle Database Resource Manager Examples	27-52
27.7.1	Multilevel Plan Example	27-52
27.7.2	Examples of Using the Utilization Limit Attribute	27-55
27.7.3	Example of Using Several Resource Allocation Methods	27-60
27.7.4	Example of Managing Parallel Statements Using Directive Attributes	27-61
27.7.5	An Oracle-Supplied Mixed Workload Plan	27-63
27.8	Managing Multiple Database Instances on a Single Server	27-64
27.8.1	About Instance Caging	27-64
27.8.2	Enabling Instance Caging	27-65
27.9	Maintaining Consumer Groups, Plans, and Directives	27-66
27.9.1	Updating a Consumer Group	27-66
27.9.2	Deleting a Consumer Group	27-67
27.9.3	Updating a Plan	27-67
27.9.4	Deleting a Plan	27-68
27.9.5	Updating a Resource Plan Directive	27-68
27.9.6	Deleting a Resource Plan Directive	27-69
27.10	Viewing Database Resource Manager Configuration and Status	27-70

27.10.1	Viewing Consumer Groups Granted to Users or Roles	27-70
27.10.2	Viewing Plan Information	27-71
27.10.3	Viewing Current Consumer Groups for Sessions	27-71
27.10.4	Viewing the Currently Active Plans	27-71
27.11	Monitoring Oracle Database Resource Manager	27-72
27.12	Interacting with Operating-System Resource Control	27-78
27.12.1	Guidelines for Using Operating-System Resource Control	27-78
27.13	Oracle Database Resource Manager Reference	27-79
27.13.1	Predefined Resource Plans and Consumer Groups	27-79
27.13.2	Predefined Consumer Group Mapping Rules	27-81
27.13.3	Resource Manager Data Dictionary Views	27-82

28 Oracle Scheduler Concepts

28.1	Overview of Oracle Scheduler	28-1
28.2	Jobs and Supporting Scheduler Objects	28-3
28.2.1	About Jobs and Supporting Scheduler Objects	28-4
28.2.2	Programs	28-4
28.2.3	Schedules	28-5
28.2.4	Jobs	28-6
28.2.4.1	About Jobs	28-6
28.2.4.2	Specifying a Job Action	28-6
28.2.4.3	Specifying a Job Schedule	28-7
28.2.4.4	Specifying a Job Destination	28-7
28.2.4.5	Specifying a Job Credential	28-7
28.2.5	Destinations	28-8
28.2.5.1	About Destinations	28-8
28.2.5.2	About Destinations and Scheduler Agents	28-9
28.2.6	File Watchers	28-10
28.2.7	Credentials	28-10
28.2.8	Chains	28-11
28.2.9	Job Classes	28-13
28.2.10	Windows	28-14
28.2.10.1	About Windows	28-15
28.2.10.2	Overlapping Windows	28-16
28.2.11	Groups	28-18
28.2.11.1	About Groups	28-19
28.2.11.2	Destination Groups	28-19
28.2.11.3	Window Groups	28-19
28.2.12	Incompatibilities	28-20
28.3	More About Jobs	28-20

28.3.1	Job Categories	28-21
28.3.1.1	Database Jobs	28-22
28.3.1.2	External Jobs	28-23
28.3.1.3	Multiple-Destination Jobs	28-26
28.3.1.4	Chain Jobs	28-27
28.3.1.5	Detached Jobs	28-28
28.3.1.6	Lightweight Jobs	28-29
28.3.1.7	In-Memory Jobs	28-29
28.3.1.8	Script Jobs	28-30
28.3.2	Job Instances	28-31
28.3.3	Job Arguments	28-32
28.3.4	How Programs, Jobs, and Schedules are Related	28-32
28.4	Scheduler Architecture	28-33
28.4.1	Scheduler Components	28-33
28.4.2	The Job Table	28-34
28.4.3	The Job Coordinator	28-34
28.4.3.1	About The Job Coordinator	28-34
28.4.3.2	Job Coordinator Actions	28-35
28.4.3.3	Maximum Number of Scheduler Job Processes	28-35
28.4.4	How Jobs Execute	28-36
28.4.5	After Jobs Complete	28-36
28.4.6	Using the Scheduler in Real Application Clusters Environments	28-36
28.4.6.1	The Scheduler and Real Application Clusters	28-37
28.4.6.2	Service Affinity when Using the Scheduler	28-37
28.5	Scheduler Support for Oracle Data Guard	28-38

29 Scheduling Jobs with Oracle Scheduler

29.1	About Scheduler Objects and Their Naming	29-2
29.2	Creating, Running, and Managing Jobs	29-2
29.2.1	Job Tasks and Their Procedures	29-3
29.2.2	Creating Jobs	29-4
29.2.2.1	Overview of Creating Jobs	29-5
29.2.2.2	Specifying Job Actions, Schedules, Programs, and Styles	29-6
29.2.2.3	Specifying Scheduler Job Credentials	29-9
29.2.2.4	Specifying Destinations	29-10
29.2.2.5	Creating Multiple-Destination Jobs	29-14
29.2.2.6	Setting Job Arguments	29-15
29.2.2.7	Setting Additional Job Attributes	29-16
29.2.2.8	Creating Detached Jobs	29-16
29.2.2.9	Creating Multiple Jobs in a Single Transaction	29-17

29.2.2.10	Techniques for External Jobs	29-18
29.2.3	Altering Jobs	29-20
29.2.4	Running Jobs	29-21
29.2.5	Stopping Jobs	29-21
29.2.6	Stopping External Jobs	29-22
29.2.7	Stopping a Chain Job	29-23
29.2.8	Dropping Jobs	29-23
29.2.9	Dropping Running Jobs	29-23
29.2.10	Dropping Multiple Jobs	29-24
29.2.11	Disabling Jobs	29-25
29.2.12	Enabling Jobs	29-25
29.2.13	Copying Jobs	29-26
29.3	Creating and Managing Programs to Define Jobs	29-26
29.3.1	Program Tasks and Their Procedures	29-27
29.3.2	Creating Programs with Scheduler	29-27
29.3.2.1	Creating Programs	29-27
29.3.2.2	Defining Program Arguments	29-28
29.3.3	Altering Programs	29-29
29.3.4	Dropping Programs	29-29
29.3.5	Disabling Programs	29-30
29.3.6	Enabling Programs	29-30
29.4	Creating and Managing Schedules to Define Jobs	29-31
29.4.1	Schedule Tasks and Their Procedures	29-31
29.4.2	Creating Schedules	29-32
29.4.3	Altering Schedules	29-32
29.4.4	Dropping Schedules	29-32
29.4.5	Setting the Repeat Interval	29-33
29.4.5.1	About Setting the Repeat Interval	29-33
29.4.5.2	Using the Scheduler Calendaring Syntax	29-34
29.4.5.3	Using a PL/SQL Expression	29-36
29.4.5.4	Differences Between PL/SQL Expression and Calendaring Syntax Behavior	29-37
29.4.5.5	Repeat Intervals and Daylight Savings	29-37
29.5	Using Events to Start Jobs	29-38
29.5.1	About Events	29-38
29.5.2	Starting Jobs with Events Raised by Your Application	29-39
29.5.2.1	About Events Raised by Your Application	29-39
29.5.2.2	Creating an Event-Based Job	29-41
29.5.2.3	Altering an Event-Based Job	29-42
29.5.2.4	Creating an Event Schedule	29-43
29.5.2.5	Altering an Event Schedule	29-43

29.5.2.6	Passing Event Messages into an Event-Based Job	29-43
29.5.3	Starting a Job When a File Arrives on a System	29-44
29.5.3.1	About File Watchers	29-45
29.5.3.2	Enabling File Arrival Events from Remote Systems	29-46
29.5.3.3	Creating File Watchers and File Watcher Jobs	29-46
29.5.3.4	File Arrival Example	29-49
29.5.3.5	Managing File Watchers	29-50
29.5.3.6	Viewing File Watcher Information	29-52
29.6	Creating and Managing Job Chains	29-52
29.6.1	About Creating and Managing Job Chains	29-54
29.6.2	Chain Tasks and Their Procedures	29-54
29.6.3	Creating Chains	29-55
29.6.4	Defining Chain Steps	29-56
29.6.5	Adding Rules to a Chain	29-58
29.6.6	Setting an Evaluation Interval for Chain Rules	29-61
29.6.7	Enabling Chains	29-61
29.6.8	Creating Jobs for Chains	29-62
29.6.9	Dropping Chains	29-63
29.6.10	Running Chains	29-63
29.6.11	Dropping Chain Rules	29-64
29.6.12	Disabling Chains	29-64
29.6.13	Dropping Chain Steps	29-65
29.6.14	Stopping Chains	29-65
29.6.15	Stopping Individual Chain Steps	29-65
29.6.16	Pausing Chains	29-66
29.6.17	Skiping Chain Steps	29-67
29.6.18	Running Part of a Chain	29-67
29.6.19	Monitoring Running Chains	29-67
29.6.20	Handling Stalled Chains	29-68
29.7	Using Incompatibility Definitions	29-68
29.7.1	Creating a Job or Program Incompatibility	29-69
29.7.2	Adding a Job or Program to an Incompatibility	29-70
29.7.3	Removing a Job or Program from an Incompatibility	29-70
29.7.4	Dropping an Incompatibility	29-71
29.8	Managing Job Resources	29-71
29.8.1	Creating or Dropping a Resource	29-72
29.8.2	Altering a Resource	29-72
29.8.3	Setting a Resource Constraint for a Job	29-73
29.9	Prioritizing Jobs	29-73
29.9.1	Managing Job Priorities with Job Classes	29-74
29.9.1.1	Job Class Tasks and Their Procedures	29-75

29.9.1.2	Creating Job Classes	29-75
29.9.1.3	Altering Job Classes	29-76
29.9.1.4	Dropping Job Classes	29-76
29.9.2	Setting Relative Job Priorities Within a Job Class	29-76
29.9.3	Managing Job Scheduling and Job Priorities with Windows	29-77
29.9.3.1	About Job Scheduling and Job Priorities with Windows	29-78
29.9.3.2	Window Tasks and Their Procedures	29-78
29.9.3.3	Creating Windows	29-79
29.9.3.4	Altering Windows	29-80
29.9.3.5	Opening Windows	29-80
29.9.3.6	Closing Windows	29-81
29.9.3.7	Dropping Windows	29-82
29.9.3.8	Disabling Windows	29-82
29.9.3.9	Enabling Windows	29-83
29.9.4	Managing Job Scheduling and Job Priorities with Window Groups	29-83
29.9.4.1	Window Group Tasks and Their Procedures	29-84
29.9.4.2	Creating Window Groups	29-84
29.9.4.3	Dropping Window Groups	29-85
29.9.4.4	Adding a Member to a Window Group	29-85
29.9.4.5	Removing a Member from a Window Group	29-86
29.9.4.6	Enabling a Window Group	29-86
29.9.4.7	Disabling a Window Group	29-86
29.9.5	Allocating Resources Among Jobs Using Resource Manager	29-86
29.9.6	Example of Resource Allocation for Jobs	29-87
29.10	Monitoring Jobs	29-88
29.10.1	About Monitoring Jobs	29-88
29.10.2	The Job Log	29-89
29.10.2.1	Viewing the Job Log	29-89
29.10.2.2	Run Details	29-90
29.10.2.3	Precedence of Logging Levels in Jobs and Job Classes	29-91
29.10.3	Monitoring Multiple Destination Jobs	29-92
29.10.4	Monitoring Job State with Events Raised by the Scheduler	29-93
29.10.4.1	About Job State Events	29-93
29.10.4.2	Altering a Job to Raise Job State Events	29-95
29.10.4.3	Consuming Job State Events with your Application	29-95
29.10.5	Monitoring Job State with E-mail Notifications	29-96
29.10.5.1	About E-mail Notifications	29-96
29.10.5.2	Adding E-mail Notifications for a Job	29-97
29.10.5.3	Removing E-mail Notifications for a Job	29-98
29.10.5.4	Viewing Information About E-mail Notifications	29-99

30 Administering Oracle Scheduler

30.1	Configuring Oracle Scheduler	30-1
30.1.1	Setting Oracle Scheduler Privileges	30-2
30.1.2	Setting Scheduler Preferences	30-3
30.1.3	Using the Oracle Scheduler Agent to Run Remote Jobs	30-5
30.1.3.1	Enabling and Disabling Databases for Remote Jobs	30-6
30.1.3.2	Installing and Configuring the Scheduler Agent on a Remote Host	30-8
30.1.3.3	Performing Tasks with the Scheduler Agent	30-9
30.2	Monitoring and Managing the Scheduler	30-12
30.2.1	Viewing the Currently Active Window and Resource Plan	30-12
30.2.2	Finding Information About Currently Running Jobs	30-13
30.2.3	Monitoring and Managing Window and Job Logs	30-14
30.2.3.1	Job Log	30-14
30.2.3.2	Window Log	30-15
30.2.3.3	Purging Logs	30-16
30.2.4	Managing Scheduler Security	30-17
30.3	Import/Export and the Scheduler	30-17
30.4	Troubleshooting the Scheduler	30-18
30.4.1	A Job Does Not Run	30-18
30.4.1.1	About Job States	30-19
30.4.1.2	Viewing the Job Log	30-20
30.4.1.3	Troubleshooting Remote Jobs	30-20
30.4.1.4	About Job Recovery After a Failure	30-20
30.4.2	A Program Becomes Disabled	30-21
30.4.3	A Window Fails to Take Effect	30-21
30.5	Examples of Using the Scheduler	30-21
30.5.1	Examples of Creating Job Classes	30-22
30.5.2	Examples of Setting Attributes	30-23
30.5.3	Examples of Creating Chains	30-24
30.5.4	Examples of Creating Jobs and Schedules Based on Events	30-26
30.5.5	Example of Creating a Job In an Oracle Data Guard Environment	30-27
30.6	Scheduler Reference	30-28
30.6.1	Scheduler Privileges	30-28
30.6.2	Scheduler Data Dictionary Views	30-29

Part V Distributed Database Management

31 Distributed Database Concepts

31.1	Distributed Database Architecture	31-1
31.1.1	Homogenous Distributed Database Systems	31-2
31.1.1.1	About Homogenous Distributed Database Systems	31-2
31.1.1.2	Distributed Databases Versus Distributed Processing	31-3
31.1.1.3	Distributed Databases Versus Replicated Databases	31-4
31.1.2	Heterogeneous Distributed Database Systems	31-4
31.1.2.1	About Heterogeneous Distributed Database Systems	31-5
31.1.2.2	Heterogeneous Services	31-5
31.1.2.3	Transparent Gateway Agents	31-5
31.1.2.4	Generic Connectivity	31-6
31.1.3	Client/Server Database Architecture	31-6
31.2	Database Links	31-7
31.2.1	What Are Database Links?	31-8
31.2.2	What Are Shared Database Links?	31-10
31.2.3	Why Use Database Links?	31-11
31.2.4	Global Database Names in Database Links	31-11
31.2.5	Global Name as a Loopback Database Link	31-13
31.2.6	Names for Database Links	31-13
31.2.7	Types of Database Links	31-14
31.2.8	Users of Database Links	31-15
31.2.8.1	Overview of Database Link Users	31-15
31.2.8.2	Connected User Database Links	31-16
31.2.8.3	Fixed User Database Links	31-17
31.2.8.4	Current User Database Links	31-17
31.2.9	Creation of Database Links: Examples	31-18
31.2.10	Schema Objects and Database Links	31-19
31.2.10.1	Naming of Schema Objects Using Database Links	31-20
31.2.10.2	Authorization for Accessing Remote Schema Objects	31-20
31.2.10.3	Synonyms for Schema Objects	31-21
31.2.10.4	Schema Object Name Resolution	31-21
31.2.11	Database Link Restrictions	31-22
31.3	Distributed Database Administration	31-22
31.3.1	Site Autonomy	31-23
31.3.2	Distributed Database Security	31-24
31.3.2.1	Authentication Through Database Links	31-24
31.3.2.2	Authentication Without Passwords	31-26
31.3.2.3	Supporting User Accounts and Roles	31-26
31.3.2.4	Centralized User and Privilege Management	31-26
31.3.2.5	Data Encryption	31-30

31.3.3	Auditing Database Links	31-30
31.3.4	Administration Tools	31-31
31.3.4.1	Cloud Control and Distributed Databases	31-31
31.3.4.2	Third-Party Administration Tools	31-31
31.3.4.3	SNMP Support	31-31
31.4	Transaction Processing in a Distributed System	31-32
31.4.1	Remote SQL Statements	31-33
31.4.2	Distributed SQL Statements	31-33
31.4.3	Shared SQL for Remote and Distributed Statements	31-34
31.4.4	Remote Transactions	31-34
31.4.5	Distributed Transactions	31-34
31.4.6	Two-Phase Commit Mechanism	31-35
31.4.7	Database Link Name Resolution	31-35
31.4.7.1	About Database Link Name Resolution	31-36
31.4.7.2	Name Resolution When the Global Database Name Is Complete	31-36
31.4.7.3	Name Resolution When the Global Database Name Is Partial	31-37
31.4.7.4	Name Resolution When No Global Database Name Is Specified	31-37
31.4.7.5	Terminating the Search for Name Resolution	31-37
31.4.8	Schema Object Name Resolution	31-38
31.4.8.1	About Schema Object Name Resolution	31-38
31.4.8.2	Example of Global Object Name Resolution: Complete Object Name	31-39
31.4.8.3	Example of Global Object Name Resolution: Partial Object Name	31-40
31.4.9	Global Name Resolution in Views, Synonyms, and Procedures	31-41
31.4.9.1	About Global Name Resolution in Views, Synonyms, and Procedures	31-41
31.4.9.2	What Happens When Global Names Change	31-41
31.4.9.3	Scenarios for Global Name Changes	31-41
31.5	Distributed Database Application Development	31-43
31.5.1	Transparency in a Distributed Database System	31-43
31.5.1.1	Location Transparency	31-44
31.5.1.2	SQL and COMMIT Transparency	31-45
31.5.2	PL/SQL and Remote Procedure Calls (RPCs)	31-45
31.5.3	Distributed Query Optimization	31-46
31.6	Character Set Support for Distributed Environments	31-46
31.6.1	About Character Set Support for Distributed Environments	31-47
31.6.2	Client/Server Environment	31-47
31.6.3	Homogeneous Distributed Environment	31-48
31.6.4	Heterogeneous Distributed Environment	31-48

32 Managing a Distributed Database

32.1	Managing Global Names in a Distributed System	32-1
32.1.1	Understanding How Global Database Names Are Formed	32-2
32.1.2	Determining Whether Global Naming Is Enforced	32-3
32.1.3	Viewing a Global Database Name	32-3
32.1.4	Changing the Domain in a Global Database Name	32-4
32.1.5	Changing a Global Database Name: Scenario	32-4
32.2	Creating Database Links	32-7
32.2.1	Obtaining Privileges Necessary for Creating Database Links	32-7
32.2.2	Specifying Link Types	32-8
32.2.2.1	Creating Private Database Links	32-8
32.2.2.2	Creating Public Database Links	32-9
32.2.2.3	Creating Global Database Links	32-10
32.2.3	Specifying Link Users	32-10
32.2.3.1	Creating Fixed User Database Links	32-10
32.2.3.2	Creating Connected User and Current User Database Links	32-11
32.2.4	Using Connection Qualifiers to Specify Service Names Within Link Names	32-12
32.3	Using Shared Database Links	32-13
32.3.1	Determining Whether to Use Shared Database Links	32-14
32.3.2	Creating Shared Database Links	32-15
32.3.3	Configuring Shared Database Links	32-15
32.3.3.1	Creating Shared Links to Dedicated Servers	32-15
32.3.3.2	Creating Shared Links to Shared Servers	32-16
32.4	Managing Database Links	32-17
32.4.1	Closing Database Links	32-18
32.4.2	Dropping Database Links	32-18
32.4.2.1	Dropping a Private Database Link	32-19
32.4.2.2	Dropping a Public Database Link	32-19
32.4.3	Limiting the Number of Active Database Link Connections	32-19
32.5	Viewing Information About Database Links	32-20
32.5.1	Determining Which Links Are in the Database	32-20
32.5.2	Determining Which Link Connections Are Open	32-21
32.5.3	Determining the Host of Outgoing Database Links	32-23
32.5.4	Determining Information About Incoming Database Links	32-23
32.5.5	Determining the Source of High SCN Activity for Incoming Database Links	32-24
32.6	Creating Location Transparency	32-25
32.6.1	Using Views to Create Location Transparency	32-25
32.6.2	Using Synonyms to Create Location Transparency	32-26
32.6.2.1	Creating Synonyms	32-27

32.6.2.2	Managing Privileges and Synonyms	32-28
32.6.3	Using Procedures to Create Location Transparency	32-28
32.6.3.1	Using Local Procedures to Reference Remote Data	32-29
32.6.3.2	Using Local Procedures to Call Remote Procedures	32-29
32.6.3.3	Using Local Synonyms to Reference Remote Procedures	32-30
32.6.3.4	Managing Procedures and Privileges	32-30
32.7	Managing Statement Transparency	32-30
32.8	Managing a Distributed Database: Examples	32-32
32.8.1	Example 1: Creating a Public Fixed User Database Link	32-32
32.8.2	Example 2: Creating a Public Fixed User Shared Database Link	32-33
32.8.3	Example 3: Creating a Public Connected User Database Link	32-33
32.8.4	Example 4: Creating a Public Connected User Shared Database Link	32-34
32.8.5	Example 5: Creating a Public Current User Database Link	32-34

33 Developing Applications for a Distributed Database System

33.1	Managing the Distribution of Application Data	33-1
33.2	Controlling Connections Established by Database Links	33-2
33.3	Maintaining Referential Integrity in a Distributed System	33-3
33.4	Tuning Distributed Queries	33-3
33.4.1	Using Collocated Inline Views	33-4
33.4.2	Using Cost-Based Optimization	33-5
33.4.2.1	How Does Cost-Based Optimization Work?	33-5
33.4.2.2	Rewriting Queries for Cost-Based Optimization	33-6
33.4.2.3	Setting Up Cost-Based Optimization	33-6
33.4.3	Using Hints	33-8
33.4.3.1	About Using Hints	33-8
33.4.3.2	Using the NO_MERGE Hint	33-9
33.4.3.3	Using the DRIVING_SITE Hint	33-9
33.4.4	Analyzing the Execution Plan	33-9
33.4.4.1	Generating the Execution Plan	33-10
33.4.4.2	Viewing the Execution Plan	33-10
33.5	Handling Errors in Remote Procedures	33-11

34 Distributed Transactions Concepts

34.1	What Are Distributed Transactions?	34-1
34.1.1	DML and DDL Transactions	34-2
34.1.2	Transaction Control Statements	34-3
34.2	Session Trees for Distributed Transactions	34-3
34.2.1	About Session Trees for Distributed Transactions	34-4

34.2.2	Clients	34-5
34.2.3	Database Servers	34-5
34.2.4	Local Coordinators	34-5
34.2.5	Global Coordinator	34-5
34.2.6	Commit Point Site	34-6
34.2.6.1	About the Commit Point Site	34-6
34.2.6.2	How a Distributed Transaction Commits	34-7
34.2.6.3	Commit Point Strength	34-7
34.3	Two-Phase Commit Mechanism	34-9
34.3.1	About the Two-Phase Commit Mechanism	34-9
34.3.2	Prepare Phase	34-10
34.3.2.1	About Prepare Phase	34-10
34.3.2.2	Types of Responses in the Prepare Phase	34-11
34.3.2.3	Steps in the Prepare Phase	34-12
34.3.3	Commit Phase	34-13
34.3.3.1	Steps in the Commit Phase	34-13
34.3.3.2	Guaranteeing Global Database Consistency	34-13
34.3.4	Forget Phase	34-14
34.4	In-Doubt Transactions	34-14
34.4.1	About In-Doubt Transactions	34-15
34.4.2	Automatic Resolution of In-Doubt Transactions	34-15
34.4.2.1	Failure During the Prepare Phase	34-15
34.4.2.2	Failure During the Commit Phase	34-16
34.4.3	Manual Resolution of In-Doubt Transactions	34-17
34.4.4	Relevance of System Change Numbers for In-Doubt Transactions	34-18
34.5	Distributed Transaction Processing: Case Study	34-18
34.5.1	About the Distributed Transaction Processing Case Study	34-19
34.5.2	Stage 1: Client Application Issues DML Statements	34-19
34.5.3	Stage 2: Oracle Database Determines Commit Point Site	34-20
34.5.4	Stage 3: Global Coordinator Sends Prepare Response	34-21
34.5.5	Stage 4: Commit Point Site Commits	34-22
34.5.6	Stage 5: Commit Point Site Informs Global Coordinator of Commit	34-22
34.5.7	Stage 6: Global and Local Coordinators Tell All Nodes to Commit	34-23
34.5.8	Stage 7: Global Coordinator and Commit Point Site Complete the Commit	34-23

35 Managing Distributed Transactions

35.1	Specifying the Commit Point Strength of a Node	35-2
35.2	Naming Transactions	35-2
35.3	Viewing Information About Distributed Transactions	35-3
35.3.1	Determining the ID Number and Status of Prepared Transactions	35-3

35.3.2	Tracing the Session Tree of In-Doubt Transactions	35-5
35.4	Deciding How to Handle In-Doubt Transactions	35-6
35.4.1	Discovering Problems with a Two-Phase Commit	35-7
35.4.2	Determining Whether to Perform a Manual Override	35-7
35.4.3	Analyzing the Transaction Data	35-8
35.4.3.1	Find a Node that Committed or Rolled Back	35-8
35.4.3.2	Look for Transaction Comments	35-8
35.4.3.3	Look for Transaction Advice	35-9
35.5	Manually Overriding In-Doubt Transactions	35-9
35.5.1	Manually Committing an In-Doubt Transaction	35-10
35.5.1.1	Privileges Required to Commit an In-Doubt Transaction	35-10
35.5.1.2	Committing Using Only the Transaction ID	35-10
35.5.1.3	Committing Using an SCN	35-10
35.5.2	Manually Rolling Back an In-Doubt Transaction	35-11
35.6	Purging Pending Rows from the Data Dictionary	35-12
35.6.1	About Purging Pending Rows from the Data Dictionary	35-12
35.6.2	Executing the PURGE_LOST_DB_ENTRY Procedure	35-13
35.6.3	Determining When to Use DBMS_TRANSACTION	35-13
35.7	Manually Committing an In-Doubt Transaction: Example	35-14
35.7.1	Step 1: Record User Feedback	35-15
35.7.2	Step 2: Query DBA_2PC_PENDING	35-15
35.7.2.1	Determining the Global Transaction ID	35-16
35.7.2.2	Determining the State of the Transaction	35-16
35.7.2.3	Looking for Comments or Advice	35-16
35.7.3	Step 3: Query DBA_2PC_NEIGHBORS on Local Node	35-17
35.7.3.1	Obtaining Database Role and Database Link Information	35-17
35.7.3.2	Determining the Commit Point Site	35-18
35.7.4	Step 4: Querying Data Dictionary Views on All Nodes	35-18
35.7.4.1	Checking the Status of Pending Transactions at sales	35-19
35.7.4.2	Determining the Coordinators and Commit Point Site at sales	35-19
35.7.4.3	Checking the Status of Pending Transactions at HQ	35-20
35.7.5	Step 5: Commit the In-Doubt Transaction	35-21
35.7.6	Step 6: Check for Mixed Outcome Using DBA_2PC_PENDING	35-21
35.8	Data Access Failures Due to Locks	35-21
35.8.1	Transaction Timeouts	35-22
35.8.2	Locks from In-Doubt Transactions	35-22
35.9	Simulating Distributed Transaction Failure	35-22
35.9.1	Forcing a Distributed Transaction to Fail	35-23
35.9.2	Disabling and Enabling RECO	35-23
35.10	Managing Read Consistency	35-24

Part VI Managing a Multitenant Environment

36 Overview of Managing a Multitenant Environment

36.1	About a Multitenant Environment	36-1
36.1.1	Components of a CDB	36-2
36.1.2	Common Users and Local Users	36-3
36.1.3	Separation of Duties in CDB and PDB Administration	36-3
36.1.4	Application Containers	36-3
36.2	Purpose of a Multitenant Environment	36-5
36.3	Prerequisites for a Multitenant Environment	36-6
36.4	Tasks and Tools for a Multitenant Environment	36-7
36.4.1	Tasks for a Multitenant Environment	36-7
36.4.2	Tools for a Multitenant Environment	36-10

37 Creating and Configuring a CDB

37.1	About Creating a CDB	37-1
37.2	Planning for CDB Creation	37-2
37.2.1	Decide How to Configure the CDB	37-2
37.2.2	Prerequisites for CDB Creation	37-8
37.3	Using DBCA to Create a CDB	37-8
37.4	Using the CREATE DATABASE Statement to Create a CDB	37-9
37.4.1	About Creating a CDB with the CREATE DATABASE Statement	37-10
37.4.1.1	About Enabling PDBs	37-11
37.4.1.2	About the Names and Locations of the Root's Files and the CDB Seed's Files	37-11
37.4.1.3	About the Attributes of the CDB Seed's Data Files	37-13
37.4.1.4	About the CDB's Undo Mode	37-14
37.4.2	Step 1: Specify an Instance Identifier (SID)	37-14
37.4.3	Step 2: Ensure That the Required Environment Variables Are Set	37-15
37.4.4	Step 3: Choose a Database Administrator Authentication Method	37-16
37.4.5	Step 4: Create the Initialization Parameter File	37-16
37.4.6	Step 5: (Windows Only) Create an Instance	37-17
37.4.7	Step 6: Connect to the Instance	37-18
37.4.8	Step 7: Create a Server Parameter File	37-19
37.4.9	Step 8: Start the Instance	37-20
37.4.10	Step 9: Create a CDB with the CREATE DATABASE Statement	37-20
37.5	Configuring EM Express for a CDB	37-27
37.6	After Creating a CDB	37-29

38 Creating and Removing PDBs with SQL*Plus

38.1	About Creating and Removing PDBs	38-2
38.1.1	Techniques for Creating a PDB	38-2
38.1.2	The CREATE PLUGGABLE DATABASE Statement	38-5
38.1.2.1	Storage Limits	38-7
38.1.2.2	File Location of the New PDB	38-7
38.1.2.3	Restrictions on PDB File Locations	38-11
38.1.2.4	Source File Locations When Plugging In an Unplugged PDB	38-12
38.1.2.5	Renaming a Service	38-15
38.1.2.6	Temp File Reuse	38-16
38.1.2.7	Default Tablespace	38-16
38.1.2.8	User Tablespaces	38-16
38.1.2.9	PDB Tablespace Logging	38-18
38.1.2.10	PDB Inclusion in Standby CDBs	38-19
38.1.2.11	Excluding Data When Cloning a PDB	38-20
38.1.2.12	Parallelize PDB Creation	38-21
38.1.2.13	PDB Refresh	38-21
38.1.2.14	Application Container and Application Seed	38-23
38.1.2.15	PDB Listener Host Name and Port Number	38-24
38.1.3	Summary of Clauses for Creating a PDB	38-25
38.2	Preparing for PDBs	38-33
38.3	Creating a PDB Using the Seed	38-34
38.3.1	About Creating a PDB from the Seed	38-34
38.3.2	Creating a PDB from the Seed	38-37
38.4	Creating a PDB by Cloning an Existing PDB or Non-CDB	38-41
38.4.1	About Cloning a PDB	38-41
38.4.2	Cloning a Local PDB	38-48
38.4.3	Cloning a Remote PDB or Non-CDB	38-53
38.4.4	After Cloning a PDB	38-57
38.5	Creating a PDB by Relocating It	38-58
38.5.1	About Relocating a PDB	38-58
38.5.2	Relocating a PDB	38-63
38.6	Creating a PDB by Plugging an Unplugged PDB into a CDB	38-66
38.6.1	About Plugging In an Unplugged PDB	38-66
38.6.2	Plugging In an Unplugged PDB	38-69
38.6.3	After Plugging in an Unplugged PDB	38-76
38.7	Creating a PDB as a Proxy PDB	38-77
38.7.1	About Creating a Proxy PDB	38-77
38.7.2	Creating a Proxy PDB	38-82
38.8	Creating a PDB Using a Non-CDB	38-84

38.8.1	About Creating a PDB Using a Non-CDB	38-84
38.8.2	Using the DBMS_PDB Package on a Non-CDB	38-85
38.8.2.1	About Using the DBMS_PDB Package on a Non-CDB	38-86
38.8.2.2	Using the DBMS_PDB Package to Create an Unplugged PDB	38-87
38.9	Unplugging a PDB from a CDB	38-89
38.9.1	About Unplugging a PDB	38-90
38.9.2	Unplugging a PDB	38-93
38.10	Dropping a PDB	38-94

39 Creating and Removing PDBs with Cloud Control

39.1	Getting Started with Creating and Removing PDBs with Cloud Control	39-1
39.2	Overview of Creating and Removing PDBs with Cloud Control	39-2
39.3	Provisioning a PDB with Cloud Control	39-3
39.3.1	Creating a New PDB with Cloud Control	39-4
39.3.1.1	Prerequisites	39-4
39.3.1.2	Procedure	39-4
39.3.2	Plugging In an Unplugged PDB with Cloud Control	39-7
39.3.2.1	Prerequisites	39-7
39.3.2.2	Procedure	39-8
39.3.3	Cloning a PDB with Cloud Control	39-11
39.3.3.1	Prerequisites	39-11
39.3.3.2	Procedure	39-12
39.3.4	Migrating a Non-CDB to a PDB with Cloud Control	39-15
39.3.4.1	Prerequisites	39-15
39.3.4.2	Procedure	39-16
39.4	Removing PDBs with Cloud Control	39-17
39.4.1	Unplugging and Dropping a PDB with Cloud Control	39-17
39.4.1.1	Prerequisites	39-17
39.4.1.2	Procedure	39-17
39.4.2	Deleting PDBs with Cloud Control	39-20
39.4.2.1	Prerequisites	39-20
39.4.2.2	Procedure	39-20
39.5	Viewing PDB Job Details with Cloud Control	39-22
39.5.1	Viewing Create PDB Job Details with Cloud Control	39-22
39.5.2	Viewing Unplug PDB Job Details with Cloud Control	39-23
39.5.3	Viewing Delete PDB Job Details with Cloud Control	39-23

40 Creating and Removing Application Containers and Seeds with SQL*Plus

40.1	Creating and Removing Application Containers with SQL*Plus	40-1
40.1.1	Creating Application Containers	40-2
40.1.1.1	About Creating an Application Container	40-2
40.1.1.2	Preparing for Application Containers	40-3
40.1.1.3	Creating an Application Container	40-4
40.1.2	Unplugging an Application Container from a CDB	40-7
40.1.2.1	About Unplugging an Application Container	40-7
40.1.2.2	Unplugging an Application Container	40-8
40.1.3	Dropping an Application Container	40-9
40.2	Creating and Removing Application Seeds with SQL*Plus	40-10
40.2.1	Creating Application Seeds	40-11
40.2.1.1	About Creating an Application Seed	40-11
40.2.1.2	Preparing for an Application Seed	40-12
40.2.1.3	Creating an Application Seed	40-12
40.2.2	Unplugging an Application Seed from an Application Container	40-16
40.2.2.1	About Unplugging an Application Seed	40-16
40.2.2.2	Unplugging an Application Seed	40-17
40.2.3	Dropping an Application Seed	40-18
40.3	Creating an Application PDB	40-19

41 Administering a CDB with SQL*Plus

41.1	About Administering a CDB	41-2
41.1.1	About the Current Container	41-2
41.1.2	About Administrative Tasks in a CDB	41-3
41.1.3	About Using Manageability Features in a CDB	41-6
41.1.4	About Managing Database Objects in a CDB	41-12
41.1.5	About Flashing Back a PDB	41-12
41.1.6	About Restricting PDB Users for Enhanced Security	41-13
41.2	Accessing a Container in a CDB with SQL*Plus	41-14
41.2.1	About Accessing a Container in a CDB with SQL*Plus	41-15
41.2.2	Connecting to a Container Using the SQL*Plus CONNECT Command	41-16
41.2.2.1	Connecting to the Root Using the SQL*Plus CONNECT Command	41-16
41.2.2.2	Connecting to a PDB Using the SQL*Plus CONNECT Command	41-17
41.2.3	Switching to a Container Using the ALTER SESSION Statement	41-18
41.3	Executing Code in Containers Using the DBMS_SQL Package	41-22
41.4	Modifying a CDB	41-23
41.4.1	About Modifying a CDB	41-24

41.4.2	About the Statements That Modify a CDB	41-25
41.4.3	Managing Tablespaces in a CDB	41-25
41.4.3.1	About Managing Tablespaces in a CDB	41-26
41.4.3.2	About Managing Permanent Tablespaces in a CDB	41-26
41.4.3.3	About Managing Temporary Tablespaces in a CDB	41-26
41.4.4	Modifying an Entire CDB	41-27
41.4.5	Modifying the Root	41-28
41.4.6	Modifying the Open Mode of PDBs	41-29
41.4.6.1	About the Open Mode of a PDB	41-29
41.4.6.2	About Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE	41-30
41.4.6.3	About Modifying the Open Mode of PDBs with the SQL*Plus STARTUP Command	41-35
41.4.6.4	Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE	41-36
41.4.6.5	Modifying the Open Mode of PDBs with the SQL*Plus STARTUP Command	41-38
41.4.7	Preserving or Discarding the Open Mode of PDBs When the CDB Restarts	41-39
41.5	Using the ALTER SYSTEM SET Statement in a CDB	41-41
41.6	Issuing DML Statements on Containers in a CDB	41-42
41.6.1	About Issuing DML Statements on Containers in a CDB	41-42
41.6.2	Specifying the Default Container for DML Statements in a CDB	41-44
41.7	Executing DDL Statements in a CDB	41-44
41.7.1	About Executing DDL Statements in a CDB	41-44
41.7.2	Executing a DDL Statement in the Current Container	41-46
41.7.3	Executing a DDL Statement in All Containers in a CDB	41-47
41.8	Managing the CDB Undo Mode	41-47
41.8.1	About the CDB Undo Mode	41-48
41.8.2	Configuring a CDB to Use Local Undo Mode	41-49
41.8.3	Configuring a CDB to Use Shared Undo Mode	41-50
41.9	Running Oracle-Supplied SQL Scripts in a CDB	41-51
41.9.1	About Running Oracle-Supplied SQL Scripts in a CDB	41-51
41.9.2	Syntax and Parameters for catcon.pl	41-51
41.9.3	Running the catcon.pl Script	41-54
41.10	Shutting Down a CDB Instance	41-57

42 Administering CDBs and PDBs with Cloud Control

42.1	Administering CDB Storage and Schema Objects with Cloud Control	42-1
42.1.1	About Managing and Monitoring CDB Storage and Schema Objects	42-1
42.1.2	Managing CDB Storage and Schema Objects	42-2
42.1.3	Managing Per-Container Storage and Schema Objects	42-2

42.1.4	Monitoring Storage and Schema Alerts	42-3
42.2	Administering PDBs with Cloud Control	42-3
42.2.1	Switching Between PDBs	42-3
42.2.2	Altering the Open Mode of a PDB	42-4

43 Administering PDBs with SQL*Plus

43.1	About Administering PDBs	43-1
43.2	Connecting to a PDB with SQL*Plus	43-3
43.3	Modifying a PDB	43-4
43.3.1	Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement	43-4
43.3.1.1	About Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement	43-5
43.3.1.2	Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement	43-9
43.3.1.3	Changing the Global Database Name of a PDB	43-11
43.3.2	Modifying a PDB with the SQL*Plus STARTUP and SHUTDOWN Commands	43-12
43.3.2.1	Using the STARTUP SQL*Plus Command on a PDB	43-13
43.3.2.2	Using the SQL*Plus SHUTDOWN Command on a PDB	43-14
43.4	Using the ALTER SYSTEM Statement to Modify a PDB	43-15
43.4.1	About Using the ALTER SYSTEM Statement on a PDB	43-15
43.4.2	Using the ALTER SYSTEM Statement on a PDB	43-18
43.5	Managing Services Associated with PDBs	43-18
43.5.1	About Services Associated with PDBs	43-19
43.5.2	Creating, Modifying, or Removing a Service for a PDB	43-20
43.6	Refreshing a PDB	43-22
43.7	Modifying the Listener Settings of a Referenced PDB	43-22
43.7.1	Altering the Listener Host Name of a Referenced PDB	43-23
43.7.2	Altering the Listener Port Number of a Referenced PDB	43-24

44 Administering Application Containers with SQL*Plus

44.1	About Administering Application Containers with SQL*Plus	44-2
44.2	About Modifying an Application Root	44-4
44.3	Managing Applications in an Application Container	44-5
44.3.1	About Managing Applications in an Application Container	44-6
44.3.1.1	Application Module Names	44-8
44.3.2	Installing Applications in an Application Container	44-9
44.3.2.1	About Installing Applications in an Application Container	44-9
44.3.2.2	Installing an Application in an Application Container with Automated Propagation	44-10

44.3.3	Upgrading Applications in an Application Container	44-11
44.3.3.1	About Upgrading Applications in an Application Container	44-11
44.3.3.2	Upgrading an Application in an Application Container	44-14
44.3.4	Patching Applications in an Application Container	44-15
44.3.4.1	About Patching Applications in an Application Container	44-15
44.3.4.2	Patching an Application in an Application Container with Automated Propagation	44-16
44.3.5	Migrating an Existing Application to an Application Container	44-17
44.3.5.1	About Migrating an Existing Application to an Application Container	44-17
44.3.5.2	Creating an Application Root Using an Existing PDB	44-18
44.3.5.3	Creating an Application PDB Using an Existing PDB	44-20
44.3.6	Synchronizing Applications in an Application PDB	44-20
44.3.7	Synchronizing an Application Root Replica with a Proxy PDB	44-21
44.3.7.1	About Synchronizing an Application Root Replica with a Proxy PDB	44-22
44.3.7.2	Creating a Proxy PDB That References an Application Root Replica	44-24
44.3.8	Setting the Compatibility Version of an Application	44-30
44.3.9	Performing Bulk Inserts During Application Install, Upgrade, and Patch Operations	44-31
44.3.10	Uninstalling Applications from an Application Container	44-33
44.3.10.1	About Uninstalling Applications from an Application Container	44-33
44.3.10.2	Uninstalling an Application from an Application Container	44-34
44.4	Managing Application Common Objects	44-35
44.4.1	About Application Common Objects	44-36
44.4.2	Restrictions for Application Common Objects	44-39
44.4.3	Creating Application Common Objects	44-40
44.4.4	Issuing DML Statements on Application Common Objects	44-43
44.4.5	Modifying Application Common Objects with DDL Statements	44-46
44.5	Issuing DML Statements on Containers in an Application Container	44-47
44.5.1	About Issuing DML Statements on Containers in an Application Container	44-47
44.5.2	Specifying the Default Container for DML Statements in an Application Container	44-49
44.6	Partitioning by PDB with Container Maps	44-49
44.6.1	About Partitioning by PDB with Container Maps	44-50
44.6.2	Creating a Container Map	44-53

45 Viewing Information About CDBs and PDBs with SQL*Plus

45.1	About CDB and Container Information in Views	45-2
------	--	------

45.2	About Viewing Information When the Current Container Is a Not the CDB Root	45-3
45.3	About Viewing Information When the Current Container Is the CDB Root	45-3
45.4	Views for a CDB	45-4
45.5	Determining Whether a Database Is a CDB	45-7
45.6	Viewing Information About the Containers in a CDB	45-8
45.7	Viewing Information About PDBs	45-9
45.8	Viewing the Open Mode of Each PDB	45-9
45.9	Querying Container Data Objects	45-10
45.10	Querying Across Containers with the CONTAINERS Clause	45-14
45.10.1	About Querying Across Containers with the CONTAINERS Clause	45-14
45.10.2	Querying User-Created Tables and Views Across All Containers	45-16
45.10.3	Querying Application Common Objects Across Application PDBs	45-17
45.11	Determining the Current Container ID or Name	45-19
45.12	Listing the Initialization Parameters That Are Modifiable in PDBs	45-20
45.13	Viewing the History of PDBs	45-21
45.14	Viewing Information About Applications in Application Containers	45-22
45.14.1	Viewing Information About Applications	45-23
45.14.2	Viewing Information About Application Status	45-24
45.14.3	Viewing Information About Application Statements	45-25
45.14.4	Viewing Information About Application Versions	45-27
45.14.5	Viewing Information About Application Patches	45-27
45.14.6	Viewing Information About Application Errors	45-28
45.14.7	Listing the Shared Database Objects in an Application Container	45-29
45.14.8	Listing the Extended Data-Linked Objects in an Application Container	45-29

46 Using Oracle Resource Manager for PDBs with SQL*Plus

46.1	About Using Oracle Resource Manager with CDBs and PDBs	46-2
46.1.1	About Managing Resources at the CDB Level and PDB Level	46-3
46.1.2	What Solutions Does Resource Manager Provide for a CDB?	46-3
46.1.3	CDB Resource Plans	46-4
46.1.3.1	About CDB Resource Plans	46-5
46.1.3.2	Shares for Allocating Resources to PDBs	46-6
46.1.3.3	Utilization Limits for PDBs	46-7
46.1.3.4	The Default Directive for PDBs	46-9
46.1.4	PDB Resource Plans	46-11
46.1.5	Background and Administrative Tasks and Consumer Groups	46-13
46.1.6	Initialization Parameters That Control Memory for PDBs	46-14
46.1.7	Initialization Parameters That Limit I/O for PDBs	46-17
46.2	Prerequisites for Using Resource Manager with a CDB	46-18
46.3	Creating a CDB Resource Plan for Individual PDBs	46-18

46.3.1	Creating a CDB Resource Plan for Individual PDBs: A Scenario	46-19
46.4	Creating a CDB Resource Plan with PDB Performance Profiles	46-21
46.4.1	Creating a CDB Resource Plan for PDB Performance Profiles: A Scenario	46-22
46.5	Enabling and Disabling a CDB Resource Plan	46-25
46.5.1	Enabling a CDB Resource Plan	46-25
46.5.2	Disabling a CDB Resource Plan	46-26
46.6	Creating a PDB Resource Plan	46-27
46.7	Enabling and Disabling a PDB Resource Plan	46-27
46.7.1	Enabling a PDB Resource Plan	46-28
46.7.2	Disabling a PDB Resource Plan	46-28
46.8	Maintaining Plans and Directives in a CDB	46-29
46.8.1	Managing a CDB Resource Plan	46-29
46.8.1.1	Updating a CDB Resource Plan	46-30
46.8.1.2	Managing CDB Resource Plan Directives for a PDB	46-30
46.8.1.3	Managing CDB Resource Plan Directives for a PDB Performance Profile	46-33
46.8.1.4	Updating the Default Directive for PDBs in a CDB Resource Plan	46-36
46.8.1.5	Updating the Default Directive for Maintenance Tasks in a CDB Resource Plan	46-37
46.8.1.6	Deleting a CDB Resource Plan	46-38
46.8.2	Modifying a PDB Resource Plan	46-39
46.9	Viewing Information About Plans and Directives in a CDB	46-40
46.9.1	Viewing CDB Resource Plans	46-40
46.9.2	Viewing CDB Resource Plan Directives	46-41
46.10	Monitoring PDBs Managed by Oracle Database Resource Manager	46-42
46.10.1	Monitoring CPU Usage for PDBs	46-43
46.10.2	Monitoring Parallel Execution for PDBs	46-44
46.10.3	Monitoring the I/O Generated by PDBs	46-45
46.10.4	Monitoring Memory Usage for PDBs	46-45

47 Using Oracle Resource Manager for PDBs with Cloud Control

47.1	About CDB Resource Manager and Cloud Control	47-1
47.2	Creating a CDB Resource Plan with Cloud Control	47-1
47.3	Creating a PDB Resource Plan with Cloud Control	47-2

48 Using Oracle Scheduler with a CDB

48.1	DBMS_SCHEDULER Invocations in a CDB	48-1
48.2	Job Coordinator and Slave Processes in a CDB	48-2

48.3	Using DBMS_JOB	48-2
48.4	Processes to Close a PDB	48-3
48.5	New and Changed Views	48-3

Part VII Sharded Database Management

49 Overview of Oracle Sharding

49.1	About Sharding	49-1
49.2	Benefits of Sharding	49-2
49.3	Components of the Oracle Sharding Architecture	49-3
49.4	Application Suitability for Sharding	49-7

50 Sharded Database Schema Design

50.1	Sharded Table	50-1
50.2	Sharded Table Family	50-3
50.3	Duplicated Tables	50-7
50.4	Non-Table Objects Created on All Shards	50-9
50.5	DDL Execution in a Sharded Database	50-9
50.6	DDL Syntax Extensions for the Sharded Database	50-16

51 Physical Organization of a Sharded Database

51.1	Sharding as Distributed Partitioning	51-1
51.2	Partitions, Tablespaces, and Chunks	51-2

52 Sharding Methods

52.1	System-Managed Sharding	52-1
52.2	Composite Sharding	52-4
52.3	Using Subpartitions with Sharding	52-6

53 Design Considerations for Sharded Database Applications

53.1	Considerations for Sharded Database Schema Design	53-1
53.2	Developing Applications for Oracle Sharding	53-1

54 Routing in an SDB Environment

54.1	Direct Routing to a Shard	54-1
54.1.1	About Direct Routing to a Shard	54-1
54.1.2	Sharding APIs	54-2
54.2	Queries and DMLs via Proxy Routing in an SDB	54-7
54.2.1	About Proxy Routing in a Sharded Database	54-7
54.2.2	Oracle Sharding Coordinator	54-8
54.2.3	Querying and DMLs Using Proxy Routing	54-9
54.2.4	Proxy Routing for Single-Shard Queries	54-10
54.2.5	Proxy Routing for Multi-Shard Queries	54-10
54.2.6	Resiliency of Proxy Routing	54-11
54.2.7	Supported Query Shapes in Proxy Routing	54-11

55 Shard-Level High Availability

55.1	About Sharding and Replication	55-1
55.2	Using Oracle Data Guard with an SDB	55-1

56 Sharded Database Deployment

56.1	Introduction to SDB Deployment	56-1
56.2	Oracle Sharding Prerequisites	56-3
56.3	Installing Oracle Database Software	56-3
56.4	Installing the Shard Director Software	56-4
56.5	Creating the Shard Catalog Database	56-5
56.6	Setting Up the Oracle Sharding Management and Routing Tier	56-6
56.7	Creating a System-Managed SDB	56-9
56.7.1	Deploying a System-Managed SDB	56-10

A Support for DBMS_JOB

A.1	Oracle Scheduler Replaces DBMS_JOB	A-1
A.1.1	Configuring DBMS_JOB	A-1
A.1.2	Using Both DBMS_JOB and Oracle Scheduler	A-2
A.2	Moving from DBMS_JOB to Oracle Scheduler	A-2
A.2.1	Creating a Job	A-2
A.2.2	Altering a Job	A-3
A.2.3	Removing a Job from the Job Queue	A-3

Index

Preface

This document describes how to create, configure, and administer an Oracle database.

- [Audience](#)
- [Documentation Accessibility](#)
- [Related Documents](#)
- [Conventions](#)

Audience

This document is intended for database administrators who perform the following tasks:

- Create and configure one or more Oracle databases
- Monitor and tune Oracle databases
- Oversee routine maintenance operations for Oracle databases
- Create and maintain schema objects, such as tables, indexes, and views
- Schedule system and user jobs
- Diagnose, repair, and report problems

To use this document, you should be familiar with relational database concepts. You should also be familiar with the operating system environment under which you are running Oracle Database.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

Related Documents

For more information, see these Oracle resources:

- *Oracle Database 2 Day DBA*
- *Oracle Database Concepts*
- *Oracle Database SQL Language Reference*
- *Oracle Database Reference*
- *Oracle Database PL/SQL Packages and Types Reference*
- *Oracle Automatic Storage Management Administrator's Guide*
- *Oracle Database VLDB and Partitioning Guide*

Many of the examples in this book use the sample schemas. See *Oracle Database Sample Schemas* for information about these schemas.

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
<i>italic</i>	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
<code>monospace</code>	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Changes in This Release for Oracle Database Administrator's Guide

There are changes in this document for recent releases of Oracle Database.

- [Changes in Oracle Database 12c Release 2 \(12.2.0.1\)](#)
- [Changes in Oracle Database 12c Release 1 \(12.1.0.2\)](#)
- [Changes in Oracle Database 12c Release 1 \(12.1.0.1\)](#)

Changes in Oracle Database 12c Release 2 (12.2.0.1)

The following are changes in *Oracle Database Administrator's Guide* for Oracle Database 12c Release 2 (12.2.0.1).

- [New Features](#)

New Features

The following features are new in this release:

- Oracle Sharding

Oracle Sharding is a scalability and availability feature that supports distribution and replication of data across a pool of discrete Oracle databases that share no hardware or software.

See "[Sharded Database Management](#)".

- New features for the Oracle Multitenant option:

- Application containers

An application container is an optional component of a multitenant container database (CDB) that consists of an application root and all of the application PDBs associated with it. An application container stores data for one or more applications.

See "[Application Containers](#)".

- Application common objects

Application common objects are created in an application root and are shared with the application PDBs that belong to the application root.

See "[Managing Application Common Objects](#)".

- Support for thousands of pluggable databases (PDBs) in a single CDB

A CDB can contain up to 4,096 PDBs.

- Use different character sets for PDBs

When the character set of the CDB root is AL32UTF8, any container in the CDB can use a character set that is different from the CDB root and different from other containers in the CDB.

See "[Decide How to Configure the CDB](#)" and *Oracle Database Globalization Support Guide*.

- Relocate a PDB from one CDB to another

A PDB can be relocated in one operation with minimal down time.
See "[Creating a PDB by Relocating It](#)".
- Proxy PDB

A proxy PDB references a PDB in a different CDB and provides fully functional access to the referenced PDB.
See "[Creating a PDB as a Proxy PDB](#)"
- Hot PDB cloning

The source PDB can be in open read/write mode during a PDB clone operation.
See "[Creating a PDB by Cloning an Existing PDB or Non-CDB](#)".
- Rename services during PDB creation

The `SERVICE_NAME_CONVERT` clause of the `CREATE PLUGGABLE DATABASE` statement renames the user-defined services of the new PDB based on the service names of the source PDB.
See "[Renaming a Service](#)".
- Switch to a specific service for a container in a CDB

You can specify a service name in an `ALTER SESSION SET CONTAINER` statement.
See "[Switching to a Container Using the ALTER SESSION Statement](#)".
- Manage the memory usage of PDBs in a CDB

You can configure guarantees and limits for SGA and PGA memory, using PDB initialization parameters.
See "[Initialization Parameters That Control Memory for PDBs](#)".
- Limit the I/O generated by specific PDBs

Two new initialization parameters, `MAX_IOPS` and `MAX_MBPS`, enable you to limit disk I/O generated by a PDB. `MAX_IOPS` limits the number of I/O operations, and `MAX_MBPS` limits the megabytes for I/O operations.
See "[Initialization Parameters That Limit I/O for PDBs](#)".
- PDB performance profiles

You can specify Resource Manager directives for a set of PDBs using PDB performance profiles.
See "[Creating New CDB Resource Plan Directives for a PDB Performance Profile](#)".
- Monitor PDBs managed by Oracle Database Resource Manager

A set of dynamic performance views enables you to monitor the results of your Oracle Database Resource Manager settings for PDBs.

See "[Monitoring PDBs Managed by Oracle Database Resource Manager](#)".

- Prioritize PDB upgrades

You can prioritize the PDBs in a CDB when you upgrade the CDB. The PDBs with higher priority are upgraded before PDBs with lower priority.

See [Oracle Database Upgrade Guide](#).

- CDB undo mode

A CDB can run in local undo mode or shared undo mode. Local undo mode means that every container in the CDB uses local undo. Shared undo mode means that there is one active undo tablespace for a single-instance CDB. For an Oracle RAC CDB, there is one active undo tablespace for each instance.

See "[Managing the CDB Undo Mode](#)".

- Parallelized PDB creation

The PARALLEL clause of the CREATE PLUGGABLE DATABASE statement specifies whether to use parallel execution servers during PDB creation and, optionally, the degree of parallelism.

See "[Parallelize PDB Creation](#)".

- Unplugging PDBs and plugging in PDBs with an archive file

A PDB can be unplugged into compressed archive of the XML file that describes the PDB and the files used by the PDB (such as the data files and wallet file). The archive file has a .pdb extension, and it can be used to plug the PDB into a CDB or application container.

["About Unplugging a PDB"](#) and ["About Plugging In an Unplugged PDB"](#).

- PDB refresh

You can create a PDB as a refreshable clone and refresh the PDB with changes made to the source PDB.

See "[PDB Refresh](#)" and "[Refreshing a PDB](#)".

- Improved support for default tablespace specification during PDB creation

You can specify a default tablespace for a PDB that is created using techniques such as cloning and plugging in the PDB. Previously, a default tablespace could be specified only if the PDB was created from the CDB seed.

See "[Default Tablespace](#)".

- Extended USER_TABLESPACES clause during PDB creation

The creation mode of user tablespaces can be different than the creation mode of the PDB. For example, during PDB creation, the user tablespaces can move a tablespace's files even when file copy is specified for the PDB.

See "[User Tablespaces](#)".

- Improvements to online redefinition of tables:

- In past releases, tables with BFILE columns could not be redefined online. In Oracle Database 12c Release 2 (12.2.0.1), tables with BFILE columns can be redefined online.

- For online table redefinition that did not change the shape of the table, you can enable rollback of a table to return the table to its original definition and preserve DML changes made to the table.

See "[Rolling Back Online Table Redefinition](#)".

- You can refresh dependent fast refreshable materialized views during online table redefinition by setting the `refresh_dep_mviews` parameter to `Y` in the `REDEF_TABLE` procedure or the `START_REDEF_TABLE` procedure.

See "[Refreshing Dependent Materialized Views During Online Table Redefinition](#)".

- Optimize the performance of bulk updates to a table with the `EXECUTE_UPDATE` procedure in the `DBMS_REDEFINITION` package. Performance is optimized because the updates are not logged in the redo log.

See "[Optimizing the Performance of Bulk Updates](#)".

- You can query the `V$ONLINE_REDEF` view to monitor the progress of an online table redefinition operation.

See "[Monitoring Online Table Redefinition Progress](#)".

- When online table redefinition fails, often you can correct the problem that caused the failure and restart the online redefinition process where it last stopped.

See "[Restarting Online Table Redefinition After a Failure](#)".

- Limit PGA usage with Resource Manager

Resource Manager can limit the amount of PGA memory that can be allocated to each session in a particular consumer group.

See "[Program Global Area \(PGA\)](#)".

- Improvements in index compression

You can specify a high level of advanced index compression in addition to the low level available in past releases. The high level of advanced index compression saves more space than the low level.

See "[Creating an Index Using Advanced Index Compression](#)".

- Hybrid Columnar Compression can be enabled for array inserts

Rows inserted with an array insert can be compressed using Hybrid Columnar Compression. In past releases, only rows inserted with a direct-path `INSERT` could be compressed using Hybrid Columnar Compression.

See "[About Table Compression](#)".

- Improvements in table move operations

When the `ONLINE` keyword is included in an `ALTER TABLE MOVE` statement, data manipulation language (DML) operations are supported during the move operation. Also, indexes are usable during the move operation when the `ONLINE` keyword is included and the `UPDATE INDEXES` clause is included.

See "[About Moving a Table to a New Segment or Tablespace](#)".

- New `SYSRAC` administrative privileges for separation of duties

Oracle Database now provides an new administrative privilege for tasks related to Oracle Real Application Clusters (Oracle RAC) operations.

- See "Administrative Privileges".
- New database resident connection pooling parameter for long running transactions

To prevent long running transactions from being rolled back because of the limit specified in the `MAX_THINK_TIME` parameter, the new parameter `MAX_TXN_THINK_TIME` for subprograms in the `DBMS_CONNECTION_POOL` package specifies the maximum amount of time, in seconds, for any sessions with a transaction in progress.

See "[Configuration Parameters for Database Resident Connection Pooling](#)".
- Additional information available about the state of each connection in the database resident connection pool

New columns added to the `V$CPOOL_CONN_INFO` view provide more information about the current state of each connection in the connection pool.

See "[Determining the States of Connections in the Connection Pool](#)".
- Improved monitoring for database links

New views and supplied PL/SQL functions enable you to determine the host name of an outgoing database link, view detailed information about information about incoming database links, and determine the source of high system change number (SCN) activity for incoming database links.

See "[Determining the Host of Outgoing Database Links](#)", "[Determining Information About Incoming Database Links](#)", and "[Determining the Source of High SCN Activity for Incoming Database Links](#)".
- Object quarantine

Object quarantine isolates an object that has raised an error and monitors the object for impacts on the system.

See "[Monitoring Quarantined Objects](#)".
- Delay of instance abort

The `INSTANCE_ABORT_DELAY_TIME` initialization parameter specifies a delay time when an error causes an instance to abort.

See "[Delaying Instance Abort](#)".
- Prespawned processes

Oracle Database can prespawn processes for better client connection performance.

See "[Managing Prespawned Processes](#)".
- Partitioned external tables

For large amounts of data, partitioning for external tables provides fast query performance and enhanced data maintenance.

See "[Partitioning External Tables](#)".

Changes in Oracle Database 12c Release 1 (12.1.0.2)

The following are changes in *Oracle Database Administrator's Guide* for Oracle Database 12c Release 1 (12.1.0.2).

- [New Features](#)

New Features

The following features are new in this release:

- In-Memory Column Store

The In-Memory Column Store (IM column store) is an optional area in the SGA that stores whole tables, table partitions, individual columns, and materialized views in a compressed columnar format. The database uses special techniques to scan columnar data extremely rapidly. The IM column store is a supplement to rather than a replacement for the database buffer cache.

See "[Improving Query Performance with the In-Memory Column Store](#)".

- Data Pump Support for the In-Memory Column Store

Data Pump can keep, override, or drop the In-Memory clause for database objects being imported.

See [Oracle Database In-Memory Guide](#).

- Force full database caching mode

To improve performance, you can force an instance to store the database in the buffer cache.

See "[Using Force Full Database Caching Mode](#)".

- Big Table Cache

The Automatic Big Table Caching feature enables parallel queries to use the buffer cache.

See "[Memory Architecture Overview](#)".

- Attribute-clustered tables

Attribute clustering specifies a directive for heap-organized tables to store data in close proximity on disk, providing performance and data storage benefits. This directive is only applicable for direct path operations, such as a bulk insert or a move operation.

See "[Consider Using Attribute-Clustered Tables](#)".

- Zone maps

A zone is a set of contiguous data blocks on disk. A zone map tracks the minimum and maximum of specified columns for all individual zones. The primary benefit of zone maps is I/O reduction for table scans.

See "[Consider Using Zone Maps](#)".

- Advanced index compression

Advanced index compression results in excellent compression ratios while still providing efficient access to the indexes. Advanced index compression works at the block level to provide the best compression for each block, which means that users do not require knowledge of data characteristics. Advanced index compression automatically chooses the right compression for each block.

See "[Creating an Index Using Advanced Index Compression](#)".

- Preserving the open mode of PDBs when the CDB restarts

You can preserve the open mode of one or more PDBs when the CDB restarts by using the `ALTER PLUGGABLE DATABASE` SQL statement with a `pdb_save_or_discard_state` clause.

See "[Preserving or Discarding the Open Mode of PDBs When the CDB Restarts](#)".

- The `USER_TABLESPACES` clause of the `CREATE PLUGGABLE DATABASE` statement

You can use this clause to separate the data for multiple schemas into different PDBs. For example, when you move a non-CDB to a PDB, and the non-CDB had a number of schemas that each supported different application, you can use this clause to separate the data belonging to each schema into a separate PDB, assuming that each schema used a separate tablespace in the non-CDB.

See "[User Tablespaces](#)".

- Excluding data when cloning a PDB

The `NO DATA` clause of the `CREATE PLUGGABLE DATABASE` statement specifies that a PDB's data model definition is cloned but not the PDB's data.

See "[Excluding Data When Cloning a PDB](#)".

- Default Oracle Managed Files file system directory or Oracle ASM disk group for a PDB's files

The `CREATE_FILE_DEST` clause specifies the default location.

See "[File Location of the New PDB](#)".

- Create a PDB by cloning a non-CDB

You can create a PDB by cloning a non-CDB with a `CREATE PLUGGABLE DATABASE` statement that includes the `FROM` clause.

See "[Creating a PDB by Cloning an Existing PDB or Non-CDB](#)".

- The `logging_clause` of the `CREATE PLUGGABLE DATABASE` and `ALTER PLUGGABLE DATABASE` statement

This clause specifies the logging attribute of the PDB. The logging attribute controls whether certain DML operations are logged in the redo log file (`LOGGING`) or not (`NOLOGGING`).

See "[PDB Tablespace Logging](#)" for information about this clause and the `CREATE PLUGGABLE DATABASE` statement. See "[Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement](#)" for information about this clause and the `ALTER PLUGGABLE DATABASE` statement.

- The `pdb_force_logging_clause` of the `ALTER PLUGGABLE DATABASE` statement

This clause places a PDB into force logging or force nologging mode or takes a PDB out of force logging or force nologging mode.

See "[Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement](#)".

- The `STANDBYS` clause of the `CREATE PLUGGABLE DATABASE` statement

This clause specifies whether the new PDB is included in standby CDBs.

See "[PDB Inclusion in Standby CDBs](#)".

- Querying user-created tables and views across all PDBs

The `CONTAINERS` clause enables you to query user-created tables and views across all PDBs in a CDB.

See [Querying User-Created Tables and Views Across All PDBs](#).

- Oracle Clusterware support for the Diagnosability Framework
Oracle Clusterware uses the Diagnosability Framework and ADR for recording diagnostic trace data and the Clusterware alert log.
See "[ADR in an Oracle Clusterware Environment](#)".
- READ object privilege and READ ANY TABLE system privilege
READ privilege on an object enables a user to select from an object without providing the user with any other privileges.
See "[System and Object Privileges for External Tables](#)" and *Oracle Database Security Guide* for more information.

Changes in Oracle Database 12c Release 1 (12.1.0.1)

The following are changes in *Oracle Database Administrator's Guide* for Oracle Database 12c Release 1 (12.1.0.1).

- [New Features](#)
- [Deprecated Features](#)

New Features

The following features are new in this release:

- Oracle Multitenant option
Oracle Multitenant option enables an Oracle database to function as a multitenant container database (CDB) that includes one or many customer-created pluggable databases (PDBs). A PDB is a portable collection of schemas, schema objects, and nonschema objects that appears to an Oracle Net client as a non-CDB. All Oracle databases before Oracle Database 12c were non-CDBs. You can unplug a PDB from a CDB and plug it into a different CDB.
See [Managing a Multitenant Environment](#).
- Resource Manager support for a multitenant environment
Resource Manager can manage resources on the CDB level and on the PDB level. You can create a CDB resource plan that allocates resources to the entire CDB and to individual PDBs. You can allocate more resources to some PDBs and less to others, or you can specify that all PDBs share resources equally.
See [Using Oracle Resource Manager for PDBs with SQL*Plus](#).
- Full transportable export/import
Full transportable export/import enables you to move a database from one database instance to another. Transporting a database is much faster than other methods that move a database, such as full database export/import. In addition, you can use full transportable export/import to move a non-CDB (or an Oracle Database 11g Release 2 (11.2.0.3) database) into a PDB that is part of a CDB.
See [Transporting Data](#).
- New administrative privileges for separation of duties

Oracle Database now provides administrative privileges for tasks related to Oracle Recovery Manager (Oracle RMAN), Oracle Data Guard, and Transparent Data Encryption. Each new administrative privilege grants the minimum required privileges to complete tasks in each area of administration. The new administrative privileges enable you to avoid granting `SYSDBA` administrative privilege for many common tasks.

See "[Administrative Privileges](#)"

- Database Smart Flash Cache support for multiple flash devices

A database instance can access and combine multiple flash devices for Database Smart Flash Cache without requiring a volume manager.

See "[Database Smart Flash Cache Initialization Parameters](#)".

- Temporary undo

Undo for temporary objects is stored in a temporary tablespace, not in the undo tablespace. Using temporary undo reduces the amount of undo stored in the undo tablespace and the size of the redo log. It also enables data manipulation language (DML) operations on temporary tables in a physical standby database with the Oracle Active Data Guard option.

See "[Managing Temporary Undo](#)". Also, see *Oracle Data Guard Concepts and Administration* for information about the benefits of temporary undo in an Oracle Data Guard environment.

- Move a data file online

You can move a data file when the data file is online and being accessed. This capability simplifies maintenance operations, such as moving data to a different storage device.

See "[Renaming and Relocating Online Data Files](#)".

- Multiple indexes on the same set of columns

You can create multiple indexes on the same set of columns to perform application migrations without dropping an existing index and recreating it with different attributes.

See "[Understand When to Create Multiple Indexes on the Same Set of Columns](#)".

- Move a partition or subpartition online

DML operations can continue to run uninterrupted on a partition or subpartition that is being moved without using online table redefinition.

See "[Moving a Table to a New Segment or Tablespace](#)".

- Online redefinition of a table in one step

You can use the `REDEF_TABLE` procedure in the `DBMS_REDEFINITION` package to perform online redefinition of a table's storage properties in a single call to the procedure.

See "[Performing Online Redefinition with the REDEF_TABLE Procedure](#)".

- Online redefinition of tables with multiple partitions

To minimize downtime when redefining multiple partitions in a table, you can redefine these partitions online in a single session.

See "[Online Redefinition of One or More Partitions](#)".

- Online redefinition of tables with Virtual Private Database (VPD) policies
To minimize downtime, tables with VPD policies can be redefined online.
See "[Handling Virtual Private Database \(VPD\) Policies During Online Redefinition](#)".
- New time limit parameter in the `FINISH_REDEF_TABLE` procedure
The `dml_lock_timeout` parameter in the `FINISH_REDEF_TABLE` procedure in the `DBMS_REDEFINITION` package can specify how long the procedure waits for pending DML to commit.
See step 8 in "[Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION](#)".
- Invisible columns
You can make individual table columns invisible. Any generic access of a table does not show the invisible columns in the table.
See "[Understand Invisible Columns](#)".
- Optimized `ALTER TABLE . . . ADD COLUMN` with default value for nullable columns
A nullable column is a column created without using the `NOT NULL` constraint. For certain types of tables, when adding a nullable column that has a default value, the database can optimize the resource usage and storage requirements for the operation. It does so by storing the default value for the new column as table metadata, avoiding the need to store the value in all existing records.
See "[Adding Table Columns](#)".
- Copy-on-write cloning of a database with CloneDB
When cloning a database with CloneDB, Oracle Database can create the files in a CloneDB database based on copy-on-write technology, so that only the blocks that are modified in the CloneDB database require additional storage on disk.
See "[Cloning a Database with CloneDB](#)".
- DDL log
When the logging of DDL statements is enabled, DDL statements are recorded in a separate DDL log instead of the alert log.
See "[DDL Log](#)".
- Debug log
Some information that can be used to debug a problem is recorded in a separate debug log instead of the alert log.
See "[Debug Log](#)".
- Full-word options for the Server Control (SRVCTL) utility
For improved usability, each SRVCTL utility option is a full word instead of single letter.
See "[SRVCTL Command Reference for Oracle Restart](#)".
- Transaction Guard and Application Continuity
Transaction Guard ensures at-most-once execution of transactions to protect applications from duplicate transaction submissions and associated logical errors.

Transaction Guard enables Application Continuity, which is the ability to replay transactions and continue processing after recoverable communication errors.

See "[Transaction Guard and Application Continuity](#)".

- Enhanced statement queuing

Critical statements can bypass the parallel statement queue. You can set the resource plan directive `PARALLEL_STMT_CRITICAL` to `BYPASS_QUEUE` for a high-priority consumer group so that parallel statements from the consumer group bypass the parallel statement queue.

See "[Creating Resource Plan Directives](#)".

- New Job Types

Several new script jobs have been added that permit running custom user scripts using SQL*Plus, the RMAN interpreter, or a command shell for the computer platform.

See "[Script Jobs](#)".

Deprecated Features

The following features are deprecated in this release and may be unsupported in a future release:

- The `IGNORECASE` argument of `ORAPWD`

To support strong authentication, Oracle recommends that you set `IGNORECASE` to `n` or omit `IGNORECASE` entirely. The default value of this optional `ORAPWD` argument is `n`.

See "[Creating a Database Password File with ORAPWD](#)" for further information.

- Single-character options with Server Control (SRVCTL) utility commands

All SRVCTL commands have been enhanced to accept full-word options instead of the single-letter options. All new SRVCTL command options added in this release support full-word options only and do not have single-letter equivalents. The use of single-character options with SRVCTL commands might be unsupported in a future release.

See "[SRVCTL Command Reference for Oracle Restart](#)" for further information.

- The `FILE_MAPPING` initialization parameter

The `FILE_MAPPING` initialization parameter is deprecated. It is still supported for backward compatibility.

See *Oracle Database Reference* for information about the `FILE_MAPPING` initialization parameter.

- `*_SCHEDULER_CREDENTIALS`

This view continues to be available for backward compatibility.

See "[Specifying Scheduler Job Credentials](#)" for further information.

Oracle Database Upgrade Guide

Part I

Basic Database Administration

Database administrators have specific responsibilities and must understand how to complete database administration tasks.

- **Getting Started with Database Administration**
To get started with database administration, you must understand basic database concepts, such as the types of database users, database security, and privileges. You must also be able to complete basic tasks, such as submitting commands and SQL to the database and creating a password file.
- **Creating and Configuring an Oracle Database**
After you plan your database, you can create the database with a graphical tool or a SQL command.
- **Starting Up and Shutting Down**
When you start up a database, you create an instance of that database and you determine the state of the database. Shutting down a currently running Oracle Database instance can optionally close and dismount a database.
- **Configuring Automatic Restart of an Oracle Database**
Configure your Oracle database with the Oracle Restart feature to automatically restart the database, the listener, and other Oracle components after a hardware or software failure or whenever your database host computer restarts.
- **Managing Processes**
Oracle Databases uses several processes so that multiple users and applications can connect to a single database instance simultaneously.
- **Managing Memory**
Memory management involves maintaining optimal sizes for the Oracle Database instance memory structures as demands on the database change.
- **Managing Users and Securing the Database**
Establish a security policy for every database.
- **Monitoring the Database**
It is important that you monitor the operation of your database on a regular basis. Doing so not only informs you of errors that have not yet come to your attention but also gives you a better understanding of the normal operation of your database. Being familiar with normal behavior in turn helps you recognize when something is wrong.
- **Managing Diagnostic Data**
Oracle Database includes an advanced fault diagnosability infrastructure for collecting and managing diagnostic data. **Diagnostic data** includes the trace files, dumps, and core files that are also present in previous releases, plus new types of diagnostic data that enable customers and Oracle Support to identify, investigate, track, and resolve problems quickly and effectively.

1

Getting Started with Database Administration

To get started with database administration, you must understand basic database concepts, such as the types of database users, database security, and privileges. You must also be able to complete basic tasks, such as submitting commands and SQL to the database and creating a password file.

- [Types of Oracle Database Users](#)
The types of users and their roles and responsibilities depend on the database site. A small site can have one database administrator who administers the database for application developers and users. A very large site can find it necessary to divide the duties of a database administrator among several people and among several areas of specialization.
- [Tasks of a Database Administrator](#)
You must complete several specific tasks to design, implement, and maintain an Oracle Database.
- [SQL Statements](#)
The primary means of communicating with Oracle Database is by submitting SQL statements.
- [Identifying Your Oracle Database Software Release](#)
As many as five numbers may be required to fully identify a release.
- [About Database Administrator Security and Privileges](#)
To perform the administrative tasks of an Oracle Database DBA, you need specific privileges within the database and possibly in the operating system of the server on which the database runs. Ensure that access to a database administrator's account is tightly controlled.
- [Database Administrator Authentication](#)
As a DBA, you often perform special operations such as shutting down or starting up a database. Because only a DBA should perform these operations, the database administrator user names require a secure authentication scheme.
- [Creating and Maintaining a Database Password File](#)
You can create a database password file using the password file creation utility, ORAPWD. For some operating systems, you can create this file as part of your standard installation.
- [Data Utilities](#)
Oracle utilities are available to help you maintain the data in your Oracle Database.

1.1 Types of Oracle Database Users

The types of users and their roles and responsibilities depend on the database site. A small site can have one database administrator who administers the database for application developers and users. A very large site can find it necessary to divide the

duties of a database administrator among several people and among several areas of specialization.

- **Database Administrators**

Each database requires at least one database administrator (DBA). An Oracle Database system can be large and can have many users. Therefore, database administration is sometimes not a one-person job, but a job for a group of DBAs who share responsibility.

- **Security Officers**

In some cases, a site assigns one or more security officers to a database. A security officer enrolls users, controls and monitors user access to the database, and maintains system security.

- **Network Administrators**

Some sites have one or more network administrators. A network administrator, for example, administers Oracle networking products, such as Oracle Net Services.

- **Application Developers**

Application developers design and implement database applications.

- **Application Administrators**

An Oracle Database site can assign one or more application administrators to administer a particular application. Each application can have its own administrator.

- **Database Users**

Database users interact with the database through applications or utilities.

1.1.1 Database Administrators

Each database requires at least one database administrator (DBA). An Oracle Database system can be large and can have many users. Therefore, database administration is sometimes not a one-person job, but a job for a group of DBAs who share responsibility.

A database administrator's responsibilities can include the following tasks:

- Installing and upgrading the Oracle Database server and application tools
- Allocating system storage and planning future storage requirements for the database system
- Creating primary database storage structures (tablespaces) after application developers have designed an application
- Creating primary objects (tables, views, indexes) once application developers have designed an application
- Modifying the database structure, as necessary, from information given by application developers
- Enrolling users and maintaining system security
- Ensuring compliance with Oracle license agreements
- Controlling and monitoring user access to the database
- Monitoring and optimizing the performance of the database
- Planning for backup and recovery of database information
- Maintaining archived data on tape

- Backing up and restoring the database
- Contacting Oracle for technical support

1.1.2 Security Officers

In some cases, a site assigns one or more security officers to a database. A security officer enrolls users, controls and monitors user access to the database, and maintains system security.

As a DBA, you might not be responsible for these duties if your site has a separate security officer.

See *Oracle Database Security Guide* for information about the duties of security officers.

1.1.3 Network Administrators

Some sites have one or more network administrators. A network administrator, for example, administers Oracle networking products, such as Oracle Net Services.

See *Oracle Database Net Services Administrator's Guide* for information about the duties of network administrators.

See Also:

[Distributed Database Management](#), for information on network administration in a distributed environment

1.1.4 Application Developers

Application developers design and implement database applications.

Their responsibilities include the following tasks:

- Designing and developing the database application
- Designing the database structure for an application
- Estimating storage requirements for an application
- Specifying modifications of the database structure for an application
- Relaying this information to a database administrator
- Tuning the application during development
- Establishing security measures for an application during development

Application developers can perform some of these tasks in collaboration with DBAs. See *Oracle Database Development Guide* for information about application development tasks.

1.1.5 Application Administrators

An Oracle Database site can assign one or more application administrators to administer a particular application. Each application can have its own administrator.

1.1.6 Database Users

Database users interact with the database through applications or utilities.

A typical user's responsibilities include the following tasks:

- Entering, modifying, and deleting data, where permitted
- Generating reports from the data

1.2 Tasks of a Database Administrator

You must complete several specific tasks to design, implement, and maintain an Oracle Database.

 **Note:**

When upgrading to a new release, back up your existing production environment, both software and database, before installation. For information on preserving your existing production database, see *Oracle Database Upgrade Guide*.

- **Task 1: Evaluate the Database Server Hardware**
Evaluate how Oracle Database and its applications can best use the available computer resources.
- **Task 2: Install the Oracle Database Software**
As the database administrator, you install the Oracle Database server software and any front-end tools and database applications that access the database.
- **Task 3: Plan the Database**
As the database administrator, you must plan the logical storage structure of the database, the overall database design, and a backup strategy for the database.
- **Task 4: Create and Open the Database**
After you complete the database design, you can create the database and open it for normal use.
- **Task 5: Back Up the Database**
After you create the database structure, perform the backup strategy you planned for the database.
- **Task 6: Enroll System Users**
After you back up the database structure, you can enroll the users of the database in accordance with your Oracle license agreement, and grant appropriate privileges and roles to these users.

- [Task 7: Implement the Database Design](#)
After you create and start the database, and enroll the system users, you can implement the planned logical structure database by creating all necessary tablespaces. When you have finished creating tablespaces, you can create the database objects.
- [Task 8: Back Up the Fully Functional Database](#)
When the database is fully implemented, again back up the database. In addition to regularly scheduled backups, you should always back up your database immediately after implementing changes to the database structure.
- [Task 9: Tune Database Performance](#)
Optimizing the performance of the database is one of your ongoing responsibilities as a DBA. Oracle Database provides a database resource management feature that helps you to control the allocation of resources among various user groups.
- [Task 10: Download and Install Patches](#)
After installation and on a regular basis, download and install patches.
- [Task 11: Roll Out to Additional Hosts](#)
After you have an Oracle Database installation properly configured, tuned, patched, and tested, you may want to roll that exact installation out to other hosts.

1.2.1 Task 1: Evaluate the Database Server Hardware

Evaluate how Oracle Database and its applications can best use the available computer resources.

This evaluation should reveal the following information:

- How many disk drives are available to the Oracle products
- How many, if any, dedicated tape drives are available to Oracle products
- How much memory is available to the instances of Oracle Database you will run (see your system configuration documentation)

1.2.2 Task 2: Install the Oracle Database Software

As the database administrator, you install the Oracle Database server software and any front-end tools and database applications that access the database.

In some distributed processing installations, the database is controlled by a central computer (database server) and the database tools and applications are executed on remote computers (clients). In this case, you must also install the Oracle Net components necessary to connect the remote systems to the computer that executes Oracle Database.

For more information on what software to install, see "[Identifying Your Oracle Database Software Release](#)".

 **See Also:**

For specific requirements and instructions for installation, see the following documentation:

- The Oracle documentation specific to your operating system
- The installation guides for your front-end tools and Oracle Net drivers

1.2.3 Task 3: Plan the Database

As the database administrator, you must plan the logical storage structure of the database, the overall database design, and a backup strategy for the database.

It is important to plan how the logical storage structure of the database will affect system performance and various database management operations. For example, before creating any tablespaces for your database, you should know how many data files will comprise the tablespace, what type of information will be stored in each tablespace, and on which disk drives the data files will be physically stored. When planning the overall logical storage of the database structure, take into account the effects that this structure will have when the database is actually created and running. Consider how the logical storage structure of the database will affect:

- The performance of the computer running Oracle Database
- The performance of the database during data access operations
- The efficiency of backup and recovery procedures for the database

Plan the relational design of the database objects and the storage characteristics for each of these objects. By planning the relationship between each object and its physical storage before creating it, you can directly affect the performance of the database as a unit. Be sure to plan for the growth of the database.

In distributed database environments, this planning stage is extremely important. The physical location of frequently accessed data dramatically affects application performance.

During the planning stage, develop a backup strategy for the database. You can alter the logical storage structure or design of the database to improve backup efficiency.

It is beyond the scope of this book to discuss relational and distributed database design. If you are not familiar with such design issues, see accepted industry-standard documentation.

[Oracle Database Structure and Storage](#), and [Schema Objects](#), provide specific information on creating logical storage structures, objects, and integrity constraints for your database.

1.2.4 Task 4: Create and Open the Database

After you complete the database design, you can create the database and open it for normal use.

You can create a database at installation time, using the Database Configuration Assistant, or you can supply your own scripts for creating a database.

See [Creating and Configuring an Oracle Database](#), for information on creating a database and [Starting Up and Shutting Down](#) for guidance in starting up the database.

1.2.5 Task 5: Back Up the Database

After you create the database structure, perform the backup strategy you planned for the database.

Create any additional redo log files, take the first full database backup (online or offline), and schedule future database backups at regular intervals.

 **See Also:**

Oracle Database Backup and Recovery User's Guide

1.2.6 Task 6: Enroll System Users

After you back up the database structure, you can enroll the users of the database in accordance with your Oracle license agreement, and grant appropriate privileges and roles to these users.

See [Managing Users and Securing the Database](#) for guidance in this task.

1.2.7 Task 7: Implement the Database Design

After you create and start the database, and enroll the system users, you can implement the planned logical structure database by creating all necessary tablespaces. When you have finished creating tablespaces, you can create the database objects.

[Oracle Database Structure and Storage](#) and [Schema Objects](#) provide information on creating logical storage structures and objects for your database.

1.2.8 Task 8: Back Up the Fully Functional Database

When the database is fully implemented, again back up the database. In addition to regularly scheduled backups, you should always back up your database immediately after implementing changes to the database structure.

1.2.9 Task 9: Tune Database Performance

Optimizing the performance of the database is one of your ongoing responsibilities as a DBA. Oracle Database provides a database resource management feature that helps you to control the allocation of resources among various user groups.

The database resource manager is described in [Managing Resources with Oracle Database Resource Manager](#).

 **See Also:**

Oracle Database Performance Tuning Guide for information about tuning your database and applications

1.2.10 Task 10: Download and Install Patches

After installation and on a regular basis, download and install patches.

Patches are available as single interim patches and as patchsets (or **patch releases**). Interim patches address individual software bugs and may or may not be needed at your installation. Patch releases are collections of bug fixes that are applicable for all customers. Patch releases have release numbers. For example, if you installed Oracle Database 12c Release 1 (12.1.0.1), then the first patch release will have a release number of 12.1.0.2.

 **See Also:**

Oracle Database Installation Guide for your platform for instructions on downloading and installing patches.

1.2.11 Task 11: Roll Out to Additional Hosts

After you have an Oracle Database installation properly configured, tuned, patched, and tested, you may want to roll that exact installation out to other hosts.

Reasons to do this include the following:

- You have multiple production database systems.
- You want to create development and test systems that are identical to your production system.

Instead of installing, tuning, and patching on each additional host, you can clone your tested Oracle Database installation to other hosts, saving time and avoiding inconsistencies. There are two types of cloning available to you:

- Cloning an Oracle home—Just the configured and patched binaries from the Oracle home directory and subdirectories are copied to the destination host and "fixed" to match the new environment. You can then start an instance with this cloned home and create a database.

You can use Oracle Enterprise Manager Cloud Control to clone an Oracle home to one or more destination hosts. You can manually clone an Oracle home using a set of provided scripts and Oracle Universal Installer.

- Cloning a database—The tuned database, including database files, initialization parameters, and so on, are cloned to an existing Oracle home (possibly a cloned home).

You can use Cloud Control to clone an Oracle database instance to an existing Oracle home.

See Also:

- [Oracle Universal Installer and OPatch User's Guide for Windows and UNIX](#) for information about cloning Oracle software
- The Cloud Control online help for instructions for cloning a database
- "[Cloning a Database with CloneDB](#)"
- "[Creating a PDB by Cloning an Existing PDB or Non-CDB](#)"

1.3 SQL Statements

The primary means of communicating with Oracle Database is by submitting SQL statements.

- [Submitting Commands and SQL to the Database](#)

There are several ways to submit SQL statements and commands to Oracle Database.

- [About SQL*Plus](#)

SQL*Plus is the primary command-line interface to your Oracle database. You use SQL*Plus to start up and shut down the database, set database initialization parameters, create and manage users, create and alter database objects (such as tables and indexes), insert and update data, run SQL queries, and more.

- [Connecting to the Database with SQL*Plus](#)

When you connect with SQL*Plus, you are connecting to the Oracle instance.

1.3.1 Submitting Commands and SQL to the Database

There are several ways to submit SQL statements and commands to Oracle Database.

- Directly, using the command-line interface of SQL*Plus

- Indirectly, using a graphical user interface, such as Oracle Enterprise Manager Database Express (EM Express) or Oracle Enterprise Manager Cloud Control (Cloud Control)

With these tools, you use an intuitive graphical interface to administer the database, and the tool submits SQL statements and commands behind the scenes.

See *Oracle Database 2 Day DBA* and the online help for the tool for more information.

- Directly, using SQL Developer

Developers use SQL Developer to create and test database schemas and applications, although you can also use it for database administration tasks.

See *Oracle SQL Developer User's Guide* for more information.

Oracle Database also supports a superset of SQL, which includes commands for starting up and shutting down the database, modifying database configuration, and so on.

1.3.2 About SQL*Plus

SQL*Plus is the primary command-line interface to your Oracle database. You use SQL*Plus to start up and shut down the database, set database initialization parameters, create and manage users, create and alter database objects (such as tables and indexes), insert and update data, run SQL queries, and more.

Before you can submit SQL statements and commands, you must connect to the database. With SQL*Plus, you can connect locally or remotely. **Connecting locally** means connecting to an Oracle database running on the same computer on which you are running SQL*Plus. **Connecting remotely** means connecting over a network to an Oracle database that is running on a remote computer. Such a database is referred to as a **remote database**. The SQL*Plus executable on the local computer is provided by a full Oracle Database installation, an Oracle Client installation, or an Instant Client installation.

 **See Also:**

*SQL*Plus User's Guide and Reference*

1.3.3 Connecting to the Database with SQL*Plus

When you connect with SQL*Plus, you are connecting to the Oracle instance.

- [About Connecting to the Database with SQL*Plus](#)
Oracle Database includes the following components: the Oracle Database instance, which is a collection of processes and memory, and a set of disk files that contain user data and system data.
- [Step 1: Open a Command Window](#)
Take the necessary action on your platform to open a window into which you can enter operating system commands.
- [Step 2: Set Operating System Environment Variables](#)
Depending on your platform, you may have to set environment variables before starting SQL*Plus, or at least verify that they are set properly.
- [Step 3: Start SQL*Plus](#)
Start SQL*Plus.
- [Step 4: Submit the SQL*Plus CONNECT Command](#)
Submit the SQL*Plus CONNECT command to initially connect to the Oracle database instance or at any time to reconnect as a different user.

1.3.3.1 About Connecting to the Database with SQL*Plus

Oracle Database includes the following components: the Oracle Database instance, which is a collection of processes and memory, and a set of disk files that contain user data and system data.

Each instance has an instance ID, also known as a system ID (SID). Because there can be multiple Oracle instances on a host computer, each with its own set of data files, you must identify the instance to which you want to connect. For a local

connection, you identify the instance by setting operating system environment variables. For a remote connection, you identify the instance by specifying a network address and a database service name. For both local and remote connections, you must set environment variables to help the operating system find the SQL*Plus executable and to provide the executable with a path to its support files and scripts.

 **See Also:**

Oracle Database Concepts for background information about the Oracle instance

1.3.3.2 Step 1: Open a Command Window

Take the necessary action on your platform to open a window into which you can enter operating system commands.

- Open a command window.

1.3.3.3 Step 2: Set Operating System Environment Variables

Depending on your platform, you may have to set environment variables before starting SQL*Plus, or at least verify that they are set properly.

For example, on most platforms, `ORACLE_SID` and `ORACLE_HOME` must be set. In addition, it is advisable to set the `PATH` environment variable to include the `ORACLE_HOME/bin` directory. Some platforms may require additional environment variables:

- On the UNIX and Linux platforms, set environment variables by entering operating system commands.
- On the Windows platform, Oracle Universal Installer (OUI) automatically assigns values to `ORACLE_HOME` and `ORACLE_SID` in the Windows registry.

If you did not create a database upon installation, OUI does not set `ORACLE_SID` in the registry; after you create your database at a later time, you must set the `ORACLE_SID` environment variable from a command window.

UNIX and Linux installations come with two scripts, `oraenv` and `coraenv`, that you can use to easily set environment variables. For more information, see *Administrator's Reference for UNIX Systems*.

For all platforms, when switching between instances with different Oracle homes, you must change the `ORACLE_HOME` environment variable. If multiple instances share the same Oracle home, you must change only `ORACLE_SID` when switching instances.

See the *Oracle Database Installation Guide* or administration guide for your operating system for details on environment variables and for information on switching instances.

Example 1-1 Setting Environment Variables in UNIX (C Shell)

```
setenv ORACLE_SID orcl
setenv ORACLE_HOME /u01/app/oracle/product/12.1.0/db_1
setenv LD_LIBRARY_PATH $ORACLE_HOME/lib:/usr/lib:/usr/dt/lib:/usr/openwin/lib:/usr/ccs/lib
```

Example 1-2 Setting Environment Variables in Windows

```
SET ORACLE_SID=orawin2
```

Example 1-2 assumes that `ORACLE_HOME` and `ORACLE_SID` are set in the registry but that you want to override the registry value of `ORACLE_SID` to connect to a different instance.

On Windows, environment variable values that you set in a command prompt window override the values in the registry.

1.3.3.4 Step 3: Start SQL*Plus

Start SQL*Plus.

1. Do one of the following:

- Ensure that the `PATH` environment variable contains `ORACLE_HOME/bin`.
- Change directory to `ORACLE_HOME/bin`.

2. Enter the following command (case-sensitive on UNIX and Linux):

```
sqlplus /nolog
```

1.3.3.5 Step 4: Submit the SQL*Plus CONNECT Command

Submit the SQL*Plus CONNECT command to initially connect to the Oracle database instance or at any time to reconnect as a different user.

- In SQL*Plus, submit the CONNECT command.

Example 1-3 Connecting to a Local Database User

This simple example connects to a local database as user `SYSTEM`. SQL*Plus prompts for the `SYSTEM` user password.

```
connect system
```

Example 1-4 Connecting to a Local Database User with SYSDBA Privilege

This example connects to a local database as user `SYS` with the `SYSDBA` privilege. SQL*Plus prompts for the `SYS` user password.

```
connect sys as sysdba
```

When connecting as user `SYS`, you must connect AS `SYSDBA`.

Example 1-5 Connecting to a Local Database User with SYSBACKUP Privilege

This example connects to a local database as user `SYSBACKUP` with the `SYSBACKUP` privilege. SQL*Plus prompts for the `SYSBACKUP` user password.

```
connect sysbackup as sysbackup
```

When connecting as user SYSBACKUP, you must connect AS SYSBACKUP.

Example 1-6 Connecting Locally with SYSDBA Privilege with Operating System Authentication

This example connects locally with the SYSDBA privilege with operating system authentication.

```
connect / as sysdba
```

Example 1-7 Connecting with Easy Connect Syntax

This example uses easy connect syntax to connect as user salesadmin to a remote database running on the host dbhost.example.com. The Oracle Net listener (the listener) is listening on the default port (1521). The database service is sales.example.com. SQL*Plus prompts for the salesadmin user password.

```
connect salesadmin@"dbhost.example.com/sales.example.com"
```

Example 1-8 Connecting with Easy Connect Syntax with the Service Handler Type Indicated

This example is identical to [Example 1-7](#), except that the service handler type is indicated.

```
connect salesadmin@"dbhost.example.com/sales.example.com:dedicated"
```

Example 1-9 Connecting with Easy Connect Syntax with a Nondefault Listener Port

This example is identical to [Example 1-7](#), except that the listener is listening on the nondefault port number 1522.

```
connect salesadmin@"dbhost.example.com:1522/sales.example.com"
```

Example 1-10 Connecting with Easy Connect Syntax with the Host IP Address

This example is identical to [Example 1-7](#), except that the host IP address is substituted for the host name.

```
connect salesadmin@"192.0.2.5/sales.example.com"
```

Example 1-11 Connecting with an IPv6 Address

This example connects using an IPv6 address. Note the enclosing square brackets.

```
connect salesadmin@"[2001:0DB8:0:0::200C:417A]/sales.example.com"
```

Example 1-12 Connecting by Specifying an Instance

This example specifies the instance to which to connect and omits the database service name. Note that when you specify only the instance, you cannot specify the service handler type.

```
connect salesadmin@"dbhost.example.com/orcl"
```

Example 1-13 Connecting with a Net Service Name

This example connects remotely as user salesadmin to the database service designated by the net service name sales1. SQL*Plus prompts for the salesadmin user password.

```
connect salesadmin@sales1
```

Example 1-14 Connecting with External Authentication

This example connects remotely with external authentication to the database service designated by the net service name sales1.

```
connect /@sales1
```

Example 1-15 Connecting with SYSDBA Privilege and External Authentication

This example connects remotely with the SYSDBA privilege and with external authentication to the database service designated by the net service name sales1.

```
connect /@sales1 as sysdba
```

Example 1-16 Connecting as a User with a Service Name

This example connects remotely as user salesadmin to the database service designated by the net service name sales1. The database session starts in the rev21 edition. SQL*Plus prompts for the salesadmin user password.

```
connect salesadmin@sales1 edition=rev21
```

 **Note:**

If you come across any issues while connecting to the database as a user with the SYSDBA privileges, then refer to My Oracle Support Notes 69642.1, 233223.1, 18089.1, and 747456.1.

- [Syntax of the SQL*Plus CONNECT Command](#)

Use the SQL*Plus CONNECT command to initially connect to the Oracle instance or to reconnect to the Oracle instance.

1.3.3.5.1 Syntax of the SQL*Plus CONNECT Command

Use the SQL*Plus CONNECT command to initially connect to the Oracle instance or to reconnect to the Oracle instance.

Syntax

```
CONN[ECT] [logon] [AS {SYSOPER | SYSDBA | SYSBACKUP | SYSDG | SYSKM | SYSRAC}]
```

The syntax of *logon* is as follows:

```
{username | /}@{connect_identifier} [edition={edition_name | DATABASE_DEFAULT}]
```

When you provide the *username*, SQL*Plus prompts for a password. The password is not echoed as you type it.

The following table describes the syntax components of the CONNECT command.

Syntax Component	Description
/	Calls for external authentication of the connection request. A database password is not used in this type of authentication. The most common form of external authentication is operating system authentication, where the database user is authenticated by having logged in to the host operating system with a certain host user account. External authentication can also be performed with an Oracle wallet or by a network service. See <i>Oracle Database Security Guide</i> for more information. See also " Using Operating System Authentication ".
AS {SYSOPER SYSDBA SYSBACKUP SYSDG SYSKM SYSRAC}	Indicates that the database user is connecting with an administrative privilege. Only certain predefined administrative users or users who have been added to the password file may connect with these privileges. See " Administrative Privileges " for more information.
username	A valid database user name. The database authenticates the connection request by matching <i>username</i> against the data dictionary and prompting for a user password.
connect_identifier (1)	An Oracle Net connect identifier, for a remote connection. The exact syntax depends on the Oracle Net configuration. If omitted, SQL*Plus attempts connection to a local instance. A common connect identifier is a <i>net service name</i> . This is an alias for an Oracle Net connect descriptor (network address and database service name). The alias is typically resolved in the <i>tnsnames.ora</i> file on the local computer, but can be resolved in other ways. See <i>Oracle Database Net Services Administrator's Guide</i> for more information on connect identifiers.

Syntax Component	Description
<i>connect_identifier</i> (2)	<p>As an alternative, a connect identifier can use <i>easy connect</i> syntax.</p> <p>Easy connect provides out-of-the-box TCP/IP connectivity for remote databases without having to configure Oracle Net Services on the client (local) computer.</p> <p>Easy connect syntax for the connect identifier is as follows (the enclosing double-quotes must be included):</p> <pre>"host[:port][/:service_name][:server][/:instance_name]"</pre> <p>where:</p> <ul style="list-style-type: none"> • <i>host</i> is the host name or IP address of the computer hosting the remote database. Both IP version 4 (IPv4) and IP version 6 (IPv6) addresses are supported. IPv6 addresses must be enclosed in square brackets. See <i>Oracle Database Net Services Administrator's Guide</i> for information about IPv6 addressing. • <i>port</i> is the TCP port on which the Oracle Net listener on <i>host</i> listens for database connections. If omitted, 1521 is assumed. • <i>service_name</i> is the database service name to which to connect. It can be omitted if the Net Services listener configuration on the remote host designates a default service. If no default service is configured, then <i>service_name</i> must be supplied. Each database typically offers a standard service with a name equal to the global database name, which is made up of the DB_NAME and DB_DOMAIN initialization parameters as follows: <pre>DB_NAME.DB_DOMAIN</pre> <p>If DB_DOMAIN is null, then the standard service name is just the DB_NAME. For example, if DB_NAME is orcl and DB_DOMAIN is us.example.com, then the standard service name is orcl.us.example.com.</p> <p>See "Managing Application Workloads with Database Services" for more information.</p> <ul style="list-style-type: none"> • <i>server</i> is the type of service handler. Acceptable values are dedicated, shared, and pooled. If omitted, then the default type of server is chosen by the listener: shared server if configured, otherwise dedicated server. • <i>instance_name</i> is the instance to which to connect. You can specify both service name and instance name, which you would typically do only for Oracle Real Application Clusters (Oracle RAC) environments. For Oracle RAC or single instance environments, if you specify only instance name, then you connect to the default database service. If there is no default service configured in the listener.ora file, then an error is generated. You can obtain the instance name from the INSTANCE_NAME initialization parameter. <p>See <i>Oracle Database Net Services Administrator's Guide</i> for more information on easy connect.</p>
<i>edition</i> ={ <i>edition_name</i> DATABASE_DEFAULT}	<p>Specifies the edition in which the new database session starts. If you specify an edition, then it must exist, and you must have the USE privilege on it. If this clause is not specified, then the database default edition is used for the session.</p> <p>See <i>Oracle Database Development Guide</i> for information on editions and edition-based redefinition.</p>

1.4 Identifying Your Oracle Database Software Release

As many as five numbers may be required to fully identify a release.

Because Oracle Database continues to evolve and can require maintenance, Oracle periodically produces new releases. Not all customers initially subscribe to a new release or require specific maintenance for their existing release. As a result, multiple releases of the product exist simultaneously.

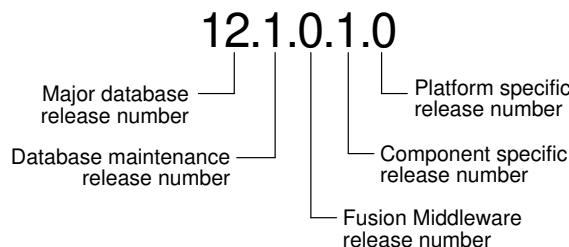

- [Release Number Format](#)
Oracle Database release numbers conform to a specific format.
- [Checking Your Current Release Number](#)
To identify the release of Oracle Database that is currently installed and to see the release levels of other database components you are using, query the data dictionary view `PRODUCT_COMPONENT_VERSION`.

1.4.1 Release Number Format

Oracle Database release numbers conform to a specific format.

To understand the release nomenclature used by Oracle, examine the following example of an Oracle Database release labeled "12.1.0.1.0".

Figure 1-1 Example of an Oracle Database Release Number

- **Major Database Release Number**
The first numeral is the most general identifier. It represents a major new version of the software that contains significant new functionality.
- **Database Maintenance Release Number**
The second numeral represents a maintenance release level. Some new features may also be included.
- **Fusion Middleware Release Number**
The third numeral reflects the release level of Oracle Fusion Middleware.
- **Component-Specific Release Number**
The fourth numeral identifies a release level specific to a component. Different components can have different numbers in this position depending upon, for example, component patch sets or interim releases.
- **Platform-Specific Release Number**
The fifth numeral identifies a platform-specific release. Usually this is a patch set. When different platforms require the equivalent patch set, this numeral will be the same across the affected platforms.

1.4.1.1 Major Database Release Number

The first numeral is the most general identifier. It represents a major new version of the software that contains significant new functionality.

1.4.1.2 Database Maintenance Release Number

The second numeral represents a maintenance release level. Some new features may also be included.

1.4.1.3 Fusion Middleware Release Number

The third numeral reflects the release level of Oracle Fusion Middleware.

1.4.1.4 Component-Specific Release Number

The fourth numeral identifies a release level specific to a component. Different components can have different numbers in this position depending upon, for example, component patch sets or interim releases.

1.4.1.5 Platform-Specific Release Number

The fifth numeral identifies a platform-specific release. Usually this is a patch set. When different platforms require the equivalent patch set, this numeral will be the same across the affected platforms.

1.4.2 Checking Your Current Release Number

To identify the release of Oracle Database that is currently installed and to see the release levels of other database components you are using, query the data dictionary view `PRODUCT_COMPONENT_VERSION`.

A sample query follows. (You can also query the `V$VERSION` view to see component-level information.) Other product release levels may increment independent of the database server.

```
COL PRODUCT FORMAT A40
COL VERSION FORMAT A15
COL STATUS FORMAT A15
SELECT * FROM PRODUCT_COMPONENT_VERSION;

PRODUCT          VERSION      STATUS
-----           -----
NLSRTL           12.1.0.0.1  Production
Oracle Database 12c Enterprise Edition 12.1.0.0.1  Production
PL/SQL            12.1.0.0.1  Production
...

```

It is important to convey to Oracle the results of this query when you report problems with the software.

1.5 About Database Administrator Security and Privileges

To perform the administrative tasks of an Oracle Database DBA, you need specific privileges within the database and possibly in the operating system of the server on which the database runs. Ensure that access to a database administrator's account is tightly controlled.

- [The Database Administrator's Operating System Account](#)
To perform many of the administrative duties for a database, you must be able to execute operating system commands.
- [Administrative User Accounts](#)
Oracle Database provides several administrative user accounts that are associated with administrative privileges.

1.5.1 The Database Administrator's Operating System Account

To perform many of the administrative duties for a database, you must be able to execute operating system commands.

Depending on the operating system on which Oracle Database is running, you might need an operating system account or ID to gain access to the operating system. If so, your operating system account might require operating system privileges or access rights that other database users do not require (for example, to perform Oracle Database software installation). Although you do not need the Oracle Database files to be stored in your account, you should have access to them.

See Also:

Your operating system-specific Oracle documentation. The method of creating the account of the database administrator is specific to the operating system.

1.5.2 Administrative User Accounts

Oracle Database provides several administrative user accounts that are associated with administrative privileges.

- [About Administrative User Accounts](#)
Administrative user accounts have special privileges required to administer areas of the database, such as the CREATE ANY TABLE or ALTER SESSION privilege, or EXECUTE privileges on packages owned by the SYS schema.
- [SYS](#)
When you create an Oracle database, the user SYS is automatically created with all the privileges.
- [SYSTEM](#)
When you create an Oracle database, the user SYSTEM is also automatically created and granted the DBA role.
- [SYSPACKUP, SYSDG, SYSKM, and SYSRAC](#)
When you create an Oracle database, the following users are automatically created to facilitate separation of duties for database administrators: SYSPACKUP, SYSDG, SYSKM, and SYSRAC.
- [The DBA Role](#)
A predefined DBA role is automatically created with every Oracle Database installation. This role contains most database system privileges. Therefore, the DBA role should be granted only to actual database administrators.

1.5.2.1 About Administrative User Accounts

Administrative user accounts have special privileges required to administer areas of the database, such as the CREATE ANY TABLE or ALTER SESSION privilege, or EXECUTE privileges on packages owned by the SYS schema.

The following administrative user accounts are automatically created when Oracle Database is installed:

- SYS
- SYSTEM
- SYSPACKUP
- SYSDG
- SYSKM
- SYSRAC

 **Note:**

Both Oracle Universal Installer (OUI) and Database Configuration Assistant (DBCA) now prompt for SYS and SYSTEM passwords and do not accept the default passwords "change_on_install" or "manager", respectively.

If you create the database manually, then Oracle strongly recommends that you specify passwords for SYS and SYSTEM at database creation time, rather than using these default passwords. See "[Protecting Your Database: Specifying Passwords for Users SYS and SYSTEM](#)" for more information.

Create at least one additional administrative user and grant to that user an appropriate administrative role to use when performing daily administrative tasks. Do not use `SYS` and `SYSTEM` for these purposes.

 **Note:**

In this release of Oracle Database and in subsequent releases, several enhancements are being made to ensure the security of default database user accounts. You can find a security checklist for this release in *Oracle Database Security Guide*. Oracle recommends that you read this checklist and configure your database accordingly.

1.5.2.2 SYS

When you create an Oracle database, the user `SYS` is automatically created with all the privileges.

All of the base tables and views for the database data dictionary are stored in the schema `SYS`. These base tables and views are critical for the operation of Oracle Database. To maintain the integrity of the data dictionary, tables in the `SYS` schema are manipulated only by the database. They should never be modified by any user or database administrator, and no one should create any tables in the schema of user `SYS`. (However, you can change the storage parameters of the data dictionary settings if necessary.)

Ensure that most database users are never able to connect to Oracle Database using the `SYS` account.

1.5.2.3 SYSTEM

When you create an Oracle database, the user `SYSTEM` is also automatically created and granted the `DBA` role.

The `SYSTEM` user name is used to create additional tables and views that display administrative information, and internal tables and views used by various Oracle Database options and tools. Never use the `SYSTEM` schema to store tables of interest to non-administrative users.

1.5.2.4 SYSBACKUP, SYSDG, SYSKM, and SYSRAC

When you create an Oracle database, the following users are automatically created to facilitate separation of duties for database administrators: `SYSBACKUP`, `SYSDG`, `SYSKM`, and `SYSRAC`.

These users separate duties in the following ways:

- `SYSBACKUP` facilitates Oracle Recovery Manager (RMAN) backup and recovery operations either from RMAN or SQL*Plus.
- `SYSDG` facilitates Data Guard operations. The user can perform operations either with Data Guard Broker or with the `DGMGR` command-line interface.
- `SYSKM` facilitates Transparent Data Encryption keystore operations.

- **SYSRAC** facilitates Oracle Real Application Clusters (Oracle RAC) operations by connecting to the database by the Clusterware agent on behalf of Oracle RAC utilities such as SRVCTL.

The **SYSRAC** administrative privilege cannot be granted to database users and is not supported in a password file. The **SYSRAC** administrative privilege is used only by the Oracle agent of Oracle Clusterware to connect to the database using operating system authentication.

Each of these accounts provides a designated user for the new administrative privilege with the same name. Specifically, the **SYSBACKUP** account provides a designated user for the **SYSBACKUP** administrative privilege. The **SYSDG** account provides a designated user for the **SYSDG** administrative privilege. The **SYSKM** account provides a designated user for the **SYSKM** administrative privilege.

Create a user and grant to that user an appropriate administrative privilege to use when performing daily administrative tasks. Doing so enables you to manage each user account separately, and each user account can have a distinct password. Do not use the **SYSBACKUP**, **SYSDG**, or **SYSKM** user account for these purposes. These accounts are locked by default and should remain locked.

To use one of these administrative privileges, a user must exercise the privilege when connecting by specifying AS **SYSBACKUP**, AS **SYSDG**, or AS **SYSKM**. If the authentication succeeds, then the user is connected with a session in which the administrative privilege is enabled. In this case, the session user is the corresponding administrative user account. For example, if user **bradmin** connects with the AS **SYSBACKUP** administrative privilege, then the session user is **SYSBACKUP**.

 **Note:**

The **SYSBACKUP**, **SYSDG**, **SYSKM**, and **SYSRAC** user accounts cannot be dropped.

 **See Also:**

- ["Administrative Privileges"](#)
- [Oracle Database Security Guide](#)

1.5.2.5 The DBA Role

A predefined **DBA** role is automatically created with every Oracle Database installation. This role contains most database system privileges. Therefore, the **DBA** role should be granted only to actual database administrators.

 **Note:**

The DBA role does not include the SYSDBA, SYSOPER, SYSBACKUP, SYSDG, or SYSKM system privileges. These are special administrative privileges that allow an administrator to perform basic database administration tasks, such as creating the database and instance startup and shutdown. These administrative privileges are discussed in "[Administrative Privileges](#)".

 **See Also:**

- [Oracle Database Security Guide](#) for more information about administrative user accounts
- ["Using Password File Authentication"](#)

1.6 Database Administrator Authentication

As a DBA, you often perform special operations such as shutting down or starting up a database. Because only a DBA should perform these operations, the database administrator user names require a secure authentication scheme.

- [Administrative Privileges](#)
Administrative privileges that are required for an administrator to perform basic database operations are granted through special system privileges.
- [Operations Authorized by Administrative Privileges](#)
Each administrative privilege authorizes a specific set of operations.
- [Authentication Methods for Database Administrators](#)
Database administrators can be authenticated with account passwords, operating system (OS) authentication, password files, or strong authentication with a directory-based authentication service, such as Oracle Internet Directory.
- [Using Operating System Authentication](#)
Membership in special operating system groups enables a DBA to authenticate to the database through the operating system rather than with a database user name and password. This is known as operating system authentication.
- [Using Password File Authentication](#)
You can use password file authentication for an Oracle database instance and for an Oracle Automatic Storage Management (Oracle ASM) instance. The password file for an Oracle database is called a database password file, and the password file for Oracle ASM is called an Oracle ASM password file.

1.6.1 Administrative Privileges

Administrative privileges that are required for an administrator to perform basic database operations are granted through special system privileges.

These privileges are:

- SYSDBA
- SYSOPER
- SYSBACKUP
- SYSDG
- SYSKM
- SYSRAC

Excluding the `SYSRAC` privilege, grant these privileges to users depending upon the level of authorization they require. The `SYSRAC` privilege cannot be granted to users because it is used only by the Oracle agent of Oracle Clusterware to connect to the database using operating system authentication.

Starting with Oracle Database 12c Release 1 (12.1), the `SYSBACKUP`, `SYSDG`, and `SYSKM` administrative privileges are available. Starting with Oracle Database 12c Release 2 (12.2), the `SYSRAC` administrative privilege is available. Each new administrative privilege grants the minimum required privileges to complete tasks in each area of administration. The new administrative privileges enable you to avoid granting `SYSDBA` administrative privilege for many common tasks.

 **Note:**

These administrative privileges allow access to a database instance even when the database is not open. Control of these privileges is totally outside of the database itself. Methods for authenticating database administrators with these privileges include operating system (OS) authentication, password files, and strong authentication with a directory-based authentication service.

These privileges can also be thought of as types of connections that enable you to perform certain database operations for which privileges cannot be granted in any other fashion. For example, if you have the `SYSDBA` privilege, then you can connect to the database by specifying the `AS SYSDBA` clause in the `CONNECT` command and perform `STARTUP` and `SHUTDOWN` operations. See "[Authentication Methods for Database Administrators](#)".

1.6.2 Operations Authorized by Administrative Privileges

Each administrative privilege authorizes a specific set of operations.

The following table lists the operations that are authorized by each administrative privilege:

Administrative Privilege	Operations Authorized
SYSDBA	<ul style="list-style-type: none"> • Perform STARTUP and SHUTDOWN operations • ALTER DATABASE: open, mount, back up, or change character set • CREATE DATABASE • DROP DATABASE • CREATE SPFILE • ALTER DATABASE ARCHIVELOG • ALTER DATABASE RECOVER • Includes the RESTRICTED SESSION privilege <p>This administrative privilege allows most operations, including the ability to view user data. It is the most powerful administrative privilege.</p>
SYSOPER	<ul style="list-style-type: none"> • Perform STARTUP and SHUTDOWN operations • CREATE SPFILE • ALTER DATABASE: open, mount, or back up • ALTER DATABASE ARCHIVELOG • ALTER DATABASE RECOVER (Complete recovery only. Any form of incomplete recovery, such as UNTIL TIME CHANGE CANCEL CONTROLFILE requires connecting as SYSDBA.) • Includes the RESTRICTED SESSION privilege <p>This privilege allows a user to perform basic operational tasks, but without the ability to view user data.</p>
SYSBACKUP	<p>This privilege allows a user to perform backup and recovery operations either from Oracle Recovery Manager (RMAN) or SQL*Plus.</p> <p>See <i>Oracle Database Security Guide</i> for the full list of operations allowed by this administrative privilege.</p>
SYSDG	<p>This privilege allows a user to perform Data Guard operations. You can use this privilege with either Data Guard Broker or the DGMGR command-line interface.</p> <p>See <i>Oracle Database Security Guide</i> for the full list of operations allowed by this administrative privilege.</p>
SYSKM	<p>This privilege allows a user to perform Transparent Data Encryption keystore operations.</p> <p>See <i>Oracle Database Security Guide</i> for the full list of operations allowed by this administrative privilege.</p>
SYSRAC	<p>This privilege allows the Oracle agent of Oracle Clusterware to perform Oracle Real Application Clusters (Oracle RAC) operations.</p> <p>See <i>Oracle Database Security Guide</i> for the full list of operations allowed by this administrative privilege.</p>

The manner in which you are authorized to use these privileges depends upon the method of authentication that you use.

When you connect with an administrative privilege, you connect with a current schema that is not generally associated with your username. For SYSDBA, the current schema is SYS. For SYSOPER, the current schema is PUBLIC. For SYSBACKUP, SYSDG, and SYSRAC, the current schema is SYS for name resolution purposes. However, the current schema for SYSKM is SYSKM.

Also, when you connect with an administrative privilege, you connect with a specific session user. When you connect as SYSDBA, the session user is SYS. For SYSOPER, the

session user is PUBLIC. For SYSBACKUP, SYSDG, SYSKM, and SYSRAC, the session user is SYSBACKUP, SYSDG, SYSKM, and SYSRAC, respectively.

 **See Also:**

- ["Administrative User Accounts"](#)
- ["Using Operating System Authentication"](#)
- ["Using Password File Authentication"](#)
- *Oracle Database SQL Language Reference* for more information about the current schema and the session user
- *Oracle Database Security Guide*

Example 1-17 Current Schema When Connecting AS SYSDBA

This example illustrates that a user is assigned another schema (SYS) when connecting with the SYSDBA administrative privilege. Assume that the sample user mydba has been granted the SYSDBA administrative privilege and has issued the following command and statement:

```
CONNECT mydba
CREATE TABLE admin_test(name VARCHAR2(20));
```

Later, user mydba issues this command and statement:

```
CONNECT mydba AS SYSDBA
SELECT * FROM admin_test;
```

User mydba now receives the following error:

```
ORA-00942: table or view does not exist
```

Having connected as SYSDBA, user mydba now references the SYS schema, but the table was created in the mydba schema.

Example 1-18 Current Schema and Session User When Connecting AS SYSBACKUP

This example illustrates that a user is assigned another schema (SYS) and another session user (SYSBACKUP) when connecting with the SYSBACKUP administrative privilege. Assume that the sample user mydba has been granted the SYSBACKUP administrative privilege and has issued the following command and statements:

```
CONNECT mydba AS SYSBACKUP
SELECT SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA') FROM DUAL;
SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA')
-----
SYS
SELECT SYS_CONTEXT('USERENV', 'SESSION_USER') FROM DUAL;
SYS_CONTEXT('USERENV', 'SESSION_USER')
```

SYSBACKUP

1.6.3 Authentication Methods for Database Administrators

Database administrators can be authenticated with account passwords, operating system (OS) authentication, password files, or strong authentication with a directory-based authentication service, such as Oracle Internet Directory.

- [About Authentication Methods for Database Administrators](#)
There are several ways to authenticate database administrators.
- [Nonsecure Remote Connections](#)
To connect to Oracle Database as a privileged user over a nonsecure connection, you must be authenticated by a password file.
- [Local Connections and Secure Remote Connections](#)
You can connect to Oracle Database as a privileged user over a local connection or a secure remote connection.

1.6.3.1 About Authentication Methods for Database Administrators

There are several ways to authenticate database administrators.

Oracle database can authenticate database administrators through the data dictionary, (using an account password) like other users. Keep in mind that database passwords are case-sensitive. See *Oracle Database Security Guide* for more information about case-sensitive database passwords.

In addition to normal data dictionary authentication, the following methods are available for authenticating database administrators with the SYSDBA, SYSOPER, SYSBACKUP, SYSDG, or SYSKM privilege:

- Operating system (OS) authentication
- Password file including Kerberos and SSL authentication services
- Strong authentication with a directory-based authentication service, such as Oracle Internet Directory

 **Note:**

The SYSRAC privilege only allows OS authentication by the Oracle agent of Oracle Clusterware. Password files and strong authentication cannot be used with the SYSRAC privilege.

These methods are required to authenticate a database administrator when the database is not started or otherwise unavailable. (They can also be used when the database is available.)

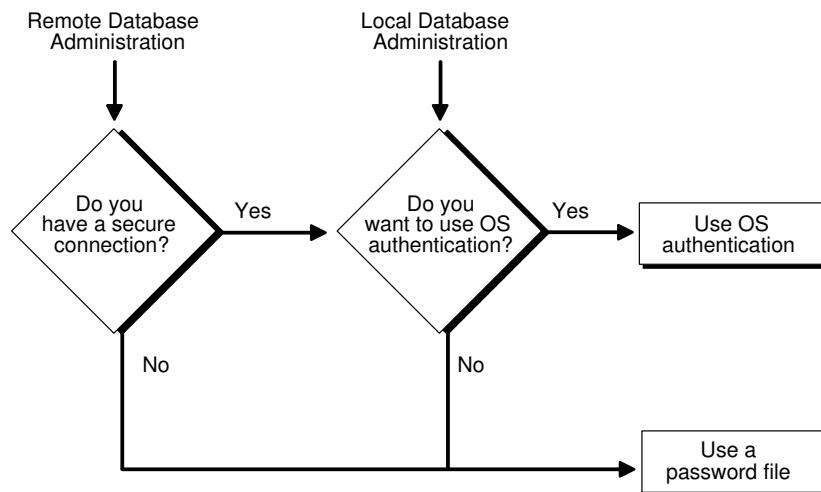

The remainder of this section focuses on operating system authentication and password file authentication. See *Oracle Database Security Guide* for information about authenticating database administrators with directory-based authentication services.

 **Note:**

Operating system authentication takes precedence over password file authentication. If you meet the requirements for operating system authentication, then even if you use a password file, you will be authenticated by operating system authentication.

Your choice is influenced by whether you intend to administer your database locally on the same system where the database resides, or whether you intend to administer many different databases from a single remote client. The following figure illustrates the choices you have for database administrator authentication schemes.

Figure 1-2 Database Administrator Authentication Methods

If you are performing remote database administration, then consult your Oracle Net documentation to determine whether you are using a secure connection. Most popular connection protocols, such as TCP/IP and DECnet, are not secure.

 **See Also:**

- *Oracle Database Security Guide* for information about authenticating database administrators with directory-based authentication services.
- *Oracle Database Net Services Administrator's Guide*

1.6.3.2 Nonsecure Remote Connections

To connect to Oracle Database as a privileged user over a nonsecure connection, you must be authenticated by a password file.

When using password file authentication, the database uses a password file to keep track of database user names that have been granted the SYSDBA, SYSOPER,

SYSBACKUP, SYSDG, or SYSKM administrative privilege. This form of authentication is discussed in "[Using Password File Authentication](#)".

1.6.3.3 Local Connections and Secure Remote Connections

You can connect to Oracle Database as a privileged user over a local connection or a secure remote connection.

You can connect in two ways:

- If the database has a password file and you have been granted a system privilege, then you can connect and be authenticated by a password file.
- If the server is not using a password file, or if you have not been granted a system privilege and are therefore not in the password file, then you can use operating system authentication. On most operating systems, authentication for database administrators involves placing the operating system username of the database administrator in a special group.

For example, users in the OSDBA group are granted the SYSDBA administrative privilege. Similarly, the OSOPER group is used to grant SYSOPER administrative privilege to users, the OSBACKUPDBA group is used to grant SYSBACKUP administrative privilege to users, the OSDGDBA group is used to grant SYSDG administrative privilege to users, the OSKMDBA group is used to grant SYSKM administrative privilege to users, and the OSRACDBA group is used to grant SYSRAC administrative privilege to users.

1.6.4 Using Operating System Authentication

Membership in special operating system groups enables a DBA to authenticate to the database through the operating system rather than with a database user name and password. This is known as operating system authentication.

- [Operating System Groups](#)
Operating system groups are created and assigned specific names as part of the database installation process.
- [Preparing to Use Operating System Authentication](#)
DBAs can authenticate to the database through the operating system rather than with a database user name and password.
- [Connecting Using Operating System Authentication](#)
A user can connect to the database using operating system authentication.

1.6.4.1 Operating System Groups

Operating system groups are created and assigned specific names as part of the database installation process.

The default names of the operating system groups vary depending upon your operating system, and are listed in the following table:

Operating System Group	UNIX or Linux User Group	Windows User Group
OSDBA	dba	ORA_DBA (for all Oracle homes) ORA_HOMENAME_DBA (for each specific Oracle home)
OSOPER	oper	ORA_OPER (for all Oracle homes) ORA_HOMENAME_OPER (for each specific Oracle home)
OSBACKUPDBA	backupdba	ORA_HOMENAME_SYSBACKUP
OSDGDBA	dgdba	ORA_HOMENAME_SYSDG
OSKMDBA	kmdba	ORA_HOMENAME_SYSKM
OSRACDBA	racdba	ORA_HOMENAME_SYSRAC

For the Windows user group names, replace *HOMENAME* with the Oracle home name.

Oracle Universal Installer uses these default names, but, on UNIX or Linux, you can override them. On UNIX or Linux, one reason to override them is if you have multiple instances running on the same host computer in different Oracle homes. If each instance has a different person as the principal DBA, then you can improve the security of each instance by creating different groups for each instance.

For example, for two instances on the same UNIX or Linux host in different Oracle homes, the OSDBA group for the first instance might be named dba1, and OSDBA for the second instance might be named dba2. The first DBA would be a member of dba1 only, and the second DBA would be a member of dba2 only. Thus, when using operating system authentication, each DBA would be able to connect only to his assigned instance.

On Windows, default user group names cannot be changed. The *HOMENAME* placeholder enables you to have different user group names when you have multiple instances running on the same host Windows computer.

Membership in a group affects your connection to the database in the following ways:

- If you are a member of the OSDBA group, and you specify AS SYSDBA when you connect to the database, then you connect to the database with the SYSDBA administrative privilege.
- If you are a member of the OSOPER group, and you specify AS SYSOPER when you connect to the database, then you connect to the database with the SYSOPER administrative privilege.
- If you are a member of the OSBACKUPDBA group, and you specify AS SYSBACKUP when you connect to the database, then you connect to the database with the SYSBACKUP administrative privilege.
- If you are a member of the OSDGDBA group, and you specify AS SYSDG when you connect to the database, then you connect to the database with the SYSDG administrative privilege.
- If you are a member of the OSKMDBA group, and you specify AS SYSKM when you connect to the database, then you connect to the database with the SYSKM administrative privilege.

- If you are a member of the OSRACDBA group, and you specify AS SYSRAC when you connect to the database, then you connect to the database with the SYSRAC administrative privilege.
- If you are not a member of one of these operating system groups, and you attempt to connect as SYSDBA, SYSOPER, SYSBACKUP, SYSDG, SYSKM, or SYSRAC, then the CONNECT command fails.

 **See Also:**

Your operating system specific Oracle documentation for information about creating the OSDBA and OSOPER groups

1.6.4.2 Preparing to Use Operating System Authentication

DBAs can authenticate to the database through the operating system rather than with a database user name and password.

To enable operating system authentication of an administrative user:

1. Create an operating system account for the user.
2. Add the account to the appropriate operating-system defined groups.

1.6.4.3 Connecting Using Operating System Authentication

A user can connect to the database using operating system authentication.

You can use operating system authentication by performing one of the following actions.

- A user can be authenticated, enabled as an administrative user, and connected to a local database by typing one of the following SQL*Plus commands:

```
CONNECT / AS SYSDBA
CONNECT / AS SYSOPER
CONNECT / AS SYSBACKUP
CONNECT / AS SYSDG
CONNECT / AS SYSKM
```

- For the Windows platform only, remote operating system authentication over a secure connection is supported. You must specify the net service name for the remote database:

```
CONNECT /@net_service_name AS SYSDBA
CONNECT /@net_service_name AS SYSOPER
CONNECT /@net_service_name AS SYSBACKUP
CONNECT /@net_service_name AS SYSDG
CONNECT /@net_service_name AS SYSKM
```

Both the client computer and database host computer must be on a Windows domain.

 **Note:**

The SYSRAC administrative privilege is used only by the Oracle agent of Oracle Clusterware to connect to the database using operating system authentication.

 **See Also:**

- ["Connecting to the Database with SQL*Plus"](#)
- *SQL*Plus User's Guide and Reference* for the syntax of the CONNECT command

1.6.5 Using Password File Authentication

You can use password file authentication for an Oracle database instance and for an Oracle Automatic Storage Management (Oracle ASM) instance. The password file for an Oracle database is called a database password file, and the password file for Oracle ASM is called an Oracle ASM password file.

- [Preparing to Use Password File Authentication](#)
To prepare for password file authentication, you must create the password file, set the REMOTE_LOGIN_PASSWORDFILE initialization parameter, and grant privileges.
- [Connecting Using Password File Authentication](#)
Using password file authentication, administrative users can be connected and authenticated to a local or remote database by using the SQL*Plus CONNECT command. By default, passwords are case-sensitive.

 **See Also:**

Oracle Automatic Storage Management Administrator's Guide for information about creating an Oracle ASM password file.

1.6.5.1 Preparing to Use Password File Authentication

To prepare for password file authentication, you must create the password file, set the REMOTE_LOGIN_PASSWORDFILE initialization parameter, and grant privileges.

To enable authentication of an administrative user using password file authentication, you must do the following:

1. If it is not already created, then create the password file using the ORAPWD utility:

```
orapwd FILE=filename FORMAT=12.2
```

See "[Creating and Maintaining a Database Password File](#)" for details.

 **Note:**

- When you invoke the Database Configuration Assistant (DBCA) as part of the Oracle Database installation process, DBCA creates a password file.
- The administrative privileges SYSBACKUP, SYSDG, and SYSKM are not supported in the password file when the file is created with the FORMAT=LEGACY argument.
- 12.2 is the default for the FORMAT command-line argument.
- The administrative privilege SYSRAC is not supported in the password file.
- The administrative privileges can be granted to external users only when the file is created with the FORMAT=12.2 argument. FORMAT=12.2 also enables SSL and Kerberos authentication for administrative users.
- When you create a database password file that is stored in an Oracle ASM disk group, it can be shared among the multiple Oracle RAC database instances. The password file is not duplicated on each Oracle RAC database instance.

2. Set the `REMOTE_LOGIN_PASSWORDFILE` initialization parameter to exclusive. (This is the default).

 **Note:**

`REMOTE_LOGIN_PASSWORDFILE` is a static initialization parameter and therefore cannot be changed without restarting the database.

3. Connect to the database as user `SYS` (or as another user with the administrative privileges).
4. If the user does not already exist in the database, then create the user and assign a password.

Keep in mind that database passwords are case-sensitive. See *Oracle Database Security Guide* for more information about case-sensitive database passwords.

5. Grant the `SYSDBA`, `SYSOPER`, `SYSBACKUP`, `SYSDG`, or `SYSKM` administrative privilege to the user. For example:

```
GRANT SYSDBA to mydba;
```

This statement adds the user to the password file, thereby enabling connection AS `SYSDBA`, AS `SYSOPER`, AS `SYSBACKUP`, AS `SYSDG`, or AS `SYSKM`.

 **See Also:**

["Creating and Maintaining a Database Password File"](#) for instructions for creating and maintaining a password file

1.6.5.2 Connecting Using Password File Authentication

Using password file authentication, administrative users can be connected and authenticated to a local or remote database by using the SQL*Plus CONNECT command. By default, passwords are case-sensitive.

To connect using password file authentication:

- In SQL*Plus, execute the CONNECT command with a valid username and password and the AS SYSDBA, AS SYSOPER, AS SYSBACKUP, AS SYSDG, or AS SYSKM clause.

For example, if user `mydba` has been granted the `SYSDBA` privilege, then `mydba` can connect as follows:

```
CONNECT mydba AS SYSDBA
```

However, if user `mydba` has not been granted the `SYSOPER` privilege, then the following command fails:

```
CONNECT mydba AS SYSOPER
```

 **Note:**

Operating system authentication takes precedence over password file authentication. Specifically, if you are a member of the appropriate operating system group, such as OSDBA or OSOPER, and you connect with the appropriate clause (for example, AS SYSDBA), then you will be connected with associated administrative privileges regardless of the *username/password* that you specify.

If you are not in the one of the operating system groups, and you are not in the password file, then attempting to connect with the clause fails.

 **See Also:**

1.7 Creating and Maintaining a Database Password File

You can create a database password file using the password file creation utility, ORAPWD. For some operating systems, you can create this file as part of your standard installation.

- [ORAPWD Syntax and Command Line Argument Descriptions](#)
The ORAPWD command creates and maintains a password file.
- [Creating a Database Password File with ORAPWD](#)
You can create a database password file with ORAPWD.
- [Sharing and Disabling the Database Password File](#)
You use the initialization parameter `REMOTE_LOGIN_PASSWORDFILE` to control whether a database password file is shared among multiple Oracle Database instances. You can also use this parameter to disable password file authentication.
- [Keeping Administrator Passwords Synchronized with the Data Dictionary](#)
If you change the `REMOTE_LOGIN_PASSWORDFILE` initialization parameter from `none` to exclusive or shared, then you must ensure that the passwords stored in the data dictionary and the passwords stored in the password file for the non-SYS administrative users, such as SYSDBA, SYSOPER, SYSBACKUP, SYSDG, and SYSKM users are the same.
- [Adding Users to a Database Password File](#)
When you grant SYSDBA, SYSOPER, SYSBACKUP, SYSDG, or SYSKM administrative privilege to a user, that user's name and privilege information are added to the database password file.
- [Granting and Revoking Administrative Privileges](#)
Use the `GRANT` statement to grant administrative privileges. Use the `REVOKE` statement to revoke administrative privileges.
- [Viewing Database Password File Members](#)
The `V$PFILE_USERS` view contains information about users that have been granted administrative privileges.
- [Removing a Database Password File](#)
You can remove a database password file if it is no longer needed.

See Also:

- ["Using Password File Authentication"](#)
- ["Authentication Methods for Database Administrators"](#)
- [Oracle Automatic Storage Management Administrator's Guide](#) for information about creating and maintaining an Oracle ASM password file

1.7.1 ORAPWD Syntax and Command Line Argument Descriptions

The ORAPWD command creates and maintains a password file.

The syntax of the ORAPWD command is as follows:

```

orapwd FILE=filename [FORCE={y|n}] [ASM={y|n}] [DBUNIQUENAME=dbname]
[FORMAT={12.2|12}] [SYS={Y|password|external('sys-external-name')}] 
[SYSBACKUP={password|external('sysbackup-external-name')}]
[SYSDG={password|external('sysdg-external-name')}]
[SYSKM={password|external('syskm-external-name')}]
[DELETE={y|n}] [INPUT_FILE=input-fname]

orapwd DESCRIBE FILE=filename

```

Command arguments are summarized in the following table.

Argument	Description
FILE	If the DESCRIBE argument is not included, then specify the name to assign to the new password file. You must supply a complete path. If you supply only a file name, the file is written to the current directory. If the DESCRIBE argument is included, then specify the name of an existing password file.
FORCE	(Optional) If <i>y</i> , permits overwriting an existing password file.
ASM	(Optional) If <i>y</i> , create an Oracle ASM password file in an Oracle ASM disk group. If <i>n</i> , the default, create a password file in the operating system file system. When the DBUNIQUENAME argument is specified, the password file is a database password file. When the DBUNIQUENAME argument is not specified, the password file can be a database password file or an Oracle ASM password file.
DBUNIQUENAME	Unique database name used to identify database password files residing in an ASM disk group only. This argument is required when the database password file is stored on an Oracle ASM disk group. This argument is ignored when an Oracle ASM password file is created by setting the ASM argument to <i>y</i> .
FORMAT	(Optional) Specify one of the following values: <ul style="list-style-type: none"> • 12.2, the default, creates the password file in 12.2 format. This format supports granting administrative privileges to external users and enables SSL and Kerberos authentication for administrative users. • 12 creates the password file in Oracle Database 12c format. This format supports the SYSBACKUP, SYSDG, and SYSKM administrative privileges.
SYS	(Optional) This argument can be set to either <i>Y</i> , <i>password</i> , or <i>external ('sys-external-name')</i> . If <i>SYS=Y</i> and <i>INPUT_FILE</i> is specified to migrate password file entries, then you will be prompted to enter the new password for the <i>SYS</i> administrative user. If <i>password</i> , then you will be prompted to enter the password for the <i>SYS</i> administrative user. If <i>external ('sys-external-name')</i> , then replace <i>sys-external-name</i> with the external name for SSL or Kerberos authentication for the <i>SYS</i> administrative user.
SYSBACKUP	(Optional) This argument can be set to either <i>password</i> , <i>external ('sysbackup-external-name')</i> , <i>y</i> , or <i>n</i> . If <i>password</i> , then you will be prompted to enter the password for the <i>SYSBACKUP</i> administrative user. If <i>external ('sysbackup-external-name')</i> , then replace <i>sysbackup-external-name</i> with the external name for SSL or Kerberos authentication for the <i>SYSBACKUP</i> administrative user.

Argument	Description
SYSdg	<p>(Optional) This argument can be set to either <i>password</i>, external('sysdg-external-name'), y, or n.</p> <p>If <i>password</i>, then you will be prompted to enter the password for the SYSdg administrative user.</p> <p>If external('sysdg-external-name'), then replace <i>sysdg-external-name</i> with the external name for SSL or Kerberos authentication for the SYSdg administrative user.</p>
SYSkm	<p>(Optional) This argument can be set to either <i>password</i>, external('syskm-external-name'), y, or n.</p> <p>If <i>password</i>, then you will be prompted to enter the password for the SYSkm administrative user.</p> <p>If external('syskm-external-name'), then replace <i>syskm-external-name</i> with the external name for SSL or Kerberos authentication for the SYSkm administrative user.</p> <p>If y, creates a SYSkm entry in the password file. You are prompted for the password. The password is stored in the created password file.</p> <p>If n, no SYSkm entry is created in the password file.</p> <p>Note: The y and n values in the SYSkm argument are deprecated in Oracle Database 12c Release 2 (12.2.0.1) and may be unsupported in a future release.</p>
DELETE	<p>(Optional) If y, delete the specified password file.</p> <p>If n, the default, create the specified password file.</p>
INPUT_FILE	<p>(Optional) Name of the input password file. ORAPWD migrates the entries in the input file to a new password file.</p> <p>This argument can be used to convert a password file from one format to another, for example from 12 format to 12.2 format.</p> <p>This argument also can be used to reset the password for the SYS administrative user.</p> <p>ORAPWD cannot migrate an input password that is stored in an Oracle ASM disk group.</p>
DESCRIBE	<p>Describes the properties of the specified password file, including the FORMAT value (12.2 or 12).</p>

There are no spaces permitted around the equal-to (=) character.

The following sections provide more information about some of the ORAPWD command line arguments.

FILE

This argument sets the name of the password file being created. This argument is mandatory.

If you specify a location on an Oracle ASM disk group, then the database password file is shared automatically among the nodes in the cluster. When you use an Oracle ASM disk group to store the password file, and you are not using Oracle Managed Files, you must specify the name of the password file, including its full path. The full path is not required if you are using Oracle Managed Files.

If you do not specify a location on an Oracle ASM disk group, then the file name required for the password file is operating system specific. Some operating systems require the password file to adhere to a specific format and be located in a specific

directory. Other operating systems allow the use of environment variables to specify the name and location of the password file.

The following table lists the required name and location for the password file on the UNIX, Linux, and Windows platforms. For other platforms, consult your platform-specific documentation.

Platform	Required Name	Required Location
UNIX and Linux	orapwORACLE_SID	ORACLE_HOME/dbs
Windows	PWDORACLE_SID.ora	ORACLE_HOME\\database

For example, for a database instance with the SID `orcldw`, the password file must be named `orapworcldw` on Linux and `PWDorcldw.ora` on Windows.

In an Oracle Real Application Clusters (Oracle RAC) environment on a platform that requires an environment variable to be set to the path of the password file, the environment variable for each instance must point to the same password file.

For a policy-managed Oracle RAC database or an Oracle RAC One Node database with ORACLE_SID of the form `db_unique_name_n`, where `n` is a number, the password file is searched for first using `ORACLE_HOME/dbs/orapwsid_prefix` or `ORACLE_HOME\\database\\PWDsid_prefix.ora`. The `sid_prefix` (the first 8 characters of the database name) is used to locate the password file.

Note:

It is critically important to the security of your system that you protect your password file and the environment variables that identify the location of the password file. Any user with access to these could potentially compromise the security of the connection.

See Also:

[Using Oracle Managed Files](#)

FORCE

This argument, if set to `y`, enables you to overwrite an existing password file. An error is returned if a password file of the same name already exists and this argument is omitted or set to `n`.

ASM

If this argument is set to `y`, then `ORAPWD` creates an Oracle ASM password file. The `FILE` argument must specify a location in the Oracle ASM disk group.

If this argument is set to `n`, the default, then `ORAPWD` creates a password file. The `FILE` argument can specify a location in the Oracle ASM disk group or in the operating system file system. When the `DBUNIQUENAME` argument is specified, the password file is a database password file. When the `DBUNIQUENAME` argument is not specified, the password file can be a database password file or an Oracle ASM password file.

 **See Also:**

Oracle Automatic Storage Management Administrator's Guide for information about creating and maintaining an Oracle ASM password file

DBUNIQUENAME

This argument sets the unique database name for a database password file being created on an Oracle ASM disk group. It identifies which database resource to update with the database password file location.

This argument is not required when a database password file is created on an operating system file system.

This argument is ignored when an Oracle ASM password file is created by setting the `ASM` argument to `y`.

FORMAT

If this argument is set to `12.2`, the default, then `ORAPWD` creates a database password file in `12.2` format. `12.2` format is required for the password file to support granting administrative privileges to external users and SSL and Kerberos authentication for administrative users. Password profiles assigned to the users are also enforced on the administrative users.

If this argument is set to `12`, then `ORAPWD` creates a database password file in Oracle Database `12c` format. Oracle Database `12c` format is required for the password file to support `SYSBACKUP`, `SYSDG`, and `SYSKM` administrative privileges.

If this argument is set to `legacy`, then `ORAPWD` creates a database password file that is in the format before Oracle Database `12c`. The password file supports `SYSDBA` and `SYSOPER` administrative privileges, but it does not support `SYSBACKUP`, `SYSDG`, and `SYSKM` administrative privileges.

SYS

If `SYS=Y` and `INPUT_FILE` is specified to migrate password file entries, then you will be prompted to enter the new password for the `SYS` administrative user.

If `password`, then you will be prompted to enter the password for the `SYS` administrative user.

If `external('sys-external-name')`, then replace `sys-external-name` with the external name for SSL or Kerberos authentication for the `SYS` administrative user.

SYSBACKUP

If `password`, then you will be prompted to enter the password for the `SYSBACKUP` administrative user.

If `external('sysbackup-external-name')`, then replace `sysbackup-external-name` with the external name for SSL or Kerberos authentication for the `SYSDG` administrative user.

SYSDG

If `password`, then you will be prompted to enter the password for the `SYSDG` administrative user.

If `external('sysdg-external-name')`, then replace `sysdg-external-name` with the external name for SSL or Kerberos authentication for the `SYSKM` administrative user.

SYSKM

If `password`, then you will be prompted to enter the password for the `SYSKM` administrative user.

If `external('syskm-external-name')`, then replace `syskm-external-name` with the external name for SSL or Kerberos authentication for the `SYSKM` administrative user.

DELETE

If this argument is set to `y`, then `ORAPWD` deletes the specified password file. When `y` is specified, `FILE`, `ASM`, or `DBUNIQUENAME` must be specified. When `FILE` is specified, the file must be located on an `ASM` disk group.

If this argument is set to `n`, the default, then `ORAPWD` creates the password file.

INPUT_FILE

This argument specifies the name of the input password file. `ORAPWD` migrates the entries in the input file to a new password file. This argument can convert a password file from one format to another, for example from `12` format to `12.2` format.

This argument also can be used to reset the password for the `SYS` administrative user. When the `INPUT_FILE` argument is specified, `ORAPWD` does not create any new entries. Therefore, `ORAPWD` ignores the following arguments:

- `PASSWORD`
- `SYSBACKUP`
- `SYSDG`
- `SYSKM`

When an input file is specified and the new password file replaces the input file, `FORCE` must be set to `y`.

Note:

When the `FORMAT` argument is not specified, by default the new password file is created in `12.2` format from the input file.

See Also:

["Administrative Privileges"](#) and ["Adding Users to a Database Password File"](#)

1.7.2 Creating a Database Password File with ORAPWD

You can create a database password file with `ORAPWD`.

To create a database password file:

- Run the `ORAPWD` command.

Example 1-19 Creating a Database Password File Located in an Oracle ASM Disk Group

The following command creates a database password file in `12.2` format named `orapworcl` that is located in an Oracle `ASM` disk group. The `DBUNIQUENAME` argument is required because the database password file is located in an Oracle `ASM` disk group.

```
orapwd FILE='+DATA/orcl/orapworcl' DBUNIQUENAME='orcl' FORMAT=12.2
```

Example 1-20 Creating a Database Password File with a SYSBACKUP Entry

The following example is similar to [Example 1-19](#) except that it creates a SYSBACKUP entry in the database password file. The password file is in 12.2 format by default.

```
orapwd FILE='+DATA/orcl/orapworcl' DBUNIQUENAME='orcl' SYSBACKUP=password FORMAT=12.2
```

Example 1-21 Creating a Database Password File with External Authentication for SYS and SYSKM

The following example is similar to [Example 1-19](#) except that it specifies an external name for the SYS and SYSKM administrative users.

```
orapwd FILE='+DATA/orcl/orapworcl' DBUNIQUENAME='orcl' FORMAT=12.2
sys=external('KerberosUserSYS@example.com')
syskm=external('KerberosUserSYSKM@example.com')
```

Example 1-22 Creating a Database Password File Located in a File System

The following command creates a database password file in 12.2 format named orapworcl that is located in the default location in an operating system file system.

```
orapwd FILE='/u01/oracle/dbs/orapworcl' FORMAT=12.2
```

Example 1-23 Migrating a Legacy Database Password File to Oracle Database 12c Format

The following command migrates a database password file in legacy format 12.2 format. The password file is named orapworcl, and it is located in an operating system file system. The new database password file replaces the existing database password file. Therefore, FORCE must be set to y.

```
orapwd FILE='/u01/oracle/dbs/orapworcl' FORMAT=12.2 INPUT_FILE='/u01/oracle/dbs/
orapworcl' FORCE=y
```

Example 1-24 Resetting the Password for the SYS Administrative User

The following command resets the password for the SYS administrative user. The new database password file replaces the existing database password file. Therefore, FORCE must be set to y.

```
orapwd FILE='/u01/oracle/dbs/orapworcl' SYS=Y INPUT_FILE='/u01/oracle/dbs/orapworcl'
FORCE=y
```

You are prompted to enter the new password for the SYS administrative user.

Example 1-25 Describing a Password File

The following command describes the orapworcl password file.

```
orapwd DESCRIBE FILE='orapworcl'
Password file Description : format=12.2
```

1.7.3 Sharing and Disabling the Database Password File

You use the initialization parameter `REMOTE_LOGIN_PASSWORDFILE` to control whether a database password file is shared among multiple Oracle Database instances. You can also use this parameter to disable password file authentication.

To share a password file or disable password file authentication:

- Set the `REMOTE_LOGIN_PASSWORDFILE` initialization parameter.

You can set the `REMOTE_LOGIN_PASSWORDFILE` initialization parameter to one of the following values:

- `none`: Setting this parameter to `none` causes Oracle Database to behave as if the password file does not exist. That is, no privileged connections are allowed over nonsecure connections.
- `exclusive`: (The default) An exclusive password file can be used with only one database. Only an exclusive file can be modified. Using an exclusive password file enables you to add, modify, and delete users. It also enables you to change the password for `SYS`, `SYSBACKUP`, `SYSDG`, or `SYSKM` with the `ALTER USER` command.

When an exclusive password file is stored on an Oracle ASM disk group, it can be used by a single-instance database or multiple instances of an Oracle Real Application Clusters (Oracle RAC) database.

When an exclusive password file is stored on an operating system, it can be used with only one instance of one database.

- `shared`: A shared password file can be used by multiple databases running on the same server, or multiple instances of an Oracle RAC database, even when it is stored on an operating system. A shared password file is read-only and cannot be modified. Therefore, you cannot add users to a shared password file. Any attempt to do so or to change the password of `SYS` or other users with the administrative privileges generates an error. All users needing administrative privileges must be added to the password file when `REMOTE_LOGIN_PASSWORDFILE` is set to `exclusive`. After all users are added, you can change `REMOTE_LOGIN_PASSWORDFILE` to `shared`, and then share the file.

This option is useful if you are administering multiple databases with a single password file.

You cannot specify `shared` for an Oracle ASM password file.

If `REMOTE_LOGIN_PASSWORDFILE` is set to `exclusive` or `shared` and the password file is missing, this is equivalent to setting `REMOTE_LOGIN_PASSWORDFILE` to `none`.

1.7.4 Keeping Administrator Passwords Synchronized with the Data Dictionary

If you change the `REMOTE_LOGIN_PASSWORDFILE` initialization parameter from `none` to `exclusive` or `shared`, then you must ensure that the passwords stored in the data dictionary and the passwords stored in the password file for the non-SYS

administrative users, such as SYSDBA, SYSOPER, SYSBACKUP, SYSDG, and SYSKM users are the same.

 **Note:**

Starting with Oracle Database 12c Release 2 (12.2), authentication for the SYS user happens using only the password file and not using the data dictionary.

To synchronize the passwords for non-SYS administrative users, such as SYSDBA, SYSOPER, SYSBACKUP, SYSDG, and SYSKM users, you must first revoke and then regrant the privileges to these users as follows:

1. Find all users who have been granted the SYSDBA privilege.

```
SELECT USERNAME FROM V$PFILE_USERS WHERE USERNAME != 'SYS' AND SYSDBA='TRUE';
```

2. Revoke and then re-grant the SYSDBA privilege to these users.

```
REVOKE SYSDBA FROM non-SYS-user;
GRANT SYSDBA TO non-SYS-user;
```

3. Find all users who have been granted the SYSOPER privilege.

```
SELECT USERNAME FROM V$PFILE_USERS WHERE USERNAME != 'SYS' AND SYSOPER='TRUE';
```

4. Revoke and regrant the SYSOPER privilege to these users.

```
REVOKE SYSOPER FROM non-SYS-user;
GRANT SYSOPER TO non-SYS-user;
```

5. Find all users who have been granted the SYSBACKUP privilege.

```
SELECT USERNAME FROM V$PFILE_USERS WHERE USERNAME != 'SYS' AND SYSBACKUP
= 'TRUE';
```

6. Revoke and regrant the SYSBACKUP privilege to these users.

```
REVOKE SYSBACKUP FROM non-SYS-user;
GRANT SYSBACKUP TO non-SYS-user;
```

7. Find all users who have been granted the SYSDG privilege.

```
SELECT USERNAME FROM V$PFILE_USERS WHERE USERNAME != 'SYS' AND SYSDG='TRUE';
```

8. Revoke and regrant the SYSDG privilege to these users.

```
REVOKE SYSDG FROM non-SYS-user;
GRANT SYSDG TO non-SYS-user;
```

9. Find all users who have been granted the SYSKM privilege.

```
SELECT USERNAME FROM V$PFILE_USERS WHERE USERNAME != 'SYS' AND SYSKM='TRUE';
```

10. Revoke and regrant the SYSKM privilege to these users.

```
REVOKE SYSKM FROM non-SYS-user;
GRANT SYSKM TO non-SYS-user;
```

1.7.5 Adding Users to a Database Password File

When you grant SYSDBA, SYSOPER, SYSBACKUP, SYSDG, or SYSKM administrative privilege to a user, that user's name and privilege information are added to the database password file.

A user's name remains in the password file only as long as that user has at least one of these privileges. If you revoke all of these privileges, then Oracle Database removes the user from the password file.

 **Note:**

The password file must be created with the `FORMAT=12.2` or `FORMAT=12` argument to support SYSBACKUP, SYSDG, or SYSKM administrative privilege.

Creating a Password File and Adding New Users to It

Use the following procedure to create a password file and add new users to it:

1. Follow the instructions for creating a password file as explained in "[Creating a Database Password File with ORAPWD](#)".
2. Set the `REMOTE_LOGIN_PASSWORDFILE` initialization parameter to `exclusive`. (This is the default.)

Oracle Database issues an error if you attempt to grant these privileges and the initialization parameter `REMOTE_LOGIN_PASSWORDFILE` is not set correctly.

 **Note:**

`REMOTE_LOGIN_PASSWORDFILE` is a static initialization parameter and therefore cannot be changed without restarting the database.

3. Connect with SYSDBA privileges as shown in the following example, and enter the SYS password when prompted:

```
CONNECT SYS AS SYSDBA
```
4. Start up the instance and create the database if necessary, or mount and open an existing database.
5. Create users as necessary. Grant SYSDBA, SYSOPER, SYSBACKUP, SYSDG, or SYSKM administrative privilege to yourself and other users as appropriate. See "[Granting and Revoking Administrative Privileges](#)".

1.7.6 Granting and Revoking Administrative Privileges

Use the `GRANT` statement to grant administrative privileges. Use the `REVOKE` statement to revoke administrative privileges.

To grant the SYSDBA, SYSOPER, SYSBACKUP, SYSDG, or SYSKM administrative privilege to a user:

- Run the GRANT statement.

For example:

```
GRANT SYSDBA TO mydba;
```

To revoke the administrative privilege from a user:

- Run the REVOKE statement.

For example:

```
REVOKE SYSDBA FROM mydba;
```

The WITH ADMIN OPTION is ignored if it is specified in the GRANT statement that grants an administrative privilege, and the following rules apply:

- A user currently connected as SYSDBA can grant any administrative privilege to another user and revoke any administrative privilege from another user.
- A user currently connected as SYSOPER *cannot* grant any administrative privilege to another user and *cannot* revoke any administrative privilege from another user.
- A user currently connected as SYSBACKUP can grant or revoke another user's SYSBACKUP administrative privilege.
- A user currently connected as SYSDG can grant or revoke another user's SYSDG administrative privilege.
- A user currently connected as SYSKM can grant or revoke another user's SYSKM administrative privilege.

Administrative privileges cannot be granted to roles, because roles are available only after database startup. Do not confuse the database administrative privileges with operating system roles.

 **See Also:**

Oracle Database Security Guide for more information on administrative privileges

1.7.7 Viewing Database Password File Members

The V\$PFILE_USERS view contains information about users that have been granted administrative privileges.

To determine which users have been granted administrative privileges:

- Query the V\$PFILE_USERS view.

 **See Also:**

Oracle Database Reference for information about the V\$PFILE_USERS view

1.7.8 Removing a Database Password File

You can remove a database password file if it is no longer needed.

If you determine that you no longer require a database password file to authenticate users, then to remove it:

- Delete the database password file, and optionally reset the `REMOTE_LOGIN_PASSWORDFILE` initialization parameter to `none`.

After you remove this file, only those users who can be authenticated by the operating system can perform `SYSDBA`, `SYSOPER`, `SYSBACKUP`, `SYSDG`, or `SYSKM` database administration operations.

1.8 Data Utilities

Oracle utilities are available to help you maintain the data in your Oracle Database.

SQL*Loader

SQL*Loader is used both by database administrators and by other users of Oracle Database. It loads data from standard operating system files (such as, files in text or C data format) into database tables.

Export and Import Utilities

The Data Pump utility enables you to archive data and to move data between one Oracle Database and another. Also available are the original Import (IMP) and Export (EXP) utilities for importing and exporting data from and to earlier releases.

See Also:

- *Oracle Database Utilities* for detailed information about SQL*Loader
- *Oracle Database Utilities* for detailed information about Data Pump

Creating and Configuring an Oracle Database

After you plan your database, you can create the database with a graphical tool or a SQL command.

- [About Creating an Oracle Database](#)

You typically create a database during Oracle Database software installation. However, you can also create a database after installation.

- [Considerations Before Creating the Database](#)

Database creation prepares several operating system files to work together as an Oracle Database. You only need to create a database once, regardless of how many data files it has or how many instances access it. You can create a database to erase information in an existing database and create a new database with the same name and physical structure.

- [Creating a Database with DBCA](#)

Oracle Database Configuration Assistant (DBCA) is a tool for creating and configuring an Oracle database.

- [Creating a Database with the CREATE DATABASE Statement](#)

Using the `CREATE DATABASE` SQL statement is a more manual approach to creating a database than using Oracle Database Configuration Assistant (DBCA). One advantage of using this statement over using DBCA is that you can create databases from within scripts.

- [Specifying CREATE DATABASE Statement Clauses](#)

When you execute a `CREATE DATABASE` statement, Oracle Database performs several operations. The actual operations performed depend on the clauses that you specify in the `CREATE DATABASE` statement and the initialization parameters that you have set.

- [Specifying Initialization Parameters](#)

You can add or edit basic initialization parameters before you create your new database.

- [Managing Initialization Parameters Using a Server Parameter File](#)

Initialization parameters for the Oracle Database have traditionally been stored in a text initialization parameter file. For better manageability, you can choose to maintain initialization parameters in a binary server parameter file that is persistent across database startup and shutdown.

- [Managing Application Workloads with Database Services](#)

A database service is a named representation of one or more database instances. Services enable you to group database workloads and route a particular work request to an appropriate instance.

- [Considerations After Creating a Database](#)

After you create a database the instance is left running, and the database is open and available for normal database use. You may want to perform specific actions after creating a database.

- [Cloning a Database with CloneDB](#)
CloneDB enables you to clone a database multiple times without copying the data files into several different locations. Instead, CloneDB uses copy-on-write technology, so that only the blocks that are modified require additional storage on disk.
- [Dropping a Database](#)
Dropping a database involves removing its data files, online redo logs, control files, and initialization parameter files.
- [Database Data Dictionary Views](#)
You can query data dictionary views for information about your database content and structure.
- [Database Configuration Assistant Command Reference for Silent Mode](#)
This section provides detailed information about the syntax and options for the Database Configuration Assistant (DBCA) silent mode commands.

 **See Also:**

- [Using Oracle Managed Files](#) for information about creating a database whose underlying operating system files are automatically created and managed by the Oracle Database server
- Your platform-specific Oracle Real Application Clusters (Oracle RAC) installation guide for information about creating a database in an Oracle RAC environment

2.1 About Creating an Oracle Database

You typically create a database during Oracle Database software installation. However, you can also create a database after installation.

Reasons to create a database after installation are as follows:

- You used Oracle Universal Installer (OUI) to install software only, and did not create a database.
- You want to create another database (and database instance) on the same host computer as an existing Oracle database. In this case, this chapter assumes that the new database uses the same Oracle home as the existing database. You can also create the database in a new Oracle home by running OUI again.
- You want to make a copy of (clone) a database.

The specific methods for creating a database are:

- With Database Configuration Assistant (DBCA), a graphical tool.
See "[Creating a Database with DBCA](#)"
- With the `CREATE DATABASE` SQL statement.
See "[Creating a Database with the CREATE DATABASE Statement](#)"

2.2 Considerations Before Creating the Database

Database creation prepares several operating system files to work together as an Oracle Database. You only need to create a database once, regardless of how many data files it has or how many instances access it. You can create a database to erase information in an existing database and create a new database with the same name and physical structure.

- [Planning for Database Creation](#)

Prepare to create the database by research and careful planning.

- [About Selecting a Character Set](#)

It is important to select the right character set for your database. Oracle recommends AL32UTF8 as the database character set.

- [Meeting Creation Prerequisites](#)

Prerequisites must be met before creating a database.

2.2.1 Planning for Database Creation

Prepare to create the database by research and careful planning.

[Table 2-1](#) lists some recommended actions:

Table 2-1 Database Planning Tasks

Action	Additional Information
Plan the database tables and indexes and estimate the amount of space they will require.	Oracle Database Structure and Storage Schema Objects
Plan the layout of the underlying operating system files your database will comprise. Proper distribution of files can improve database performance dramatically by distributing the I/O during file access. You can distribute I/O in several ways when you install Oracle software and create your database. For example, you can place redo log files on separate disks or use striping. You can situate data files to reduce contention. And you can control data density (number of rows to a data block). If you create a Fast Recovery Area, Oracle recommends that you place it on a storage device that is different from that of the data files.	Using Oracle Managed Files Oracle Automatic Storage Management Administrator's Guide Oracle Database Performance Tuning Guide
To greatly simplify this planning task, consider using Oracle Managed Files and Automatic Storage Management to create and manage the operating system files that comprise your database storage.	Your Oracle operating system-specific documentation, including the appropriate Oracle Database installation guide.
Select the global database name , which is the name and location of the database within the network structure. Create the global database name by setting both the DB_NAME and DB_DOMAIN initialization parameters.	" Determining the Global Database Name "

Table 2-1 (Cont.) Database Planning Tasks

Action	Additional Information
Familiarize yourself with the initialization parameters contained in the initialization parameter file. Become familiar with the concept and operation of a server parameter file . A server parameter file lets you store and manage your initialization parameters persistently in a server-side disk file.	"About Initialization Parameters and Initialization Parameter Files" "What Is a Server Parameter File?" <i>Oracle Database Reference</i>
Select the database character set. All character data, including data in the data dictionary, is stored in the database character set. You specify the database character set when you create the database. See "About Selecting a Character Set" for details.	<i>Oracle Database Globalization Support Guide</i>
Consider which time zones your database must support. Oracle Database uses one of two time zone files as the source of valid time zones. The default time zone file is <code>timezlr_11.dat</code> . It contains more time zones than the smaller time zone file, <code>timezone_11.dat</code> .	"Specifying the Database Time Zone File"
Select the standard database block size. This is specified at database creation by the <code>DB_BLOCK_SIZE</code> initialization parameter and cannot be changed after the database is created. The SYSTEM tablespace and most other tablespaces use the standard block size. Additionally, you can specify up to four nonstandard block sizes when creating tablespaces.	"Specifying Database Block Sizes"
If you plan to store online redo log files on disks with a 4K byte sector size, determine whether you must manually specify redo log block size.	"Planning the Block Size of Redo Log Files"
Determine the appropriate initial sizing for the SYSAUX tablespace.	"About the SYSAUX Tablespace"
Plan to use a default tablespace for non-SYSTEM users to prevent inadvertently saving database objects in the SYSTEM tablespace.	"Creating a Default Permanent Tablespace"
Plan to use an undo tablespace to manage your undo data.	Managing Undo
Develop a backup and recovery strategy to protect the database from failure. It is important to protect the control file by multiplexing, to choose the appropriate backup mode, and to manage the online redo log and archived redo log files.	Managing the Redo Log Managing Archived Redo Log Files Managing Control Files <i>Oracle Database Backup and Recovery User's Guide</i>
Familiarize yourself with the principles and options of starting up and shutting down an instance and mounting and opening a database.	Starting Up and Shutting Down

2.2.2 About Selecting a Character Set

It is important to select the right character set for your database. Oracle recommends AL32UTF8 as the database character set.

AL32UTF8 is Oracle's name for the UTF-8 encoding of the Unicode standard. The Unicode standard is the universal character set that supports most of the currently spoken languages of the world. The use of the Unicode standard is indispensable for any multilingual technology, including database processing.

After a database is created and accumulates production data, changing the database character set is a time consuming and complex project. Therefore, it is very important to select the right character set at installation time. Even if the database does not currently store multilingual data but is expected to store multilingual data within a few years, the choice of AL32UTF8 for the database character set is usually the only good decision. The universality and flexibility of Unicode typically outweighs some additional cost associated with it, such as slightly slower text processing compared to single-byte character sets and higher storage space requirements for non-ASCII text compared to non-Unicode character sets.

If you do not want to use AL32UTF8, and you are not restricted in your choice by a vendor requirement, then Oracle suggests that you use one of the character sets listed as recommended for the database. The recommended character sets were selected based on the requirements of modern client operating systems. Oracle Universal Installer (OUI) presents the recommended list only, and Database Configuration Assistant (DBCA) must be used separately to choose a non-recommended character set. In addition, the default database creation configuration in DBCA allows the selection of the recommended character sets only. You must use the advanced configuration mode of DBCA or the `CREATE DATABASE` statement to select a non-recommended character set.

If no character set choice is presented in an OUI or a DBCA installation mode, then AL32UTF8 is used as the database character set, unless a custom database template with another character set has been selected.

 **Note:**

- Oracle recommends using AL32UTF8 as the database character set. AL32UTF8 is the proper implementation of the Unicode encoding UTF-8. Starting with Oracle Database 12c Release 2, AL32UTF8 is used as the default database character set while creating a database using Oracle Universal Installer (OUI) as well as Oracle Database Configuration Assistant (DBCA).
- You can only select an ASCII-based character set for the database on an ASCII-based platform.

Caution:

Do not use UTF8 as the database character set unless required for compatibility with Oracle Database clients and servers in Oracle8i Release 1 (8.1.7) and earlier, or unless explicitly requested by your application vendor. Despite having a very similar name, UTF8 is not a proper implementation of the Unicode encoding UTF-8. If the UTF8 character set is used where UTF-8 processing is expected, data loss and security issues may occur. This is especially true for Web related data, such as XML and URL addresses.

AL32UTF8 and UTF8 character sets are not compatible with each other as they have different maximum character widths. AL32UTF8 has a maximum character width of 4 bytes, whereas UTF8 has a maximum character width of 3 bytes.

See Also:

Oracle Database Globalization Support Guide for information about the character sets recommended for the database

2.2.3 Meeting Creation Prerequisites

Prerequisites must be met before creating a database.

Before you can create a new database, the following prerequisites must be met:

- The desired Oracle software must be installed. This includes setting various environment variables unique to your operating system and establishing the directory structure for software and database files.
- Sufficient memory must be available to start the Oracle Database instance.
- Sufficient disk storage space must be available for the planned database on the computer that runs Oracle Database.

All of these are discussed in the *Oracle Database Installation Guide* specific to your operating system. If you use the Oracle Universal Installer, it will guide you through your installation and provide help in setting environment variables and establishing directory structure and authorizations.

2.3 Creating a Database with DBCA

Oracle Database Configuration Assistant (DBCA) is a tool for creating and configuring an Oracle database.

- [About Creating a Database with DBCA](#)

Oracle strongly recommends using the Database Configuration Assistant (DBCA) to create a database, because it is a more automated approach, and your database is ready to use when DBCA completes.

- [About Creating a Database with Interactive DBCA](#)
The easiest way to create a database is with Database Configuration Assistant (DBCA).
- [About Creating a Database with Noninteractive/Silent DBCA](#)
You can create a database using the noninteractive/silent mode of Database Configuration Assistant (DBCA).

2.3.1 About Creating a Database with DBCA

Oracle strongly recommends using the Database Configuration Assistant (DBCA) to create a database, because it is a more automated approach, and your database is ready to use when DBCA completes.

DBCA can be launched by the Oracle Universal Installer (OUI), depending upon the type of install that you select. You can also launch DBCA as a standalone tool at any time after Oracle Database installation.

You can run DBCA in interactive mode or noninteractive/silent mode. Interactive mode provides a graphical interface and guided workflow for creating and configuring a database. Noninteractive/silent mode enables you to script database creation. You can run DBCA in noninteractive/silent mode by specifying command-line arguments, a response file, or both.

2.3.2 About Creating a Database with Interactive DBCA

The easiest way to create a database is with Database Configuration Assistant (DBCA).

See *Oracle Database 2 Day DBA* for detailed information about creating a database interactively with DBCA.

2.3.3 About Creating a Database with Noninteractive/Silent DBCA

You can create a database using the noninteractive/silent mode of Database Configuration Assistant (DBCA).

See the following documentation for details on using the noninteractive/silent mode of DBCA:

- "[Database Configuration Assistant Command Reference for Silent Mode](#)"
- Appendix A of the installation guide for your platform
- [DBCA Examples](#)
Examples illustrate how to create a database with noninteractive/silent mode of Database Configuration Assistant (DBCA).

2.3.3.1 DBCA Examples

Examples illustrate how to create a database with noninteractive/silent mode of Database Configuration Assistant (DBCA).

The following example creates a database by passing command-line arguments to DBCA:

```
dbca -silent -createDatabase -templateName General_Purpose.dbs  
-gdbname oradb.example.com -sid oradb -responseFile NO_VALUE  
-characterSet AL32UTF8 -memoryPercentage 30 -emConfiguration LOCAL
```

```
Enter SYSTEM user password:  
password  
Enter SYS user password:  
password  
Copying database files  
1% complete  
3% complete  
...
```

To ensure completely silent operation, you can redirect stdout to a file. If you do this, however, you must supply passwords for the administrative accounts in command-line arguments or the response file.

To view brief help for DBCA command-line arguments, enter the following command:

```
dbca -help
```

For more detailed argument information, including defaults, view the response file template found on your distribution media. Appendix A of your platform installation guide provides the name and location of this file.

2.4 Creating a Database with the CREATE DATABASE Statement

Using the CREATE DATABASE SQL statement is a more manual approach to creating a database than using Oracle Database Configuration Assistant (DBCA). One advantage of using this statement over using DBCA is that you can create databases from within scripts.

- **About Creating a Database with the CREATE DATABASE Statement**

When you use the CREATE DATABASE statement, you must complete additional actions before you have an operational database. These actions include building views on the data dictionary tables and installing standard PL/SQL packages. You perform these actions by running the supplied scripts.

- **Step 1: Specify an Instance Identifier (SID)**

The ORACLE_SID environment variable is used to distinguish this instance from other Oracle Database instances that you may create later and run concurrently on the same host computer.

- **Step 2: Ensure That the Required Environment Variables Are Set**

Depending on your platform, before you can start SQL*Plus (as required in a later step), you may have to set environment variables, or at least verify that they are set properly.

- **Step 3: Choose a Database Administrator Authentication Method**

You must be authenticated and granted appropriate system privileges in order to create a database.

- **Step 4: Create the Initialization Parameter File**

When an Oracle instance starts, it reads an initialization parameter file. This file can be a text file, which can be created and modified with a text editor, or a binary file, which is created and dynamically modified by the database. The binary file, which is preferred, is called a **server parameter file**. In this step, you create a text

initialization parameter file. In a later step, you create a server parameter file from the text file.

- **Step 5: (Windows Only) Create an Instance**
On the Windows platform, before you can connect to an instance, you must manually create it if it does not already exist. The ORADIM command creates an Oracle Database instance by creating a new Windows service.
- **Step 6: Connect to the Instance**
Start SQL*Plus and connect to your Oracle Database instance with the SYSDBA administrative privilege.
- **Step 7: Create a Server Parameter File**
The server parameter file enables you to change initialization parameters with the ALTER SYSTEM command and persist the changes across a database shutdown and startup. You create the server parameter file from your edited text initialization file.
- **Step 8: Start the Instance**
Start an instance without mounting a database.
- **Step 9: Issue the CREATE DATABASE Statement**
To create the new database, use the CREATE DATABASE statement.
- **Step 10: Create Additional Tablespaces**
To make the database functional, you must create additional tablespaces for your application data.
- **Step 11: Run Scripts to Build Data Dictionary Views**
Run the scripts necessary to build data dictionary views, synonyms, and PL/SQL packages, and to support proper functioning of SQL*Plus.
- **Step 12: (Optional) Run Scripts to Install Additional Options**
You may want to run other scripts. The scripts that you run are determined by the features and options you choose to use or install.
- **Step 13: Back Up the Database**
Take a full backup of the database to ensure that you have a complete set of files from which to recover if a media failure occurs.
- **Step 14: (Optional) Enable Automatic Instance Startup**
You might want to configure the Oracle instance to start automatically when its host computer restarts.

2.4.1 About Creating a Database with the CREATE DATABASE Statement

When you use the CREATE DATABASE statement, you must complete additional actions before you have an operational database. These actions include building views on the data dictionary tables and installing standard PL/SQL packages. You perform these actions by running the supplied scripts.

If you have existing scripts for creating your database, then consider editing those scripts to take advantage of new Oracle Database features.

The instructions in this section apply to *single-instance installations only*. See the Oracle Real Application Clusters (Oracle RAC) installation guide for your platform for instructions for creating an Oracle RAC database.

 **Note:**

- *Single-instance* does not mean that only one Oracle instance can reside on a single host computer. In fact, multiple Oracle instances (and their associated databases) can run on a single host computer. A **single-instance database** is a database that is accessed by only one Oracle instance at a time, as opposed to an Oracle RAC database, which is accessed concurrently by multiple Oracle instances on multiple nodes.
- Starting in Oracle Database 12c Release 2 (12.2), read-only and read/write instances can coexist within a single Oracle RAC database. This configuration is useful for the scalability of parallel queries.

 **Tip:**

If you are using Oracle Automatic Storage Management (Oracle ASM) to manage your disk storage, then you must start the Oracle ASM instance and configure your disk groups before performing these steps. See *Oracle Automatic Storage Management Administrator's Guide*.

 **See Also:**

- *Oracle Real Application Clusters Administration and Deployment Guide* for more information on Oracle RAC
- *Oracle Clusterware Administration and Deployment Guide* for information about configuring read-only and read/write instances that coexist within a single Oracle RAC database

2.4.2 Step 1: Specify an Instance Identifier (SID)

The `ORACLE_SID` environment variable is used to distinguish this instance from other Oracle Database instances that you may create later and run concurrently on the same host computer.

1. Decide on a unique Oracle system identifier (SID) for your instance.
2. Open a command window.

 **Note:**

Use this command window for the subsequent steps.

3. Set the `ORACLE_SID` environment variable.

Restrictions related to the valid characters in an ORACLE_SID are platform-specific. On some platforms, the SID is case-sensitive.

 **Note:**

It is common practice to set the SID to be equal to the database name. The maximum number of characters for the database name is eight. For more information, see the discussion of the DB_NAME initialization parameter in *Oracle Database Reference*.

The following example for UNIX and Linux operating systems sets the SID for the instance that you will connect to in [Step 6: Connect to the Instance](#):

- Bourne, Bash, or Korn shell:

```
ORACLE_SID=mynewdb  
export ORACLE_SID
```

- C shell:

```
setenv ORACLE_SID mynewdb
```

The following example sets the SID for the Windows operating system:

```
set ORACLE_SID=mynewdb
```

 **See Also:**

Oracle Database Concepts for background information about the Oracle instance

2.4.3 Step 2: Ensure That the Required Environment Variables Are Set

Depending on your platform, before you can start SQL*Plus (as required in a later step), you may have to set environment variables, or at least verify that they are set properly.

- Set required environment variables.

For example, on most platforms, ORACLE_SID and ORACLE_HOME must be set. In addition, it is advisable to set the PATH variable to include the ORACLE_HOME/bin directory. On the UNIX and Linux platforms, you must set these environment variables manually. On the Windows platform, OUI automatically assigns values to ORACLE_HOME and ORACLE_SID in the Windows registry. If you did not create a database upon installation, OUI does not set ORACLE_SID in the registry, and you will have to set the ORACLE_SID environment variable when you create your database later.

2.4.4 Step 3: Choose a Database Administrator Authentication Method

You must be authenticated and granted appropriate system privileges in order to create a database.

- Decide on an authentication method.

You can be authenticated as an administrator with the required privileges in the following ways:

- With a password file
- With operating system authentication

To be authenticated with a password file, create the password file as described in "[Creating and Maintaining a Database Password File](#)". To be authenticated with operating system authentication, ensure that you log in to the host computer with a user account that is a member of the appropriate operating system user group. On the UNIX and Linux platforms, for example, this is typically the dba user group. On the Windows platform, the user installing the Oracle software is automatically placed in the required user group.

See Also:

- "[About Database Administrator Security and Privileges](#)"
- "[Database Administrator Authentication](#)" for information about password files and operating system authentication

2.4.5 Step 4: Create the Initialization Parameter File

When an Oracle instance starts, it reads an initialization parameter file. This file can be a text file, which can be created and modified with a text editor, or a binary file, which is created and dynamically modified by the database. The binary file, which is preferred, is called a **server parameter file**. In this step, you create a text initialization parameter file. In a later step, you create a server parameter file from the text file.

- Create the initialization parameter file.

One way to create the text initialization parameter file is to edit the sample presented in "[Sample Initialization Parameter File](#)".

If you create the initialization parameter file manually, ensure that it contains at least the parameters listed in [Table 37-2](#). All other parameters not listed have default values.

Table 2-2 Recommended Minimum Initialization Parameters

Parameter Name	Mandatory	Notes
DB_NAME	Yes	Database identifier. Must correspond to the value used in the CREATE DATABASE statement. Maximum 8 characters.

Table 2-2 (Cont.) Recommended Minimum Initialization Parameters

Parameter Name	Mandatory	Notes
CONTROL_FILES	No	Strongly recommended. If not provided, then the database instance creates one control file in the same location as the initialization parameter file. Providing this parameter enables you to multiplex control files. See " Creating Initial Control Files " for more information.
MEMORY_TARGET	No	Sets the total amount of memory used by the instance and enables automatic memory management. You can choose other initialization parameters instead of this one for more manual control of memory usage. See " Configuring Memory Manually ".

For convenience, store your initialization parameter file in the Oracle Database default location, using the default file name. Then when you start your database, it will not be necessary to specify the `PFILE` clause of the `STARTUP` command, because Oracle Database automatically looks in the default location for the initialization parameter file.

For more information about initialization parameters and the initialization parameter file, including the default name and location of the initialization parameter file for your platform, see "[About Initialization Parameters and Initialization Parameter Files](#)".

See Also:

- ["Specifying Initialization Parameters"](#)
- *Oracle Database Reference* for details on all initialization parameters

2.4.6 Step 5: (Windows Only) Create an Instance

On the Windows platform, before you can connect to an instance, you must manually create it if it does not already exist. The `ORADIM` command creates an Oracle Database instance by creating a new Windows service.

To create an instance:

- Enter the following command at a Windows command prompt:

```
oradim -NEW -SID sid -STARTMODE MANUAL -PFILE file
```

Replace the following placeholders with appropriate values:

- `sid` - The desired SID (for example `mynewdb`)
- `file` - The full path to the text initialization parameter file

 **Caution:**

Do not set the `-STARTMODE` argument to `AUTO` at this point, because this causes the new instance to start and attempt to mount the database, which does not exist yet. You can change this parameter to `AUTO`, if desired, in [Step 14: \(Optional\) Enable Automatic Instance Startup.](#)

Most Oracle Database services log on to the system using the privileges of the Oracle Home User. The service runs with the privileges of this user. The `ORADIM` command prompts you for the password to this user account. You can specify other options using `ORADIM`.

 **See Also:**

- *Oracle Database Platform Guide for Microsoft Windows* for more information on the `ORADIM` command and the Oracle Home User
- *Oracle Database Installation Guide for Microsoft Windows* for more information about the Oracle Home User

2.4.7 Step 6: Connect to the Instance

Start SQL*Plus and connect to your Oracle Database instance with the `SYSDBA` administrative privilege.

- To authenticate with a password file, enter the following commands, and then enter the `SYS` password when prompted:

```
$ sqlplus /nolog  
SQL> CONNECT SYS AS SYSDBA
```

- To authenticate with operating system authentication, enter the following commands:

```
$ sqlplus /nolog  
SQL> CONNECT / AS SYSDBA
```

SQL*Plus outputs the following message:

```
Connected to an idle instance.
```

 **Note:**

SQL*Plus may output a message similar to the following:

```
Connected to:  
Oracle Database 12c Enterprise Edition Release 12.1.0.1.0 - 64bit  
Production  
With the Partitioning, OLAP, Advanced Analytics and Real Application  
Testing options
```

If so, the instance is already started. You may have connected to the wrong instance. Exit SQL*Plus with the `EXIT` command, check that `ORACLE_SID` is set properly, and repeat this step.

2.4.8 Step 7: Create a Server Parameter File

The server parameter file enables you to change initialization parameters with the `ALTER SYSTEM` command and persist the changes across a database shutdown and startup. You create the server parameter file from your edited text initialization file.

- Run the following SQL*Plus command:

```
CREATE SPFILE FROM PFILE;
```

This SQL*Plus command reads the text initialization parameter file (PFILE) with the default name from the default location, creates a server parameter file (SPFILE) from the text initialization parameter file, and writes the SPFILE to the default location with the default SPFILE name.

You can also supply the file name and path for both the PFILE and SPFILE if you are not using default names and locations.

 **Tip:**

The database must be restarted before the server parameter file takes effect.

 **Note:**

Although creating a server parameter file is optional at this point, it is recommended. If you do not create a server parameter file, the instance continues to read the text initialization parameter file whenever it starts.

Important—If you are using Oracle Managed Files and your initialization parameter file does not contain the `CONTROL_FILES` parameter, then you must create a server parameter file now so the database can save the names and locations of the control files that it creates during the `CREATE DATABASE` statement. See "[Specifying Oracle Managed Files at Database Creation](#)" for more information.

 **See Also:**

- "[Managing Initialization Parameters Using a Server Parameter File](#)"
- [Oracle Database SQL Language Reference](#) for more information on the CREATE SPFILE command

2.4.9 Step 8: Start the Instance

Start an instance without mounting a database.

- Run the STARTUP command with the NOMOUNT clause.

Typically, you do this only during database creation or while performing maintenance on the database. In this example, because the initialization parameter file or server parameter file is stored in the default location, you are not required to specify the PFILE clause:

```
STARTUP NOMOUNT
```

At this point, the instance memory is allocated and its processes are started. The database itself does not yet exist.

 **See Also:**

- [Starting Up and Shutting Down](#) for information about using the STARTUP command
- "[Managing Initialization Parameters Using a Server Parameter File](#)"

2.4.10 Step 9: Issue the CREATE DATABASE Statement

To create the new database, use the CREATE DATABASE statement.

- Run the CREATE DATABASE statement.

 **Note:**

If you are creating a multitenant container database (CDB), then see the examples in "[Creating a CDB with the CREATE DATABASE Statement](#)".

Example 1

The following statement creates a database `mynewdb`. This database name must agree with the `DB_NAME` parameter in the initialization parameter file. This example assumes the following:

- The initialization parameter file specifies the number and location of control files with the `CONTROL_FILES` parameter.
- The directory `/u01/app/oracle/oradata/mynewdb` exists.
- The directories `/u01/logs/my` and `/u02/logs/my` exist.

```
CREATE DATABASE mynewdb
  USER SYS IDENTIFIED BY sys_password
  USER SYSTEM IDENTIFIED BY system_password
  LOGFILE GROUP 1 ('/u01/logs/my/redo01a.log','/u02/logs/my/redo01b.log') SIZE 100M BLOCKSIZE 512,
    GROUP 2 ('/u01/logs/my/redo02a.log','/u02/logs/my/redo02b.log') SIZE 100M BLOCKSIZE 512,
    GROUP 3 ('/u01/logs/my/redo03a.log','/u02/logs/my/redo03b.log') SIZE 100M BLOCKSIZE 512
  MAXLOGHISTORY 1
  MAXLOGFILES 16
  MAXLOGMEMBERS 3
  MAXDATAFILES 1024
  CHARACTER SET AL32UTF8
  NATIONAL CHARACTER SET AL16UTF16
  EXTENT MANAGEMENT LOCAL
  DATAFILE '/u01/app/oracle/oradata/mynewdb/system01.dbf'
    SIZE 700M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
  SYSAUX DATAFILE '/u01/app/oracle/oradata/mynewdb/sysaux01.dbf'
    SIZE 550M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
  DEFAULT TABLESPACE users
    DATAFILE '/u01/app/oracle/oradata/mynewdb/users01.dbf'
      SIZE 500M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED
  DEFAULT TEMPORARY TABLESPACE temptbs1
    TEMPFILE '/u01/app/oracle/oradata/mynewdb/temp01.dbf'
      SIZE 20M REUSE AUTOEXTEND ON NEXT 640K MAXSIZE UNLIMITED
  UNDO TABLESPACE undotbs1
    DATAFILE '/u01/app/oracle/oradata/mynewdb/undotbs01.dbf'
      SIZE 200M REUSE AUTOEXTEND ON NEXT 5120K MAXSIZE UNLIMITED
  USER_DATA TABLESPACE usertbs
    DATAFILE '/u01/app/oracle/oradata/mynewdb/usertbs01.dbf'
      SIZE 200M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED;
```

A database is created with the following characteristics:

- The database is named `mynewdb`. Its global database name is `mynewdb.us.example.com`, where the domain portion (`us.example.com`) is taken from the initialization parameter file. See "[Determining the Global Database Name](#)".
- Three control files are created as specified by the `CONTROL_FILES` initialization parameter, which was set before database creation in the initialization parameter file. See "[Sample Initialization Parameter File](#)" and "[Specifying Control Files](#)".
- The passwords for user accounts `SYS` and `SYSTEM` are set to the values that you specified. The passwords are case-sensitive. The two clauses that specify the passwords for `SYS` and `SYSTEM` are not mandatory in this release of Oracle Database. However, if you specify either clause, then you must specify both clauses. For further information about the use of these clauses, see "[Protecting Your Database: Specifying Passwords for Users SYS and SYSTEM](#)".
- The new database has three redo log file groups, each with two members, as specified in the `LOGFILE` clause. `MAXLOGFILES`, `MAXLOGMEMBERS`, and `MAXLOGHISTORY` define limits for the redo log. See "[Choosing the Number of Redo Log Files](#)". The block size for the redo log files is set to 512 bytes, the same size as physical sectors on disk. The `BLOCKSIZE` clause is optional if block size is to be the same as physical sector size (the default). Typical sector size and thus typical block size is

512. Permissible values for `BLOCKSIZE` are 512, 1024, and 4096. For newer disks with a 4K sector size, optionally specify `BLOCKSIZE` as 4096. See "[Planning the Block Size of Redo Log Files](#)" for more information.

- `MAXDATAFILES` specifies the maximum number of data files that can be open in the database. This number affects the initial sizing of the control file.

 **Note:**

You can set several limits during database creation. Some of these limits are limited by and affected by operating system limits. For example, if you set `MAXDATAFILES`, Oracle Database allocates enough space in the control file to store `MAXDATAFILES` file names, even if the database has only one data file initially. However, because the maximum control file size is limited and operating system dependent, you might not be able to set all `CREATE DATABASE` parameters at their theoretical maximums.

For more information about setting limits during database creation, see the *Oracle Database SQL Language Reference* and your operating system-specific Oracle documentation.

- The `AL32UTF8` character set is used to store data in this database.
- The `AL16UTF16` character set is specified as the `NATIONAL CHARACTER SET` used to store data in columns specifically defined as `NCHAR`, `NCLOB`, or `NVARCHAR2`.
- The `SYSTEM` tablespace, consisting of the operating system file `/u01/app/oracle/oradata/mynewdb/system01.dbf`, is created as specified by the `DATAFILE` clause. If a file with that name already exists, then it is overwritten.
- The `SYSTEM` tablespace is created as a locally managed tablespace. See "[Creating a Locally Managed SYSTEM Tablespace](#)".
- A `SYSAUX` tablespace is created, consisting of the operating system file `/u01/app/oracle/oradata/mynewdb/sysaux01.dbf` as specified in the `SYSAUX` `DATAFILE` clause. See "[About the SYSAUX Tablespace](#)".
- The `DEFAULT TABLESPACE` clause creates and names a default permanent tablespace for this database.
- The `DEFAULT TEMPORARY TABLESPACE` clause creates and names a default temporary tablespace for this database. See "[Creating a Default Temporary Tablespace](#)".
- The `UNDO TABLESPACE` clause creates and names an undo tablespace that is used to store undo data for this database if you have specified `UNDO_MANAGEMENT=AUTO` in the initialization parameter file. If you omit this parameter, then it defaults to `AUTO`. See "[Using Automatic Undo Management: Creating an Undo Tablespace](#)".
- The `USER_DATA TABLESPACE` clause creates and names the tablespace for storing user data and database options such as Oracle XML DB.
- Online redo logs will not initially be archived, because the `ARCHIVELOG` clause is not specified in this `CREATE DATABASE` statement. This is customary during database creation. You can later use an `ALTER DATABASE` statement to switch to `ARCHIVELOG` mode. The initialization parameters in the initialization parameter file for `mynewdb` relating to archiving are `LOG_ARCHIVE_DEST_1` and `LOG_ARCHIVE_FORMAT`. See [Managing Archived Redo Log Files](#).

 **Tips:**

- Ensure that all directories used in the CREATE DATABASE statement exist. The CREATE DATABASE statement does not create directories.
- If you are not using Oracle Managed Files, then every tablespace clause must include a DATAFILE or TEMPFILE clause.
- If database creation fails, then you can look at the alert log to determine the reason for the failure and to determine corrective actions. See "[Viewing the Alert Log](#)". If you receive an error message that contains a process number, then examine the trace file for that process. Look for the trace file that contains the process number in the trace file name. See "[Finding Trace Files](#)" for more information.
- To resubmit the CREATE DATABASE statement after a failure, you must first shut down the instance and delete any files created by the previous CREATE DATABASE statement.

Example 2

This example illustrates creating a database with Oracle Managed Files, which enables you to use a much simpler CREATE DATABASE statement. To use Oracle Managed Files, the initialization parameter DB_CREATE_FILE_DEST must be set. This parameter defines the base directory for the various database files that the database creates and automatically names. The following statement is an example of setting this parameter in the initialization parameter file:

```
DB_CREATE_FILE_DEST='/u01/app/oracle/oradata'
```

With Oracle Managed Files and the following CREATE DATABASE statement, the database creates the SYSTEM and SYSAUX tablespaces, creates the additional tablespaces specified in the statement, and chooses default sizes and properties for all data files, control files, and redo log files. Note that these properties and the other default database properties set by this method may not be suitable for your production environment, so it is recommended that you examine the resulting configuration and modify it if necessary.

```
CREATE DATABASE mynewdb
USER SYS IDENTIFIED BY sys_password
USER SYSTEM IDENTIFIED BY system_password
EXTENT MANAGEMENT LOCAL
DEFAULT TEMPORARY TABLESPACE temp
UNDO TABLESPACE undotbs1
DEFAULT TABLESPACE users;
```

 **Tip:**

If your CREATE DATABASE statement fails, and if you did not complete Step 7, then ensure that there is not a pre-existing server parameter file (SPFILE) for this instance that is setting initialization parameters in an unexpected way. For example, an SPFILE contains a setting for the complete path to all control files, and the CREATE DATABASE statement fails if those control files do not exist. Ensure that you shut down and restart the instance (with STARTUP NOMOUNT) after removing an unwanted SPFILE. See "[Managing Initialization Parameters Using a Server Parameter File](#)" for more information.

 **See Also:**

- ["Specifying CREATE DATABASE Statement Clauses"](#)
- ["Specifying Oracle Managed Files at Database Creation"](#)
- [Using Oracle Managed Files](#)
- *Oracle Database SQL Language Reference* for more information about specifying the clauses and parameter values for the CREATE DATABASE statement

2.4.11 Step 10: Create Additional Tablespaces

To make the database functional, you must create additional tablespaces for your application data.

- Run the CREATE TABLESPACE statement to create additional tablespaces.

The following sample script creates some additional tablespaces:

```
CREATE TABLESPACE apps_tbs LOGGING
    DATAFILE '/u01/app/oracle/oradata/mynewdb/apps01.dbf'
        SIZE 500M REUSE AUTOEXTEND ON NEXT 1280K MAXSIZE UNLIMITED
        EXTENT MANAGEMENT LOCAL;
-- create a tablespace for indexes, separate from user tablespace (optional)
CREATE TABLESPACE indx_tbs LOGGING
    DATAFILE '/u01/app/oracle/oradata/mynewdb/indx01.dbf'
        SIZE 100M REUSE AUTOEXTEND ON NEXT 1280K MAXSIZE UNLIMITED
        EXTENT MANAGEMENT LOCAL;
```

For information about creating tablespaces, see [Managing Tablespaces](#).

2.4.12 Step 11: Run Scripts to Build Data Dictionary Views

Run the scripts necessary to build data dictionary views, synonyms, and PL/SQL packages, and to support proper functioning of SQL*Plus.

1. In SQL*Plus, connect to your Oracle Database instance with the SYSDBA administrative privilege:

```
@?/rdbms/admin/catalog.sql
@?/rdbms/admin/catproc.sql
@?/rdbms/admin/utlrp.sql
```

- 2.** In SQL*Plus, connect to your Oracle Database instance as SYSTEM user:

```
@?/sqlplus/admin/pupbld.sql
```

The at-sign (@) is shorthand for the command that runs a SQL*Plus script. The question mark (?) is a SQL*Plus variable indicating the Oracle home directory. The following table contains descriptions of the scripts:

Script	Description
catalog.sql	Creates the views of the data dictionary tables, the dynamic performance views, and public synonyms for many of the views. Grants PUBLIC access to the synonyms.
catproc.sql	Runs all scripts required for or used with PL/SQL.
utlrp.sql	Recompiles all PL/SQL modules that are in an invalid state, including packages, procedures, and types.
pupbld.sql	Required for SQL*Plus. Enables SQL*Plus to disable commands by user.

2.4.13 Step 12: (Optional) Run Scripts to Install Additional Options

You may want to run other scripts. The scripts that you run are determined by the features and options you choose to use or install.

- Run scripts to install additional options.

Many of the scripts available to you are described in the *Oracle Database Reference*.

If you plan to install other Oracle products to work with this database, then see the installation instructions for those products. Some products require you to create additional data dictionary tables. Usually, command files are provided to create and load these tables into the database data dictionary.

See your Oracle documentation for the specific products that you plan to install for installation and administration instructions.

2.4.14 Step 13: Back Up the Database

Take a full backup of the database to ensure that you have a complete set of files from which to recover if a media failure occurs.

- Back up the database.

For information on backing up a database, see *Oracle Database Backup and Recovery User's Guide*.

2.4.15 Step 14: (Optional) Enable Automatic Instance Startup

You might want to configure the Oracle instance to start automatically when its host computer restarts.

- Configure the Oracle instance to start automatically when its host computer restarts.

See your operating system documentation for instructions. For example, on Windows, use the following command to configure the database service to start the instance upon computer restart:

```
ORADIM -EDIT -SID sid -STARTMODE AUTO -SRVCSTART SYSTEM [-SPFILE]
```

You must use the `-SPFILE` argument if you want the instance to read an SPFILE upon automatic restart.

 **See Also:**

- [Configuring Automatic Restart of an Oracle Database](#)
- [*Oracle Database Platform Guide for Microsoft Windows*](#) for more information on the ORADIM command.

2.5 Specifying CREATE DATABASE Statement Clauses

When you execute a `CREATE DATABASE` statement, Oracle Database performs several operations. The actual operations performed depend on the clauses that you specify in the `CREATE DATABASE` statement and the initialization parameters that you have set.

- [About CREATE DATABASE Statement Clauses](#)
You can use the `CREATE DATABASE` clauses to simplify the creation and management of your database.
- [Protecting Your Database: Specifying Passwords for Users SYS and SYSTEM](#)
To protect your database, specify passwords for users `SYS` and `SYSTEM`.
- [Creating a Locally Managed SYSTEM Tablespace](#)
During database creation, create a locally managed `SYSTEM` tablespace. A locally managed tablespace uses a bitmap stored in each data file to manage the extents.
- [Specify Data File Attributes for the SYSAUX Tablespace](#)
The `SYSAUX` tablespace is created by default, but you can specify its data file attributes during database creation.
- [Using Automatic Undo Management: Creating an Undo Tablespace](#)
Automatic undo management uses an undo tablespace.
- [Creating a Default Permanent Tablespace](#)
Oracle strongly recommends that you create a default permanent tablespace. Oracle Database assigns to this tablespace any non-`SYSTEM` users for whom you do not explicitly specify a different permanent tablespace.
- [Creating a Default Temporary Tablespace](#)
When you create a default temporary tablespace, Oracle Database assigns it as the temporary tablespace for users who are not explicitly assigned a temporary tablespace.
- [Specifying Oracle Managed Files at Database Creation](#)
You can minimize the number of clauses and parameters that you specify in your `CREATE DATABASE` statement by using the Oracle Managed Files feature.

- [Supporting Bigfile Tablespaces During Database Creation](#)
Oracle Database simplifies management of tablespaces and enables support for extremely large databases by letting you create **bigfile tablespaces**.
- [Specifying the Database Time Zone and Time Zone File](#)
Oracle Database datetime and interval data types and time zone support make it possible to store consistent information about the time of events and transactions.
- [Specifying FORCE LOGGING Mode](#)
Some data definition language statements (such as `CREATE TABLE`) allow the `NOLOGGING` clause, which causes some database operations not to generate redo records in the database redo log. The `NOLOGGING` setting can speed up operations that can be easily recovered outside of the database recovery mechanisms, but it can negatively affect media recovery and standby databases.

2.5.1 About CREATE DATABASE Statement Clauses

You can use the `CREATE DATABASE` clauses to simplify the creation and management of your database.

When you execute a `CREATE DATABASE` statement, Oracle Database performs at least these operations:

- Creates the data files for the database
- Creates the control files for the database
- Creates the online redo logs for the database and establishes the `ARCHIVELOG` mode
- Creates the `SYSTEM` tablespace
- Creates the `SYSAUX` tablespace
- Creates the data dictionary
- Sets the character set that stores data in the database
- Sets the database time zone
- Mounts and opens the database for use

2.5.2 Protecting Your Database: Specifying Passwords for Users SYS and SYSTEM

To protect your database, specify passwords for users `SYS` and `SYSTEM`.

- In the `CREATE DATABASE` statement, include clauses that specify the password for users `SYS` and `SYSTEM`.

The clauses of the `CREATE DATABASE` statement used for specifying the passwords for users `SYS` and `SYSTEM` are:

- `USER SYS IDENTIFIED BY password`
- `USER SYSTEM IDENTIFIED BY password`

If you omit these clauses, then these users are assigned the default passwords `change_on_install` and `manager`, respectively. A record is written to the alert log indicating that the default passwords were used. To protect your database, you must

change these passwords using the `ALTER USER` statement immediately after database creation.

Oracle strongly recommends that you specify these clauses, even though they are optional in this release of Oracle Database. The default passwords are commonly known, and if you neglect to change them later, then you leave database vulnerable to attack by malicious users.

When choosing a password, keep in mind that passwords are case-sensitive. Also, there may be password formatting requirements for your database. See the section entitled "How Oracle Database Checks the Complexity of Passwords" in *Oracle Database Security Guide* for more information.

 **See Also:**

["Some Security Considerations"](#)

2.5.3 Creating a Locally Managed SYSTEM Tablespace

During database creation, create a locally managed SYSTEM tablespace. A locally managed tablespace uses a bitmap stored in each data file to manage the extents.

- Specify the `EXTENT MANAGEMENT LOCAL` clause in the `CREATE DATABASE` statement to create a locally managed `SYSTEM` tablespace.

If you do not specify the `EXTENT MANAGEMENT LOCAL` clause, then by default the database creates a dictionary-managed `SYSTEM` tablespace. Dictionary-managed tablespaces are deprecated.

If you create your database with a locally managed `SYSTEM` tablespace, and if you are not using Oracle Managed Files, then ensure that the following conditions are met:

- You specify the `DEFAULT TEMPORARY TABLESPACE` clause in the `CREATE DATABASE` statement.
- You include the `UNDO TABLESPACE` clause in the `CREATE DATABASE` statement.

 **See Also:**

- Oracle Database SQL Language Reference* for more specific information about the use of the `DEFAULT TEMPORARY TABLESPACE` and `UNDO TABLESPACE` clauses when `EXTENT MANAGEMENT LOCAL` is specified for the `SYSTEM` tablespace
- ["Locally Managed Tablespaces"](#)
- ["Migrating the SYSTEM Tablespace to a Locally Managed Tablespace"](#)

2.5.4 Specify Data File Attributes for the SYSAUX Tablespace

The SYSAUX tablespace is created by default, but you can specify its data file attributes during database creation.

To specify data file attributes for the SYSAUX tablespace:

- Include the SYSAUX DATAFILE clause in the CREATE DATABASE statement.

If you include a DATAFILE clause for the SYSTEM tablespace, then you must specify the SYSAUX DATAFILE clause as well, or the CREATE DATABASE statement will fail. This requirement does not exist if the Oracle Managed Files feature is enabled (see "Specifying Oracle Managed Files at Database Creation").

- [About the SYSAUX Tablespace](#)

The SYSAUX tablespace is always created at database creation. The SYSAUX tablespace serves as an auxiliary tablespace to the SYSTEM tablespace. Because it is the default tablespace for many Oracle Database features and products that previously required their own tablespaces, it reduces the number of tablespaces required by the database. It also reduces the load on the SYSTEM tablespace.

2.5.4.1 About the SYSAUX Tablespace

The SYSAUX tablespace is always created at database creation. The SYSAUX tablespace serves as an auxiliary tablespace to the SYSTEM tablespace. Because it is the default tablespace for many Oracle Database features and products that previously required their own tablespaces, it reduces the number of tablespaces required by the database. It also reduces the load on the SYSTEM tablespace.

You can specify only data file attributes for the SYSAUX tablespace, using the SYSAUX DATAFILE clause in the CREATE DATABASE statement. Mandatory attributes of the SYSAUX tablespace are set by Oracle Database and include:

- PERMANENT
- READ WRITE
- EXTENT MANAGEMENT LOCAL
- SEGMENT SPACE MANAGEMENT AUTO

You cannot alter these attributes with an ALTER TABLESPACE statement, and any attempt to do so will result in an error. You cannot drop or rename the SYSAUX tablespace.

The size of the SYSAUX tablespace is determined by the size of the database components that occupy SYSAUX. You can view a list of these components by querying the V\$SYSAUX_OCCUPANTS view. Based on the initial sizes of these components, the SYSAUX tablespace must be at least 400 MB at the time of database creation. The space requirements of the SYSAUX tablespace will increase after the database is fully deployed, depending on the nature of its use and workload. For more information on how to manage the space consumption of the SYSAUX tablespace on an ongoing basis, see the "[Managing the SYSAUX Tablespace](#)".

The SYSAUX tablespace has the same security attributes as the SYSTEM tablespace.

 **See Also:**

["Managing the SYSAUX Tablespace"](#)

2.5.5 Using Automatic Undo Management: Creating an Undo Tablespace

Automatic undo management uses an undo tablespace.

- To enable automatic undo management, set the `UNDO_MANAGEMENT` initialization parameter to `AUTO` in your initialization parameter file. Or, omit this parameter, and the database defaults to automatic undo management.

In this mode, undo data is stored in an undo tablespace and is managed by Oracle Database. To define and name the undo tablespace yourself, you must include the `UNDO TABLESPACE` clause in the `CREATE DATABASE` statement at database creation time. If you omit this clause, and automatic undo management is enabled, then the database creates a default undo tablespace named `SYS_UNDOTBS`.

 **Note:**

If you decide to define the undo tablespace yourself, then ensure that its block size matches the highest data file block size for the database.

 **See Also:**

- ["Specifying the Method of Undo Space Management"](#)
- [Managing Undo](#) for information about the creation and use of undo tablespaces

2.5.6 Creating a Default Permanent Tablespace

Oracle strongly recommends that you create a default permanent tablespace. Oracle Database assigns to this tablespace any non-SYSTEM users for whom you do not explicitly specify a different permanent tablespace.

To specify a default permanent tablespace for the database:

- Include the `DEFAULT TABLESPACE` clause in the `CREATE DATABASE` statement

If you do not specify the `DEFAULT TABLESPACE` clause, then the `SYSTEM` tablespace is the default permanent tablespace for non-SYSTEM users.

 **See Also:**

Oracle Database SQL Language Reference for the syntax of the DEFAULT TABLESPACE clause of CREATE DATABASE and ALTER DATABASE

2.5.7 Creating a Default Temporary Tablespace

When you create a default temporary tablespace, Oracle Database assigns it as the temporary tablespace for users who are not explicitly assigned a temporary tablespace.

To create a default temporary tablespace for the database:

- Include the DEFAULT TEMPORARY TABLESPACE clause in the CREATE DATABASE statement.

You can explicitly assign a temporary tablespace or tablespace group to a user in the CREATE USER statement. However, if you do not do so, and if no default temporary tablespace has been specified for the database, then by default these users are assigned the SYSTEM tablespace as their temporary tablespace. It is not good practice to store temporary data in the SYSTEM tablespace, and it is cumbersome to assign every user a temporary tablespace individually. Therefore, Oracle recommends that you use the DEFAULT TEMPORARY TABLESPACE clause of CREATE DATABASE.

 **Note:**

When you specify a locally managed SYSTEM tablespace, the SYSTEM tablespace *cannot* be used as a temporary tablespace. In this case you must create a default temporary tablespace. This behavior is explained in "[Creating a Locally Managed SYSTEM Tablespace](#)".

 **See Also:**

- *Oracle Database SQL Language Reference* for the syntax of the DEFAULT TEMPORARY TABLESPACE clause of CREATE DATABASE and ALTER DATABASE
- "[Temporary Tablespaces](#)" for information about creating and using temporary tablespaces
- "[Multiple Temporary Tablespaces: Using Tablespace Groups](#)" for information about creating and using temporary tablespace groups

2.5.8 Specifying Oracle Managed Files at Database Creation

You can minimize the number of clauses and parameters that you specify in your CREATE DATABASE statement by using the Oracle Managed Files feature.

- Specify either a directory or Oracle Automatic Storage Management (Oracle ASM) disk group in which your files are created and managed by Oracle Database.

By including any of the initialization parameters DB_CREATE_FILE_DEST, DB_CREATE_ONLINE_LOG_DEST_n, or DB_RECOVERY_FILE_DEST in your initialization parameter file, you instruct Oracle Database to create and manage the underlying operating system files of your database. Oracle Database will automatically create and manage the operating system files for the following database structures, depending on which initialization parameters you specify and how you specify clauses in your CREATE DATABASE statement:

- Tablespaces and their data files
- Temporary tablespaces and their temp files
- Control files
- Online redo logs
- Archived redo log files
- Flashback logs
- Block change tracking files
- RMAN backups

 **See Also:**

["Specifying a Fast Recovery Area"](#) for information about setting initialization parameters that create a Fast Recovery Area

The following CREATE DATABASE statement shows briefly how the Oracle Managed Files feature works, assuming you have specified required initialization parameters:

```
CREATE DATABASE mynewdb
    USER SYS IDENTIFIED BY sys_password
    USER SYSTEM IDENTIFIED BY system_password
    EXTENT MANAGEMENT LOCAL
    UNDO TABLESPACE undotbs1
    DEFAULT TEMPORARY TABLESPACE temptbs1
    DEFAULT TABLESPACE users;
```

- The SYSTEM tablespace is created as a locally managed tablespace. Without the EXTENT MANAGEMENT LOCAL clause, the SYSTEM tablespace is created as dictionary managed, which is not recommended.
- No DATAFILE clause is specified, so the database creates an Oracle managed data file for the SYSTEM tablespace.
- No LOGFILE clauses are included, so the database creates two Oracle managed redo log file groups.

- No SYSAUX DATAFILE is included, so the database creates an Oracle managed data file for the SYSAUX tablespace.
- No DATAFILE subclause is specified for the UNDO TABLESPACE and DEFAULT TABLESPACE clauses, so the database creates an Oracle managed data file for each of these tablespaces.
- No TEMPFILE subclause is specified for the DEFAULT TEMPORARY TABLESPACE clause, so the database creates an Oracle managed temp file.
- If no CONTROL_FILES initialization parameter is specified in the initialization parameter file, then the database also creates an Oracle managed control file.
- If you are using a server parameter file (see "[Managing Initialization Parameters Using a Server Parameter File](#)"), then the database automatically sets the appropriate initialization parameters.

 **See Also:**

- [Using Oracle Managed Files](#), for information about the Oracle Managed Files feature and how to use it
- *Oracle Automatic Storage Management Administrator's Guide*. for information about Automatic Storage Management

2.5.9 Supporting Bigfile Tablespaces During Database Creation

Oracle Database simplifies management of tablespaces and enables support for extremely large databases by letting you create **bigfile tablespaces**.

Bigfile tablespaces can contain only one file, but that file can have up to 4G blocks. The maximum number of data files in an Oracle Database is limited (usually to 64K files). Therefore, bigfile tablespaces can significantly enhance the storage capacity of an Oracle Database.

This section discusses the clauses of the CREATE DATABASE statement that let you include support for bigfile tablespaces.

- [Specifying the Default Tablespace Type](#)
The SET DEFAULT...TABLESPACE clause of the CREATE DATABASE statement determines the default type of tablespace for this database in subsequent CREATE TABLESPACE statements.
- [Overriding the Default Tablespace Type](#)
The SYSTEM and SYSAUX tablespaces are always created with the default tablespace type. However, you optionally can explicitly override the default tablespace type for the UNDO and DEFAULT TEMPORARY tablespace during the CREATE DATABASE operation.

 **See Also:**

"[Bigfile Tablespaces](#)" for more information about bigfile tablespaces

2.5.9.1 Specifying the Default Tablespace Type

The `SET DEFAULT...TABLESPACE` clause of the `CREATE DATABASE` statement determines the default type of tablespace for this database in subsequent `CREATE TABLESPACE` statements.

- Specify either `SET DEFAULT BIGFILE TABLESPACE` or `SET DEFAULT SMALLFILE TABLESPACE`.

If you omit this clause, then the default is a **smallfile tablespace**, which is the traditional type of Oracle Database tablespace. A smallfile tablespace can contain up to 1022 files with up to 4M blocks each.

The use of bigfile tablespaces further enhances the Oracle Managed Files feature, because bigfile tablespaces make data files completely transparent for users. SQL syntax for the `ALTER TABLESPACE` statement has been extended to allow you to perform operations on tablespaces, rather than the underlying data files.

The `CREATE DATABASE` statement shown in "[Specifying Oracle Managed Files at Database Creation](#)" can be modified as follows to specify that the default type of tablespace is a bigfile tablespace:

```
CREATE DATABASE mynewdb
  USER SYS IDENTIFIED BY sys_password
  USER SYSTEM IDENTIFIED BY system_password
  SET DEFAULT BIGFILE TABLESPACE
  UNDO TABLESPACE undotbs1
  DEFAULT TEMPORARY TABLESPACE temptbs1;
```

To dynamically change the default tablespace type after database creation, use the `SET DEFAULT TABLESPACE` clause of the `ALTER DATABASE` statement:

```
ALTER DATABASE SET DEFAULT BIGFILE TABLESPACE;
```

You can determine the current default tablespace type for the database by querying the `DATABASE_PROPERTIES` data dictionary view as follows:

```
SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES
  WHERE PROPERTY_NAME = 'DEFAULT_TBS_TYPE';
```

2.5.9.2 Overriding the Default Tablespace Type

The `SYSTEM` and `SYSAUX` tablespaces are always created with the default tablespace type. However, you optionally can explicitly override the default tablespace type for the `UNDO` and `DEFAULT TEMPORARY` tablespace during the `CREATE DATABASE` operation.

- Specify an `UNDO TABLESPACE` clause or a `DEFAULT TEMPORARY TABLESPACE` clause that overrides the default tablespace type.

For example, you can create a bigfile `UNDO` tablespace in a database with the default tablespace type of `smallfile` as follows:

```
CREATE DATABASE mynewdb
...
  BIGFILE UNDO TABLESPACE undotbs1
    DATAFILE '/u01/oracle/oradata/mynewdb/undotbs01.dbf'
    SIZE 200M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED;
```

You can create a smallfile DEFAULT TEMPORARY tablespace in a database with the default tablespace type of bigfile as follows:

```
CREATE DATABASE mynewdb
  SET DEFAULT BIGFILE TABLESPACE
  ...
    SMALLFILE DEFAULT TEMPORARY TABLESPACE tempt$1
      TEMPFILE '/u01/oracle/oradata/mynewdb/temp01.dbf'
      SIZE 20M REUSE
  ...
```

2.5.10 Specifying the Database Time Zone and Time Zone File

Oracle Database datetime and interval data types and time zone support make it possible to store consistent information about the time of events and transactions.

- [Setting the Database Time Zone](#)
You can set the database time zone with the `SET TIME_ZONE` clause of the `CREATE DATABASE` statement.
- [About the Database Time Zone Files](#)
Two time zone files are included in a subdirectory of the Oracle home directory. The time zone files contain the valid time zone names.
- [Specifying the Database Time Zone File](#)
All databases that share information must use the same time zone data file.

2.5.10.1 Setting the Database Time Zone

You can set the database time zone with the `SET TIME_ZONE` clause of the `CREATE DATABASE` statement.

- Set the database time zone when the database is created by using the `SET TIME_ZONE` clause of the `CREATE DATABASE` statement.

If you do not set the database time zone, then it defaults to the time zone of the host operating system.

You can change the database time zone for a session by using the `SET TIME_ZONE` clause of the `ALTER SESSION` statement.

See Also:

Oracle Database Globalization Support Guide for more information about setting the database time zone

2.5.10.2 About the Database Time Zone Files

Two time zone files are included in a subdirectory of the Oracle home directory. The time zone files contain the valid time zone names.

The following information is also included for each time zone:

- Offset from Coordinated Universal Time (UTC)

- Transition times for Daylight Saving Time
- Abbreviations for standard time and Daylight Saving Time

The default time zone file is *ORACLE_HOME/oracore/zoneinfo/timezIrg_11.dat*. A smaller time zone file with fewer time zones can be found in *ORACLE_HOME/oracore/zoneinfo/timezone_11.dat*.

To view the time zone names in the file being used by your database, use the following query:

```
SELECT * FROM V$TIMEZONE_NAMES;
```

 **See Also:**

Oracle Database Globalization Support Guide for more information about managing and selecting time zone files

2.5.10.3 Specifying the Database Time Zone File

All databases that share information must use the same time zone data file.

The database server always uses the large time zone file by default.

To use the small time zone file on the client and know that all your data will refer only to regions in the small file:

- Set the `ORA_TZFILE` environment variable on the client to the full path name of the `timezone_version.dat` file on the client, where `version` matches the time zone file version that is being used by the database server.

If you are already using the default larger time zone file on the client, then it is not practical to change to the smaller time zone file, because the database may contain data with time zones that are not part of the smaller file.

2.5.11 Specifying FORCE LOGGING Mode

Some data definition language statements (such as `CREATE TABLE`) allow the `NOLOGGING` clause, which causes some database operations not to generate redo records in the database redo log. The `NOLOGGING` setting can speed up operations that can be easily recovered outside of the database recovery mechanisms, but it can negatively affect media recovery and standby databases.

Oracle Database lets you force the writing of redo records even when `NOLOGGING` has been specified in DDL statements. The database never generates redo records for temporary tablespaces and temporary segments, so forced logging has no affect for objects.

- [Using the FORCE LOGGING Clause](#)
You can force the writing of redo records even when `NOLOGGING` is specified in DDL statements.
- [Performance Considerations of FORCE LOGGING Mode](#)
`FORCE LOGGING` mode results in some performance degradation.

 **See Also:**

Oracle Database SQL Language Reference for information about operations that can be done in NOLOGGING mode

2.5.11.1 Using the FORCE LOGGING Clause

You can force the writing of redo records even when NOLOGGING is specified in DDL statements.

To put the database into FORCE LOGGING mode:

- Include the FORCE LOGGING clause in the CREATE DATABASE statement.

If you do not specify this clause, then the database is not placed into FORCE LOGGING mode.

Use the ALTER DATABASE statement to place the database into FORCE LOGGING mode after database creation. This statement can take a considerable time for completion, because it waits for all unlogged direct writes to complete.

You can cancel FORCE LOGGING mode using the following SQL statement:

```
ALTER DATABASE NO FORCE LOGGING;
```

Independent of specifying FORCE LOGGING for the database, you can selectively specify FORCE LOGGING or NO FORCE LOGGING at the tablespace level. However, if FORCE LOGGING mode is in effect for the database, it takes precedence over the tablespace setting. If it is not in effect for the database, then the individual tablespace settings are enforced. Oracle recommends that either the entire database is placed into FORCE LOGGING mode, or individual tablespaces be placed into FORCE LOGGING mode, but not both.

The FORCE LOGGING mode is a persistent attribute of the database. That is, if the database is shut down and restarted, it remains in the same logging mode. However, if you re-create the control file, the database is not restarted in the FORCE LOGGING mode unless you specify the FORCE LOGGING clause in the CREATE CONTROL FILE statement.

 **See Also:**

["Controlling the Writing of Redo Records"](#) for information about using the FORCE LOGGING clause for tablespace creation.

2.5.11.2 Performance Considerations of FORCE LOGGING Mode

FORCE LOGGING mode results in some performance degradation.

If the primary reason for specifying FORCE LOGGING is to ensure complete media recovery, and there is no standby database active, then consider the following:

- How many media failures are likely to happen?

- How serious is the damage if unlogged direct writes cannot be recovered?
- Is the performance degradation caused by forced logging tolerable?

If the database is running in NOARCHIVELOG mode, then generally there is no benefit to placing the database in FORCE LOGGING mode. Media recovery is not possible in NOARCHIVELOG mode, so if you combine it with FORCE LOGGING, the result may be performance degradation with little benefit.

2.6 Specifying Initialization Parameters

You can add or edit basic initialization parameters before you create your new database.

- [About Initialization Parameters and Initialization Parameter Files](#)
When an Oracle instance starts, it reads initialization parameters from an initialization parameter file. This file must at a minimum specify the DB_NAME parameter. All other parameters have default values.
- [Determining the Global Database Name](#)
The global database name consists of the user-specified local database name and the location of the database within a network structure.
- [Specifying a Fast Recovery Area](#)
The Fast Recovery Area is a location in which Oracle Database can store and manage files related to backup and recovery. It is distinct from the database area, which is a location for the current database files (data files, control files, and online redo logs).
- [Specifying Control Files](#)
Every database has a control file, which contains entries that describe the structure of the database (such as its name, the timestamp of its creation, and the names and locations of its data files and redo files). The CONTROL_FILES initialization parameter specifies one or more names of control files, separated by commas.
- [Specifying Database Block Sizes](#)
The DB_BLOCK_SIZE initialization parameter specifies the standard block size for the database.
- [Specifying the Maximum Number of Processes](#)
The PROCESSES initialization parameter determines the maximum number of operating system processes that can be connected to Oracle Database concurrently.
- [Specifying the DDL Lock Timeout](#)
You can specify the amount of time that blocking DDL statements wait for locks.
- [Specifying the Method of Undo Space Management](#)
Every Oracle Database must have a method of maintaining information that is used to undo changes to the database. Such information consists of records of the actions of transactions, primarily before they are committed. Collectively these records are called **undo data**.
- [Specifying the Database Compatibility Level](#)
The COMPATIBLE initialization parameter controls the database compatibility level.

- [Setting the License Parameter](#)

If you use named user licensing, Oracle Database can help you enforce this form of licensing. You can set a limit on the number of users created in the database. Once this limit is reached, you cannot create more users.

 [See Also:](#)

- [Oracle Database Reference](#) for descriptions of all initialization parameters including their default settings
- [Managing Memory](#) for a discussion of the initialization parameters that pertain to memory management

2.6.1 About Initialization Parameters and Initialization Parameter Files

When an Oracle instance starts, it reads initialization parameters from an initialization parameter file. This file must at a minimum specify the `DB_NAME` parameter. All other parameters have default values.

The initialization parameter file can be either a read-only text file, a `PFILE`, or a read/write binary file.

The binary file is called a **server parameter file**. A server parameter file enables you to change initialization parameters with `ALTER SYSTEM` commands and to persist the changes across a shutdown and startup. It also provides a basis for self-tuning by Oracle Database. For these reasons, it is recommended that you use a server parameter file. You can create one manually from your edited text initialization file, or automatically by using Database Configuration Assistant (DCA) to create your database.

Before you manually create a server parameter file, you can start an instance with a text initialization parameter file. Upon startup, the Oracle instance first searches for a server parameter file in a default location, and if it does not find one, searches for a text initialization parameter file. You can also override an existing server parameter file by naming a text initialization parameter file as an argument of the `STARTUP` command.

Default file names and locations for the text initialization parameter file are shown in the following table:

Platform	Default Name	Default Location
UNIX and Linux	<code>initORACLE_SID.ora</code> For example, the initialization parameter file for the <code>mynewdb</code> database is named: <code>initmynewdb.ora</code>	<code>ORACLE_HOME/dbs</code>
Windows	<code>initORACLE_SID.ora</code>	<code>ORACLE_HOME\database</code>

If you are creating an Oracle database for the first time, Oracle suggests that you minimize the number of parameter values that you alter. As you become more familiar with your database and environment, you can dynamically tune many initialization parameters using the `ALTER SYSTEM` statement. If you are using a text initialization

parameter file, then your changes are effective only for the current instance. To make them permanent, you must update them manually in the initialization parameter file, or they will be lost over the next shutdown and startup of the database. If you are using a server parameter file, then initialization parameter file changes made by the `ALTER SYSTEM` statement can persist across shutdown and startup.

- [Sample Initialization Parameter File](#)

Oracle Database provides generally appropriate values in a sample text initialization parameter file. You can edit these Oracle-supplied initialization parameters and add others, depending upon your configuration and options and how you plan to tune the database.

- [Text Initialization Parameter File Format](#)

The text initialization parameter file specifies the values of parameters in name/value pairs.

 **See Also:**

- ["Determining the Global Database Name"](#) for information about the `DB_NAME` parameter
- ["Managing Initialization Parameters Using a Server Parameter File"](#)
- ["About Initialization Parameter Files and Startup"](#)

2.6.1.1 Sample Initialization Parameter File

Oracle Database provides generally appropriate values in a sample text initialization parameter file. You can edit these Oracle-supplied initialization parameters and add others, depending upon your configuration and options and how you plan to tune the database.

The sample text initialization parameter file is named `init.ora` and is found in the following location on most platforms:

`ORACLE_HOME/dbs`

The following is the content of the sample file:

```
#####
# Example INIT.ORA file
#
# This file is provided by Oracle Corporation to help you start by providing
# a starting point to customize your RDBMS installation for your site.
#
# NOTE: The values that are used in this file are only intended to be used
# as a starting point. You may want to adjust/tune those values to your
# specific hardware and needs. You may also consider using Database
# Configuration Assistant tool (DBCA) to create INIT file and to size your
# initial set of tablespaces based on the user input.
#####
#
# Change '<ORACLE_BASE>' to point to the oracle base (the one you specify at
# install time)
#
db_name='ORCL'
```

```
memory_target=1G
processes = 150
db_block_size=8192
db_domain=''
db_recovery_file_dest='<ORACLE_BASE>/flash_recovery_area'
db_recovery_file_dest_size=2G
diagnostic_dest='<ORACLE_BASE>'
dispatchers='(PROTOCOL=TCP) (SERVICE=ORCLXDB)'
open_cursors=300
remote_login_passwordfile='EXCLUSIVE'
undo_tablespace='UNDOTBS1'
# You may want to ensure that control files are created on separate physical
# devices
control_files = (ora_control1, ora_control2)
compatible ='12.0.0'
```

2.6.1.2 Text Initialization Parameter File Format

The text initialization parameter file specifies the values of parameters in name/value pairs.

The text initialization parameter file (PFILE) must contain name/value pairs in one of the following forms:

- For parameters that accept only a single value:

```
parameter_name=value
```

- For parameters that accept one or more values (such as the CONTROL_FILES parameter):

```
parameter_name=(value[,value] ...)
```

Parameter values of type string must be enclosed in single quotes ('). Case (upper or lower) in file names is significant only if case is significant on the host operating system.

For parameters that accept multiple values, to enable you to easily copy and paste name/value pairs from the alert log, you can repeat a parameter on multiple lines, where each line contains a different value.

```
control_files='/u01/app/oracle/oradata/orcl/control01.ctl'
control_files='/u01/app/oracle/oradata/orcl/control02.ctl'
control_files='/u01/app/oracle/oradata/orcl/control03.ctl'
```

If you repeat a parameter that does not accept multiple values, then only the last value specified takes effect.

See Also:

- *Oracle Database Reference* for more information about the content and syntax of the text initialization parameter file
- "Alert Log"

2.6.2 Determining the Global Database Name

The global database name consists of the user-specified local database name and the location of the database within a network structure.

- Set the DB_NAME and DB_DOMAIN initialization parameters.

The DB_NAME initialization parameter determines the local name component of the database name, and the DB_DOMAIN parameter, which is optional, indicates the domain (logical location) within a network structure. The combination of the settings for these two parameters must form a database name that is unique within a network.

For example, to create a database with a global database name of test.us.example.com, edit the parameters of the new parameter file as follows:

```
DB_NAME = test
DB_DOMAIN = us.example.com
```

You can rename the GLOBAL_NAME of your database using the ALTER DATABASE RENAME GLOBAL_NAME statement. However, you must also shut down and restart the database after first changing the DB_NAME and DB_DOMAIN initialization parameters and recreating the control files. Recreating the control files is easily accomplished with the command ALTER DATABASE BACKUP CONTROLFILE TO TRACE. See *Oracle Database Backup and Recovery User's Guide* for more information.

- [DB_NAME Initialization Parameter](#)

The DB_NAME initialization parameter specifies a database identifier.

- [DB_DOMAIN Initialization Parameter](#)

In a distributed database system, the DB_DOMAIN initialization parameter specifies the logical location of the database within the network structure.

See Also:

[Oracle Database Utilities](#) for information about using the DBNEWID utility, which is another means of changing a database name

2.6.2.1 DB_NAME Initialization Parameter

The DB_NAME initialization parameter specifies a database identifier.

DB_NAME must be set to a text string of no more than 8 characters. The database name must start with an alphabetic character. During database creation, the name provided for DB_NAME is recorded in the data files, redo log files, and control file of the database. If during database instance startup the value of the DB_NAME parameter (in the parameter file) and the database name in the control file are different, then the database does not start.

2.6.2.2 DB_DOMAIN Initialization Parameter

In a distributed database system, the DB_DOMAIN initialization parameter specifies the logical location of the database within the network structure.

DB_DOMAIN is a text string that specifies the network domain where the database is created. If the database you are about to create will ever be part of a distributed database system, then give special attention to this initialization parameter before database creation. This parameter is optional.

 **See Also:**

[Distributed Database Management](#) for more information about distributed databases

2.6.3 Specifying a Fast Recovery Area

The Fast Recovery Area is a location in which Oracle Database can store and manage files related to backup and recovery. It is distinct from the database area, which is a location for the current database files (data files, control files, and online redo logs).

Specify the Fast Recovery Area with the following initialization parameters:

- DB_RECOVERY_FILE_DEST: Location of the Fast Recovery Area. This can be a directory, file system, or Automatic Storage Management (Oracle ASM) disk group.
In an Oracle Real Application Clusters (Oracle RAC) environment, this location must be on a cluster file system, Oracle ASM disk group, or a shared directory configured through NFS.
- DB_RECOVERY_FILE_DEST_SIZE: Specifies the maximum total bytes to be used by the Fast Recovery Area. This initialization parameter must be specified before DB_RECOVERY_FILE_DEST is enabled.

In an Oracle RAC environment, the settings for these two parameters must be the same on all instances.

You cannot enable these parameters if you have set values for the LOG_ARCHIVE_DEST and LOG_ARCHIVE DUPLEX_DEST parameters. You must disable those parameters before setting up the Fast Recovery Area. You can instead set values for the LOG_ARCHIVE_DEST_n parameters.

Oracle recommends using a Fast Recovery Area, because it can simplify backup and recovery operations for your database.

 **See Also:**

Oracle Database Backup and Recovery User's Guide to learn how to create and use a Fast Recovery Area

2.6.4 Specifying Control Files

Every database has a control file, which contains entries that describe the structure of the database (such as its name, the timestamp of its creation, and the names and locations of its data files and redo files). The `CONTROL_FILES` initialization parameter specifies one or more names of control files, separated by commas.

- Set the `CONTROL_FILES` initialization parameter.

When you execute the `CREATE DATABASE` statement, the control files listed in the `CONTROL_FILES` parameter are created.

If you do not include `CONTROL_FILES` in the initialization parameter file, then Oracle Database creates a control file in the same directory as the initialization parameter file, using a default operating system-dependent file name. If you have enabled Oracle Managed Files, the database creates Oracle managed control files.

If you want the database to create new operating system files when creating database control files, the file names listed in the `CONTROL_FILES` parameter must not match any file names that currently exist on your system. If you want the database to reuse or overwrite existing files when creating database control files, ensure that the file names listed in the `CONTROL_FILES` parameter match the file names that are to be reused, and include a `CONTROFILE REUSE` clause in the `CREATE DATABASE` statement.

Oracle strongly recommends you use at least two control files stored on separate physical disk drives for each database.

See Also:

- "[Managing Control Files](#)"
- "[Specifying Oracle Managed Files at Database Creation](#)"

2.6.5 Specifying Database Block Sizes

The `DB_BLOCK_SIZE` initialization parameter specifies the standard block size for the database.

- Set the `DB_BLOCK_SIZE` initialization parameter.

This block size is used for the `SYSTEM` tablespace and by default in other tablespaces. Oracle Database can support up to four additional nonstandard block sizes.

- [DB_BLOCK_SIZE Initialization Parameter](#)

The most commonly used block size should be picked as the standard block size. In many cases, this is the only block size that you must specify.

- [Nonstandard Block Sizes](#)

You can create tablespaces of nonstandard block sizes.

2.6.5.1 DB_BLOCK_SIZE Initialization Parameter

The most commonly used block size should be picked as the standard block size. In many cases, this is the only block size that you must specify.

- Set the DB_BLOCK_SIZE initialization parameter.

Typically, DB_BLOCK_SIZE is set to either 4K or 8K. If you do not set a value for this parameter, then the default data block size is operating system specific, which is generally adequate.

You cannot change the block size after database creation except by re-creating the database. If the database block size is different from the operating system block size, then ensure that the database block size is a multiple of the operating system block size. For example, if your operating system block size is 2K (2048 bytes), the following setting for the DB_BLOCK_SIZE initialization parameter is valid:

```
DB_BLOCK_SIZE=4096
```

A larger data block size provides greater efficiency in disk and memory I/O (access and storage of data). Therefore, consider specifying a block size larger than your operating system block size if the following conditions exist:

- Oracle Database is on a large computer system with a large amount of memory and fast disk drives. For example, databases controlled by mainframe computers with vast hardware resources typically use a data block size of 4K or greater.
- The operating system that runs Oracle Database uses a small operating system block size. For example, if the operating system block size is 1K and the default data block size matches this, the database may be performing an excessive amount of disk I/O during normal operation. For best performance in this case, a database block should consist of multiple operating system blocks.

See Also:

Your operating system specific Oracle documentation for details about the default block size.

2.6.5.2 Nonstandard Block Sizes

You can create tablespaces of nonstandard block sizes.

To create tablespaces of nonstandard block sizes:

- Specify the BLOCKSIZE clause in a CREATE TABLESPACE statement.

These nonstandard block sizes can have any of the following power-of-two values: 2K, 4K, 8K, 16K or 32K. Platform-specific restrictions regarding the maximum block size apply, so some of these sizes may not be allowed on some platforms.

To use nonstandard block sizes, you must configure subcaches within the buffer cache area of the SGA memory for all of the nonstandard block sizes that you intend to use. The initialization parameters used for configuring these subcaches are described in "[Using Automatic Shared Memory Management](#)".

The ability to specify multiple block sizes for your database is especially useful if you are transporting tablespaces between databases. You can, for example, transport a tablespace that uses a 4K block size from an OLTP environment to a data warehouse environment that uses a standard block size of 8K.

 **Note:**

A 32K block size is valid only on 64-bit platforms.

 **Caution:**

Oracle recommends against specifying a 2K block size when 4K sector size disks are in use, because performance degradation can occur. For an explanation, see "[Planning the Block Size of Redo Log Files](#)".

 **See Also:**

- ["Creating Tablespaces"](#)
- ["Transporting Tablespaces Between Databases"](#)

2.6.6 Specifying the Maximum Number of Processes

The `PROCESSES` initialization parameter determines the maximum number of operating system processes that can be connected to Oracle Database concurrently.

- Set the `PROCESSES` initialization parameter.

The value of this parameter must be a minimum of one for each background process plus one for each user process. The number of background processes will vary according the database features that you are using. For example, if you are using Advanced Queuing or the file mapping feature, then you will have additional background processes. If you are using Automatic Storage Management, then add three additional processes for the database instance.

If you plan on running 50 user processes, a good estimate would be to set the `PROCESSES` initialization parameter to 70.

2.6.7 Specifying the DDL Lock Timeout

You can specify the amount of time that blocking DDL statements wait for locks.

A data definition language (DDL) statement is either nonblocking or blocking, and both types of DDL statements require exclusive locks on internal structures. If these locks are unavailable when a DDL statement runs, then nonblocking and blocking DDL statements behave differently:

- Nonblocking DDL waits until every concurrent DML transaction that references the object affected by the DDL either commits or rolls back.
- Blocking DDL fails, though it might have succeeded if it had been executed subseconds later when the locks become available.

To enable blocking DDL statements to wait for locks, specify a **DDL lock timeout**—the number of seconds a DDL command waits for its required locks before failing.

- To specify a DDL lock timeout, set the `DDL_LOCK_TIMEOUT` parameter.

The permissible range of values for `DDL_LOCK_TIMEOUT` is 0 to 1,000,000. The default is 0. You can set `DDL_LOCK_TIMEOUT` at the system level, or at the session level with an `ALTER SESSION` statement.

 **Note:**

The `DDL_LOCK_TIMEOUT` parameter does not affect nonblocking DDL statements.

 **See Also:**

- *Oracle Database Reference*
- *Oracle Database Development Guide*
- *Oracle Database SQL Language Reference*

2.6.8 Specifying the Method of Undo Space Management

Every Oracle Database must have a method of maintaining information that is used to undo changes to the database. Such information consists of records of the actions of transactions, primarily before they are committed. Collectively these records are called **undo data**.

To set up an environment for automatic undo management using an undo tablespace.

- Set the `UNDO_MANAGEMENT` initialization parameter to `AUTO`, which is the default.
- **UNDO MANAGEMENT Initialization Parameter**
The `UNDO_MANAGEMENT` initialization parameter determines whether an instance starts in automatic undo management mode, which stores undo in an undo tablespace. Set this parameter to `AUTO` to enable automatic undo management mode. `AUTO` is the default if the parameter is omitted or is null.
- **UNDO_TABLESPACE Initialization Parameter**
The `UNDO_TABLESPACE` initialization parameter enables you to override that default undo tablespace for an instance.

 **See Also:**

[Managing Undo](#)

2.6.8.1 UNDO_MANAGEMENT Initialization Parameter

The `UNDO_MANAGEMENT` initialization parameter determines whether an instance starts in automatic undo management mode, which stores undo in an undo tablespace. Set this parameter to `AUTO` to enable automatic undo management mode. `AUTO` is the default if the parameter is omitted or is null.

2.6.8.2 UNDO_TABLESPACE Initialization Parameter

The `UNDO_TABLESPACE` initialization parameter enables you to override that default undo tablespace for an instance.

When an instance starts up in automatic undo management mode, it attempts to select an undo tablespace for storage of undo data. If the database was created in automatic undo management mode, then the default undo tablespace (either the system-created `SYS_UNDOTBS` tablespace or the user-specified undo tablespace) is the undo tablespace used at instance startup. You can override this default for the instance by specifying a value for the `UNDO_TABLESPACE` initialization parameter. This parameter is especially useful for assigning a particular undo tablespace to an instance in an Oracle Real Application Clusters environment.

If no undo tablespace is specified by the `UNDO_TABLESPACE` initialization parameter, then the first available undo tablespace in the database is chosen. If no undo tablespace is available, then the instance starts without an undo tablespace, and undo data is written to the `SYSTEM` tablespace. You should avoid running in this mode.

 **Note:**

When using the `CREATE DATABASE` statement to create a database, do not include an `UNDO_TABLESPACE` parameter in the initialization parameter file. Instead, include an `UNDO TABLESPACE` clause in the `CREATE DATABASE` statement.

2.6.9 Specifying the Database Compatibility Level

The `COMPATIBLE` initialization parameter controls the database compatibility level.

- Set the `COMPATIBLE` initialization parameter to a release number.
- [About The COMPATIBLE Initialization Parameter](#)

The `COMPATIBLE` initialization parameter enables or disables the use of features in the database that affect file format on disk. For example, if you create an Oracle Database 12c database, but specify `COMPATIBLE=11.0.0` in the initialization parameter file, then features that require Oracle Database 12c compatibility generate an error if you try to use them. Such a database is said to be at the 11.0.0 compatibility level.

2.6.9.1 About The COMPATIBLE Initialization Parameter

The `COMPATIBLE` initialization parameter enables or disables the use of features in the database that affect file format on disk. For example, if you create an Oracle Database 12c database, but specify `COMPATIBLE=11.0.0` in the initialization parameter file, then features that require Oracle Database 12c compatibility generate an error if you try to use them. Such a database is said to be at the 11.0.0 compatibility level.

You can advance the compatibility level of your database by changing the `COMPATIBLE` initialization parameter. If you do, then there is no way to start the database using a lower compatibility level setting, except by doing a point-in-time recovery to a time before the compatibility was advanced.

The default value for the `COMPATIBLE` parameter is the release number of the most recent major release.

 **Note:**

- For Oracle Database 12c, the default value of the `COMPATIBLE` parameter is `12.0.0`. The minimum value is `11.0.0`. If you create an Oracle Database using the default value, then you can immediately use all the new features in this release, and you can never downgrade the database.
- When you set this parameter in a server parameter file (SPFILE) using the `ALTER SYSTEM` statement, you must specify `SCOPE=SPFILE`, and you must restart the database for the change to take effect.
- The `COMPATIBLE` initialization parameter must be specified as at least three decimal numbers with each pair separated by a dot, such as `12.0.0`.

 **See Also:**

- *Oracle Database Upgrade Guide* for a detailed discussion of database compatibility and the `COMPATIBLE` initialization parameter
- *Oracle Database Reference*
- *Oracle Database Backup and Recovery User's Guide* for information about point-in-time recovery of your database

2.6.10 Setting the License Parameter

If you use named user licensing, Oracle Database can help you enforce this form of licensing. You can set a limit on the number of users created in the database. Once this limit is reached, you cannot create more users.

 **Note:**

This mechanism assumes that each person accessing the database has a unique user name and that no people share a user name. Therefore, so that named user licensing can help you ensure compliance with your Oracle license agreement, do not allow multiple users to log in using the same user name.

To limit the number of users created in a database, set the `LICENSE_MAX_USERS` initialization parameter in the database initialization parameter file.

The following example sets the `LICENSE_MAX_USERS` initialization parameter:

```
LICENSE_MAX_USERS = 200
```

 **Note:**

Oracle no longer offers licensing by the number of concurrent sessions. Therefore the `LICENSE_MAX_SESSIONS` and `LICENSE_SESSIONS_WARNING` initialization parameters are no longer needed and have been deprecated.

2.7 Managing Initialization Parameters Using a Server Parameter File

Initialization parameters for the Oracle Database have traditionally been stored in a text initialization parameter file. For better manageability, you can choose to maintain initialization parameters in a binary server parameter file that is persistent across database startup and shutdown.

- [What Is a Server Parameter File?](#)

A server parameter file can be thought of as a repository for initialization parameters that is maintained on the system running the Oracle Database server. It is, by design, a server-side initialization parameter file.

- [Migrating to a Server Parameter File](#)

If you are currently using a text initialization parameter file, then you can migrate to a server parameter file.

- [Server Parameter File Default Names and Locations](#)

Oracle recommends that you allow the database to give the SPFILE the default name and store it in the default location. This eases administration of your

database. For example, the `STARTUP` command assumes this default location to read the `SPFILE`.

- **Creating a Server Parameter File**

You use the `CREATE SPFILE` statement to create a server parameter file. You must have the `SYSDBA`, `SYSOPER`, or `SYSBACKUP` administrative privilege to execute this statement.

- **The SPFILE Initialization Parameter**

The `SPFILE` initialization parameter contains the name of the current server parameter file.

- **Changing Initialization Parameter Values**

You can change initialization parameter values to affect the operation of a database instance.

- **Clearing Initialization Parameter Values**

You can use the `ALTER SYSTEM RESET` statement to clear an initialization parameter value. When you do so, the initialization parameter value is changed to its default value or its startup value.

- **Exporting the Server Parameter File**

You can use the `CREATE PFILE` statement to export a server parameter file (`SPFILE`) to a text initialization parameter file.

- **Backing Up the Server Parameter File**

You can create a backup of your server parameter file (`SPFILE`) by exporting it. If the backup and recovery strategy for your database is implemented using Recovery Manager (RMAN), then you can use RMAN to create a backup of the `SPFILE`. The `SPFILE` is backed up automatically by RMAN when you back up your database, but RMAN also enables you to specifically create a backup of the currently active `SPFILE`.

- **Recovering a Lost or Damaged Server Parameter File**

You can recover the server parameter file (`SPFILE`). If your server parameter file (`SPFILE`) becomes lost or corrupted, then the current instance may fail, or the next attempt at starting the database instance may fail.

- **Methods for Viewing Parameter Settings**

You can view parameter settings using several different methods.

2.7.1 What Is a Server Parameter File?

A server parameter file can be thought of as a repository for initialization parameters that is maintained on the system running the Oracle Database server. It is, by design, a server-side initialization parameter file.

Initialization parameters stored in a server parameter file are persistent, in that any changes made to the parameters while an instance is running can persist across instance shutdown and startup. This arrangement eliminates the need to manually update initialization parameters to make persistent any changes effected by `ALTER SYSTEM` statements. It also provides a basis for self-tuning by the Oracle Database server.

A server parameter file is initially built from a text initialization parameter file using the `CREATE SPFILE` statement. (It can also be created directly by the Database Configuration Assistant.) The server parameter file is a binary file that cannot be edited using a text editor. Oracle Database provides other interfaces for viewing and modifying parameter settings in a server parameter file.

 **Note:**

Although you can open the binary server parameter file with a text editor and view its text, *do not* manually edit it. Doing so will corrupt the file. You will not be able to start your instance, and if the instance is running, it could fail.

When you issue a `STARTUP` command with no `PFILE` clause, the Oracle instance searches an operating system–specific default location for a server parameter file from which to read initialization parameter settings. If no server parameter file is found, the instance searches for a text initialization parameter file. If a server parameter file exists but you want to override it with settings in a text initialization parameter file, you must specify the `PFILE` clause when issuing the `STARTUP` command. Instructions for starting an instance using a server parameter file are contained in "[Starting Up a Database](#)".

2.7.2 Migrating to a Server Parameter File

If you are currently using a text initialization parameter file, then you can migrate to a server parameter file.

To migrate to a server parameter file:

1. If the initialization parameter file is located on a client system, then transfer the file (for example, FTP) from the client system to the server system.

 **Note:**

If you are migrating to a server parameter file in an Oracle Real Application Clusters environment, you must combine all of your instance-specific initialization parameter files into a single initialization parameter file. Instructions for doing this and other actions unique to using a server parameter file for instances that are part of an Oracle Real Application Clusters installation are discussed in *Oracle Real Application Clusters Administration and Deployment Guide* and in your platform-specific Oracle Real Application Clusters Installation Guide.

2. Create a server parameter file in the default location using the `CREATE SPFILE FROM PFILE` statement. See "[Creating a Server Parameter File](#)" for instructions.

This statement reads the text initialization parameter file to create a server parameter file. The database does not have to be started to issue a `CREATE SPFILE` statement.

3. Start up or restart the instance.

The instance finds the new `SPFILE` in the default location and starts up with it.

2.7.3 Server Parameter File Default Names and Locations

Oracle recommends that you allow the database to give the SPFILE the default name and store it in the default location. This eases administration of your database. For example, the `STARTUP` command assumes this default location to read the SPFILE.

The following table shows the default name and location for both the text initialization parameter file (PFILE) and server parameter file (SPFILE) for the UNIX, Linux, and Windows platforms, both with and without the presence of Oracle Automatic Storage Management (Oracle ASM). The table assumes that the SPFILE is a file.

Table 2-3 PFILE and SPFILE Default Names and Locations on UNIX, Linux, and Windows

Platform	PFILE Default Name	SPFILE Default Name	PFILE Default Location	SPFILE Default Location
UNIX and Linux	<code>initORACLE_SID.ora</code>	<code>spfileORACLE_SID.ora</code>	<code>Oracle_Home/dbs</code> or the same location as the data files	Without Oracle ASM: <code>Oracle_Home/dbs</code> or the same location as the data files When Oracle ASM is present: In the same disk group as the data files (assuming the database was created with DBCA)
Windows	<code>initORACLE_SID.ora</code>	<code>spfileORACLE_SID.ora</code>	<code>Oracle_Home\database</code>	Without Oracle ASM: <code>OH\database</code> When Oracle ASM is present: In the same disk group as the data files (assuming the database was created with DBCA)

Note:

Upon startup, the instance first searches for an SPFILE named `spfileORACLE_SID.ora`, and if not found, searches for `spfile.ora`. Using `spfile.ora` enables all Real Application Cluster (Oracle RAC) instances to use the same server parameter file.

If neither SPFILE is found, the instance searches for the text initialization parameter file `initORACLE_SID.ora`.

If you create an SPFILE in a location other than the default location, you must create in the default PFILE location a "stub" PFILE that points to the server parameter file. For more information, see "[Starting Up a Database](#)".

When you create the database with DBCA when Oracle ASM is present, DBCA places the SPFILE in an Oracle ASM disk group, and also causes this stub PFILE to be created.

2.7.4 Creating a Server Parameter File

You use the `CREATE SPFILE` statement to create a server parameter file. You must have the `SYSDBA`, `SYSOPER`, or `SYSBACKUP` administrative privilege to execute this statement.

To create a server parameter file:

- Run the `CREATE SPFILE` statement.

 **Note:**

When you use the Database Configuration Assistant to create a database, it automatically creates a server parameter file for you.

The `CREATE SPFILE` statement can be executed before or after instance startup. However, if the instance has been started using a server parameter file, an error is raised if you attempt to re-create the same server parameter file that is currently being used by the instance.

You can create a server parameter file (SPFILE) from an existing text initialization parameter file or from memory. Creating the SPFILE from memory means copying the current values of initialization parameters in the running instance to the SPFILE.

The following example creates a server parameter file from text initialization parameter file `/u01/oracle/dbs/init.ora`. In this example no `SPFILE` name is specified, so the file is created with the platform-specific default name and location shown in [Table 2-3](#).

```
CREATE SPFILE FROM PFILE='/u01/oracle/dbs/init.ora';
```

The next example illustrates creating a server parameter file and supplying a name and location.

```
CREATE SPFILE='/u01/oracle/dbs/test_spfile.ora'  
FROM PFILE='/u01/oracle/dbs/test_init.ora';
```

The next example illustrates creating a server parameter file in the default location from the current values of the initialization parameters in memory.

```
CREATE SPFILE FROM MEMORY;
```

Whether you use the default SPFILE name and default location or specify an SPFILE name and location, if an SPFILE of the same name already exists in the location, it is overwritten without a warning message.

When you create an SPFILE from a text initialization parameter file, comments specified on the same lines as a parameter setting in the initialization parameter file are maintained in the SPFILE. All other comments are ignored.

2.7.5 The SPFILE Initialization Parameter

The `SPFILE` initialization parameter contains the name of the current server parameter file.

When the default server parameter file is used by the database—that is, you issue a STARTUP command and do not specify a PFILE parameter—the value of SPFILE is internally set by the server. The SQL*Plus command SHOW PARAMETERS SPFILE (or any other method of querying the value of a parameter) displays the name of the server parameter file that is currently in use.

2.7.6 Changing Initialization Parameter Values

You can change initialization parameter values to affect the operation of a database instance.

- [About Changing Initialization Parameter Values](#)

The ALTER SYSTEM statement enables you to set, change, or restore to default the values of initialization parameters. If you are using a text initialization parameter file, the ALTER SYSTEM statement changes the value of a parameter only for the current instance, because there is no mechanism for automatically updating text initialization parameters on disk. You must update them manually to be passed to a future instance. Using a server parameter file overcomes this limitation.

- [Setting or Changing Initialization Parameter Values](#)

With a server parameter file, use the SET clause of the ALTER SYSTEM statement to set or change initialization parameter values.

2.7.6.1 About Changing Initialization Parameter Values

The ALTER SYSTEM statement enables you to set, change, or restore to default the values of initialization parameters. If you are using a text initialization parameter file, the ALTER SYSTEM statement changes the value of a parameter only for the current instance, because there is no mechanism for automatically updating text initialization parameters on disk. You must update them manually to be passed to a future instance. Using a server parameter file overcomes this limitation.

There are two kinds of initialization parameters:

- **Dynamic initialization parameters** can be changed for the current Oracle Database instance. The changes take effect immediately.
- **Static initialization parameters** cannot be changed for the current instance. You must change these parameters in the text initialization file or server parameter file and then restart the database before changes take effect.

2.7.6.2 Setting or Changing Initialization Parameter Values

With a server parameter file, use the SET clause of the ALTER SYSTEM statement to set or change initialization parameter values.

- Run an ALTER SYSTEM SET statement.

For example, the following statement changes the maximum number of failed login attempts before the connection is dropped. It includes a comment, and explicitly states that the change is to be made only in the server parameter file.

```
ALTER SYSTEM SET SEC_MAX_FAILED_LOGIN_ATTEMPTS=3
COMMENT='Reduce from 10 for tighter security.'
SCOPE=SPFILE;
```

The next example sets a complex initialization parameter that takes a list of attributes. Specifically, the parameter value being set is the `LOG_ARCHIVE_DEST_n` initialization parameter. This statement could change an existing setting for this parameter or create a new archive destination.

```
ALTER SYSTEM
  SET LOG_ARCHIVE_DEST_4='LOCATION=/u02/oracle/rbdb1/' ,MANDATORY , 'REOPEN=2'
    COMMENT='Add new destination on Nov 29'
  SCOPE=SPFILE;
```

When a value consists of a list of parameters, you cannot edit individual attributes by the position or ordinal number. You must specify the complete list of values each time the parameter is updated, and the new list completely replaces the old list.

- [The SCOPE Clause in ALTER SYSTEM SET Statements](#)

The optional `SCOPE` clause in `ALTER SYSTEM SET` statements specifies the scope of an initialization parameter change.

2.7.6.2.1 The SCOPE Clause in ALTER SYSTEM SET Statements

The optional `SCOPE` clause in `ALTER SYSTEM SET` statements specifies the scope of an initialization parameter change.

SCOPE Clause	Description
<code>SCOPE = SPFILE</code>	<p>The change is applied in the server parameter file only. The effect is as follows:</p> <ul style="list-style-type: none"> • No change is made to the current instance. • For both dynamic and static parameters, the change is effective at the next startup and is persistent. <p>This is the only <code>SCOPE</code> specification allowed for static parameters.</p>
<code>SCOPE = MEMORY</code>	<p>The change is applied in memory only. The effect is as follows:</p> <ul style="list-style-type: none"> • The change is made to the current instance and is effective immediately. • For dynamic parameters, the effect is immediate, but it is not persistent because the server parameter file is not updated. <p>For static parameters, this specification is not allowed.</p>
<code>SCOPE = BOTH</code>	<p>The change is applied in both the server parameter file and memory. The effect is as follows:</p> <ul style="list-style-type: none"> • The change is made to the current instance and is effective immediately. • For dynamic parameters, the effect is persistent because the server parameter file is updated. <p>For static parameters, this specification is not allowed.</p>

It is an error to specify `SCOPE=SPFILE` or `SCOPE=BOTH` if the instance did not start up with a server parameter file. The default is `SCOPE=BOTH` if a server parameter file was used to start up the instance, and `MEMORY` if a text initialization parameter file was used to start up the instance.

For dynamic parameters, you can also specify the `DEFERRED` keyword. When specified, the change is effective only for future sessions.

When you specify `SCOPE` as `SPFILE` or `BOTH`, an optional `COMMENT` clause lets you associate a text string with the parameter update. The comment is written to the server parameter file.

2.7.7 Clearing Initialization Parameter Values

You can use the `ALTER SYSTEM RESET` statement to clear an initialization parameter value. When you do so, the initialization parameter value is changed to its default value or its startup value.

The `ALTER SYSTEM RESET` statement includes a `SCOPE` clause. When executed in a non-CDB or a multitenant container database (CDB) root, the `ALTER SYSTEM RESET` statement and `SCOPE` clause behave differently than when the statement is executed in a pluggable database (PDB), an application root, or an application PDB.

The startup value of a parameter is the value of the parameter in memory after the instance's startup or PDB open has completed. This value can be seen in the `VALUE` and `DISPLAY_VALUE` columns in the `v$SYSTEM_PARAMETER` view immediately after startup. The startup value can be different from the value in the spfile or the default value (if the parameter is not set in the spfile), since the value of the parameter can be adjusted internally at startup.

The `SCOPE` values for the `ALTER SYSTEM RESET` statement behave as follows in a non-CDB and in the `CDB$ROOT` of a CDB:

- `SCOPE=SPFILE`: If an instance is using spfile, removes the parameter from the spfile; the default value takes effect upon the next instance startup.
- `SCOPE=MEMORY`: The startup value takes effect immediately. However, the change is not stored in instance's spfile and will be lost upon instance restart.
- `SCOPE=BOTH`: If an instance is using spfile, removes the parameter from the spfile; the default value takes effect immediately and the change is available across instance restart.

 **Note:**

`SCOPE=BOTH` changes the way `SCOPE=MEMORY` behaves. After `SCOPE=BOTH` is issued, `SCOPE=MEMORY` always resets the parameter to the default value.

The `SCOPE` values for the `ALTER SYSTEM RESET` statement behave as follows in a PDB, an application root, or an application PDB:

- `SCOPE=SPFILE`: Removes the parameter from the container's spfile; the container will inherit the parameter value from its root upon the next PDB open.
- `SCOPE=MEMORY`: There are two cases:
 - The parameter is present in container's spfile when the container is opened. The parameter value is updated to the startup value for the parameter. This change is not stored in container's spfile and will be lost upon the next container open.
 - The parameter is not present in container's spfile when the container is opened. The container starts inheriting the parameter value from its root.
- `SCOPE=BOTH`: Removes the parameter from the container's spfile; the container will inherit the parameter value from its root.

 **Note:**

- SCOPE=BOTH changes the way SCOPE=MEMORY behaves. After SCOPE=BOTH is issued, the container always inherits the parameter value from its root when SCOPE=MEMORY is issued.
- In a case where a container inherits a parameter value from its root, a PDB inherits the value from CDB\$ROOT. In an application container, an application PDB inherits the parameter value from its application root, and an application root inherits the parameter value from CDB\$ROOT.

 **See Also:**

- *Oracle Database SQL Language Reference* for information about the ALTER SYSTEM command
- "[Managing a Multitenant Environment](#)"

2.7.8 Exporting the Server Parameter File

You can use the CREATE PFILE statement to export a server parameter file (SPFILE) to a text initialization parameter file.

- Run a CREATE PFILE statement.

Exporting the server parameter file might be necessary for several reasons:

- For diagnostic purposes, listing all of the parameter values currently used by an instance. This is analogous to the SQL*Plus SHOW PARAMETERS command or selecting from the V\$PARAMETER or V\$PARAMETER2 views.
- To modify the server parameter file by first exporting it, editing the resulting text file, and then re-creating it using the CREATE SPFILE statement

The exported file can also be used to start up an instance using the PFILE clause.

You must have the SYSDBA, SYSOPER, or SYSBACKUP administrative privilege to execute the CREATE PFILE statement. The exported file is created on the database server system. It contains any comments associated with the parameter in the same line as the parameter setting.

The following example creates a text initialization parameter file from the SPFILE:

```
CREATE PFILE FROM SPFILE;
```

Because no names were specified for the files, the database creates an initialization parameter file with a platform-specific name, and it is created from the platform-specific default server parameter file.

The following example creates a text initialization parameter file from a server parameter file, but in this example the names of the files are specified:

```
CREATE PFILE='/u01/oracle/dbs/test_init.ora'  
FROM SPFILE='/u01/oracle/dbs/test_spfile.ora';
```

 **Note:**

An alternative is to create a PFILE from the current values of the initialization parameters in memory. The following is an example of the required command:

```
CREATE PFILE='/u01/oracle/dbs/test_init.ora' FROM MEMORY;
```

2.7.9 Backing Up the Server Parameter File

You can create a backup of your server parameter file (SPFILE) by exporting it. If the backup and recovery strategy for your database is implemented using Recovery Manager (RMAN), then you can use RMAN to create a backup of the SPFILE. The SPFILE is backed up automatically by RMAN when you back up your database, but RMAN also enables you to specifically create a backup of the currently active SPFILE.

- Back up the server parameter file either by exporting it or by using RMAN.

 **See Also:**

["Exporting the Server Parameter File"](#)

Oracle Database Backup and Recovery User's Guide

2.7.10 Recovering a Lost or Damaged Server Parameter File

You can recover the server parameter file (SPFILE). If your server parameter file (SPFILE) becomes lost or corrupted, then the current instance may fail, or the next attempt at starting the database instance may fail.

There are several ways to recover the SPFILE:

- If the instance is running, issue the following command to re-create the SPFILE from the current values of initialization parameters in memory:

```
CREATE SPFILE FROM MEMORY;
```

This command creates the SPFILE with the default name and in the default location. You can also create the SPFILE with a new name or in a specified location. See "[Creating a Server Parameter File](#)" for examples.

- If you have a valid text initialization parameter file (PFILE), re-create the SPFILE from the PFILE with the following statement:

```
CREATE SPFILE FROM PFILE;
```

This command assumes that the PFILE is in the default location and has the default name. See "[Creating a Server Parameter File](#)" for the command syntax to use when the PFILE is not in the default location or has a nondefault name.

- Restore the SPFILE from backup.
See "[Backing Up the Server Parameter File](#)" for more information.
- If none of the previous methods are possible in your situation, perform these steps:
 1. Create a text initialization parameter file (PFILE) from the parameter value listings in the alert log.
When an instance starts up, the initialization parameters used for startup are written to the alert log. You can copy and paste this section from the text version of the alert log (without XML tags) into a new PFILE.
See "[Viewing the Alert Log](#)" for more information.
 2. Create the SPFILE from the PFILE.
See "[Creating a Server Parameter File](#)" for instructions.

Read/Write Errors During a Parameter Update

If an error occurs while reading or writing the server parameter file during a parameter update, the error is reported in the alert log and all subsequent parameter updates to the server parameter file are ignored. At this point, you can take one of the following actions:

- Shut down the instance, recover the server parameter file and described earlier in this section, and then restart the instance.
- Continue to run the database if you do not care that subsequent parameter updates will not be persistent.

2.7.11 Methods for Viewing Parameter Settings

You can view parameter settings using several different methods.

Method	Description
SHOW PARAMETERS	This SQL*Plus command displays the values of initialization parameters in effect for the current session.
SHOW SPPARAMETERS	This SQL*Plus command displays the values of initialization parameters in the server parameter file (SPFILE).
CREATE PFILE	This SQL statement creates a text initialization parameter file (PFILE) from the SPFILE or from the current in-memory settings. You can then view the PFILE with any text editor.
V\$PARAMETER	This view displays the values of initialization parameters in effect for the current session.
V\$PARAMETER2	This view displays the values of initialization parameters in effect for the current session. It is easier to distinguish list parameter values in this view because each list parameter value appears in a separate row.
V\$SYSTEM_PARAMETER	This view displays the values of initialization parameters in effect for the instance. A new session inherits parameter values from the instance-wide values.

Method	Description
V\$SYSTEM_PARAMETER2	This view displays the values of initialization parameters in effect for the instance. A new session inherits parameter values from the instance-wide values. It is easier to distinguish list parameter values in this view because each list parameter value appears in a separate row.
V\$SPPARMETER	This view displays the current contents of the SPFILE. The view returns FALSE values in the ISSPECIFIED column if an SPFILE is not being used by the instance.

2.8 Managing Application Workloads with Database Services

A database service is a named representation of one or more database instances. Services enable you to group database workloads and route a particular work request to an appropriate instance.

- **Database Services**

A database service represents a single database. This database can be a single-instance database or an Oracle Real Application Clusters (Oracle RAC) database with multiple concurrent database instances. A global database service is a service provided by multiple databases synchronized through data replication.

- **Global Data Services**

Starting with Oracle Database 12c, you can use Global Data Services (GDS) for workload management involving multiple Oracle databases. GDS enables administrators to automatically and transparently manage client workloads across replicated databases that offer common services. These common services are known as global services.

- **Database Service Data Dictionary Views**

You can query data dictionary views to find information about database services.

2.8.1 Database Services

A database service represents a single database. This database can be a single-instance database or an Oracle Real Application Clusters (Oracle RAC) database with multiple concurrent database instances. A global database service is a service provided by multiple databases synchronized through data replication.

- **About Database Services**

Database services divide workloads for a single database into mutually disjoint groupings.

- [Database Services and Performance](#)
Database services offer an extra dimension in performance tuning.
- [Oracle Database Features That Use Database Services](#)
Several Oracle Database features support database services.
- [Creating Database Services](#)
There are a few ways to create database services, depending on your database configuration.

2.8.1.1 About Database Services

Database services divide workloads for a single database into mutually disjoint groupings.

Each database service represents a workload with common attributes, service-level thresholds, and priorities. The grouping is based on attributes of work that might include the application function to be used, the priority of execution for the application function, the job class to be managed, or the data range used in the application function or job class. For example, the Oracle E-Business Suite defines a database service for each responsibility, such as general ledger, accounts receivable, order entry, and so on. When you configure database services, you give each service a unique name, associated performance goals, and associated importance. The database services are tightly integrated with Oracle Database and are maintained in the data dictionary.

Connection requests can include a database service name. Thus, middle-tier applications and client/server applications use a service by specifying the database service as part of the connection in TNS connect data. If no database service name is included and the Net Services file listener.ora designates a default database service, then the connection uses the default database service.

Database services enable you to configure a workload for a single database, administer it, enable and disable it, and measure the workload as a single entity. You can do this using standard tools such as the Database Configuration Assistant (DBCA), Oracle Net Configuration Assistant, and Oracle Enterprise Manager Cloud Control (Cloud Control). Cloud Control supports viewing and operating services as a whole, with drill down to the instance-level when needed.

In an Oracle Real Application Clusters (Oracle RAC) environment, a database service can span one or more instances and facilitate workload balancing based on transaction performance. This capability provides end-to-end unattended recovery, rolling changes by workload, and full location transparency. Oracle RAC also enables you to manage several database service features with Cloud Control, the DBCA, and the Server Control utility (SRVCTL).

Database services describe applications, application functions, and data ranges as either functional services or data-dependent services. Functional services are the most common mapping of workloads. Sessions using a particular function are grouped together. In contrast, data-dependent routing routes sessions to database services based on data keys. The mapping of work requests to database services occurs in the object relational mapping layer for application servers and TP monitors. For example, in Oracle RAC, these ranges can be completely dynamic and based on demand because the database is shared.

In addition to database services that are used by applications, Oracle Database also supports two internal database services: SYS\$BACKGROUND is used by the background

processes only, and `SYS$USERS` is the default database service for user sessions that are not associated with services.

Using database services requires no changes to your application code. Client-side work can connect to a named database service. Server-side work, such as Oracle Scheduler, parallel execution, and Oracle Database Advanced Queuing, set the database service name as part of the workload definition. Work requests executing under a database service inherit the performance thresholds for the service and are measured as part of the service.

2.8.1.2 Database Services and Performance

Database services offer an extra dimension in performance tuning.

Tuning by "service and SQL" can replace tuning by "session and SQL" in the majority of systems where all sessions are anonymous and shared. With database services, workloads are visible and measurable. Resource consumption and waits are attributable by application. Additionally, resources assigned to database services can be augmented when loads increase or decrease. This dynamic resource allocation enables a cost-effective solution for meeting demands as they occur. For example, database services are measured automatically, and the performance is compared to service-level thresholds. Performance violations are reported to Cloud Control, enabling the execution of automatic or scheduled solutions.

2.8.1.3 Oracle Database Features That Use Database Services

Several Oracle Database features support database services.

The Automatic Workload Repository (AWR) manages the performance of services. AWR records database service performance, including execution times, wait classes, and resources consumed by services. AWR alerts warn when database service response time thresholds are exceeded. The dynamic views report current service performance metrics with one hour of history. Each database service has quality-of-service thresholds for response time and CPU consumption.

In addition, the Database Resource Manager can map database services to consumer groups. Therefore, you can automatically manage the priority of one database service relative to others. You can use consumer groups to define relative priority in terms of either ratios or resource consumption.

You also can specify an edition attribute for a database service. Editions make it possible to have two or more versions of the same objects in the database. When you

specify an edition attribute for a database service, all subsequent connections that specify the database service use this edition as the initial session edition.

Specifying an edition as a database service attribute can make it easier to manage resource usage. For example, database services associated with an edition can be placed on a separate instance in an Oracle RAC environment, and the Database Resource Manager can manage resources used by different editions by associating resource plans with the corresponding database services.

For Oracle Scheduler, you optionally assign a database service when you create a job class. During execution, jobs are assigned to job classes, and job classes can run within database services. Using database services with job classes ensures that the work executed by the job scheduler is identified for workload management and performance tuning.

For parallel query and parallel DML, the query coordinator connects to a database service just like any other client. The parallel query processes inherit the database service for the duration of the execution. At the end of query execution, the parallel execution processes revert to the default database service.

- ["Setting the Edition Attribute of a Database Service"](#)
- ["Scheduling Jobs with Oracle Scheduler"](#)

2.8.1.4 Creating Database Services

There are a few ways to create database services, depending on your database configuration.

 **Note:**

This section describes creating services locally. You can also create services to operate globally. See ["Global Data Services"](#) for more information.

To create a database service:

- If your single-instance database is being managed by Oracle Restart, use the SRVCTL utility to create the database service.

```
srvctl add service -db db_unique_name -service service_name
```
- If your single-instance database is not being managed by Oracle Restart, do one of the following:
 - Append the desired database service name to the SERVICE_NAMES parameter.
 - Call the DBMS_SERVICE.CREATE_SERVICE package procedure.

- (Optional) Define database service attributes with Cloud Control or with `DBMS_SERVICE.MODIFY_SERVICE`.

Oracle Net Listener (the listener) receives incoming client connection requests and manages the traffic of these requests to the database server. The listener handles connections for registered services, and it supports dynamic service registration.

 **See Also:**

- [Oracle Database PL/SQL Packages and Types Reference](#) for information about the `DBMS_SERVICE` package
- [Oracle Real Application Clusters Administration and Deployment Guide](#) for information about creating a service in an Oracle RAC environment
- [Oracle Database Net Services Administrator's Guide](#) for more information about Oracle Net Listener and services

2.8.2 Global Data Services

Starting with Oracle Database 12c, you can use Global Data Services (GDS) for workload management involving multiple Oracle databases. GDS enables administrators to automatically and transparently manage client workloads across replicated databases that offer common services. These common services are known as global services.

GDS enables you to integrate multiple databases in various locations into private GDS configurations that can be shared by global clients. Benefits include the following:

- Enables central management of global resources
- Provides global scalability, availability, and run-time load balancing
- Allows you to dynamically add databases to the GDS configuration and dynamically migrate global services
- Extends service management, load balancing, and failover capabilities for distributed environments of replicated databases that use features such as Oracle Active Data Guard, Oracle GoldenGate, and so on
- Provides high availability through seamless failover of global services across databases (located both locally or globally)
- Provides workload balancing both within and between data centers through services, connection load balancing, and runtime load balancing
- Allows efficient utilization of the resources of the GDS configuration to service client requests

 **See Also:**

- *Oracle Database Global Data Services Concepts and Administration Guide*
- *Oracle Database Concepts*

2.8.3 Database Service Data Dictionary Views

You can query data dictionary views to find information about database services.

You can find information about database services in the following views:

- DBA_SERVICES
- ALL_SERVICES or V\$SERVICES
- V\$ACTIVE_SERVICES
- V\$SERVICE_STATS
- V\$SERVICE_EVENT
- V\$SERVICE_WAIT_CLASS
- V\$SERV_MOD_ACT_STATS
- V\$SERVICEMETRIC
- V\$SERVICEMETRIC_HISTORY

The following additional views also contain some information about database services:

- V\$SESSION
- V\$ACTIVE_SESSION_HISTORY
- DBA_RSRC_GROUP_MAPPINGS
- DBA_SCHEDULER_JOB_CLASSES
- DBA_THRESHOLDS

The ALL_SERVICES view includes a GLOBAL_SERVICE column, and the V\$SERVICES and V\$ACTIVE_SERVICES views contain a GLOBAL column. These views and columns enable you to determine whether a database service is a global service.

2.9 Considerations After Creating a Database

After you create a database the instance is left running, and the database is open and available for normal database use. You may want to perform specific actions after creating a database.

- [Some Security Considerations](#)
Configure your database so that it is secure.
- [Transparent Data Encryption](#)
Transparent Data Encryption is a feature that enables encryption of individual database columns before storing them in the data file, or enables encryption of entire tablespaces. If users attempt to circumvent the database access control

mechanisms by looking inside data files directly with operating system tools, Transparent Data Encryption prevents such users from viewing sensitive information.

- [A Secure External Password Store](#)

For large-scale deployments where applications use password credentials to connect to databases, it is possible to store such credentials in a client-side Oracle wallet. An Oracle wallet is a secure software container that is used to store authentication and signing credentials.

- [Transaction Guard and Application Continuity](#)

Transaction Guard uses a logical transaction ID to prevent the possibility of a client application submitting duplicate transactions after a recoverable error.

Application Continuity enables the replay, in a nondisruptive and rapid manner, of a request against the database after a recoverable error that makes the database session unavailable.

- [File System Server Support in the Database](#)

An Oracle database can be configured to store file system objects and access them from any NFS client. The database stores both the files and their metadata. The database responds to file system requests from the NFS daemon process in the operating system (OS) kernel.

- [The Oracle Database Sample Schemas](#)

Oracle Database includes sample schemas that help you to become familiar with Oracle Database functionality. Some Oracle Database documentation and training materials use the sample schemas in examples.

2.9.1 Some Security Considerations

Configure your database so that it is secure.

You can find security guidelines for this release in *Oracle Database Security Guide*. Oracle recommends that you read these guidelines and configure your database accordingly.

After the database is created, you can configure it to take advantage of Oracle Identity Management.

A newly created database has at least three user accounts that are important for administering your database: SYS, SYSTEM, and SYSMAN. Additional administrative accounts are provided that should be used only by authorized users. To protect these accounts from being used by unauthorized users familiar with their Oracle-supplied passwords, these accounts are initially locked with their passwords expired. As the database administrator, you are responsible for the unlocking and resetting of these accounts.

 **Note:**

To prevent unauthorized access and protect the integrity of your database, it is important that new passwords for user accounts `SYS` and `SYSTEM` be specified when the database is created. This is accomplished by specifying the following `CREATE DATABASE` clauses when manually creating your database, or by using DBCA to create the database:

- `USER SYS IDENTIFIED BY`
- `USER SYSTEM IDENTIFIED BY`

 **See Also:**

- "[Administrative User Accounts](#)" for more information about the users `SYS` and `SYSTEM`
- *Oracle Database Enterprise User Security Administrator's Guide* for information about Oracle Identity Management
- *Oracle Database 2 Day + Security Guide* for a complete list of predefined user accounts created with each new Oracle Database installation
- *Oracle Database Security Guide* to learn how to add new users and change passwords
- *Oracle Database SQL Language Reference* for the syntax of the `ALTER USER` statement used for unlocking user accounts

2.9.2 Transparent Data Encryption

Transparent Data Encryption is a feature that enables encryption of individual database columns before storing them in the data file, or enables encryption of entire tablespaces. If users attempt to circumvent the database access control mechanisms by looking inside data files directly with operating system tools, Transparent Data Encryption prevents such users from viewing sensitive information.

Users who have the `CREATE TABLE` privilege can choose one or more columns in a table to be encrypted. The data is encrypted in the data files. Database users with appropriate privileges can view the data in unencrypted format. For information on enabling Transparent Data Encryption, see *Oracle Database Advanced Security Guide*.

 **See Also:**

- "[Consider Encrypting Columns That Contain Sensitive Data](#)"
- "[Encrypted Tablespaces](#)"

2.9.3 A Secure External Password Store

For large-scale deployments where applications use password credentials to connect to databases, it is possible to store such credentials in a client-side Oracle wallet. An Oracle wallet is a secure software container that is used to store authentication and signing credentials.

Storing database password credentials in a client-side Oracle wallet eliminates the need to embed usernames and passwords in application code, batch jobs, or scripts. This reduces the risk of exposing passwords in the clear in scripts and application code, and simplifies maintenance because you need not change your code each time usernames and passwords change. In addition, not having to change application code also makes it easier to enforce password management policies for these user accounts.

When you configure a client to use the external password store, applications can use the following syntax to connect to databases that use password authentication:

```
CONNECT /@database_alias
```

Note that you need not specify database login credentials in this CONNECT command. Instead your system looks for database login credentials in the client wallet.

See Also:

- [Oracle Database Security Guide](#)
- [Oracle Database Enterprise User Security Administrator's Guide](#)

2.9.4 Transaction Guard and Application Continuity

Transaction Guard uses a logical transaction ID to prevent the possibility of a client application submitting duplicate transactions after a recoverable error. Application Continuity enables the replay, in a nondisruptive and rapid manner, of a request against the database after a recoverable error that makes the database session unavailable.

Transaction Guard is a reliable protocol and API that application developers can use to provide a known outcome for the last open transaction on a database session that becomes unavailable. After an outage, the commit message that is sent from the database to the client is not durable. If the connection breaks between an application (the client) and an Oracle database (the server), then the client receives an error message indicating that the communication failed. This error message does not inform the client about the success or failure of commit operations or procedure calls.

Transaction Guard uses a concept called the logical transaction identifier (LTXID), a globally unique identifier that identifies the transaction from the application's perspective. When a recoverable outage occurs, the application uses the LTXID to determine the outcome of the transaction. This outcome can be returned to the client instead of the ambiguous communication error. The user can decide whether to resubmit the transaction. The application also can be coded to resubmit the transaction if the states are correct.

Application Continuity masks outages from end users and applications by recovering the in-flight database sessions following recoverable outages, for both unplanned and planned outages. After a successful replay, the application can continue using a new session where the original database session left off. Application Continuity performs this recovery so that the outage appears to the application as a delayed execution.

Application Continuity is enabled at the service level and is invoked for outages that are recoverable. These outages typically are related to underlying software, foreground, hardware, communications, network, or storage layers. Application Continuity supports queries, ALTER SESSION statements, Java and OCI APIs, PL/SQL, DDL, and the last uncommitted transaction before the failure. Application Continuity determines whether the last in-flight transaction committed or not, and whether the last user call completed or not, using Transaction Guard.

 **See Also:**

- *Oracle Database Concepts* for a conceptual overview of Transaction Guard and Application Continuity
- *Oracle Database Development Guide* for complete information about Transaction Guard and Application Continuity

2.9.5 File System Server Support in the Database

An Oracle database can be configured to store file system objects and access them from any NFS client. The database stores both the files and their metadata. The database responds to file system requests from the NFS daemon process in the operating system (OS) kernel.

When you configure the Oracle File System (OFS) server in a database and create a file system, you can store unstructured data, such as emails, videos, audio files, credit card bills, documents, photo images, and so on, inside the database. You can manipulate and manage these unstructured objects without using SQL. Instead, you can use operating system utilities for NFS support.

To enable NFS access in the database, set the `OFS_THREADS` initialization parameter to configure a sufficient number of OFS threads to process the NFS requests. The `OFS_THREADS` initialization parameter controls the number of OFS threads to create when the first file system is mounted with the database. The number of threads specified by the `OFS_THREADS` parameter are created only once for the database instance and subsequent file systems do not create any additional threads. The default value of the `OFS_THREADS` initialization parameter is 4. At database startup, OFSD background process is the sole OFS process that is spawned by the database server.

You can use the `DBMS_FS` package to create a file system in the database using a specified database object. You can also use this package to mount and unmount a specified file system.

 **See Also:**

- *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information about the Oracle File System (OFS)
- *Oracle Database PL/SQL Packages and Types Reference* for more information about the `DBMS_FS` package

2.9.6 The Oracle Database Sample Schemas

Oracle Database includes sample schemas that help you to become familiar with Oracle Database functionality. Some Oracle Database documentation and training materials use the sample schemas in examples.

The schemas and installation instructions are described in detail in *Oracle Database Sample Schemas*.

 **Note:**

Oracle strongly recommends that you do not install the sample schemas in a production database.

2.10 Cloning a Database with CloneDB

CloneDB enables you to clone a database multiple times without copying the data files into several different locations. Instead, CloneDB uses copy-on-write technology, so that only the blocks that are modified require additional storage on disk.

- [About Cloning a Database with CloneDB](#)
It is often necessary to clone a production database for testing purposes or other purposes.
- [Cloning a Database with CloneDB](#)
You can clone a database with CloneDB.
- [After Cloning a Database with CloneDB](#)
After a CloneDB database is created, you can use it in almost any way you use your production database. Initially, a CloneDB database uses a minimal amount of storage for each data file. Changes to rows in a CloneDB database cause storage space to be allocated on demand.

2.10.1 About Cloning a Database with CloneDB

It is often necessary to clone a production database for testing purposes or other purposes.

Common reasons to clone a production database include the following:

- Deployment of a new application, or an update of an existing application, that uses the database
- A planned operating system upgrade on the system that runs the database

- New storage for the database installation
- Reporting
- Analysis of older data

Before deploying a new application, performing an operating system upgrade, or using new storage, thorough testing is required to ensure that the database works properly under the new conditions. Cloning can be achieved by making copies of the production data files in one or more test environments, but these copies typically require large amounts of storage space to be allocated and managed.

With CloneDB, you can clone a database multiple times without copying the data files into several different locations. Instead, Oracle Database creates the files in the CloneDB database using copy-on-write technology, so that only the blocks that are modified in the CloneDB database require additional storage on disk.

Cloning a database in this way provides the following advantages:

- It reduces the amount of storage required for testing purposes.
- It enables the rapid creation of multiple database clones for various purposes.

The CloneDB databases use the data files of a database backup. Using the backup data files ensures that the production data files are not accessed by the CloneDB instances and that the CloneDB instances do not compete for the production database's resources, such as CPU and I/O resources.

The instructions in this chapter describe cloning a non-CDB. You can also clone a pluggable database (PDB) in a CDB using the `CREATE PLUGGABLE DATABASE` statement. If your underlying file system supports storage snapshots, then you can use the `SNAPSHOT COPY` clause of the `CREATE PLUGGABLE DATABASE` statement to clone a PDB using a storage snapshot.

 **Note:**

The CloneDB feature is not intended for performance testing.

 **See Also:**

["Creating a PDB by Cloning an Existing PDB or Non-CDB"](#)

2.10.2 Cloning a Database with CloneDB

You can clone a database with CloneDB.

Before cloning a database, the following prerequisites must be met:

- Each CloneDB database must use Direct NFS Client, and the backup of the production database must be located on an NFS volume.

Direct NFS Client enables an Oracle database to access network attached storage (NAS) devices directly, rather than using the operating system kernel NFS client.

This CloneDB database feature is available on platforms that support Direct NFS Client.

See *Oracle Grid Infrastructure Installation Guide* for your operating system for information about Direct NFS Client.

- At least 2 MB of additional System Global Area (SGA) memory is required to track the modified blocks in a CloneDB database.

See [Managing Memory](#).

- Storage for the database backup and for the changed blocks in each CloneDB database is required.

The storage required for the database backup depends on the method used to perform the backup. A single full RMAN backup requires the most storage.

Storage snapshots carried out using the features of a storage appliance adhere to the requirements of the storage appliance. A single backup can support multiple CloneDB databases.

The amount of storage required for each CloneDB database depends on the write activity in that database. Every block that is modified requires an available block of storage. Therefore, the total storage requirement depends on the number of blocks modified in the CloneDB database over time.

This section describes the steps required to create one CloneDB database and uses these sample databases and directories:

- The Oracle home for the production database PROD1 is /u01/prod1/oracle.
- The files for the database backup are in /u02/oracle/backup/prod1.
- The Oracle home for CloneDB database CLONE1 is /u03/clone1/oracle.

To clone a database with CloneDB:

1. Create a backup of your production database. You have the following backup options:

- An online backup

If you perform an online backup, then ensure that your production database is in ARCHIVELOG mode and that all of the necessary archived redo log files are saved and accessible to the CloneDB database environment.

- A full offline backup

If you perform a full offline backup, then ensure that the backup files are accessible to the CloneDB database environment.

- A backup that copies the database files

If you specify BACKUP AS COPY in RMAN, then RMAN copies each file as an image copy, which is a bit-for-bit copy of a database file created on disk.

Image copies are identical to copies created with operating system commands such as `cp` on Linux or `COPY` on Windows, but are recorded in the RMAN repository and so are usable by RMAN. You can use RMAN to make image copies while the database is open. Ensure that the copied database files are accessible to the CloneDB database environment.

See *Oracle Database Backup and Recovery User's Guide* for information about backing up a database.

2. Create a text initialization parameter file (PFILE) if one does not exist.

If you are using a server parameter file (SPFILE), then run the following statement on the production database to create a PFILE:

```
CREATE PFILE FROM SPFILE;
```

3. Create SQL scripts for cloning the production database.

You will use one or more SQL scripts to create a CloneDB database in a later step. To create the SQL scripts, you can either use an Oracle-supplied Perl script called clonedb.pl, or you can create a SQL script manually.

To use the clonedb.pl Perl script, complete the following steps:

- a. Set the following environment variables at an operating system prompt:

MASTER_COPY_DIR - Specify the directory that contains the backup created in Step 1. Ensure that this directory contains only the backup of the data files of the production database.

CLOSE_FILE_CREATE_DEST - Specify the directory where CloneDB database files will be created, including data files, log files, control files.

CLONEDB_NAME - Specify the name of the CloneDB database.

S7000_TARGET - If the NFS host providing the file system for the backup and the CloneDB database is a Sun Storage 7000, then specify the name of the host. Otherwise, do not set this environment variable. Set this environment variable only if cloning must be done using storage snapshots. You can use S7000 storage arrays for Direct NFS Client without setting this variable.

- b. Run the clonedb.pl Perl script.

The script is in the \$ORACLE_HOME/rdbms/install directory and has the following syntax:

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/install/clonedb.pl  
prod_db_pfile [sql_script1] [sql_script2]
```

Specify the following options:

prod_db_pfile - Specify the full path of the production database's PFILE.

sql_script1 - Specify a name for the first SQL script generated by clonedb.pl. The default is crtbd.sql.

sql_script2 - Specify a name for the second SQL script generated by clonedb.pl. The default is dbren.sql.

The clonedb.pl script copies the production database's PFILE to the CloneDB database's directory. It also creates two SQL scripts that you will use to create the CloneDB database.

- c. Check the two SQL scripts that were generated by the clonedb.pl Perl script, and make changes if necessary.
d. Modify the initialization parameters for the CloneDB database environment, and save the file.

Change any initialization parameter that is specific to the CloneDB database environment, such as parameters that control SGA size, PGA target, the number of CPUs, and so on. The CLONEDB parameter must be set to TRUE, and the initialization parameter file includes this parameter. See *Oracle Database Reference* for information about initialization parameters.

- e. In SQL*Plus, connect to the CloneDB database with SYSDBA administrative privilege.
- f. Run the SQL scripts generated by the clonedb.pl Perl script.

For example, if the scripts use the default names, then run the following scripts at the SQL prompt:

```
crtdb.sql  
dbren.sql
```

To create a SQL script manually, complete the following steps:

- a. Connect to the database with SYSDBA or SYSBACKUP administrative privilege.

See "[Connecting to the Database with SQL*Plus](#)".

- b. Generate a backup control file script from your production database by completing the following steps:

Run the following SQL statement:

```
ALTER DATABASE BACKUP CONTROLFILE TO TRACE;
```

This statement generates a trace file that contains the SQL statements that create the control file. The trace file containing the CREATE CONTROLFILE statement is stored in a directory determined by the DIAGNOSTIC_DEST initialization parameter. Check the database alert log for the name and location of this trace file.

- c. Open the trace file generated in Step 3.b, and copy the STARTUP NOMOUNT and CREATE CONTROLFILE statements in the trace file to a new SQL script.

- d. Edit the new SQL script you created in Step 3.c in the following ways:

Change the name of the database to the name of the CloneDB database you are creating. For example, change PROD1 to CLONE1.

Change the locations of the log files to a directory in the CloneDB database environment. For example, change /u01/prod1/oracle/dbs/t_log1.f to /u03/clone1/oracle/dbs/t_log1.f.

Change the locations of the data files to the backup location. For example, change /u01/prod1/oracle/dbs/t_db1.f to /u02/oracle/backup/prod1/t_db1.f.

The following is an example of the original statements generated by the ALTER DATABASE BACKUP CONTROLFILE TO TRACE statement:

```
STARTUP NOMOUNT  
CREATE CONTROLFILE REUSE DATABASE "PROD1" NORESETLOGS ARCHIVELOG  
  MAXLOGFILES 32  
  MAXLOGMEMBERS 2  
  MAXDATAFILES 32  
  MAXINSTANCES 1  
  MAXLOGHISTORY 292  
LOGFILE  
  GROUP 1 '/u01/prod1/oracle/dbs/t_log1.f'  SIZE 25M BLOCKSIZE 512,  
  GROUP 2 '/u01/prod1/oracle/dbs/t_log2.f'  SIZE 25M BLOCKSIZE 512  
  -- STANDBY LOGFILE  
DATAFILE  
  '/u01/prod1/oracle/dbs/t_db1.f',  
  '/u01/prod1/oracle/dbs/t_ax1.f',  
  '/u01/prod1/oracle/dbs/t_undo1.f',  
  '/u01/prod1/oracle/dbs/t_xdb1.f',  
  '/u01/prod1/oracle/dbs/undots.dbf'
```

```
CHARACTER SET WE8ISO8859P1
;
```

The following is an example of the modified statements in the new SQL script:

```
STARTUP NOMOUNT PFILE=/u03/clone1/oracle/dbs/clone1.ora
CREATE CONTROLFILE REUSE DATABASE "CLONE1" RESETLOGS ARCHIVELOG
    MAXLOGFILES 32
    MAXLOGMEMBERS 2
    MAXDATAFILES 32
    MAXINSTANCES 1
    MAXLOGHISTORY 292
LOGFILE
    GROUP 1 '/u03/clone1/oracle/dbs/t_log1.f'  SIZE 25M BLOCKSIZE 512,
    GROUP 2 '/u03/clone1/oracle/dbs/t_log2.f'  SIZE 25M BLOCKSIZE 512
-- STANDBY LOGFILE
DATAFILE
    '/u02/oracle/backup/prod1/t_db1.f',
    '/u02/oracle/backup/prod1/t_ax1.f',
    '/u02/oracle/backup/prod1/t_undol.f',
    '/u02/oracle/backup/prod1/t_xdb1.f',
    '/u02/oracle/backup/prod1/undots.dbf'
CHARACTER SET WE8ISO8859P1
;
```

If you have a storage level snapshot taken on a data file, then you can replace the RMAN backup file names with the storage snapshot names.

- e. After you edit the SQL script, save it to a location that is accessible to the CloneDB database environment.

Make a note of the name and location of the new SQL script. You will run the script in a subsequent step. In this example, assume the name of the script is `create_clonedb1.sql`

- f. Copy the text initialization parameter file (PFILE) from the production database environment to the CloneDB database environment.

For example, copy the text initialization parameter file from `/u01/prod1/oracle/dbs` to `/u03/clone1/oracle/dbs`. The name and location of the file must match the name and location specified in the `STARTUP NOMOUNT` command in the modified SQL script. In the example in Step 3.d, the file is `/u03/clone1/oracle/dbs/clone1.ora`.

- g. Modify the initialization parameters for the CloneDB database environment, and save the file.

Add the `CLONEDB` parameter, and ensure that this parameter is set to `TRUE`. Change any other initialization parameter that is specific to the CloneDB database environment, such as parameters that control SGA size, PGA target, the number of CPUs, and so on. See *Oracle Database Reference* for information about initialization parameters.

- h. In SQL*Plus, connect to the CloneDB database with `SYSDBA` administrative privilege.
- i. Run the SQL script you saved in Step 3.e.

For example, enter the following in SQL*Plus:

```
@create_clonedb1.sql
```

- j. For each data file in the backup location, run the CLONEDB_RENAMEFILE procedure in the DBMS_DNFS package and specify the appropriate location in the CloneDB database environment.

For example, run the following procedure if the backup data file is /u02/oracle/backup/prod1/t_db1.f and the CloneDB database data file is /u03/clone1/oracle/dbs/t_db1.f:

```
BEGIN
  DBMS_DNFS.CLONEDB_RENAMEFILE(
    srcfile => '/u02/oracle/backup/prod1/t_db1.f',
    destfile => '/u03/clone1/oracle/dbs/t_db1.f');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for more information about the DBMS_DNFS package.

4. If you created your CloneDB database from an online backup, then recover the CloneDB database. This step is not required if you performed a full offline backup or a BACKUP AS COPY backup.

For example, run the following SQL statement on the CloneDB database:

```
RECOVER DATABASE USING BACKUP CONTROLFILE UNTIL CANCEL;
```

This statement prompts for the archived redo log files for the period when the backup was performed.

5. Open the database by running the following SQL statement:

```
ALTER DATABASE OPEN RESETLOGS;
```

The CloneDB database is ready for use.

To create additional CloneDB databases of the production database, repeat Steps 3 - 5 for each CloneDB database.

2.10.3 After Cloning a Database with CloneDB

After a CloneDB database is created, you can use it in almost any way you use your production database. Initially, a CloneDB database uses a minimal amount of storage for each data file. Changes to rows in a CloneDB database cause storage space to be allocated on demand.

You can use the same backup files to create multiple CloneDB databases. This backup can be taken either by RMAN or by storage level snapshots. If you have a storage level snapshot taken on a data file, then you can replace the RMAN backup file names with the storage snapshot names.

You can use the V\$CLONEDFILE view to show information about each data file in the CloneDB database. This information includes the data file name in the backup, the corresponding data file name in the CloneDB database, the number of blocks read from the backup file, and the number of requests issued against the backup file.

Because CloneDB databases use the backup files as their backend storage, the backup files must be available to each CloneDB database for it to run. If the backup files become unavailable, then the CloneDB databases return errors.

When your use of a CloneDB database is complete, you can destroy the CloneDB database environment. You can delete all of the files in the CloneDB database

environment without affecting the production database environment or the backup environment.

See Also:

Oracle Database Reference for more information about the V\$CLONEDFILE view

2.11 Dropping a Database

Dropping a database involves removing its data files, online redo logs, control files, and initialization parameter files.

WARNING:

Dropping a database deletes all data in the database.

To drop a database:

- Submit the following statement:

```
DROP DATABASE;
```

The `DROP DATABASE` statement first deletes all control files and all other database files listed in the control file. It then shuts down the database instance.

To use the `DROP DATABASE` statement successfully, the database must be mounted in exclusive and restricted mode.

The `DROP DATABASE` statement has no effect on archived redo log files, nor does it have any effect on copies or backups of the database. It is best to use RMAN to delete such files.

If you used the Database Configuration Assistant to create your database, you can use that tool to delete (drop) your database and remove the files.

See Also:

"[Altering Database Availability](#)"

2.12 Database Data Dictionary Views

You can query data dictionary views for information about your database content and structure.

You can view information about your database content and structure using the following views:

View	Description
DATABASE_PROPERTY IES	Displays permanent database properties
GLOBAL_NAME	Displays the global database name
V\$DATABASE	Contains database information from the control file

Related Topics

- [Methods for Viewing Parameter Settings](#)
You can view parameter settings using several different methods.

2.13 Database Configuration Assistant Command Reference for Silent Mode

This section provides detailed information about the syntax and options for the Database Configuration Assistant (DBCA) silent mode commands.

- [DBCA Command-Line Syntax Overview](#)
This section provides an overview of the command-line syntax of DBCA in silent mode.
- [About DBCA Templates](#)
You can use DBCA to create a database from a template supplied by Oracle or from a template that you create.
- [Database User Authentication in DBCA Commands Using Oracle Wallet](#)
You can use Oracle wallet as a secure external password store for authenticating database users in DBCA silent mode commands.
- [DBCA Silent Mode Commands](#)
This section lists all the DBCA silent mode commands along with their syntax and parameter description.

See Also:

Oracle Database 2 Day DBA for information about using DBCA in the interactive mode

2.13.1 DBCA Command-Line Syntax Overview

This section provides an overview of the command-line syntax of DBCA in silent mode.

DBCA silent mode has the following command syntax:

```
dbca [-silent] [command [options]] [-h|-help]
```

The following table describes the DBCA silent mode command syntax.

Table 2-4 DBCA Silent Mode Command Syntax Description

Option	Description
-silent	Specify -silent to run DBCA in silent mode. In silent mode, DBCA uses values that you specify as command-line options to create or modify a database.
<i>command options</i>	Specify a DBCA command and valid options for the command.
-h -help	Displays help for DBCA. You can display help for a specific command by entering the following: <code>dbca <i>command</i> -help</code> For example, to display the help for the -createDatabase command, enter the following: <code>dbca -createDatabase -help</code>

The following example illustrates how to create a database with the silent mode of DBCA:

```
dbca -silent -createDatabase -templateName General_Purpose.dbc
      -gdbname oradb.example.com
      -sid oradb
      -characterSet AL32UTF8
      -memoryPercentage 30
      -emConfiguration DBEXPRESS
```

```
Enter SYSTEM user password:
password
Enter SYS user password:
password
Copying database files
1% complete
3% complete
...
```

To ensure completely silent operation, you can redirect stdout to a file. If you do this, however, you may have to supply passwords for the administrative users in command-line arguments or the response file.

Note:

If you use Oracle wallet as a secure external password store for storing passwords for the administrative users, then you do not have to supply passwords for these users in the command-line arguments or in the response file. See "["Database User Authentication in DBCA Commands Using Oracle Wallet"](#) for more information.

To view brief help for DBCA command-line arguments, enter the following command:

```
dbca -help
```

For more detailed argument information, including defaults, view the response file template found on your distribution media. See the Oracle Database installation guide for your platform to get information about the name and location of the response file template.

 **See Also:**

["DBCA Silent Mode Commands"](#)

2.13.2 About DBCA Templates

You can use DBCA to create a database from a template supplied by Oracle or from a template that you create.

A DBCA template is an XML file that contains information required to create a database. Oracle ships templates for the following two workload types:

- General purpose OR online transaction processing
- Data warehouse

Select the template suited to the type of workload your database will support. If you are not sure which to choose, then use the "General purpose OR online transaction processing" template. You can also create custom templates to meet your specific workload requirements.

 **Note:**

The General Purpose or online transaction processing template and the data Warehouse template create a database with the COMPATIBLE initialization parameter set to 12.1.0.2.0.

2.13.3 Database User Authentication in DBCA Commands Using Oracle Wallet

You can use Oracle wallet as a secure external password store for authenticating database users in DBCA silent mode commands.

Oracle wallet is a secure software container external to Oracle Database, which can be used to store authentication credentials of Oracle Database users. You can use the following DBCA silent mode command parameters to use Oracle wallet for authenticating database users:

- `useWalletForDBCredentials` : Specify `true` to use Oracle wallet for database user authentication, else specify `false`. Default is `false`.

If `true` is specified, then provide the following additional parameters:

- `dbCredentialsWalletLocation`: Directory in which the Oracle wallet files are stored.

- (Optional) `dbCredentialsWalletPassword`: Password for the Oracle wallet account user. If the Oracle wallet is *auto-login* enabled, then you need not specify this password.

You can store the following keys and associated passwords in the Oracle wallet that can be used by DBCA in silent mode for authenticating users:

- `oracle.dbsecurity.sysPassword`: SYS user password
- `oracle.dbsecurity.systemPassword`: SYSTEM user password
- `oracle.dbsecurity.pdbAdminPassword`: Pluggable database (PDB) administrator password
- `oracle.dbsecurity.dbsnmpPassword`: DBSNMP user password
- `oracle.dbsecurity.asmsnmpPassword`: ASMSNMP user password
- `oracle.dbsecurity.lbacsy>Password`: LBACSYS user password
- `oracle.dbsecurity.sysdbaUserPassword`: SYSDBA role user password for the database that you are creating or configuring
- `oracle.dbsecurity.oracleHomeUserPassword`: Oracle home user password
- `oracle.dbsecurity.dvUserPassword`: Oracle Data Vault user password
- `oracle.dbsecurity.dvAccountManagerPassword`: Oracle Data Vault account manager password
- `oracle.dbsecurity.emPassword`: Enterprise Manager administrator password
- `oracle.dbsecurity.asmPassword`: ASM user password
- `oracle.dbsecurity.asmsysPassword`: ASMSYS user password
- `oracle.dbsecurity.walletPassword`: Oracle wallet account user password for authenticating with a directory service
- `oracle.dbsecurity.userDNPassword`: Directory service user password
- `oracle.dbsecurity.srcDBsysdbaUserPassword`: SYSDBA role user password for the database that you are using as a source to perform certain operations, such as duplicating a database
- `oracle.dbsecurity.dbLinkUserPassword`: Database link user password

Note:

If you are using Oracle Unified Directory (OUD), then the OUD account passwords should be stored in the wallet using the following keys:

- `oracle.dbsecurity.walletPassword`
- `oracle.dbsecurity.userDNPassword`

 **See Also:**

Oracle Database Security Guide for information about configuring Oracle wallet as a secure external password store using the `mkstore` command-line utility

2.13.4 DBCA Silent Mode Commands

This section lists all the DBCA silent mode commands along with their syntax and parameter description.

- **createDatabase**
The `createDatabase` command creates a database.
- **createDuplicateDB**
The `createDuplicateDB` command duplicates a database.
- **configureDatabase**
The `configureDatabase` command configures a database.
- **createTemplateFromDB**
The `createTemplateFromDB` command creates a database template from an existing database.
- **createCloneTemplate**
The `createCloneTemplate` command creates a clone (seed) database template from an existing database.
- **generateScripts**
The `generateScripts` command generates scripts, which can be used to create a database.
- **deleteDatabase**
The `deleteDatabase` command deletes a database.
- **createPluggableDatabase**
The `createPluggableDatabase` command creates a PDB in a CDB.
- **unplugDatabase**
The `unplugDatabase` command unplugs a pluggable database (PDB) from a multitenant container database (CDB).
- **deletePluggableDatabase**
The `deletePluggableDatabase` command deletes a PDB.
- **configurePluggableDatabase**
The `configurePluggableDatabase` command configures a PDB.
- **addInstance**
The `addInstance` command adds a database instance to an administrator-managed Oracle RAC database.
- **deleteInstance**
The `deleteInstance` command deletes a database instance from an administrator-managed Oracle RAC database.
- **executePrereqs**
The `executePrereqs` command executes the prerequisites checks and reports the results. This command can be used to check the environment before running dbca to create a database.

2.13.4.1 createDatabase

The `createDatabase` command creates a database.

Syntax and Parameters

Use the `dbca -createDatabase` command with the following syntax:

```
dbca -createDatabase
  -responseFile | (-gdbName,-templateName)
  -responseFile response_file_directory
  -gdbName global_database_name
  -templateName database_template_name
  [-sid database_system_identifier]
  [-createAsContainerDatabase {true | false}]
  [-numberOfPDBs number_of_pdbs]
  [-pdbName pdb_name]
  [-pdbStorageMAXSizeInMB maximum_storage_size_of_the_pdb]
  [-pdbStorageMAXTempSizeInMB maximum_temporary_storage_size_of_the_pdb]
  [-useLocalUndoForPDBs {true | false}]
  [-pdbAdminPassword pdb_administrator_password]
  [-pdbOptions pdb_options]
  [-sysPassword SYS_user_password]
  [-systemPassword SYSTEM_user_password]
  [-emConfiguration {DBEXPRESS | CENTRAL | BOTH | NONE}
    [-dbsnmpPassword DBSNMP_user_password]
    [-omsHost Oracle_Management_Server_host_name]
    [-omsPort Oracle_Management_Server_port_number]
    [-emUser EM_administrator_user_name]
    [-emPassword EM_administrator_user_password]
    [-emExpressPort EM_Express_port]
    [-emExpressPortAsGlobalPort EM_Express_global_port]]
  [-dvConfiguration {true | false}
    -dvUserName Database_Vault_owner_name
    -dvUserPassword Database_Vault_owner_password
    [-dvAccountManagerName Database_Vault_account_manager_name
      -dvAccountManagerPassword Database_Vault_account_manager_password]]
  [-olsConfiguration {true | false}
    [-configureWithOID configure_with_OID_flag]]
  [-datafileDestination data_files_directory]
  [-redoLogFileSize maximum_redo_log_file_size]
  [-recoveryAreaDestination recovery_files_directory

Table 2-5 createDatabase Parameters

Parameter	Required/ Optional	Description
-responseFile <i>response_file_directory</i>	Required	Absolute directory path of the response file.
-gdbName <i>global_database_name</i>	Required	Global database name in the form <i>database_name.domain_name</i> .
-templateName <i>database_template_name</i>	Required	Name of an existing database template in the default location or the complete path to a database template that is not in the default location.
-sid <i>database_system_identifier</i>	Optional	Database system identifier (SID). The SID uniquely identifies the instance that runs the database. If it is not specified, then it defaults to the database name.

Table 2-5 (Cont.) createDatabase Parameters

Parameter	Required/ Optional	Description
-createAsContainerDatabase {true false}	Optional	<p>Specify true to create a CDB. Specify false to create a non-CDB. Default is false.</p> <p>When true is specified, the following additional parameters are optional:</p> <ul style="list-style-type: none"> • -numberOfPDBs: Number of PDBs to create. The default is 0 (zero). • -dbName: Base name of each PDB. A number is appended to each name if -numberOfPDBs is greater than 1. This parameter must be specified if -numberOfPDBs is greater than 0 (zero). • -pdbStorageMAXSizeInMB: Maximum storage size for the PDBs in megabytes. • -pdbStorageMAXTempSizeInMB: Maximum temporary storage size for the PDBs in megabytes. • -useLocalUndoForPDBs {true false}: Specify whether local undo should be used for the PDBs. • -pdbAdminPassword: PDB administrator password. • -pdbOptions: Specify PDB options as comma separated list in name:value format. <p>Example: JSERVER:true, DV:false</p>
-sysPassword <i>SYS_user_password</i>	Optional	SYS user password for the new database.
-systemPassword <i>SYSTEM_user_password</i>	Optional	SYSTEM user password for the new database.
-emConfiguration {DBEXPRESS CENTRAL BOTH NONE}	Optional	<p>Enterprise Manager configuration settings.</p> <p>When DBEXPRESS, CENTRAL, or BOTH is specified, specify the following additional parameters:</p> <ul style="list-style-type: none"> • -dbsnmpPassword: DBSNMP user password. • -omsHost: Oracle Management Server host name. • -omsPort: Oracle Management Server port number. • -emUser: User name for Enterprise Manager administrator. • -emPassword: Password for Enterprise Manager administrator. • -emExpressPort: Enterprise Manager Express port number. • -emExpressPortAsGlobalPort: Enterprise Manager Express global port number.

Table 2-5 (Cont.) createDatabase Parameters

Parameter	Required/ Optional	Description
<code>-dvConfiguration {true false}</code>	Optional	<p>Specify true to enable and configure Database Vault, else specify false. Default is false.</p> <p>When true is specified, the following additional Database Vault parameters are required:</p> <ul style="list-style-type: none"> • <code>-dvUserName</code>: Specify Database Vault owner name. • <code>-dvUserPassword</code>: Specify Database Vault owner password. • <code>-dvAccountManagerName</code>: Specify Database Vault account manager name. • <code>-dvAccountManagerPassword</code>: Specify Database Vault account manager password.
<code>-olsConfiguration {true false}</code>	Optional	<p>Specify true to enable and configure Oracle Label Security (OLS), else specify false. Default is false.</p> <p>When true is specified, you can additionally specify the <code>-configureWithOID</code> parameter, if you want to configure Oracle Label Security (OLS) with Oracle Internet Directory (OID).</p>
<code>-datafileDestination <i>data_files_directory</i></code>	Optional	Complete path to the location of the database data files.
<code>-redoLogFileSize <i>maximum_size_of_redo_log_file</i></code>	Optional	Size of each online redo log in megabytes.
<code>-recoveryAreaDestination <i>fast_recovery_area_directory</i></code>	Optional	<p>Destination directory for the Fast Recovery Area, which is a backup and recovery area. Specify NONE to disable Fast Recovery Area.</p> <p>Additionally, you can specify the Fast Recovery Area size in megabytes using the parameter <code>-recoveryAreaSize</code>. This parameter is optional.</p>
<code>-datafileJarLocation <i>data_files_backup_directory</i></code>	Optional	Absolute directory path of the database backup data files stored in a compressed RMAN backup format (files with .dfb extensions).
<code>-storageType {FS ASM}</code>	Optional	<p>Specify the storage type of either FS or ASM.</p> <ul style="list-style-type: none"> • FS: File system storage type. When FS is specified, your database files are managed by the file system of your operating system. You can specify the directory path where the database files are to be stored using a database template or the <code>-datafileDestination</code> parameter. Oracle Database can create and manage the actual files. • ASM: Oracle Automatic Storage Management (Oracle ASM) storage type. When ASM is specified, your database files are placed in Oracle ASM disk groups. Oracle Database automatically manages database file placement and naming. When ASM is specified, you can also specify the ASMSNMP password using the <code>-asmsnmpPassword</code> parameter. This parameter is optional.

Table 2-5 (Cont.) createDatabase Parameters

Parameter	Required/ Optional	Description
-useWalletForDBCredentials ls {true false}	Optional	<p>Specify true to use Oracle Wallet for database credentials, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -dbCredentialsWalletLocation: Directory location for the Oracle Wallet files. • -dbCredentialsWalletPassword: Password for the Oracle Wallet account. <p>Note: If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:</p> <ul style="list-style-type: none"> • oracle.dbsecurity.walletPassword • oracle.dbsecurity.userDNPassword
-runCVUChecks {true false}	Optional	Specify true to run Cluster Verification Utility checks periodically for Oracle RAC databases, else specify false. Default is false.
-nodelist <i>database_nodes_list</i>	Optional	List of database nodes separated by comma.
-enableArchive {true false}	Optional	<p>Specify true to enable log file archive, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -archiveLogMode {AUTO MANUAL}: Specify either the automatic archive mode or the manual archive mode. Default is automatic archive mode. • -archiveLogDest: Directory path for storing the archive log files.
-memoryMgmtType {AUTO AUTO_SGA CUSTOM_SGA}	Optional	<p>Specify one of the following memory management types:</p> <ul style="list-style-type: none"> • AUTO: Automatic memory management for SGA and PGA. • AUTO_SGA: Automatic shared memory management for SGA. • CUSTOM_SGA: Manual shared memory management for SGA. <p>Note: If the total physical memory of a database instance is greater than 4 GB, then you cannot specify the Automatic Memory Management option AUTO during the database installation and creation. Oracle recommends that you specify the Automatic Shared Memory Management option AUTO_SGA in such environments.</p>
-createListener <i>new_database_listener</i>	Optional	Database listener to register the database in the form <i>listener_name:port</i> .
-useOMF {true false}	Optional	Specify true to use Oracle-Managed Files (OMF), else specify false. Default is false.

Table 2-5 (Cont.) createDatabase Parameters

Parameter	Required/ Optional	Description
<code>-dbOptions</code> <i>database_options</i>	Optional	Specify database options as comma separated list of name:value pairs. Example: JSERVER:true,DV:false
<code>-customScripts</code> <i>custom_scripts_list</i>	Optional	Specify a comma separated list of SQL scripts that needs to be run after the database creation. The scripts are run in the order they are listed.
<code>-oracleHomeUserName</code> <i>Oracle_Home_user_name</i>	Optional	Oracle Home user name and password.
<code>-oracleHomeUserPassword</code> <i>Oracle_Home_user_password</i>		
<code>-policyManaged</code>	Optional	<p>Policy-managed database.</p> <p>You can specify the following additional parameters:</p> <ul style="list-style-type: none"> • <code>-serverPoolName</code>: Specify the single server pool name when creating a new server pool or specify a comma separated list of existing server pools. • <code>-pqPoolName</code>: Specify the PQ pool name. • <code>-createServerPool</code>: Specify this parameter for creating a new server pool. : — <code>-pqPoolName</code>: Specify the PQ pool name. — <code>-force</code>: Specify this parameter to create the server pool by force when adequate free servers are not available. — <code>-pqCardinality</code>: Specify the PQ cardinality of the new server pool. — <code>-cardinality</code>: Specify the cardinality of the new server pool.
<code>-adminManaged</code>	Optional	Administrator-managed database.
<code>-databaseConfigType</code> <code>{SINGLE RAC RACONENODE}</code>	Optional	<p>Specify one of the following database configuration types:</p> <ul style="list-style-type: none"> • <code>SINGLE</code>: Single individual database. • <code>RAC</code>: Oracle RAC database. • <code>RACONENODE</code>: Oracle RAC One Node database. <p>For Oracle RAC One Node database, you can specify the service name using the <code>-RACOneNodeServiceName</code> parameter.</p>
<code>-characterSet</code> <i>database_character_set</i>	Optional	Character set of the database.
<code>-nationalCharacterSet</code> <i>database_national_character_set</i>	Optional	National character set of the database.

Table 2-5 (Cont.) createDatabase Parameters

Parameter	Required/ Optional	Description
<code>-registerWithDirService {true false}</code>	Optional	<p>Specify true to register with a Lightweight Directory Access Protocol (LDAP) service, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters are required:</p> <ul style="list-style-type: none"> • <code>-dirServiceUserName</code>: Username for the LDAP service. • <code>-dirServicePassword</code>: Password for the LDAP service. • <code>-databaseCN</code>: Database common name. • <code>-dirServiceCertificatePath</code>: Directory path to the certificate file to use when configuring SSL between the database and the directory service. • <code>-dirServiceUser</code>: Directory service user name. • <code>-ldapDirectoryAccessType {PASSWORD SSL}</code>: LDAP directory access type. • <code>-useSYSAuthForLDAPAccess {true false}</code>: Specify whether to use SYS user authentication for LDAP access. • <code>-walletPassword</code>: Password for the database wallet.
<code>-listeners</code> <code>listeners_list</code>	Optional	A comma-separated list of listeners for the database.
<code>-variablesFile</code> <code>variables_file</code>	Optional	Name of the variables file with the complete directory path in the database template.
<code>-variables</code> <code>variables_list</code>	Optional	A comma-separated list of name=value pairs for the variables in the database template.
<code>-initParams</code> <code>initialization_params_list</code>	Optional	<p>A comma-separated list of name=value pairs of initialization parameter values for the database.</p> <p>You can additionally provide the <code>-initParamsEscapeChar</code> parameter for using a specific escape character between multiple values of an initialization parameter. If an escape character is not specified, backslash (/) is used as the default escape character.</p>
<code>-sampleSchema {true false}</code>	Optional	<p>Specify true to include the HR sample schema (EXAMPLE tablespace) in your database. Oracle guides and educational materials contain examples based on the sample schemas. Oracle strongly recommends that you do not install the sample schemas in a production database.</p> <p>Specify false to create the database without the HR sample schema. Default is false.</p>

Table 2-5 (Cont.) createDatabase Parameters

Parameter	Required/ Optional	Description
<pre>-memoryPercentage percentage_of_total_memory_to_assign_to_oracle_database or -totalMemory total_memory_to_assign_to_oracle_database_in_MB</pre>	Optional	<p>Specify either <code>-memoryPercentage</code> or <code>-totalMemory</code>.</p> <ul style="list-style-type: none"> • <code>-memoryPercentage</code> The percentage of physical memory that can be used by the database. • <code>-totalMemory</code>. Total amount of physical memory, in megabytes, that can be used by the database.
<pre>-databaseType {MULTIPURPOSE DATA_WAREHOUSING OLTP}</pre>	Optional	<p>Specify <code>MULTIPURPOSE</code> if the database is for both OLTP and data warehouse purposes.</p> <p>Specify <code>DATA_WAREHOUSING</code> if the primary purpose of the database is a data warehouse.</p> <p>Specify <code>OLTP</code> if the primary purpose of the database is online transaction processing.</p>

2.13.4.2 createDuplicateDB

The `createDuplicateDB` command duplicates a database.

Syntax and Parameters

Use the `dbca -createDuplicateDB` command with the following syntax:

```
dbca -createDuplicateDB
      -gdbName global_database_name
      -primaryDBConnectionString easy_connect_string_to_primary
      -sid database_system_identifier
      [-createAsStandby
          [-dbUniqueName db_unique_name_for_standby]]
      [-customScripts scripts_list]
      [-datafileDestination data_files_directory]
      [-initParams initialization_parameters
          [-initParamsEscapeChar initialization_parameters_escape_character]]
      [-useWalletForDBCredentials {true | false}
          -dbCredentialsWalletPassword wallet_account_password
          -dbCredentialsWalletLocation wallet_files_directory]
```

Table 2-6 createDuplicateDB Parameters

Parameter	Required/ Optional	Description
<code>-gdbName <i>global_database_name</i></code>	Required	Global database name of the duplicate database in the form <i>database_name.domain_name</i>
<code>-primaryDBConnecti onString <i>easy_connect_stri ng_to_primary</i></code>	Required	Easy connect string for connecting to the primary database in the following form: <i>"host[:port][/:service_name][:server][/:instance_name]"</i>
<code>-sid <i>db_unique_name_for_standby</i></code>	Required	Database system identifier of the duplicate database The SID uniquely identifies the instance that runs the database. If it is not specified, then it defaults to the database name.
<code>-createAsStandby</code>	Optional	Specifies that the duplicate database is a standby database for the primary database Optionally, use the <code>-dbUniqueName</code> parameter to set the unique database name for the standby database. If the <code>-dbUniqueName</code> parameter is not specified, then the value of the <code>DB_NAME</code> initialization parameter is used.
<code>-customScripts <i>scripts_list</i></code>	Optional	A comma separated list of SQL scripts that are run after the duplicate database is created. The scripts are run in the order listed.
<code>-datafileDestinati on <i>data_files_directory</i></code>	Optional	Complete directory path for database data files.
<code>-initParams <i>initialization_pa rameters_list</i></code>	Optional	A comma-separated list of name=value pairs of initialization parameter values for the database. You can additionally provide the <code>-initParamsEscapeChar</code> parameter for using a specific escape character between multiple values of an initialization parameter. If an escape character is not specified, backslash (/) is used as the default escape character.

Table 2-6 (Cont.) createDuplicateDB Parameters

Parameter	Required/ Optional	Description
-useWalletForDBCredentials {true false}	Optional	<p>Specify true to use Oracle Wallet for database credentials, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -dbCredentialsWalletPassword: Password for the Oracle Wallet account. • -dbCredentialsWalletLocation: Directory location for the Oracle Wallet files. <p>Note:</p> <p>If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:</p> <ul style="list-style-type: none"> • oracle.dbsecurity.walletPassword • oracle.dbsecurity.userDNPassword

2.13.4.3 configureDatabase

The `configureDatabase` command configures a database.

Syntax and Parameters

Use the `dbca -configureDatabase` command with the following syntax:

```
dbca -configureDatabase
      -sourceDB source_database_sid
      [-sysDBAUserName user_name
       -sysDBAPassword password]
      [-registerWithDirService | -unregisterWithDirService | -regenerateDBPassword {true | false}
       -dirServiceUserName directory_service_user_name
       -dirServicePassword directory_service_password
       -databaseCN database_common_name
       -walletPassword wallet_password]
      [-addDBOption options_list]
      [-dvConfiguration {true | false}
       -dvUserName Database_Vault_owner_username
       -dvUserPassword Database_Vault_owner_password
       -dvAccountManagerName Database_Vault_account_manager
       -dvAccountManagerPassword Database_Vault_account_manager_password]
      [-olsConfiguration {true | false}
       -configureWithOID configure_with_OID_flag]
      [-useWalletForDBCredentials {true | false}
       -dbCredentialsWalletPassword wallet_account_password
       -dbCredentialsWalletLocation wallet_files_directory]
```

Table 2-7 configureDatabase Parameters

Parameter	Required/ Optional	Description
<code>-sourceDB <i>source_database_id</i></code>	Required	The database system identifier of the database being configured.
<code>-sysDBAUserName <i>user_name</i></code>	Optional	Username of a user that has SYSDBA administrative privilege.
<code>-sysDBAPassword <i>password</i></code>	Optional	Password of the user granted SYSDBA administrative privilege.
<code>-registerWithDirService -unregisterWithDirService -regenerateDBPassword {true false}</code>	Optional	<p>Set one of the following parameters to either true or false:</p> <ul style="list-style-type: none"> • <code>-registerWithDirService</code>: true registers with a Lightweight Directory Access Protocol (LDAP) service; false, the default, does not register with an LDAP service. • <code>-unregisterWithDirService</code>: true unregisters from an LDAP service; false, the default, does not unregister from an LDAP service. • <code>-regenerateDBPassword</code>: true regenerates the database password for an LDAP service; false, the default, does not regenerate the database password for an LDAP service. <p>When true is specified, the following additional parameters are required:</p> <ul style="list-style-type: none"> • <code>-dirServiceUserName</code>: Username for the LDAP service. • <code>-dirServicePassword</code>: Password for the LDAP service. • <code>-databaseCN</code>: Database common name. • <code>-walletPassword</code>: Password for the database wallet.
<code>-addDBOption</code>	Optional	<p>Specify any of the following Oracle Database options in a comma separated list:</p> <ul style="list-style-type: none"> • JSERVER • ORACLE_TEXT • IMEDIA • CWMLITE • SPATIAL • OMS • APEX • DV

Table 2-7 (Cont.) configureDatabase Parameters

Parameter	Required/ Optional	Description
-dvConfiguration {true false}	Optional	<p>Specify false, the default, to indicate that the database will not use Oracle Database Vault.</p> <p>Specify true to configure and enable Database Vault, or specify false to not configure and enable Database Vault.</p> <p>When true is specified, the following additional Database Vault parameters are required:</p> <ul style="list-style-type: none"> • -dvUserName: Specify the Database Vault owner username. • -dvUserPassword: Specify Database Vault owner password. • -dvAccountManagerName: Specify a separate Database Vault account manager. • -dvAccountManagerPassword: Specify the Database Vault account manager password.
-olsConfiguration {true false}	Optional	<p>Specify true to enable and configure Oracle Label Security, else specify false. Default is false.</p> <p>When true is specified, you can additionally specify the -configureWithOID parameter to configure Oracle Label Security with Oracle Internet Directory (OID). This parameter is optional.</p>
-useWalletForDBCredentials {true false}	Optional	<p>Specify true to use Oracle Wallet for database credentials, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -dbCredentialsWalletLocation: Directory location for the Oracle Wallet files. • -dbCredentialsWalletPassword: Password for the Oracle Wallet account. <p>Note:</p> <p>If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:</p> <ul style="list-style-type: none"> • oracle.dbsecurity.walletPassword • oracle.dbsecurity.userDNPassword

2.13.4.4 createTemplateFromDB

The `createTemplateFromDB` command creates a database template from an existing database.

Syntax and Parameters

Use the `dbca -createTemplateFromDB` command with the following syntax:

```
dbca -createTemplateFromDB
      -sourceDB source_database_sid
      -templateName new_database_template_name
      -sysDBAUUserName SYSDBA_user_name
```

```

-sysDBAPassword SYSDBA_user_password
[-maintainFileLocations {true | false}]
[-connectionString easy_connect_string]
[-useWalletForDBCredentials {true | false}]
    -dbCredentialsWalletPassword wallet_account_password
    -dbCredentialsWalletLocation wallet_files_directory

```

Table 2-8 createTemplateFromDB Parameters

Parameter	Required/ Optional	Description
<code>-sourceDB <i>source_database_sid</i></code>	Required	The source database system identifier (SID).
<code>-templateName <i>new_database_template_name</i></code>	Required	Name of the new database template.
<code>-sysDBAUserName <i>SYSDBA_user_name</i></code>	Required	User name of a user that has SYSDBA privileges.
<code>-sysDBAPassword <i>SYSDBA_user_password</i></code>	Required	Password of the user that has SYSDBA privileges.
<code>-maintainFileLocations {true false}</code>	Optional	Specify true to use the file locations of the database in the template. Specify false, the default, to use different file locations in the template. The file locations are determined by Oracle Flexible Architecture (OFA).
<code>-connectionString <i>easy_connect_string</i></code>	Optional	Easy connect string for connecting to a remote database in the following format: <i>"host[:port][/:service_name][:server]//instance_name"</i>
<code>-useWalletForDBCredentials {true false}</code>	Optional	Specify true to use Oracle Wallet for database credentials, else specify false. Default is false. When true is specified, the following additional parameters can be provided: <ul style="list-style-type: none"> • <code>-dbCredentialsWalletPassword</code>: Password for the Oracle Wallet account. • <code>-dbCredentialsWalletLocation</code>: Directory location for the Oracle Wallet files. Note: If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys: <ul style="list-style-type: none"> • <code>oracle.dbsecurity.walletPassword</code> • <code>oracle.dbsecurity.userDNPassword</code>

2.13.4.5 createCloneTemplate

The `createCloneTemplate` command creates a clone (seed) database template from an existing database.

Syntax and Parameters

Use the `dbca -createCloneTemplate` command with the following syntax:

```
dbca -createCloneTemplate
      -sourceSID source_database_sid | -sourceDB source_database_name
      -templateName new_database_template_name
      [-promptForWalletPassword]
      [-rmanParallelism parallelism_integer_value]
      [-maxBackupSetSizeInMB maximum_backup_set_size_in_MB]
      [-dataFileBackup {true | false}]
      [-datafileJarLocation data_files_backup_directory]
      [-sysDBAUserName SYSDBA_user_name]
      [-sysDBAPassword SYSDBA_user_password]
      [-useWalletForDBCredentials {true | false}]
          -dbCredentialsWalletPassword wallet_account_password
          -dbCredentialsWalletLocation wallet_files_directory
```

Table 2-9 createCloneTemplate Parameters

Parameter	Required/ Optional	Description
-sourceSID <i>source_database_sid</i> or -sourceDB <i>source_database_name</i>	Required	Specify either the source database system identifier (SID) or the source database name.
-templateName <i>new_database_template_name</i>	Required	Name of the new database template.
-sysDBAUserName <i>SYSDBA_user_name</i>	Optional	User name of a user having the SYSDBA privileges.
-sysDBAPassword <i>SYSDBA_user_password</i>	Optional	Password of the user having the SYSDBA privileges.
-maxBackupSetSizeInMB <i>maximum_backup_set_size_in_MB</i>	Optional	Maximum backup set size in megabytes.
-rmanParallelism <i>parallelism_integer_value</i>	Optional	Parallelism integer value for RMAN operations.
-datafileJarLocation <i>data_files_backup_directory</i>	Optional	Complete directory path to store data files as a backup in a compressed format.
-dataFileBackup {true false}	Optional	Specify true to take the data files backup, else specify false.

Table 2-9 (Cont.) createCloneTemplate Parameters

Parameter	Required/ Optional	Description
-useWalletForDBCredentials ls {true false}	Optional	<p>Specify true to use Oracle Wallet for database credentials, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -dbCredentialsWalletPassword: Password for the Oracle Wallet account. • -dbCredentialsWalletLocation: Directory location for the Oracle Wallet files. <p>Note: If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:</p> <ul style="list-style-type: none"> • oracle.dbsecurity.walletPassword • oracle.dbsecurity.userDNPassword

2.13.4.6 generateScripts

The `generateScripts` command generates scripts, which can be used to create a database.

Syntax and Parameters

Use the `dbca -generateScripts` command with the following syntax:

```
dbca -generateScripts
      -templateName database_template_name
      -gdbName global_database_name
      [-sid database_system_identifier]
      [-scriptDest sql_scripts_directory]
      [-createAsContainerDatabase {true | false}
          [-numberOfPDBs number_of_pdb_to_create]
          [-dbName pdb_name]
          [-pdbStorageMAXSizeInMB maximum_storage_size_of_the_pdb]
          [-pdbStorageMAXTempSizeInMB maximum_temporary_storage_size_of_the_pdb]
          [-useLocalUndoForPDBs {true | false}]
          [-pdbAdminPassword pdb_administrator_password]
          [-pdbOptions pdb_options]
          [-sysPassword SYS_user_password]
          [-systemPassword SYSTEM_user_password]
          [-emConfiguration {DBEXPRESS | CENTRAL | BOTH | NONE}
              [-dbsnmpPassword DBSNMP_user_password]
              [-omsHost EM_Management_Server_host_name]
              [-omsPort EM_Management_Server_port_number]
              [-emUser EM_administrator_name]
              [-emPassword EM_administrator_password]
              [-emExpressPort EM_Express_port]
              [-emExpressPortAsGlobalPort EM_Express_global_port]]
          [-dvConfiguration {true | false}
              -dvUserName Database_Vault_owner_user_name
              -dvUserPassword Database_Vault_owner_user_password
              [-dvAccountManagerName Database_Vault_account_manager_name

Table 2-10 generateScripts Parameters

Parameter	Required/ Optional	Description
<code>-templateName</code> <i>database_template_name</i>	Required	Name of an existing database template in the default location or the complete path of a template that is not in the default location.
<code>-gdbName</code> <i>global_database_name</i>	Required	Global database name in the form <i>database_name.domain_name</i> .
<code>-sid</code> <i>database_system_identifier</i>	Optional	Database system identifier (SID). The SID uniquely identifies the instance that runs the database. If it is not specified, then it defaults to the database name.
<code>-scriptDest</code> <i>scripts_directory</i>	Optional	Complete directory path to store the scripts.
<code>-createAsContainerDatabase</code> <code>{true false}</code>	Optional	<p>Specify true to create a CDB, else specify false to create a non-CDB. Default is false.</p> <p>When true is specified, the following optional parameters can be provided:</p> <ul style="list-style-type: none"> • <code>-numberOfPDBs</code>: Number of PDBs to create. Default is 0 (zero). • <code>-pdbName</code>: Name of each PDB. A number is appended to each PDB name if <code>-numberOfPDBs</code> value is greater than 1. This parameter must be specified if <code>-numberOfPDBs</code> value is greater than 0 (zero). • <code>-pdbStorageMAXSizeInMB</code>: Maximum storage size for a PDB in megabytes. • <code>-pdbStorageMAXTempSizeInMB</code>: Maximum temporary storage size for a PDB in megabytes. • <code>-useLocalUndoForPDBs {true false}</code>: Flag indicating whether local undo should be used for the PDBs. • <code>-pdbAdminPassword</code>: PDB administrator password. • <code>-pdbOptions</code>: PDB options in the form of comma separated list. Each option must be specified in the name:value format. <p style="text-align: center;">Example: JSERVER:true,DV:false</p>
<code>-sysPassword</code> <i>SYS_user_password</i>	Optional	SYS user password for the new database.
<code>-systemPassword</code> <i>SYSTEM_user_password</i>	Optional	SYSTEM user password for the new database.

Table 2-10 (Cont.) generateScripts Parameters

Parameter	Required/ Optional	Description
-emConfiguration {DBEXPRESS CENTRAL BOTH NONE}	Optional	<p>Enterprise Manager configuration settings.</p> <p>When DBEXPRESS, CENTRAL, or BOTH is specified, specify the following additional parameters:</p> <ul style="list-style-type: none"> • -dbsnmpPassword: DBSNMP user password. • -omsHost: Oracle Management Server host name. • -omsPort: Oracle Management Server port number. • -emUser: User name for Enterprise Manager administrator. • -emPassword: Password for Enterprise Manager administrator. • -emExpressPort: Enterprise Manager Express port number. • -emExpressPortAsGlobalPort: Enterprise Manager Express global port number.
-dvConfiguration {true false}	Optional	<p>Specify true to enable and configure Database Vault, else specify false. Default is false.</p> <p>When true is specified, the following additional Database Vault parameters are required:</p> <ul style="list-style-type: none"> • -dvUserName: Database Vault owner name. • -dvUserPassword: Database Vault owner password. • -dvAccountManagerName: Database Vault account manager name. • -dvAccountManagerPassword: Database Vault account manager password.
-olsConfiguration {true false}	Optional	<p>Specify true to enable and configure Oracle Label Security (OLS), else specify false. Default is false.</p> <p>When true is specified, you can additionally specify the -configureWithOID parameter to configure Oracle Label Security (OLS) with Oracle Internet Directory (OID). This parameter is optional.</p>
-datafileDestination <i>data_files_directory</i>	Optional	Complete path to the location of the database's data files.
-redoLogFileSize <i>maximum_size_of_online_redo_log</i>	Optional	Size of each online redo log file in megabytes.
-recoveryAreaDestination <i>fast_recovery_area_directory</i>	Optional	<p>Directory for the Fast Recovery Area, which is a backup and recovery area. Specify NONE to disable the Fast Recovery Area.</p> <p>Additionally, you can specify the Fast Recovery Area size in megabytes using the parameter -recoveryAreaSize. This parameter is optional.</p>
-datafileJarLocation <i>data_files_backup_directory</i>	Optional	Directory of the database backup data files in a compressed RMAN backup format (files with .dfb extensions).
-responseFile <i>response_file_directory</i>	Optional	Directory path of the response file.

Table 2-10 (Cont.) generateScripts Parameters

Parameter	Required/ Optional	Description
-storageType {FS ASM}	Optional	<p>Specify the storage type of either FS or ASM.</p> <ul style="list-style-type: none"> • FS: File system storage type. When FS is specified, your database files are managed by the file system of your operating system. You can specify the directory path where the database files are to be stored using a database template or the -datafileDestination parameter. Oracle Database can create and manage the actual files. • ASM: Oracle Automatic Storage Management (Oracle ASM) storage type. When ASM is specified, your database files are placed in Oracle ASM disk groups. Oracle Database automatically manages database file placement and naming. When ASM is specified, you can also specify the ASMSNMP password using the -asmsnmpPassword parameter. This parameter is optional.
-runCVUChecks {true false}	Optional	Specify true to run Cluster Verification Utility checks periodically for Oracle RAC databases, else specify false. Default is false.
-nodelist <i>database_nodes_list</i>	Optional	List of database nodes separated by comma.
-enableArchive {true false}	Optional	<p>Specify true to enable log file archive, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -archiveLogMode {AUTO MANUAL}: Specify either the automatic archive mode or the manual archive mode. Default is automatic archive mode. • -archiveLogDest: Directory for storing the archive log files.
-memoryMgmtType {AUTO AUTO_SGA CUSTOM_SGA}	Optional	<p>Specify one of the following memory management types:</p> <ul style="list-style-type: none"> • AUTO: Automatic memory management for SGA and PGA. • AUTO_SGA: Automatic shared memory management for SGA. • CUSTOM_SGA: Manual shared memory management for SGA. <p>Note: If the total physical memory of a database instance is greater than 4 GB, then you cannot specify the Automatic Memory Management option AUTO during the database installation and creation. Oracle recommends that you specify the Automatic Shared Memory Management option AUTO_SGA in such environments.</p>
-createListener <i>new_database_listener</i>	Optional	Database listener to register the database with in the form <i>listener_name:port</i> .
-useOMF {true false}	Optional	Specify true to use Oracle-Managed Files (OMF), else specify false.

Table 2-10 (Cont.) generateScripts Parameters

Parameter	Required/ Optional	Description
<code>-dbOptions</code> <i>database_options</i>	Optional	Specify database options as a comma separated list of name:value pairs. Example: JSERVER:true,DV:false
<code>-customScripts</code> <i>custom_sql_scripts_list</i>	Optional	Specify a comma separated list of SQL scripts that need to be run after the database creation. The scripts are run in the order they are listed.
<code>-policyManaged</code>	Optional	Policy-managed database. You can specify the following additional parameters: <ul style="list-style-type: none">• <code>-serverPoolName</code>: Specify the single server pool name when creating a new server pool or specify a comma separated list of existing server pools.• <code>-pqPoolName</code>: Specify the PQ pool name.• <code>-createServerPool</code>: Specify this parameter for creating a new server pool.<ul style="list-style-type: none">— <code>-pqPoolName</code>: Specify the PQ pool name.— <code>-force</code>: Specify this parameter to create the server pool by force when adequate free servers are not available.— <code>-pqCardinality</code>: Specify the PQ cardinality of the new server pool.— <code>-cardinality</code>: Specify the cardinality of the new server pool.
<code>-adminManaged</code>	Optional	Administrator-managed database.
<code>-databaseConfigType</code> <i>{SINGLE RAC RACONENODE}</i>	Optional	Specify one of the following database configuration types: <ul style="list-style-type: none">• <code>SINGLE</code>: Single individual database.• <code>RAC</code>: Oracle RAC database.• <code>RACONENODE</code>: Oracle RAC One Node database. For Oracle RAC One Node database, you can specify the service name using the <code>-RACOneNodeServiceName</code> parameter.
<code>-characterSet</code> <i>database_character_set</i>	Optional	Character set of the database.
<code>-nationalCharacterSet</code> <i>database_national_character_set</i>	Optional	National character set of the database.

Table 2-10 (Cont.) generateScripts Parameters

Parameter	Required/ Optional	Description
<code>-registerWithDirService {true false}</code>	Optional	<p>Specify true to register with a Lightweight Directory Access Protocol (LDAP) service, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters are required:</p> <ul style="list-style-type: none"> • <code>-dirServiceUserName</code>: User name for the LDAP service. • <code>-dirServicePassword</code>: Password for the LDAP service. • <code>-databaseCN</code>: Database common name. • <code>-dirServiceCertificatePath</code>: Directory service certificate file path. • <code>-dirServiceUser</code>: Directory service user name. • <code>-ldapDirectoryAccessType {PASSWORD SSL}</code>: LDAP directory access type. • <code>-useSYSAuthForLDAPAccess {true false}</code>: Specify whether to use SYS user authentication for LDAP access. • <code>-walletPassword</code>: Password for the database wallet.
<code>-listeners</code> <code>listeners_list</code>	Optional	A comma-separated list of listeners for the database.
<code>-variablesFile</code> <code>variables_file</code>	Optional	Directory path to the file that contains the variables and their values for the database template.
<code>-variables</code> <code>variables_list</code>	Optional	A comma-separated list of name=value pairs of variables for the database template.
<code>-initParams</code> <code>initialization_parameters_list</code>	Optional	<p>A comma-separated list of name=value pairs of initialization parameter values of the database.</p> <p>You can additionally provide the <code>-initParamsEscapeChar</code> parameter for using a specific escape character between multiple values of an initialization parameter. If an escape character is not specified, backslash (/) is used as the default escape character.</p>
<code>-sampleSchema {true false}</code>	Optional	<p>Specify true to include the HR sample schema (EXAMPLE tablespace) in your database, else specify false. Default is false.</p> <p>Oracle guides and educational materials contain examples based on the sample schemas. Oracle strongly recommends that you do not install the sample schemas in a production database.</p>
<code>-memoryPercentage</code> <code>percentage_of_total_memory_assigned_to_the_database</code>	Optional	The percentage of physical memory that can be used by the database.
<code>-totalMemory</code> <code>total_memory_assigned_to_the_database_in_MB</code>	Optional	Total amount of physical memory, in megabytes, that can be used by the database.

Table 2-10 (Cont.) generateScripts Parameters

Parameter	Required/ Optional	Description
-databaseType {MULTIPURPOSE DATA_WAREHOUSING OLTP}	Optional	<p>Specify MULTIPURPOSE if the database is for both OLTP and data warehouse purposes.</p> <p>Specify DATA_WAREHOUSING if the primary purpose of the database is a data warehouse.</p> <p>Specify OLTP if the primary purpose of the database is online transaction processing.</p>
-useWalletForDBCredentials ls {true false}	Optional	<p>Specify true to use Oracle Wallet for database credentials, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -dbCredentialsWalletLocation: Directory location for the Oracle Wallet files. • -dbCredentialsWalletPassword: Password for the Oracle Wallet account. <p>Note:</p> <p>If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:</p> <ul style="list-style-type: none"> • oracle.dbsecurity.walletPassword • oracle.dbsecurity.userDNPassword

2.13.4.7 deleteDatabase

The `deleteDatabase` command deletes a database.

Syntax and Parameters

Use the `dbca -deleteDatabase` command with the following syntax:

```
dbca -deleteDatabase
      -sourceDB database_name_or_sid
      [-sysDBAUserName SYSDBA_user_name]
      [-sysDBAPassword SYSDBA_user_password]
      [-forceArchiveLogDeletion]
      [-deRegisterEMCloudControl
          [-omsHost Oracle_Management_Server_host_name
           -omsPort Oracle_Management_Server_port_number
           -emUser EM_administrator_user_name
           -emPassword EM_administrator_password]]
      [-unregisterWithDirService {true | false}
          -dirServiceUserName directory_service_user_name
          [-dirServicePassword directory_service_user_password
           [-walletPassword wallet_password]]]
      [-sid database_system_identifier]
      [-useWalletForDBCredentials {true | false}
          -dbCredentialsWalletPassword wallet_account_password
          -dbCredentialsWalletLocation wallet_files_directory]
```

Table 2-11 deleteDatabase Parameters

Parameter	Required/ Optional	Description
<code>-sourceDB <i>database_name_or_sid</i></code>	Required	Database unique name for an Oracle RAC database or database system identifier (SID) for a single instance database.
<code>-sysDBAUserName <i>SYSDBA_user_name</i></code>	Optional	User name of the user having the SYSDBA privileges.
<code>-sysDBAPassword <i>SYSDBA_password</i></code>	Optional	Password of the user having the SYSDBA privileges.
<code>-forceArchiveLogDeletion</code>	Optional	Specify this parameter to delete the database archive logs.
<code>-deRegisterEMCloudControl</code>	Optional	Specify this parameter along with the following parameters to unregister the database with Enterprise Manager Cloud Control: <ul style="list-style-type: none"> • <code>-omsHost</code>: Oracle Management Server host name. • <code>-omsPort</code>: Oracle Management Server port number. • <code>-emUser</code>: User name for Enterprise Manager administrator. • <code>-emPassword</code>: Password for Enterprise Manager administrator.
<code>-unregisterWithDirService {true false}</code>	Optional	Specify this parameter along with the following parameters to unregister the database with the directory service: <ul style="list-style-type: none"> • <code>-dirServiceUserName</code>: User name for the directory service. • <code>-dirServicePassword</code>: Password for the directory service user. • <code>-walletPassword</code>: Password for the database wallet.
<code>-sid <i>database_system_identifier</i></code>	Optional	Database system identifier (SID).
<code>-useWalletForDBCredentials {true false}</code>	Optional	Specify true to use Oracle Wallet for database credentials, else specify false. Default is false. When true is specified, the following additional parameters can be provided: <ul style="list-style-type: none"> • <code>-dbCredentialsWalletLocation</code>: Directory location for the Oracle Wallet files. • <code>-dbCredentialsWalletPassword</code>: Password for the Oracle Wallet account. <p>Note: If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys: <ul style="list-style-type: none"> • <code>oracle.dbsecurity.walletPassword</code> • <code>oracle.dbsecurity.userDNPassword</code> </p>

2.13.4.8 createPluggableDatabase

The `createPluggableDatabase` command creates a PDB in a CDB.

Syntax and Parameters

Use the `dbca -createPluggableDatabase` command with the following syntax:

```
dbca -createPluggableDatabase
      -sourceDB cdb_sid
      -pdbName new_pdb_name
      [-createAsClone {true | false}]
      [-createPDBFrom {DEFAULT | FILEARCHIVE | RMANBACKUP | USINGXML}
          [-pdbArchiveFile pdb_archive_file_name_with_directory_path]
          [-PDBBackupfile pdb_backup_file_name_with_directory_path]
          [-PDBMetadataFile pdb_metadata_file_name_with_directory_path]
          [-pdbAdminUserName pdb_administrator_name]
          [-pdbAdminPassword pdb_administrator_password]
          [-createNewPDBAdminUser {true | false}]
          [-sourceFileNameConvert method_to_locate_pdb_files]
          [-fileNameConvert names_of_pdb_files]
          [-pdbStorageMAXSizeInMB maximum_storage_size_for_the_pdb_in_MB]
          [-pdbStorageMAXTempSizeInMB maximum_temporary_storage_size_for_the_pdb_in_MB]
          [-workArea directory_to_unzip_PDB_archive_files_for_FILEARCHIVE_option]
          [-copyPDBFiles {true | false}]]
      [-pdbDatafileDestination pdb_data_files_directory]
      [-useMetaDataTableSpace {true | false}]
      [-registerWithDirService {true | false}
          -dirServiceUserName directory_service_user_name
          -dirServicePassword directory_service_user_password
          [-databaseCN directory_service_database_common_name]
          [-dirServiceCertificatePath certificate_file_directory_path]
          [-dirServiceUser active_directory_account_user_name]
          [-walletPassword wallet_password]]
      [-lbacsPassword LBACSYS_user_password]
      [-createUserTableSpace {true | false}]
      [-pdbStorageMAXSizeInMB maximum_storage_size_for_the_pdb_in_MB]
      [-pdbStorageMAXTempSizeInMB maximum_temporary_storage_size_for_the_pdb_in_MB]
      [-customScripts custom_sql_scripts_to_run_after_PDB_creation]
      [-pdbUseMultipleBackup number_of_pdb_backups_to_create]
      [-dvConfiguration {true | false}
          -dvUserName Database_Vault_owner_name
          -dvUserPassword Database_Vault_owner_password
          [-dvAccountManagerName Database_Vault_account_manager_name]
          [-dvAccountManagerPassword Database_Vault_account_manager_password]]
      [-useWalletForDBCredentials {true | false}
          -dbCredentialsWalletPassword wallet_account_password
          -dbCredentialsWalletLocation wallet_files_directory]
```

Table 2-12 createPluggableDatabase Parameters

Parameter	Required/ Optional	Description
<code>-sourceDB</code> <i>cdb_sid</i>	Required	The database system identifier (SID) of the CDB.

Table 2-12 (Cont.) createPluggableDatabase Parameters

Parameter	Required/ Optional	Description
<code>-pdbName</code> <i>new_pdb_name</i>	Required	Name of the new PDB to create. Note: For Oracle RAC databases, the PDB name must be unique in the cluster.
<code>-createAsClone</code> <code>{true false}</code>	Optional	Specify <code>true</code> if the files you plan to use to create the new PDB are the same files that were used to create an existing PDB. Specifying <code>true</code> ensures that Oracle Database generates unique PDB DBID, GUID, and other identifiers expected for the new PDB. Specify <code>false</code> , the default, if the files you plan to use to create the new PDB are not the same files that were used to create an existing PDB.

Table 2-12 (Cont.) createPluggableDatabase Parameters

Parameter	Required/ Optional	Description
<code>-createPDBFrom {DEFAULT FILEARCHIVE RMANBACKUP USINGXML}</code>	Optional	<p>Specify DEFAULT to create the PDB from the CDB's seed. When you specify DEFAULT, the following additional parameters are required:</p> <ul style="list-style-type: none"> • <code>-pdbAdminUserName</code>: The user name of the PDB's local administrator. • <code>-pdbAdminPassword</code>: The password for the PDB's local administrator. <p>Specify FILEARCHIVE to create the PDB from an unplugged PDB's files. When you specify FILEARCHIVE, the following additional parameter is required:</p> <ul style="list-style-type: none"> • <code>-pdbArchiveFile</code>: Complete path and name for unplugged PDB's archive file. <p>The archive file contains all of the files for the PDB, including its XML metadata file and its data files. Typically, the archive file has a .gz extension.</p> <ul style="list-style-type: none"> • <code>-createNewPDBAdminUser</code>: Specify true to create a new PDB administrator or false to avoid creating a new PDB administrator. • <code>-workArea</code>: Specify the directory location where the PDB archive files need to be unzipped. <p>Specify RMANBACKUP to create the PDB from a Recovery Manager (RMAN) backup. When you specify RMANBACKUP, the following additional parameters are required:</p> <ul style="list-style-type: none"> • <code>-pdbBackUpfile</code>: Complete path and name for the PDB backup file. • <code>-pdbMetadataFile</code>: Complete path and name for the PDB's XML metadata file. <p>Specify USINGXML to create the PDB from an unplugged PDB's XML metadata file. When you specify USINGXML, the following additional parameter is required:</p> <ul style="list-style-type: none"> • <code>-pdbMetadataFile</code>: Complete path and name for the PDB's XML metadata file. <p>Specify the following optional parameters, if required:</p> <ul style="list-style-type: none"> • <code>-sourceFileNameConvert</code>: This parameter specifies how to locate PDB files listed in the PDB XML metadata file. • <code>-fileNameConvert</code>: This parameter specifies the names of the PDB's files. • <code>-pdbStorageMAXSizeInMB</code>: Specify the maximum storage size for the PDB in megabytes. • <code>-pdbStorageMAXTempSizeInMB</code>: Specify the maximum temporary storage size for the PDB in megabytes.

Table 2-12 (Cont.) createPluggableDatabase Parameters

Parameter	Required/ Optional	Description
- copyPDBFiles {true false}	Optional	<ul style="list-style-type: none"> -copyPDBFiles {true false}: Specify true if the PDB data files need to be copied, else specify false. <p>See "The CREATE PLUGGABLE DATABASE Statement" for more information about these clauses.</p>
- pdbDatafileDestination <i>pdb_data_files_directory</i>	Optional	<p>Compete directory path to the new PDB data files. When this parameter is not specified, either Oracle Managed Files or the PDB_FILE_NAME_CONVERT initialization parameter specifies how to generate the names and locations of the files. If you use both Oracle Managed Files and the PDB_FILE_NAME_CONVERT initialization parameter, then Oracle Managed Files takes precedence.</p> <p>When this parameter is not specified, Oracle Managed Files is not enabled, and the PDB_FILE_NAME_CONVERT initialization parameter is not set, by default a path to a subdirectory with the name of the PDB in the directory for the root's files is used.</p>
- useMetaDataFileLocation {true false}	Optional	<p>Specify true to use the data file path defined in XML metadata file within a PDB archive when extracting data files.</p> <p>Specify false, the default, to not use the data file path defined in XML metadata file within a PDB archive when extracting data files.</p>
- registerWithDirService {true false}	Optional	<p>Specify true to register the PDB with a Lightweight Directory Access Protocol (LDAP) service, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters are required:</p> <ul style="list-style-type: none"> -dirServiceUserName: User name for the LDAP service. -dirServicePassword: Password for the LDAP service. -dirServiceUser: User name for the Active Directory account. -dirServiceCertificatePath: Certificate file path of the directory service. -databaseCN: Common name of the directory service database. -walletPassword: Password for the database wallet.
-lbacsySPassword <i>LBACSYS_user_password</i>	Optional	Specify the LBACSYS user password if you want to configure OLS with a directory service.

Table 2-12 (Cont.) createPluggableDatabase Parameters

Parameter	Required/ Optional	Description
-createUserTableSpace {true false}	Optional	Specify true if a default user tablespace needs to be created in the new PDB.
-pdbStorageMAXSizeInMB <i>maximum_storage_size_for_the_pdb_in_MB</i>	Optional	Specify the maximum storage size for the PDB in megabytes.
-pdbStorageMAXTempSizeInMB <i>maximum_temporary_storage_size_for_the_pdb_in_MB</i>	Optional	Specify the maximum temporary storage size for the PDB in megabytes.
-pdbUseMultipleBackups <i>number_of_pdb_backups_to_create</i>	Optional	Specify the number of PDB backups to create.
-customScripts <i>lcustom_sql_scripts_to_run_after_PDB_creation</i>	Optional	Specify a list of custom SQL scripts to run after the PDB creation.
-dvConfiguration {true false}	Optional	Specify true to enable and configure Database Vault, else specify false. Default is false. When true is specified, the following additional Database Vault parameters are required: <ul style="list-style-type: none"> • -dvUserName: Specify the Database Vault owner name. • -dvUserPassword: Specify Database Vault owner password. • -dvAccountManagerName: Specify a separate Database Vault account manager name. • -dvAccountManagerPassword: Specify the Database Vault account manager password.

Table 2-12 (Cont.) createPluggableDatabase Parameters

Parameter	Required/ Optional	Description
-useWalletForDBCredentials {true false}	Optional	<p>Specify true to use Oracle Wallet for database credentials, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -dbCredentialsWalletLocation: Directory location for the Oracle Wallet files. • -dbCredentialsWalletPassword: Password for the Oracle Wallet account. <p>Note:</p> <p>If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:</p> <ul style="list-style-type: none"> • oracle.dbsecurity.walletPassword • oracle.dbsecurity.userDNPassword

2.13.4.9 unplugDatabase

The `unplugDatabase` command unplugs a pluggable database (PDB) from a multitenant container database (CDB).

Syntax and Parameters

Use the `dbca -unplugDatabase` command with the following syntax:

```
dbca -unplugDatabase
      -sourceDB cdb_sid
      -pdbName pdb_name
      [-unregisterWithDirService {true | false}
        -dirServiceUserName directory_service_user_name
        -dirServicePassword directory_service_user_password
        -walletPassword wallet_password]
      [-archiveType {TAR | RMAN | NONE}
        [-rmanParallelism parallelism_integer_value]
        [-pdbArchiveFile pdb_archive_file_directory]
        [-PDBBackUpfile pdb_backup_file_directory]
        [-PDBMetadataFile pdb_metadata_file_directory]
        [-rmanParallelism parallelism_integer_value]]
      [-useWalletForDBCredentials {true | false}
        -dbCredentialsWalletPassword wallet_account_password
        -dbCredentialsWalletLocation wallet_files_directory]
```

Table 2-13 unplugDatabase Parameters

Parameter	Required/ Optional	Description
<code>-sourceDB cdb_sid</code>	Required	The database system identifier (SID) of the CDB.
<code>-pdbName pdb_name</code>	Required	Name of the PDB.

Table 2-13 (Cont.) unplugDatabase Parameters

Parameter	Required/ Optional	Description
-archiveType {TAR RMAN NONE}	Optional	<p>Specify TAR to store the unplugged PDB files in a tar file.</p> <p>Specify RMAN to store the unplugged PDB files in an RMAN backup.</p> <p>Specify NONE to store the unplugged PDB files without using a tar file or an RMAN backup.</p> <p>Specify any of the following parameters:</p> <ul style="list-style-type: none"> • -pdbArchiveFile: Specify absolute file path and name for the PDB Archive file. • -pdbBackUpfile: Specify absolute file path and name for the PDB backup file when archive type is RMAN. specify comma separated file paths, if there are multiple backups to be taken when creating the PDB. • -pdbMetadataFile: Specify absolute file path and name for the PDB metadata file when archive type is RMAN or NONE. • -rmanParallelism: Specify the RMAN parallelism integer value.
-unregisterWithDirService {true false}	Optional	<p>Specify true to unregister the PDB from the LDAP service, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters are required:</p> <ul style="list-style-type: none"> • -dirServiceUserName: User name for the LDAP service. • -dirServicePassword: Password for the LDAP service user. • -walletPassword: Password for the database wallet.
-useWalletForDBCredentials {true false}	Optional	<p>Specify true to use Oracle Wallet for database credentials, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -dbCredentialsWalletPassword: Password for the Oracle Wallet account. • -dbCredentialsWalletLocation: Directory location for the Oracle Wallet files. <p>Note:</p> <p>If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:</p> <ul style="list-style-type: none"> • oracle.dbsecurity.walletPassword • oracle.dbsecurity.userDNPassword

2.13.4.10 deletePluggableDatabase

The `deletePluggableDatabase` command deletes a PDB.

Syntax and Parameters

Use the `dbca -deletePluggableDatabase` command with the following syntax:

```
dbca -deletePluggableDatabase
      -sourceDB cdb_sid
      -pdbName pdb_name
      [-useWalletForDBCredentials {true | false}]
          -dbCredentialsWalletPassword wallet_account_password
          -dbCredentialsWalletLocation wallet_files_directory
```

Table 2-14 deletePluggableDatabase Parameters

Parameter	Required/ Optional	Description
<code>-sourceDB <i>cdb_sid</i></code>	Required	The database system identifier (SID) of the CDB.
<code>-pdbName <i>pdb_name</i></code>	Required	Name of the PDB to delete.
<code>-useWalletForDBCredentials {true false}</code>	Optional	Specify true to use Oracle Wallet for database credentials, else specify false. Default is false. When true is specified, the following additional parameters can be provided: <ul style="list-style-type: none"> <code>-dbCredentialsWalletPassword</code>: Password for the Oracle Wallet account. <code>-dbCredentialsWalletLocation</code>: Directory location for the Oracle Wallet files.
		Note: If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys: <ul style="list-style-type: none"> <code>oracle.dbsecurity.walletPassword</code> <code>oracle.dbsecurity.userDNPassword</code>

2.13.4.11 configurePluggableDatabase

The `configurePluggableDatabase` command configures a PDB.

Syntax and Parameters

Use the `dbca -configurePluggableDatabase` command with the following syntax:

```
dbca -configurePluggableDatabase
      -sourceDB source_database_sid
      -pdbName new_pdb_name
      [-dvConfiguration {true | false}]
          -dvUserName Database_Vault_owner_username
          -dvUserPassword Database_Vault_owner_password
          -dvAccountManagerName Database_Vault_account_manager
          -dvAccountManagerPassword Database_Vault_account_manager_password
      [-olsConfiguration {true | false}]
          [-configureWithOID configure_with_OID_flag]
      [-registerWithDirService {true | false} | -unregisterWithDirService {true | false}]
          -dirServiceUserName directory_service_user_name
          -dirServicePassword directory_service_password
          [-databaseCN database_common_name]
          -walletPassword wallet_password
      [-lbacsPassword LBACSYS_user_password]
      [-useWalletForDBCredentials {true | false}]
          -dbCredentialsWalletPassword wallet_account_password
          -dbCredentialsWalletLocation wallet_files_directory
```

Table 2-15 configurePluggableDatabase Parameters

Parameter	Required/ Optional	Description
<code>-sourceDB source_database_ sid</code>	Required	The database system identifier of the CDB
<code>-pdbName new_pdb_name</code>	Required	Name of the PDB
<code>-dvConfiguration {true false}</code>	Optional	<p>Specify <code>false</code>, the default, to indicate that the PDB will not use Oracle Database Vault.</p> <p>Specify <code>true</code> to configure and enable Database Vault.</p> <p>When <code>true</code> is specified, the following additional Database Vault parameters are required:</p> <ul style="list-style-type: none"> • <code>-dvUserName</code>: Specify the Database Vault owner username. • <code>-dvUserPassword</code>: Specify Database Vault owner password. • <code>-dvAccountManagerName</code>: Specify a separate Database Vault account manager. • <code>-dvAccountManagerPassword</code>: Specify the Database Vault account manager password.
<code>- olsConfiguration {true false}</code>	Optional	<p>Specify <code>true</code> to enable and configure Oracle Label Security (OLS) for the PDB, else specify <code>false</code>. Default is <code>false</code>.</p> <p>When <code>true</code> is specified, you can additionally specify the <code>-configureWithOID</code> parameter to configure Oracle Label Security (OLS) with Oracle Internet Directory (OID). This parameter is optional.</p>
<code>- registerWithDirS ervice {true false} - unregisterDi rService {true false}</code>	Optional	<p>Specify <code>true</code> to register with a Lightweight Directory Access Protocol (LDAP) service.</p> <p>Specify <code>false</code>, the default, to unregister from an LDAP service.</p> <p>When <code>true</code> is specified, the following additional parameters are required:</p> <ul style="list-style-type: none"> • <code>-dirServiceUserName</code>: Username for the LDAP service • <code>-dirServicePassword</code>: Password for the LDAP service • <code>-databaseCN</code>: Database common name. • <code>-walletPassword</code>: Password for the database wallet
<code>-lbacsy>Password</code>	Optional	Specify the LBACSYS user password when configuring Oracle Label Security. This parameter is required when configuring Oracle Label Security.

Table 2-15 (Cont.) configurePluggableDatabase Parameters

Parameter	Required/ Optional	Description
-useWalletForDBCredentials {true false}	Optional	<p>Specify true to use Oracle Wallet for database credentials, else specify false. Default is false.</p> <p>When true is specified, the following additional parameters can be provided:</p> <ul style="list-style-type: none"> • -dbCredentialsWalletLocation: Directory location for the Oracle Wallet files. • -dbCredentialsWalletPassword: Password for the Oracle Wallet account. <p>Note: If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:</p> <ul style="list-style-type: none"> • oracle.dbsecurity.walletPassword • oracle.dbsecurity.userDNPassword

2.13.4.12 addInstance

The `addInstance` command adds a database instance to an administrator-managed Oracle RAC database.

Syntax and Parameters

Use the `dbca -addInstance` command with the following syntax:

```
dbca -addInstance
      -gdbName global_database_name
      -nodeName database_instance_node_name
      [-updateDirService {true | false}
          -dirServiceUserName directory_service_user_name
          -dirServicePassword directory_service_user_password]
      [-instanceName database_instance_name]
      [-sysDBAUserName SYSDBA_user_name]
      [-sysDBAPassword SYSDBA_user_password]
      [-useWalletForDBCredentials {true | false}
          -dbCredentialsWalletPassword wallet_account_password
          -dbCredentialsWalletLocation wallet_files_directory]
```

Table 2-16 addInstance Parameters

Parameter	Required/ Optional	Description
<code>-gdbName</code> <i>global_database_name</i>	Required	Global database name in the form <i>database_name.domain_name</i> .
<code>-nodeName</code> <i>database_instance_node_name</i>	Required	Node name of the database instance.
<code>-instanceName</code> <i>database_instance_name</i>	Optional	Database instance name.

Table 2-16 (Cont.) addInstance Parameters

Parameter	Required/ Optional	Description
<code>-sysDBAUserName</code> <code>SYSDBA_user_name</code>	Optional	User name of the database user having the SYSDBA privileges.
<code>-sysDBAPassword</code> <code>SYSDBA_user_password</code>	Optional	Password of the database user having the SYSDBA privileges.
<code>-updateDirService</code> <code>{true false}</code>	Optional	Specify true to register the database with a directory service, else specify false. When true is specified, the following additional parameters are required: <ul style="list-style-type: none"> • <code>-dirServiceUserName</code>: User name for the directory service. • <code>-dirServicePassword</code>: Password for the directory service user.
<code>-useWalletForDBCredentials</code> <code>{true false}</code>	Optional	Specify true to use Oracle Wallet for database credentials, else specify false. Default is false. When true is specified, the following additional parameters can be provided: <ul style="list-style-type: none"> • <code>-dbCredentialsWalletPassword</code>: Password for the Oracle Wallet account. • <code>-dbCredentialsWalletLocation</code>: Directory location for the Oracle Wallet files. <p>Note: If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys: <ul style="list-style-type: none"> • <code>oracle.dbsecurity.walletPassword</code> • <code>oracle.dbsecurity.userDNPassword</code> </p>

2.13.4.13 deleteInstance

The `deleteInstance` command deletes a database instance from an administrator-managed Oracle RAC database.

Syntax and Parameters

Use the `dbca -deleteInstance` command with the following syntax:

```
dbca -deleteInstance
      -gdbName global_database_name
      -instanceName database_instance_name
      [-nodeName database_instance_node_name]
      [-updateDirService {true | false}
           -dirServiceUserName directory_service_user_name
           -dirServicePassword directory_service_user_password]
      [-sysDBAUserName SYSDBA_user_name]
      [-sysDBAPassword SYSDBA_user_password]
      [-useWalletForDBCredentials {true | false}
           -dbCredentialsWalletPassword wallet_account_password
           -dbCredentialsWalletLocation wallet_files_directory]
```

Table 2-17 deleteInstance Parameters

Parameter	Required/ Optional	Description
<code>-gdbName</code> <i>global_database_name</i>	Required	Global database name in the form <i>database_name.domain_name</i> .
<code>-instanceName</code> <i>database_instance_name</i>	Required	Database instance name.
<code>-nodeName</code> <i>node_name_of_database_instance</i>	Optional	Node name of the database instance.
<code>-sysDBAUserName</code> <i>SYSDBA_user_name</i>	Optional	User name of the database user having the SYSDBA privileges.
<code>-sysDBAPassword</code> <i>SYSDBA_user_password</i>	Optional	Password of the database user having the SYSDBA privileges.
<code>-updateDirService</code> <code>{true false}</code>	Optional	Specify true to unregister the database with the directory service, else specify false. Default is false. When true is specified, the following additional parameters are required: <ul style="list-style-type: none"> • <code>-dirServiceUserName</code>: User name for the directory service. • <code>-dirServicePassword</code>: Password for the directory service user.
<code>-useWalletForDBCredentials</code> <code>{true false}</code>	Optional	Specify true to use Oracle Wallet for database credentials, else specify false. Default is false. When true is specified, the following additional parameters can be provided: <ul style="list-style-type: none"> • <code>-dbCredentialsWalletPassword</code>: Password for the Oracle Wallet account. • <code>-dbCredentialsWalletLocation</code>: Directory location for the Oracle Wallet files.

Note:

If you are using Oracle Unified Directory (OUD), then the OUD passwords should be stored in the wallet using the following keys:

- `oracle.dbsecurity.walletPassword`
- `oracle.dbsecurity.userDNPassword`

2.13.4.14 executePrereqs

The `executePrereqs` command executes the prerequisites checks and reports the results. This command can be used to check the environment before running `dbca` to create a database.

Syntax and Parameters

Use the `dbca -executePrereqs` command with the following syntax:

```
dbca -executePrereqs
      -databaseConfigType {SINGLE | RAC | RACONENODE}
```

[-RACOneNodeServiceName *RAC_node_service_name*]
[-nodelist *database_nodes_list*]

Table 2-18 executePrereqs Parameters

Parameter	Required/ Optional	Description
-databaseConfigType {SINGLE RAC RACONENODE}	Required	<p>Specify one of the following database configuration types:</p> <ul style="list-style-type: none"> • SINGLE: Single individual database. • RAC: Oracle RAC database. • RAONENODE: Oracle RAC One Node database. <p>For Oracle RAC One Node database, you can specify the service name using the -RACOneNodeServiceName parameter.</p>
-nodelist <i>database_nodes_list</i>	Optional	List of database nodes separated by comma.

3

Starting Up and Shutting Down

When you start up a database, you create an instance of that database and you determine the state of the database. Shutting down a currently running Oracle Database instance can optionally close and dismount a database.

- [Starting Up a Database](#)

When you start up a database, you create an instance of that database and you determine the state of the database. Normally, you start up an instance by mounting and opening the database. Doing so makes the database available for any valid user to connect to and perform typical data access operations.

- [Altering Database Availability](#)

You can alter the availability of a database. You may want to do this in order to restrict access for maintenance reasons or to make the database read only.

- [Shutting Down a Database](#)

You can shut down a database with SQL*Plus or Oracle Restart.

- [Quiescing a Database](#)

A quiesced database allows only DBA transactions, queries, fetches, or PL/SQL statements.

- [Suspending and Resuming a Database](#)

The `ALTER SYSTEM SUSPEND` statement halts all input and output (I/O) to data files (file header and file data) and control files. The suspended state lets you back up a database without I/O interference. When the database is suspended all preexisting I/O operations are allowed to complete and any new database accesses are placed in a queued state. Use the `ALTER SYSTEM RESUME` statement to resume normal database operations.

- [Delaying Instance Abort](#)

The `INSTANCE_ABORT_DELAY_TIME` initialization parameter specifies the amount of time, in seconds, to delay shutting down a database when an error causes the instance to abort.

 **See Also:**

Oracle Real Application Clusters Administration and Deployment Guide for additional information specific to an Oracle Real Application Clusters environment

3.1 Starting Up a Database

When you start up a database, you create an instance of that database and you determine the state of the database. Normally, you start up an instance by mounting and opening the database. Doing so makes the database available for any valid user to connect to and perform typical data access operations.

- [About Database Startup Options](#)
When Oracle Restart is not in use, you can start up a database instance with SQL*Plus, Recovery Manager, or Oracle Enterprise Manager Cloud Control (Cloud Control). If your database is being managed by Oracle Restart, the recommended way to start the database is with SRVCTL.
- [Specifying Initialization Parameters at Startup](#)
To start an instance, the database must read instance configuration parameters (the initialization parameters) from either a server parameter file (**SPFILE**) or a text initialization parameter file (**PFILE**). The database looks for these files in a default location. You can specify nondefault locations for these files, and the method for doing so depends on whether you start the database with SQL*Plus (when Oracle Restart is not in use) or with SRVCTL (when the database is being managed with Oracle Restart).
- [About Automatic Startup of Database Services](#)
When your database is managed by Oracle Restart, you can configure startup options for each individual database service (service).
- [Preparing to Start Up an Instance](#)
You must perform some preliminary steps before attempting to start an instance of your database using SQL*Plus.
- [Starting Up an Instance](#)
You can start up an instance using SQL*Plus or Oracle Restart.

3.1.1 About Database Startup Options

When Oracle Restart is not in use, you can start up a database instance with SQL*Plus, Recovery Manager, or Oracle Enterprise Manager Cloud Control (Cloud Control). If your database is being managed by Oracle Restart, the recommended way to start the database is with SRVCTL.

See [Configuring Automatic Restart of an Oracle Database](#) for information about Oracle Restart.

- [Starting Up a Database Using SQL*Plus](#)
You can start a SQL*Plus session, connect to Oracle Database with administrator privileges, and then issue the `STARTUP` command. Using SQL*Plus in this way is the only method described in detail in this book.
- [Starting Up a Database Using Recovery Manager](#)
You can also use Recovery Manager (RMAN) to execute `STARTUP` and `SHUTDOWN` commands. You may prefer to do this if you are within the RMAN environment and do not want to invoke SQL*Plus.
- [Starting Up a Database Using Cloud Control](#)
You can use Cloud Control to administer your database, including starting it up and shutting it down. Cloud Control combines a GUI console, agents, common services, and tools to provide an integrated and comprehensive systems management platform for managing Oracle products. Cloud Control enables you to perform the functions discussed in this book using a GUI interface, rather than command line operations.
- [Starting Up a Database Using SRVCTL](#)
When Oracle Restart is installed and configured for your database, Oracle recommends that you use SRVCTL to start the database.

3.1.1.1 Starting Up a Database Using SQL*Plus

You can start a SQL*Plus session, connect to Oracle Database with administrator privileges, and then issue the STARTUP command. Using SQL*Plus in this way is the only method described in detail in this book.

- Run the SQL*Plus STARTUP command.

Related Topics

- *SQL*Plus User's Guide and Reference*

3.1.1.2 Starting Up a Database Using Recovery Manager

You can also use Recovery Manager (RMAN) to execute STARTUP and SHUTDOWN commands. You may prefer to do this if you are within the RMAN environment and do not want to invoke SQL*Plus.

- Run an RMAN STARTUP command.

See Also:

Oracle Database Backup and Recovery Reference for information about the RMAN STARTUP command

3.1.1.3 Starting Up a Database Using Cloud Control

You can use Cloud Control to administer your database, including starting it up and shutting it down. Cloud Control combines a GUI console, agents, common services, and tools to provide an integrated and comprehensive systems management platform for managing Oracle products. Cloud Control enables you to perform the functions discussed in this book using a GUI interface, rather than command line operations.

- In Cloud Control, start the database instance.

See Also:

The Cloud Control online help

3.1.1.4 Starting Up a Database Using SRVCTL

When Oracle Restart is installed and configured for your database, Oracle recommends that you use SRVCTL to start the database.

Starting the database instance with SRVCTL ensures that:

- Any components on which the database depends (such as Oracle Automatic Storage Management and the Oracle Net listener) are automatically started first, and in the proper order.

- The database is started according to the settings in its Oracle Restart configuration. An example of such a setting is the server parameter file location.
- Environment variables stored in the Oracle Restart configuration for the database are set before starting the instance.

To start a database instance with SRVCTL:

- Run the `srvctl start database` command.

See "["srvctl start database"](#)" and "["Starting and Stopping Components Managed by Oracle Restart"](#)" for details.

3.1.2 Specifying Initialization Parameters at Startup

To start an instance, the database must read instance configuration parameters (the initialization parameters) from either a server parameter file (`SPFILE`) or a text initialization parameter file (`PFILE`). The database looks for these files in a default location. You can specify nondefault locations for these files, and the method for doing so depends on whether you start the database with SQL*Plus (when Oracle Restart is not in use) or with SRVCTL (when the database is being managed with Oracle Restart).

- [About Initialization Parameter Files and Startup](#)
When you start the database instance, it attempts to read the initialization parameters from an `SPFILE` in a platform-specific default location. If it finds no `SPFILE`, then it searches for a text initialization parameter file.
- [Starting Up with SQL*Plus with a Nondefault Server Parameter File](#)
With SQL*Plus, you can use the `PFILE` clause to start an instance with a nondefault server parameter file.
- [Starting Up with SRVCTL with a Nondefault Server Parameter File](#)
If your database is being managed by Oracle Restart, then you can specify the location of a nondefault `SPFILE` by setting or modifying the `SPFILE` location option in the Oracle Restart configuration for the database.

 **See Also:**

[Creating and Configuring an Oracle Database](#), for more information about initialization parameters, initialization parameter files, and server parameter files

3.1.2.1 About Initialization Parameter Files and Startup

When you start the database instance, it attempts to read the initialization parameters from an `SPFILE` in a platform-specific default location. If it finds no `SPFILE`, then it searches for a text initialization parameter file.

[Table 2-3](#) lists `PFILE` and `SPFILE` default names and locations.

In the platform-specific default location, Oracle Database locates your initialization parameter file by examining file names in the following order:

1. The location specified by the `-spfile` option in the SRVCTL commands `srvctl add database` or `srvctl modify database`

You can check the current setting with the `srvctl config database` command.

2. `spfileORACLE_SID.ora`
3. `spfile.ora`
4. `initORACLE_SID.ora`

The first three files are SPFILEs and the fourth is a text initialization parameter file. If DBCA created the SPFILE in an Oracle Automatic Storage Management disk group, then the database searches for the SPFILE in the disk group.

When `AS COPY` is not specified in a `CREATE SPFILE` statement and the database is defined as a resource in Oracle Clusterware, if you specify both the `spfile_name` and the `FROM PFILE` clause, then this statement automatically updates the SPFILE name and location in the database resource. When `AS COPY` is specified in a `CREATE SPFILE` statement, the SPFILE is copied, and the database resource is not updated.

 **Note:**

The `spfile.ora` file is included in this search path because in an Oracle Real Application Clusters environment one server parameter file is used to store the initialization parameter settings for all instances. There is no instance-specific location for storing a server parameter file.

For more information about the server parameter file for an Oracle Real Application Clusters environment, see *Oracle Real Application Clusters Administration and Deployment Guide*.

If you (or the Database Configuration Assistant) created a server parameter file, but you want to override it with a text initialization parameter file, then you can do so with SQL*Plus, specifying the `PFILE` clause of the `STARTUP` command to identify the initialization parameter file:

```
STARTUP PFILE = /u01/oracle/dbs/init.ora
```

Nondefault Server Parameter Files

A nondefault server parameter file (SPFILE) is an SPFILE that is in a location other than the default location. It is not usually necessary to start an instance with a nondefault SPFILE. However, should such a need arise, both SRVCTL (with Oracle Restart) and SQL*Plus provide ways to do so. These are described later in this section.

Initialization Files and Oracle Automatic Storage Management

A database that uses Oracle Automatic Storage Management (Oracle ASM) usually has a nondefault SPFILE. If you use the Database Configuration Assistant (DBCA) to configure a database to use Oracle ASM, DBCA creates an SPFILE for the database instance in an Oracle ASM disk group, and then causes a text initialization parameter file (PFILE) to be created in the default location in the local file system to point to the SPFILE, as explained in the next section.

Related Topics

- [SRVCTL Command Reference for Oracle Restart](#)

You can reference details about the syntax and options for SRVCTL commands specific to Oracle Restart.

3.1.2.2 Starting Up with SQL*Plus with a Nondefault Server Parameter File

With SQL*Plus, you can use the `PFILE` clause to start an instance with a nondefault server parameter file.

To start up with SQL*Plus with a nondefault server parameter file:

1. Create a one-line text initialization parameter file that contains only the `SPFILE` parameter. The value of the parameter is the nondefault server parameter file location.

For example, create a text initialization parameter file `/u01/oracle/dbs/spf_init.ora` that contains only the following parameter:

```
SPFILE = /u01/oracle/dbs/test_spfile.ora
```

 **Note:**

You cannot use the `IFILE` initialization parameter within a text initialization parameter file to point to a server parameter file. In this context, you must use the `SPFILE` initialization parameter.

2. Start up the instance pointing to this initialization parameter file.

```
STARTUP PFILE = /u01/oracle/dbs/spf_init.ora
```

The `SPFILE` must reside on the database host computer. Therefore, the preceding method also provides a means for a client system to start a database that uses an `SPFILE`. It also eliminates the need for a client system to maintain a client-side initialization parameter file. When the client system reads the initialization parameter file containing the `SPFILE` parameter, it passes the value to the server where the specified `SPFILE` is read.

3.1.2.3 Starting Up with SRVCTL with a Nondefault Server Parameter File

If your database is being managed by Oracle Restart, then you can specify the location of a nondefault `SPFILE` by setting or modifying the `SPFILE` location option in the Oracle Restart configuration for the database.

To start up with SRVCTL with a nondefault server parameter file:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Enter the following command:

```
srvctl modify database -db db_unique_name -spfile spfile_path
```

where `db_unique_name` must match the `DB_UNIQUE_NAME` initialization parameter setting for the database.

3. Enter the following command:

```
srvctl start database -db db_unique_name [options]
```

See "[SRVCTL Command Reference for Oracle Restart](#)" for more information.

3.1.3 About Automatic Startup of Database Services

When your database is managed by Oracle Restart, you can configure startup options for each individual database service (service).

If you set the management policy for a service to AUTOMATIC (the default), the service starts automatically when you start the database with SRVCTL. If you set the management policy to MANUAL, the service does not automatically start, and you must manually start it with SRVCTL. A MANUAL setting does not prevent Oracle Restart from monitoring the service when it is running and restarting it if a failure occurs.

In an Oracle Data Guard (Data Guard) environment in which databases are managed by Oracle Restart, you can additionally control automatic startup of services by assigning Data Guard roles to the services in their Oracle Restart configurations. A service automatically starts upon manual database startup only if the management policy of the service is AUTOMATIC and if one of its assigned roles matches the current role of the database.

See "[srvctl add service](#)" and "[srvctl modify service](#)" for the syntax for setting the management policy of and Data Guard roles for a service.

 **Note:**

When using Oracle Restart, Oracle strongly recommends that you use SRVCTL to create database services.

3.1.4 Preparing to Start Up an Instance

You must perform some preliminary steps before attempting to start an instance of your database using SQL*Plus.

 **Note:**

The following instructions are for installations where Oracle Restart is not in use. If your database is being managed by Oracle Restart, follow the instructions in "[Starting and Stopping Components Managed by Oracle Restart](#)".

To prepare for starting an instance:

1. Ensure that any Oracle components on which the database depends are started.

For example, if the database stores data in Oracle Automatic Storage Management (Oracle ASM) disk groups, ensure that the Oracle ASM instance is running and the required disk groups are mounted. Also, it is preferable to start the Oracle Net listener before starting the database.

2. If you intend to use operating system authentication, log in to the database host computer as a member of the OSDBA group.
3. Ensure that environment variables are set so that you connect to the desired Oracle instance.
4. Start SQL*Plus without connecting to the database:

```
SQLPLUS /NOLOG
```

5. Connect to Oracle Database as SYSOPER, SYSDBA, SYSBACKUP, or SYSDG. For example:

```
CONNECT username AS SYSDBA
```

-or-

```
CONNECT / AS SYSDBA
```

Now you are connected to the database and ready to start up an instance of your database.

See Also:

- ["Using Operating System Authentication"](#)
- ["Submitting Commands and SQL to the Database"](#) for information about setting environment variables to connect to an Oracle instance
- [SQL*Plus User's Guide and Reference](#) for descriptions and syntax for the CONNECT, STARTUP, and SHUTDOWN commands

3.1.5 Starting Up an Instance

You can start up an instance using SQL*Plus or Oracle Restart.

- [About Starting Up an Instance](#)

When Oracle Restart is not in use, you use the SQL*Plus STARTUP command to start up an Oracle Database instance. If your database is being managed by Oracle Restart, Oracle recommends that you use the `srvctl start database` command.

- [Starting an Instance, and Mounting and Opening a Database](#)

Normal database operation means that an instance is started and the database is mounted and open. This mode allows any valid user to connect to the database and perform data access operations.

- [Starting an Instance Without Mounting a Database](#)

You can start an instance without mounting a database. Typically, you do so only during database creation.

- [Starting an Instance and Mounting a Database](#)

You can start an instance and mount a database without opening it, allowing you to perform specific maintenance operations.

- [Restricting Access to an Instance at Startup](#)
You can start an instance, and optionally mount and open a database, in restricted mode so that the instance is available only to administrative personnel (not general database users).
- [Forcing an Instance to Start](#)
In unusual circumstances, you might experience problems when attempting to start a database instance, and you can force a database instance to start.
- [Starting an Instance, Mounting a Database, and Starting Complete Media Recovery](#)
If you know that media recovery is required, then you can start an instance, mount a database to the instance, and have the recovery process automatically start.
- [Automatic Database Startup at Operating System Start](#)
Many sites use procedures to enable automatic startup of one or more Oracle Database instances and databases immediately following a system start.
- [Starting Remote Instances](#)
If your local Oracle Database server is part of a distributed database, then you might want to start a remote instance and database.

3.1.5.1 About Starting Up an Instance

When Oracle Restart is not in use, you use the SQL*Plus STARTUP command to start up an Oracle Database instance. If your database is being managed by Oracle Restart, Oracle recommends that you use the `srvctl start database` command.

With SQL*Plus and Oracle Restart, you can start an instance in various modes:

- **NOMOUNT**—Start the instance without mounting a database. This does not allow access to the database and usually would be done only for database creation or the re-creation of control files.
- **MOUNT**—Start the instance and mount the database, but leave it closed. This state allows for certain DBA activities, but does not allow general access to the database.
- **OPEN**—Start the instance, and mount and open the database. This can be done in unrestricted mode, allowing access to all users, or in restricted mode, allowing access for database administrators only.
- **FORCE**—Force the instance to start after a startup or shutdown problem.
- **OPEN RECOVER**—Start the instance and have complete media recovery begin immediately.

Note:

You cannot start a database instance if you are connected to the database through a shared server process.

The following scenarios describe and illustrate the various states in which you can start up an instance. Some restrictions apply when combining clauses of the STARTUP command or combining startup options for the `srvctl start database` command.

 **Note:**

It is possible to encounter problems starting up an instance if control files, database files, or online redo logs are not available. If one or more of the files specified by the `CONTROL_FILES` initialization parameter does not exist or cannot be opened when you attempt to mount a database, Oracle Database returns a warning message and does not mount the database. If one or more of the data files or online redo logs is not available or cannot be opened when attempting to open a database, the database returns a warning message and does not open the database.

 **See Also:**

- *SQL*Plus User's Guide and Reference* for details on the `STARTUP` command syntax
- "[Starting and Stopping Components Managed by Oracle Restart](#)" for instructions for starting a database that is managed by Oracle Restart.

3.1.5.2 Starting an Instance, and Mounting and Opening a Database

Normal database operation means that an instance is started and the database is mounted and open. This mode allows any valid user to connect to the database and perform data access operations.

The following command starts an instance, reads the initialization parameters from the default location, and then mounts and opens the database.

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
STARTUP	<code>srvctl start database -db db_unique_name</code>

where `db_unique_name` matches the `DB_UNIQUE_NAME` initialization parameter.

3.1.5.3 Starting an Instance Without Mounting a Database

You can start an instance without mounting a database. Typically, you do so only during database creation.

Use one of the following commands:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
STARTUP NOMOUNT	<code>srvctl start database -db db_unique_name -startoption nomount</code>

3.1.5.4 Starting an Instance and Mounting a Database

You can start an instance and mount a database without opening it, allowing you to perform specific maintenance operations.

For example, the database must be mounted but not open during the following tasks:

- Starting with Oracle Database 12c Release 1 (12.1.0.2), putting a database instance in force full database caching mode. For more information, see "[Using Force Full Database Caching Mode](#)".
- Enabling and disabling redo log archiving options. For more information, see [Managing Archived Redo Log Files](#).
- Performing full database recovery. For more information, see *Oracle Database Backup and Recovery User's Guide*.

The following command starts an instance and mounts the database, but leaves the database closed:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
STARTUP MOUNT	srvctl start database -db db_unique_name -startoption mount

3.1.5.5 Restricting Access to an Instance at Startup

You can start an instance, and optionally mount and open a database, in restricted mode so that the instance is available only to administrative personnel (not general database users).

Use this mode of instance startup when you must accomplish one of the following tasks:

- Perform an export or import of data
- Perform a data load (with SQL*Loader)
- Temporarily prevent typical users from using data
- Perform certain migration or upgrade operations

Typically, all users with the CREATE SESSION system privilege can connect to an open database. Opening a database in restricted mode allows database access only to users with both the CREATE SESSION and RESTRICTED SESSION system privilege. Only database administrators should have the RESTRICTED SESSION system privilege.

Further, when the instance is in restricted mode, a database administrator cannot access the instance remotely through an Oracle Net listener, but can only access the instance locally from the system that the instance is running on.

The following command starts an instance (and mounts and opens the database) in restricted mode:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
STARTUP RESTRICT	srvctl start database -db db_unique_name -startoption restrict

You can use the restrict mode in combination with the mount, nomount, and open modes.

Later, use the `ALTER SYSTEM` statement to disable the `RESTRICTED SESSION` feature:

```
ALTER SYSTEM DISABLE RESTRICTED SESSION;
```

If you open the database in nonrestricted mode and later find that you must restrict access, you can use the `ALTER SYSTEM` statement to do so, as described in "[Restricting Access to an Open Database](#)".

 **See Also:**

Oracle Database SQL Language Reference for more information on the `ALTER SYSTEM` statement

3.1.5.6 Forcing an Instance to Start

In unusual circumstances, you might experience problems when attempting to start a database instance, and you can force a database instance to start.

You should not force a database to start unless you are faced with the following:

- You cannot shut down the current instance with the `SHUTDOWN NORMAL`, `SHUTDOWN IMMEDIATE`, or `SHUTDOWN TRANSACTIONAL` commands.
- You experience problems when starting an instance.

If one of these situations arises, you can usually solve the problem by starting a new instance (and optionally mounting and opening the database) using one of these commands:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
STARTUP FORCE	<code>srvctl start database -db db_unique_name -startoption force</code>

If an instance is running, the force mode shuts it down with mode `ABORT` before restarting it. In this case, the alert log shows the message "Shutting down instance (abort)" followed by "Starting ORACLE instance (normal)."

 **See Also:**

["Shutting Down with the Abort Mode"](#) to understand the side effects of aborting the current instance

3.1.5.7 Starting an Instance, Mounting a Database, and Starting Complete Media Recovery

If you know that media recovery is required, then you can start an instance, mount a database to the instance, and have the recovery process automatically start.

To do so, use one of these commands:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
STARTUP OPEN	srvctl start database -db db_unique_name -startoption
RECOVER	"open,recover"

If you attempt to perform recovery when no recovery is required, Oracle Database issues an error message.

3.1.5.8 Automatic Database Startup at Operating System Start

Many sites use procedures to enable automatic startup of one or more Oracle Database instances and databases immediately following a system start.

The procedures for performing this task are specific to each operating system. For information about automatic startup, see your operating system specific Oracle documentation.

The preferred (and platform-independent) method of configuring automatic startup of a database is Oracle Restart. See [Configuring Automatic Restart of an Oracle Database](#) for details.

3.1.5.9 Starting Remote Instances

If your local Oracle Database server is part of a distributed database, then you might want to start a remote instance and database.

Procedures for starting and stopping remote instances vary widely depending on communication protocol and operating system.

3.2 Altering Database Availability

You can alter the availability of a database. You may want to do this in order to restrict access for maintenance reasons or to make the database read only.

- [Mounting a Database to an Instance](#)

When you perform specific administrative operations, the database must be started and mounted to an instance, but closed. You can achieve this scenario by starting the instance and mounting the database.

- [Opening a Closed Database](#)

When a database is mounted but closed, you can make it available for general use by opening it.

- [Opening a Database in Read-Only Mode](#)

Opening a database in read-only mode enables you to query an open database while eliminating any potential for online data content changes.

- [Restricting Access to an Open Database](#)

When a database is in restricted mode, only users with the RESTRICTED SESSION privilege can initiate new connections. Users connecting as SYSDBA or connecting with the DBA role have this privilege.

3.2.1 Mounting a Database to an Instance

When you perform specific administrative operations, the database must be started and mounted to an instance, but closed. You can achieve this scenario by starting the instance and mounting the database.

- To mount a database to a previously started, but not opened instance, use the SQL statement ALTER DATABASE with the MOUNT clause as follows:

```
ALTER DATABASE MOUNT;
```

 **See Also:**

["Starting an Instance and Mounting a Database"](#) for a list of operations that require the database to be mounted and closed (and procedures to start an instance and mount a database in one step)

3.2.2 Opening a Closed Database

When a database is mounted but closed, you can make it available for general use by opening it.

- To open a mounted database, use the ALTER DATABASE SQL statement with the OPEN clause:

```
ALTER DATABASE OPEN;
```

After executing this statement, any valid Oracle Database user with the CREATE SESSION system privilege can connect to the database.

3.2.3 Opening a Database in Read-Only Mode

Opening a database in read-only mode enables you to query an open database while eliminating any potential for online data content changes.

While opening a database in read-only mode guarantees that data files and redo log files are not written to, it does not restrict database recovery or operations that change the state of the database without generating redo. For example, you can take data files offline or bring them online since these operations do not affect data content.

If a query against a database in read-only mode uses temporary tablespace, for example to do disk sorts, then the issuer of the query must have a locally managed tablespace assigned as the default temporary tablespace. Otherwise, the query will fail. This is explained in "[Creating a Locally Managed Temporary Tablespace](#)".

The following statement opens a database in read-only mode:

```
ALTER DATABASE OPEN READ ONLY;
```

You can also open a database in read/write mode as follows:

```
ALTER DATABASE OPEN READ WRITE;
```

However, read/write is the default mode.

 **Note:**

You cannot use the `RESETLOGS` clause with a `READ ONLY` clause.

Limitations of a Read-only Database

- An application must not write database objects while executing against a read-only database. For example, an application writes database objects when it inserts, deletes, updates, or merges rows in a database table, including a global temporary table. An application writes database objects when it manipulates a database sequence. An application writes database objects when it locks rows, when it runs `EXPLAIN PLAN`, or when it executes DDL. Many of the functions and procedures in Oracle-supplied PL/SQL packages, such as `DBMS_SCHEDULER`, write database objects. If your application calls any of these functions and procedures, or if it performs any of the preceding operations, your application writes database objects and hence is not read-only.
- When executing on a read-only database, you must commit or roll back any in-progress transaction that involves one database link before you use another database link. This is true even if you execute a generic `SELECT` statement on the first database link and the *transaction* is currently read-only.
- You cannot compile or recompile PL/SQL stored procedures on a read-only database. To minimize PL/SQL invalidation because of remote procedure calls, use `REMOTE_DEPENDENCIES_MODE=SIGNATURE` in any session that does remote procedure calls on a read-only database.
- You cannot invoke a remote procedure (even a read-only remote procedure) from a read-only database if the remote procedure has never been called on the database. This limitation applies to remote procedure calls in anonymous PL/SQL blocks and in SQL statements. You can either put the remote procedure call in a stored procedure, or you can invoke the remote procedure in the database before it becomes read only.

 **See Also:**

Oracle Database SQL Language Reference for more information about the `ALTER DATABASE` statement

3.2.4 Restricting Access to an Open Database

When a database is in restricted mode, only users with the RESTRICTED SESSION privilege can initiate new connections. Users connecting as SYSDBA or connecting with the DBA role have this privilege.

To place an already running instance in restricted mode:

- Run the SQL statement `ALTER SYSTEM` with the `ENABLE RESTRICTED SESSION` clause.

When you place a running instance in restricted mode, no user sessions are terminated or otherwise affected. Therefore, after placing an instance in restricted mode, consider killing (terminating) all current user sessions before performing administrative tasks.

To lift an instance from restricted mode, use `ALTER SYSTEM` with the `DISABLE RESTRICTED SESSION` clause.

See Also:

- "[Terminating Sessions](#)" for directions for killing user sessions
- "[Restricting Access to an Instance at Startup](#)" to learn some reasons for placing an instance in restricted mode

3.3 Shutting Down a Database

You can shut down a database with SQL*Plus or Oracle Restart.

- [About Shutting Down the Database](#)**

When Oracle Restart is not in use, you can shut down a database instance with SQL*Plus by connecting as SYSOPER, SYSDBA, SYSBACKUP, or SYSDG and issuing the `SHUTDOWN` command. If your database is being managed by Oracle Restart, the recommended way to shut down the database is with the `srvctl stop database` command.

- [Shutting Down with the Normal Mode](#)**

When you shut down a database with the normal mode, the database waits for all connected users to disconnect before shutting down. Normal mode is the default mode of shutdown.

- [Shutting Down with the Immediate Mode](#)**

When you shut down a database with the immediate mode, Oracle Database terminates any executing SQL statements and disconnects users. Active transactions are terminated and uncommitted changes are rolled back.

- [Shutting Down with the Transactional Mode](#)**

When you shut down a database with transactional mode, the database prevents users from starting new transactions, but waits for all current transactions to complete before shutting down. This mode can take a significant amount of time depending on the nature of the current transactions.

- [Shutting Down with the Abort Mode](#)
You can shut down a database instantaneously by aborting the database instance.
- [Shutdown Timeout](#)
Shutdown modes that wait for users to disconnect or for transactions to complete have a limit on the amount of time that they wait.

3.3.1 About Shutting Down the Database

When Oracle Restart is not in use, you can shut down a database instance with SQL*Plus by connecting as SYSOPER, SYSDBA, SYSBACKUP, or SYSDG and issuing the SHUTDOWN command. If your database is being managed by Oracle Restart, the recommended way to shut down the database is with the `srvctl stop database` command.

Control is not returned to the session that initiates a database shutdown until shutdown is complete. Users who attempt connections while a shutdown is in progress receive a message like the following:

```
ORA-01090: shutdown in progress - connection is not permitted
```

 **Note:**

You cannot shut down a database if you are connected to the database through a shared server process.

There are several modes for shutting down a database: normal, immediate, transactional, and abort. Some shutdown modes wait for certain events to occur (such as transactions completing or users disconnecting) before actually bringing down the database. There is a one-hour timeout period for these events.

 **See Also:**

[Configuring Automatic Restart of an Oracle Database](#) for information about Oracle Restart.

3.3.2 Shutting Down with the Normal Mode

When you shut down a database with the normal mode, the database waits for all connected users to disconnect before shutting down. Normal mode is the default mode of shutdown.

To shut down a database in normal situations, use one of these commands:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
SHUTDOWN [NORMAL]	<code>srvctl stop database -db db_unique_name -stopoption normal</code>

The NORMAL clause of the SQL*Plus SHUTDOWN command is optional because this is the default shutdown method. For SRVCTL, if the -stopoption option is omitted, the shutdown operation proceeds according to the stop options stored in the Oracle Restart configuration for the database. The default stop option is immediate.

Normal database shutdown proceeds with the following conditions:

- No new connections are allowed after the statement is issued.
- Before the database is shut down, the database waits for all currently connected users to disconnect from the database.

The next startup of the database will not require any instance recovery procedures.

3.3.3 Shutting Down with the Immediate Mode

When you shut down a database with the immediate mode, Oracle Database terminates any executing SQL statements and disconnects users. Active transactions are terminated and uncommitted changes are rolled back.

Use immediate database shutdown only in the following situations:

- To initiate an automated and unattended backup
- When a power shutdown is going to occur soon
- When the database or one of its applications is functioning irregularly and you cannot contact users to ask them to log off or they are unable to log off

To shut down a database immediately, use one of the following commands:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
SHUTDOWN IMMEDIATE	srvctl stop database -db db_unique_name -stopoption immediate

Immediate database shutdown proceeds with the following conditions:

- No new connections are allowed, nor are new transactions allowed to be started, after the statement is issued.
- Any uncommitted transactions are rolled back. (If long uncommitted transactions exist, this method of shutdown might not complete quickly, despite its name.)
- Oracle Database does not wait for users currently connected to the database to disconnect. The database implicitly rolls back active transactions and disconnects all connected users.

The next startup of the database will not require any instance recovery procedures.

3.3.4 Shutting Down with the Transactional Mode

When you shut down a database with transactional mode, the database prevents users from starting new transactions, but waits for all current transactions to complete before shutting down. This mode can take a significant amount of time depending on the nature of the current transactions.

When you want to perform a planned shutdown of an instance while allowing active transactions to complete first, use one of the following commands:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
SHUTDOWN TRANSACTIONAL	srvctl stop database -db db_unique_name -stopoption transactional

Transactional database shutdown proceeds with the following conditions:

- No new connections are allowed, nor are new transactions allowed to be started, after the statement is issued.
- After all transactions have completed, any client still connected to the instance is disconnected.
- At this point, the instance shuts down just as it would when a `SHUTDOWN IMMEDIATE` statement is submitted.

The next startup of the database will not require any instance recovery procedures.

A transactional shutdown prevents clients from losing work, and at the same time, does not require all users to log off.

3.3.5 Shutting Down with the Abort Mode

You can shut down a database instantaneously by aborting the database instance.

If possible, perform this type of shutdown *only* in the following situations:

- The database or one of its applications is functioning irregularly *and* none of the other types of shutdown works.
- You must shut down the database instantaneously (for example, if you know a power shutdown is going to occur in one minute).
- You experience problems when starting a database instance.

When you must do a database shutdown by aborting transactions and user connections, use one of the following commands:

SQL*Plus	SRVCTL (When Oracle Restart Is In Use)
SHUTDOWN ABORT	srvctl stop database -db db_unique_name -stopoption abort

An aborted database shutdown proceeds with the following conditions:

- No new connections are allowed, nor are new transactions allowed to be started, after the statement is issued.
- Current client SQL statements being processed by Oracle Database are immediately terminated.
- Uncommitted transactions are not rolled back.
- Oracle Database does not wait for users currently connected to the database to disconnect. The database implicitly disconnects all connected users.

The next startup of the database *will* require automatic instance recovery procedures.

3.3.6 Shutdown Timeout

Shutdown modes that wait for users to disconnect or for transactions to complete have a limit on the amount of time that they wait.

If all events blocking the shutdown do not occur within one hour, the shutdown operation aborts with the following message: ORA-01013: user requested cancel of current operation. This message is also displayed if you interrupt the shutdown process, for example by pressing CTRL-C. Oracle recommends that you do not attempt to interrupt an instance shutdown. Instead, allow the shutdown process to complete, and then restart the instance.

After ORA-01013 occurs, you must consider the instance to be in an unpredictable state. You must therefore continue the shutdown process by resubmitting a SHUTDOWN command. If subsequent SHUTDOWN commands continue to fail, you must submit a SHUTDOWN ABORT command to bring down the instance. You can then restart the instance.

3.4 Quiescing a Database

A quiesced database allows only DBA transactions, queries, fetches, or PL/SQL statements.

- [About Quiescing a Database](#)

Occasionally you might want to put a database in a state that allows only DBA transactions, queries, fetches, or PL/SQL statements. Such a state is referred to as a **quiesced state**, in the sense that no ongoing non-DBA transactions, queries, fetches, or PL/SQL statements are running in the system.

- [Placing a Database into a Quiesced State](#)

When you place a database in quiesced state, non-DBA active sessions will continue until they become inactive. An active session is one that is currently inside of a transaction, a query, a fetch, or a PL/SQL statement; or a session that is currently holding any shared resources (for example, enqueues). No inactive sessions are allowed to become active.

- [Restoring the System to Normal Operation](#)

When you restore the system to normal operation, all non-DBA activity is allowed to proceed.

- [Viewing the Quiesce State of an Instance](#)

You can view the quiesce state of an instance by querying the V\$INSTANCE view.

3.4.1 About Quiescing a Database

Occasionally you might want to put a database in a state that allows only DBA transactions, queries, fetches, or PL/SQL statements. Such a state is referred to as a **quiesced state**, in the sense that no ongoing non-DBA transactions, queries, fetches, or PL/SQL statements are running in the system.

 **Note:**

In this discussion of quiesce database, a DBA is defined as user `SYS` or `SYSTEM`. Other users, including those with the `DBA` role, are not allowed to issue the `ALTER SYSTEM QUIESCE DATABASE` statement or proceed after the database is quiesced.

The quiesced state lets administrators perform actions that cannot safely be done otherwise. These actions include:

- Actions that fail if concurrent user transactions access the same object--for example, changing the schema of a database table or adding a column to an existing table where a no-wait lock is required.
- Actions whose undesirable intermediate effect can be seen by concurrent user transactions--for example, a multistep procedure for reorganizing a table when the table is first exported, then dropped, and finally imported. A concurrent user who attempts to access the table after it was dropped, but before import, would not have an accurate view of the situation.

Without the ability to quiesce the database, you would need to shut down the database and reopen it in restricted mode. This is a serious restriction, especially for systems requiring 24 x 7 availability. Quiescing a database is much a smaller restriction, because it eliminates the disruption to users and the downtime associated with shutting down and restarting the database.

When the database is in the quiesced state, it is through the facilities of the Database Resource Manager that non-DBA sessions are prevented from becoming active. Therefore, while this statement is in effect, any attempt to change the current resource plan will be queued until after the system is unquiesced. See [Managing Resources with Oracle Database Resource Manager](#) for more information about the Database Resource Manager.

3.4.2 Placing a Database into a Quiesced State

When you place a database in quiesced state, non-DBA active sessions will continue until they become inactive. An active session is one that is currently inside of a transaction, a query, a fetch, or a PL/SQL statement; or a session that is currently holding any shared resources (for example, enqueues). No inactive sessions are allowed to become active.

For example, If a user issues a SQL query in an attempt to force an inactive session to become active, the query will appear to be hung. When the database is later unquiesced, the session is resumed, and the blocked action is processed.

- To place a database into a quiesced state, issue the following SQL statement:

```
ALTER SYSTEM QUIESCE RESTRICTED;
```

Once all non-DBA sessions become inactive, the `ALTER SYSTEM QUIESCE RESTRICTED` statement completes, and the database is in a quiesced state. In an Oracle Real Application Clusters environment, this statement affects all instances, not just the one that issues the statement.

The `ALTER SYSTEM QUIESCE RESTRICTED` statement may wait a long time for active sessions to become inactive. You can determine the sessions that are blocking the

quiesce operation by querying the V\$BLOCKING QUIESCE view. This view returns only a single column: SID (Session ID). You can join it with V\$SESSION to get more information about the session, as shown in the following example:

```
select bl.sid, user, osuser, type, program
from v$blocking_quiesce bl, v$session se
where bl.sid = se.sid;
```

If you interrupt the request to quiesce the database, or if your session terminates abnormally before all active sessions are quiesced, then Oracle Database automatically reverses any partial effects of the statement.

For queries that are carried out by successive multiple Oracle Call Interface (OCI) fetches, the ALTER SYSTEM QUIESCE RESTRICTED statement does not wait for all fetches to finish. It only waits for the current fetch to finish.

For both dedicated and shared server connections, all non-DBA logins after this statement is issued are queued by the Database Resource Manager, and are not allowed to proceed. To the user, it appears as if the login is hung. The login will resume when the database is unquiesced.

The database remains in the quiesced state even if the session that issued the statement exits. A DBA must log in to the database to issue the statement that specifically unquiesces the database.

Note:

You cannot perform a cold backup when the database is in the quiesced state, because Oracle Database background processes may still perform updates for internal purposes even while the database is quiesced. In addition, the file headers of online data files continue to appear to be accessible. They do not look the same as if a clean shutdown had been performed. However, you can still take online backups while the database is in a quiesced state.

See Also:

- *Oracle Database Reference* for more information about the V\$BLOCKING QUIESCE view
- *Oracle Database Reference* for more information about the V\$SESSION view

3.4.3 Restoring the System to Normal Operation

When you restore the system to normal operation, all non-DBA activity is allowed to proceed.

- To restore the database to normal operation, issue the following SQL statement:

```
ALTER SYSTEM UNQUIESCE;
```

In an Oracle Real Application Clusters environment, this statement is not required to be issued from the same session, or even the same instance, as that which quiesced the database. If the session issuing the `ALTER SYSTEM UNQUIESCE` statement terminates abnormally, then the Oracle Database server ensures that the unquiesce operation completes.

3.4.4 Viewing the Quiesce State of an Instance

You can view the quiesce state of an instance by querying the `V$INSTANCE` view.

To view the quiesce state of an instance:

- Query the `ACTIVE_STATE` column of the `V$INSTANCE` view.

The column has one of these values:

- `NORMAL`: Normal unquiesced state.
- `QUIESCING`: Being quiesced, but some non-DBA sessions are still active.
- `QUIESCED`: Quiesced; no non-DBA sessions are active or allowed.

3.5 Suspending and Resuming a Database

The `ALTER SYSTEM SUSPEND` statement halts all input and output (I/O) to data files (file header and file data) and control files. The suspended state lets you back up a database without I/O interference. When the database is suspended all preexisting I/O operations are allowed to complete and any new database accesses are placed in a queued state. Use the `ALTER SYSTEM RESUME` statement to resume normal database operations.

To suspend database operations:

- Run the `ALTER SYSTEM SUSPEND` statement.

To resume database operations:

- Run the `ALTER SYSTEM RESUME` statement.

The suspend command is not specific to an instance. In an Oracle Real Application Clusters environment, when you issue the suspend command on one system, internal locking mechanisms propagate the halt request across instances, thereby quiescing all active instances in a given cluster. However, if a new instance is started while another instance is being suspended, then the new instance is not suspended.

The `SUSPEND` and `RESUME` commands can be issued from different instances. For example, if instances 1, 2, and 3 are running, and you issue an `ALTER SYSTEM SUSPEND` statement from instance 1, then you can issue a `RESUME` statement from instance 1, 2, or 3 with the same effect.

The suspend/resume feature is useful in systems that allow you to mirror a disk or file and then split the mirror, providing an alternative backup and restore solution. If you use a system that cannot split a mirrored disk from an existing database while writes are occurring, then you can use the suspend/resume feature to facilitate the split.

The suspend/resume feature is not a suitable substitute for normal shutdown operations, because copies of a suspended database can contain uncommitted updates.

 **Note:**

Do not use the `ALTER SYSTEM SUSPEND` statement as a substitute for placing a tablespace in hot backup mode. Precede any database suspend operation by an `ALTER TABLESPACE BEGIN BACKUP` statement.

The following statements illustrate `ALTER SYSTEM SUSPEND/RESUME` usage. The `V$INSTANCE` view is queried to confirm database status.

```
SQL> ALTER SYSTEM SUSPEND;
System altered
SQL> SELECT DATABASE_STATUS FROM V$INSTANCE;
DATABASE_STATUS
-----
SUSPENDED

SQL> ALTER SYSTEM RESUME;
System altered
SQL> SELECT DATABASE_STATUS FROM V$INSTANCE;
DATABASE_STATUS
-----
ACTIVE
```

 **See Also:**

Oracle Database Backup and Recovery User's Guide for details about backing up a database using the database suspend/resume feature

3.6 Delaying Instance Abort

The `INSTANCE_ABORT_DELAY_TIME` initialization parameter specifies the amount of time, in seconds, to delay shutting down a database when an error causes the instance to abort.

Some errors cause the Oracle database instance to abort. You can use the `INSTANCE_ABORT_DELAY_TIME` initialization parameter to specify the amount of time to delay shutting down the instance. A database administrator can use the delay time to get information about the error and minimize problems that can result when an instance aborts. For example, a database administrator might use the delay time to get diagnostics, redirect connections using Transparent Application Failover (TAF), and flush the buffer cache. A message is written to the alert log when a delayed abort is initiated.

 **Caution:**

Do not set the `INSTANCE_ABORT_DELAY_TIME` value too high. Since the instance is closing because of an error, some processes or resources might be corrupted or unavailable, which can make complex actions impossible.

To delay instance abort:

- Set the `INSTANCE_ABORT_DELAY_TIME` initialization parameter to the number of seconds to delay shutting down an instance when an error causes it to abort.

This parameter is set to 0 by default.

Example 3-1 Setting the `INSTANCE_ABORT_DELAY_TIME` Initialization Parameter

```
ALTER SYSTEM SET INSTANCE_ABORT_DELAY_TIME=60;
```

Configuring Automatic Restart of an Oracle Database

Configure your Oracle database with the Oracle Restart feature to automatically restart the database, the listener, and other Oracle components after a hardware or software failure or whenever your database host computer restarts.

- [About Oracle Restart](#)
Oracle Restart enhances the availability of Oracle databases in a single-instance environment.
- [Configuring Oracle Restart](#)
To configure Oracle Restart, you can add components, remove components, or modify options for components.
- [Starting and Stopping Components Managed by Oracle Restart](#)
When Oracle Restart is in use, Oracle strongly recommends that you use the SRVCTL utility to start and stop components.
- [Stopping and Restarting Oracle Restart for Maintenance Operations](#)
When several components in an Oracle home are managed by Oracle Restart, you can stop Oracle Restart and the components managed by Oracle Restart in the Oracle home.
- [SRVCTL Command Reference for Oracle Restart](#)
You can reference details about the syntax and options for SRVCTL commands specific to Oracle Restart.
- [CRSCTL Command Reference](#)
You can reference details about the syntax for the CRSCTL commands that are relevant for Oracle Restart.

4.1 About Oracle Restart

Oracle Restart enhances the availability of Oracle databases in a single-instance environment.

- [Oracle Restart Overview](#)
When you install Oracle Restart, various Oracle components can be automatically restarted after a hardware or software failure or whenever your database host computer restarts.
- [About Startup Dependencies](#)
Oracle Restart ensures that Oracle components are started in the proper order, in accordance with component dependencies.
- [About Starting and Stopping Components with Oracle Restart](#)
Oracle Restart automatically restarts various Oracle components when required, and automatically stops Oracle components in an orderly fashion when you manually shut down your system.

- [About Starting and Stopping Oracle Restart](#)
The CRSCTL utility starts and stops Oracle Restart.
- [Oracle Restart Configuration](#)
Oracle Restart maintains a list of all the Oracle components that it manages, and maintains configuration information for each component.
- [Oracle Restart Integration with Oracle Data Guard](#)
Oracle Restart is integrated with Oracle Data Guard (Data Guard) and the Oracle Data Guard Broker (the broker).
- [Fast Application Notification with Oracle Restart](#)
Oracle Restart uses Oracle Notification Services (ONS) and Oracle Advanced Queues to publish Fast Application Notification (FAN) high availability events. Integrated Oracle clients use FAN to provide fast notification to clients when the service or instance goes down. The client can automate the failover of database connections between a primary database and a standby database.

4.1.1 Oracle Restart Overview

When you install Oracle Restart, various Oracle components can be automatically restarted after a hardware or software failure or whenever your database host computer restarts.

[Table 4-1](#) lists these components.

Table 4-1 Oracle Components Automatically Restarted by Oracle Restart

Component	Notes
Database instance	Oracle Restart can accommodate multiple databases on a single host computer.
Oracle Net listener	-
Database services	Does not include the default service created upon installation because it is automatically managed by Oracle Database. Also does not include any default services created during database creation or global services. For more information about global services, see the <i>Oracle Database Global Data Services Concepts and Administration Guide</i> .
Oracle Automatic Storage Management (Oracle ASM) instance	-
Oracle ASM disk groups	Restarting a disk group means mounting it.
Oracle Notification Services (ONS)	In an Oracle Grid Infrastructure for Standalone Servers (Oracle Restart) environment, ONS can be used in Oracle Data Guard installations for automating failover of connections between primary and standby database through Fast Application Notification (FAN). ONS is a service for sending FAN events to integrated clients upon failover.

Oracle Restart runs periodic check operations to monitor the health of these components. If a check operation fails for a component, the component is shut down and restarted.

Oracle Restart is used in standalone server (non-clustered) environments only. For Oracle Real Application Clusters (Oracle RAC) environments, the functionality to automatically restart components is provided by Oracle Clusterware.

Oracle Restart runs out of the Oracle Grid Infrastructure home, which you install separately from Oracle Database homes. See the *Oracle Grid Infrastructure Installation Guide* for your platform for information about installing the Oracle Grid Infrastructure home.

See Also:

- ["Configuring Oracle Restart"](#)
- *Oracle Automatic Storage Management Administrator's Guide* for information about Oracle Automatic Storage Management

4.1.2 About Startup Dependencies

Oracle Restart ensures that Oracle components are started in the proper order, in accordance with component dependencies.

For example, if database files are stored in Oracle ASM disk groups, then before starting the database instance, Oracle Restart ensures that the Oracle ASM instance is started and the required disk groups are mounted. Likewise, if a component must be shut down, Oracle Restart ensures that dependent components are cleanly shut down first.

Oracle Restart also manages the weak dependency between database instances and the Oracle Net listener (the listener): When a database instance is started, Oracle Restart attempts to start the listener. If the listener startup fails, then the database is still started. If the listener later fails, Oracle Restart does not shut down and restart any database instances.

4.1.3 About Starting and Stopping Components with Oracle Restart

Oracle Restart automatically restarts various Oracle components when required, and automatically stops Oracle components in an orderly fashion when you manually shut down your system.

There may be times, however, when you want to manually start or stop individual Oracle components. Oracle Restart includes the Server Control (SRVCTL) utility that you use to manually start and stop Oracle Restart-managed components. When Oracle Restart is in use, Oracle strongly recommends that you use SRVCTL to manually start and stop components.

After you stop a component with SRVCTL, Oracle Restart does not automatically restart that component if a failure occurs. If you then start the component with SRVCTL, that component is again available for automatic restart.

Oracle utilities such as SQL*Plus, the Listener Control utility (`LSNRCTL`), and `ASCMCMD` are integrated with Oracle Restart. If you shut down the database with SQL*Plus, Oracle Restart does not interpret this as a database failure and does not attempt to restart the

database. Similarly, if you shut down the Oracle ASM instance with SQL*Plus or ASMCMD, Oracle Restart does not attempt to restart it.

An important difference between starting a component with SRVCTL and starting it with SQL*Plus (or another utility) is the following:

- When you start a component with SRVCTL, any components on which this component depends are automatically started first, and in the proper order.
- When you start a component with SQL*Plus (or another utility), other components in the dependency chain are not automatically started; you must ensure that any components on which this component depends are started.

In addition, Oracle Restart enables you to start and stop all of the components managed by Oracle Restart in a specified Oracle home using a single command. The Oracle home can be an Oracle Database home or an Oracle Grid Infrastructure home. This capability is useful when you are installing a patch.

 **See Also:**

["Starting and Stopping Components Managed by Oracle Restart"](#)

4.1.4 About Starting and Stopping Oracle Restart

The CRSCTL utility starts and stops Oracle Restart.

You can also use the CRSCTL utility to enable or disable Oracle high availability services. Oracle Restart uses Oracle high availability services to start and stop automatically the components managed by Oracle Restart. For example, Oracle high availability services daemons automatically start databases, listeners, and Oracle ASM instances. When Oracle high availability services are disabled, none of the components managed by Oracle Restart are started when a node is rebooted.

Typically, you use the CRSCTL utility when you must stop all of the running Oracle software in an Oracle installation. For example, you might need to stop Oracle Restart when you are installing a patch or performing operating system maintenance. When the maintenance is complete, you use the CRSCTL utility to start Oracle Restart.

 **See Also:**

["Stopping and Restarting Oracle Restart for Maintenance Operations"](#) for information about using the CRSCTL utility

4.1.5 Oracle Restart Configuration

Oracle Restart maintains a list of all the Oracle components that it manages, and maintains configuration information for each component.

All of this information is collectively known as the **Oracle Restart configuration**. When Oracle Restart starts a component, it starts the component according to the

configuration information for that component. For example, the Oracle Restart configuration includes the location of the server parameter file (SPFILE) for databases, and the TCP port to listen on for listeners.

If you install Oracle Restart and then create your database with Database Configuration Assistant (DBCA), DBCA automatically adds the database to the Oracle Restart configuration. When DBCA then starts the database, the required dependencies between the database and other components (for example disk groups in which the database stores data) are established, and Oracle Restart begins to manage the database.

You can manually add and remove components from the Oracle Restart configuration with SRVCTL commands. For example, if you install Oracle Restart onto a host on which a database is already running, you can use SRVCTL to add that database to the Oracle Restart configuration. When you manually add a component to the Oracle Restart configuration and then start it with SRVCTL, Oracle Restart begins to manage the component, restarting it when required.

 **Note:**

Adding a component to the Oracle Restart configuration is also referred to as "registering a component with Oracle Restart."

Other SRVCTL commands enable you to view the status and configuration of Oracle Restart-managed components, temporarily disable and then reenable management for components, and more.

When Oracle Restart is installed, many operations that create Oracle components automatically add the components to the Oracle Restart configuration. [Table 4-2](#) lists some create operations and whether the created component is automatically added.

Table 4-2 Create Operations and the Oracle Restart Configuration

Create Operation	Created Component Automatically Added to Oracle Restart Configuration?
Create a database with OUI or DBCA	Yes
Create a database with the CREATE DATABASE SQL statement	No
Create an Oracle ASM instance with OUI, DBCA, or ASMCA	Yes
Create a disk group (any method)	Yes
Add a listener with NETCA	Yes
Create a database service with SRVCTL	Yes
Create a database service by modifying the SERVICE_NAMES initialization parameter ¹	No
Create a database service with DBMS_SERVICE.CREATE_SERVICE	No

Table 4-2 (Cont.) Create Operations and the Oracle Restart Configuration

Create Operation	Created Component Automatically Added to Oracle Restart Configuration?
Create a standby database	No

¹ Not recommended when Oracle Restart is in use

Table 4-3 lists some delete/drop/remove operations and whether the deleted component is also automatically removed from the Oracle Restart configuration.

Table 4-3 Delete/Drop/Remove Operations and the Oracle Restart Configuration

Operation	Deleted Component Automatically Removed from Oracle Restart Configuration?
Delete a database with DBCA	Yes
Delete a database by removing database files with operating system commands ¹	No
Delete a listener with NETCA	Yes
Drop an Oracle ASM disk group (any method)	Yes
Delete a database service with SRVCTL	Yes
Delete a database service by any other means	No

¹ Not recommended

4.1.6 Oracle Restart Integration with Oracle Data Guard

Oracle Restart is integrated with Oracle Data Guard (Data Guard) and the Oracle Data Guard Broker (the broker).

When a database shutdown and restart is required in response to a role change request, Oracle Restart shuts down and restarts the database in an orderly fashion (taking dependencies into account), and according to the settings in the Oracle Restart configuration. Oracle Restart also ensures that, following a Data Guard role transition, all database services configured to run in the new database role are active and all services not configured to run in the new role are stopped.

In addition, the Oracle Restart configuration supports Data Guard-related configuration options for the following components:

- **Databases**—When you add a database to the Oracle Restart configuration, you can specify the current Data Guard role for the database: PRIMARY, PHYSICAL_STANDBY, LOGICAL_STANDBY, or SNAPSHOT_STANDBY. If the role is later changed using the broker, Oracle Restart automatically updates the database configuration with the new role. If you change the database role without using the

broker, you must manually modify the database's role in the Oracle Restart configuration to reflect the new role.

- **Database Services**—When adding a database service to the Oracle Restart configuration, you can specify one or more Data Guard roles for the service. When this configuration option is present, upon database open Oracle Restart starts the service only if one of the service roles matches the current database role.

 **See Also:**

- [Oracle Data Guard Concepts and Administration](#) for information about Oracle Data Guard
- ["Fast Application Notification with Oracle Restart"](#)
- ["Automating the Failover of Connections Between Primary and Standby Databases"](#)

4.1.7 Fast Application Notification with Oracle Restart

Oracle Restart uses Oracle Notification Services (ONS) and Oracle Advanced Queues to publish Fast Application Notification (FAN) high availability events. Integrated Oracle clients use FAN to provide fast notification to clients when the service or instance goes down. The client can automate the failover of database connections between a primary database and a standby database.

- [Overview of Fast Application Notification](#)
FAN is a high availability notification mechanism that Oracle Restart can use to notify other processes about configuration changes that include service status changes, such as UP or DOWN events.
- [Application High Availability with Services and FAN](#)
Oracle Database focuses on maintaining service availability. With Oracle Restart, Oracle services are designed to be continuously available. Oracle Restart monitors the database and its services and, when configured, sends event notifications using FAN.

 **See Also:**

[Oracle Database Advanced Queuing User's Guide](#)

4.1.7.1 Overview of Fast Application Notification

FAN is a high availability notification mechanism that Oracle Restart can use to notify other processes about configuration changes that include service status changes, such as UP or DOWN events.

FAN provides the ability to immediately terminate inflight transaction when an instance or server fails. Integrated Oracle clients receive the events and respond. Applications can respond either by propagating the error to the user or by resubmitting the

transactions and masking the error from the application user. When a `DOWN` event occurs, integrated clients immediately clean up connections to the terminated database. When an `UP` event occurs, the clients create new connections to the new primary database instance.

Oracle Restart publishes FAN events whenever a managed instance or service goes up or down. After a failover, the Oracle Data Guard Broker (broker) publishes FAN events. These FAN events can be used in the following ways:

- Applications can use FAN with Oracle Restart without programmatic changes if they use one of these Oracle integrated database clients: Oracle Database JDBC, Universal Connection Pool for Java, Oracle Call Interface, and Oracle Database ODP.NET. These clients can be configured for Fast Connection Failover (FCF) to automatically connect to a new primary database after a failover.
- FAN server-side callouts can be configured on the database tier.

For `DOWN` events, such as a failed primary database, FAN provides immediate notification to the clients so that they can failover as fast as possible to the new primary database. The clients do not wait for a timeout. The clients are notified immediately, and they must be configured to failover when they are notified.

For `UP` events, when services and instances are started, new connections can be created so that the application can immediately take advantage of the extra resources.

Through server-side callouts, you can also use FAN to:

- Log status information
- Page DBAs or open support tickets when resources fail to start
- Automatically start dependent external applications that must be co-located with a service

FAN events are published using ONS and Oracle Database Advanced Queuing queues. The queues are configured automatically when you configure a service. You must configure ONS manually using SRVCTL commands.

The Connection Manager (CMAN) and Oracle Net Services listeners are integrated with FAN events, enabling the CMAN and the listener to immediately de-register services provided by the failed instance and to avoid erroneously sending connection requests to a failed database.

 **See Also:**

Oracle Data Guard Broker for information about FAN events in an Oracle Data Guard environment

4.1.7.2 Application High Availability with Services and FAN

Oracle Database focuses on maintaining service availability. With Oracle Restart, Oracle services are designed to be continuously available. Oracle Restart monitors the database and its services and, when configured, sends event notifications using FAN.

- [Managing Unplanned Outages](#)
If Oracle Restart detects an outage, then it isolates the failed component and recovers the dependent components. If the failed component is the database instance, then after Oracle Data Guard fails over to the standby database, Oracle Restart on the new primary database starts any services defined with the current role.
- [Managing Planned Outages](#)
For repairs, upgrades, and changes that require you to shut down the primary database, Oracle Restart provides interfaces that disable and enable services to minimize service disruption to application users.
- [Fast Application Notification High Availability Events](#)
Understand FAN event record parameters and the event types.
- [Using Fast Application Notification Callouts](#)
FAN callouts are server-side executables that Oracle Restart executes immediately when high availability events occur.
- [Oracle Clients That Are Integrated with Fast Application Notification](#)
Oracle has integrated FAN with many of the common Oracle client drivers that are used to connect to Oracle Restart databases. Therefore, the easiest way to use FAN is to use an integrated Oracle Client.

4.1.7.2.1 Managing Unplanned Outages

If Oracle Restart detects an outage, then it isolates the failed component and recovers the dependent components. If the failed component is the database instance, then after Oracle Data Guard fails over to the standby database, Oracle Restart on the new primary database starts any services defined with the current role.

FAN events are published by Oracle Restart and the Oracle Data Guard Broker through ONS and Advanced Queuing. You can also perform notifications using FAN callouts.

 **Note:**

Oracle Restart does not run callouts with guaranteed ordering. Callouts are run asynchronously, and they are subject to scheduling variability.

With Oracle Restart, restart and recovery are automatic, including the restarting of the subsystems, such as the listener and the Oracle Automatic Storage Management (Oracle ASM) processes, not just the database. You can use FAN callouts to report faults to your fault management system and to initiate repair jobs.

4.1.7.2.2 Managing Planned Outages

For repairs, upgrades, and changes that require you to shut down the primary database, Oracle Restart provides interfaces that disable and enable services to minimize service disruption to application users.

Using Oracle Data Guard Broker with Oracle Restart allows a coordinated failover of the database service from the primary to the standby for the duration of the planned outage. Once you complete the operation, you can return the service to normal operation.

The management policy for a service controls whether the service starts automatically when the database is restarted. If the management policy for a service is set to AUTOMATIC, then it restarts automatically. If the management policy for a service is set to MANUAL, then it must be started manually.

 **See Also:**

["Modifying the Oracle Restart Configuration for a Component"](#)

4.1.7.2.3 Fast Application Notification High Availability Events

Understand FAN event record parameters and the event types.

Table 4-4 describes the FAN event record parameters and the event types, followed by name-value pairs for the event properties. The event type is always the first entry and the timestamp is always the last entry. In the following example, the name in the name-value pair is shown in **Fan event type (service_member)**, and the value in the name-value pair is shown in **Properties**:

```
FAN event type: service_member
Properties: version=1.0 service=ERP database=FINPROD instance=FINPROD host=node1
status=up
```

Table 4-4 Event Record Parameters and Descriptions

Parameter	Description
VERSION	Version of the event record. Used to identify release changes.
EVENT TYPE	SERVICE, SERVICE_MEMBER, DATABASE, INSTANCE, NODE, ASM, SRV_PRECONNECT. Note that database and Instance types provide the database service, such as DB_UNIQUE_NAME.DB_DOMAIN.
DATABASE UNIQUE NAME	The unique database supporting the service; matches the initialization parameter value for DB_UNIQUE_NAME, which defaults to the value of the initialization parameter DB_NAME.
INSTANCE	The name of the instance that supports the service; matches the ORACLE_SID value.
NODE NAME	The name of the node that supports the service or the node that has stopped; matches the node name known to Cluster Synchronization Services (CSS).
SERVICE	The service name; matches the service in DBA_SERVICES.
STATUS	Values are UP, DOWN, NOT_RESTARTING, PRECONN_UP, PRECONN_DOWN, and UNKNOWN.
REASON	Data_Guard_Failover, Failure, Dependency, User, Autostart, Restart.
CARDINALITY	The number of service members that are currently active; included in all UP events.
TIMESTAMP	The local time zone to use when ordering notification events.

A FAN record matches the database signature of each session as shown in [Table 4-5](#).

Table 4-5 FAN Parameters and Matching Database Signatures

FAN Parameter	Matching Oracle Database Signature
SERVICE	sys_context('userenv', 'service_name')
DATABASE UNIQUE NAME	sys_context('userenv', 'db_unique_name')
INSTANCE	sys_context('userenv', 'instance_name')
NODE NAME	sys_context('userenv', 'server_host')

4.1.7.2.4 Using Fast Application Notification Callouts

FAN callouts are server-side executables that Oracle Restart executes immediately when high availability events occur.

You can use FAN callouts to automate the following activities when events occur, such as:

- Opening fault tracking tickets
- Sending messages to pagers
- Sending e-mail
- Starting and stopping server-side applications
- Maintaining an uptime log by logging each event as it occurs

To use FAN callouts:

- Place an executable in the directory grid_home/racg/usrco on both the primary and the standby database servers. If you are using scripts, then set the shell as the first line of the executable.

The following is an example file for the grid_home/racg/usrco/callout.sh callout:

```
#!/bin/ksh
$FAN_LOGFILE= [your path name]/admin/log/`hostname`_uptime.log
echo $* "reported=`date`" >> $FAN_LOGFILE &
```

The following output is from the previous example:

```
NODE VERSION=1.0 host=sun880-2 status=nodedown reason=
timestamp=08-Oct-2004 04:02:14 reported=Fri Oct 8 04:02:14 PDT 2004
```

A FAN record matches the database signature of each session, as shown in [Table 4-5](#). Use this information to take actions on sessions that match the FAN event data.

 **See Also:**

[Table 4-4](#) for information about the callout and event details

4.1.7.2.5 Oracle Clients That Are Integrated with Fast Application Notification

Oracle has integrated FAN with many of the common Oracle client drivers that are used to connect to Oracle Restart databases. Therefore, the easiest way to use FAN is to use an integrated Oracle Client.

You can use the CMAN session pools, Oracle Call Interface, Universal Connection Pool for Java, JDBC simplefan API, and ODP.NET connection pools. The overall goal is to enable applications to consistently obtain connections to the available primary database at anytime.

 **See Also:**

["Automating the Failover of Connections Between Primary and Standby Databases"](#)

4.2 Configuring Oracle Restart

To configure Oracle Restart, you can add components, remove components, or modify options for components.

- [About Configuring Oracle Restart](#)

If you install Oracle Restart by installing the Oracle Grid Infrastructure for Standalone Servers and then create your database, the database is automatically added to the Oracle Restart configuration, and is then automatically restarted when required. However, if you install Oracle Restart on a host computer on which a database already exists, you must manually add the database, the listener, the Oracle Automatic Storage Management (Oracle ASM) instance, and possibly other components to the Oracle Restart configuration.

- [Preparing to Run SRVCTL](#)

Many Oracle Restart tasks require that you run the SRVCTL utility. You must ensure that you run SRVCTL from the correct Oracle home, and that you log in to the host computer with the correct user account.

- [Obtaining Help for SRVCTL](#)

Online help is available for the SRVCTL utility.

- [Adding Components to the Oracle Restart Configuration](#)

In most cases, creating an Oracle component on a host that is running Oracle Restart automatically adds the component to the Oracle Restart configuration. However, in some cases, you must add components manually.

- [Removing Components from the Oracle Restart Configuration](#)

When you use an Oracle-recommended method to delete an Oracle component, the component is also automatically removed from the Oracle Restart configuration.

- [Disabling and Enabling Oracle Restart Management for a Component](#)

You can temporarily disable Oracle Restart management for a component. One reason to do this is when you are performing maintenance on the component. For example, if a component must be repaired, then you might not want it to be

automatically restarted if it fails or if the host computer is restarted. When maintenance is complete, you can reenable management for the component.

- [Viewing Component Status](#)
You can use SRVCTL to view the running status (running or not running) for any component managed by Oracle Restart. For some components, additional information is also displayed.
- [Viewing the Oracle Restart Configuration for a Component](#)
You can use SRVCTL to view the Oracle Restart configuration for any component. Oracle Restart maintains different configuration information for each component type. In one form of the SRVCTL command, you can obtain a list of components managed by Oracle Restart.
- [Modifying the Oracle Restart Configuration for a Component](#)
You can use SRVCTL to modify the Oracle Restart configuration of a component. For example, you can modify the port number that a listener listens on when Oracle Restart starts it, or the server parameter file (SPFILE) that Oracle Restart points to when it starts a database.
- [Managing Environment Variables in the Oracle Restart Configuration](#)
The Oracle Restart configuration can store name/value pairs for environment variables.
- [Creating and Deleting Database Services with SRVCTL](#)
When managing a database with Oracle Restart, Oracle recommends that you use SRVCTL to create and delete database services. When you use SRVCTL to add a database service, the service is automatically added to the Oracle Restart configuration and a dependency between the service and the database is established. Thus, if you start the service, Oracle Restart first starts the database if it is not started.
- [Enabling FAN Events in an Oracle Restart Environment](#)
To enable Oracle Restart to publish Fast Application Notification (FAN) events, you must create an Oracle Notification Services (ONS) network that includes the Oracle Restart servers and the integrated clients.
- [Automating the Failover of Connections Between Primary and Standby Databases](#)
In a configuration that uses Oracle Restart and Oracle Data Guard primary and standby databases, the database services fail over automatically from the primary to the standby during either a switchover or failover.
- [Enabling Clients for Fast Connection Failover](#)
Fast Connection Failover provides high availability to Fast Application Notification (FAN) integrated clients, such as clients that use JDBC, OCI, or ODP.NET. If you configure the client to use fast connection failover, then the client automatically subscribes to FAN events and can react to database UP and DOWN events. In response, Oracle Database gives the client a connection to an active instance that provides the requested database service.

4.2.1 About Configuring Oracle Restart

If you install Oracle Restart by installing the Oracle Grid Infrastructure for Standalone Servers and then create your database, the database is automatically added to the Oracle Restart configuration, and is then automatically restarted when required. However, if you install Oracle Restart on a host computer on which a database already exists, you must manually add the database, the listener, the Oracle Automatic Storage Management (Oracle ASM) instance, and possibly other components to the Oracle Restart configuration.

After configuring Oracle Restart to manage your database, you may want to:

- Add additional components to the Oracle Restart configuration.
- Remove components from the Oracle Restart configuration.
- Temporarily suspend Oracle Restart management for one or more components.
- Modify the Oracle Restart configuration options for an individual component.

 **See Also:**

["About Oracle Restart"](#)

4.2.2 Preparing to Run SRVCTL

Many Oracle Restart tasks require that you run the SRVCTL utility. You must ensure that you run SRVCTL from the correct Oracle home, and that you log in to the host computer with the correct user account.

Table 4-6 lists the components that you can configure with SRVCTL, and for each component, lists the Oracle home from which you must run SRVCTL.

Table 4-6 Determining the Oracle Home from which to Start SRVCTL

Component Being Configured	Oracle Home from which to Start SRVCTL
Database, database service	Database home
Oracle ASM instance, disk group, listener ¹ , ONS	Oracle Grid Infrastructure home

¹ Assumes the listener was started from the Oracle Grid Infrastructure home. If you installed Oracle Restart for an existing database, the listener may have been started from the database home, in which case you start SRVCTL from the database home.

To prepare to run SRVCTL:

1. Use [Table 4-6](#) to determine the Oracle home from which you must run SRVCTL.
2. If you intend to run a SRVCTL command that modifies the Oracle Restart configuration (add, remove, enable, disable, and so on), then do one of the following:
 - On UNIX and Linux, log in to the database host computer as the user who installed the Oracle home that you determined in Step 1.
 - On Windows, log in to the database host computer as an Administrator.Otherwise, log in to the host computer as any user.
3. Open the command window that you will use to enter the SRVCTL commands.
To enter commands, you might need to ensure that the SRVCTL program is in your PATH environment variable. Otherwise, you can enter the absolute path to the program.

4.2.3 Obtaining Help for SRVCTL

Online help is available for the SRVCTL utility.

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Enter the following command:

```
srvctl
```

For more detailed help, enter the following command:

```
srvctl -help
```

For detailed help on a particular command, enter:

```
srvctl command -help
```

For example, to obtain help for the add command and the different options for each component type, enter:

```
srvctl add -help
```

For detailed help on a particular command for a particular component type, enter:

```
srvctl command object -help
```

For example, to obtain help about adding a database service, enter the following command:

```
srvctl add service -help
```

See "[SRVCTL Command Reference for Oracle Restart](#)" for a list of SRVCTL commands and [Table 4-7](#) for a list of components.

Starting with Oracle Database 12c, single-letter parameters are deprecated in favor of keyword parameters. To support backward compatibility, you can use a mix of single-letter parameters and new keyword parameters. The help shows the keyword parameters by default, but you can obtain the single-letter equivalents, where applicable, by adding the `-compatible` parameter after the `-help` parameter.

For example, to obtain help about adding a database service that includes the single-letter equivalents, enter the following command:

```
srvctl add service -help -compatible
```

The single-letter equivalents appear in parentheses next to the keyword parameters. Parameters that are new in Oracle Database 12c do not have single-letter equivalents.

4.2.4 Adding Components to the Oracle Restart Configuration

In most cases, creating an Oracle component on a host that is running Oracle Restart automatically adds the component to the Oracle Restart configuration. However, in some cases, you must add components manually.

(See [Table 4-2](#).) The component is then automatically restarted when required.

The following are occasions when you must manually add components to the Oracle Restart configuration with SRVCTL:

- You install Oracle Restart after creating the database.
- You create an additional Oracle database on the same host computer using the CREATE DATABASE SQL statement.
- You create a database service with DBMS_SERVICE.CREATE_SERVICE package procedure. (The recommended way is to use SRVCTL.)

Note:

Adding a component to the Oracle Restart configuration is also referred to as "registering a component with Oracle Restart."

Adding a component to the Oracle Restart configuration does not start that component. You must use a `srvctl start` command to start it.

When you add a component to the Oracle Restart configuration with SRVCTL, you can specify optional configuration settings for the component.

To add a component to the Oracle Restart configuration with SRVCTL:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Enter the following command:

```
srvctl add object options
```

where *object* is one of the components listed in [Table 4-7](#). See the SRVCTL `add` command for available options for each component.

Example 4-1 Adding a Database

This example adds a database with a `DB_UNIQUE_NAME` of `dbcrm`. The mandatory `-oraclehome` option specifies the Oracle home location.

```
srvctl add database -db dbcrm -oraclehome /u01/app/oracle/product/12.1.0/dbhome_1
```

Example 4-2 Adding a Database Service

For the database with the `DB_UNIQUE_NAME` of `dbcrm`, this example both creates a new database service named `crmbatch` and adds it to the Oracle Restart configuration.

```
srvctl add service -db dbcrm -service crmbatch
```

See "[Creating and Deleting Database Services with SRVCTL](#)" for more examples.

Example 4-3 Adding the Default Listener

This example adds the default listener to the Oracle Restart configuration.

```
srvctl add listener
```

 **Note:**

When you install a database or manually add a database to the Oracle Restart configuration, and you have a separate Oracle Grid Infrastructure installation owner user, then you must also add the grid user as a member of the OSRACDBA group of that database to enable Oracle Grid Infrastructure components to connect to the database. This is because the Oracle Grid Infrastructure components must be able to connect to the database as SYSRAC to start and stop the database.

For example, if the host user who installed the Oracle Grid Infrastructure home is named `grid` and the OSRACDBA group of the Oracle home is named `racdba`, then user `grid` must be a member of the `racdba` group.

 **See Also:**

- ["Starting and Stopping Components Managed by Oracle Restart"](#)
- ["Operating System Groups"](#)
- ["SRVCTL Command Reference for Oracle Restart"](#)

4.2.5 Removing Components from the Oracle Restart Configuration

When you use an Oracle-recommended method to delete an Oracle component, the component is also automatically removed from the Oracle Restart configuration.

For example, if you use Database Configuration Assistant (DBCA) to delete a database, DBCA removes the database from the Oracle Restart configuration. Likewise, if you use Oracle Net Configuration Assistant (NETCA) to delete a listener, NETCA removes the listener from the Oracle Restart configuration. See [Table 4-3](#) for more examples. If you use a non-recommended or manual method to delete an Oracle component, you must first use SRVCTL to remove the component from the Oracle Restart configuration. Failing to do so could result in an error.

To remove a component from the Oracle Restart configuration:

1. Prepare to run SRVCTL as described in ["Preparing to Run SRVCTL"](#).
2. Enter the following command:

```
srvctl remove object [options]
```

where `object` is one of the components listed in [Table 4-7](#). See the SRVCTL `remove` command for available options for each component.

Example 4-4 Removing a Database

This example removes a database with a DB_UNIQUE_NAME of `dbcrm`.

```
srvctl remove database -db dbcrm
```

 **See Also:**

["SRVCTL Command Reference for Oracle Restart"](#)

4.2.6 Disabling and Enabling Oracle Restart Management for a Component

You can temporarily disable Oracle Restart management for a component. One reason to do this is when you are performing maintenance on the component. For example, if a component must be repaired, then you might not want it to be automatically restarted if it fails or if the host computer is restarted. When maintenance is complete, you can reenable management for the component.

When you disable a component:

- It is no longer automatically restarted.
- It is no longer automatically started through a dependency.
- It cannot be started with SRVCTL.
- Any component dependent on this resource is no longer automatically started or restarted.

To disable or enable automatic restart for a component:

1. Prepare to run SRVCTL, as described in ["Preparing to Run SRVCTL"](#).
2. Do one of the following:

- To disable a component, enter the following command:

```
srvctl disable object [options]
```

- To enable a component, enter the following command:

```
srvctl enable object [options]
```

Replace *object* with one of the components listed in [Table 4-7](#). See the SRVCTL [disable](#) command and the [enable](#) command for available options for each component.

Example 4-5 Disabling Automatic Restart for a Database

This example disables automatic restart for a database with a DB_UNIQUE_NAME of dbcrm.

```
srvctl disable database -db dbcrm
```

Example 4-6 Disabling Automatic Restart for an Oracle ASM Disk Group

This example disables automatic restart for the Oracle ASM disk group named recovery.

```
srvctl disable diskgroup -diskgroup recovery
```

Example 4-7 Enabling Automatic Restart for an Oracle ASM Disk Group

This example reenables automatic restart for the disk group recovery.

```
srvctl enable diskgroup -diskgroup recovery
```

 **See Also:**

["SRVCTL Command Reference for Oracle Restart"](#)

4.2.7 Viewing Component Status

You can use SRVCTL to view the running status (running or not running) for any component managed by Oracle Restart. For some components, additional information is also displayed.

To view component status:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Enter the following command:

```
srvctl status object [options]
```

where *object* is one of the components listed in [Table 4-7](#). See the SRVCTL [status](#) command for available options for each component.

Example 4-8 Viewing Status of a Database

This example displays the status of the database with a DB_UNIQUE_NAME of dbcrm.

```
srvctl status database -db dbcrm
```

```
Database is running.
```

 **See Also:**

["SRVCTL Command Reference for Oracle Restart"](#)

4.2.8 Viewing the Oracle Restart Configuration for a Component

You can use SRVCTL to view the Oracle Restart configuration for any component. Oracle Restart maintains different configuration information for each component type. In one form of the SRVCTL command, you can obtain a list of components managed by Oracle Restart.

To view component configuration:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Enter the following command:

```
srvctl config object options
```

where *object* is one of the components listed in [Table 4-7](#). See the SRVCTL [config](#) command for available options for each component.

Example 4-9 Viewing a List of All Databases Managed by Oracle Restart

```
srvctl config database
```

```
dbcsm  
orcl
```

Example 4-10 Viewing the Configuration of a Particular Database

This example displays the configuration of the database with a DB_UNIQUE_NAME of orcl.

```
srvctl config database -db orcl
```

```
Database unique name: orcl
Database name: orcl
Oracle home: /u01/app/oracle/product/12.1.0/dbhome_1
Oracle user: oracle
Spfile: +DATA/orcl/spfileorcl.ora
Domain: us.example.com
Start options: open
Stop options: immediate
Database role:
Management policy: automatic
Disk Groups: DATA
Services: mfg,sales
```

 **See Also:**

["SRVCTL Command Reference for Oracle Restart"](#)

4.2.9 Modifying the Oracle Restart Configuration for a Component

You can use SRVCTL to modify the Oracle Restart configuration of a component. For example, you can modify the port number that a listener listens on when Oracle Restart starts it, or the server parameter file (SPFILE) that Oracle Restart points to when it starts a database.

To modify the Oracle Restart configuration for a component:

1. Prepare to run SRVCTL as described in "Preparing to Run SRVCTL".
2. Enter the following command:

```
srvctl modify object options
```

where *object* is one of the components listed in [Table 4-7](#). See the SRVCTL **modify** command for available options for each component.

Example 4-11 Modifying the Oracle Restart Configuration for a Database

For the database with a DB_UNIQUE_NAME of dbcrm, the following command changes the management policy to MANUAL and the start option to NOMOUNT.

```
srvctl modify database -db dbcrm -policy MANUAL -startoption NOMOUNT
```

With a `MANUAL` management policy, the database is never automatically started when the database host computer is restarted. However, Oracle Restart continues to monitor the database and restarts it if a failure occurs.

 **See Also:**

- ["Viewing the Oracle Restart Configuration for a Component"](#)
- ["SRVCTL Command Reference for Oracle Restart"](#)

4.2.10 Managing Environment Variables in the Oracle Restart Configuration

The Oracle Restart configuration can store name/value pairs for environment variables.

- [About Environment Variables in the Oracle Restart Configuration](#)
You can set environment variable values in the Oracle Restart configuration.
- [Setting and Unsetting Environment Variables](#)
You use SRVCTL to set and unset environment variable values in the Oracle Restart configuration for a component.
- [Viewing Environment Variables](#)
You use SRVCTL to view the values of environment variables in the Oracle Restart configuration for a component.

4.2.10.1 About Environment Variables in the Oracle Restart Configuration

You can set environment variable values in the Oracle Restart configuration.

If you typically set environment variables (other than `ORACLE_HOME` and `ORACLE_SID`) before starting your Oracle database, then you can set these environment variable values in the Oracle Restart configuration. You can store any number environment variables in the individual configurations of the following components:

- Database instance
- Listener
- Oracle ASM instance

When Oracle Restart starts one of these components, it first sets environment variables for that component to the values stored in the component configuration. Although you can set environment variables that are used by Oracle components in this manner, this capability is primarily intended for operating system environment variables.

The following sections provide instructions for setting, unsetting, and viewing environment variables:

- [Setting and Unsetting Environment Variables](#)
- [Viewing Environment Variables](#)

 **Note:**

Do not use this facility to set standard environment variables like ORACLE_HOME and ORACLE_SID; these are set automatically by Oracle Restart.

4.2.10.2 Setting and Unsetting Environment Variables

You use SRVCTL to set and unset environment variable values in the Oracle Restart configuration for a component.

To set or unset environment variables in the configuration:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".

2. Do one of the following:

- To set an environment variable in the configuration, enter the following command:

```
srvctl setenv {asm|database|listener} options
```

- To remove an environment variable from the configuration, enter the following command:

```
srvctl unsetenv {asm|database|listener} options
```

See the SRVCTL [setenv](#) command and the [unsetenv](#) command for available options for each component.

Example 4-12 Setting Database Environment Variables

This example sets the NLS_LANG and the AIX AIXTHREAD_SCOPE environment variables in the Oracle Restart configuration for the database with a DB_UNIQUE_NAME of dbcrm:

```
srvctl setenv database -db dbcrm -envs "NLS_LANG=AMERICAN_AMERICA.AL32UTF8,  
AIXTHREAD_SCOPE=S"
```

 **See Also:**

"[SRVCTL Command Reference for Oracle Restart](#)"

4.2.10.3 Viewing Environment Variables

You use SRVCTL to view the values of environment variables in the Oracle Restart configuration for a component.

To view environment variable values in the configuration:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Enter the following command:

```
srvctl getenv {database|listener|asm} options
```

See the SRVCTL [getenv](#) command for available options for each component.

Example 4-13 Viewing All Environment Variables for a Database

This example gets and displays the environment variables in the Oracle Restart configuration for the database with a DB_UNIQUE_NAME of dbcrm:

```
srvctl getenv database -db dbcrm

dbcrm:
NLS_LANG=AMERICAN_AMERICA
AIXTHREAD_SCOPE=S
GCONF_LOCAL_LOCKS=1
```

Example 4-14 Viewing Specific Environment Variables for a Database

This example gets and displays the NLS_LANG and AIXTHREAD_SCOPE environment variables from the Oracle Restart configuration for the same database:

```
srvctl getenv database -db dbcrm -envs "NLS_LANG,AIXTHREAD_SCOPE"

dbcrm:
NLS_LANG=AMERICAN_AMERICA
AIXTHREAD_SCOPE=S
```

 **See Also:**

["SRVCTL Command Reference for Oracle Restart"](#)

4.2.11 Creating and Deleting Database Services with SRVCTL

When managing a database with Oracle Restart, Oracle recommends that you use SRVCTL to create and delete database services. When you use SRVCTL to add a database service, the service is automatically added to the Oracle Restart configuration and a dependency between the service and the database is established. Thus, if you start the service, Oracle Restart first starts the database if it is not started.

When you use SRVCTL to delete a database service, the service is also removed from the Oracle Restart configuration.

To create a database service with SRVCTL:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Enter the following command:

```
srvctl add service -db db_unique_name -service service_name [options]
```

The database service is created and added to the Oracle Restart configuration. See the [srvctl add service](#) command for available options.

To delete a database service with SRVCTL:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Enter the following command:

```
srvctl remove service -db db_unique_name -service service_name [-force]
```

The database service is removed from the Oracle Restart configuration. If the `-force` flag is present, the service is removed even if it is still running. Without this flag, an error occurs if the service is running.

Example 4-15 Creating a Database Service

For the database with the `DB_UNIQUE_NAME` of `dbcrm`, this example creates a new database service named `crmbatch`.

```
srvctl add service -db dbcrm -service crmbatch
```

Example 4-16 Creating a Role-Based Database Service

This example creates the `crmbatch` database service and assigns it the Data Guard role of `PHYSICAL_STANDBY`. The service is automatically started only if the current role of the `dbcrm` database is physical standby.

```
srvctl add service -db dbcrm -service crmbatch -role PHYSICAL_STANDBY
```

 **See Also:**

["SRVCTL Command Reference for Oracle Restart"](#)

4.2.12 Enabling FAN Events in an Oracle Restart Environment

To enable Oracle Restart to publish Fast Application Notification (FAN) events, you must create an Oracle Notification Services (ONS) network that includes the Oracle Restart servers and the integrated clients.

These clients can include Oracle Connection Manager (CMAN), Java Database Connectivity (JDBC), and Universal Connection Pool (UCP) clients. If you are using Oracle Call Interface or ODP.NET clients, then you must enable Oracle Advanced Queuing (AQ) HA notifications for your services. In addition, ONS must be running on the server.

To enable FAN events in an Oracle Restart environment:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Add the database to the Oracle Restart Configuration if it is not already managed by Oracle Restart. See "[Adding Components to the Oracle Restart Configuration](#)".
3. Add ONS to the configuration:

```
srvctl add ons
```

ONS is disabled when it is added.

4. Enable ONS:

```
srvctl enable ons
```

5. Start ONS:

```
srvctl start ons
```

6. Add the service to the Oracle Restart Configuration.

For Oracle Call Interface and ODP.NET clients, ensure that the `-notification` option is set to `TRUE` to enable the database queue.

See "[Creating and Deleting Database Services with SRVCTL](#)".

7. Enable each client for fast connection failover. See "[Enabling Clients for Fast Connection Failover](#)".

 **See Also:**

["SRVCTL Command Reference for Oracle Restart"](#)

4.2.13 Automating the Failover of Connections Between Primary and Standby Databases

In a configuration that uses Oracle Restart and Oracle Data Guard primary and standby databases, the database services fail over automatically from the primary to the standby during either a switchover or failover.

You can use Oracle Notification Services (ONS) to immediately notify clients of the failover of services between the primary and standby databases. The Oracle Data Guard Broker uses Fast Application Notification (FAN) to send notifications to clients when a failover occurs. Integrated Oracle clients automatically failover connections and applications can mask the failure from end-users.

To automate connection failover, you must create an ONS network that includes the Oracle Restart servers and the integrated clients (CMAN, listener, JDBC, and UCP). If you are using Oracle Call Interface or ODP.NET clients, you must enable the Oracle Advanced Queuing queue. The database and the services must be managed by Oracle Restart and the Oracle Data Guard Broker to automate the failover of services.

To automate the failover of services between primary and standby databases:

1. Configure the primary and standby database with the Oracle Data Guard Broker. See [Oracle Data Guard Broker](#).
2. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
3. Add the primary database to the Oracle Restart configuration on the primary server if it has not been added. Ensure that you specify `PRIMARY` for the database role. See "[Adding Components to the Oracle Restart Configuration](#)".
4. Add the standby database to the Oracle Restart configuration on the standby server if it has not been added. Ensure that you specify the appropriate standby database role.
5. Enable FAN events on both the primary database server and the standby database server. "[Enabling FAN Events in an Oracle Restart Environment](#)".
6. Add the services that clients will use to connect to the databases to the Oracle Restart configuration on the primary database and the standby database. When you add a service, ensure that:
 - The `-role` option is set to the proper role for each service

- The `-notification` option is set to `TRUE` if you are using ODP.NET or Oracle Call Interface

See "[Creating and Deleting Database Services with SRVCTL](#)".

7. Enable each client for fast connection failover. See "[Enabling Clients for Fast Connection Failover](#)".

 **See Also:**

["SRVCTL Command Reference for Oracle Restart"](#)

4.2.14 Enabling Clients for Fast Connection Failover

Fast Connection Failover provides high availability to Fast Application Notification (FAN) integrated clients, such as clients that use JDBC, OCI, or ODP.NET. If you configure the client to use fast connection failover, then the client automatically subscribes to FAN events and can react to database UP and DOWN events. In response, Oracle Database gives the client a connection to an active instance that provides the requested database service.

- [About Enabling Clients for Fast Connection Failover](#)

In a configuration with a standby database, after you have added Oracle Notification Services (ONS) to your Oracle Restart configurations and enabled Oracle Advanced Queuing (AQ) HA notifications for your services, you can enable clients for fast connection failover.

- [Enabling Fast Connection Failover for JDBC Clients](#)

Enabling FAN for the Oracle Universal Connection Pool enables Fast Connection Failover (FCF) for the client. Your application can use either thick or thin JDBC clients to use FCF.

- [Enabling Fast Connection Failover for Oracle Call Interface Clients](#)

Oracle Call Interface clients can enable Fast Connection Failover (FCF) by registering to receive notifications about Oracle Restart high availability FAN events and respond when events occur.

- [Enabling Fast Connection Failover for ODP.NET Clients](#)

Oracle Data Provider for .NET (ODP.NET) connection pools can subscribe to notifications that indicate when services are down. After a `DOWN` event, Oracle Database cleans up sessions in the connection pool that go to the instance that stops, and ODP.NET proactively disposes connections that are no longer valid.

4.2.14.1 About Enabling Clients for Fast Connection Failover

In a configuration with a standby database, after you have added Oracle Notification Services (ONS) to your Oracle Restart configurations and enabled Oracle Advanced Queuing (AQ) HA notifications for your services, you can enable clients for fast connection failover.

The clients receive Fast Application Notification (FAN) events and can relocate connections to the current primary database after an Oracle Data Guard failover. See "[Automating the Failover of Connections Between Primary and Standby Databases](#)" for information about adding ONS.

For databases with no standby database configured, you can still configure the client FAN events. When there is a failure, you can configure the client to retry the connection to the database. Since Oracle Restart will restart the failed database, the client can reconnect when the database restarts. Ensure that you program the appropriate delay and retries on the connection string, as illustrated in the examples in this section.

4.2.14.2 Enabling Fast Connection Failover for JDBC Clients

Enabling FAN for the Oracle Universal Connection Pool enables Fast Connection Failover (FCF) for the client. Your application can use either thick or thin JDBC clients to use FCF.

To configure the JDBC client, set the `FastConnectionFailoverEnabled` property before making the first `getConnection()` request to a data source. When you enable Fast Connection Failover, the failover applies to every connection in the connection cache. If your application explicitly creates a connection cache using the Connection Cache Manager, then you must first set `FastConnectionFailoverEnabled`.

This section describes how to enable FCF for JDBC with the Universal Connection Pool. For thick JDBC clients, if you enable Fast Connection Failover, do not enable Transparent Application Failover (TAF), either on the client or for the service. Enabling FCF with thin or thick JDBC clients enables the connection pool to receive and react to all FAN events.

To enable Fast Connection Failover for JDBC clients:

1. On a cache enabled `DataSource`, set the `DataSource` property `FastConnectionFailoverEnabled` to `true` as in the following example to enable FAN for the Oracle JDBC Implicit Connection Cache:

```
PoolDataSource pds = PoolDataSourceFactory.getPoolDataSource();
pds.setONSConfiguration("nodes=primaryhost:6200,standbyhost:6200");
pds.setFastConnectionFailoverEnabled(true);
pds.setURL("jdbc:oracle:thin:@(DESCRIPTION=
    (LOAD_BALANCE=on)
    (ADDRESS=(PROTOCOL=TCP)(HOST=primaryhost)(PORT=1521))
    (ADDRESS=(PROTOCOL=TCP)(HOST=standbyhost)(PORT=1521))
    (CONNECT_DATA=(service_name=service_name)))");
```

.....

In this example, `primaryhost` is the server for the primary database, and `standbyhost` is the server for the standby database.

Applications must have both `ucp.jar` and `ons.jar` in their `CLASSPATH`.

 **Note:**

Use the following system property to enable FAN without making data source changes: `-D oracle.jdbc.FastConnectionFailover=true`.

2. When you start the application, ensure that the `ons.jar` file is located on the application `CLASSPATH`. The `ons.jar` file is part of the Oracle client installation.

 **See Also:**

- *Oracle Database JDBC Developer's Guide*
- *Oracle Universal Connection Pool Developer's Guide*

4.2.14.3 Enabling Fast Connection Failover for Oracle Call Interface Clients

Oracle Call Interface clients can enable Fast Connection Failover (FCF) by registering to receive notifications about Oracle Restart high availability FAN events and respond when events occur.

This improves the session failover response time in Oracle Call Interface and removes terminated connections from connection and session pools. This feature works on Oracle Call Interface applications, including those that use Transparent Application Failover (TAF), connection pools, or session pools.

First, you must enable a service for high availability events to automatically populate the Advanced Queuing ALERT_QUEUE. If your application is using TAF, then enable the TAF settings for the service. Configure client applications to connect to an Oracle Restart database. Clients can register callbacks that are used whenever an event occurs. This reduces the time that it takes to detect a connection failure.

During DOWN event processing, Oracle Call Interface:

- Terminates affected connections at the client and returns an error
- Removes connections from the Oracle Call Interface connection pool and the Oracle Call Interface session pool

The session pool maps each session to a physical connection in the connection pool, and there can be multiple sessions for each connection.

- Fails over the connection if you have configured TAF

If TAF is not configured, then the client only receives an error.

 **Note:**

Oracle Call Interface does not manage UP events.

To Enable Fast Connection Failover for an Oracle Call Interface client:

1. Ensure that the service that you are using has Advanced Queuing notifications enabled by setting the services' values using the SRVCTL modify command. For example:

```
srvctl modify service -db proddb -service gl.us.example.com -notification true -role primary -failovertype select -failovermethod basic -failoverretry 5 -failoverdelay 180 -clbgoal long
```

2. Enable OCI_EVENTS at environment creation time on the client as follows:

```
( OCIEnvCreate(...) )
```

3. Link client applications with the client thread or operating system library.
4. (Optional) Register a client EVENT callback.
5. Ensure that the client uses an Oracle Net connect descriptor that includes all primary and standby hosts in the ADDRESS_LIST. For example:

```
gl =
(DESCRIPTION =
  (CONNECT_TIMEOUT=10)(RETRY_COUNT=3)
  (ADDRESS_LIST =
    (ADDRESS = (PROTOCOL = TCP)(HOST = BOSTON1)(PORT = 1521))
    (ADDRESS = (PROTOCOL = TCP)(HOST = CHICAGO1)(PORT = 1521))
    (LOAD_BALANCE = yes)
  )
  (CONNECT_DATA=
    (SERVICE_NAME=gl.us.example.com)))
```

To see the alert information, query the views DBA_OUTSTANDING_ALERTS and DBA_ALERT_HISTORY.

See Also:

- *Oracle Call Interface Programmer's Guide*
- *Oracle Database Net Services Administrator's Guide* for information about configuring TAF

4.2.14.4 Enabling Fast Connection Failover for ODP.NET Clients

Oracle Data Provider for .NET (ODP.NET) connection pools can subscribe to notifications that indicate when services are down. After a DOWN event, Oracle Database cleans up sessions in the connection pool that go to the instance that stops, and ODP.NET proactively disposes connections that are no longer valid.

All three ODP.NET providers (core, managed, and unmanaged) support FCF.

To enable Fast Connection Failover for ODP.NET clients:

1. Enable Fast Application Notification (FAN) by using SRVCTL modify service command, as in the following example:

```
srvctl modify service -db dbname -service gl -notification true
```
2. Enable Fast Connection Failover for ODP.NET connection pools by subscribing to FAN high availability events. Set the HA Events connection string attribute to true at connection time. In newer ODP.NET versions, HA Events is set to true by default. The pooling attribute must be set to true, which is the default. The following example illustrates these settings, where *user_name* is the name of the user and *password* is the user password:

```
// C#
using System;
using Oracle.ManagedDataAccess.Client;
//using Oracle.DataAccess.Client;

class HAEEventEnablingSample
```

```
{  
    static void Main()  
{  
        OracleConnection con = new OracleConnection();  
  
        // Open a connection using ConnectionString attributes  
        // Also, enable "load balancing"  
        con.ConnectionString =  
            "User Id=user_name;Password=password;Data Source=oracle;" +  
            "Min Pool Size=10;Connection Lifetime=120;Connection Timeout=60;" +  
            "HA Events=true;Incr Pool Size=5;Decr Pool Size=2";  
  
        con.Open();  
  
        // Create more connections and perform work against the database here.  
  
        // Dispose OracleConnection object  
        con.Dispose();  
    }  
}
```

3. Ensure that the client uses an Oracle Net connect descriptor that includes all primary and standby hosts in the ADDRESS_LIST. For example:

```
gl =  
(DESCRIPTION =  
  (CONNECT_TIMEOUT=10)(RETRY_COUNT=3)  
  (ADDRESS_LIST =  
    (ADDRESS = (PROTOCOL = TCP)(HOST = BOSTON1)(PORT = 1521))  
    (ADDRESS = (PROTOCOL = TCP)(HOST = CHICAGO1)(PORT = 1521))  
    (LOAD_BALANCE = yes)  
  )  
  (CONNECT_DATA=  
    (SERVICE_NAME=gl.us.example.com))  
)
```

 **See Also:**

- *Oracle Data Provider for .NET Developer's Guide for Microsoft Windows* for information about ODP.NET
- "[SRVCTL Command Reference for Oracle Restart](#)"

4.3 Starting and Stopping Components Managed by Oracle Restart

When Oracle Restart is in use, Oracle strongly recommends that you use the SRVCTL utility to start and stop components.

Use the SRVCTL utility to start and stop components for the following reasons:

- When starting a component with SRVCTL, Oracle Restart can first start any components on which this component depends. When stopping a component with SRVCTL, Oracle Restart can stop any dependent components first.
- SRVCTL always starts a component according to its Oracle Restart configuration. Starting a component by other means may not.

For example, if you specified a server parameter file (SPFILE) location when you added a database to the Oracle Restart configuration, and that location is not the default location for SPFILEs, if you start the database with SQL*Plus, the SPFILE specified in the configuration may not be used.

See the [srvctl add database](#) command for a table of configuration options for a database instance.

- When you start a component with SRVCTL, environment variables stored in the Oracle Restart configuration for the component are set.

See "[Managing Environment Variables in the Oracle Restart Configuration](#)" for more information.

You can start and stop any component managed by Oracle Restart with SRVCTL.

To start or stop a component managed by Oracle Restart with SRVCTL:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Do one of the following:

- To start a component, enter the following command:

```
srvctl start object [options]
```

- To stop a component, enter the following command:

```
srvctl stop object [options]
```

where *object* is one of the components listed in [Table 4-7](#). See the SRVCTL [start](#) command and the [stop](#) command for available options for each component.

Example 4-17 Starting a Database

This example starts the database with a DB_UNIQUE_NAME of dbcrm:

```
srvctl start database -db dbcrm
```

Example 4-18 Starting a Database NOMOUNT

This example starts the database instance without mounting the database:

```
srvctl start database -db dbcrm -startoption nomount
```

Example 4-19 Starting the Default Listener

This example starts the default listener:

```
srvctl start listener
```

Example 4-20 Starting a Specified Listener

This example starts the listener named crmlistener:

```
srvctl start listener -listener crmlistener
```

Example 4-21 Starting Database Services

This example starts the database services `bizdev` and support for the database with a `DB_UNIQUE_NAME` of `dbcrrm`. If the database is not started, Oracle Restart first starts the database.

```
srvctl start service -db dbcrrm -service "bizdev,support"
```

Example 4-22 Starting (Mounting) Oracle ASM Disk Groups

This example starts (mounts) the Oracle ASM disk groups `data` and `recovery`. The user running this command must be a member of the OSASM group.

```
srvctl start diskgroup -diskgroup "data,recovery"
```

Example 4-23 Shutting Down a Database

This example stops (shuts down) the database with a `DB_UNIQUE_NAME` of `dbcrrm`. Because a stop option (`-stopoption`) is not provided, the database shuts down according to the stop option in its Oracle Restart configuration. The default stop option is `IMMEDIATE`.

```
srvctl stop database -db dbcrrm
```

Example 4-24 Shutting Down a Database with the ABORT option

This example does a `SHUTDOWN ABORT` of the database with a `DB_UNIQUE_NAME` of `dbcrrm`.

```
srvctl stop database -db dbcrrm -stopoption abort
```

Note:

After relinking Oracle executables, use the SRVCTL utility to start and stop components when Oracle Restart is in use. Typically, relinking Oracle executables is required on a Linux or UNIX-based operating system after you apply an operating system patch or after an operating system upgrade. See *Oracle Database Administrator's Reference for Linux and UNIX-Based Operating Systems* for more information about relinking.

If you use SQL*Plus to start and stop components, then you must first run the `setasmgidwrap` script after relinking. See *Oracle Database Upgrade Guide* for information about running this script.

See Also:

The SRVCTL [start](#) command

4.4 Stopping and Restarting Oracle Restart for Maintenance Operations

When several components in an Oracle home are managed by Oracle Restart, you can stop Oracle Restart and the components managed by Oracle Restart in the Oracle home.

You can also disable Oracle Restart so that it is not restarted if the node reboots. You might need to do this when you are performing maintenance that includes the Oracle home, such as installing a patch. When the maintenance operation is complete, you can enable and restart Oracle Restart, and you can restart the components managed by Oracle Restart in the Oracle home.

Use both the SRVCTL utility and the CRSCTL utility for the stop and start operations:

- The `stop home` SRVCTL command stops all of the components that are managed by Oracle Restart in the specified Oracle home. The `start home` SRVCTL command starts these components. The Oracle home can be an Oracle Database home or an Oracle Grid Infrastructure home.

When you use the `home` object, a state file, specified in the `-statefile` option, tracks the state of each component. The `stop` and `status` commands create the state file. The `start` command uses the state file to identify the components to restart.

In addition, you can check the status of the components managed by Oracle Restart using the `status home` command.

- The `stop` CRSCTL command stops Oracle Restart, and the `disable` CRSCTL command ensures that the components managed by Oracle Restart do not restart automatically. The `enable` CRSCTL command enables automatic restart and the `start` CRSCTL command restarts Oracle Restart.

To stop and start the components in an Oracle home while installing a patch:

1. Prepare to run SRVCTL as described in "[Preparing to Run SRVCTL](#)".
2. Use the SRVCTL utility to stop the components managed by Oracle Restart in an Oracle home:

```
srvctl stop home -oraclehome oracle_home -statefile state_file [-stopoption  
stop_options] [-force]
```

where `oracle_home` is the complete path of the Oracle home and `state_file` is the complete path to the state file. State information for the Oracle home is recorded in the specified state file. Make a note of the state file location because it must be specified in Step 7.

Before stopping the components in an Oracle Grid Infrastructure home, ensure that you first stop the components in a dependent Oracle Database home.

3. If you are patching an Oracle Grid Infrastructure home, then disable and stop Oracle Restart. Otherwise, go to Step 4.

To disable and stop Oracle Restart, use the CRSCTL utility to run the following commands:

```
crsctl disable has
```

```
crsctl stop has
```

4. Perform the maintenance operation.
5. Use the CRSCTL utility to enable automatic restart of the components managed by Oracle Restart:

```
crsctl enable has
```

6. Use the CRSCTL utility to start Oracle Restart:

```
crsctl start has
```

7. Use the SRVCTL utility to start the components that were stopped in Step 2:

```
srvctl start home -oraclehome oracle_home -statefile state_file
```

The state file must match the state file specified in Step 2.

8. (Optional) Use the SRVCTL utility to check the status of the components managed by Oracle Restart in the Oracle home:

```
srvctl status home -oraclehome oracle_home -statefile state_file
```

Example 4-25 Stopping Components Managed by Oracle Restart in an Oracle Home

```
srvctl stop home -oraclehome /u01/app/oracle/product/12.1.0/dbhome_1 -statefile /usr1/or_state
```

Example 4-26 Starting Components Managed by Oracle Restart in an Oracle Home

```
srvctl start home -oraclehome /u01/app/oracle/product/12.1.0/dbhome_1 -statefile /usr1/or_state
```

Example 4-27 Displaying the Status of Components Managed by Oracle Restart in an Oracle Home

```
srvctl status home -oraclehome /u01/app/oracle/product/12.1.0/dbhome_1 -statefile /usr1/or_state
```

4.5 SRVCTL Command Reference for Oracle Restart

You can reference details about the syntax and options for SRVCTL commands specific to Oracle Restart.

See *Oracle Real Application Clusters Administration and Deployment Guide* for the full list of SRVCTL commands.

SRVCTL Command Syntax and Options Overview

SRVCTL expects the following command syntax:

```
srvctl command object options
```

where:

- *command* is a verb such as start, stop, or remove.
- *object* is the component on which SRVCTL performs the command, such as database, listener, and so on. You can also use component abbreviations. See [Table 4-7](#) for a complete list of components and their abbreviations.
- *options* extend the use of a preceding command combination to include additional parameters for the command. For example, the -db option indicates that a database unique name follows, and the -service option indicates that a comma-delimited list of database service names follows.

Note:

On the Windows platform, when specifying a comma-delimited list, you must enclose the list within double-quotes ("....."). You must also use double-quotes on the UNIX and Linux platforms if any list member contains shell metacharacters.

Case Sensitivity

SRVCTL commands and components are case insensitive. Options are case sensitive. Database and database service names are case insensitive and case preserving.

Command Parameters Input File

You can specify command parameters in a file rather than directly on the command line. Using a command parameters input file is useful in the following situations:

- You want to run a command with very long parameter values or a command with numerous parameters
- You want to bypass shell processing of certain special characters

To specify a command parameters input file, use the -file parameter with a value that is the location of the command parameters file. SRVCTL processes the command parameters from the command parameters file instead of from the command line.

SRVCTL Components Summary

[Table 4-7](#) lists the keywords that can be used for the *object* portion of SRVCTL commands. You can use either the full name or the abbreviation for each component keyword.

Table 4-7 Component Keywords and Abbreviations

Component	Abbreviation	Description
asm	asm	Oracle ASM instance
database	db	Database instance
diskgroup	dg	Oracle ASM disk group
home	home	Oracle home or Oracle Clusterware home
listener	lsnr	Oracle Net listener
service	serv	Database service
ons	ons	Oracle Notification Services (ONS)

- **add**
The `srvctl add` command adds the specified component to the Oracle Restart configuration, and optionally sets Oracle Restart configuration parameters for the component. After a component is added, Oracle Restart begins to manage it, restarting it when required.
- **config**
The `srvctl config` command displays the Oracle Restart configuration of the specified component or set of components.
- **disable**
Disables a component, which suspends management of that component by Oracle Restart.
- **downgrade**
The `srvctl downgrade` command downgrades the database configuration after you manually downgrade the database.
- **enable**
The `srvctl enable` command reenables the specified disabled component.
- **getenv**
Gets and displays environment variables and their values from the Oracle Restart configuration for a database, listener, or Oracle ASM instance.
- **modify**
Modifies the Oracle Restart configuration of a component. The change takes effect when the component is next restarted.
- **remove**
Removes the specified component from the Oracle Restart configuration. Oracle Restart no longer manages the component. Any environment variable settings for the component are also removed.
- **setenv**
The `setenv` command sets values of environment variables in the Oracle Restart configuration for a database, a listener, or the Oracle ASM instance.
- **start**
Starts the specified component or components.

- [status](#)
Displays the running status of the specified component or set of components.
- [stop](#)
Stops the specified component or components.
- [unsetenv](#)
The `unsetenv` command deletes one or more environment variables from the Oracle Restart configuration for a database, a listener, or an Oracle ASM instance.
- [update](#)
The `srvctl update` command updates the running database to switch to the specified startup option.
- [upgrade](#)
The `srvctl upgrade` command upgrades the resources types and resources from an older version to a newer version.

 **See Also:**

[Table 4-1](#)

4.5.1 add

The `srvctl add` command adds the specified component to the Oracle Restart configuration, and optionally sets Oracle Restart configuration parameters for the component. After a component is added, Oracle Restart begins to manage it, restarting it when required.

To perform `srvctl add` operations, you must be logged in to the database host computer with the proper user account. See "[Preparing to Run SRVCTL](#)" for more information.

 **Note:**

There is no `srvctl add` command for Oracle ASM disk groups. Disk groups are automatically added to the Oracle Restart configuration when they are first mounted. If you remove a disk group from the Oracle Restart configuration and later want to add it back, connect to the Oracle ASM instance with SQL*Plus and use an `ALTER DISKGROUP ... MOUNT` command.

- [srvctl add asm](#)
Adds an Oracle ASM instance to the Oracle Restart configuration.
- [srvctl add database](#)
Adds a database to the Oracle Restart configuration.
- [srvctl add listener](#)
Adds a listener to the Oracle Restart configuration.
- [srvctl add ons](#)
Adds Oracle Notification Services (ONS) to an Oracle Restart configuration.

- [srvctl add service](#)
Adds a database service to the Oracle Restart configuration.

4.5.1.1 srvctl add asm

Adds an Oracle ASM instance to the Oracle Restart configuration.

- [Syntax and Options](#)
- [Example](#)

4.5.1.1.1 Syntax and Options

Use the `srvctl add asm` command with the following syntax:

```
srvctl add asm [-listener listener_name] [-spfile spfile]
[-pwfile password_file_path] [-diskstring asm_diskstring]
```

Table 4-8 srvctl add asm Options

Option	Description
<code>-listener <i>listener_name</i></code>	Name of the listener with which Oracle ASM should register. A weak dependency is established with this listener. (Before starting the Oracle ASM instance, Oracle Restart attempts to start the listener. If the listener does not start, the Oracle ASM instance is still started. If the listener later fails, Oracle Restart does not restart Oracle ASM.) If omitted, defaults to the listener named <code>listener</code> .
<code>-spfile <i>spfile</i></code>	The full path of the server parameter file for the database. If omitted, the default SPFILE is used.
<code>-pwfile <i>password_file_path</i></code>	The full path of the Oracle ASM password file.
<code>-diskstring <i>asm_diskstring</i></code>	Oracle ASM disk group discovery string. An Oracle ASM discovery string is a comma-delimited list of strings that limits the set of disks that an Oracle ASM instance discovers. The discovery strings can include wildcard characters. Only disks that match one of the strings are discovered.

4.5.1.1.2 Example

An example of this command is:

```
srvctl add asm -listener crmlistener
```

 **See Also:**

Oracle Automatic Storage Management Administrator's Guide for more information about Oracle ASM disk group discovery strings

4.5.1.2 srvctl add database

Adds a database to the Oracle Restart configuration.

After adding a database to the Oracle Restart configuration, if the database then accesses data in an Oracle ASM disk group, a dependency between the database that disk group is created. Oracle Restart then ensures that the disk group is mounted before attempting to start the database.

However, if the database and Oracle ASM instance are not running when you add the database to the Oracle Restart configuration, you must manually establish the dependency between the database and its disk groups by specifying the `-diskgroup` option in the SRVCTL command. See the example later in this section.

 **Note:**

When you manually add a database to the Oracle Restart configuration, you must also add the Oracle grid infrastructure software owner as a member of the OSDBA group of that database. This is because the grid infrastructure components must be able to connect to the database as SYSDBA to start and stop the database.

For example, if the host user who installed the grid infrastructure home is named `grid` and the OSDBA group of the new database is named `dba`, then user `grid` must be a member of the `dba` group.

- [Syntax and Options](#)
- [Examples](#)

4.5.1.2.1 Syntax and Options

Use the `srvctl add database` command with the following syntax:

```
srvctl add database -db db_unique_name -oraclehome oracle_home
[-domain domain_name] [-dbname db_name] [-instance instance_name]
[-spfile spfile][-pwfile password_file_path] [-startoption start_options]
[-stopoption stop_options]
[-role {PRIMARY | PHYSICAL_STANDBY | LOGICAL_STANDBY |
        SNAPSHOT_STANDBY | FAR_SYNC}]
[-policy {AUTOMATIC | MANUAL | NORESTART}] [-diskgroup disk_group_list]
[-verbose]
```

Table 4-9 `srvctl add database` Options

Syntax	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.

Table 4-9 (Cont.) srvctl add database Options

Syntax	Description
<code>-oraclehome oracle_home</code>	The full path of Oracle home for the database
<code>-domain <i>domain_name</i></code>	The domain for the database. Must match the DB_DOMAIN initialization parameter.
<code>-dbname <i>db_name</i></code>	If provided, must match the DB_NAME initialization parameter setting. You must include this option if DB_NAME is different from the unique name given by the -db option
<code>-instance <i>instance_name</i></code>	The instance name. You must include this option if the instance name is different from the unique name given by the -db option. For example, if the unique name includes an underscore, and the instance name omits the underscore, then use this parameter to specify the instance name.
<code>-spfile <i>spfile</i></code>	The full path of the server parameter file for the database. If omitted, the default SPFILE is used.
<code>-pwfile <i>password_file_path</i></code>	The full path of the database password file.
<code>-startoption <i>start_options</i></code>	Startup options for the database (OPEN, MOUNT, or NOMOUNT). If omitted, defaults to OPEN. See Also: <i>SQL*Plus User's Guide and Reference</i> for more information about startup options
<code>-stopoption <i>stop_options</i></code>	Shutdown options for the database (NORMAL, IMMEDIATE, TRANSACTIONAL, or ABORT). If omitted, defaults to IMMEDIATE. See Also: <i>SQL*Plus User's Guide and Reference</i> for more information about shutdown options
<code>-role {PRIMARY PHYSICAL_STANDBY LOGICAL_STANDBY SNAPSHOT_STANDBY FAR_SYNC}</code>	The current role of the database (PRIMARY, PHYSICAL_STANDBY, LOGICAL_STANDBY, SNAPSHOT_STANDBY, or FAR_SYNC). The default is PRIMARY. Applicable in Oracle Data Guard environments only. See Also: <i>Oracle Data Guard Concepts and Administration</i> for more information about database roles
<code>-policy {AUTOMATIC MANUAL NORESTART}</code>	Management policy for the database. <ul style="list-style-type: none"> • AUTOMATIC (default): The database is automatically restored to its previous running condition (started or stopped) upon restart of the database host computer. • MANUAL: The database is never automatically restarted upon restart of the database host computer. A MANUAL setting does not prevent Oracle Restart from monitoring the database while it is running and restarting it if a failure occurs. • NORESTART: Similar to the MANUAL setting, the database is never automatically restarted upon restart of the database host computer. A NORESTART setting, however, never restarts the database even if a failure occurs.
<code>-diskgroup <i>disk_group_list</i></code>	Comma separated list of disk groups upon which the database is dependent. When starting the database, Oracle Restart first ensures that these disk groups are mounted. This option is required only if the database instance and the Oracle ASM instance are not started when adding the database. Otherwise, the dependency is recorded automatically between the database and its disk groups.

Table 4-9 (Cont.) srvctl add database Options

Syntax	Description
<code>-verbose</code>	Verbose output

4.5.1.2.2 Examples

This example adds the database with the DB_UNIQUE_NAME dbcrm:

```
srvctl add database -db dbcrm -oraclehome /u01/app/oracle/product/12.1.0/dbhome_1
```

This example adds the same database and also establishes a dependency between the database and the disk groups DATA and RECOVERY.

```
srvctl add database -db dbcrm -oraclehome /u01/app/oracle/product/12.1.0/dbhome_1
-diskgroup "DATA,RECOVERY"
```

See Also:

- ["Oracle Restart Integration with Oracle Data Guard"](#)
- [Oracle Data Guard Concepts and Administration](#)

4.5.1.3 srvctl add listener

Adds a listener to the Oracle Restart configuration.

- [Syntax and Options](#)
- [Example](#)

4.5.1.3.1 Syntax and Options

Use the `srvctl add listener` command with the following syntax:

```
srvctl add listener [-listener listener_name] [-endpoints endpoints] [-skip]
[-oraclehome oracle_home]
```

Table 4-10 srvctl add listener Options

Option	Description
<code>-listener <i>listener_name</i></code>	Listener name. If omitted, defaults to LISTENER
<code>-endpoints <i>endpoints</i></code>	Comma separated TCP ports or listener endpoints. If omitted, defaults to TCP:1521. <i>endpoints</i> syntax is: " [TCP:] <i>port</i> [, ...] [/IPC: <i>key</i>] [/NMP: <i>pipe_name</i>] [/TCPS: <i>s_port</i>] [/SDP: <i>port</i>] "
<code>-skip</code>	Skip checking for port conflicts with the supplied endpoints

Table 4-10 (Cont.) srvctl add listener Options

Option	Description
<code>-oraclehome</code> <code>oracle_home</code>	Oracle home for the listener. If omitted, the Oracle Grid Infrastructure home is assumed.

4.5.1.3.2 Example

The following command adds a listener (named `LISTENER`) running out of the database Oracle home and listening on TCP port 1522:

```
srvctl add listener -endpoints TCP:1522
                     -oraclehome /u01/app/oracle/product/12.1.0/dbhome_1
```

4.5.1.4 srvctl add ons

Adds Oracle Notification Services (ONS) to an Oracle Restart configuration.

ONS must be added to an Oracle Restart configuration to enable the sending of Fast Application Notification (FAN) events after an Oracle Data Guard failover.

When ONS is added to an Oracle Restart configuration, it is initially disabled. You can enable it with the `srvctl enable ons` command.

- [Syntax and Options](#)

 **See Also:**

["srvctl enable ons"](#)

4.5.1.4.1 Syntax and Options

Use the `srvctl add ons` command with the following syntax:

```
srvctl add ons [-emport em_port] [-onslocalport ons_local_port]
                [-onsremoteport ons_remote_port] [-remoteservers host[:port],[host[:port]]...]
                [-verbose]
```

Table 4-11 srvctl add ons Options

Option	Description
<code>-emport em_port</code>	ONS listening port for Oracle Enterprise Manager Cloud Control (Cloud Control). The default is 2016.
<code>-onslocalport</code> <code>ons_local_port</code>	ONS listening port for local client connections. The default is 6100.
<code>-onsremoteport</code> <code>ons_remote_port</code>	ONS listening port for connections from remote hosts. The default is 6200.

Table 4-11 (Cont.) srvctl add ons Options

Option	Description
-remoteservers host[:port], [host[:port],...]	A list of <i>host</i> : <i>port</i> pairs of remote hosts that are part of the ONS network Note: If <i>port</i> is not specified for a remote host, then <i>ons_remote_port</i> is used.
-verbose	Verbose output

4.5.1.5 srvctl add service

Adds a database service to the Oracle Restart configuration.

Creates the database service if it does not exist. This method of creating a service is preferred over using the DBMS_SERVICE PL/SQL package.

- [Syntax and Options](#)
- [Example](#)

4.5.1.5.1 Syntax and Options

Use the `srvctl add service` command with the following syntax:

```
srvctl add service -db db_unique_name -service service_name
[-role [PRIMARY][,PHYSICAL_STANDBY][,LOGICAL_STANDBY][,SNAPSHOT_STANDBY]]
[-policy {AUTOMATIC | MANUAL}]
[-failovertype {NONE | SESSION | SELECT | TRANSACTION}]
[-failovermethod {NONE | BASIC}] [-failoverdelay integer]
[-failoverretry integer] [-clbgoal {SHORT | LONG}]
[-rlbgoal {SERVICE_TIME | THROUGHPUT | NONE}] [-notification {TRUE | FALSE}]
[-edition edition_name] [-pdb pluggable_database]
[-sql_transformation_profile sql_transformation_profile]
[-commit_outcome {TRUE | FALSE}] [-retention retention]
[-replay_init_time replay_init_time] [-drain_timeout timeout]
[-stopoption stop_option] [-session_state {STATIC | DYNAMIC}]
[-global {TRUE | FALSE}] [-maxlag max_lag_time] [-force] [-verbose]
```

Table 4-12 srvctl add service Options

Option	Description
-db <i>db_unique_name</i>	Unique name for the database The name must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
-service <i>service_name</i>	The database service name

Table 4-12 (Cont.) srvctl add service Options

Option	Description
<code>-role [PRIMARY] [,PHYSICAL_STANDBY] [,LOGICAL_STANDBY] [,SNAPSHOT_STANDBY] Y]</code>	A list of service roles This option is applicable in Oracle Data Guard environments only. When this option is present, upon database open, the service is started only when one of its service roles matches the current database role. See Also: <i>Oracle Data Guard Concepts and Administration</i> for more information about database roles
<code>-policy {AUTOMATIC MANUAL}</code>	Management policy for the service If AUTOMATIC (the default), the service is automatically started upon restart of the database, either by a planned restart (with SRVCTL) or after a failure. Automatic restart is also subject to the service role, however (the <code>-role</code> option). If MANUAL, the service is never automatically restarted upon planned restart of the database (with SRVCTL). A MANUAL setting does not prevent Oracle Restart from monitoring the service when it is running and restarting it if a failure occurs.
<code>-failovertype {NONE SESSION SELECT TRANSACTION}</code>	To enable Application Continuity for OCI and Java, use TRANSACTION. If the failover type is TRANSACTION, then OCI and Java attempt to recover the in progress transaction upon receipt of a recoverable error. When failover type is TRANSACTION, the <code>-commit_outcome</code> option must be set to TRUE. To enable Transparent Application Failover (TAF) for OCI, use SELECT or SESSION.
<code>-failovermethod {NONE BASIC}</code>	TAF failover method for backward compatibility only If the failover type (<code>-failovertype</code>) is set to a value other than NONE, then use BASIC for this option.
<code>-failoverdelay integer</code>	For Application Continuity and TAF, the time delay, in seconds, between reconnect attempts for each incident at failover
<code>-failoverretry integer</code>	For Application Continuity and TAF, the number of attempts to connect after an incident
<code>-clbgoal {SHORT LONG}</code>	Connection load balancing goal Use SHORT for run-time load balancing. Use LONG for long running connections, such as batch jobs.
<code>-rlbgoal {SERVICE_TIME THROUGHPUT NONE}</code>	Run-time load balancing goal Use SERVICE_TIME to balance connections by response time. Use THROUGHPUT to balance connections by throughput.
<code>-notification {TRUE FALSE}</code>	Enable Fast Application Notification (FAN) for OCI connections

Table 4-12 (Cont.) srvctl add service Options

Option	Description
<code>-edition</code> <code>edition_name</code>	The initial session edition of the service When an edition is specified for a service, all subsequent connections that specify the service use this edition as the initial session edition. However, if a session connection specifies a different edition, then the edition specified in the session connection is used for the initial session edition. SRVCTL does not validate the specified edition name. During connection, the connect user must have <code>USE</code> privilege on the specified edition. If the edition does not exist or if the connect user does not have <code>USE</code> privilege on the specified edition, then an error is raised.
<code>-pdb</code> <code>pluggable_database</code>	In a multitenant container database (CDB), the name of the pluggable database (PDB) to associate with the service If this option is set to an empty string, then the service is associated with root.
<code>-</code> <code>sql_translational_profile</code> <code>sql_translational_profile</code>	A SQL translation profile for a service that you are adding after you have migrated applications from a non-Oracle database to an Oracle database This parameter corresponds to the SQL translation profile parameter in the DBMS_SERVICE service attribute.
Notes:	
	<ul style="list-style-type: none"> Before using the SQL translation framework, you must migrate all server-side application objects and data to the Oracle database. Use the <code>srvctl config service</code> command to display the SQL translation profile.
	See Also: <i>Oracle Database Migration Guide</i> for more information about using a SQL translation profile
<code>-commit_outcome</code> <code>{TRUE FALSE}</code>	For Transaction Guard, when TRUE a transaction's commit outcome is accessible after the transaction's session fails due to a recoverable outage. If FALSE, the default, then a transaction's commit outcome is not retained. When this option is set to TRUE, the outcome of a transaction's commit is durable, and an applications can determine the commit status of a transaction after an outage. You can set <code>commit_outcome</code> to TRUE for a user-defined service. The <code>commit_outcome</code> setting has no effect on Oracle Active Data Guard and read-only databases. See Also: See <i>Oracle Database Development Guide</i> for more information.
<code>-retention</code> <code>retention</code>	If <code>commit_outcome</code> is set to TRUE, then this option determines the amount of time, in seconds, that the commit outcome is retained. The default is 24 hours (86400). If <code>commit_outcome</code> is set to FALSE, then this option cannot be set.

Table 4-12 (Cont.) srvctl add service Options

Option	Description
<code>-replay_init_time</code> <i>replay_init_time</i>	For Application Continuity, this option specifies the difference between the time, in seconds, of original execution of the first operation of a request and the time that the replay is ready to start after a successful reconnect. Application Continuity will not replay after the specified amount of time has passed. This option is intended to avoid the unintentional execution of a transaction when a system is recovered after a long period of time. The default is 5 minutes (300). The maximum value is 24 hours (86400). If failovertype is not set to TRANSACTION, then this option is not used.
<code>-drain_timeout</code> <i>timeout</i>	This option specifies the time allowed for resource draining to be completed in seconds. Permitted values are NULL, 0, or any positive integer. The draining period is intended for planned maintenance operations. During the draining period, all current client requests are processed, but new requests are not accepted. How draining works depends on the setting of the <code>-stopoption</code> option. The default value is NULL, which means that this option is not set. If the option is not set, and <code>-drain_timeout</code> has been set on the service, then this value is used. If it is set to 0, then draining does not occur.
<code>-stopoption</code> <i>stop_option</i>	This option specifies the mode in which the service is stopped. The following values are permitted: <ul style="list-style-type: none"> • IMMEDIATE specifies that sessions are permitted to drain before the service is stopped. • TRANSACTIONAL specifies that sessions are permitted to drain for the amount of time specified in the <code>-drain_timeout</code> option. The service is stopped when the time limit is reached, and any remaining sessions are terminated. • NONE is the default.
<code>-session_state</code> {STATIC DYNAMIC}	For Application Continuity, this parameter specifies whether the session state that is not transactional is changed by the application. Oracle recommends a setting of DYNAMIC for most applications. Note: This parameter is considered only if <code>-failovertype</code> is set to TRANSACTION for Application Continuity. It describes how non-transactional is changed during a request. Examples of session state are NLS settings, optimizer preferences, event settings, PL/SQL global variables, temporary tables, advanced queues, LOBs, and result cache. If non-transactional values change after the request starts, then use the default, DYNAMIC. Most applications should use DYNAMIC mode. If you are unsure, then use DYNAMIC mode.
<code>-global</code> {TRUE FALSE}	If TRUE, then the service is a Global Data Services (GDS) service and is managed by the Global Services Manager (GSM). If FALSE, the default, then the service is not a GDS service. The global attribute of a service cannot be changed after the service is added. See <i>Oracle Database Global Data Services Concepts and Administration Guide</i> for more information.

Table 4-12 (Cont.) srvctl add service Options

Option	Description
<code>-maxlag</code> <code>maximum_lag_time</code>	Maximum replication lag time in seconds. Must be a non-negative integer. The default value is ANY.
<code>-force</code>	Force the add operation even though a listener is not configured for a network.
<code>-verbose</code>	Verbose output

4.5.1.5.2 Example

This example adds the `sales` service for the database with `DB_UNIQUE_NAME dbcrm`. The service is started only when `dbcrm` is in `PRIMARY` mode.

```
srvctl add service -db dbcrm -service sales -role PRIMARY
```

See Also:

- The section in *Oracle Database PL/SQL Packages and Types Reference* on the `DBMS_SERVICE` package for more information about the options for this command
- "[Oracle Restart Integration with Oracle Data Guard](#)"
- "[Oracle Data Guard Concepts and Administration](#)"
- "[Creating, Modifying, or Removing a Service for a PDB](#)"

4.5.2 config

The `srvctl config` command displays the Oracle Restart configuration of the specified component or set of components.

- [**srvctl config asm**](#)
Displays the Oracle Restart configuration information for the Oracle ASM instance.
- [**srvctl config database**](#)
Displays the Oracle Restart configuration information for the specified database, or lists all databases managed by Oracle Restart.
- [**srvctl config listener**](#)
Displays the Oracle Restart configuration information for all Oracle Restart–managed listeners or for the specified listener.
- [**srvctl config ons**](#)
Displays the current configuration information for Oracle Notification Services (ONS).
- [**srvctl config service**](#)
For the specified database, displays the Oracle Restart configuration information for the specified database service or for all Oracle Restart–managed database services.

4.5.2.1 srvctl config asm

Displays the Oracle Restart configuration information for the Oracle ASM instance.

- [Syntax and Options](#)
- [Example](#)

4.5.2.1.1 Syntax and Options

Use the `srvctl config asm` command with the following syntax:

```
srvctl config asm [-all]
```

Table 4-13 `srvctl config asm` Options

Option	Description
-all	Display enabled/disabled status also

4.5.2.1.2 Example

An example of this command is:

```
srvctl config asm -all
```

```
asm home: /u01/app/oracle/product/12.1.0/grid
ASM is enabled.
```

4.5.2.2 srvctl config database

Displays the Oracle Restart configuration information for the specified database, or lists all databases managed by Oracle Restart.

- [Syntax and Options](#)
- [Example](#)

4.5.2.2.1 Syntax and Options

Use the `srvctl config database` command with the following syntax:

```
srvctl config database [-db db_unique_name [-all]] [-verbose]
```

Table 4-14 `srvctl config database` Options

Option	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
-all	Display detailed configuration information

Table 4-14 (Cont.) srvctl config database Options

Option	Description
-verbose	Verbose output

4.5.2.2 Example

An example of this command to list all Oracle Restart–managed databases is:

```
srvctl config database

dbcrm
orcl
```

An example of this command to display configuration and enabled/disabled status for the database with the DB_UNIQUE_ID orcl is:

```
srvctl config database -db orcl -all

Database unique name: orcl
Database name: orcl
Oracle home: /u01/app/oracle/product/12.1.0/dbhome_1
Oracle user: oracle
Spfile: +DATA/orcl/spfileorcl.ora
Domain: us.example.com
Start options: open
Stop options: immediate
Database role:
Management policy: automatic
Disk Groups: DATA
Services: mfg,sales
Database is enabled
```

4.5.2.3 srvctl config listener

Displays the Oracle Restart configuration information for all Oracle Restart–managed listeners or for the specified listener.

- [Syntax and Options](#)
- [Example](#)

4.5.2.3.1 Syntax and Options

Use the `srvctl config listener` command with the following syntax:

```
srvctl config listener [-listener listener_name]
```

Table 4-15 srvctl config listener Options

Option	Description
<code>-listener <i>listener_name</i></code>	Listener name. If omitted, configuration information for all Oracle Restart–managed listeners is displayed.

4.5.2.3.2 Example

This example displays the configuration information and enabled/disabled status for the default listener:

```
srvctl config listener

Name: LISTENER
Home: /u01/app/oracle/product/12.1.0/dbhome_1
End points: TCP:1521
Listener is enabled.
```

4.5.2.4 srvctl config ons

Displays the current configuration information for Oracle Notification Services (ONS).

- [Syntax and Options](#)

4.5.2.4.1 Syntax and Options

Use the `srvctl config ons` command with the following syntax:

```
srvctl config ons
```

4.5.2.5 srvctl config service

For the specified database, displays the Oracle Restart configuration information for the specified database service or for all Oracle Restart–managed database services.

- [Syntax and Options](#)
- [Example](#)

4.5.2.5.1 Syntax and Options

Use the `srvctl config service` command with the following syntax:

```
srvctl config service -db db_unique_name [-service service_name] [-verbose]
```

Table 4-16 `srvctl config service` Options

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
<code>-service service_name</code>	Database service name. If omitted, SRVCTL displays configuration information for all Oracle Restart–managed services for the database.
<code>-verbose</code>	Verbose output

4.5.2.5.2 Example

An example of this command is:

```
srvctl config service -db dbcrm -service sales

Service name: sales
Service is enabled
Cardinality: SINGLETON
Disconnect: true
Service role: PRIMARY
Management policy: automatic
DTP transaction: false
AQ HA notifications: false
Failover type: NONE
Failover method: NONE
TAF failover retries: 0
TAF failover delay: 0
Connection Load Balancing Goal: NONE
Runtime Load Balancing Goal: NONE
TAF policy specification: NONE
Edition: e2
```

4.5.3 disable

Disables a component, which suspends management of that component by Oracle Restart.

The `srvctl disable` command is intended to be used when a component must be repaired or shut down for maintenance, and should not be restarted automatically. When you disable a component:

- It is no longer automatically restarted.
- It is no longer automatically started through a dependency.
- It cannot be started with SRVCTL.

To perform `srvctl disable` operations, you must be logged in to the database host computer with the proper user account. See "[Preparing to Run SRVCTL](#)" for more information.

- [**srvctl disable asm**](#)
Disables the Oracle ASM instance.
- [**srvctl disable database**](#)
Disables the specified database.
- [**srvctl disable diskgroup**](#)
Disables an Oracle ASM disk group.
- [**srvctl disable listener**](#)
Disables the specified listener or all listeners.
- [**srvctl disable ons**](#)
Disables Oracle Notification Services (ONS).
- [**srvctl disable service**](#)
Disables one or more database services.

 **See Also:**

The [enable](#) command

4.5.3.1 srvctl disable asm

Disables the Oracle ASM instance.

- [Syntax and Options](#)

4.5.3.1.1 Syntax and Options

Use the `srvctl disable asm` command with the following syntax:

```
srvctl disable asm
```

4.5.3.2 srvctl disable database

Disables the specified database.

- [Syntax and Options](#)
- [Example](#)

4.5.3.2.1 Syntax and Options

Use the `srvctl disable database` command with the following syntax:

```
srvctl disable database -db db_unique_name
```

Table 4-17 `srvctl disable database` Options

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.

4.5.3.2.2 Example

An example of this command is:

```
srvctl disable database -db dbcrm
```

4.5.3.3 srvctl disable diskgroup

Disables an Oracle ASM disk group.

- [Syntax and Options](#)
- [Example](#)

4.5.3.3.1 Syntax and Options

Use the `srvctl disable diskgroup` command with the following syntax:

```
srvctl disable diskgroup -diskgroup diskgroup_name
```

Table 4-18 `srvctl disable diskgroup` Options

Option	Description
<code>-diskgroup</code> <i>diskgroup_name</i>	Disk group name

4.5.3.3.2 Example

An example of this command is:

```
srvctl disable diskgroup -diskgroup DATA
```

4.5.3.4 `srvctl disable listener`

Disables the specified listener or all listeners.

- [Syntax and Options](#)
- [Example](#)

4.5.3.4.1 Syntax and Options

Use the `srvctl disable listener` command with the following syntax:

```
srvctl disable listener [-listener listener_name]
```

Table 4-19 `srvctl disable listener` Options

Option	Description
<code>-listener</code> <i>listener_name</i>	Listener name. If omitted, all listeners are disabled.

4.5.3.4.2 Example

An example of this command is:

```
srvctl disable listener -listener crmlistener
```

4.5.3.5 `srvctl disable ons`

Disables Oracle Notification Services (ONS).

- [Syntax and Options](#)

4.5.3.5.1 Syntax and Options

Use the `srvctl disable ons` command with the following syntax:

```
srvctl disable ons [-verbose]
```

Table 4-20 **srvctl disable ons Options**

Option	Description
-verbose	Verbose output

4.5.3.6 srvctl disable service

Disables one or more database services.

- [Syntax and Options](#)
- [Example](#)

4.5.3.6.1 Syntax and Options

Use the `srvctl disable service` command with the following syntax:

```
srvctl disable service -db db_unique_name -service service_name_list
[-global_override]
```

Table 4-21 **srvctl disable service Options**

Option	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .
-service <i>service_name_list</i>	Comma-delimited list of database service names
-global_override	If the service is a Global Data Services (GDS) service, then this option must be specified to disable the service. An error is returned if you attempt to disable a GDS service and <code>-global_override</code> is not included. This option is ignored if the service is not a GDS service. See <i>Oracle Database Global Data Services Concepts and Administration Guide</i> for more information.

4.5.3.6.2 Example

The following example disables the database service `sales` and `mfg`:

```
srvctl disable service -db dbcrm -service sales,mfg
```

4.5.4 downgrade

The `srvctl downgrade` command downgrades the database configuration after you manually downgrade the database.

- [srvctl downgrade database](#)
The `srvctl downgrade database` command downgrades the configuration of a database and its services from its current version to the specified lower version.

4.5.4.1 `srvctl downgrade database`

The `srvctl downgrade database` command downgrades the configuration of a database and its services from its current version to the specified lower version.

- [Syntax and Options](#)

4.5.4.1.1 Syntax and Options

Use the `srvctl downgrade database` command with the following syntax:

```
srvctl downgrade database -db db_unique_name -oraclehome oracle_home
                           -targetversion to_version
```

Table 4-22 `srvctl downgrade database` Options

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .
<code>-oraclehome oracle_home</code>	The full path of Oracle home for the database
<code>-targetversion to_version</code>	The version to which to downgrade

4.5.5 `enable`

The `srvctl enable` command reenables the specified disabled component.

When you enable a component:

- Oracle Restart can automatically restart it.
- It can be automatically started through a dependency.
- You can start it manually with SRVCTL.

If the component is already enabled, then the command is ignored.

When you add a component to the Oracle Restart configuration, it is enabled by default.

To perform `srvctl enable` operations, you must be logged in to the database host computer with the proper user account. See "[Preparing to Run SRVCTL](#)" for more information.

- [srvctl enable asm](#)
Enables an Oracle ASM instance.
- [srvctl enable database](#)
Enables the specified database.

- [srvctl enable diskgroup](#)
Enables an Oracle ASM disk group.
- [srvctl enable listener](#)
Enables the specified listener or all listeners.
- [srvctl enable ons](#)
Enables Oracle Notification Services (ONS).
- [srvctl enable service](#)
Enables one or more database services for the specified database.

 **See Also:**

The [disable](#) command

4.5.5.1 `srvctl enable asm`

Enables an Oracle ASM instance.

- [Syntax and Options](#)

4.5.5.1.1 Syntax and Options

Use the `srvctl enable asm` command with the following syntax:

```
srvctl enable asm
```

4.5.5.2 `srvctl enable database`

Enables the specified database.

- [Syntax and Options](#)
- [Example](#)

4.5.5.2.1 Syntax and Options

Use the `srvctl enable database` command with the following syntax:

```
srvctl enable database -db db_unique_name
```

Table 4-23 `srvctl enable database` Options

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .

4.5.5.2.2 Example

An example of this command is:

```
srvctl enable database -db dbcrm
```

4.5.5.3 srvctl enable diskgroup

Enables an Oracle ASM disk group.

- [Syntax and Options](#)
- [Example](#)

4.5.5.3.1 Syntax and Options

Use the `srvctl enable diskgroup` command with the following syntax:

```
srvctl enable diskgroup -diskgroup diskgroup_name
```

Table 4-24 `srvctl enable diskgroup` Options

Option	Description
<code>-diskgroup</code> <i>diskgroup_name</i>	Disk group name

4.5.5.3.2 Example

An example of this command is:

```
srvctl enable diskgroup -diskgroup DATA
```

4.5.5.4 srvctl enable listener

Enables the specified listener or all listeners.

- [Syntax and Options](#)
- [Example](#)

4.5.5.4.1 Syntax and Options

Use the `srvctl enable listener` command with the following syntax:

```
srvctl enable listener [-listener listener_name]
```

Table 4-25 `srvctl enable listener` Options

Option	Description
<code>-listener</code> <i>listener_name</i>	Listener name. If omitted, all listeners are enabled.

4.5.5.4.2 Example

An example of this command is:

```
srvctl enable listener -listener crmlistener
```

4.5.5.5 srvctl enable ons

Enables Oracle Notification Services (ONS).

- [Syntax and Options](#)

4.5.5.5.1 Syntax and Options

Use the `srvctl enable ons` command with the following syntax:

```
srvctl enable ons [-verbose]
```

Table 4-26 `srvctl enable ons` Options

Option	Description
<code>-verbose</code>	Verbose output

4.5.5.6 srvctl enable service

Enables one or more database services for the specified database.

- [Syntax and Options](#)
- [Example](#)

4.5.5.6.1 Syntax and Options

Use the `srvctl enable service` command with the following syntax:

```
srvctl enable service -db db_unique_name -service service_name_list
[-global_override]
```

Table 4-27 `srvctl enable service` Options

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .
<code>-service service_name_list</code>	Comma-delimited list of database service names
<code>-global_override</code>	If the service is a Global Data Services (GDS) service, then this option must be specified to enable the service. An error is returned if you attempt to enable a GDS service and <code>-global_override</code> is not included. This option is ignored if the service is not a GDS service. See <i>Oracle Database Global Data Services Concepts and Administration Guide</i> for more information.

4.5.5.6.2 Example

The following example enables the database services `sales` and `mfg` in the database with `DB_UNIQUE_NAME` `dbcram`:

```
srvctl enable service -db dbcrm -service "sales,mfg"
```

4.5.6 getenv

Gets and displays environment variables and their values from the Oracle Restart configuration for a database, listener, or Oracle ASM instance.

- [srvctl getenv asm](#)
Displays the configured environment variables for the Oracle ASM instance.
- [srvctl getenv database](#)
Displays the configured environment variables for the specified database.
- [srvctl getenv listener](#)
Displays the configured environment variables for the specified listener.

See Also:

- [setenv command](#)
- [unsetenv command](#)
- ["Managing Environment Variables in the Oracle Restart Configuration"](#)

4.5.6.1 srvctl getenv asm

Displays the configured environment variables for the Oracle ASM instance.

- [Syntax and Options](#)
- [Example](#)

4.5.6.1.1 Syntax and Options

Use the `srvctl getenv asm` command with the following syntax:

```
srvctl getenv asm [-envs name_list]
```

Table 4-28 `srvctl getenv asm` Options

Options	Description
<code>-envs name_list</code>	Comma-delimited list of names of environment variables to display. If omitted, SRVCTL displays all configured environment variables for Oracle ASM.

4.5.6.1.2 Example

The following example displays all configured environment variables for the Oracle ASM instance:

```
srvctl getenv asm
```

4.5.6.2 srvctl getenv database

Displays the configured environment variables for the specified database.

- [Syntax and Options](#)
- [Example](#)

4.5.6.2.1 Syntax and Options

Use the `srvctl getenv database` command with the following syntax:

```
srvctl getenv database -db db_unique_name [-envs name_list]
```

Table 4-29 srvctl getenv database Options

Options	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .
<code>-envs name_list</code>	Comma-delimited list of names of environment variables to display. If omitted, SRVCTL displays all configured environment variables.

4.5.6.2.2 Example

The following example displays all configured environment variables for the database with `DB_UNIQUE_NAME` `dbcrrm`:

```
srvctl getenv database -db dbcrrm
```

4.5.6.3 srvctl getenv listener

Displays the configured environment variables for the specified listener.

- [Syntax and Options](#)
- [Example](#)

4.5.6.3.1 Syntax and Options

Use the `srvctl getenv listener` command with the following syntax:

```
srvctl getenv listener [-listener listener_name] [-envs name_list]
```

Table 4-30 **srvctl getenv listener Options**

Options	Description
-listener <i>listener_name</i>	Listener name. If omitted, SRVCTL lists environment variables for all listeners.
-envs <i>name_list</i>	Comma-delimited list of names of environment variables to display. If omitted, SRVCTL displays all configured environment variables.

4.5.6.3.2 Example

The following example displays all configured environment variables for the listener named `crmlistener`:

```
srvctl getenv listener -listener crmlistener
```

4.5.7 modify

Modifies the Oracle Restart configuration of a component. The change takes effect when the component is next restarted.

To perform `srvctl modify` operations, you must be logged in to the database host computer with the proper user account. See "[Preparing to Run SRVCTL](#)" for more information.

- [srvctl modify asm](#)
Modifies the Oracle Restart configuration for the Oracle ASM instance.
- [srvctl modify database](#)
Modifies the Oracle Restart configuration for a database.
- [srvctl modify listener](#)
Modifies the Oracle Restart configuration for the specified listener or all listeners.
- [srvctl modify ons](#)
Modifies Oracle Notification Services (ONS).
- [srvctl modify service](#)
Modifies the Oracle Restart configuration of a database service.

4.5.7.1 `srvctl modify asm`

Modifies the Oracle Restart configuration for the Oracle ASM instance.

- [Syntax and Options](#)
- [Example](#)

4.5.7.1.1 Syntax and Options

Use the `srvctl modify asm` command with the following syntax:

```
srvctl modify asm [-listener listener_name] [-spfile spfile]
[-pwfile password_file_path] [-diskstring asm_diskstring]
```

Table 4-31 **srvctl modify asm Options**

Option	Description
<code>-listener <i>listener_name</i></code>	Name of the listener with which Oracle ASM must register. A weak dependency is established with this listener. (Before Oracle ASM is started, Oracle Restart ensures that this listener is started.)
<code>-spfile <i>spfile</i></code>	The full path of the server parameter file for the database. If omitted, the default SPFILE is used.
<code>-pwfile <i>password_file_path</i></code>	The full path of the Oracle ASM password file.
<code>-diskstring <i>asm_diskstring</i></code>	Oracle ASM disk group discovery string. An Oracle ASM discovery string is a comma-delimited list of strings that limits the set of disks that an Oracle ASM instance discovers. The discovery strings can include wildcard characters. Only disks that match one of the strings are discovered.

4.5.7.1.2 Example

An example of this command is:

```
srvctl modify asm -listener crmlistener
```

 **See Also:**

Oracle Automatic Storage Management Administrator's Guide for more information about Oracle ASM disk group discovery strings

4.5.7.2 srvctl modify database

Modifies the Oracle Restart configuration for a database.

- [Syntax and Options](#)
- [Example](#)

4.5.7.2.1 Syntax and Options

Use the `srvctl modify database` command with the following syntax:

```
srvctl modify database [-db db_unique_name] [-oraclehome oracle_home]
[-user oracle_user] [-domain domain_name] [-dbname db_name]
[-instance instance_name] [-instance instance_name] [-spfile spfile]
[-pwfile password_file_path] [-startoption start_options]
[-stopoption stop_options]
[-role {PRIMARY | PHYSICAL_STANDBY | LOGICAL_STANDBY | SNAPSHOT_STANDBY}]
[-policy {AUTOMATIC | MANUAL | NORESTART}]
[{-diskgroup "diskgroup_list" | -nodiskgroup}] [-force]
```

Table 4-32 **srvctl modify database Options**

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
<code>-user oracle_user</code>	Name of the Oracle user who owns the Oracle home directory
<code>-diskgroup disk_group_list</code>	Comma separated list of disk groups upon which the database is dependent. When starting the database, Oracle Restart first ensures that these disk groups are mounted. This option is required only if the database instance and the Oracle ASM instance are not started when adding the database. Otherwise, the dependency is recorded automatically between the database and its disk groups.
<code>-nodiskgroup</code>	Remove the database's dependency on Oracle ASM disk groups
<code>-force</code>	Force the operation even though some resources might be stopped.
(Other options)	See Table 4-9

4.5.7.2.2 Example

The following example changes the role of the database with DB_UNIQUE_NAME dbcrm to LOGICAL_STANDBY:

```
srvctl modify database -db dbcrm -role logical_standby
```

See Also:

- ["Oracle Restart Integration with Oracle Data Guard"](#)
- [Oracle Data Guard Concepts and Administration](#)

4.5.7.3 srvctl modify listener

Modifies the Oracle Restart configuration for the specified listener or all listeners.

- [Syntax and Options](#)
- [Example](#)

4.5.7.3.1 Syntax and Options

Use the `srvctl modify listener` command with the following syntax:

```
srvctl modify listener [-listener listener_name] [-endpoints endpoints]
[-oraclehome oracle_home]
```

Table 4-33 `srvctl modify listener Options`

Option	Description
<code>-listener listener_name</code>	Listener name. If omitted, all listener configurations are modified.
<code>-endpoints endpoints</code>	Comma separated TCP ports or listener endpoints. <i>endpoints</i> syntax is: <code>"[TCP:]port[, ...] [/IPC:key] [/NMP:pipe_name] [/TCPS:s_port] [/SDP:port]"</code>
<code>-oraclehome oracle_home</code>	New Oracle home for the listener

4.5.7.3.2 Example

This example modifies the TCP port on which the listener named `cramlistener` listens:

```
srvctl modify listener -listener crmlistener -endpoints TCP:1522
```

4.5.7.4 `srvctl modify ons`

Modifies Oracle Notification Services (ONS).

- [Syntax and Options](#)

4.5.7.4.1 Syntax and Options

Use the `srvctl modify ons` command with the following syntax:

```
srvctl modify ons [-emport em_port] [-onslocalport ons_local_port]  
[-onsremoteport ons_remote_port] [-remoteservers host[:port],[host[:port]]...]  
[-verbose]
```

Table 4-34 `srvctl modify ons Options`

Option	Description
<code>-emport em_port</code>	ONS listening port for Cloud Control. The default is 2016.
<code>-onslocalport ons_local_port</code>	ONS listening port for local client connections
<code>-onsremoteport ons_remote_port</code>	ONS listening port for connections from remote hosts
<code>-remoteservers host[:port], [host[:port]],...</code>	A list of <i>host</i> : <i>port</i> pairs of remote hosts that are part of the ONS network Note: If <i>port</i> is not specified for a remote host, then <code>ons_remote_port</code> is used.
<code>-verbose</code>	Verbose output

4.5.7.5 `srvctl modify service`

Modifies the Oracle Restart configuration of a database service.

 **Note:**

Oracle recommends that you limit configuration changes to the minimum requirement and that you not perform other service operations while the online service modification is in progress.

- [Syntax and Options](#)
- [Example](#)

4.5.7.5.1 Syntax and Options

Use the `srvctl modify service` command with the following syntax:

```
srvctl modify service -db db_unique_name -service service_name
[-role [PRIMARY][,PHYSICAL_STANDBY][,LOGICAL_STANDBY][,SNAPSHOT_STANDBY]]
[-policy {AUTOMATIC | MANUAL}]
[-failovertype {NONE | SESSION | SELECT | TRANSACTION}]
[-failovermethod {NONE | BASIC}] [-failoverdelay integer]
[-failoverretry integer] [-clbgoal {SHORT | LONG}]
[-rlbgoal {SERVICE_TIME | THROUGHPUT | NONE}] [-notification {TRUE | FALSE}]
[-edition edition_name] [-pdb pluggable_database]
[-sql_transformation_profile sql_transformation_profile]
[-commit_outcome {TRUE | FALSE}] [-retention retention]
[-replay_init_time replay_init_time] [-drain_timeout timeout]
[-stopoption stop_option] [-session_state {STATIC | DYNAMIC}]
[-global_override] [-verbose]
```

Table 4-35 `srvctl modify service` Options

Option	Description
<code>-db</code>	Unique name for the database
<code>db_unique_name</code>	The name must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .
<code>-service</code>	Service name
<code>service_name</code>	
<code>-role [PRIMARY]</code> [, <code>PHYSICAL_STANDBY</code>] [, <code>LOGICAL_STANDBY</code>] [, <code>SNAPSHOT_STANDBY</code>]	A list of service roles This option is applicable in Oracle Data Guard environments only. When this option is present, upon database startup, the service is started only when one of its service roles matches the current database role. See Also: <i>Oracle Data Guard Concepts and Administration</i> for more information about database roles

Table 4-35 (Cont.) srvctl modify service Options

Option	Description
<code>-policy {AUTOMATIC MANUAL}</code>	Management policy for the service If AUTOMATIC (the default), the service is automatically started upon restart of the database, either by a planned restart (with SRVCTL) or after a failure. Automatic restart is also subject to the service role, however (the <code>-role</code> option). If MANUAL, the service is never automatically restarted upon planned restart of the database (with SRVCTL). A MANUAL setting does not prevent Oracle Restart from monitoring the service when it is running and restarting it if a failure occurs.
<code>-failovertype {NONE SESSION SELECT TRANSACTION}</code>	To enable Application Continuity for OCI and Java, use TRANSACTION. If the failover type is TRANSACTION, then OCI and Java attempt to recover the inflight transaction upon receipt of a recoverable error. When failover type is TRANSACTION, the <code>commit_outcome</code> option must be set to TRUE. To enable Transparent Application Failover (TAF) for OCI, use SELECT or SESSION.
<code>-failovermethod {NONE BASIC}</code>	TAF failover method for backward compatibility only If the failover type (<code>-failovertype</code>) is set to a value other than NONE, then use BASIC for this option.
<code>-failoverdelay integer</code>	For Application Continuity and TAF, the time delay, in seconds, between reconnect attempts for each incident at failover
<code>-failoverretry integer</code>	For Application Continuity and TAF, the number of attempts to connect after an incident
<code>-clbgoal {SHORT LONG}</code>	Connection load balancing goal Use SHORT for run-time load balancing. Use LONG for long running connections, such as batch jobs.
<code>-rlbgoal {SERVICE_TIME THROUGHPUT NONE}</code>	Run-time load balancing goal Use SERVICE_TIME to balance connections by response time. Use THROUGHPUT to balance connections by throughput.
<code>-notification {TRUE FALSE}</code>	Enable Fast Application Notification (FAN) for OCI connections
<code>-edition edition_name</code>	The initial session edition of the service If this option is not specified, then the edition is not modified for the service. If this option is specified but <code>edition_name</code> is empty, then the edition is set to NULL. A NULL edition has no effect. When an edition is specified for a service, all subsequent connections that specify the service use this edition as the initial session edition. However, if a session connection specifies a different edition, then the edition specified in the session connection is used for the initial session edition. SRVCTL does not validate the specified edition name. During connection, the connect user must have USE privilege on the specified edition. If the edition does not exist or if the connect user does not have USE privilege on the specified edition, then an error is raised.

Table 4-35 (Cont.) srvctl modify service Options

Option	Description
<code>-pdb</code> <code>pluggable_database</code>	In a CDB, the name of the PDB to associate with the service If this option is set to an empty string, then the service is associated with root.
<code>-sql_transformation_profile</code> <code>sql_transformation_profile</code>	A SQL translation profile for a service that you are adding after you have migrated applications from a non-Oracle database to an Oracle database Note: Before using the SQL translation framework, you must migrate all server-side application objects and data to the Oracle database. See Also: <i>Oracle Database Migration Guide</i> for more information about using a SQL translation profile
<code>-commit_outcome</code> {TRUE FALSE}	For Transaction Guard, when TRUE a transaction's commit outcome is accessible after the transaction's session fails due to a recoverable outage. If FALSE, the default, then a transaction's commit outcome is not retained. When this option is set to TRUE, the outcome of a transaction's commit is durable, and an application can determine the commit status of a transaction after an outage. You can set <code>commit_outcome</code> to TRUE for a user-defined service. The <code>commit_outcome</code> setting has no effect on Oracle Active Data Guard and read-only databases. See Also: See <i>Oracle Database Development Guide</i> for more information.
<code>-retention</code> <code>retention</code>	If <code>commit_outcome</code> is set to TRUE, then this option determines the amount of time, in seconds, that the commit outcome is retained. The default is 24 hours (86400). If <code>commit_outcome</code> is set to FALSE, then this option cannot be set.
<code>-replay_init_time</code> <code>replay_init_time</code>	For Application Continuity, this option specifies the difference between the time, in seconds, of original execution of the first operation of a request and the time that the replay is ready to start after a successful reconnect. Application Continuity will not replay after the specified amount of time has passed. This option is intended to avoid the unintentional execution of a transaction when a system is recovered after a long period of time. The default is 5 minutes (300). The maximum value is 24 hours (86400). If failovertype is not set to TRANSACTION, then this option is not used.
<code>-drain_timeout</code> <code>timeout</code>	This option specifies the time allowed for resource draining to be completed in seconds. Permitted values are NULL, 0, or any positive integer. The draining period is intended for planned maintenance operations. During the draining period, all current client requests are processed, but new requests are not accepted. How draining works depends on the setting of the <code>-stopoption</code> option. The default value is NULL, which means that this option is not set. If the option is not set, and <code>-drain_timeout</code> has been set on the service, then this value is used. If it is set to 0, then draining does not occur.

Table 4-35 (Cont.) srvctl modify service Options

Option	Description
<code>-stopoption</code> <code>stop_option</code>	This option specifies the mode in which the service is stopped. The following values are permitted: <ul style="list-style-type: none"> • <code>IMMEDIATE</code> specifies that sessions are permitted to drain before the service is stopped. • <code>TRANSACTIONAL</code> specifies that sessions are permitted to drain for the amount of time specified in the <code>-drain_timeout</code> option. The service is stopped when the time limit is reached, and any remaining sessions are terminated. • <code>NONE</code> is the default.
<code>-session_state</code> <code>{STATIC DYNAMIC}</code>	For Application Continuity, this parameter specifies whether the session state that is not transactional is changed by the application. Oracle recommends a setting of <code>DYNAMIC</code> for most applications. Note: This parameter is considered only if <code>-failovertype</code> is set to <code>TRANSACTION</code> for Application Continuity. It describes how non-transactional is changed during a request. Examples of session state are NLS settings, optimizer preferences, event settings, PL/SQL global variables, temporary tables, advanced queues, LOBs, and result cache. If non-transactional values change after the request starts, then use the default, <code>DYNAMIC</code> . Most applications should use <code>DYNAMIC</code> mode. If you are unsure, then use <code>DYNAMIC</code> mode.
<code>-global_override</code>	If the service is a Global Data Services (GDS) service, then this option must be specified to modify any of the following service attributes: <ul style="list-style-type: none"> • <code>-role</code> • <code>-policy</code> • <code>-failovertype</code> • <code>-failovermethod</code> • <code>-failoverdelay</code> • <code>-failoverretry</code> • <code>-edition</code> • <code>-clbgoal</code> • <code>-rlbgoal</code> • <code>-notification</code> An error is returned if you attempt to modify one of these options for a GDS service and <code>-global_override</code> is not included. This option is ignored if the service is not a GDS service. See <i>Oracle Database Global Data Services Concepts and Administration Guide</i> for more information.
<code>-verbose</code>	Verbose output

4.5.7.5.2 Example

For the database with a `DB_UNIQUE_NAME` of `dbcrm`, the following command changes the Oracle Data Guard role of the database service named `support` to `standby`:

```
srvctl modify service -db dbcrm -service support -role standby
```

 **See Also:**

"[Managing Services Associated with PDBs](#)"

4.5.8 remove

Removes the specified component from the Oracle Restart configuration. Oracle Restart no longer manages the component. Any environment variable settings for the component are also removed.

Before you remove a component from the Oracle Restart configuration, you must use SRVCTL to stop it. Oracle recommends that you disable the component before removing it, but this is not required.

To perform `srvctl remove` operations, you must be logged in to the database host computer with the proper user account. See "[Preparing to Run SRVCTL](#)" for more information.

- [`srvctl remove asm`](#)
Removes an Oracle ASM instance.
- [`srvctl remove database`](#)
Removes a database. Prompts for confirmation first.
- [`srvctl remove diskgroup`](#)
Removes an Oracle ASM disk group.
- [`srvctl remove listener`](#)
Removes the specified listener or all listeners.
- [`srvctl remove ons`](#)
Removes Oracle Notification Services (ONS).
- [`srvctl remove service`](#)
Removes the specified database service.

 **See Also:**

- [`stop` command](#)
- [`disable` command](#)

4.5.8.1 `srvctl remove asm`

Removes an Oracle ASM instance.

- [Syntax and Options](#)
- [Example](#)

4.5.8.1.1 Syntax and Options

Use the `srvctl remove asm` command with the following syntax:

```
srvctl remove asm [-force]
```

Table 4-36 **srvctl remove asm Options**

Options	Description
-force	Force remove, even when disk groups and databases that use Oracle ASM exist or when the Oracle ASM instance is running.

4.5.8.1.2 Example

An example of this command is:

```
srvctl remove asm
```

4.5.8.2 srvctl remove database

Removes a database. Prompts for confirmation first.

- [Syntax and Options](#)
- [Example](#)

4.5.8.2.1 Syntax and Options

Use the `srvctl remove database` command with the following syntax:

 **Note:**

After running this command, ensure that the password file is in the default location if you want to connect to the database as the `SYS` user with the `SYS` user's password.

```
srvctl remove database -db db_unique_name [-force] [-noprompt] [-verbose]
```

Table 4-37 **srvctl remove database Options**

Options	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .
-force	Force. Removes the database even if it is running.
-noprompt	Suppresses the confirmation prompt and removes immediately
-verbose	Verbose output. A success or failure message is displayed.

4.5.8.2.2 Example

An example of this command is:

```
srvctl remove database -db dbcrm
```

4.5.8.3 srvctl remove diskgroup

Removes an Oracle ASM disk group.

- [Syntax and Options](#)
- [Example](#)

4.5.8.3.1 Syntax and Options

Use the `srvctl remove diskgroup` command with the following syntax:

```
srvctl remove diskgroup -diskgroup diskgroup_name [-force]
```

Table 4-38 `srvctl remove diskgroup` Options

Option	Description
<code>-diskgroup <i>diskgroup_name</i></code>	Disk group name
<code>-force</code>	Force. Removes the disk group even if files are open on it.

4.5.8.3.2 Example

This example removes the disk group named `DATA`. An error is returned if files are open on this disk group.

```
srvctl remove diskgroup -diskgroup DATA
```

4.5.8.4 srvctl remove listener

Removes the specified listener or all listeners.

- [Syntax and Options](#)
- [Example](#)

4.5.8.4.1 Syntax and Options

Use the `srvctl remove listener` command with the following syntax:

```
srvctl remove listener [-listener listener_name | -all] [-force]
```

Table 4-39 `srvctl remove listener` Options

Options	Description
<code>-listener <i>listener_name</i></code>	Name of the listener that you want to remove. If omitted, then the default is LISTENER.

Table 4-39 (Cont.) srvctl remove listener Options

Options	Description
-all	Remove all listeners
-force	Force. Removes the listener even if databases are using it.

4.5.8.4.2 Example

The following command removes the listener lsnr01:

```
srvctl remove listener -listener lsnr01
```

4.5.8.5 srvctl remove ons

Removes Oracle Notification Services (ONS).

- [Syntax and Options](#)

4.5.8.5.1 Syntax and Options

Use the `srvctl remove ons` command as follows:

```
srvctl remove ons [-force] [-verbose]
```

Table 4-40 srvctl remove ons Options

Options	Description
-force	Force. Removes ONS even if it is enabled.
-verbose	Verbose output

4.5.8.6 srvctl remove service

Removes the specified database service.

- [Syntax and Options](#)
- [Example](#)

4.5.8.6.1 Syntax and Options

Use the `srvctl remove service` command as follows:

```
srvctl remove service -db db_unique_name -service service_name [-global_override]
```

Table 4-41 **srvctl remove service Options**

Options	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
-service <i>service_name</i>	Service name
-global_override	If the service is a Global Data Services (GDS) service, then this option must be specified to remove the service. An error is returned if you attempt to remove a GDS service and -global_override is not included. This option is ignored if the service is not a GDS service. See <i>Oracle Database Global Data Services Concepts and Administration Guide</i> for more information.

4.5.8.6.2 Example

An example of this command is:

```
srvctl remove service -db dbcrm -service sales
```

4.5.9 setenv

The `setenv` command sets values of environment variables in the Oracle Restart configuration for a database, a listener, or the Oracle ASM instance.

To perform `srvctl setenv` operations, you must be logged in to the database host computer with the proper user account. See "[Preparing to Run SRVCTL](#)" for more information.

- [**srvctl setenv asm**](#)
Sets the values of environment variables in the Oracle Restart configuration for the Oracle ASM instance. Before starting the instance, Oracle Restart sets environment variables to the values stored in the configuration.
- [**srvctl setenv database**](#)
Sets the values of environment variables in the Oracle Restart configuration for a database instance. Before starting the instance, Oracle Restart sets environment variables to the values stored in the configuration.
- [**srvctl setenv listener**](#)
Sets the values of environment variables in the Oracle Restart configuration for a listener. Before starting the listener, Oracle Restart sets environment variables to the values stored in the configuration.

 **See Also:**

- [getenv command](#)
- [unsetenv command](#)
- ["Managing Environment Variables in the Oracle Restart Configuration"](#)

4.5.9.1 srvctl setenv asm

Sets the values of environment variables in the Oracle Restart configuration for the Oracle ASM instance. Before starting the instance, Oracle Restart sets environment variables to the values stored in the configuration.

- [Syntax and Options](#)
- [Example](#)

4.5.9.1.1 Syntax and Options

Use the `srvctl setenv asm` command with the following syntax:

```
srvctl setenv asm {-envs name=val[,name=val,...] | -env name=val}
```

Table 4-42 `srvctl setenv database` Options

Options	Description
<code>-envs name=val[,name=val,...]</code>	Comma-delimited list of name/value pairs of environment variables
<code>-env name=val</code>	Enables single environment variable to be set to a value that contains commas or other special characters

4.5.9.1.2 Example

The following example sets the AIX operating system environment variable `AIXTHREAD_SCOPE` in the Oracle ASM instance configuration:

```
srvctl setenv asm -envs AIXTHREAD_SCOPE=S
```

4.5.9.2 srvctl setenv database

Sets the values of environment variables in the Oracle Restart configuration for a database instance. Before starting the instance, Oracle Restart sets environment variables to the values stored in the configuration.

- [Syntax and Options](#)
- [Example](#)

4.5.9.2.1 Syntax and Options

Use the `srvctl setenv database` command with the following syntax:

```
srvctl setenv database -db db_unique_name
{-envs name=val[,name=val,...] | -env name=val}
```

Table 4-43 **srvctl setenv database Options**

Options	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
-envs <i>name=val[,name=val,...]</i>	Comma-delimited list of name/value pairs of environment variables
-env <i>name=val</i>	Enables single environment variable to be set to a value that contains commas or other special characters

4.5.9.2.2 Example

The following example sets the LANG environment variable in the configuration of the database with a DB_UNIQUE_NAME of dbcrm:

```
srvctl setenv database -db dbcrm -envs LANG=en
```

4.5.9.3 srvctl setenv listener

Sets the values of environment variables in the Oracle Restart configuration for a listener. Before starting the listener, Oracle Restart sets environment variables to the values stored in the configuration.

- [Syntax and Options](#)
- [Example](#)

4.5.9.3.1 Syntax and Options

Use the `srvctl setenv listener` command with the following syntax:

```
srvctl setenv listener [-listener listener_name]
{-envs name=val[,name=val,...] | -env name=val}
```

Table 4-44 **srvctl setenv listener Options**

Options	Description
-listener <i>listener_name</i>	Listener name. If omitted, sets the specified environment variables in all listener configurations.
-envs <i>name=val[,name=val,...]</i>	Comma-delimited list of name/value pairs of environment variables
-env <i>name=val</i>	Enables single environment variable to be set to a value that contains commas or other special characters

4.5.9.3.2 Example

The following example sets the AIX operating system environment variable AIXTHREAD_SCOPE in the configuration of the listener named crmlistener:

```
srvctl setenv listener -listener crmlistener -envs AIXTHREAD_SCOPE=S
```

4.5.10 start

Starts the specified component or components.

- [svrctl start asm](#)
Starts the Oracle ASM instance.
- [svrctl start database](#)
Starts the specified database instance.
- [svrctl start diskgroup](#)
Starts (mounts) an Oracle ASM disk group.
- [svrctl start home](#)
Starts all of the components that are managed by Oracle Restart in the specified Oracle home. The Oracle home can be an Oracle Database home or an Oracle Grid Infrastructure home.
- [svrctl start listener](#)
Starts the specified listener or all listeners.
- [svrctl start ons](#)
Starts Oracle Notification Services (ONS).
- [svrctl start service](#)
Starts the specified database service or services.

 **See Also:**

["Starting and Stopping Components Managed by Oracle Restart"](#)

4.5.10.1 svrctl start asm

Starts the Oracle ASM instance.

For this command, SRVCTL connects "/" as sysasm" to perform the operation. To run such operations, the owner of the executables in the Oracle Grid Infrastructure home must be a member of the OSASM group, and users running the commands must also be in the OSASM group.

- [Syntax and Options](#)
- [Example](#)

4.5.10.1.1 Syntax and Options

Use the `svrctl start asm` command with the following syntax:

```
srvctl start asm [-startoption start_options]
```

Table 4-45 **srvctl start asm Option**

Option	Description
-startoption <i>start_options</i>	Comma-delimited list of options for the startup command (OPEN, MOUNT, NOMOUNT, or FORCE). If omitted, defaults to normal startup (OPEN). See Also: <i>SQL*Plus User's Guide and Reference</i> for more information about startup options

4.5.10.1.2 Example

This example starts the Oracle ASM instance, which then mounts any disk groups named in the `ASM_DISKGROUPS` initialization parameter:

```
srvctl start asm
```

This example starts the Oracle ASM instance without mounting any disk groups:

```
srvctl start asm -startoption nomount
```

4.5.10.2 `srvctl start database`

Starts the specified database instance.

For this command, SRVCTL connects "/" as sysdba" to perform the operation. To run such operations, the owner of the Oracle executables in the database Oracle home must be a member of the OSDBA group (for example, the dba group on UNIX and Linux), and users running the commands must also be in the OSDBA group.

- [Syntax and Options](#)
- [Example](#)

4.5.10.2.1 Syntax and Options

Use the `srvctl start database` command with the following syntax:

```
srvctl start database -db db_unique_name [-startoption start_options] [-verbose]
```

Table 4-46 **srvctl start database Options**

Option	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .

Table 4-46 (Cont.) srvctl start database Options

Option	Description
-startoption <i>start_options</i>	Comma-delimited list of options for the startup command (for example: OPEN, MOUNT, NOMOUNT, RESTRICT, and so on) Notes: <ul style="list-style-type: none"> This command parameter does not support the PFILE option or the QUIET option, but it supports all other database startup options. For multi-word startup options, such as <code>read only</code> and <code>read write</code>, separate the words with a space and enclose in single quotation marks (' '). For example, '<code>read only</code>'. See Also: <i>SQL*Plus User's Guide and Reference</i> for more information about startup options
-verbose	Verbose output

4.5.10.2.2 Example

An example of this command is:

```
srvctl start database -db dbcrm -startoption nomount
```

4.5.10.3 srvctl start diskgroup

Starts (mounts) an Oracle ASM disk group.

- [Syntax and Options](#)
- [Example](#)

4.5.10.3.1 Syntax and Options

Use the `srvctl start diskgroup` command with the following syntax:

```
srvctl start diskgroup -diskgroup diskgroup_name
```

Table 4-47 srvctl start diskgroup Options

Option	Description
-diskgroup <i>diskgroup_name</i>	Disk group name

4.5.10.3.2 Example

An example of this command is:

```
srvctl start diskgroup -diskgroup DATA
```

4.5.10.4 srvctl start home

Starts all of the components that are managed by Oracle Restart in the specified Oracle home. The Oracle home can be an Oracle Database home or an Oracle Grid Infrastructure home.

This command starts the components that were stopped by a `srvctl stop home`. This command uses the information in the specified state file to identify the components to start.

 **Note:**

Use this command to restart components after you install a patch in an Oracle home.

- [Syntax and Options](#)

4.5.10.4.1 Syntax and Options

Use the `srvctl start home` command with the following syntax:

```
srvctl start home -oraclehome oracle_home -statefile state_file
```

Table 4-48 `srvctl start home` Options

Option	Description
<code>-oraclehome</code> <i>oracle_home</i>	Complete path of the Oracle home
<code>-statefile</code> <i>state_file</i>	Complete path of the state file. The state file contains the current state information for the components in the Oracle home and is created when the <code>srvctl stop home</code> command or the <code>srvctl status home</code> command is run.

4.5.10.5 `srvctl start listener`

Starts the specified listener or all listeners.

- [Syntax and Options](#)
- [Example](#)

4.5.10.5.1 Syntax and Options

Use the `srvctl start listener` command with the following syntax:

```
srvctl start listener [-listener listener_name]
```

Table 4-49 `srvctl start listener` Options

Option	Description
<code>-listener</code> <i>listener_name</i>	Listener name. If omitted, all Oracle Restart-managed listeners are started.

4.5.10.5.2 Example

An example of this command is:

```
srvctl start listener -listener listener
```

4.5.10.6 srvctl start ons

Starts Oracle Notification Services (ONS).

- [Syntax and Options](#)

4.5.10.6.1 Syntax and Options

Use the `srvctl start ons` command with the following syntax:

```
srvctl start ons [-verbose]
```

Table 4-50 `srvctl start ons` Options

Option	Description
<code>-verbose</code>	Verbose output

4.5.10.7 srvctl start service

Starts the specified database service or services.

- [Syntax and Options](#)
- [Example](#)

4.5.10.7.1 Syntax and Options

Use the `srvctl start service` command with the following syntax:

```
srvctl start service -db db_unique_name [-service service_name_list |  
-pdb pluggable_database] [-startoption start_options] [-global_override] [-  
verbose]
```

Table 4-51 `srvctl start service` Options

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
<code>-service service_name_list</code>	Comma-delimited list of service names. The service name list is optional and, if not provided, SRVCTL starts all of the database's services.
<code>-pdb pluggable_database</code>	In a CDB, the name of the PDB associated with the service If this option is set to an empty string, then the service is associated with root.

Table 4-51 (Cont.) srvctl start service Options

Option	Description
<code>-startoption start_options</code>	Options for database startup (for example: OPEN, MOUNT, NOMOUNT and so on) if the database must be started first See Also: <i>SQL*Plus User's Guide and Reference</i> for more information about startup options
<code>-global_override</code>	If the service is a Global Data Services (GDS) service, then this option must be specified to start the service. An error is returned if you attempt to start a GDS service and <code>-global_override</code> is not included. This option is ignored if the service is not a GDS service. See <i>Oracle Database Global Data Services Concepts and Administration Guide</i> for more information.
<code>-verbose</code>	Verbose output

4.5.10.7.2 Example

For the database with a `DB_UNIQUE_NAME` of `dbcrrm`, the following example starts the `sales` database service:

```
srvctl start service -db dbcrrm -service sales
```

4.5.11 status

Displays the running status of the specified component or set of components.

- [srvctl status asm](#)
Displays the running status of the Oracle ASM instance.
- [srvctl status database](#)
Displays the running status of the specified database.
- [srvctl status diskgroup](#)
Displays the running status of an Oracle ASM disk group.
- [srvctl status home](#)
Displays the running status of all of the components that are managed by Oracle Restart in the specified Oracle home. The Oracle home can be an Oracle Database home or an Oracle Grid Infrastructure home.
- [srvctl status listener](#)
Displays the running status of the specified listener or of all Oracle Restart-managed listeners.
- [srvctl status ons](#)
Displays the running status of Oracle Notification Services (ONS).
- [srvctl status service](#)
Displays the running status of one or more database services.

4.5.11.1 `srvctl status asm`

Displays the running status of the Oracle ASM instance.

- [Syntax and Options](#)
- [Example](#)

4.5.11.1.1 Syntax and Options

Use the `srvctl status asm` command with the following syntax:

```
srvctl status asm [-all] [-verbose]
```

Table 4-52 `srvctl status asm` Options

Option	Description
<code>-all</code>	Display enabled/disabled status also
<code>-verbose</code>	Verbose output

4.5.11.1.2 Example

An example of this command is:

```
srvctl status asm
ASM is running on dbhost
```

4.5.11.2 `srvctl status database`

Displays the running status of the specified database.

- [Syntax and Options](#)
- [Example](#)

4.5.11.2.1 Syntax and Options

Use the `srvctl status database` command with the following syntax:

```
srvctl status database -db db_unique_name [-force] [-verbose]
```

Table 4-53 `srvctl status database` Options

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
<code>-force</code>	Display a message if the database is disabled
<code>-verbose</code>	Verbose output. Lists the database services that are running.

4.5.11.2.2 Example

An example of this command is:

```
srvctl status database -db dbcrm -verbose  
  
Database dbcrm is running with online services mfg,sales
```

4.5.11.3 srvctl status diskgroup

Displays the running status of an Oracle ASM disk group.

- [Syntax and Options](#)
- [Example](#)

4.5.11.3.1 Syntax and Options

Use the `srvctl status diskgroup` command with the following syntax:

```
srvctl status diskgroup -diskgroup diskgroup_name [-all] [-verbose]
```

Table 4-54 `srvctl status diskgroup` Options

Option	Description
<code>-diskgroup <i>diskgroup_name</i></code>	Disk group name
<code>-all</code>	Display enabled/disabled status also
<code>-verbose</code>	Verbose output. Lists the database services that are running.

4.5.11.3.2 Example

An example of this command is:

```
srvctl status diskgroup -diskgroup DATA  
  
Disk Group DATA is running on dbhost
```

4.5.11.4 srvctl status home

Displays the running status of all of the components that are managed by Oracle Restart in the specified Oracle home. The Oracle home can be an Oracle Database home or an Oracle Grid Infrastructure home.

This command writes the current status of the components to the specified state file.

- [Syntax and Options](#)

4.5.11.4.1 Syntax and Options

Use the `srvctl status home` command with the following syntax:

```
srvctl status home -oraclehome oracle_home -statefile state_file
```

Table 4-55 `srvctl status home` Options

Option	Description
<code>-oraclehome oracle_home</code>	Complete path of the Oracle home
<code>-statefile state_file</code>	Complete path of the state file

4.5.11.5 `srvctl status listener`

Displays the running status of the specified listener or of all Oracle Restart–managed listeners.

- [Syntax and Options](#)
- [Example](#)

4.5.11.5.1 Syntax and Options

Use the `srvctl status listener` command with the following syntax:

```
srvctl status listener [-listener listener_name] [-verbose]
```

Table 4-56 `srvctl status listener` Options

Option	Description
<code>-listener listener_name</code>	Listener name. If omitted, the status of all listeners is displayed.
<code>-verbose</code>	Verbose output. Lists the database services that are running.

4.5.11.5.2 Example

An example of this command is:

```
srvctl status listener -listener crmlistener
```

```
Listener CRMLISTENER is running on dbhost
```

4.5.11.6 `srvctl status ons`

Displays the running status of Oracle Notification Services (ONS).

- [Syntax and Options](#)

4.5.11.6.1 Syntax and Options

Use the `srvctl status ons` command with the following syntax:

```
srvctl status ons [-verbose]
```

Table 4-57 **srvctl status ons Options**

Option	Description
-verbose	Verbose output. Lists the database services that are running.

4.5.11.7 srvctl status service

Displays the running status of one or more database services.

- [Syntax and Options](#)
- [Example](#)

4.5.11.7.1 Syntax and Options

Use the `srvctl status service` command with the following syntax:

```
srvctl status service -db db_unique_name
[-service service_name_list | -pdb pluggable_database]
[-force] [-verbose]
```

Table 4-58 **srvctl status service Options**

Option	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
-service <i>service_name_list</i>	Comma-delimited list of service names. If omitted, status is listed for all database services for the designated database.
-pdb <i>pluggable_database</i>	In a multitenant container database (CDB), the name of the pluggable database (PDB) associated with the service If this option is set to an empty string, then the service is associated with root.
-force	Display a message if a service is disabled
-verbose	Verbose output

4.5.11.7.2 Example

For the database with the DB_UNIQUE_NAME of `dbcram`, the following example displays the running status of the service `sales`:

```
srvctl status service -db dbcram -service sales
Service sales is running on dbhost
```

4.5.12 stop

Stops the specified component or components.

If you want a component to remain stopped after you issue a `srvctl stop` command, disable the component. See the [disable](#) command.

 **Note:**

If a component is stopped and is not disabled, it could restart as a result of another planned operation. That is, although a stopped component will not restart as a result of a failure, it might be started if a dependent component is started with a `srvctl start` command.

- [srvctl stop asm](#)
Stops the Oracle ASM instance.
- [srvctl stop database](#)
Stops a database and its services.
- [srvctl stop diskgroup](#)
Stops (dismounts) an Oracle ASM disk group.
- [srvctl stop home](#)
Stops all of the components that are managed by Oracle Restart in the specified Oracle home. The Oracle home can be an Oracle Database home or an Oracle Grid Infrastructure home.
- [srvctl stop listener](#)
Stops the designated listener or all Oracle Restart–managed listeners. Stopping a listener does not cause databases that are registered with the listener to be stopped.
- [srvctl stop ons](#)
Stops Oracle Notification Services (ONS).
- [srvctl stop service](#)
Stops one or more database services.

 **See Also:**

["Starting and Stopping Components Managed by Oracle Restart"](#)

4.5.12.1 `srvctl stop asm`

Stops the Oracle ASM instance.

- [Syntax and Options](#)
- [Example](#)

4.5.12.1.1 Syntax and Options

Use the `srvctl stop asm` command with the following syntax:

```
srvctl stop asm [-stopoption stop_options] [-force]
```

Table 4-59 **srvctl stop asm Option**

Option	Description
-stopoption <i>stop_options</i>	Options for the shutdown operation, for example, NORMAL, TRANSACTIONAL, IMMEDIATE, or ABORT See Also: <i>SQL*Plus User's Guide and Reference</i> for more information about shutdown options
-force	Force. Must be present if disk groups are currently started (mounted). This option enables SRVCTL to stop the disk groups before stopping Oracle ASM. Each dependent database instance is also stopped according to its stop options, or with the ABORT option if the configured stop options fail.

4.5.12.1.2 Example

An example of this command is:

```
srvctl stop asm -stopoption abort -force
```

4.5.12.2 srvctl stop database

Stops a database and its services.

- [Syntax and Options](#)
- [Example](#)

4.5.12.2.1 Syntax and Options

Use the `srvctl stop database` command with the following syntax:

```
srvctl stop database -db db_unique_name [-stopoption stop_options]
[-drain_timeout timeout] [-force] [-verbose]
```

Table 4-60 **srvctl stop database Options**

Option	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
-stopoption <i>stop_options</i>	SHUTDOWN command options (for example: NORMAL, TRANSACTIONAL, IMMEDIATE, or ABORT). Default is IMMEDIATE.

Table 4-60 (Cont.) srvctl stop database Options

Option	Description
-drain_timeout <i>timeout</i>	This option specifies the time allowed for resource draining to be completed in seconds. Permitted values are NULL, 0, or any positive integer. The draining period is intended for planned maintenance operations. During the draining period, all current client requests are processed, but new requests are not accepted. How draining works depends on the setting of the -stopoption option. The default value is NULL, which means that this option is not set. If the option is not set, and -drain_timeout has been set on the service, then this value is used. If it is set to 0, then draining does not occur.
-force	Stops the database, its services, and any resources that depend on the services
-verbose	Verbose output

4.5.12.2 Example

An example of this command is:

```
srvctl stop database -db dbcrm
```

4.5.12.3 srvctl stop diskgroup

Stops (dismounts) an Oracle ASM disk group.

- [Syntax and Options](#)
- [Example](#)

4.5.12.3.1 Syntax and Options

Use the `srvctl stop diskgroup` command with the following syntax:

```
srvctl stop diskgroup -diskgroup diskgroup_name [-force]
```

Table 4-61 srvctl stop diskgroup Options

Option	Description
-diskgroup <i>diskgroup_name</i>	Disk group name
-force	Force. Dismount the disk group even if some files in the disk group are open.

4.5.12.3.2 Example

This example stops the disk group named `DATA`. An error is returned if files are open on this disk group.

```
srvctl stop diskgroup -diskgroup DATA
```

4.5.12.4 srvctl stop home

Stops all of the components that are managed by Oracle Restart in the specified Oracle home. The Oracle home can be an Oracle Database home or an Oracle Grid Infrastructure home.

This command identifies the components that it stopped in the specified state file.

 **Note:**

- Before stopping the components in an Oracle Grid Infrastructure home, stop the components in a dependent Oracle Database home.
- Use this command to stop components before you install a patch in an Oracle home.

- [Syntax and Options](#)

4.5.12.4.1 Syntax and Options

Use the `srvctl stop home` command with the following syntax:

```
srvctl stop home -oraclehome oracle_home -statefile state_file
[-stopoption stop_options] [-force]
```

Table 4-62 `srvctl stop home` Options

Option	Description
<code>-oraclehome</code> <code>oracle_home</code>	Complete path of the Oracle home
<code>-statefile</code> <code>state_file</code>	Complete path to where you want the state file to be written
<code>-stopoption</code> <code>stop_options</code>	SHUTDOWN command options for the database (for example: NORMAL, TRANSACTIONAL, IMMEDIATE, or ABORT). Default is IMMEDIATE. See Also: <i>SQL*Plus User's Guide and Reference</i> for more information about shutdown options
<code>-force</code>	Force stop each component

4.5.12.5 srvctl stop listener

Stops the designated listener or all Oracle Restart–managed listeners. Stopping a listener does not cause databases that are registered with the listener to be stopped.

- [Syntax and Options](#)
- [Example](#)

4.5.12.5.1 Syntax and Options

Use the `srvctl stop listener` command with the following syntax:

```
srvctl stop listener [-listener listener_name] [-force]
```

Table 4-63 **srvctl stop listener Options**

Option	Description
<code>-listener <i>listener_name</i></code>	Listener name. If omitted, all Oracle Restart-managed listeners are stopped.
<code>-force</code>	Force. Passes the stop command with the <code>-f</code> option to Oracle Clusterware. See <i>Oracle Clusterware Administration and Deployment Guide</i> for more information about the Oracle Clusterware <code>-f</code> option.

4.5.12.5.2 Example

An example of this command is:

```
srvctl stop listener -listener crmlistener
```

4.5.12.6 srvctl stop ons

Stops Oracle Notification Services (ONS).

- [Syntax and Options](#)

4.5.12.6.1 Syntax and Options

Use the `srvctl stop ons` command with the following syntax:

```
srvctl stop ons [-verbose]
```

Table 4-64 **srvctl stop ons Options**

Option	Description
<code>-verbose</code>	Verbose output

4.5.12.7 srvctl stop service

Stops one or more database services.

- [Syntax and Options](#)
- [Example](#)

4.5.12.7.1 Syntax and Options

Use the `srvctl stop service` command with the following syntax:

```
srvctl stop service -db db_unique_name [-service service_name_list |  
-pdb pluggable_database] [-drain_timeout timeout] [-stopoption stop_option]  
[-global_override] [-wait wait_option] [-force] [-verbose]
```

Table 4-65 **srvctl stop service Options**

Option	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
<code>-service service_name_list</code>	Comma-delimited list of database service names. If you do not provide a service name list, then SRVCTL stops all services on the database.
<code>-pdb pluggable_database</code>	In a CDB, the name of the PDB associated with the service. If this option is set to an empty string, then the service is associated with root.
<code>-drain_timeout timeout</code>	This option specifies the time allowed for resource draining to be completed in seconds. Permitted values are NULL, 0, or any positive integer. The draining period is intended for planned maintenance operations. During the draining period, all current client requests are processed, but new requests are not accepted. How draining works depends on the setting of the -stopoption option. The default value is NULL, which means that this option is not set. If the option is not set, and -drain_timeout has been set on the service, then this value is used. If it is set to 0, then draining does not occur.
<code>-stopoption stop_option</code>	This option specifies the mode in which the service is stopped. The following values are permitted: <ul style="list-style-type: none"> • IMMEDIATE specifies that sessions are permitted to drain before the service is stopped. • TRANSACTIONAL specifies that sessions are permitted to drain for the amount of time specified in the -drain_timeout option. The service is stopped when the time limit is reached, and any remaining sessions are terminated. • NONE is the default.
<code>-global_override</code>	If the service is a Global Data Services (GDS) service, then this option must be specified to stop the service. An error is returned if you attempt to stop a GDS service and -global_override is not included. This option is ignored if the service is not a GDS service. See <i>Oracle Database Global Data Services Concepts and Administration Guide</i> for more information.
<code>-wait wait_option</code>	This option specifies whether to wait until service draining is completed before stopping the service. Specify YES to wait or NO to stop the service without waiting.
<code>-force</code>	Force. This option disconnects all of the stopped services' sessions immediately. Uncommitted transactions are rolled back. If this option is omitted, active sessions remain connected to the services, but no further connections to the services can be made.
<code>-verbose</code>	Verbose output

4.5.12.7.2 Example

The following example stops the sales database service on the database with a DB_UNIQUE_NAME of dbcrm:

```
srvctl stop service -db dbcrm -service sales
```

4.5.13 unsetenv

The `unsetenv` command deletes one or more environment variables from the Oracle Restart configuration for a database, a listener, or an Oracle ASM instance.

To perform `srvctl unsetenv` operations, you must be logged in to the database host computer with the proper user account. See "Preparing to Run SRVCTL" for more information.

- [svrctl unsetenv asm](#)
Removes the specified environment variables from the Oracle Restart configuration for the Oracle ASM instance.
- [svrctl unsetenv database](#)
Removes the specified environment variables from the Oracle Restart configuration for the specified database.
- [svrctl unsetenv listener](#)
Removes the specified environment variables from the Oracle Restart configuration for the specified listener or all listeners.

See Also:

- [setenv command](#)
- [getenv command](#)
- ["Managing Environment Variables in the Oracle Restart Configuration"](#)

4.5.13.1 svrctl unsetenv asm

Removes the specified environment variables from the Oracle Restart configuration for the Oracle ASM instance.

- [Syntax and Options](#)
- [Example](#)

4.5.13.1.1 Syntax and Options

Use the `srvctl unsetenv asm` command with the following syntax:

```
srvctl unsetenv asm -envs name_list
```

Table 4-66 **srvctl unsetenv asm Options**

Options	Description
-envs <i>name_list</i>	Comma-delimited list of environment variables to remove

4.5.13.1.2 Example

The following example removes the AIX operating system environment variable AIXTHREAD_SCOPE from the Oracle ASM instance configuration:

```
srvctl unsetenv asm -envs AIXTHREAD_SCOPE
```

4.5.13.2 srvctl unsetenv database

Removes the specified environment variables from the Oracle Restart configuration for the specified database.

- [Syntax and Options](#)
- [Example](#)

4.5.13.2.1 Syntax and Options

Use the `srvctl unsetenv database` command as follows:

```
srvctl unsetenv database -db db_unique_name -envs name_list
```

Table 4-67 **srvctl unsetenv database Options**

Options	Description
-db <i>db_unique_name</i>	Unique name for the database. Must match the DB_UNIQUE_NAME initialization parameter setting. If DB_UNIQUE_NAME is unspecified, then this option must match the DB_NAME initialization parameter setting. The default setting for DB_UNIQUE_NAME uses the setting for DB_NAME.
-envs <i>name_list</i>	Comma-delimited list of environment variables to remove

4.5.13.2.2 Example

The following example deletes the AIXTHREAD_SCOPE environment variable from the Oracle Restart configuration for the database with a DB_UNIQUE_NAME of dbcrm:

```
srvctl unsetenv database -db dbcrm -envs AIXTHREAD_SCOPE
```

4.5.13.3 srvctl unsetenv listener

Removes the specified environment variables from the Oracle Restart configuration for the specified listener or all listeners.

- [Syntax and Options](#)

- [Example](#)

4.5.13.3.1 Syntax and Options

Use the `srvctl unsetenv listener` command with the following syntax:

```
srvctl unsetenv listener [-listener listener_name] -envs name_list
```

Table 4-68 `srvctl unsetenv listener` Options

Options	Description
<code>-listener <i>listener_name</i></code>	Listener name. If omitted, the specified environment variables are removed from the configurations of all listeners.
<code>-envs <i>name_list</i></code>	Comma-delimited list of environment variables to remove

4.5.13.3.2 Example

The following example removes the AIX operating system environment variable `AIXTHREAD_SCOPE` from the listener configuration for the listener named `crmlistener`:

```
srvctl unsetenv listener -listener crmlistener -envs AIXTHREAD_SCOPE
```

4.5.14 update

The `srvctl update` command updates the running database to switch to the specified startup option.

- [srvctl update database](#)

The `srvctl update database` command changes the open mode of the database.

4.5.14.1 `srvctl update database`

The `srvctl update database` command changes the open mode of the database.

- [Syntax and Options](#)

4.5.14.1.1 Syntax and Options

Use the `srvctl update database` command as follows:

```
srvctl update database -db db_unique_name --startoption start_options
```

Table 4-69 `srvctl upgrade database` Options

Option	Description
<code>-db <i>db_unique_name</i></code>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .
<code>-startoption <i>start_options</i></code>	Startup options for the database. Examples of startup options are <code>OPEN</code> , <code>MOUNT</code> , or <code>"READ ONLY"</code> .

4.5.15 upgrade

The `srvctl upgrade` command upgrades the resources types and resources from an older version to a newer version.

- [srvctl upgrade database](#)

The `srvctl upgrade database` command upgrades the configuration of a database and all of its services to the version of the database home from where this command is run.

4.5.15.1 `srvctl upgrade database`

The `srvctl upgrade database` command upgrades the configuration of a database and all of its services to the version of the database home from where this command is run.

- [Syntax and Options](#)

4.5.15.1.1 Syntax and Options

Use the `srvctl upgrade database` command as follows:

```
srvctl upgrade database -db db_unique_name -oraclehome oracle_home
```

Table 4-70 `srvctl upgrade database` Options

Parameter	Description
<code>-db db_unique_name</code>	Unique name for the database. Must match the <code>DB_UNIQUE_NAME</code> initialization parameter setting. If <code>DB_UNIQUE_NAME</code> is unspecified, then this option must match the <code>DB_NAME</code> initialization parameter setting. The default setting for <code>DB_UNIQUE_NAME</code> uses the setting for <code>DB_NAME</code> .
<code>-oraclehome oracle_home</code>	The full path of Oracle home for the database

4.6 CRSCTL Command Reference

You can reference details about the syntax for the CRSCTL commands that are relevant for Oracle Restart.

 **Note:**

You must be the root user or Oracle grid infrastructure software owner to run these CRSCTL commands.

CRSCTL Command Syntax Overview

CRSCTL expects the following command syntax:

`crsctl command has`

where *command* is a verb such as start, stop, or enable. The has object indicates Oracle high availability services.

Case Sensitivity

CRSCTL commands and components are case insensitive.

- **check**
Displays the Oracle Restart status.
- **config**
Displays the Oracle Restart configuration.
- **disable**
Disables automatic restart of Oracle Restart.
- **enable**
Enables automatic restart of Oracle Restart.
- **start**
Starts Oracle Restart.
- **stop**
Stops Oracle Restart.

4.6.1 check

Displays the Oracle Restart status.

Syntax and Options

`crsctl check has`

4.6.2 config

Displays the Oracle Restart configuration.

Syntax and Options

`crsctl config has`

4.6.3 disable

Disables automatic restart of Oracle Restart.

Syntax and Options

`crsctl disable has`

4.6.4 enable

Enables automatic restart of Oracle Restart.

Syntax and Options

`crsctl enable has`

4.6.5 start

Starts Oracle Restart.

Syntax and Options

crsctl start has

4.6.6 stop

Stops Oracle Restart.

Syntax and Options

crsctl stop has [-f]

Table 4-71 crsctl stop has Options

Options	Description
-f	Force. If any resources that are managed by Oracle Restart are still running, then try to stop these resources gracefully. If a resource cannot be stopped gracefully, then try to force the resource to stop. For example, if an Oracle ASM instance is running, then SHUTDOWN IMMEDIATE attempts to stop the Oracle ASM instance gracefully, while SHUTDOWN ABORT attempts to force the Oracle ASM instance to stop. When the -f option <i>is not</i> specified, this command tries to stop resources managed by Oracle Restart gracefully but does not try to force them to stop.

 **Note:**

For a database resource, this command always uses SHUTDOWN ABORT, regardless of whether the -f option is specified.

5

Managing Processes

Oracle Databases uses several processes so that multiple users and applications can connect to a single database instance simultaneously.

- [About Dedicated and Shared Server Processes](#)

Oracle Database creates server processes to handle the requests of user processes connected to an instance.

- [About Database Resident Connection Pooling](#)

Database Resident Connection Pooling (DRCP) provides a connection pool in the database server for typical Web application usage scenarios where the application acquires a database connection, works on it for a relatively short duration, and then releases it. DRCP pools "dedicated" servers. A **pooled server** is the equivalent of a server foreground process and a database session combined.

- [Configuring Oracle Database for Shared Server](#)

You can enable shared server and set or alter shared server initialization parameters.

- [Configuring Database Resident Connection Pooling](#)

The database server is preconfigured to allow database resident connection pooling. However, you must explicitly enable this feature by starting the connection pool.

- [About Oracle Database Background Processes](#)

To maximize performance and accommodate many users, a multiprocess Oracle Database system uses **background processes**. Background processes consolidate functions that would otherwise be handled by multiple database programs running for each user process. Background processes asynchronously perform I/O and monitor other Oracle Database processes to provide increased parallelism for better performance and reliability.

- [Managing Prespawned Processes](#)

Oracle Database can prespawn processes for better client connection performance.

- [Managing Processes for Parallel SQL Execution](#)

You can manage parallel processing of SQL statements. In this configuration, Oracle Database can divide the work of processing an SQL statement among multiple parallel processes.

- [Managing Processes for External Procedures](#)

An external procedure is a procedure or function written in a programming language and stored in a shared library. An Oracle server can call external procedures or functions using PL/SQL routines.

- [Terminating Sessions](#)

Sometimes it is necessary to terminate current user sessions. For example, you might want to perform an administrative operation and need to terminate all non-administrative sessions.

- [Process and Session Data Dictionary Views](#)
You can query data dictionary views for information about processes and sessions.

5.1 About Dedicated and Shared Server Processes

Oracle Database creates server processes to handle the requests of user processes connected to an instance.

A server process can be either of the following:

- A **dedicated server process**, which services only one user process
- A **shared server process**, which can service multiple user processes

Your database is always enabled to allow dedicated server processes, but you must specifically configure and enable shared server by setting one or more initialization parameters.

- [Dedicated Server Processes](#)
A dedicated server process services only one user process.
- [Shared Server Processes](#)
A shared server process can service multiple user processes.

5.1.1 Dedicated Server Processes

A dedicated server process services only one user process.

[Figure 5-1](#) illustrates how dedicated server processes work. In this diagram two user processes are connected to the database through dedicated server processes.

In general, it is better to be connected through a **dispatcher** and use a shared server process. This is illustrated in [Figure 5-2](#). A shared server process can be more efficient because it keeps the number of processes required for the running instance low.

In the following situations, however, users and administrators should explicitly connect to an instance using a dedicated server process:

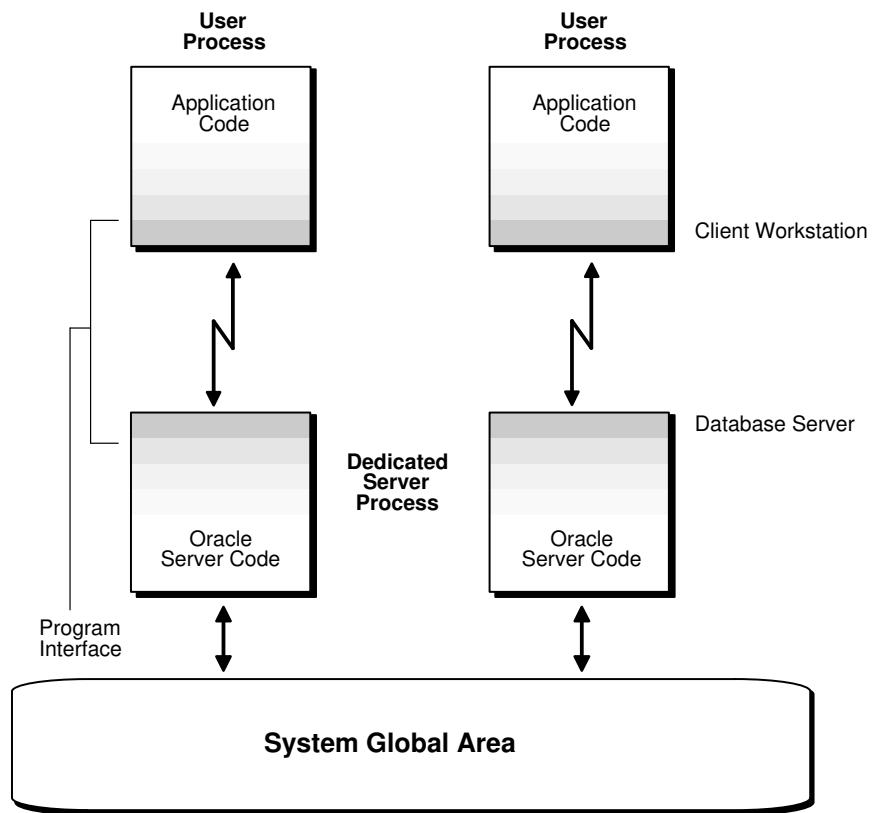

- To submit a batch job (for example, when a job can allow little or no idle time for the server process)
- To use Recovery Manager (RMAN) to back up, restore, or recover a database

To request a dedicated server connection when Oracle Database is configured for shared server, users must connect using a net service name that is configured to use a dedicated server. Specifically, the net service name value should include the SERVER=DEDICATED clause in the connect descriptor.

See Also:

[Oracle Database Net Services Administrator's Guide](#) for more information about requesting a dedicated server connection

Figure 5-1 Oracle Database Dedicated Server Processes

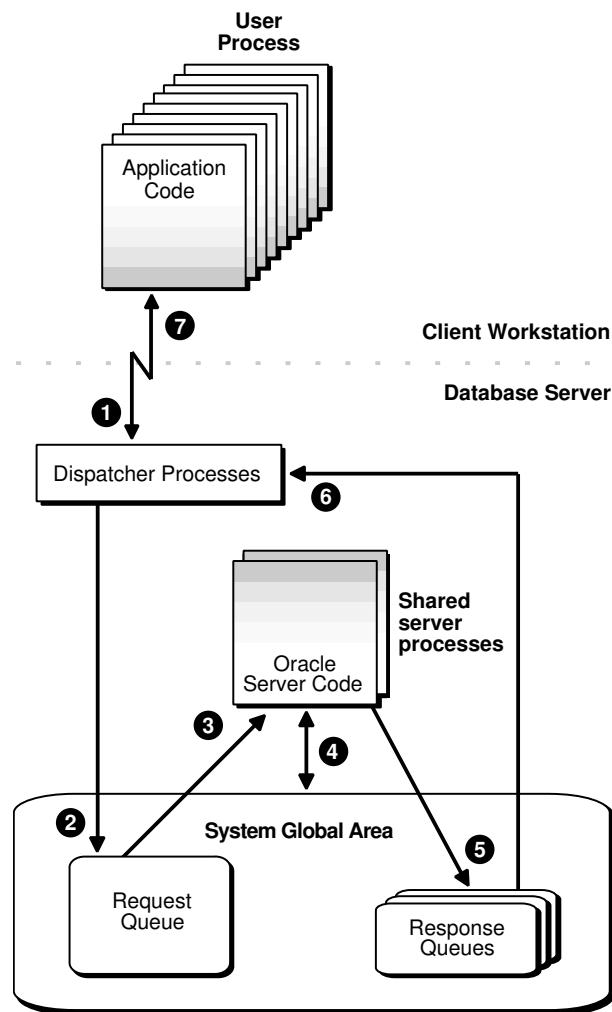

5.1.2 Shared Server Processes

A shared server process can service multiple user processes.

Consider an order entry system with dedicated server processes. A customer phones the order desk and places an order, and the clerk taking the call enters the order into the database. For most of the transaction, the clerk is on the telephone talking to the customer. A server process is not needed during this time, so the server process dedicated to the clerk's user process remains idle. The system is slower for other clerks entering orders, because the idle server process is holding system resources.

Shared server architecture eliminates the need for a dedicated server process for each connection (see [Figure 5-2](#)).

Figure 5-2 Oracle Database Shared Server Processes

In a shared server configuration, client user processes connect to a dispatcher. The dispatcher can support multiple client connections concurrently. Each client connection is bound to a **virtual circuit**, which is a piece of shared memory used by the dispatcher for client database connection requests and replies. The dispatcher places a virtual circuit on a common queue when a request arrives.

An idle shared server process picks up the virtual circuit from the common queue, services the request, and relinquishes the virtual circuit before attempting to retrieve another virtual circuit from the common queue. This approach enables a small pool of server processes to serve a large number of clients. A significant advantage of shared server architecture over the dedicated server model is the reduction of system resources, enabling the support of an increased number of users.

For even better resource management, shared server can be configured for **session multiplexing**, which combines multiple sessions for transmission over a single network connection in order to conserve the operating system's resources.

Shared server architecture requires Oracle Net Services. User processes targeting the shared server must connect through Oracle Net Services, even if they are on the same system as the Oracle Database instance.

 **See Also:**

Oracle Database Net Services Administrator's Guide for more detailed information about shared server, including features such as session multiplexing

5.2 About Database Resident Connection Pooling

Database Resident Connection Pooling (DRCP) provides a connection pool in the database server for typical Web application usage scenarios where the application acquires a database connection, works on it for a relatively short duration, and then releases it. DRCP pools "dedicated" servers. A **pooled server** is the equivalent of a server foreground process and a database session combined.

DRCP complements middle-tier connection pools that share connections between threads in a middle-tier process. In addition, DRCP enables sharing of database connections across middle-tier processes on the same middle-tier host and even across middle-tier hosts. This results in significant reduction in key database resources needed to support a large number of client connections, thereby reducing the database tier memory footprint and boosting the scalability of both the middle-tier and the database tier. Having a pool of readily available servers also has the additional benefit of reducing the cost of creating and tearing down client connections.

DRCP is especially relevant for architectures with multi-process single threaded application servers (such as PHP/Apache) that cannot perform middle-tier connection pooling. The database can still scale to tens of thousands of simultaneous connections with DRCP.

 **Note:**

- Starting with Oracle Database 12c Release 2 (12.2.0.1), proxy sessions that belong to the same user can be shared.
- On Windows platforms, setting the `SQLNET.AUTHENTICATION_SERVICES` parameter value to `nts` is not supported with DRCP.

 **See Also:**

- *Oracle Database Concepts* for more details on DRCP
- *Oracle Database Development Guide* for more information about DRCP, including restrictions on using DRCP
- *Oracle Call Interface Programmer's Guide* for information about options that are available when obtaining a DRCP session
- *Oracle Database Development Guide* for information about sharing proxy sessions

When To Use Database Resident Connection Pooling

Database resident connection pooling is useful when multiple clients access the database and when any of the following apply:

- A large number of client connections need to be supported with minimum memory usage.
- The client applications are similar and can share or reuse sessions.
Applications are similar if they connect with the same database credentials and use the same schema.
- The client applications acquire a database connection, work on it for a relatively short duration, and then release it.
- Session affinity is not required across client requests.
- There are multiple processes and multiple hosts on the client side.

Advantages of Database Resident Connection Pooling

Using database resident connection pooling provides the following advantages:

- Enables resource sharing among multiple middle-tier client applications.
- Improves scalability of databases and applications by reducing resource usage.

Database Resident Connection Pooling and LOGON/LOGOFF Triggers

LOGON triggers fire for every authentication and every time a new session is created in DRCP.

LOGOFF triggers fire on every log off and when the sessions are destroyed in DRCP. Therefore, a LOGOFF trigger fires when a session is terminated due to an idle time limit.

- [Comparing DRCP to Dedicated Server and Shared Server](#)
Understand the differences between dedicated server, shared server, and database resident connection pooling.

 See Also:

- Oracle Database PL/SQL Language Reference
- Oracle Database Security Guide

5.2.1 Comparing DRCP to Dedicated Server and Shared Server

Understand the differences between dedicated server, shared server, and database resident connection pooling.

[Table 5-1](#) lists the differences between dedicated server, shared server, and database resident connection pooling.

Table 5-1 Dedicated Servers, Shared Servers, and Database Resident Connection Pooling

Dedicated Server	Shared Server	Database Resident Connection Pooling
When a client request is received, a new server process and a session are created for the client.	When the first request is received from a client, the Dispatcher process places this request on a common queue. The request is picked up by an available shared server process. The Dispatcher process then manages the communication between the client and the shared server process.	When the first request is received from a client, the Connection Broker picks an available pooled server and hands off the client connection to the pooled server. If no pooled servers are available, the Connection Broker creates one. If the pool has reached its maximum size, the client request is placed on the wait queue until a pooled server is available.
Releasing database resources involves terminating the session and server process.	Releasing database resources involves terminating the session.	Releasing database resources involves releasing the pooled server to the pool.
Memory requirement is proportional to the number of server processes and sessions. There is one server and one session for each client.	Memory requirement is proportional to the sum of the shared servers and sessions. There is one session for each client.	Memory requirement is proportional to the number of pooled servers and their sessions. There is one session for each pooled server.
Session memory is allocated from the PGA.	Session memory is allocated from the SGA.	Session memory is allocated from the PGA.

Example of Memory Usage for Dedicated Server, Shared Server, and Database Resident Connection Pooling

Consider an application in which the memory required for each session is 400 KB and the memory required for each server process is 4 MB. The pool size is 100 and the number of shared servers used is 100.

If there are 5000 client connections, the memory used by each configuration is as follows:

- Dedicated Server
Memory used = $5000 \times (400 \text{ KB} + 4 \text{ MB}) = 22 \text{ GB}$
- Shared Server

Memory used = 5000 X 400 KB + 100 X 4 MB = 2.5 GB

Out of the 2.5 GB, 2 GB is allocated from the SGA.

- Database Resident Connection Pooling

Memory used = 100 X (400 KB + 4 MB) + (5000 X 35KB)= 615 MB

The cost of each connection to the broker is approximately 35 KB.

5.3 Configuring Oracle Database for Shared Server

You can enable shared server and set or alter shared server initialization parameters.

- [Initialization Parameters for Shared Server](#)

A set of initialization parameters control shared server operation.

- [Memory Management for Shared Server](#)

Shared server requires some user global area (UGA) in either the shared pool or large pool. For installations with a small number of simultaneous sessions, the default sizes for these system global area (SGA) components are generally sufficient. However, if you expect a large number of sessions for your installation, you may have to tune memory to support shared server.

- [Enabling Shared Server](#)

Shared server is enabled by setting the `SHARED_SERVERS` initialization parameter to a value greater than 0. The other shared server initialization parameters need not be set.

- [Configuring Dispatchers](#)

The `DISPATCHERS` initialization parameter configures dispatcher processes in the shared server architecture. At least one dispatcher process is required for shared server to work. If you do not specify a dispatcher, but you enable shared server by setting `SHARED_SERVER` to a nonzero value, then by default Oracle Database creates one dispatcher for the TCP protocol.

- [Disabling Shared Server](#)

You disable shared server by setting the `SHARED_SERVERS` initialization parameter to 0. You can do this dynamically with the `ALTER SYSTEM` statement.

- [Shared Server Data Dictionary Views](#)

You can query data dictionary views for information about your shared server configuration and to monitor performance.

See Also:

- ["About Dedicated and Shared Server Processes"](#)
- [Oracle Database SQL Language Reference](#) for further information about the `ALTER SYSTEM` statement

5.3.1 Initialization Parameters for Shared Server

A set of initialization parameters control shared server operation.

The following initialization parameters control shared server operation:

- **SHARED_SERVERS:** Specifies the initial number of shared servers to start and the minimum number of shared servers to keep. This is the only required parameter for using shared servers.
- **MAX_SHARED_SERVERS:** Specifies the maximum number of shared servers that can run simultaneously.
- **SHARED_SERVER_SESSIONS:** Specifies the total number of shared server user sessions that can run simultaneously. Setting this parameter enables you to reserve user sessions for dedicated servers.
- **DISPATCHERS:** Configures dispatcher processes in the shared server architecture.
- **MAX_DISPATCHERS:** Specifies the maximum number of dispatcher processes that can run simultaneously. This parameter can be ignored for now. It will only be useful in a future release when the number of dispatchers is auto-tuned according to the number of concurrent connections.
- **CIRCUITS:** Specifies the total number of virtual circuits that are available for inbound and outbound network sessions.

 **See Also:**

Oracle Database Reference for more information about these initialization parameters

5.3.2 Memory Management for Shared Server

Shared server requires some user global area (UGA) in either the shared pool or large pool. For installations with a small number of simultaneous sessions, the default sizes for these system global area (SGA) components are generally sufficient. However, if you expect a large number of sessions for your installation, you may have to tune memory to support shared server.

See the "Configuring and Using Memory" section of *Oracle Database Performance Tuning Guide* for guidelines.

5.3.3 Enabling Shared Server

Shared server is enabled by setting the `SHARED_SERVERS` initialization parameter to a value greater than 0. The other shared server initialization parameters need not be set.

- Set shared server dynamically by setting the `SHARED_SERVERS` initialization parameter to a nonzero value with the `ALTER SYSTEM` statement.
- Set the `SHARED_SERVERS` initialization parameter to a nonzero value at database startup by including it in the initialization parameter file.

Because shared server requires at least one dispatcher in order to work, a dispatcher is brought up even if no dispatcher has been configured. Dispatchers are discussed in "[Configuring Dispatchers](#)".

 **Note:**

If `SHARED_SERVERS` is not included in the initialization parameter file at database startup, but `DISPATCHERS` is included and it specifies at least one dispatcher, shared server is enabled. In this case, the default for `SHARED_SERVERS` is 1.

If neither `SHARED_SERVERS` nor `DISPATCHERS` is included in the initialization file, you cannot start shared server after the instance is brought up by just altering the `DISPATCHERS` parameter. You must specifically alter `SHARED_SERVERS` to a nonzero value to start shared server.

 **Note:**

If you create your Oracle database with Database Configuration Assistant (DBCA), DBCA configures a dispatcher for Oracle XML DB (XDB). This is because XDB protocols like HTTP and FTP require shared server. This results in a `SHARED_SERVER` value of 1. Although shared server is enabled, this configuration permits only sessions that connect to the XDB service to use shared server. To enable shared server for regular database sessions (for submitting SQL statements), you must add an additional dispatcher configuration, or replace the existing configuration with one that is not specific to XDB. See "[Configuring Dispatchers](#)" for instructions.

- [About Determining a Value for SHARED_SERVERS](#)

The `SHARED_SERVERS` initialization parameter specifies the minimum number of shared servers that you want created when the instance is started. After instance startup, Oracle Database can dynamically adjust the number of shared servers based on how busy existing shared servers are and the length of the request queue.

- [Decreasing the Number of Shared Server Processes](#)

You can decrease the minimum number of shared servers that must be kept active by dynamically setting the `SHARED_SERVERS` parameter to a lower value. Thereafter, until the number of shared servers is decreased to the value of the `SHARED_SERVERS` parameter, any shared servers that become inactive are marked by PMON for termination.

- [Limiting the Number of Shared Server Processes](#)

The `MAX_SHARED_SERVERS` initialization parameter specifies the maximum number of shared servers that can be automatically created by PMON. It has no default value.

- [Limiting the Number of Shared Server Sessions](#)

The `SHARED_SERVER_SESSIONS` initialization parameter specifies the maximum number of concurrent shared server user sessions.

- [Protecting Shared Memory](#)

The `CIRCUITS` initialization parameter sets a maximum limit on the number of virtual circuits that can be created in shared memory. This parameter has no default. If it is not specified, then the system can create circuits as needed, limited by the `DISPATCHERS` initialization parameter and system resources.

5.3.3.1 About Determining a Value for SHARED_SERVERS

The `SHARED_SERVERS` initialization parameter specifies the minimum number of shared servers that you want created when the instance is started. After instance startup, Oracle Database can dynamically adjust the number of shared servers based on how busy existing shared servers are and the length of the request queue.

In typical systems, the number of shared servers stabilizes at a ratio of one shared server for every ten connections. For OLTP applications, when the rate of requests is low, or when the ratio of server usage to request is low, the connections-to-servers ratio could be higher. In contrast, in applications where the rate of requests is high or the server usage-to-request ratio is high, the connections-to-server ratio could be lower.

The PMON (process monitor) background process cannot terminate shared servers below the value specified by `SHARED_SERVERS`. Therefore, you can use this parameter to stabilize the load and minimize strain on the system by preventing PMON from terminating and then restarting shared servers because of coincidental fluctuations in load.

If you know the average load on your system, you can set `SHARED_SERVERS` to an optimal value. The following example shows how you can use this parameter:

Assume a database is being used by a telemarketing center staffed by 1000 agents. On average, each agent spends 90% of the time talking to customers and only 10% of the time looking up and updating records. To keep the shared servers from being terminated as agents talk to customers and then spawned again as agents access the database, a DBA specifies that the optimal number of shared servers is 100.

However, not all work shifts are staffed at the same level. On the night shift, only 200 agents are needed. Since `SHARED_SERVERS` is a dynamic parameter, a DBA reduces the number of shared servers to 20 at night, thus allowing resources to be freed up for other tasks such as batch jobs.

5.3.3.2 Decreasing the Number of Shared Server Processes

You can decrease the minimum number of shared servers that must be kept active by dynamically setting the `SHARED_SERVERS` parameter to a lower value. Thereafter, until the number of shared servers is decreased to the value of the `SHARED_SERVERS` parameter, any shared servers that become inactive are marked by PMON for termination.

- Set shared server dynamically by setting the `SHARED_SERVERS` initialization parameter to a nonzero value with the `ALTER SYSTEM` statement.

For example, the following statement reduces the number of shared servers:

```
ALTER SYSTEM SET SHARED_SERVERS = 5;
```

Setting `SHARED_SERVERS` to 0 disables shared server. For more information, see "[Disabling Shared Server](#)".

5.3.3.3 Limiting the Number of Shared Server Processes

The `MAX_SHARED_SERVERS` initialization parameter specifies the maximum number of shared servers that can be automatically created by PMON. It has no default value.

If no value is specified, then PMON starts as many shared servers as is required by the load, subject to these limitations:

- The process limit (set by the `PROCESSES` initialization parameter)
- A minimum number of free process slots (at least one-eighth of the total process slots, or two slots if `PROCESSES` is set to less than 24)
- System resources

To limit the number of shared server processes:

- Set the `MAX_SHARED_SERVERS` initialization parameter.

The value of `SHARED_SERVERS` overrides the value of `MAX_SHARED_SERVERS`. Therefore, you can force PMON to start more shared servers than the `MAX_SHARED_SERVERS` value by setting `SHARED_SERVERS` to a value higher than `MAX_SHARED_SERVERS`. You can subsequently place a new upper limit on the number of shared servers by dynamically altering the `MAX_SHARED_SERVERS` to a value higher than `SHARED_SERVERS`.

The primary reason to limit the number of shared servers is to reserve resources, such as memory and CPU time, for other processes. For example, consider the case of the telemarketing center discussed previously:

The DBA wants to reserve two thirds of the resources for batch jobs at night. He sets `MAX_SHARED_SERVERS` to less than one third of the maximum number of processes (`PROCESSES`). By doing so, the DBA ensures that even if all agents happen to access the database at the same time, batch jobs can connect to dedicated servers without having to wait for the shared servers to be brought down after processing agents' requests.

Another reason to limit the number of shared servers is to prevent the concurrent run of too many server processes from slowing down the system due to heavy swapping, although `PROCESSES` can serve as the upper bound for this rather than `MAX_SHARED_SERVERS`.

Still other reasons to limit the number of shared servers are testing, debugging, performance analysis, and tuning. For example, to see how many shared servers are needed to efficiently support a certain user community, you can vary `MAX_SHARED_SERVERS` from a very small number upward until no delay in response time is noticed by the users.

5.3.3.4 Limiting the Number of Shared Server Sessions

The `SHARED_SERVER_SESSIONS` initialization parameter specifies the maximum number of concurrent shared server user sessions.

Setting this parameter, which is a dynamic parameter, lets you reserve database sessions for dedicated servers. This in turn ensures that administrative tasks that require dedicated servers, such as backing up or recovering the database, are not preempted by shared server sessions.

To limit the number of shared server sessions:

- Set the SHARED_SERVER_SESSIONS initialization parameter.

This parameter has no default value. If it is not specified, the system can create shared server sessions as needed, limited by the SESSIONS initialization parameter.

5.3.3.5 Protecting Shared Memory

The CIRCUITS initialization parameter sets a maximum limit on the number of virtual circuits that can be created in shared memory. This parameter has no default. If it is not specified, then the system can create circuits as needed, limited by the DISPATCHERS initialization parameter and system resources.

To protect shared memory by limiting the number of virtual circuits that can be created in shared memory:

- Set the CIRCUITS initialization parameter.

5.3.4 Configuring Dispatchers

The DISPATCHERS initialization parameter configures dispatcher processes in the shared server architecture. At least one dispatcher process is required for shared server to work. If you do not specify a dispatcher, but you enable shared server by setting SHARED_SERVER to a nonzero value, then by default Oracle Database creates one dispatcher for the TCP protocol.

The equivalent DISPATCHERS explicit setting of the initialization parameter for this configuration is:

```
dispatchers= "(PROTOCOL=tcp)"
```

You can configure more dispatchers, using the DISPATCHERS initialization parameter, if either of the following conditions apply:

- You must configure a protocol other than TCP/IP. You configure a protocol address with one of the following attributes of the DISPATCHERS parameter:
 - ADDRESS
 - DESCRIPTION
 - PROTOCOL
- You want to configure one or more of the optional dispatcher attributes:
 - DISPATCHERS
 - CONNECTIONS
 - SESSIONS
 - LISTENER
 - MULTIPLEX
 - SERVICE

 **Note:**

Database Configuration Assistant helps you configure this parameter.

To configure a protocol other than TCP/IP or to configure additional dispatchers:

- Set the **DISPATCHERS** initialization parameter and specify the appropriate attributes.
- [DISPATCHERS Initialization Parameter Attributes](#)
You can set several attributes for the **DISPATCHERS** initialization parameter.
- [Determining the Number of Dispatchers](#)
Once you know the number of possible connections for each process for the operating system, calculate the initial number of dispatchers to create during instance startup, for each network protocol.
- [Setting the Initial Number of Dispatchers](#)
You can specify multiple dispatcher configurations by setting **DISPATCHERS** to a comma separated list of strings, or by specifying multiple **DISPATCHERS** initialization parameters in the initialization parameter file.
- [Altering the Number of Dispatchers](#)
You can control the number of dispatcher processes in the instance. Unlike the number of shared servers, the number of dispatchers does not change automatically. You change the number of dispatchers explicitly with the **ALTER SYSTEM** statement. You can increase the number of dispatchers to more than the limit specified by the **MAX_DISPATCHERS** parameter.
- [Shutting Down Specific Dispatcher Processes](#)
With the **ALTER SYSTEM SET DISPATCHERS** statement, you leave it up to the database to determine which dispatchers to shut down to reduce the number of dispatchers. Alternatively, it is possible to shut down specific dispatcher processes.

5.3.4.1 DISPATCHERS Initialization Parameter Attributes

You can set several attributes for the **DISPATCHERS** initialization parameter.

A protocol address is required and is specified using one or more of the following attributes:

Attribute	Description
ADDRESS	Specify the network protocol address of the endpoint on which the dispatchers listen.
DESCRIPTION	Specify the network description of the endpoint on which the dispatchers listen, including the network protocol address. The syntax is as follows: (DESCRIPTION=(ADDRESS=...))

Attribute	Description
PROTOCOL	<p>Specify the network protocol for which the dispatcher generates a listening endpoint. For example:</p> <p>(PROTOCOL=tcp)</p> <p>See the <i>Oracle Database Net Services Reference</i> for further information about protocol address syntax.</p>

The following attribute specifies how many dispatchers this configuration should have. It is optional and defaults to 1.

Attribute	Description
DISPATCHERS	Specify the initial number of dispatchers to start.

The following attributes tell the instance about the network attributes of each dispatcher of this configuration. They are all optional.

Attribute	Description
CONNECTIONS	Specify the maximum number of network connections to allow for each dispatcher.
SESSIONS	Specify the maximum number of network sessions to allow for each dispatcher.
LISTENER	Specify an alias name for the listeners with which the LREG process registers dispatcher information. Set the alias to a name that is resolved through a naming method.
MULTIPLEX	Used to enable the Oracle Connection Manager session multiplexing feature.
SERVICE	Specify the service names the dispatchers register with the listeners.

You can specify either an entire attribute name a substring consisting of at least the first three characters. For example, you can specify SESSIONS=3, SES=3, SESS=3, or SESSI=3, and so forth.

See Also:

Oracle Database Reference for more detailed descriptions of the attributes of the DISPATCHERS initialization parameter

5.3.4.2 Determining the Number of Dispatchers

Once you know the number of possible connections for each process for the operating system, calculate the initial number of dispatchers to create during instance startup, for each network protocol.

To calculate the initial number of dispatchers to create during instance startup, use the following formula:

```
Number of dispatchers =  
CEIL ( max. concurrent sessions / connections for each dispatcher )
```

CEIL returns the result roundest up to the next whole integer.

For example, assume a system that can support 970 connections for each process, and that has:

- A maximum of 4000 sessions concurrently connected through TCP/IP and
- A maximum of 2,500 sessions concurrently connected through TCP/IP with SSL

The DISPATCHERS attribute for TCP/IP should be set to a minimum of five dispatchers (4000 / 970), and for TCP/IP with SSL three dispatchers (2500 / 970):

```
DISPATCHERS='(PROT=tcp)(DISP=5)', '(PROT=tcps)(DISP=3)'
```

Depending on performance, you may need to adjust the number of dispatchers.

5.3.4.3 Setting the Initial Number of Dispatchers

You can specify multiple dispatcher configurations by setting DISPATCHERS to a comma separated list of strings, or by specifying multiple DISPATCHERS initialization parameters in the initialization parameter file.

- Set the DISPATCHERS initialization parameter.

If you specify DISPATCHERS multiple times, then the lines must be adjacent to each other in the initialization parameter file. Internally, Oracle Database assigns an INDEX value (beginning with zero) to each DISPATCHERS parameter. You can later refer to that DISPATCHERS parameter in an ALTER SYSTEM statement by its index number.

Some examples of setting the DISPATCHERS initialization parameter follow.

Example: Typical

This is a typical example of setting the DISPATCHERS initialization parameter.

```
DISPATCHERS=" (PROTOCOL=TCP) (DISPATCHERS=2)"
```

Example: Forcing the IP Address Used for Dispatchers

The following hypothetical example will create two dispatchers that will listen on the specified IP address. The address must be a valid IP address for the host that the instance is on. (The host may be configured with multiple IP addresses.)

```
DISPATCHERS=" (ADDRESS=(PROTOCOL=TCP) (HOST=144.25.16.201)) (DISPATCHERS=2)"
```

Example: Forcing the Port Used by Dispatchers

To force the dispatchers to use a specific port as the listening endpoint, add the PORT attribute as follows:

```
DISPATCHERS=" (ADDRESS=(PROTOCOL=TCP) (PORT=5000))"  
DISPATCHERS=" (ADDRESS=(PROTOCOL=TCP) (PORT=5001))"
```

5.3.4.4 Altering the Number of Dispatchers

You can control the number of dispatcher processes in the instance. Unlike the number of shared servers, the number of dispatchers does not change automatically. You change the number of dispatchers explicitly with the `ALTER SYSTEM` statement. You can increase the number of dispatchers to more than the limit specified by the `MAX_DISPATCHERS` parameter.

1. Monitor the following views to determine the load on the dispatcher processes:

- `V$QUEUE`
- `V$DISPATCHER`
- `V$DISPATCHER_RATE`

If these views indicate that the load on the dispatcher processes is consistently high, then performance may be improved by starting additional dispatcher processes to route user requests. In contrast, if the load on dispatchers is consistently low, reducing the number of dispatchers may improve performance.

 **See Also:**

Oracle Database Performance Tuning Guide for information about monitoring these views to determine dispatcher load and performance

2. To dynamically alter the number of dispatchers when the instance is running, use the `ALTER SYSTEM` statement to modify the `DISPATCHERS` attribute setting for an existing dispatcher configuration. You can also add new dispatcher configurations to start dispatchers with different network attributes.

When you reduce the number of dispatchers for a particular dispatcher configuration, the dispatchers are not immediately removed. Rather, as users disconnect, Oracle Database terminates dispatchers down to the limit you specify in `DISPATCHERS`,

For example, suppose the instance was started with this `DISPATCHERS` setting in the initialization parameter file:

```
DISPATCHERS='(PROT=tcp)(DISP=2)', '(PROT=tcps)(DISP=2)'
```

To increase the number of dispatchers for the TCP/IP protocol from 2 to 3, and decrease the number of dispatchers for the TCP/IP with SSL protocol from 2 to 1, you can issue the following statement:

```
ALTER SYSTEM SET DISPATCHERS = '(INDEX=0)(DISP=3)', '(INDEX=1)(DISP=1)';
```

or

```
ALTER SYSTEM SET DISPATCHERS = '(PROT=tcp)(DISP=3)', '(PROT=tcps)(DISP=1)';
```

 **Note:**

You need not specify (DISP=1). It is optional because 1 is the default value for the DISPATCHERS parameter.

If fewer than three dispatcher processes currently exist for TCP/IP, the database creates new ones. If multiple dispatcher processes currently exist for TCP/IP with SSL, then the database terminates the extra ones as the connected users disconnect.

- [Notes on Altering Dispatchers](#)
Understand details about altering dispatchers.

5.3.4.4.1 Notes on Altering Dispatchers

Understand details about altering dispatchers.

- The INDEX keyword can be used to identify which dispatcher configuration to modify. If you do not specify INDEX, then the first dispatcher configuration matching the DESCRIPTION, ADDRESS, or PROTOCOL specified will be modified. If no match is found among the existing dispatcher configurations, then a new dispatcher will be added.
- The INDEX value can range from 0 to $n-1$, where n is the current number of dispatcher configurations. If your ALTER SYSTEM statement specifies an INDEX value equal to n , where n is the current number of dispatcher configurations, a new dispatcher configuration will be added.
- To see the values of the current dispatcher configurations--that is, the number of dispatchers and so forth--query the V\$DISPATCHER_CONFIG dynamic performance view. To see which dispatcher configuration a dispatcher is associated with, query the CONF_INDX column of the V\$DISPATCHER view.
- When you change the DESCRIPTION, ADDRESS, PROTOCOL, CONNECTIONS, and MULTIPLEX attributes of a dispatcher configuration, the change does not take effect for existing dispatchers but only for new dispatchers. Therefore, in order for the change to be effective for all dispatchers associated with a configuration, you must forcibly terminate existing dispatchers after altering the DISPATCHERS parameter, and let the database start new ones in their place with the newly specified properties.

The attributes LISTENER and SERVICES are not subject to the same constraint. They apply to existing dispatchers associated with the modified configuration. Attribute SESSIONS applies to existing dispatchers only if its value is reduced. However, if its value is increased, it is applied only to newly started dispatchers.

5.3.4.5 Shutting Down Specific Dispatcher Processes

With the ALTER SYSTEM SET DISPATCHERS statement, you leave it up to the database to determine which dispatchers to shut down to reduce the number of dispatchers. Alternatively, it is possible to shut down specific dispatcher processes.

1. To identify the name of the specific dispatcher process to shut down, use the V\$DISPATCHER dynamic performance view.

```
SELECT NAME, NETWORK FROM V$DISPATCHER;
```

Each dispatcher is uniquely identified by a name of the form *Dnnn*.

2. Run an ALTER SYSTEM SHUTDOWN IMMEDIATE statement and specify the dispatcher name.

For example, to shut down dispatcher D002, issue the following statement:

```
ALTER SYSTEM SHUTDOWN IMMEDIATE 'D002';
```

The IMMEDIATE keyword stops the dispatcher from accepting new connections, and the database immediately terminates all existing connections through that dispatcher. After all sessions are cleaned up, the dispatcher process shuts down. If IMMEDIATE were not specified, then the dispatcher would wait until all of its users disconnected and all of its connections terminated before shutting down.

5.3.5 Disabling Shared Server

You disable shared server by setting the SHARED_SERVERS initialization parameter to 0. You can do this dynamically with the ALTER SYSTEM statement.

- Set the SHARED_SERVERS initialization parameter to 0.

When you disable shared server, no new clients can connect in shared mode. However, Oracle Database retains some shared servers until all shared server connections are closed. The number of shared servers retained is either the number specified by the preceding setting of SHARED_SERVERS or the value of the MAX_SHARED_SERVERS parameter, whichever is smaller. If both SHARED_SERVERS and MAX_SHARED_SERVERS are set to 0, then all shared servers will terminate and requests from remaining shared server clients will be queued until the value of SHARED_SERVERS or MAX_SHARED_SERVERS is raised again.

To terminate dispatchers once all shared server clients disconnect, enter this statement:

```
ALTER SYSTEM SET DISPATCHERS = '';
```

5.3.6 Shared Server Data Dictionary Views

You can query data dictionary views for information about your shared server configuration and to monitor performance.

View	Description
V\$DISPATCHER	Provides information on the dispatcher processes, including name, network address, status, various usage statistics, and index number.
V\$DISPATCHER_CONFIG	Provides configuration information about the dispatchers.
V\$DISPATCHER_RATE	Provides rate statistics for the dispatcher processes.
V\$QUEUE	Contains information on the shared server message queues.
V\$SHARED_SERVER	Contains information on the shared servers.
V\$CIRCUIT	Contains information about virtual circuits, which are user connections to the database through dispatchers and servers.
V\$SHARED_SERVER_MONI TOR	Contains information for tuning shared server.

View	Description
V\$SGA	Contains size information about various system global area (SGA) groups. May be useful when tuning shared server.
V\$SGASTAT	Contains detailed statistical information about the SGA, useful for tuning.
V\$SHARED_POOL_RESERVED	Lists statistics to help tune the reserved pool and space within the shared pool.

 **See Also:**

Oracle Database Performance Tuning Guide for specific information about monitoring and tuning shared server

5.4 Configuring Database Resident Connection Pooling

The database server is preconfigured to allow database resident connection pooling. However, you must explicitly enable this feature by starting the connection pool.

- [Enabling Database Resident Connection Pooling](#)
Oracle Database includes a default connection pool called `SYS_DEFAULT_CONNECTION_POOL`. By default, this pool is created, but not started. To enable database resident connection pooling, you must explicitly start the connection pool.
- [Configuring the Connection Pool for Database Resident Connection Pooling](#)
The connection pool is configured using default parameter values. You can use the procedures in the `DBMS_CONNECTION_POOL` package to configure the connection pool according to your usage. In an Oracle Real Application Clusters (Oracle RAC) environment, the configuration parameters are applicable to each Oracle RAC instance.
- [Data Dictionary Views for Database Resident Connection Pooling](#)
You can query data dictionary views to obtain information about your connection pool and to monitor the performance of database resident connection pooling.
- [Determining the States of Connections in the Connection Pool](#)
You can query the `V$CPOOL_CONN_INFO` view to determine the current state of each connection in the connection pool.

 **See Also:**

["About Database Resident Connection Pooling"](#)

5.4.1 Enabling Database Resident Connection Pooling

Oracle Database includes a default connection pool called `SYS_DEFAULT_CONNECTION_POOL`. By default, this pool is created, but not started. To enable database resident connection pooling, you must explicitly start the connection pool.

To enable database resident connection pooling:

1. Start the database resident connection pool, as described in "[Starting the Database Resident Connection Pool](#)".
2. Route the client connection requests to the connection pool, as described in "[Routing Client Connection Requests to the Connection Pool](#)".

Starting the Database Resident Connection Pool

To start the connection pool:

1. Start SQL*Plus and connect to the database as the `SYS` user.
2. Issue the following command:

```
SQL> EXECUTE DBMS_CONNECTION_POOL.START_POOL();
```

Once started, the connection pool remains in this state until it is explicitly stopped. The connection pool is automatically restarted when the database instance is restarted if the pool was active at the time of instance shutdown.

In an Oracle Real Application Clusters (Oracle RAC) environment, you can use any instance to manage the connection pool. Any changes you make to the pool configuration are applicable on all Oracle RAC instances.

Routing Client Connection Requests to the Connection Pool

In the client application, the connect string must specify the connect type as `POOLED`.

The following example shows an easy connect string that enables clients to connect to a database resident connection pool:

```
examplehost.company.com:1521/books.company.com:POOLED
```

The following example shows a TNS connect descriptor that enables clients to connect to a database resident connection pool:

```
(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp) (HOST=myhost)
              (PORT=1521)) (CONNECT_DATA=(SERVICE_NAME=sales)
              (SERVER=POOLED)))
```

Note:

Only the TCP protocol is supported for client connections to a database resident connection pool.

Disabling Database Resident Connection Pooling

To disable database resident connection pooling, you must explicitly stop the connection pool. Use the following steps:

1. Start SQL*Plus and connect to the database as the `SYS` user.
2. Issue the following command:

```
SQL> EXECUTE DBMS_CONNECTION_POOL.STOP_POOL();
```

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for more information on the `DBMS_CONNECTION_POOL` package.

 **Note:**

The operation of disabling the database resident connection pool can be completed only when all client requests that have been handed off to a server are completed.

5.4.2 Configuring the Connection Pool for Database Resident Connection Pooling

The connection pool is configured using default parameter values. You can use the procedures in the `DBMS_CONNECTION_POOL` package to configure the connection pool according to your usage. In an Oracle Real Application Clusters (Oracle RAC) environment, the configuration parameters are applicable to each Oracle RAC instance.

Using the CONFIGURE_POOL Procedure

The `CONFIGURE_POOL` procedure of the `DBMS_CONNECTION_POOL` package enables you to configure the connection pool with advanced options. This procedure is usually used when you must modify all the parameters of the connection pool.

Using the ALTER_PARAM Procedure

The `ALTER_PARAM` procedure of the `DBMS_CONNECTION_POOL` package enables you to alter a specific configuration parameter without affecting other parameters. For example, the following command changes the minimum number of pooled servers used:

```
SQL> EXECUTE DBMS_CONNECTION_POOL.ALTER_PARAM ('','MINSIZE','10');
```

The following example, changes the maximum number of connections that each connection broker can handle to 50000.

```
SQL> EXECUTE DBMS_CONNECTION_POOL.ALTER_PARAM ('','MAXCONN_CBROK','50000');
```

Before you execute this command, ensure that the maximum number of connections allowed by the platform on which your database is installed is not less than the value you set for MAXCONN_CBROK.

For example, in Linux, the following entry in the /etc/security/limits.conf file indicates that the maximum number of connections allowed for the user test_user is 30000.

```
test_user HARD NOFILE 30000
```

To set the maximum number of connections that each connection broker can allow to 50000, first change the value in the limits.conf file to a value not less than 50000.

Restoring the Connection Pool Default Settings

If you have made changes to the connection pool parameters, but you want to revert to the default pool settings, use the RESTORE_DEFAULT procedure of the DBMS_CONNECTION_POOL package. The command to restore the connection pool to its default settings is:

```
SQL> EXECUTE DBMS_CONNECTION_POOL.RESTORE_DEFAULTS();
```

- [Configuration Parameters for Database Resident Connection Pooling](#)
You can specify parameters for subprograms in the DBMS_CONNECTION_POOL package to configure database resident connection pooling.

See Also:

Oracle Database PL/SQL Packages and Types Reference for more information on the DBMS_CONNECTION_POOL package.

5.4.2.1 Configuration Parameters for Database Resident Connection Pooling

You can specify parameters for subprograms in the DBMS_CONNECTION_POOL package to configure database resident connection pooling.

The following table lists the parameters that you can configure for the connection pool.

Table 5-2 Configuration Parameters for Database Resident Connection Pooling

Parameter Name	Description
MINSIZE	The minimum number of pooled servers in the pool. The default value is 4.
MAXSIZE	The maximum number of pooled servers in the pool. The default value is 40.
	The connection pool reserves 5% of the pooled servers for authentication, and at least one pooled server is always reserved for authentication. When setting this parameter, ensure that there are enough pooled servers for both authentication and connections.

Table 5-2 (Cont.) Configuration Parameters for Database Resident Connection Pooling

Parameter Name	Description
INCRSIZE	The number of pooled servers by which the pool is incremented if servers are unavailable when a client application request is received. The default value is 2.
SESSION_CACHED_CURSORS	The number of session cursors to cache in each pooled server session. The default value is 20.
INACTIVITY_TIMEOUT	The maximum time, in seconds, the pooled server can stay idle in the pool. After this time, the server is terminated. The default value is 300. This parameter does not apply if the pool is at MINSIZE.
MAX_THINK_TIME	The maximum time of inactivity, in seconds, for a client after it obtains a pooled server from the pool with no open transactions in it. After obtaining a pooled server from the pool, if the client application does not issue a database call for the time specified by MAX_THINK_TIME, the pooled server is freed and the client connection is terminated. The default value is 120.
MAX_TXN_THINK_TIME	The maximum time of inactivity, in seconds, for a client after it obtains a pooled server from the pool with an open transaction. After obtaining the pooled server from the pool, if the client application does not issue a database call for the time specified by MAX_TXN_THINK_TIME, then the pooled server is freed, and the client connection is terminated. The default value of this parameter is the value of the MAX_THINK_TIME parameter. Applications can set the value of the MAX_TXN_THINK_TIME parameter to a value higher than the MAX_THINK_TIME value to allow more time for the connections with open transactions.
MAX_USE_SESSION	The number of times a pooled server can be taken and released to the pool. The default value is 500000.
MAX_LIFETIME_SESSION	The time, in seconds, to live for a pooled server in the pool. The default value is 86400.
NUM_CBROK	The number of Connection Brokers that are created to handle client requests. The default value is 1. Creating multiple Connection Broker processes helps distribute the load of client connection requests if there are a large number of client applications.
MAXCONN_CBROK	The maximum number of connections that each Connection Broker can handle. The default value is 40000. But if the maximum connections allowed by the platform on which the database is installed is lesser than the default value, this value overrides the value set using MAXCONN_CBROK. Set the per-process file descriptor limit of the operating system sufficiently high so that it supports the number of connections specified by MAXCONN_CBROK.

 See Also:

Oracle Database PL/SQL Packages and Types Reference for more information on the DBMS_CONNECTION_POOL package.

5.4.3 Data Dictionary Views for Database Resident Connection Pooling

You can query data dictionary views to obtain information about your connection pool and to monitor the performance of database resident connection pooling.

Table 5-3 Data Dictionary Views for Database Resident Connection Pooling

View	Description
DBA_CPOOL_INFO	Contains information about the connection pool such as the pool status, the maximum and minimum number of connections, and timeout for idle sessions.
V\$CPOOL_CONN_INFO	Contains information about each connection to the connection broker.
V\$CPOOL_STATS	Contains pool statistics such as the number of session requests, number of times a session that matches the request was found in the pool, and total wait time for a session request.
V\$CPOOL_CC_INFO	Contains information about the pool-to-connection class mapping for the pool.
V\$CPOOL_CC_STATS	Contains connection class level statistics for the pool.

5.4.4 Determining the States of Connections in the Connection Pool

You can query the V\$CPOOL_CONN_INFO view to determine the current state of each connection in the connection pool.

You can query this view for detailed information about the state of each connection. For example, you can determine which connections are busy or idle. To determine this information:

- Query the V\$CPOOL_CONN_INFO view.

Example 5-1 Determining How Long Connections Have Been Waiting

The following query shows the wait time for connections in the WAITING state:

```
SELECT USERNAME, SERVICE, LAST_WAIT_TIME
  FROM V$CPOOL_CONN_INFO
 WHERE CONNECTION_STATUS = 'WAITING';
```

Example 5-2 Determining How Long Connections Have Been Active

The following query shows the amount of time each connection has been active for connections in the ACTIVE state:

```
SELECT USERNAME, SERVICE, LAST_ACTIVE_TIME
  FROM V$CPOOL_CONN_INFO
 WHERE CONNECTION_STATUS = 'ACTIVE';
```

Example 5-3 Listing the Longest Running Active Connections

The following query shows lists the connections that have been in the ACTIVE state the longest amount of time:

```
SELECT USERNAME, SERVICE, ACTIVE_TIME
  FROM V$CPOOL_CONN_INFO
 WHERE CONNECTION_STATUS = 'ACTIVE'
 ORDER BY ACTIVE_TIME DESC;
```

Example 5-4 Determining the Wait Time of the Oldest Connection in the Wait Queue

The following query shows the wait time for sessions in the WAITING state:

```
SELECT USERNAME, SERVICE, LAST_WAIT_TIME
  FROM V$CPOOL_CONN_INFO
 WHERE LAST_WAIT_TIME = (
    SELECT max(LAST_WAIT_TIME)
      FROM V$CPOOL_CONN_INFO
     WHERE CONNECTION_STATUS = 'WAITING' );
```

5.5 About Oracle Database Background Processes

To maximize performance and accommodate many users, a multiprocess Oracle Database system uses **background processes**. Background processes consolidate functions that would otherwise be handled by multiple database programs running for each user process. Background processes asynchronously perform I/O and monitor other Oracle Database processes to provide increased parallelism for better performance and reliability.

Table 5-4 describes the fundamental background processes, many of which are discussed in more detail elsewhere in this book. The use of additional database features or options can cause more background processes to be present. For example:

- When you use Oracle Database Advanced Queuing, the queue monitor (QMNN) background process is present.
- When you set the FILE_MAPPING initialization parameter to true for mapping data files to physical devices on a storage subsystem, the FMON process is present.
- If you use Oracle Automatic Storage Management (Oracle ASM), then additional Oracle ASM-specific background processes are present.

Table 5-4 Oracle Database Background Processes

Process Name	Description
Database writer (DBW n or BW nn)	<p>The database writer writes modified blocks from the database buffer cache to the data files. Oracle Database allows a maximum of 100 database writer processes. The names of the first 36 database writer processes are DBW0-DBW9 and DBWa-DBWz. The names of the 37th through 100th database writer processes are BW36-BW99.</p> <p>The DB_WRITER_PROCESSES initialization parameter specifies the number of database writer processes. The database selects an appropriate default setting for this initialization parameter or adjusts a user-specified setting based on the number of CPUs and the number of processor groups.</p> <p>For more information about setting the DB_WRITER_PROCESSES initialization parameter, see the "Oracle Database Performance Tuning Guide".</p>
Log writer (LGWR)	<p>The log writer process writes redo log entries to disk. Redo log entries are generated in the redo log buffer of the system global area (SGA). LGWR writes the redo log entries sequentially into a redo log file. If the database has a multiplexed redo log, then LGWR writes the redo log entries to a group of redo log files. See " Managing the Redo Log" for information about the log writer process.</p>
Checkpoint (CKPT)	<p>At specific times, all modified database buffers in the system global area are written to the data files by DBWn. This event is called a checkpoint. The checkpoint process is responsible for signalling DBWn at checkpoints and updating all the data files and control files of the database to indicate the most recent checkpoint.</p>
System monitor (SMON)	<p>The system monitor performs recovery when a failed instance starts up again. In an Oracle Real Application Clusters database, the SMON process of one instance can perform instance recovery for other instances that have failed. SMON also cleans up temporary segments that are no longer in use and recovers terminated transactions skipped during system failure and instance recovery because of file-read or offline errors. These transactions are eventually recovered by SMON when the tablespace or file is brought back online.</p>
Process monitor (PMON)	<p>The process monitor performs process recovery when a user process fails. PMON is responsible for detecting processes that have failed. PMON is then responsible for coordinating cleanup performed by the CLMN process and the CLnn slaves. The cleanup frees resources that the process was using.</p>
Archiver (ARC n)	<p>One or more archiver processes copy the redo log files to archival storage when they are full or a log switch occurs. Archiver processes are the subject of " Managing Archived Redo Log Files".</p>
Recoverer (RECO)	<p>The recoverer process is used to resolve distributed transactions that are pending because of a network or system failure in a distributed database. At timed intervals, the local RECO attempts to connect to remote databases and automatically complete the commit or rollback of the local portion of any pending distributed transactions. For information about this process and how to start it, see " Managing Distributed Transactions".</p>
Dispatcher (D nnn)	<p>Dispatchers are optional background processes, present only when the shared server configuration is used. Shared server was discussed previously in " Configuring Oracle Database for Shared Server".</p>

 **See Also:**

Oracle Database Reference for a complete list of Oracle Database background processes

5.6 Managing Prespawned Processes

Oracle Database can prespawn processes for better client connection performance.

- [About Managing Prespawned Processes](#)

Oracle Database can prespawn foreground and background processes in process pools.

- [Managing Pools for Prespawned Processes](#)

You can use the `DBMS_PROCESS` package to configure and modify the number of prespawned processes in the foreground process pool.

5.6.1 About Managing Prespawned Processes

Oracle Database can prespawn foreground and background processes in process pools.

Oracle Database prespawns foreground processes when a dedicated broker is enabled or threaded execution mode is enabled. When a foreground process is required, it uses the prespawned processes internally to reduce the creation time. A database runs in threaded execution mode when the `THREADED_EXECUTION` initialization parameter is set to `TRUE`. When this parameter is set to `FALSE`, the default, the database runs in process mode, and Oracle Database does not prespawn foreground and background processes in process pools.

Client connection time can be more efficient when processes are prespawned. If threaded execution mode is enabled, then Oracle Database prespawns processes by default in various request pools. Each request pool is for a different kind of process.

The `V$PROCESS_POOL` view shows information about these pools, and you can manage these pools using the `DBMS_PROCESS` package.

5.6.2 Managing Pools for Prespawned Processes

You can use the `DBMS_PROCESS` package to configure and modify the number of prespawned processes in the foreground process pool.

Oracle Database can create process pools to improve the efficiency of client connections. You can use the `DBMS_PROCESS` package to manage these pools. You can view the current process pools by querying the `V$PROCESS_POOL` view.

Process pools are created only if the database is running in the multithreaded Oracle Database model.

1. Connect to the database as a user with the required privileges.

The user must have `SYSDBA` administrative privilege, and you must exercise this privilege using `AS SYSDBA` at connect time.

2. Run a subprogram in the `DBMS_PROCESS` package to manage a process pool.

Example 5-5 Stopping a Process Pool

```
SYS_DEFAULT_FOREGROUND_POOL
```

```
exec DBMS_PROCESS.STOP_POOL('SYS_DEFAULT_FOREGROUND_POOL');
```

The `ENABLED` column in the `V$PROCESS_POOL` view is `FALSE` for the process pool when it is stopped.

Example 5-6 Starting a Process Pool

```
SYS_DEFAULT_FOREGROUND_POOL

exec DBMS_PROCESS.START_POOL( 'SYS_DEFAULT_FOREGROUND_POOL' );
```

The `ENABLED` column in the `V$PROCESS_POOL` view is `TRUE` for the process pool when it is enabled.

Example 5-7 Configuring a Process Pool

You can check the current configuration of a process pool by querying the `V$PROCESS_POOL` view. For example, the following query shows the current configuration of the process pools:

```
COLUMN POOL_NAME FORMAT A30
COLUMN ENABLED FORMAT A7
COLUMN MIN_COUNT FORMAT 9999999
COLUMN BATCH_COUNT FORMAT 9999999
COLUMN INIT_COUNT FORMAT 9999999

SELECT POOL_NAME, ENABLED, MIN_COUNT, BATCH_COUNT, INIT_COUNT
FROM V$PROCESS_POOL;
```

Assume the results are the following:

POOL_NAME	ENABLED	MIN_COUNT	BATCH_COUNT	INIT_COUNT
SYS_DEFAULT_FOREGROUND_POOL	TRUE	10	20	29

For this process pool, to change the minimum number of prespawned process to 20, the number of prespawned processes created in a batch to 30, and the initial number of prespawned processes to 40, run the following procedure:

```
BEGIN
    DBMS_PROCESS.CONFIGURE_POOL(
        POOL_NAME    => 'SYS_DEFAULT_FOREGROUND_POOL',
        MIN_COUNT    => 20,
        BATCH_COUNT  => 30,
        INIT_COUNT   => 40);
END;
/
```

You can confirm your changes by running the query again.

 **See Also:**

5.7 Managing Processes for Parallel SQL Execution

You can manage parallel processing of SQL statements. In this configuration, Oracle Database can divide the work of processing an SQL statement among multiple parallel processes.

 **Note:**

The parallel execution feature described in this section is available with the Oracle Database Enterprise Edition.

- [About Parallel Execution Servers](#)
The execution of many SQL statements can be parallelized. The **degree of parallelism** is the number of parallel execution servers that can be associated with a single operation.
- [Altering Parallel Execution for a Session](#)
You control parallel SQL execution for a session using the ALTER SESSION statement.

5.7.1 About Parallel Execution Servers

The execution of many SQL statements can be parallelized. The **degree of parallelism** is the number of parallel execution servers that can be associated with a single operation.

The degree of parallelism is determined by any of the following:

- A PARALLEL clause in a statement
- For objects referred to in a query, the PARALLEL clause that was used when the object was created or altered
- A parallel hint inserted into the statement
- A default determined by the database

An example of using parallel SQL execution is contained in "[Parallelizing Table Creation](#)".

When an instance starts up, Oracle Database creates a pool of parallel execution servers which are available for any parallel operation. A process called the **parallel execution coordinator** dispatches the execution of a pool of **parallel execution**

servers and coordinates the sending of results from all of these parallel execution servers back to the user.

The parallel execution servers are enabled by default, because the PARALLEL_MAX_SERVERS initialization parameter value is set to greater than 0 by default. The processes are available for use by the various Oracle Database features that are capable of exploiting parallelism. Related initialization parameters are tuned by the database for the majority of users, but you can alter them as needed to suit your environment. For ease of tuning, some parameters can be altered dynamically.

Parallelism can be used by several features, including transaction recovery, replication, and SQL execution. In the case of parallel SQL execution, the topic discussed in this book, parallel execution server processes remain associated with a statement throughout its execution phase. When the statement is completely processed, these processes become available to process other statements.

 **Note:**

To disable parallel SQL execution in a database, set the PARALLEL_MAX_SERVERS initialization parameter value to 0.

 **See Also:**

- *Oracle Database SQL Tuning Guide* for information about using parallel hints
- *Oracle Database VLDB and Partitioning Guide* for more information about using parallel execution

5.7.2 Altering Parallel Execution for a Session

You control parallel SQL execution for a session using the ALTER SESSION statement.

- [Disabling Parallel SQL Execution](#)

You disable parallel SQL execution with an ALTER SESSION DISABLE PARALLEL DML|DDL|QUERY statement. All subsequent DML (INSERT, UPDATE, DELETE), DDL (CREATE, ALTER), or query (SELECT) operations are executed serially after such a statement is issued. They will be executed serially regardless of any parallel attribute associated with the table or indexes involved. However, statements with a PARALLEL hint override the session settings.

- [Enabling Parallel SQL Execution](#)

You enable parallel SQL execution with an ALTER SESSION ENABLE PARALLEL DML|DDL|QUERY statement. Subsequently, when a PARALLEL clause or parallel hint is associated with a statement, those DML, DDL, or query statements will execute in parallel. By default, parallel execution is enabled for DDL and query statements.

- [Forcing Parallel SQL Execution](#)

You can force parallel execution of all subsequent DML, DDL, or query statements for which parallelization is possible with the ALTER SESSION FORCE PARALLEL DML|

DDL | QUERY statement. Additionally you can force a specific degree of parallelism to be in effect, overriding any PARALLEL clause associated with subsequent statements. If you do not specify a degree of parallelism in this statement, the default degree of parallelism is used. Forcing parallel execution overrides any parallel hints in SQL statements.

5.7.2.1 Disabling Parallel SQL Execution

You disable parallel SQL execution with an ALTER SESSION DISABLE PARALLEL DML | DDL | QUERY statement. All subsequent DML (INSERT, UPDATE, DELETE), DDL (CREATE, ALTER), or query (SELECT) operations are executed serially after such a statement is issued. They will be executed serially regardless of any parallel attribute associated with the table or indexes involved. However, statements with a PARALLEL hint override the session settings.

- Run the appropriate ALTER SESSION DISABLE PARALLEL statement to disable DML, DDL, or query operations.

For example, to disable parallel DDL operations, run the following statement:

```
ALTER SESSION DISABLE PARALLEL DDL;
```

5.7.2.2 Enabling Parallel SQL Execution

You enable parallel SQL execution with an ALTER SESSION ENABLE PARALLEL DML | DDL | QUERY statement. Subsequently, when a PARALLEL clause or parallel hint is associated with a statement, those DML, DDL, or query statements will execute in parallel. By default, parallel execution is enabled for DDL and query statements.

- Run the appropriate ALTER SESSION DISABLE PARALLEL statement to enable DML, DDL, or query operations.

For example, a DML statement can be parallelized only if you specifically issue an ALTER SESSION statement to enable parallel DML:

```
ALTER SESSION ENABLE PARALLEL DML;
```

5.7.2.3 Forcing Parallel SQL Execution

You can force parallel execution of all subsequent DML, DDL, or query statements for which parallelization is possible with the ALTER SESSION FORCE PARALLEL DML | DDL | QUERY statement. Additionally you can force a specific degree of parallelism to be in effect, overriding any PARALLEL clause associated with subsequent statements. If you do not specify a degree of parallelism in this statement, the default degree of parallelism is used. Forcing parallel execution overrides any parallel hints in SQL statements.

- Run an ALTER SESSION FORCE PARALLEL statement.

For example, the following statement forces parallel execution of subsequent statements and sets the overriding degree of parallelism to 5:

```
ALTER SESSION FORCE PARALLEL DDL PARALLEL 5;
```

5.8 Managing Processes for External Procedures

An external procedure is a procedure or function written in a programming language and stored in a shared library. An Oracle server can call external procedures or functions using PL/SQL routines.

- [About External Procedures](#)

External procedures are procedures that are written in a programming language such as C, C++, or Java, compiled, and stored outside of the database, and then called by user sessions. For example, a PL/SQL program unit can call one or more C routines that are required to perform special-purpose processing.

- [DBA Tasks to Enable External Procedure Calls](#)

To enable external procedure calls, you must modify the listener and manage libraries.

5.8.1 About External Procedures

External procedures are procedures that are written in a programming language such as C, C++, or Java, compiled, and stored outside of the database, and then called by user sessions. For example, a PL/SQL program unit can call one or more C routines that are required to perform special-purpose processing.

These callable routines are stored in a dynamic link library (DLL), or a libunit in the case of a Java class method, and are registered with the base language. Oracle Database provides a special-purpose interface, the **call specification** (call spec), that enables users to call external procedures.

When a user session calls an external procedure, the database starts an external procedure agent on the database host computer. The default name of the agent is extproc. Each session has its own dedicated agent. Optionally, you can create a credential so that the agent runs as a particular operating system user. When a session terminates, the database terminates its agent.

User applications pass to the external procedure agent the name of the DLL or libunit, the name of the external procedure, and any relevant parameters. The external procedure agent then loads the DLL or libunit, runs the external procedure, and passes back to the application any values returned by the external procedure.

 **See Also:**

Oracle Database Development Guide for information about external procedures

5.8.2 DBA Tasks to Enable External Procedure Calls

To enable external procedure calls, you must modify the listener and manage libraries.

Enabling external procedure calls may involve the following DBA tasks:

- Configuring the listener to start the extproc agent

By default, the database starts the `extproc` process. Under the following circumstances, you must change this default configuration so that the listener starts the `extproc` process:

- You want to use a multithreaded `extproc` agent
- The database is running in shared server mode on Windows
- An `AGENT` clause in the `LIBRARY` specification or an `AGENT IN` clause in the `PROCEDURE` or `FUNCTION` specification redirects external procedures to a different `extproc` agent

Instructions for changing the default configuration are in *Oracle Database Development Guide*.

- Managing libraries or granting privileges related to managing libraries

The database requires DLL statements to be accessed through a schema object called a library. For security purposes, by default, only users with the `DBA` role can create and manage libraries. Therefore, you may be asked to:

- Create a directory object using the `CREATE DIRECTORY` statement for the location of the library. After the directory object is created, a `CREATE LIBRARY` statement can specify the directory object for the location of the library.
- Create a credential using the `DBMS_CREDENTIAL.CREATE_CREDENTIAL` PL/SQL procedure. After the credential is created, a `CREATE LIBRARY` statement can associate the credential with a library to run the `extproc` agent as a particular operating system user.
- Use the `CREATE LIBRARY` statement to create the library objects that the developers need.
- Grant the following privileges to developers: `CREATE LIBRARY`, `CREATE ANY LIBRARY`, `ALTER ANY LIBRARY`, `EXECUTE ANY LIBRARY`, `EXECUTE ON library_name`, and `EXECUTE ON directory_object`.

Only make an explicit grant of these privileges to trusted users, and never to the `PUBLIC` role. If you plan to create PL/SQL interfaces to libraries, then only grant the `EXECUTE` privilege to the PL/SQL interface. Do not grant `EXECUTE` on the underlying library. You must have the `EXECUTE` object privilege on the library to create the PL/SQL interface. However, users have this privilege automatically in their own schemas. Explicit grants of `EXECUTE` object privilege on a library are rarely required.

See Also:

- *Oracle Database Security Guide* for information about creating a credential using the `DBMS_CREDENTIAL.CREATE_CREDENTIAL` procedure
- *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_CREDENTIAL` package
- "["Specifying Scheduler Job Credentials"](#)" for information about using credentials with Oracle Scheduler jobs

5.9 Terminating Sessions

Sometimes it is necessary to terminate current user sessions. For example, you might want to perform an administrative operation and need to terminate all non-administrative sessions.

- [About Terminating Sessions](#)

When a session is terminated, any active transactions of the session are rolled back, and resources held by the session (such as locks and memory areas) are immediately released and available to other sessions.

- [Identifying Which Session to Terminate](#)

To identify which session to terminate, specify the session index number and serial number.

- [Terminating an Active Session](#)

Terminating an active session ends the session.

- [Terminating an Inactive Session](#)

If the session is not making a SQL call to Oracle Database (is `INACTIVE`) when it is terminated, the `ORA-00028` message is not returned immediately. The message is not returned until the user subsequently attempts to use the terminated session.

5.9.1 About Terminating Sessions

When a session is terminated, any active transactions of the session are rolled back, and resources held by the session (such as locks and memory areas) are immediately released and available to other sessions.

You terminate a current session using the SQL statement `ALTER SYSTEM KILL SESSION`. The following statement terminates the session whose system identifier is 7 and serial number is 15:

```
ALTER SYSTEM KILL SESSION '7,15';
```

You can also use the `DBMS_SERVICE.DISCONNECT_SESSION` procedure to terminate sessions with a named service at the current instance.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for more information about the `DISCONNECT_SESSION` procedure

5.9.2 Identifying Which Session to Terminate

To identify which session to terminate, specify the session index number and serial number.

To identify the system identifier (SID) and serial number of a session:

- Query the `V$SESSION` dynamic performance view.

For example, the following query identifies all sessions for the user `jward`:

```
SELECT SID, SERIAL#, STATUS
  FROM V$SESSION
 WHERE USERNAME = 'JWARD';
```

SID	SERIAL#	STATUS
7	15	ACTIVE
12	63	INACTIVE

A session is ACTIVE when it is making a SQL call to Oracle Database. A session is INACTIVE if it is not making a SQL call to the database.

 **See Also:**

Oracle Database Reference for a description of the status values for a session

5.9.3 Terminating an Active Session

Terminating an active session ends the session.

If a user session is processing a transaction (ACTIVE status) when you terminate the session, then the transaction is rolled back and the user immediately receives the following message:

ORA-00028: your session has been killed

If, after receiving the ORA-00028 message, a user submits additional statements before reconnecting to the database, then Oracle Database returns the following message:

ORA-01012: not logged on

An active session cannot be interrupted when it is performing network I/O or rolling back a transaction. Such a session cannot be terminated until the operation completes. In this case, the session holds all resources until it is terminated. Additionally, the session that issues the ALTER SYSTEM statement to terminate a session waits up to 60 seconds for the session to be terminated. If the operation that cannot be interrupted continues past one minute, the issuer of the ALTER SYSTEM statement receives a message indicating that the session has been marked to be terminated. A session marked to be terminated is indicated in V\$SESSION with a status of KILLED and a server that is something other than PSEUDO.

If you are using Application Continuity, then an active session's activity is recovered when the session terminates. If you do not want to recover a session after you terminate it, then you can include the NOREPLAY keyword in the ALTER SYSTEM statement. For example, the following statement specifies that the session will not be recovered:

```
ALTER SYSTEM KILL SESSION '7,15' NOREPLAY;
```

If you use the DBMS_SERVICE.DISCONNECT_SESSION procedure to terminate one or more sessions, then you can specify DBMS_SERVICE.NOREPLAY for the disconnect_option parameter to indicate that the sessions should not be recovered by Application Continuity. For example, to disconnect all sessions with the service

`sales.example.com` and specify that the sessions should not be recovered, run the following procedure:

```
BEGIN
    DBMS_SERVICE.DISCONNECT_SESSION(
        service_name      => 'sales.example.com',
        disconnect_option => DBMS_SERVICE.NOREPLAY);
END;
/
```

See Also:

- ["Transaction Guard and Application Continuity"](#)
- [Oracle Database PL/SQL Packages and Types Reference](#) for more information about the `DISCONNECT_SESSION` procedure

5.9.4 Terminating an Inactive Session

If the session is not making a SQL call to Oracle Database (is `INACTIVE`) when it is terminated, the `ORA-00028` message is not returned immediately. The message is not returned until the user subsequently attempts to use the terminated session.

When an inactive session has been terminated, the `STATUS` of the session in the `V$SESSION` view is `KILLED`. The row for the terminated session is removed from `V$SESSION` after the user attempts to use the session again and receives the `ORA-00028` message.

In the following example, an inactive session is terminated. First, `V$SESSION` is queried to identify the `SID` and `SERIAL#` of the session, and then the session is terminated.

```
SELECT SID,SERIAL#,STATUS,SERVER
  FROM V$SESSION
 WHERE USERNAME = 'JWARD';

----- -----
 7       15  INACTIVE   DEDICATED
 12       63  INACTIVE   DEDICATED
2 rows selected.

ALTER SYSTEM KILL SESSION '7,15';
Statement processed.

SELECT SID, SERIAL#, STATUS, SERVER
  FROM V$SESSION
 WHERE USERNAME = 'JWARD';

----- -----
 7       15  KILLED     PSEUDO
 12       63  INACTIVE   DEDICATED
2 rows selected.
```

5.10 Process and Session Data Dictionary Views

You can query data dictionary views for information about processes and sessions.

View	Description
V\$PROCESS	Contains information about the currently active processes
V\$SESSION	Lists session information for each current session
V\$SESS_IO	Contains I/O statistics for each user session
V\$SESSION_LONGOPS	Displays the status of various operations that run for longer than 6 seconds (in absolute time). These operations currently include many backup and recovery functions, statistics gathering, and query execution. More operations are added for every Oracle Database release.
V\$SESSION_WAIT	Displays the current or last wait for each session
V\$SESSION_WAIT_HISTORY	Lists the last ten wait events for each active session
V\$WAIT_CHAINS	Displays information about blocked sessions
V\$SESSTAT	Contains session statistics
V\$RESOURCE_LIMIT	Provides information about current and maximum global resource utilization for some system resources
V\$SQLAREA	Contains statistics about shared SQL areas. Contains one row for each SQL string. Provides statistics about SQL statements that are in memory, parsed, and ready for execution

6

Managing Memory

Memory management involves maintaining optimal sizes for the Oracle Database instance memory structures as demands on the database change.

- [About Memory Management](#)

The memory structures that must be managed are the system global area (SGA) and the instance program global area (instance PGA). Oracle Database supports various memory management methods, which are chosen by initialization parameter settings.

- [Memory Architecture Overview](#)

Understand basic memory structures associated with Oracle Database.

- [Using Automatic Memory Management](#)

You can allow the Oracle Database instance to automatically manage and tune memory for you.

- [Configuring Memory Manually](#)

If you prefer to exercise more direct control over the sizes of individual memory components, you can disable automatic memory management and configure the database for manual memory management.

- [Using Force Full Database Caching Mode](#)

An Oracle Database instance can cache the full database in the buffer cache.

- [Configuring Database Smart Flash Cache](#)

The Database Smart Flash Cache feature is a transparent extension of the database buffer cache using solid state device (SSD) technology. Database Smart Flash Cache can greatly improve the performance of Oracle databases by reducing the amount of disk I/O at a much lower cost than adding an equivalent amount of RAM.

- [Improving Query Performance with the In-Memory Column Store](#)

The In-Memory Column Store (IM column store) is an optional portion of the system global area (SGA) that stores copies of tables, table partitions, and other database objects. In the IM column store, data is populated by column rather than row as it is in other parts of the SGA, and data is optimized for rapid scans. The IM column store is included with the Oracle Database In-Memory option.

- [Memory Management Reference](#)

Automatic memory management is supported only on some platforms. Also, you can query a set of data dictionary views for information on memory management.

6.1 About Memory Management

The memory structures that must be managed are the system global area (SGA) and the instance program global area (instance PGA). Oracle Database supports various memory management methods, which are chosen by initialization parameter settings.

Automatic Memory Management

Oracle Database can manage the SGA memory and instance PGA memory completely automatically. You designate only the total memory size to be used by the instance, and Oracle Database dynamically exchanges memory between the SGA and the instance PGA as needed to meet processing demands. This capability is referred to as *automatic memory management*. With this memory management method, the database also dynamically tunes the sizes of the individual SGA components and the sizes of the individual PGAs. Oracle recommends automatic memory management for databases where the total size of the SGA and PGA memory is less than or equal to four gigabytes.

Manual Memory Management

If you prefer to exercise more direct control over the sizes of individual memory components, you can disable automatic memory management and configure the database for manual memory management. There are a few different methods available for manual memory management. Some of these methods retain some degree of automation. The methods therefore vary in the amount of effort and knowledge required by the DBA. These methods are:

- Automatic shared memory management - for the SGA
- Manual shared memory management - for the SGA
- Automatic PGA memory management - for the instance PGA
- Manual PGA memory management - for the instance PGA

These memory management methods are described later in this chapter.

If you create your database with Database Configuration Assistant (DBCA) and choose the basic installation option, automatic memory management is enabled when system memory is less than or equal to 4 gigabytes. When system memory is greater than 4 gigabytes, automatic memory management is disabled, and automatic shared memory management is enabled. If you choose advanced installation, then DBCA enables you to select automatic memory management or automatic shared memory management.

Oracle recommends automatic shared memory management when the total size of the SGA and PGA memory is four gigabytes or larger.

 **Note:**

The easiest way to manage memory is to use the graphical user interface of Oracle Enterprise Manager Database Express (EM Express) or Oracle Enterprise Manager Cloud Control (Cloud Control).

For information about managing memory with EM Express, see *Oracle Database 2 Day DBA*.

For information about managing memory with Cloud Control, see the Cloud Control online help.

 **See Also:**

Oracle Database Concepts for an introduction to the various automatic and manual methods of managing memory.

6.2 Memory Architecture Overview

Understand basic memory structures associated with Oracle Database.

The basic memory structures associated with Oracle Database include:

- System Global Area (SGA)

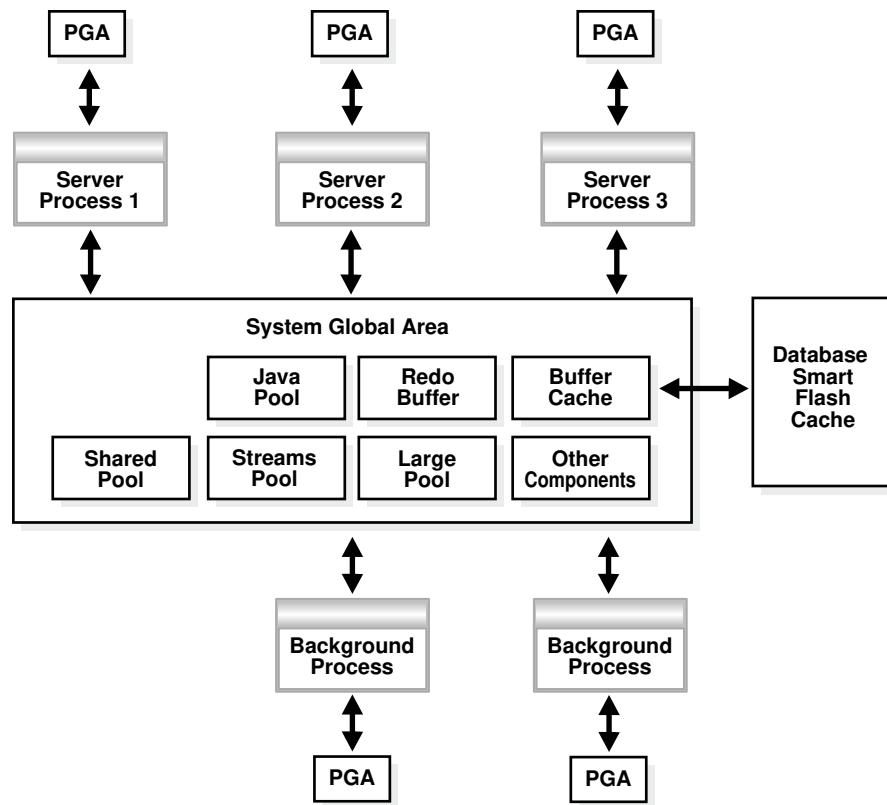

The SGA is a group of shared memory structures, known as *SGA components*, that contain data and control information for one Oracle Database instance. The SGA is shared by all server and background processes. Examples of data stored in the SGA include cached data blocks and shared SQL areas.

- Program Global Area (PGA)

A PGA is a memory region that contains data and control information for a server process. It is nonshared memory created by Oracle Database when a server process is started. Access to the PGA is exclusive to the server process. There is one PGA for each server process. Background processes also allocate their own PGAs. The total PGA memory allocated for all background and server processes attached to an Oracle Database instance is referred to as the **total instance PGA memory**, and the collection of all individual PGAs is referred to as the **total instance PGA**, or just **instance PGA**.

Figure 6-1 illustrates the relationships among these memory structures.

Figure 6-1 Oracle Database Memory Structures

If your database is running on Solaris or Oracle Linux, you can optionally add another memory component: Database Smart Flash Cache. Database Smart Flash Cache is an extension of the SGA-resident buffer cache, providing a level 2 cache for database blocks. It can improve response time and overall throughput for both read-intensive online transaction processing (OLTP) workloads and ad hoc queries and bulk data modifications in a data warehouse environment. Database Smart Flash Cache resides on one or more flash disk devices, which are solid state storage devices that use flash memory. Database Smart Flash Cache is typically more economical than additional main memory, and is an order of magnitude faster than disk drives.

Starting with Oracle Database 12c Release 1 (12.1.0.2), the big table cache enables serial queries and parallel queries to use the buffer cache. The big table cache facilitates efficient caching for large tables in data warehousing environments, even if these tables do not fully fit in the buffer cache. Table scans can use the big table cache in the following scenarios:

- Parallel queries

In single-instance and Oracle Real Application Clusters (Oracle RAC) databases, parallel queries can use the big table cache when the `DB_BIG_TABLE_CACHE_PERCENT_TARGET` initialization parameter is set to a non-zero value, and `PARALLEL_DEGREE_POLICY` is set to `AUTO` or `ADAPTIVE`.

- Serial queries

In a single-instance configuration only, serial queries can use the big table cache when the `DB_BIG_TABLE_CACHE_PERCENT_TARGET` initialization parameter is set to a non-zero value.

 **See Also:**

- ["Configuring Database Smart Flash Cache"](#)
- *Oracle Database Concepts* for more information on memory architecture in an Oracle Database instance
- *Oracle Database Reference* for more information about the `DB_BIG_TABLE_CACHE_PERCENT_TARGET` initialization parameter

6.3 Using Automatic Memory Management

You can allow the Oracle Database instance to automatically manage and tune memory for you.

- [About Automatic Memory Management](#)
The simplest way to manage instance memory is to allow the Oracle Database instance to automatically manage and tune it for you. To do so (on most platforms), you set only a *target* memory size initialization parameter (`MEMORY_TARGET`) and optionally a *maximum* memory size initialization parameter (`MEMORY_MAX_TARGET`).
- [Enabling Automatic Memory Management](#)
If you did not enable automatic memory management upon database creation (either by selecting the proper options in DBCA or by setting the appropriate initialization parameters for the `CREATE DATABASE` SQL statement), then you can enable it at a later time. Enabling automatic memory management involves a shutdown and restart of the database.
- [Monitoring and Tuning Automatic Memory Management](#)
The dynamic performance view `V$MEMORY_DYNAMIC_COMPONENTS` shows the current sizes of all dynamically tuned memory components, including the total sizes of the SGA and instance PGA.

6.3.1 About Automatic Memory Management

The simplest way to manage instance memory is to allow the Oracle Database instance to automatically manage and tune it for you. To do so (on most platforms), you set only a *target* memory size initialization parameter (`MEMORY_TARGET`) and optionally a *maximum* memory size initialization parameter (`MEMORY_MAX_TARGET`).

The total memory that the instance uses remains relatively constant, based on the value of `MEMORY_TARGET`, and the instance automatically distributes memory between the system global area (SGA) and the instance program global area (instance PGA).

As memory requirements change, the instance dynamically redistributes memory between the SGA and instance PGA.

When automatic memory management is not enabled, you must size both the SGA and instance PGA manually.

Because the `MEMORY_TARGET` initialization parameter is dynamic, you can change `MEMORY_TARGET` at any time without restarting the database. `MEMORY_MAX_TARGET`, which is not dynamic, serves as an upper limit so that you cannot accidentally set `MEMORY_TARGET` too high, and so that enough memory is set aside for the database instance in case you do want to increase total instance memory in the future. Because certain SGA components either cannot easily shrink or must remain at a minimum size, the instance also prevents you from setting `MEMORY_TARGET` too low.

 **Note:**

You cannot enable automatic memory management if the `LOCK_SGA` initialization parameter is `TRUE`. See *Oracle Database Reference* for information about this parameter.

 **See Also:**

"[Platforms That Support Automatic Memory Management](#)"

6.3.2 Enabling Automatic Memory Management

If you did not enable automatic memory management upon database creation (either by selecting the proper options in DBCA or by setting the appropriate initialization parameters for the `CREATE DATABASE` SQL statement), then you can enable it at a later time. Enabling automatic memory management involves a shutdown and restart of the database.

To enable automatic memory management:

1. Start SQL*Plus and connect to the Oracle Database instance with the `SYSDBA` administrative privilege.

See "[Connecting to the Database with SQL*Plus](#)" and "[Database Administrator Authentication](#)" for instructions.

2. Calculate the minimum value for `MEMORY_TARGET` as follows:

- a. Determine the current sizes of `SGA_TARGET` and `PGA_AGGREGATE_TARGET` in megabytes by entering the following SQL*Plus commands:

```
SHOW PARAMETER SGA_TARGET
```

NAME	TYPE	VALUE
sga_target	big integer	272M

```
SHOW PARAMETER PGA_AGGREGATE_TARGET
```

NAME	TYPE	VALUE
pga_aggregate_target	big integer	90M

See "[Enabling Automatic Shared Memory Management](#)" for information about setting the SGA_TARGET parameter if it is not set.

- b. Run the following query to determine the maximum instance PGA allocated in megabytes since the database was started:

```
SELECT VALUE/1048576 FROM V$PGASTAT WHERE NAME='maximum PGA allocated';
```

- c. Compute the maximum value between the query result from step 2b and PGA_AGGREGATE_TARGET. Add SGA_TARGET to this value.

```
MEMORY_TARGET = SGA_TARGET + MAX(PGA_AGGREGATE_TARGET, MAXIMUM PGA ALLOCATED)
```

For example, if SGA_TARGET is 272M and PGA_AGGREGATE_TARGET is 90M as shown above, and if the maximum PGA allocated is determined to be 120M, then MEMORY_TARGET should be at least 392M (272M + 120M).

- 3. Choose the value for MEMORY_TARGET that you want to use.

This can be the minimum value that you computed in step 2, or you can choose to use a larger value if you have enough physical memory available.

- 4. For the MEMORY_MAX_TARGET initialization parameter, decide on a maximum amount of memory that you would want to allocate to the database for the foreseeable future. That is, determine the maximum value for the sum of the SGA and instance PGA sizes. This number can be larger than or the same as the MEMORY_TARGET value that you chose in the previous step.
- 5. Do one of the following:

- If you started your Oracle Database instance with a server parameter file, which is the default if you created the database with the Database Configuration Assistant (DBCA), enter the following command:

```
ALTER SYSTEM SET MEMORY_MAX_TARGET = nM SCOPE = SPFILE;
```

where *n* is the value that you computed in step 4.

The SCOPE = SPFILE clause sets the value only in the server parameter file, and not for the running instance. You must include this SCOPE clause because MEMORY_MAX_TARGET is not a dynamic initialization parameter.

- If you started your instance with a text initialization parameter file, manually edit the file so that it contains the following statements:

```
memory_max_target = nM
memory_target = mM
```

where *n* is the value that you determined in step 4, and *m* is the value that you determined in step 3.

 **Note:**

In a text initialization parameter file, if you omit the line for `MEMORY_MAX_TARGET` and include a value for `MEMORY_TARGET`, then the database automatically sets `MEMORY_MAX_TARGET` to the value of `MEMORY_TARGET`. If you omit the line for `MEMORY_TARGET` and include a value for `MEMORY_MAX_TARGET`, then the `MEMORY_TARGET` parameter defaults to zero. After startup, you can then dynamically change `MEMORY_TARGET` to a nonzero value, provided that it does not exceed the value of `MEMORY_MAX_TARGET`.

6. Shut down and restart the database.
See [Starting Up and Shutting Down](#) for instructions.
7. If you started your Oracle Database instance with a server parameter file, enter the following commands:

```
ALTER SYSTEM SET MEMORY_TARGET = nM;  
ALTER SYSTEM SET SGA_TARGET = 0;  
ALTER SYSTEM SET PGA_AGGREGATE_TARGET = 0;
```

where *n* is the value that you determined in step 3.

 **Note:**

With `MEMORY_TARGET` set, the `SGA_TARGET` setting becomes the minimum size of the SGA and the `PGA_AGGREGATE_TARGET` setting becomes the minimum size of the instance PGA. By setting both of these to zero as shown, there are no minimums, and the SGA and instance PGA can grow as needed as long as their sum is less than or equal to the `MEMORY_TARGET` setting. The sizing of SQL work areas remains automatic.

You can omit the statements that set the `SGA_TARGET` and `PGA_AGGREGATE_TARGET` parameter values to zero and leave either or both of the values as positive numbers. In this case, the values act as minimum values for the sizes of the SGA or instance PGA.

In addition, you can use the `PGA_AGGREGATE_LIMIT` initialization parameter to set an instance-wide hard limit for PGA memory. You can set `PGA_AGGREGATE_LIMIT` whether or not you use automatic memory management. See "[Using Automatic PGA Memory Management](#)".

 See Also:

- ["About Automatic Memory Management"](#)
- ["Memory Architecture Overview"](#)
- *Oracle Database SQL Language Reference* for information on the ALTER SYSTEM SQL statement

6.3.3 Monitoring and Tuning Automatic Memory Management

The dynamic performance view V\$MEMORY_DYNAMIC_COMPONENTS shows the current sizes of all dynamically tuned memory components, including the total sizes of the SGA and instance PGA.

- Query the V\$MEMORY_TARGET_ADVICE view for tuning advice for the MEMORY_TARGET initialization parameter.

For example, run the following query:

```
SQL> select * from v$memory_target_advice order by memory_size;
```

MEMORY_SIZE	MEMORY_SIZE_FACTOR	ESTD_DB_TIME	ESTD_DB_TIME_FACTOR	VERSION
180	.5	458	1.344	0
270	.75	367	1.0761	0
360	1	341	1	0
450	1.25	335	.9817	0
540	1.5	335	.9817	0
630	1.75	335	.9817	0
720	2	335	.9817	0

The row with the MEMORY_SIZE_FACTOR of 1 shows the current size of memory, as set by the MEMORY_TARGET initialization parameter, and the amount of DB time required to complete the current workload. In previous and subsequent rows, the results show several alternative MEMORY_TARGET sizes. For each alternative size, the database shows the size factor (the multiple of the current size), and the estimated DB time to complete the current workload if the MEMORY_TARGET parameter were changed to the alternative size. Notice that for a total memory size smaller than the current MEMORY_TARGET size, estimated DB time increases. Notice also that in this example, there is nothing to be gained by increasing total memory size beyond 450MB. However, this situation might change if a complete workload has not yet been run.

EM Express provides an easy-to-use graphical memory advisor to help you select an optimal size for MEMORY_TARGET. See *Oracle Database 2 Day DBA* for details.

 **See Also:**

6.4 Configuring Memory Manually

If you prefer to exercise more direct control over the sizes of individual memory components, you can disable automatic memory management and configure the database for manual memory management.

- [About Manual Memory Management](#)
There are two different manual memory management methods for the SGA, and two for the instance PGA.
- [Using Automatic Shared Memory Management](#)
Automatic Shared Memory Management simplifies SGA memory management.
- [Using Manual Shared Memory Management](#)
To manage shared memory manually, you first ensure that both automatic memory management and automatic shared memory management are disabled. You then manually configure, monitor, and tune memory components..
- [Using Automatic PGA Memory Management](#)
By default, Oracle Database automatically and globally manages the total amount of memory dedicated to the instance PGA. You can control this amount by setting the initialization parameter `PGA_AGGREGATE_TARGET`.
- [Using Manual PGA Memory Management](#)
Oracle Database supports manual PGA memory management, in which you manually tune SQL work areas.

6.4.1 About Manual Memory Management

There are two different manual memory management methods for the SGA, and two for the instance PGA.

The two manual memory management methods for the SGA vary in the amount of effort and knowledge required by the DBA. With *automatic shared memory management*, you set target and maximum sizes for the SGA. The database then sets the total size of the SGA to your designated target, and dynamically tunes the sizes of many SGA components. With *manual shared memory management*, you set the sizes of several individual SGA components, thereby determining the overall SGA size. You then manually tune these individual SGA components on an ongoing basis.

For the instance PGA, there is *automatic PGA memory management*, in which you set a target size for the instance PGA. The database then sets the size of the instance PGA to your target, and dynamically tunes the sizes of individual PGAs. There is also *manual PGA memory management*, in which you set maximum work area size for

each type of SQL operator (such as sort or hash-join). This memory management method, although supported, is not recommended.

 **See Also:**

Oracle Database Concepts for an overview of Oracle Database memory management methods.

6.4.2 Using Automatic Shared Memory Management

Automatic Shared Memory Management simplifies SGA memory management.

- [About Automatic Shared Memory Management](#)

With automatic shared memory management, you specify the total amount of SGA memory available to an instance using the `SGA_TARGET` initialization parameter and Oracle Database automatically distributes this memory among the various SGA components to ensure the most effective memory utilization.

- [Components and Granules in the SGA](#)

The SGA comprises several memory **components**, which are pools of memory used to satisfy a particular class of memory allocation requests.

- [Setting Maximum SGA Size](#)

The `SGA_MAX_SIZE` initialization parameter specifies the maximum size of the System Global Area for the lifetime of the instance.

- [Setting SGA Target Size](#)

You enable the automatic shared memory management feature by setting the `SGA_TARGET` initialization parameter to a nonzero value. This parameter sets the total size of the SGA. It replaces the parameters that control the memory allocated for a specific set of individual components, which are now automatically and dynamically resized (tuned) as needed.

- [Enabling Automatic Shared Memory Management](#)

The procedure for enabling automatic shared memory management (ASMM) differs depending on whether you are changing to ASMM from manual shared memory management or from automatic memory management.

- [Setting Minimums for Automatically Sized SGA Components](#)

You can exercise some control over the size of the automatically sized SGA components by specifying minimum values for the parameters corresponding to these components. Doing so can be useful if you know that an application cannot function properly without a minimum amount of memory in specific components.

- [Dynamic Modification of SGA_TARGET](#)

The `SGA_TARGET` parameter can be dynamically increased up to the value specified for the `SGA_MAX_SIZE` parameter, and it can also be reduced.

- [Modifying Parameters for Automatically Sized Components](#)

When automatic shared memory management is enabled, the manually specified sizes of automatically sized components serve as a lower bound for the size of the components. You can modify this limit dynamically by changing the values of the corresponding parameters.

- [Modifying Parameters for Manually Sized Components](#)

Parameters for manually sized components can be dynamically altered as well. However, rather than setting a minimum size, the value of the parameter specifies the precise size of the corresponding component.

 **See Also:**

- *Oracle Database Performance Tuning Guide* for information about tuning the components of the SGA

6.4.2.1 About Automatic Shared Memory Management

With automatic shared memory management, you specify the total amount of SGA memory available to an instance using the `SGA_TARGET` initialization parameter and Oracle Database automatically distributes this memory among the various SGA components to ensure the most effective memory utilization.

When automatic shared memory management is enabled, the sizes of the different SGA components are flexible and can adapt to the needs of a workload without requiring any additional configuration. The database automatically distributes the available memory among the various components as required, allowing the system to maximize the use of all available SGA memory.

If you are using a server parameter file (`SPFILE`), the database remembers the sizes of the automatically tuned SGA components across instance shutdowns. As a result, the database instance does not need to learn the characteristics of the workload again each time the instance is started. The instance can begin with information from the previous instance and continue evaluating workload where it left off at the last shutdown.

6.4.2.2 Components and Granules in the SGA

The SGA comprises several memory **components**, which are pools of memory used to satisfy a particular class of memory allocation requests.

Examples of memory components include the shared pool (used to allocate memory for SQL and PL/SQL execution), the java pool (used for java objects and other java execution memory), and the buffer cache (used for caching disk blocks). All SGA components allocate and deallocate space in units of **granules**. Oracle Database tracks SGA memory use in internal numbers of granules for each SGA component.

The memory for dynamic components in the SGA is allocated in the unit of granules. The granule size is determined by the amount of SGA memory requested when the instance starts. Specifically, the granule size is based on the value of the `SGA_MAX_SIZE` initialization parameter. [Table 6-1](#) shows the granule size for different amounts of SGA memory.

Table 6-1 Granule Size

SGA Memory Amount	Granule Size
Less than or equal to 1 GB	4 MB

Table 6-1 (Cont.) Granule Size

SGA Memory Amount	Granule Size
Greater than 1 GB and less than or equal to 8 GB	16 MB
Greater than 8 GB and less than or equal to 16 GB	32 MB
Greater than 16 GB and less than or equal to 32 GB	64 MB
Greater than 32 GB and less than or equal to 64 GB	128 MB
Greater than 64 GB and less than or equal to 128 GB	256 MB
Greater than 128 GB	512 MB

Some platform dependencies may arise. Consult your operating system specific documentation for more details.

You can query the V\$SGAINFO view to see the granule size that is being used by an instance. The same granule size is used for all components in the SGA.

If you specify a size for a component that is not a multiple of granule size, Oracle Database rounds the specified size up to the nearest multiple. For example, if the granule size is 4 MB and you specify DB_CACHE_SIZE as 10 MB, the database actually allocates 12 MB.

6.4.2.3 Setting Maximum SGA Size

The SGA_MAX_SIZE initialization parameter specifies the maximum size of the System Global Area for the lifetime of the instance.

To set the maximum size of the System Global Area:

- Set the SGA_MAX_SIZE initialization parameter.

You can dynamically alter the initialization parameters affecting the size of the buffer caches, shared pool, large pool, Java pool, and streams pool but only to the extent that the sum of these sizes and the sizes of the other components of the SGA (fixed SGA, variable SGA, and redo log buffers) does not exceed the value specified by SGA_MAX_SIZE.

If you do not specify SGA_MAX_SIZE, then Oracle Database selects a default value that is the sum of all components specified or defaulted at initialization time. If you do specify SGA_MAX_SIZE, and at the time the database is initialized the value is less than the sum of the memory allocated for all components, either explicitly in the parameter file or by default, then the database ignores the setting for SGA_MAX_SIZE and chooses a correct value for this parameter.

6.4.2.4 Setting SGA Target Size

You enable the automatic shared memory management feature by setting the SGA_TARGET initialization parameter to a nonzero value. This parameter sets the total size of the SGA. It replaces the parameters that control the memory allocated for a specific set of individual components, which are now automatically and dynamically resized (tuned) as needed.

To enable the automatic shared memory management feature:

- Set the SGA_TARGET initialization parameter to a nonzero value.

 **Note:**

- The STATISTICS_LEVEL initialization parameter must be set to TYPICAL (the default) or ALL for automatic shared memory management to function.
- An easier way to enable automatic shared memory management is to use EM Express. When you enable automatic shared memory management and set the Total SGA Size, EM Express automatically generates the ALTER SYSTEM statements to set SGA_TARGET to the specified size and to set all automatically sized SGA components to zero. See *Oracle Database 2 Day DBA* for more information.

If you use SQL*Plus to set SGA_TARGET, then you must then set the automatically sized SGA components to zero or to a minimum value.

- [The SGA Target and Automatically Sized SGA Components](#)
Some SGA components are automatically sized when SGA_TARGET is set.
- [SGA and Virtual Memory](#)
For optimal performance in most systems, the entire SGA should fit in real memory. If it does not, and if virtual memory is used to store parts of it, then overall database system performance can decrease dramatically. The reason for this is that portions of the SGA are paged (written to and read from disk) by the operating system.
- [Monitoring and Tuning SGA Target Size](#)
The V\$SGAINFO view provides information on the current tuned sizes of various SGA components. The V\$SGA_TARGET_ADVICE view provides information that helps you decide on a value for SGA_TARGET.

6.4.2.4.1 The SGA Target and Automatically Sized SGA Components

Some SGA components are automatically sized when SGA_TARGET is set.

The following table lists the SGA components that are automatically sized when SGA_TARGET is set. For each SGA component, its corresponding initialization parameter is listed.

Table 6-2 Automatically Sized SGA Components and Corresponding Parameters

SGA Component	Initialization Parameter
Fixed SGA and other internal allocations needed by the Oracle Database instance	N/A
The shared pool	SHARED_POOL_SIZE
The large pool	LARGE_POOL_SIZE
The Java pool	JAVA_POOL_SIZE

Table 6-2 (Cont.) Automatically Sized SGA Components and Corresponding Parameters

SGA Component	Initialization Parameter
The buffer cache	DB_CACHE_SIZE
The Streams pool	STREAMS_POOL_SIZE

The manually sized parameters listed in [Table 6-3](#), if they are set, take their memory from SGA_TARGET, leaving what is available for the components listed in [Table 6-2](#).

Table 6-3 Manually Sized SGA Components that Use SGA_TARGET Space

SGA Component	Initialization Parameter
The log buffer	LOG_BUFFER
The keep and recycle buffer caches	DB_KEEP_CACHE_SIZE DB.recycle_cache_size
Nonstandard block size buffer caches	DB_nK_CACHE_SIZE

In addition to setting SGA_TARGET to a nonzero value, you must set to zero all initialization parameters listed in [Table 6-2](#) to enable full automatic tuning of the automatically sized SGA components.

Alternatively, you can set one or more of the automatically sized SGA components to a nonzero value, which is then used as the minimum setting for that component during SGA tuning. This is discussed in detail later in this section.

6.4.2.4.2 SGA and Virtual Memory

For optimal performance in most systems, the entire SGA should fit in real memory. If it does not, and if virtual memory is used to store parts of it, then overall database system performance can decrease dramatically. The reason for this is that portions of the SGA are paged (written to and read from disk) by the operating system.

See your operating system documentation for instructions for monitoring paging activity. You can also view paging activity using Cloud Control. See *Oracle Database 2 Day + Performance Tuning Guide* for more information.

6.4.2.4.3 Monitoring and Tuning SGA Target Size

The V\$SGAINFO view provides information on the current tuned sizes of various SGA components. The V\$SGA_TARGET_ADVICE view provides information that helps you decide on a value for SGA_TARGET.

To monitor and tune the SGA target size:

- Query the V\$SGAINFO and V\$SGA_TARGET_ADVICE views.

For example, run the following query:

```
SQL> select * from v$sga_target_advice order by sga_size;
-----
```

SGA_SIZE	SGA_SIZE_FACTOR	ESTD_DB_TIME	ESTD_DB_TIME_FACTOR	ESTD_PHYSICAL_READS
----------	-----------------	--------------	---------------------	---------------------

290	.5	448176	1.6578	1636103
435	.75	339336	1.2552	1636103
580	1	270344	1	1201780
725	1.25	239038	.8842	907584
870	1.5	211517	.7824	513881
1015	1.75	201866	.7467	513881
1160	2	200703	.7424	513881

The information in this view is similar to that provided in the V\$MEMORY_TARGET_ADVICE view for automatic memory management. See "[Monitoring and Tuning Automatic Memory Management](#)" for an explanation of that view.

EM Express provides an easy-to-use graphical memory advisor to help you select an optimal size for SGA_TARGET. See *Oracle Database 2 Day DBA* for details.

See Also:

- *Oracle Database Reference* for more information about the V\$SGAINFO view
- *Oracle Database Reference* for more information about the V\$SGA_TARGET_ADVICE view

6.4.2.5 Enabling Automatic Shared Memory Management

The procedure for enabling automatic shared memory management (ASMM) differs depending on whether you are changing to ASMM from manual shared memory management or from automatic memory management.

To change to ASMM from manual shared memory management:

1. Run the following query to obtain a value for SGA_TARGET:

```
SELECT (
  (SELECT SUM(value) FROM V$SGA) -
  (SELECT CURRENT_SIZE FROM V$SGA_DYNAMIC_FREE_MEMORY)
 ) "SGA_TARGET"
FROM DUAL;
```

2. Set the value of SGA_TARGET, either by editing the text initialization parameter file and restarting the database, or by issuing the following statement:

```
ALTER SYSTEM SET SGA_TARGET=value [SCOPE={SPFILE|MEMORY|BOTH}]
```

where *value* is the value computed in step 1 or is some value between the sum of all SGA component sizes and SGA_MAX_SIZE. For more information on the ALTER SYSTEM statement and its SCOPE clause, see *Oracle Database SQL Language Reference*.

3. Do one of the following:

- For more complete automatic tuning, set the values of the automatically sized SGA components listed in [Table 6-2](#) to zero. Do this by editing the text initialization parameter file or by issuing ALTER SYSTEM statements.
- To control the minimum size of one or more automatically sized SGA components, set those component sizes to the desired value. (See the next

section for details.) Set the values of the other automatically sized SGA components to zero. Do this by editing the text initialization parameter file or by issuing ALTER SYSTEM statements.

To change to ASMM from automatic memory management:

1. Set the MEMORY_TARGET initialization parameter to 0.

```
ALTER SYSTEM SET MEMORY_TARGET = 0;
```

The database sets SGA_TARGET based on current SGA memory allocation.

2. Do one of the following:

- For more complete automatic tuning, set the sizes of the automatically sized SGA components listed in [Table 6-2](#) to zero. Do this by editing the text initialization parameter file or by issuing ALTER SYSTEM statements.
- To control the minimum size of one or more automatically sized SGA components, set those component sizes to the desired value. (See the next section for details.) Set the sizes of the other automatically sized SGA components to zero. Do this by editing the text initialization parameter file or by issuing ALTER SYSTEM statements.

Example 6-1 Using ASMM

For example, suppose you currently have the following configuration of parameters for an instance configured for manual shared memory management and with SGA_MAX_SIZE set to 1200M:

- SHARED_POOL_SIZE = 200M
- DB_CACHE_SIZE = 500M
- LARGE_POOL_SIZE=200M

Also assume the following query results:

Query	Result
SELECT SUM(value) FROM V\$SGA	1200M
SELECT CURRENT_SIZE FROM V\$SGA_DYNAMIC_FREE_MEMORY	208M

You can take advantage of automatic shared memory management by issuing the following statements:

```
ALTER SYSTEM SET SGA_TARGET = 992M;
ALTER SYSTEM SET SHARED_POOL_SIZE = 0;
ALTER SYSTEM SET LARGE_POOL_SIZE = 0;
ALTER SYSTEM SET JAVA_POOL_SIZE = 0;
ALTER SYSTEM SET DB_CACHE_SIZE = 0;
ALTER SYSTEM SET STREAMS_POOL_SIZE = 0;
```

where 992M = 1200M minus 208M.

6.4.2.6 Setting Minimums for Automatically Sized SGA Components

You can exercise some control over the size of the automatically sized SGA components by specifying minimum values for the parameters corresponding to these

components. Doing so can be useful if you know that an application cannot function properly without a minimum amount of memory in specific components.

To specify the minimum amount of SGA space for a component:

- Set a value for its corresponding initialization parameter.

Manually limiting the minimum size of one or more automatically sized components reduces the total amount of memory available for dynamic adjustment. This reduction in turn limits the ability of the system to adapt to workload changes. Therefore, this practice is not recommended except in exceptional cases. The default automatic management behavior maximizes both system performance and the use of available resources.

Related Topics

- [The SGA Target and Automatically Sized SGA Components](#)

Some SGA components are automatically sized when `SGA_TARGET` is set.

6.4.2.7 Dynamic Modification of `SGA_TARGET`

The `SGA_TARGET` parameter can be dynamically increased up to the value specified for the `SGA_MAX_SIZE` parameter, and it can also be reduced.

If you reduce the value of `SGA_TARGET`, the system identifies one or more automatically tuned components for which to release memory. You can reduce `SGA_TARGET` until one or more automatically tuned components reach their minimum size. Oracle Database determines the minimum allowable value for `SGA_TARGET` taking into account several factors, including values set for the automatically sized components, manually sized components that use `SGA_TARGET` space, and number of CPUs.

The change in the amount of physical memory consumed when `SGA_TARGET` is modified depends on the operating system. On some UNIX platforms that do not support dynamic shared memory, the physical memory in use by the SGA is equal to the value of the `SGA_MAX_SIZE` parameter. On such platforms, there is no real benefit in setting `SGA_TARGET` to a value smaller than `SGA_MAX_SIZE`. Therefore, setting `SGA_MAX_SIZE` on those platforms is not recommended.

On other platforms, such as Solaris and Windows, the physical memory consumed by the SGA is equal to the value of `SGA_TARGET`.

For example, suppose you have an environment with the following configuration:

- `SGA_MAX_SIZE = 1024M`
- `SGA_TARGET = 512M`
- `DB_8K_CACHE_SIZE = 128M`

In this example, the value of `SGA_TARGET` can be resized up to 1024M and can also be reduced until one or more of the automatically sized components reaches its minimum size. The exact value depends on environmental factors such as the number of CPUs on the system. However, the value of `DB_8K_CACHE_SIZE` remains fixed at all times at 128M

 **Note:**

When enabling automatic shared memory management, it is best to set SGA_TARGET to the desired nonzero value before starting the database. Dynamically modifying SGA_TARGET from zero to a nonzero value may not achieve the desired results because the shared pool may not be able to shrink. After startup, you can dynamically tune SGA_TARGET up or down as required.

6.4.2.8 Modifying Parameters for Automatically Sized Components

When automatic shared memory management is enabled, the manually specified sizes of automatically sized components serve as a lower bound for the size of the components. You can modify this limit dynamically by changing the values of the corresponding parameters.

If the specified lower limit for the size of a given SGA component is less than its current size, then there is no immediate change in the size of that component. The new setting only limits the automatic tuning algorithm to that reduced minimum size in the future.

To set the lower bound for the size of a component:

- Set the initialization parameter for the component to the minimum.

For example, consider the following configuration:

- SGA_TARGET = 512M
- LARGE_POOL_SIZE = 256M
- Current actual large pool size = 284M

In this example, if you increase the value of LARGE_POOL_SIZE to a value greater than the actual current size of the component, the system expands the component to accommodate the increased minimum size. For example, if you increase the value of LARGE_POOL_SIZE to 300M, then the system increases the large pool incrementally until it reaches 300M. This resizing occurs at the expense of one or more automatically tuned components. If you decrease the value of LARGE_POOL_SIZE to 200, there is no immediate change in the size of that component. The new setting only limits the reduction of the large pool size to 200 M in the future.

 **Note:**

When SGA_TARGET is not set, the automatic shared memory management feature is not enabled. Therefore, the rules governing the resizing of all component parameters are the same as in earlier releases.

6.4.2.9 Modifying Parameters for Manually Sized Components

Parameters for manually sized components can be dynamically altered as well. However, rather than setting a minimum size, the value of the parameter specifies the precise size of the corresponding component.

When you increase the size of a manually sized component, extra memory is taken away from one or more automatically sized components. When you decrease the size of a manually sized component, the memory that is released is given to the automatically sized components.

To modify the precise size of a component:

- Set the initialization parameter for the component.

For example, consider this configuration:

- `SGA_TARGET = 512M`
- `DB_8K_CACHE_SIZE = 128M`

In this example, increasing `DB_8K_CACHE_SIZE` by 16M to 144M means that the 16M is taken away from the automatically sized components. Likewise, reducing `DB_8K_CACHE_SIZE` by 16M to 112M means that the 16M is given to the automatically sized components.

6.4.3 Using Manual Shared Memory Management

To manage shared memory manually, you first ensure that both automatic memory management and automatic shared memory management are disabled. You then manually configure, monitor, and tune memory components..

- [About Manual Shared Memory Management](#)

If you decide not to use automatic memory management or automatic shared memory management, you must manually configure several SGA component sizes, and then monitor and tune these sizes on an ongoing basis as the database workload changes. You can follow guidelines on setting the parameters that control the sizes of these SGA components.

- [Enabling Manual Shared Memory Management](#)

There is no initialization parameter that in itself enables manual shared memory management. You effectively enable manual shared memory management by disabling both automatic memory management and automatic shared memory management.

- [Setting the Buffer Cache Initialization Parameters](#)

The buffer cache initialization parameters determine the size of the buffer cache component of the SGA.

- [Specifying the Shared Pool Size](#)

The `SHARED_POOL_SIZE` initialization parameter is a dynamic parameter that lets you specify or adjust the size of the shared pool component of the SGA. Oracle Database selects an appropriate default value.

- [Specifying the Large Pool Size](#)

The `LARGE_POOL_SIZE` initialization parameter is a dynamic parameter that lets you specify or adjust the size of the large pool component of the SGA.

- **Specifying the Java Pool Size**
The `JAVA_POOL_SIZE` initialization parameter is a dynamic parameter that lets you specify or adjust the size of the Java pool component of the SGA.
- **Specifying the Streams Pool Size**
The `STREAMS_POOL_SIZE` initialization parameter is a dynamic parameter that lets you specify or adjust the size of the Streams Pool component of the SGA.
- **Specifying the Result Cache Maximum Size**
The `RESULT_CACHE_MAX_SIZE` initialization parameter is a dynamic parameter that enables you to specify the maximum size of the result cache component of the SGA.
- **Specifying Miscellaneous SGA Initialization Parameters**
You can set a few additional initialization parameters to control how the SGA uses memory.

6.4.3.1 About Manual Shared Memory Management

If you decide not to use automatic memory management or automatic shared memory management, you must manually configure several SGA component sizes, and then monitor and tune these sizes on an ongoing basis as the database workload changes. You can follow guidelines on setting the parameters that control the sizes of these SGA components.

If you create your database with DBCA and choose manual shared memory management, DBCA provides fields where you must enter sizes for the buffer cache, shared pool, large pool, and Java pool. It then sets the corresponding initialization parameters in the server parameter file (`SPFILE`) that it creates. If you instead create the database with the `CREATE DATABASE` SQL statement and a text initialization parameter file, you can do one of the following:

- Provide values for the initialization parameters that set SGA component sizes.
- Omit SGA component size parameters from the text initialization file. Oracle Database chooses reasonable defaults for any component whose size you do not set.

6.4.3.2 Enabling Manual Shared Memory Management

There is no initialization parameter that in itself enables manual shared memory management. You effectively enable manual shared memory management by disabling both automatic memory management and automatic shared memory management.

To enable manual shared memory management:

1. Set the `MEMORY_TARGET` initialization parameter to 0.
2. Set the `SGA_TARGET` initialization parameter to 0.

You must then set values for the various SGA components, as described in the following sections.

6.4.3.3 Setting the Buffer Cache Initialization Parameters

The buffer cache initialization parameters determine the size of the buffer cache component of the SGA.

You use them to specify the sizes of caches for the various block sizes used by the database. These initialization parameters are all dynamic.

The size of a buffer cache affects performance. Larger cache sizes generally reduce the number of disk reads and writes. However, a large cache may take up too much memory and induce memory paging or swapping.

Oracle Database supports multiple block sizes in a database. If you create tablespaces with non-standard block sizes, you must configure non-standard block size buffers to accommodate these tablespaces. The standard block size is used for the `SYSTEM` tablespace. You specify the standard block size by setting the initialization parameter `DB_BLOCK_SIZE`. Legitimate values are from 2K to 32K.

If you intend to use multiple block sizes in your database, you must have the `DB_CACHE_SIZE` and at least one `DB_nK_CACHE_SIZE` parameter set. Oracle Database assigns an appropriate default value to the `DB_CACHE_SIZE` parameter, but the `DB_nK_CACHE_SIZE` parameters default to 0, and no additional block size caches are configured.

The sizes and numbers of non-standard block size buffers are specified by the following parameters:

`DB_2K_CACHE_SIZE`
`DB_4K_CACHE_SIZE`
`DB_8K_CACHE_SIZE`
`DB_16K_CACHE_SIZE`
`DB_32K_CACHE_SIZE`

Each parameter specifies the size of the cache for the corresponding block size.

 **Note:**

- Platform-specific restrictions regarding the maximum block size apply, so some of these sizes might not be allowed on some platforms.
- A 32K block size is valid only on 64-bit platforms.

• [Example of Setting Block and Cache Sizes](#)

An example illustrates setting block and cache sizes.

• [Multiple Buffer Pools](#)

You can configure the database buffer cache with separate buffer pools that either keep data in the buffer cache or make the buffers available for new data immediately after using the data blocks.

 See Also:

["Specifying Nonstandard Block Sizes for Tablespaces"](#)

6.4.3.3.1 Example of Setting Block and Cache Sizes

An example illustrates setting block and cache sizes.

```
DB_BLOCK_SIZE=4096
DB_CACHE_SIZE=1024M
DB_2K_CACHE_SIZE=256M
DB_8K_CACHE_SIZE=512M
```

In the preceding example, the parameter `DB_BLOCK_SIZE` sets the standard block size of the database to 4K. The size of the cache of standard block size buffers is 1024MB. Additionally, 2K and 8K caches are also configured, with sizes of 256MB and 512MB, respectively.

 Note:

The `DB_nK_CACHE_SIZE` parameters cannot be used to size the cache for the standard block size. If the value of `DB_BLOCK_SIZE` is nK , it is invalid to set `DB_nK_CACHE_SIZE`. The size of the cache for the standard block size is always determined from the value of `DB_CACHE_SIZE`.

The cache has a limited size, so not all the data on disk can fit in the cache. When the cache is full, subsequent cache misses cause Oracle Database to write dirty data already in the cache to disk to make room for the new data. (If a buffer is not dirty, it does not need to be written to disk before a new block can be read into the buffer.) Subsequent access to any data that was written to disk and then overwritten results in additional cache misses.

The size of the cache affects the likelihood that a request for data results in a cache hit. If the cache is large, it is more likely to contain the data that is requested. Increasing the size of a cache increases the percentage of data requests that result in cache hits.

You can change the size of the buffer cache while the instance is running, without having to shut down the database. Do this with the `ALTER SYSTEM` statement.

Use the fixed view `V$BUFFER_POOL` to track the sizes of the different cache components and any pending resize operations.

6.4.3.3.2 Multiple Buffer Pools

You can configure the database buffer cache with separate buffer pools that either keep data in the buffer cache or make the buffers available for new data immediately after using the data blocks.

Particular schema objects (tables, clusters, indexes, and partitions) can then be assigned to the appropriate buffer pool to control the way their data blocks age out of the cache.

- The `KEEP` buffer pool retains the schema object's data blocks in memory.
- The `RECYCLE` buffer pool eliminates data blocks from memory as soon as they are no longer needed.
- The `DEFAULT` buffer pool contains data blocks from schema objects that are not assigned to any buffer pool, as well as schema objects that are explicitly assigned to the `DEFAULT` pool.

The initialization parameters that configure the `KEEP` and `RECYCLE` buffer pools are `DB_KEEP_CACHE_SIZE` and `DB_RECYCLE_CACHE_SIZE`.

 **Note:**

Multiple buffer pools are only available for the standard block size. Non-standard block size caches have a single `DEFAULT` pool.

 **See Also:**

Oracle Database Performance Tuning Guide for information about tuning the buffer cache and for more information about multiple buffer pools

6.4.3.4 Specifying the Shared Pool Size

The `SHARED_POOL_SIZE` initialization parameter is a dynamic parameter that lets you specify or adjust the size of the shared pool component of the SGA. Oracle Database selects an appropriate default value.

In releases before Oracle Database 10g, the amount of shared pool memory that was allocated was equal to the value of the `SHARED_POOL_SIZE` initialization parameter plus the amount of internal SGA overhead computed during instance startup. The internal SGA overhead refers to memory that is allocated by Oracle Database during startup, based on the values of several other initialization parameters. This memory is used to maintain state for different server components in the SGA. For example, if the `SHARED_POOL_SIZE` parameter is set to 64MB and the internal SGA overhead is computed to be 12MB, the real size of the shared pool is 64+12=76MB, although the value of the `SHARED_POOL_SIZE` parameter is still displayed as 64MB.

Starting with Oracle Database 10g, the size of the internal SGA overhead is included in the user-specified value of `SHARED_POOL_SIZE`. If you are not using automatic memory management or automatic shared memory management, the amount of shared pool memory that is allocated at startup is equal to the value of the `SHARED_POOL_SIZE` initialization parameter, rounded up to a multiple of the granule size. You must therefore set this parameter so that it includes the internal SGA overhead in addition to the desired value for shared pool size. In the previous example, if the `SHARED_POOL_SIZE` parameter is set to 64MB at startup, then the available shared pool after startup is 64-12=52MB, assuming the value of internal SGA

overhead remains unchanged. In order to maintain an effective value of 64MB for shared pool memory after startup, you must set the `SHARED_POOL_SIZE` parameter to $64+12=76$ MB.

When migrating from a release that is earlier than Oracle Database 10g, the Oracle Database 12c migration utilities recommend a new value for this parameter based on the value of internal SGA overhead in the pre-upgrade environment and based on the old value of this parameter. Beginning with Oracle Database 10g, the exact value of internal SGA overhead, also known as startup overhead in the shared pool, can be queried from the `V$SGAINFO` view. Also, in manual shared memory management mode, if the user-specified value of `SHARED_POOL_SIZE` is too small to accommodate even the requirements of internal SGA overhead, then Oracle Database generates an `ORA-00371` error during startup, with a suggested value to use for the `SHARED_POOL_SIZE` parameter. When you use automatic shared memory management in Oracle Database 12c, the shared pool is automatically tuned, and an `ORA-00371` error would not be generated.

- [The Result Cache and Shared Pool Size](#)

6.4.3.4.1 The Result Cache and Shared Pool Size

The result cache takes its memory from the shared pool. Therefore, if you expect to increase the maximum size of the result cache, take this into consideration when sizing the shared pool.

 **See Also:**

["Specifying the Result Cache Maximum Size"](#)

6.4.3.5 Specifying the Large Pool Size

The `LARGE_POOL_SIZE` initialization parameter is a dynamic parameter that lets you specify or adjust the size of the large pool component of the SGA.

The large pool is an optional component of the SGA. You must specifically set the `LARGE_POOL_SIZE` parameter to create a large pool. Configuring the large pool is discussed in *Oracle Database Performance Tuning Guide*.

6.4.3.6 Specifying the Java Pool Size

The `JAVA_POOL_SIZE` initialization parameter is a dynamic parameter that lets you specify or adjust the size of the Java pool component of the SGA.

Oracle Database selects an appropriate default value. Configuration of the Java pool is discussed in *Oracle Database Java Developer's Guide*.

6.4.3.7 Specifying the Streams Pool Size

The `STREAMS_POOL_SIZE` initialization parameter is a dynamic parameter that lets you specify or adjust the size of the Streams Pool component of the SGA.

If `STREAMS_POOL_SIZE` is set to 0, then the Oracle Streams product transfers memory from the buffer cache to the Streams Pool when it is needed. For details, see the discussion of the Streams Pool in *Oracle Streams Replication Administrator's Guide*.

6.4.3.8 Specifying the Result Cache Maximum Size

The `RESULT_CACHE_MAX_SIZE` initialization parameter is a dynamic parameter that enables you to specify the maximum size of the result cache component of the SGA.

Typically, there is no need to specify this parameter, because the default maximum size is chosen by the database based on total memory available to the SGA and on the memory management method currently in use. You can view the current default maximum size by displaying the value of the `RESULT_CACHE_MAX_SIZE` parameter. To change this maximum size, you can set `RESULT_CACHE_MAX_SIZE` with an `ALTER SYSTEM` statement, or you can specify this parameter in the text initialization parameter file. In each case, the value is rounded up to the nearest multiple of 32K.

If `RESULT_CACHE_MAX_SIZE` is 0 upon instance startup, the result cache is disabled. To reenable it you must set `RESULT_CACHE_MAX_SIZE` to a nonzero value (or remove this parameter from the text initialization parameter file to get the default maximum size) and then restart the database.

Note that after starting the database with the result cache disabled, if you use an `ALTER SYSTEM` statement to set `RESULT_CACHE_MAX_SIZE` to a nonzero value but do not restart the database, querying the value of the `RESULT_CACHE_MAX_SIZE` parameter returns a nonzero value even though the result cache is still disabled. The value of `RESULT_CACHE_MAX_SIZE` is therefore not the most reliable way to determine if the result cache is enabled. You can use the following query instead:

```
SELECT dbms_result_cache.status() FROM dual;  
  
DBMS_RESULT_CACHE.STATUS()  
-----  
ENABLED
```

The result cache takes its memory from the shared pool, so if you increase the maximum result cache size, consider also increasing the shared pool size.

The view `V$RESULT_CACHE_STATISTICS` and the PL/SQL package procedure `DBMS_RESULT_CACHE.MEMORY_REPORT` display information to help you determine the amount of memory currently allocated to the result cache.

The PL/SQL package function `DBMS_RESULT_CACHE.FLUSH` clears the result cache and releases all the memory back to the shared pool.

 See Also:

- *Oracle Database Performance Tuning Guide* for more information about the result cache
- *Oracle Database PL/SQL Packages and Types Reference* for more information about the `DBMS_RESULT_CACHE` package procedures and functions.
- *Oracle Database Reference* for more information about the `V$RESULT_CACHE_STATISTICS` view.
- *Oracle Real Application Clusters Administration and Deployment Guide* for information on setting `RESULT_CACHE_MAX_SIZE` for a cluster database.

6.4.3.9 Specifying Miscellaneous SGA Initialization Parameters

You can set a few additional initialization parameters to control how the SGA uses memory.

- [Physical Memory](#)
The `LOCK_SGA` parameter, when set to `TRUE`, locks the entire SGA into physical memory.
- [SGA Starting Address](#)
The `SHARED_MEMORY_ADDRESS` and `HI_SHARED_MEMORY_ADDRESS` parameters specify the SGA's starting address at run time.

6.4.3.9.1 Physical Memory

The `LOCK_SGA` parameter, when set to `TRUE`, locks the entire SGA into physical memory.

This parameter cannot be used with automatic memory management.

 See Also:

- *Oracle Database Reference* for more information on these initialization parameters
- ["Using Automatic Memory Management"](#)
- ["Using Automatic Shared Memory Management"](#)

6.4.3.9.2 SGA Starting Address

The `SHARED_MEMORY_ADDRESS` and `HI_SHARED_MEMORY_ADDRESS` parameters specify the SGA's starting address at run time.

These parameters are rarely used. For 64-bit platforms, `HI_SHARED_MEMORY_ADDRESS` specifies the high order 32 bits of the 64-bit address.

 **See Also:**

- *Oracle Database Reference* for more information on the SHARED_MEMORY_ADDRESS initialization parameter
- *Oracle Database Reference* for more information on the HI_SHARED_MEMORY_ADDRESS initialization parameter
- "[Using Automatic Memory Management](#)"
- "[Using Automatic Shared Memory Management](#)"

6.4.4 Using Automatic PGA Memory Management

By default, Oracle Database automatically and globally manages the total amount of memory dedicated to the instance PGA. You can control this amount by setting the initialization parameter `PGA_AGGREGATE_TARGET`.

Oracle Database then tries to ensure that the total amount of PGA memory allocated across all database server processes and background processes never exceeds this target.

If you create your database with DBCA, you can specify a value for the total instance PGA. DBCA then sets the `PGA_AGGREGATE_TARGET` initialization parameters in the server parameter file (`SPFILE`) that it creates. If you do not specify the total instance PGA, DBCA chooses a reasonable default.

If you create the database with the `CREATE DATABASE` SQL statement and a text initialization parameter file, you can provide a value for `PGA_AGGREGATE_TARGET`. If you omit this parameter, the database chooses a default value for it.

With automatic PGA memory management, sizing of SQL work areas is automatic and all `*_AREA_SIZE` initialization parameters are ignored. At any given time, the total amount of PGA memory available to active work areas on the instance is automatically derived from the parameter `PGA_AGGREGATE_TARGET`. This amount is set to the value of `PGA_AGGREGATE_TARGET` minus the PGA memory allocated for other purposes (for example, session memory). The resulting PGA memory is then allotted to individual active work areas based on their specific memory requirements.

There are dynamic performance views that provide PGA memory use statistics. Most of these statistics are enabled when `PGA_AGGREGATE_TARGET` is set.

- Statistics on allocation and use of work area memory can be viewed in the following dynamic performance views:

V\$SYSSTAT
V\$SESSTAT
V\$PGASTAT
V\$SQL_WORKAREA
V\$SQL_WORKAREA_ACTIVE

- The following three columns in the `V$PROCESS` view report the PGA memory allocated and used by an Oracle Database process:

`PGA_USED_MEM`

PGA_ALLOC_MEM
PGA_MAX_MEM

The `PGA_AGGREGATE_TARGET` setting is a target. Therefore, Oracle Database tries to limit PGA memory usage to the target, but usage can exceed the setting at times. To specify a hard limit on PGA memory usage, use the `PGA_AGGREGATE_LIMIT` initialization parameter. Oracle Database ensures that the PGA size does not exceed this limit. If the database exceeds the limit, then the database aborts calls from sessions that have the highest untunable PGA memory allocations. You can set `PGA_AGGREGATE_LIMIT` whether or not you use automatic memory management. If `PGA_AGGREGATE_LIMIT` is not set, then Oracle Database determines an appropriate default limit. See *Oracle Database Reference* for more information about this parameter.

 **Note:**

The automatic PGA memory management method applies to work areas allocated by both dedicated and shared server process. See *Oracle Database Concepts* for information about PGA memory allocation in dedicated and shared server modes.

 **See Also:**

- *Oracle Database Reference* for information about the initialization parameters and views described in this section
- *Oracle Database Performance Tuning Guide* for information about using the views described in this section

6.4.5 Using Manual PGA Memory Management

Oracle Database supports manual PGA memory management, in which you manually tune SQL work areas.

In releases earlier than Oracle Database 10g, the database administrator controlled the maximum size of SQL work areas by setting the following parameters: `SORT_AREA_SIZE`, `HASH_AREA_SIZE`, `BITMAP_MERGE_AREA_SIZE` and `CREATE_BITMAP_AREA_SIZE`. Setting these parameters is difficult, because the maximum work area size is ideally selected from the data input size and the total number of work areas active in the system. These two factors vary greatly from one work area to another and from one time to another. Thus, the various `*_AREA_SIZE` parameters are difficult to tune under the best of circumstances.

For this reason, Oracle strongly recommends that you leave automatic PGA memory management enabled.

If you decide to tune SQL work areas manually, you must set the `WORKAREA_SIZE_POLICY` initialization parameter to `MANUAL`.

 **Note:**

The initialization parameter `WORKAREA_SIZE_POLICY` is a session- and system-level parameter that can take only two values: `MANUAL` or `AUTO`. The default is `AUTO`. You can set `PGA_AGGREGATE_TARGET`, and then switch back and forth from auto to manual memory management mode. When `WORKAREA_SIZE_POLICY` is set to `AUTO`, your settings for `*_AREA_SIZE` parameters are ignored.

6.5 Using Force Full Database Caching Mode

An Oracle Database instance can cache the full database in the buffer cache.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

- [About Force Full Database Caching Mode](#)

In default caching mode, Oracle Database does not always cache the underlying data when a user queries a large table because doing so might remove more useful data from the buffer cache. Starting with Oracle Database 12c Release 1 (12.1.0.2), if the Oracle Database instance determines that there is enough space to cache the full database in the buffer cache and that it would be beneficial to do so, then the instance automatically caches the full database in the buffer cache.

- [Before Enabling Force Full Database Caching Mode](#)

The database must be at 12.0.0 or higher compatibility level to enable force full database caching mode for the database instance. In addition, ensure that the buffer cache is large enough to cache the entire database.

- [Enabling Force Full Database Caching Mode](#)

You can enable force full database caching mode for a database.

- [Disabling Force Full Database Caching Mode](#)

You can disable force full database caching mode for a database.

6.5.1 About Force Full Database Caching Mode

In default caching mode, Oracle Database does not always cache the underlying data when a user queries a large table because doing so might remove more useful data from the buffer cache. Starting with Oracle Database 12c Release 1 (12.1.0.2), if the Oracle Database instance determines that there is enough space to cache the full database in the buffer cache and that it would be beneficial to do so, then the instance automatically caches the full database in the buffer cache.

Caching the full database in the buffer cache might result in performance improvements. You can force an instance to cache the database in the buffer cache using an `ALTER DATABASE FORCE FULL DATABASE CACHING` statement. This statement puts the instance in force full database caching mode. In this mode, Oracle Database

assumes that the buffer cache is large enough to cache the full database and tries to cache all blocks that are accessed subsequently.

When an Oracle Database instance is in force full database caching mode, the following query returns YES:

```
SELECT FORCE_FULL_DB_CACHING FROM V$DATABASE;
```

When an instance is in default caching mode, NOCACHE LOBs are not cached in the buffer cache. However, when an instance is in force full database caching mode, NOCACHE LOBs can be cached in the buffer cache. Also, both LOBs that use SecureFiles LOB storage and LOBs that use BasicFiles LOB storage can be cached in the buffer cache in force full database caching mode only.

 **Note:**

- When an instance is put in force full database caching mode, database objects are not loaded into the buffer cache immediately. Instead, they are cached in the buffer cache when they are accessed.
- In a multitenant environment, force full database caching mode applies to the entire multitenant container database (CDB), including all of its pluggable databases (PDBs).
- Information about force full database caching mode is stored in the control file. If the control file is replaced or recreated, then the information about the force full database caching mode is lost. A restored control file might or might not include this information, depending on when the control file was backed up.

 **See Also:**

- [Managing a Multitenant Environment](#)
- [Managing Control Files](#)
- [Oracle Database Performance Tuning Guide](#) for information about when to use force full database caching mode

6.5.2 Before Enabling Force Full Database Caching Mode

The database must be at 12.0.0 or higher compatibility level to enable force full database caching mode for the database instance. In addition, ensure that the buffer cache is large enough to cache the entire database.

When a database is configured to use the SGA_TARGET or MEMORY_TARGET initialization parameter for automatic memory management, the size of the buffer cache might change depending on the workload. Run the following query to estimate the buffer cache size when the instance is under normal workload:

```
SELECT NAME, BYTES FROM V$SGAINFO WHERE NAME='Buffer Cache Size';
```

This query returns the buffer cache size for all possible block sizes. If your database uses multiple block sizes, then it is best to ensure that the buffer cache size for each possible block size is bigger than the total database size for that block size.

You can determine the buffer cache size for non-default block sizes with the DB_nK_CACHE_SIZE initialization parameter. With SGA_TARGET or MEMORY_TARGET, the buffer cache size for the default block size in the default pool might change depending on the workload. The following query returns the current buffer cache size for the default block size in the default pool:

```
SELECT COMPONENT, CURRENT_SIZE FROM V$SGA_DYNAMIC_COMPONENTS
  WHERE COMPONENT LIKE 'DEFAULT buffer cache';
```

If you are estimating memory requirements for running a database fully in the buffer cache, then you can estimate the size of the buffer cache as one of the following:

- If you plan to use SGA_TARGET, then you can estimate the buffer cache size as 60% of SGA_TARGET.
- If you plan to use MEMORY_TARGET, then you can estimate the SGA size as 60% of MEMORY_TARGET, and buffer cache size as 60% of SGA size. That is, you can estimate the buffer cache size as 36% of MEMORY_TARGET.

 **See Also:**

["Using Automatic Memory Management"](#)

6.5.3 Enabling Force Full Database Caching Mode

You can enable force full database caching mode for a database.

1. Connect to the instance as a user with ALTER DATABASE system privilege.
2. Ensure that the database is mounted but not open.
See "[Starting an Instance and Mounting a Database](#)".
3. Issue the following SQL statement:

```
ALTER DATABASE FORCE FULL DATABASE CACHING;
```

4. (Optional) Open the database:

```
ALTER DATABASE OPEN;
```

6.5.4 Disabling Force Full Database Caching Mode

You can disable force full database caching mode for a database.

1. Connect to the instance as a user with ALTER DATABASE system privilege.
2. Ensure that the database is mounted but not open.
See "[Starting an Instance and Mounting a Database](#)".
3. Issue the following SQL statement:

```
ALTER DATABASE NO FORCE FULL DATABASE CACHING;
```

4. (Optional) Open the database:

```
ALTER DATABASE OPEN;
```

6.6 Configuring Database Smart Flash Cache

The Database Smart Flash Cache feature is a transparent extension of the database buffer cache using solid state device (SSD) technology. Database Smart Flash Cache can greatly improve the performance of Oracle databases by reducing the amount of disk I/O at a much lower cost than adding an equivalent amount of RAM.

- [When to Configure Database Smart Flash Cache](#)

You should consider configuring Database Smart Flash Cache when certain conditions are met.

- [Sizing Database Smart Flash Cache](#)

As a general rule, size Database Smart Flash Cache to be between 2 times and 10 times the size of the buffer cache.

- [Tuning Memory for Database Smart Flash Cache](#)

For each database block moved from the buffer cache to Database Smart Flash Cache, a small amount of metadata about the block is kept in the buffer cache.

- [Database Smart Flash Cache Initialization Parameters](#)

You can use a set of initialization parameters to configure Database Smart Flash Cache.

- [Database Smart Flash Cache in an Oracle Real Applications Clusters Environment](#)

Oracle recommends that you configure a Database Smart Flash Cache on either all or none of the instances in an Oracle Real Application Clusters environment. Also, the total flash cache size configured on each instance should be approximately the same.

 [See Also:](#)

"[Memory Architecture Overview](#)" for a description of Database Smart Flash Cache

6.6.1 When to Configure Database Smart Flash Cache

You should consider configuring Database Smart Flash Cache when certain conditions are met.

Consider adding Database Smart Flash Cache when all of the following conditions are true:

- Your database is running on the Solaris or Oracle Linux operating systems. Database Smart Flash Cache is supported on these operating systems only.
- The Buffer Pool Advisory section of your Automatic Workload Repository (AWR) report or STATSPACK report indicates that doubling the size of the buffer cache would be beneficial.

- db file sequential read is a top wait event.
- You have spare CPU.

 **Note:**

You cannot share one flash file among multiple instances. However, you can share a single flash device among multiple instances if you use a logical volume manager or similar tool to statically partition the flash device.

6.6.2 Sizing Database Smart Flash Cache

As a general rule, size Database Smart Flash Cache to be between 2 times and 10 times the size of the buffer cache.

Any multiplier less than two would not provide any benefit. If you are using automatic shared memory management, make Database Smart Flash Cache between 2 times and 10 times the size of SGA_TARGET. Using 80% of the size of SGA_TARGET instead of the full size would also suffice for this calculation.

6.6.3 Tuning Memory for Database Smart Flash Cache

For each database block moved from the buffer cache to Database Smart Flash Cache, a small amount of metadata about the block is kept in the buffer cache.

For a single instance database, the metadata consumes approximately 100 bytes. For an Oracle Real Application Clusters (Oracle RAC) database, it is closer to 200 bytes. You must therefore take this extra memory requirement into account when adding Database Smart Flash Cache.

To tune memory for the Database Smart Flash Cache, complete one of the following actions:

- If you are managing memory manually, then increase the size of the buffer cache by an amount approximately equal to the number of database blocks that fit into the Database Smart Flash Cache as configured, multiplied by 100 (or 200 for Oracle RAC).
- If you are using automatic memory management, then increase the size of the MEMORY_TARGET initialization parameter using the algorithm described above. You may first have to increase the size of the MEMORY_MAX_TARGET initialization parameter .
- If you are using automatic shared memory management, then increase the size of the SGA_TARGET initialization parameter .

Also, for an Oracle RAC database that uses the flash cache, additional memory must be allocated to the shared pool for Global Cache Service (GCS) resources. Each GCS resource requires approximately 208 bytes in the shared pool.

 **Note:**

- You can choose to not increase the buffer cache size to account for Database Smart Flash Cache. In this case, the effective size of the buffer cache is reduced. In some cases, you can offset this loss by using a larger Database Smart Flash Cache.
- You can flush the Database Smart Flash Cache by issuing an `ALTER SYSTEM FLUSH FLASH_CACHE` statement. Flushing the Database Smart Flash Cache can be useful if you need to measure the performance of rewritten queries or a suite of queries from identical starting points, or if there might be corruption in the cache.

 **See Also:**

["About Memory Management"](#)

6.6.4 Database Smart Flash Cache Initialization Parameters

You can use a set of initialization parameters to configure Database Smart Flash Cache.

Table 6-4 Database Smart Flash Cache Initialization Parameters

Parameter	Description
<code>DB_FLASH_CACHE_FILE</code>	Specifies a list of paths and file names for the files to contain Database Smart Flash Cache, in either the operating system file system or an Oracle Automatic Storage Management disk group. If a specified file does not exist, then the database creates it during startup. Each file must reside on a flash device. If you configure Database Smart Flash Cache on a disk drive (spindle), then performance may suffer. A maximum of 16 files is supported.
<code>DB_FLASH_CACHE_SIZE</code>	Specifies the size of each file in your Database Smart Flash Cache. Each size corresponds with a file specified in <code>DB_FLASH_CACHE_FILE</code> . The files and sizes correspond in the order that they are specified. An error is raised if the number of specified sizes does not match the number of specified files. Each size specification must be less than or equal to the physical memory size of its flash device. The size is expressed as <i>nG</i> , indicating the number of gigabytes (GB). For example, to specify a 16 GB Database Smart Flash Cache, set <code>DB_FLASH_CACHE_SIZE</code> value to 16G.

For example, assume that your Database Smart Flash Cache uses following flash devices:

File	Size
/dev/sda	32G
/dev/sdb	32G
/dev/sdc	64G

You can set the initialization parameters to the following values:

```
DB_FLASH_CACHE_FILE = /dev/sda, /dev/sdb, /dev/sdc
```

```
DB_FLASH_CACHE_SIZE = 32G, 32G, 64G
```

You can query the V\$FLASHFILESTAT view to determine the cumulative latency and read counts of each file and compute the average latency.

You can use ALTER SYSTEM to set DB_FLASH_CACHE_SIZE to zero for each flash device you wish to disable. You can also use ALTER SYSTEM to set the size for any disabled flash device back to its original size to reenable it. However, dynamically changing the size of Database Smart Flash Cache is not supported.

See Also:

Oracle Database Reference for more information about the initialization parameters described in this section and for more information about the V\$FLASHFILESTAT view

6.6.5 Database Smart Flash Cache in an Oracle Real Applications Clusters Environment

Oracle recommends that you configure a Database Smart Flash Cache on either all or none of the instances in an Oracle Real Application Clusters environment. Also, the total flash cache size configured on each instance should be approximately the same.

6.7 Improving Query Performance with the In-Memory Column Store

The In-Memory Column Store (IM column store) is an optional portion of the system global area (SGA) that stores copies of tables, table partitions, and other database objects. In the IM column store, data is populated by column rather than row as it is in other parts of the SGA, and data is optimized for rapid scans. The IM column store is included with the Oracle Database In-Memory option.

The IM column store does not replace the buffer cache, but acts as a supplement, so that data can be stored in memory in both row and columnar formats.

Video

Storing a database object in the IM column store can improve performance significantly for the following types of operations performed on the database object:

- A query that scans a large number of rows and applies filters that use operators such as the following: =, <, >, and IN
- A query that selects a small number of columns from a table or materialized view with a large number of columns, such as a query that selects five columns from a table with 100 columns
- A query that joins a small table to a large table
- A query that aggregates data

Note:

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

6.8 Memory Management Reference

Automatic memory management is supported only on some platforms. Also, you can query a set of data dictionary views for information on memory management.

- [Platforms That Support Automatic Memory Management](#)
Some platforms support automatic memory management.
- [Memory Management Data Dictionary Views](#)
A set of dynamic performance views provide information on memory management.

6.8.1 Platforms That Support Automatic Memory Management

Some platforms support automatic memory management.

The following platforms support automatic memory management—the Oracle Database ability to automatically tune the sizes of the SGA and PGA, redistributing memory from one to the other on demand to optimize performance:

- Linux
- Solaris
- Windows
- HP-UX
- AIX

6.8.2 Memory Management Data Dictionary Views

A set of dynamic performance views provide information on memory management.

View	Description
V\$SGA	Displays summary information about the system global area (SGA).
V\$SGAINFO	Displays size information about the SGA, including the sizes of different SGA components, the granule size, and free memory.
V\$SGASTAT	Displays detailed information about how memory is allocated within the shared pool, large pool, Java pool, and Streams pool.
V\$PGASTAT	Displays PGA memory usage statistics as well as statistics about the automatic PGA memory manager when it is enabled (that is, when PGA_AGGREGATE_TARGET is set). Cumulative values in V\$PGASTAT are accumulated since instance startup.
V\$MEMORY_DYNAMIC_COMPONENTS	Displays information on the current size of all automatically tuned and static memory components, with the last operation (for example, grow or shrink) that occurred on each.
V\$SGA_DYNAMIC_COMPONENTS	Displays the current sizes of all SGA components, and the last operation for each component.
V\$SGA_DYNAMIC_FREE_MEMORY	Displays information about the amount of SGA memory available for future dynamic SGA resize operations.
V\$MEMORY_CURRENT_RESIZE_OPS	Displays information about resize operations that are currently in progress. A resize operation is an enlargement or reduction of the SGA, the instance PGA, or a dynamic SGA component.
V\$SGA_CURRENT_RESIZE_OPS	Displays information about dynamic SGA component resize operations that are currently in progress.
V\$MEMORY_RESIZE_OPS	Displays information about the last 800 completed memory component resize operations, including automatic grow and shrink operations for SGA_TARGET and PGA_AGGREGATE_TARGET.
V\$SGA_RESIZE_OPS	Displays information about the last 800 completed SGA component resize operations.
V\$MEMORY_TARGET_ADVICE	Displays information that helps you tune MEMORY_TARGET if you enabled automatic memory management.
V\$SGA_TARGET_ADVICE	Displays information that helps you tune SGA_TARGET.
V\$PGA_TARGET_ADVICE	Displays information that helps you tune PGA_AGGREGATE_TARGET.
V\$IM_SEGMENTS	Displays information about the storage allocated for all segments in the IM column store.
Note: This view is available starting with Oracle Database 12c Release 1 (12.1.0.2).	

Managing Users and Securing the Database

Establish a security policy for every database.

- [The Importance of Establishing a Security Policy for Your Database](#)

It is important to develop a security policy for every database. The security policy establishes methods for protecting your database from accidental or malicious destruction of data or damage to the database infrastructure.

- [Managing Users and Resources](#)

To connect to the database, each user must specify a valid user name that has been previously defined to the database. An account must have been established for the user, with information about the user being stored in the data dictionary.

- [User Privileges and Roles](#)

Privileges and roles are used to control user access to data and the types of SQL statements that can be executed.

- [Auditing Database Activity](#)

You can monitor and record selected user database actions, including those performed by administrators. You can monitor system-wide actions as well as actions performed on individual database objects. This type of monitoring is called database auditing.

- [Predefined User Accounts](#)

Oracle Database includes several predefined user accounts.

7.1 The Importance of Establishing a Security Policy for Your Database

It is important to develop a security policy for every database. The security policy establishes methods for protecting your database from accidental or malicious destruction of data or damage to the database infrastructure.

Each database can have an administrator, referred to as the security administrator, who is responsible for implementing and maintaining the database security policy. If the database system is small, the database administrator can have the responsibilities of the security administrator. However, if the database system is large, a designated person or group of people may have sole responsibility as security administrator.

For information about establishing security policies for your database, see *Oracle Database Security Guide*.

7.2 Managing Users and Resources

To connect to the database, each user must specify a valid user name that has been previously defined to the database. An account must have been established for the user, with information about the user being stored in the data dictionary.

When you create a database user (account), you specify the following attributes of the user:

- User name
- Authentication method
- Default tablespace
- Temporary tablespace
- Other tablespaces and quotas
- User profile

To learn how to create and manage users, see *Oracle Database Security Guide*.

7.3 User Privileges and Roles

Privileges and roles are used to control user access to data and the types of SQL statements that can be executed.

The table that follows describes the three types of privileges and roles:

Type	Description
System privilege	A system-defined privilege usually granted only by administrators. These privileges allow users to perform specific database operations.
Object privilege	A system-defined privilege that controls access to a specific object.
Role	A collection of privileges and other roles. Some system-defined roles exist, but most are created by administrators. Roles group together privileges and other roles, which facilitates the granting of multiple privileges and roles to users.

Privileges and roles can be granted to other users by users who have been granted the privilege to do so. The granting of roles and privileges starts at the administrator level. At database creation, the administrative user `SYS` is created and granted all system privileges and predefined Oracle Database roles. User `SYS` can then grant privileges and roles to other users, and also grant those users the right to grant specific privileges to others.

To learn how to administer privileges and roles for users, see *Oracle Database Security Guide*.

7.4 Auditing Database Activity

You can monitor and record selected user database actions, including those performed by administrators. You can monitor system-wide actions as well as actions performed on individual database objects. This type of monitoring is called database auditing.

You can create unified audit policies and manage these audit policies using SQL statements. Oracle Database provides default unified audit policies that contain the standard audit settings, and you can create custom unified audit policies. You can also create fine-grained audit policies using the `DBMS_FGA` PL/SQL package.

 **See Also:**

Complete background information and instructions for database auditing are in the following documents:

- *Oracle Database 2 Day + Security Guide*
- *Oracle Database Security Guide*

7.5 Predefined User Accounts

Oracle Database includes several predefined user accounts.

The three types of predefined accounts are:

- Administrative accounts (SYS, SYSTEM, SYSBACKUP, SYSDG, SYSKM, SYSRAC, SYSMAN, and DBSNMP)

SYS, SYSTEM, SYSBACKUP, SYSDG, SYSKM, and SYSRAC are described in "[About Database Administrator Security and Privileges](#)". SYSMAN is used to perform Oracle Enterprise Manager Cloud Control administration tasks. The management agent of Cloud Control uses the DBSNMP account to monitor and manage the database. You must not delete these accounts.

- Sample schema accounts

These optional accounts are used for examples in Oracle Database documentation and instructional materials. Examples are HR, SH, and OE. You must unlock these accounts and reset their passwords before using them.

- Internal accounts.

These accounts are created so that individual Oracle Database features or components can have their own schemas. You must not delete internal accounts, and you must not attempt to log in with them.

 **See Also:**

Oracle Database 2 Day + Security Guide for a table of predefined accounts.

Monitoring the Database

It is important that you monitor the operation of your database on a regular basis. Doing so not only informs you of errors that have not yet come to your attention but also gives you a better understanding of the normal operation of your database. Being familiar with normal behavior in turn helps you recognize when something is wrong.

- [Monitoring Errors and Alerts](#)
You can monitor database errors and alerts to prevent, detect, and solve problems.
- [Monitoring Performance](#)
Monitoring performance includes monitoring locks and wait events and querying a set of data dictionary views.
- [Monitoring Quarantined Objects](#)
Object quarantine enables an Oracle database to function even when there are corrupted, unrecoverable objects. The V\$QUARANTINE view contains information about quarantined objects.

8.1 Monitoring Errors and Alerts

You can monitor database errors and alerts to prevent, detect, and solve problems.

Note:

The easiest and best way to monitor the database for errors and alerts is with the Database Home page in Oracle Enterprise Manager Cloud Control (Cloud Control). See the Cloud Control online help for more information. This section provides alternate methods for monitoring, using data dictionary views, PL/SQL packages, and other command-line facilities.

- [Monitoring Errors with Trace Files and the Alert Log](#)
A trace file is a file that contains diagnostic data used to investigate problems. An alert log is a file that provides a chronological log of database messages and errors.
- [Monitoring a Database with Server-Generated Alerts](#)
A server-generated alert is a notification from the Oracle Database server of an impending problem.

8.1.1 Monitoring Errors with Trace Files and the Alert Log

A trace file is a file that contains diagnostic data used to investigate problems. An alert log is a file that provides a chronological log of database messages and errors.

- [About Monitoring Errors with Trace Files and the Alert Log](#)
The trace file and alert log contain information about errors.

- [Controlling the Size of an Alert Log](#)
To control the size of an alert log, you must manually delete the file when you no longer need it. Otherwise the database continues to append to the file.
- [Controlling the Size of Trace Files](#)
You can control the maximum size of all trace files (excluding the alert log) using the initialization parameter `MAX_DUMP_FILE_SIZE`.
- [Controlling When Oracle Database Writes to Trace Files](#)
Background processes always write to a trace file when appropriate.
- [Reading the Trace File for Shared Server Sessions](#)
If shared server is enabled, each session using a dispatcher is routed to a shared server process, and trace information is written to the server trace file only if the session has enabled tracing (or if an error is encountered). Therefore, to track tracing for a specific session that connects using a dispatcher, you might have to explore several shared server trace files.

8.1.1.1 About Monitoring Errors with Trace Files and the Alert Log

The trace file and alert log contain information about errors.

Each server and background process can write to an associated **trace file**. When an internal error is detected by a process, it dumps information about the error to its trace file. Some of the information written to a trace file is intended for the database administrator, and other information is for Oracle Support Services. Trace file information is also used to tune applications and instances.

 **Note:**

Critical errors also create incidents and incident dumps in the Automatic Diagnostic Repository. See [Managing Diagnostic Data](#) for more information.

The **alert log** is a chronological log of messages and errors, and includes the following items:

- All internal errors (ORA-00600), block corruption errors (ORA-01578), and deadlock errors (ORA-00060) that occur
- Administrative operations, such as some CREATE, ALTER, and DROP statements and STARTUP, SHUTDOWN, and ARCHIVELOG statements
- Messages and errors relating to the functions of shared server and dispatcher processes
- Errors occurring during the automatic refresh of a materialized view
- The values of all initialization parameters that had nondefault values at the time the database and instance start

Oracle Database uses the alert log to record these operations as an alternative to displaying the information on an operator's console (although some systems also display information on the console). If an operation is successful, a "completed" message is written in the alert log, along with a timestamp.

The alert log is maintained as both an XML-formatted file and a text-formatted file. You can view either format of the alert log with any text editor or you can use the ADRCI utility to view the XML-formatted version of the file with the XML tags stripped.

Check the alert log and trace files of an instance periodically to learn whether the background processes have encountered errors. For example, when the log writer process (LGWR) cannot write to a member of a log group, an error message indicating the nature of the problem is written to the LGWR trace file and the alert log. Such an error message means that a media or I/O problem has occurred and should be corrected immediately.

Oracle Database also writes values of initialization parameters to the alert log, in addition to other important statistics.

The alert log and all trace files for background and server processes are written to the Automatic Diagnostic Repository, the location of which is specified by the `DIAGNOSTIC_DEST` initialization parameter. The names of trace files are operating system specific, but each file usually includes the name of the process writing the file (such as LGWR and RECO).

See Also:

- [Managing Diagnostic Data](#) for information on the Automatic Diagnostic Repository.
- ["Alert Log"](#) for additional information about the alert log.
- ["Viewing the Alert Log"](#)
- [Oracle Database Utilities](#) for information on the ADRCI utility.
- Your operating system specific Oracle documentation for information about the names of trace files

8.1.1.2 Controlling the Size of an Alert Log

To control the size of an alert log, you must manually delete the file when you no longer need it. Otherwise the database continues to append to the file.

You can safely delete the alert log while the instance is running, although you should consider making an archived copy of it first. This archived copy could prove valuable if you should have a future problem that requires investigating the history of an instance.

To control the size of an alert log:

- Delete the alert log file.

8.1.1.3 Controlling the Size of Trace Files

You can control the maximum size of all trace files (excluding the alert log) using the initialization parameter `MAX_DUMP_FILE_SIZE`.

You can set this parameter in the following ways:

- A numerical value specifies the maximum size in operating system blocks. The specified value is multiplied by the block size to obtain the limit.
- A number followed by a K, M, or G suffix specifies the file size in kilobytes, megabytes, or gigabytes.
- UNLIMITED, which is the default, specifies no limit.
- [Trace File Segmentation and MAX_DUMP_FILE_SIZE](#)
Oracle Database can automatically segment trace files based on the limit you specify with the MAX_DUMP_FILE_SIZE initialization parameter. When a limit is reached, the database renames the current trace file using a sequential number, and creates an empty file with the original name.

 **See Also:**

- [Oracle Database Reference](#) for more information about the MAX_DUMP_FILE_SIZE initialization parameter
- ["About the Oracle Database Fault Diagnosability Infrastructure"](#) for more information about IPS

8.1.1.3.1 Trace File Segmentation and MAX_DUMP_FILE_SIZE

Oracle Database can automatically segment trace files based on the limit you specify with the MAX_DUMP_FILE_SIZE initialization parameter. When a limit is reached, the database renames the current trace file using a sequential number, and creates an empty file with the original name.

The following table describes how trace files are segmented based on the MAX_DUMP_FILE_SIZE setting.

Table 8-1 The MAX_DUMP_FILE_SIZE Parameter and Trace File Segmentation

MAX_DUMP_FILE_SIZE Setting	Trace File Segmentation
UNLIMITED	Trace files are not segmented.
Larger than 15M	Trace files are segmented on a boundary that is 1/5 of the MAX_DUMP_FILE_SIZE setting. Trace files with sizes that are less than this boundary in size are not segmented. For example, if the MAX_DUMP_FILE_SIZE setting is 100M, then the boundary is 20 MB (1/5 of 100 MB).
15M or less	Trace files are not segmented.

There can be up to five segments, but the total combined size of the segments cannot exceed the MAX_DUMP_FILE_SIZE limit. When the combined size of all segments of the trace file exceeds the specified limit, the oldest segment after the first segment is deleted, and a new, empty segment is created. Therefore, the trace file always contains the most recent trace information. The first segment is not deleted because it might contain relevant information about the initial state of the process.

Segmentation improves space management for trace files. Specifically, segmentation enables you to manage trace files in the following ways:

- You can purge old trace files when they are no longer needed.
- You can diagnose problems with smaller trace files and isolate trace files that must be packaged for the incident packaging service (IPS).

 **Note:**

Any segment that covers a time range that includes an incident is not deleted. It is kept in addition to the five default segments.

8.1.1.4 Controlling When Oracle Database Writes to Trace Files

Background processes always write to a trace file when appropriate.

In the case of the ARCn background process, it is possible, through the LOG_ARCHIVE_TRACE initialization parameter, to control the amount and type of trace information that is produced. To do so:

- Follow the instructions described in "[Controlling Trace Output Generated by the Archivelog Process](#)".

Other background processes do not have this flexibility.

Trace files are written on behalf of server processes whenever critical errors occur. Additionally, setting the initialization parameter SQL_TRACE = TRUE causes the SQL trace facility to generate performance statistics for the processing of all SQL statements for an instance and write them to the Automatic Diagnostic Repository.

Optionally, you can request that trace files be generated for server processes. Regardless of the current value of the SQL_TRACE initialization parameter, each session can enable or disable trace logging on behalf of the associated server process by using the SQL statement ALTER SESSION SET SQL_TRACE. This example enables the SQL trace facility for a specific session:

```
ALTER SESSION SET SQL_TRACE TRUE;
```

Use the DBMS_SESSION or the DBMS_MONITOR packages to control SQL tracing for a session.

 **Note:**

The SQL trace facility for server processes can cause significant system overhead resulting in severe performance impact, so you should enable this feature only when collecting statistics.

 **See Also:**

- [Managing Diagnostic Data](#) for more information on how the database handles critical errors, otherwise known as "incidents."

8.1.1.5 Reading the Trace File for Shared Server Sessions

If shared server is enabled, each session using a dispatcher is routed to a shared server process, and trace information is written to the server trace file only if the session has enabled tracing (or if an error is encountered). Therefore, to track tracing for a specific session that connects using a dispatcher, you might have to explore several shared server trace files.

To help you, Oracle provides a command line utility program, `trcsess`, which consolidates all trace information pertaining to a user session in one place and orders the information by time.

 **See Also:**

Oracle Database SQL Tuning Guide for information about using the SQL trace facility and using `TKPROF` and `trcsess` to interpret the generated trace files

8.1.2 Monitoring a Database with Server-Generated Alerts

A server-generated alert is a notification from the Oracle Database server of an impending problem.

- [About Monitoring a Database with Server-Generated Alerts](#)
A server-generated alert may contain suggestions for correcting the problem. Notifications are also provided when the problem condition has been cleared.
- [Setting and Retrieving Thresholds for Server-Generated Alerts](#)
You can view and change threshold settings for the server alert metrics using the `SET_THRESHOLD` and `GET_THRESHOLD` procedures of the `DBMS_SERVER_ALERT` PL/SQL package.
- [Viewing Server-Generated Alerts](#)
The easiest way to view server-generated alerts is by accessing the Database Home page of Cloud Control, but there are other methods of viewing these alerts.
- [Server-Generated Alerts Data Dictionary Views](#)
You can query data dictionary views for information about server-generated alerts.

8.1.2.1 About Monitoring a Database with Server-Generated Alerts

A server-generated alert may contain suggestions for correcting the problem. Notifications are also provided when the problem condition has been cleared.

Alerts are automatically generated when a problem occurs or when data does not match expected values for metrics, such as the following:

- Physical Reads Per Second
- User Commits Per Second
- SQL Service Response Time

Server-generated alerts can be based on threshold levels or can issue simply because an event has occurred. Threshold-based alerts can be triggered at both threshold warning and critical levels. The value of these levels can be customer-defined or internal values, and some alerts have default threshold levels which you can change if appropriate. For example, by default a server-generated alert is generated for tablespace space usage when the percentage of space usage exceeds either the 85% warning or 97% critical threshold level. Examples of alerts not based on threshold levels are:

- Snapshot Too Old
- Resumable Session Suspended
- Recovery Area Space Usage

An alert message is sent to the predefined persistent queue `ALERT_QUE` owned by the user `SYS`. Cloud Control reads this queue and provides notifications about outstanding server alerts, and sometimes suggests actions for correcting the problem. The alerts are displayed on the Cloud Control Database Home page and can be configured to send email or pager notifications to selected administrators. If an alert cannot be written to the alert queue, a message about the alert is written to the Oracle Database alert log.

Background processes periodically flush the data to the Automatic Workload Repository to capture a history of metric values. The alert history table and `ALERT_QUE` are purged automatically by the system at regular intervals.

8.1.2.2 Setting and Retrieving Thresholds for Server-Generated Alerts

You can view and change threshold settings for the server alert metrics using the `SET_THRESHOLD` and `GET_THRESHOLD` procedures of the `DBMS_SERVER_ALERT` PL/SQL package.

Note:

The most convenient way to set and retrieve threshold values is to use the graphical interface of Cloud Control. See the Cloud Control online help about managing alerts for instructions.

- [Setting Threshold Levels](#)

The `SET_THRESHOLD` procedure in the `DBMS_SERVER_ALERT` package can set threshold levels.

- [Retrieving Threshold Information](#)

The `GET_THRESHOLD` procedure in the `DBMS_SERVER_ALERT` package can retrieve threshold information.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_SERVER_ALERT package

8.1.2.2.1 Setting Threshold Levels

The SET_THRESHOLD procedure in the DBMS_SERVER_ALERT package can set threshold levels.

To set threshold levels:

- Run SET_THRESHOLD procedure in the DBMS_SERVER_ALERT package, and specify the appropriate arguments.

The following example shows how to set thresholds with the SET_THRESHOLD procedure for CPU time for each user call for an instance:

```
DBMS_SERVER_ALERT.SET_THRESHOLD(
    DBMS_SERVER_ALERT.CPU_TIME_PER_CALL, DBMS_SERVER_ALERT.OBJECT_TYPE_SERVICE,
    DBMS_SERVER_ALERT.OBJECT_TYPE_SERVICE, 'main.regress.rdbms.dev.us.example.com');
```

In this example, a warning alert is issued when CPU time exceeds 8000 microseconds for each user call and a critical alert is issued when CPU time exceeds 10,000 microseconds for each user call. The arguments include:

- CPU_TIME_PER_CALL specifies the metric identifier. For a list of support metrics, see *Oracle Database PL/SQL Packages and Types Reference*.
- The observation period is set to 1 minute. This period specifies the number of minutes that the condition must deviate from the threshold value before the alert is issued.
- The number of consecutive occurrences is set to 2. This number specifies how many times the metric value must violate the threshold values before the alert is generated.
- The name of the instance is set to inst1.
- The constant DBMS_ALERT.OBJECT_TYPE_SERVICE specifies the object type on which the threshold is set. In this example, the service name is main.regress.rdbms.dev.us.example.com.

8.1.2.2 Retrieving Threshold Information

The GET_THRESHOLD procedure in the DBMS_SERVER_ALERT package can retrieve threshold information.

To retrieve threshold values:

- Run the GET_THRESHOLD procedure in the DBMS_SERVER_ALERT package and specify the appropriate arguments.

The following example retrieves threshold values:

```
DECLARE
    warning_operator      BINARY_INTEGER;
```

```

warning_value      VARCHAR2(60);
critical_operator  BINARY_INTEGER;
critical_value     VARCHAR2(60);
observation_period BINARY_INTEGER;
consecutive_occurrences BINARY_INTEGER;

BEGIN
DBMS_SERVER_ALERT.GET_THRESHOLD(
DBMS_SERVER_ALERT.CPU_TIME_PER_CALL, warning_operator, warning_value,
critical_operator, critical_value, observation_period,
consecutive_occurrences, 'inst1',
DBMS_SERVER_ALERT.OBJECT_TYPE_SERVICE, 'main.regress.rdbms.dev.us.example.com');
DBMS_OUTPUT.PUT_LINE('Warning operator:      ' || warning_operator);
DBMS_OUTPUT.PUT_LINE('Warning value:       ' || warning_value);
DBMS_OUTPUT.PUT_LINE('Critical operator:   ' || critical_operator);
DBMS_OUTPUT.PUT_LINE('Critical value:     ' || critical_value);
DBMS_OUTPUT.PUT_LINE('Observation period: ' || observation_period);
DBMS_OUTPUT.PUT_LINE('Consecutive occurrences:' || consecutive_occurrences);
END;
/

```

You can also check specific threshold settings with the `DBA_THRESHOLDS` view. For example:

```

SELECT metrics_name, warning_value, critical_value, consecutive_occurrences
FROM DBA_THRESHOLDS
WHERE metrics_name LIKE '%CPU Time%';

```

8.1.2.3 Viewing Server-Generated Alerts

The easiest way to view server-generated alerts is by accessing the Database Home page of Cloud Control, but there are other methods of viewing these alerts.

If you use your own tool rather than Cloud Control to display alerts, then complete the following steps to view server-generated alerts:

1. Subscribe to the `ALERT_QUE`.
2. Read the `ALERT_QUE`.
3. Display an alert notification after setting the threshold levels for an alert

To create an agent and subscribe the agent to the `ALERT_QUE`, complete the following steps:

1. Run the `CREATE_AQ_AGENT` procedure of the `DBMS_AQADM` package.
2. Run the `ADD_SUBSCRIBER` procedure of the `DBMS_AQADM` package.
3. Associate a database user with the subscribing agent, because only a user associated with the subscribing agent can access queued messages in the secure `ALERT_QUE`.
4. Assign the enqueue privilege to the user by running the `ENABLE_DB_ACCESS` and `GRANT_QUEUE_PRIVILEGE` procedures of the `DBMS_AQADM` package.
5. Register with the `DBMS_AQ.REGISTER` procedure to receive an asynchronous notification when an alert is enqueued to `ALERT_QUE`. The notification can be in the form of email, HTTP post, or PL/SQL procedure.

To read an alert message, complete the following steps:

1. Use the `DBMS_AQ.DEQUEUE` procedure or `OCIAQDeq` call.
2. After the message has been dequeued, use the `DBMS_SERVER_ALERT.EXPAND_MESSAGE` procedure to expand the text of the message.

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_AQ` package
- *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_AQADM` package

8.1.2.4 Server-Generated Alerts Data Dictionary Views

You can query data dictionary views for information about server-generated alerts.

View	Description
<code>DBA_THRESHOLDS</code>	Lists the threshold settings defined for the instance
<code>DBA_OUTSTANDING_ALERTS</code>	Describes the outstanding alerts in the database
<code>DBA_ALERT_HISTORY</code>	Lists a history of alerts that have been cleared
<code>V\$ALERT_TYPES</code>	Provides information such as group and type for each alert
<code>V\$METRICNAME</code>	Contains the names, identifiers, and other information about the system metrics
<code>V\$METRIC</code>	Contains system-level metric values
<code>V\$METRIC_HISTORY</code>	Contains a history of system-level metric values

8.2 Monitoring Performance

Monitoring performance includes monitoring locks and wait events and querying a set of data dictionary views.

Monitoring database performance is covered in detail in *Oracle Database Performance Tuning Guide* and *Oracle Database SQL Tuning Guide*.

- **Monitoring Locks**
Locks are mechanisms that prevent destructive interaction between transactions accessing the same resource. The resources can be either user objects, such as tables and rows, or system objects not visible to users, such as shared data structures in memory and data dictionary rows.
- **About Monitoring Wait Events**
Wait events are statistics that are incremented by a server process to indicate that it had to wait for an event to complete before being able to continue processing. A session could wait for a variety of reasons, including waiting for more input, waiting for the operating system to complete a service such as a disk write, or it could wait for a lock or latch.

- [Performance Monitoring Data Dictionary Views](#)
You can query a set of data dictionary views to monitor an Oracle Database instance.

8.2.1 Monitoring Locks

Locks are mechanisms that prevent destructive interaction between transactions accessing the same resource. The resources can be either user objects, such as tables and rows, or system objects not visible to users, such as shared data structures in memory and data dictionary rows.

Oracle Database automatically obtains and manages necessary locks when executing SQL statements, so you need not be concerned with such details. However, the database also lets you lock data manually.

A deadlock can occur when two or more users are waiting for data locked by each other. Deadlocks prevent some transactions from continuing to work. Oracle Database automatically detects deadlock situations and resolves them by rolling back one of the statements involved in the deadlock, thereby releasing one set of the conflicting row locks.

Oracle Database is designed to avoid deadlocks, and they are not common. Most often they occur when transactions explicitly override the default locking of the database. Deadlocks can affect the performance of your database, so Oracle provides some scripts and views that enable you to monitor locks.

To monitor locks:

1. Run the `catblock.sql`, which creates lock views.
2. Run the `utllockt.sql` script, which uses the views created by `catblock.sql` to display, in a tree fashion, the sessions in the system that are waiting for locks and the locks that they are waiting for.

The location of the script files is operating system dependent.

See Also:

- ["Performance Monitoring Data Dictionary Views"](#)
- *Oracle Database Concepts* contains more information about locks.

8.2.2 About Monitoring Wait Events

Wait events are statistics that are incremented by a server process to indicate that it had to wait for an event to complete before being able to continue processing. A session could wait for a variety of reasons, including waiting for more input, waiting for the operating system to complete a service such as a disk write, or it could wait for a lock or latch.

When a session is waiting for resources, it is not doing any useful work. A large number of waits is a source of concern. Wait event data reveals various symptoms of problems that might be affecting performance, such as latch contention, buffer contention, and I/O contention.

Oracle provides several views that display wait event statistics. A discussion of these views and their role in instance tuning is contained in *Oracle Database Performance Tuning Guide*.

8.2.3 Performance Monitoring Data Dictionary Views

You can query a set of data dictionary views to monitor an Oracle Database instance.

These views are general in their scope. Other views, more specific to a process, are discussed in the section of this book where the process is described.

View	Description
V\$LOCK	Lists the locks currently held by Oracle Database and outstanding requests for a lock or latch
DBA_BLOCKERS	Displays a session if it is holding a lock on an object for which another session is waiting
DBA_WAITERS	Displays a session if it is waiting for a locked object
DBA_DDL_LOCKS	Lists all DDL locks held in the database and all outstanding requests for a DDL lock
DBA_DML_LOCKS	Lists all DML locks held in the database and all outstanding requests for a DML lock
DBA_LOCK	Lists all locks or latches held in the database and all outstanding requests for a lock or latch
DBA_LOCK_INTERNAL	Displays a row for each lock or latch that is being held, and one row for each outstanding request for a lock or latch
V\$LOCKED_OBJECT	Lists all locks acquired by every transaction on the system
V\$SESSION_WAIT	Lists the resources or events for which active sessions are waiting
V\$SYSSTAT	Contains session statistics
V\$RESOURCE_LIMIT	Provides information about current and maximum global resource utilization for some system resources
V\$SQLAREA	Contains statistics about shared SQL area and contains one row for each SQL string. Also provides statistics about SQL statements that are in memory, parsed, and ready for execution
V\$LATCH	Contains statistics for nonparent latches and summary statistics for parent latches

8.3 Monitoring Quarantined Objects

Object quarantine enables an Oracle database to function even when there are corrupted, unrecoverable objects. The V\$QUARANTINE view contains information about quarantined objects.

- [About Object Quarantine](#)

Object quarantine isolates an object that has raised an error and monitors the object for impacts on the system.

- [Viewing Quarantined Objects](#)

The V\$QUARANTINE view stores information about the objects that are currently quarantined.

8.3.1 About Object Quarantine

Object quarantine isolates an object that has raised an error and monitors the object for impacts on the system.

Some Oracle Database errors, such as ORA-00600 and ORA-07445, typically cause the process to abort, which can cause the database to abort. When such an error is encountered, object quarantine attempts to isolate the resource that caused the error so that the database can continue to run. The resource is isolated in memory so that it does not affect the rest of the database. The v\$QUARANTINE view stores information about the objects that are currently quarantined.

Most database resources can raise errors that can cause a database to abort. For example, library cache memory objects can raise such errors.

In a multitenant environment, a multitenant container database (CDB) can, in some cases, use object quarantine to isolate and abort a pluggable database (PDB) that has raised a serious error instead of aborting the CDB.

A quarantined resource typically remains quarantined until the database is restarted. If a resource is quarantined for a PDB in a CDB, then the resource is quarantined until the PDB is closed and re-opened.

8.3.2 Viewing Quarantined Objects

The v\$QUARANTINE view stores information about the objects that are currently quarantined.

1. Connect to the database as an administrative user.
2. Query the v\$QUARANTINE view.

Example 8-1 Querying the V\$QUARANTINE View

This query shows the resources that are currently quarantined.

```
COLUMN OBJECT FORMAT A10
COLUMN ADDRESS FORMAT A10
COLUMN BYTES FORMAT 999999999
COLUMN ERROR FORMAT A20
COLUMN TIMESTAMP FORMAT A20

SELECT OBJECT, ADDRESS, BYTES, ERROR, TIMESTAMP
  FROM V$QUARANTINE;
```

Your output is similar to the following:

OBJECT	ADDRESS	BYTES	ERROR	TIMESTAMP
session	0000000078 B54BC8	9528	ORA-00600: internal error code, argument s: [12345], [], [], [], [], [], [], [], [], [], [], []	16-SEP-15 01.17.42.2 85878 PM -07:00

This output shows the following about the quarantined resource:

- The name of the resource is “session.”
- The start address of the memory region being quarantined is 0000000078B54BC8. Typically, this is the address of the resource, such as the session in this example.
- The resource is using 9528 bytes of memory in quarantine.
- The message of the error that caused the resource to be placed in quarantine is “ORA-00600 internal error code.”
- The timestamp shows the date and time of the error.

Managing Diagnostic Data

Oracle Database includes an advanced fault diagnosability infrastructure for collecting and managing diagnostic data. **Diagnostic data** includes the trace files, dumps, and core files that are also present in previous releases, plus new types of diagnostic data that enable customers and Oracle Support to identify, investigate, track, and resolve problems quickly and effectively.

- [About the Oracle Database Fault Diagnosability Infrastructure](#)

Oracle Database includes a fault diagnosability infrastructure for preventing, detecting, diagnosing, and resolving database problems.

- [Investigating, Reporting, and Resolving a Problem](#)

You can use the Enterprise Manager Support Workbench (Support Workbench) to investigate and report a problem (critical error), and in some cases, resolve the problem. You can use a "roadmap" that summarizes the typical set of tasks that you must perform.

- [Viewing Problems with the Support Workbench](#)

You can use the Support Workbench home page in Cloud Control to view all the problems or the problems in a specific time period.

- [Adding Problems Manually to the Automatic Diagnostic Repository](#)

You can use Support Workbench in Cloud Control to manually add a problem to the ADR.

- [Viewing the Alert Log](#)

You can view the alert log with a text editor, with Cloud Control, or with the ADRCI utility.

- [Finding Trace Files](#)

Trace files are stored in the Automatic Diagnostic Repository (ADR), in the `trace` directory under each ADR home. To help you locate individual trace files within this directory, you can use data dictionary views. For example, you can find the path to your current session's trace file or to the trace file for each Oracle Database process.

- [Running Health Checks with Health Monitor](#)

You can run diagnostic checks on a database with Health Monitor.

- [Repairing SQL Failures with the SQL Repair Advisor](#)

In the rare case that a SQL statement fails with a critical error, you can run the SQL Repair Advisor to try to repair the failed statement.

- [Repairing Data Corruptions with the Data Recovery Advisor](#)

You use the Data Recovery Advisor to repair data block corruptions, undo corruptions, data dictionary corruptions, and more.

- [Creating, Editing, and Uploading Custom Incident Packages](#)

Using the Enterprise Manager Support Workbench (Support Workbench), you can create, edit, and upload custom incident packages. With custom incident packages, you have fine control over the diagnostic data that you send to Oracle Support.

9.1 About the Oracle Database Fault Diagnosability Infrastructure

Oracle Database includes a fault diagnosability infrastructure for preventing, detecting, diagnosing, and resolving database problems.

- [Fault Diagnosability Infrastructure Overview](#)

The fault diagnosability infrastructure aids in preventing, detecting, diagnosing, and resolving problems. The problems that are targeted in particular are critical errors such as those caused by code bugs, metadata corruption, and customer data corruption.

- [Incidents and Problems](#)

A **problem** is a critical error in a database instance, Oracle Automatic Storage Management (Oracle ASM) instance, or other Oracle product or component. An **incident** is a single occurrence of a problem.

- [Fault Diagnosability Infrastructure Components](#)

The fault diagnosability infrastructure consists of several components, including the Automatic Diagnostic Repository (ADR), various logs, trace files, the Enterprise Manager Support Workbench, and the ADRCI Command-Line Utility.

- [Structure, Contents, and Location of the Automatic Diagnostic Repository](#)

The Automatic Diagnostic Repository (ADR) is a directory structure that is stored outside of the database. It is therefore available for problem diagnosis when the database is down.

9.1.1 Fault Diagnosability Infrastructure Overview

The fault diagnosability infrastructure aids in preventing, detecting, diagnosing, and resolving problems. The problems that are targeted in particular are critical errors such as those caused by code bugs, metadata corruption, and customer data corruption.

When a critical error occurs, it is assigned an incident number, and diagnostic data for the error (such as trace files) are immediately captured and tagged with this number. The data is then stored in the Automatic Diagnostic Repository (ADR)—a file-based repository outside the database—where it can later be retrieved by incident number and analyzed.

The goals of the fault diagnosability infrastructure are the following:

- First-failure diagnosis
- Problem prevention
- Limiting damage and interruptions after a problem is detected
- Reducing problem diagnostic time
- Reducing problem resolution time
- Simplifying customer interaction with Oracle Support

The keys to achieving these goals are the following technologies:

- **Automatic capture of diagnostic data upon first failure**—For critical errors, the ability to capture error information at first-failure greatly increases the chance of a quick problem resolution and reduced downtime. An always-on memory-based

tracing system proactively collects diagnostic data from many database components, and can help isolate root causes of problems. Such proactive diagnostic data is similar to the data collected by airplane "black box" flight recorders. When a problem is detected, alerts are generated and the fault diagnosability infrastructure is activated to capture and store diagnostic data. The data is stored in a repository that is outside the database (and therefore available when the database is down), and is easily accessible with command line utilities and Oracle Enterprise Manager Cloud Control (Cloud Control).

- **Standardized trace formats**—Standardizing trace formats across all database components enables DBAs and Oracle Support personnel to use a single set of tools for problem analysis. Problems are more easily diagnosed, and downtime is reduced.
- **Health checks**—Upon detecting a critical error, the fault diagnosability infrastructure can run one or more health checks to perform deeper analysis of a critical error. Health check results are then added to the other diagnostic data collected for the error. Individual health checks look for data block corruptions, undo and redo corruption, data dictionary corruption, and more. As a DBA, you can manually invoke these health checks, either on a regular basis or as required.
- **Incident packaging service (IPS) and incident packages**—The IPS enables you to automatically and easily gather the diagnostic data—traces, dumps, health check reports, and more—pertaining to a critical error and package the data into a zip file for transmission to Oracle Support. Because all diagnostic data relating to a critical error are tagged with that error's incident number, you do not have to search through trace files and other files to determine the files that are required for analysis; the incident packaging service identifies the required files automatically and adds them to the zip file. Before creating the zip file, the IPS first collects diagnostic data into an intermediate logical structure called an incident package (package). Packages are stored in the Automatic Diagnostic Repository. If you choose to, you can access this intermediate logical structure, view and modify its contents, add or remove additional diagnostic data at any time, and when you are ready, create the zip file from the package. After these steps are completed, the zip file is ready to be uploaded to Oracle Support.
- **Data Recovery Advisor**—The Data Recovery Advisor integrates with database health checks and RMAN to display data corruption problems, assess the extent of each problem (critical, high priority, low priority), describe the impact of a problem, recommend repair options, conduct a feasibility check of the customer-chosen option, and automate the repair process.
- **SQL Test Case Builder**—For many SQL-related problems, obtaining a reproducible test case is an important factor in problem resolution speed. The SQL Test Case Builder automates the sometimes difficult and time-consuming process of gathering as much information as possible about the problem and the environment in which it occurred. After quickly gathering this information, you can upload it to Oracle Support to enable support personnel to easily and accurately reproduce the problem.

9.1.2 Incidents and Problems

A **problem** is a critical error in a database instance, Oracle Automatic Storage Management (Oracle ASM) instance, or other Oracle product or component. An **incident** is a single occurrence of a problem.

- **About Incidents and Problems**
To facilitate diagnosis and resolution of critical errors, the fault diagnosability infrastructure introduces two concepts for Oracle Database: problems and incidents.
- **Incident Flood Control**
It is conceivable that a problem could generate dozens or perhaps hundreds of incidents in a short period of time. This would generate too much diagnostic data, which would consume too much space in the ADR and could possibly slow down your efforts to diagnose and resolve the problem. For these reasons, the fault diagnosability infrastructure applies *flood control* to incident generation after certain thresholds are reached.
- **Related Problems Across the Topology**
For any problem identified in a database instance, the diagnosability framework can identify related problems across the topology of your Oracle Database installation.

9.1.2.1 About Incidents and Problems

To facilitate diagnosis and resolution of critical errors, the fault diagnosability infrastructure introduces two concepts for Oracle Database: problems and incidents.

A **problem** is a critical error in a database instance, Oracle Automatic Storage Management (Oracle ASM) instance, or other Oracle product or component. Critical errors manifest as internal errors, such as ORA-00600, or other severe errors, such as ORA-07445 (operating system exception) or ORA-04031 (out of memory in the shared pool). Problems are tracked in the ADR. Each problem has a *problem key*, which is a text string that describes the problem. It includes an error code (such as ORA 600) and in some cases, one or more error parameters.

An **incident** is a single occurrence of a problem. When a problem (critical error) occurs multiple times, an incident is created for each occurrence. Incidents are timestamped and tracked in the Automatic Diagnostic Repository (ADR). Each incident is identified by a numeric incident ID, which is unique within the ADR. When an incident occurs, the database:

- Makes an entry in the alert log.
- Sends an *incident alert* to Cloud Control.
- Gathers first-failure diagnostic data about the incident in the form of dump files (incident dumps).
- Tags the incident dumps with the incident ID.
- Stores the incident dumps in an ADR subdirectory created for that incident.

Diagnosis and resolution of a critical error usually starts with an incident alert. Incident alerts are displayed on the Cloud Control Database Home page or Oracle Automatic Storage Management Home page. The Database Home page also displays in its Related Alerts section any critical alerts in the Oracle ASM instance or other Oracle products or components. After viewing an alert, you can then view the problem and its associated incidents with Cloud Control or with the ADRCI command-line utility.

See Also:

- "[Viewing Problems with the Support Workbench](#)"
- "[Investigating, Reporting, and Resolving a Problem](#)"
- "[ADRCI Command-Line Utility](#)"

9.1.2.2 Incident Flood Control

It is conceivable that a problem could generate dozens or perhaps hundreds of incidents in a short period of time. This would generate too much diagnostic data, which would consume too much space in the ADR and could possibly slow down your efforts to diagnose and resolve the problem. For these reasons, the fault diagnosability infrastructure applies *flood control* to incident generation after certain thresholds are reached.

A **flood-controlled incident** is an incident that generates an alert log entry, is recorded in the ADR, but does not generate incident dumps. Flood-controlled incidents provide a way of informing you that a critical error is ongoing, without overloading the system with diagnostic data. You can choose to view or hide flood-controlled incidents when viewing incidents with Cloud Control or the ADRCI command-line utility.

Threshold levels for incident flood control are predetermined and cannot be changed. They are defined as follows:

- After five incidents occur for the same problem key in one hour, subsequent incidents for this problem key are flood-controlled. Normal (non-flood-controlled) recording of incidents for that problem key begins again in the next hour.
- After 25 incidents occur for the same problem key in one day, subsequent incidents for this problem key are flood-controlled. Normal recording of incidents for that problem key begins again on the next day.

In addition, after 50 incidents for the same problem key occur in one hour, or 250 incidents for the same problem key occur in one day, subsequent incidents for this problem key are not recorded at all in the ADR. In these cases, the database writes a message to the alert log indicating that no further incidents will be recorded. As long as incidents continue to be generated for this problem key, this message is added to the alert log every ten minutes until the hour or the day expires. Upon expiration of the hour or day, normal recording of incidents for that problem key begins again.

9.1.2.3 Related Problems Across the Topology

For any problem identified in a database instance, the diagnosability framework can identify related problems across the topology of your Oracle Database installation.

In a single instance environment, a related problem could be identified in the local Oracle ASM instance. In an Oracle RAC environment, a related problem could be identified in any database instance or Oracle ASM instance on any other node. When investigating problems, you are able to view and gather information on any related problems.

A problem is related to the original problem if it occurs within a designated time period or shares the same execution context identifier. An **execution context identifier**

(ECID) is a globally unique identifier used to tag and track a single call through the Oracle software stack, for example, a call to Oracle Fusion Middleware that then calls into Oracle Database to retrieve data. The ECID is typically generated in the middle tier and is passed to the database as an Oracle Call Interface (OCI) attribute. When a single call has failures on multiple tiers of the Oracle software stack, problems that are generated are tagged with the same ECID so that they can be correlated. You can then determine the tier on which the originating problem occurred.

9.1.3 Fault Diagnosability Infrastructure Components

The fault diagnosability infrastructure consists of several components, including the Automatic Diagnostic Repository (ADR), various logs, trace files, the Enterprise Manager Support Workbench, and the ADRCI Command-Line Utility.

- [Automatic Diagnostic Repository \(ADR\)](#)
The ADR is a file-based repository for database diagnostic data such as traces, dumps, the alert log, health monitor reports, and more. It has a unified directory structure across multiple instances and multiple products.
- [Alert Log](#)
The alert log is an XML file that is a chronological log of messages and errors.
- [Trace Files, Dumps, and Core Files](#)
Trace files, dumps, and core files contain diagnostic data that are used to investigate problems. They are stored in the ADR.
- [DDL Log](#)
The data definition language (DDL) log is a file that has the same format and basic behavior as the alert log, but it only contains the DDL statements issued by the database.
- [Debug Log](#)
An Oracle Database component can detect conditions, states, or events that are unusual, but which do not inhibit correct operation of the detecting component. The component can issue a warning about these conditions, states, or events. The debug log is a file that records these warnings.
- [Other ADR Contents](#)
In addition to files mentioned in the previous sections, the ADR contains health monitor reports, data repair records, SQL test cases, incident packages, and more. These components are described later in the chapter.
- [Enterprise Manager Support Workbench](#)
The Enterprise Manager Support Workbench (Support Workbench) is a facility that enables you to investigate, report, and in some cases, repair problems (critical errors), all with an easy-to-use graphical interface.
- [ADRCI Command-Line Utility](#)
The ADR Command Interpreter (ADRCI) is a utility that enables you to investigate problems, view health check reports, and package first-failure diagnostic data, all within a command-line environment.

9.1.3.1 Automatic Diagnostic Repository (ADR)

The ADR is a file-based repository for database diagnostic data such as traces, dumps, the alert log, health monitor reports, and more. It has a unified directory structure across multiple instances and multiple products.

The database, Oracle Automatic Storage Management (Oracle ASM), the listener, Oracle Clusterware, and other Oracle products or components store all diagnostic data in the ADR. Each instance of each product stores diagnostic data underneath its own home directory within the ADR. For example, in an Oracle Real Application Clusters environment with shared storage and Oracle ASM, each database instance and each Oracle ASM instance has an ADR home directory. ADR's unified directory structure, consistent diagnostic data formats across products and instances, and a unified set of tools enable customers and Oracle Support to correlate and analyze diagnostic data across multiple instances. With Oracle Clusterware, each host node in the cluster has an ADR home directory.

 **Note:**

Because all diagnostic data, including the alert log, are stored in the ADR, the initialization parameters `BACKGROUND_DUMP_DEST` and `USER_DUMP_DEST` are deprecated. They are replaced by the initialization parameter `DIAGNOSTIC_DEST`, which identifies the location of the ADR.

 **See Also:**

"[Structure, Contents, and Location of the Automatic Diagnostic Repository](#)" for more information on the `DIAGNOSTIC_DEST` parameter and on ADR homes.

9.1.3.2 Alert Log

The alert log is an XML file that is a chronological log of messages and errors.

There is one alert log in each ADR home. Each alert log is specific to its component type, such as database, Oracle ASM, listener, and Oracle Clusterware.

For the database, the alert log includes messages about the following:

- Critical errors (incidents)
- Administrative operations, such as starting up or shutting down the database, recovering the database, creating or dropping a tablespace, and others.
- Errors during automatic refresh of a materialized view
- Other database events

You can view the alert log in text format (with the XML tags stripped) with Cloud Control and with the ADRCI utility. There is also a text-formatted version of the alert log stored in the ADR for backward compatibility. However, Oracle recommends that any parsing of the alert log contents be done with the XML-formatted version, because the text format is unstructured and may change from release to release.

 **See Also:**

- ["ADRCI Command-Line Utility"](#)
- ["Viewing the Alert Log"](#)

9.1.3.3 Trace Files, Dumps, and Core Files

Trace files, dumps, and core files contain diagnostic data that are used to investigate problems. They are stored in the ADR.

- [Trace Files](#)

Each server and background process can write to an associated trace file. Trace files are updated periodically over the life of the process and can contain information on the process environment, status, activities, and errors. In addition, when a process detects a critical error, it writes information about the error to its trace file.

- [Dumps](#)

A dump is a specific type of trace file. A dump is typically a one-time output of diagnostic data in response to an event (such as an incident), whereas a trace tends to be continuous output of diagnostic data.

- [Core Files](#)

A core file contains a memory dump, in an all-binary, port-specific format.

9.1.3.3.1 Trace Files

Each server and background process can write to an associated trace file. Trace files are updated periodically over the life of the process and can contain information on the process environment, status, activities, and errors. In addition, when a process detects a critical error, it writes information about the error to its trace file.

The SQL trace facility also creates trace files, which provide performance information on individual SQL statements. You can enable SQL tracing for a session or an instance.

Trace file names are platform-dependent. Typically, database background process trace file names contain the Oracle SID, the background process name, and the operating system process number, while server process trace file names contain the Oracle SID, the string "ora", and the operating system process number. The file extension is .trc. An example of a server process trace file name is orcl_ora_344.trc. Trace files are sometimes accompanied by corresponding trace metadata (.trm) files, which contain structural information about trace files and are used for searching and navigation.

Oracle Database includes tools that help you analyze trace files. For more information on application tracing, SQL tracing, and tracing tools, see *Oracle Database SQL Tuning Guide*.

 See Also:

["Finding Trace Files"](#)

9.1.3.3.2 Dumps

A dump is a specific type of trace file. A dump is typically a one-time output of diagnostic data in response to an event (such as an incident), whereas a trace tends to be continuous output of diagnostic data.

When an incident occurs, the database writes one or more dumps to the incident directory created for the incident. Incident dumps also contain the incident number in the file name.

9.1.3.3.3 Core Files

A core file contains a memory dump, in an all-binary, port-specific format.

Core file names include the string "core" and the operating system process ID. Core files are useful to Oracle Support engineers only. Core files are not found on all platforms.

9.1.3.4 DDL Log

The data definition language (DDL) log is a file that has the same format and basic behavior as the alert log, but it only contains the DDL statements issued by the database.

The DDL log is created only for the RDBMS component and only if the `ENABLE_DDL_LOGGING` initialization parameter is set to `TRUE`. When this parameter is set to `FALSE`, DDL statements are not included in any log.

The DDL log contains one log record for each DDL statement issued by the database. The DDL log is included in IPS incident packages.

There are two DDL logs that contain the same information. One is an XML file, and the other is a text file. The DDL log is stored in the `log/ddl` subdirectory of the ADR home.

 See Also:

Oracle Database Reference for more information about the `ENABLE_DDL_LOGGING` initialization parameter

9.1.3.5 Debug Log

An Oracle Database component can detect conditions, states, or events that are unusual, but which do not inhibit correct operation of the detecting component. The component can issue a warning about these conditions, states, or events. The debug log is a file that records these warnings.

These warnings recorded in the debug log are not serious enough to warrant an incident or a write to the alert log. They do warrant a record in a log file because they might be needed to diagnose a future problem.

The debug log has the same format and basic behavior as the alert log, but it only contains information about possible problems that might need to be corrected.

The debug log reduces the amount of information in the alert log and trace files. It also improves the visibility of debug information.

The debug log is included in IPS incident packages. The debug log's contents are intended for Oracle Support. Database administrators should not use the debug log directly.

 **Note:**

Because there is a separate debug log in Oracle Database 12c, the alert log and the trace files are streamlined. They now contain fewer warnings of the type that are recorded in the debug log.

9.1.3.6 Other ADR Contents

In addition to files mentioned in the previous sections, the ADR contains health monitor reports, data repair records, SQL test cases, incident packages, and more. These components are described later in the chapter.

9.1.3.7 Enterprise Manager Support Workbench

The Enterprise Manager Support Workbench (Support Workbench) is a facility that enables you to investigate, report, and in some cases, repair problems (critical errors), all with an easy-to-use graphical interface.

The Support Workbench provides a self-service means for you to gather first-failure diagnostic data, obtain a support request number, and upload diagnostic data to Oracle Support with a minimum of effort and in a very short time, thereby reducing time-to-resolution for problems. The Support Workbench also recommends and provides easy access to Oracle advisors that help you repair SQL-related problems, data corruption problems, and more.

9.1.3.8 ADRCI Command-Line Utility

The ADR Command Interpreter (ADRCI) is a utility that enables you to investigate problems, view health check reports, and package first-failure diagnostic data, all within a command-line environment.

You can then upload the package to Oracle Support. ADRCI also enables you to view the names of the trace files in the ADR, and to view the alert log with XML tags stripped, with and without content filtering.

For more information on ADRCI, see *Oracle Database Utilities*.

9.1.4 Structure, Contents, and Location of the Automatic Diagnostic Repository

The Automatic Diagnostic Repository (ADR) is a directory structure that is stored outside of the database. It is therefore available for problem diagnosis when the database is down.

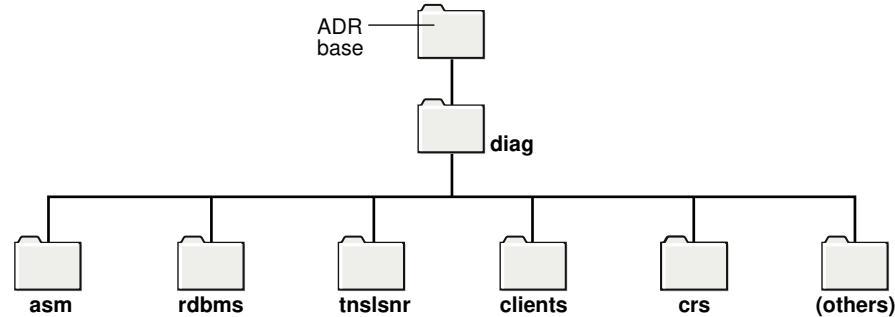

The ADR root directory is known as **ADR base**. Its location is set by the `DIAGNOSTIC_DEST` initialization parameter. If this parameter is omitted or left null, the database sets `DIAGNOSTIC_DEST` upon startup as follows:

- If environment variable `ORACLE_BASE` is set, `DIAGNOSTIC_DEST` is set to the directory designated by `ORACLE_BASE`.
- If environment variable `ORACLE_BASE` is not set, `DIAGNOSTIC_DEST` is set to `ORACLE_HOME/log`.

Within ADR base, there can be multiple ADR homes, where each ADR home is the root directory for all diagnostic data—traces, dumps, the alert log, and so on—for a particular instance of a particular Oracle product or component. For example, in an Oracle Real Application Clusters environment with Oracle ASM, each database instance, Oracle ASM instance, and listener has an ADR home.

ADR homes reside in ADR base subdirectories that are named according to the product or component type. [Figure 9-1](#) illustrates these top-level subdirectories.

Figure 9-1 Product/Component Type Subdirectories in the ADR

 **Note:**

Additional subdirectories might be created in the ADR depending on your configuration. Some products automatically purge expired diagnostic data from ADR. For other products, you can use the ADRCI utility `PURGE` command at regular intervals to purge expired diagnostic data.

The location of each ADR home is given by the following path, which starts at the ADR base directory:

`diag/product_type/product_id/instance_id`

As an example, [Table 9-1](#) lists the values of the various path components for an Oracle Database instance.

Table 9-1 ADR Home Path Components for Oracle Database

Path Component	Value for Oracle Database
product_type	rdbms
product_id	<i>DB_UNIQUE_NAME</i>
instance_id	<i>SID</i>

For example, for a database with a SID and database unique name both equal to `orclbi`, the ADR home would be in the following location:

`ADR_base/diag/rdbms/orclbi/orclbi/`

Similarly, the ADR home path for the Oracle ASM instance in a single-instance environment would be:

`ADR_base/diag/asm/+asm/+asm/`

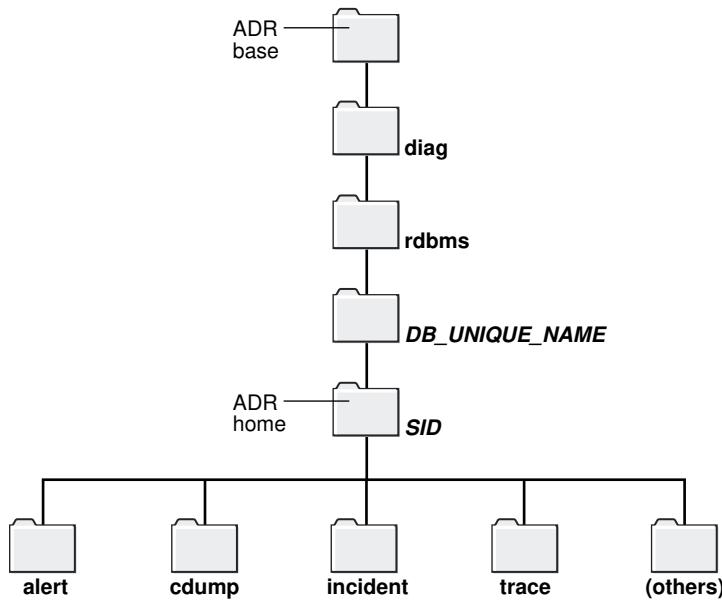

ADR Home Subdirectories

Within each ADR home directory are subdirectories that contain the diagnostic data. [Table 9-2](#) lists some of these subdirectories and their contents.

Table 9-2 ADR Home Subdirectories

Subdirectory Name	Contents
alert	The XML-formatted alert log
cdump	Core files
incident	Multiple subdirectories, where each subdirectory is named for a particular incident, and where each contains dumps pertaining only to that incident
trace	Background and server process trace files, SQL trace files, and the text-formatted alert log
(others)	Other subdirectories of ADR home, which store incident packages, health monitor reports, logs other than the alert log (such as the DDL log and the debug log), and other information

[Figure 9-2](#) illustrates the complete directory hierarchy of the ADR for a database instance.

Figure 9-2 ADR Directory Structure for a Database Instance**ADR in an Oracle Clusterware Environment**

Oracle Clusterware uses ADR and has its own Oracle home and Oracle base. The ADR directory structure for Oracle Clusterware is different from that of a database instance. There is only one instance of Oracle Clusterware on a system, so Clusterware ADR homes use only a system's host name as a differentiator.

When Oracle Clusterware is configured, the ADR home uses `crs` for both the product type and the instance ID, and the system host name is used for the product ID. Thus, on a host named `dbprod01`, the CRS ADR home would be:

`ADR_base/diag/crs/dbprod01/crs/`

See Also:

Oracle Clusterware Administration and Deployment Guide

ADR in an Oracle Real Application Clusters Environment

In an Oracle Real Application Clusters (Oracle RAC) environment, each node can have ADR base on its own local storage, or ADR base can be set to a location on shared storage. You can use ADRCI to view aggregated diagnostic data from all instances on a single report.

ADR in Oracle Client

Each installation of Oracle Client includes an ADR for diagnostic data associated with critical failures in any of the Oracle Client components. The ADRCI utility is installed with Oracle Client so that you can examine diagnostic data and package it to enable it for upload to Oracle Support.

Viewing ADR Locations with the V\$DIAG_INFO View

The V\$DIAG_INFO view lists all important ADR locations for the current Oracle Database instance.

```
SELECT * FROM V$DIAG_INFO;
```

INST_ID	NAME	VALUE
1	Diag Enabled	TRUE
1	ADR Base	/u01/oracle
1	ADR Home	/u01/oracle/diag/rdbms/orclbi/orclbi
1	Diag Trace	/u01/oracle/diag/rdbms/orclbi/orclbi/trace
1	Diag Alert	/u01/oracle/diag/rdbms/orclbi/orclbi/alert
1	Diag Incident	/u01/oracle/diag/rdbms/orclbi/orclbi/incident
1	Diag Cdmp	/u01/oracle/diag/rdbms/orclbi/orclbi/cdmp
1	Health Monitor	/u01/oracle/diag/rdbms/orclbi/orclbi/hm
1	Default Trace File	/u01/oracle/diag/rdbms/orclbi/orclbi/trace/orcl_ora_22769.trc
1	Active Problem Count	8
1	Active Incident Count	20

The following table describes some of the information displayed by this view.

Table 9-3 Data in the V\$DIAG_INFO View

Name	Description
ADR Base	Path of ADR base
ADR Home	Path of ADR home for the current database instance
Diag Trace	Location of background process trace files, server process trace files, SQL trace files, and the text-formatted version of the alert log
Diag Alert	Location of the XML-formatted version of the alert log
Default Trace File	Path to the trace file for the current session

Viewing Critical Errors with the V\$DIAG_CRITICAL_ERROR View

The V\$DIAG_CRITICAL_ERROR view lists all of the non-internal errors designated as critical errors for the current Oracle Database release. The view does not list internal errors because internal errors are always designated as critical errors.

The following example shows the output for the V\$DIAG_CRITICAL_ERROR view:

```
SELECT * FROM V$DIAG_CRITICAL_ERROR;
```

FACILITY	ERROR
ORA	7445
ORA	4030
ORA	4031
ORA	29740
ORA	255
ORA	355
ORA	356
ORA	239
ORA	240
ORA	494

ORA	3137
ORA	227
ORA	353
ORA	1578
ORA	32701
ORA	32703
ORA	29770
ORA	29771
ORA	445
ORA	25319
OCI	3106
OCI	3113
OCI	3135

The following table describes the information displayed by this view.

Table 9-4 Data in the V\$DIAG_CRITICAL_ERROR View

Column	Description
FACILITY	The facility that can report the error, such as Oracle Database (ORA) or Oracle Call Interface (OCI)
ERROR	The error number

 **See Also:**

"[About Incidents and Problems](#)" for more information about internal errors

9.2 Investigating, Reporting, and Resolving a Problem

You can use the Enterprise Manager Support Workbench (Support Workbench) to investigate and report a problem (critical error), and in some cases, resolve the problem. You can use a "roadmap" that summarizes the typical set of tasks that you must perform.

 **Note:**

The tasks described in this section are all Cloud Control–based. You can also accomplish all of these tasks (or their equivalents) with the `ADRCI` command-line utility, with PL/SQL packages such as `DBMS_HM` and `DBMS_SQLDIAG`, and with other software tools. See *Oracle Database Utilities* for more information on the `ADRCI` utility, and see *Oracle Database PL/SQL Packages and Types Reference* for information on PL/SQL packages.

- [Roadmap—Investigating, Reporting, and Resolving a Problem](#)

You can begin investigating a problem by starting from the Support Workbench home page in Cloud Control. However, the more typical workflow begins with a critical error alert on the Database Home page.

- [Task 1: View Critical Error Alerts in Cloud Control](#)
You begin the process of investigating problems (critical errors) by reviewing critical error alerts on the Database Home page or Oracle Automatic Storage Management Home page.
- [Task 2: View Problem Details](#)
You continue your investigation from the Incident Manager Problem Details page.
- [Task 3: \(Optional\) Gather Additional Diagnostic Information](#)
You can perform the following activities to gather additional diagnostic information for a problem. This additional information is then automatically included in the diagnostic data uploaded to Oracle Support. If you are unsure about performing these activities, then check with your Oracle Support representative.
- [Task 4: \(Optional\) Create a Service Request](#)
At this point, you can create an Oracle Support service request and record the service request number with the problem information.
- [Task 5: Package and Upload Diagnostic Data to Oracle Support](#)
For this task, you use the quick packaging process of the Support Workbench to package and upload the diagnostic information for the problem to Oracle Support.
- [Task 6: Track the Service Request and Implement Any Repairs](#)
After uploading diagnostic information to Oracle Support, you might perform various activities to track the service request, to collect additional diagnostic information, and to implement repairs.

 **See Also:**

["About the Oracle Database Fault Diagnosability Infrastructure"](#) for more information on problems and their diagnostic data

9.2.1 Roadmap—Investigating, Reporting, and Resolving a Problem

You can begin investigating a problem by starting from the Support Workbench home page in Cloud Control. However, the more typical workflow begins with a critical error alert on the Database Home page.

[Figure 9-3](#) illustrates the tasks that you complete to investigate, report, and in some cases, resolve a problem.

Figure 9-3 Workflow for Investigating, Reporting, and Resolving a Problem

The following are task descriptions. Subsequent sections provide details for each task.

- **Task 1: View Critical Error Alerts in Cloud Control**

Start by accessing the Database Home page in Cloud Control and reviewing critical error alerts. Select an alert for which to view details, and then go to the Problem Details page.

- **Task 2: View Problem Details**

Examine the problem details and view a list of all incidents that were recorded for the problem. Display findings from any health checks that were automatically run.

- **Task 3: (Optional) Gather Additional Diagnostic Information**

Optionally run additional health checks or other diagnostics. For SQL-related errors, optionally invoke the SQL Test Case Builder, which gathers all required data related to a SQL problem and packages the information in a way that enables the problem to be reproduced at Oracle Support.

- **Task 4: (Optional) Create a Service Request**

Optionally create a service request with My Oracle Support and record the service request number with the problem information. If you skip this step, you can create a service request later, or the Support Workbench can create one for you.

- **Task 5: Package and Upload Diagnostic Data to Oracle Support**

Invoke a guided workflow (*a wizard*) that automatically packages the gathered diagnostic data for a problem and uploads the data to Oracle Support.

- **Task 6: Track the Service Request and Implement Any Repairs**

Optionally maintain an activity log for the service request in the Support Workbench. Run Oracle advisors to help repair SQL failures or corrupted data.

 **See Also:**

"[Viewing Problems with the Support Workbench](#)"

9.2.2 Task 1: View Critical Error Alerts in Cloud Control

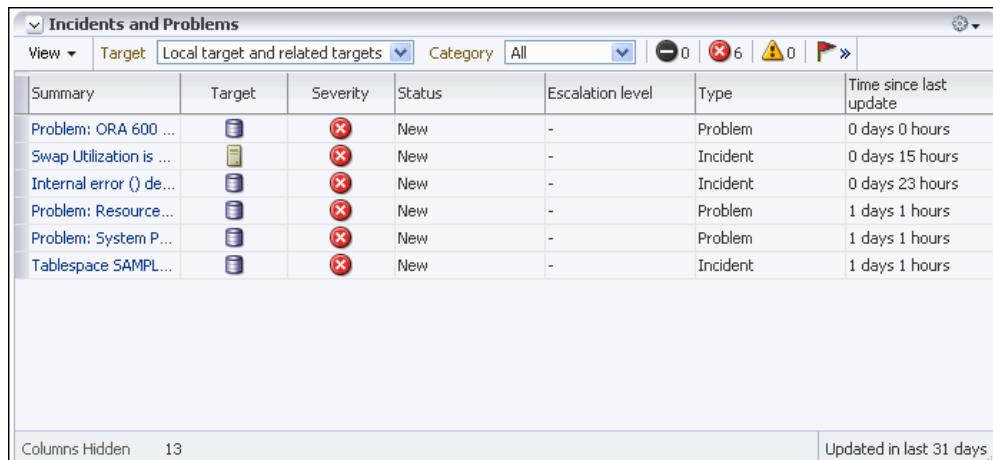

You begin the process of investigating problems (critical errors) by reviewing critical error alerts on the Database Home page or Oracle Automatic Storage Management Home page.

To view critical error alerts:

1. Access the Database Home page in Cloud Control.
2. View the alerts in the Incidents and Problems section.

If necessary, click the hide/show icon next to the Alerts heading to display the alerts.

Also, in the Category list, you can select a particular category to view alerts for only that category.

The screenshot shows a table titled 'Incidents and Problems' with the following data:

Summary	Target	Severity	Status	Escalation level	Type	Time since last update
Problem: ORA 600 ...			New	-	Problem	0 days 0 hours
Swap Utilization is ...			New	-	Incident	0 days 15 hours
Internal error () de...			New	-	Incident	0 days 23 hours
Problem: Resource...			New	-	Problem	1 days 1 hours
Problem: System P ...			New	-	Problem	1 days 1 hours
Tablespace SAMPL...			New	-	Incident	1 days 1 hours

Columns Hidden 13 Updated in last 31 days

3. In the Summary column, click the message of the critical error alert that you want to investigate.

The General subpage of the Incident Manager Problem Details page appears. This page includes:

- Problem details
- Controls that allow you to acknowledge, clear, or record a comment about the alert in the Tracking section
- Links that enable you to diagnose the problem using Support Workbench and package the diagnostics in the Guided Resolution section.

Other sections might appear depending on the type of problem you are investigating.

To view more information about the problem, click the following subpages on the Incident Manager Problem Details page:

- The Incidents subpage contains information about individual incidents for the problem.
 - The My Oracle Support Knowledge subpage provides access to My Oracle Support for more information about the problem.
 - The Updates subpage shows any updates entered about the problem.
 - The Related Problems subpage shows other open problems with the same problem key as the current problem.
- 4.** Perform one of the following actions:
- To view the details of the problem associated with the critical error alert that you are investigating, proceed with "[Task 2: View Problem Details](#)".
 - If there are several related problems and you want to view more information about them, then complete these steps:
 - View problems and incidents as described in "[Viewing Problems with the Support Workbench](#)".
 - Select a single problem and view problem details, as described in "[Viewing Problems with the Support Workbench](#)".
 - Continue with "[Task 3: \(Optional\) Gather Additional Diagnostic Information](#)".

9.2.3 Task 2: View Problem Details

You continue your investigation from the Incident Manager Problem Details page.

To view problem details:

- 1.** On the General subpage of the Incident Manager Problem Details page, click **Support Workbench: Problem Details** in the Diagnostics subsection.

The Support Workbench Problem Details page appears.

- 2.** (Optional) Complete one or more of the following actions:

- In the Investigate and Resolve section, under Diagnose, click Related Problems Across Topology.

A page appears showing any related problems in the local Oracle Automatic Storage Management (Oracle ASM) instance, or in the database or Oracle ASM instances on other nodes in an Oracle Real Application Clusters environment. This step is recommended if any critical alerts appear in the Related Alerts section on the Cloud Control Database Home page.

See "[Related Problems Across the Topology](#)" for more information.

- To view incident details, in the Incidents subpage, select an incident, and then click **View**.

The Incident Details page appears, showing the Dump Files subpage.

- On the Incident Details page, select **Checker Findings** to view the Checker Findings subpage.

This page displays findings from any health checks that were automatically run when the critical error was detected.

9.2.4 Task 3: (Optional) Gather Additional Diagnostic Information

You can perform the following activities to gather additional diagnostic information for a problem. This additional information is then automatically included in the diagnostic data uploaded to Oracle Support. If you are unsure about performing these activities, then check with your Oracle Support representative.

- Manually invoke additional health checks.
See "[Running Health Checks with Health Monitor](#)".
- Invoke the SQL Test Case Builder.

9.2.5 Task 4: (Optional) Create a Service Request

At this point, you can create an Oracle Support service request and record the service request number with the problem information.

If you choose to skip this task, then the Support Workbench will automatically create a draft service request for you in "[Task 5: Package and Upload Diagnostic Data to Oracle Support](#)".

To create a service request:

1. From the Enterprise menu, select **My Oracle Support**, then **Service Requests**.
The My Oracle Support Login and Registration page appears.
2. Log in to My Oracle Support and create a service request in the usual manner.
(Optional) Remember the service request number (SR#) for the next step.
3. (Optional) Return to the Problem Details page, and then do the following:
 - a. In the Summary section, click the **Edit** button that is adjacent to the SR# label.
 - b. Enter the SR#, and then click **OK**.

The SR# is recorded in the Problem Details page. This is for your reference only.
See "[Viewing Problems with the Support Workbench](#)" for information about returning to the Problem Details page.

9.2.6 Task 5: Package and Upload Diagnostic Data to Oracle Support

For this task, you use the quick packaging process of the Support Workbench to package and upload the diagnostic information for the problem to Oracle Support.

Quick packaging has a minimum of steps, organized in a guided workflow (a wizard). The wizard assists you with creating an incident package (package) for a single problem, creating a zip file from the package, and uploading the file. With quick packaging, you are not able to edit or otherwise customize the diagnostic information that is uploaded. However, quick packaging is the more direct, straightforward method to package and upload diagnostic data.

To edit or remove sensitive data from the diagnostic information, enclose additional user files (such as application configuration files or scripts), or perform other customizations before uploading, you must use the custom packaging process, which

is a more manual process and has more steps. See "[Creating, Editing, and Uploading Custom Incident Packages](#)" for instructions. If you choose to follow those instructions instead of the instructions here in Task 5, do so now and then continue with [Task 6: Track the Service Request and Implement Any Repairs](#) when you are finished.

 **Note:**

The Support Workbench uses Oracle Configuration Manager to upload the diagnostic data. If Oracle Configuration Manager is not installed or properly configured, the upload may fail. In this case, a message is displayed with a request that you upload the file to Oracle Support manually. You can upload manually with My Oracle Support.

For more information about Oracle Configuration Manager, see *Oracle Configuration Manager Installation and Administration Guide*.

To package and upload diagnostic data to Oracle Support:

1. On the Support Workbench Problem Details page, in the Investigate and Resolve section, click **Quick Package**.

The Create New Package page of the Quick Packaging wizard appears.

 **Note:**

See "[Viewing Problems with the Support Workbench](#)" for instructions for returning to the Problem Details page if you are not already there.

2. (Optional) Enter a package name and description.
3. Fill in any remaining fields on the page. If you have created a service request for this problem, then select the **No** option button for Create new Service Request (SR).

If you select the **Yes** option button for Create new Service Request (SR), then the Quick Packaging wizard creates a draft service request on your behalf. You must later log in to My Oracle Support and fill in the details of the service request.

Click **Next**.

The Quick Packaging wizard displays a page indicating that it is processing the command to create a new package. When it finished, the Quick Packaging: View Contents page is displayed.

4. Review the contents on the View Contents page, making a note of the size of the created package, then click **Next**.

The Quick Packaging: View Manifest page appears.

5. Review the information on this page, making a note of the location of the manifest (listed next to the heading Path). After you have reviewed the information, click **Next**.

The Quick Packaging: Schedule page appears.

6. Choose either **Immediately**, or **Later**. If you select **Later**, then you provide additional information about the time the package should be submitted to My Oracle Support. After you have made your choice and provided any necessary information, click **Submit**.

The Processing: Packaging and Sending the Package progress page appears.

When the Quick Packaging wizard is complete, if a new draft service request was created, then the confirmation message contains a link to the draft service request in My Oracle Support in Cloud Control. You can review and edit the service request by clicking the link.

The package created by the Quick Packaging wizard remains available in the Support Workbench. You can then modify it with custom packaging operations (such as adding new incidents) and upload again at a later time. See "[Viewing and Modifying Incident Packages](#)".

9.2.7 Task 6: Track the Service Request and Implement Any Repairs

After uploading diagnostic information to Oracle Support, you might perform various activities to track the service request, to collect additional diagnostic information, and to implement repairs.

Among these activities are the following:

- Adding an Oracle bug number to the problem information.

To do so, on the Problem Details page, click the **Edit** button that is adjacent to the Bug# label. This is for your reference only.

- Adding comments to the problem activity log.

You may want to do this to share problem status or history information with other DBAs in your organization. For example, you could record the results of your conversations with Oracle Support. To add comments, complete the following steps:

1. Access the Problem Details page for the problem, as described in "[Viewing Problems with the Support Workbench](#)".
2. Click **Activity Log** to display the Activity Log subpage.
3. In the Comment field, enter a comment, and then click **Add Comment**.

Your comment is recorded in the activity log.

- As new incidents occur, adding them to the package and reuploading.

For this activity, you must use the custom packaging method described in "[Creating, Editing, and Uploading Custom Incident Packages](#)".

- Running health checks.

See "[Running Health Checks with Health Monitor](#)".

- Running a suggested Oracle advisor to implement repairs.

Access the suggested advisor in one of the following ways:

- **Problem Details page**—In the Self-Service tab of the Investigate and Resolve section
- **Support Workbench home page**—on the Checker Findings subpage
- **Incident Details page**—on the Checker Findings subpage

Table 9-5 lists the advisors that help repair critical errors.

Table 9-5 Oracle Advisors that Help Repair Critical Errors

Advisor	Critical Errors Addressed	See
Data Recovery Advisor	Corrupted blocks, corrupted or missing files, and other data failures	"Repairing Data Corruptions with the Data Recovery Advisor"
SQL Repair Advisor	SQL statement failures	"Repairing SQL Failures with the SQL Repair Advisor"

 **See Also:**

"Viewing Problems with the Support Workbench" for instructions for viewing the Checker Findings subpage of the Incident Details page

9.3 Viewing Problems with the Support Workbench

You can use the Support Workbench home page in Cloud Control to view all the problems or the problems in a specific time period.

Figure 9-4 Support Workbench Home Page in Cloud Control

The screenshot shows the Support Workbench home page in Cloud Control. At the top, it displays a summary of problem counts: New Problems in Last 24 Hours (1), All Active Problems (1), All Problems (4); and New Incidents in Last 24 Hours (1), All Active Incidents (1), All Incidents (4). Below this, there are buttons for 'View' (Last Week) and 'Package'. A search bar allows filtering by problem key. A table lists four active incidents with columns for Select, Details, ID, Description, Number Of Incidents, Last Incident, Last Comment, Active, Packaged, and SR#. The incidents are: ORA 600 [13011], PKey3: ORA-600_dbgris01:123,_addr=0xa9876543, Resource Usage 2, and System Performance 1. Below the table is a section titled 'Performance and Critical Error Timeline' showing a line graph of Active Sessions from October 10 to 17, 2012. The graph tracks CPU, User I/O, and Wait metrics. A legend indicates: CPU (green), User I/O (blue), and Wait (orange). A callout box highlights three specific entries in the timeline: Resource Usage 2 (blue dot), PKey3: ORA-600_dbgris01:123,_addr=0xa9876543 (green dot), and ORA 600 [13011] (orange dot).

To access the Support Workbench home page (database or Oracle ASM):

1. Access the Database Home page in Cloud Control.
2. From the Oracle Database menu, select **Diagnostics**, then **Support Workbench**.
The Support Workbench home page for the database instance appears, showing the Problems subpage. By default the problems from the last 24 hours are displayed.
3. To view the Support Workbench home page for the Oracle ASM instance, click the link **Support Workbench (+ASM_hostname)** in the Related Links section.

To view problems and incidents:

1. On the Support Workbench home page, select the desired time period from the View list. To view all problems, select **All**.
2. (Optional) If the Performance and Critical Error Timeline section is hidden, click the **Show/Hide** icon adjacent to the section heading to show the section.
This section enables you to view any correlation between performance changes and incident occurrences.
3. (Optional) Under the Details column, click **Show** to display a list of all incidents for a problem, and then click an incident ID to display the Incident Details page.

To view details for a particular problem:

1. On the Support Workbench home page, select the problem, and then click **View**.
The Problem Details page appears, showing the Incidents subpage. The incidents subpage shows all incidents that are open and that generated dumps—that is, that were not flood-controlled.
2. (Optional) To view both normal and flood-controlled incidents, select **All** in the Data Dumped list.
3. (Optional) To view details for an incident, select the incident, and then click **View**.
The Incident Details page appears.
4. (Optional) On the Incident Details page, to view checker findings for the incident, click **Checker Findings**.
5. (Optional) On the Incident Details page, to view the user actions that are available to you for the incident, click **Additional Diagnostics**. Each user action provides a way for you to gather additional diagnostics for the incident or its problem.

 **See Also:**

"[Incident Flood Control](#)"

9.4 Adding Problems Manually to the Automatic Diagnostic Repository

You can use Support Workbench in Cloud Control to manually add a problem to the ADR.

System-generated problems, such as critical errors generated internally to the database are automatically added to the Automatic Diagnostic Repository (ADR) and tracked in the Support Workbench.

From the Support Workbench, you can gather additional diagnostic data on these problems, upload diagnostic data to Oracle Support, and in some cases, resolve the problems, all with the easy-to-use workflow that is explained in "[Investigating, Reporting, and Resolving a Problem](#)".

There may be a situation in which you want to manually add a problem that you noticed to the ADR, so that you can put that problem through that same workflow. An example of such a situation might be a global database performance problem that was not diagnosed by Automatic Diagnostic Database Monitor (ADDM). The Support Workbench includes a mechanism for you to create and work with such a user-reported problem.

To create a user-reported problem:

1. Access the Support Workbench home page.

See "[Viewing Problems with the Support Workbench](#)" for instructions.

2. Under Related Links, click **Create User-Reported Problem**.

The Create User-Reported Problem page appears.

Select	Issue type	Description	Recommended Advisor
<input type="radio"/>	System Performance	General Database Performance	ADDM
<input type="radio"/>	Query Performance	SQL Query Performance	SQL Advisor
<input type="radio"/>	Resource Usage	Memory or Hard Disk Usage	Memory Usage
<input type="radio"/>	Other	Other Issue	

TIP If you would like to create a user-reported problem for critical errors, please check if the system has already detected and created a problem from Support Workbench

3. If your problem matches one of the listed issue types, select the issue type, and then click **Run Recommended Advisor** to attempt to solve the problem with an Oracle advisor.
4. If the recommended advisor did not solve the problem, or if you did not run an advisor, do one of the following:
 - If your problem matches one of the listed issue types, select the issue type, and then click **Continue with Creation of Problem**.
 - If your problem does not match one of the listed issue types, select the issue type **Other** and then click **Continue with Creation of Problem**.

The Problem Details page appears.

5. Follow the instructions on the Problem Details page.

See "[Investigating, Reporting, and Resolving a Problem](#)" for more information.

 **See Also:**

["About the Oracle Database Fault Diagnosability Infrastructure"](#) for more information on problems and the ADR

9.5 Viewing the Alert Log

You can view the alert log with a text editor, with Cloud Control, or with the ADRCI utility.

To view the alert log with Cloud Control:

1. Access the Database Home page in Cloud Control.
2. From the Oracle Database menu, select **Diagnostics**, then **Support Workbench**.
3. Under Related Links, click **Alert Log Contents**.
The View Alert Log Contents page appears.
4. Select the number of entries to view, and then click **Go**.

To view the alert log with a text editor:

1. Connect to the database with SQL*Plus or another query tool, such as SQL Developer.
2. Query the `V$DIAG_INFO` view as shown in "[Viewing ADR Locations with the V\\$DIAG_INFO View](#)".
3. To view the text-only alert log, without the XML tags, complete these steps:
 - a. In the `V$DIAG_INFO` query results, note the path that corresponds to the `Diag Trace` entry, and change directory to that path.
 - b. Open file `alert_SID.log` with a text editor.
4. To view the XML-formatted alert log, complete these steps:
 - a. In the `V$DIAG_INFO` query results, note the path that corresponds to the `Diag Alert` entry, and change directory to that path.
 - b. Open the file `log.xml` with a text editor.

 **See Also:**

[Oracle Database Utilities](#) for information about using the ADRCI utility to view a text version of the alert log (with XML tags stripped) and to run queries against the alert log

9.6 Finding Trace Files

Trace files are stored in the Automatic Diagnostic Repository (ADR), in the `trace` directory under each ADR home. To help you locate individual trace files within this directory, you can use data dictionary views. For example, you can find the path to your current session's trace file or to the trace file for each Oracle Database process.

To find the trace file for your current session:

- Submit the following query:

```
SELECT VALUE FROM V$DIAG_INFO WHERE NAME = 'Default Trace File';
```

The full path to the trace file is returned.

To find all trace files for the current instance:

- Submit the following query:

```
SELECT VALUE FROM V$DIAG_INFO WHERE NAME = 'Diag Trace';
```

The path to the ADR trace directory for the current instance is returned.

To determine the trace file for each Oracle Database process:

- Submit the following query:

```
SELECT PID, PROGRAM, TRACEFILE FROM V$PROCESS;
```

See Also:

- ["Structure, Contents, and Location of the Automatic Diagnostic Repository"](#)
- The ADRCI `SHOW TRACEFILE` command in *Oracle Database Utilities*

9.7 Running Health Checks with Health Monitor

You can run diagnostic checks on a database with Health Monitor.

- [About Health Monitor](#)

Oracle Database includes a framework called Health Monitor for running diagnostic checks on the database.

- [Running Health Checks Manually](#)

Health Monitor can run health checks manually either by using the `DBMS_HM` PL/SQL package or by using the Cloud Control interface, found on the Checkers subpage of the Advisor Central page.

- [Viewing Checker Reports](#)

After a checker has run, you can view a report of its execution. The report contains findings, recommendations, and other information. You can view reports using

Cloud Control, the ADRCI utility, or the `DBMS_HM` PL/SQL package. The following table indicates the report formats available with each viewing method.

- [Health Monitor Views](#)
Instead of requesting a checker report, you can view the results of a specific checker run by directly querying the ADR data from which reports are created.
- [Health Check Parameters Reference](#)
Some health checks require parameters. Parameters with a default value of `(none)` are mandatory.

9.7.1 About Health Monitor

Oracle Database includes a framework called Health Monitor for running diagnostic checks on the database.

- [About Health Monitor Checks](#)
Health Monitor checks (also known as checkers, health checks, or checks) examine various layers and components of the database.
- [Types of Health Checks](#)
Health monitor runs several different types of checks.

9.7.1.1 About Health Monitor Checks

Health Monitor checks (also known as checkers, health checks, or checks) examine various layers and components of the database.

Health checks detect file corruptions, physical and logical block corruptions, undo and redo corruptions, data dictionary corruptions, and more. The health checks generate reports of their findings and, in many cases, recommendations for resolving problems. Health checks can be run in two ways:

- **Reactive**—The fault diagnosability infrastructure can run health checks automatically in response to a critical error.
- **Manual**—As a DBA, you can manually run health checks using either the `DBMS_HM` PL/SQL package or the Cloud Control interface. You can run checkers on a regular basis if desired, or Oracle Support may ask you to run a checker while working with you on a service request.

Health Monitor checks store findings, recommendations, and other information in the Automatic Diagnostic Repository (ADR).

Health checks can run in two modes:

- **DB-online** mode means the check can be run while the database is open (that is, in `OPEN` mode or `MOUNT` mode).
- **DB-offline** mode means the check can be run when the instance is available but the database itself is closed (that is, in `NOMOUNT` mode).

All the health checks can be run in DB-online mode. Only the Redo Integrity Check and the DB Structure Integrity Check can be used in DB-offline mode.

 **Note:**

"Automatic Diagnostic Repository (ADR)"

9.7.1.2 Types of Health Checks

Health monitor runs several different types of checks.

Health monitor runs the following checks:

- **DB Structure Integrity Check**—This check verifies the integrity of database files and reports failures if these files are inaccessible, corrupt or inconsistent. If the database is in mount or open mode, this check examines the log files and data files listed in the control file. If the database is in NOMOUNT mode, only the control file is checked.
- **Data Block Integrity Check**—This check detects disk image block corruptions such as checksum failures, head/tail mismatch, and logical inconsistencies within the block. Most corruptions can be repaired using Block Media Recovery. Corrupted block information is also captured in the V\$DATABASE_BLOCK_CORRUPTION view. This check does not detect inter-block or inter-segment corruption.
- **Redo Integrity Check**—This check scans the contents of the redo log for accessibility and corruption, as well as the archive logs, if available. The Redo Integrity Check reports failures such as archive log or redo corruption.
- **Undo Segment Integrity Check**—This check finds logical undo corruptions. After locating an undo corruption, this check uses PMON and SMON to try to recover the corrupted transaction. If this recovery fails, then Health Monitor stores information about the corruption in V\$CORRUPT_XID_LIST. Most undo corruptions can be resolved by forcing a commit.
- **Transaction Integrity Check**—This check is identical to the Undo Segment Integrity Check except that it checks only one specific transaction.
- **Dictionary Integrity Check**—This check examines the integrity of core dictionary objects, such as tab\$ and col\$. It performs the following operations:
 - Verifies the contents of dictionary entries for each dictionary object.
 - Performs a cross-row level check, which verifies that logical constraints on rows in the dictionary are enforced.
 - Performs an object relationship check, which verifies that parent-child relationships between dictionary objects are enforced.

The Dictionary Integrity Check operates on the following dictionary objects:

tab\$, clu\$, fet\$, uet\$, seg\$, undo\$, ts\$, file\$, obj\$, ind\$, icol\$, col\$, user\$, con\$, cdef\$, ccol\$, bootstrap\$, objauth\$, ugroup\$, tsq\$, syn\$, view\$, typed_view\$, superobj\$, seq\$, lob\$, coltype\$, subcoltype\$, ntab\$, refcon\$, opqtype\$, dependency\$, access\$, viewcon\$, icoldep\$, dual\$, sysauth\$, objpriv\$, defrole\$, and ecol\$.

9.7.2 Running Health Checks Manually

Health Monitor can run health checks manually either by using the DBMS_HM PL/SQL package or by using the Cloud Control interface, found on the Checkers subpage of the Advisor Central page.

- [Running Health Checks Using the DBMS_HM PL/SQL Package](#)
The DBMS_HM procedure for running a health check is called RUN_CHECK.
- [Running Health Checks Using Cloud Control](#)
Cloud Control provides an interface for running Health Monitor checkers.

9.7.2.1 Running Health Checks Using the DBMS_HM PL/SQL Package

The DBMS_HM procedure for running a health check is called RUN_CHECK.

1. To call RUN_CHECK, supply the name of the check and a name for the run, as follows:

```
BEGIN
    DBMS_HM.RUN_CHECK('Dictionary Integrity Check', 'my_run');
END;
/
```

2. To obtain a list of health check names, run the following query:

```
SELECT name FROM v$hm_check WHERE internal_check='N';
```

Your output is similar to the following:

NAME
DB Structure Integrity Check
Data Block Integrity Check
Redo Integrity Check
Transaction Integrity Check
Undo Segment Integrity Check
Dictionary Integrity Check

Most health checks accept input parameters. You can view parameter names and descriptions with the V\$HM_CHECK_PARAM view. Some parameters are mandatory while others are optional. If optional parameters are omitted, defaults are used. The following query displays parameter information for all health checks:

```
SELECT c.name check_name, p.name parameter_name, p.type,
p.default_value, p.description
FROM v$hm_check_param p, v$hm_check c
WHERE p.check_id = c.id and c.internal_check = 'N'
ORDER BY c.name;
```

Input parameters are passed in the `input_params` argument as name/value pairs separated by semicolons (;). The following example illustrates how to pass the transaction ID as a parameter to the Transaction Integrity Check:

```
BEGIN
    DBMS_HM.RUN_CHECK (
        check_name => 'Transaction Integrity Check',
        run_name   => 'my_run',
        input_params => 'TXN_ID=7.33.2');
```

```
END;  
/
```

See Also:

- "[Health Check Parameters Reference](#)"
- *Oracle Database PL/SQL Packages and Types Reference* for more examples of using DBMS_HM.

9.7.2.2 Running Health Checks Using Cloud Control

Cloud Control provides an interface for running Health Monitor checkers.

To run a Health Monitor Checker using Cloud Control:

1. Access the Database Home page.
2. From the Performance menu, select **Advisors Home**.
3. Click **Checkers** to view the Checkers subpage.
4. In the Checkers section, click the checker you want to run.
5. Enter values for input parameters or, for optional parameters, leave them blank to accept the defaults.
6. Click **OK**, confirm your parameters, and click **OK** again.

9.7.3 Viewing Checker Reports

After a checker has run, you can view a report of its execution. The report contains findings, recommendations, and other information. You can view reports using Cloud Control, the ADRCI utility, or the DBMS_HM PL/SQL package. The following table indicates the report formats available with each viewing method.

- [About Viewing Checker Reports](#)
Results of checker runs (findings, recommendations, and other information) are stored in the ADR, but reports are not generated immediately.
- [Viewing Reports Using Cloud Control](#)
You can also view Health Monitor reports and findings for a given checker run using Cloud Control.
- [Viewing Reports Using DBMS_HM](#)
You can view Health Monitor checker reports with the DBMS_HM package function GET_RUN_REPORT.
- [Viewing Reports Using the ADRCI Utility](#)
You can create and view Health Monitor checker reports using the ADRCI utility.

9.7.3.1 About Viewing Checker Reports

Results of checker runs (findings, recommendations, and other information) are stored in the ADR, but reports are not generated immediately.

Report Viewing Method	Report Formats Available
Cloud Control	HTML
DBMS_HM PL/SQL package	HTML, XML, and text
ADRCI utility	XML

When you request a report with the DBMS_HM PL/SQL package or with Cloud Control, if the report does not yet exist, it is first generated from the checker run data in the ADR, stored as a report file in XML format in the HM subdirectory of the ADR home for the current instance, and then displayed. If the report file already exists, it is just displayed. When using the ADRCI utility, you must first run a command to generate the report file if it does not exist, and then run another command to display its contents.

The preferred method to view checker reports is with Cloud Control.

 **Note:**

"Automatic Diagnostic Repository (ADR)"

9.7.3.2 Viewing Reports Using Cloud Control

You can also view Health Monitor reports and findings for a given checker run using Cloud Control.

To view run findings using Cloud Control:

1. Access the Database Home page.
2. From the Performance menu, select **Advisors Home**.
3. Click **Checkers** to view the Checkers subpage.
4. Click the run name for the checker run that you want to view.

The Run Detail page appears, showing the Findings subpage for that checker run.

5. Click **Runs** to display the Runs subpage.
- Cloud Control displays more information about the checker run.
6. Click **View Report** to view the report for the checker run.

The report is displayed in a new browser window.

9.7.3.3 Viewing Reports Using DBMS_HM

You can view Health Monitor checker reports with the DBMS_HM package function GET_RUN_REPORT.

This function enables you to request HTML, XML, or text formatting. The default format is text, as shown in the following SQL*Plus example:

```
SET LONG 100000
SET LONGCHUNKSIZE 1000
SET PAGESIZE 1000
SET LINESIZE 512
```

```
SELECT DBMS_HM.GET_RUN_REPORT('HM_RUN_1061') FROM DUAL;

DBMS_HM.GET_RUN_REPORT('HM_RUN_1061')
-----
Run Name          : HM_RUN_1061
Run Id            : 1061

Finding
Finding Name   : Media Block Corruption
Finding ID     : 1071
Type           : FAILURE
Status          : OPEN
Priority        : HIGH
Message         : Block 64351 in datafile 1:
                  '/u01/app/oracle/dbs/t_db1.f' is media corrupt
Message         : Object BMRTEST2 owned by SYS might be unavailable
```

See Also:

Oracle Database PL/SQL Packages and Types Reference for details on the DBMS_HM package.

9.7.3.4 Viewing Reports Using the ADRCI Utility

You can create and view Health Monitor checker reports using the ADRCI utility.

To create and view a checker report using ADRCI:

1. Ensure that operating system environment variables (such as ORACLE_HOME) are set properly, and then enter the following command at the operating system command prompt:

ADRCI

The utility starts and displays the following prompt:

```
adrci>>
```

Optionally, you can change the current ADR home. Use the SHOW HOMES command to list all ADR homes, and the SET HOMEPATH command to change the current ADR home. See *Oracle Database Utilities* for more information.

2. Enter the following command:

```
show hm_run
```

This command lists all the checker runs (stored in V\$HM_RUN) registered in the ADR repository.

3. Locate the checker run for which you want to create a report and note the checker run name. The REPORT_FILE field contains a file name if a report already exists for this checker run. Otherwise, generate the report with the following command:

```
create report hm_run run_name
```

4. To view the report, enter the following command:

```
show report hm_run run_name
```

 **Note:**

"Automatic Diagnostic Repository (ADR)"

9.7.4 Health Monitor Views

Instead of requesting a checker report, you can view the results of a specific checker run by directly querying the ADR data from which reports are created.

This data is available through the views V\$HM_RUN, V\$HM_FINDING, and V\$HM_RECOMMENDATION.

The following example queries the V\$HM_RUN view to determine a history of checker runs:

```
SELECT run_id, name, check_name, run_mode, src_incident FROM v$hm_run;
```

RUN_ID	NAME	CHECK_NAME	RUN_MODE	SRC INCIDENT
1	HM_RUN_1	DB Structure Integrity Check	REACTIVE	0
101	HM_RUN_101	Transaction Integrity Check	REACTIVE	6073
121	TXNCHK	Transaction Integrity Check	MANUAL	0
181	HMR_tab\$	Dictionary Integrity Check	MANUAL	0
.				
.				
981	Proct_ts\$	Dictionary Integrity Check	MANUAL	0
1041	HM_RUN_1041	DB Structure Integrity Check	REACTIVE	0
1061	HM_RUN_1061	Data Block Integrity Check	REACTIVE	7418

The next example queries the V\$HM_FINDING view to obtain finding details for the reactive data block check with RUN_ID 1061:

```
SELECT type, description FROM v$hm_finding WHERE run_id = 1061;
```

TYPE	DESCRIPTION
FAILURE	Block 64349 in datafile 1: '/u01/app/oracle/dbs/t_db1.f' is media corrupt
FAILURE	Block 64351 in datafile 1: '/u01/app/oracle/dbs/t_db1.f' is media corrupt

 **See Also:**

- ["Types of Health Checks"](#)
- *Oracle Database Reference* for more information on the V\$HM_* views

9.7.5 Health Check Parameters Reference

Some health checks require parameters. Parameters with a default value of (none) are mandatory.

Table 9-6 Parameters for Data Block Integrity Check

Parameter Name	Type	Default Value	Description
BLC_DF_NUM	Number	(none)	Block data file number
BLC_BL_NUM	Number	(none)	Data block number

Table 9-7 Parameters for Redo Integrity Check

Parameter Name	Type	Default Value	Description
SCN_TEXT	Text	0	SCN of the latest good redo (if known)

Table 9-8 Parameters for Undo Segment Integrity Check

Parameter Name	Type	Default Value	Description
USN_NUMBER	Text	(none)	Undo segment number

Table 9-9 Parameters for Transaction Integrity Check

Parameter Name	Type	Default Value	Description
TXN_ID	Text	(none)	Transaction ID

Table 9-10 Parameters for Dictionary Integrity Check

Parameter Name	Type	Default Value	Description
CHECK_MASK	Text	ALL	Possible values are: <ul style="list-style-type: none"> • COLUMN_CHECKS—Run column checks only. Verify column-level constraints in the core tables. • ROW_CHECKS—Run row checks only. Verify row-level constraints in the core tables. • REFERENTIAL_CHECKS—Run referential checks only. Verify referential constraints in the core tables. • ALL—Run all checks.
TABLE_NAME	Text	ALL_CORE_TABLES	Name of a single core table to check. If omitted, all core tables are checked.

9.8 Repairing SQL Failures with the SQL Repair Advisor

In the rare case that a SQL statement fails with a critical error, you can run the SQL Repair Advisor to try to repair the failed statement.

- [About the SQL Repair Advisor](#)
You run the SQL Repair Advisor after a SQL statement fails with a critical error.
- [Running the SQL Repair Advisor](#)
You run the SQL Repair Advisor from the Problem Details page of the Support Workbench.
- [Viewing, Disabling, or Removing a SQL Patch](#)
After you apply a SQL patch with the SQL Repair Advisor, you may want to view it to confirm its presence, disable it, or remove it. One reason to remove a patch is if you install a later release of Oracle Database that fixes the bug that caused the failure in the patched SQL statement.

9.8.1 About the SQL Repair Advisor

You run the SQL Repair Advisor after a SQL statement fails with a critical error.

The advisor analyzes the statement and in many cases recommends a patch to repair the statement. If you implement the recommendation, the applied SQL patch circumvents the failure by causing the query optimizer to choose an alternate execution plan for future executions.

9.8.2 Running the SQL Repair Advisor

You run the SQL Repair Advisor from the Problem Details page of the Support Workbench.

Typically, you do so when you were already notified of a critical error caused by your SQL statement and that you followed the workflow described in "[Investigating, Reporting, and Resolving a Problem](#)".

To run the SQL Repair Advisor:

1. Access the Problem Details page for the problem that pertains to the failed SQL statement.
See "[Viewing Problems with the Support Workbench](#)" for instructions.
2. In the Investigate and Resolve section, under the Resolve heading, click **SQL Repair Advisor**.

Problem Details: ORA 600 [13011]

Page Refreshed **October 17, 2012 1:23:52 PM PDT** [Refresh](#)

SQL Repair Advisor

[Incidents](#) [Activity Log](#)

3. On the SQL Repair Advisor page, complete these steps:
 - a. Modify the preset task name if desired, optionally enter a task description, modify or clear the optional time limit for the advisor task, and adjust settings to schedule the advisor to run either immediately or at a future date and time.
 - b. Click **Submit**.

A "Processing" page appears. After a short delay, the SQL Repair Results page appears.

SQL Repair Results: SQL_DIAG_1350505800642

Page Refreshed **Oct 17, 2012 1:33:19 PM PDT** [Refresh](#)

Status	COMPLETED
SQL ID	cg465sv6jcs7
Time Limit (seconds)	1800
Started	Oct 17, 2012 1:33:07 PM PDT
Completed	Oct 17, 2012 1:33:14 PM PDT
Running Time (seconds)	7

Recommendations

View	SQL Text	Parsing Schema	SQL ID	SQL Patch
Select	delete /*+ USE_HASH_AGGREGATION(@"SEL\$80F8B8C6") USE_HASH(@"SEL\$80F8B8C6" "T1"@DEL\$1..."		cg465sv6jcs7	<input checked="" type="checkbox"/>

A check mark in the SQL Patch column indicates that a recommendation is present. The absence of a check mark in this column means that the SQL Repair Advisor was unable to devise a patch for the SQL statement.

 **Note:**

If the SQL Repair Results page fails to appear, then complete these steps to display it:

- a. Go to the Database Home page.
- b. From the Performance menu, select **Advisors Home**.
- c. On the Advisor Central page, in the Results list, locate the most recent entry for the SQL Repair Advisor.
- d. Select the entry and click **View Result**.

4. If a recommendation is present (there is a check mark in the SQL Patch column), then click **View** to view the recommendation.

The Repair Recommendations page appears, showing the recommended patch for the statement.

5. Click **Implement**.

The SQL Repair Results page returns, showing a confirmation message.

6. (Optional) Click **Verify using SQL Worksheet** to run the statement in the SQL worksheet and verify that the patch successfully repaired the statement.

9.8.3 Viewing, Disabling, or Removing a SQL Patch

After you apply a SQL patch with the SQL Repair Advisor, you may want to view it to confirm its presence, disable it, or remove it. One reason to remove a patch is if you install a later release of Oracle Database that fixes the bug that caused the failure in the patched SQL statement.

To view, disable, or remove a SQL patch:

1. Access the Database Home page in Cloud Control.
2. From the Performance menu, select **SQL**, then **SQL Plan Control**.

The SQL Plan Control page appears.

3. Click **SQL Patch** to display the SQL Patch subpage.

The SQL Patch subpage displays all SQL patches in the database.

4. Locate the desired patch by examining the associated SQL text.

Click the SQL text to view the complete text of the statement. After viewing the SQL text, click **Return**.

5. To disable the patch on the SQL Patch subpage, select it, and then click **Disable**.

A confirmation message appears, and the patch status changes to **DISABLED**. You can later reenable the patch by selecting it and clicking **Enable**.

6. To remove the patch, select it, and then click **Drop**.

A confirmation message appears.

 **See Also:**

["About the SQL Repair Advisor"](#)

9.9 Repairing Data Corruptions with the Data Recovery Advisor

You use the Data Recovery Advisor to repair data block corruptions, undo corruptions, data dictionary corruptions, and more.

The Data Recovery Advisor integrates with the Enterprise Manager Support Workbench (Support Workbench), with the Health Monitor, and with the RMAN utility to display data corruption problems, assess the extent of each problem (critical, high priority, low priority), describe the impact of a problem, recommend repair options, conduct a feasibility check of the customer-chosen option, and automate the repair process.

The Cloud Control online help provides details on how to use the Data Recovery Advisor. This section describes how to access the advisor from the Support Workbench.

The Data Recovery Advisor is automatically recommended by and accessible from the Support Workbench when you are viewing health checker findings that are related to a data corruption or other data failure. The Data Recovery Advisor is also available from the Advisor Central page.

To access the Data Recovery Advisor in Cloud Control:

1. Access the Database Home page in Cloud Control.

The Data Recovery Advisor is available only when you are connected as SYSDBA.

2. From the Oracle Database menu, select **Diagnostics**, then **Support Workbench**.
3. Click **Checker Findings**.

The Checker Findings subpage appears.

Select	Description	Priority	Damage Translation	Incident ID	Status	Time Detected
<input type="checkbox"/>	All Findings					
<input checked="" type="checkbox"/>	One or more non-system datafiles are missing	High	See impact for individual child failures		Open	October 19, 2012 6:31:33 AM PDT

4. Select one or more data corruption findings and then click **Launch Recovery Advisor**.

Oracle Database 2 Day DBA and Oracle Database Backup and Recovery User's Guide for more information about the Data Recovery Advisor

9.10 Creating, Editing, and Uploading Custom Incident Packages

Using the Enterprise Manager Support Workbench (Support Workbench), you can create, edit, and upload custom incident packages. With custom incident packages, you have fine control over the diagnostic data that you send to Oracle Support.

- [Incident Packages](#)
You can collect diagnostic data into an intermediate logical structure called an incident package (package).
- [Packaging and Uploading Problems with Custom Packaging](#)
You use Support Workbench (Support Workbench) to create and upload custom incident packages (packages). Before uploading, you can manually add, edit, and remove diagnostic data files from the package.
- [Viewing and Modifying Incident Packages](#)
After creating an incident package with the custom packaging method, you can view or modify the contents of the package before uploading the package to Oracle Support.
- [Creating, Editing, and Uploading Correlated Packages](#)
After you upload a package to Oracle Support, you can create and upload one or more correlated packages.

- [Deleting Correlated Packages](#)
You delete a correlated package with the Support Workbench for the target for which you created the package.
- [Setting Incident Packaging Preferences](#)
You can set incident packaging preferences. Examples of incident packaging preferences include the number of days to retain incident information, and the number of leading and trailing incidents to include in a package for each problem.

 **See Also:**

["About the Oracle Database Fault Diagnosability Infrastructure"](#)

9.10.1 Incident Packages

You can collect diagnostic data into an intermediate logical structure called an incident package (package).

- [About Incident Packages](#)
For the customized approach to uploading diagnostic data to Oracle Support, you first collect the data into an intermediate logical structure called an incident package (package).
- [About Correlated Diagnostic Data in Incident Packages](#)
To diagnose problem, it is sometimes necessary to examine not only diagnostic data that is directly related to the problem, but also diagnostic data that is *correlated* with the directly related data.
- [About Quick Packaging and Custom Packaging](#)
The Support Workbench provides two methods for creating and uploading an incident package: the quick packaging method and the custom packaging method.
- [About Correlated Packages](#)
Correlated packages provide a means of packaging and uploading diagnostic data for related problems.

9.10.1.1 About Incident Packages

For the customized approach to uploading diagnostic data to Oracle Support, you first collect the data into an intermediate logical structure called an incident package (package).

A **package** is a collection of metadata that is stored in the Automatic Diagnostic Repository (ADR) and that points to diagnostic data files and other files both in and out of the ADR. When you create a package, you select one or more problems to add to the package. The Support Workbench then automatically adds to the package the problem information, incident information, and diagnostic data (such as trace files and dumps) associated with the selected problems. Because a problem can have many incidents (many occurrences of the same problem), by default only the first three and last three incidents for each problem are added to the package, excluding any incidents that are over 90 days old. You can change these default numbers on the Incident Packaging Configuration page of the Support Workbench.

After the package is created, you can add any type of external file to the package, remove selected files from the package, or edit selected files in the package to remove

sensitive data. As you add and remove package contents, only the package metadata is modified.

When you are ready to upload the diagnostic data to Oracle Support, you first create a zip file that contains all the files referenced by the package metadata. You then upload the zip file through Oracle Configuration Manager.

 **Note:**

If you do not have Oracle Configuration Manager installed and properly configured, then you must upload the zip file manually through My Oracle Support.

For more information about Oracle Configuration Manager, see *Oracle Configuration Manager Installation and Administration Guide*.

 **See Also:**

- ["Packaging and Uploading Problems with Custom Packaging"](#)
- ["Viewing and Modifying Incident Packages"](#)

9.10.1.2 About Correlated Diagnostic Data in Incident Packages

To diagnose problem, it is sometimes necessary to examine not only diagnostic data that is directly related to the problem, but also diagnostic data that is *correlated* with the directly related data.

Diagnostic data can be correlated by time, by process ID, or by other criteria. For example, when examining an incident, it may be helpful to also examine an incident that occurred five minutes after the original incident. Similarly, while it is clear that the diagnostic data for an incident should include the trace file for the Oracle Database process that was running when the incident occurred, it might be helpful to also include trace files for other processes that are related to the original process.

Thus, when problems and their associated incidents are added to a package, any correlated incidents are added at the same time, with their associated trace files.

During the process of creating the physical file for a package, the Support Workbench calls upon the Incident Packaging Service to finalize the package. **Finalizing** means adding to the package any additional trace files that are correlated by time to incidents in the package, and adding other diagnostic information such as the alert log, health checker reports, SQL test cases, configuration information, and so on. Therefore, the number of files in the zip file may be greater than the number of files that the Support Workbench had previously displayed as the package contents.

The Incident Packaging Service follows a set of rules to determine the trace files in the ADR that are correlated to existing package data. You can modify some of those rules in the Incident Packaging Configuration page in Cloud Control.

Because both initial package data and added correlated data may contain sensitive information, it is important to have an opportunity to remove or edit files that contain this information before uploading to Oracle Support. For this reason, the Support Workbench enables you to run a command that finalizes the package as a separate operation. After manually finalizing a package, you can examine the package contents, remove or edit files, and then generate and upload a zip file.

 **Note:**

Finalizing a package does not mean closing it to further modifications. You can continue to add diagnostic data to a finalized package. You can also finalize the same package multiple times. Each time that you finalize, any new correlated data is added.

 **See Also:**

["Setting Incident Packaging Preferences"](#)

9.10.1.3 About Quick Packaging and Custom Packaging

The Support Workbench provides two methods for creating and uploading an incident package: the quick packaging method and the custom packaging method.

Quick Packaging—This is the more automated method with a minimum of steps, organized in a guided workflow (a wizard). You select a single problem, provide a package name and description, and then schedule upload of the package contents, either immediately or at a specified date and time. The Support Workbench automatically places diagnostic data related to the problem into the package, finalizes the package, creates the zip file, and then uploads the file. With this method, you do not have the opportunity to add, edit, or remove package files or add other diagnostic data such as SQL test cases. However, it is the simplest and quickest way to get first-failure diagnostic data to Oracle Support. Quick packaging is the method used in the workflow described in ["Investigating, Reporting, and Resolving a Problem"](#).

When quick packaging is complete, the package that was created by the wizard remains. You can then modify the package with custom packaging operations at a later time and manually reupload.

Custom Packaging—This is the more manual method, with more steps. It is intended for expert Support Workbench users who want more control over the packaging process. With custom packaging, you can create a new package with one or more problems, or you can add one or more problems to an existing package. You can then perform a variety of operations on the new or updated package, including:

- Adding or removing problems or incidents
- Adding, editing, or removing trace files in the package
- Adding or removing external files of any type
- Adding other diagnostic data such as SQL test cases

- Manually finalizing the package and then viewing package contents to determine if you must edit or remove sensitive data or remove files to reduce package size.

You might conduct these operations over several days, before deciding that you have enough diagnostic information to send to Oracle Support.

With custom packaging, you create the zip file and request the upload to Oracle Support as two separate steps. Each of these steps can be performed immediately or scheduled for a future date and time.

 **See Also:**

["Task 5: Package and Upload Diagnostic Data to Oracle Support"](#) for instructions for the Quick Packaging method

9.10.1.4 About Correlated Packages

Correlated packages provide a means of packaging and uploading diagnostic data for related problems.

A database instance problem can have related problems in other database instances or in Oracle Automatic Storage Management instances, as described in "[Related Problems Across the Topology](#)". After you create and upload a package for one or more database instance problems (the "main package"), you can create and upload one or more correlated packages, each with one or more related problems. You can accomplish this only with the custom packaging workflow in Support Workbench.

 **See Also:**

["Creating, Editing, and Uploading Correlated Packages"](#)

9.10.2 Packaging and Uploading Problems with Custom Packaging

You use Support Workbench (Support Workbench) to create and upload custom incident packages (packages). Before uploading, you can manually add, edit, and remove diagnostic data files from the package.

To package and upload problems with custom packaging:

1. Access the Support Workbench home page.
See "[Viewing Problems with the Support Workbench](#)" for instructions.
2. (Optional) For each problem that you want to include in the package, indicate the service request number (SR#) associated with the problem, if any. To do so, complete the following steps for each problem:
 - a. In the Problems subpage at the bottom of the Support Workbench home page, select the problem, and then click **View**.

 **Note:**

If you do not see the desired problem in the list of problems, or if there are too many problems to scroll through, select a time period from the View list and click **Go**. You can then select the desired problem and click **View**.

The Problem Details page appears.

- b. Next to the SR# label, click **Edit**, enter a service request number, and then click **OK**.

The service request number is displayed on the Problem Details page.

- c. Return to the Support Workbench home page by clicking **Support Workbench** in the locator links at the top of the page.

Database Instance: simple.example.com > Support Workbench >
Problem Details: ORA 600 [13011]

3. On the Support Workbench home page, select the problems that you want to package, and then click **Package**.

The Select Packaging Mode page appears.

 **Note:**

The packaging process may automatically select additional correlated problems to add to the package. An example of a correlated problem is one that occurs within a few minutes of the selected problem. See "[About Correlated Diagnostic Data in Incident Packages](#)" for more information.

4. Select the **Custom packaging** option, and then click **Continue**.

The Select Package page appears.

Custom Packaging : Select Package

<input type="radio"/>	ORA600130_20121019074243	Active	ORA 600 [13011]		October 19, 2012 7:43:33 AM PDT												

5. Do one of the following:

- To create a new package, select the **Create new package** option, enter a package name and description, and then click **OK**.
- To add the selected problems to an existing package, select the **Select from existing packages** option, select the package to update, and then click **OK**.

The Customize Package page appears. It displays the problems and incidents that are contained in the package, plus a selection of packaging tasks to choose from. You run these tasks against the new package or the updated existing package.

Confirmation
Package(ORA700kst_20121019105523) has been created successfully.

Customize Package: ORA700kst_20121019105523

The package can be customized to edit its contents, to generate and include additional diagnostic data or to scrub user data. Once the package is ready it can be sent to Oracle Support.

Summary		Packaging Tasks	
Status	Active	Edit Contents	Scrub User Data

Files Excluded by User	0 <input type="button" value="Include"/>		

Incidents

Exclude						
Select All	Select None					
Select	ID	Type	Problem ID	Description	Size (MB)	Timestamp
<input type="checkbox"/>	8838	Main	6	ORA-700 [kstmchkdrift_fwd] [kstmrmrmtickcntkeeper:highres] [78284864] [1350541403758987]	2.39	October 17, 2012 11:32:26 PM PDT

- 6.** (Optional) In the Packaging Tasks section, click links to perform one or more packaging tasks. Or, use other controls on the Customize Package page and its subpages to manipulate the package. Return to the Customize Package page when you are finished.

See "[Viewing and Modifying Incident Packages](#)" for instructions for some of the most common packaging tasks.

- 7.** In the Packaging Tasks section of the Customize Package page, under the heading Send to Oracle Support, click **Finish Contents Preparation** to finalize the package.

A list (or partial list) of files included in the package is displayed. (This may take a while.) The list includes files that were determined to contain correlated diagnostic information and added by the finalization process.

See "[About Correlated Diagnostic Data in Incident Packages](#)" for a definition of package finalization.

- 8.** Click **Files** to view all the files in the package. Examine the list to see if there are any files that might contain sensitive data that you do not want to expose. If you find such files, then exclude (remove) or edit them.

See "[Editing Incident Package Files \(Copying Out and In\)](#)" and "[Removing Incident Package Files](#)" for instructions for editing and removing files.

To view the contents of a file, click the eyeglasses icon in the rightmost column in the table of files. Enter host credentials, if prompted.

 **Note:**

Trace files are generally for Oracle internal use only.

9. Click **Generate Upload File**.

The Generate Upload File page appears.

10. Select the **Full** or **Incremental** option to generate a full package zip file or an incremental package zip file.

For a full package zip file, all the contents of the package (original contents and all correlated data) are always added to the zip file.

For an incremental package zip file, only the diagnostic information that is new or modified since the last time that you created a zip file for the same package is added to the zip file. For example, if trace information was appended to a trace file since that file was last included in the generated physical file for a package, the trace file is added to the incremental package zip file. Conversely, if no changes were made to a trace file since it was last uploaded for a package, that trace file is not included in the incremental package zip file.

 **Note:**

The Incremental option is dimmed (unavailable) if an upload file was never created for the package.

11. Schedule file creation either immediately or at a future date and time (select **Immediately** or **Later**), and then click **Submit**.

File creation can use significant system resources, so it may be advisable to schedule it for a period of low system usage.

A Processing page appears, and creation of the zip file proceeds. A confirmation page appears when processing is complete.

 **Note:**

The package is automatically finalized when the zip file is created.

12. Click **OK**.

The Customize Package page returns.

13. Click **Send to Oracle**.

The View/Send Upload Files page appears.

14. (Optional) Click the **Send Correlated Packages** link to create correlated packages and send them to Oracle.

See "[Creating, Editing, and Uploading Correlated Packages](#)". When you are finished working with correlated packages, return to the View/Send Upload Files page by clicking the **Package Details** link at the top of the page, clicking **Customize Package**, and then clicking **Send to Oracle** again.

15. Select the zip files to upload, and then click **Send to Oracle**.

The Send to Oracle page appears. The selected zip files are listed in a table.

16. Fill in the requested My Oracle Support information. Next to Create new Service Request (SR), select **Yes** or **No**. If you select Yes, a draft service request is created for you. You must later log in to My Oracle Support and fill in the service request details. If you select No, enter an existing service request number.

17. Schedule the upload to take place immediately or at a future date and time, and then click **Submit**.

A Processing page appears. If the upload is completed successfully, a confirmation page appears. If the upload could not complete, an error page appears. The error page may include a message that requests that you upload the zip file to Oracle manually. If so, contact your Oracle Support representative for instructions.

18. Click **OK**.

The View/Send Upload Files page returns. Under the Time Sent column, check the status of the files that you attempted to upload.

 **Note:**

The Support Workbench uses Oracle Configuration Manager to upload the physical files. If Oracle Configuration Manager is not installed or properly configured, the upload may fail. In this case, a message is displayed with a path to the package zip file and a request that you upload the file to Oracle Support manually. You can upload manually with My Oracle Support.

For more information about Oracle Configuration Manager, see *Oracle Configuration Manager Installation and Administration Guide*.

19. (Optional) Create and upload correlated packages.

See "[Creating, Editing, and Uploading Correlated Packages](#)" for instructions.

 **See Also:**

- "[About Incidents and Problems](#)"

- "[About Quick Packaging and Custom Packaging](#)"

9.10.3 Viewing and Modifying Incident Packages

After creating an incident package with the custom packaging method, you can view or modify the contents of the package before uploading the package to Oracle Support.

In addition, after using the quick packaging method to package and upload diagnostic data, you can view or modify the contents of the package that the Support Workbench created, and then reupload the package. To modify a package, you choose from among a selection of *packaging tasks*, most of which are available from the Customize Package page.

- [Viewing Package Details](#)

The Package Details page contains information about the incidents, trace files, and other files in a package, and enables you to view and add to the package activity log.

- [Accessing the Customize Package Page](#)

The Customize Package page is used to perform various packaging tasks, such as adding and removing problems; adding, removing, and scrubbing (editing) package files; and generating and uploading the package zip file.

- [Editing Incident Package Files \(Copying Out and In\)](#)

The Support Workbench enables you to edit one or more files in an incident package.

- [Adding an External File to an Incident Package](#)

You can add any type of external file to an incident package.

- [Removing Incident Package Files](#)

You can remove one or more files of any type from the incident package.

- [Viewing and Updating the Incident Package Activity Log](#)

The Support Workbench maintains an activity log for each incident package.

See Also:

- ["About Incident Packages"](#)
- ["Packaging and Uploading Problems with Custom Packaging"](#)

9.10.3.1 Viewing Package Details

The Package Details page contains information about the incidents, trace files, and other files in a package, and enables you to view and add to the package activity log.

To view package details:

1. Access the Support Workbench home page.

See "[Viewing Problems with the Support Workbench](#)" for instructions.

2. Click **Packages** to view the Packages subpage.

A list of packages that are currently in the Automatic Diagnostic Repository (ADR) is displayed.

3. (Optional) To reduce the number of packages displayed, enter text into the **Search** field above the list, and then click **Go**.

All packages that contain the search text anywhere in the package name are displayed. To view the full list of packages, remove the text from the **Search** field and click **Go** again.

4. Under the Package Name column, click the link for the desired package.

The Package Details page appears.

9.10.3.2 Accessing the Customize Package Page

The Customize Package page is used to perform various packaging tasks, such as adding and removing problems; adding, removing, and scrubbing (editing) package files; and generating and uploading the package zip file.

To access the Customize Package page:

1. Access the Package Details page for the desired package, as described in "[Viewing Package Details](#)".
2. Click **Customize Package**.

The Customize Package page appears.

9.10.3.3 Editing Incident Package Files (Copying Out and In)

The Support Workbench enables you to edit one or more files in an incident package.

You may want to do this to delete or overwrite sensitive data in the files. To edit package files, you must first copy the files out of the package into a designated directory, edit the files with a text editor or other utility, and then copy the files back into the package, overwriting the original package files.

The following procedure assumes that the package is already created and contains diagnostic data.

To edit incident package files:

1. Access the Customize Package page for the desired incident package.
See "[Accessing the Customize Package Page](#)" for instructions.
2. In the Packaging Tasks section, under the Scrub User Data heading, click **Copy out Files to Edit contents**.
If prompted for host credentials, enter credentials and then click **OK**.
The Copy Out Files page appears. It displays the name of the host to which you can copy files.
3. Do one of the following to specify a destination directory for the files:
 - Enter a directory path in the **Destination Folder** field.
 - Click the magnifying glass icon next to the **Destination Folder** field, and then complete the following steps:
 - a. If prompted for host credentials, enter credentials for the host to which you want to copy out the files, and then click **OK**. (Select **Save as Preferred Credential** to avoid the prompt for credentials next time.)

The Browse and Select: File or Directory window appears.

- b. Select the desired destination directory, and then click **Select**.

The Browse and Select: File or Directory window closes, and the path to the selected directory appears in the Destination Folder field of the Copy Out Files page.

4. Under Files to Copy Out, select the desired files, and then click **OK**.

 **Note:**

If you do not see the desired files, then they may be on another page. Click the **Next** link to view the next page. Continue clicking **Next**, or select from the list of file numbers (to the left of the Next link) until you see the desired files. You can then select the files and click **OK**.

The Customize Package page returns, displaying a confirmation message that lists the files that were copied out.

5. Using a text editor or other utility, edit the files.
6. On the Customize Package page, in the Packaging Tasks section, under the Scrub User Data heading, click **Copy in Files to Replace Contents**.

The Copy In Files page appears. It displays the files that you copied out.

7. Select the files to copy in, and then click **OK**.

The files are copied into the package, overwriting the existing files. The Customize Package page returns, displaying a confirmation message that lists the files that were copied in.

9.10.3.4 Adding an External File to an Incident Package

You can add any type of external file to an incident package.

To add an external file to an incident package:

1. Access the Customize Package page for the desired incident package.

See "[Accessing the Customize Package Page](#)" for instructions.

2. Click the **Files** link to view the Files subpage.

From this page, you can add and remove files to and from the package.

3. Click **Add external files**.

The Add External File page appears. It displays the host name from which you may select a file.

4. Do one of the following to specify a file to add:

- Enter the full path to the file in the **File Name** field.
- Click the magnifying glass icon next to the **File Name** field, and then complete the following steps:

- a. If prompted for host credentials, enter credentials for the host on which the external file resides, and then click **OK**. (Select **Save as Preferred Credential** to avoid the prompt for credentials next time.)
- b. In the Browse and Select: File or Directory window, select the desired file and then click **Select**.

The Browse and Select window closes, and the path to the selected file appears in the File Name field of the Add External File page.

5. Click **OK**.

The Customize Package page returns, displaying the Files subpage. The selected file is now shown in the list of files.

9.10.3.5 Removing Incident Package Files

You can remove one or more files of any type from the incident package.

To remove incident package files:

1. Access the Customize Package page for the desired incident package.
See "[Accessing the Customize Package Page](#)" for instructions.
2. Click the **Files** link to view the Files subpage.

A list of files in the package is displayed.

If you have not yet generated a physical file for this package, all package files are displayed in the list. If you have already generated a physical file, then a View list appears above the files list. It enables you to choose between viewing only incremental package contents or the full package contents. The default selection is incremental package contents. This default selection displays only those package files that were created or modified since the last time that a physical file was generated for the package. Select **Full package contents** from the View list to view all package files.

3. Select the files to remove, and then click **Exclude**.

Note:

If you do not see the desired files, then they may be on another page. Click the **Next** link to view the next page. Continue clicking **Next**, or select from the list of file numbers (to the left of the Next link) until you see the desired files. You can then select the files and click **Remove**.

9.10.3.6 Viewing and Updating the Incident Package Activity Log

The Support Workbench maintains an activity log for each incident package.

Most activities that you perform on a package, such as adding or removing files or creating a package zip file, are recorded in the log. You can also add your own notes to the log. This is especially useful if multiple database administrators are working with packages.

To view and update the incident package activity log:

1. Access the Package Details page for the desired incident package.
See "[Viewing Package Details](#)" for instructions.
2. Click the **Activity Log** link to view the Activity Log subpage.
The activity log is displayed.
3. To add your own comment to the activity log, enter text into the **Comment** field, and then click **Add Comment**.
Your comment is appended to the list.

9.10.4 Creating, Editing, and Uploading Correlated Packages

After you upload a package to Oracle Support, you can create and upload one or more correlated packages.

This is recommended if critical alerts appeared in the Related Alerts section of the Database Home page. The correlated packages are associated with the original package, also known as the **main package**. The main package contains problems that occurred in a database instance. Correlated packages contain problems that occurred on other instances (Oracle ASM instances or other database instances) and that are related problems for the problems in the main package. There can be only one correlated package for each related instance.

To create, edit, and upload a correlated package:

1. View the Package Details page for the main package.
See "[Viewing Package Details](#)" for instructions.
2. On the Package Details page, click **Customize Package**.
3. On the Customize Package page, in the Packaging Tasks section, under Additional Diagnostic Data, click **Create/Update Correlated Packages**.
4. On the Correlated Packages page, under Correlated Packages, select one or more instances that have incidents and click **Create**.
A confirmation message appears, and the package IDs of the newly created correlated packages appear in the ID column.
5. Select the instance on which you created the correlated package, and click **Finish Contents Preparation**.
A confirmation message appears.
6. (Optional) View and edit a correlated package by completing these steps:
 - a. Click the package ID to view the package.
If prompted for credentials, enter them and click **Login**.
 - b. On the Package Details page, click **Files** to view the files in the package.
 - c. Click **Customize Package** and perform any desired customization tasks, as described in "[Viewing and Modifying Incident Packages](#)".
7. For each correlated package to upload, click **Generate Upload File**.
8. For each correlated package to send to Oracle, select the package and click **Send to Oracle**.

 **Note:**

If **Send to Oracle** is unavailable (dimmed), then there were no correlated incidents for the instance.

 **See Also:**

- ["About Correlated Packages"](#)
- ["Related Problems Across the Topology"](#)

9.10.5 Deleting Correlated Packages

You delete a correlated package with the Support Workbench for the target for which you created the package.

For example, if you created a correlated package for an Oracle ASM instance target, access the Support Workbench for that Oracle ASM instance.

To delete a correlated package:

1. Access the Support Workbench for the target on which you created the correlated package.

 **Tip:**

See the Related Links section at the bottom of any Support Workbench page. Or, see ["Viewing Problems with the Support Workbench"](#)

2. Click **Packages** to view the Packages subpage.
3. Locate the correlated package in the list. Verify that it is a correlated package by viewing the package description.
4. Select the package and click **Delete**.
5. On the confirmation page, click **Yes**.

 **See Also:**

- ["About Correlated Packages"](#)
- ["Related Problems Across the Topology"](#)

9.10.6 Setting Incident Packaging Preferences

You can set incident packaging preferences. Examples of incident packaging preferences include the number of days to retain incident information, and the number of leading and trailing incidents to include in a package for each problem.

By default, if a problem has many incidents, only the first three and last three incidents are packaged. You can change these and other incident packaging preferences with Cloud Control or with the ADRCI utility.

To set incident packaging preferences with Cloud Control:

1. Access the Support Workbench home page.

See "[Viewing Problems with the Support Workbench](#)" for instructions.

2. In the Related Links section at the bottom of the page, click **Incident Packaging Configuration**.

The View Incident Packaging Configuration page appears. Click **Help** to view descriptions of the settings on this page.

3. Click **Edit**.

The Edit Incident Packaging Configuration page appears.

4. Edit settings, and then click **OK** to apply changes.

See Also:

- ["About Incident Packages"](#)
- ["About Incidents and Problems"](#)
- ["Task 5: Package and Upload Diagnostic Data to Oracle Support"](#)
- *Oracle Database Utilities* for information on ADRCI

Part II

Oracle Database Structure and Storage

You can create and manage database structures and storage components.

- [Managing Control Files](#)

You can create, back up, and drop control files.

- [Managing the Redo Log](#)

You manage the redo log by completing tasks such as creating redo log groups and members, relocating and renaming redo log members, dropping redo log groups and members, and forcing log switches.

- [Managing Archived Redo Log Files](#)

You manage the archived redo log files by completing tasks such as choosing between NOARCHIVELOG or ARCHIVELOG mode and specifying archive destinations.

- [Managing Tablespaces](#)

A tablespace is a database storage unit that groups related logical structures together. The database data files are stored in tablespaces.

- [Managing Data Files and Temp Files](#)

You can manage data files and temp files by performing tasks such as creating them, altering them, and dropping them.

- [Transporting Data](#)

Transporting data moves the data from one database to another.

- [Managing Undo](#)

For a default installation, Oracle Database automatically manages undo. There is typically no need for DBA intervention. However, if your installation uses Oracle Flashback operations, you may need to perform some undo management tasks to ensure the success of these operations.

- [Using Oracle Managed Files](#)

Oracle Database can manage the files that comprise the database.

10

Managing Control Files

You can create, back up, and drop control files.

- [What Is a Control File?](#)

Every Oracle Database has a **control file**, which is a small binary file that records the physical structure of the database.

- [Guidelines for Control Files](#)

You can follow guidelines to manage the control files for a database.

- [Creating Control Files](#)

You can create, copy, rename, and relocate control files.

- [Troubleshooting After Creating Control Files](#)

After issuing the `CREATE CONTROLFILE` statement, you may encounter some errors.

- [Backing Up Control Files](#)

Use the `ALTER DATABASE BACKUP CONTROLFILE` statement to back up your control files.

- [Recovering a Control File Using a Current Copy](#)

You can recover your control file from a current backup or from a multiplexed copy.

- [Dropping Control Files](#)

You can drop control files, but the database should have at least two control files at all times.

- [Control Files Data Dictionary Views](#)

You can query a set of data dictionary views for information about control files.

See Also:

- [Oracle Database Concepts](#) for an overview of control files
- [Using Oracle Managed Files](#) for information about creating control files that are both created and managed by the Oracle Database server

10.1 What Is a Control File?

Every Oracle Database has a **control file**, which is a small binary file that records the physical structure of the database.

The control file includes:

- The database name
- Names and locations of associated data files and redo log files
- The timestamp of the database creation

- The current log sequence number
- Checkpoint information

The control file must be available for writing by the Oracle Database server whenever the database is open. Without the control file, the database cannot be mounted and recovery is difficult.

The control file of an Oracle Database is created at the same time as the database. By default, at least one copy of the control file is created during database creation. On some operating systems the default is to create multiple copies. You should create two or more copies of the control file during database creation. You can also create control files later, if you lose control files or want to change particular settings in the control files.

10.2 Guidelines for Control Files

You can follow guidelines to manage the control files for a database.

- [Provide File Names for the Control Files](#)

You specify control file names using the `CONTROL_FILES` initialization parameter in the database initialization parameter file. The instance recognizes and opens all the listed file during startup, and the instance writes to and maintains all listed control files during database operation.

- [Multiplex Control Files on Different Disks](#)

Every Oracle Database should have at least two control files, each stored on a different physical disk.

- [Back Up Control Files](#)

It is very important that you back up your control files. This is true initially, and every time you change the physical structure of your database.

- [Manage the Size of Control Files](#)

The main determinants of the size of a control file are the values set for the `MAXDATAFILES`, `MAXLOGFILES`, `MAXLOGMEMBERS`, `MAXLOGHISTORY`, and `MAXINSTANCES` parameters in the `CREATE DATABASE` statement that created the associated database.

10.2.1 Provide File Names for the Control Files

You specify control file names using the `CONTROL_FILES` initialization parameter in the database initialization parameter file. The instance recognizes and opens all the listed file during startup, and the instance writes to and maintains all listed control files during database operation.

If you do not specify files for `CONTROL_FILES` before database creation:

- If you are not using Oracle Managed Files, then the database creates a control file and uses a default file name. The default name is operating system specific.
- If you are using Oracle Managed Files, then the initialization parameters you set to enable that feature determine the name and location of the control files.
- If you are using Oracle Automatic Storage Management (Oracle ASM), you can place incomplete Oracle ASM file names in the `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST` initialization parameters. Oracle ASM then automatically creates control files in the appropriate places.

Related Topics

- [Creating Initial Control Files](#)
The initial control files of an Oracle Database are created when you issue the CREATE DATABASE statement.
- [Using Oracle Managed Files](#)
Oracle Database can manage the files that comprise the database.
- [Oracle Automatic Storage Management Administrator's Guide](#)

10.2.2 Multiplex Control Files on Different Disks

Every Oracle Database should have at least two control files, each stored on a different physical disk.

If a control file is damaged due to a disk failure, the associated instance must be shut down. Once the disk drive is repaired, the damaged control file can be restored using the intact copy of the control file from the other disk and the instance can be restarted. In this case, no media recovery is required.

The behavior of multiplexed control files is this:

- The database writes to all file names listed for the initialization parameter CONTROL_FILES in the database initialization parameter file.
- The database reads only the first file listed in the CONTROL_FILES parameter during database operation.
- If any of the control files become unavailable during database operation, the instance becomes inoperable and should be aborted.

 **Note:**

Oracle strongly recommends that your database has a minimum of two control files and that they are located on separate physical disks.

One way to multiplex control files is to store a control file copy on every disk drive that stores members of redo log groups, if the redo log is multiplexed. By storing control files in these locations, you minimize the risk that all control files and all groups of the redo log will be lost in a single disk failure.

10.2.3 Back Up Control Files

It is very important that you back up your control files. This is true initially, and every time you change the physical structure of your database.

Such structural changes include:

- Adding, dropping, or renaming data files
- Adding or dropping a tablespace, or altering the read/write state of the tablespace
- Adding or dropping redo log files or groups

The methods for backing up control files are discussed in "[Backing Up Control Files](#)".

10.2.4 Manage the Size of Control Files

The main determinants of the size of a control file are the values set for the MAXDATAFILES, MAXLOGFILES, MAXLOGMEMBERS, MAXLOGHISTORY, and MAXINSTANCES parameters in the CREATE DATABASE statement that created the associated database.

Increasing the values of these parameters increases the size of a control file of the associated database.

See Also:

- Your operating system specific Oracle documentation contains more information about the maximum control file size.
- *Oracle Database SQL Language Reference* for a description of the CREATE DATABASE statement

10.3 Creating Control Files

You can create, copy, rename, and relocate control files.

- [Creating Initial Control Files](#)

The initial control files of an Oracle Database are created when you issue the CREATE DATABASE statement.

- [Creating Additional Copies, Renaming, and Relocating Control Files](#)

You can create an additional control file copy for multiplexing by copying an existing control file to a new location and adding the file name to the list of control files.

- [Creating New Control Files](#)

You can create new control files when all of the control files for the database have been permanently damaged and you do not have a control file backup or when you want to change the database name.

10.3.1 Creating Initial Control Files

The initial control files of an Oracle Database are created when you issue the CREATE DATABASE statement.

The names of the control files are specified by the CONTROL_FILES parameter in the initialization parameter file used during database creation. The file names specified in CONTROL_FILES should be fully specified and are operating system specific. The following is an example of a CONTROL_FILES initialization parameter:

```
CONTROL_FILES = (/u01/oracle/prod/control01.ctl,  
                 /u02/oracle/prod/control02.ctl,  
                 /u03/oracle/prod/control03.ctl)
```

If files with the specified names currently exist at the time of database creation, you must specify the CONTROLFILE REUSE clause in the CREATE DATABASE statement, or

else an error occurs. Also, if the size of the old control file differs from the `SIZE` parameter of the new one, you cannot use the `REUSE` clause.

The size of the control file changes between some releases of Oracle Database, as well as when the number of files specified in the control file changes. Configuration parameters such as `MAXLOGFILES`, `MAXLOGMEMBERS`, `MAXLOGHISTORY`, `MAXDATAFILES`, and `MAXINSTANCES` affect control file size.

You can subsequently change the value of the `CONTROL_FILES` initialization parameter to add more control files or to change the names or locations of existing control files.

 **See Also:**

Your operating system specific Oracle documentation contains more information about specifying control files.

10.3.2 Creating Additional Copies, Renaming, and Relocating Control Files

You can create an additional control file copy for multiplexing by copying an existing control file to a new location and adding the file name to the list of control files.

Similarly, you rename an existing control file by copying the file to its new name or location, and changing the file name in the control file list. In both cases, to guarantee that control files do not change during the procedure, shut down the database before copying the control file.

To add a multiplexed copy of the current control file or to rename a control file:

1. Shut down the database.
2. Copy an existing control file to a new location, using operating system commands.
3. Edit the `CONTROL_FILES` parameter in the database initialization parameter file to add the new control file name, or to change the existing control file name.
4. Restart the database.

10.3.3 Creating New Control Files

You can create new control files when all of the control files for the database have been permanently damaged and you do not have a control file backup or when you want to change the database name.

- [When to Create New Control Files](#)
You must create new control files in certain situations.
- [The CREATE CONTROLFILE Statement](#)
You can create a new control file for a database using the `CREATE CONTROLFILE` statement.
- [Creating New Control Files](#)
You can create new control files for your database.

10.3.3.1 When to Create New Control Files

You must create new control files in certain situations.

It is necessary for you to create new control files in the following situations:

- All control files for the database have been permanently damaged and you do not have a control file backup.
- You want to change the database name.

For example, you would change a database name if it conflicted with another database name in a distributed environment.

 **Note:**

You can change the database name and DBID (internal database identifier) using the DBNEWID utility. See *Oracle Database Utilities* for information about using this utility.

10.3.3.2 The CREATE CONTROLFILE Statement

You can create a new control file for a database using the `CREATE CONTROLFILE` statement.

The following statement creates a new control file for the `prod` database (a database that formerly used a different database name):

```
CREATE CONTROLFILE
  SET DATABASE prod
  LOGFILE GROUP 1 ('/u01/oracle/prod/redo01_01.log',
                   '/u01/oracle/prod/redo01_02.log'),
             GROUP 2 ('/u01/oracle/prod/redo02_01.log',
                   '/u01/oracle/prod/redo02_02.log'),
             GROUP 3 ('/u01/oracle/prod/redo03_01.log',
                   '/u01/oracle/prod/redo03_02.log')
  RESETLOGS
  DATAFILE '/u01/oracle/prod/system01.dbf' SIZE 3M,
            '/u01/oracle/prod/rbs01.dbs' SIZE 5M,
            '/u01/oracle/prod/users01.dbs' SIZE 5M,
            '/u01/oracle/prod/temp01.dbs' SIZE 5M
  MAXLOGFILES 50
  MAXLOGMEMBERS 3
  MAXLOGHISTORY 400
  MAXDATAFILES 200
  MAXINSTANCES 6
  ARCHIVELOG;
```

 **Note:**

- The `CREATE CONTROLFILE` statement can potentially damage specified data files and redo log files. Omitting a file name can cause loss of the data in that file, or loss of access to the entire database. Use caution when issuing this statement and be sure to follow the instructions in "[Creating New Control Files](#)".
- If the database had forced logging enabled before creating the new control file, and you want it to continue to be enabled, then you must specify the `FORCE LOGGING` clause in the `CREATE CONTROLFILE` statement. See "[Specifying FORCE LOGGING Mode](#)".

 **See Also:**

Oracle Database SQL Language Reference describes the complete syntax of the `CREATE CONTROLFILE` statement

10.3.3.3 Creating New Control Files

You can create new control files for your database.

Complete the following steps to create a new control file.

1. Make a list of all data files and redo log files of the database.

If you follow recommendations for control file backups as discussed in "[Backing Up Control Files](#)", you will already have a list of data files and redo log files that reflect the current structure of the database. However, if you have no such list, executing the following statements will produce one.

```
SELECT MEMBER FROM V$LOGFILE;
SELECT NAME FROM V$DATAFILE;
SELECT VALUE FROM V$PARAMETER WHERE NAME = 'control_files';
```

If you have no such lists and your control file has been damaged so that the database cannot be opened, try to locate all of the data files and redo log files that constitute the database. Any files not specified in step 5 are not recoverable once a new control file has been created. Moreover, if you omit any of the files that comprise the `SYSTEM` tablespace, you might not be able to recover the database.

2. Shut down the database.

If the database is open, shut down the database normally if possible. Use the `IMMEDIATE` or `ABORT` clauses only as a last resort.

3. Back up all data files and redo log files of the database.
4. Start up a new instance, but do not mount or open the database:

```
STARTUP NOMOUNT
```

5. Create a new control file for the database using the `CREATE CONTROLFILE` statement.

When creating a new control file, specify the `RESETLOGS` clause if you have lost any redo log groups in addition to control files. In this case, you will need to recover from the loss of the redo logs (step 8). You must specify the `RESETLOGS` clause if you have renamed the database. Otherwise, select the `NORESETLOGS` clause.

6. Store a backup of the new control file on an offline storage device. See "[Backing Up Control Files](#)" for instructions for creating a backup.
7. Edit the `CONTROL_FILES` initialization parameter for the database to indicate all of the control files now part of your database as created in step 5 (not including the backup control file). If you are renaming the database, edit the `DB_NAME` parameter in your instance parameter file to specify the new name.
8. Recover the database if necessary. If you are not recovering the database, skip to step 9.

If you are creating the control file as part of recovery, recover the database. If the new control file was created using the `NORESETLOGS` clause, you can recover the database with complete, closed database recovery.

If the new control file was created using the `RESETLOGS` clause, you must specify `USING BACKUP CONTROL FILE`. If you have lost online redo logs, archived redo log files, or data files, use the procedures for recovering those files.

 **See Also:**

Oracle Database Backup and Recovery User's Guide for information about recovering your database and methods of recovering a lost control file

9. Open the database using one of the following methods:
 - If you did not perform recovery, or you performed complete, closed database recovery in step 8, open the database normally.
`ALTER DATABASE OPEN;`
 - If you specified `RESETLOGS` when creating the control file, use the `ALTER DATABASE` statement, indicating `RESETLOGS`.
`ALTER DATABASE OPEN RESETLOGS;`

The database is now open and available for use.

10.4 Troubleshooting After Creating Control Files

After issuing the `CREATE CONTROLFILE` statement, you may encounter some errors.

- [Checking for Missing or Extra Files](#)

After creating a new control file and using it to open the database, check the alert log to see if the database has detected inconsistencies between the data dictionary and the control file, such as a data file in the data dictionary includes that the control file does not list.

- [Handling Errors During CREATE CONTROLFILE](#)

If Oracle Database sends you an error when you attempt to mount and open the database after creating a new control file, the most likely cause is that you omitted a file from the CREATE CONTROLFILE statement or included one that should not have been listed.

10.4.1 Checking for Missing or Extra Files

After creating a new control file and using it to open the database, check the alert log to see if the database has detected inconsistencies between the data dictionary and the control file, such as a data file in the data dictionary includes that the control file does not list.

If a data file exists in the data dictionary but not in the new control file, the database creates a placeholder entry in the control file under the name MISSINGnnnn, where nnnn is the file number in decimal. MISSINGnnnn is flagged in the control file as being offline and requiring media recovery.

If the actual data file corresponding to MISSINGnnnn is read-only or offline normal, then you can make the data file accessible by renaming MISSINGnnnn to the name of the actual data file. If MISSINGnnnn corresponds to a data file that was not read-only or offline normal, then you cannot use the rename operation to make the data file accessible, because the data file requires media recovery that is precluded by the results of RESETLOGS. In this case, you must drop the tablespace containing the data file.

Conversely, if a data file listed in the control file is not present in the data dictionary, then the database removes references to it from the new control file. In both cases, the database includes an explanatory message in the alert log to let you know what was found.

10.4.2 Handling Errors During CREATE CONTROLFILE

If Oracle Database sends you an error when you attempt to mount and open the database after creating a new control file, the most likely cause is that you omitted a file from the CREATE CONTROLFILE statement or included one that should not have been listed.

Typically, the error is ORA-01173, ORA-01176, ORA-01177, ORA-01215, or ORA-01216. In this case, you should restore the files you backed up in "[Creating New Control Files](#)" and repeat the procedure in that task, using the correct file names.

10.5 Backing Up Control Files

Use the ALTER DATABASE BACKUP CONTROLFILE statement to back up your control files.

You have two options:

- Back up the control file to a binary file (duplicate of existing control file) using the following statement:

```
ALTER DATABASE BACKUP CONTROLFILE TO '/oracle/backup/control.bkp';
```

- Produce SQL statements that can later be used to re-create your control file:

```
ALTER DATABASE BACKUP CONTROLFILE TO TRACE;
```

This command writes a SQL script to a trace file where it can be captured and edited to reproduce the control file. View the alert log to determine the name and location of the trace file.

 **See Also:**

- [Oracle Database Backup and Recovery User's Guide](#) for more information on backing up your control files
- ["Viewing the Alert Log"](#)

10.6 Recovering a Control File Using a Current Copy

You can recover your control file from a current backup or from a multiplexed copy.

- [Recovering from Control File Corruption Using a Control File Copy](#)
If a control file becomes corrupted, then you can recover it using a control file copy.
- [Recovering from Permanent Media Failure Using a Control File Copy](#)
If there is permanent media failure, then you can recover by using a control file copy.

10.6.1 Recovering from Control File Corruption Using a Control File Copy

If a control file becomes corrupted, then you can recover it using a control file copy.

This method assumes that one of the control files specified in the `CONTROL_FILES` parameter is corrupted, that the control file directory is still accessible, and that you have a multiplexed copy of the control file.

1. With the instance shut down, use an operating system command to overwrite the bad control file with a good copy:

```
% cp /u03/oracle/prod/control03.ctl /u02/oracle/prod/control02.ctl
```

2. Start SQL*Plus and open the database:

```
SQL> STARTUP
```

10.6.2 Recovering from Permanent Media Failure Using a Control File Copy

If there is permanent media failure, then you can recover by using a control file copy.

This method assumes that one of the control files specified in the `CONTROL_FILES` parameter is inaccessible due to a permanent media failure and that you have a multiplexed copy of the control file.

1. With the instance shut down, use an operating system command to copy the current copy of the control file to a new, accessible location:

```
% cp /u01/oracle/prod/control01.ctl /u04/oracle/prod/control03.ctl
```

2. Edit the CONTROL_FILES parameter in the initialization parameter file to replace the bad location with the new location:

```
CONTROL_FILES = (/u01/oracle/prod/control01.ctl,  
                 /u02/oracle/prod/control02.ctl,  
                 /u04/oracle/prod/control03.ctl)
```

3. Start SQL*Plus and open the database:

```
SQL> STARTUP
```

If you have multiplexed control files, you can get the database started up quickly by editing the CONTROL_FILES initialization parameter. Remove the bad control file from CONTROL_FILES setting and you can restart the database immediately. Then you can perform the reconstruction of the bad control file and at some later time shut down and restart the database after editing the CONTROL_FILES initialization parameter to include the recovered control file.

10.7 Dropping Control Files

You can drop control files, but the database should have at least two control files at all times.

You want to drop control files from the database, for example, if the location of a control file is no longer appropriate.

1. Shut down the database.
2. Edit the CONTROL_FILES parameter in the database initialization parameter file to delete the old control file name.
3. Restart the database.

 **Note:**

This operation does not physically delete the unwanted control file from the disk. Use operating system commands to delete the unnecessary file after you have dropped the control file from the database.

10.8 Control Files Data Dictionary Views

You can query a set of data dictionary views for information about control files.

The following views display information about control files:

View	Description
V\$DATABASE	Displays database information from the control file
V\$CONTROLFILE	Lists the names of control files
V\$CONTROLFILE_RECORD_SECTION	Displays information about control file record sections
V\$PARAMETER	Displays the names of control files as specified in the CONTROL_FILES initialization parameter

This example lists the names of the control files.

```
SQL> SELECT NAME FROM V$CONTROLFILE;
```

NAME

/u01/oracle/prod/control01.ctl
/u02/oracle/prod/control02.ctl
/u03/oracle/prod/control03.ctl

Managing the Redo Log

You manage the redo log by completing tasks such as creating redo log groups and members, relocating and renaming redo log members, dropping redo log groups and members, and forcing log switches.

- [What Is the Redo Log?](#)

The most crucial structure for recovery operations is the **redo log**, which consists of two or more preallocated files that store all changes made to the database as they occur. Every instance of an Oracle Database has an associated redo log to protect the database in case of an instance failure.

- [Planning the Redo Log](#)

You can follow guidelines when configuring a database instance redo log.

- [Creating Redo Log Groups and Members](#)

Plan the redo log for a database and create all required groups and members of redo log files during database creation. However, there are situations where you might want to create additional groups or members. For example, adding groups to a redo log can correct redo log group availability problems.

- [Relocating and Renaming Redo Log Members](#)

You can use operating system commands to relocate redo logs, then use the `ALTER DATABASE` statement to make their new names (locations) known to the database.

- [Dropping Redo Log Groups and Members](#)

In some cases, you may want to drop an entire group of redo log members.

- [Forcing Log Switches](#)

A log switch occurs when LGWR stops writing to one redo log group and starts writing to another. By default, a log switch occurs automatically when the current redo log file group fills.

- [Verifying Blocks in Redo Log Files](#)

You can configure the database to use checksums to verify blocks in the redo log files.

- [Clearing a Redo Log File](#)

A redo log file might become corrupted while the database is open, and ultimately stop database activity because archiving cannot continue.

- [Precedence of FORCE LOGGING Settings](#)

You can set `FORCE LOGGING` and `NOLOGGING` at various levels, such as for a database, pluggable database (PDB), tablespace, or database object. When `FORCE LOGGING` is set at one or more levels, the precedence of `FORCE LOGGING` settings determines what is logged in the redo log.

- [Redo Log Data Dictionary Views](#)

You can query a set of data dictionary views for information about the redo log.

 **See Also:**

[Using Oracle Managed Files](#) for information about redo log files that are both created and managed by the Oracle Database server

11.1 What Is the Redo Log?

The most crucial structure for recovery operations is the **redo log**, which consists of two or more preallocated files that store all changes made to the database as they occur. Every instance of an Oracle Database has an associated redo log to protect the database in case of an instance failure.

- [Redo Threads](#)

When speaking in the context of multiple database instances, the redo log for each database instance is also referred to as a *redo thread*.

- [Redo Log Contents](#)

Redo log files are filled with **redo records**.

- [How Oracle Database Writes to the Redo Log](#)

The redo log for a database consists of two or more redo log files. The database requires a minimum of two files to guarantee that one is always available for writing while the other is being archived (if the database is in ARCHIVELOG mode).

11.1.1 Redo Threads

When speaking in the context of multiple database instances, the redo log for each database instance is also referred to as a *redo thread*.

In typical configurations, only one database instance accesses an Oracle Database, so only one thread is present. In an Oracle Real Application Clusters environment, however, two or more instances concurrently access a single database and each instance has its own thread of redo. A separate redo thread for each instance avoids contention for a single set of redo log files, thereby eliminating a potential performance bottleneck.

This chapter describes how to configure and manage the redo log on a standard single-instance Oracle Database. The thread number can be assumed to be 1 in all discussions and examples of statements. For information about redo log groups in an Oracle Real Application Clusters environment, see *Oracle Real Application Clusters Administration and Deployment Guide*.

11.1.2 Redo Log Contents

Redo log files are filled with **redo records**.

A redo record, also called a **redo entry**, is made up of a group of **change vectors**, each of which is a description of a change made to a single block in the database. For example, if you change a salary value in an employee table, you generate a redo record containing change vectors that describe changes to the data segment block for the table, the undo segment data block, and the transaction table of the undo segments.

Redo entries record data that you can use to reconstruct all changes made to the database, including the undo segments. Therefore, the redo log also protects rollback data. When you recover the database using redo data, the database reads the change vectors in the redo records and applies the changes to the relevant blocks.

Redo records are buffered in a circular fashion in the redo log buffer of the SGA (see "[How Oracle Database Writes to the Redo Log](#)") and are written to one of the redo log files by the Log Writer (LGWR) database background process. Whenever a transaction is committed, LGWR writes the transaction redo records from the redo log buffer of the SGA to a redo log file, and assigns a **system change number** (SCN) to identify the redo records for each committed transaction. Only when all redo records associated with a given transaction are safely on disk in the online logs is the user process notified that the transaction has been committed.

Redo records can also be written to a redo log file before the corresponding transaction is committed. If the redo log buffer fills, or another transaction commits, LGWR flushes all of the redo log entries in the redo log buffer to a redo log file, even though some redo records may not be committed. If necessary, the database can roll back these changes.

11.1.3 How Oracle Database Writes to the Redo Log

The redo log for a database consists of two or more redo log files. The database requires a minimum of two files to guarantee that one is always available for writing while the other is being archived (if the database is in ARCHIVELOG mode).

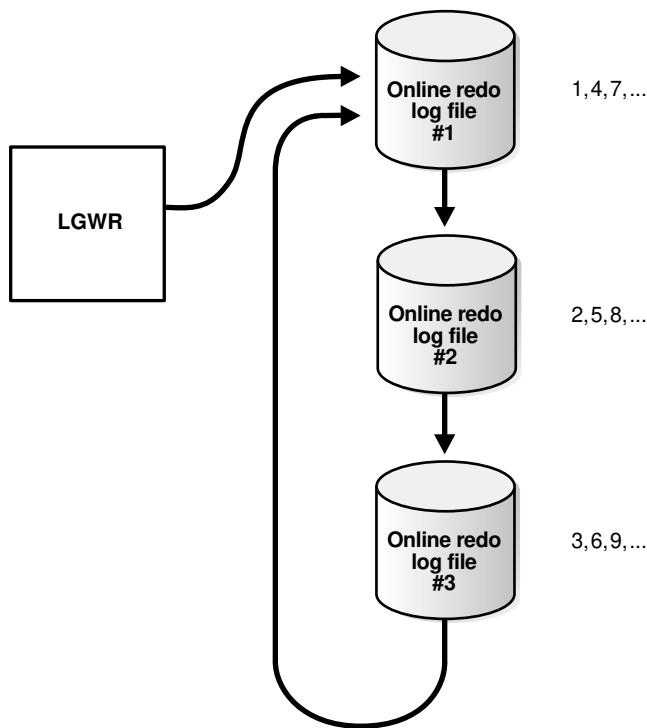

See "[Managing Archived Redo Log Files](#)" for more information.

LGWR writes to redo log files in a circular fashion. When the current redo log file fills, LGWR begins writing to the next available redo log file. When the last available redo log file is filled, LGWR returns to the first redo log file and writes to it, starting the cycle again. [Figure 11-1](#) illustrates the circular writing of the redo log file. The numbers next to each line indicate the sequence in which LGWR writes to each redo log file.

Filled redo log files are available to LGWR for reuse depending on whether archiving is enabled.

- If archiving is disabled (the database is in NOARCHIVELOG mode), a filled redo log file is available after the changes recorded in it have been written to the data files.
- If archiving is enabled (the database is in ARCHIVELOG mode), a filled redo log file is available to LGWR after the changes recorded in it have been written to the data files *and* the file has been archived.

Figure 11-1 Reuse of Redo Log Files by LGWR

- **Active (Current) and Inactive Redo Log Files**

Oracle Database uses only one redo log file at a time to store redo records written from the redo log buffer. The redo log file that LGWR is actively writing to is called the **current** redo log file.

- **Log Switches and Log Sequence Numbers**

A **log switch** is the point at which the database stops writing to one redo log file and begins writing to another. Normally, a log switch occurs when the current redo log file is completely filled and writing must continue to the next redo log file.

11.1.3.1 Active (Current) and Inactive Redo Log Files

Oracle Database uses only one redo log file at a time to store redo records written from the redo log buffer. The redo log file that LGWR is actively writing to is called the **current** redo log file.

Redo log files that are required for instance recovery are called **active** redo log files. Redo log files that are no longer required for instance recovery are called **inactive** redo log files.

If you have enabled archiving (the database is in ARCHIVELOG mode), then the database cannot reuse or overwrite an active online log file until one of the archiver background processes (ARCn) has archived its contents. If archiving is disabled (the database is in NOARCHIVELOG mode), then when the last redo log file is full, LGWR continues by overwriting the next log file in the sequence when it becomes inactive.

11.1.3.2 Log Switches and Log Sequence Numbers

A **log switch** is the point at which the database stops writing to one redo log file and begins writing to another. Normally, a log switch occurs when the current redo log file is completely filled and writing must continue to the next redo log file.

However, you can configure log switches to occur at regular intervals, regardless of whether the current redo log file is completely filled. You can also force log switches manually.

Oracle Database assigns each redo log file a new **log sequence number** every time a log switch occurs and LGWR begins writing to it. When the database archives redo log files, the archived log retains its log sequence number. A redo log file that is cycled back for use is given the next available log sequence number.

Each online or archived redo log file is uniquely identified by its log sequence number. During crash, instance, or media recovery, the database properly applies redo log files in ascending order by using the log sequence number of the necessary archived and redo log files.

11.2 Planning the Redo Log

You can follow guidelines when configuring a database instance redo log.

- [Multiplexing Redo Log Files](#)

To protect against a failure involving the redo log itself, Oracle Database allows a **multiplexed** redo log, meaning that two or more identical copies of the redo log can be automatically maintained in separate locations.

- [Placing Redo Log Members on Different Disks](#)

When setting up a multiplexed redo log, place members of a group on different physical disks. If a single disk fails, then only one member of a group becomes unavailable to LGWR and other members remain accessible to LGWR, so the instance can continue to function.

- [Planning the Size of Redo Log Files](#)

When setting the size of redo log files, consider whether you will be archiving the redo log. Redo log files should be sized so that a filled group can be archived to a single unit of offline storage media (such as a tape or disk), with the least amount of space on the medium left unused.

- [Planning the Block Size of Redo Log Files](#)

Unlike the database block size, which can be between 2K and 32K, redo log files always default to a block size that is equal to the physical sector size of the disk. Historically, this has typically been 512 bytes (512B).

- [Choosing the Number of Redo Log Files](#)

The best way to determine the appropriate number of redo log files for a database instance is to test different configurations. The optimum configuration has the fewest groups possible without hampering LGWR from writing redo log information.

- [Controlling Archive Lag](#)

You can force all enabled redo log threads to switch their current logs at regular time intervals.

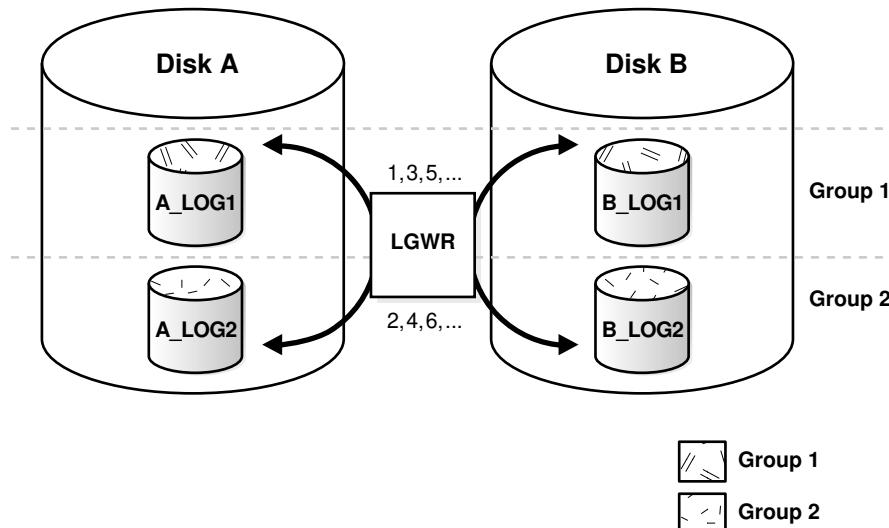

11.2.1 Multiplexing Redo Log Files

To protect against a failure involving the redo log itself, Oracle Database allows a **multiplexed** redo log, meaning that two or more identical copies of the redo log can be automatically maintained in separate locations.

For the most benefit, these locations should be on separate disks. Even if all copies of the redo log are on the same disk, however, the redundancy can help protect against I/O errors, file corruption, and so on. When redo log files are multiplexed, LGWR concurrently writes the same redo log information to multiple identical redo log files, thereby eliminating a single point of redo log failure.

Multiplexing is implemented by creating *groups* of redo log files. A **group** consists of a redo log file and its multiplexed copies. Each identical copy is said to be a **member** of the group. Each redo log group is defined by a number, such as group 1, group 2, and so on.

Figure 11-2 Multiplexed Redo Log Files

In [Figure 11-2](#), A_LOG1 and B_LOG1 are both members of Group 1, A_LOG2 and B_LOG2 are both members of Group 2, and so forth. Each member in a group must be the same size.

Each member of a log file group is concurrently active—that is, concurrently written to by LGWR—as indicated by the identical log sequence numbers assigned by LGWR. In [Figure 11-2](#), first LGWR writes concurrently to both A_LOG1 and B_LOG1. Then it writes concurrently to both A_LOG2 and B_LOG2, and so on. LGWR never writes concurrently to members of different groups (for example, to A_LOG1 and B_LOG2).

 **Note:**

Oracle recommends that you multiplex your redo log files. The loss of the log file data can be catastrophic if recovery is required. Note that when you multiplex the redo log, the database must increase the amount of I/O that it performs. Depending on your configuration, this may impact overall database performance.

- [Responding to Redo Log Failure](#)

Whenever LGWR cannot write to a member of a group, the database marks that member as `INVALID` and writes an error message to the LGWR trace file and to the database alert log to indicate the problem with the inaccessible files.

- [Legal and Illegal Configurations](#)

In most cases, a multiplexed redo log should be symmetrical: all groups of the redo log should have the same number of members. However, the database does not require that a multiplexed redo log be symmetrical.

11.2.1.1 Responding to Redo Log Failure

Whenever LGWR cannot write to a member of a group, the database marks that member as `INVALID` and writes an error message to the LGWR trace file and to the database alert log to indicate the problem with the inaccessible files.

The specific reaction of LGWR when a redo log member is unavailable depends on the reason for the lack of availability, as summarized in the table that follows.

Condition	LGWR Action
LGWR can successfully write to at least one member in a group	Writing proceeds as normal. LGWR writes to the available members of a group and ignores the unavailable members.
LGWR cannot access the next group at a log switch because the group must be archived	Database operation temporarily halts until the group becomes available or until the group is archived.
All members of the next group are inaccessible to LGWR at a log switch because of media failure	Oracle Database returns an error, and the database instance shuts down. In this case, you may need to perform media recovery on the database from the loss of a redo log file. If the database checkpoint has moved beyond the lost redo log, media recovery is not necessary, because the database has saved the data recorded in the redo log to the data files. You need only drop the inaccessible redo log group. If the database did not archive the bad log, use <code>ALTER DATABASE CLEAR LOGFILE UNARCHIVED</code> to disable archiving before the log can be dropped.
All members of a group suddenly become inaccessible to LGWR while it is writing to them	Oracle Database returns an error and the database instance immediately shuts down. In this case, you may need to perform media recovery. If the media containing the log is not actually lost—for example, if the drive for the log was inadvertently turned off—media recovery may not be needed. In this case, you need only turn the drive back on and let the database perform automatic instance recovery.

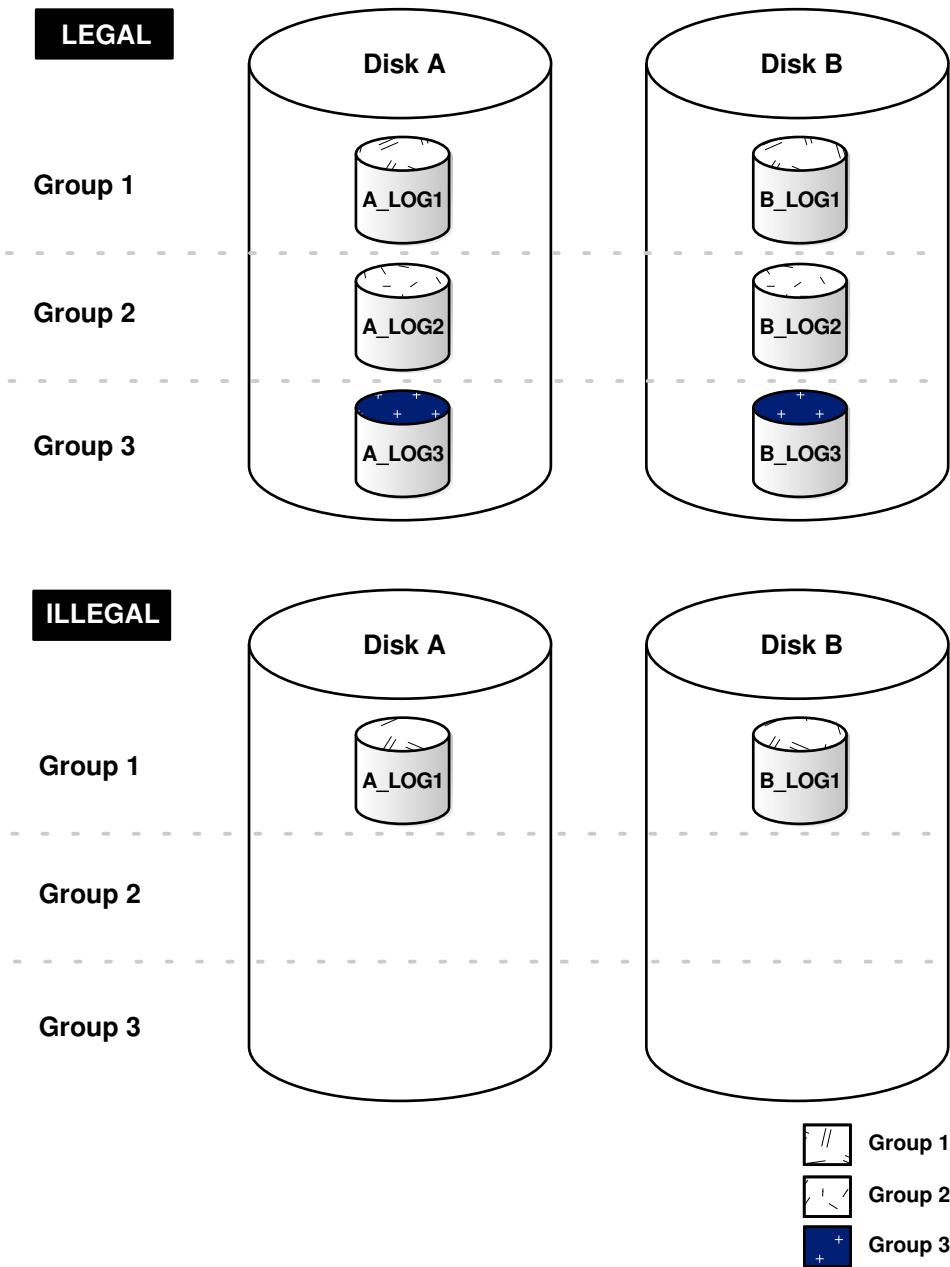

11.2.1.2 Legal and Illegal Configurations

In most cases, a multiplexed redo log should be symmetrical: all groups of the redo log should have the same number of members. However, the database does not require that a multiplexed redo log be symmetrical.

For example, one group can have only one member, and other groups can have two members. This configuration protects against disk failures that temporarily affect some redo log members but leave others intact.

The only requirement for an instance redo log is that it have at least two groups. [Figure 11-3](#) shows legal and illegal multiplexed redo log configurations. The second configuration is illegal because it has only one group.

Figure 11-3 Legal and Illegal Multiplexed Redo Log Configuration

11.2.2 Placing Redo Log Members on Different Disks

When setting up a multiplexed redo log, place members of a group on different physical disks. If a single disk fails, then only one member of a group becomes unavailable to LGWR and other members remain accessible to LGWR, so the instance can continue to function.

If you archive the redo log, spread redo log members across disks to eliminate contention between the LGWR and ARC_n background processes. For example, if you have two groups of multiplexed redo log members (a *duplexed* redo log), place each member on a different disk and set your archiving destination to a fifth disk. Doing so

will avoid contention between LGWR (writing to the members) and ARCn (reading the members).

Data files should also be placed on different disks from redo log files to reduce contention in writing data blocks and redo records.

11.2.3 Planning the Size of Redo Log Files

When setting the size of redo log files, consider whether you will be archiving the redo log. Redo log files should be sized so that a filled group can be archived to a single unit of offline storage media (such as a tape or disk), with the least amount of space on the medium left unused.

For example, suppose only one filled redo log group can fit on a tape and 49% of the tape storage capacity remains unused. In this case, it is better to decrease the size of the redo log files slightly, so that two log groups could be archived on each tape.

All members of the same multiplexed redo log group must be the same size. Members of different groups can have different sizes. However, there is no advantage in varying file size between groups. If checkpoints are not set to occur between log switches, make all groups the same size to guarantee that checkpoints occur at regular intervals.

The minimum size permitted for a redo log file is 4 MB.

See Also:

Your operating system-specific Oracle documentation. The default size of redo log files is operating system dependent.

11.2.4 Planning the Block Size of Redo Log Files

Unlike the database block size, which can be between 2K and 32K, redo log files always default to a block size that is equal to the physical sector size of the disk. Historically, this has typically been 512 bytes (512B).

Some newer high-capacity disk drives offer 4K byte (4K) sector sizes for both increased ECC capability and improved format efficiency. Most Oracle Database platforms are able to detect this larger sector size. The database then automatically creates redo log files with a 4K block size on those disks.

However, with a block size of 4K, there is increased redo wastage. In fact, the amount of redo wastage in 4K blocks versus 512B blocks is significant. You can determine the amount of redo wastage by viewing the statistics stored in the v\$SESSTAT and V\$SYSSTAT views.

```
SQL> SELECT name, value FROM v$sysstat WHERE name = 'redo wastage';
```

NAME	VALUE
redo wastage	17941684

To avoid the additional redo wastage, if you are using emulation-mode disks—4K sector size disk drives that emulate a 512B sector size at the disk interface—you can

override the default 4K block size for redo logs by specifying a 512B block size or, for some platforms, a 1K block size. However, you will incur a significant performance degradation when a redo log write is not aligned with the beginning of the 4K physical sector. Because seven out of eight 512B slots in a 4K physical sector are not aligned, performance degradation typically does occur. Thus, you must evaluate the trade-off between performance and disk wastage when planning the redo log block size on 4K sector size emulation-mode disks.

You can specify the block size of online redo log files with the `BLOCKSIZE` keyword in the `CREATE DATABASE`, `ALTER DATABASE`, and `CREATE CONTROLFILE` statements. On some platforms, the permissible block sizes are 512 and 4096. On other platforms, the permissible block sizes are 1024 and 4096.

The following statement adds a redo log file group with a block size of 512B. The `BLOCKSIZE 512` clause is valid but not required for 512B sector size disks. For 4K sector size emulation-mode disks, the `BLOCKSIZE 512` clause overrides the default 4K size.

```
ALTER DATABASE orcl ADD LOGFILE
  GROUP 4 ('/u01/logs/orcl/redo04a.log','/u01/logs/orcl/redo04b.log')
  SIZE 100M BLOCKSIZE 512 REUSE;
```

To ascertain the redo log file block size, run the following query:

```
SQL> SELECT BLOCKSIZE FROM V$LOG;
BLOCKSIZE
-----
512
```

11.2.5 Choosing the Number of Redo Log Files

The best way to determine the appropriate number of redo log files for a database instance is to test different configurations. The optimum configuration has the fewest groups possible without hampering LGWR from writing redo log information.

In some cases, a database instance may require only two groups. In other situations, a database instance may require additional groups to guarantee that a recycled group is always available to LGWR. During testing, the easiest way to determine whether the current redo log configuration is satisfactory is to examine the contents of the LGWR trace file and the database alert log. If messages indicate that LGWR frequently has to wait for a group because a checkpoint has not completed or a group has not been archived, add groups.

Consider the parameters that can limit the number of redo log files before setting up or altering the configuration of an instance redo log. The following parameters limit the number of redo log files that you can add to a database:

- The MAXLOGFILES parameter used in the CREATE DATABASE statement determines the maximum number of groups of redo log files for each database. Group values can range from 1 to MAXLOGFILES. You can exceed the MAXLOGFILES limit, and the control files expand as needed. If MAXLOGFILES is not specified for the CREATE DATABASE statement, then the database uses an operating system specific default value.
- The MAXLOGMEMBERS parameter used in the CREATE DATABASE statement determines the maximum number of members for each group. As with MAXLOGFILES, the only way to override this upper limit is to re-create the database or control file. Therefore, it is important to consider this limit before creating a database. If no MAXLOGMEMBERS parameter is specified for the CREATE DATABASE statement, then the database uses an operating system default value.

 **See Also:**

Your operating system specific Oracle documentation for the default and legal values of the MAXLOGFILES and MAXLOGMEMBERS parameters

11.2.6 Controlling Archive Lag

You can force all enabled redo log threads to switch their current logs at regular time intervals.

In a primary/standby database configuration, changes are made available to the standby database by archiving redo logs at the primary site and then shipping them to the standby database. The changes that are being applied by the standby database can lag behind the changes that are occurring on the primary database, because the standby database must wait for the changes in the primary database redo log to be archived (into the archived redo log) and then shipped to it. To limit this lag, you can set the ARCHIVE_LAG_TARGET initialization parameter. Setting this parameter lets you specify in seconds how long that lag can be.

- [Setting the ARCHIVE_LAG_TARGET Initialization Parameter](#)
When you set the ARCHIVE_LAG_TARGET initialization parameter, you cause the database to examine the current redo log for the instance periodically and determine when to switch the log.
- [Factors Affecting the Setting of ARCHIVE_LAG_TARGET](#)
There are several factors to consider when you are setting the ARCHIVE_LAG_TARGET initialization parameter.

11.2.6.1 Setting the ARCHIVE_LAG_TARGET Initialization Parameter

When you set the ARCHIVE_LAG_TARGET initialization parameter, you cause the database to examine the current redo log for the instance periodically and determine when to switch the log.

If the following conditions are met, then the instance will switch the log:

- The current log was created before n seconds ago, and the estimated archival time for the current log is m seconds (proportional to the number of redo blocks used in the current log), where $n + m$ exceeds the value of the ARCHIVE_LAG_TARGET initialization parameter.
- The current log contains redo records.

In an Oracle Real Application Clusters environment, the instance also causes other threads to switch and archive their logs if they are falling behind. This can be particularly useful when one instance in the cluster is more idle than the other instances (as when you are running a 2-node primary/secondary configuration of Oracle Real Application Clusters).

The ARCHIVE_LAG_TARGET initialization parameter provides an upper limit for how long (in seconds) the current log of the database can span. Because the estimated archival time is also considered, this is not the exact log switch time.

- Set the ARCHIVE_LAG_TARGET initialization parameter.

The following initialization parameter setting sets the log switch interval to 30 minutes (a typical value).

```
ARCHIVE_LAG_TARGET = 1800
```

A value of 0 disables this time-based log switching functionality. This is the default setting.

You can set the ARCHIVE_LAG_TARGET initialization parameter even if there is no standby database. For example, the ARCHIVE_LAG_TARGET parameter can be set specifically to force logs to be switched and archived.

ARCHIVE_LAG_TARGET is a dynamic parameter and can be set with the ALTER SYSTEM SET statement.

 **Note:**

The ARCHIVE_LAG_TARGET parameter must be set to the same value in all instances of an Oracle Real Application Clusters environment. Failing to do so results in unpredictable behavior.

11.2.6.2 Factors Affecting the Setting of ARCHIVE_LAG_TARGET

There are several factors to consider when you are setting the ARCHIVE_LAG_TARGET initialization parameter.

Consider the following factors when determining if you want to set the ARCHIVE_LAG_TARGET initialization parameter and in determining the value for this parameter.

- Overhead of switching (as well as archiving) logs
- How frequently normal log switches occur as a result of log full conditions
- How much redo loss is tolerated in the standby database

Setting ARCHIVE_LAG_TARGET may not be very useful if natural log switches already occur more frequently than the interval specified. However, in the case of irregularities

of redo generation speed, the interval does provide an upper limit for the time range each current log covers.

If the `ARCHIVE_LAG_TARGET` initialization parameter is set to a very low value, there can be a negative impact on performance. This can force frequent log switches. Set the parameter to a reasonable value so as not to degrade the performance of the primary database.

11.3 Creating Redo Log Groups and Members

Plan the redo log for a database and create all required groups and members of redo log files during database creation. However, there are situations where you might want to create additional groups or members. For example, adding groups to a redo log can correct redo log group availability problems.

To create new redo log groups and members, you must have the `ALTER DATABASE` system privilege. A database can have up to `MAXLOGFILES` groups.

- **Creating Redo Log Groups**

To create a new group of redo log files, use the SQL statement `ALTER DATABASE` with the `ADD LOGFILE` clause.

- **Creating Redo Log Members**

In some cases, it might not be necessary to create a complete group of redo log files. A group could already exist, but not be complete because one or more members of the group were dropped (for example, because of a disk failure). In this case, you can add new members to an existing group.

 **See Also:**

Oracle Database SQL Language Reference for a complete description of the `ALTER DATABASE` statement

11.3.1 Creating Redo Log Groups

To create a new group of redo log files, use the SQL statement `ALTER DATABASE` with the `ADD LOGFILE` clause.

- Run the SQL statement `ALTER DATABASE` with the `ADD LOGFILE` clause.

For example, the following statement adds a new group of redo logs to the database:

```
ALTER DATABASE
  ADD LOGFILE ('/oracle/dbs/log1c.rdo', '/oracle/dbs/log2c.rdo') SIZE 100M;
```

 **Note:**

Provide full path names of new log members to specify their location. Otherwise, the files are created in either the default or current directory of the database server, depending upon your operating system.

You can also specify the number that identifies the group using the GROUP clause:

```
ALTER DATABASE
  ADD LOGFILE GROUP 10 ('/oracle/dbs/log1c.rdo', '/oracle/dbs/log2c.rdo')
    SIZE 100M BLOCKSIZE 512;
```

Using group numbers can make administering redo log groups easier. However, the group number must be between 1 and MAXLOGFILES. Do not skip redo log file group numbers (that is, do not number your groups 10, 20, 30, and so on), or you will consume unnecessary space in the control files of the database.

In the preceding statement, the BLOCKSIZE clause is optional. See "[Planning the Block Size of Redo Log Files](#)" for more information.

11.3.2 Creating Redo Log Members

In some cases, it might not be necessary to create a complete group of redo log files. A group could already exist, but not be complete because one or more members of the group were dropped (for example, because of a disk failure). In this case, you can add new members to an existing group.

To create new redo log members for an existing group:

- Run the SQL statement `ALTER DATABASE` with the `ADD LOGFILE MEMBER` clause.

For example, the following statement adds a new redo log member to redo log group number 2:

```
ALTER DATABASE ADD LOGFILE MEMBER '/oracle/dbs/log2b.rdo' TO GROUP 2;
```

Notice that file names must be specified, but sizes need not be. The size of the new members is determined from the size of the existing members of the group.

When using the `ALTER DATABASE` statement, you can alternatively identify the target group by specifying all of the other members of the group in the `TO` clause, as shown in the following example:

```
ALTER DATABASE ADD LOGFILE MEMBER '/oracle/dbs/log2c.rdo'
  TO ('/oracle/dbs/log2a.rdo', '/oracle/dbs/log2b.rdo');
```

Note:

Fully specify the file names of new log members to indicate where the operating system files should be created. Otherwise, the files will be created in either the default or current directory of the database server, depending upon your operating system. You may also note that the status of the new log member is shown as `INVALID`. This is normal and it will change to active (blank) when it is first used.

11.4 Relocating and Renaming Redo Log Members

You can use operating system commands to relocate redo logs, then use the `ALTER DATABASE` statement to make their new names (locations) known to the database.

This procedure is necessary, for example, if the disk currently used for some redo log files is going to be removed, or if data files and several redo log files are stored on the same disk and should be separated to reduce contention.

To rename redo log members, you must have the `ALTER DATABASE` system privilege. Additionally, you might also need operating system privileges to copy files to the desired location and privileges to open and back up the database.

Before relocating your redo logs, or making any other structural changes to the database, completely back up the database in case you experience problems while performing the operation. As a precaution, after renaming or relocating a set of redo log files, immediately back up the database control file.

Use the following steps for relocating redo logs. The example used to illustrate these steps assumes:

- The log files are located on two disks: `diska` and `diskb`.
- The redo log is duplexed: one group consists of the members `/diska/logs/log1a.rdo` and `/diskb/logs/log1b.rdo`, and the second group consists of the members `/diska/logs/log2a.rdo` and `/diskb/logs/log2b.rdo`.
- The redo log files located on `diska` must be relocated to `diskc`. The new file names will reflect the new location: `/diskc/logs/log1c.rdo` and `/diskc/logs/log2c.rdo`.

To rename redo log members:

1. Shut down the database.
`SHUTDOWN`
2. Copy the redo log files to the new location.

Operating system files, such as redo log members, must be copied using the appropriate operating system commands. See your operating system specific documentation for more information about copying files.

Note:

You can execute an operating system command to copy a file (or perform other operating system commands) without exiting SQL*Plus by using the `HOST` command. Some operating systems allow you to use a character in place of the word `HOST`. For example, you can use an exclamation point (!) in UNIX.

The following example uses operating system commands (UNIX) to move the redo log members to a new location:

```
mv /diska/logs/log1a.rdo /diskc/logs/log1c.rdo
mv /diska/logs/log2a.rdo /diskc/logs/log2c.rdo
```

3. Startup the database, mount, but do not open it.

```
CONNECT / as SYSDBA
STARTUP MOUNT
```

4. Rename the redo log members.

Use the `ALTER DATABASE` statement with the `RENAME FILE` clause to rename the database redo log files.

```
ALTER DATABASE
  RENAME FILE '/diska/logs/log1a.rdo', '/diska/logs/log2a.rdo'
    TO '/diskc/logs/log1c.rdo', '/diskc/logs/log2c.rdo';
```

5. Open the database for normal operation.

The redo log alterations take effect when the database is opened.

```
ALTER DATABASE OPEN;
```

11.5 Dropping Redo Log Groups and Members

In some cases, you may want to drop an entire group of redo log members.

For example, you want to reduce the number of groups in an instance redo log. In a different case, you may want to drop one or more specific redo log members. For example, if a disk failure occurs, you may need to drop all the redo log files on the failed disk so that the database does not try to write to the inaccessible files. In other situations, particular redo log files become unnecessary. For example, a file might be stored in an inappropriate location.

- [Dropping Log Groups](#)
You can drop a redo log group.
- [Dropping Redo Log Members](#)
You can drop redo log members.

11.5.1 Dropping Log Groups

You can drop a redo log group.

To drop a redo log group, you must have the `ALTER DATABASE` system privilege. Before dropping a redo log group, consider the following restrictions and precautions:

- An instance requires at least two groups of redo log files, regardless of the number of members in the groups. (A group comprises one or more members.)
- You can drop a redo log group only if it is inactive. If you must drop the current group, then first force a log switch to occur.
- Make sure a redo log group is archived (if archiving is enabled) before dropping it. To see whether this has happened, use the `V$LOG` view.

```
SELECT GROUP#, ARCHIVED, STATUS FROM V$LOG;
```

GROUP#	ARC	STATUS
1	YES	ACTIVE
2	NO	CURRENT

```
3 YES INACTIVE
4 YES INACTIVE
```

To drop a redo log group:

- Run the SQL statement `ALTER DATABASE` with the `DROP LOGFILE` clause.

For example, the following statement drops redo log group number 3:

```
ALTER DATABASE DROP LOGFILE GROUP 3;
```

When a redo log group is dropped from the database, and you are not using the Oracle Managed Files feature, the operating system files are not deleted from disk. Rather, the control files of the associated database are updated to drop the members of the group from the database structure. After dropping a redo log group, ensure that the drop completed successfully, and then use the appropriate operating system command to delete the dropped redo log files.

When using Oracle Managed Files, the cleanup of operating systems files is done automatically for you.

11.5.2 Dropping Redo Log Members

You can drop redo log members.

To drop a redo log member, you must have the `ALTER DATABASE` system privilege. Consider the following restrictions and precautions before dropping individual redo log members:

- It is permissible to drop redo log files so that a multiplexed redo log becomes temporarily asymmetric. For example, if you use duplexed groups of redo log files, you can drop one member of one group, even though all other groups have two members each. However, you should rectify this situation immediately so that all groups have at least two members, and thereby eliminate the single point of failure possible for the redo log.
- An instance always requires at least two valid groups of redo log files, regardless of the number of members in the groups. (A group comprises one or more members.) If the member you want to drop is the last valid member of the group, you cannot drop the member until the other members become valid. To see a redo log file status, use the `V$LOGFILE` view. A redo log file becomes `INVALID` if the database cannot access it. It becomes `STALE` if the database suspects that it is not complete or correct. A stale log file becomes valid again the next time its group is made the active group.
- You can drop a redo log member only if it is *not* part of an active or current group. To drop a member of an active group, first force a log switch to occur.
- Make sure the group to which a redo log member belongs is archived (if archiving is enabled) before dropping the member. To see whether this has happened, use the `V$LOG` view.

To drop specific inactive redo log members:

- Run the `ALTER DATABASE` statement with the `DROP LOGFILE MEMBER` clause.

The following statement drops the redo log `/oracle/dbs/log3c.rdo`:

```
ALTER DATABASE DROP LOGFILE MEMBER '/oracle/dbs/log3c.rdo';
```

When a redo log member is dropped from the database, the operating system file is not deleted from disk. Rather, the control files of the associated database are updated to drop the member from the database structure. After dropping a redo log file, ensure that the drop completed successfully, and then use the appropriate operating system command to delete the dropped redo log file.

To drop a member of an active group, you must first force a log switch.

11.6 Forcing Log Switches

A log switch occurs when LGWR stops writing to one redo log group and starts writing to another. By default, a log switch occurs automatically when the current redo log file group fills.

You can force a log switch to make the currently active group inactive and available for redo log maintenance operations. For example, you want to drop the currently active group, but are not able to do so until the group is inactive. You may also want to force a log switch if the currently active group must be archived at a specific time before the members of the group are completely filled. This option is useful in configurations with large redo log files that take a long time to fill.

To force a log switch, you must have the `ALTER SYSTEM` privilege.

To force a log switch,

- Run the `ALTER SYSTEM` statement with the `SWITCH LOGFILE` clause.

For example, the following statement forces a log switch:

```
ALTER SYSTEM SWITCH LOGFILE;
```

11.7 Verifying Blocks in Redo Log Files

You can configure the database to use checksums to verify blocks in the redo log files.

If you set the initialization parameter `DB_BLOCK_CHECKSUM` to `TYPICAL` (the default), then the database computes a checksum for each database block when it is written to disk, including each redo log block as it is being written to the current log. The checksum is stored in the header of the block.

Oracle Database uses the checksum to detect corruption in a redo log block. The database verifies the redo log block when the block is read from an archived log during recovery and when it writes the block to an archive log file. An error is raised and written to the alert log if corruption is detected.

If corruption is detected in a redo log block while trying to archive it, the system attempts to read the block from another member in the group. If the block is corrupted in all members of the redo log group, then archiving cannot proceed.

The value of the `DB_BLOCK_CHECKSUM` parameter can be changed dynamically using the `ALTER SYSTEM` statement.

 **Note:**

There is a slight overhead and decrease in database performance with DB_BLOCK_CHECKSUM enabled. Monitor your database performance to decide if the benefit of using data block checksums to detect corruption outweighs the performance impact.

 **See Also:**

Oracle Database Reference for a description of the DB_BLOCK_CHECKSUM initialization parameter

11.8 Clearing a Redo Log File

A redo log file might become corrupted while the database is open, and ultimately stop database activity because archiving cannot continue.

In this situation, to reinitialize the file without shutting down the database:

- Run the ALTER DATABASE CLEAR LOGFILE SQL statement.

The following statement clears the log files in redo log group number 3:

```
ALTER DATABASE CLEAR LOGFILE GROUP 3;
```

This statement overcomes two situations where dropping redo logs is not possible:

- If there are only two log groups
- The corrupt redo log file belongs to the current group

If the corrupt redo log file has not been archived, use the UNARCHIVED keyword in the statement.

```
ALTER DATABASE CLEAR UNARCHIVED LOGFILE GROUP 3;
```

This statement clears the corrupted redo logs and avoids archiving them. The cleared redo logs are available for use even though they were not archived.

If you clear a log file that is needed for recovery of a backup, then you can no longer recover from that backup. The database writes a message in the alert log describing the backups from which you cannot recover.

 **Note:**

If you clear an unarchived redo log file, you should make another backup of the database.

To clear an unarchived redo log that is needed to bring an offline tablespace online, use the `UNRECOVERABLE DATAFILE` clause in the `ALTER DATABASE CLEAR LOGFILE` statement.

If you clear a redo log needed to bring an offline tablespace online, you will not be able to bring the tablespace online again. You will have to drop the tablespace or perform an incomplete recovery. Note that tablespaces taken offline normal do not require recovery.

11.9 Precedence of FORCE LOGGING Settings

You can set `FORCE LOGGING` and `NOLOGGING` at various levels, such as for a database, pluggable database (PDB), tablespace, or database object. When `FORCE LOGGING` is set at one or more levels, the precedence of `FORCE LOGGING` settings determines what is logged in the redo log.

You can put a multitenant container database (CDB) and a non-CDB into `FORCE LOGGING` mode. In this mode, the database logs all changes in the database except for changes in temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any `NOLOGGING` or `FORCE LOGGING` settings you specify for individual tablespaces and any `NOLOGGING` settings you specify for individual database objects.

You can also put a tablespace into `FORCE LOGGING` mode. The database logs all changes to all objects in the tablespace except changes to temporary segments, overriding any `NOLOGGING` setting for individual objects.

In addition, you can specify a logging attribute with the *logging_clause* for various types of database objects that determines whether certain DML operations will be logged in the redo log file (`LOGGING`) or not (`NOLOGGING`). You can specify a logging attribute for the following types of database objects:

- Tables
- Indexes
- Materialized views

The following table summarizes the logging settings at each level and shows the result for a non-CDB.

Table 11-1 Precedence of FORCE LOGGING Settings for a Non-CDB

Database	Tablespace	Database Object LOGGING Attribute	Result
FORCE LOGGING	Ignored	Ignored	Logged
NO FORCE LOGGING	FORCE LOGGING	Ignored	Logged
NO FORCE LOGGING	NO FORCE LOGGING	LOGGING	Logged
NO FORCE LOGGING	NO FORCE LOGGING	NOLOGGING	Not Logged

The following table summarizes the logging settings at each level and shows the result for a CDB.

Table 11-2 Precedence of FORCE LOGGING Settings for a CDB

CDB	PDB	Tablespace	Database Object LOGGING Attribute	Result
FORCE LOGGING	Ignored	Ignored	Ignored	Logged
NO FORCE LOGGING	ENABLE FORCE LOGGING	Ignored	Ignored	Logged
NO FORCE LOGGING	ENABLE FORCE NOLOGGING	Ignored	Ignored	Not Logged
NO FORCE LOGGING	DISABLE FORCE [NO]LOGGING (no setting)	FORCE LOGGING	Ignored	Logged
NO FORCE LOGGING	DISABLE FORCE [NO]LOGGING (no setting)	NO FORCE LOGGING	LOGGING	Logged
NO FORCE LOGGING	DISABLE FORCE [NO]LOGGING (no setting)	NO FORCE LOGGING	NOLOGGING	Not Logged

11.10 Redo Log Data Dictionary Views

You can query a set of data dictionary views for information about the redo log.

The following views provide information on redo logs.

View	Description
V\$LOG	Displays the redo log file information from the control file
V\$LOGFILE	Identifies redo log groups and members and member status
V\$LOG_HISTORY	Contains log history information

The following query returns the control file information about the redo log for a database.

```
SELECT GROUP#, THREAD#, SEQUENCE#, BYTES, MEMBERS, ARCHIVED,
       STATUS, FIRST_CHANGE#, FIRST_TIME
  FROM V$LOG;
```

GROUP#	THREAD#	SEQ	BYTES	MEMBERS	ARC	STATUS	FIRST_CHANGE#	FIRST_TIM
1	1	10605	1048576	1	YES	ACTIVE	11515628	16-APR-00
2	1	10606	1048576	1	NO	CURRENT	11517595	16-APR-00
3	1	10603	1048576	1	YES	INACTIVE	11511666	16-APR-00
4	1	10604	1048576	1	YES	INACTIVE	11513647	16-APR-00

To see the names of all of the member of a group, use a query similar to the following:

```
SELECT GROUP#, STATUS, MEMBER FROM V$LOGFILE;
```

GROUP#	STATUS	MEMBER
1		D:\ORANT\ORADATA\IDDB2\REDO04.LOG
2		D:\ORANT\ORADATA\IDDB2\REDO03.LOG

3	D:\ORANT\ORADATA\IDDB2\REDO02.LOG
4	D:\ORANT\ORADATA\IDDB2\REDO01.LOG

If STATUS is blank for a member, then the file is in use.

Managing Archived Redo Log Files

You manage the archived redo log files by completing tasks such as choosing between NOARCHIVELOG or ARCHIVELOG mode and specifying archive destinations.

- [What Is the Archived Redo Log?](#)
Oracle Database lets you save filled groups of redo log files to one or more offline destinations, known collectively as the **archived redo log**.
- [Choosing Between NOARCHIVELOG and ARCHIVELOG Mode](#)
You must choose between running your database in NOARCHIVELOG or ARCHIVELOG mode.
- [Controlling Archiving](#)
You can set the archiving mode for your database and adjust the number of archiver processes.
- [Specifying Archive Destinations](#)
Before you can archive redo logs, you must determine the destination to which you will archive, and familiarize yourself with the various destination states.
- [About Log Transmission Modes](#)
The two modes of transmitting archived logs to their destination are **normal archiving transmission** and **standby transmission** mode. Normal transmission involves transmitting files to a local disk. Standby transmission involves transmitting files through a network to either a local or remote standby database.
- [Managing Archive Destination Failure](#)
Sometimes archive destinations can fail, causing problems when you operate in automatic archiving mode. Oracle Database provides procedures to help you minimize the problems associated with destination failure.
- [Controlling Trace Output Generated by the Archivelog Process](#)
Background processes always write to a trace file when appropriate. In the case of the archivelog process, you can control the output that is generated to the trace file.
- [Viewing Information About the Archived Redo Log](#)
You can display information about the archived redo log using dynamic performance views or the ARCHIVE LOG LIST command.

See Also:

- [Using Oracle Managed Files](#) for information about creating an archived redo log that is both created and managed by the Oracle Database server
- [Oracle Real Application Clusters Administration and Deployment Guide](#) for information specific to archiving in the Oracle Real Application Clusters environment

12.1 What Is the Archived Redo Log?

Oracle Database lets you save filled groups of redo log files to one or more offline destinations, known collectively as the **archived redo log**.

The process of turning redo log files into archived redo log files is called **archiving**. This process is only possible if the database is running in **ARCHIVELOG mode**. You can choose automatic or manual archiving.

An archived redo log file is a copy of one of the filled members of a redo log group. It includes the redo entries and the unique log sequence number of the identical member of the redo log group. For example, if you are multiplexing your redo log, and if group 1 contains identical member files *a_log1* and *b_log1*, then the archiver process (ARCn) will archive one of these member files. Should *a_log1* become corrupted, then ARCn can still archive the identical *b_log1*. The archived redo log contains a copy of every group created since you enabled archiving.

When the database is running in ARCHIVELOG mode, the log writer process (LGWR) cannot reuse and hence overwrite a redo log group until it has been archived. The background process ARCn automates archiving operations when automatic archiving is enabled. The database starts multiple archiver processes as needed to ensure that the archiving of filled redo logs does not fall behind.

You can use archived redo log files to:

- Recover a database
- Update a standby database
- Get information about the history of a database using the LogMiner utility

See Also:

The following sources document the uses for archived redo log files:

- *Oracle Database Backup and Recovery User's Guide*
- *Oracle Data Guard Concepts and Administration* discusses setting up and maintaining a standby database
- *Oracle Database Utilities* contains instructions for using the LogMiner PL/SQL package

12.2 Choosing Between NOARCHIVELOG and ARCHIVELOG Mode

You must choose between running your database in NOARCHIVELOG or ARCHIVELOG mode.

The choice of whether to enable the archiving of filled groups of redo log files depends on the availability and reliability requirements of the application running on the database. If you cannot afford to lose any data in your database in the event of a disk

failure, use ARCHIVELOG mode. The archiving of filled redo log files can require you to perform extra administrative operations.

- **Running a Database in NOARCHIVELOG Mode**

When you run your database in NOARCHIVELOG mode, you disable the archiving of the redo log.

- **Running a Database in ARCHIVELOG Mode**

When you run a database in ARCHIVELOG mode, you enable the archiving of the redo log.

12.2.1 Running a Database in NOARCHIVELOG Mode

When you run your database in NOARCHIVELOG mode, you disable the archiving of the redo log.

The database control file indicates that filled groups are not required to be archived. Therefore, when a filled group becomes inactive after a log switch, the group is available for reuse by LGWR.

NOARCHIVELOG mode protects a database from instance failure but not from media failure. Only the most recent changes made to the database, which are stored in the online redo log groups, are available for instance recovery. If a media failure occurs while the database is in NOARCHIVELOG mode, you can only restore the database to the point of the most recent full database backup. You cannot recover transactions subsequent to that backup.

In NOARCHIVELOG mode you cannot perform online tablespace backups, nor can you use online tablespace backups taken earlier while the database was in ARCHIVELOG mode. To restore a database operating in NOARCHIVELOG mode, you can use only whole database backups taken while the database is closed. Therefore, if you decide to operate a database in NOARCHIVELOG mode, take whole database backups at regular, frequent intervals.

12.2.2 Running a Database in ARCHIVELOG Mode

When you run a database in ARCHIVELOG mode, you enable the archiving of the redo log.

The database control file indicates that a group of filled redo log files cannot be reused by LGWR until the group is archived. A filled group becomes available for archiving immediately after a redo log switch occurs.

The archiving of filled groups has these advantages:

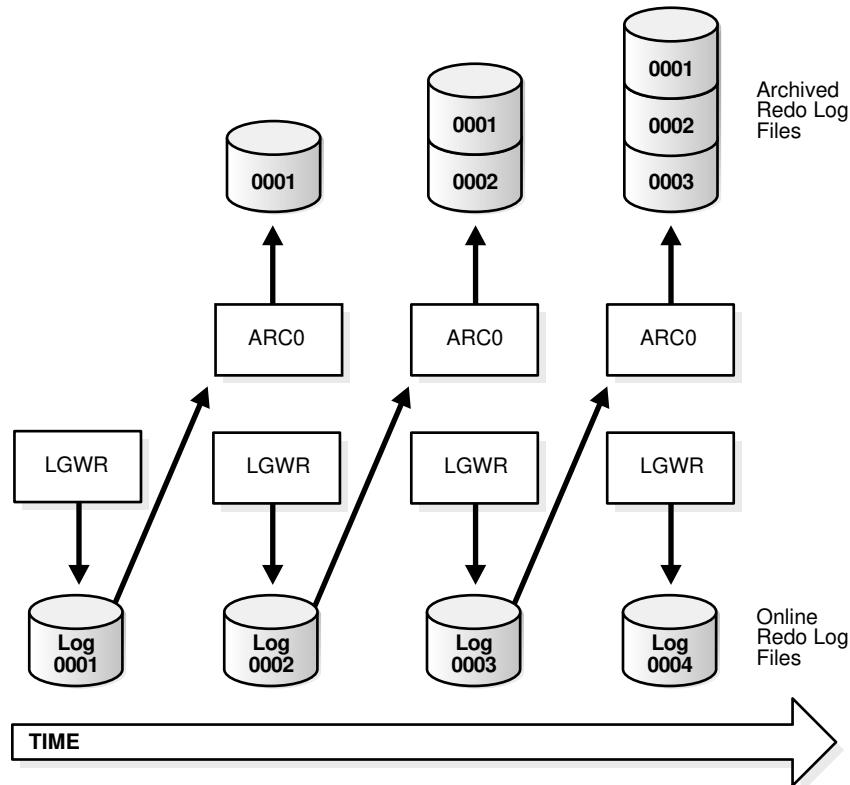

- A database backup, together with online and archived redo log files, guarantees that you can recover all committed transactions in the event of an operating system or disk failure.
- If you keep archived logs available, you can use a backup taken while the database is open and in normal system use.
- You can keep a standby database current with its original database by continuously applying the original archived redo log files to the standby.

You can configure an instance to archive filled redo log files automatically, or you can archive manually. For convenience and efficiency, automatic archiving is usually best.

Figure 12-1 illustrates how the archiver process (ARC0 in this illustration) writes filled redo log files to the database archived redo log.

If all databases in a distributed database operate in ARCHIVELOG mode, you can perform coordinated distributed database recovery. However, if any database in a distributed database is in NOARCHIVELOG mode, recovery of a global distributed database (to make all databases consistent) is limited by the last full backup of any database operating in NOARCHIVELOG mode.

Figure 12-1 Redo Log File Use in ARCHIVELOG Mode

Tip:

It is good practice to move archived redo log files and corresponding database backups from the local disk to permanent offline storage media such as tape. A primary value of archived logs is database recovery, so you want to ensure that these logs are safe should disaster strike your primary database.

12.3 Controlling Archiving

You can set the archiving mode for your database and adjust the number of archiver processes.

- [Setting the Initial Database Archiving Mode](#)
You set the initial archiving mode as part of database creation in the `CREATE DATABASE` statement.
- [Changing the Database Archiving Mode](#)
To change the archiving mode of the database, use the `ALTER DATABASE` statement with the `ARCHIVELOG` or `NOARCHIVELOG` clause.
- [Performing Manual Archiving](#)
For convenience and efficiency, automatic archiving is usually best. However, you can configure your database for manual archiving only.
- [Adjusting the Number of Archiver Processes](#)
The `LOG_ARCHIVE_MAX_PROCESSES` initialization parameter specifies the number of `ARCn` processes that the database initially starts. The default is four processes.

 **See Also:**

Your Oracle operating system specific documentation for additional information on controlling archiving modes

12.3.1 Setting the Initial Database Archiving Mode

You set the initial archiving mode as part of database creation in the `CREATE DATABASE` statement.

Usually, you can use the default of `NOARCHIVELOG` mode at database creation because there is no need to archive the redo information generated by that process. After creating the database, decide whether to change the initial archiving mode.

If you specify `ARCHIVELOG` mode, you must have initialization parameters set that specify the destinations for the archived redo log files (see "[Setting Initialization Parameters for Archive Destinations](#)").

12.3.2 Changing the Database Archiving Mode

To change the archiving mode of the database, use the `ALTER DATABASE` statement with the `ARCHIVELOG` or `NOARCHIVELOG` clause.

To change the archiving mode, you must be connected to the database with administrator privileges (`AS SYSDBA`).

The following steps switch the database archiving mode from `NOARCHIVELOG` to `ARCHIVELOG`:

1. Shut down the database instance.

`SHUTDOWN IMMEDIATE`

An open database must first be closed and any associated instances shut down before you can switch the database archiving mode. You cannot change the mode from `ARCHIVELOG` to `NOARCHIVELOG` if any data files need media recovery.

2. Back up the database.

Before making any major change to a database, always back up the database to protect against any problems. This will be your final backup of the database in NOARCHIVELOG mode and can be used if something goes wrong during the change to ARCHIVELOG mode. See *Oracle Database Backup and Recovery User's Guide* for information about taking database backups.

3. Edit the initialization parameter file to include the initialization parameters that specify the destinations for the archived redo log files (see "[Setting Initialization Parameters for Archive Destinations](#)").
4. Start a new instance and mount, but do not open, the database.

STARTUP MOUNT

To enable or disable archiving, the database must be mounted but not open.

5. Change the database archiving mode. Then open the database for normal operations.

```
ALTER DATABASE ARCHIVELOG;  
ALTER DATABASE OPEN;
```

6. Shut down the database.

SHUTDOWN IMMEDIATE

7. Back up the database.

Changing the database archiving mode updates the control file. After changing the database archiving mode, you must back up all of your database files and control file. Any previous backup is no longer usable because it was taken in NOARCHIVELOG mode.

See Also:

Oracle Real Application Clusters Administration and Deployment Guide for more information about switching the archiving mode when using Real Application Clusters

12.3.3 Performing Manual Archiving

For convenience and efficiency, automatic archiving is usually best. However, you can configure your database for manual archiving only.

When you operate your database in manual ARCHIVELOG mode, you must archive inactive groups of filled redo log files or your database operation can be temporarily suspended.

To operate your database in manual archiving mode:

1. Follow the procedure described in "[Changing the Database Archiving Mode](#)", but replace the ALTER DATABASE statement with the following statement:

```
ALTER DATABASE ARCHIVELOG MANUAL;
```

2. Connect to the database as a user with administrator privileges.
3. Ensure that the database is either mounted or open.
- 4.

Use the `ALTER SYSTEM` statement with the `ARCHIVE LOG` clause to manually archive filled redo log files. For example, the following statement archives all unarchived redo log files:

```
ALTER SYSTEM ARCHIVE LOG ALL;
```

When you use manual archiving mode, you cannot specify any standby databases in the archiving destinations.

Even when automatic archiving is enabled, you can use manual archiving for such actions as rearchiving an inactive group of filled redo log members to another location. In this case, it is possible for the instance to reuse the redo log group before you have finished manually archiving, and thereby overwrite the files. If this happens, the database writes an error message to the alert log.

Related Topics

- [Running a Database in ARCHIVELOG Mode](#)

When you run a database in `ARCHIVELOG` mode, you enable the archiving of the redo log.

12.3.4 Adjusting the Number of Archiver Processes

The `LOG_ARCHIVE_MAX_PROCESSES` initialization parameter specifies the number of `ARCn` processes that the database initially starts. The default is four processes.

To avoid any run-time overhead of starting additional `ARCn` processes:

- Set the `LOG_ARCHIVE_MAX_PROCESSES` initialization parameter to specify that up to 30 `ARCn` processes be started at instance startup.

The `LOG_ARCHIVE_MAX_PROCESSES` parameter is dynamic, so you can change it using the `ALTER SYSTEM` statement.

The following statement configures the database to start six `ARCn` processes upon startup:

```
ALTER SYSTEM SET LOG_ARCHIVE_MAX_PROCESSES=6;
```

The statement also has an immediate effect on the currently running instance. It increases or decreases the current number of running `ARCn` processes to six.

12.4 Specifying Archive Destinations

Before you can archive redo logs, you must determine the destination to which you will archive, and familiarize yourself with the various destination states.

The dynamic performance (V\$) views, listed in "[Viewing Information About the Archived Redo Log](#)", provide all needed archive information.

- [Setting Initialization Parameters for Archive Destinations](#)

You can choose to archive redo logs to a single destination or to multiple destinations.

- [Expanding Alternate Destinations with Log Archive Destination Groups](#)

You can expand the number of alternate archive destinations by using log archive destination groups.

- [Understanding Archive Destination Status](#)
Several variables determine an archive destination's status.
- [Specifying Alternate Destinations](#)
To specify that a location be an archive destination only in the event of a failure of another destination, you can make it an alternate destination. Both local and remote destinations can be alternates.

12.4.1 Setting Initialization Parameters for Archive Destinations

You can choose to archive redo logs to a single destination or to multiple destinations.

Destinations can be local—within the local file system or an Oracle Automatic Storage Management (Oracle ASM) disk group—or remote (on a standby database). When you archive to multiple destinations, a copy of each filled redo log file is written to each destination. These redundant copies help ensure that archived logs are always available in the event of a failure at one of the destinations.

To archive to only a single destination:

- Specify that destination using the `LOG_ARCHIVE_DEST` initialization parameter.

To archive to multiple destinations:

- Choose to archive to two or more locations using the `LOG_ARCHIVE_DEST_n` initialization parameters, or to archive only to a primary and secondary destination using the `LOG_ARCHIVE_DEST` and `LOG_ARCHIVE_DUPLEX_DEST` initialization parameters.

For local destinations, in addition to the local file system or an Oracle ASM disk group, you can archive to the Fast Recovery Area. The database uses the Fast Recovery Area to store and automatically manage disk space for a variety of files related to backup and recovery. See *Oracle Database Backup and Recovery User's Guide* for details about the Fast Recovery Area.

Typically, you determine archive log destinations during database planning, and you set the initialization parameters for archive destinations during database installation. However, you can use the `ALTER SYSTEM` command to dynamically add or change archive destinations after your database is running. Any destination changes that you make take effect at the next log switch (automatic or manual).

The following table summarizes the archive destination alternatives, which are further described in the sections that follow.

Method	Initialization Parameter	Host	Example
1	<code>LOG_ARCHIVE_DEST_n</code> where: <i>n</i> is an integer from 1 to 31. Archive destinations 1 to 10 are available for local or remote locations. Archive destinations 11 to 31 are available for remote locations only.	Local or remote	<code>LOG_ARCHIVE_DEST_1 = 'LOCATION=/disk1/arc'</code> <code>LOG_ARCHIVE_DEST_2 = 'LOCATION=/disk2/arc'</code> <code>LOG_ARCHIVE_DEST_3 = 'SERVICE=standby1'</code>
2	<code>LOG_ARCHIVE_DEST</code> and <code>LOG_ARCHIVE_DUPLEX_DEST</code>	Local only	<code>LOG_ARCHIVE_DEST = '/disk1/arc'</code> <code>LOG_ARCHIVE_DUPLEX_DEST = '/disk2/arc'</code>

- **Method 1: Using the LOG_ARCHIVE_DEST_n Parameter**
You can use the `LOG_ARCHIVE_DEST_n` initialization parameter to specify different destinations for archived logs.
- **Method 2: Using LOG_ARCHIVE_DEST and LOG_ARCHIVE_DUPLEX_DEST**
To specify a maximum of two locations, use the `LOG_ARCHIVE_DEST` parameter to specify a primary archive destination and the `LOG_ARCHIVE_DUPLEX_DEST` to specify an optional secondary archive destination.

12.4.1.1 Method 1: Using the LOG_ARCHIVE_DEST_n Parameter

You can use the `LOG_ARCHIVE_DEST_n` initialization parameter to specify different destinations for archived logs.

Set the `LOG_ARCHIVE_DEST_n` initialization parameter (where *n* is an integer from 1 to 31) to specify from one to 31. Each numerically suffixed parameter uniquely identifies an individual destination.

You specify the location for `LOG_ARCHIVE_DEST_n` using the keywords explained in the following table:

Keyword	Indicates	Example
LOCATION	A local file system location or Oracle ASM disk group	<code>LOG_ARCHIVE_DEST_n = 'LOCATION=/disk1/arc'</code> <code>LOG_ARCHIVE_DEST_n = 'LOCATION=+DGROUP1/orcl/arc_1'</code>
LOCATION	The Fast Recovery Area	<code>LOG_ARCHIVE_DEST_n = 'LOCATION=USE_DB_RECOVERY_FILE_DEST'</code>
SERVICE	Remote archival through Oracle Net service name.	<code>LOG_ARCHIVE_DEST_n = 'SERVICE=standby1'</code>

If you use the `LOCATION` keyword, specify one of the following:

- A valid path name in your operating system's local file system
- An Oracle ASM disk group
- The keyword `USE_DB_RECOVERY_FILE_DEST` to indicate the Fast Recovery Area

If you specify `SERVICE`, supply a net service name that Oracle Net can resolve to a connect descriptor for a standby database. The connect descriptor contains the information necessary for connecting to the remote database.

Perform the following steps to set the destination for archived redo log files using the `LOG_ARCHIVE_DEST_n` initialization parameter:

1. Set the `LOG_ARCHIVE_DEST_n` initialization parameter to specify from one to 31 archiving locations. For example, enter:

```
LOG_ARCHIVE_DEST_1 = 'LOCATION = /disk1/archive'
LOG_ARCHIVE_DEST_2 = 'LOCATION = /disk2/archive'
LOG_ARCHIVE_DEST_3 = 'LOCATION = +RECOVERY/orcl/arc_3'
```

If you are archiving to a standby database, then use the `SERVICE` keyword to specify a valid net service name. For example, enter:

```
LOG_ARCHIVE_DEST_4 = 'SERVICE = standby1'
```

2. (Optional) Set the `LOG_ARCHIVE_FORMAT` initialization parameter, using `%t` to include the thread number as part of the file name, `%s` to include the log sequence

number, and %r to include the resetlogs ID (a timestamp value represented in ub4). Use capital letters (%T, %S, and %R) to pad the file name to the left with zeroes.

 **Note:**

The database requires the specification of resetlogs ID (%r) when you include the LOG_ARCHIVE_FORMAT parameter. The default for this parameter is operating system dependent.

The incarnation of a database changes when you open it with the RESETLOGS option. Specifying %r causes the database to capture the resetlogs ID in the archived redo log file name. See *Oracle Database Backup and Recovery User's Guide* for more information about this method of recovery.

The following example shows a setting of LOG_ARCHIVE_FORMAT:

```
LOG_ARCHIVE_FORMAT = arch_%t_%s_%r.arc
```

This setting will generate archived logs as follows for thread 1; log sequence numbers 100, 101, and 102; resetlogs ID 509210197. The identical resetlogs ID indicates that the files are all from the same database incarnation:

```
/disk1/archive/arch_1_100_509210197.arc,  
/disk1/archive/arch_1_101_509210197.arc,  
/disk1/archive/arch_1_102_509210197.arc  
  
/disk2/archive/arch_1_100_509210197.arc,  
/disk2/archive/arch_1_101_509210197.arc,  
/disk2/archive/arch_1_102_509210197.arc  
  
/disk3/archive/arch_1_100_509210197.arc,  
/disk3/archive/arch_1_101_509210197.arc,  
/disk3/archive/arch_1_102_509210197.arc
```

The LOG_ARCHIVE_FORMAT initialization parameter is ignored in some cases. See *Oracle Database Reference* for more information about this parameter.

12.4.1.2 Method 2: Using LOG_ARCHIVE_DEST and LOG_ARCHIVE_DUPLEX_DEST

To specify a maximum of two locations, use the LOG_ARCHIVE_DEST parameter to specify a primary archive destination and the LOG_ARCHIVE_DUPLEX_DEST to specify an optional secondary archive destination.

All locations must be local. Whenever the database archives a redo log, it archives it to every destination specified by either set of parameters.

Perform the following steps to use method 2:

1. Specify destinations for the LOG_ARCHIVE_DEST and LOG_ARCHIVE_DUPLEX_DEST parameter (you can also specify LOG_ARCHIVE_DUPLEX_DEST dynamically using the ALTER SYSTEM statement). For example, enter:

```
LOG_ARCHIVE_DEST = '/disk1/archive'  
LOG_ARCHIVE_DUPLEX_DEST = '/disk2/archive'
```

2. Set the `LOG_ARCHIVE_FORMAT` initialization parameter as described in step 2 for method 1.

 **Note:**

If you configure a Fast Recovery Area (by setting the `DB_RECOVERY_FILE_DEST` and `DB_RECOVERY_FILE_DEST_SIZE` parameters) and do not specify any local archive destinations, the database automatically selects the Fast Recovery Area as a local archive destination and sets `LOG_ARCHIVE_DEST_1` to `USE_DB_RECOVERY_FILE_DEST`.

 **WARNING:**

You must ensure that there is sufficient disk space at all times for archive log destinations. If the database encounters a disk full error as it attempts to archive a log file, a fatal error occurs and the database stops responding. You can check the alert log for a disk full message.

 **See Also:**

12.4.2 Expanding Alternate Destinations with Log Archive Destination Groups

You can expand the number of alternate archive destinations by using log archive destination groups.

- [About Log Archive Destination Groups](#)

A log archive destination group specifies multiple archive destinations, and the destinations in the group can be prioritized. You can specify multiple groups to expand the number of possible archive destinations for your database.

- [Specifying Log Archive Destination Groups](#)

Use the `GROUP` attribute of the `LOG_ARCHIVE_DEST_n` initialization parameter to specify log archive destination groups.

12.4.2.1 About Log Archive Destination Groups

A log archive destination group specifies multiple archive destinations, and the destinations in the group can be prioritized. You can specify multiple groups to expand the number of possible archive destinations for your database.

To specify a log archive destination group, use the `GROUP` attribute of the `LOG_ARCHIVE_DEST_n` initialization parameter. There can be up to 30 log archive destinations included in a group. One member of each group is active, and the others are available for use in the event of a failure of the active destination. If the active destination becomes inactive, then Oracle Database switches to an available destination as long as one or more are available in the group. You can indicate which destinations to use first by prioritizing the destinations with the `PRIORITY` attribute.

A log archive destination group is referenced by a group number, which is specified when the group is created. There can be up to eight groups. To specify where to archive the redo data within a group, all of the log archive destinations must specify the `SERVICE` attribute.

To prioritize the destinations in a group, set the `PRIORITY` attribute for a destination to an integer in the range of 1 through 8. The lower number indicates the higher priority. The priority determines which destination within a group to make active when the database is mounted or when the active destination fails. For example, a `PRIORITY` value of 2 is higher priority than a `PRIORITY` value of 7. Therefore, if the currently active destination with the `PRIORITY` value of 1 in the group becomes inactive, then the destination with the `PRIORITY` value of 2 is used before the destination with the `PRIORITY` value of 7. If the `PRIORITY` attribute is not set for a destination, then the default value is 1.

The priority is also considered when a previously failed destination becomes available. If an active destination fails, and Oracle Database switches to a destination with a lower priority, then Oracle Database switches back to the destination with higher priority when it becomes available again. For example, if an active destination with priority 1 becomes inactive, and Oracle Database switches to a destination with priority 2, then Oracle Database switches back to the destination with priority 1 when it becomes available again, even if the priority 2 destination did not fail.

However, more than one destination assigned to the same group can have the same priority. For example, there can be three destinations with priority 1. In such a group, a failure of the active destination results in a switch to another member with the same priority. In this case, there is no switch back to the original destination when it becomes available again because both destinations have the same priority. If the second destination fails after the first destination has become available again, then the database will switch to the first destination or to another destination in the group with the same priority.

 **See Also:**

Oracle Data Guard Concepts and Administration

12.4.2.2 Specifying Log Archive Destination Groups

Use the GROUP attribute of the LOG_ARCHIVE_DEST_*n* initialization parameter to specify log archive destination groups.

You can create up to eight log archive destination groups, and each group can have up to 30 destinations specified.

To specify log archive destination groups, the database must be running in ARCHIVELOG mode.

- Set the LOG_ARCHIVE_DEST_*n* initialization parameter, and include the GROUP attribute to specify log archive destination groups.

Optionally, include the PRIORITY attribute to specify which log archive destination within a group to make active when the system is started or when a destination fails.

Example 12-1 Specifying Two Log Archive Destination Groups

This example specifies two log archive destination groups (1 and 2). Each group has three log archive destinations specified.

```
LOG_ARCHIVE_DEST_1 = 'SERVICE=SITEa
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=1'
LOG_ARCHIVE_DEST_2 = 'SERVICE=SITEb
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=1'
LOG_ARCHIVE_DEST_3 = 'SERVICE=SITEc
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=1'

LOG_ARCHIVE_DEST_4 = 'SERVICE=SITE1
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=2'
LOG_ARCHIVE_DEST_5 = 'SERVICE=SITE2
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=2'
LOG_ARCHIVE_DEST_6 = 'SERVICE=SITE3
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=2'
```

Example 12-2 Specifying Priority Within a Log Archive Destination Group

This example specifies different priority levels for destinations within a single log archive destination group. Specifically, destination 1 and 2 are both at priority level 1, destination 3 is at priority level 2, and destination 4 is at priority level 3.

```
LOG_ARCHIVE_DEST_1 = 'SERVICE=SITE1 SYNC
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=1 PRIORITY=1'
LOG_ARCHIVE_DEST_2 = 'SERVICE=SITE2 SYNC
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=1 PRIORITY=1'
LOG_ARCHIVE_DEST_3 = 'SERVICE=SITE3 ASYNC
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=1 PRIORITY=2'
LOG_ARCHIVE_DEST_4 = 'SERVICE=SITE4 ASYNC
VALID_FOR=(ONLINE_LOGFILES,PRIMARY_ROLE) GROUP=1 PRIORITY=3'
```

In this example, sites 1, 2 and 3 could be Oracle Data Guard far sync instances that only forward the redo, and site 4 is the actual remote standby database. Alternatively,

sites 1, 2, 3, and 4 could all be standby databases which are configured to cascade the redo to the other sites when they are the active destination.

The following priority rules are followed:

- The default active destination can be destination 1 or destination 2 because both are at priority level 1.
- If destination 1 is active but then becomes unavailable, then Oracle Database switches to destination 2. Similarly, if destination 2 is active but then becomes unavailable, then Oracle Database switches to destination 1. When either destination 1 or 2 is available, one of them is used.
- If both destination 1 and destination 2 become unavailable, then destination 3 is used.
- If, when destination 3 is active, destination 1 or destination 2 becomes available, Oracle Database switches to the available priority 1 destination.
- If destination 1, 2, and 3 all become unavailable, then destination 4 is used.
- If, when destination 4 is active, destination 1, 2, or 3 becomes available, Oracle Database switches to the available priority 1 destination first and then to the available priority 2 destination.

 **See Also:**

Oracle Data Guard Concepts and Administration

12.4.3 Understanding Archive Destination Status

Several variables determine an archive destination's status.

Each archive destination has the following variable characteristics that determine its status:

- **Valid/Invalid:** indicates whether the disk location or service name information is specified and valid
- **Enabled/Disabled:** indicates the availability state of the location and whether the database can use the destination
- **Active/Inactive:** indicates whether there was a problem accessing the destination

Several combinations of these characteristics are possible. To obtain the current status and other information about each destination for an instance, query the V\$ARCHIVE_DEST view.

The LOG_ARCHIVE_DEST_STATE_ *n* (where *n* is an integer from 1 to 31) initialization parameter lets you control the availability state of the specified destination (*n*).

- ENABLE indicates that the database can use the destination.
- DEFER indicates that the location is temporarily disabled.
- ALTERNATE indicates that the destination is an alternate. The availability state of an alternate destination is DEFER. If its parent destination fails, the availability state of the alternate becomes ENABLE. ALTERNATE cannot be specified for destinations LOG_ARCHIVE_DEST_11 to LOG_ARCHIVE_DEST_31.

12.4.4 Specifying Alternate Destinations

To specify that a location be an archive destination only in the event of a failure of another destination, you can make it an alternate destination. Both local and remote destinations can be alternates.

The following example makes `LOG_ARCHIVE_DEST_4` an alternate for `LOG_ARCHIVE_DEST_3`:

```
ALTER SYSTEM SET LOG_ARCHIVE_DEST_4 = 'LOCATION=/disk4/arch';
ALTER SYSTEM SET LOG_ARCHIVE_DEST_3 = 'LOCATION=/disk3/arch MAX_FAILURE=1
ALTERNATE=LOG_ARCHIVE_DEST_4';
ALTER SYSTEM SET LOG_ARCHIVE_DEST_STATE_4=ALTERNATE;
```

```
SQL> SELECT dest_name, status, destination FROM v$archive_dest;
```

DEST_NAME	STATUS	DESTINATION
LOG_ARCHIVE_DEST_1	VALID	/disk1/arch
LOG_ARCHIVE_DEST_2	VALID	/disk2/arch
LOG_ARCHIVE_DEST_3	VALID	/disk3/arch
LOG_ARCHIVE_DEST_4	ALTERNATE	/disk4/arch

12.5 About Log Transmission Modes

The two modes of transmitting archived logs to their destination are **normal archiving transmission** and **standby transmission** mode. Normal transmission involves transmitting files to a local disk. Standby transmission involves transmitting files through a network to either a local or remote standby database.

- **Normal Transmission Mode**
In normal transmission mode, the archiving destination is another disk drive of the database server.
- **Standby Transmission Mode**
In standby transmission mode, the archiving destination is either a local or remote standby database.

12.5.1 Normal Transmission Mode

In normal transmission mode, the archiving destination is another disk drive of the database server.

In this configuration archiving does not contend with other files required by the instance and can complete more quickly. Specify the destination with either the `LOG_ARCHIVE_DEST_n` or `LOG_ARCHIVE_DEST` parameters.

12.5.2 Standby Transmission Mode

In standby transmission mode, the archiving destination is either a local or remote standby database.

 **Note:**

You can maintain a standby database on a local disk, but Oracle strongly encourages you to maximize disaster protection by maintaining your standby database at a remote site.

 **See Also:**

- *Oracle Data Guard Concepts and Administration*
- *Oracle Database Net Services Administrator's Guide* for information about connecting to a remote database using a service name

12.6 Managing Archive Destination Failure

Sometimes archive destinations can fail, causing problems when you operate in automatic archiving mode. Oracle Database provides procedures to help you minimize the problems associated with destination failure.

- [Specifying the Minimum Number of Successful Destinations](#)
The optional initialization parameter `LOG_ARCHIVE_MIN_SUCCEED_DEST=n` determines the minimum number of destinations to which the database must successfully archive a redo log group before it can reuse online log files. The default value is 1. Valid values for *n* are 1 to 2 if you are using duplexing, or 1 to 31 if you are multiplexing.
- [Rearchiving to a Failed Destination](#)
Use the `REOPEN` attribute of the `LOG_ARCHIVE_DEST_n` parameter to specify whether and when `ARCn` should attempt to reread to a failed destination following an error. `REOPEN` applies to all errors, not just `OPEN` errors.

12.6.1 Specifying the Minimum Number of Successful Destinations

The optional initialization parameter `LOG_ARCHIVE_MIN_SUCCEED_DEST=n` determines the minimum number of destinations to which the database must successfully archive a redo log group before it can reuse online log files. The default value is 1. Valid values for *n* are 1 to 2 if you are using duplexing, or 1 to 31 if you are multiplexing.

- [Specifying Mandatory and Optional Destinations](#)
The `LOG_ARCHIVE_DEST_n` initialization parameter lets you specify whether a destination is `OPTIONAL` (the default) or `MANDATORY`.
- [Specifying the Number of Successful Destinations: Scenarios](#)
You can see the relationship between the `LOG_ARCHIVE_DEST_n` and `LOG_ARCHIVE_MIN_SUCCEED_DEST` initialization parameters most easily through sample scenarios.

12.6.1.1 Specifying Mandatory and Optional Destinations

The `LOG_ARCHIVE_DEST_n` initialization parameter lets you specify whether a destination is `OPTIONAL` (the default) or `MANDATORY`.

- Set the destination as `OPTIONAL` (the default) or `MANDATORY` in the `LOG_ARCHIVE_DEST_n` initialization parameter.

The `LOG_ARCHIVE_MIN_SUCCED_DEST=n` parameter uses all `MANDATORY` destinations plus some number of non-standby `OPTIONAL` destinations to determine whether LGWR can overwrite the online log. The following rules apply:

- Omitting the `MANDATORY` attribute for a destination is the same as specifying `OPTIONAL`.
- You must have at least one local destination, which you can declare `OPTIONAL` or `MANDATORY`.
- The `MANDATORY` attribute can only be specified for destinations `LOG_ARCHIVE_DEST_1` through `LOG_ARCHIVE_DEST_10`.
- When you specify a value for `LOG_ARCHIVE_MIN_SUCCED_DEST=n`, Oracle Database will treat at least one local destination as `MANDATORY`, because the minimum value for `LOG_ARCHIVE_MIN_SUCCED_DEST` is 1.
- The `LOG_ARCHIVE_MIN_SUCCED_DEST` value cannot be greater than the number of destinations, nor can it be greater than the number of `MANDATORY` destinations plus the number of `OPTIONAL` local destinations.
- If you `DEFER` a `MANDATORY` destination, and the database overwrites the online log without transferring the archived log to the standby site, then you must transfer the log to the standby manually.

If you are duplexing the archived logs, you can establish which destinations are mandatory or optional by using the `LOG_ARCHIVE_DEST` and `LOG_ARCHIVE_DUPLEX_DEST` parameters. The following rules apply:

- Any destination declared by `LOG_ARCHIVE_DEST` is mandatory.
- Any destination declared by `LOG_ARCHIVE_DUPLEX_DEST` is optional if `LOG_ARCHIVE_MIN_SUCCED_DEST = 1` and mandatory if `LOG_ARCHIVE_MIN_SUCCED_DEST = 2`.

12.6.1.2 Specifying the Number of Successful Destinations: Scenarios

You can see the relationship between the `LOG_ARCHIVE_DEST_n` and `LOG_ARCHIVE_MIN_SUCCED_DEST` initialization parameters most easily through sample scenarios.

- **Scenario for Archiving to Optional Local Destinations**
In this scenario, you archive to three local destinations, each of which you declare as `OPTIONAL`.
- **Scenario for Archiving to Both Mandatory and Optional Destinations**
In this scenario, you archive to `MANDATORY` and `OPTIONAL` local destinations.

12.6.1.2.1 Scenario for Archiving to Optional Local Destinations

In this scenario, you archive to three local destinations, each of which you declare as OPTIONAL.

[Table 12-1](#) illustrates the possible values for LOG_ARCHIVE_MIN_SUCCEED_DEST=n in this case.

Table 12-1 LOG_ARCHIVE_MIN_SUCCEED_DEST Values for Scenario 1

Value	Meaning
1	The database can reuse log files only if at least one of the OPTIONAL destinations succeeds.
2	The database can reuse log files only if at least two of the OPTIONAL destinations succeed.
3	The database can reuse log files only if all of the OPTIONAL destinations succeed.
4 or greater	ERROR: The value is greater than the number of destinations.

This scenario shows that even though you do not explicitly set any of your destinations to MANDATORY using the LOG_ARCHIVE_DEST_n parameter, the database must successfully archive to one or more of these locations when LOG_ARCHIVE_MIN_SUCCEED_DEST is set to 1, 2, or 3.

12.6.1.2.2 Scenario for Archiving to Both Mandatory and Optional Destinations

In this scenario, you archive to MANDATORY and OPTIONAL local destinations.

Consider a case in which:

- You specify two MANDATORY destinations.
- You specify two OPTIONAL destinations.
- No destination is a standby database.

[Table 12-2](#) shows the possible values for LOG_ARCHIVE_MIN_SUCCEED_DEST=n.

Table 12-2 LOG_ARCHIVE_MIN_SUCCEED_DEST Values for Scenario 2

Value	Meaning
1	The database ignores the value and uses the number of MANDATORY destinations (in this example, 2).
2	The database can reuse log files even if no OPTIONAL destination succeeds.
3	The database can reuse logs only if at least one OPTIONAL destination succeeds.
4	The database can reuse logs only if both OPTIONAL destinations succeed.
5 or greater	ERROR: The value is greater than the number of destinations.

This case shows that the database must archive to the destinations you specify as MANDATORY, regardless of whether you set LOG_ARCHIVE_MIN_SUCCEED_DEST to archive to a smaller number of destinations.

12.6.2 Rearchiving to a Failed Destination

Use the REOPEN attribute of the LOG_ARCHIVE_DEST_n parameter to specify whether and when ARCn should attempt to rearchive to a failed destination following an error. REOPEN applies to all errors, not just OPEN errors.

REOPEN=n sets the minimum number of seconds before ARCn should try to reopen a failed destination. The default value for n is 300 seconds. A value of 0 is the same as turning off the REOPEN attribute; ARCn will not attempt to archive after a failure. If you do not specify the REOPEN keyword, ARCn will never reopen a destination following an error.

You cannot use REOPEN to specify the number of attempts ARCn should make to reconnect and transfer archived logs. The REOPEN attempt either succeeds or fails.

When you specify REOPEN for an OPTIONAL destination, the database can overwrite online logs if there is an error. If you specify REOPEN for a MANDATORY destination, the database stalls the production database when it cannot successfully archive. In this situation, consider the following options:

- Archive manually to the failed destination.
- Change the destination by deferring the destination, specifying the destination as optional, or changing the service.
- Drop the destination.

When using the REOPEN keyword, note the following:

- ARCn reopens a destination only when *starting* an archive operation from the beginning of the log file, never *during* a current operation. ARCn always retries the log copy from the beginning.
- If you specified REOPEN, either with a specified time the default, ARCn checks to see whether the time of the recorded error plus the REOPEN interval is less than the current time. If it is, ARCn retries the log copy.
- The REOPEN clause successfully affects the ACTIVE=TRUE destination state. The VALID and ENABLED states are not changed.

Something wrong here. A destination can be inactive, or valid, or disabled. There is no ACTIVE status. So I think maybe it should say, "The REOPEN clause sets the destination status to VALID" ...? DL

12.7 Controlling Trace Output Generated by the Archivelog Process

Background processes always write to a trace file when appropriate. In the case of the archivelog process, you can control the output that is generated to the trace file.

To control the output that is generated to the trace file for the archivelog process:

- Set the LOG_ARCHIVE_TRACE initialization parameter to specify a **trace level**, such as 0, 1, 2, 4, 8, and so on.

You can combine tracing levels by specifying a value equal to the sum of the individual levels that you would like to trace. For example, setting `LOG_ARCHIVE_TRACE=12` will generate trace level 8 and 4 output. You can set different values for the primary and any standby database.

The default value for the `LOG_ARCHIVE_TRACE` parameter is 0. At this level, the archivelog process generates appropriate alert and trace entries for error conditions.

You can change the value of this parameter dynamically using the `ALTER SYSTEM` statement. For example:

```
ALTER SYSTEM SET LOG_ARCHIVE_TRACE=12;
```

Changes initiated in this manner will take effect at the start of the next archiving operation.

 **See Also:**

- "[Monitoring Errors with Trace Files and the Alert Log](#)"
- *Oracle Database Reference* for more information about the `LOG_ARCHIVE_TRACE` initialization parameter, including descriptions of the valid values for this parameter
- *Oracle Data Guard Concepts and Administration* for information about using this parameter with a standby database

12.8 Viewing Information About the Archived Redo Log

You can display information about the archived redo log using dynamic performance views or the `ARCHIVE LOG LIST` command.

- [Archived Redo Log Files Views](#)
You can query a set of dynamic performance views for information about archived redo log files.
- [Using the ARCHIVE LOG LIST Command](#)
The SQL*Plus command `ARCHIVE LOG LIST` displays archiving information for the connected instance.

12.8.1 Archived Redo Log Files Views

You can query a set of dynamic performance views for information about archived redo log files.

Several dynamic performance views contain useful information about archived redo log files, as summarized in the following table.

Dynamic Performance View	Description
V\$DATABASE	Shows if the database is in ARCHIVELOG or NOARCHIVELOG mode and if MANUAL (archiving mode) has been specified.

Dynamic Performance View	Description
V\$ARCHIVED_LOG	Displays historical archived log information from the control file. If you use a recovery catalog, the RC_ARCHIVED_LOG view contains similar information.
V\$ARCHIVE_DEST	Describes the current instance, all archive destinations, and the current value, mode, and status of these destinations.
V\$ARCHIVE_PROCESSES	Displays information about the state of the various archive processes for an instance.
V\$BACKUP_REDOLOG	Contains information about any backups of archived logs. If you use a recovery catalog, the RC_BACKUP_REDOLOG contains similar information.
V\$LOG	Displays all redo log groups for the database and indicates which need to be archived.
V\$LOG_HISTORY	Contains log history information such as which logs have been archived and the SCN range for each archived log.

For example, the following query displays which redo log group requires archiving:

```
SELECT GROUP#, ARCHIVED
      FROM SYS.V$LOG;
```

GROUP#	ARC
-----	---
1	YES
2	NO

To see the current archiving mode, query the V\$DATABASE view:

```
SELECT LOG_MODE FROM SYS.V$DATABASE;

LOG_MODE
-----
NOARCHIVELOG
```

12.8.2 Using the ARCHIVE LOG LIST Command

The SQL*Plus command ARCHIVE LOG LIST displays archiving information for the connected instance.

For example:

```
SQL> ARCHIVE LOG LIST

Database log mode          Archive Mode
Automatic archival        Enabled
Archive destination        D:\oracle\oradata\IDDB2\archive
Oldest online log sequence 11160
Next log sequence to archive 11163
Current log sequence       11163
```

This display tells you all the necessary information regarding the archived redo log settings for the current instance:

- The database is currently operating in ARCHIVELOG mode.
- Automatic archiving is enabled.

- The archived redo log destination is D:\oracle\oradata\IDDB2\archive.
- The oldest filled redo log group has a sequence number of 11160.
- The next filled redo log group to archive has a sequence number of 11163.
- The current redo log file has a sequence number of 11163.

See Also:

*SQL*Plus User's Guide and Reference* for more information on the ARCHIVE LOG LIST command

Managing Tablespaces

A tablespace is a database storage unit that groups related logical structures together. The database data files are stored in tablespaces.

- [Guidelines for Managing Tablespaces](#)
You can follow guidelines for working with tablespaces.
- [Creating Tablespaces](#)
You create a tablespace to group related logical structures, such as tables and indexes, together. The database data files are stored in tablespaces.
- [Consider Storing Tablespaces in the In-Memory Column Store](#)
You can enable a tablespace for the In-Memory Column Store during tablespace creation or by altering a tablespace. When this enable a tablespace for the In-Memory Column Store, all tables in the tablespace are enabled for the In-Memory Column Store by default.
- [Specifying Nonstandard Block Sizes for Tablespaces](#)
You can create tablespaces with block sizes different from the standard database block size, which is specified by the `DB_BLOCK_SIZE` initialization parameter. This feature lets you transport tablespaces with unlike block sizes between databases.
- [Controlling the Writing of Redo Records](#)
For some database operations, you can control whether the database generates redo records.
- [Altering Tablespace Availability](#)
You can take an online tablespace offline so that it is temporarily unavailable for general use. The rest of the database remains open and available for users to access data. Conversely, you can bring an offline tablespace online to make the schema objects within the tablespace available to database users. The database must be open to alter the availability of a tablespace.
- [Using Read-Only Tablespaces](#)
A tablespace can be put into read-only mode. This prevents any data stored in it from being updated.
- [Altering and Maintaining Tablespaces](#)
You can alter and maintain tablespaces by performing such tasks as adding data files and temp files to them.
- [Renaming Tablespaces](#)
Using the `RENAME TO` clause of the `ALTER TABLESPACE`, you can rename a permanent or temporary tablespace.
- [Dropping Tablespaces](#)
You can drop a tablespace and its contents (the segments contained in the tablespace) from the database if the tablespace and its contents are no longer required.
- [Managing the SYSAUX Tablespace](#)
The `SYSAUX` tablespace was installed as an auxiliary tablespace to the `SYSTEM` tablespace when you created your database. Some database components that

formerly created and used separate tablespaces now occupy the SYSAUX tablespace.

- [Correcting Problems with Locally Managed Tablespaces](#)
Oracle Database includes aids for correcting problems with locally managed tablespaces.
- [Migrating the SYSTEM Tablespace to a Locally Managed Tablespace](#)
Use the DBMS_SPACE_ADMIN.TABLESPACE_MIGRATE_TO_LOCAL procedure to migrate the SYSTEM tablespace from dictionary-managed to locally managed.
- [Viewing Information About Tablespaces](#)
Oracle Database includes data dictionary views that you can query for information about tablespaces.

 **See Also:**

- [Oracle Database Concepts](#)
- [Using Oracle Managed Files](#) for information about creating data files and temp files that are both created and managed by the Oracle Database server
- ["Transporting Tablespaces Between Databases"](#)

13.1 Guidelines for Managing Tablespaces

You can follow guidelines for working with tablespaces.

- [Use Multiple Tablespaces](#)
Using multiple tablespaces allows you more flexibility in performing database operations.
- [Assign Tablespace Quotas to Users](#)
Grant to users who will be creating tables, clusters, materialized views, indexes, and other objects the privilege to create the object and a **quota** (space allowance or limit) in the tablespace intended to hold the object segment.

13.1.1 Use Multiple Tablespaces

Using multiple tablespaces allows you more flexibility in performing database operations.

When a database has multiple tablespaces, you can:

- Separate user data from data dictionary data to reduce I/O contention.
- Separate data of one application from the data of another to prevent multiple applications from being affected if a tablespace must be taken offline.
- Store the data files of different tablespaces on different disk drives to reduce I/O contention.
- Take individual tablespaces offline while others remain online, providing better overall availability.

- Optimizing tablespace use by reserving a tablespace for a particular type of database use, such as high update activity, read-only activity, or temporary segment storage.
- Back up individual tablespaces.

Some operating systems set a limit on the number of files that can be open simultaneously. Such limits can affect the number of tablespaces that can be simultaneously online. To avoid exceeding your operating system limit, plan your tablespaces efficiently. Create only enough tablespaces to fulfill your needs, and create these tablespaces with as few files as possible. If you must increase the size of a tablespace, then add one or two large data files, or create data files with autoextension enabled, rather than creating many small data files.

Review your data in light of these factors and decide how many tablespaces you need for your database design.

13.1.2 Assign Tablespace Quotas to Users

Grant to users who will be creating tables, clusters, materialized views, indexes, and other objects the privilege to create the object and a **quota** (space allowance or limit) in the tablespace intended to hold the object segment.

 **Note:**

For PL/SQL objects such as packages, procedures, and functions, users only need the privileges to create the objects. No explicit tablespace quota is required to create these PL/SQL objects.

 **See Also:**

Oracle Database Security Guide for information about creating users and assigning tablespace quotas.

13.2 Creating Tablespaces

You create a tablespace to group related logical structures, such as tables and indexes, together. The database data files are stored in tablespaces.

- [About Creating Tablespaces](#)

To create a new tablespace, use the SQL statement `CREATE TABLESPACE` or `CREATE TEMPORARY TABLESPACE`. You must have the `CREATE TABLESPACE` system privilege to create a tablespace.

- [Locally Managed Tablespaces](#)

A locally managed tablespace uses a bitmap stored in each data file to manage the extents.

- [Bigfile Tablespaces](#)
Bigfile tablespaces can increase the storage capacity of a database and reduce the burden of managing many data files and temp files.
- [Tablespaces with Default Compression Attributes](#)
When you create a tablespace, you can specify that all tables and indexes, or their partitions, created in a tablespace are compressed by default.
- [Encrypted Tablespaces](#)
You can encrypt any permanent tablespace to protect sensitive data.
- [Temporary Tablespaces](#)
Temporary tablespaces can improve the concurrency of multiple sort operations that do not fit in memory. These tablespaces also improve the efficiency of space management operations during sorts.
- [Temporary Tablespace Groups](#)
A temporary tablespace group is a tablespace group that is assigned as the default temporary tablespace for the database.

13.2.1 About Creating Tablespaces

To create a new tablespace, use the SQL statement `CREATE TABLESPACE` or `CREATE TEMPORARY TABLESPACE`. You must have the `CREATE TABLESPACE` system privilege to create a tablespace.

Before you can create a tablespace, you must create a database to contain it. The primary tablespace in any database is the `SYSTEM` tablespace, which contains information basic to the functioning of the database server, such as the data dictionary and the system rollback segment. The `SYSTEM` tablespace is the first tablespace created at database creation. It is managed as any other tablespace, but requires a higher level of privilege and is restricted in some ways. For example, you cannot rename or drop the `SYSTEM` tablespace or take it offline.

The `SYSAUX` tablespace, which acts as an auxiliary tablespace to the `SYSTEM` tablespace, is also always created when you create a database. It contains the schemas used by various Oracle products and features, so that those products do not require their own tablespaces. As for the `SYSTEM` tablespace, management of the `SYSAUX` tablespace requires a higher level of security and you cannot rename or drop it. The management of the `SYSAUX` tablespace is discussed separately in "[Managing the SYSAUX Tablespace](#)".

The steps for creating tablespaces vary by operating system, but the first step is always to use your operating system to create a directory structure in which your data files will be allocated. On most operating systems, you specify the size and fully specified file names of data files when you create a new tablespace or alter an existing tablespace by adding data files. Whether you are creating a new tablespace or modifying an existing one, the database automatically allocates and formats the data files as specified.

You can also use the `CREATE UNDO TABLESPACE` statement to create a special type of tablespace called an **undo tablespace**, which is specifically designed to contain undo records. These are records generated by the database that are used to roll back, or undo, changes to the database for recovery, read consistency, or as requested by a `ROLLBACK` statement. Creating and managing undo tablespaces is the subject of [Managing Undo](#).

You can use the `ALTER TABLESPACE` or `ALTER DATABASE` statements to alter the tablespace. You must have the `ALTER TABLESPACE` or `ALTER DATABASE` system privilege, correspondingly.

See Also:

- "[Creating and Configuring an Oracle Database](#)" and your Oracle Database installation documentation for your operating system for information about tablespaces that are created at database creation
- *Oracle Database SQL Language Reference* for more information about the syntax and semantics of the `CREATE TABLESPACE`, `CREATE TEMPORARY TABLESPACE`, `ALTER TABLESPACE`, and `ALTER DATABASE` statements.
- "[Specifying Database Block Sizes](#)" for information about initialization parameters necessary to create tablespaces with nonstandard block sizes

13.2.2 Locally Managed Tablespaces

A locally managed tablespace uses a bitmap stored in each data file to manage the extents.

- [About Locally Managed Tablespaces](#)
Locally managed tablespaces track all extent information in the tablespace itself by using bitmaps.
- [Creating a Locally Managed Tablespace](#)
Create a locally managed tablespace by specifying `LOCAL` in the `EXTENT MANAGEMENT` clause of the `CREATE TABLESPACE` statement.
- [Specifying Segment Space Management in Locally Managed Tablespaces](#)
In a locally managed tablespace, there are two methods that Oracle Database can use to manage segment space: automatic and manual.

13.2.2.1 About Locally Managed Tablespaces

Locally managed tablespaces track all extent information in the tablespace itself by using bitmaps.

Locally managed tablespaces provide the following benefits:

- Fast, concurrent space operations. Space allocations and deallocations modify locally managed resources (bitmaps stored in header files).
- Enhanced performance
- Readable standby databases are allowed, because locally managed temporary tablespaces do not generate any undo or redo.
- Space allocation is simplified, because when the `AUTOALLOCATE` clause is specified, the database automatically selects the appropriate extent size.
- User reliance on the data dictionary is reduced, because the necessary information is stored in file headers and bitmap blocks.

- Coalescing free extents is unnecessary for locally managed tablespaces.

All tablespaces, including the SYSTEM tablespace, can be locally managed.

The DBMS_SPACE_ADMIN package provides maintenance procedures for locally managed tablespaces.

 **See Also:**

- "[Creating a Locally Managed SYSTEM Tablespace](#)", "[Migrating the SYSTEM Tablespace to a Locally Managed Tablespace](#)", and "[Diagnosing and Repairing Locally Managed Tablespace Problems](#)"
- "[Bigfile Tablespaces](#)" for information about creating another type of locally managed tablespace that contains only a single data file or temp file.
- [Oracle Database PL/SQL Packages and Types Reference](#) for information on the DBMS_SPACE_ADMIN package

13.2.2.2 Creating a Locally Managed Tablespace

Create a locally managed tablespace by specifying LOCAL in the EXTENT MANAGEMENT clause of the CREATE TABLESPACE statement.

This is the default for new permanent tablespaces, but you must specify the EXTENT MANAGEMENT LOCAL clause to specify either the AUTOALLOCATE clause or the UNIFORM clause. You can have the database manage extents for you automatically with the AUTOALLOCATE clause (the default), or you can specify that the tablespace is managed with uniform extents of a specific size (UNIFORM).

If you expect the tablespace to contain objects of varying sizes requiring many extents with different extent sizes, then AUTOALLOCATE is the best choice. AUTOALLOCATE is also a good choice if it is not important for you to have a lot of control over space allocation and deallocation, because it simplifies tablespace management. Some space may be wasted with this setting, but the benefit of having Oracle Database manage your space most likely outweighs this drawback.

If you want exact control over unused space, and you can predict exactly the space to be allocated for an object or objects and the number and size of extents, then UNIFORM is a good choice. This setting ensures that you will never have unusable space in your tablespace.

When you do not explicitly specify the type of extent management, Oracle Database determines extent management as follows:

- If the CREATE TABLESPACE statement omits the DEFAULT storage clause, then the database creates a locally managed autoallocated tablespace.
- If the CREATE TABLESPACE statement includes a DEFAULT storage clause, then the database considers the following:
 - If you specified the MINIMUM EXTENT clause, the database evaluates whether the values of MINIMUM EXTENT, INITIAL, and NEXT are equal and the value of PCTINCREASE is 0. If so, the database creates a locally managed uniform

tablespace with extent size = INITIAL. If the MINIMUM EXTENT, INITIAL, and NEXT parameters are not equal, or if PCTINCREASE is not 0, then the database ignores any extent storage parameters you may specify and creates a locally managed, autoallocated tablespace.

- If you did not specify MINIMUM EXTENT clause, then the database evaluates only whether the storage values of INITIAL and NEXT are equal and PCTINCREASE is 0. If so, the tablespace is locally managed and uniform. Otherwise, the tablespace is locally managed and autoallocated.

For example, the following statement creates a locally managed tablespace named lmtbsb and specifies AUTOALLOCATE:

```
CREATE TABLESPACE lmtbsb DATAFILE '/u02/oracle/data/lmtbsb01.dbf' SIZE 50M  
EXTENT MANAGEMENT LOCAL AUTOALLOCATE;
```

AUTOALLOCATE causes the tablespace to be system managed with a minimum extent size of 64K.

The alternative to AUTOALLOCATE is UNIFORM, which specifies that the tablespace is managed with extents of uniform size. You can specify that size in the SIZE clause of UNIFORM. If you omit SIZE, then the default size is 1M.

The following example creates a tablespace with uniform 128K extents. (In a database with 2K blocks, each extent would be equivalent to 64 database blocks). Each 128K extent is represented by a bit in the extent bitmap for this file.

```
CREATE TABLESPACE lmtbsb DATAFILE '/u02/oracle/data/lmtbsb01.dbf' SIZE 50M  
EXTENT MANAGEMENT LOCAL UNIFORM SIZE 128K;
```

You cannot specify the DEFAULT storage clause, MINIMUM EXTENT, or TEMPORARY when you explicitly specify EXTENT MANAGEMENT LOCAL. To create a temporary locally managed tablespace, use the CREATE TEMPORARY TABLESPACE statement.

Note:

When you allocate a data file for a locally managed tablespace, you should allow space for metadata used for space management (the extent bitmap or space header segment) which are part of user space. For example, if you specify the UNIFORM clause in the extent management clause but you omit the SIZE parameter, then the default extent size is 1MB. In that case, the size specified for the data file must be larger (at least one block plus space for the bitmap) than 1MB.

13.2.2.3 Specifying Segment Space Management in Locally Managed Tablespaces

In a locally managed tablespace, there are two methods that Oracle Database can use to manage segment space: automatic and manual.

Manual segment space management uses linked lists called "freelists" to manage free space in the segment, while automatic segment space management uses bitmaps. Automatic segment space management is the more efficient method, and is the default for all new permanent, locally managed tablespaces.

Automatic segment space management delivers better space utilization than manual segment space management. It is also self-tuning, in that it scales with increasing number of users or instances. In an Oracle Real Application Clusters environment, automatic segment space management allows for a dynamic affinity of space to instances. In addition, for many standard workloads, application performance with automatic segment space management is better than the performance of a well-tuned application using manual segment space management.

Although automatic segment space management is the default for all new permanent, locally managed tablespaces, you can explicitly enable it with the SEGMENT SPACE MANAGEMENT AUTO clause.

For example, the following statement creates tablespace lmtbsb with automatic segment space management:

```
CREATE TABLESPACE lmtbsb DATAFILE '/u02/oracle/data/lmtbsb01.dbf' SIZE 50M
  EXTENT MANAGEMENT LOCAL
  SEGMENT SPACE MANAGEMENT AUTO;
```

The SEGMENT SPACE MANAGEMENT MANUAL clause disables automatic segment space management.

The segment space management that you specify at tablespace creation time applies to all segments subsequently created in the tablespace. You cannot change the segment space management mode of a tablespace.

 **Note:**

- If you set extent management to LOCAL UNIFORM, then you must ensure that each extent contains at least 5 database blocks.
- If you set extent management to LOCAL AUTOALLOCATE, and if the database block size is 16K or greater, then Oracle manages segment space by creating extents with a minimum size of 5 blocks rounded up to 64K.
- You cannot specify automatic segment space management for the SYSTEM tablespace.

Locally managed tablespaces using automatic segment space management can be created as single-file or bigfile tablespaces, as described in "[Bigfile Tablespaces](#)".

13.2.3 Bigfile Tablespaces

Bigfile tablespaces can increase the storage capacity of a database and reduce the burden of managing many data files and temp files.

- [About Bigfile Tablespaces](#)

A **bigfile tablespace** is a tablespace with a single, but potentially very large (up to 4G blocks) data file. Traditional smallfile tablespaces, in contrast, can contain multiple data files, but the files cannot be as large.

- [Creating a Bigfile Tablespace](#)

To create a bigfile tablespace, specify the BIGFILE keyword of the CREATE TABLESPACE statement (CREATE BIGFILE TABLESPACE ...).

- [Identifying a Bigfile Tablespace](#)

You can query a set of data dictionary views for information about bigfile tablespaces.

13.2.3.1 About Bigfile Tablespaces

A **bigfile tablespace** is a tablespace with a single, but potentially very large (up to 4G blocks) data file. Traditional smallfile tablespaces, in contrast, can contain multiple data files, but the files cannot be as large.

The benefits of bigfile tablespaces are the following:

- A bigfile tablespace with 8K blocks can contain a 32 terabyte data file. A bigfile tablespace with 32K blocks can contain a 128 terabyte data file. The maximum number of data files in an Oracle Database is limited (usually to 64K files). Therefore, bigfile tablespaces can significantly enhance the storage capacity of an Oracle Database.
- Bigfile tablespaces can reduce the number of data files needed for a database. An additional benefit is that the `DB_FILES` initialization parameter and `MAXDATAFILES` parameter of the `CREATE DATABASE` and `CREATE CONTROLFILE` statements can be adjusted to reduce the amount of SGA space required for data file information and the size of the control file.
- Bigfile tablespaces simplify database management by providing data file transparency. SQL syntax for the `ALTER TABLESPACE` statement lets you perform operations on tablespaces, rather than the underlying individual data files.

Bigfile tablespaces are supported only for locally managed tablespaces with automatic segment space management, with three exceptions: locally managed undo tablespaces, temporary tablespaces, and the `SYSTEM` tablespace.

 **Note:**

- Bigfile tablespaces are intended to be used with Automatic Storage Management (Oracle ASM) or other logical volume managers that supports striping or RAID, and dynamically extensible logical volumes.
- Avoid creating bigfile tablespaces on a system that does not support striping because of negative implications for parallel query execution and RMAN backup parallelization.
- Using bigfile tablespaces on platforms that do not support large file sizes is not recommended and can limit tablespace capacity. See your operating system specific documentation for information about maximum supported file sizes.

13.2.3.2 Creating a Bigfile Tablespace

To create a bigfile tablespace, specify the `BIGFILE` keyword of the `CREATE TABLESPACE` statement (`CREATE BIGFILE TABLESPACE ...`).

Oracle Database automatically creates a locally managed tablespace with automatic segment space management. You can, but need not, specify `EXTENT MANAGEMENT LOCAL` and `SEGMENT SPACE MANAGEMENT AUTO` in this statement. However, the database

returns an error if you specify EXTENT MANAGEMENT DICTIONARY or SEGMENT SPACE MANAGEMENT MANUAL. The remaining syntax of the statement is the same as for the CREATE TABLESPACE statement, but you can only specify one data file. For example:

```
CREATE BIGFILE TABLESPACE bigtbs
    DATAFILE '/u02/oracle/data/bigtbs01.dbf' SIZE 50G
...
```

You can specify SIZE in kilobytes (K), megabytes (M), gigabytes (G), or terabytes (T).

If the default tablespace type was set to BIGFILE at database creation, you need not specify the keyword BIGFILE in the CREATE TABLESPACE statement. A bigfile tablespace is created by default.

If the default tablespace type was set to BIGFILE at database creation, but you want to create a traditional (smallfile) tablespace, then specify a CREATE SMALLFILE TABLESPACE statement to override the default tablespace type for the tablespace that you are creating.

See Also:

"[Supporting Bigfile Tablespaces During Database Creation](#)"

13.2.3.3 Identifying a Bigfile Tablespace

You can query a set of data dictionary views for information about bigfile tablespaces.

The following views contain a BIGFILE column that identifies a tablespace as a bigfile tablespace:

- DBA_TABLESPACES
- USER_TABLESPACES
- V\$TABLESPACE

Query these views for information about bigfile tablespaces.

You can also identify a bigfile tablespace by the relative file number of its single data file. That number is 1024 on most platforms, but 4096 on OS/390.

13.2.4 Tablespaces with Default Compression Attributes

When you create a tablespace, you can specify that all tables and indexes, or their partitions, created in a tablespace are compressed by default.

- [About Tablespaces with Default Compression Attributes](#)

When you create a tablespace, you can specify the default compression of data for all tables and indexes created in the tablespace. The default compression level also applies to the partitions that comprise the tablespace. Compressing this data can reduce disk use.

- [Creating Tablespaces with Default Compression Attributes](#)

When you create a tablespace, you can specify the type of table compression using the DEFAULT keyword, followed by the table compression clause including

the compression type. You can also specify the type of index compression using the `DEFAULT` keyword, followed by index compression clause and the index compression type.

13.2.4.1 About Tablespaces with Default Compression Attributes

When you create a tablespace, you can specify the default compression of data for all tables and indexes created in the tablespace. The default compression level also applies to the partitions that comprise the tablespace. Compressing this data can reduce disk use.

13.2.4.2 Creating Tablespaces with Default Compression Attributes

When you create a tablespace, you can specify the type of table compression using the `DEFAULT` keyword, followed by the table compression clause including the compression type. You can also specify the type of index compression using the `DEFAULT` keyword, followed by index compression clause and the index compression type.

The following statement indicates that all tables and partitions created in the tablespace are to use advanced row compression, unless otherwise specified:

```
CREATE TABLESPACE ... DEFAULT ROW STORE COMPRESS ADVANCED ... ;
```

You can override the default tablespace compression specification when you create a table or partition in that tablespace.

The following statement indicates that all indexes created in the tablespace are to use high level advanced index compression, unless otherwise specified:

```
CREATE TABLESPACE ... DEFAULT INDEX COMPRESS ADVANCED HIGH ... ;
```

You can override the default tablespace compression specification when you create an index in that tablespace.

See Also:

- "[Consider Using Table Compression](#)" for information about the various types of table compression
- "[Creating an Index Using Advanced Index Compression](#)" for information about the various types of index compression
- *Oracle Database SQL Language Reference* for the exact syntax to use when creating a tablespace with a default compression type

13.2.5 Encrypted Tablespaces

You can encrypt any permanent tablespace to protect sensitive data.

- [About Encrypted Tablespaces](#)

Encrypted tablespaces primarily protect your data from unauthorized access by means other than through the database. For example, when encrypted

tablespaces are written to backup media for travel from one Oracle database to another or for travel to an off-site facility for storage, they remain encrypted.

- [Creating Encrypted Tablespaces](#)
You can create encrypted tablespaces to protect your data from unauthorized access.
- [Viewing Information About Encrypted Tablespaces](#)
You can query the DBA_TABLESPACES and USER_TABLESPACES data dictionary views for information about encrypted tablespaces.

13.2.5.1 About Encrypted Tablespaces

Encrypted tablespaces primarily protect your data from unauthorized access by means other than through the database. For example, when encrypted tablespaces are written to backup media for travel from one Oracle database to another or for travel to an off-site facility for storage, they remain encrypted.

Also, encrypted tablespaces protect data from users who try to circumvent the security features of the database and access database files directly through the operating system file system. Tablespace encryption is completely transparent to your applications, so no application modification is necessary.

Tablespace encryption does not address all security issues. It does not, for example, provide access control from within the database. Any user who is granted privileges on objects stored in an encrypted tablespace can access those objects without providing any kind of additional password or key.

When you encrypt a tablespace, all tablespace blocks are encrypted. All segment types are supported for encryption, including tables, clusters, indexes, LOBs (BASICFILE and SECUREFILE), table and index partitions, and so on.

 **Note:**

There is no need to use LOB encryption on SECUREFILE LOBs stored in an encrypted tablespace.

To maximize security, data from an encrypted tablespace is automatically encrypted when written to the undo tablespace, to the redo logs, and to any temporary tablespace. However, starting with Oracle Database 12c Release 2 (12.2.0.1), you can optionally encrypt undo tablespaces and temporary tablespaces.

For partitioned tables and indexes that have different partitions in different tablespaces, it is permitted to use both encrypted and non-encrypted tablespaces in the same table or index.

Tablespace encryption uses the Transparent Data Encryption feature of Oracle Database, which requires that you create a keystore to store the master encryption key for the database. The keystore must be open before you can create the encrypted tablespace and before you can store or retrieve encrypted data. When you open the keystore, it is available to all session, and it remains open until you explicitly close it or until the database is shut down.

Transparent Data Encryption supports industry-standard encryption algorithms, including the following types of encryption algorithms Advanced Encryption Standard (AES) and Triple Data Encryption Standard (3DES) algorithms:

- Advanced Encryption Standard (AES)
- ARIA
- GHOST
- SEED
- Triple Data Encryption Standard (3DES)

See *Oracle Database Advanced Security Guide* for detailed information about the supported encryption algorithms.

The encryption key length is implied by the algorithm name. For example, the AES128 algorithm uses 128-bit keys. You specify the algorithm to use when you create the tablespace, and different tablespaces can use different algorithms. Although longer key lengths theoretically provide greater security, there is a trade-off in CPU overhead. If you do not specify the algorithm in your `CREATE TABLESPACE` statement, then AES128 is the default. There is no disk space overhead for encrypting a tablespace.

After an encrypted table is created, you can use an `ALTER TABLESPACE` statement to decrypt it or change its key. You can also use an `ALTER TABLESPACE` statement to encrypt a tablespace that is not encrypted.

Restrictions

The following are restrictions for encrypted tablespaces:

- Encrypted tablespaces are subject to restrictions when they are transported to another database. See "[General Limitations on Transporting Data](#)".
- When recovering a database with encrypted tablespaces (for example after a `SHUTDOWN ABORT` or a catastrophic error that brings down the database instance), you must open the keystore after database mount and before database open, so that the recovery process can decrypt data blocks and redo.

In addition, see *Oracle Database Advanced Security Guide* for general restrictions for Transparent Data Encryption.

See Also:

- *Oracle Database 2 Day + Security Guide* for more information about Transparent Data Encryption and for instructions about creating and opening keystores
- "[Consider Encrypting Columns That Contain Sensitive Data](#)" for an alternative to encrypting an entire tablespace
- *Oracle Real Application Clusters Administration and Deployment Guide* for information on using a keystore in an Oracle Real Application Clusters environment
- *Oracle Database SQL Language Reference* for information about the `CREATE TABLESPACE` statement

13.2.5.2 Creating Encrypted Tablespaces

You can create encrypted tablespaces to protect your data from unauthorized access.

To encrypt a tablespace, you must open the database with the COMPATIBLE initialization parameter set to 11.1.0 or higher. Any user who can create a tablespace can create an encrypted tablespace.

To create an encrypted tablespace:

- Run a CREATE TABLESPACE statement with an ENCRYPTION clause.

Examples

The following statement creates an encrypted tablespace with the default encryption algorithm:

```
CREATE TABLESPACE securespace
DATAFILE '/u01/app/oracle/oradata/orcl/secure01.dbf' SIZE 100M
ENCRYPTION ENCRYPT;
```

The following statement creates the same tablespace with the AES256 algorithm:

```
CREATE TABLESPACE securespace
DATAFILE '/u01/app/oracle/oradata/orcl/secure01.dbf' SIZE 100M
ENCRYPTION USING 'AES256' ENCRYPT;
```

See Also:

Oracle Database Advanced Security Guide

13.2.5.3 Viewing Information About Encrypted Tablespaces

You can query the DBA_TABLESPACES and USER_TABLESPACES data dictionary views for information about encrypted tablespaces.

The DBA_TABLESPACES and USER_TABLESPACES data dictionary views include a column named ENCRYPTED. This column contains YES for encrypted tablespaces.

The view V\$ENCRYPTED_TABLESPACES lists all currently encrypted tablespaces. The following query displays the name and encryption algorithm of encrypted tablespaces:

```
SELECT t.name, e.encryptionalg algorithm
FROM v$tablespace t, v$encrypted_tablespaces e
WHERE t.ts# = e.ts#;
```

NAME	ALGORITHM
SECURESPACE	AES256

Note:

You can convert an existing tablespace to an encrypted tablespace.

 **See Also:**

Oracle Database Advanced Security Guide for information about convert an existing tablespace to an encrypted tablespace

13.2.6 Temporary Tablespaces

Temporary tablespaces can improve the concurrency of multiple sort operations that do not fit in memory. These tablespaces also improve the efficiency of space management operations during sorts.

- [About Temporary Tablespaces](#)

A **temporary tablespace** contains transient data that persists only for the duration of the session. Temporary tablespaces can improve the concurrency of multiple sort operations that do not fit in memory and can improve the efficiency of space management operations during sorts.

- [Creating a Locally Managed Temporary Tablespace](#)

Because space management is much simpler and more efficient in locally managed tablespaces, they are ideally suited for temporary tablespaces.

- [Creating a Bigfile Temporary Tablespace](#)

Just as for regular tablespaces, you can create single-file (bigfile) temporary tablespaces.

- [Viewing Space Usage for Temporary Tablespaces](#)

The `DBA_TEMP_FREE_SPACE` dictionary view contains information about space usage for each temporary tablespace.

13.2.6.1 About Temporary Tablespaces

A **temporary tablespace** contains transient data that persists only for the duration of the session. Temporary tablespaces can improve the concurrency of multiple sort operations that do not fit in memory and can improve the efficiency of space management operations during sorts.

Temporary tablespaces are used to store the following:

- Intermediate sort results
- Temporary tables and temporary indexes
- Temporary LOBs
- Temporary B-trees

Within a temporary tablespace, all sort operations for a particular instance share a single *sort segment*, and sort segments exist for every instance that performs sort operations that require temporary space. A sort segment is created by the first statement after startup that uses the temporary tablespace for sorting, and is released only at shutdown.

By default, a single temporary tablespace named `TEMP` is created for each new Oracle Database installation. You can create additional temporary tablespaces with the `CREATE TABLESPACE` statement. You can assign a temporary tablespace to each

database user with the CREATE USER or ALTER USER statement. A single temporary tablespace can be shared by multiple users.

You cannot explicitly create objects in a temporary tablespace.

Note:

The exception to the preceding statement is a temporary table. When you create a temporary table, its rows are stored in your default temporary tablespace, unless you create the table in a new temporary tablespace. See "[Creating a Temporary Table](#)" for more information.

Starting with Oracle Database 12c Release 2 (12.2), local temporary tablespaces are available. A local temporary tablespace stores separate, non-shared temp files for every database instance. A local temporary tablespace is used only for spilling temporary results of SQL statements, such as queries that involve sorts, hash aggregations, and joins. These results are only accessible within an instance. In contrast, a shared temporary tablespace resides on a shared disk and is available to all instances. To create a local temporary tablespace, use a CREATE LOCAL TEMPORARY TABLESPACE statement. Shared temporary tablespaces were available in prior releases of Oracle Database and were called "temporary tablespaces." In this *Oracle Database Administrator's Guide*, the term "temporary tablespace" refers to a shared temporary tablespace unless specified otherwise.

Default Temporary Tablespace

Users who are not explicitly assigned a temporary tablespace use the database default temporary tablespace, which for new installations is TEMP. You can change the default temporary tablespace for the database with the following command:

```
ALTER DATABASE DEFAULT TEMPORARY TABLESPACE tablespace_name;
```

To determine the current default temporary tablespace for the database, run the following query:

```
SELECT PROPERTY_NAME, PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE
  PROPERTY_NAME='DEFAULT_TEMP_TABLESPACE';

PROPERTY_NAME          PROPERTY_VALUE
-----                  -----
DEFAULT_TEMP_TABLESPACE      TEMP
```

Space Allocation in a Temporary Tablespace

You can view the allocation and deallocation of space in a temporary tablespace sort segment using the V\$SORT_SEGMENT view. The V\$TEMPSEG_USAGE view identifies the current sort users in those segments.

When a sort operation that uses temporary space completes, allocated extents in the sort segment are not deallocated; they are just marked as free and available for reuse. The DBA_TEMP_FREE_SPACE view displays the total allocated and free space in each temporary tablespace. See "[Viewing Space Usage for Temporary Tablespaces](#)" for more information. You can manually shrink a locally managed temporary tablespace that has a large amount of unused space. See "[Shrinking a Locally Managed Temporary Tablespace](#)" for details.

 See Also:

- *Oracle Database Performance Tuning Guide* for a discussion on tuning sorts
- *Oracle Real Application Clusters Administration and Deployment Guide* for more information about local temporary tablespace

13.2.6.2 Creating a Locally Managed Temporary Tablespace

Because space management is much simpler and more efficient in locally managed tablespaces, they are ideally suited for temporary tablespaces.

Locally managed temporary tablespaces use **temp files**, which do not modify data outside of the temporary tablespace or generate any redo for temporary tablespace data. Because of this, they enable you to perform on-disk sorting operations in a read-only or standby database.

You also use different views for viewing information about temp files than you would for data files. The V\$TEMPFILE and DBA_TEMP_FILES views are analogous to the V\$DATAFILE and DBA_DATA_FILES views.

To create a locally managed temporary tablespace, you use the CREATE TEMPORARY TABLESPACE statement, which requires that you have the CREATE TABLESPACE system privilege.

The following statement creates a temporary tablespace in which each extent is 16M. Each 16M extent (which is the equivalent of 8000 blocks when the standard block size is 2K) is represented by a bit in the bitmap for the file.

```
CREATE TEMPORARY TABLESPACE lmtemp TEMPFILE '/u02/oracle/data/lmtemp01.dbf'  
SIZE 20M REUSE  
EXTENT MANAGEMENT LOCAL UNIFORM SIZE 16M;
```

The extent management clause is optional for temporary tablespaces because all temporary tablespaces are created with locally managed extents of a uniform size. If an extent size is specified in the EXTENT SIZE clause, then it is used. If it is not specified, then, Oracle Database uses the tablespace size and file sizes to determine the default extent size.

 Note:

On some operating systems, the database does not allocate space for the temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. See your operating system documentation to determine whether the database allocates temp file space in this way on your system.

13.2.6.3 Creating a Bigfile Temporary Tablespace

Just as for regular tablespaces, you can create single-file (bigfile) temporary tablespaces.

To create a bigfile temporary tablespace:

- Run the `CREATE BIGFILE TEMPORARY TABLESPACE` statement to create a single-temp file tablespace.

See the sections "[Creating a Bigfile Tablespace](#)" and "[Altering a Bigfile Tablespace](#)" for information about bigfile tablespaces, but consider that you are creating temporary tablespaces that use temp files instead of data files.

13.2.6.4 Viewing Space Usage for Temporary Tablespaces

The `DBA_TEMP_FREE_SPACE` dictionary view contains information about space usage for each temporary tablespace.

The information includes the space allocated and the free space. You can query this view for these statistics using the following statement:

```
SELECT * from DBA_TEMP_FREE_SPACE;
```

TABLESPACE_NAME	TABLESPACE_SIZE	ALLOCATED_SPACE	FREE_SPACE
TEMP	250609664	250609664	249561088

13.2.7 Temporary Tablespace Groups

A temporary tablespace group is a tablespace group that is assigned as the default temporary tablespace for the database.

- [Multiple Temporary Tablespaces: Using Tablespace Groups](#)
A **tablespace group** enables a user to consume temporary space from multiple tablespaces. Using a tablespace group, rather than a single temporary tablespace, can alleviate problems caused where one tablespace is inadequate to hold the results of a sort, particularly on a table that has many partitions. A tablespace group enables parallel execution servers in a single parallel operation to use multiple temporary tablespaces.
- [Creating a Tablespace Group](#)
You create a tablespace group implicitly when you include the `TABLESPACE GROUP` clause in the `CREATE TEMPORARY TABLESPACE` or `ALTER TABLESPACE` statement and the specified tablespace group does not currently exist.

- **Changing Members of a Tablespace Group**
You can add a tablespace to an existing tablespace group by specifying the existing group name in the TABLESPACE GROUP clause of the CREATE TEMPORARY TABLESPACE or ALTER TABLESPACE statement.
- **Assigning a Tablespace Group as the Default Temporary Tablespace**
Use the ALTER DATABASE . . . DEFAULT TEMPORARY TABLESPACE statement to assign a tablespace group as the default temporary tablespace for the database.

13.2.7.1 Multiple Temporary Tablespaces: Using Tablespace Groups

A **tablespace group** enables a user to consume temporary space from multiple tablespaces. Using a tablespace group, rather than a single temporary tablespace, can alleviate problems caused where one tablespace is inadequate to hold the results of a sort, particularly on a table that has many partitions. A tablespace group enables parallel execution servers in a single parallel operation to use multiple temporary tablespaces.

A tablespace group has the following characteristics:

- It contains at least one tablespace. There is no explicit limit on the maximum number of tablespaces that are contained in a group.
- It shares the namespace of tablespaces, so its name cannot be the same as any tablespace.
- You can specify a tablespace group name wherever a tablespace name would appear when you assign a default temporary tablespace for the database or a temporary tablespace for a user.

You do not explicitly create a tablespace group. Rather, it is created implicitly when you assign the first temporary tablespace to the group. The group is deleted when the last temporary tablespace it contains is removed from it.

The view DBA_TABLESPACE_GROUPS lists tablespace groups and their member tablespaces.

See Also:

Oracle Database Security Guide for more information about assigning a temporary tablespace or tablespace group to a user

13.2.7.2 Creating a Tablespace Group

You create a tablespace group implicitly when you include the TABLESPACE GROUP clause in the CREATE TEMPORARY TABLESPACE or ALTER TABLESPACE statement and the specified tablespace group does not currently exist.

For example, if neither group1 nor group2 exists, then the following statements create those groups, each of which has only the specified tablespace as a member:

```
CREATE TEMPORARY TABLESPACE lmtemp2 TEMPFILE '/u02/oracle/data/lmtemp201.dbf'  
      SIZE 50M  
      TABLESPACE GROUP group1;
```

```
ALTER TABLESPACE lmtemp TABLESPACE GROUP group2;
```

13.2.7.3 Changing Members of a Tablespace Group

You can add a tablespace to an existing tablespace group by specifying the existing group name in the TABLESPACE GROUP clause of the CREATE TEMPORARY TABLESPACE or ALTER TABLESPACE statement.

For example, the following statement adds a tablespace to an existing group. It creates and adds tablespace lmtemp3 to group1, so that group1 contains tablespaces lmtemp2 and lmtemp3.

```
CREATE TEMPORARY TABLESPACE lmtemp3 TEMPFILE '/u02/oracle/data/lmtemp301.dbf'  
      SIZE 25M  
      TABLESPACE GROUP group1;
```

The following statement also adds a tablespace to an existing group, but in this case because tablespace lmtemp2 already belongs to group1, it is in effect moved from group1 to group2:

```
ALTER TABLESPACE lmtemp2 TABLESPACE GROUP group2;
```

Now group2 contains both lmtemp and lmtemp2, while group1 consists of only lmtemp3.

You can remove a tablespace from a group as shown in the following statement:

```
ALTER TABLESPACE lmtemp3 TABLESPACE GROUP '';
```

Tablespace lmtemp3 no longer belongs to any group. Further, since there are no longer any members of group1, this results in the implicit deletion of group1.

13.2.7.4 Assigning a Tablespace Group as the Default Temporary Tablespace

Use the ALTER DATABASE...DEFAULT TEMPORARY TABLESPACE statement to assign a tablespace group as the default temporary tablespace for the database.

For example:

```
ALTER DATABASE DEFAULT TEMPORARY TABLESPACE group2;
```

Any user who has not explicitly been assigned a temporary tablespace will now use tablespaces lmtemp and lmtemp2.

If a tablespace group is specified as the default temporary tablespace, you cannot drop any of its member tablespaces. You must first remove the tablespace from the tablespace group. Likewise, you cannot drop a single temporary tablespace as long as it is the default temporary tablespace.

13.3 Consider Storing Tablespaces in the In-Memory Column Store

You can enable a tablespace for the In-Memory Column Store during tablespace creation or by altering a tablespace. When this enables a tablespace for the In-Memory Column Store, all tables in the tablespace are enabled for the In-Memory Column Store by default.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

The In-Memory Column Store is an optional portion of the system global area (SGA) that stores copies of tables, table partitions, and other database objects that is optimized for rapid scans. In the In-Memory Column Store, table data is stored by column rather than row in the SGA.

 **See Also:**

["Improving Query Performance with the In-Memory Column Store"](#)

13.4 Specifying Nonstandard Block Sizes for Tablespaces

You can create tablespaces with block sizes different from the standard database block size, which is specified by the `DB_BLOCK_SIZE` initialization parameter. This feature lets you transport tablespaces with unlike block sizes between databases.

To create a tablespace with a block size different from the database standard block size:

- Use the `BLOCKSIZE` clause of the `CREATE TABLESPACE` statement.

In order for the `BLOCKSIZE` clause to succeed, you must have already set the `DB_CACHE_SIZE` and at least one `DB_nK_CACHE_SIZE` initialization parameter. Further, and the integer you specify in the `BLOCKSIZE` clause must correspond with the setting of one `DB_nK_CACHE_SIZE` parameter setting. Although redundant, specifying a `BLOCKSIZE` equal to the standard block size, as specified by the `DB_BLOCK_SIZE` initialization parameter, is allowed.

The following statement creates tablespace `lmtbsb`, but specifies a block size that differs from the standard database block size (as specified by the `DB_BLOCK_SIZE` initialization parameter):

```
CREATE TABLESPACE lmtbsb DATAFILE '/u02/oracle/data/lmtbsb01.dbf' SIZE 50M  
EXTENT MANAGEMENT LOCAL UNIFORM SIZE 128K  
BLOCKSIZE 8K;
```

 **See Also:**

- "[Specifying Database Block Sizes](#)"
- "[Setting the Buffer Cache Initialization Parameters](#)" for information about the DB_CACHE_SIZE and DB_nK_CACHE_SIZE parameter settings
- "[Transporting Tablespaces Between Databases](#)"

13.5 Controlling the Writing of Redo Records

For some database operations, you can control whether the database generates redo records.

Without redo, no media recovery is possible. However, suppressing redo generation can improve performance, and may be appropriate for easily recoverable operations. An example of such an operation is a CREATE TABLE...AS SELECT statement, which can be repeated in case of database or instance failure.

To suppress redo when these operations are performed for objects within the tablespace:

- Specify the NOLOGGING clause in the CREATE TABLESPACE statement.

If you do not include this clause, or if you specify LOGGING instead, then the database generates redo when changes are made to objects in the tablespace. Redo is never generated for temporary segments or in temporary tablespaces, regardless of the logging attribute.

The logging attribute specified at the tablespace level is the default attribute for objects created within the tablespace. You can override this default logging attribute by specifying LOGGING or NOLOGGING at the schema object level--for example, in a CREATE TABLE statement.

If you have a standby database, NOLOGGING mode causes problems with the availability and accuracy of the standby database. To overcome this problem, you can specify FORCE LOGGING mode. When you include the FORCE LOGGING clause in the CREATE TABLESPACE statement, you force the generation of redo records for all operations that make changes to objects in a tablespace. This overrides any specification made at the object level.

If you transport a tablespace that is in FORCE LOGGING mode to another database, the new tablespace will not maintain the FORCE LOGGING mode.

 See Also:

- *Oracle Database SQL Language Reference* for information about operations that can be done in NOLOGGING mode
- "[Specifying FORCE LOGGING Mode](#)" for more information about FORCE LOGGING mode and for information about the effects of the FORCE LOGGING clause used with the CREATE DATABASE statement

13.6 Altering Tablespace Availability

You can take an online tablespace offline so that it is temporarily unavailable for general use. The rest of the database remains open and available for users to access data. Conversely, you can bring an offline tablespace online to make the schema objects within the tablespace available to database users. The database must be open to alter the availability of a tablespace.

To alter the availability of a tablespace, use the ALTER TABLESPACE statement. You must have the ALTER TABLESPACE or MANAGE TABLESPACE system privilege.

- [Taking Tablespaces Offline](#)

Taking a tablespace offline makes it unavailable for normal access.

- [Bringing Tablespaces Online](#)

You can bring any tablespace in an Oracle Database online whenever the database is open. A tablespace is normally online so that the data contained within it is available to database users.

 See Also:

- ["Altering Data File Availability"](#) for information about altering the availability of individual data files within a tablespace

13.6.1 Taking Tablespaces Offline

Taking a tablespace offline makes it unavailable for normal access.

You may want to take a tablespace offline for any of the following reasons:

- To make a portion of the database unavailable while allowing normal access to the remainder of the database
- To perform an offline tablespace backup (even though a tablespace can be backed up while online and in use)
- To make an application and its group of tables temporarily unavailable while updating or maintaining the application
- To rename or relocate tablespace data files

See "[Renaming and Relocating Data Files](#)" for details.

To take a tablespace offline:

- Run an `ALTER TABLESPACE` statement with the `OFFLINE` clause.

When a tablespace is taken offline, the database takes all the associated files offline.

You cannot take the following tablespaces offline:

- `SYSTEM`
- The undo tablespace
- Temporary tablespaces

Before taking a tablespace offline, consider altering the tablespace allocation of any users who have been assigned the tablespace as a default tablespace. Doing so is advisable because those users will not be able to access objects in the tablespace while it is offline.

You can specify any of the following parameters as part of the `ALTER TABLESPACE...OFFLINE` statement:

Clause	Description
<code>NORMAL</code>	A tablespace can be taken offline normally if no error conditions exist for any of the data files of the tablespace. No data file in the tablespace can be currently offline as the result of a write error. When you specify <code>OFFLINE NORMAL</code> , the database takes a checkpoint for all data files of the tablespace as it takes them offline. <code>NORMAL</code> is the default.
<code>TEMPORARY</code>	A tablespace can be taken offline temporarily, even if there are error conditions for one or more files of the tablespace. When you specify <code>OFFLINE TEMPORARY</code> , the database takes offline the data files that are not already offline, checkpointing them as it does so. If no files are offline, but you use the temporary clause, media recovery is not required to bring the tablespace back online. However, if one or more files of the tablespace are offline because of write errors, and you take the tablespace offline temporarily, the tablespace requires recovery before you can bring it back online.
<code>IMMEDIATE</code>	A tablespace can be taken offline immediately, without the database taking a checkpoint on any of the data files. When you specify <code>OFFLINE IMMEDIATE</code> , media recovery for the tablespace is required before the tablespace can be brought online. You cannot take a tablespace offline immediately if the database is running in <code>NOARCHIVELOG</code> mode.

 **Note:**

If you must take a tablespace offline, use the `NORMAL` clause (the default) if possible. This setting guarantees that the tablespace will not require recovery to come back online, even if after incomplete recovery you reset the redo log sequence using an `ALTER DATABASE OPEN RESETLOGS` statement.

Specify `TEMPORARY` only when you cannot take the tablespace offline normally. In this case, only the files taken offline because of errors need to be recovered before the

tablespace can be brought online. Specify `IMMEDIATE` only after trying both the normal and temporary settings.

The following example takes the `users` tablespace offline normally:

```
ALTER TABLESPACE users OFFLINE NORMAL;
```

13.6.2 Bringing Tablespaces Online

You can bring any tablespace in an Oracle Database online whenever the database is open. A tablespace is normally online so that the data contained within it is available to database users.

To bring a tablespace online:

- Run an `ALTER TABLESPACE` statement with the `ONLINE` clause.

If a tablespace to be brought online was not taken offline "cleanly" (that is, using the `NORMAL` clause of the `ALTER TABLESPACE OFFLINE` statement), you must first perform media recovery on the tablespace before bringing it online. Otherwise, the database returns an error and the tablespace remains offline.

For example, the following statement brings the `users` tablespace online:

```
ALTER TABLESPACE users ONLINE;
```

See Also:

Oracle Database Backup and Recovery User's Guide for information about performing media recovery

13.7 Using Read-Only Tablespaces

A tablespace can be put into read-only mode. This prevents any data stored in it from being updated.

- [About Read-Only Tablespaces](#)
Making a tablespace read-only prevents write operations on the data files in the tablespace.
- [Making a Tablespace Read-Only](#)
You can make a tablespace read-only using the `ALTER TABLESPACE` statement with the `READ ONLY` clause.
- [Making a Read-Only Tablespace Writable](#)
Making a read-only tablespace writable allows write operations on the data files in the tablespace.
- [Creating a Read-Only Tablespace on a WORM Device](#)
You can create a read-only tablespace on a CD-ROM or WORM (Write Once-Read Many) device.
- [Delaying the Opening of Data Files in Read-Only Tablespaces](#)
You can delay the opening of data files for read-only tablespaces until there is an attempt to access them.

13.7.1 About Read-Only Tablespaces

Making a tablespace read-only prevents write operations on the data files in the tablespace.

The primary purpose of read-only tablespaces is to eliminate the need to perform backup and recovery of large, static portions of a database. Read-only tablespaces also provide a way to protect historical data so that users cannot modify it. Making a tablespace read-only prevents updates on all tables in the tablespace, regardless of a user's update privilege level.

 **Note:**

Making a tablespace read-only cannot in itself be used to satisfy archiving or data publishing requirements, because the tablespace can only be brought online in the database in which it was created. However, you can meet such requirements by using the transportable tablespace feature, as described in "[Transporting Tablespaces Between Databases](#)".

You can drop items, such as tables or indexes, from a read-only tablespace, but you cannot create or alter objects in a read-only tablespace. You can execute statements that update the file description in the data dictionary, such as `ALTER TABLE...ADD` or `ALTER TABLE...MODIFY`, but you will not be able to use the new description until the tablespace is made read/write. Note that you cannot add a column of data type `BLOB` when you alter a table definition.

Read-only tablespaces can be transported to other databases. And, since read-only tablespaces can never be updated, they can reside on CD-ROM or WORM (Write Once-Read Many) devices.

 **See Also:**

["Transporting Tablespaces Between Databases"](#)

13.7.2 Making a Tablespace Read-Only

You can make a tablespace read-only using the `ALTER TABLESPACE` statement with the `READ ONLY` clause.

All tablespaces are initially created as read/write. You must have the `ALTER TABLESPACE` or `MANAGE TABLESPACE` system privilege.

Before you can make a tablespace read-only, the following conditions must be met.

- The tablespace must be online. This is necessary to ensure that there is no undo information that must be applied to the tablespace.
- The tablespace cannot be the active undo tablespace or `SYSTEM` tablespace.

- The tablespace must not currently be involved in an online backup, because the end of a backup updates the header file of all data files in the tablespace.
- The tablespace cannot be a temporary tablespace.

To change a tablespace to read-only:

- Use the READ ONLY clause in the ALTER TABLESPACE statement.

For example the following statement makes the flights tablespace read-only:

```
ALTER TABLESPACE flights READ ONLY;
```

For better performance while accessing data in a read-only tablespace, you can issue a query that accesses all of the blocks of the tables in the tablespace just before making it read-only. A simple query, such as `SELECT COUNT (*)`, executed against each table ensures that the data blocks in the tablespace can be subsequently accessed most efficiently. This eliminates the need for the database to check the status of the transactions that most recently modified the blocks.

You can issue the `ALTER TABLESPACE...READ ONLY` statement while the database is processing transactions. After the statement is issued, the tablespace is put into a transitional read-only mode, and the `ALTER` command waits for existing transactions to complete by committing or by rolling back. No further DML operations are allowed to the tablespace, and if a DML statement attempts further changes, then an error is returned.

The `ALTER TABLESPACE...READ ONLY` statement waits for the following transactions to either commit or roll back before returning: transactions that have pending or uncommitted changes to the tablespace and that were started before you issued the statement. If a transaction started before the statement remains active, but rolls back to a savepoint, rolling back its changes to the tablespace, then the statement no longer waits for this active transaction.

If you find it is taking a long time for the `ALTER TABLESPACE` statement to complete, then you can identify the transactions that are preventing the read-only state from taking effect. You can then notify the owners of those transactions and decide whether to terminate the transactions, if necessary.

The following example identifies the transaction entry for the `ALTER TABLESPACE...READ ONLY` statement and displays its session address (`saddr`):

```
SELECT SQL_TEXT, SADDR
  FROM V$SQLAREA,V$SESSION
 WHERE V$SQLAREA.ADDRESS = V$SESSION.SQL_ADDRESS
   AND SQL_TEXT LIKE 'alter tablespace%';
```

SQL_TEXT	SADDR
-----	-----
alter tablespace tbs1 read only	80034AF0

The start SCN of each active transaction is stored in the `V$TRANSACTION` view. Displaying this view sorted by ascending start SCN lists the transactions in execution order. From the preceding example, you already know the session address of the transaction entry for the read-only statement, and you can now locate it in the `V$TRANSACTION` view. All transactions with smaller start SCN, which indicates an earlier execution, can potentially hold up the quiesce and subsequent read-only state of the tablespace.

```

SELECT SES_ADDR, START_SCNB
  FROM V$TRANSACTION
 ORDER BY START_SCNB;

SES_ADDR START_SCNB
-----
800352A0      3621  --> waiting on this txn
80035A50      3623  --> waiting on this txn
80034AF0      3628  --> this is the ALTER TABLESPACE statement
80037910      3629  --> don't care about this txn

```

You can now find the owners of the blocking transactions.

```

SELECT T.SES_ADDR, S.USERNAME, S.MACHINE
  FROM V$SESSION S, V$TRANSACTION T
 WHERE T.SES_ADDR = S.SADDR
 ORDER BY T.SES_ADDR

```

SES_ADDR	USERNAME	MACHINE
800352A0	DAVIDB	DAVIDBLAP
80035A50	MIKEL	LAB61
80034AF0	DBA01	STEVEFLAP
80037910	NICKD	NICKDLAP

After making the tablespace read-only, it is advisable to back it up immediately. As long as the tablespace remains read-only, no further backups of the tablespace are necessary, because no changes can be made to it.

See Also:

Oracle Database Backup and Recovery User's Guide

13.7.3 Making a Read-Only Tablespace Writable

Making a read-only tablespace writable allows write operations on the data files in the tablespace.

You must have the `ALTER TABLESPACE` or `MANAGE TABLESPACE` system privilege.

To change a tablespace to allow write operations:

- Use the `READ WRITE` keywords in the `ALTER TABLESPACE` statement

A prerequisite to making the tablespace read/write is that all of the data files in the tablespace, as well as the tablespace itself, must be online. Use the `DATAFILE...ONLINE` clause of the `ALTER DATABASE` statement to bring a data file online. The `V$DATAFILE` view lists the current status of data files.

For example, the following statement makes the `flights` tablespace writable:

```
ALTER TABLESPACE flights READ WRITE;
```

Making a read-only tablespace writable updates the control file entry for the data files, so that you can use the read-only version of the data files as a starting point for recovery.

13.7.4 Creating a Read-Only Tablespace on a WORM Device

You can create a read-only tablespace on a CD-ROM or WORM (Write Once-Read Many) device.

Follow these steps to create a read-only tablespace on a CD-ROM or WORM device.

1. Create a writable tablespace on another device. Create the objects that belong in the tablespace and insert your data.
2. Alter the tablespace to make it read-only.
3. Copy the data files of the tablespace onto the WORM device. Use operating system commands to copy the files.
4. Take the tablespace offline.
5. Rename the data files to coincide with the names of the data files you copied onto your WORM device. Use `ALTER TABLESPACE` with the `RENAME DATAFILE` clause. Renaming the data files changes their names in the control file.
6. Bring the tablespace back online.

13.7.5 Delaying the Opening of Data Files in Read-Only Tablespaces

You can delay the opening of data files for read-only tablespaces until there is an attempt to access them.

When substantial portions of a very large database are stored in read-only tablespaces that are located on slow-access devices or hierarchical storage, you should consider setting the `READ_ONLY_OPEN_DELAYED` initialization parameter to `TRUE`. This speeds certain operations, primarily opening the database, by causing data files in read-only tablespaces to be accessed for the first time only when an attempt is made to read data stored within them.

Setting `READ_ONLY_OPEN_DELAYED=TRUE` has the following side-effects:

- A missing or bad read-only file is not detected at open time. It is only discovered when there is an attempt to access it.
- `ALTER SYSTEM CHECK DATAFILES` does not check read-only files.
- `ALTER TABLESPACE...ONLINE` and `ALTER DATABASE DATAFILE...ONLINE` do not check read-only files. They are checked only upon the first access.
- `V$RECOVER_FILE`, `V$BACKUP`, and `V$DATAFILE_HEADER` do not access read-only files. Read-only files are indicated in the results list with the error "DELAYED OPEN", with zeroes for the values of other columns.
- `V$DATAFILE` does not access read-only files. Read-only files have a size of "0" listed.
- `V$RECOVERY_LOG` does not access read-only files. Logs they could need for recovery are not added to the list.
- `ALTER DATABASE NOARCHIVELOG` does not access read-only files. It proceeds even if there is a read-only file that requires recovery.

 **Note:**

- RECOVER DATABASE and ALTER DATABASE OPEN RESETLOGS continue to access all read-only data files regardless of the parameter value. To avoid accessing read-only files for these operations, take those files offline.
- If a backup control file is used, the read-only status of some files may be inaccurate. This can cause some of these operations to return unexpected results. Care should be taken in this situation.

13.8 Altering and Maintaining Tablespaces

You can alter and maintain tablespaces by performing such tasks as adding data files and temp files to them.

- [Increasing the Size of a Tablespace](#)
You can increase the size of a tablespace by either increasing the size of a data file in the tablespace or adding one.
- [Altering a Locally Managed Tablespace](#)
You can add a data file to a locally managed tablespace, alter its availability, make it read-only or read/write, rename it, or enable/disable autoextension.
- [Altering a Bigfile Tablespace](#)
You can resize or autoextend a bigfile tablespace.
- [Altering a Locally Managed Temporary Tablespace](#)
You can alter a locally managed temporary tablespace to add a temp file, take a temp file offline, or bring a temp file online.
- [Shrinking a Locally Managed Temporary Tablespace](#)
You can shrink locally managed temporary tablespaces and release unused space.

13.8.1 Increasing the Size of a Tablespace

You can increase the size of a tablespace by either increasing the size of a data file in the tablespace or adding one.

See "[Changing Data File Size](#)" and "[Creating Data Files and Adding Data Files to a Tablespace](#)" for more information.

Additionally, you can enable automatic file extension (`AUTOEXTEND`) to data files and bigfile tablespaces. See "[Enabling and Disabling Automatic Extension for a Data File](#)".

13.8.2 Altering a Locally Managed Tablespace

You can add a data file to a locally managed tablespace, alter its availability, make it read-only or read/write, rename it, or enable/disable autoextension.

You cannot alter a locally managed tablespace to a locally managed temporary tablespace, nor can you change its method of segment space management. Coalescing free extents is unnecessary for locally managed tablespaces. However,

you can use the `ALTER TABLESPACE` statement on locally managed tablespaces for some operations, including the following:

- Adding a data file. For example:

```
ALTER TABLESPACE lmtbsb
    ADD DATAFILE '/u02/oracle/data/lmtbsb02.dbf' SIZE 1M;
```

- Altering tablespace availability (ONLINE/OFFLINE).
- Making a tablespace read-only or read/write.
- Renaming a data file, or enabling or disabling the autoextension of the size of a data file in the tablespace.

See Also:

- "["Altering Tablespace Availability "](#)"
- "["About Read-Only Tablespaces"](#)"
- "["Managing Data Files and Temp Files"](#)"

13.8.3 Altering a Bigfile Tablespace

You can resize or autoextend a bigfile tablespace.

Two clauses of the `ALTER TABLESPACE` statement support data file transparency when you are using bigfile tablespaces:

- RESIZE: The RESIZE clause lets you resize the single data file in a bigfile tablespace to an absolute size, without referring to the data file. For example:

```
ALTER TABLESPACE bigtbs RESIZE 80G;
```

- AUTOEXTEND (used outside of the ADD DATAFILE clause):

With a bigfile tablespace, you can use the AUTOEXTEND clause outside of the ADD DATAFILE clause. For example:

```
ALTER TABLESPACE bigtbs AUTOEXTEND ON NEXT 20G;
```

An error is raised if you specify an ADD DATAFILE clause for a bigfile tablespace.

13.8.4 Altering a Locally Managed Temporary Tablespace

You can alter a locally managed temporary tablespace to add a temp file, take a temp file offline, or bring a temp file online.

 **Note:**

You cannot use the `ALTER TABLESPACE` statement, with the `TEMPORARY` keyword, to change a locally managed permanent tablespace into a locally managed temporary tablespace. You must use the `CREATE TEMPORARY TABLESPACE` statement to create a locally managed temporary tablespace.

You can use `ALTER TABLESPACE` to add a temp file, take a temp file offline, or bring a temp file online, as illustrated in the following examples:

```
ALTER TABLESPACE lmtemp
  ADD TEMPFILE '/u02/oracle/data/lmtemp02.dbf' SIZE 18M REUSE;

ALTER TABLESPACE lmtemp TEMPFILE OFFLINE;
ALTER TABLESPACE lmtemp TEMPFILE ONLINE;
```

 **Note:**

You cannot take a temporary tablespace offline. Instead, you take its temp file offline. The view `V$TEMPFILE` displays online status for a temp file.

The `ALTER DATABASE` statement can be used to alter temp files.

The following statements take offline and bring online temp files. They behave identically to the last two `ALTER TABLESPACE` statements in the previous example.

```
ALTER DATABASE TEMPFILE '/u02/oracle/data/lmtemp02.dbf' OFFLINE;
ALTER DATABASE TEMPFILE '/u02/oracle/data/lmtemp02.dbf' ONLINE;
```

The following statement resizes a temp file:

```
ALTER DATABASE TEMPFILE '/u02/oracle/data/lmtemp02.dbf' RESIZE 18M;
```

The following statement drops a temp file and deletes its operating system file:

```
ALTER DATABASE TEMPFILE '/u02/oracle/data/lmtemp02.dbf' DROP
  INCLUDING DATAFILES;
```

The tablespace to which this temp file belonged remains. A message is written to the alert log for the temp file that was deleted. If an operating system error prevents the deletion of the file, the statement still succeeds, but a message describing the error is written to the alert log.

It is also possible to use the `ALTER DATABASE` statement to enable or disable the automatic extension of an existing temp file, and to rename a temp file. See *Oracle Database SQL Language Reference* for the required syntax.

 Note:

To rename a temp file, you take the temp file offline, use operating system commands to rename or relocate the temp file, and then use the `ALTER DATABASE RENAME FILE` command to update the database control files.

13.8.5 Shrinking a Locally Managed Temporary Tablespace

You can shrink locally managed temporary tablespaces and release unused space.

Large sort operations performed by the database may result in a temporary tablespace growing and occupying a considerable amount of disk space. After the sort operation completes, the extra space is not released; it is just marked as free and available for reuse. Therefore, a single large sort operation might result in a large amount of allocated temporary space that remains unused after the sort operation is complete. For this reason, the database enables you to shrink locally managed temporary tablespaces and release unused space.

To shrink a temporary tablespace:

- Use the `SHRINK SPACE` clause of the `ALTER TABLESPACE` statement.

To shrink a specific temp file of a temporary tablespace:

- Use the `SHRINK TEMPFILE` clause of the `ALTER TABLESPACE` statement .

Shrinking frees as much space as possible while maintaining the other attributes of the tablespace or temp file. The optional `KEEP` clause defines a minimum size for the tablespace or temp file.

Shrinking is an online operation, which means that user sessions can continue to allocate sort extents if needed, and already-running queries are not affected.

The following example shrinks the locally managed temporary tablespace `lmtmp1` while ensuring a minimum size of 20M.

```
ALTER TABLESPACE lmtmp1 SHRINK SPACE KEEP 20M;
```

The following example shrinks the temp file `lmtmp02.dbf` of the locally managed temporary tablespace `lmtmp2`. Because the `KEEP` clause is omitted, the database attempts to shrink the temp file to the minimum possible size.

```
ALTER TABLESPACE lmtmp2 SHRINK TEMPFILE '/u02/oracle/data/lmtmp02.dbf';
```

13.9 Renaming Tablespaces

Using the `RENAME TO` clause of the `ALTER TABLESPACE`, you can rename a permanent or temporary tablespace.

For example, the following statement renames the `users` tablespace:

```
ALTER TABLESPACE users RENAME TO usersts;
```

When you rename a tablespace the database updates all references to the tablespace name in the data dictionary, control file, and (online) data file headers. The database does not change the tablespace ID so if this tablespace were, for example, the default

tablespace for a user, then the renamed tablespace would show as the default tablespace for the user in the `DBA_USERS` view.

The following affect the operation of this statement:

- If the tablespace being renamed is the `SYSTEM` tablespace or the `SYSAUX` tablespace, then it will not be renamed and an error is raised.
- If any data file in the tablespace is offline, or if the tablespace is offline, then the tablespace is not renamed and an error is raised.
- If the tablespace is read only, then data file headers are not updated. This should not be regarded as corruption; instead, it causes a message to be written to the alert log indicating that data file headers have not been renamed. The data dictionary and control file are updated.
- If the tablespace is the default temporary tablespace, then the corresponding entry in the database properties table is updated and the `DATABASE_PROPERTIES` view shows the new name.
- If the tablespace is an undo tablespace and if the following conditions are met, then the tablespace name is changed to the new tablespace name in the server parameter file (`SPFILE`).
 - The server parameter file was used to start up the database.
 - The tablespace name is specified as the `UNDO_TABLESPACE` for any instance.

If a traditional initialization parameter file (`PFILE`) is being used then a message is written to the alert log stating that the initialization parameter file must be manually changed.

13.10 Dropping Tablespaces

You can drop a tablespace and its contents (the segments contained in the tablespace) from the database if the tablespace and its contents are no longer required.

You must have the `DROP TABLESPACE` system privilege to drop a tablespace.

Note:

Once a tablespace has been dropped, the data in the tablespace is not recoverable. Therefore, ensure that all data contained in a tablespace to be dropped will not be required in the future. Also, immediately before and after dropping a tablespace from a database, back up the database completely. This is *strongly recommended* so that you can recover the database if you mistakenly drop a tablespace, or if the database experiences a problem in the future after the tablespace has been dropped.

When you drop a tablespace, the file pointers in the control file of the associated database are removed. You can optionally direct Oracle Database to delete the operating system files (data files) that constituted the dropped tablespace. If you do not direct the database to delete the data files at the same time that it deletes the tablespace, you must later use the appropriate commands of your operating system to delete them.

You cannot drop a tablespace that contains any active segments. For example, if a table in the tablespace is currently being used or the tablespace contains undo data needed to roll back uncommitted transactions, you cannot drop the tablespace. The tablespace can be online or offline, but it is best to take the tablespace offline before dropping it.

To drop a tablespace:

- Use the `DROP TABLESPACE` statement.

The following statement drops the `users` tablespace, including the segments in the tablespace:

```
DROP TABLESPACE users INCLUDING CONTENTS;
```

If the tablespace is empty (does not contain any tables, views, or other structures), you do not need to specify the `INCLUDING CONTENTS` clause. Use the `CASCADE CONSTRAINTS` clause to drop all referential integrity constraints from tables outside the tablespace that refer to primary and unique keys of tables inside the tablespace.

To delete the data files associated with a tablespace at the same time that the tablespace is dropped, use the `INCLUDING CONTENTS AND DATAFILES` clause. The following statement drops the `users` tablespace and its associated data files:

```
DROP TABLESPACE users INCLUDING CONTENTS AND DATAFILES;
```

A message is written to the alert log for each data file that is deleted. If an operating system error prevents the deletion of a file, the `DROP TABLESPACE` statement still succeeds, but a message describing the error is written to the alert log.

 **See Also:**

["Dropping Data Files"](#)

13.11 Managing the SYSAUX Tablespace

The `SYSAUX` tablespace was installed as an auxiliary tablespace to the `SYSTEM` tablespace when you created your database. Some database components that formerly created and used separate tablespaces now occupy the `SYSAUX` tablespace.

If the `SYSAUX` tablespace becomes unavailable, core database functionality will remain operational. The database features that use the `SYSAUX` tablespace could fail, or function with limited capability.

- [Monitoring Occupants of the SYSAUX Tablespace](#)
You can monitor the occupants of the `SYSAUX` tablespace.
- [Moving Occupants Out Of or Into the SYSAUX Tablespace](#)
The `V$SYSAUX_OCCUPANTS` view provides a move procedure for each occupant of the `SYSAUX` tablespace.
- [Controlling the Size of the SYSAUX Tablespace](#)
The `SYSAUX` tablespace is occupied by several database components, and its total size is governed by the space consumed by those components. The space

consumed by the components, in turn, depends on which features or functionality are being used and on the nature of the database workload.

13.11.1 Monitoring Occupants of the SYSAUX Tablespace

You can monitor the occupants of the SYSAUX tablespace.

The list of registered occupants of the SYSAUX tablespace are discussed in "[About the SYSAUX Tablespace](#)". These components can use the SYSAUX tablespace, and their installation provides the means of establishing their occupancy of the SYSAUX tablespace.

To monitor the occupants of the SYSAUX tablespace:

- Query the V\$SYSAUX_OCCUPANTS view.

This view lists the following information about the occupants of the SYSAUX tablespace:

- Name of the occupant
- Occupant description
- Schema name
- Move procedure
- Current space usage

View information is maintained by the occupants.

 **See Also:**

Oracle Database Reference for a detailed description of the V\$SYSAUX_OCCUPANTS view

13.11.2 Moving Occupants Out Of or Into the SYSAUX Tablespace

The V\$SYSAUX_OCCUPANTS view provides a move procedure for each occupant of the SYSAUX tablespace.

You will have an option at component install time to specify that you do not want the component to reside in SYSAUX. Also, if you later decide that the component should be relocated to a designated tablespace, you can use the move procedure for that component, as specified in the V\$SYSAUX_OCCUPANTS view, to perform the move.

The move procedure also lets you move a component from another tablespace into the SYSAUX tablespace.

13.11.3 Controlling the Size of the SYSAUX Tablespace

The SYSAUX tablespace is occupied by several database components, and its total size is governed by the space consumed by those components. The space consumed by

the components, in turn, depends on which features or functionality are being used and on the nature of the database workload.

The largest portion of the `SYSAUX` tablespace is occupied by the Automatic Workload Repository (AWR). The space consumed by the AWR is determined by several factors, including the number of active sessions in the system at any given time, the snapshot interval, and the historical data retention period. A typical system with an average of 10 concurrent active sessions may require approximately 200 to 300 MB of space for its AWR data.

The following table provides guidelines on sizing the `SYSAUX` tablespace based on the system configuration and expected load.

Parameter/Recommendation	Small	Medium	Large
Number of CPUs	2	8	32
Number of concurrently active sessions	10	20	100
Number of user objects: tables and indexes	500	5,000	50,000
Estimated <code>SYSAUX</code> size at steady state with default configuration	500 MB	2 GB	5 GB

You can control the size of the AWR by changing the snapshot interval and historical data retention period. For more information on managing the AWR snapshot interval and retention period, see *Oracle Database Performance Tuning Guide*.

Another major occupant of the `SYSAUX` tablespace is the embedded Oracle Enterprise Manager Cloud Control repository. This repository is used by Cloud Control to store its metadata. The size of this repository depends on database activity and on configuration-related information stored in the repository.

Other database components in the `SYSAUX` tablespace will grow in size only if their associated features (for example, Oracle Text and Oracle Streams) are in use. If the features are not used, then these components do not have any significant effect on the size of the `SYSAUX` tablespace.

13.12 Correcting Problems with Locally Managed Tablespaces

Oracle Database includes aids for correcting problems with locally managed tablespaces.

- [Diagnosing and Repairing Locally Managed Tablespace Problems](#)
Oracle Database includes the `DBMS_SPACE_ADMIN` package, which is a collection of aids for diagnosing and repairing problems in locally managed tablespaces.
- [Scenario 1: Fixing Bitmap When Allocated Blocks are Marked Free \(No Overlap\)](#)
The `TABLESPACE_VERIFY` procedure discovers that a segment has allocated blocks that are marked free in the bitmap, but no overlap between segments is reported.
- [Scenario 2: Dropping a Corrupted Segment](#)
You cannot drop a segment because the bitmap has segment blocks marked "free". The system has automatically marked the segment corrupted.

- [Scenario 3: Fixing Bitmap Where Overlap is Reported](#)
The TABLESPACE_VERIFY procedure reports some overlapping. Some of the real data must be sacrificed based on previous internal errors.
- [Scenario 4: Correcting Media Corruption of Bitmap Blocks](#)
A set of bitmap blocks has media corruption.
- [Scenario 5: Migrating from a Dictionary-Managed to a Locally Managed Tablespace](#)
Use the TABLESPACE_MIGRATE_TO_LOCAL procedure to migrate a dictionary-managed tablespace to a locally managed tablespace.

13.12.1 Diagnosing and Repairing Locally Managed Tablespace Problems

Oracle Database includes the DBMS_SPACE_ADMIN package, which is a collection of aids for diagnosing and repairing problems in locally managed tablespaces.

DBMS_SPACE_ADMIN Package Procedures

The following table lists the DBMS_SPACE_ADMIN package procedures. See *Oracle Database PL/SQL Packages and Types Reference* for details on each procedure.

Procedure	Description
ASSM_SEGMENT_VERIFY	Verifies the integrity of segments created in tablespaces that have automatic segment space management enabled. Outputs a dump file named <i>sid_ora_process_id.trc</i> to the location that corresponds to the Diag Trace entry in the V\$DIAG_INFO view. Use SEGMENT_VERIFY for tablespaces with manual segment space management.
ASSM_TABLESPACE_VERIFY	Verifies the integrity of tablespaces that have automatic segment space management enabled. Outputs a dump file named <i>sid_ora_process_id.trc</i> to the location that corresponds to the Diag Trace entry in the V\$DIAG_INFO view. Use TABLESPACE_VERIFY for tablespaces with manual segment space management.
DROP_EMPTY_SEGMENTS	Drops segments from empty tables or table partitions and dependent objects
MATERIALIZE_DEFERRED_SEGMENTS	Materializes segments for tables and table partitions with deferred segment creation and their dependent objects.
SEGMENT_CORRUPT	Marks the segment corrupt or valid so that appropriate error recovery can be done
SEGMENT_DROP_CORRUPT	Drops a segment currently marked corrupt (without reclaiming space)

Procedure	Description
SEGMENT_DUMP	Dumps the segment header and bitmap blocks of a specific segment to a dump file named <code>sid_ora_process_id.trc</code> in the location that corresponds to the Diag Trace entry in the V\$DIAG_INFO view. Provides an option to select a slightly abbreviated dump, which includes segment header and includes bitmap block summaries, without percent-free states of each block.
SEGMENT_VERIFY	Verifies the consistency of the extent map of the segment
TABLESPACE_FIX_BITMAPS	Marks the appropriate DBA range (extent) as free or used in bitmap
TABLESPACE_FIX_SEGMENT_STAT_ES	Fixes the state of the segments in a tablespace in which migration was stopped
TABLESPACE_MIGRATE_FROM_LOCAL	Migrates a locally managed tablespace to dictionary-managed tablespace
TABLESPACE_MIGRATE_TO_LOCAL	Migrates a dictionary-managed tablespace to a locally managed tablespace
TABLESPACE_REBUILD_BITMAPS	Rebuilds the appropriate bitmaps
TABLESPACE_REBUILD_QUOTAS	Rebuilds quotas for a specific tablespace
TABLESPACE_RELOCATE_BITMAPS	Relocates the bitmaps to the specified destination
TABLESPACE_VERIFY	Verifies that the bitmaps and extent maps for the segments in the tablespace are synchronized

The following scenarios describe typical situations in which you can use the DBMS_SPACE_ADMIN package to diagnose and resolve problems.

Note:

Some of these procedures can result in lost and unrecoverable data if not used properly. You should work with Oracle Support Services if you have doubts about these procedures.

See Also:

- [Oracle Database PL/SQL Packages and Types Reference](#) for details about the DBMS_SPACE_ADMIN package
- ["Viewing ADR Locations with the V\\$DIAG_INFO View"](#)

13.12.2 Scenario 1: Fixing Bitmap When Allocated Blocks are Marked Free (No Overlap)

The TABLESPACE_VERIFY procedure discovers that a segment has allocated blocks that are marked free in the bitmap, but no overlap between segments is reported.

In this scenario, perform the following tasks:

1. Call the SEGMENT_DUMP procedure to dump the ranges that the administrator allocated to the segment.
2. For each range, call the TABLESPACE_FIX_BITMAPS procedure with the TABLESPACE_EXTENT_MAKE_USED option to mark the space as used.
3. Call TABLESPACE_REBUILD_QUOTAS to rebuild quotas.

13.12.3 Scenario 2: Dropping a Corrupted Segment

You cannot drop a segment because the bitmap has segment blocks marked "free". The system has automatically marked the segment corrupted.

In this scenario, perform the following tasks:

1. Call the SEGMENT_VERIFY procedure with the SEGMENT_VERIFY_EXTENTS_GLOBAL option. If no overlaps are reported, then proceed with steps 2 through 5.
2. Call the SEGMENT_DUMP procedure to dump the DBA ranges allocated to the segment.
3. For each range, call TABLESPACE_FIX_BITMAPS with the TABLESPACE_EXTENT_MAKE_FREE option to mark the space as free.
4. Call SEGMENT_DROP_CORRUPT to drop the SEG\$ entry.
5. Call TABLESPACE_REBUILD_QUOTAS to rebuild quotas.

13.12.4 Scenario 3: Fixing Bitmap Where Overlap is Reported

The TABLESPACE_VERIFY procedure reports some overlapping. Some of the real data must be sacrificed based on previous internal errors.

After choosing the object to be sacrificed, in this case say, table t1, perform the following tasks:

1. Make a list of all objects that t1 overlaps.
2. Drop table t1. If necessary, follow up by calling the SEGMENT_DROP_CORRUPT procedure.
3. Call the SEGMENT_VERIFY procedure on all objects that t1 overlapped. If necessary, call the TABLESPACE_FIX_BITMAPS procedure to mark appropriate bitmap blocks as used.
4. Rerun the TABLESPACE_VERIFY procedure to verify that the problem is resolved.

13.12.5 Scenario 4: Correcting Media Corruption of Bitmap Blocks

A set of bitmap blocks has media corruption.

In this scenario, perform the following tasks:

1. Call the TABLESPACE_REBUILD_BITMAPS procedure, either on all bitmap blocks, or on a single block if only one is corrupt.
2. Call the TABLESPACE_REBUILD_QUOTAS procedure to rebuild quotas.
3. Call the TABLESPACE_VERIFY procedure to verify that the bitmaps are consistent.

13.12.6 Scenario 5: Migrating from a Dictionary-Managed to a Locally Managed Tablespace

Use the TABLESPACE_MIGRATE_TO_LOCAL procedure to migrate a dictionary-managed tablespace to a locally managed tablespace.

This operation is done online, but space management operations are blocked until the migration has been completed. Therefore, you can read or modify data while the migration is in progress, but if you are loading a large amount of data that requires the allocation of additional extents, then the operation may be blocked.

Assume that the database block size is 2K and the existing extent sizes in tablespace tbs_1 are 10, 50, and 10,000 blocks (used, used, and free). The MINIMUM EXTENT value is 20K (10 blocks). Allow the system to choose the bitmap allocation unit. The value of 10 blocks is chosen, because it is the highest common denominator and does not exceed MINIMUM EXTENT.

The statement to convert tbs_1 to a locally managed tablespace is as follows:

```
EXEC DBMS_SPACE_ADMIN.TABLESPACE_MIGRATE_TO_LOCAL ('tbs_1');
```

If you choose to specify an allocation unit size, it must be a factor of the unit size calculated by the system.

13.13 Migrating the SYSTEM Tablespace to a Locally Managed Tablespace

Use the DBMS_SPACE_ADMIN.TABLESPACE_MIGRATE_TO_LOCAL procedure to migrate the SYSTEM tablespace from dictionary-managed to locally managed.

Before performing the migration the following conditions must be met:

- The database has a default temporary tablespace that is not SYSTEM.
- There are no rollback segments in the dictionary-managed tablespace.
- There is at least one online rollback segment in a locally managed tablespace, or if using automatic undo management, an undo tablespace is online.
- All tablespaces other than the tablespace containing the undo space (that is, the tablespace containing the rollback segment or the undo tablespace) are in read-only mode.

- The SYSAUX tablespace is offline.
- The system is in restricted mode.
- There is a cold backup of the database.

All of these conditions, except for the cold backup, are enforced by the TABLESPACE_MIGRATE_TO_LOCAL procedure.

The following statement performs the migration:

```
SQL> EXECUTE DBMS_SPACE_ADMIN.TABLESPACE_MIGRATE_TO_LOCAL('SYSTEM');
```

 **Note:**

After the SYSTEM tablespace is migrated to locally managed, any dictionary-managed tablespaces in the database cannot be made read/write. If you want to use the dictionary-managed tablespaces in read/write mode, then Oracle recommends that you first migrate these tablespaces to locally managed before migrating the SYSTEM tablespace.

13.14 Viewing Information About Tablespaces

Oracle Database includes data dictionary views that you can query for information about tablespaces.

- [Tablespace Data Dictionary Views](#)

The following data dictionary and dynamic performance views provide useful information about the tablespaces of a database.

- [Example 1: Listing Tablespaces and Default Storage Parameters](#)

You can query the DBA_TABLESPACES view to list the names and default storage parameters.

- [Example 2: Listing the Data Files and Associated Tablespaces of a Database](#)

You can query the DBA_DATA_FILES view to list the names, sizes, and associated tablespaces of a database.

- [Example 3: Displaying Statistics for Free Space \(Extents\) of Each Tablespace](#)

You can query the DBA_FREE_SPACE view to display statistics about free extents and coalescing activity for each tablespace in the database.

13.14.1 Tablespace Data Dictionary Views

The following data dictionary and dynamic performance views provide useful information about the tablespaces of a database.

View	Description
V\$TABLESPACE	Name and number of all tablespaces from the control file.
V\$ENCRYPTED_TABLESPACES	Name and encryption algorithm of all encrypted tablespaces.
DBA_TABLESPACES, USER_TABLESPACES	Descriptions of all (or user accessible) tablespaces.

View	Description
DBA_TABLESPACE_GROUPS	Displays the tablespace groups and the tablespaces that belong to them.
DBA_SEGMENTS, USER_SEGMENTS	Information about segments within all (or user accessible) tablespaces.
DBA_EXTENTS, USER_EXTENTS	Information about data extents within all (or user accessible) tablespaces.
DBA_FREE_SPACE, USER_FREE_SPACE	Information about free extents within all (or user accessible) tablespaces.
DBA_TEMP_FREE_SPACE	Displays the total allocated and free space in each temporary tablespace.
V\$DATAFILE	Information about all data files, including tablespace number of owning tablespace.
V\$TEMPFILE	Information about all temp files, including tablespace number of owning tablespace.
DBA_DATA_FILES	Shows files (data files) belonging to tablespaces.
DBA_TEMP_FILES	Shows files (temp files) belonging to temporary tablespaces.
V\$TEMP_EXTENT_MAP	Information for all extents in all locally managed temporary tablespaces.
V\$TEMP_EXTENT_POOL	For locally managed temporary tablespaces: the state of temporary space cached and used for by each instance.
V\$TEMP_SPACE_HEADER	Shows space used/free for each temp file.
DBA_USERS	Default and temporary tablespaces for all users.
DBA_TS_QUOTAS	Lists tablespace quotas for all users.
V\$SORT_SEGMENT	Information about every sort segment in a given instance. The view is only updated when the tablespace is of the TEMPORARY type.
V\$TEMPSEG_USAGE	Describes temporary (sort) segment usage by user for temporary or permanent tablespaces.

13.14.2 Example 1: Listing Tablespaces and Default Storage Parameters

You can query the DBA_TABLESPACES view to list the names and default storage parameters.

To list the names and default storage parameters of all tablespaces in a database, use the following query on the DBA_TABLESPACES view:

```
SELECT TABLESPACE_NAME "TABLESPACE",
       INITIAL_EXTENT "INITIAL_EXT",
       NEXT_EXTENT "NEXT_EXT",
       MIN_EXTENTS "MIN_EXT",
       MAX_EXTENTS "MAX_EXT",
       PCT_INCREASE
  FROM DBA_TABLESPACES;

TABLESPACE  INITIAL_EXT  NEXT_EXT  MIN_EXT  MAX_EXT    PCT_INCREASE
```

RBS	1048576	1048576	2	40	0
SYSTEM	106496	106496	1	99	1
TEMP	106496	106496	1	99	0
TESTTBS	57344	16384	2	10	1
USERS	57344	57344	1	99	1

13.14.3 Example 2: Listing the Data Files and Associated Tablespaces of a Database

You can query the `DBA_DATA_FILES` view to list the names, sizes, and associated tablespaces of a database.

To list the names, sizes, and associated tablespaces of a database, enter the following query on the `DBA_DATA_FILES` view:

```
SELECT FILE_NAME, BLOCKS, TABLESPACE_NAME
      FROM DBA_DATA_FILES;
```

FILE_NAME	BLOCKS	TABLESPACE_NAME
/U02/ORACLE/IDDB3/DBF/RBS01.DBF	1536	RBS
/U02/ORACLE/IDDB3/DBF/SYSTEM01.DBF	6586	SYSTEM
/U02/ORACLE/IDDB3/DBF/TEMP01.DBF	6400	TEMP
/U02/ORACLE/IDDB3/DBF/TESTTBS01.DBF	6400	TESTTBS
/U02/ORACLE/IDDB3/DBF/USERS01.DBF	384	USERS

13.14.4 Example 3: Displaying Statistics for Free Space (Extents) of Each Tablespace

You can query the `DBA_FREE_SPACE` view to display statistics about free extents and coalescing activity for each tablespace in the database.

To produce statistics about free extents and coalescing activity for each tablespace in the database, enter the following query:

```
SELECT TABLESPACE_NAME "TABLESPACE", FILE_ID,
       COUNT(*) "PIECES",
       MAX(blocks) "MAXIMUM",
       MIN(blocks) "MINIMUM",
       AVG(blocks) "AVERAGE",
       SUM(blocks) "TOTAL"
      FROM DBA_FREE_SPACE
     GROUP BY TABLESPACE_NAME, FILE_ID;
```

TABLESPACE	FILE_ID	PIECES	MAXIMUM	MINIMUM	AVERAGE	TOTAL
RBS	2	1	955	955	955	955
SYSTEM	1	1	119	119	119	119
TEMP	4	1	6399	6399	6399	6399
TESTTBS	5	5	6364	3	1278	6390
USERS	3	1	363	363	363	363

`PIECES` shows the number of free space extents in the tablespace file, `MAXIMUM` and `MINIMUM` show the largest and smallest contiguous area of space in database blocks, `AVERAGE` shows the average size in blocks of a free space extent, and `TOTAL` shows the amount of free space in each tablespace file in blocks. This query is useful when you

are going to create a new object or you know that a segment is about to extend, and you want to ensure that there is enough space in the containing tablespace.

Managing Data Files and Temp Files

You can manage data files and temp files by performing tasks such as creating them, altering them, and dropping them.

Note:

Temp files are a special class of data files that are associated only with temporary tablespaces. Information in this chapter applies to both data files and temp files except where differences are noted. Temp files are further described in "[Creating a Locally Managed Temporary Tablespace](#)"

- [Guidelines for Managing Data Files](#)
You can follow guidelines for managing data files.
- [Creating Data Files and Adding Data Files to a Tablespace](#)
You can create data files and associate them with a tablespace using several different SQL statements.
- [Changing Data File Size](#)
You can alter the size of a data file. For example, you can increase the size of one or more data files when more space is needed in the database.
- [Altering Data File Availability](#)
You must alter data file availability to perform certain tasks, such as performing an offline backup of a data file or relocating an offline data file.
- [Renaming and Relocating Data Files](#)
You can rename online or offline data files to either change their names or relocate them.
- [Dropping Data Files](#)
You use the `DROP DATAFILE` and `DROP TEMPFILE` clauses of the `ALTER TABLESPACE` statement to drop a single data file or temp file.
- [Verifying Data Blocks in Data Files](#)
To configure the database to use checksums to verify data blocks, set the initialization parameter `DB_BLOCK_CHECKSUM` to `TYPICAL` (the default).
- [Copying Files Using the Database Server](#)
You can use the `DBMS_FILE_TRANSFER` package to copy a file within a database or transfer a file between databases.
- [Mapping Files to Physical Devices](#)
In an environment where data files are file system files, it is relatively straight forward to see the association between a tablespace and the underlying device. Oracle Database provides views, such as `DBA_TABLESPACES`, `DBA_DATA_FILES`, and `V$DATAFILE`, that provide a mapping of files onto devices. These mappings, along with device statistics can be used to evaluate I/O performance.

- [Data Files Data Dictionary Views](#)

A set of data dictionary views provides useful information about the data files of a database.

 **See Also:**

- [Using Oracle Managed Files](#) for information about creating data files and temp files that are both created and managed by the Oracle Database server
- [Oracle Database Concepts](#)

14.1 Guidelines for Managing Data Files

You can follow guidelines for managing data files.

- [About Data Files](#)

Data files are physical files of the operating system that store the data of all logical structures in the database. They must be explicitly created for each tablespace.

- [Determine the Number of Data Files](#)

You must determine the number of data files for your database.

- [Determine the Size of Data Files](#)

When creating a tablespace, you should estimate the potential size of database objects and create sufficient data files.

- [Place Data Files Appropriately](#)

Tablespace location is determined by the physical location of the data files that constitute that tablespace. Use the hardware resources of your computer appropriately.

- [Store Data Files Separate from Redo Log Files](#)

Data files should not be stored on the same disk drive that stores the database redo log files. If the data files and redo log files are stored on the same disk drive and that disk drive fails, the files cannot be used in your database recovery procedures.

14.1.1 About Data Files

Data files are physical files of the operating system that store the data of all logical structures in the database. They must be explicitly created for each tablespace.

Oracle Database assigns each data file two associated file numbers, an absolute file number and a relative file number, that are used to uniquely identify it. These numbers are described in the following table:

Type of File Number	Description
Absolute	Uniquely identifies a data file <i>in the database</i> . This file number can be used in many SQL statements that reference data files in place of using the file name. The absolute file number can be found in the FILE# column of the V\$DATAFILE or V\$TEMPFILE view, or in the FILE_ID column of the DBA_DATA_FILES or DBA_TEMP_FILES view.
Relative	Uniquely identifies a data file <i>within a tablespace</i> . For small and medium size databases, relative file numbers usually have the same value as the absolute file number. However, when the number of data files in a database exceeds a threshold (typically 1023), the relative file number differs from the absolute file number. In a bigfile tablespace, the relative file number is always 1024 (4096 on OS/390 platform).

14.1.2 Determine the Number of Data Files

You must determine the number of data files for your database.

- [About Determining the Number of Data Files](#)

At least one data file is required for the SYSTEM and SYSAUX tablespaces of a database. Your database should contain several other tablespaces with their associated data files or temp files. The number of data files that you anticipate creating for your database can affect the settings of initialization parameters and the specification of CREATE DATABASE statement clauses.

- [Determine a Value for the DB_FILES Initialization Parameter](#)

When starting an Oracle Database instance, the DB_FILES initialization parameter indicates the amount of SGA space to reserve for data file information and thus, the maximum number of data files that can be created for the instance.

- [Consider Possible Limitations When Adding Data Files to a Tablespace](#)

There are some limitations to consider when adding data files to a tablespace.

- [Consider the Performance Impact of the Number of Data Files](#)

The number of data files contained in a tablespace, and ultimately the database, can have an impact upon performance.

14.1.2.1 About Determining the Number of Data Files

At least one data file is required for the SYSTEM and SYSAUX tablespaces of a database. Your database should contain several other tablespaces with their associated data files or temp files. The number of data files that you anticipate creating for your database can affect the settings of initialization parameters and the specification of CREATE DATABASE statement clauses.

Be aware that your operating system might impose limits on the number of data files contained in your Oracle Database. Also consider that the number of data files, and how and where they are allocated can affect the performance of your database.

 **Note:**

One means of controlling the number of data files in your database and simplifying their management is to use bigfile tablespaces. Bigfile tablespaces comprise a single, very large data file and are especially useful in ultra large databases and where a logical volume manager is used for managing operating system files. Bigfile tablespaces are discussed in "[Bigfile Tablespaces](#)".

Consider the following guidelines when determining the number of data files for your database.

14.1.2.2 Determine a Value for the DB_FILES Initialization Parameter

When starting an Oracle Database instance, the `DB_FILES` initialization parameter indicates the amount of SGA space to reserve for data file information and thus, the maximum number of data files that can be created for the instance.

This limit applies for the life of the instance. You can change the value of `DB_FILES` (by changing the initialization parameter setting), but the new value does not take effect until you shut down and restart the instance.

When determining a value for `DB_FILES`, take the following into consideration:

- If the value of `DB_FILES` is too low, you cannot add data files beyond the `DB_FILES` limit without first shutting down the database.
- If the value of `DB_FILES` is too high, memory is unnecessarily consumed.

14.1.2.3 Consider Possible Limitations When Adding Data Files to a Tablespace

There are some limitations to consider when adding data files to a tablespace.

You can add data files to traditional smallfile tablespaces, subject to the following limitations:

- Operating systems often impose a limit on the number of files a process can open simultaneously. More data files cannot be created when the operating system limit of open files is reached.
- Operating systems impose limits on the number and size of data files.
- The database imposes a maximum limit on the number of data files for any Oracle Database opened by any instance. This limit is operating system specific.
- You cannot exceed the number of data files specified by the `DB_FILES` initialization parameter.
- When you issue `CREATE DATABASE` or `CREATE CONTROLFILE` statements, the `MAXDATAFILES` parameter specifies an initial size of the data file portion of the control file. However, if you attempt to add a new file whose number is greater than `MAXDATAFILES`, but less than or equal to `DB_FILES`, the control file will expand automatically so that the data files section can accommodate more files.

14.1.2.4 Consider the Performance Impact of the Number of Data Files

The number of data files contained in a tablespace, and ultimately the database, can have an impact upon performance.

Oracle Database allows more data files in the database than the operating system defined limit. The database DBWn processes can open all online data files. Oracle Database is capable of treating open file descriptors as a cache, automatically closing files when the number of open file descriptors reaches the operating system-defined limit. This can have a negative performance impact. When possible, adjust the operating system limit on open file descriptors so that it is larger than the number of online data files in the database.

 **See Also:**

- Your operating system specific Oracle documentation for more information on operating system limits
- *Oracle Database SQL Language Reference* for more information about the MAXDATAFILES parameter of the CREATE DATABASE or CREATE CONTROLFILE statement

14.1.3 Determine the Size of Data Files

When creating a tablespace, you should estimate the potential size of database objects and create sufficient data files.

Later, if needed, you can create additional data files and add them to a tablespace to increase the total amount of disk space allocated to it, and consequently the database. Preferably, place data files on multiple devices to ensure that data is spread evenly across all devices.

14.1.4 Place Data Files Appropriately

Tablespace location is determined by the physical location of the data files that constitute that tablespace. Use the hardware resources of your computer appropriately.

For example, if several disk drives are available to store the database, consider placing potentially contending data files on separate disks. This way, when users query information, both disk drives can work simultaneously, retrieving data at the same time.

 **See Also:**

Oracle Database Performance Tuning Guide for information about I/O and the placement of data files

14.1.5 Store Data Files Separate from Redo Log Files

Data files should not be stored on the same disk drive that stores the database redo log files. If the data files and redo log files are stored on the same disk drive and that disk drive fails, the files cannot be used in your database recovery procedures.

If you multiplex your redo log files, then the likelihood of losing all of your redo log files is low, so you can store data files on the same drive as some redo log files.

14.2 Creating Data Files and Adding Data Files to a Tablespace

You can create data files and associate them with a tablespace using several different SQL statements.

In all cases, you can either specify the file specifications for the data files being created, or you can use the Oracle Managed Files feature to create files that are created and managed by the database server. The table includes a brief description of the statement, as used to create data files, and references the section of this book where use of the statement is specifically described:

SQL Statement	Description	Additional Information
CREATE TABLESPACE	Creates a tablespace and the data files that comprise it	" Creating Tablespaces "
CREATE TEMPORARY TABLESPACE	Creates a locally-managed temporary tablespace and the <i>tempfiles</i> (temp files are a special kind of data file) that comprise it	" Creating a Locally Managed Temporary Tablespace "
ALTER TABLESPACE ... ADD DATAFILE	Creates and adds a data file to a tablespace	" Altering a Locally Managed Tablespace "
ALTER TABLESPACE ... ADD TEMPFILE	Creates and adds a temp file to a temporary tablespace	" Altering a Locally Managed Temporary Tablespace "
CREATE DATABASE	Creates a database and associated data files	" Creating a Database with the CREATE DATABASE Statement "
ALTER DATABASE ... CREATE DATAFILE	Creates a new empty data file in place of an old one--useful to re-create a data file that was lost with no backup.	See <i>Oracle Database Backup and Recovery User's Guide</i> .

If you add new data files to a tablespace and do not fully specify the file names, the database creates the data files in the default database directory or the current directory, depending upon your operating system. Oracle recommends you always specify a fully qualified name for a data file. Unless you want to reuse existing files, make sure the new file names do not conflict with other files. Old files that have been previously dropped will be overwritten.

If a statement that creates a data file fails, the database removes any created operating system files. However, because of the large number of potential errors that

can occur with file systems and storage subsystems, there can be situations where you must manually remove the files using operating system commands.

14.3 Changing Data File Size

You can alter the size of a data file. For example, you can increase the size of one or more data files when more space is needed in the database.

- [Enabling and Disabling Automatic Extension for a Data File](#)

You can create data files or alter existing data files so that they automatically increase in size when more space is needed in the database. The file size increases in specified increments up to a specified maximum.

- [Manually Resizing a Data File](#)

You can manually increase or decrease the size of a data file using the `ALTER DATABASE` statement.

14.3.1 Enabling and Disabling Automatic Extension for a Data File

You can create data files or alter existing data files so that they automatically increase in size when more space is needed in the database. The file size increases in specified increments up to a specified maximum.

Setting your data files to extend automatically provides these advantages:

- Reduces the need for immediate intervention when a tablespace runs out of space
- Ensures applications will not halt or be suspended because of failures to allocate extents

You can specify automatic file extension by specifying an `AUTOEXTEND ON` clause when you create data files using the following SQL statements:

- `CREATE DATABASE`
- `ALTER DATABASE`
- `CREATE TABLESPACE`
- `ALTER TABLESPACE`

To enable or disable automatic extension for a data file:

1. Determine whether a data file is auto-extensible by querying the `DBA_DATA_FILES` view and examining the `AUTOEXTENSIBLE` column.
2. Enable or disable automatic file extension for existing data files, or manually resize a data file, using the `ALTER DATABASE` statement with the `AUTOEXTEND` clause. For a bigfile tablespace, use the `ALTER TABLESPACE` statement with the `AUTOEXTEND` clause.

The following example enables automatic extension for a data file added to the `users` tablespace:

```
ALTER TABLESPACE users
ADD DATAFILE '/u02/oracle/rbdb1/users03.dbf' SIZE 10M
  AUTOEXTEND ON
  NEXT 512K
  MAXSIZE 250M;
```

The value of `NEXT` is the minimum size of the increments added to the file when it extends. The value of `MAXSIZE` is the maximum size to which the file can automatically extend.

The next example disables the automatic extension for the data file.

```
ALTER DATABASE DATAFILE '/u02/oracle/rbdb1/users03.dbf'  
    AUTOEXTEND OFF;
```

 **See Also:**

Oracle Database SQL Language Reference for more information about the SQL statements for creating or altering data files

14.3.2 Manually Resizing a Data File

You can manually increase or decrease the size of a data file using the `ALTER DATABASE` statement.

Therefore, you can add more space to your database without adding more data files. This is beneficial if you are concerned about reaching the maximum number of data files allowed in your database.

For a bigfile tablespace, you can use the `ALTER TABLESPACE` statement to resize a data file. You are not allowed to add a data file to a bigfile tablespace.

Manually reducing the sizes of data files enables you to reclaim unused space in the database. This is useful for correcting errors in estimates of space requirements.

In the following example, assume that the data file `/u02/oracle/rbdb1/stuff01.dbf` has extended up to 250M. However, because its tablespace now stores smaller objects, the data file can be reduced in size.

The following statement decreases the size of data file `/u02/oracle/rbdb1/stuff01.dbf`:

```
ALTER DATABASE DATAFILE '/u02/oracle/rbdb1/stuff01.dbf'  
    RESIZE 100M;
```

 **Note:**

It is not always possible to decrease the size of a file to a specific value. It could be that the file contains data beyond the specified decreased size, in which case the database will return an error.

14.4 Altering Data File Availability

You must alter data file availability to perform certain tasks, such as performing an offline backup of a data file or relocating an offline data file.

- **About Altering Data File Availability**
You can alter the availability of individual data files or temp files by taking them offline or bringing them online. Offline data files are unavailable to the database and cannot be accessed until they are brought back online.
- **Bringing Data Files Online or Taking Offline in ARCHIVELOG Mode**
To bring an individual data file online or take an individual data file offline, issue the `ALTER DATABASE` statement and include the `DATAFILE` clause.
- **Taking Data Files Offline in NOARCHIVELOG Mode**
To take a data file offline when the database is in `NOARCHIVELOG` mode, use the `ALTER DATABASE` statement with both the `DATAFILE` and `OFFLINE FOR DROP` clauses.
- **Altering the Availability of All Data Files or Temp Files in a Tablespace**
Clauses of the `ALTER TABLESPACE` statement allow you to change the online or offline status of all of the data files or temp files within a tablespace.

14.4.1 About Altering Data File Availability

You can alter the availability of individual data files or temp files by taking them offline or bringing them online. Offline data files are unavailable to the database and cannot be accessed until they are brought back online.

Reasons for altering data file availability include the following:

- You want to perform an offline backup of a data file.
- You want to rename or relocate an offline data file. You can first take the data file offline or take the tablespace offline.
- The database has problems writing to a data file and automatically takes the data file offline. Later, after resolving the problem, you can bring the data file back online manually.
- A data file becomes missing or corrupted. You must take it offline before you can open the database.

The data files of a read-only tablespace can be taken offline or brought online, but bringing a file online does not affect the read-only status of the tablespace. You cannot write to the data file until the tablespace is returned to the read/write state.

Note:

You can make all data files of a tablespace temporarily unavailable by taking the tablespace itself offline. You *must* leave these files in the tablespace to bring the tablespace back online, although you can relocate or rename them following procedures similar to those shown in "[Renaming and Relocating Data Files](#)".

For more information, see "[Taking Tablespaces Offline](#)".

To take a data file offline or bring it online, you must have the `ALTER DATABASE` system privilege. To take all data files or temp files offline using the `ALTER TABLESPACE` statement, you must have the `ALTER TABLESPACE` or `MANAGE TABLESPACE` system privilege. In an Oracle Real Application Clusters environment, the database must be open in exclusive mode.

14.4.2 Bringing Data Files Online or Taking Offline in ARCHIVELOG Mode

To bring an individual data file online or take an individual data file offline, issue the ALTER DATABASE statement and include the DATAFILE clause.

The following statement brings the specified data file online:

```
ALTER DATABASE DATAFILE '/u02/oracle/rbdb1/stuff01.dbf' ONLINE;
```

To take the same file offline, issue the following statement:

```
ALTER DATABASE DATAFILE '/u02/oracle/rbdb1/stuff01.dbf' OFFLINE;
```

 **Note:**

To use this form of the ALTER DATABASE statement, the database must be in ARCHIVELOG mode. This requirement prevents you from accidentally losing the data file, since taking the data file offline while in NOARCHIVELOG mode is likely to result in losing the file.

14.4.3 Taking Data Files Offline in NOARCHIVELOG Mode

To take a data file offline when the database is in NOARCHIVELOG mode, use the ALTER DATABASE statement with both the DATAFILE and OFFLINE FOR DROP clauses.

- The OFFLINE keyword causes the database to mark the data file OFFLINE, whether or not it is corrupted, so that you can open the database.
- The FOR DROP keywords mark the data file for subsequent dropping. Such a data file can no longer be brought back online.

 **Note:**

This operation does not actually drop the data file. It remains in the data dictionary, and you must drop it yourself using one of the following methods:

- An ALTER TABLESPACE ... DROP DATAFILE statement.
After an OFFLINE FOR DROP, this method works for dictionary managed tablespaces only.
- A DROP TABLESPACE ... INCLUDING CONTENTS AND DATAFILES statement
- If the preceding methods fail, an operating system command to delete the data file. This is the least desirable method, as it leaves references to the data file in the data dictionary and control files.

The following statement takes the specified data file offline and marks it to be dropped:

```
ALTER DATABASE DATAFILE '/u02/oracle/rbdb1/users03.dbf' OFFLINE FOR DROP;
```

14.4.4 Altering the Availability of All Data Files or Temp Files in a Tablespace

Clauses of the `ALTER TABLESPACE` statement allow you to change the online or offline status of all of the data files or temp files within a tablespace.

Specifically, the statements that affect online/offline status are:

- `ALTER TABLESPACE ... DATAFILE {ONLINE|OFFLINE}`
- `ALTER TABLESPACE ... TEMPFILE {ONLINE|OFFLINE}`

You are required only to enter the tablespace name, not the individual data files or temp files. All of the data files or temp files are affected, but the online/offline status of the tablespace itself is not changed.

In most cases the preceding `ALTER TABLESPACE` statements can be issued whenever the database is mounted, even if it is not open. However, the database *must not* be open if the tablespace is the `SYSTEM` tablespace, an undo tablespace, or the default temporary tablespace. The `ALTER DATABASE DATAFILE` and `ALTER DATABASE TEMPFILE` statements also have `ONLINE/OFFLINE` clauses, however in those statements you must enter all of the file names for the tablespace.

The syntax is different from the `ALTER TABLESPACE...ONLINE|OFFLINE` statement that alters tablespace availability, because that is a different operation. The `ALTER TABLESPACE` statement takes data files offline as well as the tablespace, but it cannot be used to alter the status of a temporary tablespace or its temp file(s).

14.5 Renaming and Relocating Data Files

You can rename online or offline data files to either change their names or relocate them.

- [Renaming and Relocating Online Data Files](#)

You can use the `ALTER DATABASE MOVE DATAFILE` SQL statement to rename or relocate online data files. This statement enables you to rename or relocate a data file while the database is open and users are accessing the data file.

- [Renaming and Relocating Offline Data Files](#)

You can rename and relocate offline data files.

14.5.1 Renaming and Relocating Online Data Files

You can use the `ALTER DATABASE MOVE DATAFILE` SQL statement to rename or relocate online data files. This statement enables you to rename or relocate a data file while the database is open and users are accessing the data file.

When you rename or relocate online data files, the pointers to the data files, as recorded in the database control file, are changed. The files are also physically renamed or relocated at the operating system level.

You might rename or relocate online data files because you want to allow users to access the data files when you perform one of the following tasks:

- Move the data files from one type of storage to another

- Move data files that are accessed infrequently to lower cost storage
- Make a tablespace read-only and move its data files to write-once storage
- Move a database into Oracle Automatic Storage Management (Oracle ASM)

When you run the `ALTER DATABASE MOVE DATAFILE` statement and a file with the same name exists in the destination location, you can specify the `REUSE` option to overwrite the existing file. When `REUSE` is not specified, and a file with the same name exists in the destination location, the existing file is not overwritten, and the statement returns an error.

By default, when you run the `ALTER DATABASE MOVE DATAFILE` statement and specify a new location for a data file, the statement moves the data file. However, you can specify the `KEEP` option to retain the data file in the old location and copy it to the new location. In this case, the database only uses the data file in the new location when the statement completes successfully.

When you rename or relocate a data file with `ALTER DATABASE MOVE DATAFILE` statement, Oracle Database creates a copy of the data file when it is performing the operation. Ensure that there is adequate disk space for the original data file and the copy during the operation.

You can view the name, location, and online status of each data file by querying the `DBA_DATA_FILES` view.

Note:

- The `ALTER DATABASE MOVE DATAFILE` statement raises an error if the specified data file is offline.
- If you are using a standby database, then you can perform an online move data file operation independently on the primary and on the standby (either physical or logical). The standby is not affected when a data file is moved on the primary, and vice versa. See *Oracle Data Guard Concepts and Administration* for more information.
- A flashback operation does not relocate a moved data file to its previous location. If you move a data file online from one location to another and later flash back the database to a point in time before the move, then the data file remains in the new location, but the contents of the data file are changed to the contents at the time specified in the flashback. See *Oracle Database Backup and Recovery User's Guide* for more information about flashback database operations.
- When you relocate a data file on the Windows platform, the original data file might be retained in the old location, even when the `KEEP` option is omitted. In this case, the database only uses the data file in the new location when the statement completes successfully. You can delete the old data file manually after the operation completes if necessary.

To rename or relocate online data files:

1. In SQL*Plus, connect to the database as a user with ALTER DATABASE system privilege.

See "[Starting Up a Database Using SQL*Plus](#)".

2. Issue the ALTER DATABASE MOVE DATAFILE statement and specify the data file.

Example 14-1 Renaming an Online Data File

This example renames the data file `user1.dbf` to `user01.dbf` while keeping the data file in the same location.

```
ALTER DATABASE MOVE DATAFILE '/u01/oracle/rbdb1/user1.dbf'  
TO '/u01/oracle/rbdb1/user01.dbf';
```

Example 14-2 Relocating an Online Data File

This example moves the data file `user1.dbf` from the `/u01/oracle/rbdb1/` directory to the `/u02/oracle/rbdb1/` directory. After the operation, the file is no longer in the `/u01/oracle/rbdb1/` directory.

```
ALTER DATABASE MOVE DATAFILE '/u01/oracle/rbdb1/user1.dbf'  
TO '/u02/oracle/rbdb1/user1.dbf';
```

Example 14-3 Copying an Online Data File

This example copies the data file `user1.dbf` from the `/u01/oracle/rbdb1/` directory to the `/u02/oracle/rbdb1/` directory. After the operation, the old file is retained in the `/u01/oracle/rbdb1/` directory.

```
ALTER DATABASE MOVE DATAFILE '/u01/oracle/rbdb1/user1.dbf'  
TO '/u02/oracle/rbdb1/user1.dbf' KEEP;
```

Example 14-4 Relocating an Online Data File and Overwriting an Existing File

This example moves the data file `user1.dbf` from the `/u01/oracle/rbdb1/` directory to the `/u02/oracle/rbdb1/` directory. If a file with the same name exists in the `/u02/oracle/rbdb1/` directory, then the statement overwrites the file.

```
ALTER DATABASE MOVE DATAFILE '/u01/oracle/rbdb1/user1.dbf'  
TO '/u02/oracle/rbdb1/user1.dbf' REUSE;
```

Example 14-5 Relocating an Online Data File to Oracle ASM

This example moves the data file `user1.dbf` from the `/u01/oracle/rbdb1/` directory to an Oracle ASM location.

```
ALTER DATABASE MOVE DATAFILE '/u01/oracle/rbdb1/user1.dbf'  
TO '+dgroup_01/data/orcl/datafile/user1.dbf';
```

Example 14-6 Moving a File from One ASM Location to Another ASM Location

This example moves the data file from one Oracle ASM location to another Oracle ASM location.

```
ALTER DATABASE MOVE DATAFILE '+dgroup_01/data/orcl/datafile/user1.dbf'  
TO '+dgroup_02/data/orcl/datafile/user1.dbf';
```

You also can move an online data file with Oracle ASM by mirroring the data file and then removing the original file location from the mirror. The online data file move operation might be faster when you use Oracle ASM to move the file instead of the `ALTER DATABASE MOVE DATAFILE` statement.

 **See Also:**

- *Oracle Database SQL Language Reference* for more information about the `ALTER DATABASE` statement
- *Oracle Automatic Storage Management Administrator's Guide*

14.5.2 Renaming and Relocating Offline Data Files

You can rename and relocate offline data files.

When you rename and relocate offline data files, only the pointers to the data files, as recorded in the database control file, are changed. Files are not physically renamed, and they are not copied at the operating system level.

- [Procedures for Renaming and Relocating Offline Data Files in a Single Tablespace](#)

You can rename and relocate offline data files that can be used for a single tablespace. You must have `ALTER TABLESPACE` system privilege to perform these procedures.

- [Renaming and Relocating Offline Data Files in Multiple Tablespaces](#)

You can rename and relocate data files in one or more tablespaces using the `ALTER DATABASE RENAME FILE` statement.

14.5.2.1 Procedures for Renaming and Relocating Offline Data Files in a Single Tablespace

You can rename and relocate offline data files that can be used for a single tablespace. You must have `ALTER TABLESPACE` system privilege to perform these procedures.

- [Renaming Offline Data Files in a Single Tablespace](#)

You can rename offline data files in a single tablespace.

- [Relocating Offline Data Files in a Single Tablespace](#)

You can relocate offline data files in a single tablespace.

 **See Also:**

- ["Taking Tablespaces Offline"](#) for more information about taking tablespaces offline in preparation for renaming or relocating data files

14.5.2.1.1 Renaming Offline Data Files in a Single Tablespace

You can rename offline data files in a single tablespace.

To rename offline data files in a single tablespace, complete the following steps:

1. Take the tablespace that contains the data files offline. The database must be open.

For example:

```
ALTER TABLESPACE users OFFLINE NORMAL;
```

2. Rename the data files using the operating system.
3. Use the ALTER TABLESPACE statement with the RENAME DATAFILE clause to change the file names within the database.

For example, the following statement renames the data files /u02/oracle/rbdb1/user1.dbf and /u02/oracle/rbdb1/user2.dbf to /u02/oracle/rbdb1/users01.dbf and /u02/oracle/rbdb1/users02.dbf, respectively:

```
ALTER TABLESPACE users
  RENAME DATAFILE '/u02/oracle/rbdb1/user1.dbf',
                '/u02/oracle/rbdb1/user2.dbf'
    TO '/u02/oracle/rbdb1/users01.dbf',
        '/u02/oracle/rbdb1/users02.dbf';
```

Always provide complete file names (including their paths) to properly identify the old and new data files. In particular, specify the old data file name exactly as it appears in the DBA_DATA_FILES view of the data dictionary.

4. Back up the database. After making any structural changes to a database, always perform an immediate and complete backup.
5. Bring the tablespace back online using an ALTER TABLESPACE statement with the ONLINE clause:

```
ALTER TABLESPACE users ONLINE
```

14.5.2.1.2 Relocating Offline Data Files in a Single Tablespace

You can relocate offline data files in a single tablespace.

Here is a sample procedure for relocating an offline data file.

Assume the following conditions:

- An open database has a tablespace named users that is made up of data files all located on the same disk.
- The data files of the users tablespace are to be relocated to different and separate disk drives.
- You are currently connected with administrator privileges to the open database.
- You have a current backup of the database.

Complete the following steps:

1. If you do not know the specific file names or sizes, you can obtain this information by issuing the following query of the data dictionary view DBA_DATA_FILES:

```
SQL> SELECT FILE_NAME, BYTES FROM DBA_DATA_FILES
2> WHERE TABLESPACE_NAME = 'USERS';

FILE_NAME                      BYTES
-----
/u02/oracle/rbdb1/users01.dbf    102400000
/u02/oracle/rbdb1/users02.dbf    102400000
```

- 2.** Take the tablespace containing the data files offline:

```
ALTER TABLESPACE users OFFLINE NORMAL;
```

- 3.** Copy the data files to their new locations and rename them using the operating system. You can copy the files using the DBMS_FILE_TRANSFER package discussed in "Copying Files Using the Database Server".

 **Note:**

You can temporarily exit SQL*Plus to execute an operating system command to copy a file by using the SQL*Plus HOST command.

- 4.** Rename the data files within the database.

The data file pointers for the files that comprise the `users` tablespace, recorded in the control file of the associated database, must now be changed from the old names to the new names.

Use the `ALTER TABLESPACE...RENAME DATAFILE` statement.

```
ALTER TABLESPACE users
  RENAME DATAFILE '/u02/oracle/rbdb1/users01.dbf',
                 '/u02/oracle/rbdb1/users02.dbf'
  TO '/u03/oracle/rbdb1/users01.dbf',
      '/u04/oracle/rbdb1/users02.dbf';
```

- 5.** Back up the database. After making any structural changes to a database, always perform an immediate and complete backup.
- 6.** Bring the tablespace back online using an `ALTER TABLESPACE` statement with the `ONLINE` clause:

```
ALTER TABLESPACE users ONLINE
```

14.5.2.2 Renaming and Relocating Offline Data Files in Multiple Tablespaces

You can rename and relocate data files in one or more tablespaces using the `ALTER DATABASE RENAME FILE` statement.

This method is the only choice if you want to rename or relocate data files of several tablespaces in one operation. You must have the `ALTER DATABASE` system privilege.

 **Note:**

To rename or relocate data files of the `SYSTEM` tablespace, the default temporary tablespace, or the active undo tablespace you must use this `ALTER DATABASE` method because you cannot take these tablespaces offline.

To rename data files in multiple tablespaces, follow these steps.

1. Ensure that the database is mounted but closed.

 **Note:**

Optionally, the database does not have to be closed, but the data files (or temp files) must be offline.

2. Copy the data files to be renamed to their new locations and new names, using the operating system. You can copy the files using the DBMS_FILE_TRANSFER package discussed in "[Copying Files Using the Database Server](#)".
3. Use ALTER DATABASE to rename the file pointers in the database control file.

For example, the following statement renames the data files /u02/oracle/rbdb1/sort01.dbf and /u02/oracle/rbdb1/user3.dbf to /u02/oracle/rbdb1/temp01.dbf and /u02/oracle/rbdb1/users03.dbf, respectively:

```
ALTER DATABASE
  RENAME FILE '/u02/oracle/rbdb1/sort01.dbf',
    '/u02/oracle/rbdb1/user3.dbf'
  TO '/u02/oracle/rbdb1/temp01.dbf',
    '/u02/oracle/rbdb1/users03.dbf';
```

Always provide complete file names (including their paths) to properly identify the old and new data files. In particular, specify the old data file names exactly as they appear in the DBA_DATA_FILES view.

4. Back up the database. After making any structural changes to a database, always perform an immediate and complete backup.

14.6 Dropping Data Files

You use the DROP DATAFILE and DROP TEMPFILE clauses of the ALTER TABLESPACE statement to drop a single data file or temp file.

The data file must be empty. (A data file is considered to be empty when no extents remain allocated from it.) When you drop a data file or temp file, references to the data file or temp file are removed from the data dictionary and control files, and the physical file is deleted from the file system or Oracle Automatic Storage Management (Oracle ASM) disk group.

The following example drops the data file identified by the alias example_df3.f in the Oracle ASM disk group DGROUP1. The data file belongs to the example tablespace.

```
ALTER TABLESPACE example DROP DATAFILE '+DGROUP1/example_df3.f';
```

The next example drops the temp file lmtemp02.dbf, which belongs to the lmtemp tablespace.

```
ALTER TABLESPACE lmtemp DROP TEMPFILE '/u02/oracle/data/lmtemp02.dbf';
```

This is equivalent to the following statement:

```
ALTER DATABASE TEMPFILE '/u02/oracle/data/lmtemp02.dbf' DROP
  INCLUDING DATAFILES;
```

 **Note:**

If there are sessions using a temp file, and you attempt to drop the temp file, then an error is returned, and the temp file is not dropped. In this case, the temp file is taken offline, and queries that attempt to use the temp file will fail while the temp file is offline.

See *Oracle Database SQL Language Reference* for `ALTER TABLESPACE` syntax details.

Restrictions for Dropping Data Files

The following are restrictions for dropping data files and temp files:

- The database must be open.
- If a data file is not empty, it cannot be dropped.

If you must remove a data file that is not empty and that cannot be made empty by dropping schema objects, you must drop the tablespace that contains the data file.

- You cannot drop the first or only data file in a tablespace.

Therefore, `DROP DATAFILE` cannot be used with a bigfile tablespace.

- You cannot drop data files in a read-only tablespace that was migrated from dictionary managed to locally managed. Dropping a data file from all other read-only tablespaces is supported.
- You cannot drop data files in the `SYSTEM` tablespace.
- If a data file in a locally managed tablespace is offline, it cannot be dropped.

 **See Also:**

[Dropping Tablespaces](#)

14.7 Verifying Data Blocks in Data Files

To configure the database to use checksums to verify data blocks, set the initialization parameter `DB_BLOCK_CHECKSUM` to `TYPICAL` (the default).

This setting causes the `DBWn` process and the direct loader to calculate a checksum for each block and to store the checksum in the block header when writing the block to disk.

The checksum is verified when the block is read, but only if `DB_BLOCK_CHECKSUM` is `TRUE` and the last write of the block stored a checksum. If corruption is detected, the database returns message `ORA-01578` and writes information about the corruption to the alert log.

The value of the `DB_BLOCK_CHECKSUM` parameter can be changed dynamically using the `ALTER SYSTEM` statement. Regardless of the setting of this parameter, checksums are always used to verify data blocks in the `SYSTEM` tablespace.

 **See Also:**

Oracle Database Reference for more information about the DB_BLOCK_CHECKSUM initialization parameter

14.8 Copying Files Using the Database Server

You can use the DBMS_FILE_TRANSFER package to copy a file within a database or transfer a file between databases.

- [About Copying Files Using the Database Server](#)

You do not necessarily have to use the operating system to copy a file within a database, or transfer a file between databases as you would do when using the transportable tablespace feature.

- [Copying a File on a Local File System](#)

You can use the COPY_FILE procedure in the DBMS_FILE_TRANSFER package to copy a file on a local file system.

- [Third-Party File Transfer](#)

Although the procedures in the DBMS_FILE_TRANSFER package typically are invoked as local procedure calls, they can also be invoked as remote procedure calls. A remote procedure call lets you copy a file within a database even when you are connected to a different database.

- [Advanced File Transfer Mechanisms](#)

You can create more sophisticated file transfer mechanisms using both the DBMS_FILE_TRANSFER package and the DBMS_SCHEDULER package.

- [File Transfer and the DBMS_SCHEDULER Package](#)

You can use the DBMS_SCHEDULER package to transfer files automatically within a single database and between databases.

14.8.1 About Copying Files Using the Database Server

You do not necessarily have to use the operating system to copy a file within a database, or transfer a file between databases as you would do when using the transportable tablespace feature.

You can use the DBMS_FILE_TRANSFER package, or you can use Streams propagation. Using Streams is not discussed in this book, but an example of using the DBMS_FILE_TRANSFER package is shown in "[Copying a File on a Local File System](#)".

The DBMS_FILE_TRANSFER package can use a local file system or an Oracle Automatic Storage Management (Oracle ASM) disk group as the source or destination for a file transfer. Only Oracle database files (data files, temp files, control files, and so on) can be involved in transfers to and from Oracle ASM.

Caution:

Do not use the DBMS_FILE_TRANSFER package to copy or transfer a file that is being modified by a database because doing so may result in an inconsistent file.

On UNIX systems, the owner of a file created by the DBMS_FILE_TRANSFER package is the owner of the shadow process running the instance. Normally, this owner is ORACLE. A file created using DBMS_FILE_TRANSFER is always writable and readable by all processes in the database, but non privileged users who need to read or write such a file directly may need access from a system administrator.

See Also:

- *Oracle Streams Concepts and Administration*
- "[Transporting Tablespaces Between Databases](#)"
- *Oracle Database PL/SQL Packages and Types Reference* for a description of the DBMS_FILE_TRANSFER package.

14.8.2 Copying a File on a Local File System

You can use the COPY_FILE procedure in the DBMS_FILE_TRANSFER package to copy a file on a local file system.

The following example illustrates using the COPY_FILE procedure in the DBMS_FILE_TRANSFER package to copy a file on a local file system. The example copies a binary file named db1.dat from the /usr/admin/source directory to the /usr/admin/destination directory as db1_copy.dat on a local file system:

1. In SQL*Plus, connect as an administrative user who can grant privileges and create directory objects using SQL.
2. Use the SQL command CREATE DIRECTORY to create a directory object for the directory from which you want to copy the file. A directory object is similar to an alias for the directory. For example, to create a directory object called SOURCE_DIR for the /usr/admin/source directory on your computer system, execute the following statement:

```
CREATE DIRECTORY SOURCE_DIR AS '/usr/admin/source';
```

3. Use the SQL command CREATE DIRECTORY to create a directory object for the directory into which you want to copy the binary file. For example, to create a directory object called DEST_DIR for the /usr/admin/destination directory on your computer system, execute the following statement:

```
CREATE DIRECTORY DEST_DIR AS '/usr/admin/destination';
```

4. Grant the required privileges to the user who will run the COPY_FILE procedure. In this example, the strmadmin user runs the procedure.

```
GRANT EXECUTE ON DBMS_FILE_TRANSFER TO strmadmin;  
  
GRANT READ ON DIRECTORY source_dir TO strmadmin;  
  
GRANT WRITE ON DIRECTORY dest_dir TO strmadmin;
```

5. Connect as `strmadmin` user and provide the user password when prompted:

```
CONNECT strmadmin
```

6. Run the `COPY_FILE` procedure to copy the file:

```
BEGIN  
    DBMS_FILE_TRANSFER.COPY_FILE(  
        source_directory_object      => 'SOURCE_DIR',  
        source_file_name            => 'db1.dat',  
        destination_directory_object => 'DEST_DIR',  
        destination_file_name       => 'db1_copy.dat');  
END;  
/
```

The `source_file_name` parameter must specify a file that is in the directory specified by the `source_directory_object` parameter before running the procedure, and the `destination_file_name` parameter must specify the new name of the file in the new location specified in the `destination_directory_object` parameter. Relative paths and symbolic links are not allowed in the directory objects for the `source_directory_object` and `destination_directory_object` parameters.

Caution:

Do not use the `DBMS_FILE_TRANSFER` package to copy or transfer a file that is being modified by a database because doing so may result in an inconsistent file.

14.8.3 Third-Party File Transfer

Although the procedures in the `DBMS_FILE_TRANSFER` package typically are invoked as local procedure calls, they can also be invoked as remote procedure calls. A remote procedure call lets you copy a file within a database even when you are connected to a different database.

For example, you can make a copy of a file on database `DB`, even if you are connected to another database, by executing the following remote procedure call:

```
DBMS_FILE_TRANSFER.COPY_FILE@DB(...)
```

Using remote procedure calls enables you to copy a file between two databases, even if you are not connected to either database. For example, you can connect to database `A` and then transfer a file from database `B` to database `C`. In this example, database `A` is the third party because it is neither the source of nor the destination for the transferred file.

A third-party file transfer can both push and pull a file. Continuing with the previous example, you can perform a third-party file transfer if you have a database link from `A`

to either B or C, and that database has a database link to the other database. Database A does not need a database link to both B and C.

For example, if you have a database link from A to B, and another database link from B to C, then you can run the following procedure at A to transfer a file from B to C:

```
DBMS_FILE_TRANSFER.PUT_FILE@B( . . . )
```

This configuration pushes the file.

Alternatively, if you have a database link from A to C, and another database link from C to B, then you can run the following procedure at database A to transfer a file from B to C:

```
DBMS_FILE_TRANSFER.GET_FILE@C( . . . )
```

This configuration pulls the file.

14.8.4 Advanced File Transfer Mechanisms

You can create more sophisticated file transfer mechanisms using both the DBMS_FILE_TRANSFER package and the DBMS_SCHEDULER package.

For example, when several databases have a copy of the file you want to transfer, you can consider factors such as source availability, source load, and communication bandwidth to the destination database when deciding which source database to contact first and which source databases to try if failures occur. In this case, the information about these factors must be available to you, and you must create the mechanism that considers these factors.

As another example, when early completion time is more important than load, you can submit several Scheduler jobs to transfer files in parallel. As a final example, knowing something about file layout on the source and destination databases enables you to minimize disk contention by performing or scheduling simultaneous transfers only if they use different I/O devices.

14.8.5 File Transfer and the DBMS_SCHEDULER Package

You can use the DBMS_SCHEDULER package to transfer files automatically within a single database and between databases.

Third-party file transfers are also supported by the DBMS_SCHEDULER package. You can monitor a long-running file transfer done by the Scheduler using the V\$SESSION_LONGOPS dynamic performance view at the databases reading or writing the file. Any database links used by a Scheduler job must be fixed user database links.

You can use a restartable Scheduler job to improve the reliability of file transfers automatically, especially if there are intermittent failures. If a file transfer fails before the destination file is closed, then you can restart the file transfer from the beginning once the database has removed any partially written destination file. Hence you should consider using a restartable Scheduler job to transfer a file if the rest of the job is restartable. See [Scheduling Jobs with Oracle Scheduler](#) for more information on Scheduler jobs.

 **Note:**

If a single restartable job transfers several files, then you should consider restart scenarios in which some of the files have been transferred already and some have not been transferred yet.

14.9 Mapping Files to Physical Devices

In an environment where data files are file system files, it is relatively straight forward to see the association between a tablespace and the underlying device. Oracle Database provides views, such as `DBA_TABLESPACES`, `DBA_DATA_FILES`, and `V$DATAFILE`, that provide a mapping of files onto devices. These mappings, along with device statistics can be used to evaluate I/O performance.

However, with the introduction of host based Logical Volume Managers (LVM), and sophisticated storage subsystems that provide RAID (Redundant Array of Inexpensive Disks) features, it is not easy to determine file to device mapping. This poses a problem because it becomes difficult to determine your "hottest" files when they are hidden behind a "black box". This section presents the Oracle Database approach to resolving this problem.

 **Note:**

This section presents an overview of the Oracle Database file mapping interface and explains how to use the `DBMS_STORAGE_MAP` package and dynamic performance views to expose the mapping of files onto physical devices. You can more easily access this functionality through the Oracle Enterprise Manager Cloud Control. It provides an easy to use graphical interface for mapping files to physical devices. See the Cloud Control online help for more information.

- [Overview of Oracle Database File Mapping Interface](#)
To acquire an understanding of I/O performance, one must have detailed knowledge of the storage hierarchy in which files reside.
- [How the Oracle Database File Mapping Interface Works](#)
Oracle Database file mapping includes the following components: the FMON is a background process, the FMPUTL process, and mapping libraries.
- [Using the Oracle Database File Mapping Interface](#)
You can use the Oracle Database file mapping interface to enable file mapping and obtain information about file mapping in a set of views.
- [File Mapping Examples](#)
Examples illustrates some of the powerful capabilities of the Oracle Database file mapping feature.

14.9.1 Overview of Oracle Database File Mapping Interface

To acquire an understanding of I/O performance, one must have detailed knowledge of the storage hierarchy in which files reside.

Oracle Database provides a mechanism to show a complete mapping of a file to intermediate layers of logical volumes to actual physical devices. This is accomplished through a set of dynamic performance views (`v$ views`). Using these views, you can locate the exact disk on which any block of a file resides.

To build these views, storage vendors must provide mapping libraries that are responsible for mapping their particular I/O stack elements. The database communicates with these libraries through an external non-Oracle Database process that is spawned by a background process called FMON. FMON is responsible for managing the mapping information. Oracle provides a PL/SQL package, `DBMS_STORAGE_MAP`, that you use to invoke mapping operations that populate the mapping views.

 **Note:**

If you are not using Oracle Automatic Storage Management, then the file mapping interface is not available on Windows platforms. If you are using Oracle Automatic Storage Management, then the file mapping interface is available on all platforms.

 **See Also:**

Oracle Automatic Storage Management Administrator's Guide for information about using file mapping with Oracle ASM

14.9.2 How the Oracle Database File Mapping Interface Works

Oracle Database file mapping includes the following components: the FMON is a background process, the FMPUTL process, and mapping libraries.

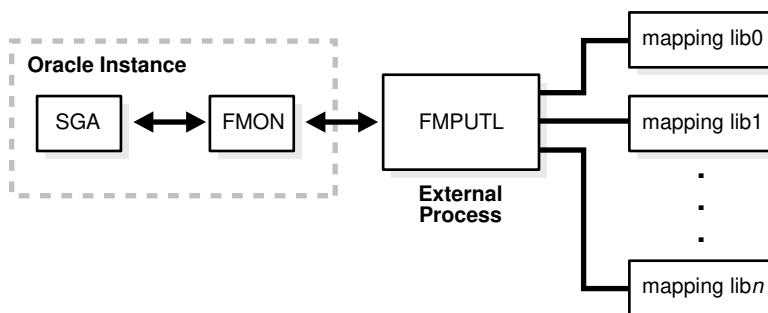

- [Components of File Mapping](#)
The file mapping mechanism includes several components.
- [Mapping Structures](#)
You must understand mapping structures and the Oracle Database representation of these structures to interpret the information in the mapping views.
- [Example of Mapping Structures](#)
An example illustrates mapping structures.
- [Configuration ID](#)
The configuration ID captures the version information associated with elements or files.

14.9.2.1 Components of File Mapping

The file mapping mechanism includes several components.

The following figure shows the components of the file mapping mechanism.

Figure 14-1 Components of File Mapping

Note:

Starting with Oracle Database 12c, the `FILE_MAPPING` initialization parameter, the `FMPUTL` process, and the mapping libraries are deprecated.

- **FMON**
FMON is a background process started by the database whenever the `FILE_MAPPING` initialization parameter is set to `true`. FMON builds map information and refreshing mapping information when a change occurs.
- **External Process (FMPUTL)**
FMON spawns an external non-Oracle Database process called `FMPUTL`, that communicates directly with the vendor supplied mapping libraries.
- **Mapping Libraries**
Oracle Database uses mapping libraries to discover mapping information for the elements that are owned by a particular mapping library.

14.9.2.1.1 FMON

FMON is a background process started by the database whenever the `FILE_MAPPING` initialization parameter is set to `true`. FMON builds map information and refreshing mapping information when a change occurs.

FMON is responsible for:

- Building mapping information, which is stored in the SGA. This information is composed of the following structures:
 - Files
 - File system extents

- Elements
- Subelements

These structures are explained in "[Mapping Structures](#)".

- Refreshing mapping information when a change occurs because of:
 - Changes to data files (size)
 - Addition or deletion of data files
 - Changes to the storage configuration (not frequent)
- Saving mapping information in the data dictionary to maintain a view of the information that is persistent across startup and shutdown operations
- Restoring mapping information into the SGA at instance startup. This avoids the need for a potentially expensive complete rebuild of the mapping information on every instance startup.

You help control this mapping using procedures that are invoked with the DBMS_STORAGE_MAP package.

14.9.2.1.2 External Process (FMPUTL)

FMON spawns an external non-Oracle Database process called FMPUTL, that communicates directly with the vendor supplied mapping libraries.

This process obtains the mapping information through all levels of the I/O stack, assuming that mapping libraries exist for all levels. On some platforms the external process requires that the SETUID bit is set to ON because root privileges are needed to map through all levels of the I/O mapping stack.

The external process is responsible for discovering the mapping libraries and dynamically loading them into its address space.

14.9.2.1.3 Mapping Libraries

Oracle Database uses mapping libraries to discover mapping information for the elements that are owned by a particular mapping library.

Through these mapping libraries information about individual I/O stack elements is communicated. This information is used to populate dynamic performance views that can be queried by users.

Mapping libraries need to exist for all levels of the stack for the mapping to be complete, and different libraries may own their own parts of the I/O mapping stack. For example, a VERITAS VxVM library would own the stack elements related to the VERITAS Volume Manager, and an EMC library would own all EMC storage specific layers of the I/O mapping stack.

Mapping libraries are vendor supplied. However, Oracle currently supplies a mapping library for EMC storage. The mapping libraries available to a database server are identified in a special file named filemap.ora.

14.9.2.2 Mapping Structures

You must understand mapping structures and the Oracle Database representation of these structures to interpret the information in the mapping views.

The following are the primary structures that compose the mapping information:

- **Files**

A file mapping structure provides a set of attributes for a file, including file size, number of file system extents that the file is composed of, and the file type.

- **File system extents**

A file system extent mapping structure describes a contiguous chunk of blocks residing on one element. This includes the device offset, the extent size, the file offset, the type (data or parity), and the name of the element where the extent resides.

 **Note:**

File system extents are different from Oracle Database extents. File system extents are physical contiguous blocks of data written to a device as managed by the file system. Oracle Database extents are logical structures managed by the database, such as tablespace extents.

- **Elements**

An element mapping structure is the abstract mapping structure that describes a storage component within the I/O stack. Elements may be mirrors, stripes, partitions, RAID5, concatenated elements, and disks. These structures are the mapping building blocks.

- **Subelements**

A subelement mapping structure describes the link between an element and the next elements in the I/O mapping stack. This structure contains the subelement number, size, the element name where the subelement exists, and the element offset.

All of these mapping structures are illustrated in the following example.

14.9.2.3 Example of Mapping Structures

An example illustrates mapping structures.

Consider an Oracle Database which is composed of two data files X and Y. Both files X and Y reside on a file system mounted on volume A. File X is composed of two extents while file Y is composed of only one extent.

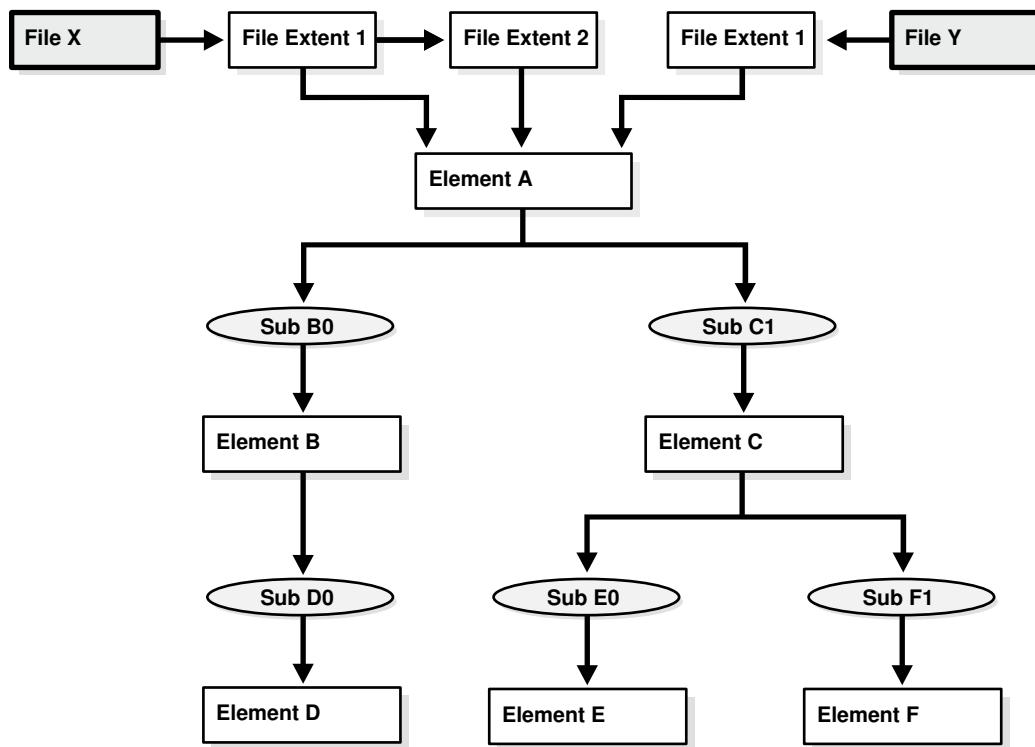

The two extents of File X and the one extent of File Y both map to Element A. Element A is striped to Elements B and C. Element A maps to Elements B and C by way of Subelements B0 and C1, respectively.

Element B is a partition of Element D (a physical disk), and is mapped to Element D by way of subelement D0.

Element C is mirrored over Elements E and F (both physical disks), and is mirrored to those physical disks by way of Subelements E0 and F1, respectively.

All of the mapping structures are illustrated in [Figure 14-2](#).

Figure 14-2 Illustration of Mapping Structures

Note that the mapping structures represented are sufficient to describe the entire mapping information for the Oracle Database instance and consequently to map every logical block within the file into a (element name, element offset) tuple (or more in case of mirroring) at each level within the I/O stack.

14.9.2.4 Configuration ID

The configuration ID captures the version information associated with elements or files.

The vendor library provides the configuration ID and updates it whenever a change occurs. Without a configuration ID, there is no way for the database to tell whether the mapping has changed.

There are two kinds of configuration IDs:

- Persistent

These configuration IDs are persistent across instance shutdown

- Non-persistent

The configuration IDs are not persistent across instance shutdown. The database is only capable of refreshing the mapping information while the instance is up.

14.9.3 Using the Oracle Database File Mapping Interface

You can use the Oracle Database file mapping interface to enable file mapping and obtain information about file mapping in a set of views.

- [Enabling File Mapping](#)
You can enable file mapping.
- [Using the DBMS_STORAGE_MAP Package](#)
The DBMS_STORAGE_MAP package enables you to control the mapping operations.
- [Obtaining Information from the File Mapping Views](#)
Mapping information generated by DBMS_STORAGE_MAP package is captured in dynamic performance views.

14.9.3.1 Enabling File Mapping

You can enable file mapping.

To enable file mapping:

1. Ensure that a valid filemap.ora file exists in the /opt/ORCLfmap/prot1_32/etc directory for 32-bit platforms, or in the /opt/ORCLfmap/prot1_64/etc directory for 64-bit platforms.

 **Note:**

While the format and content of the filemap.ora file is discussed here, it is for informational reasons only. The filemap.ora file is created by the database when your system is installed. Until such time that vendors supply their own libraries, there will be only one entry in the filemap.ora file, and that is the Oracle-supplied EMC library. This file should be modified manually by uncommenting this entry *only* if an EMC Symmetrix array is available.

The filemap.ora file is the configuration file that describes all of the available mapping libraries. FMON requires that a filemap.ora file exists and that it points to a valid path to mapping libraries. Otherwise, it will not start successfully.

The following row must be included in filemap.ora for each library:

`lib=vendor_name:library_path`

where:

- *vendor_name* should be `Oracle` for the EMC Symmetric library
- *library_path* is the full path of the mapping library

Note that the ordering of the libraries in this file is extremely important. The libraries are queried based on their order in the configuration file.

The file mapping service can be started even if no mapping libraries are available. The filemap.ora file still must be present even though it is empty. In this case, the mapping service is constrained in the sense that new mapping information cannot be discovered. Only restore and drop operations are allowed in such a configuration.

2. Set the `FILE_MAPPING` initialization parameter to `TRUE`.

The instance does not have to be shut down to set this parameter. You can set it using the following `ALTER SYSTEM` statement:

```
ALTER SYSTEM SET FILE_MAPPING=TRUE;
```

3. Invoke the appropriate DBMS_STORAGE_MAP mapping procedure. You have two options:
 - In a cold startup scenario, the Oracle Database is just started and no mapping operation has been invoked yet. You execute the DBMS_STORAGE_MAP.MAP_ALL procedure to build the mapping information for the entire I/O subsystem associated with the database.
 - In a warm start scenario where the mapping information is already built, you have the option to invoke the DBMS_STORAGE_MAP.MAP_SAVE procedure to save the mapping information in the data dictionary. (Note that this procedure is invoked in DBMS_STORAGE_MAP.MAP_ALL() by default.) This forces all of the mapping information in the SGA to be flushed to disk.

Once you restart the database, use DBMS_STORAGE_MAP.RESTORE() to restore the mapping information into the SGA. If needed, DBMS_STORAGE_MAP.MAP_ALL() can be called to refresh the mapping information.

14.9.3.2 Using the DBMS_STORAGE_MAP Package

The DBMS_STORAGE_MAP package enables you to control the mapping operations.

The various procedures available to you are described in the following table.

Procedure	Use to:
MAP_OBJECT	Build the mapping information for the database object identified by object name, owner, and type
MAP_ELEMENT	Build mapping information for the specified element
MAP_FILE	Build mapping information for the specified file name
MAP_ALL	Build entire mapping information for all types of database files (excluding archive logs)
DROP_ELEMENT	Drop the mapping information for a specified element
DROP_FILE	Drop the file mapping information for the specified file name
DROP_ALL	Drop all mapping information in the SGA for this instance
SAVE	Save into the data dictionary the required information needed to regenerate the entire mapping
RESTORE	Load the entire mapping information from the data dictionary into the shared memory of the instance
LOCK_MAP	Lock the mapping information in the SGA for this instance
UNLOCK_MAP	Unlock the mapping information in the SGA for this instance

See Also:

- *Oracle Database PL/SQL Packages and Types Reference* for a description of the DBMS_STORAGE_MAP package
- "[File Mapping Examples](#)" for an example of using the DBMS_STORAGE_MAP package

14.9.3.3 Obtaining Information from the File Mapping Views

Mapping information generated by `DBMS_STORAGE_MAP` package is captured in dynamic performance views.

Brief descriptions of these views are presented here.

View	Description
<code>V\$MAP_LIBRARY</code>	Contains a list of all mapping libraries that have been dynamically loaded by the external process
<code>V\$MAP_FILE</code>	Contains a list of all file mapping structures in the shared memory of the instance
<code>V\$MAP_FILE_EXTENT</code>	Contains a list of all file system extent mapping structures in the shared memory of the instance
<code>V\$MAP_ELEMENT</code>	Contains a list of all element mapping structures in the SGA of the instance
<code>V\$MAP_EXT_ELEMENT</code>	Contains supplementary information for all element mapping
<code>V\$MAP_SUBELEMENT</code>	Contains a list of all subelement mapping structures in the shared memory of the instance
<code>V\$MAP_COMP_LIST</code>	Contains supplementary information for all element mapping structures.
<code>V\$MAP_FILE_IO_STACK</code>	The hierarchical arrangement of storage containers for the file displayed as a series of rows. Each row represents a level in the hierarchy.

However, the information generated by the `DBMS_STORAGE_MAP.MAP_OBJECT` procedure is captured in a global temporary table named `MAP_OBJECT`. This table displays the hierarchical arrangement of storage containers for objects. Each row in the table represents a level in the hierarchy. A description of the `MAP_OBJECT` table follows.

Column	Data Type	Description
<code>OBJECT_NAME</code>	<code>VARCHAR2(2000)</code>	Name of the object
<code>OBJECT_OWNER</code>	<code>VARCHAR2(2000)</code>	Owner of the object
<code>OBJECT_TYPE</code>	<code>VARCHAR2(2000)</code>	Object type
<code>FILE_MAP_IDX</code>	<code>NUMBER</code>	File index (corresponds to <code>FILE_MAP_IDX</code> in <code>V\$MAP_FILE</code>)
<code>DEPTH</code>	<code>NUMBER</code>	Element depth within the I/O stack
<code>ELEM_IDX</code>	<code>NUMBER</code>	Index corresponding to element
<code>CU_SIZE</code>	<code>NUMBER</code>	Contiguous set of logical blocks of the file, in HKB (half KB) units, that is resident contiguously on the element
<code>STRIDE</code>	<code>NUMBER</code>	Number of HKB between contiguous units (CU) in the file that are contiguous on this element. Used in RAID5 and striped files.
<code>NUM CU</code>	<code>NUMBER</code>	Number of contiguous units that are adjacent to each other on this element that are separated by <code>STRIDE</code> HKB in the file. In RAID5, the number of contiguous units also include the parity stripes.

Column	Data Type	Description
ELEM_OFFSET	NUMBER	Element offset in HKB units
FILE_OFFSET	NUMBER	Offset in HKB units from the start of the file to the first byte of the contiguous units
DATA_TYPE	VARCHAR2(2000)	Data type (DATA, PARITY, or DATA AND PARITY)
PARITY_POS	NUMBER	Position of the parity. Only for RAID5. This field is needed to distinguish the parity from the data part.
PARITY_PERIOD	NUMBER	Parity period. Only for RAID5.

14.9.4 File Mapping Examples

Examples illustrates some of the powerful capabilities of the Oracle Database file mapping feature.

These capabilities include:

- The ability to map all the database files that span a particular device
- The ability to map a particular file into its corresponding devices
- The ability to map a particular database object, including its block distribution at all levels within the I/O stack

Consider an Oracle Database instance which is composed of two data files:

- t_db1.f
- t_db2.f

These files are created on a Solaris UFS file system mounted on a VERITAS VxVM host based striped volume, /dev/vx/dsk/ipfdg/ipf-vol1, that consists of the following host devices as externalized from an EMC Symmetrix array:

- /dev/vx/rdmp/c2t1d0s2
- /dev/vx/rdmp/c2t1d1s2

Note that the following examples require the execution of a MAP_ALL() operation.

- [Example 1: Map All Database Files that Span a Device](#)
An example illustrates returning all Oracle Database files associated with a host device.
- [Example 2: Map a File Into Its Corresponding Devices](#)
An example displays a topological graph of a data file.
- [Example 3: Map a Database Object](#)
An example displays the block distribution at all levels within the I/O stack for a table.

14.9.4.1 Example 1: Map All Database Files that Span a Device

An example illustrates returning all Oracle Database files associated with a host device.

The following query returns all Oracle Database files associated with the /dev/vx/rdmp/c2t1d1s2 host device:

```
SELECT UNIQUE me.ELEM_NAME, mf.FILE_NAME
  FROM V$MAP_FILE_IO_STACK fs, V$MAP_FILE mf, V$MAP_ELEMENT me
 WHERE mf.FILE_MAP_IDX = fs.FILE_MAP_IDX
   AND me.ELEM_IDX = fs.ELEM_IDX
   AND me.ELEM_NAME = '/dev/vx/rdmp/c2t1d1s2';
```

The query results are:

ELEM_NAME	FILE_NAME
/dev/vx/rdmp/c2t1d1s2	/oracle/dbs/t_db1.f
/dev/vx/rdmp/c2t1d1s2	/oracle/dbs/t_db2.f

14.9.4.2 Example 2: Map a File Into Its Corresponding Devices

An example displays a topological graph of a data file.

The following query displays a topological graph of the /oracle/dbs/t_db1.f data file:

```
WITH fv AS
  (SELECT FILE_MAP_IDX, FILE_NAME FROM V$MAP_FILE
   WHERE FILE_NAME = '/oracle/dbs/t_db1.f')
SELECT fv.FILE_NAME, LPAD(' ', 4 * (LEVEL - 1)) || el.ELEM_NAME ELEM_NAME
  FROM V$MAP_SUBELEMENT sb, V$MAP_ELEMENT el, fv,
       (SELECT UNIQUE ELEM_IDX FROM V$MAP_FILE_IO_STACK io, fv
        WHERE io.FILE_MAP_IDX = fv.FILE_MAP_IDX) fs
 WHERE el.ELEM_IDX = sb.CHILD_IDX
   AND fs.ELEM_IDX = el.ELEM_IDX
 START WITH sb.PARENT_IDX IN
  (SELECT DISTINCT ELEM_IDX
   FROM V$MAP_FILE_EXTENT fe, fv
   WHERE fv.FILE_MAP_IDX = fe.FILE_MAP_IDX)
 CONNECT BY PRIOR sb.CHILD_IDX = sb.PARENT_IDX;
```

The resulting topological graph is:

FILE_NAME	ELEM_NAME
/oracle/dbs/t_db1.f	_sym_plex/_dev/vx/rdsk/ipfdg/ipf-voll_-1_-1
/oracle/dbs/t_db1.f	_sym_subdisk/_dev/vx/rdsk/ipfdg/ipf-voll_0_0_0
/oracle/dbs/t_db1.f	/dev/vx/rdmp/c2t1d0s2
/oracle/dbs/t_db1.f	_sym_symdev_000183600407_00C
/oracle/dbs/t_db1.f	_sym_hyper_000183600407_00C_0
/oracle/dbs/t_db1.f	_sym_hyper_000183600407_00C_1
/oracle/dbs/t_db1.f	_sym_subdisk/_dev/vx/rdsk/ipfdg/ipf-voll_0_1_0
/oracle/dbs/t_db1.f	/dev/vx/rdmp/c2t1d1s2
/oracle/dbs/t_db1.f	_sym_symdev_000183600407_00D
/oracle/dbs/t_db1.f	_sym_hyper_000183600407_00D_0
/oracle/dbs/t_db1.f	_sym_hyper_000183600407_00D_1

14.9.4.3 Example 3: Map a Database Object

An example displays the block distribution at all levels within the I/O stack for a table.

This example displays the block distribution at all levels within the I/O stack for the scott.bonus table.

A MAP_OBJECT() operation must first be executed as follows:

```
EXECUTE DBMS_STORAGE_MAP.MAP_OBJECT('BONUS', 'SCOTT', 'TABLE');
```

The query is as follows:

```
SELECT io.OBJECT_NAME o_name, io.OBJECT_OWNER o_owner, io.OBJECT_TYPE o_type,
       mf.FILE_NAME, me.ELEM_NAME, io.DEPTH,
       (SUM(io.CU_SIZE * (io.NUM CU - DECODE(io.PARITY_PERIOD, 0, 0,
                                              TRUNC(io.NUM CU / io.PARITY_PERIOD)))) / 2) o_size
    FROM MAP_OBJECT io, V$MAP_ELEMENT me, V$MAP_FILE mf
   WHERE io.OBJECT_NAME = 'BONUS'
     AND io.OBJECT_OWNER = 'SCOTT'
     AND io.OBJECT_TYPE = 'TABLE'
     AND me.ELEM_IDX = io.ELEM_IDX
     AND mf.FILE_MAP_IDX = io.FILE_MAP_IDX
  GROUP BY io.ELEM_IDX, io.FILE_MAP_IDX, me.ELEM_NAME, mf.FILE_NAME, io.DEPTH,
           io.OBJECT_NAME, io.OBJECT_OWNER, io.OBJECT_TYPE
 ORDER BY io.DEPTH;
```

The following is the result of the query. Note that the `o_size` column is expressed in KB.

O_NAME	O_OWNER	O_TYPE	FILE_NAME	ELEM_NAME	DEPTH	O_SIZE
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	/dev/vx/dsk/ipfdg/ipf-voll	0	20
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_plex_/_dev/vx/rdsk/ipf	1	20
				pdg/if-voll_-1_-1		
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_subdisk_/_dev/vx/rdsk/	2	12
				ipfdg/ipf-voll_0_1_0		
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_subdisk_/_dev/vx/rdsk/ipf	2	8
				dg/ipf-voll_0_2_0		
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	/dev/vx/rdmp/c2t1d1s2	3	12
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	/dev/vx/rdmp/c2t1d2s2	3	8
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_symdev_000183600407_00D	4	12
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_symdev_000183600407_00E	4	8
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_hyper_000183600407_00D_0	5	12
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_hyper_000183600407_00D_1	5	12
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_hyper_000183600407_00E_0	6	8
BONUS	SCOTT	TABLE	/oracle/dbs/t_db1.f	_sym_hyper_000183600407_00E_1	6	8

14.10 Data Files Data Dictionary Views

A set of data dictionary views provides useful information about the data files of a database.

View	Description
DBA_DATA_FILES	Provides descriptive information about each data file, including the tablespace to which it belongs and the file ID. The file ID can be used to join with other views for detail information.
DBA_EXTENTS	DBA view describes the extents comprising all segments in the database. Contains the file ID of the data file containing the extent. USER view describes extents of the segments belonging to objects owned by the current user.
USER_EXTENTS	
DBA_FREE_SPACE	DBA view lists the free extents in all tablespaces. Includes the file ID of the data file containing the extent. USER view lists the free extents in the tablespaces accessible to the current user.
USER_FREE_SPACE	
V\$DATAFILE	Contains data file information from the control file
V\$DATAFILE_HEADER	Contains information from data file headers

This example illustrates the use of one of these views, V\$DATAFILE.

```
SELECT NAME,
       FILE#,
       STATUS,
       CHECKPOINT_CHANGE# "CHECKPOINT"
  FROM   V$DATAFILE;
```

NAME	FILE#	STATUS	CHECKPOINT
/u01/oracle/rbdb1/system01.dbf	1	SYSTEM	3839
/u02/oracle/rbdb1/temp01.dbf	2	ONLINE	3782
/u02/oracle/rbdb1/users03.dbf	3	OFFLINE	3782

FILE# lists the file number of each data file; the first data file in the SYSTEM tablespace created with the database is always file 1. STATUS lists other information about a data file. If a data file is part of the SYSTEM tablespace, its status is SYSTEM (unless it requires recovery). If a data file in a non-SYSTEM tablespace is online, its status is ONLINE. If a data file in a non-SYSTEM tablespace is offline, its status can be either OFFLINE or RECOVER. CHECKPOINT lists the final SCN (system change number) written for the most recent checkpoint of a data file.

15

Transporting Data

Transporting data moves the data from one database to another.

- [About Transporting Data](#)
You can transport data at the following levels: database, tablespaces, tables, partitions, and subpartitions.
- [Transporting Databases](#)
You can transport a database to a new Oracle Database instance.
- [Transporting Tablespaces Between Databases](#)
You can transport tablespaces between databases.
- [Transporting Tables, Partitions, or Subpartitions Between Databases](#)
You can transport tables, partitions, and subpartitions between databases.
- [Converting Data Between Platforms](#)
When you perform a transportable operation, and the source platform and the target platform are of different endianness, you must convert the data being transported to the target format. If they are of the same endianness, then no conversion is necessary and data can be transported as if they were on the same platform. You can use the DBMS_FILE_TRANSFER package or the RMAN CONVERT command to convert data.
- [Guidelines for Transferring Data Files](#)
You should follow a set of guidelines when transferring the data files.

15.1 About Transporting Data

You can transport data at the following levels: database, tablespaces, tables, partitions, and subpartitions.

- [Purpose of Transporting Data](#)
Transporting data is much faster than performing either an export/import or unload/load of the same data. It is faster because, for user-defined tablespaces, the data files containing all of the actual data are copied to the target location, and you use Data Pump to transfer only the metadata of the database objects to the new database.
- [Transporting Data: Scenarios](#)
Transporting data is useful in several scenarios.
- [Transporting Data Across Platforms](#)
You can transport data across platforms.
- [General Limitations on Transporting Data](#)
There are general limitations on transporting data. There are also limitations that are specific to full transportable export/import, transportable tablespaces, or transportable tables.
- [Compatibility Considerations for Transporting Data](#)
When transporting data, Oracle Database computes the lowest compatibility level at which the target database must run.

15.1.1 Purpose of Transporting Data

Transporting data is much faster than performing either an export/import or unload/load of the same data. It is faster because, for user-defined tablespaces, the data files containing all of the actual data are copied to the target location, and you use Data Pump to transfer only the metadata of the database objects to the new database.

You can transport data at any of the following levels:

- Database

You can use the **full transportable export/import** feature to move an entire database to a different database instance.

- Tablespaces

You can use the **transportable tablespaces** feature to move a set of tablespaces between databases.

- Tables, partitions, and subpartitions

You can use the **transportable tables** feature to move a set of tables, partitions, and subpartitions between databases.

Transportable tablespaces and transportable tables only transports data that resides in user-defined tablespaces. However, full transportable export/import transports data that resides in both user-defined and administrative tablespaces, such as SYSTEM and SYSAUX. Full transportable export/import transports metadata for objects contained within the user-defined tablespaces and both the metadata and data for user-defined objects contained within the administrative tablespaces. Specifically, with full transportable export/import, the export dump file includes only the metadata for objects contained within the user-defined tablespaces, but it includes both the metadata and the data for user-defined objects contained within the administrative tablespaces.

15.1.2 Transporting Data: Scenarios

Transporting data is useful in several scenarios.

- [Scenarios for Full Transportable Export/import](#)

The full transportable export/import feature is useful in several scenarios.

- [Scenarios for Transportable Tablespaces or Transportable Tables](#)

The transportable tablespaces or transportable tables feature is useful in several scenarios.

15.1.2.1 Scenarios for Full Transportable Export/import

The full transportable export/import feature is useful in several scenarios.

- [Moving a Non-CDB Into a CDB](#)

The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB) that includes one or many customer-created pluggable databases (PDBs). You can move a non-CDB into a CDB by transporting the database.

- [Moving a Database to a New Computer System](#)

You can use full transportable export/import to move a database from one computer system to another. You might want to move a database to a new

computer system to upgrade the hardware or to move the database to a different platform.

- [Upgrading to a New Release of Oracle Database](#)

You can use full transportable export/import to upgrade a database from an Oracle Database 11g Release 2 (11.2.0.3) or later to Oracle Database 12c.

15.1.2.1.1 Moving a Non-CDB Into a CDB

The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB) that includes one or many customer-created pluggable databases (PDBs). You can move a non-CDB into a CDB by transporting the database.

The transported database becomes a pluggable database (PDB) associated with the CDB. Full transportable export/import can move an Oracle Database 11g Release 2 (11.2.0.3) or later database into an Oracle Database 12c CDB efficiently.

See Also:

- ["Transporting a Database Using an Export Dump File"](#) for instructions that describe transporting a non-CDB into a PDB in an Oracle Database 12c CDB
- ["Transporting a Database Over the Network"](#) for an example that transports an Oracle Database 11g Release 2 (11.2.0.3) database into a PDB in an Oracle Database 12c CDB
- ["Creating a PDB Using a Non-CDB"](#)

15.1.2.1.2 Moving a Database to a New Computer System

You can use full transportable export/import to move a database from one computer system to another. You might want to move a database to a new computer system to upgrade the hardware or to move the database to a different platform.

See Also:

- ["Transporting Databases"](#)
- ["Transporting Data Across Platforms"](#)

15.1.2.1.3 Upgrading to a New Release of Oracle Database

You can use full transportable export/import to upgrade a database from an Oracle Database 11g Release 2 (11.2.0.3) or later to Oracle Database 12c.

To do so, install Oracle Database 12c and create an empty database. Next, use full transportable export/import to transport the Oracle Database 11g Release 2 (11.2.0.3) database into the Oracle Database 12c database.

 **See Also:**

- ["Transporting Databases"](#)
- [Oracle Database Installation Guide](#)

15.1.2.2 Scenarios for Transportable Tablespaces or Transportable Tables

The transportable tablespaces or transportable tables feature is useful in several scenarios.

- [Scenarios That Apply to Transportable Tablespaces or Transportable Tables](#)
For some scenarios, either transportable tablespaces or transportable tables can be useful. For other scenarios, only transportable tablespaces can be useful, or only transportable tables can be useful.
- [Transporting and Attaching Partitions for Data Warehousing](#)
You can use transportable tables and tranportable tablespaces to attach partitions for data warehousing.
- [Publishing Structured Data on CDs](#)
Transportable tablespaces and transportable tables both provide a way to publish structured data on CDs.
- [Mounting the Same Tablespace Read-Only on Multiple Databases](#)
You can use transportable tablespaces to mount a tablespace read-only on multiple databases.
- [Archiving Historical Data](#)
When you use transportable tablespaces or transportable tables, the transported data is a self-contained set of files that can be imported into any Oracle database. Therefore, you can archive old or historical data in an enterprise data warehouse using the transportable tablespaces and transportable tables procedures.
- [Using Transportable Tablespaces to Perform TSPITR](#)
You can use transportable tablespaces to perform tablespace point-in-time recovery (TSPITR).
- [Copying or Moving Individual Tables](#)
You can use transportable tables to move a table or a set of tables from one database to another without transporting the entire tablespaces that contain the tables. You can also copy or move individual partitions and subpartitions from one database to another using transportable tables.

15.1.2.2.1 Scenarios That Apply to Transportable Tablespaces or Transportable Tables

For some scenarios, either transportable tablespaces or transportable tables can be useful. For other scenarios, only transportable tablespaces can be useful, or only transportable tables can be useful.

[Table 15-1](#) shows which feature can be used for each scenario.

Table 15-1 Scenarios for Transportable Tablespaces and Transportable Tables

Scenarios	Transportable Tablespaces	Transportable Tables
Transporting and Attaching Partitions for Data Warehousing	Yes	Yes
Publishing Structured Data on CDs	Yes	Yes
Archiving Historical Data	Yes	Yes
Using Transportable Tablespaces to Perform TSPITR	Yes	No
Copying or Moving Individual Tables	No	Yes

The following sections describe these scenarios in more detail.

15.1.2.2.2 Transporting and Attaching Partitions for Data Warehousing

You can use transportable tables and transportable tablespaces to attach partitions for data warehousing.

Typical enterprise data warehouses contain one or more large fact tables. These fact tables can be partitioned by date, making the enterprise data warehouse a historical database. You can build indexes to speed up star queries. Oracle recommends that you build local indexes for such historically partitioned tables to avoid rebuilding global indexes every time you drop the oldest partition from the historical database.

Suppose every month you would like to load one month of data into the data warehouse. There is a large fact table in the data warehouse called `sales`, which has the following columns:

```
CREATE TABLE sales (invoice_no NUMBER,
    sale_year INT NOT NULL,
    sale_month INT NOT NULL,
    sale_day INT NOT NULL)
PARTITION BY RANGE (sale_year, sale_month, sale_day)
    (partition jan2011 VALUES LESS THAN (2011, 2, 1),
     partition feb2011 VALUES LESS THAN (2011, 3, 1),
     partition mar2011 VALUES LESS THAN (2011, 4, 1),
     partition apr2011 VALUES LESS THAN (2011, 5, 1),
     partition may2011 VALUES LESS THAN (2011, 6, 1),
     partition jun2011 VALUES LESS THAN (2011, 7, 1));
```

You create a local non-prefixed index:

```
CREATE INDEX sales_index ON sales(invoice_no) LOCAL;
```

Initially, all partitions are empty, and are in the same default tablespace. Each month, you want to create one partition and attach it to the partitioned `sales` table.

Suppose it is July 2011, and you would like to load the July sales data into the partitioned table. In a staging database, you create a table, `jul_sales` with the same column types as the `sales` table. Optionally, you can create a new tablespace, `ts_jul`, before you create the table, and create the table in this tablespace. You can create the table `jul_sales` using the `CREATE TABLE ... AS SELECT` statement. After creating and populating `jul_sales`, you can also create an index, `jul_sale_index`, for the table, indexing the same column as the local index in the `sales` table. For detailed

information about creating and populating a staging table in a data warehousing environment, see *Oracle Database Data Warehousing Guide*.

After creating the table and building the index, transport the table's data to the data warehouse in one of the following ways:

- You can use transportable tables to transport the `jul_sales` table to the data warehouse.
- If you created the `ts_jul` tablespace, then you can use transportable tablespaces to transport the tablespace `ts_jul` to the data warehouse.

In the data warehouse, add a partition to the `sales` table for the July sales data. This also creates another partition for the local non-prefixed index:

```
ALTER TABLE sales ADD PARTITION jul2011 VALUES LESS THAN (2011, 8, 1);
```

Attach the transported table `jul_sales` to the table `sales` by exchanging it with the new partition:

```
ALTER TABLE sales EXCHANGE PARTITION jul2011 WITH TABLE jul_sales
  INCLUDING INDEXES
  WITHOUT VALIDATION;
```

This statement places the July sales data into the new partition `jul2011`, attaching the new data to the partitioned table. This statement also converts the index `jul_sale_index` into a partition of the local index for the `sales` table. This statement should return immediately, because it only operates on the structural information and it simply switches database pointers. If you know that the data in the new partition does not overlap with data in previous partitions, you are advised to specify the `WITHOUT VALIDATION` clause. Otherwise, the statement goes through all the new data in the new partition in an attempt to validate the range of that partition.

If all partitions of the `sales` table came from the same staging database (the staging database is never destroyed), then the exchange statement always succeeds. In general, however, if data in a partitioned table comes from different databases, then the exchange operation might fail. For example, if the `jan2011` partition of `sales` did not come from the same staging database, then the preceding exchange operation can fail, returning the following error:

```
ORA-19728: data object number conflict between table JUL_SALES and partition JAN2011
in table SALES
```

To resolve this conflict, move the offending partition by issuing the following statement:

```
ALTER TABLE sales MOVE PARTITION jan2011;
```

Then retry the exchange operation.

After the exchange succeeds, you can safely drop `jul_sales` and `jul_sale_index` (both are now empty). Thus you have successfully loaded the July sales data into your data warehouse.

15.1.2.2.3 Publishing Structured Data on CDs

Transportable tablespaces and transportable tables both provide a way to publish structured data on CDs.

You can copy the data to be published, including the data files and export dump file, to a CD. This CD can then be distributed. If you are using transportable tablespaces, then you must generate a transportable set before copying the data to the CD.

When customers receive this CD, they can add the CD contents to an existing database without having to copy the data files from the CD to disk storage. For example, suppose on a Microsoft Windows system D: drive is the CD drive. You can import the data in data file catalog.f and the export dump file expdat.dmp as follows:

```
impdp user_name/password DUMPFILE=expdat.dmp DIRECTORY=dpump_dir  
TRANSPORT_DATAFILES='D:\catalog.f'
```

You can remove the CD while the database is still up. Subsequent queries to the data return an error indicating that the database cannot open the data files on the CD. However, operations to other parts of the database are not affected. Placing the CD back into the drive makes the data readable again.

Removing the CD is the same as removing the data files of a read-only tablespace. If you shut down and restart the database, then the database indicates that it cannot find the removed data file and does not open the database (unless you set the initialization parameter READ_ONLY_OPEN_DELAYED to TRUE). When READ_ONLY_OPEN_DELAYED is set to TRUE, the database reads the file only when someone queries the data. Thus, when transporting data from a CD, set the READ_ONLY_OPEN_DELAYED initialization parameter to TRUE, unless the CD is permanently attached to the database.

15.1.2.2.4 Mounting the Same Tablespace Read-Only on Multiple Databases

You can use transportable tablespaces to mount a tablespace read-only on multiple databases.

In this way, separate databases can share the same data on disk instead of duplicating data on separate disks. The tablespace data files must be accessible by all databases. To avoid database corruption, the tablespace must remain read-only in all the databases mounting the tablespace, and the tablespace's data files must be read-only at the operating system level.

The following are two scenarios for mounting the same tablespace read-only on multiple databases:

- The tablespace originates in a database that is separate from the databases that will share the tablespace.

You generate a transportable set in the source database, put the transportable set onto a disk that is accessible to all databases, and then import the metadata into each database on which you want to mount the tablespace.

- The tablespace already belongs to one of the databases that will share the tablespace.

It is assumed that the data files are already on a shared disk. In the database where the tablespace already exists, you make the tablespace read-only, generate the transportable set, and then import the tablespace into the other databases, leaving the data files in the same location on the shared disk.

You can make a disk accessible by multiple computers in several ways. You can use either a cluster file system or raw disk. You can also use network file system (NFS), but be aware that if a user queries the shared tablespace while NFS is down, the database will hang until the NFS operation times out.

Later, you can drop the read-only tablespace in some of the databases. Doing so does not modify the data files for the tablespace. Thus, the drop operation does not corrupt the tablespace. Do not make the tablespace read/write unless only one database is mounting the tablespace.

15.1.2.2.5 Archiving Historical Data

When you use transportable tablespaces or transportable tables, the transported data is a self-contained set of files that can be imported into any Oracle database.

Therefore, you can archive old or historical data in an enterprise data warehouse using the transportable tablespaces and transportable tables procedures.

 **See Also:**

Oracle Database Data Warehousing Guide for more details

15.1.2.2.6 Using Transportable Tablespaces to Perform TSPITR

You can use transportable tablespaces to perform tablespace point-in-time recovery (TSPITR).

 **See Also:**

Oracle Database Backup and Recovery User's Guide for information about how to perform TSPITR using transportable tablespaces

15.1.2.2.7 Copying or Moving Individual Tables

You can use transportable tables to move a table or a set of tables from one database to another without transporting the entire tablespaces that contain the tables. You can also copy or move individual partitions and subpartitions from one database to another using transportable tables.

 **See Also:**

"Transporting Tables, Partitions, or Subpartitions Between Databases"

15.1.3 Transporting Data Across Platforms

You can transport data across platforms.

This capability can be used to:

- Allow a database to be migrated from one platform to another

- Provide an easier and more efficient means for content providers to publish structured data and distribute it to customers running Oracle Database on different platforms
- Simplify the distribution of data from a data warehouse environment to data marts, which are often running on smaller platforms
- Enable the sharing of read-only tablespaces between Oracle Database installations on different operating systems or platforms, assuming that your storage system is accessible from those platforms and the platforms all have the same endianness, as described in the sections that follow.

Many, but not all, platforms are supported for cross-platform data transport. You can query the V\$TRANSPORTABLE_PLATFORM view to see the platforms that are supported, and to determine each platform's endian format (byte ordering). The following query displays the platforms that support cross-platform data transport:

```
COLUMN PLATFORM_NAME FORMAT A40
COLUMN ENDIAN_FORMAT A14

SELECT PLATFORM_ID, PLATFORM_NAME, ENDIAN_FORMAT
  FROM V$TRANSPORTABLE_PLATFORM
 ORDER BY PLATFORM_ID;
```

PLATFORM_ID	PLATFORM_NAME	ENDIAN_FORMAT
1	Solaris[tm] OE (32-bit)	Big
2	Solaris[tm] OE (64-bit)	Big
3	HP-UX (64-bit)	Big
4	HP-UX IA (64-bit)	Big
5	HP Tru64 UNIX	Little
6	AIX-Based Systems (64-bit)	Big
7	Microsoft Windows IA (32-bit)	Little
8	Microsoft Windows IA (64-bit)	Little
9	IBM zSeries Based Linux	Big
10	Linux IA (32-bit)	Little
11	Linux IA (64-bit)	Little
12	Microsoft Windows x86 64-bit	Little
13	Linux x86 64-bit	Little
15	HP Open VMS	Little
16	Apple Mac OS	Big
17	Solaris Operating System (x86)	Little
18	IBM Power Based Linux	Big
19	HP IA Open VMS	Little
20	Solaris Operating System (x86-64)	Little
21	Apple Mac OS (x86-64)	Little

If source platform and the target platform are of the same endianness, then no conversion is necessary, and data can be transported as if they were on the same platform.

If the source platform and the target platform are of different endianness, then the data being transported must be converted to the target platform format. You can convert the data using one of the following methods:

- The GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package

When you use one of these procedures to move data files between the source platform and the target platform, each block in each data file is converted to the target platform's endianness. The conversion occurs on the target platform.

- The RMAN CONVERT command

Running the RMAN CONVERT command is an additional step that can be completed on the source or target platform. It converts the data being transported to the target platform format.

Before the data in a data file can be transported to a different platform, the data file header must identify the platform to which it belongs. When you are transporting read-only tablespaces between Oracle Database installations on different platforms, you can accomplish this by making the data file read/write at least once.

See Also:

["Converting Data Between Platforms"](#)

15.1.4 General Limitations on Transporting Data

There are general limitations on transporting data. There are also limitations that are specific to full transportable export/import, transportable tablespaces, or transportable tables.

Be aware of the following general limitations as you plan to transport data:

- The source and the target databases must use compatible database character sets. Specifically, one of the following must be true:
 - The database character sets of the source and the target databases are the same.
 - The source database character set is a strict (binary) subset of the target database character set, and the following three conditions are true:
 - * The source database is Oracle Database 10g Release 1 (10.1.0.3) or later.
 - * The tablespaces to be transported contain no table columns with character length semantics or the maximum character width is the same in both the source and target database character sets.
 - * The data to be transported contains no columns with the CLOB data type, or the source and the target database character sets are both single-byte or both multibyte.
 - The source database character set is a strict (binary) subset of the target database character set, and the following two conditions are true:
 - * The source database is before Oracle Database 10g Release 1 (10.1.0.3).
 - * The maximum character width is the same in the source and target database character sets.

 **Note:**

The subset-superset relationship between character sets recognized by Oracle Database is documented in the *Oracle Database Globalization Support Guide*.

- The source and the target databases must use compatible national character sets. Specifically, one of the following must be true:
 - The national character sets of the source and target databases are the same.
 - The source database is Oracle Database 10g Release 1 (10.1.0.3) or later and the tablespaces to be transported contain no columns with NCHAR, NVARCHAR2, or NCLOB data type.
- When running a transportable export operation, the following limitations apply:
 - The default tablespace of the user performing the export must not be one of the tablespaces being transported.
 - The default tablespace of the user performing the export must be writable.
- In a non-CDB, you cannot transport a tablespace to a target database that contains a tablespace of the same name.

In a CDB, you cannot transport a tablespace to a target container that contains a tablespace of the same name. However, different containers can have tablespaces with the same name.

You can use the `REMAP_TABLESPACE` import parameter to import the database objects into a different tablespace. Alternatively, before the transport operation, you can rename either the tablespace to be transported or the target tablespace.

Starting with Oracle Database 12c Release 2 (12.2), the Recovery Manager (RMAN) `RECOVER` command can move tables to a different schema while remapping a tablespace. See *Oracle Database Backup and Recovery User's Guide* for more information.

- In a CDB, the default Data Pump directory object, `DATA_PUMP_DIR`, does not work with PDBs. You must define an explicit directory object within the PDB that you are using with Data Pump export/import.
- Transporting data with XMLTypes has the following limitations:
 - The target database must have XML DB installed.
 - Schemas referenced by XMLType tables cannot be the XML DB standard schemas.
 - If the schema for a transported XMLType table is not present in the target database, then it is imported and registered. If the schema already exists in the target database, then a message is displayed during import.
 - You must use only Data Pump to export and import the metadata for data that contains XMLTypes.

The following query returns a list of tablespaces that contain XMLTypes:

```
select distinct p.tablespace_name from dba_tablespaces p,
      dba_xml_tables x, dba_users u, all_all_tables t where
      t.table_name=x.table_name and t.tablespace_name=p.tablespace_name
      and x.owner=u.username;
```

See *Oracle XML DB Developer's Guide* for information on XMLTypes.

- Types whose interpretation is application-specific and opaque to the database (such as RAW, BFILE, and the AnyTypes) can be transported, but they are not converted as part of the cross-platform transport operation. Their actual structure is known only to the application, so the application must address any endianness issues after these types are moved to the new platform. Types and objects that use these opaque types, either directly or indirectly, are also subject to this limitation.
- When you transport a tablespace containing tables with `TIMESTAMP WITH LOCAL TIME ZONE (TSLTZ)` data between databases with different time zones, the tables with the TSLTZ data are not transported. Error messages describe the tables that were not transported. However, tables in the tablespace that do not contain TSLTZ data are transported.

You can determine the time zone of a database with the following query:

```
SELECT DBTIMEZONE FROM DUAL;
```

You can alter the time zone for a database with an `ALTER DATABASE` SQL statement.

You can use Data Pump to perform a conventional export/import of tables with TSLTZ data after the transport operation completes.

- Analytic workspaces cannot be part of cross-platform transport operations. If the source platform and target platform are different, then use Data Pump export/import to export and import analytic workspaces. See *Oracle OLAP DML Reference* for more information about analytic workspaces.

 **Note:**

Do not invoke Data Pump export utility `expdp` or import utility `impdp` as `SYSDBA`, except at the request of Oracle technical support. `SYSDBA` is used internally and has specialized functions; its behavior is not the same as for general users.

Certain limitations are specific to full transportable export/import, transportable tablespaces, or transportable tables. See the appropriate section for information:

- "[Limitations on Full Transportable Export/import](#)"
- "[Limitations on Transportable Tablespaces](#)"
- "[Limitations on Transportable Tables](#)"

15.1.5 Compatibility Considerations for Transporting Data

When transporting data, Oracle Database computes the lowest compatibility level at which the target database must run.

A tablespace or table can always be transported to a database with the same or higher compatibility setting using transportable tablespaces, whether the target database is on the same or a different platform. The database signals an error if the compatibility

level of the source database is higher than the compatibility level of the target database.

The following table shows the minimum compatibility requirements of the source and target databases in various scenarios. The source and target database need not have the same compatibility setting.

Table 15-2 Minimum Compatibility Requirements

Transport Scenario	Minimum Compatibility Setting	
	Source Database	Target Database
Transporting a database using full transportable export/import	12.0 (COMPATIBLE initialization parameter setting for an Oracle Database 12c database) 12 (VERSION Data Pump export parameter setting for an 11.2.0.3 or later database)	12.0 (COMPATIBLE initialization parameter setting)
Transporting a tablespace between databases on the same platform using transportable tablespaces	8.0 (COMPATIBLE initialization parameter setting)	8.0 (COMPATIBLE initialization parameter setting)
Transporting a tablespace with different database block size than the target database using transportable tablespaces	9.0 (COMPATIBLE initialization parameter setting)	9.0 (COMPATIBLE initialization parameter setting)
Transporting a tablespace between databases on different platforms using transportable tablespaces	10.0 (COMPATIBLE initialization parameter setting)	10.0 (COMPATIBLE initialization parameter setting)
Transporting tables between databases	11.1.0.6 (COMPATIBLE initialization parameter setting for an Oracle Database 12c database)	11.1.0.6 (COMPATIBLE initialization parameter setting)

When you use full transportable export/import, the source database must be an Oracle Database 11g Release 2 (11.2.0.3) or later database, and the target database must be an Oracle Database 12c database. When transporting a database from Oracle Database 11g Release 2 (11.2.0.3) or a later to Oracle Database 12c, the VERSION Data Pump export parameter must be set to 12 or higher. When transporting a database from Oracle Database 12c to Oracle Database 12c, the COMPATIBLE initialization parameter must be set to 12.0.0 or higher.

15.2 Transporting Databases

You can transport a database to a new Oracle Database instance.

- [Introduction to Full Transportable Export/Import](#)

You can use the full transportable export/import feature to copy an entire database from one Oracle Database instance to another.

- [Limitations on Full Transportable Export/Import](#)

There are limitations on full transportable export/import.

- [Transporting a Database Using an Export Dump File](#)
You can transport a database using an export dump file.
- [Transporting a Database Over the Network](#)
You can transport a database over the network.

15.2.1 Introduction to Full Transportable Export/Import

You can use the full transportable export/import feature to copy an entire database from one Oracle Database instance to another.

You can use Data Pump to produce an export dump file, transport the dump file to the target database if necessary, and then import the export dump file. Alternatively, you can use Data Pump to copy the database over the network.

The tablespaces in the database being transported can be either dictionary managed or locally managed. The tablespaces in the database are not required to be of the same block size as the target database standard block size.

 **Note:**

This method for transporting a database requires that you place the user-defined tablespaces in the database in read-only mode until you complete the export. If this is undesirable, then you can use the transportable tablespaces from backup feature described in *Oracle Database Backup and Recovery User's Guide*.

 **See Also:**

["About Transporting Data"](#)

15.2.2 Limitations on Full Transportable Export/import

There are limitations on full transportable export/import.

Be aware of the following limitations on full transportable export/import:

- The general limitations described in "[General Limitations on Transporting Data](#)" apply to full transportable export/import.
- Full transportable export/import can export and import user-defined database objects in administrative tablespaces using conventional Data Pump export/import, such as direct path or external table. Administrative tablespaces are non-user tablespaces supplied with Oracle Database, such as the SYSTEM and SYSAUX tablespaces.
- Full transportable export/import cannot transport a database object that is defined in both an administrative tablespace (such as SYSTEM and SYSAUX) and a user-defined tablespace. For example, a partitioned table might be stored in both a user-defined tablespace and an administrative tablespace. If you have such database objects in your database, then you can redefine them before transporting

them so that they are stored entirely in either an administrative tablespace or a user-defined tablespace. If the database objects cannot be redefined, then you can use conventional Data Pump export/import.

- When transporting a database over the network using full transportable export/import, auditing cannot be enabled for tables stored in an administrative tablespace (such as `SYSTEM` and `SYSAUX`) when the audit trail information itself is stored in a user-defined tablespace. See *Oracle Database Security Guide* for more information about auditing.

15.2.3 Transporting a Database Using an Export Dump File

You can transport a database using an export dump file.

The following list of tasks summarizes the process of transporting a database using an export dump file. Details for each task are provided in the subsequent example.

1. At the source database, place each of the user-defined tablespaces in read-only mode and export the database.

Ensure that the following parameters are set to the specified values:

- `TRANSPORTABLE=ALWAYS`
- `FULL=Y`

If the source database is an Oracle Database 11g Release 2 (11.2.0.3) or later Oracle Database 11g database, then you must set the `VERSION` parameter to 12 or higher.

If the source database contains any encrypted tablespaces or tablespaces containing tables with encrypted columns, then you must either specify `ENCRYPTION_PWD_PROMPT=YES`, or specify the `ENCRYPTION_PASSWORD` parameter.

The export dump file includes the metadata for objects contained within the user-defined tablespaces and both the metadata and data for user-defined objects contained within the administrative tablespaces, such as `SYSTEM` and `SYSAUX`.

2. Transport the export dump file.

Copy the export dump file to a place that is accessible to the target database.

3. Transport the data files for all of the user-defined tablespaces in the database.

Copy the data files to a place that is accessible to the target database.

If the source platform and target platform are different, then check the endian format of each platform by running the query on the `V$TRANSPORTABLE_PLATFORM` view in "[Transporting Data Across Platforms](#)".

If the source platform's endian format is different from the target platform's endian format, then use one of the following methods to convert the data files:

- Use the `GET_FILE` or `PUT_FILE` procedure in the `DBMS_FILE_TRANSFER` package to transfer the data files. These procedures convert the data files to the target platform's endian format automatically.
- Use the `RMAN CONVERT` command to convert the data files to the target platform's endian format.

See "[Converting Data Between Platforms](#)" for more information.

4. (Optional) Restore the user-defined tablespaces to read/write mode on the source database.
5. At the target database, import the database.

When the import is complete, the user-defined tablespaces are in read/write mode.

Example

These tasks for transporting a database are illustrated more fully in the example that follows, where it is assumed the following data files and tablespaces exist:

Tablespace	Type	Data File
sales	User-defined	/u01/app/oracle/oradata/mydb/sales01.dbf
customers	User-defined	/u01/app/oracle/oradata/mydb/cust01.dbf
employees	User-defined	/u01/app/oracle/oradata/mydb/emp01.dbf
SYSTEM	Administrative	/u01/app/oracle/oradata/mydb/system01.dbf
SYSAUX	Administrative	/u01/app/oracle/oradata/mydb/sysaux01.dbf

This example makes the following additional assumptions:

- The target database is a new database that is being populated with the data from the source database. The name of the source database is `mydb`.
- Both the source database and the target database are Oracle Database 12c databases.

Complete the following tasks to transport the database using an export dump file:

Task 1 Generate the Export Dump File

Generate the export dump file by completing the following steps:

1. Start SQL*Plus and connect to the database as an administrator or as a user who has either the `ALTER TABLESPACE` or `MANAGE TABLESPACE` system privilege.
See "[Connecting to the Database with SQL*Plus](#)" for instructions.
2. Make all of the user-defined tablespaces in the database read-only.

```
ALTER TABLESPACE sales READ ONLY;
```

```
ALTER TABLESPACE customers READ ONLY;
```

```
ALTER TABLESPACE employees READ ONLY;
```

3. Invoke the Data Pump export utility as a user with `DATAPUMP_EXP_FULL_DATABASE` role and specify the full transportable export/import options.

```
SQL> HOST
```

```
$ expdp user_name full=y dumpfile=expdat.dmp directory=data_pump_dir
      transportable=always logfile=export.log
```

```
Password: password
```

You must always specify `TRANSPORTABLE=ALWAYS`, which determines whether the transportable option is used.

This example specifies the following Data Pump parameters:

- The `FULL` parameter specifies that the entire database is being exported.
- The `DUMPFILE` parameter specifies the name of the structural information export dump file to be created, `expdat.dmp`.
- The `DIRECTORY` parameter specifies the directory object that points to the operating system or Oracle Automatic Storage Management location of the dump file. You must create the `DIRECTORY` object before invoking Data Pump, and you must grant the `READ` and `WRITE` object privileges on the directory to the user running the Export utility. See *Oracle Database SQL Language Reference* for information on the `CREATE DIRECTORY` command.

In a non-CDB, the directory object `DATA_PUMP_DIR` is created automatically. Read and write access to this directory is automatically granted to the `DBA` role, and thus to users `SYS` and `SYSTEM`.

However, the directory object `DATA_PUMP_DIR` is not created automatically in a PDB. Therefore, when importing into a PDB, create a directory object in the PDB and specify the directory object when you run Data Pump.

See Also:

- [Oracle Database Utilities](#) for information about the default directory when the `DIRECTORY` parameter is omitted
- [Overview of Managing a Multitenant Environment](#) for more information about PDBs
- The `LOGFILE` parameter specifies the file name of the log file to be written by the export utility. In this example, the log file is written to the same directory as the dump file, but it can be written to a different location.

To perform a full transportable export on an Oracle Database 11g Release 2 (11.2.0.3) or later Oracle Database 11g database, use the `VERSION` parameter, as shown in the following example:

```
expdp user_name full=y dumpfile=expdat.dmp directory=data_pump_dir  
transportable=always version=12 logfile=export.log
```

Full transportable import is supported only for Oracle Database 12c databases.

Note:

In this example, the Data Pump utility is used to export only data dictionary structural information (metadata) for the user-defined tablespaces. Actual data is unloaded only for the administrative tablespaces (`SYSTEM` and `SYSAUX`), so this operation goes relatively quickly even for large user-defined tablespaces.

4. Check the log file for errors, and take note of the dump file and data files that you must transport to the target database. `expdp` outputs the names and paths of these files in messages like these:

```
*****
Dump file set for SYSTEM.SYS_EXPORT_TRANSPORTABLE_01 is:
  /u01/app/oracle/admin/mydb/dpdump/expdat.dmp
*****
Datafiles required for transportable tablespace SALES:
  /u01/app/oracle/oradata/mydb/sales01.dbf
Datafiles required for transportable tablespace CUSTOMERS:
  /u01/app/oracle/oradata/mydb/cust01.dbf
Datafiles required for transportable tablespace EMPLOYEES:
  /u01/app/oracle/oradata/mydb/emp01.dbf
```

5. When finished, exit back to SQL*Plus:

```
$ exit
```

 **See Also:**

Oracle Database Utilities for information about using the Data Pump utility

Task 2 Transport the Export Dump File

Transport the dump file to the directory pointed to by the `DATA_PUMP_DIR` directory object, or to any other directory of your choosing. The new location must be accessible to the target database.

At the target database, run the following query to determine the location of `DATA_PUMP_DIR`:

```
SELECT * FROM DBA_DIRECTORIES WHERE DIRECTORY_NAME = 'DATA_PUMP_DIR';

OWNER      DIRECTORY_NAME      DIRECTORY_PATH
-----
SYS        DATA_PUMP_DIR       C:\app\orauser\admin\orawin\dpdump\
```

Task 3 Transport the Data Files for the User-Defined Tablespaces

Transport the data files of the user-defined tablespaces in the database to a place that is accessible to the target database.

In this example, transfer the following data files from the source database to the target database:

- `sales01.dbf`
- `cust01.dbf`
- `emp01.dbf`

If you are transporting the database to a platform different from the source platform, then determine if cross-platform database transport is supported for both the source and target platforms, and determine the endianness of each platform. If both platforms have the same endianness, then no conversion is necessary. Otherwise you must do a conversion of each tablespace in the database either at the source or target database.

If you are transporting the database to a different platform, you can execute the following query on each platform. If the query returns a row, then the platform supports cross-platform tablespace transport.

```
SELECT d.PLATFORM_NAME, ENDIAN_FORMAT
  FROM V$TRANSPORTABLE_PLATFORM tp, V$DATABASE d
 WHERE tp.PLATFORM_NAME = d.PLATFORM_NAME;
```

The following is the query result from the source platform:

PLATFORM_NAME	ENDIAN_FORMAT
Solaris[tm] OE (32-bit)	Big

The following is the query result from the target platform:

PLATFORM_NAME	ENDIAN_FORMAT
Microsoft Windows IA (32-bit)	Little

In this example, you can see that the endian formats are different. Therefore, in this case, a conversion is necessary for transporting the database. Use either the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package to transfer the data files. These procedures convert the data files to the target platform's endian format automatically. Transport the data files to the location of the existing data files of the target database. On the UNIX and Linux platforms, this location is typically /u01/app/oracle/oradata/dbname/ or +DISKGROUP/dbname/datafile/. Alternatively, you can use the RMAN CONVERT command to convert the data files. See "["Converting Data Between Platforms"](#)" for more information.

 **Note:**

If no endianness conversion of the tablespaces is needed, then you can transfer the files using any file transfer method.

 **See Also:**

["Guidelines for Transferring Data Files"](#)

Task 4 (Optional) Restore Tablespaces to Read/Write Mode

Make the transported tablespaces read/write again at the source database, as follows:

```
ALTER TABLESPACE sales READ WRITE;
ALTER TABLESPACE customers READ WRITE;
ALTER TABLESPACE employees READ WRITE;
```

You can postpone this task to first ensure that the import process succeeds.

Task 5 At the Target Database, Import the Database

Invoke the Data Pump import utility as a user with DATAPUMP_IMP_FULL_DATABASE role and specify the full transportable export/import options.

```
impdp user_name full=Y dumpfile=expdat.dmp directory=data_pump_dir
      transport_datafiles=
        '/u01/app/oracle/oradata/mydb/sales01.dbf',
        '/u01/app/oracle/oradata/mydb/cust01.dbf',
```

```
'/u01/app/oracle/oradata/mydb/emp01.dbf'  
logfile=import.log  
  
Password: password
```

This example specifies the following Data Pump parameters:

- The `FULL` parameter specifies that the entire database is being imported in `FULL` mode.
- The `DUMPFILE` parameter specifies the exported file containing the metadata for the user-defined tablespaces and both the metadata and data for the administrative tablespaces to be imported.
- The `DIRECTORY` parameter specifies the directory object that identifies the location of the export dump file. You must create the `DIRECTORY` object before invoking Data Pump, and you must grant the `READ` and `WRITE` object privileges on the directory to the user running the Import utility. See *Oracle Database SQL Language Reference* for information on the `CREATE DIRECTORY` command.

In a non-CDB, the directory object `DATA_PUMP_DIR` is created automatically. Read and write access to this directory is automatically granted to the `DBA` role, and thus to users `SYS` and `SYSTEM`.

However, the directory object `DATA_PUMP_DIR` is not created automatically in a PDB. Therefore, when importing into a PDB, create a directory object in the PDB and specify the directory object when you run Data Pump.

 **See Also:**

- *Oracle Database Utilities* for information about the default directory when the `DIRECTORY` parameter is omitted
- [Overview of Managing a Multitenant Environment](#) for more information about PDBs

- The `TRANSPORT_DATAFILES` parameter identifies all of the data files to be imported. You can specify the `TRANSPORT_DATAFILES` parameter multiple times in a parameter file specified with the `PARFILE` parameter if there are many data files.
- The `LOGFILE` parameter specifies the file name of the log file to be written by the import utility. In this example, the log file is written to the directory from which the dump file is read, but it can be written to a different location.

After this statement executes successfully, check the import log file to ensure that no unexpected error has occurred.

When dealing with a large number of data files, specifying the list of data file names in the statement line can be a laborious process. It can even exceed the statement line limit. In this situation, you can use an import parameter file. For example, you can invoke the Data Pump import utility as follows:

```
impdp user_name parfile='par.f'
```

For example, `par.f` might contain the following lines:

```
FULL=Y
DUMPFILE=expdat.dmp
DIRECTORY=data_pump_dir
TRANSPORT_DATAFILES=
  '/u01/app/oracle/oradata/mydb/sales01.dbf',
  '/u01/app/oracle/oradata/mydb/cust01.dbf',
  '/u01/app/oracle/oradata/mydb/emp01.dbf'
LOGFILE=import.log
```

 **Note:**

- During the import, user-defined tablespaces might be temporarily made read/write for metadata loading. Ensure that no user changes are made to the data during the import. At the successful completion of the import, all user-defined tablespaces are made read/write.
- When performing a network database import, the `TRANSPORTABLE` parameter must be set to `always`.
- When you are importing into a PDB in a CDB, specify the connect identifier for the PDB after the user name. For example, if the connect identifier for the PDB is `hrpdb`, then enter the following when you run the Oracle Data Pump Import utility:

```
impdp user_name@hrpdb ...
```

 **See Also:**

- [Oracle Database Utilities](#) for information about using the import utility
- [Managing a Multitenant Environment](#)

15.2.4 Transporting a Database Over the Network

You can transport a database over the network.

To transport a database over the network, you perform an import using the `NETWORK_LINK` parameter, the import is performed using a database link, and there is no dump file involved.

The following list of tasks summarizes the process of transporting a database over the network. Details for each task are provided in the subsequent example.

1. Create a database link from the target database to the source database.

The import operation must be performed by a user on the target database with `DATAPUMP_IMP_FULL_DATABASE` role, and the database link must connect to a user on the source database with `DATAPUMP_EXP_FULL_DATABASE` role. The user on the source database cannot be a user with `SYSDBA` administrative privilege. If the database link is a connected user database link, then the user on the target database cannot be a user with `SYSDBA` administrative privilege. See "[Users of Database Links](#)" for information about connected user database links.

2. In the source database, make the user-defined tablespaces in the database read-only.
3. Transport the data files for all of the user-defined tablespaces in the database.

Copy the data files to a place that is accessible to the target database.

If the source platform and target platform are different, then check the endian format of each platform by running the query on the V\$TRANSPORTABLE_PLATFORM view in "[Transporting Data Across Platforms](#)".

If the source platform's endian format is different from the target platform's endian format, then use one of the following methods to convert the data files:

- Use the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package to transfer the data files. These procedures convert the data files to the target platform's endian format automatically.
- Use the RMAN CONVERT command to convert the data files to the target platform's endian format.

See "[Converting Data Between Platforms](#)" for more information.

4. At the target database, import the database.

Invoke the Data Pump utility to import the metadata for the user-defined tablespaces and both the metadata and data for the administrative tablespaces.

Ensure that the following parameters are set to the specified values:

- TRANSPORTABLE=ALWAYS
- TRANSPORT_DATAFILES=*list_of_datafiles*
- FULL=Y
- NETWORK_LINK=*source_database_link*

Replace *source_database_link* with the name of the database link to the source database.

- VERSION=12

If the source database is an Oracle Database 11g Release 2 (11.2.0.3) or later Oracle Database 11g database, then the VERSION parameter is required and must be set to 12. If the source database is an Oracle Database 12c database, then the VERSION parameter is not required.

If the source database contains any encrypted tablespaces or tablespaces containing tables with encrypted columns, then you must either specify ENCRYPTION_PWD_PROMPT=YES, or specify the ENCRYPTION_PASSWORD parameter.

The Data Pump network import copies the metadata for objects contained within the user-defined tablespaces and both the metadata and data for user-defined objects contained within the administrative tablespaces, such as SYSTEM and SYSAUX.

When the import is complete, the user-defined tablespaces are in read/write mode.

5. (Optional) Restore the user-defined tablespaces to read/write mode on the source database.

Example

These tasks for transporting a database are illustrated more fully in the example that follows, where it is assumed the following data files and tablespaces exist:

Tablespace	Type	Data File
sales	User-defined	/u01/app/oracle/oradata/mydb/sales01.dbf
customers	User-defined	/u01/app/oracle/oradata/mydb/cust01.dbf
employees	User-defined	/u01/app/oracle/oradata/mydb/emp01.dbf
SYSTEM	Administrative	/u01/app/oracle/oradata/mydb/system01.dbf
SYSAUX	Administrative	/u01/app/oracle/oradata/mydb/sysaux01.dbf

This example makes the following additional assumptions:

- The target database is a new database that is being populated with the data from the source database. The name of the source database is `sourcedb`.
- The source database and target database are running on the same platform with the same endianness.

To check the endianness of a platform, run the following query:

```
SELECT d.PLATFORM_NAME, ENDIAN_FORMAT
      FROM V$TRANSPORTABLE_PLATFORM tp, V$DATABASE d
     WHERE tp.PLATFORM_NAME = d.PLATFORM_NAME;
```

- The `sales` tablespace is encrypted. The other tablespaces are not encrypted.
- The source database is an Oracle Database 11g Release 2 (11.2.0.3) database and the target database is an Oracle Database 12c database.

 **Note:**

This example illustrates the tasks required to transport an Oracle Database 11g Release 2 (11.2.0.3) or later Oracle Database 11g database to a new Oracle Database 12c PDB inside of a CDB. See [Managing a Multitenant Environment](#). These tasks also illustrate how to transport one non-CDB to another non-CDB.

Complete the following tasks to transport the database over the network:

Task 1 Create a Database Link from the Target Database to the Source Database

Create a database link from the target database to the source database by completing the following steps:

1. Ensure that network connectivity is configured between the source database and the target database.

See *Oracle Database Net Services Administrator's Guide* for instructions.

2. Start SQL*Plus and connect to the target database as the administrator who will transport the database with Data Pump import. This user must have DATAPUMP_IMP_FULL_DATABASE role to transport the database.

See "[Connecting to the Database with SQL*Plus](#)" for instructions.

3. Create the database link:

```
CREATE PUBLIC DATABASE LINK sourcedb USING 'sourcedb';
```

Specify the service name for the source database in the using clause.

During the import operation, the database link must connect to a user on the source database with DATAPUMP_EXP_FULL_DATABASE role. The user on the source database cannot be a user with SYSDBA administrative privilege.

 **See Also:**

- ["Creating Database Links"](#)
- *Oracle Database SQL Language Reference*

Task 2 Make the User-Defined Tablespaces Read-Only

Complete the following steps:

1. Start SQL*Plus and connect to the source database as an administrator or as a user who has either the ALTER TABLESPACE or MANAGE TABLESPACE system privilege.

See "[Connecting to the Database with SQL*Plus](#)" for instructions.

2. Make all of the user-defined tablespaces in the database read-only.

```
ALTER TABLESPACE sales READ ONLY;
```

```
ALTER TABLESPACE customers READ ONLY;
```

```
ALTER TABLESPACE employees READ ONLY;
```

Task 3 Transport the Data Files for the User-Defined Tablespaces

Transport the data files to the location of the existing data files of the target database. On the UNIX and Linux platforms, this location is typically /u01/app/oracle/oradata/*dbname* or +DISKGROUP/*dbname*/datafile/.

In this example, transfer the following data files from the source database to the target database:

- sales01.dbf
- cust01.dbf
- emp01.dbf

 **See Also:**

- ["Guidelines for Transferring Data Files"](#)

Task 4 At the Target Database, Import the Database

Invoke the Data Pump import utility as a user with DATAPUMP_IMP_FULL_DATABASE role and specify the full transportable export/import options.

```
impdp user_name full=Y network_link=sourcedb transportable=always
  transport_datafiles=
    '/u01/app/oracle/oradata/mydb/sales01.dbf',
    '/u01/app/oracle/oradata/mydb/cust01.dbf',
    '/u01/app/oracle/oradata/mydb/emp01.dbf'
  encryption_pwd_prompt=YES version=12 logfile=import.log

Password: password
```

This example specifies the following Data Pump parameters:

- The FULL parameter specifies that the entire database is being imported in FULL mode.
- The NETWORK_LINK parameter specifies the database link used for the network import.
- The TRANSPORTABLE parameter specifies that the import uses the transportable option.
- The TRANSPORT_DATAFILES parameter identifies all of the data files to be imported. You can specify the TRANSPORT_DATAFILES parameter multiple times in a parameter file specified with the PARFILE parameter if there are many data files.
- The ENCRYPTION_PWD_PROMPT parameter instructs Data Pump to prompt you for the encryption password, and Data Pump encrypts data and metadata sent over the network connection. Either the ENCRYPTION_PWD_PROMPT parameter or the ENCRYPTION_PASSWORD parameter is required when encrypted tablespaces or tables with encrypted columns are part of the import operation.
- The VERSION parameter is set to 12 because the source database is an Oracle Database 11g Release 2 (11.2.0.3) or later Oracle Database 11g database.
- The LOGFILE parameter specifies the file name of the log file to be written by the import utility.

After this statement executes successfully, check the import log file to ensure that no unexpected error has occurred.

When dealing with a large number of data files, specifying the list of data file names in the statement line can be a laborious process. It can even exceed the statement line limit. In this situation, you can use an import parameter file.

Use of an import parameter file is also recommended when encrypted tablespaces or tables with encrypted columns are part of the import operation. In this case, specify ENCRYPTION_PWD_PROMPT=YES in the import parameter file.

For example, you can invoke the Data Pump import utility as follows:

```
impdp user_name parfile='par.f'
```

For example, par.f might contain the following lines:

```
FULL=Y
NETWORK_LINK=sourcedb
TRANSPORTABLE=always
TRANSPORT_DATAFILES=
  '/u01/app/oracle/oradata/mydb/sales01.dbf',
```

```
'/u01/app/oracle/oradata/mydb/cust01.dbf',
'/u01/app/oracle/oradata/mydb/emp01.dbf'
ENCRYPTION_PWD_PROMPT=YES
VERSION=12
LOGFILE=import.log
```

 **Note:**

- During the import, user-defined tablespaces might be temporarily made read/write for metadata loading. Ensure that no user changes are made to the data during the import. At the successful completion of the import, all user-defined tablespaces are made read/write.
- When you are importing into a PDB in a CDB, specify the connect identifier for the PDB after the user name. For example, if the connect identifier for the PDB is hrpdb, then enter the following when you run the Oracle Data Pump Import utility:

```
impdp user_name@hrpdb ...
```

 **See Also:**

Oracle Database Utilities for information about using the import utility

Task 5 (Optional) Restore User-Defined Tablespaces to Read/Write Mode

Make the user-defined tablespaces read/write again at the source database, as follows:

```
ALTER TABLESPACE sales READ WRITE;
ALTER TABLESPACE customers READ WRITE;
ALTER TABLESPACE employees READ WRITE;
```

You can postpone this task to first ensure that the import process succeeds.

15.3 Transporting Tablespaces Between Databases

You can transport tablespaces between databases.

 **Note:**

To import a transportable tablespace set into an Oracle database on a different platform, both databases must have compatibility set to at least 10.0.0. See "[Compatibility Considerations for Transporting Data](#)" for a discussion of database compatibility for transporting tablespaces across release levels.

- [Introduction to Transportable Tablespaces](#)
You can use the transportable tablespaces feature to copy a set of tablespaces from one Oracle Database to another.
- [Limitations on Transportable Tablespaces](#)
There are limitations on transportable tablespace.
- [Transporting Tablespaces Between Databases](#)
You can transport a tablespace between databases.

15.3.1 Introduction to Transportable Tablespaces

You can use the transportable tablespaces feature to copy a set of tablespaces from one Oracle Database to another.

The tablespaces being transported can be either dictionary managed or locally managed. The transported tablespaces are not required to be of the same block size as the target database standard block size. These scenarios are discussed in "[Transporting Data: Scenarios](#)".

There are two ways to transport a tablespace:

- Manually, following the steps described in this section. This involves issuing commands to SQL*Plus and Data Pump.
- Using the Transport Tablespaces Wizard in Oracle Enterprise Manager Cloud Control

To run the Transport Tablespaces Wizard:

1. Log in to Cloud Control with a user that has the `DATAPUMP_EXP_FULL_DATABASE` role.
2. Access the Database Home page.
3. From the Schema menu, select **Database Export/Import**, then **Transport Tablespaces**.

Note:

- This method for transporting tablespaces requires that you place the tablespaces to be transported in read-only mode until you complete the transporting process. If this is undesirable, you can use the transportable tablespaces from backup feature, described in *Oracle Database Backup and Recovery User's Guide*.
- You must use Data Pump for transportable tablespaces. The only circumstance under which you can use the original import and export utilities, IMP and EXP, is for a backward migration of XMLType data to an Oracle Database 10g Release 2 (10.2) or earlier database. See *Oracle Database Utilities* for more information on these utilities and to *Oracle XML DB Developer's Guide* for more information on XMLTypes.

 **See Also:**

- ["About Transporting Data"](#)
- *Oracle Database Data Warehousing Guide* for information about using transportable tablespaces in a data warehousing environment

15.3.2 Limitations on Transportable Tablespaces

There are limitations on transportable tablespace.

Be aware of the following limitations for transportable tablespaces:

- The general limitations described in ["General Limitations on Transporting Data"](#) apply to transportable tablespaces.
- When transporting a tablespace set, objects with underlying objects (such as materialized views) or contained objects (such as partitioned tables) are not transportable unless all of the underlying or contained objects are in the tablespace set.
- Transportable tablespaces cannot transport tables with `TIMESTAMP WITH TIMEZONE` (TSTZ) data across platforms with different time zone file versions. These tables are skipped automatically in a transportable tablespaces operation. These tables can be exported and imported conventionally.

See *Oracle Database Utilities* for more information.

- Administrative tablespaces, such as `SYSTEM` and `SYSAUX`, cannot be included in a transportable tablespace set.

15.3.3 Transporting Tablespaces Between Databases

You can transport a tablespace between databases.

The following list of tasks summarizes the process of transporting a tablespace. Details for each task are provided in the subsequent example.

1. Pick a self-contained set of tablespaces.
2. At the source database, place the set of tablespaces in read-only mode and generate a transportable tablespace set.

A transportable tablespace set (or transportable set) consists of data files for the set of tablespaces being transported and an export dump file containing structural information (metadata) for the set of tablespaces. You use Data Pump to perform the export.

3. Transport the export dump file.

Copy the export dump file to a place that is accessible to the target database.

4. Transport the tablespace set.

Copy the data files to a place that is accessible to the target database.

If the source platform and target platform are different, then check the endian format of each platform by running the query on the V\$TRANSPORTABLE_PLATFORM view in "Transporting Data Across Platforms".

If the source platform's endian format is different from the target platform's endian format, then use one of the following methods to convert the data files:

- Use the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package to transfer the data files. These procedures convert the data files to the target platform's endian format automatically.
- Use the RMAN CONVERT command to convert the data files to the target platform's endian format.

See "[Converting Data Between Platforms](#)" for more information.

5. (Optional) Restore tablespaces to read/write mode on the source database.
6. At the target database, import the tablespace set.

Invoke the Data Pump utility to import the metadata for the tablespace set.

Example 15-1 Example

These tasks for transporting a tablespace are illustrated more fully in the example that follows, where it is assumed the following data files and tablespaces exist:

Tablespace	Data File
sales_1	/u01/app/oracle/oradata/salesdb/sales_101.dbf
sales_2	/u01/app/oracle/oradata/salesdb/sales_201.dbf

- [Task 1: Pick a Self-Contained Set of Tablespaces](#)

There may be logical or physical dependencies between objects in the transportable set and those outside of the set. You can only transport a set of tablespaces that is self-contained. In this context "self-contained" means that there are no references from inside the set of tablespaces pointing outside of the tablespaces.

- [Task 2: Generate a Transportable Tablespace Set](#)

After ensuring you have a self-contained set of tablespaces that you want to transport, generate a transportable tablespace set.

- [Task 3: Transport the Export Dump File](#)

Transport the dump file to the directory pointed to by the DATA_PUMP_DIR directory object, or to any other directory of your choosing. The new location must be accessible to the target database.

- [Task 4: Transport the Tablespace Set](#)

Transport the data files of the tablespaces to a place that is accessible to the target database.

- [Task 5: \(Optional\) Restore Tablespaces to Read/Write Mode](#)

Make the transported tablespaces read/write again at the source database.

- [Task 6: Import the Tablespace Set](#)

To complete the transportable tablespaces operation, import the tablespace set.

15.3.3.1 Task 1: Pick a Self-Contained Set of Tablespaces

There may be logical or physical dependencies between objects in the transportable set and those outside of the set. You can only transport a set of tablespaces that is self-contained. In this context "self-contained" means that there are no references from inside the set of tablespaces pointing outside of the tablespaces.

Some examples of self contained tablespace violations are:

- An index inside the set of tablespaces is for a table outside of the set of tablespaces.

 **Note:**

It is not a violation if a corresponding index for a table is outside of the set of tablespaces.

- A partitioned table is partially contained in the set of tablespaces.

The tablespace set you want to copy must contain either all partitions of a partitioned table, or none of the partitions of a partitioned table. To transport a subset of a partition table, you must exchange the partitions into tables.

See *Oracle Database VLDB and Partitioning Guide* for information about exchanging partitions.

- A referential integrity constraint points to a table across a set boundary.

When transporting a set of tablespaces, you can choose to include referential integrity constraints. However, doing so can affect whether a set of tablespaces is self-contained. If you decide not to transport constraints, then the constraints are not considered as pointers.

- A table inside the set of tablespaces contains a `LOB` column that points to `LOBs` outside the set of tablespaces.
- An XML DB schema (`*.xsd`) that was registered by user A imports a global schema that was registered by user B, and the following is true: the default tablespace for user A is tablespace A, the default tablespace for user B is tablespace B, and only tablespace A is included in the set of tablespaces.

To determine whether a set of tablespaces is self-contained, you can invoke the `TRANSPORT_SET_CHECK` procedure in the Oracle supplied package `DBMS_TTS`. You must have been granted the `EXECUTE_CATALOG_ROLE` role (initially signed to `SYS`) to execute this procedure.

When you invoke the `DBMS_TTS` package, you specify the list of tablespaces in the transportable set to be checked for self containment. You can optionally specify if constraints must be included. For strict or full containment, you must additionally set the `TTS_FULL_CHECK` parameter to `TRUE`.

The strict or full containment check is for cases that require capturing not only references going outside the transportable set, but also those coming into the set. Tablespace Point-in-Time Recovery (TSPITR) is one such case where dependent objects must be fully contained or fully outside the transportable set.

For example, it is a violation to perform TSPITR on a tablespace containing a table `t` but not its index `i` because the index and data will be inconsistent after the transport. A full containment check ensures that there are no dependencies going outside or coming into the transportable set. See the example for TSPITR in the *Oracle Database Backup and Recovery User's Guide*.

 **Note:**

The default for transportable tablespaces is to check for self containment rather than full containment.

The following statement can be used to determine whether tablespaces `sales_1` and `sales_2` are self-contained, with referential integrity constraints taken into consideration (indicated by `TRUE`).

```
EXECUTE DBMS_TTS.TRANSPORT_SET_CHECK('sales_1,sales_2', TRUE);
```

After invoking this PL/SQL package, you can see all violations by selecting from the `TRANSPORT_SET_VIOLATIONS` view. If the set of tablespaces is self-contained, this view is empty. The following example illustrates a case where there are two violations: a foreign key constraint, `dept_fk`, across the tablespace set boundary, and a partitioned table, `jim.sales`, that is partially contained in the tablespace set.

```
SELECT * FROM TRANSPORT_SET_VIOLATIONS;

VIOLATIONS
-----
Constraint DEPT_FK between table JIM.EMP in tablespace SALES_1 and table
JIM.DEPT in tablespace OTHER
Partitioned table JIM.SALES is partially contained in the transportable set
```

These violations must be resolved before `sales_1` and `sales_2` are transportable. As noted in the next task, one choice for bypassing the integrity constraint violation is to not export the integrity constraints.

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference* for more information about the `DBMS_TTS` package
- *Oracle Database Backup and Recovery User's Guide* for information specific to using the `DBMS_TTS` package for TSPITR

15.3.3.2 Task 2: Generate a Transportable Tablespace Set

After ensuring you have a self-contained set of tablespaces that you want to transport, generate a transportable tablespace set.

To generate a transportable tablespace set:

1. Start SQL*Plus and connect to the database as an administrator or as a user who has either the ALTER TABLESPACE or MANAGE TABLESPACE system privilege.

See "[Connecting to the Database with SQL*Plus](#)" for instructions.

2. Make all tablespaces in the set read-only.

```
ALTER TABLESPACE sales_1 READ ONLY;
```

```
ALTER TABLESPACE sales_2 READ ONLY;
```

3. Invoke the Data Pump export utility as a user with DATAPUMP_EXP_FULL_DATABASE role and specify the tablespaces in the transportable set.

```
SQL> HOST
```

```
$ expdp user_name dumpfile=expdat.dmp directory=data_pump_dir
      transport tablespaces=sales_1,sales_2 logfile=tts_export.log
```

```
Password: password
```

You must always specify TRANSPORT_TABLESPACES, which specifies that the transportable option is used. This example specifies the following additional Data Pump parameters:

- The DUMPFILE parameter specifies the name of the structural information export dump file to be created, `expdat.dmp`.
- The DIRECTORY parameter specifies the directory object that points to the operating system or Oracle Automatic Storage Management location of the dump file. You must create the DIRECTORY object before invoking Data Pump, and you must grant the READ and WRITE object privileges on the directory to the user running the Export utility. See *Oracle Database SQL Language Reference* for information on the CREATE DIRECTORY command.

In a non-CDB, the directory object DATA_PUMP_DIR is created automatically. Read and write access to this directory is automatically granted to the DBA role, and thus to users SYS and SYSTEM.

However, the directory object DATA_PUMP_DIR is not created automatically in a PDB. Therefore, when importing into a PDB, create a directory object in the PDB and specify the directory object when you run Data Pump.

See Also:

- [Oracle Database Utilities](#) for information about the default directory when the DIRECTORY parameter is omitted
- [Overview of Managing a Multitenant Environment](#) for more information about PDBs

- The LOGFILE parameter specifies the file name of the log file to be written by the export utility. In this example, the log file is written to the same directory as the dump file, but it can be written to a different location.
- Triggers and indexes are included in the export operation by default.

To perform a transport tablespace operation with a strict containment check, use the TRANSPORT_FULL_CHECK parameter, as shown in the following example:

```
expdp use_name dumpfile=expdat.dmp directory=data_pump_dir
      transport tablespaces=sales_1,sales_2 transport_full_check=y
      logfile=tts_export.log
```

In this case, the Data Pump export utility verifies that there are no dependencies between the objects inside the transportable set and objects outside the transportable set. If the tablespace set being transported is not self-contained, then the export fails and indicates that the transportable set is not self-contained. You must then return to Task 2 to resolve all violations.

 **Note:**

In this example, the Data Pump utility is used to export only data dictionary structural information (metadata) for the tablespaces. No actual data is unloaded, so this operation goes relatively quickly even for large tablespace sets.

4. Check the log file for errors, and take note of the dump file and data files that you must transport to the target database. `expdp` outputs the names and paths of these files in messages like these:

```
*****
Dump file set for SYSTEM.SYS_EXPORT_TRANSPORTABLE_01 is:
  /u01/app/oracle/admin/salesdb/dpdump/expdat.dmp
*****
Datafiles required for transportable tablespace SALES_1:
  /u01/app/oracle/oradata/salesdb/sales_101.dbf
Datafiles required for transportable tablespace SALES_2:
  /u01/app/oracle/oradata/salesdb/sales_201.dbf
```

5. When finished, exit back to SQL*Plus:

```
$ EXIT
```

 **See Also:**

Oracle Database Utilities for information about using the Data Pump utility

15.3.3.3 Task 3: Transport the Export Dump File

Transport the dump file to the directory pointed to by the `DATA_PUMP_DIR` directory object, or to any other directory of your choosing. The new location must be accessible to the target database.

At the target database, run the following query to determine the location of `DATA_PUMP_DIR`:

```
SELECT * FROM DBA_DIRECTORIES WHERE DIRECTORY_NAME = 'DATA_PUMP_DIR';

OWNER      DIRECTORY_NAME      DIRECTORY_PATH
-----  -----
SYS        DATA_PUMP_DIR      C:\app\orauser\admin\orawin\dpdump\
```

15.3.3.4 Task 4: Transport the Tablespace Set

Transport the data files of the tablespaces to a place that is accessible to the target database.

In this example, transfer the following files from the source database to the target database:

- sales_101.dbf
- sales_201.dbf

If you are transporting the tablespace set to a platform different from the source platform, then determine if cross-platform tablespace transport is supported for both the source and target platforms, and determine the endianness of each platform. If both platforms have the same endianness, no conversion is necessary. Otherwise you must do a conversion of the tablespace set either at the source or target database.

If you are transporting sales_1 and sales_2 to a different platform, you can execute the following query on each platform. If the query returns a row, the platform supports cross-platform tablespace transport.

```
SELECT d.PLATFORM_NAME, ENDIAN_FORMAT
      FROM V$TRANSPORTABLE_PLATFORM tp, V$DATABASE d
     WHERE tp.PLATFORM_NAME = d.PLATFORM_NAME;
```

The following is the query result from the source platform:

PLATFORM_NAME	ENDIAN_FORMAT
Solaris[tm] OE (32-bit)	Big

The following is the result from the target platform:

PLATFORM_NAME	ENDIAN_FORMAT
Microsoft Windows IA (32-bit)	Little

In this example, you can see that the endian formats are different. Therefore, in this case, a conversion is necessary for transporting the database. Use either the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package to transfer the data files. These procedures convert the data files to the target platform's endian format automatically. Transport the data files to the location of the existing data files of the target database. On the UNIX and Linux platforms, this location is typically /u01/app/oracle/oradata/dbname/ or +DISKGROUP/dbname/datafile/. Alternatively, you can use the RMAN CONVERT command to convert the data files. See "["Converting Data Between Platforms"](#)" for more information.

 **Note:**

If no endianness conversion of the tablespaces is needed, then you can transfer the files using any file transfer method.

 **See Also:**

["Guidelines for Transferring Data Files"](#)

15.3.3.5 Task 5: (Optional) Restore Tablespaces to Read/Write Mode

Make the transported tablespaces read/write again at the source database.

The following statements make the `sales_1` and `sales_2` tablespaces read/write:

```
ALTER TABLESPACE sales_1 READ WRITE;
ALTER TABLESPACE sales_2 READ WRITE;
```

You can postpone this task to first ensure that the import process succeeds.

15.3.3.6 Task 6: Import the Tablespace Set

To complete the transportable tablespaces operation, import the tablespace set.

To import the tablespace set:

1. Invoke the Data Pump import utility as a user with `DATAPUMP_IMP_FULL_DATABASE` role and import the tablespace metadata.

```
impdp user_name dumpfile=expdat.dmp directory=data_pump_dir
      transport_datafiles=
      'c:\app\orauser\oradata\orawin\sales_101.dbf',
      'c:\app\orauser\oradata\orawin\sales_201.dbf'
      remap_schema=sales1:crm1  remap_schema=sales2:crm2
      logfile=tts_import.log
```

Password: *password*

This example specifies the following Data Pump parameters:

- The `DUMPFILE` parameter specifies the exported file containing the metadata for the tablespaces to be imported.
- The `DIRECTORY` parameter specifies the directory object that identifies the location of the export dump file. You must create the `DIRECTORY` object before invoking Data Pump, and you must grant the `READ` and `WRITE` object privileges on the directory to the user running the Import utility. See *Oracle Database SQL Language Reference* for information on the `CREATE DIRECTORY` command.

In a non-CDB, the directory object `DATA_PUMP_DIR` is created automatically. Read and write access to this directory is automatically granted to the `DBA` role, and thus to users `SYS` and `SYSTEM`.

However, the directory object `DATA_PUMP_DIR` is not created automatically in a PDB. Therefore, when importing into a PDB, create a directory object in the PDB and specify the directory object when you run Data Pump.

 **See Also:**

- [Oracle Database Utilities](#) for information about the default directory when the DIRECTORY parameter is omitted
 - [Overview of Managing a Multitenant Environment](#) for more information about PDBs
- The TRANSPORT_DATAFILES parameter identifies all of the data files containing the tablespaces to be imported.

You can specify the TRANSPORT_DATAFILES parameter multiple times in a parameter file specified with the PARFILE parameter if there are many data files.

- The REMAP_SCHEMA parameter changes the ownership of database objects. If you do not specify REMAP_SCHEMA, then all database objects (such as tables and indexes) are created in the same user schema as in the source database, and those users must already exist in the target database. If they do not exist, then the import utility returns an error. In this example, objects in the tablespace set owned by sales1 in the source database will be owned by crm1 in the target database after the tablespace set is imported. Similarly, objects owned by sales2 in the source database will be owned by crm2 in the target database. In this case, the target database is not required to have users sales1 and sales2, but must have users crm1 and crm2.

Starting with Oracle Database 12c Release 2 (12.2), the Recovery Manager (RMAN) RECOVER command can move tables to a different schema while remapping a table. See *Oracle Database Backup and Recovery User's Guide* for more information.

- The LOGFILE parameter specifies the file name of the log file to be written by the import utility. In this example, the log file is written to the directory from which the dump file is read, but it can be written to a different location.

After this statement executes successfully, all tablespaces in the set being copied remain in read-only mode. Check the import log file to ensure that no error has occurred.

When dealing with a large number of data files, specifying the list of data file names in the statement line can be a laborious process. It can even exceed the statement line limit. In this situation, you can use an import parameter file. For example, you can invoke the Data Pump import utility as follows:

```
impdp user_name parfile='par.f'
```

The par.f parameter file contains the following:

```
DUMPFILE=expdat.dmp
DIRECTORY=data_pump_dir
TRANSPORT_DATAFILES=
'C:\app\orauser\oradata\orawin\sales_101.dbf',
'C:\app\orauser\oradata\orawin\sales_201.dbf'
REMAP_SCHEMA=sales1:crm1  REMAP_SCHEMA=sales2:crm2
LOGFILE=tts_import.log
```

 See Also:

Oracle Database Utilities for information about using the import utility

2. If required, put the tablespaces into read/write mode on the target database.

15.4 Transporting Tables, Partitions, or Subpartitions Between Databases

You can transport tables, partitions, and subpartitions between databases.

- [Introduction to Transportable Tables](#)

You can use the transportable tables feature to copy a set of tables, partitions, or subpartitions from one Oracle Database to another. A transportable tables operation moves metadata for the specified tables, partitions, or subpartitions to the target database.

- [Limitations on Transportable Tables](#)

There are limitations on transportable tables.

- [Transporting Tables, Partitions, or Subpartitions Using an Export Dump File](#)

You can transport tables, partitions, or subpartitions between databases using an export file.

- [Transporting Tables, Partitions, or Subpartitions Over the Network](#)

To transport tables over the network, you perform an import using the `NETWORK_LINK` parameter, the import is performed using a database link, and there is no dump file involved.

15.4.1 Introduction to Transportable Tables

You can use the transportable tables feature to copy a set of tables, partitions, or subpartitions from one Oracle Database to another. A transportable tables operation moves metadata for the specified tables, partitions, or subpartitions to the target database.

A transportable tables operation automatically identifies the tablespaces used by the specified tables. To move the data, you copy the data files for these tablespaces to the target database. The Data Pump import automatically frees the blocks in the data files occupied by tables, partitions, or subpartitions that were not part of the transportable tables operation. It also frees the blocks occupied by the dependent objects of the tables that were not part of the transportable tables operation.

You can transport the tables, partitions, and subpartitions in the following ways:

- Using an export dump file

During the export, specify the `TABLES` parameter and set the `TRANSPORTABLE` parameter to `ALWAYS`. During import, do not specify the `TRANSPORTABLE` parameter. Data Pump import recognizes the transportable tables operation automatically.

- Over the network

During the import, specify the `TABLES` parameter, set the `TRANSPORTABLE` parameter to `ALWAYS`, and specify the `NETWORK_LINK` parameter to identify the source database.

15.4.2 Limitations on Transportable Tables

There are limitations on transportable tables.

Be aware of the following limitations for transportable tables:

- The general limitations described in "[General Limitations on Transporting Data](#)" apply to transportable tables.
- You cannot transport a table to a target database that contains a table of the same name in the same schema. However, you can use the `REMAP_TABLE` import parameter to import the data into a different table. Alternatively, before the transport operation, you can rename either the table to be transported or the target table.

Starting with Oracle Database 12c Release 2 (12.2), the Recovery Manager (RMAN) `RECOVER` command can move tables to a different schema while remapping a table. See *Oracle Database Backup and Recovery User's Guide* for more information.

- You cannot transport tables with `TIMESTAMP WITH TIMEZONE` (TSTZ) data across platforms with different time zone file versions.

See *Oracle Database Utilities* for more information.

15.4.3 Transporting Tables, Partitions, or Subpartitions Using an Export Dump File

You can transport tables, partitions, or subpartitions between databases using an export file.

The following list of tasks summarizes the process of transporting tables between databases using an export dump file. Details for each task are provided in the subsequent example.

1. Pick a set of tables, partitions, or subpartitions.

If you are transporting partitions, then you can specify partitions from only one table in a transportable tables operation, and no other tables can be transported in the same operation. Also, if only a subset of a table's partitions are exported in a transportable tables operation, then on import each partition becomes a non-partitioned table.

2. At the source database, place the tablespaces associated with the data files for the tables, partitions, or subpartitions in read-only mode.

To view the tablespace for a table, query the `DBA_TABLES` view. To view the data file for a tablespace, query the `DBA_DATA_FILES` view.

3. Perform the Data Pump export.

4. Transport the export dump file.

Copy the export dump file to a place that is accessible to the target database.

5. Transport the data files for the tables, partitions, or subpartitions.

Copy the data files to a place that is accessible to the target database.

If the source platform and target platform are different, then check the endian format of each platform by running the query on the V\$TRANSPORTABLE_PLATFORM view in "Transporting Data Across Platforms".

If the source platform's endian format is different from the target platform's endian format, then use one of the following methods to convert the data files:

- Use the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package to transfer the data files. These procedures convert the data files to the target platform's endian format automatically.
- Use the RMAN CONVERT command to convert the data files to the target platform's endian format.

See "[Converting Data Between Platforms](#)" for more information.

6. (Optional) Restore tablespaces to read/write mode on the source database.
7. At the target database, perform the import.

Invoke the Data Pump utility to import the metadata for the tables.

Example

These tasks for transporting tables, partitions, and subpartitions using a Data Pump dump file are illustrated more fully in the example that follows, where it is assumed that the following partitions exist in the sh.sales_prt table:

- sales_q1_2000
- sales_q2_2000
- sales_q3_2000
- sales_q4_2000

This example transports two of these partitions to the target database.

The following SQL statements create the sales_prt table and its and partitions in the sh schema and the tablespace and data file for the table. The statements also insert data into the partitions by using data in the sh sample schemas.

```
CREATE TABLESPACE sales_prt_tbs
  DATAFILE 'sales_prt.dbf' SIZE 20M
  ONLINE;

CREATE TABLE sh.sales_prt
  (prod_id      NUMBER(6),
   cust_id      NUMBER,
   time_id      DATE,
   channel_id   CHAR(1),
   promo_id     NUMBER(6),
   quantity_sold NUMBER(3),
   amount_sold   NUMBER(10,2))
  PARTITION BY RANGE (time_id)
    (PARTITION SALES_Q1_2000 VALUES LESS THAN
     (TO_DATE('01-APR-2000', 'DD-MON-YYYY', 'NLS_DATE_LANGUAGE =
American')),
     PARTITION SALES_Q2_2000 VALUES LESS THAN
     (TO_DATE('01-JUL-2000', 'DD-MON-YYYY', 'NLS_DATE_LANGUAGE =
American')),
     PARTITION SALES_Q3_2000 VALUES LESS THAN
```

```

        (TO_DATE('01-OCT-2000','DD-MON-YYYY','NLS_DATE_LANGUAGE =
American')) ,
PARTITION SALES_Q4_2000 VALUES LESS THAN
        (TO_DATE('01-JAN-2001','DD-MON-YYYY','NLS_DATE_LANGUAGE =
American')))
TABLESPACE sales_prt_tbs;

INSERT INTO sh.sales_prt PARTITION(sales_q1_2000)
SELECT * FROM sh.sales PARTITION(sales_q1_2000);

INSERT INTO sh.sales_prt PARTITION(sales_q2_2000)
SELECT * FROM sh.sales PARTITION(sales_q2_2000);

INSERT INTO sh.sales_prt PARTITION(sales_q3_2000)
SELECT * FROM sh.sales PARTITION(sales_q3_2000);

INSERT INTO sh.sales_prt PARTITION(sales_q4_2000)
SELECT * FROM sh.sales PARTITION(sales_q4_2000);

COMMIT;

```

This example makes the following additional assumptions:

- The name of the source database is `sourcedb`.
- The source database and target database are running on the same platform with the same endianness. To check the endianness of a platform, run the following query:

```

SELECT d.PLATFORM_NAME, ENDIAN_FORMAT
      FROM V$TRANSPORTABLE_PLATFORM tp, V$DATABASE d
     WHERE tp.PLATFORM_NAME = d.PLATFORM_NAME;

```

- Only the `sales_q1_2000` and `sales_q2_2000` partitions are transported to the target database. The other two partitions are not transported.

Complete the following tasks to transport the partitions using an export dump file:

Task 1 Generate the Export Dump File

Generate the export dump file by completing the following steps:

1. Start SQL*Plus and connect to the source database as an administrator or as a user who has either the `ALTER TABLESPACE` or `MANAGE TABLESPACE` system privilege.

See "[Connecting to the Database with SQL*Plus](#)" for instructions.

2. Make all of the tablespaces that contain the tables being transported read-only.

```
ALTER TABLESPACE sales_prt_tbs READ ONLY;
```

3. Invoke the Data Pump export utility as a user with `DATAPUMP_EXP_FULL_DATABASE` role and specify the transportable tables options.

```
SQL> HOST
```

```
expdp user_name dumpfile=sales_prt.dmp directory=data_pump_dir
      tables=sh.sales_prt:sales_q1_2000,sh.sales_prt:sales_q2_2000
      transportable=always logfile=exp.log
```

```
Password: password
```

You must always specify TRANSPORTABLE=ALWAYS, which specifies that the transportable option is used.

This example specifies the following additional Data Pump parameters:

- The DUMPFILE parameter specifies the name of the structural information export dump file to be created, sales_prt.dmp.
- The DIRECTORY parameter specifies the directory object that points to the operating system or Oracle Automatic Storage Management location of the dump file. You must create the DIRECTORY object before invoking Data Pump, and you must grant the READ and WRITE object privileges on the directory to the user running the Export utility. See *Oracle Database SQL Language Reference* for information on the CREATE DIRECTORY command.

In a non-CDB, the directory object DATA_PUMP_DIR is created automatically. Read and write access to this directory is automatically granted to the DBA role, and thus to users SYS and SYSTEM.

However, the directory object DATA_PUMP_DIR is not created automatically in a PDB. Therefore, when importing into a PDB, create a directory object in the PDB and specify the directory object when you run Data Pump.

See Also:

- *Oracle Database Utilities* for information about the default directory when the DIRECTORY parameter is omitted
- [Overview of Managing a Multitenant Environment](#) for more information about PDBs

- The TABLES parameter specifies the tables, partitions, or subpartitions being exported.
 - The LOGFILE parameter specifies the file name of the log file to be written by the export utility. In this example, the log file is written to the same directory as the dump file, but it can be written to a different location.
4. Check the log file for unexpected errors, and take note of the dump file and data files that you must transport to the target database. `expdp` outputs the names and paths of these files in messages like these:

```
Processing object type TABLE_EXPORT/TABLE/PLUGTS_BLK
Processing object type TABLE_EXPORT/TABLE/TABLE
Processing object type TABLE_EXPORT/TABLE/END_PLUGTS_BLK
Master table "SYSTEM"."SYS_EXPORT_TABLE_01" successfully loaded/unloaded
*****
Dump file set for SYSTEM.SYS_EXPORT_TABLE_01 is:
  /u01/app/oracle/rdbms/log/sales_prt.dmp
*****
Datafiles required for transportable tablespace SALES_PRT_TBS:
  /u01/app/oracle/oradata/sourcedb/sales_prt.dbf
Job "SYSTEM"."SYS_EXPORT_TABLE_01" successfully completed at 11:32:13
```

5. When finished, exit back to SQL*Plus:

```
$ exit
```

 **See Also:**

Oracle Database Utilities for information about using the Data Pump utility

Task 2 Transport the Export Dump File

Transport the dump file to the directory pointed to by the `DATA_PUMP_DIR` directory object on the target database, or to any other directory of your choosing. The new location must be accessible to the target database.

In this example, transfer the `sales_prt.dmp` dump file from the source database to the target database.

At the target database, run the following query to determine the location of `DATA_PUMP_DIR`:

```
SELECT * FROM DBA_DIRECTORIES WHERE DIRECTORY_NAME = 'DATA_PUMP_DIR';

OWNER      DIRECTORY_NAME      DIRECTORY_PATH
-----      -----
SYS        DATA_PUMP_DIR       /u01/app/oracle/rdbms/log/
```

Task 3 Transport the Data Files for the Tables

Transport the data files of the tablespaces containing the tables being transported to a place that is accessible to the target database.

Typically, you transport the data files to the location of the existing data files of the target database. On the UNIX and Linux platforms, this location is typically `/u01/app/oracle/oradata/dbname/` or `+DISKGROUP/dbname/datafile/`.

In this example, transfer the `sales_prt.dbf` data file from the source database to the target database.

 **See Also:**

["Guidelines for Transferring Data Files"](#)

Task 4 (Optional) Restore Tablespaces to Read/Write Mode

Make the tablespaces that contain the tables being transported read/write again at the source database, as follows:

```
ALTER TABLESPACE sales_prt_tbs READ WRITE;
```

You can postpone this task to first ensure that the import process succeeds.

Task 5 At the Target Database, Import the Partitions

At the target database, invoke the Data Pump import utility as a user with `DATAPUMP_IMP_FULL_DATABASE` role and specify the transportable tables options.

```
impdp user_name dumpfile=sales_prt.dmp directory=data_pump_dir
      transport_datafiles='/u01/app/oracle/oradata/targetdb/sales_prt.dbf'
      tables=sh.sales_prt:sales_q1_2000,sh.sales_prt:sales_q2_2000
      logfile=imp.log
```

Password: *password*

This example specifies the following Data Pump parameters:

- The `DUMPFILE` parameter specifies the exported file containing the metadata for the data to be imported.
- The `DIRECTORY` parameter specifies the directory object that identifies the location of the export dump file. You must create the `DIRECTORY` object before invoking Data Pump, and you must grant the `READ` and `WRITE` object privileges on the directory to the user running the Import utility. See *Oracle Database SQL Language Reference* for information on the `CREATE DIRECTORY` command.

In a non-CDB, the directory object `DATA_PUMP_DIR` is created automatically. Read and write access to this directory is automatically granted to the `DBA` role, and thus to users `SYS` and `SYSTEM`.

However, the directory object `DATA_PUMP_DIR` is not created automatically in a PDB. Therefore, when importing into a PDB, create a directory object in the PDB and specify the directory object when you run Data Pump.

 **See Also:**

- *Oracle Database Utilities* for information about the default directory when the `DIRECTORY` parameter is omitted
- [Overview of Managing a Multitenant Environment](#) for more information about PDBs

- The `TRANSPORT_DATAFILES` parameter identifies all of the data files to be imported. You can specify the `TRANSPORT_DATAFILES` parameter multiple times in a parameter file specified with the `PARFILE` parameter if there are many data files.
- The `TABLES` parameter specifies the tables, partitions, or subpartitions being imported.
- The `LOGFILE` parameter specifies the file name of the log file to be written by the import utility. In this example, the log file is written to the directory from which the dump file is read, but it can be written to a different location.

After this statement executes successfully, check the import log file to ensure that no unexpected error has occurred.

When dealing with a large number of data files, specifying the list of data file names in the statement line can be a laborious process. It can even exceed the statement line limit. In this situation, you can use an import parameter file. For example, you can invoke the Data Pump import utility as follows:

```
impdp user_name parfile='par.f'
```

For example, `par.f` might contain the following lines:

```
DUMPFILE=sales_prt.dmp
DIRECTORY=data_pump_dir
TRANSPORT_DATAFILES='/u01/app/oracle/oradata/targetdb/sales_prt.dbf'
TABLES=sh.sales_prt:sales_q1_2000,sh.sales_prt:sales_q2_2000
LOGFILE=imp.log
```

 **Note:**

- The partitions are imported as separate tables in the target database because this example transports a subset of partitions.
- During the import, tablespaces might be temporarily made read/write for metadata loading. Ensure that no user changes are made to the data during the import. At the successful completion of the import, all user-defined tablespaces are made read/write.
- When performing a network database import, the `TRANSPORTABLE` parameter must be set to `always`.

 **See Also:**

Oracle Database Utilities for information about using the import utility

15.4.4 Transporting Tables, Partitions, or Subpartitions Over the Network

To transport tables over the network, you perform an import using the `NETWORK_LINK` parameter, the import is performed using a database link, and there is no dump file involved.

The following list of tasks summarizes the process of transporting tables, partitions, and subpartitions between databases over the network. Details for each task are provided in the subsequent example.

1. Pick a set of tables, partitions, or subpartitions.

If you are transporting partitions, then you can specify partitions from only one table in a transportable tables operation, and no other tables can be transported in the same operation. Also, if only a subset of a table's partitions are exported in a transportable tables operation, then on import each partition becomes a non-partitioned table.

2. At the source database, place the tablespaces associated with the data files for the tables, partitions, or subpartitions in read-only mode.

To view the tablespace for a table, query the `DBA_TABLES` view. To view the data file for a tablespace, query the `DBA_DATA_FILES` view.

3. Transport the data files for the tables, partitions, or subpartitions.

Copy the data files to a place that is accessible to the target database.

If the source platform and target platform are different, then check the endian format of each platform by running the query on the `V$TRANSPORTABLE_PLATFORM` view in "[Transporting Data Across Platforms](#)".

If the source platform's endian format is different from the target platform's endian format, then use one of the following methods to convert the data files:

- Use the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package to transfer the data files. These procedures convert the data files to the target platform's endian format automatically.
- Use the RMAN CONVERT command to convert the data files to the target platform's endian format.

See "[Converting Data Between Platforms](#)" for more information.

4. At the target database, perform the import.

Invoke the Data Pump utility to import the metadata for the tables.

5. (Optional) Restore tablespaces to read/write mode on the source database.

Example

These tasks for transporting tables over the network are illustrated more fully in the example that follows, where it is assumed that the tables exist in the source database:

Table	Tablespace	Data File
hr.emp_ttbs	emp_tsp	/u01/app/oracle/oradata/sourcedb/emp.dbf
oe.orders_ttbs	orders_tsp	/u01/app/oracle/oradata/sourcedb/orders.dbf

This example transports these tables to the target database. To complete the example, these tables must exist on the source database.

The following SQL statements create the tables in the hr schema and the tablespaces and data files for the tables. The statements also insert data into the tables by using data in the hr and oe sample schemas.

```

CREATE TABLESPACE emp_tsp
  DATAFILE 'emp.dbf' SIZE 1M
  ONLINE;

CREATE TABLE hr.emp_ttbs(
  employee_id    NUMBER(6),
  first_name     VARCHAR2(20),
  last_name      VARCHAR2(25),
  email          VARCHAR2(25),
  phone_number   VARCHAR2(20),
  hire_date      DATE,
  job_id         VARCHAR2(10),
  salary          NUMBER(8,2),
  commission_pct NUMBER(2,2),
  manager_id     NUMBER(6),
  department_id  NUMBER(4))
TABLESPACE emp_tsp;

INSERT INTO hr.emp_ttbs SELECT * FROM hr.employees;

CREATE TABLESPACE orders_tsp
  DATAFILE 'orders.dbf' SIZE 1M
  ONLINE;

CREATE TABLE oe.orders_ttbs(
  order_id        NUMBER(12),
  order_date      TIMESTAMP WITH LOCAL TIME ZONE,
  order_mode      VARCHAR2(8),
  customer_id    NUMBER(6),

```

```

order_status  NUMBER(2),
order_total    NUMBER(8,2),
sales_rep_id   NUMBER(6),
promotion_id   NUMBER(6))
TABLESPACE orders_tsp;

INSERT INTO oe.orders_ttbs SELECT * FROM oe.orders;

COMMIT;

```

This example makes the following additional assumptions:

- The name of the source database is `sourcedb`.
- The source database and target database are running on the same platform with the same endianness. To check the endianness of a platform, run the following query:

```

SELECT d.PLATFORM_NAME, ENDIAN_FORMAT
      FROM V$TRANSPORTABLE_PLATFORM tp, V$DATABASE d
     WHERE tp.PLATFORM_NAME = d.PLATFORM_NAME;

```

Complete the following tasks to transport the tables over the network:

Task 1 Create a Database Link from the Target Database to the Source Database

Create a database link from the target database to the source database by completing the following steps:

1. Ensure that network connectivity is configured between the source database and the target database.
See *Oracle Database Net Services Administrator's Guide* for instructions.
2. Start SQL*Plus and connect to the target database as the administrator who will transport the data with Data Pump import. This user must have `DATAPUMP_IMP_FULL_DATABASE` role to transport the data.
See "[Connecting to the Database with SQL*Plus](#)" for instructions.
3. Create the database link:

```
CREATE PUBLIC DATABASE LINK sourcedb USING 'sourcedb';
```

Specify the service name for the source database in the using clause.

During the import operation, the database link must connect to a user on the source database with `DATAPUMP_EXP_FULL_DATABASE` role. The user on the source database cannot be a user with `SYSDBA` administrative privilege.

See Also:

- "[Creating Database Links](#)"
- *Oracle Database SQL Language Reference*

Task 2 Make the Tablespaces Containing the Tables Read-Only

At the source database, complete the following steps:

1. Start SQL*Plus and connect to the source database as an administrator or as a user who has either the ALTER TABLESPACE or MANAGE TABLESPACE system privilege.

See "[Connecting to the Database with SQL*Plus](#)" for instructions.

2. Make all of the tablespaces that contain data to be transported read-only.

```
ALTER TABLESPACE emp_tsp READ ONLY;
ALTER TABLESPACE orders_tsp READ ONLY;
```

Task 3 Transport the Data Files for the Tables

Transport the data files of the tablespaces containing the tables being transported to a place that is accessible to the target database.

Typically, you transport the data files to the location of the existing data files of the target database. On the UNIX and Linux platforms, this location is typically /u01/app/oracle/oradata/dbname/ or +DISKGROUP/dbname/datafile/.

In this example, transfer the emp.dbf and orders.dbf data files from the source database to the target database.

See Also:

["Guidelines for Transferring Data Files"](#)

Task 4 At the Target Database, Import the Database

Invoke the Data Pump import utility as a user with DATAPUMP_IMP_FULL_DATABASE role and specify the full transportable export/import options.

```
impdp user_name network_link=sourcedb transportable=always
      transport_datafiles=
        '/u01/app/oracle/oradata/targetdb/emp.dbf'
        '/u01/app/oracle/oradata/targetdb/orders.dbf'
      tables=hr.emp_ttbs,oe.orders_ttbs
      logfile=import.log
```

Password: password

This example specifies the following Data Pump parameters:

- The NETWORK_LINK parameter specifies the database link to the source database used for the network import.
- The TRANSPORTABLE parameter specifies that the import uses the transportable option.
- The TRANSPORT_DATAFILES parameter identifies all of the data files to be imported. You can specify the TRANSPORT_DATAFILES parameter multiple times in a parameter file specified with the PARFILE parameter if there are many data files.
- The TABLES parameter specifies the tables to be imported.
- The LOGFILE parameter specifies the file name of the log file to be written by the import utility.

After this statement executes successfully, check the import log file to ensure that no unexpected error has occurred.

When dealing with a large number of data files, specifying the list of data file names in the statement line can be a laborious process. It can even exceed the statement line

limit. In this situation, you can use an import parameter file. For example, you can invoke the Data Pump import utility as follows:

```
impdp user_name parfile='par.f'
```

For example, `par.f` might contain the following lines:

```
NETWORK_LINK=sourcedb
TRANSPORTABLE=always
TRANSPORT_DATAFILES=
  '/u01/app/oracle/oradata/targetdb/emp.dbf'
  '/u01/app/oracle/oradata/targetdb/orders.dbf'
TABLES=hr.emp_ttbs,oe.orders_ttbs
LOGFILE=import.log
```

 **Note:**

During the import, user-defined tablespaces might be temporarily made read/write for metadata loading. Ensure that no user changes are made to the data during the import. At the successful completion of the import, all user-defined tablespaces are made read/write.

 **See Also:**

Oracle Database Utilities for information about using the import utility

Task 5 (Optional) Restore Tablespaces to Read/Write Mode

Make the tables that contain the tables being transported read/write again at the source database, as follows:

```
ALTER TABLESPACE emp_tsp READ WRITE;
ALTER TABLESPACE orders_tsp READ WRITE;
```

15.5 Converting Data Between Platforms

When you perform a transportable operation, and the source platform and the target platform are of different endianness, you must convert the data being transported to the target format. If they are of the same endianness, then no conversion is necessary and data can be transported as if they were on the same platform. You can use the DBMS_FILE_TRANSFER package or the RMAN CONVERT command to convert data.

 **Note:**

Some limitations might apply that are not described in these sections. Refer to the following documentation for more information:

- ["Transporting Data Across Platforms"](#) for information about checking the endianness of platforms
- [Oracle Database PL/SQL Packages and Types Reference](#) for information about limitations related to the DBMS_FILE_TRANSFER package
- [Oracle Database Backup and Recovery Reference](#) for information about limitations related to the RMAN CONVERT command

• [Converting Data Between Platforms Using the DBMS_FILE_TRANSFER Package](#)

You can use the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package to convert data between platforms during the data file transfer.

• [Converting Data Between Platforms Using RMAN](#)

When you use the RMAN CONVERT command to convert data, you can either convert the data on the source platform after running Data Pump export, or you can convert it on the target platform before running Data Pump import. In either case, you must transfer the data files from the source system to the target system.

15.5.1 Converting Data Between Platforms Using the DBMS_FILE_TRANSFER Package

You can use the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package to convert data between platforms during the data file transfer.

When you use one of these procedures to move data files between the source platform and the target platform, each block in each data file is converted to the target platform's endianness.

This section uses an example to describe how to use the DBMS_FILE_TRANSFER package to convert a data file to a different platform. The example makes the following assumptions:

- The GET_FILE procedure will transfer the data file.
- The mytable.342.123456789 data file is being transferred to a different platform.
- The endianness of the source platform is different from the endianness of the target platform.
- The global name of the source database is dbsa.example.com.
- Both the source database and the target database use Oracle Automatic Storage Management (Oracle ASM).

 **Note:**

You can also use the DBMS_FILE_TRANSFER package to transfer data files between platforms with the same endianness.

Complete the following steps to convert the data file by transferring it with the GET_FILE procedure:

1. Connect to the source database as an administrative user that can create directory objects.

See "[Connecting to the Database with SQL*Plus](#)" for instructions.

2. Create a directory object for the directory that contains the data file that will be transferred to the target database.

For example, to create a directory object named sales_dir_source for the +data/dbsa/datafile directory, execute the following SQL statement:

```
CREATE OR REPLACE DIRECTORY sales_dir_source
AS '+data/dbsa/datafile';
```

The specified file system directory must exist when you create the directory object.

3. Connect to the target database as an administrative user that can create database links, create directory objects, and run the procedures in the DBMS_FILE_TRANSFER package.

See "[Connecting to the Database with SQL*Plus](#)" for instructions.

4. Create a database link from the target database to the source database.

The connected user at the source database must have read privilege on the directory object you created in Step 2.

See "[Creating Database Links](#)".

5. Create a directory object to store the data files that will be transferred to the target database.

The user at the local database who will run the procedure in the DBMS_FILE_TRANSFER package must have write privilege on the directory object.

For example, to create a directory object named sales_dir_target for the +data/dbsb/datafile directory, execute the following SQL statement:

```
CREATE OR REPLACE DIRECTORY sales_dir_target
AS '+data/dbsb/datafile';
```

6. Run the GET_FILE procedure in the DBMS_FILE_TRANSFER package to transfer the data file.

For example, run the following procedure to transfer the mytable.342.123456789 data file from the source database to the target database using the database link you created in Step 4:

```
BEGIN
  DBMS_FILE_TRANSFER.GET_FILE(
    source_directory_object      => 'sales_dir_source',
    source_file_name            => 'mytable.342.123456789',
    source_database              => 'dbsa.example.com',
    destination_directory_object => 'sales_dir_target',
    destination_file_name       => 'mytable');
END;
/
```

 **Note:**

In this example, the destination data file name is `mytable`. Oracle ASM does not allow a fully qualified file name form in the `destination_file_name` parameter of the `GET_FILE` procedure.

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference* for more information about using the `DBMS_FILE_TRANSFER` package
- *Oracle Automatic Storage Management Administrator's Guide* for information about fully qualified file name forms in ASM

15.5.2 Converting Data Between Platforms Using RMAN

When you use the RMAN `CONVERT` command to convert data, you can either convert the data on the source platform after running Data Pump export, or you can convert it on the target platform before running Data Pump import. In either case, you must transfer the data files from the source system to the target system.

You can convert data with the following RMAN `CONVERT` commands:

- `CONVERT DATAFILE`
- `CONVERT TABLESPACE`
- `CONVERT DATABASE`

 **Note:**

Datatype restrictions apply to the RMAN `CONVERT` command.

- [Converting Tablespaces on the Source System After Export](#)

An example illustrates how to use the RMAN `CONVERT TABLESPACE` command to convert tablespaces to a different platform.

- [Converting Data Files on the Target System Before Import](#)

An example illustrates how to use the RMAN `CONVERT DATAFILE` command to convert data files to a different platform.

15.5.2.1 Converting Tablespaces on the Source System After Export

An example illustrates how to use the RMAN CONVERT TABLESPACE command to convert tablespaces to a different platform.

The example makes the following assumptions:

- The `sales_1` and `sales_2` tablespaces are being transported to a different platform.
- The endianness of the source platform is different from the endianness of the target platform.
- You want to convert the data on the source system, before transporting the tablespace set to the target system.
- You have completed the Data Pump export on the source database.

Complete the following steps to convert the tablespaces on the source system:

1. At a command prompt, start RMAN and connect to the source database:

```
$ RMAN TARGET /
Recovery Manager: Release 12.1.0.1.0 - Production
Copyright (c) 1982, 2012, Oracle and/or its affiliates. All rights reserved.
connected to target database: salesdb (DBID=3295731590)
```

2. Use the RMAN CONVERT TABLESPACE command to convert the data files into a temporary location on the source platform.

In this example, assume that the temporary location, directory `/tmp`, has already been created. The converted data files are assigned names by the system.

```
RMAN> CONVERT TABLESPACE sales_1,sales_2
2> TO PLATFORM 'Microsoft Windows IA (32-bit)'
3> FORMAT '/tmp/%U';

Starting conversion at source at 30-SEP-08
using channel ORA_DISK_1
channel ORA_DISK_1: starting datafile conversion
input datafile file number=00007 name=/u01/app/oracle/oradata/salesdb/
sales_101.dbf
converted datafile=/tmp/data_D-SALESDB_I-1192614013_TS-SALES_1_FNO-7_03jru08s
channel ORA_DISK_1: datafile conversion complete, elapsed time: 00:00:45
channel ORA_DISK_1: starting datafile conversion
input datafile file number=00008 name=/u01/app/oracle/oradata/salesdb/
sales_201.dbf
converted datafile=/tmp/data_D-SALESDB_I-1192614013_TS-SALES_2_FNO-8_04jru0aa
channel ORA_DISK_1: datafile conversion complete, elapsed time: 00:00:25
Finished conversion at source at 30-SEP-08
```

 **See Also:**

Oracle Database Backup and Recovery Reference for a description of the RMAN CONVERT command

3. Exit Recovery Manager:

```
RMAN> exit  
Recovery Manager complete.
```

4. Transfer the data files to the target system.

See "[Guidelines for Transferring Data Files](#)".

15.5.2.2 Converting Data Files on the Target System Before Import

An example illustrates how to use the RMAN CONVERT DATAFILE command to convert data files to a different platform.

During the conversion, you identify the data files by file name, not by tablespace name. Until the tablespace metadata is imported, the target instance has no way of knowing the desired tablespace names.

The example makes the following assumptions:

- You have not yet converted the data files for the tablespaces being transported.
If you used the DBMS_FILE_TRANSFER package to transfer the data files to the target system, then the data files were converted automatically during the file transfer.
See "[Converting Data Between Platforms Using the DBMS_FILE_TRANSFER Package](#)".
- The following data files are being transported to a different platform:
 - C:\Temp\sales_101.dbf
 - C:\Temp\sales_201.dbf

The data files must be accessible to the target database. If they are not accessible to the target database, then transfer the data files to the target system. See "[Guidelines for Transferring Data Files](#)".

- The endianness of the source platform is different from the endianness of the target platform.
- You want to convert the data on the target system, before performing the Data Pump import.
- The converted data files are placed in C:\app\orauser\oradata\orawin\, which is the location of the existing data files for the target system:

Complete the following steps to convert the tablespaces on the target system:

1. If you are in SQL*Plus, then return to the host system:

```
SQL> HOST
```

2. Use the RMAN CONVERT DATAFILE command to convert the data files on the target platform:

```
C:\>RMAN TARGET /
```

```
Recovery Manager: Release 12.1.0.1.0 - Production

Copyright (c) 1982, 2012, Oracle and/or its affiliates. All rights reserved.

connected to target database: ORAWIN (DBID=3462152886)

RMAN> CONVERT DATAFILE
2>'C:\Temp\sales_101.dbf',
3>'C:\Temp\sales_201.dbf'
4>TO PLATFORM="Microsoft Windows IA (32-bit)"
5>FROM PLATFORM="Solaris[tm] OE (32-bit)"
6>DB_FILE_NAME_CONVERT=
7>'C:\Temp\', 'C:\app\orauser\oradata\orawin\
8> PARALLELISM=4;
```

If the source location, the target location, or both do not use Oracle Automatic Storage Management (Oracle ASM), then the source and target platforms are optional. RMAN determines the source platform by examining the data file, and the target platform defaults to the platform of the host running the conversion.

If both the source and target locations use Oracle ASM, then you must specify the source and target platforms in the `DB_FILE_NAME_CONVERT` clause.

 **See Also:**

Oracle Database Backup and Recovery Reference for a description of the RMAN `CONVERT` command

3. Exit Recovery Manager:

```
RMAN> exit
Recovery Manager complete.
```

15.6 Guidelines for Transferring Data Files

You should follow a set of guidelines when transferring the data files.

If both the source and target are file systems, then you can transport using:

- Any facility for copying flat files (for example, an operating system copy utility or `ftp`)
- The `DBMS_FILE_TRANSFER` package
- RMAN
- Any facility for publishing on CDs

If either the source or target is an Oracle Automatic Storage Management (Oracle ASM) disk group, then you can use:

- `ftp` to or from the `/sys/asm` virtual folder in the XML DB repository

See *Oracle Automatic Storage Management Administrator's Guide* for more information.

- The `DBMS_FILE_TRANSFER` package
- RMAN

Do not transport the data files for the administrative tablespaces (such as SYSTEM and SYSAUX) or any undo or temporary tablespaces.

If you are transporting data of a different block size than the standard block size of the database receiving the data, then you must first have a DB_nK_CACHE_SIZE initialization parameter entry in the receiving database parameter file.

For example, if you are transporting data with an 8K block size into a database with a 4K standard block size, then you must include a DB_8K_CACHE_SIZE initialization parameter entry in the parameter file. If it is not already included in the parameter file, then this parameter can be set using the ALTER SYSTEM SET statement.

See *Oracle Database Reference* for information about specifying values for the DB_nK_CACHE_SIZE initialization parameter.

Starting with Oracle Database 12c, the GET_FILE or PUT_FILE procedure in the DBMS_FILE_TRANSFER package can convert data between platforms during the data file transfer. See "[Converting Data Between Platforms](#)".

Starting with Oracle Database 12c, RMAN can transfer files using network-enabled restore. RMAN restores database files, over the network, from a remote database instance by using the FROM SERVICE clause of the RESTORE command. The primary advantage of network-enabled restore is that it eliminates the requirement for a restore of the backup to a staging area on disk and the need to transfer the copy. Therefore, network-enabled restore saves disk space and time. This technique can also provide the following advantages during file transfer: compression, encryption, and transfer of used data blocks only. See *Oracle Database Backup and Recovery User's Guide* for more information.

 **Note:**

Exercise caution when using the UNIX dd utility to copy raw-device files between databases, and note that Oracle Database 12c does not support raw devices for database files. The dd utility can be used to copy an entire source raw-device file, or it can be invoked with options that instruct it to copy only a specific range of blocks from the source raw-device file.

It is difficult to ascertain actual data file size for a raw-device file because of hidden control information that is stored as part of the data file. If you must use the dd utility to operate on raw devices, then specify the entire source raw-device file contents. If you move database file content from a raw device to either ASM or a file system to adhere to the desupport of raw devices with Oracle Database 12c, then use an Oracle-provided tool such as RMAN.

 **See Also:**

"[Copying Files Using the Database Server](#)" for information about using the DBMS_FILE_TRANSFER package to copy the files that are being transported and their metadata

Managing Undo

For a default installation, Oracle Database automatically manages undo. There is typically no need for DBA intervention. However, if your installation uses Oracle Flashback operations, you may need to perform some undo management tasks to ensure the success of these operations.

- **What Is Undo?**

Oracle Database creates and manages information that is used to roll back, or undo, changes to the database. Such information consists of records of the actions of transactions, primarily before they are committed. These records are collectively referred to as **undo**.

- **Introduction to Automatic Undo Management**

Oracle Database can manage undo information and space automatically.

- **Setting the Minimum Undo Retention Period**

You specify the minimum undo retention period (in seconds) by setting the `UNDO_RETENTION` initialization parameter.

- **Sizing a Fixed-Size Undo Tablespace**

Automatic tuning of undo retention typically achieves better results with a fixed-size undo tablespace. If you decide to use a fixed-size undo tablespace, then the Undo Advisor can help you estimate needed capacity.

- **Managing Undo Tablespaces**

You manage undo tablespaces by completing tasks such as creating, altering, and dropping them. You can also switch undo tablespaces and establish user quotas for undo space.

- **Migrating to Automatic Undo Management**

If you are currently using rollback segments to manage undo space, Oracle strongly recommends that you migrate your database to automatic undo management.

- **Managing Temporary Undo**

By default, undo records for temporary tables are stored in the undo tablespace and are logged in the redo, which is the same way undo is managed for persistent tables. However, you can use the `TEMP_UNDO_ENABLED` initialization parameter to separate undo for temporary tables from undo for persistent tables. When this parameter is set to `TRUE`, the undo for temporary tables is called **temporary undo**.

- **Undo Space Data Dictionary Views**

You can query a set of views for information about undo space in the automatic undo management mode.

 **See Also:**

[Using Oracle Managed Files](#) for information about creating an undo tablespace whose data files are both created and managed by Oracle Database.

16.1 What Is Undo?

Oracle Database creates and manages information that is used to roll back, or undo, changes to the database. Such information consists of records of the actions of transactions, primarily before they are committed. These records are collectively referred to as **undo**.

Undo records are used to:

- Roll back transactions when a ROLLBACK statement is issued
- Recover the database
- Provide read consistency
- Analyze data as of an earlier point in time by using Oracle Flashback Query
- Recover from logical corruptions using Oracle Flashback features

When a ROLLBACK statement is issued, undo records are used to undo changes that were made to the database by the uncommitted transaction. During database recovery, undo records are used to undo any uncommitted changes applied from the redo log to the data files. Undo records provide read consistency by maintaining the before image of the data for users who are accessing the data at the same time that another user is changing it.

 **See Also:**

[Oracle Database Concepts](#)

16.2 Introduction to Automatic Undo Management

Oracle Database can manage undo information and space automatically.

- [Overview of Automatic Undo Management](#)

Oracle provides a fully automated mechanism, referred to as automatic undo management, for managing undo information and space. With automatic undo management, the database manages undo segments in an undo tablespace.

- [The Undo Retention Period](#)

The **undo retention period** is the minimum amount of time that Oracle Database attempts to retain old undo information before overwriting it.

16.2.1 Overview of Automatic Undo Management

Oracle provides a fully automated mechanism, referred to as automatic undo management, for managing undo information and space. With automatic undo management, the database manages undo segments in an undo tablespace.

Automatic undo management is the default mode for a newly installed database. An auto-extending undo tablespace named `UNDOTBS1` is automatically created when you create the database with Database Configuration Assistant (DBCA).

You can also create an undo tablespace explicitly. The methods of creating an undo tablespace are explained in "[Creating an Undo Tablespace](#)".

When the database instance starts, the database automatically selects the first available undo tablespace. If no undo tablespace is available, then the instance starts without an undo tablespace and stores undo records in the `SYSTEM` tablespace. This is not recommended, and an alert message is written to the alert log file to warn that the system is running without an undo tablespace.

If the database contains multiple undo tablespaces, then you can optionally specify at startup that you want to use a specific undo tablespace. This is done by setting the `UNDO_TABLESPACE` initialization parameter, as shown in this example:

```
UNDO_TABLESPACE = undotbs_01
```

If the tablespace specified in the initialization parameter does not exist, the `STARTUP` command fails. The `UNDO_TABLESPACE` parameter can be used to assign a specific undo tablespace to an instance in an Oracle Real Application Clusters environment.

The database can also run in *manual undo management mode*. In this mode, undo space is managed through rollback segments, and no undo tablespace is used.

 **Note:**

Space management for rollback segments is complex. Oracle strongly recommends leaving the database in automatic undo management mode.

The following is a summary of the initialization parameters for undo management:

Initialization Parameter	Description
<code>UNDO_MANAGEMENT</code>	If <code>AUTO</code> or null, enables automatic undo management. If <code>MANUAL</code> , sets manual undo management mode. The default is <code>AUTO</code> .
<code>UNDO_TABLESPACE</code>	Optional, and valid only in automatic undo management mode. Specifies the name of an undo tablespace. Use only when the database has multiple undo tablespaces and you want to direct the database instance to use a particular undo tablespace.

When automatic undo management is enabled, if the initialization parameter file contains parameters relating to manual undo management, they are ignored.

 **Note:**

Earlier releases of Oracle Database default to manual undo management mode. To change to automatic undo management, you must first create an undo tablespace and then change the `UNDO_MANAGEMENT` initialization parameter to `AUTO`. If your Oracle Database is Oracle9i or later and you want to change to automatic undo management, see *Oracle Database Upgrade Guide* for instructions.

A null `UNDO_MANAGEMENT` initialization parameter defaults to automatic undo management mode in Oracle Database 11g and later, but defaults to manual undo management mode in earlier releases. You must therefore use caution when upgrading a previous release to the current release. *Oracle Database Upgrade Guide* describes the correct method of migrating to automatic undo management mode, including information on how to size the undo tablespace.

16.2.2 The Undo Retention Period

The **undo retention period** is the minimum amount of time that Oracle Database attempts to retain old undo information before overwriting it.

- [About the Undo Retention Period](#)

When automatic undo management is enabled, there is always a current **undo retention period**, which is the minimum amount of time that Oracle Database attempts to retain old undo information before overwriting it.

- [Automatic Tuning of Undo Retention](#)

Oracle Database automatically tunes the undo retention period based on how the undo tablespace is configured.

- [Retention Guarantee](#)

To guarantee the success of long-running queries or Oracle Flashback operations, you can enable retention guarantee.

- [Undo Retention Tuning and Alert Thresholds](#)

For a fixed-size undo tablespace, the database calculates the best possible retention based on database statistics and on the size of the undo tablespace.

- [Tracking the Tuned Undo Retention Period](#)

You can determine the current retention period by querying the `TUNED_UNDORETENTION` column of the `V$UNDOSTAT` view.

16.2.2.1 About the Undo Retention Period

When automatic undo management is enabled, there is always a current **undo retention period**, which is the minimum amount of time that Oracle Database attempts to retain old undo information before overwriting it.

After a transaction is committed, undo data is no longer needed for rollback or transaction recovery purposes. However, for consistent read purposes, long-running queries may require this old undo information for producing older images of data blocks. Furthermore, the success of several Oracle Flashback features can also depend upon the availability of older undo information. For these reasons, it is desirable to retain the old undo information for as long as possible.

Old (committed) undo information that is older than the current undo retention period is said to be *expired* and its space is available to be overwritten by new transactions. Old undo information with an age that is less than the current undo retention period is said to be *unexpired* and is retained for consistent read and Oracle Flashback operations.

Oracle Database automatically tunes the undo retention period based on undo tablespace size and system activity. You can optionally specify a minimum undo retention period (in seconds) by setting the `UNDO_RETENTION` initialization parameter. The exact impact this parameter on undo retention is as follows:

- The `UNDO_RETENTION` parameter is ignored for a fixed size undo tablespace. The database always tunes the undo retention period for the best possible retention, based on system activity and undo tablespace size. See "[Automatic Tuning of Undo Retention](#)" for more information.
- For an undo tablespace with the `AUTOEXTEND` option enabled, the database attempts to honor the minimum retention period specified by `UNDO_RETENTION`. When space is low, instead of overwriting unexpired undo information, the tablespace auto-extends. If the `MAXSIZE` clause is specified for an auto-extending undo tablespace, when the maximum size is reached, the database may begin to overwrite unexpired undo information. The `UNDOTBS1` tablespace that is automatically created by DBCA is auto-extending.

16.2.2.2 Automatic Tuning of Undo Retention

Oracle Database automatically tunes the undo retention period based on how the undo tablespace is configured.

- If the undo tablespace is configured with the `AUTOEXTEND` option, the database dynamically tunes the undo retention period to be somewhat longer than the longest-running active query on the system. However, this retention period may be insufficient to accommodate Oracle Flashback operations. Oracle Flashback operations resulting in `snapshot too old` errors are the indicator that you must intervene to ensure that sufficient undo data is retained to support these operations. To better accommodate Oracle Flashback features, you can either set the `UNDO_RETENTION` parameter to a value equal to the longest expected Oracle Flashback operation, or you can change the undo tablespace to fixed size.
- If the undo tablespace is fixed size, the database dynamically tunes the undo retention period for the best possible retention for that tablespace size and the current system load. This best possible retention time is typically significantly greater than the duration of the longest-running active query.

If you decide to change the undo tablespace to fixed-size, you must choose a tablespace size that is sufficiently large. If you choose an undo tablespace size that is too small, the following two errors could occur:

- DML could fail because there is not enough space to accommodate undo for new transactions.
- Long-running queries could fail with a `snapshot too old` error, which means that there was insufficient undo data for read consistency.

See "[Sizing a Fixed-Size Undo Tablespace](#)" for more information.

 **Note:**

Automatic tuning of undo retention is not supported for LOBs. This is because undo information for LOBs is stored in the segment itself and not in the undo tablespace. For LOBs, the database attempts to honor the minimum undo retention period specified by `UNDO_RETENTION`. However, if space becomes low, unexpired LOB undo information may be overwritten.

 **See Also:**

["Setting the Minimum Undo Retention Period"](#)

16.2.2.3 Retention Guarantee

To guarantee the success of long-running queries or Oracle Flashback operations, you can enable retention guarantee.

If retention guarantee is enabled, then the specified minimum undo retention is guaranteed; the database never overwrites unexpired undo data even if it means that transactions fail due to lack of space in the undo tablespace. If retention guarantee is not enabled, then the database can overwrite unexpired undo when space is low, thus lowering the undo retention for the system. This option is disabled by default.

 **WARNING:**

Enabling retention guarantee can cause multiple DML operations to fail. Use with caution.

You enable retention guarantee by specifying the `RETENTION GUARANTEE` clause for the undo tablespace when you create it with either the `CREATE DATABASE` or `CREATE UNDO TABLESPACE` statement. Or, you can later specify this clause in an `ALTER TABLESPACE` statement. You disable retention guarantee with the `RETENTION NOGUARANTEE` clause.

You can use the `DBA_TABLESPACES` view to determine the retention guarantee setting for the undo tablespace. A column named `RETENTION` contains a value of `GUARANTEE`, `NOGUARANTEE`, or `NOT APPLY`, where `NOT APPLY` is used for tablespaces other than the undo tablespace.

16.2.2.4 Undo Retention Tuning and Alert Thresholds

For a fixed-size undo tablespace, the database calculates the best possible retention based on database statistics and on the size of the undo tablespace.

For optimal undo management, rather than tuning based on 100% of the tablespace size, the database tunes the undo retention period based on 70% of the tablespace size, or on the warning alert threshold percentage for space used, whichever is lower.

(The warning alert threshold defaults to 70%, but can be changed.) Therefore, if you set the warning alert threshold of the undo tablespace below 70%, this may reduce the tuned size of the undo retention period. For more information on tablespace alert thresholds, see "[Managing Tablespace Alerts](#)".

16.2.2.5 Tracking the Tuned Undo Retention Period

You can determine the current retention period by querying the `TUNED_UNDORETENTION` column of the `V$UNDOSTAT` view.

This view contains one row for each 10-minute statistics collection interval over the last 4 days. (Beyond 4 days, the data is available in the `DBA_HIST_UNDOSTAT` view.) `TUNED_UNDORETENTION` is given in seconds.

```
select to_char(begin_time, 'DD-MON-RR HH24:MI') begin_time,
       to_char(end_time, 'DD-MON-RR HH24:MI') end_time, tuned_undoretention
  from v$undostat order by end_time;
```

BEGIN_TIME	END_TIME	TUNED_UNDORETENTION
04-FEB-05 00:01	04-FEB-05 00:11	12100
...		
07-FEB-05 23:21	07-FEB-05 23:31	86700
07-FEB-05 23:31	07-FEB-05 23:41	86700
07-FEB-05 23:41	07-FEB-05 23:51	86700
07-FEB-05 23:51	07-FEB-05 23:52	86700

576 rows selected.

See *Oracle Database Reference* for more information about `V$UNDOSTAT`.

16.3 Setting the Minimum Undo Retention Period

You specify the minimum undo retention period (in seconds) by setting the `UNDO_RETENTION` initialization parameter.

As described in "[About the Undo Retention Period](#)", the current undo retention period may be automatically tuned to be greater than `UNDO_RETENTION`, or, unless retention guarantee is enabled, less than `UNDO_RETENTION` if space in the undo tablespace is low.

To set the minimum undo retention period:

- Do one of the following:
 - Set `UNDO_RETENTION` in the initialization parameter file.
`UNDO_RETENTION = 1800`
 - Change `UNDO_RETENTION` at any time using the `ALTER SYSTEM` statement:
`ALTER SYSTEM SET UNDO_RETENTION = 2400;`

The effect of an `UNDO_RETENTION` parameter change is immediate, but it can only be honored if the current undo tablespace has enough space.

16.4 Sizing a Fixed-Size Undo Tablespace

Automatic tuning of undo retention typically achieves better results with a fixed-size undo tablespace. If you decide to use a fixed-size undo tablespace, then the Undo Advisor can help you estimate needed capacity.

You can access the Undo Advisor through Oracle Enterprise Manager Database Express (EM Express) or through the DBMS_ADVISOR PL/SQL package. EM Express is the preferred method of accessing the advisor. For more information on using the Undo Advisor through EM Express, see *Oracle Database 2 Day DBA*.

The Undo Advisor relies for its analysis on data collected in the Automatic Workload Repository (AWR). It is therefore important that the AWR have adequate workload statistics available so that the Undo Advisor can make accurate recommendations. For newly created databases, adequate statistics may not be available immediately. In such cases, continue to use the default auto-extending undo tablespace until at least one workload cycle completes.

An adjustment to the collection interval and retention period for AWR statistics can affect the precision and the type of recommendations that the advisor produces. See *Oracle Database Performance Tuning Guide* for more information.

To use the Undo Advisor, you first estimate these two values:

- The length of your expected longest running query

After the database has completed a workload cycle, you can view the Longest Running Query field on the System Activity subpage of the Automatic Undo Management page.

- The longest interval that you will require for Oracle Flashback operations

For example, if you expect to run Oracle Flashback queries for up to 48 hours in the past, your Oracle Flashback requirement is 48 hours.

You then take the maximum of these two values and use that value as input to the Undo Advisor.

Running the Undo Advisor does not alter the size of the undo tablespace. The advisor just returns a recommendation. You must use ALTER DATABASE statements to change the tablespace data files to fixed sizes.

The following example assumes that the undo tablespace has one auto-extending data file named undotbs.dbf. The example changes the tablespace to a fixed size of 300MB.

```
ALTER DATABASE DATAFILE '/oracle/dbs/undotbs.dbf' RESIZE 300M;
ALTER DATABASE DATAFILE '/oracle/dbs/undotbs.dbf' AUTOEXTEND OFF;
```

 **Note:**

To make the undo tablespace fixed-size, Oracle suggests that you first allow enough time after database creation to run a full workload, thus allowing the undo tablespace to grow to its minimum required size to handle the workload. Then, you can use the Undo Advisor to determine, if desired, how much larger to set the size of the undo tablespace to allow for long-running queries and Oracle Flashback operations.

- Activating the Undo Advisor PL/SQL Interface

You can activate the Undo Advisor by creating an undo advisor task through the advisor framework.

 **See Also:**

Oracle Database 2 Day DBA for instructions for computing the minimum undo tablespace size with the Undo Advisor

16.4.1 Activating the Undo Advisor PL/SQL Interface

You can activate the Undo Advisor by creating an undo advisor task through the advisor framework.

The following example creates an undo advisor task to evaluate the undo tablespace. The name of the advisor is 'Undo Advisor'. The analysis is based on Automatic Workload Repository snapshots, which you must specify by setting parameters START_SNAPSHOT and END_SNAPSHOT. In the following example, the START_SNAPSHOT is "1" and END_SNAPSHOT is "2".

```
DECLARE
    tid      NUMBER;
    tname   VARCHAR2(30);
    oid      NUMBER;
BEGIN
    DBMS_ADVISOR.CREATE_TASK('Undo Advisor', tid, tname, 'Undo Advisor Task');
    DBMS_ADVISOR.CREATE_OBJECT(tname, 'UNDO_TBS', null, null, null, 'null', oid);
    DBMS_ADVISOR.SET_TASK_PARAMETER(tname, 'TARGET_OBJECTS', oid);
    DBMS_ADVISOR.SET_TASK_PARAMETER(tname, 'START_SNAPSHOT', 1);
    DBMS_ADVISOR.SET_TASK_PARAMETER(tname, 'END_SNAPSHOT', 2);
    DBMS_ADVISOR.SET_TASK_PARAMETER(tname, 'INSTANCE', 1);
    DBMS_ADVISOR.execute_task(tname);
END;
/
```

After you have created the advisor task, you can view the output and recommendations in the Automatic Database Diagnostic Monitor in EM Express. This information is also available in the DBA_ADVISOR_* data dictionary views (DBA_ADVISOR_TASKS, DBA_ADVISOR_OBJECTS, DBA_ADVISOR_FINDINGS, DBA_ADVISOR_RECOMMENDATIONS, and so on).

 **See Also:**

- ["Using the Segment Advisor"](#) for an example of creating an advisor task for a different advisor
- [Oracle Database 2 Day DBA](#) for information about the Automatic Database Diagnostic Monitor in EM Express
- [Oracle Database Reference](#) for information about the DBA_ADVISOR_* data dictionary views

16.5 Managing Undo Tablespaces

You manage undo tablespaces by completing tasks such as creating, altering, and dropping them. You can also switch undo tablespaces and establish user quotas for undo space.

- [Creating an Undo Tablespace](#)
Although Database Configuration Assistant (DBCA) automatically creates an undo tablespace for new installations, there may be occasions when you want to manually create an undo tablespace.
- [Altering an Undo Tablespace](#)
You can alter an undo tablespace using the `ALTER TABLESPACE` statement.
- [Dropping an Undo Tablespace](#)
Use the `DROP TABLESPACE` statement to drop an undo tablespace.
- [Switching Undo Tablespaces](#)
You can switch from using one undo tablespace to another. Because the `UNDO_TABLESPACE` initialization parameter is a dynamic parameter, the `ALTER SYSTEM SET` statement can be used to assign a new undo tablespace.
- [Establishing User Quotas for Undo Space](#)
You can use the Oracle Database Resource Manager to establish user quotas for undo space. The Database Resource Manager directive `UNDO_POOL` allows DBAs to limit the amount of undo space consumed by a group of users (resource consumer group).
- [Managing Space Threshold Alerts for the Undo Tablespace](#)
Oracle Database provides proactive help in managing tablespace disk space use by alerting you when tablespaces run low on available space.

16.5.1 Creating an Undo Tablespace

Although Database Configuration Assistant (DBCA) automatically creates an undo tablespace for new installations, there may be occasions when you want to manually create an undo tablespace.

- [About Creating an Undo Tablespace](#)
When you are creating a database, you can create an undo tablespace with the `CREATE DATABASE` statement. In an existing database, you can create an undo tablespace with the `CREATE UNDO TABLESPACE` statement.

- **Using CREATE DATABASE to Create an Undo Tablespace**
You can create a specific undo tablespace using the UNDO TABLESPACE clause of the CREATE DATABASE statement.
- **Using the CREATE UNDO TABLESPACE Statement**
The CREATE UNDO TABLESPACE statement is the same as the CREATE TABLESPACE statement, but the UNDO keyword is specified. The database determines most of the attributes of the undo tablespace, but you can specify the DATAFILE clause.

16.5.1.1 About Creating an Undo Tablespace

When you are creating a database, you can create an undo tablespace with the CREATE DATABASE statement. In an existing database, you can create an undo tablespace with the CREATE UNDO TABLESPACE statement.

There are two methods of creating an undo tablespace. The first method creates the undo tablespace when the CREATE DATABASE statement is issued. This occurs when you are creating a new database, and the instance is started in automatic undo management mode (`UNDO_MANAGEMENT = AUTO`). The second method is used with an existing database. It uses the CREATE UNDO TABLESPACE statement.

You cannot create database objects in an undo tablespace. It is reserved for system-managed undo data.

Oracle Database enables you to create a single-file undo tablespace. Single-file, or bigfile, tablespaces are discussed in "[Bigfile Tablespaces](#)".

16.5.1.2 Using CREATE DATABASE to Create an Undo Tablespace

You can create a specific undo tablespace using the UNDO TABLESPACE clause of the CREATE DATABASE statement.

The following statement illustrates using the UNDO TABLESPACE clause in a CREATE DATABASE statement. The undo tablespace is named `undotbs_01` and one data file, `/u01/oracle/rbdb1/undo0101.dbf`, is allocated for it.

```
CREATE DATABASE rbdb1
  CONTROLFILE REUSE
  .
  .
  .
  UNDO TABLESPACE undotbs_01 DATAFILE '/u01/oracle/rbdb1/undo0101.dbf';
```

If the undo tablespace cannot be created successfully during CREATE DATABASE, the entire CREATE DATABASE operation fails. You must clean up the database files, correct the error and retry the CREATE DATABASE operation.

The CREATE DATABASE statement also lets you create a single-file undo tablespace at database creation. This is discussed in "[Supporting Bigfile Tablespaces During Database Creation](#)".

 **See Also:**

Oracle Database SQL Language Reference for the syntax for using the CREATE DATABASE statement to create an undo tablespace

16.5.1.3 Using the CREATE UNDO TABLESPACE Statement

The CREATE UNDO TABLESPACE statement is the same as the CREATE TABLESPACE statement, but the UNDO keyword is specified. The database determines most of the attributes of the undo tablespace, but you can specify the DATAFILE clause.

This example creates the undotbs_02 undo tablespace with the AUTOEXTEND option:

```
CREATE UNDO TABLESPACE undotbs_02
    DATAFILE '/u01/oracle/rbdb1/undo0201.dbf' SIZE 2M REUSE AUTOEXTEND ON;
```

You can create multiple undo tablespaces, but only one of them can be active at any one time.

 **See Also:**

Oracle Database SQL Language Reference for the syntax for using the CREATE UNDO TABLESPACE statement to create an undo tablespace

16.5.2 Altering an Undo Tablespace

You can alter an undo tablespaces using the ALTER TABLESPACE statement.

However, since most aspects of undo tablespaces are system managed, you need only be concerned with the following actions:

- Adding a data file
- Renaming a data file
- Bringing a data file online or taking it offline
- Beginning or ending an open backup on a data file
- Enabling and disabling undo retention guarantee

These are also the only attributes you are permitted to alter.

If an undo tablespace runs out of space, or you want to prevent it from doing so, you can add more files to it or resize existing data files.

The following example adds another data file to undo tablespace undotbs_01:

```
ALTER TABLESPACE undotbs_01
    ADD DATAFILE '/u01/oracle/rbdb1/undo0102.dbf' AUTOEXTEND ON NEXT 1M
        MAXSIZE UNLIMITED;
```

You can use the ALTER DATABASE...DATAFILE statement to resize or extend a data file.

 **See Also:**

- ["Changing Data File Size"](#)
- *Oracle Database SQL Language Reference* for `ALTER TABLESPACE` syntax

16.5.3 Dropping an Undo Tablespace

Use the `DROP TABLESPACE` statement to drop an undo tablespace.

The following example drops the undo tablespace `undotbs_01`:

```
DROP TABLESPACE undotbs_01;
```

An undo tablespace can only be dropped if it is not currently used by any instance. If the undo tablespace contains any outstanding transactions (for example, a transaction died but has not yet been recovered), the `DROP TABLESPACE` statement fails. However, since `DROP TABLESPACE` drops an undo tablespace even if it contains unexpired undo information (within retention period), you must be careful not to drop an undo tablespace if undo information is needed by some existing queries.

`DROP TABLESPACE` for undo tablespaces behaves like `DROP TABLESPACE...INCLUDING CONTENTS`. All contents of the undo tablespace are removed.

 **See Also:**

Oracle Database SQL Language Reference for `DROP TABLESPACE` syntax

16.5.4 Switching Undo Tablespaces

You can switch from using one undo tablespace to another. Because the `UNDO_TABLESPACE` initialization parameter is a dynamic parameter, the `ALTER SYSTEM SET` statement can be used to assign a new undo tablespace.

The following statement switches to a new undo tablespace:

```
ALTER SYSTEM SET UNDO_TABLESPACE = undotbs_02;
```

Assuming `undotbs_01` is the current undo tablespace, after this command successfully executes, the instance uses `undotbs_02` in place of `undotbs_01` as its undo tablespace.

If any of the following conditions exist for the tablespace being switched to, an error is reported and no switching occurs:

- The tablespace does not exist
- The tablespace is not an undo tablespace

- The tablespace is already being used by another instance (in an Oracle RAC environment only)

The database is online while the switch operation is performed, and user transactions can be executed while this command is being executed. When the switch operation completes successfully, all transactions started after the switch operation began are assigned to transaction tables in the new undo tablespace.

The switch operation does not wait for transactions in the old undo tablespace to commit. If there are any pending transactions in the old undo tablespace, the old undo tablespace enters into a PENDING OFFLINE mode (status). In this mode, existing transactions can continue to execute, but undo records for new user transactions cannot be stored in this undo tablespace.

An undo tablespace can exist in this PENDING OFFLINE mode, even after the switch operation completes successfully. A PENDING OFFLINE undo tablespace cannot be used by another instance, nor can it be dropped. Eventually, after all active transactions have committed, the undo tablespace automatically goes from the PENDING OFFLINE mode to the OFFLINE mode. From then on, the undo tablespace is available for other instances (in an Oracle Real Application Cluster environment).

If the parameter value for UNDO TABLESPACE is set to " (two single quotes), then the current undo tablespace is switched out and the next available undo tablespace is switched in. Use this statement with care because there may be no undo tablespace available.

The following example unassigns the current undo tablespace:

```
ALTER SYSTEM SET UNDO_TABLESPACE = '';
```

16.5.5 Establishing User Quotas for Undo Space

You can use the Oracle Database Resource Manager to establish user quotas for undo space. The Database Resource Manager directive UNDO_POOL allows DBAs to limit the amount of undo space consumed by a group of users (resource consumer group).

You can specify an undo pool for each consumer group. An undo pool controls the amount of total undo that can be generated by a consumer group. When the total undo generated by a consumer group exceeds its undo limit, the current UPDATE transaction generating the undo is terminated. No other members of the consumer group can perform further updates until undo space is freed from the pool.

When no UNDO_POOL directive is explicitly defined, users are allowed unlimited undo space.

 **See Also:**

[Managing Resources with Oracle Database Resource Manager](#)

16.5.6 Managing Space Threshold Alerts for the Undo Tablespace

Oracle Database provides proactive help in managing tablespace disk space use by alerting you when tablespaces run low on available space.

See "[Managing Tablespace Alerts](#)" for information on how to set alert thresholds for the undo tablespace.

In addition to the proactive undo space alerts, Oracle Database also provides alerts if your system has long-running queries that cause SNAPSHOT TOO OLD errors. To prevent excessive alerts, the long query alert is issued at most once every 24 hours. When the alert is generated, you can check the Undo Advisor Page of EM Express to get more information about the undo tablespace. For more information on using the Undo Advisor through EM Express, see *Oracle Database 2 Day DBA*.

16.6 Migrating to Automatic Undo Management

If you are currently using rollback segments to manage undo space, Oracle strongly recommends that you migrate your database to automatic undo management.

For instructions, see *Oracle Database Upgrade Guide*.

16.7 Managing Temporary Undo

By default, undo records for temporary tables are stored in the undo tablespace and are logged in the redo, which is the same way undo is managed for persistent tables. However, you can use the TEMP_UNDO_ENABLED initialization parameter to separate undo for temporary tables from undo for persistent tables. When this parameter is set to TRUE, the undo for temporary tables is called **temporary undo**.

- [About Managing Temporary Undo](#)

Temporary undo records are stored in the database's temporary tablespaces and thus are not logged in the redo log. When temporary undo is enabled, some of the segments used by the temporary tablespaces store the temporary undo, and these segments are called **temporary undo segments**.

- [Enabling and Disabling Temporary Undo](#)

You can enable or disable temporary undo for a session or for the system. To do so, set the TEMP_UNDO_ENABLED initialization parameter.

16.7.1 About Managing Temporary Undo

Temporary undo records are stored in the database's temporary tablespaces and thus are not logged in the redo log. When temporary undo is enabled, some of the segments used by the temporary tablespaces store the temporary undo, and these segments are called **temporary undo segments**.

When temporary undo is enabled, it might be necessary to increase the size of the temporary tablespaces to account for the undo records.

Enabling temporary undo provides the following benefits:

- Temporary undo reduces the amount of undo stored in the undo tablespaces.

Less undo in the undo tablespaces can result in more realistic undo retention period requirements for undo records.

- Temporary undo reduces the size of the redo log.
Performance is improved because less data is written to the redo log, and components that parse redo log records, such as LogMiner, perform better because there is less redo data to parse.
- Temporary undo enables data manipulation language (DML) operations on temporary tables in a physical standby database with the Oracle Active Data Guard option. However, data definition language (DDL) operations that create temporary tables must be issued on the primary database.

You can enable temporary undo for a specific session or for the whole system. When you enable temporary undo for a session using an `ALTER SESSION` statement, the session creates temporary undo without affecting other sessions. When you enable temporary undo for the system using an `ALTER SYSTEM` statement, all existing sessions and new sessions create temporary undo.

When a session uses temporary objects for the first time, the current value of the `TEMP_UNDO_ENABLED` initialization parameter is set for the rest of the session. Therefore, if temporary undo is enabled for a session and the session uses temporary objects, then temporary undo cannot be disabled for the session. Similarly, if temporary undo is disabled for a session and the session uses temporary objects, then temporary undo cannot be enabled for the session.

Temporary undo is enabled by default for a physical standby database with the Oracle Active Data Guard option. The `TEMP_UNDO_ENABLED` initialization parameter has no effect on a physical standby database with Active Data Guard option because of the default setting.

 **Note:**

Temporary undo can be enabled only if the compatibility level of the database is 12.0.0 or higher.

 **See Also:**

- ["Creating a Temporary Table"](#)
- ["About the Undo Retention Period"](#)
- [Oracle Database Reference](#) for more information about the `TEMP_UNDO_ENABLED` initialization parameter
- [Oracle Data Guard Concepts and Administration](#)
- [Oracle Database Concepts](#) for more information about temporary undo segments

16.7.2 Enabling and Disabling Temporary Undo

You can enable or disable temporary undo for a session or for the system. To do so, set the `TEMP_UNDO_ENABLED` initialization parameter.

To enable or disable temporary undo:

1. In SQL*Plus, connect to the database.

If you are enabling or disabling temporary undo for a session, then start the session in SQL*Plus.

If you are enabling or disabling temporary undo for the system, then connect as an administrative user with the `ALTER SYSTEM` system privilege in SQL*Plus.

See "[Connecting to the Database with SQL*Plus](#)".

2. Set the `TEMP_UNDO_ENABLED` initialization parameter:

- To enable temporary undo for a session, run the following SQL statement:

```
ALTER SESSION SET TEMP_UNDO_ENABLED = TRUE;
```

- To disable temporary undo for a session, run the following SQL statement:

```
ALTER SESSION SET TEMP_UNDO_ENABLED = FALSE;
```

- To enable temporary undo for the system, run the following SQL statement:

```
ALTER SYSTEM SET TEMP_UNDO_ENABLED = TRUE;
```

After temporary undo is enabled for the system, a session can disable temporary undo using the `ALTER SESSION` statement.

- To disable temporary undo for the system, run the following SQL statement:

```
ALTER SYSTEM SET TEMP_UNDO_ENABLED = FALSE;
```

After temporary undo is disabled for the system, a session can enable temporary undo using the `ALTER SESSION` statement.

You can also enable temporary undo for the system by setting `TEMP_UNDO_ENABLED` to `TRUE` in a server parameter file or a text initialization parameter file. In this case, all new sessions create temporary undo unless temporary undo is disabled for the system by an `ALTER SYSTEM` statement or for a session by an `ALTER SESSION` statement.

See Also:

- *Oracle Database Reference* for more information about the `TEMP_UNDO_ENABLED` initialization parameter
- *Oracle Data Guard Concepts and Administration* for information about enabling and disabling temporary undo in an Oracle Data Guard environment

16.8 Undo Space Data Dictionary Views

You can query a set of views for information about undo space in the automatic undo management mode.

In addition to views listed here, you can obtain information from the views available for viewing tablespace and data file information. See "[Data Files Data Dictionary Views](#)" for information on getting information about those views.

The following dynamic performance views are useful for obtaining space information about the undo tablespace:

View	Description
V\$UNDOSTAT	Contains statistics for monitoring and tuning undo space. Use this view to help estimate the amount of undo space required for the current workload. The database also uses this information to help tune undo usage in the system. This view is meaningful only in automatic undo management mode.
V\$TEMPUNDOSTAT	Contains statistics for monitoring and tuning temporary undo space. Use this view to help estimate the amount of temporary undo space required in the temporary tablespaces for the current workload. The database also uses this information to help tune temporary undo usage in the system. This view is meaningful only when temporary undo is enabled.
V\$ROLLSTAT	For automatic undo management mode, information reflects behavior of the undo segments in the undo tablespace
V\$TRANSACTION	Contains undo segment information
DBA_UNDO_EXTENTS	Shows the status and size of each extent in the undo tablespace.
DBA_HIST_UNDOSTAT	Contains statistical snapshots of V\$UNDOSTAT information.

The V\$UNDOSTAT view is useful for monitoring the effects of transaction execution on undo space in the current instance. Statistics are available for undo space consumption, transaction concurrency, the tuning of undo retention, and the length and SQL ID of long-running queries in the instance.

Each row in the view contains statistics collected in the instance for a ten-minute interval. The rows are in descending order by the BEGIN_TIME column value. Each row belongs to the time interval marked by (BEGIN_TIME, END_TIME). Each column represents the data collected for the particular statistic in that time interval. The first row of the view contains statistics for the (partial) current time period. The view contains a total of 576 rows, spanning a 4 day cycle.

The following example shows the results of a query on the V\$UNDOSTAT view.

```
SELECT TO_CHAR(BEGIN_TIME, 'MM/DD/YYYY HH24:MI:SS') BEGIN_TIME,
       TO_CHAR(END_TIME, 'MM/DD/YYYY HH24:MI:SS') END_TIME,
       UNDOTSN, UNDOBLKS, TXNCOUNT, MAXCONCURRENCY AS "MAXCON"
  FROM v$UNDOSTAT WHERE rownum <= 144;
```

BEGIN_TIME	END_TIME	UNDOTSN	UNDOBLKS	TXNCOUNT	MAXCON
10/28/2004 14:25:12	10/28/2004 14:32:17	8	74	12071108	3

```
10/28/2004 14:15:12 10/28/2004 14:25:12      8      49  12070698      2
10/28/2004 14:05:12 10/28/2004 14:15:12      8     125  12070220      1
10/28/2004 13:55:12 10/28/2004 14:05:12      8      99  12066511      3
...
10/27/2004 14:45:12 10/27/2004 14:55:12      8      15   11831676      1
10/27/2004 14:35:12 10/27/2004 14:45:12      8     154  11831165      2
```

144 rows selected.

The preceding example shows how undo space is consumed in the system for the previous 24 hours from the time 14:35:12 on 10/27/2004.

Using Oracle Managed Files

Oracle Database can manage the files that comprise the database.

- [About Oracle Managed Files](#)
Oracle Managed Files eases database administration, reduces errors, and reduces wasted disk space.
- [Enabling the Creation and Use of Oracle Managed Files](#)
You set certain initialization parameters to enable and use Oracle Managed Files.
- [Creating Oracle Managed Files](#)
You can use Oracle Managed Files to create data files, temp files, control files, redo log files, and archived log.
- [Operation of Oracle Managed Files](#)
The file names of Oracle Managed Files are accepted in SQL statements wherever a file name is used to identify an existing file.
- [Scenarios for Using Oracle Managed Files](#)
Scenarios illustrate how to use Oracle Managed Files.

17.1 About Oracle Managed Files

Oracle Managed Files eases database administration, reduces errors, and reduces wasted disk space.

- [What Is Oracle Managed Files?](#)
Using Oracle Managed Files simplifies the administration of an Oracle Database. Oracle Managed Files eliminates the need for you, the DBA, to directly manage the operating system files that comprise an Oracle Database.
- [Who Can Use Oracle Managed Files?](#)
Oracle Managed Files is most useful for certain types of databases.
- [What Is a Logical Volume Manager?](#)
A logical volume manager (LVM) is a software package available with most operating systems. Sometimes it is called a logical disk manager (LDM). It allows pieces of multiple physical disks to be combined into a single contiguous address space that appears as one disk to higher layers of software.
- [What Is a File System?](#)
A file system is a data structure built inside a contiguous disk address space. A file manager (FM) is a software package that manipulates file systems, but it is sometimes called the file system.
- [Benefits of Using Oracle Managed Files](#)
Oracle Managed Files provides several benefits.
- [Oracle Managed Files and Existing Functionality](#)
Using Oracle Managed Files does not eliminate any existing functionality.

17.1.1 What Is Oracle Managed Files?

Using Oracle Managed Files simplifies the administration of an Oracle Database. Oracle Managed Files eliminates the need for you, the DBA, to directly manage the operating system files that comprise an Oracle Database.

With Oracle Managed Files, you specify file system directories in which the database automatically creates, names, and manages files at the database object level. For example, you need only specify that you want to create a tablespace; you do not need to specify the name and path of the tablespace's data file with the `DATAFILE` clause. This feature works well with a logical volume manager (LVM).

The database internally uses standard file system interfaces to create and delete files as needed for the following database structures:

- Tablespaces
- Redo log files
- Control files
- Archived logs
- Block change tracking files
- Flashback logs
- RMAN backups

Through initialization parameters, you specify the file system directory to be used for a particular type of file. The database then ensures that a unique file, an Oracle managed file, is created and deleted when no longer needed.

This feature does not affect the creation or naming of administrative files such as trace files, audit files, alert logs, and core files.

See Also:

Oracle Automatic Storage Management Administrator's Guide for information about Oracle Automatic Storage Management (Oracle ASM), the Oracle Database integrated file system and volume manager that extends the power of Oracle Managed Files. With Oracle Managed Files, files are created and managed automatically for you, but with Oracle ASM, you get the additional benefits of features such as striping, software mirroring, and dynamic storage configuration, without the need to purchase a third-party logical volume manager.

17.1.2 Who Can Use Oracle Managed Files?

Oracle Managed Files is most useful for certain types of databases.

Oracle Managed Files are most useful for the following types of databases:

- Databases that are supported by the following:

- A logical volume manager that supports striping/RAID and dynamically extensible logical volumes
- A file system that provides large, extensible files
- Low end or test databases

Because Oracle Managed Files require that you use the operating system file system, you lose control over how files are laid out on the disks, and thus, you lose some I/O tuning ability.

17.1.3 What Is a Logical Volume Manager?

A logical volume manager (LVM) is a software package available with most operating systems. Sometimes it is called a logical disk manager (LDM). It allows pieces of multiple physical disks to be combined into a single contiguous address space that appears as one disk to higher layers of software.

An LVM can make the logical volume have better capacity, performance, reliability, and availability characteristics than any of the underlying physical disks. It uses techniques such as mirroring, striping, concatenation, and RAID 5 to implement these characteristics.

Some LVMs allow the characteristics of a logical volume to be changed after it is created, even while it is in use. The volume may be resized or mirrored, or it may be relocated to different physical disks.

17.1.4 What Is a File System?

A file system is a data structure built inside a contiguous disk address space. A file manager (FM) is a software package that manipulates file systems, but it is sometimes called the file system.

All operating systems have file managers. The primary task of a file manager is to allocate and deallocate disk space into files within a file system.

A file system allows the disk space to be allocated to a large number of files. Each file is made to appear as a contiguous address space to applications such as Oracle Database. The files may not actually be contiguous within the disk space of the file system. Files can be created, read, written, resized, and deleted. Each file has a name associated with it that is used to refer to the file.

A file system is commonly built on top of a logical volume constructed by an LVM. Thus all the files in a particular file system have the same performance, reliability, and availability characteristics inherited from the underlying logical volume. A file system is a single pool of storage that is shared by all the files in the file system. If a file system is out of space, then none of the files in that file system can grow. Space available in one file system does not affect space in another file system. However some LVM/FM combinations allow space to be added or removed from a file system.

An operating system can support multiple file systems. Multiple file systems are constructed to give different storage characteristics to different files as well as to divide the available disk space into pools that do not affect each other.

17.1.5 Benefits of Using Oracle Managed Files

Oracle Managed Files provides several benefits.

Consider the following benefits of using Oracle Managed Files:

- They make the administration of the database easier.

There is no need to invent file names and define specific storage requirements. A consistent set of rules is used to name all relevant files. The file system defines the characteristics of the storage and the pool where it is allocated.
- They reduce corruption caused by administrators specifying the wrong file.

Each Oracle managed file and file name is unique. Using the same file in two different databases is a common mistake that can cause very large down times and loss of committed transactions. Using two different names that refer to the same file is another mistake that causes major corruptions.
- They reduce wasted disk space consumed by obsolete files.

Oracle Database automatically removes old Oracle Managed Files when they are no longer needed. Much disk space is wasted in large systems simply because no one is sure if a particular file is still required. This also simplifies the administrative task of removing files that are no longer required on disk and prevents the mistake of deleting the wrong file.
- They simplify creation of test and development databases.

You can minimize the time spent making decisions regarding file structure and naming, and you have fewer file management tasks. You can focus better on meeting the actual requirements of your test or development database.
- Oracle Managed Files make development of portable third-party tools easier.

Oracle Managed Files eliminate the need to put operating system specific file names in SQL scripts.

17.1.6 Oracle Managed Files and Existing Functionality

Using Oracle Managed Files does not eliminate any existing functionality.

Existing databases are able to operate as they always have. New files can be created as managed files while old ones are administered in the old way. Thus, a database can have a mixture of Oracle managed and unmanaged files.

17.2 Enabling the Creation and Use of Oracle Managed Files

You set certain initialization parameters to enable and use Oracle Managed Files.

- [Initialization Parameters That Enable Oracle Managed Files](#)

The following table lists the initialization parameters that enable the use of Oracle Managed Files.
- [Setting the DB_CREATE_FILE_DEST Initialization Parameter](#)

The DB_CREATE_FILE_DEST initialization parameter specifies the location of important database files.
- [Setting the DB_RECOVERY_FILE_DEST Parameter](#)

Include the DB_RECOVERY_FILE_DEST and DB_RECOVERY_FILE_DEST_SIZE parameters in your initialization parameter file to identify the default location for the Fast Recovery Area.

- [Setting the DB_CREATE_ONLINE_LOG_DEST_n Initialization Parameters](#)
The DB_CREATE_ONLINE_LOG_DEST_n initialization parameters specify the locations of the redo log files and the control files.

17.2.1 Initialization Parameters That Enable Oracle Managed Files

The following table lists the initialization parameters that enable the use of Oracle Managed Files.

Initialization Parameter	Description
DB_CREATE_FILE_DEST	Defines the location of the default file system directory or Oracle ASM disk group where the database creates data files or temp files when no file specification is given in the create operation. Also used as the default location for redo log and control files if DB_CREATE_ONLINE_LOG_DEST_n are not specified.
DB_CREATE_ONLINE_LOG_DEST_n	Defines the location of the default file system directory or Oracle ASM disk group for redo log files and control file creation when no file specification is given in the create operation. By changing n, you can use this initialization parameter multiple times, where n specifies a multiplexed copy of the redo log or control file. You can specify up to five multiplexed copies.
DB_RECOVERY_FILE_DEST	Defines the location of the Fast Recovery Area, which is the default file system directory or Oracle ASM disk group where the database creates RMAN backups when no format option is used, archived logs when no other local destination is configured, and flashback logs. Also used as the default location for redo log and control files or multiplexed copies of redo log and control files if DB_CREATE_ONLINE_LOG_DEST_n are not specified. When this parameter is specified, the DB_RECOVERY_FILE_DEST_SIZE initialization parameter must also be specified.

The file system directories specified by these parameters must already exist; the database does not create them. The directory must also have permissions to allow the database to create the files in it.

The default location is used whenever a location is not explicitly specified for the operation creating the file. The database creates the file name, and a file thus created is an Oracle managed file.

Both of these initialization parameters are dynamic, and can be set using the ALTER SYSTEM or ALTER SESSION statement.

See Also:

- [Oracle Database Reference](#) for additional information about initialization parameters
- ["How Oracle Managed Files Are Named"](#)

17.2.2 Setting the DB_CREATE_FILE_DEST Initialization Parameter

The DB_CREATE_FILE_DEST initialization parameter specifies the location of important database files.

Include the DB_CREATE_FILE_DEST initialization parameter in your initialization parameter file to identify the default location for the database server to create:

- Data files
- Temp files
- Redo log files
- Control files
- Block change tracking files

You specify the name of a file system directory that becomes the default location for the creation of the operating system files for these entities. The following example sets /u01/app/oracle/oradata as the default directory to use when creating Oracle Managed Files:

```
DB_CREATE_FILE_DEST = '/u01/app/oracle/oradata'
```

17.2.3 Setting the DB_RECOVERY_FILE_DEST Parameter

Include the DB_RECOVERY_FILE_DEST and DB_RECOVERY_FILE_DEST_SIZE parameters in your initialization parameter file to identify the default location for the Fast Recovery Area.

The Fast Recovery Area contains:

- Redo log files or multiplexed copies of redo log files
- Control files or multiplexed copies of control files
- RMAN backups (data file copies, control file copies, backup pieces, control file autobackups)
- Archived logs
- Flashback logs

You specify the name of file system directory that becomes the default location for creation of the operating system files for these entities. For example:

```
DB_RECOVERY_FILE_DEST = '/u01/app/oracle/fast_recovery_area'  
DB_RECOVERY_FILE_DEST_SIZE = 20G
```

17.2.4 Setting the DB_CREATE_ONLINE_LOG_DEST_n Initialization Parameters

The DB_CREATE_ONLINE_LOG_DEST_n initialization parameters specify the locations of the redo log files and the control files.

Include the DB_CREATE_ONLINE_LOG_DEST_n initialization parameters in your initialization parameter file to identify the default locations for the database server to create:

- Redo log files
- Control files

You specify the name of a file system directory or Oracle ASM disk group that becomes the default location for the creation of the files for these entities. You can specify up to five multiplexed locations.

For the creation of redo log files and control files only, this parameter overrides any default location specified in the DB_CREATE_FILE_DEST and DB_RECOVERY_FILE_DEST initialization parameters. If you do not specify a DB_CREATE_FILE_DEST parameter, but you do specify the DB_CREATE_ONLINE_LOG_DEST_n parameter, then only redo log files and control files can be created as Oracle Managed Files.

It is recommended that you specify at least two parameters. For example:

```
DB_CREATE_ONLINE_LOG_DEST_1 = '/u02/oradata'  
DB_CREATE_ONLINE_LOG_DEST_2 = '/u03/oradata'
```

This allows multiplexing, which provides greater fault-tolerance for the redo log and control file if one of the destinations fails.

17.3 Creating Oracle Managed Files

You can use Oracle Managed Files to create data files, temp files, control files, redo log files, and archived log.

- [When Oracle Database Creates Oracle Managed Files](#)
Oracle Database creates Oracle Managed Files when certain conditions are met.
- [How Oracle Managed Files Are Named](#)
The file names of Oracle Managed Files comply with the Optimal Flexible Architecture (OFA) standard for file naming.
- [Creating Oracle Managed Files at Database Creation](#)
The CREATE DATABASE statement can perform actions related to Oracle Managed Files.
- [Creating Data Files for Tablespaces Using Oracle Managed Files](#)
Oracle Database can create data files for tablespaces using Oracle Managed Files when certain conditions are met.
- [Creating Temp Files for Temporary Tablespaces Using Oracle Managed Files](#)
Oracle Database can create temp files for temporary tablespaces using Oracle Managed Files when certain conditions are met.
- [Creating Control Files Using Oracle Managed Files](#)
Oracle Database can create control files using Oracle Managed Files when certain conditions are met.
- [Creating Redo Log Files Using Oracle Managed Files](#)
Redo log files are created at database creation time. They can also be created when you issue either of the following statements: ALTER DATABASE ADD LOGFILE and ALTER DATABASE OPEN RESETLOGS.
- [Creating Archived Logs Using Oracle Managed Files](#)
Archived logs are created by a background process or by a SQL statement.

17.3.1 When Oracle Database Creates Oracle Managed Files

Oracle Database creates Oracle Managed Files when certain conditions are met.

If you have met any of the following conditions, then Oracle Database creates Oracle Managed Files for you, as appropriate, when no file specification is given in the create operation:

- You have included any of the DB_CREATE_FILE_DEST, DB_RECOVERY_FILE_DEST, or DB_CREATE_ONLINE_LOG_DEST_n initialization parameters in your initialization parameter file.
- You have issued the ALTER SYSTEM statement to dynamically set any of DB_RECOVERY_FILE_DEST, DB_CREATE_FILE_DEST, or DB_CREATE_ONLINE_LOG_DEST_n initialization parameters
- You have issued the ALTER SESSION statement to dynamically set any of the DB_CREATE_FILE_DEST, DB_RECOVERY_FILE_DEST, or DB_CREATE_ONLINE_LOG_DEST_n initialization parameters.

If a statement that creates an Oracle managed file finds an error or does not complete due to some failure, then any Oracle Managed Files created by the statement are automatically deleted as part of the recovery of the error or failure. However, because of the large number of potential errors that can occur with file systems and storage subsystems, there can be situations where you must manually remove the files using operating system commands.

17.3.2 How Oracle Managed Files Are Named

The file names of Oracle Managed Files comply with the Optimal Flexible Architecture (OFA) standard for file naming.

 **Note:**

The naming scheme described in this section applies only to files created in operating system file systems. The naming scheme for files created in Oracle Automatic Storage Management (Oracle ASM) disk groups is described in *Oracle Automatic Storage Management Administrator's Guide*.

The assigned names are intended to meet the following requirements:

- Database files are easily distinguishable from all other files.
- Files of one database type are easily distinguishable from other database types.
- Files are clearly associated with important attributes specific to the file type. For example, a data file name may include the tablespace name to allow for easy association of data file to tablespace, or an archived log name may include the thread, sequence, and creation date.

No two Oracle Managed Files are given the same name. The name that is used for creation of an Oracle managed file is constructed from three sources:

- The default creation location

- A file name template that is chosen based on the type of the file. The template also depends on the operating system platform and whether or not Oracle Automatic Storage Management is used.
- A unique string created by Oracle Database or the operating system. This ensures that file creation does not damage an existing file and that the file cannot be mistaken for some other file.

As a specific example, file names for Oracle Managed Files have the following format on a Solaris file system:

`destination_prefix/o1_mf_%t_%u_.dbf`

where:

- `destination_prefix` is `destination_location/db_unique_name/datafile`
where:
 - `destination_location` is the location specified in `DB_CREATE_FILE_DEST`
 - `db_unique_name` is the globally unique name (`DB_UNIQUE_NAME` initialization parameter) of the target database. If there is no `DB_UNIQUE_NAME` parameter, then the `DB_NAME` initialization parameter value is used.
- `%t` is the tablespace name.
- `%u` is an eight-character string that guarantees uniqueness

For example, assume the following parameter settings:

```
DB_CREATE_FILE_DEST      = /u01/app/oracle/oradata  
DB_UNIQUE_NAME          = PAYROLL
```

Then an example data file name would be:

`/u01/app/oracle/oradata/PAYROLL/datafile/o1_mf_tbs1_2ixh90q_.dbf`

Names for other file types are similar. Names on other platforms are also similar, subject to the constraints of the naming rules of the platform.

The examples on the following pages use Oracle managed file names as they might appear with a Solaris file system as an OMF destination.

 **Note:**

The database identifies an Oracle managed file based on its name. If you rename the file, the database is no longer able to recognize it as an Oracle managed file and will not manage the file accordingly.

17.3.3 Creating Oracle Managed Files at Database Creation

The `CREATE DATABASE` statement can perform actions related to Oracle Managed Files.

 **Note:**

The rules and defaults in this section also apply to creating a database with Database Configuration Assistant (DBCA). With DBCA, you use a graphical interface to enable Oracle Managed Files and to specify file locations that correspond to the initialization parameters described in this section.

- [Specifying Control Files at Database Creation](#)

At database creation, the control file is created in the files specified by the CONTROL_FILES initialization parameter.

- [Specifying Redo Log Files at Database Creation](#)

The LOGFILE clause is not required in the CREATE DATABASE statement, and omitting it provides a simple means of creating Oracle managed redo log files.

- [Specifying the SYSTEM and SYSAUX Tablespace Data Files at Database Creation](#)

The DATAFILE or SYSAUX DATAFILE clause is not required in the CREATE DATABASE statement, and omitting it provides a simple means of creating Oracle managed data files for the SYSTEM and SYSAUX tablespaces.

- [Specifying the Undo Tablespace Data File at Database Creation](#)

The DATAFILE subclause of the UNDO TABLESPACE clause is optional and a file name is not required in the file specification.

- [Specifying the Default Temporary Tablespace Temp File at Database Creation](#)

The TEMPFILE subclause is optional for the DEFAULT TEMPORARY TABLESPACE clause and a file name is not required in the file specification.

- [CREATE DATABASE Statement Using Oracle Managed Files: Examples](#)

Examples illustrate creating a database with the CREATE DATABASE statement when using the Oracle Managed Files feature.

 **See Also:**

Oracle Database SQL Language Reference for a description of the CREATE DATABASE statement

17.3.3.1 Specifying Control Files at Database Creation

At database creation, the control file is created in the files specified by the CONTROL_FILES initialization parameter.

If the CONTROL_FILES parameter is not set and at least one of the initialization parameters required for the creation of Oracle Managed Files is set, then an Oracle managed control file is created in the default control file destinations. In order of precedence, the default destination is defined as follows:

- One or more control files as specified in the DB_CREATE_ONLINE_LOG_DEST_n initialization parameter. The file in the first directory is the primary control file. When DB_CREATE_ONLINE_LOG_DEST_n is specified, the database does not create a

control file in DB_CREATE_FILE_DEST or in DB_RECOVERY_FILE_DEST (the Fast Recovery Area).

- If no value is specified for DB_CREATE_ONLINE_LOG_DEST_n, but values are set for both the DB_CREATE_FILE_DEST and DB_RECOVERY_FILE_DEST, then the database creates one control file in each location. The location specified in DB_CREATE_FILE_DEST is the primary control file.
- If a value is specified only for DB_CREATE_FILE_DEST, then the database creates one control file in that location.
- If a value is specified only for DB_RECOVERY_FILE_DEST, then the database creates one control file in that location.

If the CONTROL_FILES parameter is not set and none of these initialization parameters are set, then the Oracle Database default action is operating system dependent. At least one copy of a control file is created in an operating system dependent default location. Any copies of control files created in this fashion are not Oracle Managed Files, and you must add a CONTROL_FILES initialization parameter to any initialization parameter file.

If the database creates an Oracle managed control file, and if there is a server parameter file, then the database creates a CONTROL_FILES initialization parameter entry in the server parameter file. If there is no server parameter file, then you must manually include a CONTROL_FILES initialization parameter entry in the text initialization parameter file.

 **See Also:**

[Managing Control Files](#)

17.3.3.2 Specifying Redo Log Files at Database Creation

The LOGFILE clause is not required in the CREATE DATABASE statement, and omitting it provides a simple means of creating Oracle managed redo log files.

If the LOGFILE clause is omitted, then redo log files are created in the default redo log file destinations. In order of precedence, the default destination is defined as follows:

- If either the DB_CREATE_ONLINE_LOG_DEST_n is set, then the database creates a log file member in each directory specified, up to the value of the MAXLOGMEMBERS initialization parameter.
- If the DB_CREATE_ONLINE_LOG_DEST_n parameter is not set, but both the DB_CREATE_FILE_DEST and DB_RECOVERY_FILE_DEST initialization parameters are set, then the database creates one Oracle managed log file member in each of those locations. The log file in the DB_CREATE_FILE_DEST destination is the first member.
- If only the DB_CREATE_FILE_DEST initialization parameter is specified, then the database creates a log file member in that location.
- If only the DB_RECOVERY_FILE_DEST initialization parameter is specified, then the database creates a log file member in that location.

The default size of an Oracle managed redo log file is 100 MB.

Optionally, you can create Oracle managed redo log files, and override default attributes, by including the `LOGFILE` clause but omitting a file name. Redo log files are created the same way, except for the following: If no file name is provided in the `LOGFILE` clause of `CREATE DATABASE`, and none of the initialization parameters required for creating Oracle Managed Files are provided, then the `CREATE DATABASE` statement fails.

 **See Also:**

"[Managing the Redo Log](#)"

17.3.3.3 Specifying the SYSTEM and SYSAUX Tablespace Data Files at Database Creation

The `DATAFILE` or `SYSAUX DATAFILE` clause is not required in the `CREATE DATABASE` statement, and omitting it provides a simple means of creating Oracle managed data files for the `SYSTEM` and `SYSAUX` tablespaces.

If the `DATAFILE` clause is omitted, then one of the following actions occurs:

- If `DB_CREATE_FILE_DEST` is set, then one Oracle managed data file for the `SYSTEM` tablespace and another for the `SYSAUX` tablespace are created in the `DB_CREATE_FILE_DEST` directory.
- If `DB_CREATE_FILE_DEST` is not set, then the database creates one `SYSTEM` and one `SYSAUX` tablespace data file whose names and sizes are operating system dependent. Any `SYSTEM` or `SYSAUX` tablespace data file created in this manner is not an Oracle managed file.

By default, Oracle managed data files, including those for the `SYSTEM` and `SYSAUX` tablespaces, are 100MB and autoextensible. When autoextension is required, the database extends the data file by its existing size or 100 MB, whichever is smaller. You can also explicitly specify the autoextensible unit using the `NEXT` parameter of the `STORAGE` clause when you specify the data file (in a `CREATE` or `ALTER TABLESPACE` operation).

Optionally, you can create an Oracle managed data file for the `SYSTEM` or `SYSAUX` tablespace and override default attributes. This is done by including the `DATAFILE` clause, omitting a file name, but specifying overriding attributes. When a file name is not supplied and the `DB_CREATE_FILE_DEST` parameter is set, an Oracle managed data file for the `SYSTEM` or `SYSAUX` tablespace is created in the `DB_CREATE_FILE_DEST` directory with the specified attributes being overridden. However, if a file name is not supplied and the `DB_CREATE_FILE_DEST` parameter is not set, then the `CREATE DATABASE` statement fails.

When overriding the default attributes of an Oracle managed file, if a `SIZE` value is specified but no `AUTOEXTEND` clause is specified, then the data file is *not* autoextensible.

17.3.3.4 Specifying the Undo Tablespace Data File at Database Creation

The `DATAFILE` subclause of the `UNDO TABLESPACE` clause is optional and a file name is not required in the file specification.

If a file name is not supplied and the `DB_CREATE_FILE_DEST` parameter is set, then an Oracle managed data file is created in the `DB_CREATE_FILE_DEST` directory. If `DB_CREATE_FILE_DEST` is not set, then the statement fails with a syntax error.

The `UNDO TABLESPACE` clause itself is optional in the `CREATE DATABASE` statement. If it is not supplied, and automatic undo management mode is enabled (the default), then a default undo tablespace named `SYS_UNDOTS` is created and a 20 MB data file that is autoextensible is allocated as follows:

- If `DB_CREATE_FILE_DEST` is set, then an Oracle managed data file is created in the indicated directory.
- If `DB_CREATE_FILE_DEST` is not set, then the data file location is operating system specific.

 **See Also:**

" [Managing Undo](#) "

17.3.3.5 Specifying the Default Temporary Tablespace Temp File at Database Creation

The `TEMPFILE` subclause is optional for the `DEFAULT TEMPORARY TABLESPACE` clause and a file name is not required in the file specification.

If a file name is not supplied and the `DB_CREATE_FILE_DEST` parameter set, then an Oracle managed temp file is created in the `DB_CREATE_FILE_DEST` directory. If `DB_CREATE_FILE_DEST` is not set, then the `CREATE DATABASE` statement fails with a syntax error.

The `DEFAULT TEMPORARY TABLESPACE` clause itself is optional. If it is not specified, then no default temporary tablespace is created.

The default size for an Oracle managed temp file is 100 MB and the file is autoextensible with an unlimited maximum size.

17.3.3.6 CREATE DATABASE Statement Using Oracle Managed Files: Examples

Examples illustrate creating a database with the `CREATE DATABASE` statement when using the Oracle Managed Files feature.

CREATE DATABASE: Example 1

This example creates a database with the following Oracle Managed Files:

- A SYSTEM tablespace data file in directory /u01/app/oracle/oradata that is autoextensible up to an unlimited size.
- A SYSAUX tablespace data file in directory /u01/app/oracle/oradata that is autoextensible up to an unlimited size. The tablespace is locally managed with automatic segment-space management.
- Two online log groups with two members of 100 MB each, one each in /u02/oradata and /u03/oradata.
- If automatic undo management mode is enabled (the default), then an undo tablespace data file in directory /u01/app/oracle/oradata that is 20 MB and autoextensible up to an unlimited size. An undo tablespace named SYS_UNDOTS is created.
- If no CONTROL_FILES initialization parameter is specified, then two control files, one each in /u02/oradata and /u03/oradata. The control file in /u02/oradata is the primary control file.

The following parameter settings relating to Oracle Managed Files, are included in the initialization parameter file:

```
DB_CREATE_FILE_DEST = '/u01/app/oracle/oradata'  
DB_CREATE_ONLINE_LOG_DEST_1 = '/u02/oradata'  
DB_CREATE_ONLINE_LOG_DEST_2 = '/u03/oradata'
```

The following statement is issued at the SQL prompt:

```
CREATE DATABASE sample;
```

To create the database with a locally managed SYSTEM tablespace, add the EXTENT MANAGEMENT LOCAL clause:

```
CREATE DATABASE sample EXTENT MANAGEMENT LOCAL;
```

Without this clause, the SYSTEM tablespace is dictionary managed. Oracle recommends that you create a locally managed SYSTEM tablespace.

CREATE DATABASE: Example 2

This example creates a database with the following Oracle Managed Files:

- A SYSTEM tablespace data file in directory /u01/app/oracle/oradata that is autoextensible up to an unlimited size.
- A SYSAUX tablespace data file in directory /u01/app/oracle/oradata that is autoextensible up to an unlimited size. The tablespace is locally managed with automatic segment-space management.
- Two redo log files of 100 MB each in directory /u01/app/oracle/oradata. They are not multiplexed.
- An undo tablespace data file in directory /u01/app/oracle/oradata that is 20 MB and autoextensible up to an unlimited size. An undo tablespace named SYS_UNDOTS is created.
- A control file in /u01/app/oracle/oradata.

In this example, it is assumed that:

- No DB_CREATE_ONLINE_LOG_DEST_n initialization parameters are specified in the initialization parameter file.

- No CONTROL_FILES initialization parameter was specified in the initialization parameter file.
- Automatic undo management mode is enabled.

The following statements are issued at the SQL prompt:

```
ALTER SYSTEM SET DB_CREATE_FILE_DEST = '/u01/app/oracle/oradata';
CREATE DATABASE sample2 EXTENT MANAGEMENT LOCAL;
```

This database configuration is not recommended for a production database. The example illustrates how a very low-end database or simple test database can easily be created. To better protect this database from failures, at least one more control file should be created and the redo log should be multiplexed.

CREATE DATABASE: Example 3

In this example, the file size for the Oracle Managed Files for the default temporary tablespace and undo tablespace are specified. A database with the following Oracle Managed Files is created:

- A 400 MB SYSTEM tablespace data file in directory /u01/app/oracle/oradata. Because SIZE is specified, the file is not autoextensible.
- A 200 MB SYSAUX tablespace data file in directory /u01/app/oracle/oradata. Because SIZE is specified, the file is not autoextensible. The tablespace is locally managed with automatic segment-space management.
- Two redo log groups with two members of 100 MB each, one each in directories /u02/oradata and /u03/oradata.
- For the default temporary tablespace dflt_ts, a 10 MB temp file in directory /u01/app/oracle/oradata. Because SIZE is specified, the file is not autoextensible.
- For the undo tablespace undo_ts, a 100 MB data file in directory /u01/app/oracle/oradata. Because SIZE is specified, the file is not autoextensible.
- If no CONTROL_FILES initialization parameter was specified, then two control files, one each in directories /u02/oradata and /u03/oradata. The control file in /u02/oradata is the primary control file.

The following parameter settings are included in the initialization parameter file:

```
DB_CREATE_FILE_DEST = '/u01/app/oracle/oradata'
DB_CREATE_ONLINE_LOG_DEST_1 = '/u02/oradata'
DB_CREATE_ONLINE_LOG_DEST_2 = '/u03/oradata'
```

The following statement is issued at the SQL prompt:

```
CREATE DATABASE sample3
EXTENT MANAGEMENT LOCAL
DATAFILE SIZE 400M
SYSAUX DATAFILE SIZE 200M
DEFAULT TEMPORARY TABLESPACE dflt_ts TEMPFILE SIZE 10M
UNDO TABLESPACE undo_ts DATAFILE SIZE 100M;
```

 **See Also:**

["Creating a Locally Managed SYSTEM Tablespace"](#)

17.3.4 Creating Data Files for Tablespaces Using Oracle Managed Files

Oracle Database can create data files for tablespaces using Oracle Managed Files when certain conditions are met.

- [About Creating Data Files for Tablespaces Using Oracle Managed Files](#)
When certain conditions are met, the following SQL statements can create data files for tablespaces using Oracle Managed Files: CREATE TABLESPACE, CREATE UNDO TABLESPACE, and ALTER TABLESPACE ... ADD DATAFILE.
- [CREATE TABLESPACE: Examples](#)
Examples illustrate creating tablespaces with Oracle Managed Files.
- [CREATE UNDO TABLESPACE: Example](#)
An example illustrates creating an undo tablespace.
- [ALTER TABLESPACE: Example](#)
An example illustrates adding an Oracle managed autoextensible data file to a tablespace.

17.3.4.1 About Creating Data Files for Tablespaces Using Oracle Managed Files

When certain conditions are met, the following SQL statements can create data files for tablespaces using Oracle Managed Files: CREATE TABLESPACE, CREATE UNDO TABLESPACE, and ALTER TABLESPACE ... ADD DATAFILE.

The following statements can create data files:

- CREATE TABLESPACE
- CREATE UNDO TABLESPACE
- ALTER TABLESPACE ... ADD DATAFILE

When creating a tablespace, either a permanent tablespace or an undo tablespace, the DATAFILE clause is optional. When you include the DATAFILE clause, the file name is optional. If the DATAFILE clause or file name is not provided, then the following rules apply:

- If the DB_CREATE_FILE_DEST initialization parameter is specified, then an Oracle managed data file is created in the location specified by the parameter.
- If the DB_CREATE_FILE_DEST initialization parameter is not specified, then the statement creating the data file fails.

When you add a data file to a tablespace with the ALTER TABLESPACE...ADD DATAFILE statement the file name is optional. If the file name is not specified, then the same rules apply as discussed in the previous paragraph.

By default, an Oracle managed data file for a permanent tablespace is 100 MB and is autoextensible with an unlimited maximum size. However, if in your DATAFILE clause you override these defaults by specifying a SIZE value (and no AUTOEXTEND clause), then the data file is *not* autoextensible.

 **See Also:**

- "[Specifying the SYSTEM and SYSAUX Tablespace Data Files at Database Creation](#)"
- "[Specifying the Undo Tablespace Data File at Database Creation](#)"
- "[Managing Tablespaces](#)"

17.3.4.2 CREATE TABLESPACE: Examples

Examples illustrate creating tablespaces with Oracle Managed Files.

 **See Also:**

Oracle Database SQL Language Reference for a description of the CREATE TABLESPACE statement

CREATE TABLESPACE: Example 1

The following example sets the default location for data file creations to /u01/oradata and then creates a tablespace tbs_1 with a data file in that location. The data file is 100 MB and is autoextensible with an unlimited maximum size.

```
SQL> ALTER SYSTEM SET DB_CREATE_FILE_DEST = '/u01/oradata';
SQL> CREATE TABLESPACE tbs_1;
```

CREATE TABLESPACE: Example 2

This example creates a tablespace named tbs_2 with a data file in the directory /u01/oradata. The data file initial size is 400 MB, and because the SIZE clause is specified, the data file is not autoextensible.

The following parameter setting is included in the initialization parameter file:

```
DB_CREATE_FILE_DEST = '/u01/oradata'
```

The following statement is issued at the SQL prompt:

```
SQL> CREATE TABLESPACE tbs_2 DATAFILE SIZE 400M;
```

CREATE TABLESPACE: Example 3

This example creates a tablespace named tbs_3 with an autoextensible data file in the directory /u01/oradata with a maximum size of 800 MB and an initial size of 100 MB:

The following parameter setting is included in the initialization parameter file:

```
DB_CREATE_FILE_DEST = '/u01/oradata'
```

The following statement is issued at the SQL prompt:

```
SQL> CREATE TABLESPACE tbs_3 DATAFILE AUTOEXTEND ON MAXSIZE 800M;
```

CREATE TABLESPACE: Example 4

The following example sets the default location for data file creations to /u01/oradata and then creates a tablespace named tbs_4 in that directory with two data files. Both data files have an initial size of 200 MB, and because a SIZE value is specified, they are not autoextensible

```
SQL> ALTER SYSTEM SET DB_CREATE_FILE_DEST = '/u01/oradata';
SQL> CREATE TABLESPACE tbs_4 DATAFILE SIZE 200M, SIZE 200M;
```

17.3.4.3 CREATE UNDO TABLESPACE: Example

An example illustrates creating an undo tablespace.

The following example creates an undo tablespace named undotbs_1 with a data file in the directory /u01/oradata. The data file for the undo tablespace is 100 MB and is autoextensible with an unlimited maximum size.

1. Set the following initialization parameter:

```
DB_CREATE_FILE_DEST = '/u01/oradata'
```

2. Issue the following SQL statement:

```
SQL> CREATE UNDO TABLESPACE undotbs_1;
```

See Also:

Oracle Database SQL Language Reference for a description of the CREATE UNDO TABLESPACE statement

17.3.4.4 ALTER TABLESPACE: Example

An example illustrates adding an Oracle managed autoextensible data file to a tablespace.

This example adds an Oracle managed autoextensible data file to the tbs_1 tablespace. The data file has an initial size of 100 MB and a maximum size of 800 MB.

1. Set the following initialization parameter:

```
DB_CREATE_FILE_DEST = '/u01/oradata'
```

2. Issue the following SQL statement:

```
SQL> ALTER TABLESPACE tbs_1 ADD DATAFILE AUTOEXTEND ON MAXSIZE 800M;
```

 **See Also:**

Oracle Database SQL Language Reference for a description of the ALTER TABLESPACE statement

17.3.5 Creating Temp Files for Temporary Tablespaces Using Oracle Managed Files

Oracle Database can create temp files for temporary tablespaces using Oracle Managed Files when certain conditions are met.

- [About Creating Temp Files for Temporary Tablespaces Using Oracle Managed Files](#)

When certain conditions are met, the following SQL statements can create temp files for tablespaces using Oracle Managed Files: CREATE TEMPORARY TABLESPACE and ALTER TABLESPACE ... ADD TEMPFILE.

- [CREATE TEMPORARY TABLESPACE: Example](#)

An example illustrates creating a temporary tablespace.

- [ALTER TABLESPACE... ADD TEMPFILE: Example](#)

An example illustrates adding a temp file to a temporary tablespace.

17.3.5.1 About Creating Temp Files for Temporary Tablespaces Using Oracle Managed Files

When certain conditions are met, the following SQL statements can create temp files for tablespaces using Oracle Managed Files: CREATE TEMPORARY TABLESPACE and ALTER TABLESPACE ... ADD TEMPFILE.

The following statements that create temp files are relevant to the discussion in this section:

- CREATE TEMPORARY TABLESPACE
- ALTER TABLESPACE ... ADD TEMPFILE

When creating a temporary tablespace the TEMPFILE clause is optional. If you include the TEMPFILE clause, then the file name is optional. If the TEMPFILE clause or file name is not provided, then the following rules apply:

- If the DB_CREATE_FILE_DEST initialization parameter is specified, then an Oracle managed temp file is created in the location specified by the parameter.
- If the DB_CREATE_FILE_DEST initialization parameter is not specified, then the statement creating the temp file fails.

When you add a temp file to a tablespace with the ALTER TABLESPACE...ADD TEMPFILE statement the file name is optional. If the file name is not specified, then the same rules apply as discussed in the previous paragraph.

When overriding the default attributes of an Oracle managed file, if a SIZE value is specified but no AUTOEXTEND clause is specified, then the data file is *not* autoextensible.

 **See Also:**

["Specifying the Default Temporary Tablespace Temp File at Database Creation"](#)

17.3.5.2 CREATE TEMPORARY TABLESPACE: Example

An example illustrates creating a temporary tablespace.

The following example sets the default location for data file creations to /u01/oradata and then creates a tablespace named temptbs_1 with a temp file in that location. The temp file is 100 MB and is autoextensible with an unlimited maximum size.

```
SQL> ALTER SYSTEM SET DB_CREATE_FILE_DEST = '/u01/oradata';
SQL> CREATE TEMPORARY TABLESPACE temptbs_1;
```

 **See Also:**

[Oracle Database SQL Language Reference](#) for a description of the CREATE TABLESPACE statement

17.3.5.3 ALTER TABLESPACE... ADD TEMPFILE: Example

An example illustrates adding a temp file to a temporary tablespace.

The following example sets the default location for data file creations to /u03/oradata and then adds a temp file in the default location to a tablespace named temptbs_1. The temp file initial size is 100 MB. It is autoextensible with an unlimited maximum size.

```
SQL> ALTER SYSTEM SET DB_CREATE_FILE_DEST = '/u03/oradata';
SQL> ALTER TABLESPACE TBS_1 ADD TEMPFILE;
```

 **See Also:**

[Oracle Database SQL Language Reference](#) for a description of the ALTER TABLESPACE statement

17.3.6 Creating Control Files Using Oracle Managed Files

Oracle Database can create control files using Oracle Managed Files when certain conditions are met.

- [About Creating Control Files Using Oracle Managed Files](#)

When certain conditions are met, the CREATE CONTROLFILE SQL statements can create control files using Oracle Managed Files.

- [CREATE CONTROLFILE Using NORESETLOGS Keyword: Example](#)
An example illustrates creating a control file using the CREATE CONTROLFILE statement with the NORESETLOGS keyword.
- [CREATE CONTROLFILE Using RESETLOGS Keyword: Example](#)
An example illustrates creating a control file using the CREATE CONTROLFILE statement with the RESETLOGS keyword.

17.3.6.1 About Creating Control Files Using Oracle Managed Files

When certain conditions are met, the CREATE CONTROLFILE SQL statements can create control files using Oracle Managed Files.

When you issue the CREATE CONTROLFILE statement, a control file is created (or reused, if REUSE is specified) in the files specified by the CONTROL_FILES initialization parameter. If the CONTROL_FILES parameter is not set, then the control file is created in the default control file destinations. The default destination is determined according to the precedence documented in "[Specifying Control Files at Database Creation](#)".

If Oracle Database creates an Oracle managed control file, and there is a server parameter file, then the database creates a CONTROL_FILES initialization parameter for the server parameter file. If there is no server parameter file, then you must create a CONTROL_FILES initialization parameter manually and include it in the initialization parameter file.

If the data files in the database are Oracle Managed Files, then the database-generated file names for the files must be supplied in the DATAFILE clause of the statement.

If the redo log files are Oracle Managed Files, then the NORESETLOGS or RESETLOGS keyword determines what can be supplied in the LOGFILE clause:

- If the NORESETLOGS keyword is used, then the database-generated file names for the Oracle managed redo log files must be supplied in the LOGFILE clause.
- If the RESETLOGS keyword is used, then the redo log file names can be supplied as with the CREATE DATABASE statement. See "[Specifying Redo Log Files at Database Creation](#)".

The sections that follow contain examples of using the CREATE CONTROLFILE statement with Oracle Managed Files.

See Also:

- [Oracle Database SQL Language Reference](#) for a description of the CREATE CONTROLFILE statement
- ["Specifying Control Files at Database Creation"](#)

17.3.6.2 CREATE CONTROLFILE Using NORESETLOGS Keyword: Example

An example illustrates creating a control file using the `CREATE CONTROLFILE` statement with the `NORESETLOGS` keyword.

The following `CREATE CONTROLFILE` statement is generated by an `ALTER DATABASE BACKUP CONTROLFILE TO TRACE` statement for a database with Oracle managed data files and redo log files:

```
CREATE CONTROLFILE
  DATABASE sample
  LOGFILE
    GROUP 1 ('/u01/oradata/SAMPLE/onlinelog/o1_mf_1_o220rtt9_.log',
              '/u02/oradata/SAMPLE/onlinelog/o1_mf_1_v2o0b2i3_.log')
              SIZE 100M,
    GROUP 2 ('/u01/oradata/SAMPLE/onlinelog/o1_mf_2_p22056iw_.log',
              '/u02/oradata/SAMPLE/onlinelog/o1_mf_2_p02rcyg3_.log')
              SIZE 100M
  NORESETLOGS
  DATAFILE '/u01/oradata/SAMPLE/datafile/o1_mf_system_xu34ybm2_.dbf'
            SIZE 100M,
            '/u01/oradata/SAMPLE/datafile/o1_mf_sysaux_aawbmz51_.dbf'
            SIZE 100M,
            '/u01/oradata/SAMPLE/datafile/o1_mf_sys_undo_apqbmz51_.dbf'
            SIZE 100M
  MAXLOGFILES 5
  MAXLOGHISTORY 100
  MAXDATAFILES 10
  MAXINSTANCES 2
  ARCHIVELOG;
```

17.3.6.3 CREATE CONTROLFILE Using RESETLOGS Keyword: Example

An example illustrates creating a control file using the `CREATE CONTROLFILE` statement with the `RESETLOGS` keyword.

The following is an example of a `CREATE CONTROLFILE` statement with the `RESETLOGS` option. Some combination of `DB_CREATE_FILE_DEST`, `DB_RECOVERY_FILE_DEST`, and `DB_CREATE_ONLINE_LOG_DEST_n` or must be set.

```
CREATE CONTROLFILE
  DATABASE sample
  RESETLOGS
  DATAFILE '/u01/oradata/SAMPLE/datafile/o1_mf_system_aawbmz51_.dbf',
            '/u01/oradata/SAMPLE/datafile/o1_mf_sysaux_axybzmz51_.dbf',
            '/u01/oradata/SAMPLE/datafile/o1_mf_sys_undo_azzbmz51_.dbf'
            SIZE 100M
  MAXLOGFILES 5
  MAXLOGHISTORY 100
  MAXDATAFILES 10
  MAXINSTANCES 2
  ARCHIVELOG;
```

Later, you must issue the `ALTER DATABASE OPEN RESETLOGS` statement to re-create the redo log files. This is discussed in "[Using the ALTER DATABASE OPEN RESETLOGS Statement](#)". If the previous log files are Oracle Managed Files, then they are not deleted.

17.3.7 Creating Redo Log Files Using Oracle Managed Files

Redo log files are created at database creation time. They can also be created when you issue either of the following statements: `ALTER DATABASE ADD LOGFILE` and `ALTER DATABASE OPEN RESETLOGS`.

- [Using the `ALTER DATABASE ADD LOGFILE` Statement](#)

The `ALTER DATABASE ADD LOGFILE` statement lets you later add a new group to your current redo log.

- [Using the `ALTER DATABASE OPEN RESETLOGS` Statement](#)

If you previously created a control file specifying `RESETLOGS` and either did not specify file names or specified nonexistent file names, then the database creates redo log files for you when you issue the `ALTER DATABASE OPEN RESETLOGS` statement.

 **See Also:**

Oracle Database SQL Language Reference for a description of the `ALTER DATABASE` statement

17.3.7.1 Using the `ALTER DATABASE ADD LOGFILE` Statement

The `ALTER DATABASE ADD LOGFILE` statement lets you later add a new group to your current redo log.

The file name in the `ADD LOGFILE` clause is optional if you are using Oracle Managed Files. If a file name is not provided, then a redo log file is created in the default log file destination. The default destination is determined according to the precedence documented in "["Specifying Redo Log Files at Database Creation"](#)".

If a file name is not provided and you have not provided one of the initialization parameters required for creating Oracle Managed Files, then the statement returns an error.

The default size for an Oracle managed log file is 100 MB.

You continue to add and drop redo log file members by specifying complete file names.

 **See Also:**

- ["Specifying Redo Log Files at Database Creation"](#)
- ["About Creating Control Files Using Oracle Managed Files"](#)

Adding New Redo Log Files: Example

The following example creates a log group with a member in `/u01/oradata` and another member in `/u02/oradata`. The size of each log file is 100 MB.

The following parameter settings are included in the initialization parameter file:

```
DB_CREATE_ONLINE_LOG_DEST_1 = '/u01/oradata'
DB_CREATE_ONLINE_LOG_DEST_2 = '/u02/oradata'
```

The following statement is issued at the SQL prompt:

```
SQL> ALTER DATABASE ADD LOGFILE;
```

17.3.7.2 Using the ALTER DATABASE OPEN RESETLOGS Statement

If you previously created a control file specifying `RESETLOGS` and either did not specify file names or specified nonexistent file names, then the database creates redo log files for you when you issue the `ALTER DATABASE OPEN RESETLOGS` statement.

The rules for determining the directories in which to store redo log files, when none are specified in the control file, are the same as those discussed in "["Specifying Redo Log Files at Database Creation"](#)".

17.3.8 Creating Archived Logs Using Oracle Managed Files

Archived logs are created by a background process or by a SQL statement.

Archived logs are created in the `DB_RECOVERY_FILE_DEST` location when:

- The `ARC` or `LGWR` background process archives an online redo log or
- An `ALTER SYSTEM ARCHIVE LOG CURRENT` statement is issued.

For example, assume that the following parameter settings are included in the initialization parameter file:

```
DB_RECOVERY_FILE_DEST_SIZE = 20G
DB_RECOVERY_FILE_DEST      = '/u01/oradata'
LOG_ARCHIVE_DEST_1          = 'LOCATION=USE_DB_RECOVERY_FILE_DEST'
```

17.4 Operation of Oracle Managed Files

The file names of Oracle Managed Files are accepted in SQL statements wherever a file name is used to identify an existing file.

These file names, like other file names, are stored in the control file and, if using Recovery Manager (RMAN) for backup and recovery, in the RMAN catalog. They are visible in all of the usual fixed and dynamic performance views that are available for monitoring data files and temp files (for example, `V$DATAFILE` or `DBA_DATA_FILES`).

The following are some examples of statements using database-generated file names:

```
SQL> ALTER DATABASE
  2> RENAME FILE '/u01/oradata/mydb/datafile/o1_mf_tbs01_ziw3bopb_.dbf'
  3> TO '/u01/oradata/mydb/tbs0101.dbf';

SQL> ALTER DATABASE
  2> DROP LOGFILE '/u01/oradata/mydb/onlinelog/o1_mf_1_wo94n2xi_.log';

SQL> ALTER TABLE emp
  2> ALLOCATE EXTENT
  3> (DATAFILE '/u01/oradata/mydb/datafile/o1_mf_tbs1_2ixfh90q_.dbf');
```

You can backup and restore Oracle managed data files, temp files, and control files as you would corresponding non Oracle Managed Files. Using database-generated file names does not impact the use of logical backup files such as export files. This is particularly important for tablespace point-in-time recovery (TSPITR) and transportable tablespace export files.

There are some cases where Oracle Managed Files behave differently, including operations that drop files or rename file, and operations involving standby databases.

- [Dropping Data Files and Temp Files](#)

Unlike files that are not managed by the database, when an Oracle managed data file or temp file is dropped, the file name is removed from the control file and the file is automatically deleted from the file system.

- [Dropping Redo Log Files](#)

When an Oracle managed redo log file is dropped, its Oracle Managed Files are deleted. You specify the group or members to be dropped.

- [Renaming Files](#)

With Oracle Managed Files, SQL statements that rename files do not actually rename the files on the operating system, but rather, the names in the control file are changed.

- [Managing Standby Databases](#)

The data files, control files, and redo log files in a standby database can be managed by the database. This is independent of whether Oracle Managed Files are used on the primary database.

17.4.1 Dropping Data Files and Temp Files

Unlike files that are not managed by the database, when an Oracle managed data file or temp file is dropped, the file name is removed from the control file and the file is automatically deleted from the file system.

The statements that delete Oracle Managed Files when they are dropped are:

- `DROP TABLESPACE`
- `ALTER DATABASE TEMPFILE ... DROP`

You can also use these statements, which always delete files, Oracle managed or not:

- `ALTER TABLESPACE ... DROP DATAFILE`
- `ALTER TABLESPACE ... DROP TEMPFILE`

17.4.2 Dropping Redo Log Files

When an Oracle managed redo log file is dropped, its Oracle Managed Files are deleted. You specify the group or members to be dropped.

The following statements drop and delete redo log files:

- `ALTER DATABASE DROP LOGFILE`
- `ALTER DATABASE DROP LOGFILE MEMBER`

17.4.3 Renaming Files

With Oracle Managed Files, SQL statements that rename files do not actually rename the files on the operating system, but rather, the names in the control file are changed.

The following statements are used to rename files:

- `ALTER DATABASE RENAME FILE`
- `ALTER TABLESPACE ... RENAME DATAFILE`

You must specify each file name using the conventions for file names on your operating system when you issue this statement.

 **Note:**

If the old file is an Oracle managed file and it exists, then it is deleted.

17.4.4 Managing Standby Databases

The data files, control files, and redo log files in a standby database can be managed by the database. This is independent of whether Oracle Managed Files are used on the primary database.

When recovery of a standby database encounters redo for the creation of a data file, if the data file is an Oracle managed file, then the recovery process creates an empty file in the local default file system location. This allows the redo for the new file to be applied immediately without any human intervention.

When recovery of a standby database encounters redo for the deletion of a tablespace, it deletes any Oracle managed data files in the local file system. Note that this is independent of the `INCLUDING DATAFILES` option issued at the primary database.

17.5 Scenarios for Using Oracle Managed Files

Scenarios illustrate how to use Oracle Managed Files.

- [Scenario 1: Create and Manage a Database with Multiplexed Redo Logs](#)
An example illustrates creating and managing a database with multiplexed redo logs.
- [Scenario 2: Create and Manage a Database with Database and Fast Recovery Areas](#)
An example illustrates creating and managing a database with both database and fast recovery areas.
- [Scenario 3: Adding Oracle Managed Files to an Existing Database](#)
An example illustrates adding Oracle Managed Files to an existing database.

17.5.1 Scenario 1: Create and Manage a Database with Multiplexed Redo Logs

An example illustrates creating and managing a database with multiplexed redo logs.

In this scenario, a DBA creates a database where the data files and redo log files are created in separate directories. The redo log files and control files are multiplexed. The database uses an undo tablespace, and has a default temporary tablespace. The following are tasks involved with creating and maintaining this database.

1. Setting the initialization parameters

The DBA includes three generic file creation defaults in the initialization parameter file before creating the database. Automatic undo management mode (the default) is also specified.

```
DB_CREATE_FILE_DEST = '/u01/oradata'  
DB_CREATE_ONLINE_LOG_DEST_1 = '/u02/oradata'  
DB_CREATE_ONLINE_LOG_DEST_2 = '/u03/oradata'  
UNDO_MANAGEMENT = AUTO
```

The DB_CREATE_FILE_DEST parameter sets the default file system directory for the data files and temp files.

The DB_CREATE_ONLINE_LOG_DEST_1 and DB_CREATE_ONLINE_LOG_DEST_2 parameters set the default file system directories for redo log file and control file creation. Each redo log file and control file is multiplexed across the two directories.

2. Creating a database

Once the initialization parameters are set, the database can be created by using this statement:

```
SQL> CREATE DATABASE sample  
2>   DEFAULT TEMPORARY TABLESPACE dflttmp;
```

Because a DATAFILE clause is not present and the DB_CREATE_FILE_DEST initialization parameter is set, the SYSTEM tablespace data file is created in the default file system (/u01/oradata in this scenario). The file name is uniquely generated by the database. The file is autoextensible with an initial size of 100 MB and an unlimited maximum size. The file is an Oracle managed file. A similar data file is created for the SYSAUX tablespace.

Because a LOGFILE clause is not present, two redo log groups are created. Each log group has two members, with one member in the DB_CREATE_ONLINE_LOG_DEST_1 location and the other member in the DB_CREATE_ONLINE_LOG_DEST_2 location. The file names are uniquely generated by the database. The log files are created with a size of 100 MB. The log file members are Oracle Managed Files.

Similarly, because the CONTROL_FILES initialization parameter is not present, and two DB_CREATE_ONLINE_LOG_DEST_n initialization parameters are specified, two control files are created. The control file located in the DB_CREATE_ONLINE_LOG_DEST_1 location is the primary control file; the control file located in the DB_CREATE_ONLINE_LOG_DEST_2 location is a multiplexed copy. The file names are uniquely generated by the database. They are Oracle Managed

Files. Assuming there is a server parameter file, a CONTROL_FILES initialization parameter is generated.

Automatic undo management mode is specified, but because an undo tablespace is not specified and the DB_CREATE_FILE_DEST initialization parameter is set, a default undo tablespace named UNDOTBS is created in the directory specified by DB_CREATE_FILE_DEST. The data file is a 20 MB data file that is autoextensible. It is an Oracle managed file.

Lastly, a default temporary tablespace named df1tmp is specified. Because DB_CREATE_FILE_DEST is included in the parameter file, the temp file for df1tmp is created in the directory specified by that parameter. The temp file is 100 MB and is autoextensible with an unlimited maximum size. It is an Oracle managed file.

The resultant file tree, with generated file names, is as follows:

```
/u01
    /oradata
        /SAMPLE
            /datafile
                /o1_mf_system_cmr7t30p_.dbf
                /o1_mf_sysaux_cmr7t88p_.dbf
                /o1_mf_sys_undo_2ixfh90q_.dbf
                /o1_mf_df1tmp_157se6ff_.tmp

/u02
    /oradata
        /SAMPLE
            /onlinelog
                /o1_mf_1_0rrm31z_.log
                /o1_mf_2_2xyz16am_.log
            /controlfile
                /o1_mf_cmr7t30p_.ctl

/u03
    /oradata
        /SAMPLE
            /onlinelog
                /o1_mf_1_ixfvm8w9_.log
                /o1_mf_2_q89tmp28_.log
            /controlfile
                /o1_mf_x1sr8t36_.ctl
```

The internally generated file names can be seen when selecting from the usual views. For example:

```
SQL> SELECT NAME FROM V$DATAFILE;

NAME
-----
/u01/oradata/SAMPLE/datafile/o1_mf_system_cmr7t30p_.dbf
/u01/oradata/SAMPLE/datafile/o1_mf_sysaux_cmr7t88p_.dbf
/u01/oradata/SAMPLE/datafile/o1_mf_sys_undo_2ixfh90q_.dbf
```

3 rows selected

3. Managing control files

The control file was created when generating the database, and a CONTROL_FILES initialization parameter was added to the parameter file. If needed, then the DBA can re-create the control file or build a new one for the database using the CREATE CONTROLFILE statement.

The correct Oracle managed file names must be used in the `DATAFILE` and `LOGFILE` clauses. The `ALTER DATABASE BACKUP CONTROLFILE TO TRACE` statement generates a script with the correct file names. Alternatively, the file names can be found by selecting from the `V$DATAFILE`, `V$TEMPFILE`, and `V$LOGFILE` views. The following example re-creates the control file for the sample database:

```
CREATE CONTROLFILE REUSE
  DATABASE sample
  LOGFILE
    GROUP 1 ('/u02/oradata/SAMPLE/onlinelog/o1_mf_1_0rrm31z_.log',
             '/u03/oradata/SAMPLE/onlinelog/o1_mf_1_ixfvm8w9_.log'),
    GROUP 2 ('/u02/oradata/SAMPLE/onlinelog/o1_mf_2_2xyz16am_.log',
             '/u03/oradata/SAMPLE/onlinelog/o1_mf_2_q89tmp28_.log')
  NORESETLOGS
  DATAFILE '/u01/oradata/SAMPLE/datafile/o1_mf_system_cmr7t30p_.dbf',
            '/u01/oradata/SAMPLE/datafile/o1_mf_sysaux_cmr7t88p_.dbf',
            '/u01/oradata/SAMPLE/datafile/o1_mf_sys_undo_2ixfh90q_.dbf',
            '/u01/oradata/SAMPLE/datafile/o1_mf_dflttmp_157se6ff_.tmp'
  MAXLOGFILES 5
  MAXLOGHISTORY 100
  MAXDATAFILES 10
  MAXINSTANCES 2
  ARCHIVELOG;
```

The control file created by this statement is located as specified by the `CONTROL_FILES` initialization parameter that was generated when the database was created. The `REUSE` clause causes any existing files to be overwritten.

4. Managing the redo log

To create a new group of redo log files, the DBA can use the `ALTER DATABASE ADD LOGFILE` statement. The following statement adds a log file with a member in the `DB_CREATE_ONLINE_LOG_DEST_1` location and a member in the `DB_CREATE_ONLINE_LOG_DEST_2` location. These files are Oracle Managed Files.

```
SQL> ALTER DATABASE ADD LOGFILE;
```

Log file members continue to be added and dropped by specifying complete file names.

The `GROUP` clause can be used to drop a log group. In the following example the operating system file associated with each Oracle managed log file member is automatically deleted.

```
SQL> ALTER DATABASE DROP LOGFILE GROUP 3;
```

5. Managing tablespaces

The default storage for all data files for future tablespace creations in the sample database is the location specified by the `DB_CREATE_FILE_DEST` initialization parameter (`/u01/oradata` in this scenario). Any data files for which no file name is specified, are created in the file system specified by the initialization parameter `DB_CREATE_FILE_DEST`. For example:

```
SQL> CREATE TABLESPACE tbs_1;
```

The preceding statement creates a tablespace whose storage is in `/u01/oradata`. A data file is created with an initial of 100 MB and it is autoextensible with an unlimited maximum size. The data file is an Oracle managed file.

When the tablespace is dropped, the Oracle Managed Files for the tablespace are automatically removed. The following statement drops the tablespace and all the Oracle Managed Files used for its storage:

```
SQL> DROP TABLESPACE tbs_1;
```

Once the first data file is full, the database does not automatically create a new data file. More space can be added to the tablespace by adding another Oracle managed data file. The following statement adds another data file in the location specified by DB_CREATE_FILE_DEST:

```
SQL> ALTER TABLESPACE tbs_1 ADD DATAFILE;
```

The default file system can be changed by changing the initialization parameter. This does not change any existing data files. It only affects future creations. This can be done dynamically using the following statement:

```
SQL> ALTER SYSTEM SET DB_CREATE_FILE_DEST='/u04/oradata' ;
```

6. Archiving redo information

Archiving of redo log files is no different for Oracle Managed Files, than it is for unmanaged files. A file system location for the archived redo log files can be specified using the LOG_ARCHIVE_DEST_n initialization parameters. The file names are formed based on the LOG_ARCHIVE_FORMAT parameter or its default. The archived logs are not Oracle Managed Files.

7. Backup, restore, and recover

Since an Oracle managed file is compatible with standard operating system files, you can use operating system utilities to backup or restore Oracle Managed Files. All existing methods for backing up, restoring, and recovering the database work for Oracle Managed Files.

17.5.2 Scenario 2: Create and Manage a Database with Database and Fast Recovery Areas

An example illustrates creating and managing a database with both database and fast recovery areas.

In this scenario, a DBA creates a database where the control files and redo log files are multiplexed. Archived logs and RMAN backups are created in the Fast Recovery Area. The following tasks are involved in creating and maintaining this database:

1. Setting the initialization parameters

The DBA includes the following generic file creation defaults:

```
DB_CREATE_FILE_DEST = '/u01/oradata'  
DB_RECOVERY_FILE_DEST_SIZE = 10G  
DB_RECOVERY_FILE_DEST = '/u02/oradata'  
LOG_ARCHIVE_DEST_1 = 'LOCATION = USE_DB_RECOVERY_FILE_DEST'
```

The DB_CREATE_FILE_DEST parameter sets the default file system directory for data files, temp files, control files, and redo logs.

The DB_RECOVERY_FILE_DEST parameter sets the default file system directory for control files, redo logs, and RMAN backups.

The `LOG_ARCHIVE_DEST_1` configuration '`LOCATION=USE_DB_RECOVERY_FILE_DEST`' redirects archived logs to the `DB_RECOVERY_FILE_DEST` location.

The `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST` parameters set the default directory for log file and control file creation. Each redo log and control file is multiplexed across the two directories.

2. Creating a database
3. Managing control files
4. Managing the redo log
5. Managing tablespaces

Tasks 2, 3, 4, and 5 are the same as in Scenario 1, except that the control files and redo logs are multiplexed across the `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST` locations.

6. Archiving redo log information

Archiving online logs is no different for Oracle Managed Files than it is for unmanaged files. The archived logs are created in `DB_RECOVERY_FILE_DEST` and are Oracle Managed Files.

7. Backup, restore, and recover

An Oracle managed file is compatible with standard operating system files, so you can use operating system utilities to backup or restore Oracle Managed Files. All existing methods for backing up, restoring, and recovering the database work for Oracle Managed Files. When no format option is specified, all disk backups by RMAN are created in the `DB_RECOVERY_FILE_DEST` location. The backups are Oracle Managed Files.

17.5.3 Scenario 3: Adding Oracle Managed Files to an Existing Database

An example illustrates adding Oracle Managed Files to an existing database.

Assume in this case that an existing database does not have any Oracle Managed Files, but the DBA would like to create new tablespaces with Oracle Managed Files and locate them in directory `/u03/oradata`.

1. Setting the initialization parameters

To allow automatic data file creation, set the `DB_CREATE_FILE_DEST` initialization parameter to the file system directory in which to create the data files. This can be done dynamically as follows:

```
SQL> ALTER SYSTEM SET DB_CREATE_FILE_DEST = '/u03/oradata';
```

2. Creating tablespaces

Once `DB_CREATE_FILE_DEST` is set, the `DATAFILE` clause can be omitted from a `CREATE TABLESPACE` statement. The data file is created in the location specified by `DB_CREATE_FILE_DEST` by default. For example:

```
SQL> CREATE TABLESPACE tbs_2;
```

When the `tbs_2` tablespace is dropped, its data files are automatically deleted.

Part III

Schema Objects

You can create and manage schema objects in Oracle Database.

- [Managing Schema Objects](#)

You can create and manage several types of schema objects with Oracle Database.

- [Managing Space for Schema Objects](#)

Managing space for schema objects involves tasks such as managing tablespace alerts and space allocation, reclaiming unused space, dropping unused object storage, monitoring space usage, and capacity planning.

- [Managing Tables](#)

Managing tables includes tasks such as creating tables, loading tables, altering tables, and dropping tables.

- [Managing Indexes](#)

- [Managing Clusters](#)

Using clusters can improve performance and reduce disk space requirements.

- [Managing Hash Clusters](#)

Hash clusters can improve the performance of data retrieval.

- [Managing Views, Sequences, and Synonyms](#)

You can create and manage views, sequences, and synonyms with Oracle Database.

- [Repairing Corrupted Data](#)

You can detect and correct data block corruption.

Managing Schema Objects

You can create and manage several types of schema objects with Oracle Database.

- **Creating Multiple Tables and Views in a Single Operation**

You can create several tables and views and grant privileges in one operation using the `CREATE SCHEMA` statement. If an individual table, view or grant fails, the entire statement is rolled back. None of the objects are created, nor are the privileges granted.

- **Analyzing Tables, Indexes, and Clusters**

You can collect statistics on schema objects, analyze the statistics, and validate the schema objects.

- **Truncating Tables and Clusters**

You can delete all rows of a table or all rows in a group of clustered tables so that the table (or cluster) still exists, but is completely empty. For example, consider a table that contains monthly data, and at the end of each month, you must empty it (delete all rows) after archiving its data.

- **Enabling and Disabling Triggers**

Database triggers are procedures that are stored in the database and activated ("fired") when specific conditions occur, such as adding a row to a table.

- **Managing Integrity Constraints**

Integrity constraints are rules that restrict the values for one or more columns in a table. Constraint clauses can appear in either `CREATE TABLE` or `ALTER TABLE` statements, and identify the column or columns affected by the constraint and identify the conditions of the constraint.

- **Renaming Schema Objects**

There are several ways to rename an object.

- **Managing Object Dependencies**

Oracle Database provides an automatic mechanism to ensure that a dependent object is always up to date with respect to its referenced objects. You can also manually recompile invalid object.

- **Managing Object Name Resolution**

Object names referenced in SQL statements can consist of several pieces, separated by periods. Oracle Database performs specific actions to resolve an object name.

- **Switching to a Different Schema**

Use an `ALTER SESSION` SQL statement to switch to a different schema.

- **Managing Editions**

Application developers who are upgrading their applications using edition-based redefinition may ask you to perform edition-related tasks that require DBA privileges.

- **Displaying Information About Schema Objects**

Oracle Database provides a PL/SQL package that enables you to determine the DDL that created an object and data dictionary views that you can use to display information about schema objects.

18.1 Creating Multiple Tables and Views in a Single Operation

You can create several tables and views and grant privileges in one operation using the `CREATE SCHEMA` statement. If an individual table, view or grant fails, the entire statement is rolled back. None of the objects are created, nor are the privileges granted.

Specifically, the `CREATE SCHEMA` statement can include *only* `CREATE TABLE`, `CREATE VIEW`, and `GRANT` statements. You must have the privileges necessary to issue the included statements. You are not actually creating a schema, that is done when the user is created with a `CREATE USER` statement. Rather, you are populating the schema.

The following statement creates two tables and a view that joins data from the two tables:

```
CREATE SCHEMA AUTHORIZATION scott
  CREATE TABLE dept (
    deptno NUMBER(3,0) PRIMARY KEY,
    dname VARCHAR2(15),
    loc VARCHAR2(25))
  CREATE TABLE emp (
    empno NUMBER(5,0) PRIMARY KEY,
    ename VARCHAR2(15) NOT NULL,
    job VARCHAR2(10),
    mgr NUMBER(5,0),
    hiredate DATE DEFAULT (sysdate),
    sal NUMBER(7,2),
    comm NUMBER(7,2),
    deptno NUMBER(3,0) NOT NULL
    CONSTRAINT dept_fkey REFERENCES dept)
  CREATE VIEW sales_staff AS
    SELECT empno, ename, sal, comm
    FROM emp
    WHERE deptno = 30
    WITH CHECK OPTION CONSTRAINT sales_staff_cnst
    GRANT SELECT ON sales_staff TO human_resources;
```

The `CREATE SCHEMA` statement does not support Oracle Database extensions to the ANSI `CREATE TABLE` and `CREATE VIEW` statements, including the `STORAGE` clause.

 **See Also:**

Oracle Database SQL Language Reference for syntax and other information about the `CREATE SCHEMA` statement

18.2 Analyzing Tables, Indexes, and Clusters

You can collect statistics on schema objects, analyze the statistics, and validate the schema objects.

- [About Analyzing Tables, Indexes, and Clusters](#)
You can collect information about schema objects and analyze that information.
- [Using DBMS_STATS to Collect Table and Index Statistics](#)
You can use the DBMS_STATS package or the ANALYZE statement to gather statistics about the physical storage characteristics of a table, index, or cluster. These statistics are stored in the data dictionary and can be used by the optimizer to choose the most efficient execution plan for SQL statements accessing analyzed objects.
- [Validating Tables, Indexes, Clusters, and Materialized Views](#)
To verify the integrity of the structure of a table, index, cluster, or materialized view, use the ANALYZE statement with the VALIDATE STRUCTURE option.
- [Cross Validation of a Table and an Index with a Query](#)
In some cases, an ANALYZE statement takes an inordinate amount of time to complete. In these cases, you can use a SQL query to validate an index.
- [Listing Chained Rows of Tables and Clusters](#)
You can look at the chained and migrated rows of a table or cluster using the ANALYZE statement with the LIST CHAINED ROWS clause. The results of this statement are stored in a specified table created explicitly to accept the information returned by the LIST CHAINED ROWS clause. These results are useful in determining whether you have enough room for updates to rows.

18.2.1 About Analyzing Tables, Indexes, and Clusters

You can collect information about schema objects and analyze that information.

You analyze a schema object (table, index, or cluster) to:

- Collect and manage statistics for it
- Verify the validity of its storage format
- Identify migrated and chained rows of a table or cluster

Note:

Do not use the COMPUTE and ESTIMATE clauses of ANALYZE to collect optimizer statistics. These clauses have been deprecated. Instead, use the DBMS_STATS package, which lets you collect statistics in parallel, collect global statistics for partitioned objects, and fine tune your statistics collection in other ways. The cost-based optimizer, which depends upon statistics, will eventually use only statistics that have been collected by DBMS_STATS. See *Oracle Database PL/SQL Packages and Types Reference* for more information on the DBMS_STATS package.

You must use the ANALYZE statement (rather than DBMS_STATS) for statistics collection not related to the cost-based optimizer, such as:

- To use the VALIDATE or LIST CHAINED ROWS clauses
- To collect information on freelist blocks

18.2.2 Using DBMS_STATS to Collect Table and Index Statistics

You can use the DBMS_STATS package or the ANALYZE statement to gather statistics about the physical storage characteristics of a table, index, or cluster. These statistics are stored in the data dictionary and can be used by the optimizer to choose the most efficient execution plan for SQL statements accessing analyzed objects.

Oracle recommends using the more versatile DBMS_STATS package for gathering optimizer statistics, but you must use the ANALYZE statement to collect statistics unrelated to the optimizer, such as empty blocks, average space, and so forth.

The DBMS_STATS package allows both the gathering of statistics, including utilizing parallel execution, and the external manipulation of statistics. Statistics can be stored in tables outside of the data dictionary, where they can be manipulated without affecting the optimizer. Statistics can be copied between databases or backup copies can be made.

The following DBMS_STATS procedures enable the gathering of optimizer statistics:

- GATHER_INDEX_STATS
- GATHER_TABLE_STATS
- GATHER_SCHEMA_STATS
- GATHER_DATABASE_STATS

See Also:

- Oracle Database SQL Tuning Guide for information about using DBMS_STATS to gather statistics for the optimizer
- Oracle Database PL/SQL Packages and Types Reference for a description of the DBMS_STATS package

18.2.3 Validating Tables, Indexes, Clusters, and Materialized Views

To verify the integrity of the structure of a table, index, cluster, or materialized view, use the ANALYZE statement with the VALIDATE STRUCTURE option.

If the structure is valid, then no error is returned. However, if the structure is corrupt, then you receive an error message.

For example, in rare cases such as hardware or other system failures, an index can become corrupted and not perform correctly. When validating the index, you can confirm that every entry in the index points to the correct row of the associated table. If the index is corrupt, then you can drop and re-create it.

If a table, index, or cluster is corrupt, then drop it and re-create it. If a materialized view is corrupt, then perform a complete refresh and ensure that you have remedied the problem. If the problem is not corrected, then drop and re-create the materialized view.

The following statement analyzes the emp table:

```
ANALYZE TABLE emp VALIDATE STRUCTURE;
```

You can validate an object and all dependent objects (for example, indexes) by including the `CASCADE` option. The following statement validates the `emp` table and all associated indexes:

```
ANALYZE TABLE emp VALIDATE STRUCTURE CASCADE;
```

By default the `CASCADE` option performs a complete validation. Because this operation can be resource intensive, you can perform a faster version of the validation by using the `FAST` clause. This version checks for the existence of corruptions using an optimized check algorithm, but does not report details about the corruption. If the `FAST` check finds a corruption, then you can then use the `CASCADE` option without the `FAST` clause to locate it. The following statement performs a fast validation on the `emp` table and all associated indexes:

```
ANALYZE TABLE emp VALIDATE STRUCTURE CASCADE FAST;
```

If fast validation takes an inordinate amount of time, then you have the option of validating individual indexes with a SQL query. See "[Cross Validation of a Table and an Index with a Query](#)".

You can specify that you want to perform structure validation online while DML is occurring against the object being validated. Validation is less comprehensive with ongoing DML affecting the object, but this is offset by the flexibility of being able to perform `ANALYZE` online. The following statement validates the `emp` table and all associated indexes online:

```
ANALYZE TABLE emp VALIDATE STRUCTURE CASCADE ONLINE;
```

See Also:

Oracle Database SQL Language Reference for more information on the `ANALYZE` statement

18.2.4 Cross Validation of a Table and an Index with a Query

In some cases, an `ANALYZE` statement takes an inordinate amount of time to complete. In these cases, you can use a SQL query to validate an index.

If the query determines that there is an inconsistency between a table and an index, then you can use an `ANALYZE` statement for a thorough analysis of the index. Since typically most objects in a database are not corrupt, you can use this quick query to eliminate a number of tables as candidates for corruption and only use the `ANALYZE` statement on tables that might be corrupt.

To validate an index, run the following query:

```
SELECT /*+ FULL(ALIAS) PARALLEL(ALIAS, DOP) */ SUM(ORA_HASH(ROWID))
  FROM table_name ALIAS
 WHERE ALIAS.index_column IS NOT NULL
   MINUS SELECT /*+ INDEX_FFS(ALIAS index_name)
    PARALLEL_INDEX(ALIAS, index_name, DOP) */ SUM(ORA_HASH(ROWID))
  FROM table_name ALIAS WHERE ALIAS.index_column IS NOT NULL;
```

When you run the query, make the following substitutions:

- Enter the table name for the *table_name* placeholder.
- Enter the index column for the *index_column* placeholder.
- Enter the index name for the *index_name* placeholder.

If the query returns any rows, then there is a possible inconsistency, and you can use an `ANALYZE` statement for further diagnosis.

 **See Also:**

Oracle Database SQL Language Reference for more information about the `ANALYZE` statement

18.2.5 Listing Chained Rows of Tables and Clusters

You can look at the chained and migrated rows of a table or cluster using the `ANALYZE` statement with the `LIST CHAINED ROWS` clause. The results of this statement are stored in a specified table created explicitly to accept the information returned by the `LIST CHAINED ROWS` clause. These results are useful in determining whether you have enough room for updates to rows.

- [Creating a CHAINED_ROWS Table](#)

To create the table to accept data returned by an `ANALYZE...LIST CHAINED ROWS` statement, execute the `UTLCHAIN.SQL` or `UTLCHN1.SQL` script.

- [Eliminating Migrated or Chained Rows in a Table](#)

You can use the information in the `CHAINED_ROWS` table to reduce or eliminate migrated and chained rows in an existing table.

18.2.5.1 Creating a CHAINED_ROWS Table

To create the table to accept data returned by an `ANALYZE...LIST CHAINED ROWS` statement, execute the `UTLCHAIN.SQL` or `UTLCHN1.SQL` script.

These scripts are provided by the database. They create a table named `CHAINED_ROWS` in the schema of the user submitting the script.

 **Note:**

Your choice of script to execute for creating the `CHAINED_ROWS` table depends on the compatibility level of your database and the type of table you are analyzing. See the *Oracle Database SQL Language Reference* for more information.

After a `CHAINED_ROWS` table is created, you specify it in the `INTO` clause of the `ANALYZE` statement. For example, the following statement inserts rows containing information about the chained rows in the `emp_dept` cluster into the `CHAINED_ROWS` table:

```
ANALYZE CLUSTER emp_dept LIST CHAINED ROWS INTO CHAINED_ROWS;
```

 See Also:

- *Oracle Database Reference* for a description of the CHAINED_ROWS table
- "[Using the Segment Advisor](#)" for information on how the Segment Advisor reports tables with excess row chaining.

18.2.5.2 Eliminating Migrated or Chained Rows in a Table

You can use the information in the CHAINED_ROWS table to reduce or eliminate migrated and chained rows in an existing table.

Use the following procedure:

1. Use the ANALYZE statement to collect information about migrated and chained rows.

```
ANALYZE TABLE order_hist LIST CHAINED ROWS;
```

2. Query the output table:

```
SELECT *
FROM CHAINED_ROWS
WHERE TABLE_NAME = 'ORDER_HIST';

OWNER_NAME  TABLE_NAME  CLUST... HEAD_ROWID      TIMESTAMP
-----  -----  -----  -----
SCOTT      ORDER_HIST    ... AAAAluAAHAAAAA1AAA 04-MAR-96
SCOTT      ORDER_HIST    ... AAAAluAAHAAAAA1AAB 04-MAR-96
SCOTT      ORDER_HIST    ... AAAAluAAHAAAAA1AAC 04-MAR-96
```

The output lists all rows that are either migrated or chained.

3. If the output table shows that you have many migrated or chained rows, then you can eliminate migrated rows by continuing through the following steps:
4. Create an intermediate table with the same columns as the existing table to hold the migrated and chained rows:

```
CREATE TABLE int_order_hist
AS SELECT *
  FROM order_hist
 WHERE ROWID IN
       (SELECT HEAD_ROWID
         FROM CHAINED_ROWS
        WHERE TABLE_NAME = 'ORDER_HIST');
```

5. Delete the migrated and chained rows from the existing table:

```
DELETE FROM order_hist
 WHERE ROWID IN
       (SELECT HEAD_ROWID
         FROM CHAINED_ROWS
        WHERE TABLE_NAME = 'ORDER_HIST');
```

6. Insert the rows of the intermediate table into the existing table:

```
INSERT INTO order_hist
SELECT *
  FROM int_order_hist;
```

7. Drop the intermediate table:

```
DROP TABLE int_order_history;
```

8. Delete the information collected in step 1 from the output table:

```
DELETE FROM CHAINED_ROWS  
WHERE TABLE_NAME = 'ORDER_HIST';
```

9. Use the ANALYZE statement again, and query the output table.

Any rows that appear in the output table are chained. You can eliminate chained rows only by increasing your data block size. It might not be possible to avoid chaining in all situations. Chaining is often unavoidable with tables that have a LONG column or large CHAR or VARCHAR2 columns.

18.3 Truncating Tables and Clusters

You can delete all rows of a table or all rows in a group of clustered tables so that the table (or cluster) still exists, but is completely empty. For example, consider a table that contains monthly data, and at the end of each month, you must empty it (delete all rows) after archiving its data.

- [Using DELETE to Truncate a Table](#)

You can delete the rows of a table using the `DELETE` SQL statement.

- [Using DROP and CREATE to Truncate a Table](#)

You can drop a table and then re-create the table to truncate it.

- [Using TRUNCATE](#)

You can delete all rows of the table using the `TRUNCATE` statement.

18.3.1 Using DELETE to Truncate a Table

You can delete the rows of a table using the `DELETE` SQL statement.

For example, the following statement deletes all rows from the `emp` table:

```
DELETE FROM emp;
```

If there are many rows present in a table or cluster when using the `DELETE` statement, significant system resources are consumed as the rows are deleted. For example, CPU time, redo log space, and undo segment space from the table and any associated indexes require resources. Also, as each row is deleted, triggers can be fired. The space previously allocated to the resulting empty table or cluster remains associated with that object. With `DELETE` you can choose which rows to delete, whereas `TRUNCATE` and `DROP` affect the entire object.

 **See Also:**

Oracle Database SQL Language Reference for syntax and other information about the `DELETE` statement

18.3.2 Using DROP and CREATE to Truncate a Table

You can drop a table and then re-create the table to truncate it.

For example, the following statements drop and then re-create the `emp` table:

```
DROP TABLE emp;
CREATE TABLE emp ( ... );
```

When dropping and re-creating a table or cluster, all associated indexes, integrity constraints, and triggers are also dropped, and all objects that depend on the dropped table or clustered table are invalidated. Also, all grants for the dropped table or clustered table are dropped.

18.3.3 Using TRUNCATE

You can delete all rows of the table using the `TRUNCATE` statement.

For example, the following statement truncates the `emp` table:

```
TRUNCATE TABLE emp;
```

Using the `TRUNCATE` statement provides a fast, efficient method for deleting all rows from a table or cluster. A `TRUNCATE` statement does not generate any undo information and it commits immediately. It is a DDL statement and cannot be rolled back. A `TRUNCATE` statement does not affect any structures associated with the table being truncated (constraints and triggers) or authorizations. A `TRUNCATE` statement also specifies whether space currently allocated for the table is returned to the containing tablespace after truncation.

You can truncate any table or cluster in your own schema. Any user who has the `DROP ANY TABLE` system privilege can truncate a table or cluster in any schema.

Before truncating a table or clustered table containing a parent key, all referencing foreign keys in different tables must be disabled. A self-referential constraint does not have to be disabled.

As a `TRUNCATE` statement deletes rows from a table, triggers associated with the table are not fired. Also, a `TRUNCATE` statement does not generate any audit information corresponding to `DELETE` statements if auditing is enabled. Instead, a single audit record is generated for the `TRUNCATE` statement being issued.

A hash cluster cannot be truncated, nor can tables within a hash or index cluster be individually truncated. Truncation of an index cluster deletes all rows from all tables in the cluster. If all the rows must be deleted from an individual clustered table, use the `DELETE` statement or drop and re-create the table.

The `TRUNCATE` statement has several options that control whether space currently allocated for a table or cluster is returned to the containing tablespace after truncation.

These options also apply to any associated indexes. When a table or cluster is truncated, all associated indexes are also truncated. The storage parameters for a truncated table, cluster, or associated indexes are not changed as a result of the truncation.

These `TRUNCATE` options are:

- `DROP STORAGE`, the default option, reduces the number of extents allocated to the resulting table to the original setting for `MINEXTENTS`. Freed extents are then returned to the system and can be used by other objects.
- `DROP ALL STORAGE` drops the segment. In addition to the `TRUNCATE TABLE` statement, `DROP ALL STORAGE` also applies to the `ALTER TABLE TRUNCATE (SUB)PARTITION` statement. This option also drops any dependent object segments associated with the partition being truncated.

`DROP ALL STORAGE` is not supported for clusters.

```
TRUNCATE TABLE emp DROP ALL STORAGE;
```

- `REUSE STORAGE` specifies that all space currently allocated for the table or cluster remains allocated to it. For example, the following statement truncates the `emp_dept` cluster, leaving all extents previously allocated for the cluster available for subsequent inserts and deletes:

```
TRUNCATE CLUSTER emp_dept REUSE STORAGE;
```

 **See Also:**

- *Oracle Database SQL Language Reference* for syntax and other information about the `TRUNCATE TABLE` statement
- *Oracle Database SQL Language Reference* for syntax and other information about the `TRUNCATE CLUSTER` statement
- *Oracle Database Security Guide* for information about auditing

18.4 Enabling and Disabling Triggers

Database triggers are procedures that are stored in the database and activated ("fired") when specific conditions occur, such as adding a row to a table.

You can use triggers to supplement the standard capabilities of the database to provide a highly customized database management system. For example, you can create a trigger to restrict DML operations against a table, allowing only statements issued during regular business hours.

- **About Enabling and Disabling Triggers**
An enabled trigger executes its trigger body if a triggering statement is issued and the trigger restriction, if any, evaluates to true. By default, triggers are enabled when first created. A disabled trigger does not execute its trigger body, even if a triggering statement is issued and the trigger restriction (if any) evaluates to true.
- **Enabling Triggers**
You enable a disabled trigger using the `ALTER TRIGGER` statement with the `ENABLE` option.
- **Disabling Triggers**
You disable a trigger using the `ALTER TRIGGER` statement with the `DISABLE` option.

18.4.1 About Enabling and Disabling Triggers

An enabled trigger executes its trigger body if a triggering statement is issued and the trigger restriction, if any, evaluates to true. By default, triggers are enabled when first created. A disabled trigger does not execute its trigger body, even if a triggering statement is issued and the trigger restriction (if any) evaluates to true.

Database triggers can be associated with a table, schema, or database. They are implicitly fired when:

- DML statements are executed (`INSERT`, `UPDATE`, `DELETE`) against an associated table
 - Certain DDL statements are executed (for example: `ALTER`, `CREATE`, `DROP`) on objects within a database or schema
 - A specified database event occurs (for example: `STARTUP`, `SHUTDOWN`, `SERVERERROR`)

This is not a complete list. See the *Oracle Database SQL Language Reference* for a full list of statements and database events that cause triggers to fire.

Create triggers with the CREATE TRIGGER statement. They can be defined as firing BEFORE or AFTER the triggering event, or INSTEAD OF it. The following statement creates a trigger scott.emp_permit_changes on table scott.emp. The trigger fires before any of the specified statements are executed.

```
CREATE TRIGGER scott.emp_permit_changes
  BEFORE
  DELETE OR INSERT OR UPDATE
  ON scott.emp
  .
  .
  .
pl/sql block
  .
  .
  .
```

You can later remove a trigger from the database by issuing the `DROP TRIGGER` statement.

To enable or disable triggers using the ALTER TABLE statement, you must own the table, have the ALTER object privilege for the table, or have the ALTER ANY TABLE system privilege. To enable or disable an individual trigger using the ALTER TRIGGER statement, you must own the trigger or have the ALTER ANY TRIGGER system privilege.

See Also:

- *Oracle Database Concepts* for a more detailed description of triggers
 - *Oracle Database SQL Language Reference* for syntax of the CREATE TRIGGER statement
 - *Oracle Database PL/SQL Language Reference* for information about creating and using triggers

18.4.2 Enabling Triggers

You enable a disabled trigger using the `ALTER TRIGGER` statement with the `ENABLE` option.

To enable the disabled trigger named `reorder` on the `inventory` table, enter the following statement:

```
ALTER TRIGGER reorder ENABLE;
```

To enable all triggers defined for a specific table, use the `ALTER TABLE` statement with the `ENABLE ALL TRIGGERS` option. To enable all triggers defined for the `INVENTORY` table, enter the following statement:

```
ALTER TABLE inventory
    ENABLE ALL TRIGGERS;
```

 **See Also:**

Oracle Database SQL Language Reference for syntax and other information about the `ALTER TRIGGER` statement

18.4.3 Disabling Triggers

You disable a trigger using the `ALTER TRIGGER` statement with the `DISABLE` option.

Consider temporarily disabling a trigger if one of the following conditions is true:

- An object that the trigger references is not available.
- You must perform a large data load and want it to proceed quickly without firing triggers.
- You are loading data into the table to which the trigger applies.

To disable the trigger `reorder` on the `inventory` table, enter the following statement:

```
ALTER TRIGGER reorder DISABLE;
```

You can disable all triggers associated with a table at the same time using the `ALTER TABLE` statement with the `DISABLE ALL TRIGGERS` option. For example, to disable all triggers defined for the `inventory` table, enter the following statement:

```
ALTER TABLE inventory
    DISABLE ALL TRIGGERS;
```

18.5 Managing Integrity Constraints

Integrity constraints are rules that restrict the values for one or more columns in a table. Constraint clauses can appear in either `CREATE TABLE` or `ALTER TABLE` statements, and identify the column or columns affected by the constraint and identify the conditions of the constraint.

- [Integrity Constraint States](#)
Integrity constraints enforce business rules and prevent the entry of invalid information into tables.
- [Setting Integrity Constraints Upon Definition](#)
When an integrity constraint is defined in a `CREATE TABLE` or `ALTER TABLE` statement, it can be enabled, disabled, or validated or not validated as determined by your specification of the `ENABLE/DISABLE` clause. If the `ENABLE/DISABLE` clause is not specified in a constraint definition, the database automatically enables and validates the constraint.
- [Modifying, Renaming, or Dropping Existing Integrity Constraints](#)
You can use the `ALTER TABLE` statement to enable, disable, modify, or drop a constraint. When the database is using a `UNIQUE` or `PRIMARY KEY` index to enforce a constraint, and constraints associated with that index are dropped or disabled, the index is dropped, unless you specify otherwise.
- [Deferring Constraint Checks](#)
When the database checks a constraint, it signals an error if the constraint is not satisfied. You can defer checking the validity of constraints until the end of a transaction. When you issue the `SET CONSTRAINTS` statement, the `SET CONSTRAINTS` mode lasts for the duration of the transaction, or until another `SET CONSTRAINTS` statement resets the mode.
- [Reporting Constraint Exceptions](#)
If exceptions exist when a constraint is validated, then an error is returned and the integrity constraint remains nonvalidated. When a statement is not successfully executed because integrity constraint exceptions exist, the statement is rolled back. If exceptions exist, then you cannot validate the constraint until all exceptions to the constraint are either updated or deleted.
- [Viewing Constraint Information](#)
Oracle Database provides a set of views that enable you to see constraint definitions on tables and to identify columns that are specified in constraints.

See Also:

- *Oracle Database Concepts* for a more thorough discussion of integrity constraints
- *Oracle Database Development Guide* for detailed information and examples of using integrity constraints in applications

18.5.1 Integrity Constraint States

Integrity constraints enforce business rules and prevent the entry of invalid information into tables.

- [About Integrity Constraint States](#)

You can specify that a constraint is enabled (`ENABLE`) or disabled (`DISABLE`). If a constraint is enabled, data is checked as it is entered or updated in the database, and data that does not conform to the constraint is prevented from being entered. If a constraint is disabled, then data that does not conform can be allowed to enter the database.

- [About Disabling Constraints](#)
To enforce the rules defined by integrity constraints, the constraints should always be enabled, but you can consider disabling them in certain situations.
- [About Enabling Constraints](#)
While a constraint is enabled, no row violating the constraint can be inserted into the table.
- [About the Enable Novalidate Constraint State](#)
When a constraint is in the enable novalidate state, all subsequent statements are checked for conformity to the constraint. However, any existing data in the table is not checked.
- [Efficient Use of Integrity Constraints: A Procedure](#)
It is important to use integrity constraint states in a particular order.

18.5.1.1 About Integrity Constraint States

You can specify that a constraint is enabled (`ENABLE`) or disabled (`DISABLE`). If a constraint is enabled, data is checked as it is entered or updated in the database, and data that does not conform to the constraint is prevented from being entered. If a constraint is disabled, then data that does not conform can be allowed to enter the database.

Additionally, you can specify that existing data in the table must conform to the constraint (`VALIDATE`). Conversely, if you specify `NOVALIDATE`, you are not ensured that existing data conforms.

An integrity constraint defined on a table can be in one of the following states:

- `ENABLE, VALIDATE`
- `ENABLE, NOVALIDATE`
- `DISABLE, VALIDATE`
- `DISABLE, NOVALIDATE`

For details about the meaning of these states and an understanding of their consequences, see the *Oracle Database SQL Language Reference*. Some of these consequences are discussed here.

18.5.1.2 About Disabling Constraints

To enforce the rules defined by integrity constraints, the constraints should always be enabled, but you can consider disabling them in certain situations.

However, consider temporarily disabling the integrity constraints of a table for the following performance reasons:

- When loading large amounts of data into a table
- When performing batch operations that make massive changes to a table (for example, changing every employee's number by adding 1000 to the existing number)
- When importing or exporting one table at a time

In all three cases, temporarily disabling integrity constraints can improve the performance of the operation, especially in data warehouse configurations.

It is possible to enter data that violates a constraint while that constraint is disabled. Thus, you should always enable the constraint after completing any of the operations listed in the preceding bullet list.

18.5.1.3 About Enabling Constraints

While a constraint is enabled, no row violating the constraint can be inserted into the table.

However, while the constraint is disabled such a row can be inserted. This row is known as an exception to the constraint. If the constraint is in the enable novalidated state, violations resulting from data entered while the constraint was disabled remain. The rows that violate the constraint must be either updated or deleted in order for the constraint to be put in the validated state.

You can identify exceptions to a specific integrity constraint while attempting to enable the constraint. See "[Reporting Constraint Exceptions](#)". All rows violating constraints are noted in an EXCEPTIONS table, which you can examine.

18.5.1.4 About the Enable Novalidate Constraint State

When a constraint is in the enable novalidate state, all subsequent statements are checked for conformity to the constraint. However, any existing data in the table is not checked.

A table with enable novalidated constraints can contain invalid data, but it is not possible to add new invalid data to it. Enabling constraints in the novalidated state is most useful in data warehouse configurations that are uploading valid OLTP data.

Enabling a constraint does not require validation. Enabling a constraint novalidate is much faster than enabling and validating a constraint. Also, validating a constraint that is already enabled does not require any DML locks during validation (unlike validating a previously disabled constraint). Enforcement guarantees that no violations are introduced during the validation. Hence, enabling without validating enables you to reduce the downtime typically associated with enabling a constraint.

18.5.1.5 Efficient Use of Integrity Constraints: A Procedure

It is important to use integrity constraint states in a particular order.

Using integrity constraint states in the following order can ensure the best benefits:

1. Disable state.
2. Perform the operation (load, export, import).
3. Enable novalidate state.
4. Enable state.

Some benefits of using constraints in this order are:

- No locks are held.
- All constraints can go to enable state concurrently.
- Constraint enabling is done in parallel.
- Concurrent activity on table is permitted.

18.5.2 Setting Integrity Constraints Upon Definition

When an integrity constraint is defined in a CREATE TABLE or ALTER TABLE statement, it can be enabled, disabled, or validated or not validated as determined by your specification of the ENABLE/DISABLE clause. If the ENABLE/DISABLE clause is not specified in a constraint definition, the database automatically enables and validates the constraint.

- [Disabling Constraints Upon Definition](#)
You can disable an integrity constraint when you define it.
- [Enabling Constraints Upon Definition](#)
You can enable an integrity constraint when you define it.

18.5.2.1 Disabling Constraints Upon Definition

You can disable an integrity constraint when you define it.

The following CREATE TABLE and ALTER TABLE statements both define and disable integrity constraints:

```
CREATE TABLE emp (
    empno NUMBER(5) PRIMARY KEY DISABLE, . . . ;

ALTER TABLE emp
    ADD PRIMARY KEY (empno) DISABLE;
```

An ALTER TABLE statement that defines and disables an integrity constraint never fails because of rows in the table that violate the integrity constraint. The definition of the constraint is allowed because its rule is not enforced.

18.5.2.2 Enabling Constraints Upon Definition

You can enable an integrity constraint when you define it.

The following CREATE TABLE and ALTER TABLE statements both define and enable integrity constraints:

```
CREATE TABLE emp (
    empno NUMBER(5) CONSTRAINT emp_pk PRIMARY KEY, . . . ;

ALTER TABLE emp
    ADD CONSTRAINT emp_pk PRIMARY KEY (empno);
```

An ALTER TABLE statement that defines and attempts to enable an integrity constraint can fail because rows of the table violate the integrity constraint. If this case, the statement is rolled back and the constraint definition is not stored and not enabled.

When you enable a UNIQUE or PRIMARY KEY constraint an associated index is created.

 **Note:**

An efficient procedure for enabling a constraint that can make use of parallelism is described in "[Efficient Use of Integrity Constraints: A Procedure](#)".

 **See Also:**

"[Creating an Index Associated with a Constraint](#)"

18.5.3 Modifying, Renaming, or Dropping Existing Integrity Constraints

You can use the `ALTER TABLE` statement to enable, disable, modify, or drop a constraint. When the database is using a `UNIQUE` or `PRIMARY KEY` index to enforce a constraint, and constraints associated with that index are dropped or disabled, the index is dropped, unless you specify otherwise.

While enabled foreign keys reference a `PRIMARY` or `UNIQUE` key, you cannot disable or drop the `PRIMARY` or `UNIQUE` key constraint or the index.

- [Disabling and Enabling Constraints](#)

You can disable enabled integrity constraints and enable disabled integrity constraints.

- [Renaming Constraints](#)

The `ALTER TABLE...RENAME CONSTRAINT` statement enables you to rename any currently existing constraint for a table. The new constraint name must not conflict with any existing constraint names for a user.

- [Dropping Constraints](#)

You can drop an integrity constraint if the rule that it enforces is no longer true, or if the constraint is no longer needed.

18.5.3.1 Disabling and Enabling Constraints

You can disable enabled integrity constraints and enable disabled integrity constraints.

The following statements disable integrity constraints. The second statement specifies that the associated indexes are to be kept.

```
ALTER TABLE dept
    DISABLE CONSTRAINT dname_ukey;

ALTER TABLE dept
    DISABLE PRIMARY KEY KEEP INDEX,
    DISABLE UNIQUE (dname, loc) KEEP INDEX;
```

The following statements enable novalidate disabled integrity constraints:

```
ALTER TABLE dept
    ENABLE NOVALIDATE CONSTRAINT dname_ukey;
```

```
ALTER TABLE dept
    ENABLE NOVALIDATE PRIMARY KEY,
    ENABLE NOVALIDATE UNIQUE (dname, loc);
```

The following statements enable or validate disabled integrity constraints:

```
ALTER TABLE dept
    MODIFY CONSTRAINT dname_key VALIDATE;

ALTER TABLE dept
    MODIFY PRIMARY KEY ENABLE NOVALIDATE;
```

The following statements enable disabled integrity constraints:

```
ALTER TABLE dept
    ENABLE CONSTRAINT dname_ukey;

ALTER TABLE dept
    ENABLE PRIMARY KEY,
    ENABLE UNIQUE (dname, loc);
```

To disable or drop a UNIQUE key or PRIMARY KEY constraint and all dependent FOREIGN KEY constraints in a single step, use the CASCADE option of the DISABLE or DROP clauses. For example, the following statement disables a PRIMARY KEY constraint and any FOREIGN KEY constraints that depend on it:

```
ALTER TABLE dept
    DISABLE PRIMARY KEY CASCADE;
```

18.5.3.2 Renaming Constraints

The ALTER TABLE...RENAME CONSTRAINT statement enables you to rename any currently existing constraint for a table. The new constraint name must not conflict with any existing constraint names for a user.

The following statement renames the dname_ukey constraint for table dept:

```
ALTER TABLE dept
    RENAME CONSTRAINT dname_ukey TO dname_unikey;
```

When you rename a constraint, all dependencies on the base table remain valid.

The RENAME CONSTRAINT clause provides a means of renaming system generated constraint names.

18.5.3.3 Dropping Constraints

You can drop an integrity constraint if the rule that it enforces is no longer true, or if the constraint is no longer needed.

You can drop the constraint using the ALTER TABLE statement with one of the following clauses:

- DROP PRIMARY KEY
- DROP UNIQUE
- DROP CONSTRAINT

The following two statements drop integrity constraints. The second statement keeps the index associated with the PRIMARY KEY constraint:

```
ALTER TABLE dept
    DROP UNIQUE (dname, loc);

ALTER TABLE emp
    DROP PRIMARY KEY KEEP INDEX
    DROP CONSTRAINT dept_fkey;
```

If FOREIGN KEYS reference a UNIQUE or PRIMARY KEY, you must include the CASCADE CONSTRAINTS clause in the DROP statement, or you cannot drop the constraint.

18.5.4 Deferring Constraint Checks

When the database checks a constraint, it signals an error if the constraint is not satisfied. You can defer checking the validity of constraints until the end of a transaction. When you issue the SET CONSTRAINTS statement, the SET CONSTRAINTS mode lasts for the duration of the transaction, or until another SET CONSTRAINTS statement resets the mode.

 **Note:**

- You cannot issue a SET CONSTRAINT statement inside a trigger.
- Deferrable unique and primary keys must use nonunique indexes.

- [Set All Constraints Deferred](#)

When constraints must be deferred for a transaction, you must set all constraints deferred before you actually begin processing any data within the application being used to manipulate the data.

- [Check the Commit \(Optional\)](#)

You can check for constraint violations before committing by issuing the SET CONSTRAINTS ALL IMMEDIATE statement just before issuing the COMMIT.

18.5.4.1 Set All Constraints Deferred

When constraints must be deferred for a transaction, you must set all constraints deferred before you actually begin processing any data within the application being used to manipulate the data.

Use the following DML statement to set all deferrable constraints deferred:

```
SET CONSTRAINTS ALL DEFERRED;
```

 **Note:**

The SET CONSTRAINTS statement applies only to the current transaction. The defaults specified when you create a constraint remain as long as the constraint exists. The ALTER SESSION SET CONSTRAINTS statement applies for the current session only.

18.5.4.2 Check the Commit (Optional)

You can check for constraint violations before committing by issuing the `SET CONSTRAINTS ALL IMMEDIATE` statement just before issuing the `COMMIT`.

If there are any problems with a constraint, then this statement fails and the constraint causing the error is identified. If you commit while constraints are violated, then the transaction is rolled back and you receive an error message.

18.5.5 Reporting Constraint Exceptions

If exceptions exist when a constraint is validated, then an error is returned and the integrity constraint remains novalidated. When a statement is not successfully executed because integrity constraint exceptions exist, the statement is rolled back. If exceptions exist, then you cannot validate the constraint until all exceptions to the constraint are either updated or deleted.

To determine which rows violate the integrity constraint, issue the `ALTER TABLE` statement with the `EXCEPTIONS` option in the `ENABLE` clause. The `EXCEPTIONS` option places the rowid, table owner, table name, and constraint name of all exception rows into a specified table.

You must create an appropriate exceptions report table to accept information from the `EXCEPTIONS` option of the `ENABLE` clause before enabling the constraint. You can create an exception table by executing the `UTLEXCPT.SQL` script or the `UTLEXPT1.SQL` script.

 **Note:**

Your choice of script to execute for creating the `EXCEPTIONS` table depends on the type of table you are analyzing. See the *Oracle Database SQL Language Reference* for more information.

Both of these scripts create a table named `EXCEPTIONS`. You can create additional exceptions tables with different names by modifying and resubmitting the script.

The following statement attempts to validate the `PRIMARY KEY` of the `dept` table, and if exceptions exist, information is inserted into a table named `EXCEPTIONS`:

```
ALTER TABLE dept ENABLE PRIMARY KEY EXCEPTIONS INTO EXCEPTIONS;
```

If duplicate primary key values exist in the `dept` table and the name of the `PRIMARY KEY` constraint on `dept` is `sys_c00610`, then the following query will display those exceptions:

```
SELECT * FROM EXCEPTIONS;
```

The following exceptions are shown:

FROWID	OWNER	TABLE_NAME	CONSTRAINT
AAAAZ9AABAAABvqAAB	SCOTT	DEPT	SYS_C00610
AAAAZ9AABAAABvqAAG	SCOTT	DEPT	SYS_C00610

A more informative query would be to join the rows in an exception report table and the master table to list the actual rows that violate a specific constraint, as shown in the following statement and results:

```
SELECT deptno, dname, loc FROM dept, EXCEPTIONS
  WHERE EXCEPTIONS.constraint = 'SYS_C00610'
    AND dept.rowid = EXCEPTIONS.row_id;
```

DEPTNO	DNAME	LOC
10	ACCOUNTING	NEW YORK
10	RESEARCH	DALLAS

All rows that violate a constraint must be either updated or deleted from the table containing the constraint. When updating exceptions, you must change the value violating the constraint to a value consistent with the constraint or to a null. After the row in the master table is updated or deleted, the corresponding rows for the exception in the exception report table should be deleted to avoid confusion with later exception reports. The statements that update the master table and the exception report table should be in the same transaction to ensure transaction consistency.

To correct the exceptions in the previous examples, you might issue the following transaction:

```
UPDATE dept SET deptno = 20 WHERE dname = 'RESEARCH';
DELETE FROM EXCEPTIONS WHERE constraint = 'SYS_C00610';
COMMIT;
```

When managing exceptions, the goal is to eliminate all exceptions in your exception report table.

Note:

While you are correcting current exceptions for a table with the constraint disabled, it is possible for other users to issue statements creating new exceptions. You can avoid this by marking the constraint `ENABLE NOVALIDATE` before you start eliminating exceptions.

See Also:

Oracle Database Reference for a description of the `EXCEPTIONS` table

18.5.6 Viewing Constraint Information

Oracle Database provides a set of views that enable you to see constraint definitions on tables and to identify columns that are specified in constraints.

View	Description
DBA_CONSTRAINTS	DBA view describes all constraint definitions in the database.
ALL_CONSTRAINTS	ALL view describes constraint definitions accessible to current user. USER view describes constraint definitions owned by the current user.
USER_CONSTRAINTS	
DBA_CONS_COLUMNS	DBA view describes all columns in the database that are specified in constraints. ALL view describes only those columns accessible to current user that are specified in constraints. USER view describes only those columns owned by the current user that are specified in constraints.
ALL_CONS_COLUMNS	
USER_CONS_COLUMNS	

 **See Also:**

- *Oracle Database Reference* for information about the *_CONSTRAINTS views
- *Oracle Database Reference* for information about the *_CONS_COLUMNS views

18.6 Renaming Schema Objects

There are several ways to rename an object.

To rename an object, it must be in your schema. You can rename schema objects in either of the following ways:

- Drop and re-create the object
- Rename the object using the `RENAME` statement
- Rename the object using the `ALTER ... RENAME` statement (for indexes and triggers)

If you drop and re-create an object, all privileges granted for that object are lost. Privileges must be regranted when the object is re-created.

A table, view, sequence, or a private synonym of a table, view, or sequence can be renamed using the `RENAME` statement. When using the `RENAME` statement, integrity constraints, indexes, and grants made for the object are carried forward for the new name. For example, the following statement renames the `sales_staff` view:

```
RENAME sales_staff TO dept_30;
```

 **Note:**

You cannot use `RENAME` for a stored PL/SQL program unit, public synonym, or cluster. To rename such an object, you must drop and re-create it.

Before renaming a schema object, consider the following effects:

- All views and PL/SQL program units dependent on a renamed object become invalid, and must be recompiled before next use.
- All synonyms for a renamed object return an error when used.

 **See Also:**

Oracle Database SQL Language Reference for syntax of the `RENAME` statement

18.7 Managing Object Dependencies

Oracle Database provides an automatic mechanism to ensure that a dependent object is always up to date with respect to its referenced objects. You can also manually recompile invalid object.

- [About Object Dependencies and Object Invalidation](#)

Some types of schema objects reference other objects. An object that references another object is called a **dependent object**, and an object being referenced is a **referenced object**. These references are established at compile time, and if the compiler cannot resolve them, the dependent object being compiled is marked *invalid*.

- [Manually Recompiling Invalid Objects with DDL](#)

You can use an `ALTER` statement to manually recompile a single schema object.

- [Manually Recompiling Invalid Objects with PL/SQL Package Procedures](#)

The `RECOMP_SERIAL` procedure recompiles all invalid objects in a specified schema, or all invalid objects in the database if you do not supply the schema name argument. The `RECOMP_PARALLEL` procedure does the same, but in parallel, employing multiple CPUs.

18.7.1 About Object Dependencies and Object Invalidation

Some types of schema objects reference other objects. An object that references another object is called a **dependent object**, and an object being referenced is a **referenced object**. These references are established at compile time, and if the compiler cannot resolve them, the dependent object being compiled is marked *invalid*.

For example, a view contains a query that references tables or other views, and a PL/SQL subprogram might invoke other subprograms and might use static SQL to reference tables or views.

Oracle Database provides an automatic mechanism to ensure that a dependent object is always up to date with respect to its referenced objects. When a dependent object is created, the database tracks dependencies between the dependent object and its referenced objects. When a referenced object is changed in a way that might affect a dependent object, the dependent object is marked invalid. An invalid dependent object must be recompiled against the new definition of a referenced object before the dependent object can be used. Recompilation occurs automatically when the invalid dependent object is referenced.

It is important to be aware of changes that can invalidate schema objects, because invalidation affects applications running on the database. This section describes how

objects become invalid, how you can identify invalid objects, and how you can validate invalid objects.

Object Invalidation

In a typical running application, you would not expect to see views or stored procedures become invalid, because applications typically do not change table structures or change view or stored procedure definitions during normal execution. Changes to tables, views, or PL/SQL units typically occur when an application is patched or upgraded using a patch script or ad-hoc DDL statements. Dependent objects might be left invalid after a patch has been applied to change a set of referenced objects.

Use the following query to display the set of invalid objects in the database:

```
SELECT object_name, object_type FROM dba_objects
WHERE status = 'INVALID';
```

The Database Home page in Oracle Enterprise Manager Cloud Control displays an alert when schema objects become invalid.

Object invalidation affects applications in two ways. First, an invalid object must be revalidated before it can be used by an application. Revalidation adds latency to application execution. If the number of invalid objects is large, the added latency on the first execution can be significant. Second, invalidation of a procedure, function or package can cause exceptions in other sessions concurrently executing the procedure, function or package. If a patch is applied when the application is in use in a different session, the session executing the application notices that an object in use has been invalidated and raises one of the following 4 exceptions: ORA-04061, ORA-04064, ORA-04065 or ORA-04068. These exceptions must be remedied by restarting application sessions following a patch.

You can force the database to recompile a schema object using the appropriate SQL statement with the `COMPILE` clause. See "[Manually Recompiling Invalid Objects with DDL](#)" for more information.

If you know that there are a large number of invalid objects, use the `UTL_RECOMP` PL/SQL package to perform a mass recompilation. See "[Manually Recompiling Invalid Objects with PL/SQL Package Procedures](#)" for details.

The following are some general rules for the invalidation of schema objects:

- Between a referenced object and each of its dependent objects, the database tracks the elements of the referenced object that are involved in the dependency. For example, if a single-table view selects only a subset of columns in a table, only those columns are involved in the dependency. For each dependent of an object, if a change is made to the definition of any element involved in the dependency (including dropping the element), the dependent object is invalidated. Conversely, if changes are made only to definitions of elements that are not involved in the dependency, the dependent object remains valid.

In many cases, therefore, developers can avoid invalidation of dependent objects and unnecessary extra work for the database if they exercise care when changing schema objects.

- Dependent objects are *cascade invalidated*. If any object becomes invalid for any reason, all of that object's dependent objects are immediately invalidated.

- If you revoke any object privileges on a schema object, dependent objects are cascade invalidated.

 **See Also:**

Oracle Database Concepts for more detailed information about schema object dependencies

18.7.2 Manually Recompiling Invalid Objects with DDL

You can use an ALTER statement to manually recompile a single schema object.

For example, to recompile package body `Pkg1`, you would execute the following DDL statement:

```
ALTER PACKAGE pkg1 COMPILE REUSE SETTINGS;
```

 **See Also:**

Oracle Database SQL Language Reference for syntax and other information about the various ALTER statements

18.7.3 Manually Recompiling Invalid Objects with PL/SQL Package Procedures

The `RECOMP_SERIAL` procedure recompiles all invalid objects in a specified schema, or all invalid objects in the database if you do not supply the schema name argument. The `RECOMP_PARALLEL` procedure does the same, but in parallel, employing multiple CPUs.

Following an application upgrade or patch, it is good practice to revalidate invalid objects to avoid application latencies that result from on-demand object revalidation. Oracle provides the `UTL_RECOMP` package to assist in object revalidation.

Examples

Execute the following PL/SQL block to revalidate all invalid objects in the database, in parallel and in dependency order:

```
begin
    utl_recomp.recomp_parallel();
end;
/
```

You can also revalidate individual invalid objects using the package `DBMS_UTILITY`. The following PL/SQL block revalidates the procedure `UPDATE_SALARY` in schema `HR`:

```
begin
    dbms_utility.validate('HR', 'UPDATE_SALARY', namespace=>1);
```

```
end;  
/
```

The following PL/SQL block revalidates the package body `HR.ACCT_MGMT`:

```
begin  
    dbms_utility.validate('HR', 'ACCT_MGMT', namespace=>2);  
end;  
/
```

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference* for more information on the `UTL_RECOMP` package
- *Oracle Database PL/SQL Packages and Types Reference* for more information on the `DBMS.Utility` package

18.8 Managing Object Name Resolution

Object names referenced in SQL statements can consist of several pieces, separated by periods. Oracle Database performs specific actions to resolve an object name.

The following describes how the database resolves an object name.

1. Oracle Database attempts to qualify the first piece of the name referenced in the SQL statement. For example, in `scott.emp`, `scott` is the first piece. If there is only one piece, the one piece is considered the first piece.
 - a. In the current schema, the database searches for an object whose name matches the first piece of the object name. If it does not find such an object, it continues with step 1.b.
 - b. The database searches for a public synonym that matches the first piece of the name. If it does not find one, it continues with step 1.c.
 - c. The database searches for a schema whose name matches the first piece of the object name. If it finds one, then the schema is the qualified schema, and it continues with step 1.d.If no schema is found in step 1.c, the object cannot be qualified and the database returns an error.
 - d. In the qualified schema, the database searches for an object whose name matches the second piece of the object name.If the second piece does not correspond to an object in the previously qualified schema or there is not a second piece, then the database returns an error.
2. A schema object has been qualified. Any remaining pieces of the name must match a valid part of the found object. For example, if `scott.emp.deptno` is the name, `scott` is qualified as a schema, `emp` is qualified as a table, and `deptno` must correspond to a column (because `emp` is a table). If `emp` is qualified as a package, `deptno` must correspond to a public constant, variable, procedure, or function of that package.

When global object names are used in a distributed database, either explicitly or indirectly within a synonym, the local database resolves the reference locally. For example, it resolves a synonym to global object name of a remote table. The partially resolved statement is shipped to the remote database, and the remote database completes the resolution of the object as described here.

Because of how the database resolves references, it is possible for an object to depend on the nonexistence of other objects. This situation occurs when the dependent object uses a reference that would be interpreted differently were another object present. For example, assume the following:

- At the current point in time, the `company` schema contains a table named `emp`.
- A PUBLIC synonym named `emp` is created for `company.emp` and the SELECT privilege for `company.emp` is granted to the PUBLIC role.
- The `jward` schema does not contain a table or private synonym named `emp`.
- The user `jward` creates a view in his schema with the following statement:

```
CREATE VIEW dept_salaries AS
    SELECT deptno, MIN(sal), AVG(sal), MAX(sal) FROM emp
    GROUP BY deptno
    ORDER BY deptno;
```

When `jward` creates the `dept_salaries` view, the reference to `emp` is resolved by first looking for `jward.emp` as a table, view, or private synonym, none of which is found, and then as a public synonym named `emp`, which is found. As a result, the database notes that `jward.dept_salaries` depends on the nonexistence of `jward.emp` and on the existence of `public.emp`.

Now assume that `jward` decides to create a new view named `emp` in his schema using the following statement:

```
CREATE VIEW emp AS
    SELECT empno, ename, mgr, deptno
    FROM company.emp;
```

Notice that `jward.emp` does not have the same structure as `company.emp`.

As it attempts to resolve references in object definitions, the database internally makes note of dependencies that the new dependent object has on "nonexistent" objects--schema objects that, if they existed, would change the interpretation of the object's definition. Such dependencies must be noted in case a nonexistent object is later created. If a nonexistent object is created, all dependent objects must be invalidated so that dependent objects can be recompiled and verified and all dependent function-based indexes must be marked unusable.

Therefore, in the previous example, as `jward.emp` is created, `jward.dept_salaries` is invalidated because it depends on `jward.emp`. Then when `jward.dept_salaries` is used, the database attempts to recompile the view. As the database resolves the reference to `emp`, it finds `jward.emp` (`public.emp` is no longer the referenced object). Because `jward.emp` does not have a `sal` column, the database finds errors when replacing the view, leaving it invalid.

In summary, you must manage dependencies on nonexistent objects checked during object resolution in case the nonexistent object is later created.

 **See Also:**

["Schema Objects and Database Links"](#) for information about name resolution in a distributed database

18.9 Switching to a Different Schema

Use an `ALTER SESSION` SQL statement to switch to a different schema.

The following statement sets the schema of the current session to the schema name specified in the statement.

```
ALTER SESSION SET CURRENT_SCHEMA = <schema name>
```

In subsequent SQL statements, Oracle Database uses this schema name as the schema qualifier when the qualifier is omitted. In addition, the database uses the temporary tablespace of the specified schema for sorts, joins, and storage of temporary database objects. The session retains its original privileges and does not acquire any extra privileges by the preceding `ALTER SESSION` statement.

In the following example, provide the password when prompted:

```
CONNECT scott
ALTER SESSION SET CURRENT_SCHEMA = joe;
SELECT * FROM emp;
```

Because `emp` is not schema-qualified, the table name is resolved under schema `joe`. But if `scott` does not have select privilege on table `joe.emp`, then `scott` cannot execute the `SELECT` statement.

18.10 Managing Editions

Application developers who are upgrading their applications using edition-based redefinition may ask you to perform edition-related tasks that require DBA privileges.

- [About Editions and Edition-Based Redefinition](#)
Edition-based redefinition enables you to upgrade an application's database objects while the application is in use, thus minimizing or eliminating down time. This is accomplished by changing (redefining) database objects in a private environment known as an **edition**.
- [DBA Tasks for Edition-Based Redefinition](#)
A user must have the required privileges to perform tasks related to edition-based redefinition.
- [Setting the Database Default Edition](#)
There is always a default edition for the database. This is the edition that a database session initially uses if it does not explicitly indicate an edition when connecting.
- [Querying the Database Default Edition](#)
The database default edition is stored as a database property.

- [Setting the Edition Attribute of a Database Service](#)
You can set the edition attribute of a database service when you create the service, or you can modify an existing database service to set its edition attribute.
- [Using an Edition](#)
To view or modify objects in a particular edition, you must *use* the edition first. You can specify an edition to use when you connect to the database. If you do not specify an edition, then your session starts in the database default edition.
- [Editions Data Dictionary Views](#)
There are several data dictionary views that aid with managing editions.

18.10.1 About Editions and Edition-Based Redefinition

Edition-based redefinition enables you to upgrade an application's database objects while the application is in use, thus minimizing or eliminating down time. This is accomplished by changing (redefining) database objects in a private environment known as an **edition**.

Only when all changes have been made and tested do you make the new version of the application available to users.

 **See Also:**

Oracle Database Development Guide for a complete discussion of edition-based redefinition

18.10.2 DBA Tasks for Edition-Based Redefinition

A user must have the required privileges to perform tasks related to edition-based redefinition.

[Table 18-1](#) summarizes the edition-related tasks that require privileges typically granted only to DBAs. Any user that is granted the `DBA` role can perform these tasks.

Table 18-1 DBA Tasks for Edition-Based Redefinition

Task	See
Grant or revoke privileges to create, alter, and drop editions	The CREATE EDITION and DROP EDITION SQL statements
Enable editions for a schema	<i>Oracle Database Development Guide</i>
Set the database default edition	" Setting the Database Default Edition "
Set the edition attribute of a database service	" Setting the Edition Attribute of a Database Service "

18.10.3 Setting the Database Default Edition

There is always a default edition for the database. This is the edition that a database session initially uses if it does not explicitly indicate an edition when connecting.

To set the database default edition:

1. Connect to the database as a user with the `ALTER DATABASE` privilege and `USE` privilege `WITH GRANT OPTION` on the edition.
2. Enter the following statement:

```
ALTER DATABASE DEFAULT EDITION = edition_name;
```

 **See Also:**

["Connecting to the Database with SQL*Plus"](#)

18.10.4 Querying the Database Default Edition

The database default edition is stored as a database property.

To query the database default edition:

1. Connect to the database as any user.
2. Enter the following statement:

```
SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE
  PROPERTY_NAME = 'DEFAULT_EDITION';

PROPERTY_VALUE
-----
ORACLE$BASE
```

 **Note:**

The property name `DEFAULT_EDITION` is case sensitive and must be supplied as upper case.

18.10.5 Setting the Edition Attribute of a Database Service

You can set the edition attribute of a database service when you create the service, or you can modify an existing database service to set its edition attribute.

 Note:

The number of database services for an instance has an upper limit. See *Oracle Database Reference* for more information about this limit.

- [About Setting the Edition Attribute of a Database Service](#)

When you set the edition attribute of a service, all subsequent connections that specify the service, such as client connections and `DBMS_SCHEDULER` jobs, use this edition as the initial session edition. However, if a session connection specifies a different edition, then the edition specified in the session connection is used for the session edition.

- [Setting the Edition Attribute During Database Service Creation](#)

You can use the `SRVCTL` utility or the `DBMS_SERVICE` package to set the edition attribute of a database service when you create the service.

- [Setting the Edition Attribute of an Existing Database Service](#)

You can use the `SRVCTL` utility or the `DBMS_SERVICE` package to set the edition attribute of an existing database service.

18.10.5.1 About Setting the Edition Attribute of a Database Service

When you set the edition attribute of a service, all subsequent connections that specify the service, such as client connections and `DBMS_SCHEDULER` jobs, use this edition as the initial session edition. However, if a session connection specifies a different edition, then the edition specified in the session connection is used for the session edition.

To check the edition attribute of a database service, query the `EDITION` column in the `ALL_SERVICES` view or the `DBA_SERVICES` view.

18.10.5.2 Setting the Edition Attribute During Database Service Creation

You can use the `SRVCTL` utility or the `DBMS_SERVICE` package to set the edition attribute of a database service when you create the service.

Follow the instructions in "Creating Database Services" and use the appropriate option for setting the edition attribute for the database service:

- If your single-instance database is being managed by Oracle Restart, use the `SRVCTL` utility to create the database service and specify the `-edition` option to set its edition attribute.

For the database with the `DB_UNIQUE_NAME` of `dbcrm`, this example creates a new database service named `crmbatch` and sets the edition attribute of the database service to `e2`:

```
srvctl add service -db dbcrm -service crmbatch -edition e2
```

- If your single-instance database is not being managed by Oracle Restart, use the `DBMS_SERVICE.CREATE_SERVICE` procedure, and specify the `edition` parameter to set the edition attribute of the database service.

18.10.5.3 Setting the Edition Attribute of an Existing Database Service

You can use the `SRVCTL` utility or the `DBMS_SERVICE` package to set the edition attribute of an existing database service.

To set the edition attribute of an existing database service:

1. Stop the database service.
2. Set the edition attribute of the database service using the appropriate option:
 - If your single-instance database is being managed by Oracle Restart, use the `SRVCTL` utility to modify the database service and specify the `-edition` option to set its edition attribute.

For the database with the `DB_UNIQUE_NAME` of `dbcsm`, this example modifies a database service named `crmbatch` and sets the edition attribute of the service to `e3`:

```
srvctl modify service -db dbcsm -service crmbatch -edition e3
```

- If your single-instance database is not being managed by Oracle Restart, use the `DBMS_SERVICE.MODIFY_SERVICE` procedure, and specify the `edition` parameter to set the edition attribute of the database service. Ensure that the `modify_edition` parameter is set to `TRUE` when you run the `MODIFY_SERVICE` procedure.
3. Start the database service.

 **See Also:**

- [Configuring Automatic Restart of an Oracle Database](#) for information managing database services using Oracle Restart
- [Oracle Database PL/SQL Packages and Types Reference](#) for information about managing database services using the `DBMS_SERVICE` package

18.10.6 Using an Edition

To view or modify objects in a particular edition, you must use the edition first. You can specify an edition to use when you connect to the database. If you do not specify an edition, then your session starts in the database default edition.

To use a different edition, submit the following statement:

```
ALTER SESSION SET EDITION=edition_name;
```

The following statements first set the current edition to `e2` and then to `ora$base`:

```
ALTER SESSION SET EDITION=e2;
...
ALTER SESSION SET EDITION=ora$base;
```

 **See Also:**

- *Oracle Database Development Guide* for more information about using editions, and for instructions for determining the current edition
- "[Connecting to the Database with SQL*Plus](#)"

18.10.7 Editions Data Dictionary Views

There are several data dictionary views that aid with managing editions.

The following table lists three of them. For a complete list, see *Oracle Database Development Guide*.

View	Description
*_EDITIONS	Lists all editions in the database. (Note: USER_EDITIONS does not exist.)
*_OBJECTS	Describes every object in the database that is visible (actual or inherited) in the current edition.
*_OBJECTS_AE	Describes every actual object in the database, across all editions.

18.11 Displaying Information About Schema Objects

Oracle Database provides a PL/SQL package that enables you to determine the DDL that created an object and data dictionary views that you can use to display information about schema objects.

- [Using a PL/SQL Package to Display Information About Schema Objects](#)
The Oracle-supplied PL/SQL package procedure `DBMS_METADATA.GET_DDL` lets you obtain metadata (in the form of DDL used to create the object) about a schema object.
- [Schema Objects Data Dictionary Views](#)
These views display general information about schema objects.

18.11.1 Using a PL/SQL Package to Display Information About Schema Objects

The Oracle-supplied PL/SQL package procedure `DBMS_METADATA.GET_DDL` lets you obtain metadata (in the form of DDL used to create the object) about a schema object.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for a description of the `DBMS_METADATA` package

Example: Using the DBMS_METADATA Package

The DBMS_METADATA package is a powerful tool for obtaining the complete definition of a schema object. It enables you to obtain all of the attributes of an object in one pass. The object is described as DDL that can be used to (re)create it.

In the following statements the GET_DDL function is used to fetch the DDL for all tables in the current schema, filtering out nested tables and overflow segments. The SET_TRANSFORM_PARAM (with the handle value equal to DBMS_METADATA.SESSION_TRANSFORM meaning "for the current session") is used to specify that storage clauses are not to be returned in the SQL DDL. Afterwards, the session-level transform parameters are reset to their defaults. Once set, transform parameter values remain in effect until specifically reset to their defaults.

```
EXECUTE DBMS_METADATA.SET_TRANSFORM_PARAM(
    DBMS_METADATA.SESSION_TRANSFORM,'STORAGE',false);
SELECT DBMS_METADATA.GET_DDL('TABLE',u.table_name)
FROM USER_ALL_TABLES u
WHERE u.nested='NO'
AND (u.iot_type is null or u.iot_type='IOT');
EXECUTE DBMS_METADATA.SET_TRANSFORM_PARAM(
    DBMS_METADATA.SESSION_TRANSFORM,'DEFAULT');
```

The output from DBMS_METADATA.GET_DDL is a LONG data type. When using SQL*Plus, your output may be truncated by default. Issue the following SQL*Plus command before issuing the DBMS_METADATA.GET_DDL statement to ensure that your output is not truncated:

```
SQL> SET LONG 9999
```

18.11.2 Schema Objects Data Dictionary Views

These views display general information about schema objects.

View	Description
DBA_OBJECTS	DBA view describes all schema objects in the database. ALL view describes objects accessible to current user. USER view describes objects owned by the current user.
ALL_OBJECTS	
USER_OBJECTS	
DBA_CATALOG	List the name, type, and owner (USER view does not display owner) for all tables, views, synonyms, and sequences in the database.
ALL_CATALOG	
USER_CATALOG	
DBA_DEPENDENCIES	List all dependencies between procedures, packages, functions, package bodies, and triggers, including dependencies on views without any database links.
ALL_DEPENDENCIES	
USER_DEPENDENCIES	

- [Example 1: Displaying Schema Objects By Type](#)

You can query the USER_OBJECTS view to list all of the objects owned by the user issuing the query.

- [Example 2: Displaying Dependencies of Views and Synonyms](#)

When you create a view or a synonym, the view or synonym is based on its underlying base object. The ALL_DEPENDENCIES, USER_DEPENDENCIES, and

DBA_DEPENDENCIES data dictionary views can be used to reveal the dependencies for a view.

18.11.2.1 Example 1: Displaying Schema Objects By Type

You can query the USER_OBJECTS view to list all of the objects owned by the user issuing the query.

The following query lists all of the objects owned by the user issuing the query:

```
SELECT OBJECT_NAME, OBJECT_TYPE  
      FROM USER_OBJECTS;
```

The following is the query output:

OBJECT_NAME	OBJECT_TYPE
EMP_DEPT	CLUSTER
EMP	TABLE
DEPT	TABLE
EMP_DEPT_INDEX	INDEX
PUBLIC_EMP	SYNONYM
EMP_MGR	VIEW

18.11.2.2 Example 2: Displaying Dependencies of Views and Synonyms

When you create a view or a synonym, the view or synonym is based on its underlying base object. The ALL_DEPENDENCIES, USER_DEPENDENCIES, and DBA_DEPENDENCIES data dictionary views can be used to reveal the dependencies for a view.

The ALL_SYNONYMS, USER_SYNONYMS, and DBA_SYNONYMS data dictionary views can be used to list the base object of a synonym. For example, the following query lists the base objects for the synonyms created by user jward:

```
SELECT TABLE_OWNER, TABLE_NAME, SYNONYM_NAME  
      FROM DBA_SYNONYMS  
     WHERE OWNER = 'JWARD';
```

The following is the query output:

TABLE_OWNER	TABLE_NAME	SYNONYM_NAME
SCOTT	DEPT	DEPT
SCOTT	EMP	EMP

Managing Space for Schema Objects

Managing space for schema objects involves tasks such as managing tablespace alerts and space allocation, reclaiming unused space, dropping unused object storage, monitoring space usage, and capacity planning.

- **Managing Tablespace Alerts**

Oracle Database provides proactive help in managing disk space for tablespaces by alerting you when available space is running low.

- **Managing Resumable Space Allocation**

You can suspend, and later resume, the execution of large database operations.

- **Reclaiming Unused Space**

You can reclaim unused space. Segment Advisor, is an Oracle Database component that identifies segments that have space available for reclamation.

- **Dropping Unused Object Storage**

The DBMS_SPACE_ADMIN package includes the `DROP_EMPTY_SEGMENTS` procedure, which enables you to drop segments for empty tables and partitions that have been migrated from previous releases. This includes segments of dependent objects of the table, such as index segments, where possible.

- **Understanding Space Usage of Data Types**

When creating tables and other data structures, you must know how much space they will require. Each data type has different space requirements.

- **Displaying Information About Space Usage for Schema Objects**

Oracle Database provides data dictionary views and PL/SQL packages that allow you to display information about the space usage of schema objects.

- **Capacity Planning for Database Objects**

Oracle Database provides two ways to plan capacity for database objects: with Cloud Control or with the DBMS_SPACE PL/SQL package. Three procedures in the DBMS_SPACE package enable you to predict the size of new objects and monitor the size of existing database objects.

19.1 Managing Tablespace Alerts

Oracle Database provides proactive help in managing disk space for tablespaces by alerting you when available space is running low.

- **About Managing Tablespace Alerts**

Two alert thresholds are defined by default: **warning** and **critical**. The warning threshold is the limit at which space is beginning to run low. The critical threshold is a serious limit that warrants your immediate attention. The database issues alerts at both thresholds.

- **Setting Alert Thresholds**

For each tablespace, you can set just percent-full thresholds, just free-space-remaining thresholds, or both types of thresholds simultaneously. Setting either type of threshold to zero disables it.

- [Viewing Alerts](#)
You view alerts by accessing a Database Home page in Cloud Control and viewing the Incidents and Problems section.
- [Limitations](#)
Threshold-based alerts have the some limitations.

19.1.1 About Managing Tablespace Alerts

Two alert thresholds are defined by default: **warning** and **critical**. The warning threshold is the limit at which space is beginning to run low. The critical threshold is a serious limit that warrants your immediate attention. The database issues alerts at both thresholds.

There are two ways to specify alert thresholds for both locally managed and dictionary managed tablespaces:

- By percent full
For both warning and critical thresholds, when space used becomes greater than or equal to a percent of total space, an alert is issued.
- By free space remaining (in kilobytes (KB))
For both warning and critical thresholds, when remaining space falls below an amount in KB, an alert is issued. Free-space-remaining thresholds are more useful for very large tablespaces.

Alerts for locally managed tablespaces are server-generated. For dictionary managed tablespaces, Oracle Enterprise Manager Cloud Control (Cloud Control) provides this functionality. See "[Monitoring a Database with Server-Generated Alerts](#)" for more information.

New tablespaces are assigned alert thresholds as follows:

- **Locally managed tablespace**—When you create a new locally managed tablespace, it is assigned the default threshold values defined for the database. A newly created database has a default of 85% full for the warning threshold and 97% full for the critical threshold. Defaults for free space remaining thresholds for a new database are both zero (disabled). You can change these database defaults, as described later in this section.
- **Dictionary managed tablespace**—When you create a new dictionary managed tablespace, it is assigned the threshold values that Cloud Control lists for "All others" in the metrics categories "Tablespace Free Space (MB) (dictionary managed)" and "Tablespace Space Used (%) (dictionary managed)." You change these values on the Metric and Policy Settings page.

 **Note:**

In a database that is upgraded from Oracle 9*i* or earlier to Oracle Database 10*g* or later, database defaults for all locally managed tablespace alert thresholds are set to zero. This setting effectively disables the alert mechanism to avoid excessive alerts in a newly migrated database.

19.1.2 Setting Alert Thresholds

For each tablespace, you can set just percent-full thresholds, just free-space-remaining thresholds, or both types of thresholds simultaneously. Setting either type of threshold to zero disables it.

The ideal setting for the warning threshold is one that issues an alert early enough for you to resolve the problem before it becomes critical. The critical threshold should be one that issues an alert still early enough so that you can take immediate action to avoid loss of service.

To set alert threshold values for locally managed tablespaces:

- Do one of the following:
 - Use the Tablespaces page of Cloud Control.
See the Cloud Control online help for information about changing the space usage alert thresholds for a tablespace.
 - Use the `DBMS_SERVER_ALERT.SET_THRESHOLD` package procedure.
See *Oracle Database PL/SQL Packages and Types Reference* for details.

To set alert threshold values for dictionary managed tablespaces:

- Use the Tablespaces page of Cloud Control.
See the Cloud Control online help for information about changing the space usage alert thresholds for a tablespace.

Example - Setting an Alert Threshold with Cloud Control

You receive an alert in Cloud Control when a space usage threshold for a tablespace is reached. There are two types of space usage alerts that you can enable: **warning**, for when tablespace space is somewhat low, and **critical**, for when the tablespace is almost completely full and action must be taken immediately.

For both warning and critical alerts, you can specify alert thresholds in the following ways:

- By space used (%)

When space used becomes greater than or equal to a percentage of total space, an alert is issued.

- By free space (MB)

When remaining space falls below an amount (in MB), an alert is issued.

Free-space thresholds are more useful for large tablespaces. For example, for a 10 TB tablespace, setting the percentage full critical alert to as high as 99 percent means that the database would issue an alert when there is still 100 GB of free space remaining. Usually, 100 GB remaining would not be a critical situation, and the alert would not be useful. For this tablespace, it might be better to use a free-space threshold, which you could set to issue a critical alert when 5 GB of free space remains.

For both warning and critical alerts for a tablespace, you can enable either the space used threshold or the free-space threshold, or you can enable both thresholds.

To change space usage alert thresholds for tablespaces:

1. Go to the Database Home page.
2. From the **Administration** menu, select **Storage**, then **Tablespaces**.
The Tablespaces page appears.
3. Select the tablespace whose threshold you want to change, and then click **Edit**.
The Edit Tablespace page appears, showing the General subpage.
4. Click the **Thresholds** tab at the top of the page to display the Thresholds subpage.
5. In the Space Used (%) section, do one of the following:
 - Accept the default thresholds.
 - Select **Specify Thresholds**, and then enter a **Warning (%)** threshold and a **Critical (%)** threshold.
 - Select **Disable Thresholds** to disable the percentage full thresholds.
6. In the Free Space (MB) section, do one of the following:
 - Accept the default thresholds.
 - Select **Specify Thresholds**, and then enter a **Warning (MB)** threshold and a **Critical (MB)** threshold.
 - Select **Disable Thresholds** to disable the threshold for free space remaining.
7. Click **Apply**.

A confirmation message appears.

Example—Setting an Alert Threshold Value with a Package Procedure

The following example sets the free-space-remaining thresholds in the `USERS` tablespace to 10 MB (warning) and 2 MB (critical), and disables the percent-full thresholds. The `USERS` tablespace is a locally managed tablespace.

```
BEGIN
DBMS_SERVER_ALERT.SET_THRESHOLD(
    metrics_id          => DBMS_SERVER_ALERT.TABLESPACE_BYT_FREE,
    warning_operator    => DBMS_SERVER_ALERT.OPERATOR_LE,
    warning_value       => '10240',
    critical_operator   => DBMS_SERVER_ALERT.OPERATOR_LE,
    critical_value      => '2048',
    observation_period  => 1,
    consecutive_occurrences => 1,
    instance_name       => NULL,
    object_type         => DBMS_SERVER_ALERT.OBJECT_TYPE_TABLESPACE,
    object_name         => 'USERS');

DBMS_SERVER_ALERT.SET_THRESHOLD(
    metrics_id          => DBMS_SERVER_ALERT.TABLESPACE_PCT_FULL,
    warning_operator    => DBMS_SERVER_ALERT.OPERATOR_GT,
    warning_value       => '0',
    critical_operator   => DBMS_SERVER_ALERT.OPERATOR_GT,
    critical_value      => '0',
    observation_period  => 1,
    consecutive_occurrences => 1,
    instance_name       => NULL,
```

```
object_type      => DBMS_SERVER_ALERT.OBJECT_TYPE_TABLESPACE,  
object_name      => 'USERS' );  
END;  
/
```

 **Note:**

When setting nonzero values for percent-full thresholds, use the greater-than-or-equal-to operator, OPERATOR_GE.

Restoring a Tablespace to Database Default Thresholds

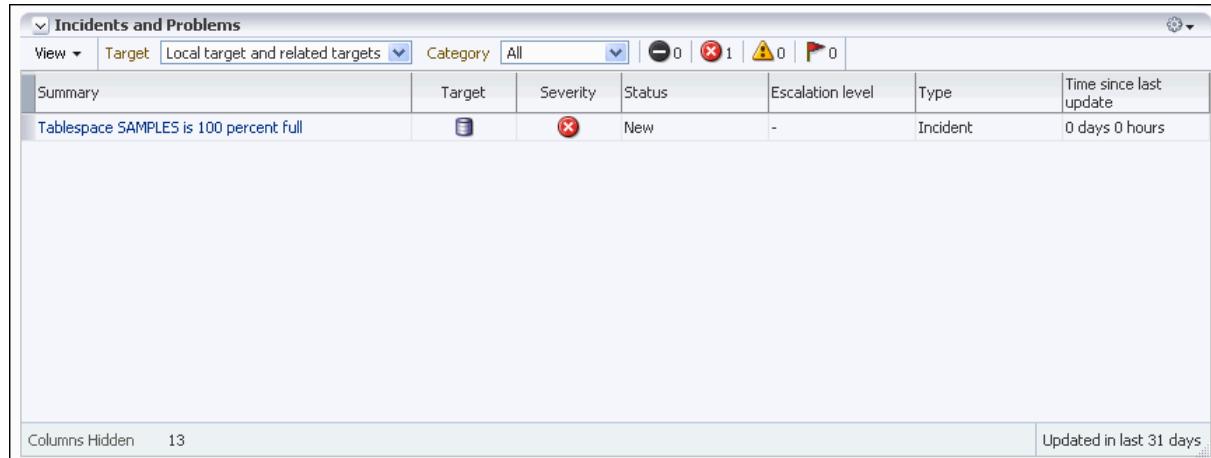

After explicitly setting values for locally managed tablespace alert thresholds, you can cause the values to revert to the database defaults by setting them to `NULL` with `DBMS_SERVER_ALERT.SET_THRESHOLD`.

Modifying Database Default Thresholds

To modify database default thresholds for locally managed tablespaces, invoke `DBMS_SERVER_ALERT.SET_THRESHOLD` as shown in the previous example, but set `object_name` to `NULL`. All tablespaces that use the database default are then switched to the new default.

19.1.3 Viewing Alerts

You view alerts by accessing a Database Home page in Cloud Control and viewing the Incidents and Problems section.

Summary	Target	Severity	Status	Escalation level	Type	Time since last update
Tablespace SAMPLES is 100 percent full		X	New	-	Incident	0 days 0 hours

You can also view alerts for locally managed tablespaces with the `DBA_OUTSTANDING_ALERTS` view. See "[Server-Generated Alerts Data Dictionary Views](#)" for more information.

19.1.4 Limitations

Threshold-based alerts have the some limitations.

These limitations include the following:

- Alerts are not issued for locally managed tablespaces that are offline or in read-only mode. However, the database reactivates the alert system for such tablespaces after they become read/write or available.
- When you take a tablespace offline or put it in read-only mode, you should disable the alerts for the tablespace by setting the thresholds to zero. You can then reenable the alerts by resetting the thresholds when the tablespace is once again online and in read/write mode.

 **See Also:**

- "[Monitoring a Database with Server-Generated Alerts](#)" for additional information on server-generated alerts in general
- *Oracle Database PL/SQL Packages and Types Reference* for information on the procedures of the `DBMS_SERVER_ALERT` package and how to use them
- "[Reclaiming Unused Space](#)" for various ways to reclaim space that is no longer being used in the tablespace
- "[Purging Objects in the Recycle Bin](#)" for information on reclaiming recycle bin space

19.2 Managing Resumable Space Allocation

You can suspend, and later resume, the execution of large database operations.

- [Resumable Space Allocation Overview](#)
Oracle Database provides a means for suspending, and later resuming, the execution of large database operations in the event of space allocation failures. Therefore, you can take corrective action instead of the Oracle Database server returning an error to the user. After the error condition is corrected, the suspended operation automatically resumes. This feature is called **resumable space allocation**. The statements that are affected are called resumable statements.
- [Enabling and Disabling Resumable Space Allocation](#)
You enable and disable resumable space allocation by running SQL statements and setting certain initialization parameters.
- [Using a LOGON Trigger to Set Default Resumable Mode](#)
Another method of setting default resumable mode, other than setting the `RESUMABLE_TIMEOUT` initialization parameter, is that you can register a database level `LOGON` trigger to alter a user's session to enable resumable and set a timeout interval.
- [Detecting Suspended Statements](#)
When a resumable statement is suspended, the error is not raised to the client. In order for corrective action to be taken, Oracle Database provides alternative methods for notifying users of the error and for providing information about the circumstances.

- [Operation-Suspended Alert](#)
When a resumable session is suspended, an operation-suspended alert is issued on the object that needs allocation of resource for the operation to complete.
- [Resumable Space Allocation Example: Registering an AFTER SUSPEND Trigger](#)
An example illustrates how to create a system wide AFTER SUSPEND trigger and register it as user `sys` at the database level.

19.2.1 Resumable Space Allocation Overview

Oracle Database provides a means for suspending, and later resuming, the execution of large database operations in the event of space allocation failures. Therefore, you can take corrective action instead of the Oracle Database server returning an error to the user. After the error condition is corrected, the suspended operation automatically resumes. This feature is called **resumable space allocation**. The statements that are affected are called resumable statements.

- [How Resumable Space Allocation Works](#)
An overview shows how resumable space allocation works.
- [What Operations are Resumable?](#)
Some operations are resumable.
- [What Errors are Correctable?](#)
Some errors are correctable.
- [Resumable Space Allocation and Distributed Operations](#)
In a distributed environment, if a user enables or disables resumable space allocation, or a DBA alters the `RESUMABLE_TIMEOUT` initialization parameter, then the local instance is affected. `RESUMABLE` cannot be enabled remotely.
- [Parallel Execution and Resumable Space Allocation](#)
In parallel execution, if one of the parallel execution server processes encounters a correctable error, then that server process suspends its execution.

19.2.1.1 How Resumable Space Allocation Works

An overview shows how resumable space allocation works.

1. A statement executes in resumable mode only if its session has been enabled for resumable space allocation by one of the following actions:
 - The `ALTER SESSION ENABLE RESUMABLE` statement is issued in the session before the statement executes when the `RESUMABLE_TIMEOUT` initialization parameter is set to a nonzero value.
 - The `ALTER SESSION ENABLE RESUMABLE TIMEOUT timeout_value` statement is issued in the session before the statement executes, and the `timeout_value` is a nonzero value.
2. A resumable statement is suspended when one of the following conditions occur (these conditions result in corresponding errors being signalled for non-resumable statements):
 - Out of space condition
 - Maximum extents reached condition
 - Space quota exceeded condition.

3. When the execution of a resumable statement is suspended, there are mechanisms to perform user supplied operations, log errors, and query the status of the statement execution. When a resumable statement is suspended the following actions are taken:
 - The error is reported in the alert log.
 - The system issues the Resumable Session Suspended alert.
 - If the user registered a trigger on the AFTER SUSPEND system event, the user trigger is executed. A user supplied PL/SQL procedure can access the error message data using the DBMS_RESUMABLE package and the DBA_OR_USER_RESUMABLE view.
4. Suspending a statement automatically results in suspending the transaction. Thus all transactional resources are held through a statement suspend and resume.
5. When the error condition is resolved (for example, as a result of user intervention or perhaps sort space released by other queries), the suspended statement automatically resumes execution and the Resumable Session Suspended alert is cleared.
6. A suspended statement can be forced to throw the exception using the DBMS_RESUMABLE.ABORT() procedure. This procedure can be called by a DBA, or by the user who issued the statement.
7. A suspension time out interval, specified by the RESUMABLE_TIMEOUT initialization parameter or by the timeout value in the ALTER SESSION ENABLE RESUMABLE TIMEOUT statement, is associated with resumable statements. A resumable statement that is suspended for the timeout interval wakes up and returns the exception to the user if the error condition is not resolved within the timeout interval.
8. A resumable statement can be suspended and resumed multiple times during execution.

19.2.1.2 What Operations are Resumable?

Some operations are resumable.

The following operations are resumable:

- Queries

SELECT statements that run out of temporary space (for sort areas) are candidates for resumable execution. When using OCI, the calls OCISqlExecute() and OCISqlFetch() are candidates.

- DML

INSERT, UPDATE, and DELETE statements are candidates. The interface used to execute them does not matter; it can be OCI, PL/SQL, or another interface. Also, INSERT INTO...SELECT from external tables can be resumable.

- Import/Export

As for SQL*Loader, a command line parameter controls whether statements are resumable after recoverable errors.

- DDL

The following statements are candidates for resumable execution:

- CREATE TABLE ... AS SELECT
- CREATE INDEX
- ALTER INDEX ... REBUILD
- ALTER TABLE ... MOVE PARTITION
- ALTER TABLE ... SPLIT PARTITION
- ALTER INDEX ... REBUILD PARTITION
- ALTER INDEX ... SPLIT PARTITION
- CREATE MATERIALIZED VIEW
- CREATE MATERIALIZED VIEW LOG

19.2.1.3 What Errors are Correctable?

Some errors are correctable.

There are three classes of correctable errors:

- Out of space condition

The operation cannot acquire any more extents for a table/index/temporary segment/undo segment/cluster/LOB/table partition/index partition in a tablespace. For example, the following errors fall in this category:

```
ORA-01653 unable to extend table ... in tablespace ...
ORA-01654 unable to extend index ... in tablespace ...
```

- Maximum extents reached condition

The number of extents in a table/index/temporary segment/undo segment/cluster/LOB/table partition/index partition equals the maximum extents defined on the object. For example, the following errors fall in this category:

```
ORA-01631 max # extents ... reached in table ...
ORA-01632 max # extents ... reached in index ...
```

- Space quota exceeded condition

The user has exceeded his assigned space quota in the tablespace. Specifically, this is noted by the following error:

```
ORA-01536 space quote exceeded for tablespace string
```

19.2.1.4 Resumable Space Allocation and Distributed Operations

In a distributed environment, if a user enables or disables resumable space allocation, or a DBA alters the RESUMABLE_TIMEOUT initialization parameter, then the local instance is affected. RESUMABLE cannot be enabled remotely.

In a distributed transaction, sessions on remote instances are suspended only if the remote instance has already enabled RESUMABLE on the instance or sessions at its site.

19.2.1.5 Parallel Execution and Resumable Space Allocation

In parallel execution, if one of the parallel execution server processes encounters a correctable error, then that server process suspends its execution.

Other parallel execution server processes will continue executing their respective tasks, until either they encounter an error or are blocked (directly or indirectly) by the suspended server process. When the correctable error is resolved, the suspended process resumes execution and the parallel operation continues execution. If the suspended operation is terminated, then the parallel operation aborts, throwing the error to the user.

Different parallel execution server processes may encounter one or more correctable errors. This may result in firing an `AFTER SUSPEND` trigger multiple times, in parallel. Also, if a parallel execution server process encounters a non-correctable error while another parallel execution server process is suspended, the suspended statement is immediately aborted.

For parallel execution, every parallel execution coordinator and server process has its own entry in the `DBA_` or `USER_RESUMABLE` view.

19.2.2 Enabling and Disabling Resumable Space Allocation

You enable and disable resumable space allocation by running SQL statements and setting certain initialization parameters.

- [About Enabling and Disabling Resumable Space Allocation](#)
Resumable space allocation is only possible when statements are executed within a session that has resumable mode enabled.
- [Setting the RESUMABLE_TIMEOUT Initialization Parameter](#)
You can specify a default system wide timeout interval by setting the `RESUMABLE_TIMEOUT` initialization parameter.
- [Using ALTER SESSION to Enable and Disable Resumable Space Allocation](#)
Within a session, a user can issue the `ALTER SESSION SET` statement to set the `RESUMABLE_TIMEOUT` initialization parameter and enable resumable space allocation, change a timeout value, or to disable resumable mode.

19.2.2.1 About Enabling and Disabling Resumable Space Allocation

Resumable space allocation is only possible when statements are executed within a session that has resumable mode enabled.

Resumable space allocation is enabled for a session when the `ALTER SESSION ENABLE RESUMABLE` statement is executed, and the `RESUMABLE_TIMEOUT` initialization parameter is set to a non-zero value for the session. When the `RESUMABLE_TIMEOUT` initialization parameter is set at the system level, it is the default for an `ALTER SESSION ENABLE RESUMABLE` statement that does not specify a timeout value. When an `ALTER SESSION ENABLE RESUMABLE` statement specifies a timeout value, it overrides the system default.

Resumable space allocation is disabled for a session in all of the following cases when the `ALTER SESSION ENABLE RESUMABLE` statement is executed:

- The session does not execute an `ALTER SESSION ENABLE RESUMABLE` statement.
- The session executes an `ALTER SESSION DISABLE RESUMABLE` statement.
- The session executes an `ALTER SESSION ENABLE RESUMABLE` statement, and the timeout value is zero.

 **Note:**

Because suspended statements can hold up some system resources, users must be granted the RESUMABLE system privilege before they are allowed to enable resumable space allocation and execute resumable statements.

19.2.2.2 Setting the RESUMABLE_TIMEOUT Initialization Parameter

You can specify a default system wide timeout interval by setting the RESUMABLE_TIMEOUT initialization parameter.

For example, the following setting of the RESUMABLE_TIMEOUT parameter in the initialization parameter file sets the timeout period to 1 hour:

```
RESUMABLE_TIMEOUT = 3600
```

If this parameter is set to 0, then resumable space allocation is disabled even for sessions that run an ALTER SESSION ENABLE RESUMABLE statement without a timeout value.

You can also use the ALTER SYSTEM SET statement to change the value of this parameter at the system level. For example, the following statement disables resumable space allocation for all sessions that run an ALTER SESSION ENABLE RESUMABLE statement without a timeout value:

```
ALTER SYSTEM SET RESUMABLE_TIMEOUT=0;
```

19.2.2.3 Using ALTER SESSION to Enable and Disable Resumable Space Allocation

Within a session, a user can issue the ALTER SESSION SET statement to set the RESUMABLE_TIMEOUT initialization parameter and enable resumable space allocation, change a timeout value, or to disable resumable mode.

A user can enable resumable mode for a session with the default system RESUMABLE_TIMEOUT value using the following SQL statement:

```
ALTER SESSION ENABLE RESUMABLE;
```

To disable resumable mode, a user issues the following statement:

```
ALTER SESSION DISABLE RESUMABLE;
```

The default for a new session is resumable mode disabled.

The user can also specify a timeout interval, and can provide a name used to identify a resumable statement. These are discussed separately in following sections.

- [Specifying a Timeout Interval](#)

When you enable resumable mode, you can set a timeout period, after which a suspended statement will error if no intervention has taken place.

- [Naming Resumable Statements](#)

Resumable statements can be identified by name.

 **See Also:**

["Using a LOGON Trigger to Set Default Resumable Mode"](#)

19.2.2.3.1 Specifying a Timeout Interval

When you enable resumable mode, you can set a timeout period, after which a suspended statement will error if no intervention has taken place.

The following statement specifies that resumable transactions will time out and error after 3600 seconds:

```
ALTER SESSION ENABLE RESUMABLE TIMEOUT 3600;
```

The value of `TIMEOUT` remains in effect until it is changed by another `ALTER SESSION ENABLE RESUMABLE` statement, it is changed by another means, or the session ends. If the `RESUMABLE_TIMEOUT` initialization parameter is not set, then the default timeout interval when using the `ENABLE RESUMABLE TIMEOUT` clause to enable resumable mode is 7200 seconds.

 **See Also:**

["Setting the `RESUMABLE_TIMEOUT` Initialization Parameter"](#) for other methods of changing the timeout interval for resumable space allocation

19.2.2.3.2 Naming Resumable Statements

Resumable statements can be identified by name.

The following statement assigns a name to resumable statements:

```
ALTER SESSION ENABLE RESUMABLE TIMEOUT 3600 NAME 'insert into table';
```

The `NAME` value remains in effect until it is changed by another `ALTER SESSION ENABLE RESUMABLE` statement, or the session ends. The default value for `NAME` is '`User username(userid), Session sessionid, Instance instanceid`'.

The name of the statement is used to identify the resumable statement in the `DBA_RESUMABLE` and `USER_RESUMABLE` views.

19.2.3 Using a LOGON Trigger to Set Default Resumable Mode

Another method of setting default resumable mode, other than setting the RESUMABLE_TIMEOUT initialization parameter, is that you can register a database level LOGON trigger to alter a user's session to enable resumable and set a timeout interval.

 **Note:**

If there are multiple triggers registered that change default mode and timeout for resumable statements, the result will be unspecified because Oracle Database does not guarantee the order of trigger invocation.

19.2.4 Detecting Suspended Statements

When a resumable statement is suspended, the error is not raised to the client. In order for corrective action to be taken, Oracle Database provides alternative methods for notifying users of the error and for providing information about the circumstances.

- [Notifying Users: The AFTER SUSPEND System Event and Trigger](#)

When a resumable statement encounters a correctable error, the system internally generates the AFTER SUSPEND system event. Users can register triggers for this event at both the database and schema level. If a user registers a trigger to handle this system event, the trigger is executed after a SQL statement has been suspended.

- [Using Views to Obtain Information About Suspended Statements](#)

You can query a set of views for information about the status of resumable statements.

- [Using the DBMS_RESUMABLE Package](#)

The DBMS_RESUMABLE package helps control resumable space allocation.

19.2.4.1 Notifying Users: The AFTER SUSPEND System Event and Trigger

When a resumable statement encounters a correctable error, the system internally generates the AFTER SUSPEND system event. Users can register triggers for this event at both the database and schema level. If a user registers a trigger to handle this system event, the trigger is executed after a SQL statement has been suspended.

SQL statements executed within a AFTER SUSPEND trigger are always non-resumable and are always autonomous. Transactions started within the trigger use the SYSTEM rollback segment. These conditions are imposed to overcome deadlocks and reduce the chance of the trigger experiencing the same error condition as the statement.

Users can use the USER_RESUMABLE or DBA_RESUMABLE views, or the DBMS_RESUMABLE.SPACE_ERROR_INFO function, within triggers to get information about the resumable statements.

Triggers can also call the DBMS_RESUMABLE package to terminate suspended statements and modify resumable timeout values. In the following example, the default system timeout is changed by creating a system wide AFTER SUSPEND trigger that calls DBMS_RESUMABLE to set the timeout to 3 hours:

```
CREATE OR REPLACE TRIGGER resumable_default_timeout
AFTER SUSPEND
ON DATABASE
BEGIN
    DBMS_RESUMABLE.SET_TIMEOUT(10800);
END;
/
```

 **See Also:**

Oracle Database PL/SQL Language Reference for information about triggers and system events

19.2.4.2 Using Views to Obtain Information About Suspended Statements

You can query a set of views for information about the status of resumable statements.

View	Description
DBA_RESUMABLE	These views contain rows for all currently executing or suspended resumable statements. They can be used by a DBA, AFTER SUSPEND trigger, or another session to monitor the progress of, or obtain specific information about, resumable statements.
USER_RESUMABLE	
V\$SESSION_WAIT	When a statement is suspended the session invoking the statement is put into a wait state. A row is inserted into this view for the session with the EVENT column containing "statement suspended, wait error to be cleared".

19.2.4.3 Using the DBMS_RESUMABLE Package

The DBMS_RESUMABLE package helps control resumable space allocation.

You can invoke the following procedures:

Procedure	Description
ABORT(sessionID)	This procedure aborts a suspended resumable statement. The parameter sessionID is the session ID in which the statement is executing. For parallel DML/DDL, sessionID is any session ID which participates in the parallel DML/DDL. Oracle Database guarantees that the ABORT operation always succeeds. It may be called either inside or outside of the AFTER SUSPEND trigger. The caller of ABORT must be the owner of the session with sessionID, have ALTER SYSTEM privilege, or have DBA privileges.
GET_SESSION_TIMEOUT(sessionID)	This function returns the current timeout value of resumable space allocation for the session with sessionID. This returned timeout is in seconds. If the session does not exist, this function returns -1.

Procedure	Description
SET_SESSION_TIMEOUT(sessionID , timeout)	This procedure sets the timeout interval of resumable space allocation for the session with sessionID. The parameter timeout is in seconds. The new timeout setting will apply to the session immediately. If the session does not exist, no action is taken.
GET_TIMEOUT()	This function returns the current timeout value of resumable space allocation for the current session. The returned value is in seconds.
SET_TIMEOUT(timeout)	This procedure sets a timeout value for resumable space allocation for the current session. The parameter timeout is in seconds. The new timeout setting applies to the session immediately.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for details about the DBMS_RESUMABLE package.

19.2.5 Operation-Suspended Alert

When a resumable session is suspended, an operation-suspended alert is issued on the object that needs allocation of resource for the operation to complete.

Once the resource is allocated and the operation completes, the operation-suspended alert is cleared. See "[Managing Tablespace Alerts](#)" for more information on system-generated alerts.

19.2.6 Resumable Space Allocation Example: Registering an AFTER SUSPEND Trigger

An example illustrates how to create a system wide AFTER SUSPEND trigger and register it as user SYS at the database level.

Whenever a resumable statement is suspended in any session, this trigger can have either of two effects:

- If an undo segment has reached its space limit, then a message is sent to the DBA and the statement is aborted.
- If any other recoverable error has occurred, the timeout interval is reset to 8 hours.

Here are the statements for this example:

```
CREATE OR REPLACE TRIGGER resumable_default
AFTER SUSPEND
ON DATABASE
DECLARE
/* declare transaction in this trigger is autonomous */
/* this is not required because transactions within a trigger
are always autonomous */
```

```

PRAGMA AUTONOMOUS_TRANSACTION;
cur_sid          NUMBER;
cur_inst         NUMBER;
errno            NUMBER;
err_type          VARCHAR2;
object_owner     VARCHAR2;
object_type       VARCHAR2;
table_space_name VARCHAR2;
object_name       VARCHAR2;
sub_object_name  VARCHAR2;
error_txt         VARCHAR2;
msg_body          VARCHAR2;
ret_value         BOOLEAN;
mail_conn         UTL_SMTP.CONNECTION;

BEGIN
    -- Get session ID
    SELECT DISTINCT(SID) INTO cur_SID FROM V$MYSTAT;

    -- Get instance number
    cur_inst := userenv('instance');

    -- Get space error information
    ret_value := DBMS_RESUMABLESPACE_ERROR_INFO(err_type, object_type, object_owner,
                                                table_space_name, object_name, sub_object_name);
    /*
    -- If the error is related to undo segments, log error, send email
    -- to DBA, and abort the statement. Otherwise, set timeout to 8 hours.
    --
    -- sys.rbs_error is a table which is to be
    -- created by a DBA manually and defined as
    -- (sql_text VARCHAR2(1000), error_msg VARCHAR2(4000),
    -- suspend_time DATE)
    */
    IF OBJECT_TYPE = 'UNDO SEGMENT' THEN
        /* LOG ERROR */
        INSERT INTO sys.rbs_error (
            SELECT SQL_TEXT, ERROR_MSG, SUSPEND_TIME
            FROM DBMS_RESUMABLE
            WHERE SESSION_ID = cur_sid AND INSTANCE_ID = cur_inst
        );
        SELECT ERROR_MSG INTO error_txt FROM DBMS_RESUMABLE
            WHERE SESSION_ID = cur_sid and INSTANCE_ID = cur_inst;

        -- Send email to recipient through UTL_SMTP package
        msg_body:='Subject: Space Error Occurred

Space limit reached for undo segment ' || object_name ||
on ' || TO_CHAR(SYSDATE, 'Month dd, YYYY, HH:MIam') ||
'. Error message was ' || error_txt;

        mail_conn := UTL_SMTP.OPEN_CONNECTION('localhost', 25);
        UTL_SMTP.HELO(mail_conn, 'localhost');
        UTL_SMTP.MAIL(mail_conn, 'sender@localhost');
        UTL_SMTP.RCPT(mail_conn, 'recipient@localhost');
        UTL_SMTP.DATA(mail_conn, msg_body);
        UTL_SMTP.QUIT(mail_conn);

        -- Abort the statement
        DBMS_RESUMABLE.ABORT(cur_sid);
    END IF;
END;
/

```

```
ELSE
    -- Set timeout to 8 hours
    DBMS_RESUMABLE.SET_TIMEOUT(28800);
END IF;

/* commit autonomous transaction */

19.3 Reclaiming Unused Space

You can reclaim unused space. Segment Advisor, is an Oracle Database component that identifies segments that have space available for reclamation.

- [About Reclaimable Unused Space](#)

Over time, updates and deletes on objects within a tablespace can create pockets of empty space that individually are not large enough to be reused for new data. This type of empty space is referred to as fragmented free space.

- [The Segment Advisor](#)

The Segment Advisor identifies segments that have space available for reclamation.

- [Shrinking Database Segments Online](#)

You use online segment shrink to reclaim fragmented free space below the high water mark in an Oracle Database segment.

- [Deallocating Unused Space](#)

When you deallocate unused space, the database frees the unused space at the unused (high water mark) end of the database segment and makes the space available for other segments in the tablespace.

19.3.1 About Reclaimable Unused Space

Over time, updates and deletes on objects within a tablespace can create pockets of empty space that individually are not large enough to be reused for new data. This type of empty space is referred to as fragmented free space.

Objects with fragmented free space can result in much wasted space, and can impact database performance. The preferred way to defragment and reclaim this space is to perform an **online segment shrink**. This process consolidates fragmented free space below the high water mark and compacts the segment. After compaction, the high water mark is moved, resulting in new free space above the high water mark. That space above the high water mark is then deallocated. The segment remains available for queries and DML during most of the operation, and no extra disk space need be allocated.

You use the **Segment Advisor** to identify segments that would benefit from online segment shrink. Only segments in locally managed tablespaces with automatic segment space management (ASSM) are eligible. Other restrictions on segment type exist. For more information, see "[Shrinking Database Segments Online](#)".

If a table with reclaimable space is not eligible for online segment shrink, or if you want to make changes to logical or physical attributes of the table while reclaiming space, then you can use **online table redefinition** as an alternative to segment shrink. Online redefinition is also referred to as **reorganization**. Unlike online segment shrink,

it requires extra disk space to be allocated. See "[Redefining Tables Online](#)" for more information.

19.3.2 The Segment Advisor

The Segment Advisor identifies segments that have space available for reclamation.

- [About the Segment Advisor](#)

The Segment Advisor performs its analysis by examining usage and growth statistics in the Automatic Workload Repository (AWR), and by sampling the data in the segment.

- [Using the Segment Advisor](#)

To use the Segment Advisor, check the results of Automatic Segment Advisor, and, optionally, run the Segment Advisor manually.

- [Automatic Segment Advisor](#)

The Automatic Segment Advisor is an automated maintenance task that is configured to run during all maintenance windows.

- [Running the Segment Advisor Manually](#)

You can manually run the Segment Advisor at any time with Cloud Control or with PL/SQL package procedure calls.

- [Viewing Segment Advisor Results](#)

The Segment Advisor creates several types of results: recommendations, findings, actions, and objects.

- [Configuring the Automatic Segment Advisor](#)

The Automatic Segment Advisor is an automated maintenance task. As such, you can use Cloud Control or PL/SQL package procedure calls to modify when (and if) this task runs. You can also control the resources allotted to it by modifying the appropriate resource plans.

- [Viewing Automatic Segment Advisor Information](#)

You can query views to display information specific to the Automatic Segment Advisor.

19.3.2.1 About the Segment Advisor

The Segment Advisor performs its analysis by examining usage and growth statistics in the Automatic Workload Repository (AWR), and by sampling the data in the segment.

It is configured to run during maintenance windows as an automated maintenance task, and you can also run it on demand (manually). The Segment Advisor automated maintenance task is known as the Automatic Segment Advisor. You can use this information for capacity planning and for arriving at an informed decision about which segments to shrink.

The Segment Advisor generates the following types of advice:

- If the Segment Advisor determines that an object has a significant amount of free space, it recommends online segment shrink. If the object is a table that is not eligible for shrinking, as in the case of a table in a tablespace without automatic segment space management, the Segment Advisor recommends online table redefinition.

- If the Segment Advisor determines that a table could benefit from compression with the advanced row compression method, it makes a recommendation to that effect. (Automatic Segment Advisor only. See "[Automatic Segment Advisor](#)".)
- If the Segment Advisor encounters a table with row chaining above a certain threshold, it records that fact that the table has an excess of chained rows.

 **Note:**

The Segment Advisor flags only the type of row chaining that results from updates that increase row length.

If you receive a space management alert, or if you decide that you want to reclaim space, you should start with the Segment Advisor.

19.3.2.2 Using the Segment Advisor

To use the Segment Advisor, check the results of Automatic Segment Advisor, and, optionally, run the Segment Advisor manually.

To use the Segment Advisor:

1. Check the results of the Automatic Segment Advisor.

To understand the Automatic Segment Advisor, see "[Automatic Segment Advisor](#)", later in this section. For details on how to view results, see "[Viewing Segment Advisor Results](#)".

2. (Optional) Obtain updated results on individual segments by rerunning the Segment Advisor manually.

See "[Running the Segment Advisor Manually](#)", later in this section.

19.3.2.3 Automatic Segment Advisor

The Automatic Segment Advisor is an automated maintenance task that is configured to run during all maintenance windows.

The Automatic Segment Advisor does not analyze every database object. Instead, it examines database statistics, samples segment data, and then selects the following objects to analyze:

- Tablespaces that have exceeded a critical or warning space threshold
- Segments that have the most activity
- Segments that have the highest growth rate

In addition, the Automatic Segment Advisor evaluates tables that are at least 10MB and that have at least three indexes to determine the amount of space saved if the tables are compressed with the advanced row compression method.

If an object is selected for analysis but the maintenance window expires before the Segment Advisor can process the object, the object is included in the next Automatic Segment Advisor run.

You cannot change the set of tablespaces and segments that the Automatic Segment Advisor selects for analysis. You can, however, enable or disable the Automatic

Segment Advisor task, change the times during which the Automatic Segment Advisor is scheduled to run, or adjust automated maintenance task system resource utilization. See "[Configuring the Automatic Segment Advisor](#)" for more information.

 **See Also:**

- ["Viewing Segment Advisor Results"](#)
- [Managing Automated Database Maintenance Tasks](#)
- ["Consider Using Table Compression"](#) for more information on advanced row compression

19.3.2.4 Running the Segment Advisor Manually

You can manually run the Segment Advisor at any time with Cloud Control or with PL/SQL package procedure calls.

Reasons to manually run the Segment Advisor include the following:

- You want to analyze a tablespace or segment that was not selected by the Automatic Segment Advisor.
- You want to repeat the analysis of an individual tablespace or segment to get more up-to-date recommendations.

You can request advice from the Segment Advisor at three levels:

- **Segment level**—Advice is generated for a single segment, such as an unpartitioned table, a partition or subpartition of a partitioned table, an index, or a LOB column.
- **Object level**—Advice is generated for an entire object, such as a table or index. If the object is partitioned, advice is generated on all the partitions of the object. In addition, if you run Segment Advisor manually from Cloud Control, you can request advice on the object's dependent objects, such as indexes and LOB segments for a table.
- **Tablespace level**—Advice is generated for every segment in a tablespace.

The `OBJECT_TYPE` column of [Table 19-2](#) shows the types of objects for which you can request advice.

- [Running the Segment Advisor Manually with Cloud Control](#)
You can run the Segment Advisor manually with Cloud Control
- [Running the Segment Advisor Manually with PL/SQL](#)
You can run the Segment Advisor with the `DBMS_ADVISOR` package.

19.3.2.4.1 Running the Segment Advisor Manually with Cloud Control

You can run the Segment Advisor manually with Cloud Control

You must have the `OEM_ADVISOR` role to run the Segment Advisor manually with Cloud Control. There are two ways to run the Segment Advisor:

- Using the Segment Advisor Wizard

This method enables you to request advice at the tablespace level or object level. At the object level, you can request advice on tables, indexes, table partitions, and index partitions.

- Using the Run Segment Advisor command on a schema object page.

For example, if you display a list of tables on the Tables page (accessible from the Schema menu), you can select a table and then select **Run Segment Advisor** from the Actions menu.

Figure 19-1 Tables page

Select	Schema	Table Name	Tablespace	Partitioned	Rows	Last Analyzed
<input checked="" type="radio"/>	HR	COUNTRIES	EXAMPLE	NO	25	Oct 4, 2012 1:42:44 PM PDT
<input type="radio"/>	HR	DEPARTMENTS	EXAMPLE	NO	27	Oct 4, 2012 1:42:44 PM PDT
<input type="radio"/>	HR	EMPLOYEES	EXAMPLE	NO	107	Oct 4, 2012 1:42:44 PM PDT

This method enables you to include the schema object's dependent objects in the Segment Advisor run. For example, if you select a table and select **Run Segment Advisor**, Cloud Control displays the table's dependent objects, such as partitions, index segments, LOB segments, and so on. You can then select dependent objects to include in the run.

In both cases, Cloud Control creates the Segment Advisor task as an Oracle Database Scheduler job. You can schedule the job to run immediately, or can take advantage of advanced scheduling features offered by the Scheduler.

To run the Segment Advisor manually with the Segment Advisor Wizard:

- Access the Database Home page.
- From the Performance menu, select **Advisors Home**.
The Advisor Central page appears. (See [Figure 19-2](#).)
- Under Advisors, click **Segment Advisor**.
The first page of the Segment Advisor wizard appears.
- Follow the wizard steps to schedule the Segment Advisor job, and then click **Submit** on the final wizard page.

The Advisor Central page reappears, with the new Segment Advisor job at the top of the list under the Results heading. The job status is SCHEDULED or RUNNING. (If you do not see your job, then use the search fields above the list to display it.)

5. Check the status of the job. If it is not COMPLETED, then use the **Refresh** control at the top of the page to refresh the page. (Do not use your browser's Refresh icon.)
- When the job status changes to COMPLETED, select the job by clicking in the **Select** column, and then click **View Result**.

Figure 19-2 Advisor Central page

The screenshot shows the Oracle Advisor Central interface. At the top, there are tabs for 'Advisors' (selected) and 'Checkers'. Below the tabs, there are buttons for 'View Data' and 'Real Time: 15 Second Refresh'. The main area is titled 'Advisors' and lists several advisor types: ADDM, Maximum Availability Architecture (MAA) Advisor, Segment Advisor, Streams Performance Advisor, Automatic Undo Management, Memory Advisors, SQL Advisors, Data Recovery Advisor, MTTR Advisor, and SQL Performance Analyzer.

Below this is a section titled 'Advisor Tasks' with a 'Search' field. The search field includes dropdowns for 'Advisory Type' (set to 'All Types'), 'Task Name', 'Advisor Runs' (set to 'Last 31 Days'), and 'Status' (set to 'All'). There is also a 'Go' button and a note about search behavior. A 'Change Default Parameters' link is located here.

The 'Results' section contains a table with columns: Select, Name, Advisory Type, Description, User, Status, Start Time, Duration (seconds), and Expires In (days). One row is shown, corresponding to the task 'SEGMENTADV_1437724' which is a Segment Advisor task named 'Get shrink advice based on object growth trend' run by user 'SYS' and completed on 'Oct 15, 2012 12:41:27 PM' with a duration of '2' seconds and expires in '30' days.

See Also:

[Scheduling Jobs with Oracle Scheduler](#) for more information about the advanced scheduling features of the Scheduler.

19.3.2.4.2 Running the Segment Advisor Manually with PL/SQL

You can run the Segment Advisor with the DBMS_ADVISOR package.

You use package procedures to create a Segment Advisor task, set task arguments, and then execute the task. You must have the ADVISOR privilege. [Table 19-1](#) shows the procedures that are relevant for the Segment Advisor. See *Oracle Database PL/SQL Packages and Types Reference* for more details on these procedures.

Table 19-1 DBMS_ADVISOR package procedures relevant to the Segment Advisor

Package Procedure Name	Description
CREATE_TASK	Use this procedure to create the Segment Advisor task. Specify 'Segment Advisor' as the value of the ADVISOR_NAME parameter.

Table 19-1 (Cont.) DBMS_ADVISOR package procedures relevant to the Segment Advisor

Package Procedure Name	Description
CREATE_OBJECT	<p>Use this procedure to identify the target object for segment space advice. The parameter values of this procedure depend upon the object type. Table 19-2 lists the parameter values for each type of object.</p> <p>Note: To request advice on an IOT overflow segment, use an object type of TABLE, TABLE PARTITION, or TABLE SUBPARTITION. Use the following query to find the overflow segment for an IOT and to determine the overflow segment table name to use with CREATE_OBJECT:</p> <pre>select table_name, iot_name, iot_type from dba_tables;</pre>
SET_TASK_PARAMETER	Use this procedure to describe the segment advice that you need. Table 19-3 shows the relevant input parameters of this procedure. Parameters not listed here are not used by the Segment Advisor.
EXECUTE_TASK	Use this procedure to execute the Segment Advisor task.

Table 19-2 Input Parameters for DBMS_ADVISOR.CREATE_OBJECT

OBJECT_TYPE	ATTR1	ATTR2	ATTR3	ATTR4
TABLESPACE	tablespace name	NULL	NULL	Unused. Specify NULL.
TABLE	schema name	table name	NULL	Unused. Specify NULL.
INDEX	schema name	index name	NULL	Unused. Specify NULL.
TABLE PARTITION	schema name	table name	table partition name	Unused. Specify NULL.
INDEX PARTITION	schema name	index name	index partition name	Unused. Specify NULL.
TABLE SUBPARTITION	schema name	table name	table subpartition name	Unused. Specify NULL.
INDEX SUBPARTITION	schema name	index name	index subpartition name	Unused. Specify NULL.
LOB	schema name	segment name	NULL	Unused. Specify NULL.
LOB PARTITION	schema name	segment name	lob partition name	Unused. Specify NULL.
LOB SUBPARTITION	schema name	segment name	lob subpartition name	Unused. Specify NULL.

Table 19-3 Input for DBMS_ADVISOR.SET_TASK_PARAMETER

Input Parameter	Description	Possible Values	Default Value
time_limit	The time limit for the Segment Advisor run, specified in seconds.	Any number of seconds	UNLIMITED
recommend_all	Whether the Segment Advisor should generate findings for all segments.	TRUE: Findings are generated on all segments specified, whether or not space reclamation is recommended. FALSE: Findings are generated only for those objects that generate recommendations for space reclamation.	TRUE

Example

The example that follows shows how to use the DBMS_ADVISOR procedures to run the Segment Advisor for the sample table hr.employees. The user executing these package procedures must have the EXECUTE object privilege on the package or the ADVISOR system privilege.

Note that passing an object type of TABLE to DBMS_ADVISOR.CREATE_OBJECT amounts to an object level request. If the table is not partitioned, the table segment is analyzed (without any dependent segments like index or LOB segments). If the table is partitioned, the Segment Advisor analyzes all table partitions and generates separate findings and recommendations for each.

```

variable id number;
begin
  declare
    name varchar2(100);
    descr varchar2(500);
    obj_id number;
  begin
    name:='Manual_Employees';
    descr:='Segment Advisor Example';

    dbms_advisor.create_task (
      advisor_name    => 'Segment Advisor',
      task_id         => :id,
      task_name       => name,
      task_desc       => descr);

    dbms_advisor.create_object (
      task_name       => name,
      object_type     => 'TABLE',

      attr4           => NULL,
      attr5           => NULL,
      object_id       => obj_id);

    dbms_advisor.set_task_parameter(
  
```

```

task_name      => name,
parameter      => 'recommend_all',
value          => 'TRUE');

dbms_advisor.execute_task(name);
end;
end;
/

```

19.3.2.5 Viewing Segment Advisor Results

The Segment Advisor creates several types of results: recommendations, findings, actions, and objects.

You can view results in the following ways:

- With Cloud Control
- By querying the `DBA_ADVISOR_*` views
- By calling the `DBMS_SPACE.ASA_RECOMMENDATIONS` function

[Table 19-4](#) describes the various result types and their associated `DBA_ADVISOR_*` views.

Table 19-4 Segment Advisor Result Types

Result Type	Associated View	Description
Recommendations	<code>DBA_ADVISOR_RECOMMENDATIONS</code>	If a segment would benefit from a segment shrink, reorganization, or compression, the Segment Advisor generates a recommendation for the segment. Table 19-5 shows examples of generated findings and recommendations.
Findings	<code>DBA_ADVISOR_FINDINGS</code>	Findings are a report of what the Segment Advisor observed in analyzed segments. Findings include space used and free space statistics for each analyzed segment. Not all findings result in a recommendation. (There may be only a few recommendations, but there could be many findings.) When running the Segment Advisor manually with PL/SQL, if you specify 'TRUE' for <code>recommend_all</code> in the <code>SET_TASK_PARAMETER</code> procedure, then the Segment Advisor generates a finding for each segment that qualifies for analysis, whether or not a recommendation is made for that segment. For row chaining advice, the Automatic Segment Advisor generates findings only, and not recommendations. If the Automatic Segment Advisor has no space reclamation recommendations to make, it does not generate findings. However, the Automatic Segment Advisor may generate findings for tables that could benefit from advanced row compression.
Actions	<code>DBA_ADVISOR_ACTIONS</code>	Every recommendation is associated with a suggested action to perform: either segment shrink, online redefinition (reorganization), or compression. The <code>DBA_ADVISOR_ACTIONS</code> view provides either the SQL that you can use to perform a segment shrink or table compression, or a suggestion to reorganize the object.

Table 19-4 (Cont.) Segment Advisor Result Types

Result Type	Associated View	Description
Objects	DBA_ADVISOR_OBJECTS	All findings, recommendations, and actions are associated with an object. If the Segment Advisor analyzes multiple segments, as with a tablespace or partitioned table, then one entry is created in the DBA_ADVISOR_OBJECTS view for each analyzed segment. Table 19-2 defines the columns in this view to query for information on the analyzed segments. You can correlate the objects in this view with the objects in the findings, recommendations, and actions views.

- [Viewing Segment Advisor Results with Cloud Control](#)

With Cloud Control, you can view Segment Advisor results for both Automatic Segment Advisor runs and manual Segment Advisor runs.

- [Viewing Segment Advisor Results by Querying the DBA_ADVISOR_* Views](#)

You can view Segment Advisor results by querying the DBA_ADVISOR_* views.

- [Viewing Segment Advisor Results with DBMS_SPACE.ASA_RECOMMENDATIONS](#)

The ASA_RECOMMENDATIONS procedure in the DBMS_SPACE package returns a nested table object that contains findings or recommendations for Automatic Segment Advisor runs and, optionally, manual Segment Advisor runs.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for details on the DBMS_SPACE.ASA_RECOMMENDATIONS function

19.3.2.5.1 Viewing Segment Advisor Results with Cloud Control

With Cloud Control, you can view Segment Advisor results for both Automatic Segment Advisor runs and manual Segment Advisor runs.

You can view the following types of results:

- All recommendations (multiple automatic and manual Segment Advisor runs)
- Recommendations from the last Automatic Segment Advisor run
- Recommendations from a specific run
- Row chaining findings

You can also view a list of the segments that were analyzed by the last Automatic Segment Advisor run.

To view Segment Advisor results with Cloud Control—All runs:

1. Access the Database Home page.
2. From the Administration menu, select **Storage**, then **Segment Advisor**.

The Segment Advisor Recommendations page appears. Recommendations are organized by tablespace.

3. If any recommendations are present, select a tablespace, and then click **Recommendation Details**.

The Recommendation Details page appears. You can initiate the recommended activity from this page (shrink or reorganize).

 **Note:**

Do not attempt to shrink or reorganize LOBs because doing so results in errors.

 **Tip:**

The list entries are sorted in descending order by reclaimable space. You can click column headings to change the sort order or to change from ascending to descending order.

To view Segment Advisor results with Cloud Control—Last Automatic Segment Advisor run:

1. Access the Database Home page.
2. From the Administration menu, select **Storage**, then **Segment Advisor**.

The Segment Advisor Recommendations page appears. Recommendations are organized by tablespace.

The Segment Advisor Recommendations page appears.

3. In the View list, select **Recommendations from Last Automatic Run**.
4. If any recommendations are present, select a tablespace and click **Recommendation Details**.

The Recommendation Details page appears. You can initiate the recommended activity from this page (shrink or reorganize).

 **Note:**

Do not attempt to shrink or reorganize LOBs because doing so results in errors.

To view Segment Advisor results with Cloud Control—Specific run:

1. Access the Database Home page.
 2. From the Performance menu, select **Advisors Home**.
- The Advisor Central page appears. (See [Figure 19-2](#).)
3. Check that your task appears in the list under the Results heading. If it does not, complete these steps:

- a. In the Search section of the page, under Advisor Type, select **Segment Advisor**.
- b. In the Advisor Runs list, select **All** or the desired time period.
- c. (Optional) Enter a task name.
- d. Click **Go**.

Your Segment Advisor task appears in the Results section.

4. Check the status of the job. If it is not **COMPLETED**, use the **Refresh** control at the top of the page to refresh the page. (Do not use your browser's Refresh icon.)
5. Click the task name.

The Segment Advisor Task page appears, with recommendations organized by tablespace.

6. Select a tablespace in the list, and then click **Recommendation Details**.

The Recommendation Details page appears. You can initiate the recommended activity from this page (shrink or reorganize).

To view row chaining findings:

1. Access the Database Home page.
2. From the Administration menu, select **Storage**, then **Segment Advisor**.

The Segment Advisor Recommendations page appears. Recommendations are organized by tablespace.

The Segment Advisor Recommendations page appears.

3. Under the Related Links heading, click **Chained Row Analysis**.

The Chained Row Analysis page appears, showing all segments that have chained rows, with a chained rows percentage for each.

19.3.2.5.2 Viewing Segment Advisor Results by Querying the DBA_ADVISOR_* Views

You can view Segment Advisor results by querying the DBA_ADVISOR_* views.

The headings of [Table 19-5](#) show the columns in the DBA_ADVISOR_* views that contain output from the Segment Advisor. See *Oracle Database Reference* for a description of these views. The table contents summarize the possible outcomes. In addition, [Table 19-2](#) defines the columns in the DBA_ADVISOR_OBJECTS view that contain information on the analyzed segments.

Before querying the DBA_ADVISOR_* views, you can check that the Segment Advisor task is complete by querying the STATUS column in DBA_ADVISOR_TASKS.

```
select task_name, status from dba_advisor_tasks
  where owner = 'STEVE' and advisor_name = 'Segment Advisor';
```

TASK_NAME	STATUS
Manual Employees	COMPLETED

The following example shows how to query the DBA_ADVISOR_* views to retrieve findings from all Segment Advisor runs submitted by user STEVE:

```
select af.task_name, ao.attr2 segname, ao.attr3 partition, ao.type, af.message
  from dba_advisor_findings af, dba_advisor_objects ao
 where ao.task_id = af.task_id
   and ao.object_id = af.object_id
   and ao.owner = 'STEVE';
```

TASK_NAME	SEGNAME	PARTITION	TYPE	MESSAGE
Manual_Employees	EMPLOYEES		TABLE	The free space in the object is less than 10MB.
Manual_Salestable4	SALESTABLE4	SALESTABLE4_P1	TABLE PARTITION	Perform shrink, estimated savings is 74444154 bytes.
Manual_Salestable4	SALESTABLE4	SALESTABLE4_P2	TABLE PARTITION	The free space in the object is less than 10MB.

Table 19-5 Segment Advisor Outcomes: Summary

MESSAGE column of DBA_ADVISOR_FINDINGS	MORE_INFO column of DBA_ADVISOR_FINDING S	BENEFIT_TYPE column of DBA_ADVISOR_RECOMMENDATIONS	ATTR1 column of DBA_ADVISOR_ACTIONS
Insufficient information to make a recommendation.	-	-	-

Compress object <i>object_name</i> , estimated savings is <i>xxx</i> bytes. (This outcome is generated by the Automatic Segment Advisor only)	Compress object <i>object_name</i> , estimated savings is <i>xxx</i> bytes.	-	The command to execute. For example: ALTER TABLE T1 ROW STORE COMPRESS ADVANCED For this finding, see also the ATTR2 column of DBA_ADVISOR_ACTIONS.

19.3.2.5.3 Viewing Segment Advisor Results with DBMS_SPACE.ASA_RECOMMENDATIONS

The ASA_RECOMMENDATIONS procedure in the DBMS_SPACE package returns a nested table object that contains findings or recommendations for Automatic Segment Advisor runs and, optionally, manual Segment Advisor runs.

Calling this procedure may be easier than working with the DBA_ADVISOR_* views, because the procedure performs all the required joins for you and returns information in an easily consumable format.

The following query returns recommendations by the most recent run of the Auto Segment Advisor, with the suggested command to run to follow the recommendations:

```
select tablespace_name, segment_name, segment_type, partition_name,
recommendations, c1 from
table(dbms_space.asa_recommendations('FALSE', 'FALSE', 'FALSE'));
```

TABLESPACE_NAME	SEGMENT_NAME	SEGMENT_TYPE
PARTITION_NAME		
RECOMMENDATIONS		
C1		
TVMDS_ASSM	ORDERS1	TABLE PARTITION
ORDERS1_P2		
Perform shrink, estimated savings is 57666422 bytes.		
alter table "STEVE"."ORDERS1" modify partition "ORDERS1_P2" shrink space		
TVMDS_ASSM	ORDERS1	TABLE PARTITION
ORDERS1_P1		
Perform shrink, estimated savings is 45083514 bytes.		
alter table "STEVE"."ORDERS1" modify partition "ORDERS1_P1" shrink space		
TVMDS_ASSM_NEW	ORDERS_NEW	TABLE
Perform shrink, estimated savings is 155398992 bytes.		
alter table "STEVE"."ORDERS_NEW" shrink space		
TVMDS_ASSM_NEW	ORDERS_NEW_INDEX	INDEX

```
Perform shrink, estimated savings is 102759445 bytes.  
alter index "STEVE"."ORDERS_NEW_INDEX" shrink space
```

See *Oracle Database PL/SQL Packages and Types Reference* for details on DBMS_SPACE.ASA_RECOMMENDATIONS.

19.3.2.6 Configuring the Automatic Segment Advisor

The Automatic Segment Advisor is an automated maintenance task. As such, you can use Cloud Control or PL/SQL package procedure calls to modify when (and if) this task runs. You can also control the resources allotted to it by modifying the appropriate resource plans.

You can call PL/SQL package procedures to make these changes, but the easier way to do so is to use Cloud Control.

To configure the Automatic Segment Advisor task with Cloud Control:

1. Log in to Cloud Control as user SYSTEM.
2. Access the Database Home page.
3. From the Administration menu, select **Storage**, then **Segment Advisor**.
The Segment Advisor Recommendations page appears.
4. Under the Related Links heading, click the link entitled **Automated Maintenance Tasks**.
The Automated Maintenance Tasks page appears.
5. Click **Configure**.
The Automated Maintenance Tasks Configuration page appears.

Window	Optimizer Statistics Gathering	Segment Advisor	Automatic SQL Tuning
MONDAY_WINDOW	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
TUESDAY_WINDOW	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
WEDNESDAY_WINDOW	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
THURSDAY_WINDOW	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
FRIDAY_WINDOW	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
SATURDAY_WINDOW	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
SUNDAY_WINDOW	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>

6. To completely disable the Automatic Segment Advisor, under Task Settings, select **Disabled** next to the Segment Advisor label, and then click **Apply**.
7. To disable the Automatic Segment Advisor for specific maintenance windows, clear the desired check boxes under the Segment Advisor column, and then click **Apply**.
8. To modify the start and end times and durations of maintenance windows, click **Edit Window Group**.

The Edit Window Group page appears. Click the name of a maintenance window, and then click **Edit** to change the window's schedule.

See Also:

- [Managing Automated Database Maintenance Tasks](#)

19.3.2.7 Viewing Automatic Segment Advisor Information

You can query views to display information specific to the Automatic Segment Advisor.

View	Description
DBA_AUTO_SEGADV_SUMMARY	Each row of this view summarizes one Automatic Segment Advisor run. Fields include number of tablespaces and segments processed, and number of recommendations made.

View	Description
DBA_AUTO_SEGADV_CTL	Contains control information that the Automatic Segment Advisor uses to select and process segments. Each row contains information on a single object (tablespace or segment), including whether the object has been processed, and if so, the task ID under which it was processed and the reason for selecting it.

19.3.3 Shrinking Database Segments Online

You use online segment shrink to reclaim fragmented free space below the high water mark in an Oracle Database segment.

The benefits of segment shrink are these:

- Compaction of data leads to better cache utilization, which in turn leads to better online transaction processing (OLTP) performance.
- The compacted data requires fewer blocks to be scanned in full table scans, which in turns leads to better decision support system (DSS) performance.

Segment shrink is an online, in-place operation. DML operations and queries can be issued during the data movement phase of segment shrink. Concurrent DML operations are blocked for a short time at the end of the shrink operation, when the space is deallocated. Indexes are maintained during the shrink operation and remain usable after the operation is complete. Segment shrink does not require extra disk space to be allocated.

Segment shrink reclaims unused space both above and below the high water mark. In contrast, space deallocation reclaims unused space only above the high water mark. In shrink operations, by default, the database compacts the segment, adjusts the high water mark, and releases the reclaimed space.

Segment shrink requires that rows be moved to new locations. Therefore, you must first enable row movement in the object you want to shrink and disable any rowid-based triggers defined on the object. You enable row movement in a table with the `ALTER TABLE ... ENABLE ROW MOVEMENT` command.

Shrink operations can be performed only on segments in locally managed tablespaces with automatic segment space management (ASSM). Within an ASSM tablespace, all segment types are eligible for online segment shrink except these:

- IOT mapping tables
- Tables with rowid based materialized views
- Tables with function-based indexes
- SECUREFILE LOBs
- Tables compressed with the following compression methods:
 - Basic table compression using `ROW STORE COMPRESS BASIC`
 - Warehouse compression using `COLUMN STORE COMPRESS FOR QUERY`
 - Archive compression using `COLUMN STORE COMPRESS FOR ARCHIVE`

However, tables compressed with advanced row compression using `ROW STORE COMPRESS ADVANCED` are eligible for online segment shrink. See "[Consider Using Table Compression](#)" for information about table compression methods.

 **Note:**

Shrinking database segments online might cause dependent database objects to become invalid. See "[About Object Dependencies and Object Invalidation](#)".

 **See Also:**

Oracle Database SQL Language Reference for more information on the `ALTER TABLE` command.

Invoking Online Segment Shrink

Before invoking online segment shrink, view the findings and recommendations of the Segment Advisor. For more information, see "[Using the Segment Advisor](#)".

You invoke online segment shrink with Cloud Control or with SQL commands in SQL*Plus. The remainder of this section discusses the command line method.

 **Note:**

You can invoke segment shrink directly from the Recommendation Details page in Cloud Control. Or, to invoke segment shrink for an individual table in Cloud Control, display the table on the Tables page, select the table, and then click **Shrink Segment** in the Actions list. (See [Figure 19-1](#).) Perform a similar operation in Cloud Control to shrink indexes, materialized views, and so on.

You can shrink space in a table, index-organized table, index, partition, subpartition, materialized view, or materialized view log. You do this using `ALTER TABLE`, `ALTER INDEX`, `ALTER MATERIALIZED VIEW`, or `ALTER MATERIALIZED VIEW LOG` statement with the `SHRINK SPACE` clause.

Two optional clauses let you control how the shrink operation proceeds:

- The `COMPACT` clause lets you divide the shrink segment operation into two phases. When you specify `COMPACT`, Oracle Database defragments the segment space and compacts the table rows but postpones the resetting of the high water mark and the deallocation of the space until a future time. This option is useful if you have long-running queries that might span the operation and attempt to read from blocks that have been reclaimed. The defragmentation and compaction results are saved to disk, so the data movement does not have to be redone during the second phase. You can reissue the `SHRINK SPACE` clause without the `COMPACT` clause during off-peak hours to complete the second phase.

- The CASCADE clause extends the segment shrink operation to all dependent segments of the object. For example, if you specify CASCADE when shrinking a table segment, all indexes of the table will also be shrunk. (You need not specify CASCADE to shrink the partitions of a partitioned table.) To see a list of dependent segments of a given object, you can run the OBJECT_DEPENDENT_SEGMENTS procedure of the DBMS_SPACE package.

As with other DDL operations, segment shrink causes subsequent SQL statements to be reparsed because of invalidation of cursors unless you specify the COMPACT clause.

Examples

Shrink a table and all of its dependent segments (including BASICFILE LOB segments):

```
ALTER TABLE employees SHRINK SPACE CASCADE;
```

Shrink a BASICFILE LOB segment only:

```
ALTER TABLE employees MODIFY LOB (perf_review) (SHRINK SPACE);
```

Shrink a single partition of a partitioned table:

```
ALTER TABLE customers MODIFY PARTITION cust_P1 SHRINK SPACE;
```

Shrink an IOT index segment and the overflow segment:

```
ALTER TABLE cities SHRINK SPACE CASCADE;
```

Shrink an IOT overflow segment only:

```
ALTER TABLE cities OVERFLOW SHRINK SPACE;
```

See Also:

- Oracle Database SQL Language Reference* for the syntax and restrictions of the ALTER TABLE, ALTER INDEX, ALTER MATERIALIZED VIEW, and ALTER MATERIALIZED VIEW LOG statements with the SHRINK SPACE clause
- Oracle Database SecureFiles and Large Objects Developer's Guide* for more information about LOB segments

19.3.4 Deallocating Unused Space

When you deallocate unused space, the database frees the unused space at the unused (high water mark) end of the database segment and makes the space available for other segments in the tablespace.

Before deallocation, you can run the UNUSED_SPACE procedure of the DBMS_SPACE package, which returns information about the position of the high water mark and the amount of unused space in a segment. For segments in locally managed tablespaces with automatic segment space management, use the SPACE_USAGE procedure for more accurate information on unused space.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference contains the description of the DBMS_SPACE package

The following statements deallocate unused space in a segment (table, index or cluster):

```
ALTER TABLE table DEALLOCATE UNUSED KEEP integer;
ALTER INDEX index DEALLOCATE UNUSED KEEP integer;
ALTER CLUSTER cluster DEALLOCATE UNUSED KEEP integer;
```

The KEEP clause is optional and lets you specify the amount of space retained in the segment. You can verify that the deallocated space is freed by examining the DBA_FREE_SPACE view.

 **See Also:**

- *Oracle Database SQL Language Reference* for details on the syntax and semantics of deallocating unused space
- *Oracle Database Reference* for more information about the DBA_FREE_SPACE view

19.4 Dropping Unused Object Storage

The DBMS_SPACE_ADMIN package includes the DROP_EMPTY_SEGMENTS procedure, which enables you to drop segments for empty tables and partitions that have been migrated from previous releases. This includes segments of dependent objects of the table, such as index segments, where possible.

The following example drops empty segments from every table in the database.

```
BEGIN
    DBMS_SPACE_ADMIN.DROP_EMPTY_SEGMENTS();
END;
```

The following drops empty segments from the HR.EMPLOYEES table, including dependent objects.

```
BEGIN
    DBMS_SPACE_ADMIN.DROP_EMPTY_SEGMENTS(
        schema_name  => 'HR',
        table_name   => 'EMPLOYEES');
END;
```

This procedure requires 11.2.0 or higher compatibility level.

 **See Also:**

See *Oracle Database PL/SQL Packages and Types Reference* for details about this procedure

19.5 Understanding Space Usage of Data Types

When creating tables and other data structures, you must know how much space they will require. Each data type has different space requirements.

The *Oracle Database PL/SQL Language Reference* and *Oracle Database SQL Language Reference* contain extensive descriptions of data types and their space requirements.

19.6 Displaying Information About Space Usage for Schema Objects

Oracle Database provides data dictionary views and PL/SQL packages that allow you to display information about the space usage of schema objects.

- [Using PL/SQL Packages to Display Information About Schema Object Space Usage](#)
A set of `DBMS_SPACE` subprograms provide information about schema objects.
- [Schema Objects Space Usage Data Dictionary Views](#)
A set of data dictionary views display information about space usage in schema objects.

19.6.1 Using PL/SQL Packages to Display Information About Schema Object Space Usage

A set of `DBMS_SPACE` subprograms provide information about schema objects.

Package and Procedure/Function	Description
<code>DBMS_SPACE.UNUSED_SPACE</code>	Returns information about unused space in an object (table, index, or cluster).
<code>DBMS_SPACE.FREE_BLOCKS</code>	Returns information about free data blocks in an object (table, index, or cluster) whose segment free space is managed by free lists (segment space management is <code>MANUAL</code>).
<code>DBMS_SPACE.SPACE_USAGE</code>	Returns information about free data blocks in an object (table, index, or cluster) whose segment space management is <code>AUTO</code> .

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for a description of the DBMS_SPACE package

Example: Using DBMS_SPACE.UNUSED_SPACE

The following SQL*Plus example uses the DBMS_SPACE package to obtain unused space information.

```
SQL> VARIABLE total_blocks NUMBER
SQL> VARIABLE total_bytes NUMBER
SQL> VARIABLE unused_blocks NUMBER
SQL> VARIABLE unused_bytes NUMBER
SQL> VARIABLE lastextf NUMBER
SQL> VARIABLE last_extb NUMBER
SQL> VARIABLE lastusedblock NUMBER
SQL> exec DBMS_SPACE.UNUSED_SPACE('SCOTT', 'EMP', 'TABLE', :total_blocks, -
> :total_bytes,:unused_blocks, :unused_bytes, :lastextf, -
> :last_extb, :lastusedblock);

PL/SQL procedure successfully completed.

SQL> PRINT

TOTAL_BLOCKS
-----
5

TOTAL_BYTES
-----
10240

...
LASTUSEDBLOCK
-----
3
```

19.6.2 Schema Objects Space Usage Data Dictionary Views

A set of data dictionary views display information about space usage in schema objects.

These views display information about space usage in schema objects:

View	Description
DBA_SEGMENTS	DBA view describes storage allocated for all database segments. User view describes storage allocated for segments for the current user.
USER_SEGMENTS	
DBA_EXTENTS	DBA view describes extents comprising all segments in the database. User view describes extents comprising segments for the current user.
USER_EXTENTS	

View	Description
DBA_FREE_SPACE	DBA view lists free extents in all tablespaces. User view shows free space information for tablespaces for which the user has quota.
USER_FREE_SPACE	

- **Example 1: Displaying Segment Information**

You can query the DBA_SEGMENTS view to display segment information.

- **Example 2: Displaying Extent Information**

You can query the DBA_EXTENTS data dictionary view for information about the currently allocated extents in a database.

- **Example 3: Displaying the Free Space (Extents) in a Tablespace**

You can query the DBA_FREE_SPACE data dictionary view for information about the free extents (extents not allocated to any segment) in a database.

19.6.2.1 Example 1: Displaying Segment Information

You can query the DBA_SEGMENTS view to display segment information.

The following query returns the name and size of each index segment in schema hr:

```
SELECT SEGMENT_NAME, TABLESPACE_NAME, BYTES, BLOCKS, EXTENTS
  FROM DBA_SEGMENTS
 WHERE SEGMENT_TYPE = 'INDEX'
   AND OWNER='HR'
 ORDER BY SEGMENT_NAME;
```

The query output is:

SEGMENT_NAME	TABLESPACE_NAME	BYTES	BLOCKS	EXTENTS
COUNTRY_C_ID_PK	EXAMPLE	65536	32	1
DEPT_ID_PK	EXAMPLE	65536	32	1
DEPT_LOCATION_IX	EXAMPLE	65536	32	1
EMP_DEPARTMENT_IX	EXAMPLE	65536	32	1
EMP_EMAIL_UK	EXAMPLE	65536	32	1
EMP_EMP_ID_PK	EXAMPLE	65536	32	1
EMP_JOB_IX	EXAMPLE	65536	32	1
EMP_MANAGER_IX	EXAMPLE	65536	32	1
EMP_NAME_IX	EXAMPLE	65536	32	1
JHIST_DEPARTMENT_IX	EXAMPLE	65536	32	1
JHIST_EMPLOYEE_IX	EXAMPLE	65536	32	1
JHIST_EMP_ID_ST_DATE_PK	EXAMPLE	65536	32	1
JHIST_JOB_IX	EXAMPLE	65536	32	1
JOB_ID_PK	EXAMPLE	65536	32	1
LOC_CITY_IX	EXAMPLE	65536	32	1
LOC_COUNTRY_IX	EXAMPLE	65536	32	1
LOC_ID_PK	EXAMPLE	65536	32	1
LOC_STATE_PROVINCE_IX	EXAMPLE	65536	32	1
REG_ID_PK	EXAMPLE	65536	32	1

19 rows selected.

19.6.2.2 Example 2: Displaying Extent Information

You can query the `DBA_EXTENTS` data dictionary view for information about the currently allocated extents in a database.

For example, the following query identifies the extents allocated to each index segment in the `hr` schema and the size of each of those extents:

```
SELECT SEGMENT_NAME, SEGMENT_TYPE, TABLESPACE_NAME, EXTENT_ID, BYTES, BLOCKS
  FROM DBA_EXTENTS
 WHERE SEGMENT_TYPE = 'INDEX'
   AND OWNER='HR'
 ORDER BY SEGMENT_NAME;
```

The query output is:

SEGMENT_NAME	SEGMENT_TYPE	TABLESPACE_NAME	EXTENT_ID	BYTES	BLOCKS
COUNTRY_C_ID_PK	INDEX	EXAMPLE	0	65536	32
DEPT_ID_PK	INDEX	EXAMPLE	0	65536	32
DEPT_LOCATION_IX	INDEX	EXAMPLE	0	65536	32
EMP_DEPARTMENT_IX	INDEX	EXAMPLE	0	65536	32
EMP_EMAIL_UK	INDEX	EXAMPLE	0	65536	32
EMP_EMP_ID_PK	INDEX	EXAMPLE	0	65536	32
EMP_JOB_IX	INDEX	EXAMPLE	0	65536	32
EMP_MANAGER_IX	INDEX	EXAMPLE	0	65536	32
EMP_NAME_IX	INDEX	EXAMPLE	0	65536	32
JHIST_DEPARTMENT_IX	INDEX	EXAMPLE	0	65536	32
JHIST_EMPLOYEE_IX	INDEX	EXAMPLE	0	65536	32
JHIST_EMP_ID_ST_DATE_PK	INDEX	EXAMPLE	0	65536	32
JHIST_JOB_IX	INDEX	EXAMPLE	0	65536	32
JOB_ID_PK	INDEX	EXAMPLE	0	65536	32
LOC_CITY_IX	INDEX	EXAMPLE	0	65536	32
LOC_COUNTRY_IX	INDEX	EXAMPLE	0	65536	32
LOC_ID_PK	INDEX	EXAMPLE	0	65536	32
LOC_STATE_PROVINCE_IX	INDEX	EXAMPLE	0	65536	32
REG_ID_PK	INDEX	EXAMPLE	0	65536	32

19 rows selected.

For the `hr` schema, no segment has multiple extents allocated to it.

19.6.2.3 Example 3: Displaying the Free Space (Extents) in a Tablespace

You can query the `DBA_FREE_SPACE` data dictionary view for information about the free extents (extents not allocated to any segment) in a database.

For example, the following query reveals the amount of free space available as free extents in the `SMUNDO` tablespace:

```
SELECT TABLESPACE_NAME, FILE_ID, BYTES, BLOCKS
  FROM DBA_FREE_SPACE
 WHERE TABLESPACE_NAME='SMUNDO';
```

The query output is:

TABLESPACE_NAME	FILE_ID	BYTES	BLOCKS
SMUNDO	3	65536	32

```

SMUNDO          3    65536    32
SMUNDO          3   131072    64
SMUNDO          3   131072    64
SMUNDO          3    65536    32
SMUNDO          3  3407872   1664

```

10 rows selected.

19.7 Capacity Planning for Database Objects

Oracle Database provides two ways to plan capacity for database objects: with Cloud Control or with the `DBMS_SPACE` PL/SQL package. Three procedures in the `DBMS_SPACE` package enable you to predict the size of new objects and monitor the size of existing database objects.

This documentation discusses the PL/SQL method. See Cloud Control online help and "[Using the Segment Advisor](#)" for details on capacity planning with Cloud Control.

- [Estimating the Space Use of a Table](#)

The size of a database table can vary greatly depending on tablespace storage attributes, tablespace block size, and many other factors. The `CREATE_TABLE_COST` procedure of the `DBMS_SPACE` package lets you estimate the space use cost of creating a table.

- [Estimating the Space Use of an Index](#)

The `CREATE_INDEX_COST` procedure of the `DBMS_SPACE` package lets you estimate the space use cost of creating an index on an existing table.

- [Obtaining Object Growth Trends](#)

The `OBJECT_GROWTH_TREND` function of the `DBMS_SPACE` package produces a table of one or more rows, where each row describes the space use of the object at a specific time.

19.7.1 Estimating the Space Use of a Table

The size of a database table can vary greatly depending on tablespace storage attributes, tablespace block size, and many other factors. The `CREATE_TABLE_COST` procedure of the `DBMS_SPACE` package lets you estimate the space use cost of creating a table.

See *Oracle Database PL/SQL Packages and Types Reference* for details on the parameters of this procedure.

The procedure has two variants. The first variant uses average row size to estimate size. The second variant uses column information to estimate table size. Both variants require as input the following values:

- `TABLESPACE_NAME`: The tablespace in which the object will be created. The default is the `SYSTEM` tablespace.
- `ROW_COUNT`: The anticipated number of rows in the table.
- `PCT_FREE`: The percentage of free space you want to reserve in each block for future expansion of existing rows due to updates.

In addition, the first variant also requires as input a value for `AVG_ROW_SIZE`, which is the anticipated average row size in bytes.

The second variant also requires for each anticipated column values for `COLINFOS`, which is an object type comprising the attributes `COL_TYPE` (the data type of the column) and `COL_SIZE` (the number of characters or bytes in the column).

The procedure returns two values:

- `USED_BYTES`: The actual bytes used by the data, including overhead for block metadata, `PCT_FREE` space, and so forth.
- `ALLOC_BYTES`: The amount of space anticipated to be allocated for the object taking into account the tablespace extent characteristics.

 **Note:**

The default size of the first extent of any new segment for a partitioned table is 8 MB instead of 64 KB. This helps improve performance of inserts and queries on partitioned tables. Although partitioned tables will start with a larger initial size, once sufficient data is inserted, the space consumption will be the same as in previous releases. You can override this default by setting the `INITIAL` size in the storage clause for the table. This new default only applies to table partitions and LOB partitions.

19.7.2 Estimating the Space Use of an Index

The `CREATE_INDEX_COST` procedure of the `DBMS_SPACE` package lets you estimate the space use cost of creating an index on an existing table.

The procedure requires as input the following values:

- `DDL`: The `CREATE INDEX` statement that would create the index. The table specified in this DDL statement must be an existing table.
- [Optional] `PLAN_TABLE`: The name of the plan table to use. The default is `NULL`.

The results returned by this procedure depend on statistics gathered on the segment. Therefore, be sure to obtain statistics shortly before executing this procedure. In the absence of recent statistics, the procedure does not issue an error, but it may return inappropriate results. The procedure returns the following values:

- `USED_BYTES`: The number of bytes representing the actual index data.
- `ALLOC_BYTES`: The amount of space allocated for the index in the tablespace.

19.7.3 Obtaining Object Growth Trends

The `OBJECT_GROWTH_TREND` function of the `DBMS_SPACE` package produces a table of one or more rows, where each row describes the space use of the object at a specific time.

The function retrieves the space use totals from the Automatic Workload Repository or computes current space use and combines it with historic space use changes retrieved from Automatic Workload Repository. See *Oracle Database PL/SQL*

Packages and Types Reference for detailed information on the parameters of this function.

The function requires as input the following values:

- **OBJECT_OWNER**: The owner of the object.
- **OBJECT_NAME**: The name of the object.
- **PARTITION_NAME**: The name of the table or index partition, if relevant. Specify `NULL` otherwise.
- **OBJECT_TYPE**: The type of the object.
- **START_TIME**: A `TIMESTAMP` value indicating the beginning of the growth trend analysis.
- **END_TIME**: A `TIMESTAMP` value indicating the end of the growth trend analysis. The default is "NOW".
- **INTERVAL**: The length in minutes of the reporting interval during which the function should retrieve space use information.
- **SKIP_INTERPOLATED**: Determines whether the function should omit values based on recorded statistics before and after the `INTERVAL` ('YES') or not ('NO'). This setting is useful when the result table will be displayed as a table rather than a chart, because you can see more clearly how the actual recording interval relates to the requested reporting interval.

The function returns a table, each of row of which provides space use information on the object for one interval. If the return table is very large, the results are pipelined so that another application can consume the information as it is being produced. The output table has the following columns:

- **TIMEPOINT**: A `TIMESTAMP` value indicating the time of the reporting interval. Records are not produced for values of `TIME` that precede the oldest recorded statistics for the object.
- **SPACE_USAGE**: The number of bytes actually being used by the object data.
- **SPACE_ALLOC**: The number of bytes allocated to the object in the tablespace at that time.
- **QUALITY**: A value indicating how well the requested reporting interval matches the actual recording of statistics. This information is useful because there is no guaranteed reporting interval for object size use statistics, and the actual reporting interval varies over time and from object to object.

The values of the `QUALITY` column are:

- — **GOOD**: The value whenever the value of `TIME` is based on recorded statistics with a recorded timestamp within 10% of the `INTERVAL` specified in the input parameters.
- **INTERPOLATED**: The value did not meet the criteria for `GOOD`, but was based on recorded statistics before and after the value of `TIME`. Current in-memory statistics can be collected across all instances in a cluster and treated as the "recorded" value for the present time.
- **PROJECTION**: The value of `TIME` is in the future as of the time the table was produced. In an Oracle Real Application Clusters environment, the rules for

recording statistics allow each instance to choose independently which objects will be selected.

The output returned by this function is an aggregation of values recorded across all instances in an Oracle RAC environment. Each value can be computed from a combination of GOOD and INTERPOLATED values. The aggregate value returned is marked GOOD if at least 80% of that value was derived from GOOD instance values.

Managing Tables

Managing tables includes tasks such as creating tables, loading tables, altering tables, and dropping tables.

Live SQL:

To view and run examples related to the ones in this chapter on Oracle Live SQL, go to [Oracle Live SQL: Creating and Modifying Tables](#).

- [About Tables](#)

Tables are the basic unit of data storage in an Oracle Database. Data is stored in rows and columns.

- [Guidelines for Managing Tables](#)

Following guidelines can make the management of your tables easier and can improve performance when creating the table, as well as when loading, updating, and querying the table data.

- [Creating Tables](#)

Create tables using the SQL statement `CREATE TABLE`.

- [Loading Tables](#)

There are several techniques for loading data into tables.

- [Optimizing the Performance of Bulk Updates](#)

The `EXECUTE_UPDATE` procedure in the `DBMS_REDEFINITION` package can optimize the performance of bulk updates to a table. Performance is optimized because the updates are not logged in the redo log.

- [Automatically Collecting Statistics on Tables](#)

The PL/SQL package `DBMS_STATS` lets you generate and manage statistics for cost-based optimization. You can use this package to gather, modify, view, export, import, and delete statistics. You can also use this package to identify or name statistics that have been gathered.

- [Altering Tables](#)

You alter a table using the `ALTER TABLE` statement. To alter a table, the table must be contained in your schema, or you must have either the `ALTER` object privilege for the table or the `ALTER ANY TABLE` system privilege.

- [Redefining Tables Online](#)

You can modify the logical or physical structure of a table.

- [Researching and Reversing Erroneous Table Changes](#)

To enable you to research and reverse erroneous changes to tables, Oracle Database provides a group of features that you can use to view past states of database objects or to return database objects to a previous state without using point-in-time media recovery. These features are known as **Oracle Flashback features**.

- [Recovering Tables Using Oracle Flashback Table](#)
Oracle Flashback Table enables you to restore a table to its state as of a previous point in time.
- [Dropping Tables](#)
To drop a table that you no longer need, use the `DROP TABLE` statement.
- [Using Flashback Drop and Managing the Recycle Bin](#)
When you drop a table, the database does not immediately remove the space associated with the table. The database renames the table and places it and any associated objects in a recycle bin, where, in case the table was dropped in error, it can be recovered at a later time. This feature is called Flashback Drop, and the `FLASHBACK TABLE` statement is used to restore the table.
- [Managing Index-Organized Tables](#)
An index-organized table's storage organization is a variant of a primary B-tree index. Unlike a heap-organized table, data is stored in primary key order.
- [Managing External Tables](#)
External tables do not reside in the database.
- [Tables Data Dictionary Views](#)
You can query a set of data dictionary views for information about tables.

20.1 About Tables

Tables are the basic unit of data storage in an Oracle Database. Data is stored in rows and columns.

You define a table with a table name, such as `employees`, and a set of columns. You give each column a column name, such as `employee_id`, `last_name`, and `job_id`; a data type, such as `VARCHAR2`, `DATE`, or `NUMBER`; and a width. The width can be predetermined by the data type, as in `DATE`. If columns are of the `NUMBER` data type, define precision and scale instead of width. A row is a collection of column information corresponding to a single record.

You can specify rules for each column of a table. These rules are called integrity constraints. One example is a `NOT NULL` integrity constraint. This constraint forces the column to contain a value in every row.

You can invoke Transparent Data Encryption to encrypt data before storing it. If users attempt to circumvent the database access control mechanisms by looking inside Oracle data files directly with operating system tools, encryption prevents these users from viewing sensitive data.

Tables can also include virtual columns. A **virtual column** is like any other table column, except that its value is derived by evaluating an expression. The expression can include columns from the same table, constants, SQL functions, and user-defined PL/SQL functions. You cannot explicitly write to a virtual column.

Some column types, such as `LOBS`, varrays, and nested tables, are stored in their own segments. `LOBS` and varrays are stored in `LOB` segments, while nested tables are stored in storage tables. You can specify a `STORAGE` clause for these segments that will override storage parameters specified at the table level.

After you create a table, you insert rows of data using SQL statements or using an Oracle bulk load utility. Table data can then be queried, deleted, or updated using SQL.

 **See Also:**

- [Oracle Database Concepts](#) for an overview of tables
- [Oracle Database SQL Language Reference](#) for descriptions of Oracle Database data types
- [Managing Space for Schema Objects](#) for guidelines for managing space for tables
- [Managing Schema Objects](#) for information on additional aspects of managing tables, such as specifying integrity constraints and analyzing tables
- [Oracle Database Advanced Security Guide](#) for a discussion of Transparent Data Encryption

20.2 Guidelines for Managing Tables

Following guidelines can make the management of your tables easier and can improve performance when creating the table, as well as when loading, updating, and querying the table data.

- [Design Tables Before Creating Them](#)
Usually, the application developer is responsible for designing the elements of an application, including the tables. Database administrators are responsible for establishing the attributes of the underlying tablespace that will hold the application tables.
- [Specify the Type of Table to Create](#)
You can create different types of tables with Oracle Database.
- [Specify the Location of Each Table](#)
It is advisable to specify the TABLESPACE clause in a CREATE TABLE statement to identify the tablespace that is to store the new table. For partitioned tables, you can optionally identify the tablespace that is to store each partition.
- [Consider Parallelizing Table Creation](#)
You can use parallel execution when creating tables using a subquery (AS SELECT) in the CREATE TABLE statement. Because multiple processes work together to create the table, performance of the table creation operation is improved.
- [Consider Using NOLOGGING When Creating Tables](#)
To create a table most efficiently use the NOLOGGING clause in the CREATE TABLE...AS SELECT statement. The NOLOGGING clause causes minimal redo information to be generated during the table creation.
- [Consider Using Table Compression](#)
As your database grows in size, consider using table compression to save space and improve performance.
- [Managing Table Compression Using Enterprise Manager Cloud Control](#)
You can manage table compression with Oracle Enterprise Manager Cloud Control.

- [Consider Using Segment-Level and Row-Level Compression Tiering](#)
Segment-level compression tiering enables you to specify compression at the segment level within a table. Row-level compression tiering enables you to specify compression at the row level within a table. You can use a combination of these on the same table for fine-grained control over how the data in the table is stored and managed.
- [Consider Using Attribute-Clustered Tables](#)
An attribute-clustered table is a heap-organized table that stores data in close proximity on disk based on user-specified clustering directives.
- [Consider Using Zone Maps](#)
A zone is a set of contiguous data blocks on disk. A zone map tracks the minimum and maximum of specified columns for all individual zones.
- [Consider Storing Tables in the In-Memory Column Store](#)
The In-Memory Column Store is an optional portion of the system global area (SGA) that stores copies of tables, table partitions, and other database objects that is optimized for rapid scans. In the In-Memory Column Store, table data is stored by column rather than row in the SGA.
- [Consider Using Invisible Columns](#)
You can use invisible column to make changes to a table without disrupting applications that use the table.
- [Consider Encrypting Columns That Contain Sensitive Data](#)
You can encrypt individual table columns that contain sensitive data. Examples of sensitive data include social security numbers, credit card numbers, and medical records. Column encryption is transparent to your applications, with some restrictions.
- [Understand Deferred Segment Creation](#)
When you create heap-organized tables in a locally managed tablespace, the database defers table segment creation until the first row is inserted.
- [Materializing Segments](#)
The DBMS_SPACE_ADMIN package includes the MATERIALIZE_DEFERRED_SEGMENTS() procedure, which enables you to materialize segments for tables, table partitions, and dependent objects created with deferred segment creation enabled.
- [Estimate Table Size and Plan Accordingly](#)
Estimate the sizes of tables before creating them. Preferably, do this as part of database planning. Knowing the sizes, and uses, for database tables is an important part of database planning.
- [Restrictions to Consider When Creating Tables](#)
There are restrictions to consider when you create tables.

20.2.1 Design Tables Before Creating Them

Usually, the application developer is responsible for designing the elements of an application, including the tables. Database administrators are responsible for establishing the attributes of the underlying tablespace that will hold the application tables.

Either the DBA or the applications developer, or both working jointly, can be responsible for the actual creation of the tables, depending upon the practices for a site. Working with the application developer, consider the following guidelines when designing tables:

- Use descriptive names for tables, columns, indexes, and clusters.
- Be consistent in abbreviations and in the use of singular and plural forms of table names and columns.
- Document the meaning of each table and its columns with the COMMENT command.
- Normalize each table.
- Select the appropriate data type for each column.
- Consider whether your applications would benefit from adding one or more virtual columns to some tables.
- Define columns that allow nulls last, to conserve storage space.
- Cluster tables whenever appropriate, to conserve storage space and optimize performance of SQL statements.

Before creating a table, you should also determine whether to use integrity constraints. Integrity constraints can be defined on the columns of a table to enforce the business rules of your database automatically.

20.2.2 Specify the Type of Table to Create

You can create different types of tables with Oracle Database.

Here are the types of tables that you can create:

Type of Table	Description
Ordinary (heap-organized) table	This is the basic, general purpose type of table which is the primary subject of this chapter. Its data is stored as an unordered collection (heap).
Clustered table	A clustered table is a table that is part of a cluster. A cluster is a group of tables that share the same data blocks because they share common columns and are often used together. Clusters and clustered tables are discussed in Managing Clusters .
Index-organized table	Unlike an ordinary (heap-organized) table, data for an index-organized table is stored in a B-tree index structure in a primary key sorted manner. Besides storing the primary key column values of an index-organized table row, each index entry in the B-tree stores the nonkey column values as well. Index-organized tables are discussed in " Managing Index-Organized Tables ".
Partitioned table	Partitioned tables enable your data to be broken down into smaller, more manageable pieces called partitions, or even subpartitions. Each partition can have separate physical attributes, such as compression enabled or disabled, type of compression, physical storage settings, and tablespace, thus providing a structure that can be better tuned for availability and performance. In addition, each partition can be managed individually, which can simplify and reduce the time required for backup and administration. Partitioned tables are discussed in Oracle Database VLDB and Partitioning Guide .

20.2.3 Specify the Location of Each Table

It is advisable to specify the TABLESPACE clause in a CREATE TABLE statement to identify the tablespace that is to store the new table. For partitioned tables, you can optionally identify the tablespace that is to store each partition.

Ensure that you have the appropriate privileges and quota on any tablespaces that you use. If you do not specify a tablespace in a CREATE TABLE statement, the table is created in your default tablespace.

When specifying the tablespace to contain a new table, ensure that you understand implications of your selection. By properly specifying a tablespace during the creation of each table, you can increase the performance of the database system and decrease the time needed for database administration.

The following situations illustrate how not specifying a tablespace, or specifying an inappropriate one, can affect performance:

- If users' objects are created in the SYSTEM tablespace, the performance of the database can suffer, since both data dictionary objects and user objects must contend for the same data files. Users' objects should not be stored in the SYSTEM tablespace. To avoid this, ensure that all users are assigned default tablespaces when they are created in the database.
- If application-associated tables are arbitrarily stored in various tablespaces, the time necessary to complete administrative operations (such as backup and recovery) for the data of that application can be increased.

20.2.4 Consider Parallelizing Table Creation

You can use parallel execution when creating tables using a subquery (AS SELECT) in the CREATE TABLE statement. Because multiple processes work together to create the table, performance of the table creation operation is improved.

Parallelizing table creation is discussed in the section "["Parallelizing Table Creation"](#)".

20.2.5 Consider Using NOLOGGING When Creating Tables

To create a table most efficiently use the NOLOGGING clause in the CREATE TABLE...AS SELECT statement. The NOLOGGING clause causes minimal redo information to be generated during the table creation.

Using the NOLOGGING clause has the following benefits:

- Space is saved in the redo log files.
- The time it takes to create the table is decreased.
- Performance improves for parallel creation of large tables.

The NOLOGGING clause also specifies that subsequent direct loads using SQL*Loader and direct load INSERT operations are not logged. Subsequent DML statements (UPDATE, DELETE, and conventional path insert) are unaffected by the NOLOGGING attribute of the table and generate redo.

If you cannot afford to lose the table after you have created it (for example, you will no longer have access to the data used to create the table) you should take a backup

immediately after the table is created. In some situations, such as for tables that are created for temporary use, this precaution may not be necessary.

In general, the relative performance improvement of specifying NOLOGGING is greater for larger tables than for smaller tables. For small tables, NOLOGGING has little effect on the time it takes to create a table. However, for larger tables the performance improvement can be significant, especially when also parallelizing the table creation.

20.2.6 Consider Using Table Compression

As your database grows in size, consider using table compression to save space and improve performance.

- [About Table Compression](#)

Compression saves disk space, reduces memory use in the database buffer cache, and can significantly speed query execution during reads.

- [Examples Related to Table Compression](#)

Examples illustrate using table compression.

- [Compression and Partitioned Tables](#)

A table can have both compressed and uncompressed partitions, and different partitions can use different compression methods. If the compression settings for a table and one of its partitions do not match, then the partition setting has precedence for the partition.

- [Determining If a Table Is Compressed](#)

In the *_TABLES data dictionary views, compressed tables have ENABLED in the COMPRESSION column.

- [Determining Which Rows Are Compressed](#)

To determine the compression level of a row, use the GET_COMPRESSION_TYPE function in the DBMS_COMPRESSION package.

- [Changing the Compression Level](#)

You can change the compression level for a partition, table, or tablespace.

- [Adding and Dropping Columns in Compressed Tables](#)

Some restrictions apply when adding columns to a compressed table or dropping columns from a compressed table.

- [Exporting and Importing Hybrid Columnar Compression Tables](#)

Hybrid Columnar Compression tables can be imported using the impdp command of the Data Pump Import utility.

- [Restoring a Hybrid Columnar Compression Table](#)

There may be times when a Hybrid Columnar Compression table must be restored from a backup. The table can be restored to a system that supports Hybrid Columnar Compression, or to a system that does not support Hybrid Columnar Compression.

- [Notes and Restrictions for Compressed Tables](#)

Consider notes and restrictions related to compressed tables.

- [Packing Compressed Tables](#)

If you use conventional DML on a table compressed with basic table compression or Hybrid Columnar Compression, then all inserted and updated rows are stored uncompressed or in a less-compressed format. To "pack" the compressed table so that these rows are compressed, use an ALTER TABLE MOVE statement.

20.2.6.1 About Table Compression

Compression saves disk space, reduces memory use in the database buffer cache, and can significantly speed query execution during reads.

Compression has a cost in CPU overhead for data loading and DML. However, this cost is offset by reduced I/O requirements. Because compressed table data stays compressed in memory, compression can also improve performance for DML operations, as more rows can fit in the database buffer cache (and flash cache if it is enabled).

Table compression is completely transparent to applications. It is useful in decision support systems (DSS), online transaction processing (OLTP) systems, and archival systems.

You can specify compression for a tablespace, a table, or a partition. If specified at the tablespace level, then all tables created in that tablespace are compressed by default.

Oracle Database supports several methods of table compression. They are summarized in [Table 20-1](#).

Table 20-1 Table Compression Methods

Table Compression Method	Compression Level	CPU Overhead	Applications	Notes
Basic table compression	High	Minimal	DSS	None.
Advanced row compression	High	Minimal	OLTP, DSS	None.
Warehouse compression (Hybrid Columnar Compression)	Higher	Higher	DSS	The compression level and CPU overhead depend on compression level specified (LOW or HIGH).
Archive compression (Hybrid Columnar Compression)	Highest	Highest	Archiving	The compression level and CPU overhead depend on compression level specified (LOW or HIGH).

When you use basic table compression, warehouse compression, or archive compression, compression only occurs when data is bulk loaded or array inserted into a table.

Basic table compression supports limited data types and SQL operations.

Advanced row compression is intended for OLTP applications and compresses data manipulated by any SQL operation. When you use advanced row compression, compression occurs while data is being inserted, updated, or bulk loaded into a table. Operations that permit advanced row compression include:

- Single-row inserts and updates

Inserts and updates are not compressed immediately. When updating an already compressed block, any columns that are not updated usually remain compressed. Updated columns are stored in an uncompressed format similar to any uncompressed block. The updated values are re-compressed when the block reaches a database-controlled threshold. Inserted data is also compressed when the data in the block reaches a database-controlled threshold.

- Array inserts

Array inserts include `INSERT INTO SELECT` SQL statements without the `APPEND` hint, and array inserts from programmatic interfaces such as PL/SQL and the Oracle Call Interface (OCI).

- The following direct-path `INSERT` methods:

- Direct path SQL*Loader
- `CREATE TABLE AS SELECT` statements
- Parallel `INSERT` statements
- `INSERT` statements with an `APPEND` or `APPEND_VALUES` hint

Inserts performed with these direct-path `INSERT` methods are compressed immediately.

Warehouse compression and archive compression achieve the highest compression levels because they use Hybrid Columnar Compression technology. Hybrid Columnar Compression technology uses a modified form of columnar storage instead of row-major storage. This enables the database to store similar data together, which improves the effectiveness of compression algorithms. For data that is updated, Hybrid Columnar Compression uses more CPU and moves the updated rows to row format so that future updates are faster. Because of this optimization, you should use it only for data that is updated infrequently.

The higher compression levels of Hybrid Columnar Compression are achieved only with data that is direct-path inserted or array inserted. Conventional inserts and updates are supported, but cause rows to be moved from columnar to row format, and reduce the compression level. You can use Automatic Data Optimization (ADO) policies to move these rows back to the desired level of Hybrid Columnar Compression automatically.

With Hybrid Columnar Compression (warehouse and archive), for array inserts to be compressed immediately, the following conditions must be met:

- The table must be stored in a locally managed tablespace with Automatic Segment Space Management (ASSM) enabled.
- The database compatibility level must be at 12.2.0 or higher.

Regardless of the compression method, `DELETE` operations on a compressed block are identical to `DELETE` operations on a non-compressed block. Any space obtained on a data block, caused by SQL `DELETE` operations, is reused by subsequent SQL `INSERT` operations. With Hybrid Columnar Compression technology, when all the rows in a compression unit are deleted, the space in the compression unit is available for reuse.

[Table 20-2](#) lists characteristics of each table compression method.

Table 20-2 Table Compression Characteristics

Table Compression Method	CREATE/ALTER TABLE Syntax	Direct-Path or Array Inserts	Notes
Basic table compression	ROW STORE COMPRESS [BASIC]	Rows are compressed with basic table compression.	ROW STORE COMPRESS and ROW STORE COMPRESS BASIC are equivalent. Rows inserted without using direct-path or array insert and updated rows are uncompressed.
Advanced row compression	ROW STORE COMPRESS ADVANCED	Rows are compressed with advanced row compression.	Rows inserted with or without using direct-path or array insert and updated rows are compressed using advanced row compression.
Warehouse compression (Hybrid Columnar Compression)	COLUMN STORE COMPRESS FOR QUERY [LOW HIGH]	Rows are compressed with warehouse compression.	This compression method can result in high CPU overhead. Updated rows and rows inserted without using direct-path or array insert are stored in row format instead of column format, and thus have a lower compression level.
Archive compression (Hybrid Columnar Compression)	COLUMN STORE COMPRESS FOR ARCHIVE [LOW HIGH]	Rows are compressed with archive compression.	This compression method can result in high CPU overhead. Updated rows and rows inserted without using direct-path or array insert are stored in row format instead of column format, and thus have a lower compression level.

You specify table compression with the COMPRESS clause of the CREATE TABLE statement. You can enable compression for an existing table by using these clauses in an ALTER TABLE statement. In this case, only data that is inserted or updated after compression is enabled is compressed. Using the ALTER TABLE MOVE statement also enables compression for data that is inserted and updated, but it compresses existing data as well. Similarly, you can disable table compression for an existing compressed table with the ALTER TABLE...NOCOMPRESS statement. In this case, all data that was already compressed remains compressed, and new data is inserted uncompressed.

The COLUMN STORE COMPRESS FOR QUERY HIGH option is the default data warehouse compression mode. It provides good compression and performance when using Hybrid Columnar Compression on Exadata storage. The COLUMN STORE COMPRESS FOR QUERY LOW option should be used in environments where load performance is critical. It loads faster than data compressed with the COLUMN STORE COMPRESS FOR QUERY HIGH option.

The COLUMN STORE COMPRESS FOR ARCHIVE LOW option is the default archive compression mode. It provides a high compression level and is ideal for infrequently-accessed data. The COLUMN STORE COMPRESS FOR ARCHIVE HIGH option should be used for data that is rarely accessed.

A compression advisor, provided by the DBMS_COMPRESSION package, helps you determine the expected compression level for a particular table with a particular compression method.

 **Note:**

Hybrid Columnar Compression is dependent on the underlying storage system. See *Oracle Database Licensing Information* for more information.

 **See Also:**

- *Oracle Database Concepts* for an overview of table compression
- "[About Tablespaces with Default Compression Attributes](#)"

20.2.6.2 Examples Related to Table Compression

Examples illustrate using table compression.

Example 20-1 Creating a Table with Advanced Row Compression

The following example enables advanced row compression on the table `orders`:

```
CREATE TABLE orders ... ROW STORE COMPRESS ADVANCED;
```

Data for the `orders` table is compressed during direct-path `INSERT`, array insert, and conventional DML.

Example 20-2 Creating a Table with Basic Table Compression

The following statements, which are equivalent, enable basic table compression on the `sales_history` table, which is a fact table in a data warehouse:

```
CREATE TABLE sales_history ... ROW STORE COMPRESS BASIC;  
  
CREATE TABLE sales_history ... ROW STORE COMPRESS;
```

Frequent queries are run against this table, but no DML is expected.

Example 20-3 Using Direct-Path Insert to Insert Rows Into a Table

This example demonstrates using the `APPEND` hint to insert rows into the `sales_history` table using direct-path `INSERT`.

```
INSERT /*+ APPEND */ INTO sales_history SELECT * FROM sales WHERE cust_id=8890;  
COMMIT;
```

Example 20-4 Using an Array Insert to Insert Rows Into a Table

This example demonstrates using an array insert in SQL to insert rows into the `sales_history` table.

```
INSERT INTO sales_history SELECT * FROM sales WHERE cust_id=8890;  
COMMIT;
```

This example demonstrates using an array insert in PL/SQL to insert rows into the `hr.jobs_test` table.

```
DECLARE
  TYPE table_def IS TABLE OF hr.jobs%ROWTYPE;
  array table_def := table_def();
BEGIN
  SELECT * BULK COLLECT INTO array FROM hr.jobs;
  FORALL i in array.first .. array.last
    INSERT INTO hr.jobs_test VALUES array(i);
COMMIT;
END;
/
```

 **Note:**

With Hybrid Columnar Compression (warehouse and archive), for array inserts performed in SQL, PL/SQL, or OCI to be compressed immediately, the table must be stored in a locally managed tablespace with Automatic Segment Space Management (ASSM) enabled, and the database compatibility level must be at 12.2.0 or higher.

Example 20-5 Creating a Table with Warehouse Compression

This example enables Hybrid Columnar Compression on the table `sales_history`:

```
CREATE TABLE sales_history ... COLUMN STORE COMPRESS FOR QUERY;
```

The table is created with the default `COLUMN STORE COMPRESS FOR QUERY HIGH` option. This option provides a higher level of compression than basic table compression or advanced row compression. It works well when frequent queries are run against this table and no DML is expected.

Example 20-6 Creating a Table with Archive Compression

The following example enables Hybrid Columnar Compression on the table `sales_history`:

```
CREATE TABLE sales_history ... COLUMN STORE COMPRESS FOR ARCHIVE;
```

The table is created with the default `COLUMN STORE COMPRESS FOR ARCHIVE LOW` option. This option provides a higher level of compression than basic, advanced row, or warehouse compression. It works well when load performance is critical and data is accessed infrequently. The default `COLUMN STORE COMPRESS FOR ARCHIVE LOW` option provides a lower level of compression than the `COLUMN STORE COMPRESS FOR ARCHIVE HIGH` option.

20.2.6.3 Compression and Partitioned Tables

A table can have both compressed and uncompressed partitions, and different partitions can use different compression methods. If the compression settings for a table and one of its partitions do not match, then the partition setting has precedence for the partition.

To change the compression method for a partition, do one of the following:

- To change the compression method for new data only, use `ALTER TABLE ... MODIFY PARTITION ... COMPRESS ...`

- To change the compression method for both new and existing data, use either `ALTER TABLE ... MOVE PARTITION ... COMPRESS ...` or online table redefinition.

When you execute these statements, specify the compression method. For example, run the following statement to change the compression method to advanced row compression for both new and existing data:

```
ALTER TABLE ... MOVE PARTITION ... ROW STORE COMPRESS ADVANCED...
```

20.2.6.4 Determining If a Table Is Compressed

In the `*_TABLES` data dictionary views, compressed tables have `ENABLED` in the `COMPRESSION` column.

For partitioned tables, this column is null, and the `COMPRESSION` column of the `*_TAB_PARTITIONS` views indicates the partitions that are compressed. In addition, the `COMPRESS_FOR` column indicates the compression method in use for the table or partition.

```
SQL> SELECT table_name, compression, compress_for FROM user_tables;
```

TABLE_NAME	COMPRESSION	COMPRESS_FOR
T1	DISABLED	
T2	ENABLED	BASIC
T3	ENABLED	ADVANCED
T4	ENABLED	QUERY HIGH
T5	ENABLED	ARCHIVE LOW

```
SQL> SELECT table_name, partition_name, compression, compress_for
  FROM user_tab_partitions;
```

TABLE_NAME	PARTITION_NAME	COMPRESSION	COMPRESS_FOR
SALES	Q4_2004	ENABLED	ARCHIVE HIGH
...			
SALES	Q3_2008	ENABLED	QUERY HIGH
SALES	Q4_2008	ENABLED	QUERY HIGH
SALES	Q1_2009	ENABLED	ADVANCED
SALES	Q2_2009	ENABLED	ADVANCED

20.2.6.5 Determining Which Rows Are Compressed

To determine the compression level of a row, use the `GET_COMPRESSION_TYPE` function in the `DBMS_COMPRESSION` package.

For example, the following query returns the compression type for a row in the `hr.employees` table:

```
SELECT DECODE(DBMS_COMPRESSION.GET_COMPRESSION_TYPE(
    ownname    => 'HR',
    tabname    => 'EMPLOYEES',
    subobjname => '',
    row_id     => 'AAAVEIAAGAAAABTAAD'),
  1, 'No Compression',
  2, 'Advanced Row Compression',
  4, 'Hybrid Columnar Compression for Query High',
  8, 'Hybrid Columnar Compression for Query Low',
  16, 'Hybrid Columnar Compression for Archive High');
```

```
32, 'Hybrid Columnar Compression for Archive Low',
4096, 'Basic Table Compression',
'Unknown Compression Type') compression_type
FROM DUAL;
```

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for additional information about `GET_COMPRESSION_TYPE`

20.2.6.6 Changing the Compression Level

You can change the compression level for a partition, table, or tablespace.

For example, suppose a company uses warehouse compression for its sales data, but sales data older than six months is rarely accessed. If the sales data is stored in a table that is partitioned based on the age of the data, then the compression level for the older data can be changed to archive compression to free disk space.

To change the compression level for a partition or subpartition, you can use the following statements:

- `ALTER TABLE ... MOVE PARTITION ... ONLINE`
- `ALTER TABLE ... MOVE SUBPARTITION ... ONLINE`

These two statements support the `ONLINE` keyword, which enables DML operations to run uninterrupted on the partition or subpartition that is being moved. These statements also automatically keep all the indexes updated while the partition or subpartition is being moved. You can also use the `ALTER TABLE...MODIFY PARTITION` statement or online redefinition to change the compression level for a partition.

If a table is not partitioned, then you can use the `ALTER TABLE...MOVE...COMPRESS FOR...` statement to change the compression level. The `ALTER TABLE...MOVE` statement does not permit DML statements against the table while the command is running. However, you can also use online redefinition to compress a table, which keeps the table available for queries and DML statements during the redefinition.

To change the compression level for a tablespace, use the `ALTER TABLESPACE` statement.

 **See Also:**

- "[Moving a Table to a New Segment or Tablespace](#)" for additional information about the `ALTER TABLE` command
- "[Redefining Tables Online](#)"
- *Oracle Database PL/SQL Packages and Types Reference* for additional information about the `DBMS_REDEFINITION` package

20.2.6.7 Adding and Dropping Columns in Compressed Tables

Some restrictions apply when adding columns to a compressed table or dropping columns from a compressed table.

The following restrictions apply when adding columns to compressed tables:

- Advanced row compression, warehouse compression, and archive compression: If a default value is specified for an added column and the table is already populated, then the conditions for optimized add column behavior must be met. These conditions are described in *Oracle Database SQL Language Reference*.

The following restrictions apply when dropping columns in compressed tables:

- Basic table compression: Dropping a column is not supported.
- Advanced row compression, warehouse compression, and archive compression: `DROP COLUMN` is supported, but internally the database sets the column `UNUSED` to avoid long-running decompression and recompression operations.

20.2.6.8 Exporting and Importing Hybrid Columnar Compression Tables

Hybrid Columnar Compression tables can be imported using the `impdp` command of the Data Pump Import utility.

By default, the `impdp` command preserves the table properties, and the imported table is a Hybrid Columnar Compression table. On tablespaces not supporting Hybrid Columnar Compression, the `impdp` command fails with an error. The tables can also be exported using the `expdp` command.

You can import the Hybrid Columnar Compression table as an uncompressed table using the `TRANSFORM=SEGMENT_ATTRIBUTES:n` option clause of the `impdp` command.

An uncompressed or advanced row-compressed table can be converted to Hybrid Columnar Compression format during import. To convert a non-Hybrid Columnar Compression table to a Hybrid Columnar Compression table, do the following:

- Specify default compression for the tablespace using the `ALTER TABLESPACE ... SET DEFAULT COMPRESS` command.
- Override the `SEGMENT_ATTRIBUTES` option of the imported table during import.

See Also:

- Oracle Database Utilities* for additional information about the Data Pump Import utility
- Oracle Database SQL Language Reference* for additional information about the `ALTER TABLESPACE` command

20.2.6.9 Restoring a Hybrid Columnar Compression Table

There may be times when a Hybrid Columnar Compression table must be restored from a backup. The table can be restored to a system that supports Hybrid Columnar Compression, or to a system that does not support Hybrid Columnar Compression.

When restoring a table with Hybrid Columnar Compression to a system that supports Hybrid Columnar Compression, restore the file using Oracle Recovery Manager (RMAN) as usual.

When a Hybrid Columnar Compression table is restored to a system that does not support Hybrid Columnar Compression, you must convert the table from Hybrid Columnar Compression to advanced row compression or an uncompressed format. To restore the table, do the following:

1. Ensure there is sufficient storage in environment to hold the data in uncompressed or advanced row compression format.
2. Use RMAN to restore the Hybrid Columnar Compression tablespace.
3. Complete one of the following actions to convert the table from Hybrid Columnar Compression to advanced row compression or an uncompressed format:
 - Use the following statement to change the data compression from Hybrid Columnar Compression to ROW STORE COMPRESS ADVANCED:

```
ALTER TABLE table_name MOVE ROW STORE COMPRESS ADVANCED;
```

- Use the following statement to change the data compression from Hybrid Columnar Compression to NOCOMPRESS:

```
ALTER TABLE table_name MOVE NOCOMPRESS;
```

- Use the following statement to change each partition to NOCOMPRESS:

```
ALTER TABLE table_name MOVE PARTITION partition_name NOCOMPRESS;
```

Change each partition separately.

If DML is required on the partition while it is being moved, then include the ONLINE keyword:

```
ALTER TABLE table_name MOVE PARTITION partition_name NOCOMPRESS ONLINE;
```

Moving a partition online might take longer than moving a partition offline.

- Use the following statement to move the data to NOCOMPRESS in parallel:

```
ALTER TABLE table_name MOVE NOCOMPRESS PARALLEL;
```

See Also:

- *Oracle Database Backup and Recovery User's Guide* for additional information about RMAN
- *Oracle Database SQL Language Reference* for additional information about the ALTER TABLE command

20.2.6.10 Notes and Restrictions for Compressed Tables

Consider notes and restrictions related to compressed tables.

The following are notes and restrictions related to compressed tables:

- Advanced row compression, warehouse compression, and archive compression are not supported for the following types of tables:
 - Index-organized tables
 - External tables
 - Tables with LONG or LONG RAW columns
 - Temporary tables
 - Tables with ROWDEPENDENCIES enabled
 - Clustered tables
- Online segment shrink is not supported for tables compressed with the following compression methods:
 - Basic table compression using ROW STORE COMPRESS BASIC
 - Warehouse compression using COLUMN STORE COMPRESS FOR QUERY
 - Archive compression using COLUMN STORE COMPRESS FOR ARCHIVE
- The table compression methods described in this section do not apply to SecureFiles large objects (LOBs). SecureFiles LOBs have their own compression methods. See *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information.
- Compression technology uses CPU. Ensure that you have enough available CPU to handle the additional load.
- Tables created with basic table compression have the PCT_FREE parameter automatically set to 0 unless you specify otherwise.

20.2.6.11 Packing Compressed Tables

If you use conventional DML on a table compressed with basic table compression or Hybrid Columnar Compression, then all inserted and updated rows are stored uncompressed or in a less-compressed format. To "pack" the compressed table so that these rows are compressed, use an ALTER TABLE MOVE statement.

This operation takes an exclusive lock on the table, and therefore prevents any updates and loads until it completes. If this is not acceptable, then you can use online table redefinition.

When you move a partition or subpartition, you can use the ALTER TABLE MOVE statement to compress the partition or subpartition while still allowing DML operations to run interrupted on the partition or subpartition that is being moved.

 **See Also:**

- *Oracle Database SQL Language Reference* for more details on the ALTER TABLE...COMPRESS and ALTER TABLE...MOVE statements, including restrictions
- *Oracle Database VLDB and Partitioning Guide* for more information on table partitioning
- "[Redefining Tables Online](#)"
- "[Moving a Table to a New Segment or Tablespace](#)" for more information about moving a table, partition, or subpartition

20.2.7 Managing Table Compression Using Enterprise Manager Cloud Control

You can manage table compression with Oracle Enterprise Manager Cloud Control.

- [Table Compression and Enterprise Manager Cloud Control](#)
Enterprise Manager displays several central compression pages that summarize the compression features at the database and tablespace levels and contains links to different compression pages. The Compression pages display summaries of the compressed storage space at the database level and the tablespace level.
- [Viewing the Compression Summary at the Database Level](#)
You can view the Compression Summary information at the database level.
- [Viewing the Compression Summary at the Tablespace Level](#)
You can view the Compression Summary information at the tablespace level.
- [Estimating the Compression Ratio](#)
You can run the Compression Advisor to calculate the compression ratio for a specific object.
- [Compressing an Object](#)
You can compress an object such as a table.
- [Viewing Compression Advice](#)
You can view compression advice from the Segment Advisor and take actions based on them.
- [Initiating Automatic Data Optimization on an Object](#)
You can initiate Automatic Data Optimization on an object.

20.2.7.1 Table Compression and Enterprise Manager Cloud Control

Enterprise Manager displays several central compression pages that summarize the compression features at the database and tablespace levels and contains links to different compression pages. The Compression pages display summaries of the compressed storage space at the database level and the tablespace level.

On the database level, the Compression Summary for Database page shows the total database size (total size of all the objects, both compressed and uncompressed), the total size of compressed objects in the database, the total size of uncompressed

objects in the database and the ratio of the total size of compressed objects to the total database size. This provides you with a general idea on how much storage space within a database is compressed. You can then take action based on the information displayed.

Likewise on the tablespace level, the Compression Summary for Tablespace page shows the total tablespace size (total size of all the objects, both compressed and uncompressed), the total size of compressed objects in the tablespace, the total size of uncompressed objects in the tablespace and the ratio of the total size of compressed objects to the total tablespace size.

You can use the Compression feature to perform the following tasks:

- View a summary of the compressed storage space for the top 100 tablespaces at the database level or the top 100 objects at the tablespace level. You can view a summary on how much storage space is compressed within each of top 100 tablespaces that use the most database storage, including the total size of the tablespace, the compressed size of a tablespace, the uncompressed size of tablespace, and the percentage of compressed storage within a tablespace. You can then perform compression tasks based on the information displayed.
- View the storage size that is compressed by each compression type for four object types: Table, Index, LOB (Large Objects), and DBFS (Oracle Database File System).
- Calculate the compression ratio for a specific object.
- Compress an object (tablespace, table, partition or LOB). This allows you to save storage space. You can run the Compression Advisor to ascertain how much space can be saved and then perform the compression action on the object.
- View compression advice from the Segment Advisor. You can access a link to the Segment Advisor to compress segments.

20.2.7.2 Viewing the Compression Summary at the Database Level

You can view the Compression Summary information at the database level.

1. From the **Administration** menu, choose **Storage**, then select **Compression**. Enterprise Manager displays the Compression Summary for Top 100 Tablespaces page.
2. You can view the summary information about the storage compression at the database level, including in the Space Usage section the total database size, the total size of compressed objects in the database, and the ratio of the total size of compressed objects to the total database size, and the uncompressed objects size. Similar information for segment counts is also shown here in the Segment Count section.
3. You can view the storage size that is used by each compression type for four object types: Table, Index, LOB (Large Objects), and DBFS (Oracle Database File System). Clicking each color in the chart displays a Compression Summary of Segments page, which shows compression information for the top 100 segments by size in the database for a particular object type and compression type.

20.2.7.3 Viewing the Compression Summary at the Tablespace Level

You can view the Compression Summary information at the tablespace level.

1. From the **Administration** menu, choose **Storage**, then select **Compression**.
Enterprise Manager displays the Compression Summary for Top 100 Tablespaces page.
2. In the Top 100 Permanent Tablespaces by Size table, click on the row for the tablespace for which you want to view the compression summary.
3. Click **Show Compression Details**.

Enterprise Manager displays the Compression Summary for Top 100 Objects in Tablespace page. From this page, you can view the total tablespace size, the total size of compressed objects in the tablespace, the ratio of the total size of compressed objects to the total tablespace size, and the uncompressed objects size in a tablespace.

You can also view the compressed tablespace storage size by each compression type for four object types: Table, Index, LOB and DBFS. Clicking each color in the chart displays the Compression Summary of Segments dialog box, which shows compression information for the top 100 segments by size in the tablespace for a particular object type and compression type.

Finally, you can view the compression summary for each of the top 100 segments that use the most tablespace storage.

20.2.7.4 Estimating the Compression Ratio

You can run the Compression Advisor to calculate the compression ratio for a specific object.

1. From the **Administration** menu, choose **Storage**, then select **Compression**.
Enterprise Manager displays the Compression Summary for Top 100 Tablespaces page.
2. From the Top 100 Permanent Tablespaces by Size table, select a tablespace and click **Show Compression Details** to view the compression details for the selected tablespace.
Enterprise Manager displays the Top 100 Objects By Size table.
3. Select an object and click **Estimate Compression Ratio** for the object.

Enterprise Manager displays the Estimate Compression Ratio dialog box. Enter the following information:

- Under the Input Parameters section, enter or select a Temporary Scratch Tablespace. You can enter the name directly or you can choose from the list that appears when you click the icon.
- Enter the Compression Type. You can choose from Basic, Advanced, Query Low, Query High, Archive Low, or Archive High. For HCC compression types (Query Low, Query High, Archive Low, or Archive High.), be sure the table contains at least one million rows.
- In the Schedule Job section, enter the Name of the job and a Description.
- In the Schedule section, enter the job information such as when to Start, whether or not to Repeat the job, whether or not there should be a Grace Period, and Duration information.
- Enter the Database Credentials and the Host Credentials in their respective sections.

- Click **OK**.

The job runs either immediately or is scheduled, and you are returned to the Compression Summary for Top 100 Objects in Tablespace page.

20.2.7.5 Compressing an Object

You can compress an object such as a table.

1. From the **Administration** menu, choose **Storage**, then select **Compression**.
Enterprise Manager displays the Compression Summary for Top 100 Tablespaces page.
2. From the Top 100 Permanent Tablespaces by Size table, select a tablespace and click **Show Compression Details** to view Compression details for the selected tablespace.
Enterprise Manager displays the Compression Summary for Top 100 Objects in Tablespace page.
3. Choose an object, such as a table, and click **Compress** to compress the object.

20.2.7.6 Viewing Compression Advice

You can view compression advice from the Segment Advisor and take actions based on them.

1. From the **Administration** menu, choose **Storage**, then select **Compression**.
Enterprise Manager displays the Compression Summary for Top 100 Tablespaces page.
2. In the Compression Advice section, click the number that displays in the Segments with Compression Advice field.
Enterprise Manager displays the Segment Advisor Recommendations page. You can use the Automatic Segment Advisor job to detect segment issues within maintenance windows. The recommendations are derived from the most recent runs of automatic and user-scheduled segment advisor jobs.

20.2.7.7 Initiating Automatic Data Optimization on an Object

You can initiate Automatic Data Optimization on an object.

1. From the **Administration** menu, choose **Storage**, then select **Compression**.
Enterprise Manager displays the Compression Summary for Top 100 Tablespaces page.
2. From the Top 100 Permanent Tablespaces by Size table, select a tablespace and click **Show Compression Details** to view the compression details for the selected tablespace.
Enterprise Manager displays the Compression Summary for Top 100 Objects in Tablespace page.
3. From the Top 100 Objects by Size table, select an object and click **Automatic Data Compression**.
Enterprise Manager displays the Edit page for the object where you can initiate Automatic Data Optimization on the object.

20.2.8 Consider Using Segment-Level and Row-Level Compression Tiering

Segment-level compression tiering enables you to specify compression at the segment level within a table. Row-level compression tiering enables you to specify compression at the row level within a table. You can use a combination of these on the same table for fine-grained control over how the data in the table is stored and managed.

As user modifications to segments and rows change over time, it is often beneficial to change the compression level for them. For example, some segments and rows might be modified often for a short period of time after they are added to the database, but modifications might become less frequent over time.

You can use compression tiering to specify which segments and rows are compressed based on rules. For example, you can specify that rows that have not been modified in two weeks are compressed with advanced row compression. You can also specify that segments that have not been modified in six months are compressed with warehouse compression.

The following prerequisites must be met before you can use segment-level and row-level compression tiering:

- The `HEAT_MAP` initialization parameter must be set to `ON`.
- The `COMPATIBLE` initialization parameter must be set to `12.0.0` or higher.

To use segment-level compression tiering or row-level compression tiering, execute one of the following SQL statements and include an Automatic Data Optimization (ADO) policy that specifies the rules:

- `CREATE TABLE`
- `ALTER TABLE`

Example 20-7 Row-Level Compression Tiering

This example specifies row-level compression tiering for the `oe.orders` table. Oracle Database compresses rows using warehouse (QUERY) compression after 14 days with no modifications.

```
ALTER TABLE oe.orders ILM ADD POLICY
  COLUMN STORE COMPRESS FOR QUERY
  ROW
  AFTER 14 DAYS OF NO MODIFICATION;
```

Example 20-8 Segment-Level Compression Tiering

This example specifies segment-level compression tiering for the `oe.order_items` table. Oracle Database compresses segments using archive (ARCHIVE HIGH) compression after six months with no modifications to any rows in the segment and no queries accessing any rows in the segment.

```
ALTER TABLE oe.order_items ILM ADD POLICY
  COLUMN STORE COMPRESS FOR ARCHIVE HIGH
  SEGMENT
  AFTER 6 MONTHS OF NO ACCESS;
```

 **Note:**

These examples specify Hybrid Columnar Compression, which is dependent on the underlying storage system. See *Oracle Database Licensing Information* for more information.

 **See Also:**

- "[Consider Using Table Compression](#)" for information about different compression levels
- "[Improving Query Performance with the In-Memory Column Store](#)"
- *Oracle Database VLDB and Partitioning Guide* for more information about segment-level and row-level compression tiering

20.2.9 Consider Using Attribute-Clustered Tables

An attribute-clustered table is a heap-organized table that stores data in close proximity on disk based on user-specified clustering directives.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

The directives are as follows:

- The CLUSTERING . . . BY LINEAR ORDER directive orders data in a table according to specified columns.

BY LINEAR ORDER clustering, which is the default, is best when queries qualify the prefix of columns specified in the clustering clause. For example, if queries of `sh.sales` often specify either a customer ID or both customer ID and product ID, then you could cluster data in the table using the linear column order `cust_id`, `prod_id`. Note that the specified columns can be in multiple tables.

- The CLUSTERING . . . BY INTERLEAVED ORDER directive orders data in one or more tables using a special algorithm, similar to a z-order function, that permits multicolumn I/O reduction.

BY INTERLEAVED ORDER clustering is best when queries specify a variety of column combinations. The columns can be in one or more tables. For example, if queries of `sh.sales` specify different dimensions in different orders, then you could cluster data in the `sales` table according to columns in these dimensions.

Attribute clustering is available for the following types of operations:

- Direct-path `INSERT`

See "[Improving INSERT Performance with Direct-Path INSERT](#)".

- Online redefinition

See "[Redefining Tables Online](#)".

- Data movement operations, such as `ALTER TABLE ... MOVE` operations

See "[Moving a Table to a New Segment or Tablespace](#)".

- Partition maintenance operations that create new segments, such as `ALTER TABLE ... MERGE PARTITION` operations

See *Oracle Database VLDB and Partitioning Guide*.

Attribute clustering is ignored for conventional DML.

An attribute-clustered table has the following advantages:

- More optimized single block I/O is possible for table lookups when attribute clustering is aligned with common index access. For example, optimized I/O is possible for an index range scan on the leading column you chose for attribute clustering.
- Data ordering enables more optimal pruning for Exadata storage indexes and in-memory min/max pruning.
- You can cluster fact tables based on joined attributes from other tables.
- Attribute clustering can improve data compression and in this way indirectly improve table scan costs. When the same values are close to each other on disk, the database can more easily compress them.

Attribute-clustered tables are often used in data warehousing environments, but they are useful in any environment that can benefit from these advantages. Use the `CLUSTERING` clause in a `CREATE TABLE` SQL statement to create an attribute-clustered table.

See Also:

- *Oracle Database Concepts* for conceptual information about attribute-clustered tables
- *Oracle Database Data Warehousing Guide* for information about using attribute-clustered tables
- *Oracle Database SQL Language Reference*

20.2.10 Consider Using Zone Maps

A zone is a set of contiguous data blocks on disk. A zone map tracks the minimum and maximum of specified columns for all individual zones.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

When a SQL statement contains predicates on columns stored in a zone map, the database compares the predicate values to the minimum and maximum stored in the zone to determine which zones to read during SQL execution. The primary benefit of zone maps is I/O reduction for table scans. I/O is reduced by skipping table blocks that are not needed in the query result. Use the `CREATE MATERIALIZED ZONEMAP` SQL statement to create a zone map.

Whenever attribute clustering is specified on a table, you can automatically create a zone map on the clustered columns. Due to clustering, minimum and maximum values of the columns are correlated with consecutive data blocks in the attribute-clustered table, which allows for more effective I/O pruning using the associated zone map.

 **Note:**

Zone maps and attribute-clustered tables can be used together or separately.

 **See Also:**

- ["Consider Using Attribute-Clustered Tables"](#)
- *Oracle Database Concepts* for conceptual information about zone maps
- *Oracle Database Data Warehousing Guide* for information about using zone maps
- *Oracle Database SQL Language Reference* for information about the `CREATE MATERIALIZED ZONEMAP` statement

20.2.11 Consider Storing Tables in the In-Memory Column Store

The In-Memory Column Store is an optional portion of the system global area (SGA) that stores copies of tables, table partitions, and other database objects that is optimized for rapid scans. In the In-Memory Column Store, table data is stored by column rather than row in the SGA.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

 **See Also:**

- ["Improving Query Performance with the In-Memory Column Store"](#)
- [Oracle Database Concepts](#)

20.2.12 Consider Using Invisible Columns

You can use invisible column to make changes to a table without disrupting applications that use the table.

- [Understand Invisible Columns](#)

You can make individual table columns invisible. Any generic access of a table does not show the invisible columns in the table.

- [Invisible Columns and Column Ordering](#)

There are special considerations for invisible columns and column ordering.

20.2.12.1 Understand Invisible Columns

You can make individual table columns invisible. Any generic access of a table does not show the invisible columns in the table.

For example, the following operations do not display invisible columns in the output:

- `SELECT * FROM` statements in SQL
- `DESCRIBE` commands in SQL*Plus
- `%ROWTYPE` attribute declarations in PL/SQL
- Describes in Oracle Call Interface (OCI)

You can use a `SELECT` statement to display output for an invisible column only if you explicitly specify the invisible column in the column list. Similarly, you can insert a value into an invisible column only if you explicitly specify the invisible column in the column list for the `INSERT` statement. If you omit the column list in the `INSERT` statement, then the statement can only insert values into visible columns.

You can make a column invisible during table creation or when you add a column to a table, and you can later alter the table to make the same column visible. You can also alter a table to make a visible column invisible.

You might use invisible columns if you want to make changes to a table without disrupting applications that use the table. After you add an invisible column to a table, queries and other operations that must access the invisible column must refer to the column explicitly by name. When you migrate the application to account for the invisible columns, you can make the invisible columns visible.

Virtual columns can be invisible. Also, you can use an invisible column as a partitioning key during table creation.

The following restrictions apply to invisible columns:

- The following types of tables cannot have invisible columns:

- External tables
- Cluster tables
- Temporary tables
- Attributes of user-defined types cannot be invisible.

 **Note:**

Invisible columns are not the same as system-generated hidden columns. You can make invisible columns visible, but you cannot make hidden columns visible.

 **See Also:**

- "[Creating Tables](#)"
- "[Adding Table Columns](#)"
- "[Modifying an Existing Column Definition](#)"

20.2.12.2 Invisible Columns and Column Ordering

There are special considerations for invisible columns and column ordering.

The database usually stores columns in the order in which they were listed in the CREATE TABLE statement. If you add a new column to a table, then the new column becomes the last column in the table's column order.

When a table contains one or more invisible columns, the invisible columns are not included in the column order for the table. Column ordering is important when all of the columns in a table are accessed. For example, a SELECT * FROM statement displays columns in the table's column order. Because invisible columns are not included in this type of generic access of a table, they are not included in the column order.

When you make an invisible column visible, the column is included in the table's column order as the last column. When you make a visible column invisible, the invisible column is not included in the column order, and the order of the visible columns in the table might be re-arranged.

For example, consider the following table with an invisible column:

```
CREATE TABLE mytable (a INT, b INT INVISIBLE, c INT);
```

Because column b is invisible, this table has the following column order:

Column	Column Order
a	1
c	2

Next, make column *b* visible:

```
ALTER TABLE mytable MODIFY (b VISIBLE);
```

When you make column *b* visible, it becomes the last column in the table's column order. Therefore, the table has the following column order:

Column	Column Order
a	1
c	2
b	3

Consider another example that illustrates column ordering in tables with invisible columns. The following table does not contain any invisible columns:

```
CREATE TABLE mytable2 (x INT, y INT, z INT);
```

This table has the following column order:

Column	Column Order
x	1
y	2
z	3

Next, make column *y* invisible:

```
ALTER TABLE mytable2 MODIFY (y INVISIBLE);
```

When you make column *y* invisible, column *y* is no longer included in the table's column order, and it changes the column order of column *z*. Therefore, the table has the following column order:

Column	Column Order
x	1
z	2

Make column *y* visible again:

```
ALTER TABLE mytable2 MODIFY (y VISIBLE);
```

Column *y* is now last in the table's column order:

Column	Column Order
x	1
z	2
y	3

20.2.13 Consider Encrypting Columns That Contain Sensitive Data

You can encrypt individual table columns that contain sensitive data. Examples of sensitive data include social security numbers, credit card numbers, and medical records. Column encryption is transparent to your applications, with some restrictions.

Although encryption is not meant to solve all security problems, it does protect your data from users who try to circumvent the security features of the database and access database files directly through the operating system file system.

Column encryption uses the Transparent Data Encryption feature of Oracle Database, which requires that you create a keystore to store the master encryption key for the database. The keystore must be open before you can create a table with encrypted columns and before you can store or retrieve encrypted data. When you open the keystore, it is available to all sessions, and it remains open until you explicitly close it or until the database is shut down.

Transparent Data Encryption supports industry-standard encryption algorithms, including the following types of encryption algorithms Advanced Encryption Standard (AES) and Triple Data Encryption Standard (3DES) algorithms:

- Advanced Encryption Standard (AES)
- ARIA
- GHOST
- SEED
- Triple Data Encryption Standard (3DES)

See *Oracle Database Advanced Security Guide* for detailed information about the supported encryption algorithms.

You choose the algorithm to use when you create the table. All encrypted columns in the table use the same algorithm. The default is AES192. The encryption key length is implied by the algorithm name. For example, the AES128 algorithm uses 128-bit keys.

If you plan on encrypting many columns in one or more tables, you may want to consider encrypting an entire tablespace instead and storing these tables in that tablespace. Tablespace encryption, which also uses the Transparent Data Encryption feature but encrypts at the physical block level, can perform better than encrypting many columns. Another reason to encrypt at the tablespace level is to address the following limitations of column encryption:

- Certain data types, such as object data types, are not supported for column encryption.
- You cannot use the transportable tablespace feature for a tablespace that includes tables with encrypted columns.
- Other restrictions, which are detailed in *Oracle Database Advanced Security Guide*.

 **See Also:**

- *Oracle Database Advanced Security Guide* for more information about Transparent Data Encryption
- *Oracle Database Enterprise User Security Administrator's Guide* for instructions for creating and opening keystores
- *Oracle Database SQL Language Reference* for information about the CREATE TABLE statement
- *Oracle Real Application Clusters Administration and Deployment Guide* for information on using a keystore in an Oracle Real Application Clusters environment

20.2.14 Understand Deferred Segment Creation

When you create heap-organized tables in a locally managed tablespace, the database defers table segment creation until the first row is inserted.

In addition, segment creation is deferred for any LOB columns of the table, any indexes created implicitly as part of table creation, and any indexes subsequently explicitly created on the table.

The advantages of this space allocation method are the following:

- It saves a significant amount of disk space in applications that create hundreds or thousands of tables upon installation, many of which might never be populated.
- It reduces application installation time.

There is a small performance penalty when the first row is inserted, because the new segment must be created at that time.

To enable deferred segment creation, compatibility must be set to 11.2.0 or higher.

The new clauses for the CREATE TABLE statement are:

- SEGMENT CREATION DEFERRED
- SEGMENT CREATION IMMEDIATE

These clauses override the default setting of the DEFERRED_SEGMENT_CREATION initialization parameter, TRUE, which defers segment creation. To disable deferred segment creation, set this parameter to FALSE.

Note that when you create a table with deferred segment creation, the new table appears in the *_TABLES views, but no entry for it appears in the *_SEGMENTS views until you insert the first row.

You can verify deferred segment creation by viewing the SEGMENT_CREATED column in *_TABLES, *_INDEXES, and *_LOBS views for nonpartitioned tables, and in *_TAB_PARTITIONS, *_IND_PARTITIONS, and *_LOB_PARTITIONS views for partitioned tables.

 **Note:**

With this new allocation method, it is essential that you do proper capacity planning so that the database has enough disk space to handle segment creation when tables are populated. See "[Capacity Planning for Database Objects](#)".

The following example creates two tables to demonstrate deferred segment creation. The first table uses the SEGMENT CREATION DEFERRED clause. No segments are created for it initially. The second table uses the SEGMENT CREATION IMMEDIATE clause and, therefore, segments are created for it immediately.

```
CREATE TABLE part_time_employees (
    empno NUMBER(8),
    name VARCHAR2(30),
    hourly_rate NUMBER (7,2)
)
SEGMENT CREATION DEFERRED;

CREATE TABLE hourly_employees (
    empno NUMBER(8),
    name VARCHAR2(30),
    hourly_rate NUMBER (7,2)
)
SEGMENT CREATION IMMEDIATE
PARTITION BY RANGE(empno)
(PARTITION empno_to_100 VALUES LESS THAN (100),
PARTITION empno_to_200 VALUES LESS THAN (200));
```

The following query against `USER_SEGMENTS` returns two rows for `HOURLY_EMPLOYEES`, one for each partition, but returns no rows for `PART_TIME_EMPLOYEES` because segment creation for that table was deferred.

```
SELECT segment_name, partition_name FROM user_segments;

SEGMENT_NAME          PARTITION_NAME
-----  -----
HOURLY_EMPLOYEES      EMPNO_TO_100
HOURLY_EMPLOYEES      EMPNO_TO_200
```

The `USER_TABLES` view shows that `PART_TIME_EMPLOYEES` has no segments:

```
SELECT table_name, segment_created FROM user_tables;
```

TABLE_NAME	SEGMENT_CREATED
PART_TIME_EMPLOYEES	NO
HOURLY_EMPLOYEES	N/A

For the `HOURLY_EMPLOYEES` table, which is partitioned, the `segment_created` column is N/A because the `USER_TABLES` view does not provide that information for partitioned tables. It is available from the `USER_TAB_PARTITIONS` view, shown below.

```
SELECT table_name, segment_created, partition_name
FROM user_tab_partitions;
```

TABLE_NAME	SEGMENT_CREATED	PARTITION_NAME
HOURLY_EMPLOYEES	YES	EMPNO_TO_100
HOURLY_EMPLOYEES	YES	EMPNO_TO_200

The following statements add employees to these tables.

```
INSERT INTO hourly_employees VALUES (99, 'FRose', 20.00);
INSERT INTO hourly_employees VALUES (150, 'LRose', 25.00);

INSERT INTO part_time_employees VALUES (50, 'KReilly', 10.00);
```

Repeating the same SELECT statements as before shows that PART_TIME_EMPLOYEES now has a segment, due to the insertion of row data. HOURLY_EMPLOYEES remains as before.

```
SELECT segment_name, partition_name FROM user_segments;
```

SEGMENT_NAME	PARTITION_NAME
PART_TIME_EMPLOYEES	
HOURLY_EMPLOYEES	EMPNO_TO_100
HOURLY_EMPLOYEES	EMPNO_TO_200

```
SELECT table_name, segment_created FROM user_tables;
```

TABLE_NAME	SEGMENT_CREATED
PART_TIME_EMPLOYEES	YES
HOURLY_EMPLOYEES	N/A

The USER_TAB_PARTITIONS view does not change.

See Also:

Oracle Database SQL Language Reference for notes and restrictions on deferred segment creation

20.2.15 Materializing Segments

The DBMS_SPACE_ADMIN package includes the MATERIALIZE_DEFERRED_SEGMENTS() procedure, which enables you to materialize segments for tables, table partitions, and dependent objects created with deferred segment creation enabled.

You can add segments as needed, rather than starting with more than you need and using database resources unnecessarily.

The following example materializes segments for the EMPLOYEES table in the HR schema.

```
BEGIN
  DBMS_SPACE_ADMIN.MATERIALIZE_DEFERRED_SEGMENTS(
    schema_name  => 'HR',
```

```
table_name    => 'EMPLOYEES' );  
END;
```

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for details about this procedure

20.2.16 Estimate Table Size and Plan Accordingly

Estimate the sizes of tables before creating them. Preferably, do this as part of database planning. Knowing the sizes, and uses, for database tables is an important part of database planning.

You can use the combined estimated size of tables, along with estimates for indexes, undo space, and redo log files, to determine the amount of disk space that is required to hold an intended database. From these estimates, you can make correct hardware purchases.

You can use the estimated size and growth rate of an individual table to better determine the attributes of a tablespace and its underlying data files that are best suited for the table. This can enable you to more easily manage the table disk space and improve I/O performance of applications that use the table.

 **See Also:**

["Capacity Planning for Database Objects "](#)

20.2.17 Restrictions to Consider When Creating Tables

There are restrictions to consider when you create tables.

Here are some restrictions that may affect your table planning and usage:

- Tables containing object types cannot be imported into a pre-Oracle8 database.
- You cannot merge an exported table into a preexisting table having the same name in a different schema.
- You cannot move types and extent tables to a different schema when the original data still exists in the database.
- Oracle Database has a limit on the total number of columns that a table (or attributes that an object type) can have. See *Oracle Database Reference* for this limit.

Further, when you create a table that contains user-defined type data, the database maps columns of user-defined type to relational columns for storing the user-defined type data. This causes additional relational columns to be created. This results in "hidden" relational columns that are not visible in a `DESCRIBE` table statement and are not returned by a `SELECT *` statement. Therefore, when you

create an object table, or a relational table with columns of REF, varray, nested table, or object type, be aware that the total number of columns that the database actually creates for the table can be more than those you specify.

 **See Also:**

Oracle Database Object-Relational Developer's Guide for more information about user-defined types

20.3 Creating Tables

Create tables using the SQL statement `CREATE TABLE`.

To create a new table in your schema, you must have the `CREATE TABLE` system privilege. To create a table in another user's schema, you must have the `CREATE ANY TABLE` system privilege. Additionally, the owner of the table must have a quota for the tablespace that contains the table, or the `UNLIMITED TABLESPACE` system privilege.

- [Example: Creating a Table](#)
An example illustrates creating a table.
- [Creating a Temporary Table](#)
Temporary tables are useful in applications where a result set is to be buffered (temporarily persisted), perhaps because it is constructed by running multiple DML operations.
- [Parallelizing Table Creation](#)
When you specify the `AS SELECT` clause to create a table and populate it with data from another table, you can use parallel execution.

 **See Also:**

Oracle Database SQL Language Reference for exact syntax of the `CREATE TABLE` and other SQL statements discussed in this chapter

20.3.1 Example: Creating a Table

An example illustrates creating a table.

When you issue the following statement, you create a table named `admin_emp` in the `hr` schema and store it in the `admin_tbs` tablespace:

 **Live SQL:**

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating and Modifying Tables](#).

```
CREATE TABLE hr.admin_emp (
    empno      NUMBER(5) PRIMARY KEY,
    ename      VARCHAR2(15) NOT NULL,
    ssn        NUMBER(9) ENCRYPT USING 'AES256',
    job        VARCHAR2(10),
    mgr        NUMBER(5),
    hiredate   DATE DEFAULT (sysdate),
    photo      BLOB,
    sal         NUMBER(7,2),
    hrly_rate  NUMBER(7,2) GENERATED ALWAYS AS (sal/2080),
    comm       NUMBER(7,2),
    deptno     NUMBER(3) NOT NULL
        CONSTRAINT admin_dept_fkey REFERENCES hr.departments
        (department_id),
    comments   VARCHAR2(32767),
    status      VARCHAR2(10) INVISIBLE)
TABLESPACE admin_tbs
STORAGE ( INITIAL 50K);

COMMENT ON TABLE hr.admin_emp IS 'Enhanced employee table';
```

Note the following about this example:

- Integrity constraints are defined on several columns of the table.
- The `STORAGE` clause specifies the size of the first extent. See *Oracle Database SQL Language Reference* for details on this clause.
- Encryption is defined on one column (`ssn`), through the Transparent Data Encryption feature of Oracle Database. The keystore must therefore be open for this `CREATE TABLE` statement to succeed.
- The `photo` column is of data type `BLOB`, which is a member of the set of data types called large objects (LOBs). LOBs are used to store semi-structured data (such as an XML tree) and unstructured data (such as the stream of bits in a color image).
- One column is defined as a virtual column (`hrly_rate`). This column computes the employee's hourly rate as the yearly salary divided by 2,080. See *Oracle Database SQL Language Reference* for a discussion of rules for virtual columns.
- The `comments` column is a `VARCHAR2` column that is larger than 4000 bytes. Beginning with Oracle Database 12c, the maximum size for the `VARCHAR2`, `NVARCHAR2`, and `RAW` data types is increased to 32767 bytes.

To use extended data types, set the `MAX_STRING_SIZE` initialization parameter to `EXTENDED`. See *Oracle Database Reference* for information about setting this parameter.

- The `status` column is invisible.
- A `COMMENT` statement is used to store a comment for the table. You query the `*_TAB_COMMENTS` data dictionary views to retrieve such comments. See *Oracle Database SQL Language Reference* for more information.

 See Also:

- [Oracle Database SQL Language Reference](#) for a description of the data types that you can specify for table columns
- ["Managing Integrity Constraints"](#)
- ["Understand Invisible Columns"](#)
- [Oracle Database Advanced Security Guide](#) for information about Transparent Data Encryption
- [Oracle Database SecureFiles and Large Objects Developer's Guide](#) for more information about LOBs.

20.3.2 Creating a Temporary Table

Temporary tables are useful in applications where a result set is to be buffered (temporarily persisted), perhaps because it is constructed by running multiple DML operations.

For example, assume a Web-based airlines reservations application allows a customer to create several optional itineraries. Each itinerary is represented by a row in a temporary table. The application updates the rows to reflect changes in the itineraries. When the customer decides which itinerary she wants to use, the application moves the row for that itinerary to a persistent table.

During the session, the itinerary data is private. At the end of the session, the optional itineraries are dropped.

The definition of a temporary table is visible to all sessions, but the data in a temporary table is visible only to the session that inserts the data into the table.

Use the `CREATE GLOBAL TEMPORARY TABLE` statement to create a temporary table. The `ON COMMIT` clause indicates if the data in the table is **transaction-specific** (the default) or **session-specific**, the implications of which are as follows:

ON COMMIT Setting	Implications
<code>DELETE ROWS</code>	This creates a temporary table that is transaction specific. A session becomes bound to the temporary table with a transaction's first insert into the table. The binding goes away at the end of the transaction. The database truncates the table (delete all rows) after each commit.
<code>PRESERVE ROWS</code>	This creates a temporary table that is session specific. A session gets bound to the temporary table with the first insert into the table in the session. This binding goes away at the end of the session or by issuing a <code>TRUNCATE</code> of the table in the session. The database truncates the table when you terminate the session.

This statement creates a temporary table that is transaction specific:

```
CREATE GLOBAL TEMPORARY TABLE admin_work_area
  (startdate DATE,
   enddate DATE,
   class CHAR(20))
  ON COMMIT DELETE ROWS;
```

Indexes can be created on temporary tables. They are also temporary and the data in the index has the same session or transaction scope as the data in the underlying table.

By default, rows in a temporary table are stored in the default temporary tablespace of the user who creates it. However, you can assign a temporary table to another tablespace upon creation of the temporary table by using the TABLESPACE clause of CREATE GLOBAL TEMPORARY TABLE. You can use this feature to conserve space used by temporary tables. For example, if you must perform many small temporary table operations and the default temporary tablespace is configured for sort operations and thus uses a large extent size, these small operations will consume lots of unnecessary disk space. In this case it is better to allocate a second temporary tablespace with a smaller extent size.

The following two statements create a temporary tablespace with a 64 KB extent size, and then a new temporary table in that tablespace.

```
CREATE TEMPORARY TABLESPACE tbs_t1
  TEMPFILE 'tbs_t1.f' SIZE 50m REUSE AUTOEXTEND ON
  MAXSIZE UNLIMITED
  EXTENT MANAGEMENT LOCAL UNIFORM SIZE 64K;

CREATE GLOBAL TEMPORARY TABLE admin_work_area
  (startdate DATE,
   enddate DATE,
   class CHAR(20))
  ON COMMIT DELETE ROWS
  TABLESPACE tbs_t1;
```

 **Note:**

["Temporary Tablespaces"](#)

Unlike permanent tables, temporary tables and their indexes do not automatically allocate a segment when they are created. Instead, segments are allocated when the first `INSERT` (or `CREATE TABLE AS SELECT`) is performed. Therefore, if a `SELECT`, `UPDATE`, or `DELETE` is performed before the first `INSERT`, then the table appears to be empty.

DDL operations (except `TRUNCATE`) are allowed on an existing temporary table only if no session is currently bound to that temporary table.

If you rollback a transaction, the data you entered is lost, although the table definition persists.

A transaction-specific temporary table allows only one transaction at a time. If there are several autonomous transactions in a single transaction scope, each autonomous transaction can use the table only as soon as the previous one commits.

Because the data in a temporary table is, by definition, temporary, backup and recovery of temporary table data is not available in the event of a system failure. To prepare for such a failure, you should develop alternative methods for preserving temporary table data.

20.3.3 Parallelizing Table Creation

When you specify the AS SELECT clause to create a table and populate it with data from another table, you can use parallel execution.

The CREATE TABLE...AS SELECT statement contains two parts: a CREATE part (DDL) and a SELECT part (query). Oracle Database can parallelize both parts of the statement. The CREATE part is parallelized if one of the following is true:

- A PARALLEL clause is included in the CREATE TABLE...AS SELECT statement
- An ALTER SESSION FORCE PARALLEL DDL statement is specified

The query part is parallelized if all of the following are true:

- The query includes a parallel hint specification (PARALLEL or PARALLEL_INDEX) or the CREATE part includes the PARALLEL clause or the schema objects referred to in the query have a PARALLEL declaration associated with them.
- At least one of the tables specified in the query requires either a full table scan or an index range scan spanning multiple partitions.

If you parallelize the creation of a table, that table then has a parallel declaration (the PARALLEL clause) associated with it. Any subsequent DML or queries on the table, for which parallelization is possible, will attempt to use parallel execution.

The following simple statement parallelizes the creation of a table and stores the result in a compressed format, using table compression:

```
CREATE TABLE hr.admin_emp_dept
  PARALLEL COMPRESS
  AS SELECT * FROM hr.employees
  WHERE department_id = 10;
```

In this case, the PARALLEL clause tells the database to select an optimum number of parallel execution servers when creating the table.

See Also:

- *Oracle Database VLDB and Partitioning Guide* for detailed information on using parallel execution
- "[Managing Processes for Parallel SQL Execution](#)"

20.4 Loading Tables

There are several techniques for loading data into tables.

 Note:

The default size of the first extent of any new segment for a partitioned table is 8 MB instead of 64 KB. This helps improve performance of inserts and queries on partitioned tables. Although partitioned tables will start with a larger initial size, once sufficient data is inserted, the space consumption will be the same as in previous releases. You can override this default by setting the `INITIAL` size in the storage clause for the table. This new default only applies to table partitions and LOB partitions.

- [Methods for Loading Tables](#)

There are several means of inserting or initially loading data into your tables.

- [Improving INSERT Performance with Direct-Path INSERT](#)

When loading large amounts of data, you can improve load performance by using direct-path `INSERT`.

- [Using Conventional Inserts to Load Tables](#)

During **conventional INSERT operations**, the database reuses free space in the table, interleaving newly inserted data with existing data. During such operations, the database also maintains referential integrity constraints. Unlike direct-path `INSERT` operations, conventional `INSERT` operations do not require an exclusive lock on the table.

- [Avoiding Bulk INSERT Failures with DML Error Logging](#)

You can avoid bulk `INSERT` failures by using the DML error logging feature.

20.4.1 Methods for Loading Tables

There are several means of inserting or initially loading data into your tables.

Most commonly used are the following:

Method	Description
SQL*Loader	This Oracle utility program loads data from external files into tables of an Oracle Database. Starting with Oracle Database 12c, SQL*Loader supports express mode. SQL*Loader express mode eliminates the need for a control file. Express mode simplifies loading data from external files. With express mode, SQL*Loader attempts to use the external table load method. If the external table load method is not possible, then SQL*Loader attempts to use direct path. If direct path is not possible, then SQL*Loader uses conventional path. SQL*Loader express mode automatically identifies the input datatypes based on the table column types and controls parallelism. SQL*Loader uses defaults to simplify usage, but you can override many of the defaults with command line parameters. You optionally can specify the direct path or the conventional path load method instead of using express mode. For information about SQL*Loader, see <i>Oracle Database Utilities</i> .

Method	Description
CREATE TABLE ... AS SELECT statement (CTAS)	Using this SQL statement you can create a table and populate it with data selected from another existing table, including an external table.
INSERT statement	The INSERT statement enables you to add rows to a table, either by specifying the column values or by specifying a subquery that selects data from another existing table, including an external table.
MERGE statement	<p>One form of the INSERT statement enables direct-path INSERT, which can improve performance, and is useful for bulk loading. See "Improving INSERT Performance with Direct-Path INSERT".</p> <p>If you are inserting a lot of data and want to avoid statement termination and rollback if an error is encountered, you can insert with DML error logging. See "Avoiding Bulk INSERT Failures with DML Error Logging".</p> <p>The MERGE statement enables you to insert rows into or update rows of a table, by selecting rows from another existing table. If a row in the new data corresponds to an item that already exists in the table, then an UPDATE is performed, else an INSERT is performed.</p>

 **Note:**

Only a few details and examples of inserting data into tables are included in this book. Oracle documentation specific to data warehousing and application development provide more extensive information about inserting and manipulating data in tables. See:

- [Oracle Database Data Warehousing Guide](#)
- [Oracle Database SecureFiles and Large Objects Developer's Guide](#)

 **See Also:**

["Managing External Tables"](#)

20.4.2 Improving INSERT Performance with Direct-Path INSERT

When loading large amounts of data, you can improve load performance by using direct-path INSERT.

- [About Direct-Path INSERT](#)
Direct-path insert operations are typically faster than conventional insert operations.
- [How Direct-Path INSERT Works](#)
You can use direct-path INSERT on both partitioned and nonpartitioned tables.

- [Loading Data with Direct-Path INSERT](#)
You can load data with direct-path `INSERT` by using direct-path `INSERT` SQL statements, inserting data in parallel mode, or by using the Oracle SQL*Loader utility in direct-path mode. A direct-path `INSERT` can be done in either serial or parallel mode.
- [Logging Modes for Direct-Path INSERT](#)
Direct-path `INSERT` lets you choose whether to log redo and undo information during the insert operation.
- [Additional Considerations for Direct-Path INSERT](#)

20.4.2.1 About Direct-Path `INSERT`

Direct-path insert operations are typically faster than conventional insert operations.

Oracle Database inserts data into a table in one of two ways:

- During **conventional `INSERT` operations**, the database reuses free space in the table, interleaving newly inserted data with existing data. During such operations, the database also maintains referential integrity constraints.
- During **direct-path `INSERT` operations**, the database appends the inserted data after existing data in the table. Data is written directly into data files, bypassing the buffer cache. Free space in the table is not reused, and referential integrity constraints are ignored. Direct-path `INSERT` can perform significantly better than conventional insert.

The database can insert data either in serial mode, where one process executes the statement, or in parallel mode, where multiple processes work together simultaneously to run a single SQL statement. The latter is referred to as parallel execution.

The following are benefits of direct-path `INSERT`:

- During direct-path `INSERT`, you can disable the logging of redo and undo entries to reduce load time. Conventional insert operations, in contrast, must always log such entries, because those operations reuse free space and maintain referential integrity.
- Direct-path `INSERT` operations ensure atomicity of the transaction, even when run in parallel mode. Atomicity cannot be guaranteed during parallel direct path loads (using SQL*Loader).

When performing parallel direct path loads, one notable difference between SQL*Loader and `INSERT` statements is the following: If errors occur during parallel direct path loads with SQL*Loader, the load completes, but some indexes could be marked `UNUSABLE` at the end of the load. Parallel direct-path `INSERT`, in contrast, rolls back the statement if errors occur during index update.

 **Note:**

A conventional `INSERT` operation checks for violations of NOT NULL constraints during the insert. Therefore, if a NOT NULL constraint is violated for a conventional `INSERT` operation, then the error is returned during the insert. A direct-path `INSERT` operation checks for violations of NOT NULL constraints before the insert. Therefore, if a NOT NULL constraint is violated for a direct-path `INSERT` operation, then the error is returned before the insert.

20.4.2.2 How Direct-Path `INSERT` Works

You can use direct-path `INSERT` on both partitioned and nonpartitioned tables.

- [Serial Direct-Path `INSERT` into Partitioned or Nonpartitioned Tables](#)

The single process inserts data beyond the current high water mark of the table segment or of each partition segment. (The **high-water mark** is the level at which blocks have never been formatted to receive data.) When a `COMMIT` runs, the high-water mark is updated to the new value, making the data visible to users.

- [Parallel Direct-Path `INSERT` into Partitioned Tables](#)

This situation is analogous to serial direct-path `INSERT`. Each parallel execution server is assigned one or more partitions, with no more than one process working on a single partition.

- [Parallel Direct-Path `INSERT` into Nonpartitioned Tables](#)

Each parallel execution server allocates a new temporary segment and inserts data into that temporary segment. When a `COMMIT` runs, the parallel execution coordinator merges the new temporary segments into the primary table segment, where it is visible to users.

20.4.2.2.1 Serial Direct-Path `INSERT` into Partitioned or Nonpartitioned Tables

The single process inserts data beyond the current high water mark of the table segment or of each partition segment. (The **high-water mark** is the level at which blocks have never been formatted to receive data.) When a `COMMIT` runs, the high-water mark is updated to the new value, making the data visible to users.

20.4.2.2.2 Parallel Direct-Path `INSERT` into Partitioned Tables

This situation is analogous to serial direct-path `INSERT`. Each parallel execution server is assigned one or more partitions, with no more than one process working on a single partition.

Each parallel execution server inserts data beyond the current high-water mark of its assigned partition segment(s). When a `COMMIT` runs, the high-water mark of each partition segment is updated to its new value, making the data visible to users.

20.4.2.2.3 Parallel Direct-Path `INSERT` into Nonpartitioned Tables

Each parallel execution server allocates a new temporary segment and inserts data into that temporary segment. When a `COMMIT` runs, the parallel execution coordinator merges the new temporary segments into the primary table segment, where it is visible to users.

20.4.2.3 Loading Data with Direct-Path INSERT

You can load data with direct-path `INSERT` by using direct-path `INSERT` SQL statements, inserting data in parallel mode, or by using the Oracle SQL*Loader utility in direct-path mode. A direct-path `INSERT` can be done in either serial or parallel mode.

- **Serial Mode Inserts with SQL Statements**

There are various ways to activate direct-path `INSERT` in serial mode with SQL.

- **Parallel Mode Inserts with SQL Statements**

When you are inserting in parallel mode, direct-path `INSERT` is the default. However, you can insert in parallel mode using conventional `INSERT` by using the `NOAPPEND PARALLEL` hint.

20.4.2.3.1 Serial Mode Inserts with SQL Statements

There are various ways to activate direct-path `INSERT` in serial mode with SQL.

You can activate direct-path `INSERT` in serial mode with SQL in the following ways:

- If you are performing an `INSERT` with a subquery, specify the `APPEND` hint in each `INSERT` statement, either immediately after the `INSERT` keyword, or immediately after the `SELECT` keyword in the subquery of the `INSERT` statement.
- If you are performing an `INSERT` with the `VALUES` clause, specify the `APPEND_VALUES` hint in each `INSERT` statement immediately after the `INSERT` keyword. Direct-path `INSERT` with the `VALUES` clause is best used when there are hundreds of thousands or millions of rows to load. The typical usage scenario is for array inserts using OCI. Another usage scenario might be inserts in a `FORALL` statement in PL/SQL.

If you specify the `APPEND` hint (as opposed to the `APPEND_VALUES` hint) in an `INSERT` statement with a `VALUES` clause, the `APPEND` hint is ignored and a conventional insert is performed.

The following is an example of using the `APPEND` hint to perform a direct-path `INSERT`:

```
INSERT /*+ APPEND */ INTO sales_hist SELECT * FROM sales WHERE cust_id=8890;
```

The following PL/SQL code fragment is an example of using the `APPEND_VALUES` hint:

```
FORALL i IN 1..numrecords
  INSERT /*+ APPEND_VALUES */ INTO orderdata
    VALUES(ordernum(i), custid(i), orderdate(i), shipmode(i), paymentid(i));
  COMMIT;
```

20.4.2.3.2 Parallel Mode Inserts with SQL Statements

When you are inserting in parallel mode, direct-path `INSERT` is the default. However, you can insert in parallel mode using conventional `INSERT` by using the `NOAPPEND PARALLEL` hint.

To run in parallel DML mode, the following requirements must be met:

- You must have Oracle Enterprise Edition installed.
- You must enable parallel DML in your session. To do this, submit the following statement:

```
ALTER SESSION { ENABLE | FORCE } PARALLEL DML;
```

- You must meet at least one of the following requirements:
 - Specify the parallel attribute for the target table, either at create time or subsequently
 - Specify the PARALLEL hint for each insert operation
 - Set the database initialization parameter PARALLEL_DEGREE_POLICY to AUTO

To disable direct-path INSERT, specify the NOAPPEND hint in each INSERT statement. Doing so overrides parallel DML mode.

 **Note:**

You cannot query or modify data inserted using direct-path INSERT immediately after the insert is complete. If you attempt to do so, an ORA-12838 error is generated. You must first issue a COMMIT statement before attempting to read or modify the newly-inserted data.

 **See Also:**

- "[Using Conventional Inserts to Load Tables](#)"
- *Oracle Database SQL Tuning Guide* for more information on using hints
- *Oracle Database SQL Language Reference* for more information on the subquery syntax of INSERT statements and for additional restrictions on using direct-path INSERT

20.4.2.4 Logging Modes for Direct-Path INSERT

Direct-path INSERT lets you choose whether to log redo and undo information during the insert operation.

You specify the logging mode for direct-path INSERT in the following ways:

- You can specify logging mode for a table, partition, index, or LOB storage at create time (in a CREATE statement) or subsequently (in an ALTER statement).
- If you do not specify either LOGGING or NOLOGGING at these times:
 - The logging attribute of a partition defaults to the logging attribute of its table.
 - The logging attribute of a table or index defaults to the logging attribute of the tablespace in which it resides.
 - The logging attribute of LOB storage defaults to LOGGING if you specify CACHE for LOB storage. If you do not specify CACHE, then the logging attributes defaults to that of the tablespace in which the LOB values resides.
- You set the logging attribute of a tablespace in a CREATE TABLESPACE or ALTER TABLESPACE statements.

 **Note:**

If the database or tablespace is in FORCE LOGGING mode, then direct-path INSERT always logs, regardless of the logging setting.

- [Direct-Path INSERT with Logging](#)

In this mode, Oracle Database performs full redo logging for instance and media recovery.

- [Direct-Path INSERT without Logging](#)

In this mode, Oracle Database inserts data without redo or undo logging. Instead, the database logs a small number of block range invalidation redo records and periodically updates the control file with information about the most recent direct write.

20.4.2.4.1 Direct-Path INSERT with Logging

In this mode, Oracle Database performs full redo logging for instance and media recovery.

If the database is in ARCHIVELOG mode, then you can archive redo logs to tape. If the database is in NOARCHIVELOG mode, then you can recover instance crashes but not disk failures.

20.4.2.4.2 Direct-Path INSERT without Logging

In this mode, Oracle Database inserts data without redo or undo logging. Instead, the database logs a small number of block range invalidation redo records and periodically updates the control file with information about the most recent direct write.

Direct-path INSERT without logging improves performance. However, if you subsequently must perform media recovery, the invalidation redo records mark a range of blocks as logically corrupt, because no redo data was logged for them. Therefore, it is important that you back up the data after such an insert operation.

You can significantly improve the performance of unrecoverable direct-path inserts by disabling the periodic update of the control files. You do so by setting the initialization parameter `DB_UNRECOVERABLE_SCN_TRACKING` to FALSE. However, if you perform an unrecoverable direct-path insert with these control file updates disabled, you will no longer be able to accurately query the database to determine if any data files are currently unrecoverable.

 **See Also:**

- *Oracle Database Backup and Recovery User's Guide* for more information about unrecoverable data files
- The section "Determining If a Backup Is Required After Unrecoverable Operations" in *Oracle Data Guard Concepts and Administration*

20.4.2.5 Additional Considerations for Direct-Path INSERT

When using direct-path `INSERT`, consider issues related to compressed tables, index maintenance, disk space, and locking.

- [Compressed Tables and Direct-Path INSERT](#)

If a table is created with the basic table compression, then you must use direct-path `INSERT` to compress table data as it is loaded. If a table is created with advanced row, warehouse, or archive compression, then best compression ratios are achieved with direct-path `INSERT`.

- [Index Maintenance with Direct-Path INSERT](#)

Oracle Database performs index maintenance at the end of direct-path `INSERT` operations on tables (partitioned or nonpartitioned) that have indexes.

- [Space Considerations with Direct-Path INSERT](#)

Direct-path `INSERT` requires more space than conventional path `INSERT`.

- [Locking Considerations with Direct-Path INSERT](#)

During direct-path `INSERT`, the database obtains exclusive locks on the table (or on all partitions of a partitioned table).

20.4.2.5.1 Compressed Tables and Direct-Path INSERT

If a table is created with the basic table compression, then you must use direct-path `INSERT` to compress table data as it is loaded. If a table is created with advanced row, warehouse, or archive compression, then best compression ratios are achieved with direct-path `INSERT`.

See "[Consider Using Table Compression](#)" for more information.

20.4.2.5.2 Index Maintenance with Direct-Path INSERT

Oracle Database performs index maintenance at the end of direct-path `INSERT` operations on tables (partitioned or nonpartitioned) that have indexes.

This index maintenance is performed by the parallel execution servers for parallel direct-path `INSERT` or by the single process for serial direct-path `INSERT`. You can avoid the performance impact of index maintenance by making the index unusable before the `INSERT` operation and then rebuilding it afterward.

 **See Also:**

["Making an Index Unusable"](#)

20.4.2.5.3 Space Considerations with Direct-Path INSERT

Direct-path `INSERT` requires more space than conventional path `INSERT`.

All serial direct-path `INSERT` operations, as well as parallel direct-path `INSERT` into partitioned tables, insert data above the high-water mark of the affected segment. This requires some additional space.

Parallel direct-path `INSERT` into nonpartitioned tables requires even more space, because it creates a temporary segment for each degree of parallelism. If the nonpartitioned table is not in a locally managed tablespace in automatic segment-space management mode, you can modify the values of the `NEXT` and `PCTINCREASE` storage parameter and `MINIMUM EXTENT` tablespace parameter to provide sufficient (but not excess) storage for the temporary segments. Choose values for these parameters so that:

- The size of each extent is not too small (no less than 1 MB). This setting affects the total number of extents in the object.
- The size of each extent is not so large that the parallel `INSERT` results in wasted space on segments that are larger than necessary.

After the direct-path `INSERT` operation is complete, you can reset these parameters to settings more appropriate for serial operations.

20.4.2.5.4 Locking Considerations with Direct-Path `INSERT`

During direct-path `INSERT`, the database obtains exclusive locks on the table (or on all partitions of a partitioned table).

As a result, users cannot perform any concurrent insert, update, or delete operations on the table, and concurrent index creation and build operations are not permitted. Concurrent queries, however, are supported, but the query will return only the information before the insert operation.

20.4.3 Using Conventional Inserts to Load Tables

During **conventional `INSERT` operations**, the database reuses free space in the table, interleaving newly inserted data with existing data. During such operations, the database also maintains referential integrity constraints. Unlike direct-path `INSERT` operations, conventional `INSERT` operations do not require an exclusive lock on the table.

Several other restrictions apply to direct-path `INSERT` operations that do not apply to conventional `INSERT` operations. See *Oracle Database SQL Language Reference* for information about these restrictions.

You can perform a conventional `INSERT` operation in serial mode or in parallel mode using the `NOAPPEND` hint.

The following is an example of using the `NOAPPEND` hint to perform a conventional `INSERT` in serial mode:

```
INSERT /*+ NOAPPEND */ INTO sales_hist SELECT * FROM sales WHERE cust_id=8890;
```

The following is an example of using the `NOAPPEND` hint to perform a conventional `INSERT` in parallel mode:

```
INSERT /*+ NOAPPEND PARALLEL */ INTO sales_hist
SELECT * FROM sales;
```

To run in parallel DML mode, the following requirements must be met:

- You must have Oracle Enterprise Edition installed.
- You must enable parallel DML in your session. To do this, submit the following statement:

```
ALTER SESSION { ENABLE | FORCE } PARALLEL DML;
```

- You must meet at least one of the following requirements:
 - Specify the parallel attribute for the target table, either at create time or subsequently
 - Specify the PARALLEL hint for each insert operation
 - Set the database initialization parameter PARALLEL_DEGREE_POLICY to AUTO

20.4.4 Avoiding Bulk INSERT Failures with DML Error Logging

You can avoid bulk `INSERT` failures by using the DML error logging feature.

- [Inserting Data with DML Error Logging](#)
When you load a table using an `INSERT` statement with subquery, if an error occurs, the statement is terminated and rolled back in its entirety. This can be wasteful of time and system resources. For such `INSERT` statements, you can avoid this situation by using the DML error logging feature.
- [Error Logging Table Format](#)
The error logging table has a specific format.
- [Creating an Error Logging Table](#)
You can create an error logging table manually, or you can use a PL/SQL package to automatically create one for you.
- [Error Logging Restrictions and Caveats](#)
Some errors are not logged in error logging tables.

20.4.4.1 Inserting Data with DML Error Logging

When you load a table using an `INSERT` statement with subquery, if an error occurs, the statement is terminated and rolled back in its entirety. This can be wasteful of time and system resources. For such `INSERT` statements, you can avoid this situation by using the DML error logging feature.

To use DML error logging, you add a statement clause that specifies the name of an error logging table into which the database records errors encountered during DML operations. When you add this error logging clause to the `INSERT` statement, certain types of errors no longer terminate and roll back the statement. Instead, each error is logged and the statement continues. You then take corrective action on the erroneous rows at a later time.

DML error logging works with `INSERT`, `UPDATE`, `MERGE`, and `DELETE` statements. This section focuses on `INSERT` statements.

To insert data with DML error logging:

1. Create an error logging table. (Optional)

You can create the table manually or use the `DBMS_ERRLOG` package to automatically create it for you. See "[Creating an Error Logging Table](#)" for details.

2. Execute an `INSERT` statement and include an error logging clause. This clause:

- Optionally references the error logging table that you created. If you do not provide an error logging table name, the database logs to an error logging table with a default name. The default error logging table name is `ERR$`

followed by the first 25 characters of the name of the table that is being inserted into.

- Optionally includes a **tag** (a numeric or string literal in parentheses) that gets added to the error log to help identify the statement that caused the errors. If the tag is omitted, a **NULL** value is used.
- Optionally includes a **REJECT LIMIT** subclause.

This subclause indicates the maximum number of errors that can be encountered before the **INSERT** statement terminates and rolls back. You can also specify **UNLIMITED**. The default reject limit is zero, which means that upon encountering the first error, the error is logged and the statement rolls back. For parallel DML operations, the reject limit is applied to each parallel execution server.

 **Note:**

If the statement exceeds the reject limit and rolls back, the error logging table retains the log entries recorded so far.

See *Oracle Database SQL Language Reference* for error logging clause syntax information.

3. Query the error logging table and take corrective action for the rows that generated errors.

See "[Error Logging Table Format](#)", later in this section, for details on the error logging table structure.

Example 20-9 Inserting Data with DML Error Logging

The following statement inserts rows into the **DW_EMPL** table and logs errors to the **ERR_EMPL** table. The tag 'daily_load' is copied to each log entry. The statement terminates and rolls back if the number of errors exceeds 25.

```
INSERT INTO dw_empl
  SELECT employee_id, first_name, last_name, hire_date, salary, department_id
    FROM employees
   WHERE hire_date > sysdate - 7
LOG ERRORS INTO err_empl ('daily_load') REJECT LIMIT 25
```

For more examples, see *Oracle Database SQL Language Reference* and *Oracle Database Data Warehousing Guide*.

20.4.4.2 Error Logging Table Format

The error logging table has a specific format.

The error logging table consists of two parts:

- A mandatory set of columns that describe the error. For example, one column contains the Oracle error number.

[Table 20-3](#) lists these error description columns.

- An optional set of columns that contain data from the row that caused the error. The column names match the column names from the table being inserted into (the "DML table").

The number of columns in this part of the error logging table can be zero, one, or more, up to the number of columns in the DML table. If a column exists in the error logging table that has the same name as a column in the DML table, the corresponding data from the offending row being inserted is written to this error logging table column. If a DML table column does not have a corresponding column in the error logging table, the column is not logged. If the error logging table contains a column with a name that does not match a DML table column, the column is ignored.

Because type conversion errors are one type of error that might occur, the data types of the optional columns in the error logging table must be types that can capture any value without data loss or conversion errors. (If the optional log columns were of the same types as the DML table columns, capturing the problematic data into the log could suffer the same data conversion problem that caused the error.) The database makes a best effort to log a meaningful value for data that causes conversion errors. If a value cannot be derived, `NULL` is logged for the column. An error on insertion into the error logging table causes the statement to terminate.

[Table 20-4](#) lists the recommended error logging table column data types to use for each data type from the DML table. These recommended data types are used when you create the error logging table automatically with the `DBMS_ERRLOG` package.

Table 20-3 Mandatory Error Description Columns

Column Name	Data Type	Description
ORA_ERR_NUMBE R\$	NUMBER	Oracle error number
ORA_ERR_MSG\$)	VARCHAR2(2000)	Oracle error message text
ORA_ERR_ROWI D\$	ROWID	Rowid of the row in error (for update and delete)
ORA_ERR_OPTY P\$	VARCHAR2(2)	Type of operation: insert (I), update (U), delete (D) Note: Errors from the update clause and insert clause of a MERGE operation are distinguished by the U and I values.
ORA_ERR_TAG\$)	VARCHAR2(2000)	Value of the tag supplied by the user in the error logging clause

Table 20-4 Error Logging Table Column Data Types

DML Table Column Type	Error Logging Table Column Type	Notes
NUMBER	VARCHAR2(4000)	Able to log conversion errors
CHAR/ VARCHAR2(n)	VARCHAR2(4000)	Logs any value without information loss

Table 20-4 (Cont.) Error Logging Table Column Data Types

DML Table Column Type	Error Logging Table Column Type	Notes
NCHAR/ NVARCHAR2(n)	NVARCHAR2(4000)	Logs any value without information loss
DATE/TIMESTAMP	VARCHAR2(4000)	Logs any value without information loss. Converts to character format with the default date/time format mask
RAW	RAW(2000)	Logs any value without information loss
ROWID	UROWID	Logs any rowid type
LONG/LOB		Not supported
User-defined types		Not supported

20.4.4.3 Creating an Error Logging Table

You can create an error logging table manually, or you can use a PL/SQL package to automatically create one for you.

- [Creating an Error Logging Table Automatically](#)
You use the DBMS_ERRLOG package to automatically create an error logging table.
- [Creating an Error Logging Table Manually](#)
You use standard DDL to manually create the error logging table.

20.4.4.3.1 Creating an Error Logging Table Automatically

You use the DBMS_ERRLOG package to automatically create an error logging table.

The CREATE_ERROR_LOG procedure creates an error logging table with all of the mandatory error description columns plus all of the columns from the named DML table, and performs the data type mappings shown in [Table 20-4](#).

The following statement creates the error logging table used in the previous example.

```
EXECUTE DBMS_ERRLOG.CREATE_ERROR_LOG('DW_EMPL', 'ERR_EMPL');
```

See *Oracle Database PL/SQL Packages and Types Reference* for details on DBMS_ERRLOG.

20.4.4.3.2 Creating an Error Logging Table Manually

You use standard DDL to manually create the error logging table.

See "[Error Logging Table Format](#)" for table structure requirements. You must include all mandatory error description columns. They can be in any order, but must be the first columns in the table.

20.4.4.4 Error Logging Restrictions and Caveats

Some errors are not logged in error logging tables.

Oracle Database logs the following errors during DML operations:

- Column values that are too large
- Constraint violations (NOT NULL, unique, referential, and check constraints)
- Errors raised during trigger execution
- Errors resulting from type conversion between a column in a subquery and the corresponding column of the table
- Partition mapping errors
- Certain MERGE operation errors (ORA-30926: Unable to get a stable set of rows for MERGE operation.)

Some errors are not logged, and cause the DML operation to terminate and roll back. For a list of these errors and for other DML logging restrictions, see the discussion of the `error_logging_clause` in the `INSERT` section of *Oracle Database SQL Language Reference*.

- **Space Considerations**
Ensure that you consider space requirements before using DML error logging. You require available space not only for the table being inserted into, but also for the error logging table.
- **Security**
The user who issues the `INSERT` statement with DML error logging must have `INSERT` privileges on the error logging table.

20.4.4.1 Space Considerations

Ensure that you consider space requirements before using DML error logging. You require available space not only for the table being inserted into, but also for the error logging table.

20.4.4.2 Security

The user who issues the `INSERT` statement with DML error logging must have `INSERT` privileges on the error logging table.

 **See Also:**

Oracle Database SQL Language Reference and *Oracle Database Data Warehousing Guide* for DML error logging examples.

20.5 Optimizing the Performance of Bulk Updates

The `EXECUTE_UPDATE` procedure in the `DBMS_REDEFINITION` package can optimize the performance of bulk updates to a table. Performance is optimized because the updates are not logged in the redo log.

The `EXECUTE_UPDATE` procedure automatically uses the components of online table redefinition, such an interim table, a materialized view, and a materialized view log, to enable optimized bulk updates to a table. The `EXECUTE_UPDATE` procedure also

removes fragmentation of the affected rows and ensures that the update is atomic. If the bulk updates raise any errors, then you can use the `ABORT_UPDATE` procedure to undo the changes made by the `EXECUTE_UPDATE` procedure.

The following restrictions apply to the `EXECUTE_UPDATE` procedure:

- All of the restrictions that apply to online table redefinition apply to the `EXECUTE_UPDATE` procedure and the `ABORT_UPDATE` procedure.
- You cannot run more than one `EXECUTE_UPDATE` procedure on a table at the same time.
- While the `EXECUTE_UPDATE` procedure is running on a table, do not make DML changes on the table from a different session. These DML changes are lost when the `EXECUTE_UPDATE` procedure completes.
- The table cannot have any triggers that fire on `UPDATE` statements.
- The `UPDATE` statement passed to the `EXECUTE_UPDATE` procedure cannot have a table with a partition-extended name.
- The table cannot have the following user-defined types: varrays, REFs, and nested tables.
- The table cannot have the following Oracle-supplied types: `ANYTYPE`, `ANYDATASET`, `URI` types, `SDO_TOPO_GEOMETRY`, `SDO_GEOASTER`, and `Expression`.
- The table cannot have the following types of columns: hidden column, virtual column, unused column, pseudocolumns, or identity column.
- The table cannot be an object table.
- The table cannot have a Virtual Private Database (VPD) policy.
- The table cannot have check constraints.
- The table cannot be enabled for row archival.

To optimize the performance of bulk updates:

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

2. Run the `EXECUTE_UPDATE` procedure, and specify the SQL statement that performs the bulk update.

If errors result, then use the `ABORT_UPDATE` procedure to undo the changes made by the `EXECUTE_UPDATE` procedure.

3. Perform a back up of the updated data.

Because the `EXECUTE_UPDATE` procedure does not log changes in the redo log, recovery is not possible until you perform a back up of the database or of the tablespace that contains the updated table.

Example 20-10 Performing an Optimized Bulk Update of Product Data

This example performs a bulk update on the `oe.order_items` table. Specifically, it sets the `unit_price` of each order item with a `product_id` of 3106 to 45. If the bulk update fails, then the `ABORT_UPDATE` procedure cancels all of the changes performed by the

EXECUTE_UPDATE procedure, which returns the data to its state before the procedure was run.

```
DECLARE
    update_stmt VARCHAR2(300) := 'UPDATE oe.order_items SET unit_price = 45
                                  WHERE product_id = 3106';
BEGIN
    DBMS_REDEFINITION.EXECUTE_UPDATE(update_stmt);
EXCEPTION
    WHEN NO_DATA_FOUND THEN
        DBMS_OUTPUT.PUT_LINE ('No Data found for SELECT');
        DBMS_REDEFINITION.ABORT_UPDATE(update_stmt);
    WHEN OTHERS THEN
        DBMS_OUTPUT.PUT_LINE ('Reason for failure is' || SQLERRM);
        IF (SQLCODE = 100)
        THEN
            DBMS_REDEFINITION.ABORT_UPDATE(update_stmt);
        END IF;
END;
/
```

20.6 Automatically Collecting Statistics on Tables

The PL/SQL package `DBMS_STATS` lets you generate and manage statistics for cost-based optimization. You can use this package to gather, modify, view, export, import, and delete statistics. You can also use this package to identify or name statistics that have been gathered.

Formerly, you enabled `DBMS_STATS` to automatically gather statistics for a table by specifying the `MONITORING` keyword in the `CREATE` (or `ALTER`) `TABLE` statement. The `MONITORING` and `NOMONITORING` keywords have been deprecated and statistics are collected automatically. If you do specify these keywords, they are ignored.

Monitoring tracks the approximate number of `INSERT`, `UPDATE`, and `DELETE` operations for the table since the last time statistics were gathered. Information about how many rows are affected is maintained in the SGA, until periodically (about every three hours) SMON incorporates the data into the data dictionary. This data dictionary information is made visible through the `DBA_TAB_MODIFICATIONS`, `ALL_TAB_MODIFICATIONS`, or `USER_TAB_MODIFICATIONS` views. The database uses these views to identify tables with stale statistics.

The default for the `STATISTICS_LEVEL` initialization parameter is `TYPICAL`, which enables automatic statistics collection. Automatic statistics collection and the `DBMS_STATS` package enable the optimizer to generate accurate execution plans. Setting the `STATISTICS_LEVEL` initialization parameter to `BASIC` disables the collection of many of the important statistics required by Oracle Database features and functionality. To disable monitoring of all tables, set the `STATISTICS_LEVEL` initialization parameter to `BASIC`. Automatic statistics collection and the `DBMS_STATS` package enable the optimizer to generate accurate execution plans.

 See Also:

- *Oracle Database Reference* for detailed information on the STATISTICS_LEVEL initialization parameter
- *Oracle Database SQL Tuning Guide* for information on managing optimizer statistics
- *Oracle Database PL/SQL Packages and Types Reference* for information about using the DBMS_STATS package
- "[About Automated Maintenance Tasks](#)" for information on using the Scheduler to collect statistics automatically

20.7 Altering Tables

You alter a table using the `ALTER TABLE` statement. To alter a table, the table must be contained in your schema, or you must have either the `ALTER` object privilege for the table or the `ALTER ANY TABLE` system privilege.

 Note:

Before altering a table, familiarize yourself with the consequences of doing so. The *Oracle Database SQL Language Reference* lists many of these consequences in the descriptions of the `ALTER TABLE` clauses.

If a view, materialized view, trigger, domain index, function-based index, check constraint, function, procedure or package depends on a base table, the alteration of the base table or its columns can affect the dependent object. See "[Managing Object Dependencies](#)" for information about how the database manages dependencies.

- [Reasons for Using the ALTER TABLE Statement](#)

There are several reasons to use the `ALTER TABLE` statement.

- [Altering Physical Attributes of a Table](#)

There are several considerations when you alter the physical attributes of a table.

- [Moving a Table to a New Segment or Tablespace](#)

You can move a table to a new segment or tablespace to enable compression or to perform data maintenance.

- [Manually Allocating Storage for a Table](#)

Oracle Database dynamically allocates additional extents for the data segment of a table, as required. However, perhaps you want to allocate an additional extent for a table explicitly. For example, in an Oracle Real Application Clusters environment, an extent of a table can be allocated explicitly for a specific instance.

- [Modifying an Existing Column Definition](#)

Use the `ALTER TABLE...MODIFY` statement to modify an existing column definition. You can modify column data type, default value, column constraint, column expression (for virtual columns), column encryption, and visible/invisible property.

- [Adding Table Columns](#)
To add a column to an existing table, use the `ALTER TABLE...ADD` statement.
- [Renaming Table Columns](#)
Oracle Database lets you rename existing columns in a table. Use the `RENAME COLUMN` clause of the `ALTER TABLE` statement to rename a column.
- [Dropping Table Columns](#)
You can drop columns that are no longer needed from a table, including an index-organized table. This provides a convenient means to free space in a database, and avoids your having to export/import data then re-create indexes and constraints.
- [Placing a Table in Read-Only Mode](#)
You can place a table in read-only mode with the `ALTER TABLE...READ ONLY` statement, and return it to read/write mode with the `ALTER TABLE...READ WRITE` statement.

20.7.1 Reasons for Using the `ALTER TABLE` Statement

There are several reasons to use the `ALTER TABLE` statement.

You can use the `ALTER TABLE` statement to perform any of the following actions that affect a table:

- Modify physical characteristics (`INITRANS` or storage parameters)
- Move the table to a new segment or tablespace
- Explicitly allocate an extent or deallocate unused space
- Add, drop, or rename columns, or modify an existing column definition (data type, length, default value, `NOT NULL` integrity constraint, column expression (for virtual columns), and encryption properties.)
- Modify the logging attributes of the table
- Modify the `CACHE/NOCACHE` attributes
- Add, modify or drop integrity constraints associated with the table
- Enable or disable integrity constraints or triggers associated with the table
- Modify the degree of parallelism for the table
- Rename a table
- Put a table in read-only mode and return it to read/write mode
- Add or modify index-organized table characteristics
- Alter the characteristics of an external table
- Add or modify LOB columns
- Add or modify object type, nested table, or varray columns
- Modify table partitions

Starting with Oracle Database 12c, you can perform some operations on more than two partitions or subpartitions at a time, such as split partition and merge partitions operations. See *Oracle Database VLDB and Partitioning Guide* for information.

Many of these operations are discussed in succeeding sections.

20.7.2 Altering Physical Attributes of a Table

There are several considerations when you alter the physical attributes of a table.

When altering the transaction entry setting `INITTRANS` of a table, note that a new setting for `INITTRANS` applies only to data blocks subsequently allocated for the table.

The storage parameters `INITIAL` and `MINEXTENTS` cannot be altered. All new settings for the other storage parameters (for example, `NEXT`, `PCTINCREASE`) affect only extents subsequently allocated for the table. The size of the next extent allocated is determined by the current values of `NEXT` and `PCTINCREASE`, and is not based on previous values of these parameters.

See Also:

The discussions of the physical attributes clause and the storage clause in *Oracle Database SQL Language Reference*

20.7.3 Moving a Table to a New Segment or Tablespace

You can move a table to a new segment or tablespace to enable compression or to perform data maintenance.

- [About Moving a Table to a New Segment or Tablespace](#)

The `ALTER TABLE...MOVE [PARTITION|SUBPARTITION]` statement enables you to move a table, partition, or subpartition to change any physical storage attribute, such as compression, or the tablespace, assuming you have the appropriate quota in the target tablespace.

- [Moving a Table](#)

Use the `ALTER TABLE...MOVE` statement to move a table to a new segment or tablespace.

- [Moving a Table Partition or Subpartition Online](#)

Use the `ALTER TABLE...MOVE PARTITION` statement or `ALTER TABLE...MOVE SUBPARTITION` statement to move a table partition or subpartition, respectively.

20.7.3.1 About Moving a Table to a New Segment or Tablespace

The `ALTER TABLE...MOVE [PARTITION|SUBPARTITION]` statement enables you to move a table, partition, or subpartition to change any physical storage attribute, such as compression, or the tablespace, assuming you have the appropriate quota in the target tablespace.

`ALTER TABLE...MOVE` statements support the `ONLINE` keyword, which enables data manipulation language (DML) operations to run uninterrupted on the table, partition, or subpartition that is being moved. The following statements move a table, partition, or subpartition online:

- `ALTER TABLE ... MOVE ... ONLINE`
- `ALTER TABLE ... MOVE PARTITION ... ONLINE`

- ALTER TABLE ... MOVE SUBPARTITION ... ONLINE

Moving a table changes the rowids of the rows in the table. If you move a table and include the `ONLINE` keyword and the `UPDATE INDEXES` clause, then the indexes remain usable during the move operation. If you include the `UPDATE INDEXES` clause but not the `ONLINE` keyword, then the indexes are usable immediately after the move operation. The `UPDATE INDEXES` clause can only change the storage properties for the global indexes on the table or storage properties for the index partitions of any global partitioned index on the table. If you do not include the `UPDATE INDEXES` clause, then the changes to the rowids cause the indexes on the table to be marked `UNUSABLE`, and DML accessing the table using these indexes receive an ORA-01502 error. In this case, the indexes on the table must be dropped or rebuilt.

A move operation causes any statistics for the table to become invalid, and new statistics should be collected after moving the table.

If the table includes `LOB` column(s), then this statement can be used to move the table along with `LOB` data and `LOB` index segments (associated with this table) that are explicitly specified. If not specified, then the default is to not move the `LOB` data and `LOB` index segments.

See Also:

- "[Consider Encrypting Columns That Contain Sensitive Data](#)" for more information on Transparent Data Encryption
- "[Consider Using Table Compression](#)"

20.7.3.2 Moving a Table

Use the `ALTER TABLE...MOVE` statement to move a table to a new segment or tablespace.

When you use the `ONLINE` keyword with this statement, data manipulation language (DML) operations can continue to run uninterrupted on the table that is being moved. If you do not include the `ONLINE` keyword, then concurrent DML operations are not possible on the data in the table during the move operation.

To move a table:

1. In SQL*Plus, connect as a user with the necessary privileges to alter the table.

See *Oracle Database SQL Language Reference* for information about the privileges required to alter a table.

See "[Connecting to the Database with SQL*Plus](#)".

2. Run the `ALTER TABLE ... MOVE` statement.

Example 20-11 Moving a Table to a New Tablespace in Online Mode

The following statement moves the `hr.jobs` table online to a new segment and tablespace, specifying new storage parameters. The `ONLINE` keyword means that DML operations can run on the table uninterrupted during the move operation. The `hr_tbs` tablespace must exist.

```
ALTER TABLE hr.jobs MOVE ONLINE
    STORAGE ( INITIAL 20K
              NEXT 40K
              MINEXTENTS 2
              MAXEXTENTS 20
              PCTINCREASE 0 )
TABLESPACE hr_tbs;
```

Example 20-12 Moving a Table and Updating the Table's Indexes

Assume the following statements created a table and its indexes:

```
CREATE TABLE dept_exp (
    DEPTNO NUMBER (2) NOT NULL,
    DNAME VARCHAR2 (14),
    LOC VARCHAR2 (13))
TABLESPACE tbs_1;

CREATE INDEX i1_deptno ON dept_exp(deptno) TABLESPACE tbs_1;
CREATE INDEX i2_dname ON dept_exp(dname) TABLESPACE tbs_1;
```

The following statement moves the table to a new tablespace (tbs_2) and compresses the table. It also moves index i2_dname to tablespace tbs_2 and specifies that both the i1_deptno index and the i2_dname index are usable after the move operation.

```
ALTER TABLE dept_exp MOVE
    COMPRESS TABLESPACE tbs_2
    UPDATE INDEXES
        (i1_deptno TABLESPACE tbs_1,
         i2_dname TABLESPACE tbs_2);
```

Notice that this statement does not include the `ONLINE` keyword. However, the `ONLINE` keyword is supported if DML operations must be able to run on the table uninterrupted during the move operation, or if the indexes must be usable during the move operation.

Before running these statements, the `tbs_1` and `tbs_2` tablespaces must exist.

See Also:

Oracle Database SQL Language Reference

20.7.3.3 Moving a Table Partition or Subpartition Online

Use the `ALTER TABLE...MOVE PARTITION` statement or `ALTER TABLE...MOVE SUBPARTITION` statement to move a table partition or subpartition, respectively.

When you use the `ONLINE` keyword with either of these statements, DML operations can continue to run uninterrupted on the partition or subpartition that is being moved. If you do not include the `ONLINE` keyword, then DML operations are not permitted on the data in the partition or subpartition until the move operation is complete.

When you include the `UPDATE INDEXES` clause, these statements maintain both local and global indexes during the move. Therefore, using the `ONLINE` keyword with these statements eliminates the time it takes to regain partition performance after the move by maintaining global indexes and manually rebuilding indexes.

Some restrictions apply to moving table partitions and subpartitions. See *Oracle Database SQL Language Reference* for information about these restrictions.

To move a table partition or subpartition online:

1. In SQL*Plus, connect as a user with the necessary privileges to alter the table and move the partition or subpartition.

See *Oracle Database SQL Language Reference* for information about the required privileges.

See "[Connecting to the Database with SQL*Plus](#)".

2. Run the `ALTER TABLE ... MOVE PARTITION` or `ALTER TABLE ... MOVE SUBPARTITION` statement.

Example 20-13 Moving a Table Partition to a New Segment

The following statement moves the `sales_q4_2003` partition of the `sh.sales` table to a new segment with advanced row compression and index maintenance included:

```
ALTER TABLE sales MOVE PARTITION sales_q4_2003
  ROW STORE COMPRESS ADVANCED UPDATE INDEXES ONLINE;
```

See Also:

- [Oracle Database VLDB and Partitioning Guide](#)
- [Oracle Database SQL Language Reference](#)

20.7.4 Manually Allocating Storage for a Table

Oracle Database dynamically allocates additional extents for the data segment of a table, as required. However, perhaps you want to allocate an additional extent for a table explicitly. For example, in an Oracle Real Application Clusters environment, an extent of a table can be allocated explicitly for a specific instance.

You can allocate a new extent for a table using the `ALTER TABLE...ALLOCATE EXTENT` statement.

You can also explicitly deallocate unused space using the `DEALLOCATE UNUSED` clause of `ALTER TABLE`. This is described in "[Reclaiming Unused Space](#)".

20.7.5 Modifying an Existing Column Definition

Use the `ALTER TABLE...MODIFY` statement to modify an existing column definition. You can modify column data type, default value, column constraint, column expression (for virtual columns), column encryption, and visible/invisible property.

You can increase the length of an existing column, or decrease it, if all existing data satisfies the new length. Beginning with Oracle Database 12c, you can specify a maximum size of 32767 bytes for the `VARCHAR2`, `NVARCHAR2`, and `RAW` data types. Before this release, the maximum size was 4000 bytes for the `VARCHAR2` and `NVARCHAR2` data types, and 2000 bytes for the `RAW` data type. To use extended data types, set the `MAX_STRING_SIZE` initialization parameter to `EXTENDED`.

You can change a column from byte semantics to `CHAR` semantics or vice versa. You must set the initialization parameter `BLANK_TRIMMING=TRUE` to decrease the length of a non-empty `CHAR` column.

If you are modifying a table to increase the length of a column of data type `CHAR`, then realize that this can be a time consuming operation and can require substantial additional storage, especially if the table contains many rows. This is because the `CHAR` value in each row must be blank-padded to satisfy the new column length.

If you modify the visible/invisible property of a column, then you cannot include any other column modification options in the same SQL statement.

Example 20-14 Changing the Length of a Column to a Size Larger Than 4000 Bytes

This example changes the length of the `product_description` column in the `oe.product_information` table to 32767 bytes.

```
ALTER TABLE oe.product_information MODIFY(product_description VARCHAR2(32767));
```

See Also:

- *Oracle Database SQL Language Reference* for additional information about modifying table columns and additional restrictions
- *Oracle Database Reference* for information about the `MAX_STRING_SIZE` initialization parameter

20.7.6 Adding Table Columns

To add a column to an existing table, use the `ALTER TABLE...ADD` statement.

The following statement alters the `hr.admin_emp` table to add a new column named `bonus`:

```
ALTER TABLE hr.admin_emp
ADD (bonus NUMBER (7,2));
```

 **Live SQL:**

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating and Modifying Tables](#).

If a new column is added to a table, then the column is initially `NULL` unless you specify the `DEFAULT` clause. If you specify the `DEFAULT` clause for a nullable column for some table types, then the default value is stored as metadata, but the column itself is not populated with data. However, subsequent queries that specify the new column are rewritten so that the default value is returned in the result set. This behavior optimizes the resource usage and storage requirements for the operation.

You can add a column with a `NOT NULL` constraint only if the table does not contain any rows, or you specify a default value.

 **Note:**

- If you enable basic table compression on a table, then you can add columns only if you do not specify default values.
- If you enable advanced row compression on a table, then you can add columns to that table with or without default values.
- If the new column is a virtual column, its value is determined by its column expression. (Note that a virtual column's value is calculated only when it is queried.)

 **See Also:**

- [Oracle Database SQL Language Reference](#) for rules and restrictions for adding table columns
- ["Consider Using Table Compression"](#)
- [Oracle Database Concepts](#)
- ["Example: Creating a Table"](#) for an example of a virtual column

20.7.7 Renaming Table Columns

Oracle Database lets you rename existing columns in a table. Use the `RENAME COLUMN` clause of the `ALTER TABLE` statement to rename a column.

The new name must not conflict with the name of any existing column in the table. No other clauses are allowed with the `RENAME COLUMN` clause.

The following statement renames the `comm` column of the `hr.admin_emp` table.

```
ALTER TABLE hr.admin_emp
  RENAME COLUMN comm TO commission;
```

Live SQL:

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating and Modifying Tables](#).

As noted earlier, altering a table column can invalidate dependent objects. However, when you rename a column, the database updates associated data dictionary tables to ensure that function-based indexes and check constraints remain valid.

Oracle Database also lets you rename column constraints. This is discussed in ["Renaming Constraints"](#).

Note:

The `RENAME TO` clause of `ALTER TABLE` appears similar in syntax to the `RENAME COLUMN` clause, but is used for renaming the table itself.

20.7.8 Dropping Table Columns

You can drop columns that are no longer needed from a table, including an index-organized table. This provides a convenient means to free space in a database, and avoids your having to export/import data then re-create indexes and constraints.

Note:

You cannot drop all columns from a table, nor can you drop columns from a table owned by `SYS`. Any attempt to do so results in an error.

- [Removing Columns from Tables](#)

When you issue an `ALTER TABLE...DROP COLUMN` statement, the column descriptor and the data associated with the target column are removed from each row in the table. You can drop multiple columns with one statement.

- [Marking Columns Unused](#)

If you are concerned about the length of time it could take to drop column data from all of the rows in a large table, you can use the `ALTER TABLE...SET UNUSED` statement.

- [Removing Unused Columns](#)

The `ALTER TABLE...DROP UNUSED COLUMNS` statement is the only action allowed on unused columns. It physically removes unused columns from the table and reclaims disk space.

- **Dropping Columns in Compressed Tables**

If you enable advanced row compression on a table, then you can drop table columns. If you enable basic table compression only, then you cannot drop columns.

 **See Also:**

Oracle Database SQL Language Reference for information about additional restrictions and options for dropping columns from a table

20.7.8.1 Removing Columns from Tables

When you issue an `ALTER TABLE...DROP COLUMN` statement, the column descriptor and the data associated with the target column are removed from each row in the table. You can drop multiple columns with one statement.

The following statements are examples of dropping columns from the `hr.admin_emp` table. The first statement drops only the `sal` column:

```
ALTER TABLE hr.admin_emp DROP COLUMN sal;
```

The next statement drops both the `bonus` and `comm` columns:

```
ALTER TABLE hr.admin_emp DROP (bonus, commission);
```

 **Live SQL:**

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating and Modifying Tables](#).

20.7.8.2 Marking Columns Unused

If you are concerned about the length of time it could take to drop column data from all of the rows in a large table, you can use the `ALTER TABLE...SET UNUSED` statement.

This statement marks one or more columns as unused, but does not actually remove the target column data or restore the disk space occupied by these columns. However, a column that is marked as unused is not displayed in queries or data dictionary views, and its name is removed so that a new column can reuse that name. In most cases, constraints, indexes, and statistics defined on the column are also removed. The exception is that any internal indexes for LOB columns that are marked unused are not removed.

To mark the `hiredate` and `mgr` columns as unused, execute the following statement:

```
ALTER TABLE hr.admin_emp SET UNUSED (hiredate, mgr);
```

 **Live SQL:**

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating and Modifying Tables](#).

You can later remove columns that are marked as unused by issuing an `ALTER TABLE...DROP UNUSED COLUMNS` statement. Unused columns are also removed from the target table whenever an explicit drop of any particular column or columns of the table is issued.

The data dictionary views `USER_UNUSED_COL_TABS`, `ALL_UNUSED_COL_TABS`, or `DBA_UNUSED_COL_TABS` can be used to list all tables containing unused columns. The `COUNT` field shows the number of unused columns in the table.

```
SELECT * FROM DBA_UNUSED_COL_TABS;
```

OWNER	TABLE_NAME	COUNT
HR	ADMIN_EMP	2

For external tables, the `SET UNUSED` statement is transparently converted into an `ALTER TABLE DROP COLUMN` statement. Because external tables consist of metadata only in the database, the `DROP COLUMN` statement performs equivalently to the `SET UNUSED` statement.

20.7.8.3 Removing Unused Columns

The `ALTER TABLE...DROP UNUSED COLUMNS` statement is the only action allowed on unused columns. It physically removes unused columns from the table and reclaims disk space.

In the `ALTER TABLE` statement that follows, the optional clause `CHECKPOINT` is specified. This clause causes a checkpoint to be applied after processing the specified number of rows, in this case 250. Checkpointing cuts down on the amount of undo logs accumulated during the drop column operation to avoid a potential exhaustion of undo space.

```
ALTER TABLE hr.admin_emp DROP UNUSED COLUMNS CHECKPOINT 250;
```

 **Live SQL:**

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating and Modifying Tables](#).

20.7.8.4 Dropping Columns in Compressed Tables

If you enable advanced row compression on a table, then you can drop table columns. If you enable basic table compression only, then you cannot drop columns.

 See Also:

"[Consider Using Table Compression](#)"

20.7.9 Placing a Table in Read-Only Mode

You can place a table in read-only mode with the `ALTER TABLE...READ ONLY` statement, and return it to read/write mode with the `ALTER TABLE...READ WRITE` statement.

An example of a table for which read-only mode makes sense is a configuration table. If your application contains configuration tables that are not modified after installation and that must not be modified by users, your application installation scripts can place these tables in read-only mode.

To place a table in read-only mode, you must have the `ALTER TABLE` privilege on the table or the `ALTER ANY TABLE` privilege. In addition, the `COMPATIBLE` initialization parameter must be set to `11.1.0` or higher.

The following example places the `SALES` table in read-only mode:

```
ALTER TABLE SALES READ ONLY;
```

The following example returns the table to read/write mode:

```
ALTER TABLE SALES READ WRITE;
```

When a table is in read-only mode, operations that attempt to modify table data are disallowed. A `SELECT column_list ON table_name` statement on a table must always return the same data set after a table or partition has been placed in read-only mode.

The following operations are not permitted on a read-only table:

- All DML operations on the read-only table or on a read-only partition
- `TRUNCATE TABLE`
- `SELECT FOR UPDATE`
- `ALTER TABLE RENAME/DROP COLUMN`
- `DROP` of a read-only partition or a partition of a read only table
- `ALTER TABLE SET COLUMN UNUSED`
- `ALTER TABLE DROP/TRUNCATE/EXCHANGE (SUB)PARTITION`
- `ALTER TABLE UPGRADE INCLUDING DATA` or `ALTER TYPE CASCADE INCLUDING TABLE DATA` for a type with read-only table dependents
- Online redefinition
- `FLASHBACK TABLE`

The following operations are permitted on a read-only table:

- `SELECT`
- `CREATE/ALTER/DROP INDEX`
- `ALTER TABLE ADD/MODIFY COLUMN`

- ALTER TABLE ADD/MODIFY/DROP/ENABLE/DISABLE CONSTRAINT
- ALTER TABLE for physical property changes
- ALTER TABLE DROP UNUSED COLUMNS
- ALTER TABLE ADD/COALESCE/MERGE/MODIFY/MOVE/RENAME/SPLIT (SUB) PARTITION
- ALTER TABLE MOVE
- ALTER TABLE ENABLE ROW MOVEMENT and ALTER TABLE SHRINK
- RENAME TABLE and ALTER TABLE RENAME TO
- DROP TABLE
- ALTER TABLE DEALLOCATE UNUSED
- ALTER TABLE ADD/DROP SUPPLEMENTAL LOG

 **See Also:**

- *Oracle Database SQL Language Reference* for more information about the ALTER TABLE statement
- *Oracle Database VLDB and Partitioning Guide* for more information about read-only partitions

20.8 Redefining Tables Online

You can modify the logical or physical structure of a table.

- [About Redefining Tables Online](#)
In any database system, it is occasionally necessary to modify the logical or physical structure of a table to improve the performance of queries or DML, accommodate application changes, or Manage storage. You can redefine tables online with the DBMS_REDEFINITION package.
- [Features of Online Table Redefinition](#)
Online table redefinition enables you to modify a table in several different ways while the table remains online.
- [Privileges Required for the DBMS_REDEFINITION Package](#)
Execute privileges on the DBMS_REDEFINITION package are required to run subprograms in the package. Execute privileges on the DBMS_REDEFINITION package are granted to EXECUTE_CATALOG_ROLE.
- [Restrictions for Online Redefinition of Tables](#)
Several restrictions apply to online redefinition of tables.
- [Performing Online Redefinition with the REDEF_TABLE Procedure](#)
You can use the REDEF_TABLE procedure in the DBMS_REDEFINITION package to perform online redefinition of a table's storage properties.
- [Redefining Tables Online with Multiple Procedures in DBMS_REDEFINITION](#)
You can use multiple procedures in the DBMS_REDEFINITION package to redefine tables online.

- [Results of the Redefinition Process](#)
There are several results of the redefinition process.
- [Performing Intermediate Synchronization](#)
During the redefinition process, you can synchronize the interim table with the original table if there were a large number of DML statements executed on the original table.
- [Refreshing Dependent Materialized Views During Online Table Redefinition](#)
To refresh dependent fast refreshable materialized views during online table redefinition, set the `refresh_dep_mvviews` parameter to `Y` in the `REDEF_TABLE` procedure or the `START_REDEF_TABLE` procedure.
- [Monitoring Online Table Redefinition Progress](#)
You can query the `V$ONLINE_REDEF` view to monitor the progress of an online table redefinition operation.
- [Restarting Online Table Redefinition After a Failure](#)
If online table redefinition fails, then you can check the `DBA_REDEFINITION_STATUS` view to see the error information and restartable information.
- [Rolling Back Online Table Redefinition](#)
You can enable roll back of a table after online table redefinition to return the table to its original definition and preserve DML changes made to the table.
- [Aborting Online Table Redefinition and Cleaning Up After Errors](#)
You can abort the online redefinition process. Doing so drops temporary logs and tables associated with the redefinition process. After this procedure is called, you can drop the interim table and its dependent objects.
- [Online Redefinition of One or More Partitions](#)
You can redefine online one or more partitions of a table. This is useful if, for example, you want to move partitions to a different tablespace and keep the partitions available for DML during the operation.
- [Online Table Redefinition Examples](#)
Examples illustrate online redefinition of tables.

20.8.1 About Redefining Tables Online

In any database system, it is occasionally necessary to modify the logical or physical structure of a table to improve the performance of queries or DML, accommodate application changes, or Manage storage. You can redefine tables online with the `DBMS_REDEFINITION` package.

Oracle Database provides a mechanism to make table structure modifications without significantly affecting the availability of the table. The mechanism is called **online table redefinition**. Redefining tables online provides a substantial increase in availability compared to traditional methods of redefining tables.

When a table is redefined online, it is accessible to both queries and DML during much of the redefinition process. Typically, the table is locked in the exclusive mode only during a very small window that is independent of the size of the table and complexity of the redefinition, and that is completely transparent to users. However, if there are many concurrent DML operations during redefinition, then a longer wait might be necessary before the table can be locked.

Online table redefinition requires an amount of free space that is approximately equivalent to the space used by the table being redefined. More space may be required if new columns are added.

You can perform online table redefinition with the Oracle Enterprise Manager Cloud Control (Cloud Control) Reorganize Objects wizard or with the `DBMS_REDEFINITION` package.

 **Note:**

To invoke the Reorganize Objects wizard:

1. On the Tables page of Cloud Control, click in the **Select** column to select the table to redefine.
2. In the Actions list, select **Reorganize**.
3. Click **Go**.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for a description of the `DBMS_REDEFINITION` package

20.8.2 Features of Online Table Redefinition

Online table redefinition enables you to modify a table in several different ways while the table remains online.

Online table redefinition enables you to:

- Modify the storage parameters of a table or cluster
- Move a table or cluster to a different tablespace

 **Note:**

If it is not important to keep a table available for DML when moving it to another tablespace, then you can use the simpler `ALTER TABLE MOVE` command. See "[Moving a Table to a New Segment or Tablespace](#)".

- Add, modify, or drop one or more columns in a table or cluster
- Add or drop partitioning support (non-clustered tables only)
- Change partition structure
- Change physical properties of a single table partition or subpartition, including moving it to a different tablespace in the same schema

Starting with Oracle Database 12c, you can move a partition or subpartition online without using online table redefinition. DML operations can continue to run uninterrupted on the partition or subpartition that is being moved. See "[Moving a Table to a New Segment or Tablespace](#)".

- Change physical properties of a materialized view log or an Oracle Database Advanced Queuing queue table

 **Note:**

The REDEF_TABLE procedure in the DBMS_REDEFINITION package does not support changing physical properties of an Oracle Database Advanced Queuing queue table.

- Add support for parallel queries
- Re-create a table or cluster to reduce fragmentation

 **Note:**

In many cases, online segment shrink is an easier way to reduce fragmentation. See "[Reclaiming Unused Space](#)".

- Change the organization of a normal table (heap organized) to an index-organized table, or do the reverse.
- Convert a relational table into a table with object columns, or do the reverse.
- Convert an object table into a relational table or a table with object columns, or do the reverse.
- Compress, or change the compression type for, a table, partition, index key, or LOB columns.
- Convert LOB columns from BasicFiles LOB storage to SecureFiles LOB storage, or do the reverse.
- You can enable roll back of a table after online table redefinition to return the table to its original definition and preserve DML changes made to the table.
- You can refresh dependent fast refreshable materialized views during online table redefinition by setting the refresh_dep_mvviews parameter to Y in the REDEF_TABLE procedure or the START_REDEF_TABLE procedure.
- You can query the V\$ONLINE_REDEF view to monitor the progress of an online table redefinition operation.
- When online table redefinition fails, often you can correct the problem that caused the failure and restart the online redefinition process where it last stopped.

You can combine two or more of the usage examples above into one operation. See "[Example 8](#)" in "[Online Table Redefinition Examples](#)" for an example.

20.8.3 Privileges Required for the DBMS_REDEFINITION Package

Execute privileges on the `DBMS_REDEFINITION` package are required to run subprograms in the package. Execute privileges on the `DBMS_REDEFINITION` package are granted to `EXECUTE_CATALOG_ROLE`.

In addition, for a user to redefine a table in the user's schema using the package, the user must be granted the following privileges:

- `CREATE TABLE`
- `CREATE MATERIALIZED VIEW`

The `CREATE TRIGGER` privilege is also required to execute the `COPY_TABLE_DEPENDENTS` procedure.

For a user to redefine a table in other schemas using the package, the user must be granted the following privileges:

- `CREATE ANY TABLE`
- `ALTER ANY TABLE`
- `DROP ANY TABLE`
- `LOCK ANY TABLE`
- `SELECT ANY TABLE`

The following additional privileges are required to execute `COPY_TABLE_DEPENDENTS` on tables in other schemas:

- `CREATE ANY TRIGGER`
- `CREATE ANY INDEX`

20.8.4 Restrictions for Online Redefinition of Tables

Several restrictions apply to online redefinition of tables.

The following restrictions apply to the online redefinition of tables:

- If the table is to be redefined using primary key or pseudo-primary keys (unique keys or constraints with all component columns having *not null* constraints), then the post-redefinition table must have the same primary key or pseudo-primary key columns. If the table is to be redefined using rowids, then the table must not be an index-organized table.
- After redefining a table that has a materialized view log, the subsequent refresh of any dependent materialized view must be a complete refresh.

There is an exception to this restriction. When online table redefinition uses the `REDEF_TABLE` or `START_REDEF_TABLE` procedure, and the `refresh_dep_mvviews` parameter is set to `Y` in the procedure, any dependent materialized views configured for incremental refresh are refreshed during the online table redefinition operation.

- Tables that are replicated in an n-way master configuration can be redefined, but horizontal subsetting (subset of rows in the table), vertical subsetting (subset of columns in the table), and column transformations are not allowed.

- The overflow table of an index-organized table cannot be redefined online independently.
- Tables for which Flashback Data Archive is enabled cannot be redefined online. You cannot enable Flashback Data Archive for the interim table.
- Tables with `LONG` columns can be redefined online, but those columns must be converted to `CLOBS`. Also, `LONG RAW` columns must be converted to `BLOBS`. Tables with `LOB` columns are acceptable.
- On a system with sufficient resources for parallel execution, and in the case where the interim table is not partitioned, redefinition of a `LONG` column to a `LOB` column can be executed in parallel, provided that:
 - The segment used to store the `LOB` column in the interim table belongs to a locally managed tablespace with Automatic Segment Space Management (ASSM) enabled.
 - There is a simple mapping from one `LONG` column to one `LOB` column, and the interim table has only one `LOB` column.

In the case where the interim table is partitioned, the normal methods for parallel execution for partitioning apply.

- Tables in the `SYS` and `SYSTEM` schema cannot be redefined online.
- Temporary tables cannot be redefined.
- A subset of rows in the table cannot be redefined.
- Only simple deterministic expressions, sequences, and `SYSDATE` can be used when mapping the columns in the interim table to those of the original table. For example, subqueries are not allowed.
- If new columns are being added as part of the redefinition and there are no column mappings for these columns, then they must not be declared `NOT NULL` until the redefinition is complete.
- There cannot be any referential constraints between the table being redefined and the interim table.
- Table redefinition cannot be done `NOLOGGING`.
- For materialized view logs and queue tables, online redefinition is restricted to changes in physical properties. No horizontal or vertical subsetting is permitted, nor are any column transformations. The only valid value for the column mapping string is `NULL`.
- You cannot perform online redefinition on a partition that includes one or more nested tables.
- You can convert a `VARRAY` to a nested table with the `CAST` operator in the column mapping. However, you cannot convert a nested table to a `VARRAY`.
- When the columns in the `col_mapping` parameter of the `DBMS_REDEFINITION.START_REDEF_TABLE` procedure include a sequence, the `orderby_cols` parameter must be `NULL`.
- For tables with a Virtual Private Database (VPD) security policy, when the `copy_vpd_opt` parameter is specified as `DBMS_REDEFINITION.CONS_VPD_AUTO`, the following restrictions apply:
 - The column mapping string between the original table and interim table must be `NULL` or `'*'.`

- No VPD policies can exist on the interim table.

See "[Handling Virtual Private Database \(VPD\) Policies During Online Redefinition](#)". Also, see *Oracle Database Security Guide* for information about VPD policies.

- Online redefinition cannot run on multiple tables concurrently in separate DBMS_REDEFINITION sessions if the tables are related by reference partitioning. See *Oracle Database VLDB and Partitioning Guide* for more information about reference partitioning.
- Online redefinition of an object table or XMLType table can cause a dangling REF in other tables if those other tables have a REF column that references the redefined table.

See *Oracle Database SQL Language Reference* for more information about dangling REFS.

- Tables that use Oracle Label Security (OLS) cannot be redefined online. See *Oracle Label Security Administrator's Guide*.
- Tables with fine-grained access control cannot be redefined online.
- Tables that use Oracle Real Application Security cannot be redefined online. See *Oracle Database Security Guide*.

20.8.5 Performing Online Redefinition with the REDEF_TABLE Procedure

You can use the REDEF_TABLE procedure in the DBMS_REDEFINITION package to perform online redefinition of a table's storage properties.

The REDEF_TABLE procedure enables you to perform online redefinition a table's storage properties in a single step when you want to change the following properties:

- Tablespace changes, including a tablespace change for a table, partition, index, or LOB columns
- Compression type changes, including a compression type change for a table, partition, index key, or LOB columns
- For LOB columns, a change to SECUREFILE or BASICFILE storage

When your online redefinition operation is not limited to these changes, you must perform online redefinition of the table using multiple steps. The steps include invoking multiple procedures in the DBMS_REDEFINITION package, including the following procedures: CAN_REDEF_TABLE, START_REDEF_TABLE, COPY_TABLE_DEPENDENTS, and FINISH_REDEF_TABLE.

Note:

Online table redefinition rollback is not supported when the REDEF_TABLE procedure is used to redefine a table.

 **See Also:**

- [Oracle Database PL/SQL Packages and Types Reference](#) for procedure details
- [Example 1 in "Online Table Redefinition Examples"](#)
- ["Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION"](#) for more information

20.8.6 Redefining Tables Online with Multiple Procedures in DBMS_REDEFINITION

You can use multiple procedures in the `DBMS_REDEFINITION` package to redefine tables online.

- [Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION](#)

You can use multiple procedures in the `DBMS_REDEFINITION` package to perform online redefinition of a table.

- [Constructing a Column Mapping String](#)

The column mapping string that you pass as an argument to `START_REDEF_TABLE` contains a comma-delimited list of column mapping pairs.

- [Handling Virtual Private Database \(VPD\) Policies During Online Redefinition](#)

If the original table being redefined has VPD policies specified for it, then you can use the `copy_vpd_opt` parameter in the `START_REDEF_TABLE` procedure to handle these policies during online redefinition.

- [Creating Dependent Objects Automatically](#)

You use the `COPY_TABLE_DEPENDENTS` procedure to automatically create dependent objects on the interim table.

- [Creating Dependent Objects Manually](#)

If you manually create dependent objects on the interim table with SQL*Plus or Cloud Control, then you must use the `REGISTER_DEPENDENT_OBJECT` procedure to register the dependent objects. Registering dependent objects enables the redefinition completion process to restore dependent object names to what they were before redefinition.

20.8.6.1 Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION

You can use multiple procedures in the `DBMS_REDEFINITION` package to perform online redefinition of a table.

To redefine a table online using multiple steps:

1. Choose the redefinition method: by key or by rowid

By key—Select a primary key or pseudo-primary key to use for the redefinition. Pseudo-primary keys are unique keys with all component columns having `NOT NULL` constraints. For this method, the versions of the tables before and after

redefinition should have the same primary key columns. This is the preferred and default method of redefinition.

By rowid—Use this method if no key is available. In this method, a hidden column named M_ROW\$\$ is added to the post-redefined version of the table. It is recommended that this column be dropped or marked as unused after the redefinition is complete. The final phase of redefinition automatically sets this column unused. You can then use the ALTER TABLE ... DROP UNUSED COLUMNS statement to drop it.

You cannot use this method on index-organized tables.

2. Verify that the table can be redefined online by invoking the CAN_REDEF_TABLE procedure. If the table is not a candidate for online redefinition, then this procedure raises an error indicating why the table cannot be redefined online.
3. Create an empty interim table (in the same schema as the table to be redefined) with all of the desired logical and physical attributes. If columns are to be dropped, then do not include them in the definition of the interim table. If a column is to be added, then add the column definition to the interim table. If a column is to be modified, then create it in the interim table with the properties that you want.

It is not necessary to create the interim table with all the indexes, constraints, grants, and triggers of the table being redefined, because these will be defined in step 7 when you copy dependent objects.

4. If you are redefining a partitioned table with the rowid method, then enable row movement on the interim table.

```
ALTER TABLE ... ENABLE ROW MOVEMENT;
```

5. (Optional) If you are redefining a large table and want to improve the performance of the next step by running it in parallel, issue the following statements:

```
ALTER SESSION FORCE PARALLEL DML PARALLEL degree-of-parallelism;
ALTER SESSION FORCE PARALLEL QUERY PARALLEL degree-of-parallelism;
```

6. Start the redefinition process by calling START_REDEF_TABLE, providing the following:

- The schema and table name of the table to be redefined in the `uname` and `orig_table` parameters, respectively
 - The interim table name in the `int_table` parameter
 - A column mapping string that maps the columns of table to be redefined to the columns of the interim table in the `col_mapping` parameter
- See "[Constructing a Column Mapping String](#)" for details.

- The redefinition method in the `options_flag` parameter

Package constants are provided for specifying the redefinition method.

`DBMS_REDEFINITION.CONS_USE_PK` is used to indicate that the redefinition should be done using primary keys or pseudo-primary keys.

`DBMS_REDEFINITION.CONS_USE_ROWID` is used to indicate that the redefinition should be done using rowids. If this argument is omitted, the default method of redefinition (`CONS_USE_PK`) is assumed.

- Optionally, the columns to be used in ordering rows in the `orderby_cols` parameter
- The partition name or names in the `part_name` parameter when redefining one partition or multiple partitions of a partitioned table

See "[Online Redefinition of One or More Partitions](#)" for details.

- The method for handling Virtual Private Database (VPD) policies defined on the table in the `copy_vpd_opt` parameter

See "[Handling Virtual Private Database \(VPD\) Policies During Online Redefinition](#)" for details.

Because this process involves copying data, it may take a while. The table being redefined remains available for queries and DML during the entire process.

 **Note:**

- You can query the `DBA_REDEFINITION_OBJECTS` view to list the objects currently involved in online redefinition.
- If `START_REDEF_TABLE` fails for any reason, you must call `ABORT_REDEF_TABLE`, otherwise subsequent attempts to redefine the table will fail.

7. Copy dependent objects (such as triggers, indexes, materialized view logs, grants, and constraints) and statistics from the table being redefined to the interim table, using one of the following two methods. Method 1 is the preferred method because it is more automatic, but there may be times that you would choose to use method 2. Method 1 also enables you to copy table statistics to the interim table.

- Method 1: Automatically Creating Dependent Objects

Use the `COPY_TABLE_DEPENDENTS` procedure to automatically create dependent objects on the interim table. This procedure also **registers** the dependent objects. Registering the dependent objects enables the identities of these objects and their copied counterparts to be automatically swapped later as part of the redefinition completion process. The result is that when the redefinition is completed, the names of the dependent objects will be the same as the names of the original dependent objects.

For more information, see "[Creating Dependent Objects Automatically](#)".

- Method 2: Manually Creating Dependent Objects

You can manually create dependent objects on the interim table and then register them. For more information, see "[Creating Dependent Objects Manually](#)".

 **Note:**

In Oracle9*i*, you were *required* to manually create the triggers, indexes, grants, and constraints on the interim table, and there may still be situations where you want to or must do so. In such cases, any referential constraints involving the interim table (that is, the interim table is either a parent or a child table of the referential constraint) must be created disabled. When online redefinition completes, the referential constraint is automatically enabled. In addition, until the redefinition process is either completed or aborted, any trigger defined on the interim table does not execute.

8. Execute the `FINISH_REDEF_TABLE` procedure to complete the redefinition of the table. During this procedure, the original table is locked in exclusive mode for a very short time, independent of the amount of data in the original table. However, `FINISH_REDEF_TABLE` will wait for all pending DML to commit before completing the redefinition.

You can use the `dml_lock_timeout` parameter in the `FINISH_REDEF_TABLE` procedure to specify how long the procedure waits for pending DML to commit. The parameter specifies the number of seconds to wait before the procedure ends gracefully. When you specify a non-`NULL` value for this parameter, you can restart the `FINISH_REDEF_TABLE` procedure, and it continues from the point at which it timed out. When the parameter is set to `NULL`, the procedure does not time out. In this case, if you stop the procedure manually, then you must abort the online table redefinition using the `ABORT_REDEF_TABLE` procedure and start over from step 6.

9. Wait for any long-running queries against the interim table to complete, and then drop the interim table.

If you drop the interim table while there are active queries running against it, you may encounter an `ORA-08103` error ("object no longer exists").

 **See Also:**

- ["Online Table Redefinition Examples"](#)
- *Oracle Database PL/SQL Packages and Types Reference* for package details

20.8.6.2 Constructing a Column Mapping String

The column mapping string that you pass as an argument to `START_REDEF_TABLE` contains a comma-delimited list of column mapping pairs.

Each pair has the following syntax:

`[expression] column_name`

The `column_name` term indicates a column in the interim table. The optional `expression` can include columns from the table being redefined, constants, operators, function or method calls, and so on, in accordance with the rules for expressions in a

SQL SELECT statement. However, only simple deterministic subexpressions—that is, subexpressions whose results do not vary between one evaluation and the next—plus sequences and SYSDATE can be used. No subqueries are permitted. In the simplest case, the expression consists of just a column name from the table being redefined.

If an expression is present, its value is placed in the designated interim table column during redefinition. If the expression is omitted, it is assumed that both the table being redefined and the interim table have a column named *column_name*, and the value of that column in the table being redefined is placed in the same column in the interim table.

For example, if the `override` column in the table being redefined is to be renamed to `override_commission`, and every override commission is to be raised by 2%, the correct column mapping pair is:

```
override*1.02  override_commission
```

If you supply '*' or `NULL` as the column mapping string, it is assumed that all the columns (with their names unchanged) are to be included in the interim table. Otherwise, only those columns specified explicitly in the string are considered. The order of the column mapping pairs is unimportant.

For examples of column mapping strings, see "[Online Table Redefinition Examples](#)".

Data Conversions

When mapping columns, you can convert data types, with some restrictions.

If you provide '*' or `NULL` as the column mapping string, only the implicit conversions permitted by SQL are supported. For example, you can convert from CHAR to VARCHAR2, from INTEGER to NUMBER, and so on.

To perform other data type conversions, including converting from one object type to another or one collection type to another, you must provide a column mapping pair with an expression that performs the conversion. The expression can include the `CAST` function, built-in functions like `TO_NUMBER`, conversion functions that you create, and so on.

20.8.6.3 Handling Virtual Private Database (VPD) Policies During Online Redefinition

If the original table being redefined has VPD policies specified for it, then you can use the `copy_vpd_opt` parameter in the `START_REDEF_TABLE` procedure to handle these policies during online redefinition.

You can specify the following values for this parameter:

Parameter Value	Description
<code>DBMS_REDEFINITION.CONS_VPD_NONE</code>	Specify this value if there are no VPD policies on the original table. This value is the default. If this value is specified, and VPD policies exist for the original table, then an error is raised.
<code>DBMS_REDEFINITION.CONS_VPD_AUTO</code>	Specify this value to copy the VPD policies automatically from the original table to the new table during online redefinition.

Parameter Value	Description
DBMS_REDEFINITION.CONS_VPD_MANUAL	Specify this value to copy the VPD policies manually from the original table to the new table during online redefinition.

If there are no VPD policies specified for the original table, then specify the default value of DBMS_REDEFINITION.CONS_VPD_NONE for the `copy_vpd_opt` parameter.

Specify DBMS_REDEFINITION.CONS_VPD_AUTO for the `copy_vpd_opt` parameter when the column names and column types are the same for the original table and the interim table. To use this value, the column mapping string between original table and interim table must be `NULL` or `'*'.` When you use DBMS_REDEFINITION.CONS_VPD_AUTO for the `copy_vpd_opt` parameter, only the table owner and the user invoking online redefinition can access the interim table during online redefinition.

Specify DBMS_REDEFINITION.CONS_VPD_MANUAL for the `copy_vpd_opt` parameter when either of the following conditions are true:

- There are VPD policies specified for the original table, and there are column mappings between the original table and the interim table.
- You want to add or modify VPD policies during online redefinition of the table.

To copy the VPD policies manually, you specify the VPD policies for the interim table before you run the `START_REDEF_TABLE` procedure. When online redefinition of the table is complete, the redefined table has the modified policies.

See Also:

- ["Restrictions for Online Redefinition of Tables"](#) for restrictions related to tables with VPD policies
- ["Online Table Redefinition Examples"](#) for an example that redefines a table with VPD policies
- *Oracle Database Security Guide*

20.8.6.4 Creating Dependent Objects Automatically

You use the `COPY_TABLE_DEPENDENTS` procedure to automatically create dependent objects on the interim table.

You can discover if errors occurred while copying dependent objects by checking the `num_errors` output argument. If the `ignore_errors` argument is set to `TRUE`, the `COPY_TABLE_DEPENDENTS` procedure continues copying dependent objects even if an error is encountered when creating an object. You can view these errors by querying the `DBA_REDEFINITION_ERRORS` view.

Reasons for errors include:

- A lack of system resources

- A change in the logical structure of the table that would require recoding the dependent object.

See Example 3 in "[Online Table Redefinition Examples](#)" for a discussion of this type of error.

If `ignore_errors` is set to FALSE, the `COPY_TABLE_DEPENDENTS` procedure stops copying objects as soon as any error is encountered.

After you correct any errors you can again attempt to copy the dependent objects by reexecuting the `COPY_TABLE_DEPENDENTS` procedure. Optionally you can create the objects manually and then register them as explained in "[Creating Dependent Objects Manually](#)". The `COPY_TABLE_DEPENDENTS` procedure can be used multiple times as necessary. If an object has already been successfully copied, it is not copied again.

20.8.6.5 Creating Dependent Objects Manually

If you manually create dependent objects on the interim table with SQL*Plus or Cloud Control, then you must use the `REGISTER_DEPENDENT_OBJECT` procedure to register the dependent objects. Registering dependent objects enables the redefinition completion process to restore dependent object names to what they were before redefinition.

The following are examples changes that require you to create dependent objects manually:

- Moving an index to another tablespace
- Modifying the columns of an index
- Modifying a constraint
- Modifying a trigger
- Modifying a materialized view log

When you run the `REGISTER_DEPENDENT_OBJECT` procedure, you must specify that type of the dependent object with the `dep_type` parameter. You can specify the following constants in this parameter:

- `DEMS_REDEFINITION.CONS_INDEX` when the dependent object is an index
- `DEMS_REDEFINITION.CONS_CONSTRAINT` when the dependent object type is a constraint
- `DEMS_REDEFINITION.CONS_TRIGGER` when the dependent object is a trigger
- `DEMS_REDEFINITION.CONS_MVLOG` when the dependent object is a materialized view log

You would also use the `REGISTER_DEPENDENT_OBJECT` procedure if the `COPY_TABLE_DEPENDENTS` procedure failed to copy a dependent object and manual intervention is required.

You can query the `DBA_REDEFINITION_OBJECTS` view to determine which dependent objects are registered. This view shows dependent objects that were registered explicitly with the `REGISTER_DEPENDENT_OBJECT` procedure or implicitly with the `COPY_TABLE_DEPENDENTS` procedure. Only current information is shown in the view.

The `UNREGISTER_DEPENDENT_OBJECT` procedure can be used to unregister a dependent object on the table being redefined and on the interim table.

 **Note:**

- Manually created dependent objects do not have to be identical to their corresponding original dependent objects. For example, when manually creating a materialized view log on the interim table, you can log different columns. In addition, the interim table can have more or fewer dependent objects.
- If the table being redefined includes named LOB segments, then the LOB segment names are replaced by system-generated names during online redefinition. To avoid this, you can create the interim table with new LOB segment names.

 **See Also:**

[Example 4](#) in "Online Table Redefinition Examples" for an example that registers a dependent object

20.8.7 Results of the Redefinition Process

There are several results of the redefinition process.

The following are the end results of the redefinition process:

- The original table is redefined with the columns, indexes, constraints, grants, triggers, and statistics of the interim table, assuming that either REDEF_TABLE or COPY_TABLE_DEPENDENTS was used.
- Dependent objects that were registered, either explicitly using REGISTER_DEPENDENT_OBJECT or implicitly using COPY_TABLE_DEPENDENTS, are renamed automatically so that dependent object names on the redefined table are the same as before redefinition.

 **Note:**

If no registration is done or no automatic copying is done, then you must manually rename the dependent objects.

- The referential constraints involving the interim table now involve the redefined table and are enabled.
- Any indexes, triggers, materialized view logs, grants, and constraints defined on the original table (before redefinition) are transferred to the interim table and are dropped when the user drops the interim table. Any referential constraints involving the original table before the redefinition now involve the interim table and are disabled.
- Some PL/SQL objects, views, synonyms, and other table-dependent objects may become invalidated. Only those objects that depend on elements of the table that

were changed are invalidated. For example, if a PL/SQL procedure queries only columns of the redefined table that were unchanged by the redefinition, the procedure remains valid. See "[Managing Object Dependencies](#)" for more information about schema object dependencies.

20.8.8 Performing Intermediate Synchronization

During the redefinition process, you can synchronize the interim table with the original table if there were a large number of DML statements executed on the original table.

After the redefinition process has been started by calling `START_REDEF_TABLE` and before `FINISH_REDEF_TABLE` has been called, a large number of DML statements might have been executed on the original table. If you know that this is the case, then it is recommended that you periodically synchronize the interim table with the original table.

When you start an online table redefinition operation with the `START_REDEF_TABLE` procedure, it creates an internal materialized view to facilitate synchronization. This internal materialized view is refreshed to synchronize the interim table with the original table.

To synchronize the interim table with the original table:

- Run the `SYNC_INTERIM_TABLE` procedure in the `DBMS_REDEFINITION` package.

Calling this procedure reduces the time taken by `FINISH_REDEF_TABLE` to complete the redefinition process. There is no limit to the number of times that you can call `SYNC_INTERIM_TABLE`.

The small amount of time that the original table is locked during `FINISH_REDEF_TABLE` is independent of whether `SYNC_INTERIM_TABLE` has been called.

20.8.9 Refreshing Dependent Materialized Views During Online Table Redefinition

To refresh dependent fast refreshable materialized views during online table redefinition, set the `refresh_dep_mvviews` parameter to `Y` in the `REDEF_TABLE` procedure or the `START_REDEF_TABLE` procedure.

A dependent materialized view is any materialized view that is defined on the table being redefined. Performing a complete refresh of dependent materialized views after online table redefinition can be time consuming. You can incrementally refresh fast refreshable materialized views during online table redefinition to make the operation more efficient.

The following restrictions apply to refreshing a dependent materialized view:

- The materialized view must be fast refreshable.
- ROWID materialized views are not supported.
- Materialized join views are not supported.

A complete refresh of dependent ROWID materialized views and materialized join views is required after online table redefinition.

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Perform an online redefinition of a table using one of the following methods:
 - Running the `REDEF_TABLE` procedure and ensuring that the `refresh_dep_mvviews` parameter is set to `Y`.
With this method, fast refresh of dependent materialized views is performed once at the end of the redefinition operation.
 - Starting online table redefinition with the `START_REDEF_TABLE` procedure and ensuring that the `refresh_dep_mvviews` parameter is set to `Y`. This method ends with the `FINISH_REDEF_TABLE` procedure.
With this method, fast refresh of dependent materialized views is performed when the `START_REDEF_TABLE` procedure is run, each time the `SYNC_INTERIM_TABLE` procedure is run, and when the `FINISH_REDEF_TABLE` procedure is run.

 **Note:**

- You can check the value of the `refresh_dep_mvviews` parameter for an online table redefinition operation by querying the `DBA_REDEFINITION_STATUS` view.
- You can check on the progress of a refresh that is run automatically during online table redefinition by querying the `REFRESH_STATEMENT_SQL_ID` and `REFRESH_STATEMENT` columns in the `V$ONLINE_REDEF` view. You can use the `SQL_ID` value returned in the `REFRESH_STATEMENT_SQL_ID` column to monitor the progress of a refresh in views such as the `V$SQL` view and the `V$SQL_MONITOR` view.
- If you want to change the value of the `refresh_dep_mvviews` parameter during an online table redefinition operation, then you can use the `DBMS_REDEFINITION.SET_PARAM` procedure to reset the parameter.

Example 20-15 Refreshing Dependent Materialized Views While Running the REDEF_TABLE Procedure

```
hr.employees

BEGIN
  DBMS_REDEFINITION.REDEF_TABLE(
    uname          => 'HR',
    tname          => 'EMPLOYEES',
    table_compression_type => 'ROW STORE COMPRESS ADVANCED',
    refresh_dep_mvviews => 'Y');
END;
/
```

Example 20-16 Refreshing Dependent Materialized Views While Starting with the START_REDEF_TABLE Procedure

Assume that you want to redefine the oe.orders table. The table definition is:

```
CREATE TABLE oe.orders(
    order_id      NUMBER(12),
    order_date    TIMESTAMP WITH LOCAL TIME ZONE,
    order_mode    VARCHAR2(8),
    customer_id   NUMBER(6),
    order_status  NUMBER(2),
    order_total   NUMBER(8,2),
    sales_rep_id  NUMBER(6),
    promotion_id  NUMBER(6));
```

This example redefines the table to increase the size of the order_mode column to 16. The interim table definition is:

```
CREATE TABLE oe.int_orders(
    order_id      NUMBER(12),
    order_date    TIMESTAMP WITH LOCAL TIME ZONE,
    order_mode    VARCHAR2(16),
    customer_id   NUMBER(6),
    order_status  NUMBER(2),
    order_total   NUMBER(8,2),
    sales_rep_id  NUMBER(6),
    promotion_id  NUMBER(6));
```

Also assume that this table has dependent materialized views. The table has a materialized view log created with the following statement:

```
CREATE MATERIALIZED VIEW LOG ON oe.orders WITH PRIMARY KEY, ROWID;
```

The oe.orders table has the following dependent materialized views:

```
CREATE MATERIALIZED VIEW oe.orders_pk REFRESH FAST AS
SELECT * FROM oe.orders;
```

```
CREATE MATERIALIZED VIEW oe.orders_rowid REFRESH FAST WITH ROWID AS
SELECT * FROM oe.orders;
```

The oe.orders_pk materialized view is a fast refreshable, primary key materialized view. Therefore, it can be refreshed during online table redefinition.

The oe.orders_rowid materialized view is fast refreshable, but it is a ROWID materialized view. Therefore, it cannot be refreshed during online table redefinition.

Complete the following steps to perform online table redefinition on the oe.orders table while refreshing the oe.orders_pk materialized view:

1. Start the redefinition process.

```
BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE(
```

```

        uname          => 'oe',
        orig_table    => 'orders',
        int_table     => 'int_orders',
        options_flag  => DBMS_REDEFINITION.CONS_USE_PK,
        refresh_dep_mvviews => 'Y');
END;
/

```

2. Copy dependent objects. (Automatically create any triggers, indexes, materialized view logs, grants, and constraints on oe.int_orders.)

```

DECLARE
num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname          => 'oe',
        orig_table    => 'orders',
        int_table     => 'int_orders',
        copy_indexes  => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers  => TRUE,
        copy_constraints => TRUE,
        copy_privileges => TRUE,
        ignore_errors  => TRUE,
        num_errors      => num_errors);
END;
/

```

3. Check the redefinition status:

```

SELECT REDEFINITION_ID, REFRESH_DEP_MVIEWS
  FROM DBA_REDEFINITION_STATUS
 WHERE BASE_TABLE_OWNER = 'OE' AND BASE_TABLE_NAME = 'ORDERS';

```

4. Perform DML on the original table. For example:

```

INSERT INTO oe.orders VALUES(3000,sysdate,'direct',102,1,42283.2,154,NULL);
COMMIT;

```

5. Synchronize the interim table oe.int_orders. This step refreshes the dependent materialized view oe.orders_pk.

```

BEGIN
    DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
        uname      => 'OE',
        orig_table => 'ORDERS',
        int_table  => 'INT_ORDERS');
END;
/

```

6. Check the refresh status of the dependent materialized views for the oe.orders table:

```

SELECT m.OWNER, m.MVIEW_NAME, m.STALENESS, m.LAST_REFRESH_DATE
  FROM ALL_MVIEWS m, ALL_MVIEW_DETAIL_RELATIONS d
 WHERE m.OWNER=d.OWNER AND
       m. MVIEW_NAME=d.MVIEW_NAME AND
       d.DETAILOBJ_OWNER = 'OE' AND
       d.DETAILOBJ_NAME = 'ORDERS';

```

The oe.orders_pk materialized view was refreshed during the previous step, so it has FRESH for its STALENESS status. The oe.orders_rowid materialized view was not refreshed during the previous step, so it has NEEDS_COMPILE for its STALENESS status.

7. Complete the redefinition.

```
BEGIN
    DBMS_REDEFINITION.FINISH_REDEF_TABLE(
        uname      => 'OE',
        orig_table => 'ORDERS',
        int_table  => 'INT_ORDERS');
END;
/
```

You can query the `oe.orders_pk` materialized view to confirm that the new row inserted into the `oe.orders` table exist in the materialized view because it was refreshed during online table redefinition.

Related Topics

- [Monitoring Online Table Redefinition Progress](#)

You can query the `V$ONLINE_REDEF` view to monitor the progress of an online table redefinition operation.

20.8.10 Monitoring Online Table Redefinition Progress

You can query the `V$ONLINE_REDEF` view to monitor the progress of an online table redefinition operation.

During the process of redefining a table online, some operations can take a long time to execute. While these operations are executing, you can query the `V$ONLINE_REDEF` view for detailed information about the progress of the operation. For example, it can take a long time for the `DBMS_REDEFINITION.START_REDEF_TABLE` procedure to load data into the interim table.

The `V$ONLINE_REDEF` view provides a percentage complete value for the operation in the `PROGRESS` column. This view shows the current step in the total number of steps required to complete the operation in the `OPERATION` column. For example, if there are 10 steps in the operation, then this column might show Step 6 out of 10. The view also includes a `SUBOPERATION` column and a `DETAILED_MESSAGE` column for more granular information about the current operation.

During the online table redefinition process, an internal materialized view is created, and this materialized view is refreshed during some operations to keep the original table and the interim table synchronized. You can check on the progress of a refresh that is run automatically during online table redefinition by querying the `REFRESH_STATEMENT_SQL_ID` and `REFRESH_STATEMENT` columns in the `V$ONLINE_REDEF` view. You can use the `SQL_ID` value returned in the `REFRESH_STATEMENT_SQL_ID` column to monitor the progress of a refresh in views such as the `V$SQL` view and the `V$SQL_MONITOR` view.

1. Connect to the database in a session that is separate from the session that is performing online table redefinition.
2. Query the `V$ONLINE_REDEF` view.

Example 20-17 Monitoring Online Table Redefinition Progress

This example redefines the Oracle-supplied `sh.customers` table by adding a `cust_alt_phone_number` column.

```
CREATE TABLE customers (
    cust_id          NUMBER           NOT NULL,
```

```

        cust_first_name      VARCHAR2(20)    NOT NULL,
        cust_last_name       VARCHAR2(40)     NOT NULL,
        cust_gender          CHAR(1)         NOT NULL,
        cust_year_of_birth   NUMBER(4)       NOT NULL,
        cust_marital_status  VARCHAR2(20), 
        cust_street_address  VARCHAR2(40)    NOT NULL,
        cust_postal_code     VARCHAR2(10)    NOT NULL,
        cust_city             VARCHAR2(30)    NOT NULL,
        cust_city_id          NUMBER         NOT NULL,
        cust_state_province  VARCHAR2(40)    NOT NULL,
        cust_state_province_id NUMBER        NOT NULL,
        country_id            NUMBER         NOT NULL,
        cust_main_phone_number VARCHAR2(25)   NOT NULL,
        cust_income_level     VARCHAR2(30), 
        cust_credit_limit     NUMBER, 
        cust_email             VARCHAR2(50), 
        cust_total             VARCHAR2(14)    NOT NULL,
        cust_total_id          NUMBER        NOT NULL,
        cust_src_id            NUMBER, 
        cust_eff_from          DATE, 
        cust_eff_to             DATE, 
        cust_valid              VARCHAR2(1));

```

This table contains a large amount of data, and some of the operations in the online table redefinition process will take time. This example monitors various operations by querying the V\$ONLINE_REDEF view.

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Create an interim table sh.int_customers.

```

CREATE TABLE sh.int_customers (
        cust_id          NUMBER        NOT NULL,
        cust_first_name  VARCHAR2(20)   NOT NULL,
        cust_last_name   VARCHAR2(40)   NOT NULL,
        cust_gender       CHAR(1)       NOT NULL,
        cust_year_of_birth NUMBER(4)    NOT NULL,
        cust_marital_status VARCHAR2(20), 
        cust_street_address VARCHAR2(40)  NOT NULL,
        cust_postal_code  VARCHAR2(10)  NOT NULL,
        cust_city          VARCHAR2(30)  NOT NULL,
        cust_city_id        NUMBER      NOT NULL,
        cust_state_province VARCHAR2(40) NOT NULL,
        cust_state_province_id NUMBER    NOT NULL,
        country_id          NUMBER      NOT NULL,
        cust_main_phone_number VARCHAR2(25) NOT NULL,
        cust_income_level    VARCHAR2(30), 
        cust_credit_limit      NUMBER, 
        cust_email             VARCHAR2(50), 
        cust_total             VARCHAR2(14)    NOT NULL,
        cust_total_id          NUMBER        NOT NULL,
        cust_src_id            NUMBER, 
        cust_eff_from          DATE, 
        cust_eff_to             DATE, 
        cust_valid              VARCHAR2(1));

```

```

        cust_eff_to          DATE,
        cust_valid           VARCHAR2(1),
        cust_alt_phone_number VARCHAR2(25));

```

3. Start the redefinition process, and monitor the progress of the operation.

```

BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE(
        uname      => 'sh',
        orig_table => 'customers',
        int_table  => 'int_customers',
        options_flag => DBMS_REDEFINITION.CONS_USE_PK);
END;
/

```

As this operation is running, and in a session that is separate from the session that is performing online table redefinition, query the V\$ONLINE_REDEF view to monitor its progress:

```
SELECT * FROM V$ONLINE_REDEF;
```

Output from this query might show the following:

- START_REDEF_TABLE for OPERATION
- complete refresh the materialized view for SUBOPERATION
- step 6 out of 7 for PROGRESS

4. Copy dependent objects. (Automatically create any triggers, indexes, materialized view logs, grants, and constraints on sh.int_customers.)

```

DECLARE
num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname      => 'sh',
        orig_table => 'customers',
        int_table  => 'int_customers',
        copy_indexes => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers => TRUE,
        copy_constraints => TRUE,
        copy_privileges => TRUE,
        ignore_errors  => TRUE,
        num_errors     => num_errors);
END;
/

```

As this operation is running, and in a session that is separate from the session that is performing online table redefinition, query the V\$ONLINE_REDEF view to monitor its progress:

```
SELECT * FROM V$ONLINE_REDEF;
```

Output from this query might show the following:

- COPY_TABLE_DEPENDENTS for OPERATION
- copy the indexes for SUBOPERATION
- step 3 out of 7 for PROGRESS

Note that the `ignore_errors` argument is set to TRUE for this call. The reason is that the interim table was created with a primary key constraint, and when `COPY_TABLE_DEPENDENTS` attempts to copy the primary key constraint and index from the original table, errors occur. You can ignore these errors.

5. Synchronize the interim table `hr.int_emp_redef`.

```
BEGIN
    DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
        uname      => 'sh',
        orig_table => 'customers',
        int_table  => 'int_customers');
END;
/
```

6. Complete the redefinition.

```
BEGIN
    DBMS_REDEFINITION.FINISH_REDEF_TABLE(
        uname      => 'sh',
        orig_table => 'customers',
        int_table  => 'int_customers');
END;
/
```

Related Topics

- [Refreshing Dependent Materialized Views During Online Table Redefinition](#)

To refresh dependent fast refreshable materialized views during online table redefinition, set the `refresh_dep_mviews` parameter to Y in the `REDEF_TABLE` procedure or the `START_REDEF_TABLE` procedure.

20.8.11 Restarting Online Table Redefinition After a Failure

If online table redefinition fails, then you can check the `DBA_REDEFINITION_STATUS` view to see the error information and restartable information.

If `RESTARTABLE` is Y, then you can correct the error and restart the online redefinition process where it last stopped. If `RESTARTABLE` is N, you must abort the redefinition operation.

In some cases, it is possible to restart the online redefinition of a table after a failure. Restarting the operation means that the online redefinition process begins where it stopped because of the failure, and no work is lost. For example, if a `SYNC_INTERIM_TABLE` procedure call fails because of an “unable to extent table in tablespace” error, then the problem can be corrected by increasing the size of the tablespace that ran out of space and rerunning the `SYNC_INTERIM_TABLE` procedure call.

If online table redefinition fails, then you can complete the following steps to restart it:

1. Query the `DBA_REDEFINITION_STATUS` view to determine the cause of the failure and the action required to correct it.

For example, run the following query:

```
SELECT BASE_TABLE_NAME,
       INTERIM_OBJECT_NAME,
       OPERATION,
       STATUS,
```

```
RESTARTABLE,
ACTION
FROM DBA_REDEFINITION_STATUS;
```

If the RESTARTABLE value is Y, then the operation can be restarted. If the RESTARTABLE value is N, then the operation cannot be restarted, and redefinition must be performed again from the beginning.

2. Perform the action specified in the query results from the previous step.
3. Restart the online redefinition with the operation specified in the query results, and run all of the subsequent operations to finish online redefinition of the table.

Example 20-18 SYNC_INTERIM_TABLE Procedure Call Failure

This example illustrates restarting an online redefinition operation that failed on a SYNC_INTERIM_TABLE procedure call with the following error:

```
BEGIN
DBMS_REDEFINITION.SYNC_INTERIM_TABLE('U1', 'ORIG', 'INT');
END;
/
ORA-42009: error occurred while synchronizing the redefinition
ORA-01653: unable to extend table U1.INT by 8 in tablespace my_tbs
ORA-06512: at "SYS.DBMS_REDEFINITION", line 148
ORA-06512: at "SYS.DBMS_REDEFINITION", line 2807
ORA-06512: at line 2
```

1. Query the DBA_REDEFINITION_STATUS view:

BASE_TABLE_NAME	INT_TABLE_NAME	OPERATION	STATUS	RESTARTABLE
RESTARTABLE	ACTION			
ORIG	INT	SYNC_INTERIM_TABLE	FAILED	Y
error				Fix

The online redefinition operation can be restarted because RESTARTABLE is Y in the query results. To restart the operation, correct the error returned when the operation failed and restart the operation. In this example, the error is “ORA-01653: unable to extend table U1.INT by 8 in tablespace my_tbs”.

2. Increase the size of the my_tbs tablespace by adding a data file to it:

```
ALTER TABLESPACE my_tbs
ADD DATAFILE '/u02/oracle/data/my_tbs2.dbf' SIZE 100M;
```

3. Rerun SYNC_INTERIM_TABLE procedure call:

```
BEGIN
DBMS_REDEFINITION.SYNC_INTERIM_TABLE('U1', 'ORIG', 'INT');
```

```
END;
/
```

Example 20-19 Materialized View Log Problem

After the redefinition is started on the original table, there can be a problem with the materialized view log. For example, the materialized view log might be accidentally dropped or corrupted for some reason. In such cases, errors similar to the following are returned:

```
ERROR at line 1:
ORA-42010: error occurred while synchronizing the redefinition
ORA-12034: materialized view log on "HR"."T1" younger than last refresh
```

Assume a table that was created with the following SQL statement is being redefined:

```
CREATE TABLE hr.t1(
    c1 NUMBER PRIMARY KEY,
    c2 NUMBER)
TABLESPACE example_tbs;
```

Assume an interim table was created with the following SQL statement that changes the table's tablespace:

```
CREATE TABLE hr.int_t1(
    c1 NUMBER PRIMARY KEY,
    c2 NUMBER)
TABLESPACE hr_tbs;
```

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Start the redefinition process.

```
BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE(
        uname         => 'hr',
        orig_table    => 't1',
        int_table     => 'int_t1');
END;
/
```

3. Drop the materialized view log on the original table.

```
DROP MATERIALIZED VIEW LOG ON hr.t1;
```

4. Create a new materialized view log on the original table.

```
CREATE MATERIALIZED VIEW LOG ON hr.t1
    WITH COMMIT SCN PURGE
    IMMEDIATE ASYNCHRONOUS;
```

5. Synchronize the interim table hr.int_t1.

```

BEGIN
  DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
    uname      => 'hr',
    orig_table => 't1',
    int_table  => 'int_t1');
END;
/
BEGIN
*
ERROR at line 1:
ORA-42010: error occurred while synchronizing the redefinition
ORA-12034: materialized view log on "HR"."T1" younger than last refresh

```

6. Because an error was returned, check the DBA_REDEFINITION_STATUS view.

```

COLUMN BASE_OBJECT_NAME FORMAT A11
COLUMN OPERATION FORMAT A10
COLUMN STATUS FORMAT A10
COLUMN RESTARTABLE FORMAT A11
COLUMN ERR_TXT FORMAT A15
COLUMN ACTION FORMAT A18

SELECT BASE_OBJECT_NAME, OPERATION, STATUS, RESTARTABLE, ERR_TXT,
ACTION
  FROM DBA_REDEFINITION_STATUS
 ORDER BY BASE_TABLE_NAME, BASE_OBJECT_NAME;

```

BASE_OBJECT	OPERATION	STATUS	RESTARTABLE	ERR_TXT	ACTION
T1	SYNC_REDEF	Failure	N	ORA-12034: mate Abort	
	redefinition			_TABLE	rialized view l og on "HR"."T1" younger than l ast refresh

The online redefinition operation cannot be restarted because RESTARTABLE is N in the query results, and the ACTION column indicates that the online table redefinition operation must be aborted.

7. Abort the online table redefinition operation.

```

BEGIN
  DBMS_REDEFINITION.ABORT_REDEF_TABLE(
    uname      => 'hr',
    orig_table => 't1',
    int_table  => 'int_t1');
END;
/

```

20.8.12 Rolling Back Online Table Redefinition

You can enable roll back of a table after online table redefinition to return the table to its original definition and preserve DML changes made to the table.

- [About Online Table Redefinition Rollback](#)
After online table redefinition, you can roll back the table to its definition before online table redefinition while preserving all data manipulation language (DML) changes made to the table.
- [Performing Online Table Redefinition Rollback](#)
The `ROLLBACK` procedure in the `DBMS_REDEFINITION` package returns a table that was redefined online to its original definition while preserving DML changes.

20.8.12.1 About Online Table Redefinition Rollback

After online table redefinition, you can roll back the table to its definition before online table redefinition while preserving all data manipulation language (DML) changes made to the table.

In some cases, you might want to undo an online redefinition of a table. For example, the performance of operations on the table might be worse after the redefinition than it was before the redefinition. In these cases, you can roll back the table to its original definition while preserving all of the DML changes made to the table after it was redefined. Online table redefinition rollback is used mainly when redefinition changes the storage characteristics of the table, and the changes unexpectedly result in degraded performance.

To enable rollback of online table redefinition, the `ENABLE_ROLLBACK` parameter must be set to `TRUE` in the `DBMS_REDEFINITION.START_TABLE_REDEF` procedure. When this parameter is set to true, Oracle Database maintains the interim table created during redefinition after redefinition is complete. You can run the `SYNC_INTERIM_TABLE` procedure to synchronize the interim table periodically to apply DML changes made to the redefined table to the interim table. An internal materialized view and materialized view log enables maintenance of the interim table. If you decide to roll back the online table redefinition, then the interim table is synchronized, and Oracle Database switches back to it so that the table has its original definition.

The following restrictions apply to online table redefinition rollback:

- When there is no one to one mapping of the original table's columns to interim table's columns, there must be no operators or functions in column mappings during redefinition.

There can be operators and functions in column mappings when there is a one to one mapping of the original table's columns to interim table's columns.

- When rollback is enabled for a redefinition, the table cannot be redefined again until the online table redefinition is rolled back or aborted.

20.8.12.2 Performing Online Table Redefinition Rollback

The `ROLLBACK` procedure in the `DBMS_REDEFINITION` package returns a table that was redefined online to its original definition while preserving DML changes.

To use the `ROLLBACK` procedure, online table redefinition rollback must be enabled during online table redefinition. If you decide to retain the changes made by online table redefinition, then you can run the `ABORT_ROLLBACK` procedure.

1. Perform an online redefinition of a table, starting with the `START_REDEF_TABLE` procedure and ending with the `FINISH_REDEF_TABLE` procedure.

The `ENABLE_ROLLBACK` parameter must be set to `TRUE` in the `START_REDEF_TABLE` procedure. The default for this parameter is `FALSE`.

2. Optional: Periodically, run the `SYNC_INTERIM_TABLE` procedure to apply DML changes made to the redefined table to the interim table.

You can improve the performance of the online table redefinition rollback if you periodically apply the DML changes to the interim table.

3. Choose one of the following options:

- If you want to undo the changes made by online table redefinition and return to the original table definition, then run the `ROLLBACK` procedure in the `DBMS_REDEFINITION` package.
- If you want to retain the changes made by online table redefinition, then run the `ABORT_ROLLBACK` procedure in the `DBMS_REDEFINITION` package.
Aborting the rollback stops maintenance of the interim table and removes the materialized view and materialized view log that enabled rollback.

Example 20-20 Rolling Back Online Table Redefinition

This example illustrates online redefinition of a table by changing the storage characteristics for the table. Specifically, this example compresses the tablespace for the table during online redefinition. Assume that you want to evaluate the performance of the table after online redefinition is complete. If the table does not perform as well as expected, then you want to be able to roll back the changes made by online redefinition.

Assume that the following statements created the original tablespace and table:

```
CREATE TABLESPACE tst_rollback_tbs
  DATAFILE 'tst_rollback_tbs.dbf' SIZE 10M
  ONLINE;

CREATE TABLE hr.tst_rollback
  (rllbck_id    NUMBER(6) PRIMARY KEY,
   rllbck_name  VARCHAR2(20))
TABLESPACE tst_rollback_tbs
STORAGE (INITIAL 2M);
```

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "Connecting to the Database with SQL*Plus".

2. Create a compressed tablespace for the interim table.

```
CREATE TABLESPACE tst_cmp_rollback_tbs
    DEFAULT ROW STORE COMPRESS ADVANCED
    DATAFILE 'tst_cmp_rollback_tbs.dbf' SIZE 10M
    ONLINE;
```

3. Create an interim table hr.int_tst_rollback.

```
CREATE TABLE hr.int_tst_rollback
    (rllbck_id      NUMBER(6) PRIMARY KEY,
     rllbck_name   VARCHAR2(20))
    TABLESPACE tst_cmp_rollback_tbs
    STORAGE (INITIAL 2M);
```

Ensure that the interim table uses the compressed tablespace created in the previous step.

4. Start the redefinition process.

```
BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE(
        uname          => 'hr',
        orig_table     => 'tst_rollback',
        int_table      => 'int_tst_rollback',
        options_flag   => DBMS_REDEFINITION.CONS_USE_PK,
        enable_rollback => TRUE);
END;
/
```

Ensure that `enable_rollback` is set to TRUE so that the changes made by online redefinition can be rolled back.

5. Copy dependent objects.

```
DECLARE
num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname          => 'hr',
        orig_table     => 'tst_rollback',
        int_table      => 'int_tst_rollback',
        copy_indexes   => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers  => TRUE,
        copy_constraints => TRUE,
        copy_privileges => TRUE,
        ignore_errors  => TRUE,
        num_errors      => num_errors);
END;
/
```

6. Query the `DBA_REDEFINITION_ERRORS` view to check for errors.

```
SET LONG 8000
SET PAGES 8000
COLUMN OBJECT_NAME HEADING 'Object Name' FORMAT A20
COLUMN BASE_TABLE_NAME HEADING 'Base Table Name' FORMAT A10
COLUMN DDL_TXT HEADING 'DDL That Caused Error' FORMAT A40

SELECT OBJECT_NAME, BASE_TABLE_NAME, DDL_TXT FROM
    DBA_REDEFINITION_ERRORS;
```

You can ignore errors related to the primary key and indexes.

7. Synchronize the interim table `hr.int_tst_rollback`.

```
BEGIN
  DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
    uname      => 'hr',
    orig_table => 'tst_rollback',
    int_table  => 'int_tst_rollback');
END;
/
```

8. Complete the redefinition.

```
BEGIN
  DBMS_REDEFINITION.FINISH_REDEF_TABLE(
    uname      => 'hr',
    orig_table => 'tst_rollback',
    int_table  => 'int_tst_rollback');
END;
/
```

The table `hr.tst_rollback` is locked in the exclusive mode only for a small window toward the end of this step. After this call the table `hr.tst_rollback` is redefined such that it has all the attributes of the `hr.int_tst_rollback` table. In this example, the tablespace for the `hr.tst_rollback` table is now compressed.

9. During the evaluation period, you can periodically synchronize the interim table `hr.int_tst_rollback`.

```
BEGIN
  DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
    uname      => 'hr',
    orig_table => 'tst_rollback',
    int_table  => 'int_tst_rollback');
END;
/
```

Synchronizing the tables updates the original table with the DML changes made to the redefined table. When you synchronize the tables periodically, a rollback operation is more efficient because fewer DML changes must be made to the original table. You can query the `STATUS` column of the `DBA_REDEFINITION_STATUS` view to determine the status of the rollback operation.

10. Perform one of the following actions:

- Assume that the redefined table did not perform as well as expected, and roll back the changes made by online redefinition.

```
BEGIN
  DBMS_REDEFINITION.ROLLBACK(
    uname      => 'hr',
    orig_table => 'tst_rollback',
    int_table  => 'int_tst_rollback');
END;
/
```

- Assume that the redefined table performed as expected, and abort the rollback to retain the changes made by online table redefinition and clean up the database objects that enable rollback.

```
BEGIN
  DBMS_REDEFINITION.ABORT_ROLLBACK()
```

```
        uname      => 'hr',
        orig_table => 'tst_rollback',
        int_table   => 'int_tst_rollback');
END;
/
```

20.8.13 Aborting Online Table Redefinition and Cleaning Up After Errors

You can abort the online redefinition process. Doing so drops temporary logs and tables associated with the redefinition process. After this procedure is called, you can drop the interim table and its dependent objects.

To abort the online redefinition process in the event that an error is raised during the redefinition process, or if you choose to terminate the redefinition process manually:

- Run the `ABORT_REDEF_TABLE` procedure.

If the online redefinition process must be restarted, if you do not first call `ABORT_REDEF_TABLE`, then subsequent attempts to redefine the table will fail.

Note:

It is not necessary to call the `ABORT_REDEF_TABLE` procedure if the redefinition process stops because the `FINISH_REDEF_TABLE` procedure has timed out. The `dml_lock_timeout` parameter in the `FINISH_REDEF_TABLE` procedure controls the time-out period. See step 8 in "[Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION](#)" for more information

20.8.14 Online Redefinition of One or More Partitions

You can redefine online one or more partitions of a table. This is useful if, for example, you want to move partitions to a different tablespace and keep the partitions available for DML during the operation.

You can redefine multiple partitions in a table at one time. If you do, then multiple interim tables are required during the table redefinition process. Ensure that you have enough free space and undo space to complete the table redefinition.

When you redefine multiple partitions, you can specify that the redefinition continues even if it encounters an error for a particular partition. To do so, set the `continue_after_errors` parameter to `TRUE` in redefinition procedures in the `DBMS_REDEFINITION` package. You can check the `DBA_REDEFINITION_STATUS` view to see if any errors were encountered during the redefinition process. The `STATUS` column in this view shows whether the redefinition process succeeded or failed for each partition.

You can also redefine an entire table one partition at a time to reduce resource requirements. For example, to move a very large table to a different tablespace, you can move it one partition at a time to minimize the free space and undo space required to complete the move.

Redefining partitions differs from redefining a table in the following ways:

- There is no need to copy dependent objects. It is not valid to use the COPY_TABLE_DEPENDENTS procedure when redefining a single partition.
- You must manually create and register any local indexes on the interim table.
See "[Creating Dependent Objects Manually](#)".
- The column mapping string for START_REDEF_TABLE must be NULL.

 **Note:**

Starting with Oracle Database 12c, you can use the simpler ALTER TABLE...MOVE PARTITION ... ONLINE statement to move a partition or subpartition online without using online table redefinition. DML operations can continue to run uninterrupted on the partition or subpartition that is being moved. See "[Moving a Table to a New Segment or Tablespace](#)".

- [Rules for Online Redefinition of a Single Partition](#)

The underlying mechanism for redefinition of a single partition is the **exchange partition** capability of the database (ALTER TABLE...EXCHANGE PARTITION).

 **See Also:**

Oracle Database VLDB and Partitioning Guide

20.8.14.1 Rules for Online Redefinition of a Single Partition

The underlying mechanism for redefinition of a single partition is the **exchange partition** capability of the database (ALTER TABLE...EXCHANGE PARTITION).

Rules and restrictions for online redefinition of a single partition are therefore governed by this mechanism. Here are some general restrictions:

- No logical changes (such as adding or dropping a column) are permitted.
- No changes to the partitioning method (such as changing from range partitioning to hash partitioning) are permitted.

Here are the rules for defining the interim table:

- If the partition being redefined is a range, hash, or list partition, then the interim table must be nonpartitioned.
- If the partition being redefined is a range partition of a composite range-hash partitioned table, then the interim table must be a hash partitioned table. In addition, the partitioning key of the interim table must be identical to the subpartitioning key of the range-hash partitioned table, and the number of partitions in the interim table must be identical to the number of subpartitions in the range partition being redefined.
- If the partition being redefined is a range partition of a composite range-list partitioned table, then the interim table must be a list partitioned table. In addition, the partitioning key of the interim table must be identical to the subpartitioning key

of the range-list partitioned table, and the values lists of the interim table's list partitions must exactly match the values lists of the list subpartitions in the range partition being redefined.

- If you define the interim table as compressed, then you must use the by-key method of redefinition, not the by-rowid method.

These additional rules apply if the table being redefined is a partitioned index-organized table:

- The interim table must also be index-organized.
- The original and interim tables must have primary keys on the same columns, in the same order.
- If prefix compression is enabled, then it must be enabled for both the original and interim tables, with the same prefix length.
- Both the original and interim tables must have overflow segments, or neither can have them. Likewise for mapping tables.

See Also:

- The section "Exchanging Partitions" in *Oracle Database VLDB and Partitioning Guide*
- "[Online Table Redefinition Examples](#)" for examples that redefine tables with partitions

20.8.15 Online Table Redefinition Examples

Examples illustrate online redefinition of tables.

For the following examples, see *Oracle Database PL/SQL Packages and Types Reference* for descriptions of all DBMS_REDEFINITION subprograms.

Example	Description
Example 1	Redefines a table's storage properties in a single step with the REDEF_TABLE procedure.
Example 2	Redefines a table by adding new columns and adding partitioning.
Example 3	Demonstrates redefinition with object data types.
Example 4	Demonstrates redefinition with manually registered dependent objects.
Example 5	Redefines multiple partitions, moving them to different tablespaces.
Example 6	Redefines a table with virtual private database (VPD) policies without changing the properties of any of the table's columns.
Example 7	Redefines a table with VPD policies and changes the properties of one of the table's columns.
Example 8	Redefines a table by making multiple changes using online redefinition.

Example 1

This example illustrates online redefinition of a table's storage properties using the REDEF_TABLE procedure.

The original table, named print_ads, is defined in the pm schema as follows:

Name	Null?	Type
AD_ID		NUMBER(6)
AD_TEXT		CLOB

In this table, the LOB column ad_text uses BasicFiles LOB storage.

An index for the table was created with the following SQL statement:

```
CREATE INDEX pm.print_ads_ix
    ON print_ads (ad_id)
    TABLESPACE example;
```

The table is redefined as follows:

- The table is compressed with advanced row compression.
- The table's tablespace is changed from EXAMPLE to NEWTBS. This example assumes that the NEWTBS tablespace exists.
- The index is compressed with COMPRESS 1 compression.
- The index's tablespace is changed from EXAMPLE to NEWIDXTBS. This example assumes that the NEWIDXTBS tablespace exists.
- The LOB column in the table is compressed with COMPRESS HIGH compression.
- The tablespace for the LOB column is changed from EXAMPLE to NEWLOBTBS. This example assumes that the NEWLOBTBS tablespace exists.
- The LOB column is changed to SecureFiles LOB storage.

The steps in this redefinition are illustrated below.

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Run the REDEF_TABLE procedure:

```
BEGIN
    DBMS_REDEFINITION.REDEF_TABLE(
        uname          => 'PM',
        tname          => 'PRINT_ADS',
        table_compression_type => 'ROW STORE COMPRESS ADVANCED',
        table_part_tablespace => 'NEWTBS',
        index_key_compression_type => 'COMPRESS 1',
        index_tablespace      => 'NEWIDXTBS',
        lob_compression_type  => 'COMPRESS HIGH',
        lob_tablespace        => 'NEWLOBTBS',
        lob_store_as          => 'SECUREFILE');
END;
/
```

 **Note:**

If an errors occurs, then the interim table is dropped, and the REDEF_TABLE procedure must be re-executed.

Example 2

This example illustrates online redefinition of a table by adding new columns and adding partitioning.

The original table, named `emp_redef`, is defined in the `hr` schema as follows:

Name	Type
EMPNO	NUMBER(5) <- Primary key
ENAME	VARCHAR2(15)
JOB	VARCHAR2(10)
DEPTNO	NUMBER(3)

The table is redefined as follows:

- New columns `mgr`, `hiredate`, `sal`, and `bonus` are added.
- The new column `bonus` is initialized to 0 (zero).
- The column `deptno` has its value increased by 10.
- The redefined table is partitioned by range on `empno`.

The steps in this redefinition are illustrated below.

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Verify that the table is a candidate for online redefinition. In this case you specify that the redefinition is to be done using primary keys or pseudo-primary keys.

```
BEGIN
    DBMS_REDEFINITION.CAN_REDEF_TABLE(
        uname      => 'hr',
        tname      =>'emp_redef',
        options_flag => DBMS_REDEFINITION.CONS_USE_PK);
END;
/
```

3. Create an interim table `hr.int_emp_redef`.

```
CREATE TABLE hr.int_emp_redef
    (empno      NUMBER(5) PRIMARY KEY,
     ename      VARCHAR2(15) NOT NULL,
     job       VARCHAR2(10),
     mgr       NUMBER(5),
     hiredate   DATE DEFAULT (sysdate),
     sal        NUMBER(7,2),
     deptno    NUMBER(3) NOT NULL,
     bonus      NUMBER (7,2) DEFAULT(0))
```

```
PARTITION BY RANGE(empno)
    (PARTITION emp1000 VALUES LESS THAN (1000) TABLESPACE admin_tbs,
     PARTITION emp2000 VALUES LESS THAN (2000) TABLESPACE admin_tbs2);
```

Ensure that the specified tablespaces exist.

4. Start the redefinition process.

```
BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE(
        uname      => 'hr',
        orig_table => 'emp_redef',
        int_table  => 'int_emp_redef',
        col_mapping => 'empno empno, ename ename, job job, deptno+10 deptno,
                        0 bonus',
        options_flag => DBMS_REDEFINITION.CONS_USE_PK);
END;
/
```

5. Copy dependent objects. (Automatically create any triggers, indexes, materialized view logs, grants, and constraints on hr.int_emp_redef.)

```
DECLARE
num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname      => 'hr',
        orig_table => 'emp_redef',
        int_table  => 'int_emp_redef',
        copy_indexes => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers => TRUE,
        copy_constraints => TRUE,
        copy_privileges => TRUE,
        ignore_errors  => TRUE,
        num_errors     => num_errors);
END;
/
```

Note that the `ignore_errors` argument is set to `TRUE` for this call. The reason is that the interim table was created with a primary key constraint, and when `COPY_TABLE_DEPENDENTS` attempts to copy the primary key constraint and index from the original table, errors occur. You can ignore these errors, but you must run the query shown in the next step to see if there are other errors.

6. Query the `DBA_REDEFINITION_ERRORS` view to check for errors.

```
SET LONG 8000
SET PAGES 8000
COLUMN OBJECT_NAME HEADING 'Object Name' FORMAT A20
COLUMN BASE_TABLE_NAME HEADING 'Base Table Name' FORMAT A10
COLUMN DDL_TXT HEADING 'DDL That Caused Error' FORMAT A40
```

```
SELECT OBJECT_NAME, BASE_TABLE_NAME, DDL_TXT FROM
    DBA_REDEFINITION_ERRORS;
```

Object Name	Base Table DDL That Caused Error
SYS_C006796	EMP_REDEF CREATE UNIQUE INDEX "HR"."TMP\$\$_SYS_C0067960" ON "HR"."INT_EMP_REDEF" ("EMPNO") PCTFREE 10 INITTRANS 2 MAXTRANS 255 STORAGE(INITIAL 65536 NEXT 1048576 MINEXTENTS 1 MAXEXTENTS 2147483645

```

          PCTINCREASE 0 FREELISTS 1 FREELIST GRO
          UPS 1
          BUFFER_POOL DEFAULT)
          TABLESPACE "ADMIN_TBS"
SYS_C006794    EMP_REDEF ALTER TABLE "HR"."INT_EMP_REDEF" MODIFY
                ("ENAME" CONSTRAINT "TMP$$_SYS_C0067940"
                 NOT NULL ENABLE NOVALIDATE)
SYS_C006795    EMP_REDEF ALTER TABLE "HR"."INT_EMP_REDEF" MODIFY
                ("DEPTNO" CONSTRAINT "TMP$$_SYS_C0067950"
                 NOT NULL ENABLE NOVALIDATE)
SYS_C006796    EMP_REDEF ALTER TABLE "HR"."INT_EMP_REDEF" ADD CON
                STRAINT "TMP$$_SYS_C0067960" PRIMARY KEY
                ("EMPNO")
                USING INDEX PCTFREE 10 INITTRANS 2 MAXT
                RANS 255
                STORAGE(INITIAL 65536 NEXT 1048576 MIN
                EXTENTS 1 MAXEXTENTS 2147483645
                PCTINCREASE 0 FREELISTS 1 FREELIST GRO
                UPS 1
                BUFFER_POOL DEFAULT)
                TABLESPACE "ADMIN_TBS"  ENABLE NOVALID
                ATE

```

These errors are caused by the existing primary key constraint on the interim table and can be ignored. Note that with this approach, the names of the primary key constraint and index on the post-redefined table are changed. An alternate approach, one that avoids errors and name changes, would be to define the interim table without a primary key constraint. In this case, the primary key constraint and index are copied from the original table.

 **Note:**

The best approach is to define the interim table with a primary key constraint, use `REGISTER_DEPENDENT_OBJECT` to register the primary key constraint and index, and then copy the remaining dependent objects with `COPY_TABLE_DEPENDENTS`. This approach avoids errors and ensures that the redefined table always has a primary key and that the dependent object names do not change.

7. (Optional) Synchronize the interim table `hr.int_emp_redef`.

```

BEGIN
  DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
    uname      => 'hr',
    orig_table => 'emp_redef',
    int_table  => 'int_emp_redef');
END;
/

```

8. Complete the redefinition.

```

BEGIN
  DBMS_REDEFINITION.FINISH_REDEF_TABLE(
    uname      => 'hr',
    orig_table => 'emp_redef',
    int_table  => 'int_emp_redef');
END;
/

```

The table `hr.emp_redef` is locked in the exclusive mode only for a small window toward the end of this step. After this call the table `hr.emp_redef` is redefined such that it has all the attributes of the `hr.int_emp_redef` table.

Consider specifying a non-NULL value for the `dml_lock_timeout` parameter in this procedure. See step 8 in "[Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION](#)" for more information.

9. Wait for any long-running queries against the interim table to complete, and then drop the interim table.

Example 3

This example redefines a table to change columns into object attributes. The redefined table gets a new column that is an object type.

The original table, named `customer`, is defined as follows:

Name	Type
CID	NUMBER
NAME	VARCHAR2(30)
STREET	VARCHAR2(100)
CITY	VARCHAR2(30)
STATE	VARCHAR2(2)
ZIP	NUMBER(5)

The type definition for the new object is:

```
CREATE TYPE addr_t AS OBJECT (
    street VARCHAR2(100),
    city VARCHAR2(30),
    state VARCHAR2(2),
    zip NUMBER(5, 0) );
/
```

Here are the steps for this redefinition:

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Verify that the table is a candidate for online redefinition. Specify that the redefinition is to be done using primary keys or pseudo-primary keys.

```
BEGIN
    DBMS_REDEFINITION.CAN_REDEF_TABLE(
        uname      => 'steve',
        tname      =>'customer',
        options_flag => DBMS_REDEFINITION.CONS_USE_PK);
END;
/
```

3. Create the interim table `int_customer`.

```
CREATE TABLE int_customer(
    CID   NUMBER,
    NAME  VARCHAR2(30),
```

```
    ADDR  addr_t);
```

Note that no primary key is defined on the interim table. When dependent objects are copied in step 6, the primary key constraint and index are copied.

4. Because `customer` is a very large table, specify parallel operations for the next step.

```
ALTER SESSION FORCE PARALLEL DML PARALLEL 4;
ALTER SESSION FORCE PARALLEL QUERY PARALLEL 4;
```

5. Start the redefinition process using primary keys.

```
BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE(
        uname      => 'steve',
        orig_table => 'customer',
        int_table  => 'int_customer',
        col_mapping => 'cid cid, name name,
                        addr_t(street, city, state, zip) addr');
END;
/
```

Note that `addr_t(street, city, state, zip)` is a call to the object constructor.

6. Copy dependent objects.

```
DECLARE
num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname      => 'steve',
        orig_table => 'customer',
        int_table  => 'int_customer',
        copy_indexes => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers => TRUE,
        copy_constraints => TRUE,
        copy_privileges => TRUE,
        ignore_errors  => FALSE,
        num_errors     => num_errors,
        copy_statistics => TRUE);
END;
/
```

Note that for this call, the final argument indicates that table statistics are to be copied to the interim table.

7. Optionally synchronize the interim table.

```
BEGIN
    DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
        uname      => 'steve',
        orig_table => 'customer',
        int_table  => 'int_customer');
END;
/
```

8. Complete the redefinition.

```
BEGIN
    DBMS_REDEFINITION.FINISH_REDEF_TABLE(
        uname      => 'steve',
        orig_table => 'customer',
```

```
    int_table  => 'int_customer') ;
END;
/
```

Consider specifying a non-NULL value for the `dml_lock_timeout` parameter in this procedure. See step 8 in "[Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION](#)" for more information.

9. Wait for any long-running queries against the interim table to complete, and then drop the interim table.

Example 4

This example addresses the situation where a dependent object must be manually created and registered.

The table to be redefined is defined as follows:

```
CREATE TABLE steve.t1
  (c1 NUMBER);
```

The table has an index for column `c1`:

```
CREATE INDEX steve.index1 ON steve.t1(c1);
```

Consider the case where column `c1` becomes column `c2` after the redefinition. In this case, `COPY_TABLE_DEPENDENTS` tries to create an index on the interim table corresponding to `index1`, and tries to create it on a column `c1`, which does not exist in the interim table. This results in an error. You must therefore manually create the index on column `c2` and register it.

Here are the steps for this redefinition:

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Ensure that `t1` is a candidate for online redefinition with `CAN_REDEF_TABLE`, and then begin the redefinition process with `START_REDEF_TABLE`.

```
BEGIN
  DBMS_REDEFINITION.CAN_REDEF_TABLE(
    uname      => 'steve',
    tname      => 't1',
    options_flag => DBMS_REDEFINITION.CONS_USE_ROWID);
END;
/
```

3. Create the interim table `int_t1` and create an index `int_index1` on column `c2`.

```
CREATE TABLE steve.int_t1
  (c2 NUMBER);

CREATE INDEX steve.int_index1 ON steve.int_t1(c2);
```

4. Start the redefinition process.

```
BEGIN
  DBMS_REDEFINITION.START_REDEF_TABLE(
```

```

        uname      => 'steve',
        orig_table => 't1',
        int_table   => 'int_t1',
        col_mapping => 'c1 c2',
        options_flag => DBMS_REDEFINITION.CONS_USE_ROWID);
END;
/

```

5. Register the original (`index1`) and interim (`int_index1`) dependent objects.

```

BEGIN
    DBMS_REDEFINITION.REGISTER_DEPENDENT_OBJECT(
        uname      => 'steve',
        orig_table => 't1',
        int_table   => 'int_t1',
        dep_type    => DBMS_REDEFINITION.CONS_INDEX,
        dep_owner   => 'steve',
        dep_orig_name => 'index1',
        dep_int_name  => 'int_index1');
END;
/

```

6. Copy the dependent objects.

```

DECLARE
    num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname      => 'steve',
        orig_table => 't1',
        int_table   => 'int_t1',
        copy_indexes => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers => TRUE,
        copy_constraints => TRUE,
        copy_privileges => TRUE,
        ignore_errors  => TRUE,
        num_errors     => num_errors);
END;
/

```

7. Optionally synchronize the interim table.

```

BEGIN
    DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
        uname      => 'steve',
        orig_table => 't1',
        int_table   => 'int_t1');
END;
/

```

8. Complete the redefinition.

```

BEGIN
    DBMS_REDEFINITION.FINISH_REDEF_TABLE(
        uname      => 'steve',
        orig_table => 't1',
        int_table   => 'int_t1');
END;
/

```

9. Wait for any long-running queries against the interim table to complete, and then drop the interim table.

Example 5

This example demonstrates redefining multiple partitions. It moves two of the partitions of a range-partitioned sales table to new tablespaces. The table containing the partitions to be redefined is defined as follows:

```
CREATE TABLE steve.salestable
  (s_productid NUMBER,
   s_saledate DATE,
   s_custid NUMBER,
   s_totalprice NUMBER)
TABLESPACE users
PARTITION BY RANGE(s_saledate)
(PARTITION sal10q1 VALUES LESS THAN (TO_DATE('01-APR-2010', 'DD-MON-YYYY')),
 PARTITION sal10q2 VALUES LESS THAN (TO_DATE('01-JUL-2010', 'DD-MON-YYYY')),
 PARTITION sal10q3 VALUES LESS THAN (TO_DATE('01-OCT-2010', 'DD-MON-YYYY')),
 PARTITION sal10q4 VALUES LESS THAN (TO_DATE('01-JAN-2011', 'DD-MON-YYYY')));
```

This example moves the `sal10q1` partition to the `sales1` tablespace and the `sal10q2` partition to the `sales2` tablespace. The `sal10q3` and `sal10q4` partitions are not moved.

To move the partitions, the tablespaces `sales1` and `sales2` must exist. The following examples create these tablespaces:

```
CREATE TABLESPACE sales1 DATAFILE '/u02/oracle/data/sales01.dbf' SIZE 50M
EXTENT MANAGEMENT LOCAL AUTOALLOCATE;

CREATE TABLESPACE sales2 DATAFILE '/u02/oracle/data/sales02.dbf' SIZE 50M
EXTENT MANAGEMENT LOCAL AUTOALLOCATE;
```

Note:

You can also complete this operation by executing two `ALTER TABLE ... MOVE PARTITION ... ONLINE` statements. See "[Moving a Table to a New Segment or Tablespace](#)".

The table has a local partitioned index that is defined as follows:

```
CREATE INDEX steve.sales_index ON steve.salestable
  (s_saledate, s_productid, s_custid) LOCAL;
```

Here are the steps. In the following procedure calls, note the extra argument: partition name (`part_name`).

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Ensure that `salestable` is a candidate for redefinition.

```
BEGIN
  DBMS_REDEFINITION.CAN_REDEF_TABLE(
    uname       => 'steve',
```

```

        tname      => 'salestable',
        options_flag => DBMS_REDEFINITION.CONS_USE_ROWID,
        part_name    => 'sal10q1, sal10q2');
END;
/

```

3. Create the interim tables in the new tablespaces. Because this is a redefinition of a range partition, the interim tables are nonpartitioned.

```

CREATE TABLE steve.int_salestb1
  (s_productid NUMBER,
   s_saledate DATE,
   s_custid NUMBER,
   s_totalprice NUMBER)
TABLESPACE sales1;

CREATE TABLE steve.int_salestb2
  (s_productid NUMBER,
   s_saledate DATE,
   s_custid NUMBER,
   s_totalprice NUMBER)
TABLESPACE sales2;

```

4. Start the redefinition process using rowid.

```

BEGIN
  DBMS_REDEFINITION.START_REDEF_TABLE(
    uname      => 'steve',
    orig_table => 'salestable',
    int_table  => 'int_salestb1, int_salestb2',
    col_mapping => NULL,
    options_flag => DBMS_REDEFINITION.CONS_USE_ROWID,
    part_name   => 'sal10q1, sal10q2',
    continue_after_errors => TRUE);
END;
/

```

Notice that the `part_name` parameter specifies both of the partitions and that the `int_table` parameter specifies the interim table for each partition. Also, the `continue_after_errors` parameter is set to `TRUE` so that the redefinition process continues even if it encounters an error for a particular partition.

5. Manually create any local indexes on the interim tables.

```

CREATE INDEX steve.int_sales1_index ON steve.int_salestb1
  (s_saledate, s_productid, s_custid)
TABLESPACE sales1;

CREATE INDEX steve.int_sales2_index ON steve.int_salestb2
  (s_saledate, s_productid, s_custid)
TABLESPACE sales2;

```

6. Optionally synchronize the interim tables.

```

BEGIN
  DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
    uname      => 'steve',
    orig_table => 'salestable',
    int_table  => 'int_salestb1, int_salestb2',
    part_name   => 'sal10q1, sal10q2',
    continue_after_errors => TRUE);
END;
/

```

7. Complete the redefinition.

```
BEGIN
    DBMS_REDEFINITION.FINISH_REDEF_TABLE(
        uname      => 'steve',
        orig_table => 'salestable',
        int_table  => 'int_salestbl1, int_salestb2',
        part_name   => 'sal10q1, sal10q2',
        continue_after_errors => TRUE);
END;
/
```

Consider specifying a non-NULL value for the `dml_lock_timeout` parameter in this procedure. See step 8 in "Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION" for more information.

- 8.** Wait for any long-running queries against the interim tables to complete, and then drop the interim tables.
- 9.** (Optional) Query the `DBA_REDEFINITION_STATUS` view to ensure that the redefinition succeeded for each partition.

```
SELECT BASE_TABLE_OWNER, BASE_TABLE_NAME, OPERATION, STATUS
  FROM DBA_REDEFINITION_STATUS;
```

If redefinition failed for any partition, then query the `DBA_REDEFINITION_ERRORS` view to determine the cause of the failure. Correct the conditions that caused the failure, and rerun online redefinition.
