The following query shows that two of the partitions in the table have been moved to the new tablespaces:

```
SELECT PARTITION_NAME, TABLESPACE_NAME FROM DBA_TAB_PARTITIONS
 WHERE TABLE_NAME = 'SALESTABLE';
```

PARTITION_NAME	TABLESPACE_NAME
SAL10Q1	SALES1
SAL10Q2	SALES2
SAL10Q3	USERS
SAL10Q4	USERS

4 rows selected.

Example 6

This example illustrates online redefinition of a table with virtual private database (VPD) policies. The example disables all triggers for a table without changing any of the column names or column types in the table.

The table to be redefined is defined as follows:

```
CREATE TABLE hr.employees(
    employee_id    NUMBER(6)  PRIMARY KEY,
    first_name     VARCHAR2(20),
    last_name      VARCHAR2(25)
        CONSTRAINT emp_last_name_nn NOT NULL,
    email          VARCHAR2(25)
        CONSTRAINT emp_email_nn NOT NULL,
    phone_number   VARCHAR2(20),
    hire_date      DATE
        CONSTRAINT emp_hire_date_nn NOT NULL,
```

```

job_id          VARCHAR2(10)
               CONSTRAINT emp_job_nn NOT NULL,
salary         NUMBER(8,2),
commission_pct NUMBER(2,2),
manager_id     NUMBER(6),
department_id  NUMBER(4),
               CONSTRAINT emp_salary_min
                           CHECK (salary > 0),
               CONSTRAINT emp_email_uk
                           UNIQUE (email));

```

If you installed the `HR` sample schema, then this table exists in your database.

Assume that the following `auth_emp_dep_100` function is created for the VPD policy:

```

CREATE OR REPLACE FUNCTION hr.auth_emp_dep_100(
    schema_var IN VARCHAR2,
    table_var IN VARCHAR2
)
RETURN VARCHAR2
AS
BEGIN
    SELECT USER INTO unm FROM DUAL;
    IF (unm = 'HR') THEN
        return_val := NULL;
    ELSE
        return_val := 'DEPARTMENT_ID = 100';
    END IF;
    RETURN return_val;
END auth_emp_dep_100;
/

```

The following `ADD_POLICY` procedure specifies a VPD policy for the original table `hr.employees` using the `auth_emp_dep_100` function:

```

BEGIN
    DBMS_RLS.ADD_POLICY (
        object_schema  => 'hr',
        object_name    => 'employees',
        policy_name   => 'employees_policy',
        function_schema => 'hr',
        policy_function => 'auth_emp_dep_100',
        statement_types => 'select, insert, update, delete'
    );
END;
/

```

In this example, the `hr.employees` table is redefined to disable all of its triggers. No column names or column types are changed during redefinition. Therefore, specify `DBMS_REDEFINITION.CONS_VPD_AUTO` for the `copy_vpd_opt` in the `START_REFEF_TABLE` procedure.

The steps in this redefinition are illustrated below.

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table and the required privileges for managing VPD policies.

Specifically, the user must have the privileges described in "Privileges Required for the DBMS_REDEFINITION Package" and EXECUTE privilege on the DBMS_RLS package.

See "[Connecting to the Database with SQL*Plus](#)".

2. Verify that the table is a candidate for online redefinition. In this case you specify that the redefinition is to be done using primary keys or pseudo-primary keys.

```
BEGIN
    DBMS_REDEFINITION.CAN_REDEF_TABLE('hr','employees',
        DBMS_REDEFINITION.CONS_USE_PK);
END;
/
```

3. Create an interim table hr.int_employees.

```
CREATE TABLE hr.int_employees(
    employee_id      NUMBER(6),
    first_name       VARCHAR2(20),
    last_name        VARCHAR2(25),
    email            VARCHAR2(25),
    phone_number     VARCHAR2(20),
    hire_date        DATE,
    job_id           VARCHAR2(10),
    salary            NUMBER(8,2),
    commission_pct   NUMBER(2,2),
    manager_id       NUMBER(6),
    department_id    NUMBER(4));
```

4. Start the redefinition process.

```
BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE (
        uname          => 'hr',
        orig_table     => 'employees',
        int_table      => 'int_employees',
        col_mapping    => NULL,
        options_flag   => DBMS_REDEFINITION.CONS_USE_PK,
        orderby_cols   => NULL,
        part_name      => NULL,
        copy_vpd_opt   => DBMS_REDEFINITION.CONS_VPD_AUTO);
END;
/
```

When the `copy_vpd_opt` parameter is set to `DBMS_REDEFINITION.CONS_VPD_AUTO`, only the table owner and the user invoking online redefinition can access the interim table during online redefinition.

Also, notice that the `col_mapping` parameter is set to `NULL`. When the `copy_vpd_opt` parameter is set to `DBMS_REDEFINITION.CONS_VPD_AUTO`, the `col_mapping` parameter must be `NULL` or `'*'.` See "[Handling Virtual Private Database \(VPD\) Policies During Online Redefinition](#)".

5. Copy dependent objects. (Automatically create any triggers, indexes, materialized view logs, grants, and constraints on `hr.int_employees`.)

```
DECLARE
num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname          => 'hr',
        orig_table     => 'employees',
```

```

        int_table      => 'int_employees',
        copy_indexes   => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers   => TRUE,
        copy_constraints => TRUE,
        copy_privileges  => TRUE,
        ignore_errors    => FALSE,
        num_errors       => num_errors);
END;
/

```

6. Disable all of the triggers on the interim table.

```

ALTER TABLE hr.int_employees
  DISABLE ALL TRIGGERS;

```

7. (Optional) Synchronize the interim table `hr.int_employees`.

```

BEGIN
  DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
    uname      => 'hr',
    orig_table => 'employees',
    int_table  => 'int_employees');
END;
/

```

8. Complete the redefinition.

```

BEGIN
  DBMS_REDEFINITION.FINISH_REDEF_TABLE(
    uname      => 'hr',
    orig_table => 'employees',
    int_table  => 'int_employees');
END;
/

```

The table `hr.employees` is locked in the exclusive mode only for a small window toward the end of this step. After this call the table `hr.employees` is redefined such that it has all the attributes of the `hr.int_employees` table.

Consider specifying a non-NULL value for the `dml_lock_timeout` parameter in this procedure. See step 8 in "Performing Online Redefinition with Multiple Procedures in `DBMS_REDEFINITION`" for more information.

9. Wait for any long-running queries against the interim table to complete, and then drop the interim table.

Example 7

This example illustrates online redefinition of a table with virtual private database (VPD) policies. The example changes the name of a column in the table.

The table to be redefined is defined as follows:

```

CREATE TABLE oe.orders(
  order_id      NUMBER(12) PRIMARY KEY,
  order_date    TIMESTAMP WITH LOCAL TIME ZONE CONSTRAINT order_date_nn NOT NULL,
  order_mode    VARCHAR2(8),
  customer_id   NUMBER(6) CONSTRAINT order_customer_id_nn NOT NULL,
  order_status  NUMBER(2),
  order_total   NUMBER(8,2),
  sales_rep_id  NUMBER(6),
  promotion_id  NUMBER(6),
  CONSTRAINT     order_mode_lov

```

```

        CHECK (order_mode in ('direct','online')),
CONSTRAINT order_total_min
        check (order_total >= 0));

```

If you installed the OE sample schema, then this table exists in your database.

Assume that the following auth_orders function is created for the VPD policy:

```

CREATE OR REPLACE FUNCTION oe.auth_orders(
    schema_var IN VARCHAR2,
    table_var IN VARCHAR2
)
RETURN VARCHAR2
AS
    return_val VARCHAR2 (400);
    unm      VARCHAR2(30);
BEGIN
    SELECT USER INTO unm FROM DUAL;
    IF (unm = 'OE') THEN
        return_val := NULL;
    ELSE
        return_val := 'SALES_REP_ID = 159';
    END IF;
    RETURN return_val;
END auth_orders;
/

```

The following ADD_POLICY procedure specifies a VPD policy for the original table oe.orders using the auth_orders function:

```

BEGIN
    DBMS_RLS.ADD_POLICY (
        object_schema    => 'oe',
        object_name      => 'orders',
        policy_name      => 'orders_policy',
        function_schema  => 'oe',
        policy_function  => 'auth_orders',
        statement_types   => 'select, insert, update, delete');
END;
/

```

In this example, the table is redefined to change the sales_rep_id column to sale_pid. When one or more column names or column types change during redefinition, you must specify DBMS_REDEFINITION.CONS_VPD_MANUAL for the copy_vpd_opt in the START_REFEF_TABLE procedure.

The steps in this redefinition are illustrated below.

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table and the required privileges for managing VPD policies.

Specifically, the user must have the privileges described in "Privileges Required for the DBMS_REDEFINITION Package" and EXECUTE privilege on the DBMS_RLS package.

See "[Connecting to the Database with SQL*Plus](#)".

2. Verify that the table is a candidate for online redefinition. In this case you specify that the redefinition is to be done using primary keys or pseudo-primary keys.

```

BEGIN
    DBMS_REDEFINITION.CAN_REDEF_TABLE(

```

```

        uname      => 'oe',
        tname      => 'orders',
        options_flag => DBMS_REDEFINITION.CONS_USE_PK);
END;
/

```

3. Create an interim table oe.int_orders.

```

CREATE TABLE oe.int_orders(
    order_id      NUMBER(12),
    order_date    TIMESTAMP WITH LOCAL TIME ZONE,
    order_mode    VARCHAR2(8),
    customer_id   NUMBER(6),
    order_status  NUMBER(2),
    order_total   NUMBER(8,2),
    sales_pid     NUMBER(6),
    promotion_id  NUMBER(6));

```

Note that the `sales_rep_id` column is changed to the `sales_pid` column in the interim table.

4. Start the redefinition process.

```

BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE (
        uname      => 'oe',
        orig_table => 'orders',
        int_table  => 'int_orders',
        col_mapping => 'order_id order_id, order_date order_date, order_mode
                        order_mode, customer_id customer_id, order_status
                        order_status, order_total order_total, sales_rep_id,
                        sales_pid, promotion_id promotion_id',
        options_flag => DBMS_REDEFINITION.CONS_USE_PK,
        orderby_cols => NULL,
        part_name   => NULL,
        copy_vpd_opt => DBMS_REDEFINITION.CONS_VPD_MANUAL);
END;
/

```

Because a column name is different in the original table and the interim table, `DBMS_REDEFINITION.CONS_VPD_MANUAL` must be specified for the `copy_vpd_opt` parameter. See "[Handling Virtual Private Database \(VPD\) Policies During Online Redefinition](#)".

5. Create the VPD policy on the interim table.

In this example, complete the following steps:

- Create a new function called `auth_orders_sales_pid` for the VPD policy that specifies the `sales_pid` column instead of the `sales_rep_id` column:

```

CREATE OR REPLACE FUNCTION oe.auth_orders_sales_pid(
    schema_var IN VARCHAR2,
    table_var IN VARCHAR2
)
RETURN VARCHAR2
AS
    return_val VARCHAR2 (400);
    unm      VARCHAR2(30);
BEGIN
    SELECT USER INTO unm FROM DUAL;
    IF (unm = 'OE') THEN
        return_val := NULL;
    ELSE
        return_val := 'SELECT * FROM oe.int_orders';
    END IF;
END;

```

```

    ELSE
        return_val := 'SALES_PID = 159';
    END IF;
    RETURN return_val;
END auth_orders_sales_pid;
/

```

- b. Run the ADD_POLICY procedure and specify the new function auth_orders_sales_pid and the interim table int_orders:

```

BEGIN
    DBMS_RLS.ADD_POLICY (
        object_schema      => 'oe',
        object_name        => 'int_orders',
        policy_name        => 'orders_policy',
        function_schema    => 'oe',
        policy_function   => 'auth_orders_sales_pid',
        statement_types    => 'select, insert, update, delete');
    END;
/

```

6. Copy dependent objects. (Automatically create any triggers, indexes, materialized view logs, grants, and constraints on oe.int_orders.)

```

DECLARE
num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname          => 'oe',
        orig_table     => 'orders',
        int_table      => 'int_orders',
        copy_indexes   => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers  => TRUE,
        copy_constraints => TRUE,
        copy_privileges => TRUE,
        ignore_errors  => TRUE,
        num_errors     => num_errors);
END;
/

```

Note that the ignore_errors argument is set to TRUE for this call. The reason is that the original table has an index and a constraint related to the sales_rep_id column, and this column is changed to sales_pid in the interim table. The next step shows the errors and describes how to create the index and the constraint on the interim table.

7. Query the DBA_REDEFINITION_ERRORS view to check for errors.

```

SET LONG 8000
SET PAGES 8000
COLUMN OBJECT_NAME HEADING 'Object Name' FORMAT A20
COLUMN BASE_TABLE_NAME HEADING 'Base Table Name' FORMAT A10
COLUMN DDL_TXT HEADING 'DDL That Caused Error' FORMAT A40

SELECT OBJECT_NAME, BASE_TABLE_NAME, DDL_TXT FROM
    DBA_REDEFINITION_ERRORS;

Object Name          Base Table DDL That Caused Error
----- -----
ORDERS_SALES REP FK ORDERS      ALTER TABLE "OE"."INT_ORDERS" ADD CONSTRA
                                INT "TMP$$_ORDERS_SALES REP FK1" FOREIGN KEY ("SALES REP ID")

```

```

        REFERENCES "HR"."EMPLOYEES"
        ( "EMPLOYEE"
          E_ID" ) ON DELETE SET NULL DISABLE
        CREATE INDEX "OE"."TMP$$_ORD_SALES REP_I
X0" ON "OE"."INT_ORDERS" ("SALES REP_ID"
)
        PCTFREE 10 INITTRANS 2 MAXTRANS 255 COM
PUTE STATISTICS
        STORAGE(INITIAL 65536 NEXT 1048576 MIN
EXTENTS 1 MAXEXTENTS 2147483645
        PCTINCREASE 0 FREELISTS 1 FREELIST GRO
UPS 1
        BUFFER_POOL DEFAULT)
        TABLESPACE "EXAMPLE"
        ALTER TABLE "OE"."INT_ORDERS" ADD CONSTRA
INT "TMP$$_TMP$$_ORDERS_SALES RE0" FORE
IGN KEY ("SALES REP_ID")
        REFERENCES "HR"."INT_EMPLOYEES"
        ( "EMP
LOYEE_ID" ) ON DELETE SET NULL DISABLE

```

If necessary, correct the errors reported in the output.

In this example, original table has an index and a foreign key constraint on the sales_rep_id column. The index and the constraint could not be copied to the interim table because the name of the column changed from sales_rep_id to sales_pid.

To correct the problems, add the index and the constraint on the interim table by completing the following steps:

a. Add the index:

```

ALTER TABLE oe.int_orders
    ADD (CONSTRAINT orders_sales_pid_fk
        FOREIGN KEY (sales_pid)
        REFERENCES hr.employees(employee_id)
        ON DELETE SET NULL);

```

b. Add the foreign key constraint:

```
CREATE INDEX ord_sales_pid_ix ON oe.int_orders (sales_pid);
```

8. (Optional) Synchronize the interim table oe.int_orders.

```

BEGIN
    DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
        uname      => 'oe',
        orig_table => 'orders',
        int_table  => 'int_orders');
END;
/

```

9. Complete the redefinition.

```

BEGIN
    DBMS_REDEFINITION.FINISH_REDEF_TABLE(
        uname      => 'oe',
        orig_table => 'orders',
        int_table  => 'int_orders');
END;
/

```

The table oe.orders is locked in the exclusive mode only for a small window toward the end of this step. After this call the table oe.orders is redefined such that it has all the attributes of the oe.int_orders table.

Consider specifying a non-NULL value for the `dml_lock_timeout` parameter in this procedure. See step 8 in "[Performing Online Redefinition with Multiple Procedures in DBMS_REDEFINITION](#)" for more information.

10. Wait for any long-running queries against the interim table to complete, and then drop the interim table.

Example 8

This example illustrates making multiple changes to a table using online redefinition.

The table to be redefined is defined as follows:

```
CREATE TABLE testredef.original(
    col1 NUMBER PRIMARY KEY,
    col2 VARCHAR2(10),
    col3 CLOB,
    col4 DATE)
ORGANIZATION INDEX;
```

The table is redefined as follows:

- The table is compressed with advanced row compression.
- The LOB column is changed to SecureFiles LOB storage.
- The table's tablespace is changed from `example` to `testredeftbs`, and the table's block size is changed from 8KB to 16KB.

This example assumes that the database block size is 8KB. This example also assumes that the `DB_16K_CACHE_SIZE` initialization parameter is set and that the `testredef` tablespace was created with a 16KB block size. For example:

```
CREATE TABLESPACE testredeftbs
    DATAFILE '/u01/app/oracle/oradata/testredef01.dbf' SIZE 500M   EXTENT
    MANAGEMENT LOCAL AUTOALLOCATE
    SEGMENT SPACE MANAGEMENT AUTO
    BLOCKSIZE 16384;
```

- The table is partitioned on the `col1` column.
- The `col5` column is added.
- The `col2` column is dropped.
- Columns `col3` and `col4` are renamed, and their position in the table is changed.
- The type of the `col3` column is changed from `DATE` to `TIMESTAMP`.
- The table is changed from an index-organized table (IOT) to a heap-organized table.
- The table is defragmented.

To demonstrate defragmentation, the table must be populated. For the purposes of this example, you can use this PL/SQL block to populate the table:

```
DECLARE
    V_CLOB CLOB;
BEGIN
    FOR I IN 0..999 LOOP
```

```

V_CLOB := NULL;
FOR J IN 1..1000 LOOP
    V_CLOB := V_CLOB||TO_CHAR(I,'0000');
END LOOP;
INSERT INTO testredef.original VALUES(I,TO_CHAR(I),V_CLOB,SYSDATE+I);
COMMIT;
END LOOP;
COMMIT;
END;
/

```

Run the following SQL statement to fragment the table by deleting every third row:

```
DELETE FROM testredef.original WHERE (COL1/3) <> TRUNC(COL1/3);
```

You can confirm the fragmentation by using the `DBMS_SPACE.SPACE_USAGE` procedure.

See Also:

Oracle Database PL/SQL Packages and Types Reference for more information about the `DBMS_SPACE.SPACE_USAGE` procedure

The steps in this redefinition are illustrated below.

1. In SQL*Plus, connect as a user with the required privileges for performing online redefinition of a table.

Specifically, the user must have the privileges described in "[Privileges Required for the DBMS_REDEFINITION Package](#)".

See "[Connecting to the Database with SQL*Plus](#)".

2. Verify that the table is a candidate for online redefinition. In this case you specify that the redefinition is to be done using primary keys or pseudo-primary keys.

```

BEGIN
    DBMS_REDEFINITION.CAN_REDEF_TABLE(
        uname      => 'testredef',
        tname      => 'original',
        options_flag => DBMS_REDEFINITION.CONS_USE_PK);
END;
/

```

3. Create an interim table `testredef.interim`.

```

CREATE TABLE testredef.interim(
    col1 NUMBER,
    col3 TIMESTAMP,
    col4 CLOB,
    col5 VARCHAR2(3))
LOB(col4) STORE AS SECUREFILE (NOCACHE FILESYSTEM_LIKE_LOGGING)
PARTITION BY RANGE (COL1) (
    PARTITION par1 VALUES LESS THAN (333),
    PARTITION par2 VALUES LESS THAN (666),
    PARTITION par3 VALUES LESS THAN (MAXVALUE))
TABLESPACE testredeftbls
ROW STORE COMPRESS ADVANCED;

```

4. Start the redefinition process.

```

BEGIN
    DBMS_REDEFINITION.START_REDEF_TABLE(
        uname      => 'testredef',
        orig_table => 'original',
        int_table  => 'interim',
        col_mapping => 'col1 col1, TO_TIMESTAMP(col4) col3, col3 col4',
        options_flag => DBMS_REDEFINITION.CONS_USE_PK);
END;
/

```

5. Copy the dependent objects.

```

DECLARE
    num_errors PLS_INTEGER;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
        uname      => 'testredef',
        orig_table => 'original',
        int_table  => 'interim',
        copy_indexes => DBMS_REDEFINITION.CONS_ORIG_PARAMS,
        copy_triggers => TRUE,
        copy_constraints => TRUE,
        copy_privileges => TRUE,
        ignore_errors  => TRUE,
        num_errors     => num_errors);
END;
/

```

6. Optionally synchronize the interim table.

```

BEGIN
    DBMS_REDEFINITION.SYNC_INTERIM_TABLE(
        uname      => 'testredef',
        orig_table => 'original',
        int_table  => 'interim');
END;
/

```

7. Complete the redefinition.

```

BEGIN
    DBMS_REDEFINITION.FINISH_REDEF_TABLE(
        uname      => 'testredef',
        orig_table => 'original',
        int_table  => 'interim');
END;
/

```

20.9 Researching and Reversing Erroneous Table Changes

To enable you to research and reverse erroneous changes to tables, Oracle Database provides a group of features that you can use to view past states of database objects or to return database objects to a previous state without using point-in-time media recovery. These features are known as **Oracle Flashback features**.

To research an erroneous change, you can use multiple Oracle Flashback queries to view row data at specific points in time. A more efficient approach would be to use Oracle Flashback Version Query to view all changes to a row over a period of time. With this feature, you append a `VERSIONS` clause to a `SELECT` statement that specifies a system change number (SCN) or timestamp range between which you want to view changes to row values. The query also can return associated metadata, such as the transaction responsible for the change.

After you identify an erroneous transaction, you can use Oracle Flashback Transaction Query to identify other changes that were made by the transaction. You can then use Oracle Flashback Transaction to reverse the erroneous transaction. (Note that Oracle Flashback Transaction must also reverse all dependent transactions—subsequent transactions involving the same rows as the erroneous transaction.) You also have the option of using Oracle Flashback Table, described in "[Recovering Tables Using Oracle Flashback Table](#)".

 **Note:**

You must be using automatic undo management to use Oracle Flashback features. See "[Introduction to Automatic Undo Management](#)".

 **See Also:**

Oracle Database Development Guide for information about Oracle Flashback features.

20.10 Recovering Tables Using Oracle Flashback Table

Oracle Flashback Table enables you to restore a table to its state as of a previous point in time.

It provides a fast, online solution for recovering a table that has been accidentally modified or deleted by a user or application. In many cases, Oracle Flashback Table eliminates the need for you to perform more complicated point-in-time recovery operations.

Oracle Flashback Table:

- Restores all data in a specified table to a previous point in time described by a timestamp or SCN.
- Performs the restore operation online.
- Automatically maintains all of the table attributes, such as indexes, triggers, and constraints that are necessary for an application to function with the flashed-back table.
- Maintains any remote state in a distributed environment. For example, all of the table modifications required by replication if a replicated table is flashed back.

- Maintains data integrity as specified by constraints. Tables are flushed back provided none of the table constraints are violated. This includes any referential integrity constraints specified between a table included in the FLASHBACK TABLE statement and another table that is not included in the FLASHBACK TABLE statement.
- Even after a flashback operation, the data in the original table is not lost. You can later revert to the original state.

 **Note:**

You must be using automatic undo management to use Oracle Flashback Table. See "[Introduction to Automatic Undo Management](#)".

 **See Also:**

Oracle Database Backup and Recovery User's Guide for more information about the FLASHBACK TABLE statement.

20.11 Dropping Tables

To drop a table that you no longer need, use the `DROP TABLE` statement.

The table must be contained in your schema or you must have the `DROP ANY TABLE` system privilege.

 **Note:**

Before dropping a table, familiarize yourself with the consequences of doing so:

- Dropping a table removes the table definition from the data dictionary. All rows of the table are no longer accessible.
- All indexes and triggers associated with a table are dropped.
- All views and PL/SQL program units dependent on a dropped table remain, yet become invalid (not usable). See "[Managing Object Dependencies](#)" for information about how the database manages dependencies.
- All synonyms for a dropped table remain, but return an error when used.
- All extents allocated for a table that is dropped are returned to the free space of the tablespace and can be used by any other object requiring new extents or new objects. All rows corresponding to a clustered table are deleted from the blocks of the cluster. Clustered tables are the subject of [Managing Clusters](#).

The following statement drops the `hr.int_admin_emp` table:

```
DROP TABLE hr.int_admin_emp;
```

If the table to be dropped contains any primary or unique keys referenced by foreign keys of other tables and you intend to drop the `FOREIGN KEY` constraints of the child tables, then include the `CASCADE` clause in the `DROP TABLE` statement, as shown below:

```
DROP TABLE hr.admin_emp CASCADE CONSTRAINTS;
```

When you drop a table, normally the database does not immediately release the space associated with the table. Rather, the database renames the table and places it in a recycle bin, where it can later be recovered with the `FLASHBACK TABLE` statement if you find that you dropped the table in error. If you should want to immediately release the space associated with the table at the time you issue the `DROP TABLE` statement, include the `PURGE` clause as shown in the following statement:

```
DROP TABLE hr.admin_emp PURGE;
```

Perhaps instead of dropping a table, you want to truncate it. The `TRUNCATE` statement provides a fast, efficient method for deleting all rows from a table, but it does not affect any structures associated with the table being truncated (column definitions, constraints, triggers, and so forth) or authorizations. The `TRUNCATE` statement is discussed in "Truncating Tables and Clusters".

Live SQL:

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating and Modifying Tables](#).

20.12 Using Flashback Drop and Managing the Recycle Bin

When you drop a table, the database does not immediately remove the space associated with the table. The database renames the table and places it and any associated objects in a recycle bin, where, in case the table was dropped in error, it can be recovered at a later time. This feature is called Flashback Drop, and the `FLASHBACK TABLE` statement is used to restore the table.

Before discussing the use of the `FLASHBACK TABLE` statement for this purpose, it is important to understand how the recycle bin works, and how you manage its contents.

- [What Is the Recycle Bin?](#)

The recycle bin is actually a data dictionary table containing information about dropped objects. Dropped tables and any associated objects such as indexes, constraints, nested tables, and so on are not removed and still occupy space.

- [Enabling and Disabling the Recycle Bin](#)

When the recycle bin is enabled, dropped tables and their dependent objects are placed in the recycle bin. When the recycle bin is disabled, dropped tables and their dependent objects are *not* placed in the recycle bin; they are dropped, and you must use other means to recover them (such as recovering from backup).

- [Viewing and Querying Objects in the Recycle Bin](#)

Oracle Database provides two views for obtaining information about objects in the recycle bin.

- **Purging Objects in the Recycle Bin**
If you decide that you are never going to restore an item from the recycle bin, then you can use the PURGE statement to remove the items and their associated objects from the recycle bin and release their storage space. You need the same privileges as if you were dropping the item.
- **Restoring Tables from the Recycle Bin**
Use the FLASHBACK TABLE ... TO BEFORE DROP statement to recover objects from the recycle bin.

20.12.1 What Is the Recycle Bin?

The recycle bin is actually a data dictionary table containing information about dropped objects. Dropped tables and any associated objects such as indexes, constraints, nested tables, and so on are not removed and still occupy space.

They continue to count against user space quotas, until specifically purged from the recycle bin or the unlikely situation where they must be purged by the database because of tablespace space constraints.

Each user can be thought of as having his own recycle bin, because, unless a user has the SYSDBA privilege, the only objects that the user has access to in the recycle bin are those that the user owns. A user can view his objects in the recycle bin using the following statement:

```
SELECT * FROM RECYCLEBIN;
```

Only the `DROP TABLE` SQL statement places objects in the recycle bin. It adds the table and its associated objects so that they can be recovered as a group. In addition to the table itself, the associated objects that are added to the recycle bin can include the following types of objects:

- Nested tables
- LOB segments
- Indexes
- Constraints (excluding foreign key constraints)
- Triggers
- Clusters

When you drop a tablespace including its contents, the objects in the tablespace are not placed in the recycle bin and the database purges any entries in the recycle bin for objects located in the tablespace. The database also purges any recycle bin entries for objects in a tablespace when you drop the tablespace, not including contents, and the tablespace is otherwise empty. Likewise:

- When you drop a user, any objects belonging to the user are not placed in the recycle bin and any objects in the recycle bin are purged.
- When you drop a cluster, its member tables are not placed in the recycle bin and any former member tables in the recycle bin are purged.
- When you drop a type, any dependent objects such as subtypes are not placed in the recycle bin and any former dependent objects in the recycle bin are purged.

Object Naming in the Recycle Bin

When a dropped table is moved to the recycle bin, the table and its associated objects are given system-generated names. This is necessary to avoid name conflicts that may arise if multiple tables have the same name. This could occur under the following circumstances:

- A user drops a table, re-creates it with the same name, then drops it again.
- Two users have tables with the same name, and both users drop their tables.

The renaming convention is as follows:

`BIN$unique_id$version`

where:

- `unique_id` is a 26-character globally unique identifier for this object, which makes the recycle bin name unique across all databases
- `version` is a version number assigned by the database

20.12.2 Enabling and Disabling the Recycle Bin

When the recycle bin is enabled, dropped tables and their dependent objects are placed in the recycle bin. When the recycle bin is disabled, dropped tables and their dependent objects are *not* placed in the recycle bin; they are dropped, and you must use other means to recover them (such as recovering from backup).

Disabling the recycle bin does not purge or otherwise affect objects already in the recycle bin. The recycle bin is enabled by default.

You enable and disable the recycle bin by changing the `recyclebin` initialization parameter. This parameter is not dynamic, so a database restart is required when you change it with an `ALTER SYSTEM` statement.

To enable the recycle bin:

1. Issue one of the following statements:

```
ALTER SESSION SET recyclebin = ON;  
  
ALTER SYSTEM SET recyclebin = ON SCOPE = SPFILE;
```

2. If you used `ALTER SYSTEM`, restart the database.

To disable the recycle bin:

1. Issue one of the following statements:

```
ALTER SESSION SET recyclebin = OFF;  
  
ALTER SYSTEM SET recyclebin = OFF SCOPE = SPFILE;
```

2. If you used `ALTER SYSTEM`, restart the database.

 **See Also:**

- ["About Initialization Parameters and Initialization Parameter Files"](#) for more information on initialization parameters
- ["Changing Initialization Parameter Values"](#) for a description of dynamic and static initialization parameters

20.12.3 Viewing and Querying Objects in the Recycle Bin

Oracle Database provides two views for obtaining information about objects in the recycle bin.

View	Description
USER_RECYCLEBIN	This view can be used by users to see their own dropped objects in the recycle bin. It has a synonym RECYCLEBIN, for ease of use.
DBA_RECYCLEBIN	This view gives administrators visibility to all dropped objects in the recycle bin

One use for these views is to identify the name that the database has assigned to a dropped object, as shown in the following example:

```
SELECT object_name, original_name FROM dba_recyclebin
  WHERE owner = 'HR';

OBJECT_NAME          ORIGINAL_NAME
-----
BIN$yrMK1ZaLMhfgNAgAIMenRA==$0 EMPLOYEES
```

You can also view the contents of the recycle bin using the SQL*Plus command `SHOW RECYCLEBIN`.

```
SQL> show recyclebin

ORIGINAL NAME      RECYCLEBIN NAME          OBJECT TYPE   DROP TIME
-----
EMPLOYEES          BIN$yrMK1ZaVMhfgNAgAIMenRA==$0 TABLE        2003-10-27:14:00:19
```

You can query objects that are in the recycle bin, just as you can query other objects. However, you must specify the name of the object as it is identified in the recycle bin. For example:

```
SELECT * FROM "BIN$yrMK1ZaVMhfgNAgAIMenRA==$0";
```

20.12.4 Purging Objects in the Recycle Bin

If you decide that you are never going to restore an item from the recycle bin, then you can use the `PURGE` statement to remove the items and their associated objects from the recycle bin and release their storage space. You need the same privileges as if you were dropping the item.

When you use the `PURGE` statement to purge a table, you can use the name that the table is known by in the recycle bin or the original name of the table. The recycle bin

name can be obtained from either the DBA_ or USER_RECYCLEBIN view as shown in "Viewing and Querying Objects in the Recycle Bin". The following hypothetical example purges the table hr.int_admin_emp, which was renamed to BIN\$jsleilx392mk2=293\$0 when it was placed in the recycle bin:

```
PURGE TABLE "BIN$jsleilx392mk2=293$0";
```

You can achieve the same result with the following statement:

```
PURGE TABLE int_admin_emp;
```

You can use the PURGE statement to purge all the objects in the recycle bin that are from a specified tablespace or only the tablespace objects belonging to a specified user, as shown in the following examples:

```
PURGE TABLESPACE example;
PURGE TABLESPACE example USER oe;
```

Users can purge the recycle bin of their own objects, and release space for objects, by using the following statement:

```
PURGE RECYCLEBIN;
```

If you have the SYSDBA privilege or the PURGE DBA_RECYCLEBIN system privilege, then you can purge the entire recycle bin by specifying DBA_RECYCLEBIN, instead of RECYCLEBIN in the previous statement.

You can also use the PURGE statement to purge an index from the recycle bin or to purge from the recycle bin all objects in a specified tablespace.

See Also:

Oracle Database SQL Language Reference for more information on the PURGE statement

20.12.5 Restoring Tables from the Recycle Bin

Use the FLASHBACK TABLE ... TO BEFORE DROP statement to recover objects from the recycle bin.

You can specify either the name of the table in the recycle bin or the original table name. An optional RENAME TO clause lets you rename the table as you recover it. The recycle bin name can be obtained from either the DBA_ or USER_RECYCLEBIN view as shown in "Viewing and Querying Objects in the Recycle Bin". To use the FLASHBACK TABLE ... TO BEFORE DROP statement, you need the same privileges required to drop the table.

The following example restores int_admin_emp table and assigns to it a new name:

```
FLASHBACK TABLE int_admin_emp TO BEFORE DROP
RENAME TO int2_admin_emp;
```

The system-generated recycle bin name is very useful if you have dropped a table multiple times. For example, suppose you have three versions of the int2_admin_emp table in the recycle bin and you want to recover the second version. You can do this by

issuing two FLASHBACK TABLE statements, or you can query the recycle bin and then flashback to the appropriate system-generated name, as shown in the following example. Including the create time in the query can help you verify that you are restoring the correct table.

```
SELECT object_name, original_name, createtime FROM recyclebin;

OBJECT_NAME          ORIGINAL_NAME    CREATETIME
-----              -----
BIN$yrMKlZaLMhfgNAGAIMenRA==$0  INT2_ADMIN_EMP  2006-02-05:21:05:52
BIN$yrMKlZaVMhfgNAGAIMenRA==$0  INT2_ADMIN_EMP  2006-02-05:21:25:13
BIN$yrMKlZaQMhfgNAGAIMenRA==$0  INT2_ADMIN_EMP  2006-02-05:22:05:53

FLASHBACK TABLE "BIN$yrMKlZaVMhfgNAGAIMenRA==$0" TO BEFORE DROP;
```

Restoring Dependent Objects

When you restore a table from the recycle bin, dependent objects such as indexes do not get their original names back; they retain their system-generated recycle bin names. You must manually rename dependent objects to restore their original names. If you plan to manually restore original names for dependent objects, ensure that you make note of each dependent object's system-generated recycle bin name *before* you restore the table.

The following is an example of restoring the original names of some of the indexes of the dropped table JOB_HISTORY, from the HR sample schema. The example assumes that you are logged in as the HR user.

1. After dropping JOB_HISTORY and before restoring it from the recycle bin, run the following query:

```
SELECT OBJECT_NAME, ORIGINAL_NAME, TYPE FROM RECYCLEBIN;
```

OBJECT_NAME	ORIGINAL_NAME	TYPE
BIN\$DBo9UChTZSbgQFeMiAdCcQ==\$0	JHIST_JOB_IX	INDEX
BIN\$DBo9UChuZSbgQFeMiAdCcQ==\$0	JHIST_EMPLOYEE_IX	INDEX
BIN\$DBo9UChvZSbgQFeMiAdCcQ==\$0	JHIST_DEPARTMENT_IX	INDEX
BIN\$DBo9UChwZSbgQFeMiAdCcQ==\$0	JHIST_EMP_ID_ST_DATE_PK	INDEX
BIN\$DBo9UCHxZSbgQFeMiAdCcQ==\$0	JOB_HISTORY	TABLE

2. Restore the table with the following command:

```
FLASHBACK TABLE JOB_HISTORY TO BEFORE DROP;
```

3. Run the following query to verify that all JOB_HISTORY indexes retained their system-generated recycle bin names:

```
SELECT INDEX_NAME FROM USER_INDEXES WHERE TABLE_NAME = 'JOB_HISTORY';
```

INDEX_NAME
BIN\$DBo9UChwZSbgQFeMiAdCcQ==\$0
BIN\$DBo9UChTZSbgQFeMiAdCcQ==\$0
BIN\$DBo9UChuZSbgQFeMiAdCcQ==\$0
BIN\$DBo9UChvZSbgQFeMiAdCcQ==\$0

4. Restore the original names of the first two indexes as follows:

```
ALTER INDEX "BIN$DBo9UChTZSbgQFeMiAdCcQ==$0" RENAME TO JHIST_JOB_IX;
ALTER INDEX "BIN$DBo9UChuZSbgQFeMiAdCcQ==$0" RENAME TO JHIST_EMPLOYEE_IX;
```

Note that double quotes are required around the system-generated names.

20.13 Managing Index-Organized Tables

An index-organized table's storage organization is a variant of a primary B-tree index. Unlike a heap-organized table, data is stored in primary key order.

- [What Are Index-Organized Tables?](#)

An **index-organized table** has a storage organization that is a variant of a primary B-tree. Unlike an ordinary (heap-organized) table whose data is stored as an unordered collection (heap), data for an index-organized table is stored in a B-tree index structure in a primary key sorted manner. Each leaf block in the index structure stores both the key and nonkey columns.

- [Creating Index-Organized Tables](#)

Index-organized tables provide fast primary key access and high availability.

- [Maintaining Index-Organized Tables](#)

Index-organized tables differ from ordinary tables only in physical organization. Logically, they are manipulated in the same manner as ordinary tables. You can specify an index-organized table just as you would specify a regular table in `INSERT`, `SELECT`, `DELETE`, and `UPDATE` statements.

- [Creating Secondary Indexes on Index-Organized Tables](#)

A secondary index is an index on an index-organized table. The secondary index is an independent schema object and is stored separately from the index-organized table.

- [Analyzing Index-Organized Tables](#)

Just like ordinary tables, index-organized tables are analyzed using the `DBMS_STATS` package, or the `ANALYZE` statement.

- [Using the ORDER BY Clause with Index-Organized Tables](#)

If an `ORDER BY` clause only references the primary key column or a prefix of it, then the optimizer avoids the sorting overhead, as the rows are returned sorted on the primary key columns.

- [Converting Index-Organized Tables to Regular Tables](#)

You can convert index-organized tables to regular (heap organized) tables using the Oracle import or export utilities, or the `CREATE TABLE...AS SELECT` statement.

20.13.1 What Are Index-Organized Tables?

An **index-organized table** has a storage organization that is a variant of a primary B-tree. Unlike an ordinary (heap-organized) table whose data is stored as an unordered collection (heap), data for an index-organized table is stored in a B-tree index structure in a primary key sorted manner. Each leaf block in the index structure stores both the key and nonkey columns.

The structure of an index-organized table provides the following benefits:

- Fast random access on the primary key because an index-only scan is sufficient. And, because there is no separate table storage area, changes to the table data (such as adding new rows, updating rows, or deleting rows) result only in updating the index structure.
- Fast range access on the primary key because the rows are clustered in primary key order.

- Lower storage requirements because duplication of primary keys is avoided. They are not stored both in the index and underlying table, as is true with heap-organized tables.

Index-organized tables have full table functionality. They support features such as constraints, triggers, LOB and object columns, partitioning, parallel operations, online reorganization, and replication. And, they offer these additional features:

- Prefix compression
- Overflow storage area and specific column placement
- Secondary indexes, including bitmap indexes.

Index-organized tables are ideal for OLTP applications, which require fast primary key access and high availability. For example, queries and DML on an orders table used in electronic order processing are predominantly based on primary key access, and heavy volume of concurrent DML can cause row chaining and inefficient space usage in indexes, resulting in a frequent need to reorganize. Because an index-organized table can be reorganized online and without invalidating its secondary indexes, the window of unavailability is greatly reduced or eliminated.

Index-organized tables are suitable for modeling application-specific index structures. For example, content-based information retrieval applications containing text, image and audio data require inverted indexes that can be effectively modeled using index-organized tables. A fundamental component of an internet search engine is an inverted index that can be modeled using index-organized tables.

These are but a few of the applications for index-organized tables.

 **See Also:**

- *Oracle Database Concepts* for a more thorough description of index-organized tables
- *Oracle Database VLDB and Partitioning Guide* for information about partitioning index-organized tables

20.13.2 Creating Index-Organized Tables

Index-organized tables provide fast primary key access and high availability.

- [About Creating Index-Organized Tables](#)
You use the CREATE TABLE statement to create index-organized tables.
- [Example: Creating an Index-Organized Table](#)
An example illustrates creating an index-organized table.
- [Restrictions for Index-Organized Tables](#)
Several restrictions apply when you are creating an index-organized table.
- [Creating Index-Organized Tables That Contain Object Types](#)
Index-organized tables can store object types.
- [Choosing and Monitoring a Threshold Value](#)
Choose a threshold value that can accommodate your key columns, as well as the first few nonkey columns (if they are frequently accessed).

- [Using the INCLUDING Clause](#)

In addition to specifying PCTTHRESHOLD, you can use the INCLUDING clause to control which nonkey columns are stored with the key columns in an index-organized table.

- [Parallelizing Index-Organized Table Creation](#)

The CREATE TABLE...AS SELECT statement enables you to create an index-organized table and load data from an existing table into it. By including the PARALLEL clause, the load can be done in parallel.

- [Using Prefix Compression](#)

Creating an index-organized table using prefix compression (also known as key compression) enables you to eliminate repeated occurrences of key column prefix values.

20.13.2.1 About Creating Index-Organized Tables

You use the CREATE TABLE statement to create index-organized tables.

When you create an index-organized table, but you must provide additional information:

- An ORGANIZATION INDEX qualifier, which indicates that this is an index-organized table
- A primary key, specified through a column constraint clause (for a single column primary key) or a table constraint clause (for a multiple-column primary key).

Optionally, you can specify the following:

- An OVERFLOW clause, which preserves dense clustering of the B-tree index by enabling the storage of some of the nonkey columns in a separate overflow data segment.
- A PCTTHRESHOLD value, which, when an overflow segment is being used, defines the maximum size of the portion of the row that is stored in the index block, as a percentage of block size. Rows columns that would cause the row size to exceed this maximum are stored in the overflow segment. The row is broken at a column boundary into two pieces, a head piece and tail piece. The head piece fits in the specified threshold and is stored along with the key in the index leaf block. The tail piece is stored in the overflow area as one or more row pieces. Thus, the index entry contains the key value, the nonkey column values that fit the specified threshold, and a pointer to the rest of the row.
- An INCLUDING clause, which can be used to specify the nonkey columns that are to be stored in the index block with the primary key.

20.13.2.2 Example: Creating an Index-Organized Table

An example illustrates creating an index-organized table.

The following statement creates an index-organized table:

```
CREATE TABLE admin_docindex(
    token char(20),
    doc_id NUMBER,
    token_frequency NUMBER,
    token_offsets VARCHAR2(2000),
    CONSTRAINT pk_admin_docindex PRIMARY KEY (token, doc_id))
    ORGANIZATION INDEX
```

```
TABLESPACE admin_tbs
PCTTHRESHOLD 20
OVERFLOW TABLESPACE admin_tbs2;
```

This example creates an index-organized table named `admin_docindex`, with a primary key composed of the columns `token` and `doc_id`. The `OVERFLOW` and `PCTTHRESHOLD` clauses specify that if the length of a row exceeds 20% of the index block size, then the column that exceeded that threshold and all columns after it are moved to the overflow segment. The overflow segment is stored in the `admin_tbs2` tablespace.

 **See Also:**

Oracle Database SQL Language Reference for more information about the syntax to create an index-organized table

20.13.2.3 Restrictions for Index-Organized Tables

Several restrictions apply when you are creating an index-organized table.

The following are restrictions on creating index-organized tables.

- The maximum number of columns is 1000.
- The maximum number of columns in the index portion of a row is 255, including both key and nonkey columns. If more than 255 columns are required, you must use an overflow segment.
- The maximum number of columns that you can include in the primary key is 32.
- `PCTTHRESHOLD` must be in the range of 1–50. The default is 50.
- All key columns must fit within the specified threshold.
- If the maximum size of a row exceeds 50% of the index block size and you do not specify an overflow segment, the `CREATE TABLE` statement fails.
- Index-organized tables cannot have virtual columns.
- When a table has a foreign key, and the parent of the foreign key is an index-organized table, a session that updates a row that contains the foreign key can hang when another session is updating a non-key column in the parent table.

For example, consider a scenario in which a `departments` table is an index-organized table, and `department_id` is its primary key. There is an `employees` table with a `department_id` column that is a foreign key of the `departments` table. Assume a session is updating the `department_name` in a row in the `departments` table for which the `department_id` is 20 while another session is updating a row in the `employees` table for which the `department_id` is 20. In this case, the session updating the `employees` table can hang until the session updating the `departments` table commits or rolls back.

- Index-organized tables that contain one or more LOB columns cannot be moved in parallel.

20.13.2.4 Creating Index-Organized Tables That Contain Object Types

Index-organized tables can store object types.

The following example creates object type `admin_typ`, then creates an index-organized table containing a column of object type `admin_typ`:

```
CREATE OR REPLACE TYPE admin_typ AS OBJECT
  (col1 NUMBER, col2 VARCHAR2(6));
CREATE TABLE admin_iot (c1 NUMBER primary key, c2 admin_typ)
  ORGANIZATION INDEX;
```

You can also create an index-organized table of object types. For example:

```
CREATE TABLE admin_iot2 OF admin_typ (col1 PRIMARY KEY)
  ORGANIZATION INDEX;
```

Another example, that follows, shows that index-organized tables store nested tables efficiently. For a nested table column, the database internally creates a storage table to hold all the nested table rows.

```
CREATE TYPE project_t AS OBJECT(pno NUMBER, pname VARCHAR2(80));
/
CREATE TYPE project_set AS TABLE OF project_t;
/
CREATE TABLE proj_tab (eno NUMBER, projects PROJECT_SET)
  NESTED TABLE projects STORE AS emp_project_tab
    ((PRIMARY KEY(nested_table_id, pno))
  ORGANIZATION INDEX)
  RETURN AS LOCATOR;
```

The rows belonging to a single nested table instance are identified by a `nested_table_id` column. If an ordinary table is used to store nested table columns, the nested table rows typically get de-clustered. But when you use an index-organized table, the nested table rows can be clustered based on the `nested_table_id` column.

See Also:

- *Oracle Database SQL Language Reference* for details of the syntax used for creating index-organized tables
- *Oracle Database VLDB and Partitioning Guide* for information about creating partitioned index-organized tables
- *Oracle Database Object-Relational Developer's Guide* for information about object types

20.13.2.5 Choosing and Monitoring a Threshold Value

Choose a threshold value that can accommodate your key columns, as well as the first few nonkey columns (if they are frequently accessed).

After choosing a threshold value, you can monitor tables to verify that the value you specified is appropriate. You can use the `ANALYZE TABLE ... LIST CHAINED ROWS` statement to determine the number and identity of rows exceeding the threshold value.

 **See Also:**

- "[Listing Chained Rows of Tables and Clusters](#)" for more information about chained rows
- *Oracle Database SQL Language Reference* for syntax of the `ANALYZE` statement

20.13.2.6 Using the INCLUDING Clause

In addition to specifying `PCTTHRESHOLD`, you can use the `INCLUDING` clause to control which nonkey columns are stored with the key columns in an index-organized table.

The database accommodates all nonkey columns up to and including the column specified in the `INCLUDING` clause in the index leaf block, provided it does not exceed the specified threshold. All nonkey columns beyond the column specified in the `INCLUDING` clause are stored in the overflow segment. If the `INCLUDING` and `PCTTHRESHOLD` clauses conflict, `PCTTHRESHOLD` takes precedence.

 **Note:**

Oracle Database moves all primary key columns of an indexed-organized table to the beginning of the table (in their key order) to provide efficient primary key-based access. As an example:

```
CREATE TABLE admin_iot4(a INT, b INT, c INT, d INT,
                        primary key(c,b))
                        ORGANIZATION INDEX;
```

The stored column order is: c b a d (instead of: a b c d). The last primary key column is b, based on the stored column order. The `INCLUDING` column can be the last primary key column (b in this example), or any nonkey column (that is, any column after b in the stored column order).

The following `CREATE TABLE` statement is similar to the one shown earlier in "[Example: Creating an Index-Organized Table](#)" but is modified to create an index-organized table where the `token_offsets` column value is always stored in the overflow area:

```
CREATE TABLE admin_docindex2(
    token CHAR(20),
```

```

doc_id NUMBER,
token_frequency NUMBER,
token_offsets VARCHAR2(2000),
CONSTRAINT pk_admin_docindex2 PRIMARY KEY (token, doc_id))
ORGANIZATION INDEX
TABLESPACE admin_tbs
PCTTHRESHOLD 20
INCLUDING token_frequency
OVERFLOW TABLESPACE admin_tbs2;

```

Here, only nonkey columns before `token_offsets` (in this case a single column only) are stored with the key column values in the index leaf block.

20.13.2.7 Parallelizing Index-Organized Table Creation

The `CREATE TABLE...AS SELECT` statement enables you to create an index-organized table and load data from an existing table into it. By including the `PARALLEL` clause, the load can be done in parallel.

The following statement creates an index-organized table in parallel by selecting rows from the conventional table `hr.jobs`:

```

CREATE TABLE admin_iot3(i PRIMARY KEY, j, k, l)
    ORGANIZATION INDEX
    PARALLEL
    AS SELECT * FROM hr.jobs;

```

This statement provides an alternative to parallel bulk-load using SQL*Loader.

20.13.2.8 Using Prefix Compression

Creating an index-organized table using prefix compression (also known as key compression) enables you to eliminate repeated occurrences of key column prefix values.

Prefix compression breaks an index key into a prefix and a suffix entry. Compression is achieved by sharing the prefix entries among all the suffix entries in an index block. This sharing can lead to huge savings in space, allowing you to store more keys in each index block while improving performance.

You can enable prefix compression using the `COMPRESS` clause while:

- Creating an index-organized table
- Moving an index-organized table

You can also specify the prefix length (as the number of key columns), which identifies how the key columns are broken into a prefix and suffix entry.

```

CREATE TABLE admin_iot5(i INT, j INT, k INT, l INT, PRIMARY KEY (i, j, k))
    ORGANIZATION INDEX COMPRESS;

```

The preceding statement is equivalent to the following statement:

```

CREATE TABLE admin_iot6(i INT, j INT, k INT, l INT, PRIMARY KEY(i, j, k))
    ORGANIZATION INDEX COMPRESS 2;

```

For the list of values (1,2,3), (1,2,4), (1,2,7), (1,3,5), (1,3,4), (1,4,4) the repeated occurrences of (1,2), (1,3) are compressed away.

You can also override the default prefix length used for compression as follows:

```
CREATE TABLE admin_iot7(i INT, j INT, k INT, l INT, PRIMARY KEY (i, j, k))
    ORGANIZATION INDEX COMPRESS 1;
```

For the list of values (1,2,3), (1,2,4), (1,2,7), (1,3,5), (1,3,4), (1,4,4), the repeated occurrences of 1 are compressed away.

You can disable compression as follows:

```
ALTER TABLE admin_iot5 MOVE NOCOMPRESS;
```

One application of prefix compression is in a time-series application that uses a set of time-stamped rows belonging to a single item, such as a stock price. Index-organized tables are attractive for such applications because of the ability to cluster rows based on the primary key. By defining an index-organized table with primary key (stock symbol, time stamp), you can store and manipulate time-series data efficiently. You can achieve more storage savings by compressing repeated occurrences of the item identifier (for example, the stock symbol) in a time series by using an index-organized table with prefix compression.

 **See Also:**

Oracle Database Concepts for more information about prefix compression

20.13.3 Maintaining Index-Organized Tables

Index-organized tables differ from ordinary tables only in physical organization. Logically, they are manipulated in the same manner as ordinary tables. You can specify an index-organized table just as you would specify a regular table in `INSERT`, `SELECT`, `DELETE`, and `UPDATE` statements.

- [Altering Index-Organized Tables](#)

All of the alter options available for ordinary tables are available for index-organized tables. This includes `ADD`, `MODIFY`, and `DROP COLUMNS` and `CONSTRAINTS`. However, the primary key constraint for an index-organized table cannot be dropped, deferred, or disabled.

- [Moving \(Rebuilding\) Index-Organized Tables](#)

Because index-organized tables are primarily stored in a B-tree index, you can encounter fragmentation as a consequence of incremental updates. However, you can use the `ALTER TABLE...MOVE` statement to rebuild the index and reduce this fragmentation.

20.13.3.1 Altering Index-Organized Tables

All of the alter options available for ordinary tables are available for index-organized tables. This includes `ADD`, `MODIFY`, and `DROP COLUMNS` and `CONSTRAINTS`. However, the primary key constraint for an index-organized table cannot be dropped, deferred, or disabled.

You can use the `ALTER TABLE` statement to modify physical and storage attributes for both primary key index and overflow data segments. All the attributes specified before

the `OVERFLOW` keyword are applicable to the primary key index segment. All attributes specified after the `OVERFLOW` key word are applicable to the overflow data segment. For example, you can set the `INITRANS` of the primary key index segment to 4 and the overflow of the data segment `INITRANS` to 6 as follows:

```
ALTER TABLE admin_docindex INITRANS 4 OVERFLOW INITRANS 6;
```

You can also alter `PCTTHRESHOLD` and `INCLUDING` column values. A new setting is used to break the row into head and overflow tail pieces during subsequent operations. For example, the `PCTTHRESHOLD` and `INCLUDING` column values can be altered for the `admin_docindex` table as follows:

```
ALTER TABLE admin_docindex PCTTHRESHOLD 15 INCLUDING doc_id;
```

By setting the `INCLUDING` column to `doc_id`, all the columns that follow `token_frequency` and `token_offsets`, are stored in the overflow data segment.

For index-organized tables created without an overflow data segment, you can add an overflow data segment by using the `ADD OVERFLOW` clause. For example, you can add an overflow segment to table `admin_iot3` as follows:

```
ALTER TABLE admin_iot3 ADD OVERFLOW TABLESPACE admin_tbs2;
```

20.13.3.2 Moving (Rebuilding) Index-Organized Tables

Because index-organized tables are primarily stored in a B-tree index, you can encounter fragmentation as a consequence of incremental updates. However, you can use the `ALTER TABLE...MOVE` statement to rebuild the index and reduce this fragmentation.

The following statement rebuilds the index-organized table `admin_docindex`:

```
ALTER TABLE admin_docindex MOVE;
```

You can rebuild index-organized tables online using the `ONLINE` keyword. The overflow data segment, if present, is rebuilt when the `OVERFLOW` keyword is specified. For example, to rebuild the `admin_docindex` table but not the overflow data segment, perform a move online as follows:

```
ALTER TABLE admin_docindex MOVE ONLINE;
```

To rebuild the `admin_docindex` table along with its overflow data segment perform the move operation as shown in the following statement. This statement also illustrates moving both the table and overflow data segment to new tablespaces.

```
ALTER TABLE admin_docindex MOVE TABLESPACE admin_tbs2
    OVERFLOW TABLESPACE admin_tbs3;
```

In this last statement, an index-organized table with a LOB column (CLOB) is created. Later, the table is moved with the LOB index and data segment being rebuilt and moved to a new tablespace.

```
CREATE TABLE admin_iot_lob
    (c1 number (6) primary key,
     admin_lob CLOB)
    ORGANIZATION INDEX
    LOB (admin_lob) STORE AS (TABLESPACE admin_tbs2);
```

```
ALTER TABLE admin_iot_lob MOVE LOB (admin_lob) STORE AS (TABLESPACE admin_tbs3);
```

20.13.4 Creating Secondary Indexes on Index-Organized Tables

A secondary index is an index on an index-organized table. The secondary index is an independent schema object and is stored separately from the index-organized table.

- [About Secondary Indexes on Index-Organized Tables](#)
You can create secondary indexes on an index-organized tables to provide multiple access paths.
- [Creating a Secondary Index on an Index-Organized Table](#)
You can create a secondary index on an index-organized table.
- [Maintaining Physical Guesses in Logical Rowids](#)
A logical rowid can include a guess, which identifies the block location of a row at the time the guess is made. Instead of doing a full key search, the database uses the guess to search the block directly.
- [Specifying Bitmap Indexes on Index-Organized Tables](#)
Bitmap indexes on index-organized tables are supported, provided the index-organized table is created with a mapping table.

20.13.4.1 About Secondary Indexes on Index-Organized Tables

You can create secondary indexes on an index-organized tables to provide multiple access paths.

Secondary indexes on index-organized tables differ from indexes on ordinary tables in two ways:

- They store logical rowids instead of physical rowids. This is necessary because the inherent movability of rows in a B-tree index results in the rows having no permanent physical addresses. If the physical location of a row changes, its logical rowid remains valid. One effect of this is that a table maintenance operation, such as `ALTER TABLE ... MOVE`, does not make the secondary index unusable.
- The logical rowid also includes a physical guess which identifies the database block address at which the row is likely to be found. If the physical guess is correct, a secondary index scan would incur a single additional I/O once the secondary key is found. The performance would be similar to that of a secondary index-scan on an ordinary table.

Unique and non-unique secondary indexes, function-based secondary indexes, and bitmap indexes are supported as secondary indexes on index-organized tables.

20.13.4.2 Creating a Secondary Index on an Index-Organized Table

You can create a secondary index on an index-organized table.

The following statement shows the creation of a secondary index on the `docindex` index-organized table where `doc_id` and `token` are the key columns:

```
CREATE INDEX Doc_id_index on Docindex(Doc_id, Token);
```

This secondary index allows the database to efficiently process a query, such as the following, that involves a predicate on `doc_id`:

```
SELECT Token FROM Docindex WHERE Doc_id = 1;
```

20.13.4.3 Maintaining Physical Guesses in Logical Rowids

A logical rowid can include a guess, which identifies the block location of a row at the time the guess is made. Instead of doing a full key search, the database uses the guess to search the block directly.

However, as new rows are inserted, guesses can become stale. The indexes are still usable through the primary key-component of the logical rowid, but access to rows is slower.

1. Collect index statistics with the `DBMS_STATS` package to monitor the staleness of guesses.
The database checks whether the existing guesses are still valid and records the percentage of rows with valid guesses in the data dictionary.
2. Query the `PCT_DIRECT_ACCESS` column of the `DBA_INDEXES` view (and related views) to show the statistics related to existing guesses.
3. To obtain fresh guesses, you can rebuild the secondary index.

Rebuilding a secondary index on an index-organized table involves reading the base table, unlike rebuilding an index on an ordinary table.

A quicker, more light weight means of fixing the guesses is to use the `ALTER INDEX ... UPDATE BLOCK REFERENCES` statement. This statement is performed online, while DML is still allowed on the underlying index-organized table.

After you rebuild a secondary index, or otherwise update the block references in the guesses, collect index statistics again.

20.13.4.4 Specifying Bitmap Indexes on Index-Organized Tables

Bitmap indexes on index-organized tables are supported, provided the index-organized table is created with a mapping table.

This is done by specifying the `MAPPING TABLE` clause in the `CREATE TABLE` statement that you use to create the index-organized table, or in an `ALTER TABLE` statement to add the mapping table later.

 **See Also:**

Oracle Database Concepts for a description of mapping tables

20.13.5 Analyzing Index-Organized Tables

Just like ordinary tables, index-organized tables are analyzed using the `DBMS_STATS` package, or the `ANALYZE` statement.

- [Collecting Optimizer Statistics for Index-Organized Tables](#)
To collect optimizer statistics, use the `DBMS_STATS` package.
- [Validating the Structure of Index-Organized Tables](#)
Use the `ANALYZE` statement to validate the structure of your index-organized table or to list any chained rows.

20.13.5.1 Collecting Optimizer Statistics for Index-Organized Tables

To collect optimizer statistics, use the `DBMS_STATS` package.

For example, the following statement gathers statistics for the index-organized `countries` table in the `hr` schema:

```
EXECUTE DBMS_STATS.GATHER_TABLE_STATS ('HR','COUNTRIES');
```

The `DBMS_STATS` package analyzes both the primary key index segment and the overflow data segment, and computes logical as well as physical statistics for the table.

- The logical statistics can be queried using `USER_TABLES`, `ALL_TABLES` or `DBA_TABLES`.
- You can query the physical statistics of the primary key index segment using `USER_INDEXES`, `ALL_INDEXES` or `DBA_INDEXES` (and using the primary key index name). For example, you can obtain the primary key index segment physical statistics for the table `admin_docindex` as follows:

```
SELECT LAST_ANALYZED, BLEVEL, LEAF_BLOCKS, DISTINCT_KEYS
      FROM DBA_INDEXES WHERE INDEX_NAME= 'PK_ADMIN_DOCINDEX';
```

- You can query the physical statistics for the overflow data segment using the `USER_TABLES`, `ALL_TABLES` or `DBA_TABLES`. You can identify the overflow entry by searching for `IOT_TYPE = 'IOT_OVERFLOW'`. For example, you can obtain overflow data segment physical attributes associated with the `admin_docindex` table as follows:

```
SELECT LAST_ANALYZED, NUM_ROWS, BLOCKS, EMPTY_BLOCKS
      FROM DBA_TABLES WHERE IOT_TYPE='IOT_OVERFLOW'
                        and IOT_NAME= 'ADMIN_DOCINDEX';
```

 **See Also:**

- *Oracle Database SQL Tuning Guide* for more information about collecting optimizer statistics
- *Oracle Database PL/SQL Packages and Types Reference* for more information about of the DBMS_STATS package

20.13.5.2 Validating the Structure of Index-Organized Tables

Use the ANALYZE statement to validate the structure of your index-organized table or to list any chained rows.

These operations are discussed in the following sections located elsewhere in this book:

- "[Validating Tables, Indexes, Clusters, and Materialized Views](#)"
- "[Listing Chained Rows of Tables and Clusters](#)"

 **Note:**

There are special considerations when listing chained rows for index-organized tables. These are discussed in the *Oracle Database SQL Language Reference*.

20.13.6 Using the ORDER BY Clause with Index-Organized Tables

If an ORDER BY clause only references the primary key column or a prefix of it, then the optimizer avoids the sorting overhead, as the rows are returned sorted on the primary key columns.

The following queries avoid sorting overhead because the data is already sorted on the primary key:

```
SELECT * FROM admin_docindex2 ORDER BY token, doc_id;  
SELECT * FROM admin_docindex2 ORDER BY token;
```

If, however, you have an ORDER BY clause on a suffix of the primary key column or non-primary-key columns, additional sorting is required (assuming no other secondary indexes are defined).

```
SELECT * FROM admin_docindex2 ORDER BY doc_id;  
SELECT * FROM admin_docindex2 ORDER BY token_frequency;
```

20.13.7 Converting Index-Organized Tables to Regular Tables

You can convert index-organized tables to regular (heap organized) tables using the Oracle import or export utilities, or the CREATE TABLE...AS SELECT statement.

To convert an index-organized table to a regular table:

- Export the index-organized table data using conventional path.

- Create a regular table definition with the same definition.
- Import the index-organized table data, making sure `IGNORE=Y` (ensures that object exists error is ignored).

 **Note:**

Before converting an index-organized table to a regular table, be aware that index-organized tables cannot be exported using pre-Oracle8 versions of the Export utility.

 **See Also:**

Oracle Database Utilities for more details about using the original `IMP` and `EXP` utilities and the Data Pump import and export utilities

20.14 Managing External Tables

External tables do not reside in the database.

- [About External Tables](#)

Oracle Database allows you read-only access to data in external tables. **External tables** are defined as tables that do not reside in the database, and they can be in any format for which an access driver is provided.

- [Creating External Tables](#)

You create external tables using the `CREATE TABLE` statement with an `ORGANIZATION EXTERNAL` clause. This statement creates only metadata in the data dictionary.

- [Altering External Tables](#)

You can modify an external table with the `ALTER TABLE` statement.

- [Preprocessing External Tables](#)

External tables can be preprocessed by user-supplied preprocessor programs. By using a preprocessing program, users can use data from a file that is not in a format supported by the driver.

- [Overriding Parameters for External Tables in a Query](#)

The `EXTERNAL MODIFY` clause of a `SELECT` statement modifies external table parameters.

- [Partitioning External Tables](#)

For large amounts of data, partitioning for external tables provides fast query performance and enhanced data maintenance.

- [Dropping External Tables](#)

For an external table, the `DROP TABLE` statement removes only the table metadata in the database. It has no affect on the actual data, which resides outside of the database.

- [System and Object Privileges for External Tables](#)

System and object privileges for external tables are a subset of those for regular table.

20.14.1 About External Tables

Oracle Database allows you read-only access to data in external tables. **External tables** are defined as tables that do not reside in the database, and they can be in any format for which an access driver is provided.

By providing the database with metadata describing an external table, the database is able to expose the data in the external table as if it were data residing in a regular database table. The external data can be queried directly and in parallel using SQL.

You can, for example, select, join, or sort external table data. You can also create views and synonyms for external tables. However, no DML operations (UPDATE, INSERT, or DELETE) are possible, and no indexes can be created, on external tables.

External tables provide a framework to unload the result of an arbitrary SELECT statement into a platform-independent Oracle-proprietary format that can be used by Oracle Data Pump. External tables provide a valuable means for performing basic extraction, transformation, and loading (ETL) tasks that are common for data warehousing.

You define the metadata for external tables with the CREATE TABLE...ORGANIZATION EXTERNAL statement. This external table definition can be thought of as a view that allows running any SQL query against external data without requiring that the external data first be loaded into the database. An access driver is the mechanism used to read the external data in the table. When you use external tables to unload data, the metadata is automatically created based on the data types in the SELECT statement.

Oracle Database provides access drivers for external tables. The default access driver is ORACLE_LOADER, which allows the reading of data from external files using the Oracle loader technology. The ORACLE_LOADER access driver provides data mapping capabilities which are a subset of the control file syntax of SQL*Loader utility. Another access driver, ORACLE_DATAPUMP, lets you unload data—that is, read data from the database and insert it into an external table, represented by one or more external files—and then reload it into an Oracle Database.

Starting with Oracle Database 12c Release 2 (12.2.0.1), new access drivers ORACLE_HIVE and ORACLE_HDFS are available. The ORACLE_HIVE access driver can extract data stored in Apache Hive. The ORACLE_HDFS access driver can extract data stored in a Hadoop Distributed File System (HDFS).

 **Note:**

The ANALYZE statement is not supported for gathering statistics for external tables. Use the DBMS_STATS package instead.

 **See Also:**

- *Oracle Database SQL Language Reference* for restrictions that apply to external tables
- *Oracle Database Utilities* for information about access drivers
- *Oracle Database Data Warehousing Guide* for information about using external tables for ETL in a data warehousing environment
- *Oracle Database SQL Tuning Guide* for information about using the DBMS_STATS package
- *Oracle Database Utilities* for information about the ORACLE_HIVE and ORACLE_HDFS drivers and for more information about external tables

20.14.2 Creating External Tables

You create external tables using the CREATE TABLE statement with an ORGANIZATION EXTERNAL clause. This statement creates only metadata in the data dictionary.

 **Note:**

- Starting with Oracle Database 12c Release 2 (12.2.0.1), you can partition external tables for fast query performance and enhanced data maintenance for large amounts of data.
- External tables can have virtual columns. However, a virtual column in an external table cannot be defined using the *evaluation_edition_clause* or the *unusable_edition_clause*.

The following example creates an external table and then uploads the data to a database table. Alternatively, you can unload data through the external table framework by specifying the AS *subquery* clause of the CREATE TABLE statement. External table data pump unload can use only the ORACLE_DATAPUMP access driver.

EXAMPLE: Creating an External Table and Loading Data

In this example, the data for the external table resides in the two text files empxt1.dat and empxt2.dat.

The file empxt1.dat contains the following sample data:

```
360,Jane,Janus,ST_CLERK,121,17-MAY-2001,3000,0,50,jjanus
361,Mark,Jasper,SA REP,145,17-MAY-2001,8000,.1,80,mjasper
362,Brenda,Starr,AD_ASST,200,17-MAY-2001,5500,0,10,bstarr
363,Alex,Alda,AC_MGR,145,17-MAY-2001,9000,.15,80,aalda
```

The file empxt2.dat contains the following sample data:

```
401,Jesse,Cromwell,HR REP,203,17-MAY-2001,7000,0,40,jcromwel
402,Abby,Applegate,IT PROG,103,17-MAY-2001,9000,.2,60,aappleaga
```

```
403,Carol,Cousins,AD_VP,100,17-MAY-2001,27000,.3,90,ccousins
404,John,Richardson,AC_ACCOUNT,205,17-MAY-2001,5000,0,110,jrichard
```

The following SQL statements create an external table named `admin_ext_employees` in the `hr` schema and load data from the external table into the `hr.employees` table.

```
CONNECT / AS SYSDBA;
-- Set up directories and grant access to hr
CREATE OR REPLACE DIRECTORY admin_dat_dir
AS '/flatfiles/data';
CREATE OR REPLACE DIRECTORY admin_log_dir
AS '/flatfiles/log';
CREATE OR REPLACE DIRECTORY admin_bad_dir
AS '/flatfiles/bad';
GRANT READ ON DIRECTORY admin_dat_dir TO hr;
GRANT WRITE ON DIRECTORY admin_log_dir TO hr;
GRANT WRITE ON DIRECTORY admin_bad_dir TO hr;
-- hr connects. Provide the user password (hr) when prompted.
CONNECT hr
-- create the external table
CREATE TABLE admin_ext_employees
(
    employee_id      NUMBER(4),
    first_name       VARCHAR2(20),
    last_name        VARCHAR2(25),
    job_id           VARCHAR2(10),
    manager_id       NUMBER(4),
    hire_date         DATE,
    salary            NUMBER(8,2),
    commission_pct   NUMBER(2,2),
    department_id    NUMBER(4),
    email             VARCHAR2(25)
)
ORGANIZATION EXTERNAL
(
    TYPE ORACLE_LOADER
    DEFAULT DIRECTORY admin_dat_dir
    ACCESS PARAMETERS
    (
        records delimited by newline
        badfile admin_bad_dir:'empext%a_%p.bad'
        logfile admin_log_dir:'empext%a_%p.log'
        fields terminated by ','
        missing field values are null
        (
            employee_id, first_name, last_name, job_id, manager_id,
            hire_date char date_format date mask "dd-mon-yyyy",
            salary, commission_pct, department_id, email
        )
    )
    LOCATION ('empxt1.dat', 'empxt2.dat')
)
PARALLEL
REJECT LIMIT UNLIMITED;
-- enable parallel for loading (good if lots of data to load)
ALTER SESSION ENABLE PARALLEL DML;
-- load the data in hr employees table
INSERT INTO employees (employee_id, first_name, last_name, job_id, manager_id,
                      hire_date, salary, commission_pct, department_id, email)
SELECT * FROM admin_ext_employees;
```

The following paragraphs contain descriptive information about this example.

The first few statements in this example create the directory objects for the operating system directories that contain the data sources, and for the bad record and log files specified in the access parameters. You must also grant `READ` or `WRITE` directory object privileges, as appropriate.

 **Note:**

When creating a directory object or BFILEs, ensure that the following conditions are met:

- The operating system file must not be a symbolic or hard link.
- The operating system directory path named in the Oracle Database directory object must be an existing OS directory path.
- The operating system directory path named in the directory object should not contain any symbolic links in its components.

The `TYPE` specification indicates the access driver of the external table. The access driver is the API that interprets the external data for the database. If you omit the `TYPE` specification, `ORACLE_LOADER` is the default access driver. You must specify the `ORACLE_DATAPUMP` access driver if you specify the `AS subquery` clause to unload data from one Oracle Database and reload it into the same or a different Oracle Database.

The access parameters, specified in the `ACCESS PARAMETERS` clause, are opaque to the database. These access parameters are defined by the access driver, and are provided to the access driver by the database when the external table is accessed. See *Oracle Database Utilities* for a description of the `ORACLE_LOADER` access parameters.

The `PARALLEL` clause enables parallel query on the data sources. The granule of parallelism is by default a data source, but parallel access within a data source is implemented whenever possible. For example, if `PARALLEL=3` were specified, then multiple parallel execution servers could be working on a data source. But, parallel access within a data source is provided by the access driver only if all of the following conditions are met:

- The media allows random positioning within a data source.
- It is possible to find a record boundary from a random position.
- The data files are large enough to make it worthwhile to break up into multiple chunks.

 **Note:**

Specifying a `PARALLEL` clause is of value *only* when dealing with large amounts of data. Otherwise, it is not advisable to specify a `PARALLEL` clause, and doing so can be detrimental.

The `REJECT LIMIT` clause specifies that there is no limit on the number of errors that can occur during a query of the external data. For parallel access, the `REJECT LIMIT` applies to each parallel execution server independently. For example, if a `REJECT LIMIT` of 10 is specified, then each parallel query process can allow up to 10

rejections. Therefore, with a parallel degree of two and a REJECT LIMIT of 10, the statement might fail with between 10 and 20 rejections. If one parallel server processes all 10 rejections, then the limit is reached, and the statement is terminated. However, one parallel execution server could process nine rejections and another parallel execution server could process nine rejections and the statement will succeed with 18 rejections. Hence, the only precisely enforced values for REJECT LIMIT on parallel query are 0 and UNLIMITED.

In this example, the `INSERT INTO TABLE` statement generates a dataflow from the external data source to the Oracle Database SQL engine where data is processed. As data is parsed by the access driver from the external table sources and provided to the external table interface, the external data is converted from its external representation to its Oracle Database internal data type.

See Also:

Oracle Database SQL Language Reference provides details of the syntax of the `CREATE TABLE` statement for creating external tables and specifies restrictions on the use of clauses

20.14.3 Altering External Tables

You can modify an external table with the `ALTER TABLE` statement.

You can use any of the `ALTER TABLE` clauses shown in [Table 20-5](#) to change the characteristics of an external table. No other clauses are permitted.

Table 20-5 ALTER TABLE Clauses for External Tables

ALTER TABLE Clause	Description	Example
<code>REJECT LIMIT</code>	Changes the reject limit. The default value is 0.	<code>ALTER TABLE admin_ext_employees REJECT LIMIT 100;</code>

Table 20-5 (Cont.) ALTER TABLE Clauses for External Tables

ALTER TABLE Clause	Description	Example
PROJECT COLUMN	<p>Determines how the access driver validates rows in subsequent queries:</p> <ul style="list-style-type: none"> • PROJECT COLUMN REFERENCED: the access driver processes only the columns in the select list of the query. This setting may not provide a consistent set of rows when querying a different column list from the same external table. • PROJECT COLUMN ALL: the access driver processes all of the columns defined on the external table. This setting always provides a consistent set of rows when querying an external table. This is the default. 	<pre>ALTER TABLE admin_ext_employees PROJECT COLUMN REFERENCED; ALTER TABLE admin_ext_employees PROJECT COLUMN ALL;</pre>
DEFAULT DIRECTORY	Changes the default directory specification.	<pre>ALTER TABLE admin_ext_employees DEFAULT DIRECTORY admin_dat2_dir;</pre>
ACCESS PARAMETERS	Allows access parameters to be changed without dropping and re-creating the external table metadata.	<pre>ALTER TABLE admin_ext_employees ACCESS PARAMETERS (FIELDS TERMINATED BY ' ');</pre>
LOCATION	Allows data sources to be changed without dropping and re-creating the external table metadata.	<pre>ALTER TABLE admin_ext_employees LOCATION ('empxt3.txt', 'empxt4.txt');</pre>
PARALLEL	No difference from regular tables. Allows degree of parallelism to be changed.	No new syntax
ADD COLUMN	No difference from regular tables. Allows a column to be added to an external table. Virtual columns are not permitted.	No new syntax
MODIFY COLUMN	No difference from regular tables. Allows an external table column to be modified. Virtual columns are not permitted.	No new syntax

Table 20-5 (Cont.) ALTER TABLE Clauses for External Tables

ALTER TABLE Clause	Description	Example
SET UNUSED	Transparently converted into an ALTER TABLE DROP COLUMN command. Because external tables consist of metadata only in the database, the DROP COLUMN command performs equivalently to the SET UNUSED command.	No new syntax
DROP COLUMN	No difference from regular tables. Allows an external table column to be dropped.	No new syntax
RENAME TO	No difference from regular tables. Allows external table to be renamed.	No new syntax

20.14.4 Preprocessing External Tables

External tables can be preprocessed by user-supplied preprocessor programs. By using a preprocessing program, users can use data from a file that is not in a format supported by the driver.

 **Caution:**

There are security implications to consider when using the PREPROCESSOR clause. See *Oracle Database Security Guide* for more information.

For example, a user may want to access data stored in a compressed format. Specifying a decompression program for the ORACLE_LOADER access driver allows the data to be decompressed as the access driver processes the data.

To use the preprocessing feature, you must specify the PREPROCESSOR clause in the access parameters of the ORACLE_LOADER access driver. The preprocessor must be a directory object, and the user accessing the external table must have EXECUTE privileges for the directory object. The following example includes the PREPROCESSOR clause and specifies the directory and preprocessor program.

```
CREATE TABLE sales_transactions_ext
(PROD_ID NUMBER,
CUST_ID NUMBER,
TIME_ID DATE,
CHANNEL_ID CHAR,
PROMO_ID NUMBER,
QUANTITY SOLD NUMBER,
AMOUNT SOLD NUMBER(10,2),
UNIT_COST NUMBER(10,2),
UNIT_PRICE NUMBER(10,2))
ORGANIZATION external
(TYPE oracle_loader
DEFAULT DIRECTORY data_file_dir
ACCESS PARAMETERS
```

```
(RECORDS DELIMITED BY NEWLINE
CHARACTERSET AL32UTF8
PREPROCESSOR exec_file_dir:'zcat'
BADFILE log_file_dir:'sh_sales.bad_xt'
LOGFILE log_file_dir:'sh_sales.log_xt'
FIELDS TERMINATED BY "|" LDRTRIM
( PROD_ID,
  CUST_ID,
  TIME_ID,
  CHANNEL_ID,
  PROMO_ID,
  QUANTITY_SOLD,
  AMOUNT_SOLD,
  UNIT_COST,
  UNIT_PRICE))
location ('sh_sales.dat.gz')
)REJECT LIMIT UNLIMITED;
```

The PREPROCESSOR clause is not available for databases that use Oracle Database Vault.

 **Note:**

On the Windows platform, a preprocessor program must have a .bat or .cmd extension.

 **See Also:**

- *Oracle Database Utilities* provides more information about the PREPROCESSOR clause
- *Oracle Database Security Guide* for more information about the security implications of the PREPROCESSOR clause

20.14.5 Overriding Parameters for External Tables in a Query

The EXTERNAL MODIFY clause of a SELECT statement modifies external table parameters.

You can override the following clauses for an external table in an EXTERNAL MODIFY clause:

- DEFAULT DIRECTORY
- LOCATION
- ACCESS PARAMETERS
- REJECT LIMIT

You can modify more than one clause in a single query. A bind variable can be specified for LOCATION and REJECT LIMIT, but not for DEFAULT DIRECTORY or ACCESS PARAMETERS.

The modifications only apply to the query. They do not affect the table permanently.

For partitioned external tables, only table-level clauses can be overridden.

1. Connect to the database as a user with the privileges required to query the external table.
2. Issue a SELECT statement on the external table with the EXTERNAL MODIFY clause.

Example 20-21 Overriding Parameters for External Tables in a Query

Assume an external table named `sales_external` has a REJECT LIMIT set to 25. The following query modifies this setting to REJECT LIMIT UNLIMITED:

```
SELECT * FROM sales_external EXTERNAL MODIFY (LOCATION ('sales_9.csv')
    REJECT LIMIT UNLIMITED);
```

20.14.6 Partitioning External Tables

For large amounts of data, partitioning for external tables provides fast query performance and enhanced data maintenance.

- [About Partitioning External Tables](#)

Partitioning data in external tables is similar to partitioning tables stored in the database, but there are some differences. The files for the partitioned external table can be stored on a file system, in Apache Hive storage, or in a Hadoop Distributed File System (HDFS).

- [Restrictions for Partitioned External Tables](#)

Some restrictions apply to partitioned external tables.

- [Creating a Partitioned External Table](#)

You create a non-composite partitioned external table by issuing a CREATE TABLE statement with the ORGANIZATION EXTERNAL clause and the PARTITION BY clause. To create a composite partitioned external table, the SUBPARTITION BY clause must also be included.

- [Altering a Partitioned External Table](#)

You can use the ALTER TABLE statement to modify table-level external parameters, but not the partition-level and subpartition-level parameters, of a partitioned external table.

20.14.6.1 About Partitioning External Tables

Partitioning data in external tables is similar to partitioning tables stored in the database, but there are some differences. The files for the partitioned external table can be stored on a file system, in Apache Hive storage, or in a Hadoop Distributed File System (HDFS).

Before attempting to partition external tables, you should understand the concepts related to partitioning in *Oracle Database VLDB and Partitioning Guide*.

The main reason to partition external tables is to take advantage of the same performance improvements provided by partitioning tables stored in the database. Specifically, partition pruning and partition-wise joins can improve query performance. Partition pruning means that queries can focus on a subset of the data in an external table instead of all of the data because the query can apply to only one partition. Partition-wise joins can be applied when two tables are being joined and both tables

are partitioned on the join key, or when a reference partitioned table is joined with its parent table. Partition-wise joins break a large join into smaller joins that occur between each of the partitions, completing the overall join in less time.

Most of the partitioning strategies that are supported for tables in the database are supported for external tables. External tables can be partitioned by range or list, and composite partitioning is supported. However, hash partitioning is not supported for external tables.

For a partitioned table that is stored in the database, storage for each partition is specified with a tablespace. For a partitioned external table, storage for each partition is specified by indicating the directory and files for each partition.

Clauses for Creating Partitioned External Tables

The clauses for creating a non-partitioned external table are the following:

- **TYPE** - Specifies the access driver for the type of external table (ORACLE_LOADER, ORACLE_DATAPUMP, ORACLE_HIVE, and ORACLE_HDFS).
- **DEFAULT DIRECTORY** - Specifies with a directory object the default directory to use for all input and output files that do not explicitly name a directory object.
- **ACCESS PARAMETERS** - Describe the external data source.
- **LOCATION** - Specifies the files for the external table.
- **REJECT LIMIT** - Specifies the number of errors that can occur during a query of the external data.

When you create a partitioned external table, you must include a **PARTITION** clause that defines each partition. The following table describes the clauses allowed at each level during external table creation.

Table 20-6 External Table Clauses and Partitioning

Clause	Table Level	Partition Level	Subpartition Level
TYPE	Allowed	Not Allowed	Not Allowed
DEFAULT DIRECTORY	Allowed	Allowed	Allowed
ACCESS PARAMETERS	Allowed	Not Allowed	Not Allowed
LOCATION	Not allowed	Allowed	Allowed
REJECT LIMIT	Allowed	Not allowed	Not allowed

For a non-composite partitioned table, files for a partition must be specified in the **LOCATION** clause for the partition. For a composite partitioned table, files for a subpartition must be specified in the **LOCATION** clause for the subpartition. When a partition has subpartitions, the **LOCATION** clause can be specified for subpartitions but not for the partition. If the **LOCATION** clause is omitted for a partition or subpartition, then an empty partition or subpartition is created.

In the **LOCATION** clause, the files are named in the form *directory:file*, and one clause can specify multiple files. The *directory* portion is optional. The following rules apply for the directory used by a partition or subpartition:

- When a directory is specified in the **LOCATION** clause for a partition or subpartition, then it applies to that location only.

- In the LOCATION clause for a specific partition, for each file that does not have a directory specification, use the directory specified in the DEFAULT DIRECTORY clause for the partition or table level, in order.

For example, when the ORGANIZATION EXTERNAL clause of a CREATE TABLE statement includes a DEFAULT DIRECTORY clause, and a PARTITION clause in the statement does not specify a directory for a file in its LOCATION clause, the file uses the directory specified in the DEFAULT DIRECTORY clause for the table.

- In the LOCATION clause for a specific subpartition, for each file that does not have a directory specification, use the directory specified in the DEFAULT DIRECTORY clause for the subpartition, partition, or table level, in order.

For example, when a PARTITION clause includes a DEFAULT DIRECTORY clause, and a SUBPARTITION clause in the partition does not specify a directory for a file in its LOCATION clause, the file uses the directory specified in the DEFAULT DIRECTORY clause for the partition.

- The default directory for a partition or subpartition cannot be specified in a LOCATION clause. It can only be specified in a DEFAULT DIRECTORY clause.

[Example 20-23](#) illustrates the directory rules

Using the ORACLE_HIVE Access Driver

Apache Hive has its own partitioning. To create partitioned external tables, use the CREATE_EXTDDL_FOR_HIVE procedure in the DBMS_HADOOP package. This procedure generates data definition language (DDL) statements that you can use to create a partitioned external table that corresponds with the partitioning in the Apache Hive storage.

The DBMS_HADOOP package also includes the SYNC_PARTITIONS_FOR_HIVE procedure. This procedure automatically synchronizes the partitioning of the partitioned external table in the Apache Hive storage with the partitioning metadata of the same table stored in the Oracle Database.

20.14.6.2 Restrictions for Partitioned External Tables

Some restrictions apply to partitioned external tables.

The following are restrictions for partitioned external tables:

- All restrictions that apply to non-partitioned external tables also apply to partitioned external tables.
- Partitioning restrictions that apply to tables stored in the database also apply to partitioned external tables, such as the maximum number of partitions.

- Oracle Database cannot guarantee that the external files for partitions contain data that satisfies partitioning definitions.
- Only the `DEFAULT DIRECTORY` and `LOCATION` clauses can be specified in a `PARTITION` or `SUBPARTITION` clause.
- When altering a partitioned external table with the `ALTER TABLE` statement, the following clauses are not supported: `MODIFY PARTITION`, `EXCHANGE PARTITION`, `MOVE PARTITION`, `MERGE PARTITIONS`, `SPLIT PARTITION`, `COALESCE PARTITION`, and `TRUNCATE PARTITION`.
- Reference partitioning, automatic list partitioning, and interval partitioning are not supported.
- Subpartition templates are not supported.
- The `ORACLE_DATAPUMP` access driver cannot populate external files for partitions using a `CREATE TABLE AS SELECT` statement.
- Incremental statistics are not gathered for partitioned external tables.
- In addition to restrictions on partitioning methods that can be used for the other drivers, range and composite partitioning are not supported for the `ORACLE_HIVE` access driver.
- A `SELECT` statement with the `EXTERNAL MODIFY` clause cannot override partition-level or subpartition-level clauses. Only external clauses supported at the table level can be overridden with the `EXTERNAL MODIFY` clause. Because the `LOCATION` clause is not allowed at the table level for a partitioned external table, it cannot be overridden with the `EXTERNAL MODIFY` clause.

 **See Also:**

- "[About External Tables](#)"
- *Oracle Database SQL Language Reference* provides details of the syntax of the `CREATE TABLE` statement for creating external tables and specifies restrictions on the use of clauses

20.14.6.3 Creating a Partitioned External Table

You create a non-composite partitioned external table by issuing a `CREATE TABLE` statement with the `ORGANIZATION EXTERNAL` clause and the `PARTITION BY` clause. To create a composite partitioned external table, the `SUBPARTITION BY` clause must also be included.

The `PARTITION BY` clause and the `SUBPARTITION BY` clause specify the locations of the external files for each partition and subpartition.

To create a partitioned external table, the database must be at 12.2.0 compatibility level or higher.

1. Connect to the database as a user with the privileges required to create the external table.

See *Oracle Database SQL Language Reference* for information about the required privileges.

2. Issue a CREATE TABLE statement with the ORGANIZATION EXTERNAL clause and the PARTITION BY clause. For a composite partitioned table, include the SUBPARTITION BY clause also.

Example 20-22 Creating a Partitioned External Table with Access Parameters Common to All Partitions

This example creates an external table named `orders_external_range` that is partitioned by the date data in the `order_date` column. The ACCESS PARAMETERS clause is specified at the table level for the ORACLE_LOADER access driver. The `data_dir1` directory object is the default directory object used for the partitions `month1`, `month2`, and `month3`. The `pmax` partition specifies the `data_dir2` directory object in the DEFAULT DIRECTORY clause, so the `data_dir2` directory object is used for the `pmax` partition.

```
-- Set up directories and grant access to oe
CREATE OR REPLACE DIRECTORY data_dir1
    AS '/flatfiles/data1';
CREATE OR REPLACE DIRECTORY data_dir2
    AS '/flatfiles/data2';
CREATE OR REPLACE DIRECTORY bad_dir
    AS '/flatfiles/bad';
CREATE OR REPLACE DIRECTORY log_dir
    AS '/flatfiles/log';
GRANT READ ON DIRECTORY data_dir1 TO oe;
GRANT READ ON DIRECTORY data_dir2 TO oe;
GRANT WRITE ON DIRECTORY bad_dir TO oe;
GRANT WRITE ON DIRECTORY log_dir TO oe;
-- oe connects. Provide the user password (oe) when prompted.
CONNECT oe
-- create the partitioned external table
CREATE TABLE orders_external_range(
    order_id          NUMBER(12),
    order_date        DATE NOT NULL,
    customer_id       NUMBER(6) NOT NULL,
    order_status      NUMBER(2),
    order_total       NUMBER(8,2),
    sales_rep_id      NUMBER(6))
ORGANIZATION EXTERNAL(
    TYPE ORACLE_LOADER
    DEFAULT DIRECTORY data_dir1
    ACCESS PARAMETERS(
        RECORDS DELIMITED BY NEWLINE
        BADFILE bad_dir: 'sh%a_%p.bad'
        LOGFILE log_dir: 'sh%a_%p.log'
        FIELDS TERMINATED BY '|'
        MISSING FIELD VALUES ARE NULL))
PARALLEL
REJECT LIMIT UNLIMITED
PARTITION BY RANGE (order_date)
    (PARTITION month1 VALUES LESS THAN (TO_DATE('31-12-2014', 'DD-MM-YYYY'))
        LOCATION ('sales_1.csv'),
    PARTITION month2 VALUES LESS THAN (TO_DATE('31-01-2015', 'DD-MM-YYYY'))
        LOCATION ('sales_2.csv'),
    PARTITION month3 VALUES LESS THAN (TO_DATE('28-02-2015', 'DD-MM-YYYY'))
        LOCATION ('sales_3.csv'),
```

```
PARTITION pmax VALUES LESS THAN (MAXVALUE)
    DEFAULT DIRECTORY data_dir2 LOCATION('sales_4.csv'));
```

In the previous example, the default directory `data_dir2` is specified for the `pmax` partition. You can also specify the directory for a specific location in this partition in the `LOCATION` clause in the following way:

```
PARTITION pmax VALUES LESS THAN (MAXVALUE)
    LOCATION ('data_dir2:sales_4.csv')
```

Note that, in this case, the directory `data_dir2` is specified for the location `sales_4.csv`, but the `data_dir2` directory is not the default directory for the partition. Therefore, the default directory for the `pmax` partition is the same as the default directory for the table, which is `data_dir1`.

Example 20-23 Creating a Composite List-Range Partitioned External Table

This example creates an external table named `accounts` that is partitioned by the data in the `region` column. This partition is subpartitioned using range on the data in the `balance` column. The `ACCESS PARAMETERS` clause is specified at the table level for the `ORACLE_LOADER` access driver. A `LOCATION` clause is specified for each subpartition.

There is a table-level `DEFAULT DIRECTORY` clause set to the `data_dir1` directory object, and this directory object is used for all of the subpartitions, except for the following:

- There is a partition-level `DEFAULT DIRECTORY` clause set to the `data_dir2` directory object for partition `p_southcentral`. In that partition, the following subpartitions use this default directory: `p_sc_low`, `p_sc_high`, and `p_sc_extraordinary`.
- In partition `p_southcentral`, the subpartition `p_sc_average` has a subpartition-level `DEFAULT DIRECTORY` clause set to the `data_dir3` directory object, and this subpartition uses the `data_dir3` directory object.
- As previously stated, the default directory for the `p_sc_high` subpartition is `data_dir2`. The `p_sc_high` subpartition does not have a `DEFAULT DIRECTORY` clause, and the default directory `data_dir2` is inherited from the `DEFAULT DIRECTORY` specified in the `PARTITION BY` clause for the partition `p_southcentral`. The files in the `p_sc_high` subpartition use the following directories:
 - The `psch1.csv` file uses `data_dir2`, the default directory for the subpartition.
 - The `psch2.csv` file uses the `data_dir4` directory because the `data_dir4` directory is specified for that location.

```
-- Set up the directories and grant access to oe
CREATE OR REPLACE DIRECTORY data_dir1
    AS '/stage/data1_dir';
CREATE OR REPLACE DIRECTORY data_dir2
    AS '/stage/data2_dir';
CREATE OR REPLACE DIRECTORY data_dir3
    AS '/stage/data3_dir';
CREATE OR REPLACE DIRECTORY data_dir4
    AS '/stage/data4_dir';
CREATE OR REPLACE DIRECTORY bad_dir
    AS '/stage/bad_dir';
CREATE OR REPLACE DIRECTORY log_dir
```

```

        AS '/stage/log_dir';
GRANT READ ON DIRECTORY data_dir1 TO oe;
GRANT READ ON DIRECTORY data_dir2 TO oe;
GRANT READ ON DIRECTORY data_dir3 TO oe;
GRANT READ ON DIRECTORY data_dir4 TO oe;
GRANT WRITE ON DIRECTORY bad_dir TO oe;
GRANT WRITE ON DIRECTORY log_dir TO oe;
-- oe connects. Provide the user password (oe) when prompted.
CONNECT oe
-- create the partitioned external table
CREATE TABLE accounts
( id             NUMBER,
  account_number NUMBER,
  customer_id    NUMBER,
  balance         NUMBER,
  branch_id      NUMBER,
  region          VARCHAR(2),
  status          VARCHAR2(1)
)
ORGANIZATION EXTERNAL(
  TYPE ORACLE_LOADER
  DEFAULT DIRECTORY data_dir1
  ACCESS PARAMETERS(
    RECORDS DELIMITED BY NEWLINE
    BADFILE bad_dir: 'sh%a_%p.bad'
    LOGFILE log_dir: 'sh%a_%p.log'
    FIELDS TERMINATED BY '|'
    MISSING FIELD VALUES ARE NULL))
PARALLEL
REJECT LIMIT UNLIMITED
PARTITION BY LIST (region)
SUBPARTITION BY RANGE (balance)

20.14.6.4 Altering a Partitioned External Table

You can use the `ALTER TABLE` statement to modify table-level external parameters, but not the partition-level and subpartition-level parameters, of a partitioned external table.

The locations of external files are specified in the `PARTITION BY` and `SUBPARTITION BY` clauses. External files for a partition are specified in the partition's `PARTITION BY` clause. External files for a subpartition are specified in the subpartition's `SUBPARTITION BY` clause.

The only exception is that the `LOCATION` clause cannot be specified at the table level during the creation of a partitioned external table. Therefore, the `LOCATION` clause cannot be added at the table level in an `ALTER TABLE` statement that modifies a partitioned external table.

At the partition level, only `ADD`, `DROP`, and `RENAME` operations are supported. An `ALTER TABLE` statement cannot modify the attributes of existing partitions and subpartitions. However, you can include the `DEFAULT DIRECTORY` and `LOCATION` clauses in a `PARTITION` clause or `SUBPARTITION` clause when you add a new partition or subpartition.

1. Connect to the database as a user with the privileges required to alter the external table.
2. Issue an ALTER TABLE statement.

Example 20-24 Renaming a Partition of a Partitioned External Table

This example renames a partition of the partitioned external table named orders_external_range.

```
ALTER TABLE orders_external_range RENAME PARTITION pmax TO other_months;
```

20.14.7 Dropping External Tables

For an external table, the DROP TABLE statement removes only the table metadata in the database. It has no affect on the actual data, which resides outside of the database.

20.14.8 System and Object Privileges for External Tables

System and object privileges for external tables are a subset of those for regular table.

Only the following system privileges are applicable to external tables:

- ALTER ANY TABLE
- CREATE ANY TABLE
- DROP ANY TABLE
- READ ANY TABLE
- SELECT ANY TABLE

Only the following object privileges are applicable to external tables:

- ALTER
- READ
- SELECT

However, object privileges associated with a directory are:

- READ
- WRITE

For external tables, READ privileges are required on directory objects that contain data sources, while WRITE privileges are required for directory objects containing bad, log, or discard files.

20.15 Tables Data Dictionary Views

You can query a set of data dictionary views for information about tables.

The following views allow you to access information about tables.

View	Description
DBA_TABLES	DBA view describes all relational tables in the database. ALL view describes all tables accessible to the user. USER view is restricted to tables owned by the user. Some columns in these views contain statistics that are generated by the DBMS_STATS package or ANALYZE statement.
ALL_TABLES	
USER_TABLES	
DBA_TAB_COLUMNS	These views describe the columns of tables, views, and clusters in the database. Some columns in these views contain statistics that are generated by the DBMS_STATS package or ANALYZE statement.
ALL_TAB_COLUMNS	
USER_TAB_COLUMNS	
DBA_ALL_TABLES	These views describe all relational and object tables in the database. Object tables are not specifically discussed in this book.
ALL_ALL_TABLES	
USER_ALL_TABLES	
DBA_TAB_COMMENTS	These views display comments for tables and views.
ALL_TAB_COMMENTS	Comments are entered using the COMMENT statement.
USER_TAB_COMMENTS	
DBA_COL_COMMENTS	These views display comments for table and view columns.
ALL_COL_COMMENTS	Comments are entered using the COMMENT statement.
USER_COL_COMMENTS	
DBA_EXTERNAL_TABLES	These views list the specific attributes of external tables in the database.
ALL_EXTERNAL_TABLES	
USER_EXTERNAL_TABLES	
DBA_EXTERNAL_LOCATIONS	These views list the data sources for external tables.
ALL_EXTERNAL_LOCATIONS	
USER_EXTERNAL_LOCATIONS	
DBA_XTERNAL_PART_TABLES	These views list the specific attributes of partitioned external tables in the database.
ALL_XTERNAL_PART_TABLES	
USER_XTERNAL_PART_TABLES	
S	
DBA_XTERNAL_TAB_PARTITIONS	These views list the partition-level information for partitioned external tables in the database.
ALL_XTERNAL_TAB_PARTITIONS	
USER_XTERNAL_TAB_PARTITIONS	
DBA_XTERNAL_TAB_SUBPARTITIONS	These views list the subpartition-level information for partitioned external tables in the database.
ALL_XTERNAL_TAB_SUBPARTITIONS	
USER_XTERNAL_TAB_SUBPARTITIONS	
DBA_XTERNAL_LOC_PARTITIONS	These views list the data sources for partitions in external tables.
ALL_XTERNAL_LOC_PARTITIONS	
USER_XTERNAL_LOC_PARTITIONS	

View	Description
DBA_XTERNAL_LOC_SUBPARTITIONS	These views list the data sources for subpartitions in external tables.
ALL_XTERNAL_LOC_SUBPARTITIONS	
USER_XTERNAL_LOC_SUBPARTITIONS	
DBA_TAB_HISTOGRAMS	These views describe histograms on tables and views.
ALL_TAB_HISTOGRAMS	
USER_TAB_HISTOGRAMS	
DBA_TAB_STATISTICS	These views contain optimizer statistics for tables.
ALL_TAB_STATISTICS	
USER_TAB_STATISTICS	
DBA_TAB_COL_STATISTICS	These views provide column statistics and histogram information extracted from the related TAB_COLUMNS views.
ALL_TAB_COL_STATISTICS	
USER_TAB_COL_STATISTICS	
DBA_TAB_MODIFICATIONS	These views describe tables that have been modified since the last time table statistics were gathered on them. They are not populated immediately, but after a time lapse (usually 3 hours).
ALL_TAB_MODIFICATIONS	
USER_TAB_MODIFICATIONS	
DBA_ENCRYPTED_COLUMNS	These views list table columns that are encrypted, and for each column, lists the encryption algorithm in use.
ALL_ENCRYPTED_COLUMNS	
USER_ENCRYPTED_COLUMNS	
DBA_UNUSED_COL_TABS	These views list tables with unused columns, as marked by the ALTER TABLE ... SET UNUSED statement.
ALL_UNUSED_COL_TABS	
USER_UNUSED_COL_TABS	
DBA_PARTIAL_DROP_TABS	These views list tables that have partially completed DROP COLUMN operations. These operations could be incomplete because the operation was interrupted by the user or a system failure.
ALL_PARTIAL_DROP_TABS	
USER_PARTIAL_DROP_TABS	

Example: Displaying Column Information

Column information, such as name, data type, length, precision, scale, and default data values can be listed using one of the views ending with the _COLUMNS suffix. For example, the following query lists all of the default column values for the `emp` and `dept` tables:

```
SELECT TABLE_NAME, COLUMN_NAME, DATA_TYPE, DATA_LENGTH, LAST_ANALYZED
  FROM DBA_TAB_COLUMNS
 WHERE OWNER = 'HR'
 ORDER BY TABLE_NAME;
```

The following is the output from the query:

TABLE_NAME	COLUMN_NAME	DATA_TYPE	DATA_LENGTH	LAST_ANALYZED
COUNTRIES	COUNTRY_ID	CHAR	2	05-FEB-03
COUNTRIES	COUNTRY_NAME	VARCHAR2	40	05-FEB-03
COUNTRIES	REGION_ID	NUMBER	22	05-FEB-03

DEPARTMENTS	DEPARTMENT_ID	NUMBER	22 05-FEB-03
DEPARTMENTS	DEPARTMENT_NAME	VARCHAR2	30 05-FEB-03
DEPARTMENTS	MANAGER_ID	NUMBER	22 05-FEB-03
DEPARTMENTS	LOCATION_ID	NUMBER	22 05-FEB-03
EMPLOYEES	EMPLOYEE_ID	NUMBER	22 05-FEB-03
EMPLOYEES	FIRST_NAME	VARCHAR2	20 05-FEB-03
EMPLOYEES	LAST_NAME	VARCHAR2	25 05-FEB-03
EMPLOYEES	EMAIL	VARCHAR2	25 05-FEB-03
.			
.			
LOCATIONS	COUNTRY_ID	CHAR	2 05-FEB-03
REGIONS	REGION_ID	NUMBER	22 05-FEB-03
REGIONS	REGION_NAME	VARCHAR2	25 05-FEB-03

51 rows selected.

Managing Indexes

Indexes can provide faster data access. You can create, alter, monitor, and drop indexes.

- [About Indexes](#)

Indexes are optional structures associated with tables and clusters that allow SQL queries to execute more quickly against a table.

- [Guidelines for Managing Indexes](#)

You can follow guidelines for managing indexes.

- [Creating Indexes](#)

You can create several different types of indexes. You can create indexes explicitly, and you can create indexes associated with constraints.

- [Altering Indexes](#)

You can alter an index by completing tasks such as changing its storage characteristics, rebuilding it, making it unusable, or making it visible or invisible.

- [Monitoring Space Use of Indexes](#)

If key values in an index are inserted, updated, and deleted frequently, then the index can lose its acquired space efficiency over time.

- [Dropping Indexes](#)

You can drop an index with the `DROP INDEX` statement.

- [Indexes Data Dictionary Views](#)

You can query a set of data dictionary views for information about indexes.

21.1 About Indexes

Indexes are optional structures associated with tables and clusters that allow SQL queries to execute more quickly against a table.

Just as the index in this manual helps you locate information faster than if there were no index, an Oracle Database index provides a faster access path to table data. You can use indexes without rewriting any queries. Your results are the same, but you see them more quickly.

Oracle Database provides several indexing schemes that provide complementary performance functionality. These are:

- B-tree indexes: the default and the most common
- B-tree cluster indexes: defined specifically for cluster
- Hash cluster indexes: defined specifically for a hash cluster
- Global and local indexes: relate to partitioned tables and indexes
- Reverse key indexes: most useful for Oracle Real Application Clusters applications
- Bitmap indexes: compact; work best for columns with a small set of values

- Function-based indexes: contain the precomputed value of a function/expression
- Domain indexes: specific to an application or cartridge.

Indexes are logically and physically independent of the data in the associated table. Being independent structures, they require storage space. You can create or drop an index without affecting the base tables, database applications, or other indexes. The database automatically maintains indexes when you insert, update, and delete rows of the associated table. If you drop an index, all applications continue to work. However, access to previously indexed data might be slower.

 **See Also:**

- [Oracle Database Concepts](#) for an overview of indexes
- [Managing Space for Schema Objects](#)

21.2 Guidelines for Managing Indexes

You can follow guidelines for managing indexes.

- [Create Indexes After Inserting Table Data](#)
Data is often inserted or loaded into a table using either the SQL*Loader or an import utility. It is more efficient to create an index for a table after inserting or loading the data. If you create one or more indexes before loading data, then the database must update every index as each row is inserted.
- [Index the Correct Tables and Columns](#)
Follow guidelines about tables and columns that are suitable for indexing.
- [Order Index Columns for Performance](#)
The order of columns in the CREATE INDEX statement can affect query performance. In general, specify the most frequently used columns first.
- [Limit the Number of Indexes for Each Table](#)
A table can have any number of indexes. However, the more indexes there are, the more overhead is incurred as the table is modified.
- [Drop Indexes That Are No Longer Required](#)
It is best practice to drop indexes that are no longer required.
- [Indexes and Deferred Segment Creation](#)
Index segment creation is deferred when the associated table defers segment creation. This is because index segment creation reflects the behavior of the table with which it is associated.
- [Estimate Index Size and Set Storage Parameters](#)
Estimating the size of an index before creating one can facilitate better disk space planning and management.
- [Specify the Tablespace for Each Index](#)
Indexes can be created in any tablespace. An index can be created in the same or different tablespace as the table it indexes.

- [Consider Parallelizing Index Creation](#)
You can parallelize index creation, much the same as you can parallelize table creation. Because multiple processes work together to create the index, the database can create the index more quickly than if a single server process created the index sequentially.
- [Consider Creating Indexes with NOLOGGING](#)
You can create an index and generate minimal redo log records by specifying NOLOGGING in the CREATE INDEX statement.
- [Understand When to Use Unusable or Invisible Indexes](#)
Use unusable or invisible indexes when you want to improve the performance of bulk loads, test the effects of removing an index before dropping it, or otherwise suspend the use of an index by the optimizer.
- [Understand When to Create Multiple Indexes on the Same Set of Columns](#)
You can create multiple indexes on the same set of columns when the indexes are different in some way. For example, you can create a B-tree index and a bitmap index on the same set of columns.
- [Consider Costs and Benefits of Coalescing or Rebuilding Indexes](#)
Improper sizing or increased growth can produce index fragmentation. To eliminate or reduce fragmentation, you can rebuild or coalesce the index. But before you perform either task weigh the costs and benefits of each option and choose the one that works best for your situation.
- [Consider Cost Before Disabling or Dropping Constraints](#)
Because unique and primary keys have associated indexes, you should factor in the cost of dropping and creating indexes when considering whether to disable or drop a UNIQUE or PRIMARY KEY constraint.
- [Consider Using the In-Memory Column Store to Reduce the Number of Indexes](#)
The In-Memory Column Store is an optional portion of the system global area (SGA) that stores copies of tables, table partitions, and other database objects that is optimized for rapid scans. In the In-Memory Column Store, table data is stored by column rather than row in the SGA.

 **See Also:**

- *Oracle Database SQL Tuning Guide* and *Oracle Database Data Warehousing Guide* for information about bitmap indexes
- *Oracle Database Data Cartridge Developer's Guide* for information about defining domain-specific operators and indexing schemes and integrating them into the Oracle Database server

21.2.1 Create Indexes After Inserting Table Data

Data is often inserted or loaded into a table using either the SQL*Loader or an import utility. It is more efficient to create an index for a table after inserting or loading the

data. If you create one or more indexes before loading data, then the database must update every index as each row is inserted.

Creating an index on a table that already has data requires sort space. Some sort space comes from memory allocated for the index creator. The amount for each user is determined by the initialization parameter `SORT_AREA_SIZE`. The database also swaps sort information to and from temporary segments that are only allocated during the index creation in the user's temporary tablespace.

Under certain conditions, data can be loaded into a table with SQL*Loader direct-path load, and an index can be created as data is loaded.

 **See Also:**

Oracle Database Utilities for information about using SQL*Loader for direct-path load

21.2.2 Index the Correct Tables and Columns

Follow guidelines about tables and columns that are suitable for indexing.

Use the following guidelines for determining when to create an index:

- Create an index if you frequently want to retrieve less than 15% of the rows in a large table. The percentage varies greatly according to the relative speed of a table scan and how the row data is distributed in relation to the index key. The faster the table scan, the lower the percentage; the more clustered the row data, the higher the percentage.
- To improve performance on joins of multiple tables, index columns used for joins.

 **Note:**

Primary and unique keys automatically have indexes, but you might want to create an index on a foreign key.

- Small tables do not require indexes. If a query is taking too long, then the table might have grown from small to large.

Columns That Are Suitable for Indexing

Some columns are strong candidates for indexing. Columns with one or more of the following characteristics are candidates for indexing:

- Values are relatively unique in the column.
- There is a wide range of values (good for regular indexes).
- There is a small range of values (good for bitmap indexes).
- The column contains many nulls, but queries often select all rows having a value. In this case, use the following phrase:

```
WHERE COL_X > -9.99 * power(10,125)
```

Using the preceding phrase is preferable to:

```
WHERE COL_X IS NOT NULL
```

This is because the first uses an index on `COL_X` (assuming that `COL_X` is a numeric column).

Columns That Are Not Suitable for Indexing

Columns with the following characteristics are less suitable for indexing:

- There are many nulls in the column, and you do not search on the not null values.
`LONG` and `LONG RAW` columns cannot be indexed.

Virtual Columns

You can create unique or non-unique indexes on virtual columns. A table index defined on a virtual column is equivalent to a function-based index on the table.

See Also:

"[Creating a Function-Based Index](#)"

21.2.3 Order Index Columns for Performance

The order of columns in the `CREATE INDEX` statement can affect query performance. In general, specify the most frequently used columns first.

If you create a single index across columns to speed up queries that access, for example, `col1`, `col2`, and `col3`; then queries that access just `col1`, or that access just `col1` and `col2`, are also speeded up. But a query that accessed just `col2`, just `col3`, or just `col2` and `col3` does not use the index.

Note:

In some cases, such as when the leading column has very low cardinality, the database may use a skip scan of this type of index. See *Oracle Database Concepts* for more information about index skip scan.

21.2.4 Limit the Number of Indexes for Each Table

A table can have any number of indexes. However, the more indexes there are, the more overhead is incurred as the table is modified.

Specifically, when rows are inserted or deleted, all indexes on the table must be updated as well. Also, when a column is updated, all indexes that contain the column must be updated.

Thus, there is a trade-off between the speed of retrieving data from a table and the speed of updating the table. For example, if a table is primarily read-only, then having

more indexes can be useful; but if a table is heavily updated, then having fewer indexes could be preferable.

21.2.5 Drop Indexes That Are No Longer Required

It is best practice to drop indexes that are no longer required.

Consider dropping an index if:

- It does not speed up queries. The table could be very small, or there could be many rows in the table but very few index entries.
- The queries in your applications do not use the index.
- The index must be dropped before being rebuilt.

 **See Also:**

["Monitoring Index Usage"](#)

21.2.6 Indexes and Deferred Segment Creation

Index segment creation is deferred when the associated table defers segment creation. This is because index segment creation reflects the behavior of the table with which it is associated.

 **See Also:**

["Understand Deferred Segment Creation"](#) for further information

21.2.7 Estimate Index Size and Set Storage Parameters

Estimating the size of an index before creating one can facilitate better disk space planning and management.

You can use the combined estimated size of indexes, along with estimates for tables, the undo tablespace, and redo log files, to determine the amount of disk space that is required to hold an intended database. From these estimates, you can make correct hardware purchases and other decisions.

Use the estimated size of an individual index to better manage the disk space that the index uses. When an index is created, you can set appropriate storage parameters and improve I/O performance of applications that use the index. For example, assume that you estimate the maximum size of an index before creating it. If you then set the storage parameters when you create the index, then fewer extents are allocated for the table data segment, and all of the index data is stored in a relatively contiguous section of disk space. This decreases the time necessary for disk I/O operations involving this index.

The maximum size of a single index entry is dependent on the block size of the database.

Storage parameters of an index segment created for the index used to enforce a primary key or unique key constraint can be set in either of the following ways:

- In the `ENABLE ... USING INDEX` clause of the `CREATE TABLE` or `ALTER TABLE` statement
- In the `STORAGE` clause of the `ALTER INDEX` statement

 **See Also:**

- *Oracle Database Reference* for more information about the limits related to index size
- *Oracle Database SQL Language Reference* for information about creating an index on an extended data type column

21.2.8 Specify the Tablespace for Each Index

Indexes can be created in any tablespace. An index can be created in the same or different tablespace as the table it indexes.

If you use the same tablespace for a table and its index, then it can be more convenient to perform database maintenance (such as tablespace or file backup) or to ensure application availability. All the related data is always online together.

Using different tablespaces (on different disks) for a table and its index produces better performance than storing the table and index in the same tablespace. Disk contention is reduced. But, if you use different tablespaces for a table and its index, and one tablespace is offline (containing either data or index), then the statements referencing that table are not guaranteed to work.

21.2.9 Consider Parallelizing Index Creation

You can parallelize index creation, much the same as you can parallelize table creation. Because multiple processes work together to create the index, the database can create the index more quickly than if a single server process created the index sequentially.

When creating an index in parallel, storage parameters are used separately by each query server process. Therefore, an index created with an `INITIAL` value of 5M and a parallel degree of 12 consumes at least 60M of storage during index creation.

 **See Also:**

- *Oracle Database VLDB and Partitioning Guide* for information about using parallel execution

21.2.10 Consider Creating Indexes with NOLOGGING

You can create an index and generate minimal redo log records by specifying NOLOGGING in the CREATE INDEX statement.

 **Note:**

Because indexes created using NOLOGGING are not archived, perform a backup after you create the index.

Creating an index with NOLOGGING has the following benefits:

- Space is saved in the redo log files.
- The time it takes to create the index is decreased.
- Performance improves for parallel creation of large indexes.

In general, the relative performance improvement is greater for larger indexes created without LOGGING than for smaller ones. Creating small indexes without LOGGING has little effect on the time it takes to create an index. However, for larger indexes the performance improvement can be significant, especially when you are also parallelizing the index creation.

21.2.11 Understand When to Use Unusable or Invisible Indexes

Use unusable or invisible indexes when you want to improve the performance of bulk loads, test the effects of removing an index before dropping it, or otherwise suspend the use of an index by the optimizer.

Unusable indexes

An **unusable index** is ignored by the optimizer and is not maintained by DML. One reason to make an index unusable is to improve bulk load performance. (Bulk loads go more quickly if the database does not need to maintain indexes when inserting rows.) Instead of dropping the index and later re-creating it, which requires you to recall the exact parameters of the CREATE INDEX statement, you can make the index unusable, and then rebuild it.

You can create an index in the unusable state, or you can mark an existing index or index partition unusable. In some cases the database may mark an index unusable, such as when a failure occurs while building the index. When one partition of a partitioned index is marked unusable, the other partitions of the index remain valid.

An unusable index or index partition must be rebuilt, or dropped and re-created, before it can be used. Truncating a table makes an unusable index valid.

When you make an existing index unusable, its index segment is dropped.

The functionality of unusable indexes depends on the setting of the SKIP_UNUSABLE_INDEXES initialization parameter. When SKIP_UNUSABLE_INDEXES is TRUE (the default), then:

- DML statements against the table proceed, but unusable indexes are not maintained.
- DML statements terminate with an error if there are any unusable indexes that are used to enforce the `UNIQUE` constraint.
- For nonpartitioned indexes, the optimizer does not consider any unusable indexes when creating an access plan for `SELECT` statements. The only exception is when an index is explicitly specified with the `INDEX()` hint.
- For a partitioned index where one or more of the partitions is unusable, the optimizer can use table expansion. With table expansion, the optimizer transforms the query into a `UNION ALL` statement, with some subqueries accessing indexed partitions and other subqueries accessing partitions with unusable indexes. The optimizer can choose the most efficient access method available for a partition. See *Oracle Database SQL Tuning Guide* for more information about table expansion.

When `SKIP_UNUSABLE_INDEXES` is `FALSE`, then:

- If any unusable indexes or index partitions are present, then any DML statements that would cause those indexes or index partitions to be updated are terminated with an error.
- For `SELECT` statements, if an unusable index or unusable index partition is present, but the optimizer does not choose to use it for the access plan, then the statement proceeds. However, if the optimizer does choose to use the unusable index or unusable index partition, then the statement terminates with an error.

Invisible Indexes

You can create invisible indexes or make an existing index invisible. An **invisible index** is ignored by the optimizer unless you explicitly set the `OPTIMIZER_USE_INVISIBLE_INDEXES` initialization parameter to `TRUE` at the session or system level. Unlike unusable indexes, an invisible index is maintained during DML statements. Although you can make a partitioned index invisible, you cannot make an individual index partition invisible while leaving the other partitions visible.

Using invisible indexes, you can do the following:

- Test the removal of an index before dropping it.
- Use temporary index structures for certain operations or modules of an application without affecting the overall application.
- Add an index to a set of columns on which an index already exists.

See Also:

- "[Creating an Unusable Index](#)"
- "[Creating an Invisible Index](#)"
- "[Making an Index Unusable](#)"
- "[Making an Index Invisible or Visible](#)"

21.2.12 Understand When to Create Multiple Indexes on the Same Set of Columns

You can create multiple indexes on the same set of columns when the indexes are different in some way. For example, you can create a B-tree index and a bitmap index on the same set of columns.

When you have multiple indexes on the same set of columns, only one of these indexes can be visible at a time, and any other indexes must be invisible.

You might create different indexes on the same set of columns because they provide the flexibility to meet your requirements. You can also create multiple indexes on the same set of columns to perform application migrations without dropping an existing index and recreating it with different attributes.

Different types of indexes are useful in different scenarios. For example, B-tree indexes are often used in online transaction processing (OLTP) systems with many concurrent transactions, while bitmap indexes are often used in data warehousing systems that are mostly used for queries. Similarly, locally and globally partitioned indexes are useful in different scenarios. Locally partitioned indexes are easy to manage because partition maintenance operations automatically apply to them. Globally partitioned indexes are useful when you want the partitioning scheme of an index to be different from its table's partitioning scheme.

You can create multiple indexes on the same set of columns when at least one of the following index characteristics is different:

- The indexes are of different types.

See "[About Indexes](#)" and *Oracle Database Concepts* for information about the different types of indexes.

However, the following exceptions apply:

- You cannot create a B-tree index and a B-tree cluster index on the same set of columns.
- You cannot create a B-tree index and an index-organized table on the same set of columns.
- The indexes use different partitioning.

Partitioning can be different in any of the following ways:

- Indexes that are not partitioned and indexes that are partitioned
- Indexes that are locally partitioned and indexes that are globally partitioned
- Indexes that differ in partitioning type (range or hash)
- The indexes have different uniqueness properties.

You can create both a unique and a non-unique index on the same set of columns.

See Also:

- "[Creating Multiple Indexes on the Same Set of Columns](#)"
- "[Understand When to Use Unusable or Invisible Indexes](#)"

21.2.13 Consider Costs and Benefits of Coalescing or Rebuilding Indexes

Improper sizing or increased growth can produce index fragmentation. To eliminate or reduce fragmentation, you can rebuild or coalesce the index. But before you perform either task weigh the costs and benefits of each option and choose the one that works best for your situation.

[Table 21-1](#) is a comparison of the costs and benefits associated with rebuilding and coalescing indexes.

Table 21-1 Costs and Benefits of Coalescing or Rebuilding Indexes

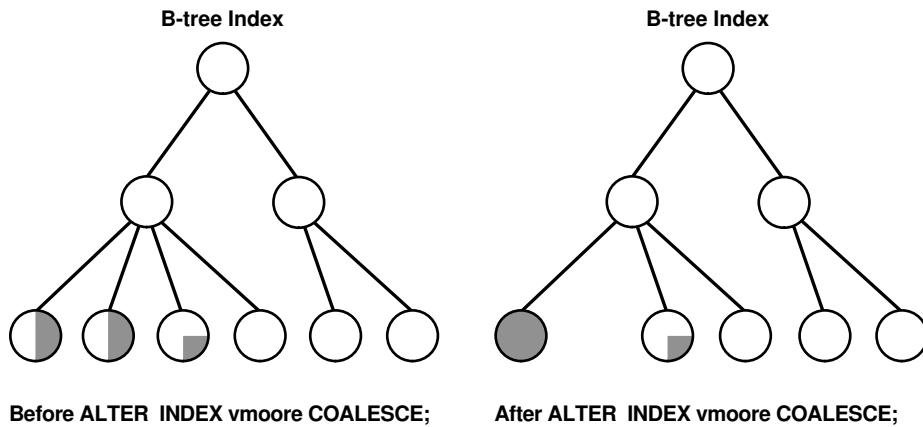

Rebuild Index	Coalesce Index
Quickly moves index to another tablespace	Cannot move index to another tablespace
Higher costs: requires more disk space	Lower costs: does not require more disk space
Creates new tree, shrinks height if applicable	Coalesces leaf blocks within same branch of tree
Enables you to quickly change storage and tablespace parameters without having to drop the original index	Quickly frees up index leaf blocks for use

In situations where you have B-tree index leaf blocks that can be freed up for reuse, you can merge those leaf blocks using the following statement:

```
ALTER INDEX vmoore COALESCE;
```

[Figure 21-1](#) illustrates the effect of an `ALTER INDEX COALESCE` on the index `vmoore`. Before performing the operation, the first two leaf blocks are 50% full. Therefore, you have an opportunity to reduce fragmentation and completely fill the first block, while freeing up the second.

Figure 21-1 Coalescing Indexes

21.2.14 Consider Cost Before Disabling or Dropping Constraints

Because unique and primary keys have associated indexes, you should factor in the cost of dropping and creating indexes when considering whether to disable or drop a UNIQUE or PRIMARY KEY constraint.

If the associated index for a UNIQUE key or PRIMARY KEY constraint is extremely large, then you can save time by leaving the constraint enabled rather than dropping and re-creating the large index. You also have the option of explicitly specifying that you want to keep or drop the index when dropping or disabling a UNIQUE or PRIMARY KEY constraint.

 **See Also:**

["Managing Integrity Constraints"](#)

21.2.15 Consider Using the In-Memory Column Store to Reduce the Number of Indexes

The In-Memory Column Store is an optional portion of the system global area (SGA) that stores copies of tables, table partitions, and other database objects that is optimized for rapid scans. In the In-Memory Column Store, table data is stored by column rather than row in the SGA.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

For tables used in OLTP or data warehousing environments, multiple indexes typically are created to improve the performance of analytic and reporting queries. These indexes can impede the performance of data manipulation language (DML) statements. When a table is stored in the In-Memory Column Store, indexes used for analytic or reporting queries can be greatly reduced or eliminated without affecting query performance. Eliminating these indexes can improve the performance of transactions and data loading operations.

 **See Also:**

"[Improving Query Performance with the In-Memory Column Store](#)"

21.3 Creating Indexes

You can create several different types of indexes. You can create indexes explicitly, and you can create indexes associated with constraints.

 **Live SQL:**

To view and run examples related to creating indexes on Oracle Live SQL, go to [Oracle Live SQL: Creating Indexes](#).

- [Prerequisites for Creating Indexes](#)
Prerequisites must be met before you can create indexes.
- [Creating an Index Explicitly](#)
You can create indexes explicitly (outside of integrity constraints) using the SQL statement `CREATE INDEX`.
- [Creating a Unique Index Explicitly](#)
Indexes can be unique or non-unique. Unique indexes guarantee that no two rows of a table have duplicate values in the key column (or columns). Non-unique indexes do not impose this restriction on the column values.
- [Creating an Index Associated with a Constraint](#)
You can create an index associated with a constraint when you issue the `CREATE TABLE` or `ALTER TABLE` SQL statement.
- [Creating a Large Index](#)
When creating an extremely large index, consider allocating a larger temporary tablespace for the index creation.
- [Creating an Index Online](#)
You can create and rebuild indexes online. Therefore, you can update base tables at the same time you are building or rebuilding indexes on that table.
- [Creating a Function-Based Index](#)
Function-based indexes facilitate queries that qualify a value returned by a function or expression. The value of the function or expression is precomputed and stored in the index.

- [Creating a Compressed Index](#)
As your database grows in size, consider using index compression to save disk space.
- [Creating an Unusable Index](#)
When you create an index in the `UNUSABLE` state, it is ignored by the optimizer and is not maintained by DML. An unusable index must be rebuilt, or dropped and re-created, before it can be used.
- [Creating an Invisible Index](#)
An invisible index is an index that is ignored by the optimizer unless you explicitly set the `OPTIMIZER_USE_INVISIBLE_INDEXES` initialization parameter to `TRUE` at the session or system level.
- [Creating Multiple Indexes on the Same Set of Columns](#)
You can create multiple indexes on the same set of columns when the indexes are different in some way.

21.3.1 Prerequisites for Creating Indexes

Prerequisites must be met before you can create indexes.

To create an index in your own schema, *at least one* of the following prerequisites must be met:

- The table or cluster to be indexed is in your own schema.
- You have `INDEX` privilege on the table to be indexed.
- You have `CREATE ANY INDEX` system privilege.

To create an index in another schema, *all* of the following prerequisites must be met:

- You have `CREATE ANY INDEX` system privilege.
- The owner of the other schema has a quota for the tablespaces to contain the index or index partitions, or `UNLIMITED TABLESPACE` system privilege.

21.3.2 Creating an Index Explicitly

You can create indexes explicitly (outside of integrity constraints) using the SQL statement `CREATE INDEX`.

The following statement creates an index named `emp_ename` for the `ename` column of the `emp` table:

```
CREATE INDEX emp_ename ON emp(ename)
    TABLESPACE users
    STORAGE (INITIAL 20K
        NEXT 20K);
```

Notice that several storage settings and a tablespace are explicitly specified for the index. If you do not specify storage options (such as `INITIAL` and `NEXT`) for an index, then the default storage options of the default or specified tablespace are automatically used.

 **Live SQL:**

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating Indexes](#).

 **See Also:**

Oracle Database SQL Language Reference for syntax and restrictions on the use of the `CREATE INDEX` statement

21.3.3 Creating a Unique Index Explicitly

Indexes can be unique or non-unique. Unique indexes guarantee that no two rows of a table have duplicate values in the key column (or columns). Non-unique indexes do not impose this restriction on the column values.

Use the `CREATE UNIQUE INDEX` statement to create a unique index. The following example creates a unique index:

```
CREATE UNIQUE INDEX dept_unique_index ON dept (dname)
    TABLESPACE indx;
```

Alternatively, you can define `UNIQUE` integrity constraints on the desired columns. The database enforces `UNIQUE` integrity constraints by automatically defining a unique index on the unique key. This is discussed in the following section. However, it is advisable that any index that exists for query performance, including unique indexes, be created explicitly.

 **Live SQL:**

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating Indexes](#).

 **See Also:**

Oracle Database SQL Tuning Guide for more information about creating an index for performance

21.3.4 Creating an Index Associated with a Constraint

You can create an index associated with a constraint when you issue the `CREATE TABLE` or `ALTER TABLE` SQL statement.

- [About Creating an Index Associated with a Constraint](#)
Oracle Database enforces a `UNIQUE` key or `PRIMARY KEY` integrity constraint on a table by creating a unique index on the unique key or primary key.
- [Specifying Storage Options for an Index Associated with a Constraint](#)
You can set the storage options for the indexes associated with `UNIQUE` and `PRIMARY KEY` constraints using the `USING INDEX` clause.
- [Specifying the Index Associated with a Constraint](#)
You can specify details about the indexes associated with constraints.

21.3.4.1 About Creating an Index Associated with a Constraint

Oracle Database enforces a `UNIQUE` key or `PRIMARY KEY` integrity constraint on a table by creating a unique index on the unique key or primary key.

This index is automatically created by the database when the constraint is enabled. No action is required by you when you issue the `CREATE TABLE` or `ALTER TABLE` statement to create the index, but you can optionally specify a `USING INDEX` clause to exercise control over its creation. This includes both when a constraint is defined and enabled, and when a defined but disabled constraint is enabled.

To enable a `UNIQUE` or `PRIMARY KEY` constraint, thus creating an associated index, the owner of the table must have a quota for the tablespace intended to contain the index, or the `UNLIMITED TABLESPACE` system privilege. The index associated with a constraint always takes the name of the constraint, unless you optionally specify otherwise.

 **Note:**

An efficient procedure for enabling a constraint that can make use of parallelism is described in "[Efficient Use of Integrity Constraints: A Procedure](#)".

21.3.4.2 Specifying Storage Options for an Index Associated with a Constraint

You can set the storage options for the indexes associated with `UNIQUE` and `PRIMARY KEY` constraints using the `USING INDEX` clause.

The following `CREATE TABLE` statement enables a `PRIMARY KEY` constraint and specifies the storage options of the associated index:

```
CREATE TABLE emp (
    empno NUMBER(5) PRIMARY KEY, age INTEGER)
ENABLE PRIMARY KEY USING INDEX
TABLESPACE users;
```

21.3.4.3 Specifying the Index Associated with a Constraint

You can specify details about the indexes associated with constraints.

If you require more explicit control over the indexes associated with `UNIQUE` and `PRIMARY KEY` constraints, the database lets you:

- Specify an existing index that the database is to use to enforce the constraint

- Specify a CREATE INDEX statement that the database is to use to create the index and enforce the constraint

These options are specified using the USING INDEX clause. The following statements present some examples.

Example 1:

```
CREATE TABLE a (
    a1 INT PRIMARY KEY USING INDEX (create index ai on a (a1)));
```

Live SQL:

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating Indexes](#).

Example 2:

```
CREATE TABLE b(
    b1 INT,
    b2 INT,
    CONSTRAINT bu1 UNIQUE (b1, b2)
        USING INDEX (create unique index bi on b(b1, b2)),
    CONSTRAINT bu2 UNIQUE (b2, b1) USING INDEX bi);
```

Example 3:

```
CREATE TABLE c(c1 INT, c2 INT);
CREATE INDEX ci ON c (c1, c2);
ALTER TABLE c ADD CONSTRAINT cpk PRIMARY KEY (c1) USING INDEX ci;
```

If a single statement creates an index with one constraint and also uses that index for another constraint, the system will attempt to rearrange the clauses to create the index before reusing it.

See Also:

["Managing Integrity Constraints"](#)

21.3.5 Creating a Large Index

When creating an extremely large index, consider allocating a larger temporary tablespace for the index creation.

To do so, complete the following steps:

- Create a new temporary tablespace using the CREATE TABLESPACE or CREATE TEMPORARY TABLESPACE statement.
- Use the TEMPORARY TABLESPACE option of the ALTER USER statement to make this your new temporary tablespace.
- Create the index using the CREATE INDEX statement.

4. Drop this tablespace using the `DROP TABLESPACE` statement. Then use the `ALTER USER` statement to reset your temporary tablespace to your original temporary tablespace.

Using this procedure can avoid the problem of expanding your usual, and usually shared, temporary tablespace to an unreasonably large size that might affect future performance.

21.3.6 Creating an Index Online

You can create and rebuild indexes online. Therefore, you can update base tables at the same time you are building or rebuilding indexes on that table.

You can perform DML operations while the index build is taking place, but DDL operations are not allowed. Parallel DML is not supported when creating or rebuilding an index online.

The following statements illustrate online index build operations:

```
CREATE INDEX emp_name ON emp (mgr, emp1, emp2, emp3) ONLINE;
```

 **Note:**

Keep in mind that the time that it takes on online index build to complete is proportional to the size of the table and the number of concurrently executing DML statements. Therefore, it is best to start online index builds when DML activity is low.

 **Live SQL:**

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating Indexes](#).

 **See Also:**

["Rebuilding an Existing Index"](#)

21.3.7 Creating a Function-Based Index

Function-based indexes facilitate queries that qualify a value returned by a function or expression. The value of the function or expression is precomputed and stored in the index.

In addition to the prerequisites for creating a conventional index, if the index is based on user-defined functions, then those functions must be marked DETERMINISTIC. Also, a function-based index is executed with the credentials of the owner of the function, so you must have the EXECUTE object privilege on the function.

 **Note:**

CREATE INDEX stores the timestamp of the most recent function used in the function-based index. This timestamp is updated when the index is validated. When performing tablespace point-in-time recovery of a function-based index, if the timestamp on the most recent function used in the index is newer than the timestamp stored in the index, then the index is marked invalid. You must use the ANALYZE INDEX...VALIDATE STRUCTURE statement to validate this index.

To illustrate a function-based index, consider the following statement that defines a function-based index (`area_index`) defined on the function `area(geo)`:

```
CREATE INDEX area_index ON rivers (area(geo));
```

In the following SQL statement, when `area(geo)` is referenced in the WHERE clause, the optimizer considers using the index `area_index`.

```
SELECT id, geo, area(geo), desc
      FROM rivers
     WHERE Area(geo) >5000;
```

Because a function-based index depends upon any function it is using, it can be invalidated when a function changes. If the function is valid, then you can use an ALTER INDEX...ENABLE statement to enable a function-based index that has been disabled. The ALTER INDEX...DISABLE statement lets you disable the use of a function-based index. Consider doing this if you are working on the body of the function.

 **Note:**

An alternative to creating a function-based index is to add a virtual column to the target table and index the virtual column. See "["About Tables"](#)" for more information.

 **See Also:**

- [Oracle Database Concepts](#) for more information about function-based indexes
- [Oracle Database Development Guide](#) for information about using function-based indexes in applications and examples of their use

21.3.8 Creating a Compressed Index

As your database grows in size, consider using index compression to save disk space.

- [Creating an Index Using Prefix Compression](#)

Creating an index using prefix compression (also known as key compression) eliminates repeated occurrences of key column prefix values. Prefix compression is most useful for non-unique indexes with a large number of duplicates on the leading columns.

- [Creating an Index Using Advanced Index Compression](#)

Advanced index compression works well on all supported indexes, including those that are not good candidates for prefix compression. Creating an index using advanced index compression can reduce the size of all unique and non-unique indexes and improves the compression ratio significantly, while still providing efficient access to the indexes.

21.3.8.1 Creating an Index Using Prefix Compression

Creating an index using prefix compression (also known as key compression) eliminates repeated occurrences of key column prefix values. Prefix compression is most useful for non-unique indexes with a large number of duplicates on the leading columns.

Prefix compression breaks an index key into a prefix and a suffix entry. Compression is achieved by sharing the prefix entries among all the suffix entries in an index block. This sharing can lead to substantial savings in space, allowing you to store more keys for each index block while improving performance.

Prefix compression can be useful in the following situations:

- You have a non-unique index where `ROWID` is appended to make the key unique. If you use prefix compression here, then the duplicate key is stored as a prefix entry on the index block without the `ROWID`. The remaining rows become suffix entries consisting of only the `ROWID`.
- You have a unique multicolumn index.

You enable prefix compression using the `COMPRESS` clause. The prefix length (as the number of key columns) can also be specified to identify how the key columns are broken into a prefix and suffix entry. For example, the following statement compresses duplicate occurrences of a key in the index leaf block:

```
CREATE INDEX hr.emp_ename ON emp(ename)
  TABLESPACE users
  COMPRESS 1;
```

You can also specify the `COMPRESS` clause during rebuild. For example, during rebuild, you can disable compression as follows:

```
ALTER INDEX hr.emp_ename REBUILD NOCOMPRESS;
```

The `COMPRESSION` column in the `ALL_INDEXES` view and `ALL_PART_INDEXES` views shows whether an index is compressed, and, if it is compressed, the type of compression enabled for the index.

Live SQL:

View and run a related example on Oracle Live SQL at [Oracle Live SQL: Creating Indexes](#).

 **See Also:**

21.3.8.2 Creating an Index Using Advanced Index Compression

Advanced index compression works well on all supported indexes, including those that are not good candidates for prefix compression. Creating an index using advanced index compression can reduce the size of all unique and non-unique indexes and improves the compression ratio significantly, while still providing efficient access to the indexes.

For a partitioned index, you can specify the compression type on a partition by partition basis. You can also specify advanced index compression on index partitions even when the parent index is not compressed.

Advanced index compression works at the block level to provide the best compression for each block.

You can enable advanced index compression using the `COMPRESS ADVANCED` clause and can specify the following compression levels:

- **LOW:** This level provides lower compression ratio at minimal CPU overhead. Before enabling `COMPRESS ADVANCED LOW`, the database must be at 12.1.0 or higher compatibility level.
- **HIGH:** This level, the default, provides higher compression ratio at some CPU overhead. Before enabling `COMPRESS ADVANCED HIGH`, the database must be at 12.2.0 or higher compatibility level.

When a `CREATE INDEX` DDL statement is executed, a block is filled with rows. At high compression level, when the block is full, it is compressed with advanced index compression if enough space is saved to insert the next row. When a block becomes full, the block might be recompressed using advanced index compression to avoid splitting the block if enough space is saved to insert the incoming key.

The `COMPRESSION` column in the `ALL_INDEXES` view shows whether an index is compressed, and, if it is compressed, the type of compression enabled for the index. The possible values for the `COMPRESSION` column are `ADVANCED HIGH`, `ADVANCED LOW`, `DISABLED`, or `ENABLED`. The `COMPRESSION` column in the `ALL_IND_PARTITIONS` and `ALL_IND_SUBPARTITIONS` views indicates whether index compression is `ENABLED` or `DISABLED` for the partition or subpartition.

 **Note:**

- Advanced index compression is not supported for bitmap indexes or index-organized tables.
- When low level advanced index compression is enabled, advanced index compression cannot be specified on a single column unique index. This restriction does not apply when high level advanced index compression is enabled.

Example 21-1 Enabling Low Level Advanced Index Compression During Index Creation

For example, the following statement enables low level advanced index compression during the creation of the `hr.emp_mndp_ix` index:

```
CREATE INDEX hr.emp_mndp_ix ON hr.employees(manager_id, department_id)
    COMPRESS ADVANCED LOW;
```

Example 21-2 Enabling High Level Advanced Index Compression During Index Rebuild

You can also specify the `COMPRESS ADVANCED` clause during an index rebuild. For example, during rebuild, you can enable high level advanced index compression for the `hr.emp_manager_ix` index as follows:

```
ALTER INDEX hr.emp_manager_ix REBUILD COMPRESS ADVANCED HIGH;
```

 **See Also:**

- *Oracle Database Upgrade Guide* for more information about the database compatibility level
- *Oracle Database SQL Language Reference*
- *Oracle Database Concepts* for a more detailed discussion of index compression
- *Oracle Database VLDB and Partitioning Guide* for information about advanced index compression and partitioned indexes

21.3.9 Creating an Unusable Index

When you create an index in the `UNUSABLE` state, it is ignored by the optimizer and is not maintained by DML. An unusable index must be rebuilt, or dropped and re-created, before it can be used.

If the index is partitioned, then all index partitions are marked `UNUSABLE`.

The database does not create an index segment when creating an unusable index.

The following procedure illustrates how to create unusable indexes and query the database for details about the index.

To create an unusable index:

1. If necessary, create the table to be indexed.

For example, create a hash-partitioned table called `hr.employees_part` as follows:

```
sh@PROD> CONNECT hr
Enter password: **
Connected.
```

```
hr@PROD> CREATE TABLE employees_part
  2    PARTITION BY HASH (employee_id) PARTITIONS 2
  3    AS SELECT * FROM employees;
```

Table created.

```
hr@PROD> SELECT COUNT(*) FROM employees_part;
          COUNT(*)
-----
          107
```

2. Create an index with the keyword UNUSABLE.

The following example creates a locally partitioned index on `employees_part`, naming the index partitions `p1_i_emp_ename` and `p2_i_emp_ename`, and making `p1_i_emp_ename` unusable:

```
hr@PROD> CREATE INDEX i_emp_ename ON employees_part (employee_id)
  2    LOCAL (PARTITION p1_i_emp_ename UNUSABLE, PARTITION p2_i_emp_ename);
Index created.
```

3. (Optional) Verify that the index is unusable by querying the data dictionary.

The following example queries the status of index `i_emp_ename` and its two partitions, showing that only partition `p2_i_emp_ename` is unusable:

```
hr@PROD> SELECT INDEX_NAME AS "INDEX OR PARTITION NAME", STATUS
  2  FROM  USER_INDEXES
  3 WHERE INDEX_NAME = 'I_EMP_ENAME'
  4 UNION ALL
  5 SELECT PARTITION_NAME AS "INDEX OR PARTITION NAME", STATUS
  6 FROM  USER_IND_PARTITIONS
  7 WHERE PARTITION_NAME LIKE '%I_EMP_ENAME%';

INDEX OR PARTITION NAME      STATUS
-----
I_EMP_ENAME                  N/A
P1_I_EMP_ENAME                UNUSABLE
P2_I_EMP_ENAME                USABLE
```

4. (Optional) Query the data dictionary to determine whether storage exists for the partitions.

For example, the following query shows that only index partition `p2_i_emp_ename` occupies a segment. Because you created `p1_i_emp_ename` as unusable, the database did not allocate a segment for it.

```
hr@PROD> COL PARTITION_NAME FORMAT a14
hr@PROD> COL SEG_CREATED FORMAT a11
```

```
hr@PROD> SELECT p.PARTITION_NAME, p.STATUS AS "PART_STATUS",
  2          p.SEGMENT_CREATED AS "SEG_CREATED",
  3  FROM    USER_IND_PARTITIONS p, USER_SEGMENTS s
  4 WHERE   s.SEGMENT_NAME = 'I_EMP_ENAME';

PARTITION_NAME PART_STA SEG_CREATED
-----
P2_I_EMP_ENAME USABLE    YES
P1_I_EMP_ENAME UNUSABLE NO
```

 **See Also:**

- ["Understand When to Use Unusable or Invisible Indexes"](#)
- ["Making an Index Unusable"](#)
- *Oracle Database SQL Language Reference* for more information on creating unusable indexes, including restrictions.

21.3.10 Creating an Invisible Index

An invisible index is an index that is ignored by the optimizer unless you explicitly set the `OPTIMIZER_USE_INVISIBLE_INDEXES` initialization parameter to `TRUE` at the session or system level.

To create an invisible index:

- Use the `CREATE INDEX` statement with the `INVISIBLE` keyword.

The following statement creates an invisible index named `emp_ename` for the `ename` column of the `emp` table:

```
CREATE INDEX emp_ename ON emp(ename)
  TABLESPACE users
  STORAGE (INITIAL 20K
           NEXT 20k)
  INVISIBLE;
```

 **See Also:**

- ["Understand When to Use Unusable or Invisible Indexes"](#)
- ["Making an Index Invisible or Visible"](#)
- *Oracle Database SQL Language Reference* for more information on creating invisible indexes

21.3.11 Creating Multiple Indexes on the Same Set of Columns

You can create multiple indexes on the same set of columns when the indexes are different in some way.

To create multiple indexes on the same set of columns, the following prerequisites must be met:

- The prerequisites for required privileges in "[Creating Indexes](#)".
- Only one index on the same set of columns can be visible at any point in time.
If you are creating a visible index, then any existing indexes on the set of columns must be invisible..

Alternatively, you can create an invisible index on the set of columns.

For example, the following steps create a B-tree index and a bitmap index on the same set of columns in the oe.orders table:

1. Create a B-tree index on the customer_id and sales_rep_id columns in the oe.orders table:

```
CREATE INDEX oe.ord_customer_ix1    ON oe.orders (customer_id, sales_rep_id);
```

The oe.ord_customer_ix1 index is visible by default.

2. Alter the index created in Step 1 to make it invisible:

```
ALTER INDEX oe.ord_customer_ix1 INVISIBLE;
```

Alternatively, you can add the INVISIBLE clause in Step 1 to avoid this step.

3. Create a bitmap index on the customer_id and sales_rep_id columns in the oe.orders table:

```
CREATE BITMAP INDEX oe.ord_customer_ix2    ON oe.orders (customer_id, sales_rep_id);
```

The oe.ord_customer_ix2 index is visible by default.

If the oe.ord_customer_ix1 index created in Step 1 is visible, then the CREATE BITMAP INDEX statement in this step returns an error.

See Also:

- "[Understand When to Create Multiple Indexes on the Same Set of Columns](#)"
- "[Understand When to Use Unusable or Invisible Indexes](#)"
- "[Creating an Invisible Index](#)"

21.4 Altering Indexes

You can alter an index by completing tasks such as changing its storage characteristics, rebuilding it, making it unusable, or making it visible or invisible.

- [About Altering Indexes](#)

To alter an index, your schema must contain the index, or you must have the `ALTER ANY INDEX` system privilege.

- [Altering Storage Characteristics of an Index](#)

Alter the storage parameters of any index, including those created by the database to enforce primary and unique key integrity constraints, using the `ALTER INDEX` statement.

- [Rebuilding an Existing Index](#)

When you rebuild an index, you use an existing index as the data source. Creating an index in this manner enables you to change storage characteristics or move to a new tablespace. Rebuilding an index based on an existing data source removes intra-block fragmentation.

- [Making an Index Unusable](#)

When you make an index unusable, it is ignored by the optimizer and is not maintained by DML. When you make one partition of a partitioned index unusable, the other partitions of the index remain valid.

- [Making an Index Invisible or Visible](#)

Making an index invisible is an alternative to making it unusable or dropping it.

- [Renaming an Index](#)

You can rename an index using an `ALTER INDEX` statement with the `RENAME` clause.

- [Monitoring Index Usage](#)

Oracle Database provides a means of monitoring indexes to determine whether they are being used. If an index is not being used, then it can be dropped, eliminating unnecessary statement overhead.

21.4.1 About Altering Indexes

To alter an index, your schema must contain the index, or you must have the `ALTER ANY INDEX` system privilege.

With the `ALTER INDEX` statement, you can:

- Rebuild or coalesce an existing index
- Deallocate unused space or allocate a new extent
- Specify parallel execution (or not) and alter the degree of parallelism
- Alter storage parameters or physical attributes
- Specify `LOGGING` or `NOLOGGING`
- Enable or disable prefix compression
- Enable or disable advanced compression
- Mark the index unusable
- Make the index invisible

- Rename the index
- Start or stop the monitoring of index usage

You cannot alter index column structure.

See Also:

- *Oracle Database SQL Language Reference* for details on the `ALTER INDEX` statement

21.4.2 Altering Storage Characteristics of an Index

Alter the storage parameters of any index, including those created by the database to enforce primary and unique key integrity constraints, using the `ALTER INDEX` statement.

For example, the following statement alters the `emp_ename` index:

```
ALTER INDEX emp_ename
    STORAGE (NEXT 40);
```

The parameters `INITIAL` and `MINEXTENTS` cannot be altered. All new settings for the other storage parameters affect only extents subsequently allocated for the index.

For indexes that implement integrity constraints, you can adjust storage parameters by issuing an `ALTER TABLE` statement that includes the `USING INDEX` subclause of the `ENABLE` clause. For example, the following statement changes the storage options of the index created on table `emp` to enforce the primary key constraint:

```
ALTER TABLE emp
    ENABLE PRIMARY KEY USING INDEX;
```

See Also:

Oracle Database SQL Language Reference for syntax and restrictions on the use of the `ALTER INDEX` statement

21.4.3 Rebuilding an Existing Index

When you rebuild an index, you use an existing index as the data source. Creating an index in this manner enables you to change storage characteristics or move to a new tablespace. Rebuilding an index based on an existing data source removes intra-block fragmentation.

Compared to dropping the index and using the `CREATE INDEX` statement, rebuilding an existing index offers better performance. Before rebuilding an existing index, compare the costs and benefits associated with rebuilding to those associated with coalescing indexes as described in "[Consider Costs and Benefits of Coalescing or Rebuilding Indexes](#)".

The following statement rebuilds the existing index `emp_name`:

```
ALTER INDEX emp_name REBUILD;
```

The `REBUILD` clause must immediately follow the index name, and precede any other options. It cannot be used with the `DEALLOCATE UNUSED` clause.

You have the option of rebuilding the index online. Rebuilding online enables you to update base tables at the same time that you are rebuilding. The following statement rebuilds the `emp_name` index online:

```
ALTER INDEX emp_name REBUILD ONLINE;
```

To rebuild an index in a different user's schema online, the `ALTER ANY INDEX` system privileges is required.

 **Note:**

Online index rebuilding has stricter limitations on the maximum key length that can be handled, compared to other methods of rebuilding an index. If an ORA-1450 (maximum key length exceeded) error occurs when rebuilding online, try rebuilding offline, coalescing, or dropping and recreating the index.

If you do not have the space required to rebuild an index, you can choose instead to coalesce the index. Coalescing an index is an online operation.

 **See Also:**

- ["Creating an Index Online"](#)
- ["Monitoring Space Use of Indexes"](#)

21.4.4 Making an Index Unusable

When you make an index unusable, it is ignored by the optimizer and is not maintained by DML. When you make one partition of a partitioned index unusable, the other partitions of the index remain valid.

You must rebuild or drop and re-create an unusable index or index partition before using it.

The following procedure illustrates how to make an index and index partition unusable, and how to query the object status.

To make an index unusable:

1. Query the data dictionary to determine whether an existing index or index partition is usable or unusable.

For example, issue the following query (output truncated to save space):

```
hr@PROD> SELECT INDEX_NAME AS "INDEX OR PART NAME", STATUS, SEGMENT_CREATED
  2  FROM  USER_INDEXES
  3 UNION ALL
  4  SELECT PARTITION_NAME AS "INDEX OR PART NAME", STATUS, SEGMENT_CREATED
  5  FROM  USER_IND_PARTITIONS;

INDEX OR PART NAME          STATUS    SEG
-----
I_EMP_ENAME                  N/A      N/A
JHIST_EMP_ID_ST_DATE_PK     VALID    YES
JHIST_JOB_IX                 VALID    YES
JHIST_EMPLOYEE_IX            VALID    YES
JHIST_DEPARTMENT_IX          VALID    YES
EMP_EMAIL_UK                  VALID    NO
.
.
.
COUNTRY_C_ID_PK              VALID    YES
REG_ID_PK                     VALID    YES
P2_I_EMP_ENAME                USABLE   YES
P1_I_EMP_ENAME                UNUSABLE NO

22 rows selected.
```

The preceding output shows that only index partition `p1_i_emp_ename` is unusable.

2. Make an index or index partition unusable by specifying the `UNUSABLE` keyword.

The following example makes index `emp_email_uk` unusable:

```
hr@PROD> ALTER INDEX emp_email_uk UNUSABLE;
```

Index altered.

The following example makes index partition `p2_i_emp_ename` unusable:

```
hr@PROD> ALTER INDEX i_emp_ename MODIFY PARTITION p2_i_emp_ename UNUSABLE;
```

Index altered.

3. (Optional) Query the data dictionary to verify the status change.

For example, issue the following query (output truncated to save space):

```
hr@PROD> SELECT INDEX_NAME AS "INDEX OR PARTITION NAME", STATUS,
  2  SEGMENT_CREATED
  3  FROM  USER_INDEXES
  4 UNION ALL
  5  SELECT PARTITION_NAME AS "INDEX OR PARTITION NAME", STATUS,
  6  SEGMENT_CREATED
  7  FROM  USER_IND_PARTITIONS;
```

INDEX OR PARTITION NAME	STATUS	SEG
I_EMP_ENAME	N/A	N/A
JHIST_EMP_ID_ST_DATE_PK	VALID	YES
JHIST_JOB_IX	VALID	YES
JHIST_EMPLOYEE_IX	VALID	YES
JHIST_DEPARTMENT_IX	VALID	YES
EMP_EMAIL_UK	UNUSABLE	NO
.		
.		
.		

```
COUNTRY_C_ID_PK          VALID    YES
REG_ID_PK                VALID    YES
P2_I_EMP_ENAME           UNUSABLE NO
P1_I_EMP_ENAME           UNUSABLE NO
```

22 rows selected.

A query of space consumed by the `i_emp_ename` and `emp_email_uk` segments shows that the segments no longer exist:

```
hr@PROD> SELECT SEGMENT_NAME, BYTES
  2  FROM  USER_SEGMENTS
  3 WHERE  SEGMENT_NAME IN ('I_EMP_ENAME', 'EMP_EMAIL_UK');

no rows selected
```

See Also:

- ["Understand When to Use Unusable or Invisible Indexes"](#)
- ["Creating an Unusable Index"](#)
- *Oracle Database SQL Language Reference* for more information about the `UNUSABLE` keyword, including restrictions

21.4.5 Making an Index Invisible or Visible

Making an index invisible is an alternative to making it unusable or dropping it.

An invisible index is ignored by the optimizer unless you explicitly set the `OPTIMIZER_USE_INVISIBLE_INDEXES` initialization parameter to `TRUE` at the session or system level. You cannot make an individual index partition invisible. Attempting to do so produces an error.

To make an index invisible:

- Submit the following SQL statement:

```
ALTER INDEX index INVISIBLE;
```

To make an invisible index visible again:

- Submit the following SQL statement:

```
ALTER INDEX index VISIBLE;
```

Note:

If there are multiple indexes on the same set of columns, then only one of these indexes can be visible at any point in time. If you try to make an index on a set of columns visible, and another index on the same set of columns is visible, then an error is returned.

To determine whether an index is visible or invisible:

- Query the dictionary views USER_INDEXES, ALL_INDEXES, or DBA_INDEXES.

For example, to determine if the index `IND1` is invisible, issue the following query:

```
SELECT INDEX_NAME, VISIBILITY FROM USER_INDEXES
  WHERE INDEX_NAME = 'IND1';

INDEX_NAME      VISIBILITY
-----  -----
IND1            VISIBLE
```

 **See Also:**

- "[Understand When to Use Unusable or Invisible Indexes](#)"
- "[Creating an Invisible Index](#)"
- "[Creating Multiple Indexes on the Same Set of Columns](#)"

21.4.6 Renaming an Index

You can rename an index using an `ALTER INDEX` statement with the `RENAME` clause.

To rename an index, issue this statement:

```
ALTER INDEX index_name RENAME TO new_name;
```

21.4.7 Monitoring Index Usage

Oracle Database provides a means of monitoring indexes to determine whether they are being used. If an index is not being used, then it can be dropped, eliminating unnecessary statement overhead.

To start monitoring the usage of an index, issue this statement:

```
ALTER INDEX index MONITORING USAGE;
```

Later, issue the following statement to stop the monitoring:

```
ALTER INDEX index NOMONITORING USAGE;
```

The view `USER_OBJECT_USAGE` can be queried for the index being monitored to see if the index has been used. The view contains a `USED` column whose value is `YES` or `NO`, depending upon if the index has been used within the time period being monitored. The view also contains the start and stop times of the monitoring period, and a `MONITORING` column (`YES/NO`) to indicate if usage monitoring is currently active.

Each time that you specify `MONITORING USAGE`, the `USER_OBJECT_USAGE` view is reset for the specified index. The previous usage information is cleared or reset, and a new start time is recorded. When you specify `NOMONITORING USAGE`, no further monitoring is performed, and the end time is recorded for the monitoring period. Until the next `ALTER`

INDEX...MONITORING USAGE statement is issued, the view information is left unchanged.

21.5 Monitoring Space Use of Indexes

If key values in an index are inserted, updated, and deleted frequently, then the index can lose its acquired space efficiency over time.

Monitor index efficiency of space usage at regular intervals by first analyzing the index structure, using the ANALYZE INDEX...VALIDATE STRUCTURE statement, and then querying the INDEX_STATS view:

```
SELECT PCT_USED FROM INDEX_STATS WHERE NAME = 'index';
```

The percentage of index space usage varies according to how often index keys are inserted, updated, or deleted. Develop a history of average efficiency of space usage for an index by performing the following sequence of operations several times:

- Analyzing statistics
- Validating the index
- Checking PCT_USED
- Dropping and rebuilding (or coalescing) the index

When you find that index space usage drops below its average, you can condense the index space by dropping the index and rebuilding it, or coalescing it.

 **See Also:**

["About Analyzing Tables, Indexes, and Clusters"](#)

21.6 Dropping Indexes

You can drop an index with the DROP INDEX statement.

To drop an index, the index must be contained in your schema, or you must have the DROP ANY INDEX system privilege.

Some reasons for dropping an index include:

- The index is no longer required.
- The index is not providing anticipated performance improvements for queries issued against the associated table. For example, the table might be very small, or there might be many rows in the table but very few index entries.
- Applications do not use the index to query the data.
- The index has become invalid and must be dropped before being rebuilt.
- The index has become too fragmented and must be dropped before being rebuilt.

When you drop an index, all extents of the index segment are returned to the containing tablespace and become available for other objects in the tablespace.

How you drop an index depends on whether you created the index explicitly with a `CREATE INDEX` statement, or implicitly by defining a key constraint on a table. If you created the index explicitly with the `CREATE INDEX` statement, then you can drop the index with the `DROP INDEX` statement. The following statement drops the `emp_ename` index:

```
DROP INDEX emp_ename;
```

You cannot drop only the index associated with an enabled `UNIQUE` key or `PRIMARY KEY` constraint. To drop a constraints associated index, you must disable or drop the constraint itself.

 **Note:**

If a table is dropped, all associated indexes are dropped automatically.

 **See Also:**

- [Oracle Database SQL Language Reference](#) for syntax and restrictions on the use of the `DROP INDEX` statement
- ["Managing Integrity Constraints"](#)
- ["Making an Index Invisible or Visible"](#) for an alternative to dropping indexes

21.7 Indexes Data Dictionary Views

You can query a set of data dictionary views for information about indexes.

The following views display information about indexes:

View	Description
DBA_INDEXES	DBA view describes indexes on all tables in the database. ALL view describes indexes on all tables accessible to the user. USER view is restricted to indexes owned by the user. Some columns in these views contain statistics that are generated by the DBMS_STATS package or ANALYZE statement.
ALL_INDEXES	
USER_INDEXES	
DBA_IND_COLUMNS	These views describe the columns of indexes on tables. Some columns in these views contain statistics that are generated by the DBMS_STATS package or ANALYZE statement.
ALL_IND_COLUMNS	
USER_IND_COLUMNS	
DBA_IND_PARTITIONS	These views display, for each index partition, the partition-level partitioning information, the storage parameters for the partition, and various partition statistics that are generated by the DBMS_STATS package.
ALL_IND_PARTITIONS	
IND_PARTITIONS	
USER_IND_PARTITIONS	

View	Description
DBA_IND_EXPRESSIONS	These views describe the expressions of function-based indexes on tables.
ALL_IND_EXPRESSIONS	
USER_IND_EXPRESSIONS	
DBA_IND_STATISTICS	These views contain optimizer statistics for indexes.
ALL_IND_STATISTICS	
USER_IND_STATISTICS	
INDEX_STATS	Stores information from the last ANALYZE INDEX...VALIDATE STRUCTURE statement.
INDEX_HISTOGRAM	Stores information from the last ANALYZE INDEX...VALIDATE STRUCTURE statement.
USER_OBJECT_USAGE	Contains index usage information produced by the ALTER INDEX...MONITORING USAGE functionality.

Managing Clusters

Using clusters can improve performance and reduce disk space requirements.

- [About Clusters](#)

A **cluster** provides an optional method of storing table data. A cluster is made up of a group of tables that share the same data blocks. The tables are grouped together because they share common columns and are often used together.

- [Guidelines for Managing Clusters](#)

You can follow guidelines for managing clusters.

- [Creating Clusters and Objects That Use Them](#)

You create a cluster using the `CREATE CLUSTER` statement. You create clustered table using the `CREATE TABLE` statement with the `CLUSTER` clause. You create a cluster index using the `CREATE INDEX` statement with the `CLUSTER` clause.

- [Altering Clusters and Objects That Use Them](#)

You can alter a cluster to change its physical attributes, size, and default degree of parallelism.

- [Dropping Clusters and Objects That Use Them](#)

You drop a cluster using the `DROP CLUSTER` statement. You drop a clustered table using the `DROP TABLE` statement. You drop a cluster index using the `DROP INDEX` statement.

- [Clusters Data Dictionary Views](#)

You can query a set of data dictionary views for information about clusters.

22.1 About Clusters

A **cluster** provides an optional method of storing table data. A cluster is made up of a group of tables that share the same data blocks. The tables are grouped together because they share common columns and are often used together.

For example, the `emp` and `dept` table share the `deptno` column. When you cluster the `emp` and `dept` tables (see [Figure 22-1](#)), Oracle Database physically stores all rows for each department from both the `emp` and `dept` tables in the same data blocks.

Because clusters store related rows of different tables together in the same data blocks, properly used clusters offer two primary benefits:

- Disk I/O is reduced and access time improves for joins of clustered tables.
- The **cluster key** is the column, or group of columns, that the clustered tables have in common. You specify the columns of the cluster key when creating the cluster. You subsequently specify the same columns when creating every table added to the cluster. Each cluster key value is stored only once each in the cluster and the cluster index, no matter how many rows of different tables contain the value.

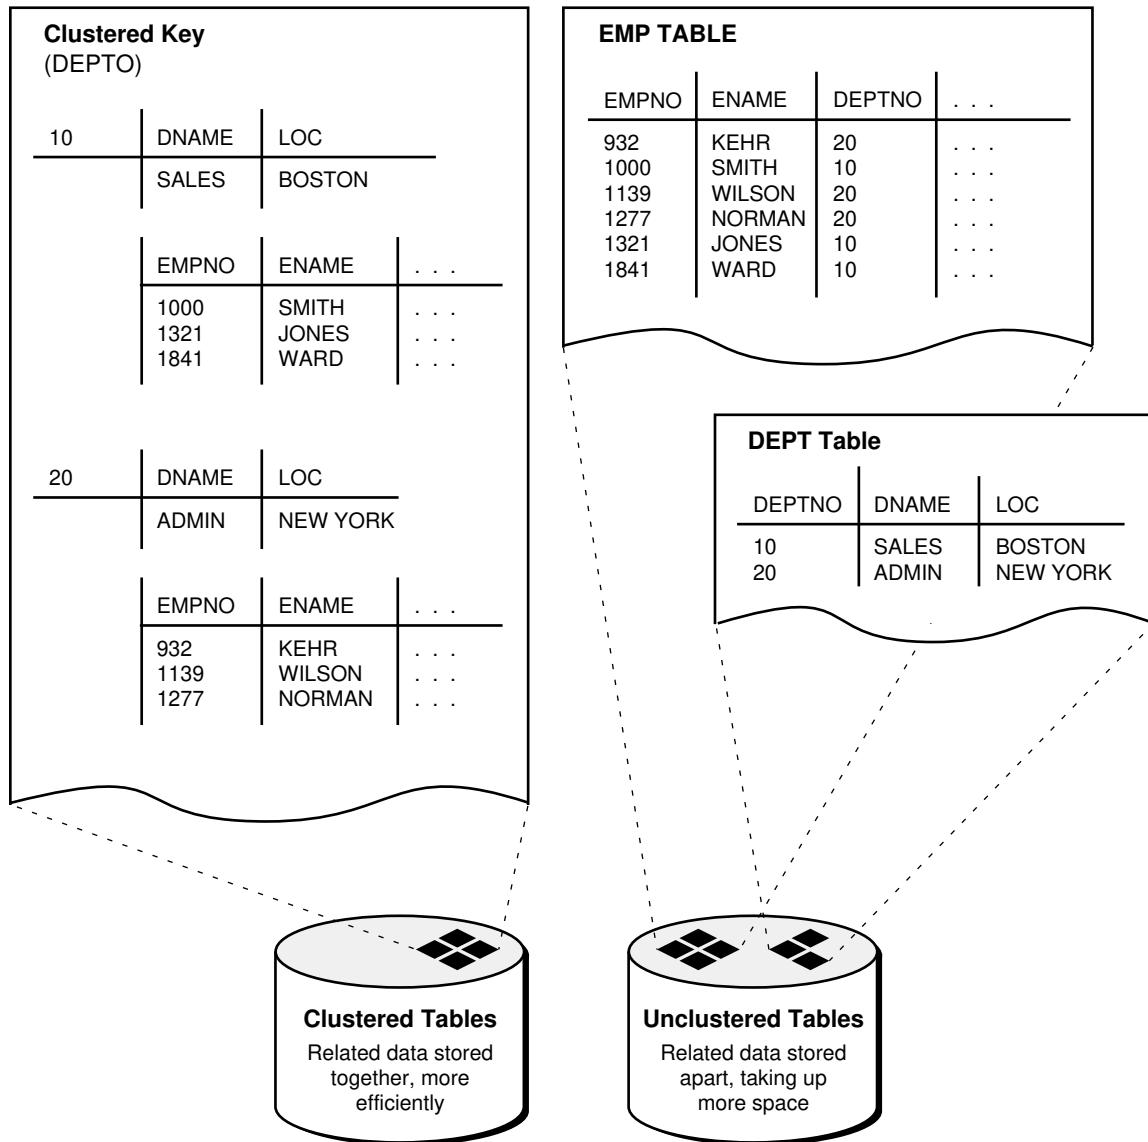

Therefore, less storage might be required to store related table and index data in a cluster than is necessary in non-clustered table format. For example, in

[Figure 22-1](#), notice how each cluster key (each deptno) is stored just once for many rows that contain the same value in both the emp and dept tables.

After creating a cluster, you can create tables in the cluster. However, before any rows can be inserted into the clustered tables, a cluster index must be created. Using clusters does not affect the creation of additional indexes on the clustered tables; they can be created and dropped as usual.

You should not use clusters for tables that are frequently accessed individually.

Figure 22-1 Clustered Table Data

 **See Also:**

- [Managing Hash Clusters](#) for a description of another type of cluster: a hash cluster
- [Managing Space for Schema Objects](#) is recommended reading before attempting tasks described in this chapter

22.2 Guidelines for Managing Clusters

You can follow guidelines for managing clusters.

- [Choose Appropriate Tables for the Cluster](#)
Use clusters for tables that are primarily queries and frequently queried together.
- [Choose Appropriate Columns for the Cluster Key](#)
Choose cluster key columns carefully. If multiple columns are used in queries that join the tables, make the cluster key a composite key. In general, the characteristics that indicate a good cluster index are the same as those for any index.
- [Specify the Space Required by an Average Cluster Key and Its Associated Rows](#)
The CREATE CLUSTER statement has an optional clause, SIZE, which is the estimated number of bytes required by an average cluster key and its associated rows.
- [Specify the Location of Each Cluster and Cluster Index Rows](#)
Always specify the TABLESPACE clause in a CREATE CLUSTER/INDEX statement to identify the tablespace to store the new cluster or index.
- [Estimate Cluster Size and Set Storage Parameters](#)
Before creating a cluster, estimate the cluster size and set the storage parameters for the data segments of a cluster.

 **See Also:**

- *Oracle Database Concepts* for more information about clusters
- *Oracle Database SQL Tuning Guide* for guidelines on when to use clusters

22.2.1 Choose Appropriate Tables for the Cluster

Use clusters for tables that are primarily queries and frequently queried together.

Use clusters for tables for which the following conditions are true:

- The tables are primarily queried--that is, tables that are *not* predominantly inserted into or updated.
- Records from the tables are frequently queried together or joined.

22.2.2 Choose Appropriate Columns for the Cluster Key

Choose cluster key columns carefully. If multiple columns are used in queries that join the tables, make the cluster key a composite key. In general, the characteristics that indicate a good cluster index are the same as those for any index.

For information about characteristics of a good index, see "[Guidelines for Managing Indexes](#)".

A good cluster key has enough unique values so that the group of rows corresponding to each key value fills approximately one data block. Having too few rows for each cluster key value can waste space and result in negligible performance gains. Cluster keys that are so specific that only a few rows share a common value can cause wasted space in blocks, unless a small `SIZE` was specified at cluster creation time (see "[Specify the Space Required by an Average Cluster Key and Its Associated Rows](#)").

Too many rows for each cluster key value can cause extra searching to find rows for that key. Cluster keys on values that are too general (for example, `male` and `female`) result in excessive searching and can result in worse performance than with no clustering.

A cluster index cannot be unique or include a column defined as `long`.

22.2.3 Specify the Space Required by an Average Cluster Key and Its Associated Rows

The `CREATE CLUSTER` statement has an optional clause, `SIZE`, which is the estimated number of bytes required by an average cluster key and its associated rows.

The database uses the `SIZE` parameter when performing the following tasks:

- Estimating the number of cluster keys (and associated rows) that can fit in a clustered data block
- Limiting the number of cluster keys placed in a clustered data block. This maximizes the storage efficiency of keys within a cluster.

`SIZE` does not limit the space that can be used by a given cluster key. For example, if `SIZE` is set such that two cluster keys can fit in one data block, any amount of the available data block space can still be used by either of the cluster keys.

By default, the database stores only one cluster key and its associated rows in each data block of the cluster data segment. Although block size can vary from one operating system to the next, the rule of one key for each block is maintained as clustered tables are imported to other databases on other systems.

If all the rows for a given cluster key value cannot fit in one block, the blocks are chained together to speed access to all the values with the given key. The cluster index points to the beginning of the chain of blocks, each of which contains the cluster key value and associated rows. If the cluster `SIZE` is such that multiple keys fit in a block, then blocks can belong to multiple chains.

22.2.4 Specify the Location of Each Cluster and Cluster Index Rows

Always specify the TABLESPACE clause in a CREATE CLUSTER/INDEX statement to identify the tablespace to store the new cluster or index.

If you have the proper privileges and tablespace quota, you can create a new cluster and the associated cluster index in any tablespace that is currently online.

The cluster and its cluster index can be created in different tablespaces. In fact, creating a cluster and its index in different tablespaces that are stored on different storage devices allows table data and index data to be retrieved simultaneously with minimal disk contention.

22.2.5 Estimate Cluster Size and Set Storage Parameters

Before creating a cluster, estimate the cluster size and set the storage parameters for the data segments of a cluster.

The following are benefits of estimating cluster size before creating the cluster:

- You can use the combined estimated size of clusters, along with estimates for indexes and redo log files, to determine the amount of disk space that is required to hold an intended database. From these estimates, you can make correct hardware purchases and other decisions.
- You can use the estimated size of an individual cluster to better manage the disk space that the cluster will use. When a cluster is created, you can set appropriate storage parameters and improve I/O performance of applications that use the cluster.

Set the storage parameters for the data segments of a cluster using the STORAGE clause of the CREATE CLUSTER or ALTER CLUSTER statement, rather than the individual CREATE or ALTER statements that put tables into the cluster. Storage parameters specified when creating or altering a clustered table are ignored. The storage parameters set for the cluster override the table storage parameters.

22.3 Creating Clusters and Objects That Use Them

You create a cluster using the CREATE CLUSTER statement. You create clustered table using the CREATE TABLE statement with the CLUSTER clause. You create a cluster index using the CREATE INDEX statement with the CLUSTER clause.

- [Creating Clusters](#)
You create a cluster using the CREATE CLUSTER statement.
- [Creating Clustered Tables](#)
You create a table in a cluster using the CREATE TABLE statement with the CLUSTER clause.
- [Creating Cluster Indexes](#)
A cluster index must be created before any rows can be inserted into any clustered table.

22.3.1 Creating Clusters

You create a cluster using the `CREATE CLUSTER` statement.

To create a cluster in your schema, you must have the `CREATE CLUSTER` system privilege and a quota for the tablespace intended to contain the cluster or the `UNLIMITED TABLESPACE` system privilege.

To create a cluster in another user's schema you must have the `CREATE ANY CLUSTER` system privilege, and the owner must have a quota for the tablespace intended to contain the cluster or the `UNLIMITED TABLESPACE` system privilege.

The following statement creates a cluster named `emp_dept`, which stores the `emp` and `dept` tables, clustered by the `deptno` column:

```
CREATE CLUSTER emp_dept (deptno NUMBER(3))
  SIZE 600
  TABLESPACE users
  STORAGE (INITIAL 200K
    NEXT 300K
    MINEXTENTS 2
    PCTINCREASE 33);
```

If no `INDEX` keyword is specified, as is true in this example, an index cluster is created by default. You can also create a `HASH` cluster, when hash parameters (`HASHKEYS`, `HASH IS`, or `SINGLE TABLE HASHKEYS`) are specified. Hash clusters are described in [Managing Hash Clusters](#).

22.3.2 Creating Clustered Tables

You create a table in a cluster using the `CREATE TABLE` statement with the `CLUSTER` clause.

To create a table in a cluster, you must have either the `CREATE TABLE` or `CREATE ANY TABLE` system privilege. You do not need a tablespace quota or the `UNLIMITED TABLESPACE` system privilege to create a table in a cluster.

For example, the `emp` and `dept` tables can be created in the `emp_dept` cluster using the following statements:

```
CREATE TABLE emp (
  empno NUMBER(5) PRIMARY KEY,
  ename VARCHAR2(15) NOT NULL,
  . . .
  deptno NUMBER(3) REFERENCES dept)
  CLUSTER emp_dept (deptno);

CREATE TABLE dept (
  deptno NUMBER(3) PRIMARY KEY, . . . )
  CLUSTER emp_dept (deptno);
```

 **Note:**

You can specify the schema for a clustered table in the `CREATE TABLE` statement. A clustered table can be in a different schema than the schema containing the cluster. Also, the names of the columns are not required to match, but their structure must match.

 **See Also:**

Oracle Database SQL Language Reference for syntax of the `CREATE TABLE` statement for creating cluster tables

22.3.3 Creating Cluster Indexes

A cluster index must be created before any rows can be inserted into any clustered table.

To create a cluster index, one of the following conditions must be true:

- Your schema contains the cluster.
- You have the `CREATE ANY INDEX` system privilege.

In either case, you must also have either a quota for the tablespace intended to contain the cluster index, or the `UNLIMITED TABLESPACE` system privilege.

The following statement creates a cluster index for the `emp_dept` cluster:

```
CREATE INDEX emp_dept_index
  ON CLUSTER emp_dept
  TABLESPACE users
  STORAGE (INITIAL 50K
           NEXT 50K
           MINEXTENTS 2
           MAXEXTENTS 10
           PCTINCREASE 33);
```

The cluster index clause (`ON CLUSTER`) identifies the cluster, `emp_dept`, for which the cluster index is being created. The statement also explicitly specifies several storage settings for the cluster and cluster index.

 **See Also:**

Oracle Database SQL Language Reference for syntax of the `CREATE INDEX` statement for creating cluster indexes

22.4 Altering Clusters and Objects That Use Them

You can alter a cluster to change its physical attributes, size, and default degree of parallelism.

- [Altering Clusters](#)
You alter a cluster using the `ALTER CLUSTER` statement.
- [Altering Clustered Tables](#)
You can alter clustered tables using the `ALTER TABLE` statement, but some parameters of a clustered table cannot be set with the `ALTER TABLE` statement.
- [Altering Cluster Indexes](#)
You alter cluster indexes exactly as you do other indexes.

22.4.1 Altering Clusters

You alter a cluster using the `ALTER CLUSTER` statement.

To alter a cluster, your schema must contain the cluster or you must have the `ALTER ANY CLUSTER` system privilege. You can alter an existing cluster to change the following settings:

- Physical attributes (`INITRANS` and storage characteristics)
- The average amount of space required to store all the rows for a cluster key value (`SIZE`)
- The default degree of parallelism

Additionally, you can explicitly allocate a new extent for the cluster, or deallocate any unused extents at the end of the cluster. The database dynamically allocates additional extents for the data segment of a cluster as required. In some circumstances, however, you might want to explicitly allocate an additional extent for a cluster. For example, when using Real Application Clusters, you can allocate an extent of a cluster explicitly for a specific instance. You allocate a new extent for a cluster using the `ALTER CLUSTER` statement with the `ALLOCATE EXTENT` clause.

When you alter the cluster size parameter (`SIZE`) of a cluster, the new settings apply to all data blocks used by the cluster, including blocks already allocated and blocks subsequently allocated for the cluster. Blocks already allocated for the table are reorganized when necessary (not immediately).

When you alter the transaction entry setting `INITRANS` of a cluster, the new setting for `INITRANS` applies only to data blocks subsequently allocated for the cluster.

The storage parameters `INITIAL` and `MINEXTENTS` cannot be altered. All new settings for the other storage parameters affect only extents subsequently allocated for the cluster.

To alter a cluster, use the `ALTER CLUSTER` statement.

 **See Also:**

Oracle Database SQL Language Reference for syntax of the `ALTER CLUSTER` statement

22.4.2 Altering Clustered Tables

You can alter clustered tables using the `ALTER TABLE` statement, but some parameters of a clustered table cannot be set with the `ALTER TABLE` statement.

However, any data block space parameters, transaction entry parameters, or storage parameters you set in an `ALTER TABLE` statement for a clustered table generate an error message (ORA-01771, illegal option for a clustered table). The database uses the parameters of the cluster for all clustered tables. Therefore, you can use the `ALTER TABLE` statement only to add or modify columns, drop non-cluster-key columns, or add, drop, enable, or disable integrity constraints or triggers for a clustered table. For information about altering tables, see "[Altering Tables](#)".

 **See Also:**

Oracle Database SQL Language Reference for syntax of the `ALTER TABLE` statement

22.4.3 Altering Cluster Indexes

You alter cluster indexes exactly as you do other indexes.

See "[Altering Indexes](#)".

 **Note:**

When estimating the size of cluster indexes, remember that the index is on each cluster key, not the actual rows. Therefore, each key appears only once in the index.

22.5 Dropping Clusters and Objects That Use Them

You drop a cluster using the `DROP CLUSTER` statement. You drop a clustered table using the `DROP TABLE` statement. You drop a cluster index using the `DROP INDEX` statement.

- [Dropping Clusters](#)

You can drop a cluster using the `DROP CLUSTER` statement.

- **Dropping Clustered Tables**
Clustered tables can be dropped individually without affecting the cluster, other clustered tables, or the cluster index. A clustered table is dropped just as a nonclustered table is dropped, with the `DROP TABLE` statement.
- **Dropping Cluster Indexes**
A cluster index can be dropped without affecting the cluster or its clustered tables. However, clustered tables cannot be used if there is no cluster index; you must re-create the cluster index to allow access to the cluster.

22.5.1 Dropping Clusters

You can drop a cluster using the `DROP CLUSTER` statement.

A cluster can be dropped if the tables within the cluster are no longer needed. When a cluster is dropped, so are the tables within the cluster and the corresponding cluster index. All extents belonging to both the cluster data segment and the index segment of the cluster index are returned to the containing tablespace and become available for other segments within the tablespace.

To drop a cluster that contains no tables, and its cluster index, use the `DROP CLUSTER` statement. For example, the following statement drops the empty cluster named `emp_dept`:

```
DROP CLUSTER emp_dept;
```

If the cluster contains one or more clustered tables and you intend to drop the tables as well, add the `INCLUDING TABLES` clause of the `DROP CLUSTER` statement, as follows:

```
DROP CLUSTER emp_dept INCLUDING TABLES;
```

If the `INCLUDING TABLES` clause is not included and the cluster contains tables, an error is returned.

If one or more tables in a cluster contain primary or unique keys that are referenced by `FOREIGN KEY` constraints of tables outside the cluster, the cluster cannot be dropped unless the dependent `FOREIGN KEY` constraints are also dropped. This can be easily done using the `CASCADE CONSTRAINTS` clause of the `DROP CLUSTER` statement, as shown in the following example:

```
DROP CLUSTER emp_dept INCLUDING TABLES CASCADE CONSTRAINTS;
```

The database returns an error if you do not use the `CASCADE CONSTRAINTS` clause and constraints exist.

See Also:

Oracle Database SQL Language Reference for syntax of the `DROP CLUSTER` statement

22.5.2 Dropping Clustered Tables

Clustered tables can be dropped individually without affecting the cluster, other clustered tables, or the cluster index. A clustered table is dropped just as a nonclustered table is dropped, with the `DROP TABLE` statement.

To drop a cluster, your schema must contain the cluster or you must have the `DROP ANY CLUSTER` system privilege. You do not need additional privileges to drop a cluster that contains tables, even if the clustered tables are not owned by the owner of the cluster.

See "[Dropping Table Columns](#)".

 **Note:**

When you drop a single table from a cluster, the database deletes each row of the table individually. To maximize efficiency when you intend to drop an entire cluster, drop the cluster including all tables by using the `DROP CLUSTER` statement with the `INCLUDING TABLES` clause. Drop an individual table from a cluster (using the `DROP TABLE` statement) only if you want the rest of the cluster to remain.

22.5.3 Dropping Cluster Indexes

A cluster index can be dropped without affecting the cluster or its clustered tables. However, clustered tables cannot be used if there is no cluster index; you must re-create the cluster index to allow access to the cluster.

Cluster indexes are sometimes dropped as part of the procedure to rebuild a fragmented cluster index.

 **Note:**

Hash cluster indexes cannot be dropped.

 **See Also:**

["Dropping Indexes"](#)

22.6 Clusters Data Dictionary Views

You can query a set of data dictionary views for information about clusters.

The following views display information about clusters:

View	Description
DBA_CLUSTERS	DBA view describes all clusters in the database. ALL view describes all clusters accessible to the user. USER view is restricted to clusters owned by the user. Some columns in these views contain statistics that are generated by the DBMS_STATS package or ANALYZE statement.
ALL_CLUSTERS	
USER_CLUSTERS	
DBA_CLU_COLUMNS	These views map table columns to cluster columns
USER_CLU_COLUMNS	

See Also:

Oracle Database Reference for complete descriptions of these views

Managing Hash Clusters

Hash clusters can improve the performance of data retrieval.

- [About Hash Clusters](#)

Storing a table in a hash cluster is an optional way to improve the performance of data retrieval. A hash cluster provides an alternative to a non-clustered table with an index or an index cluster.

- [When to Use Hash Clusters](#)

You can decide when to use hash clusters by contrasting situations where hashing is most useful against situations where there is no advantage. If you find your decision is to use indexing rather than hashing, then you should consider whether to store a table individually or as part of a cluster.

- [Creating Different Types of Hash Clusters](#)

You can use the `CREATE CLUSTER` statement with the `HASHKEYS` clause to create different types of hash clusters.

- [Altering Hash Clusters](#)

You can alter a hash cluster with the `ALTER CLUSTER` statement.

- [Dropping Hash Clusters](#)

You can drop a hash cluster using the `DROP CLUSTER` statement.

- [Hash Clusters Data Dictionary Views](#)

You can query a set of data dictionary views for information about hash clusters.

23.1 About Hash Clusters

Storing a table in a hash cluster is an optional way to improve the performance of data retrieval. A hash cluster provides an alternative to a non-clustered table with an index or an index cluster.

With an indexed table or index cluster, Oracle Database locates the rows in a table using key values that the database stores in a separate index. To use hashing, you create a hash cluster and load tables into it. The database physically stores the rows of a table in a hash cluster and retrieves them according to the results of a **hash function**.

Oracle Database uses a hash function to generate a distribution of numeric values, called **hash values**, that are based on specific cluster key values. The key of a hash cluster, like the key of an index cluster, can be a single column or composite key (multiple column key). To find or store a row in a hash cluster, the database applies the hash function to the cluster key value of the row. The resulting hash value corresponds to a data block in the cluster, which the database then reads or writes on behalf of the issued statement.

To find or store a row in an indexed table or cluster, a minimum of two (there are usually more) I/Os must be performed:

- One or more I/Os to find or store the key value in the index

- Another I/O to read or write the row in the table or cluster

In contrast, the database uses a hash function to locate a row in a hash cluster; no I/O is required. As a result, a minimum of one I/O operation is necessary to read or write a row in a hash cluster.

 **See Also:**

[Managing Space for Schema Objects](#) is recommended reading before attempting tasks described in this chapter.

23.2 When to Use Hash Clusters

You can decide when to use hash clusters by contrasting situations where hashing is most useful against situations where there is no advantage. If you find your decision is to use indexing rather than hashing, then you should consider whether to store a table individually or as part of a cluster.

 **Note:**

Even if you decide to use hashing, a table can still have separate indexes on any columns, including the cluster key.

- [Situations Where Hashing Is Useful](#)

Hashing is useful when most queries are equality queries on the cluster key and the tables in the hash cluster are primarily static in size.

- [Situations Where Hashing Is Not Advantageous](#)

Hashing is not advantageous in certain situations.

23.2.1 Situations Where Hashing Is Useful

Hashing is useful when most queries are equality queries on the cluster key and the tables in the hash cluster are primarily static in size.

Hashing is useful when you have the following conditions:

- Most queries are equality queries on the cluster key:

```
SELECT ... WHERE cluster_key = ...;
```

In such cases, the cluster key in the equality condition is hashed, and the corresponding hash key is usually found with a single read. In comparison, for an indexed table the key value must first be found in the index (usually several reads), and then the row is read from the table (another read).

- The tables in the hash cluster are primarily static in size so that you can determine the number of rows and amount of space required for the tables in the cluster. If tables in a hash cluster require more space than the initial allocation for the cluster, performance degradation can be substantial because overflow blocks are required.

23.2.2 Situations Where Hashing Is Not Advantageous

Hashing is not advantageous in certain situations.

Hashing is not advantageous in the following situations:

- Most queries on the table retrieve rows over a range of cluster key values. For example, in full table scans or queries such as the following, a hash function cannot be used to determine the location of specific hash keys. Instead, the equivalent of a full table scan must be done to fetch the rows for the query.

```
SELECT . . . WHERE cluster_key < . . . ;
```

With an index, key values are ordered in the index, so cluster key values that satisfy the `WHERE` clause of a query can be found with relatively few I/Os.

- The table is not static, but instead is continually growing. If a table grows without limit, the space required over the life of the table (its cluster) cannot be predetermined.
- Applications frequently perform full-table scans on the table and the table is sparsely populated. A full-table scan in this situation takes longer under hashing.
- You cannot afford to preallocate the space that the hash cluster will eventually need.

23.3 Creating Different Types of Hash Clusters

You can use the `CREATE CLUSTER` statement with the `HASHKEYS` clause to create different types of hash clusters.

- [Creating Hash Clusters](#)

You create a hash cluster using a `CREATE CLUSTER` statement, but you specify a `HASHKEYS` clause.

- [Creating a Sorted Hash Cluster](#)

A **sorted hash cluster** stores the rows corresponding to each value of the hash function in such a way that the database can efficiently return them in sorted order. For applications that always consume data in sorted order, sorted hash clusters can retrieve data faster by minimizing logical I/Os.

- [Creating Single-Table Hash Clusters](#)

You can create a **single-table hash cluster**, which provides fast access to rows in a table. However, this table must be the only table in the hash cluster.

- [Controlling Space Use Within a Hash Cluster](#)

When creating a hash cluster, it is important to choose the cluster key correctly and set the `HASH IS`, `SIZE`, and `HASHKEYS` parameters so that performance and space use are optimal. The following guidelines describe how to set these parameters.

- [Estimating Size Required by Hash Clusters](#)

As with index clusters, it is important to estimate the storage required for the data in a hash cluster.

23.3.1 Creating Hash Clusters

You create a hash cluster using a `CREATE CLUSTER` statement, but you specify a `HASHKEYS` clause.

The following statement creates a cluster named `trial_cluster`, clustered by the `trialno` column (the cluster key):

```
CREATE CLUSTER trial_cluster ( trialno NUMBER(5,0) )
  TABLESPACE users
  STORAGE ( INITIAL 250K
    NEXT 50K
    MINEXTENTS 1
    MAXEXTENTS 3
    PCTINCREASE 0 )
  HASH IS trialno
  HASHKEYS 150;
```

The following statement creates the `trial` table in the `trial_cluster` hash cluster:

```
CREATE TABLE trial (
  trialno NUMBER(5,0) PRIMARY KEY,
  ...
  CLUSTER trial_cluster (trialno);
```

As with index clusters, the key of a hash cluster can be a single column or a composite key (multiple column key). In the preceding example, the key is the `trialno` column.

The `HASHKEYS` value, in this case 150, specifies and limits the number of unique hash values that the hash function can generate. The database rounds the number specified to the nearest prime number.

If no `HASH IS` clause is specified, then the database uses an internal hash function. If the cluster key is already a unique identifier that is uniformly distributed over its range, then you can bypass the internal hash function and specify the cluster key as the hash value, as in the preceding example. You can also use the `HASH IS` clause to specify a user-defined hash function.

You cannot create a cluster index on a hash cluster, and you need not create an index on a hash cluster key.

See Also:

[Managing Clusters](#) for additional information about creating tables in a cluster, guidelines for setting parameters of the `CREATE CLUSTER` statement common to index and hash clusters, and the privileges required to create any cluster

23.3.2 Creating a Sorted Hash Cluster

A **sorted hash cluster** stores the rows corresponding to each value of the hash function in such a way that the database can efficiently return them in sorted order. For

applications that always consume data in sorted order, sorted hash clusters can retrieve data faster by minimizing logical I/Os.

Assume that a telecommunications company stores detailed call records for a fixed number of originating telephone numbers through a telecommunications switch. From each originating telephone number there can be an unlimited number of calls.

The application stores calls records as calls are made. Each call has a detailed call record identified by a timestamp. For example, the application stores a call record with timestamp 0, then a call record with timestamp 1, and so on.

When generating bills for each originating phone number, the application processes them in first-in, first-out (FIFO) order. The following table shows sample details for three originating phone numbers:

telephone_number	call_timestamp
6505551212	0, 1, 2, 3, 4, ...
6505551213	0, 1, 2, 3, 4, ...
6505551214	0, 1, 2, 3, 4, ...

In the following SQL statements, the `telephone_number` column is the hash key. The hash cluster is sorted on the `call_timestamp` and `call_duration` columns. The example uses the same names for the clustering and sorting columns in the table definition as in the cluster definition, but this is not required. The number of hash keys is based on 10-digit telephone numbers.

```

CREATE CLUSTER call_detail_cluster (
    telephone_number NUMBER,
    call_timestamp    NUMBER SORT,
    call_duration     NUMBER SORT )
HASHKEYS 10000
HASH IS telephone_number
SIZE 256;

CREATE TABLE call_detail (
    telephone_number      NUMBER,
    call_timestamp        NUMBER   SORT,
    call_duration         NUMBER   SORT,
    other_info            VARCHAR2(30) )
CLUSTER call_detail_cluster (
    telephone_number, call_timestamp, call_duration );

```

Example 23-1 Data Inserted in Sequential Order

Suppose that you seed the `call_detail` table with the rows in FIFO order as shown in this example.

```

INSERT INTO call_detail VALUES (6505551212, 0, 9, 'misc info');
INSERT INTO call_detail VALUES (6505551212, 1, 17, 'misc info');
INSERT INTO call_detail VALUES (6505551212, 2, 5, 'misc info');
INSERT INTO call_detail VALUES (6505551212, 3, 90, 'misc info');
INSERT INTO call_detail VALUES (6505551213, 0, 35, 'misc info');
INSERT INTO call_detail VALUES (6505551213, 1, 6, 'misc info');
INSERT INTO call_detail VALUES (6505551213, 2, 4, 'misc info');
INSERT INTO call_detail VALUES (6505551213, 3, 4, 'misc info');
INSERT INTO call_detail VALUES (6505551214, 0, 15, 'misc info');
INSERT INTO call_detail VALUES (6505551214, 1, 20, 'misc info');
INSERT INTO call_detail VALUES (6505551214, 2, 1, 'misc info');

```

```
INSERT INTO call_detail VALUES (6505551214, 3, 25, 'misc info');
COMMIT;
```

Example 23-2 Querying call_detail

In this example, you SET AUTOTRACE ON, and then query the call_detail table for the call details for the phone number 6505551212.

```
SQL> SET AUTOTRACE ON;
SQL> SELECT * FROM call_detail WHERE telephone_number = 6505551212;
```

```
TELEPHONE_NUMBER CALL_TIMESTAMP CALL_DURATION OTHER_INFO
-----
6505551212          0            9 misc info
6505551212          1           17 misc info
6505551212          2            5 misc info
6505551212          3           90 misc info

Execution Plan
-----
Plan hash value: 2118876266

-----
| Id  | Operation          | Name      | Rows  | Bytes | Cost (%CPU) |
|   0 | SELECT STATEMENT   |           |     1 |    56 |      0 (0)  |
| * 1 |  TABLE ACCESS HASH | CALL_DETAIL|     1 |    56 |            |
-----
```

The query retrieves the rows ordered by timestamp even though no sort appears in the query plan.

Suppose you then delete the existing rows and insert the same rows out of sequence:

```
DELETE FROM call_detail;
INSERT INTO call_detail VALUES (6505551213, 3, 4, 'misc info');
INSERT INTO call_detail VALUES (6505551214, 0, 15, 'misc info');
INSERT INTO call_detail VALUES (6505551212, 0, 9, 'misc info');
INSERT INTO call_detail VALUES (6505551214, 1, 20, 'misc info');
INSERT INTO call_detail VALUES (6505551214, 2, 1, 'misc info');
INSERT INTO call_detail VALUES (6505551213, 1, 6, 'misc info');
INSERT INTO call_detail VALUES (6505551213, 2, 4, 'misc info');
INSERT INTO call_detail VALUES (6505551214, 3, 25, 'misc info');
INSERT INTO call_detail VALUES (6505551212, 1, 17, 'misc info');
INSERT INTO call_detail VALUES (6505551212, 2, 5, 'misc info');
INSERT INTO call_detail VALUES (6505551212, 3, 90, 'misc info');
INSERT INTO call_detail VALUES (6505551213, 0, 35, 'misc info');
COMMIT;
```

If you rerun the same query of call_detail, the database again retrieves the rows in sorted order even though no ORDER BY clause is specified. No SORT ORDER BY operation appears in the query plan because the database performs an internal sort.

Now assume that you create a nonclustered table call_detail_nonclustered and then load it with the same sample values in [Example 23-1](#). To retrieve the data in sorted order, you must use an ORDER BY clause as follows:

```
SQL> SELECT * FROM call_detail_nonclustered WHERE telephone_number = 6505551212
2 ORDER BY call_timestamp, call_duration;
```

```
TELEPHONE_NUMBER CALL_TIMESTAMP CALL_DURATION OTHER_INFO
```

6505551212	0	9 misc info																												
6505551212	1	17 misc info																												
6505551212	2	5 misc info																												
6505551212	3	90 misc info																												
Execution Plan																														
Plan hash value: 2555750302																														
<table border="1"> <thead> <tr><th>Id</th><th>Operation</th><th>Name</th><th>Rows</th><th>Bytes</th><th>Cost (%CPU)</th><th>Time</th></tr> </thead> <tbody> <tr><td>0</td><td>SELECT STATEMENT</td><td></td><td>4</td><td>224</td><td>4 (25)</td><td>00:00:01</td></tr> <tr><td>1</td><td>SORT ORDER BY</td><td></td><td>4</td><td>224</td><td>4 (25)</td><td>00:00:01</td></tr> <tr><td>*2</td><td>TABLE ACCESS FULL</td><td>CALL_DETAIL_NONCLUSTERED</td><td>4</td><td>224</td><td>3 (0)</td><td>00:00:01</td></tr> </tbody> </table>			Id	Operation	Name	Rows	Bytes	Cost (%CPU)	Time	0	SELECT STATEMENT		4	224	4 (25)	00:00:01	1	SORT ORDER BY		4	224	4 (25)	00:00:01	*2	TABLE ACCESS FULL	CALL_DETAIL_NONCLUSTERED	4	224	3 (0)	00:00:01
Id	Operation	Name	Rows	Bytes	Cost (%CPU)	Time																								
0	SELECT STATEMENT		4	224	4 (25)	00:00:01																								
1	SORT ORDER BY		4	224	4 (25)	00:00:01																								
*2	TABLE ACCESS FULL	CALL_DETAIL_NONCLUSTERED	4	224	3 (0)	00:00:01																								

The preceding plan shows that in the nonclustered case the sort is more expensive than in the clustered case. The rows, bytes, cost, and time are all greater in the case of the table that is not stored in a sorted hash cluster.

23.3.3 Creating Single-Table Hash Clusters

You can create a **single-table hash cluster**, which provides fast access to rows in a table. However, this table must be the only table in the hash cluster.

Essentially, there must be a one-to-one mapping between hash keys and data rows. The following statement creates a single-table hash cluster named peanut with the cluster key variety:

```
CREATE CLUSTER peanut (variety NUMBER)
  SIZE 512 SINGLE TABLE HASHKEYS 500;
```

The database rounds the HASHKEYS value up to the nearest prime number, so this cluster has a maximum of 503 hash key values, each of size 512 bytes. The SINGLE TABLE clause is valid only for hash clusters. HASHKEYS must also be specified.

See Also:

Oracle Database SQL Language Reference for the syntax of the CREATE CLUSTER statement

23.3.4 Controlling Space Use Within a Hash Cluster

When creating a hash cluster, it is important to choose the cluster key correctly and set the HASH IS, SIZE, and HASHKEYS parameters so that performance and space use are optimal. The following guidelines describe how to set these parameters.

- **Choosing the Key**

Choosing the correct cluster key is dependent on the most common types of queries issued against the clustered tables.

- **Setting HASH IS**
Specify the `HASH IS` parameter only if the cluster key is a single column of the `NUMBER` data type, and contains uniformly distributed integers.
- **Setting SIZE**
`SIZE` should be set to the average amount of space required to hold all rows for any given hash key.
- **Setting HASHKEYS**
Specify the `HASHKEYS` clause to create a hash cluster and specify the number of hash values for the hash cluster.
- **Controlling Space in Hash Clusters**
Examples illustrate how to correctly choose the cluster key and set the `HASH IS`, `SIZE`, and `HASHKEYS` parameters. For all examples, assume that the data block size is 2K and that on average, 1950 bytes of each block is available data space (block size minus overhead).

23.3.4.1 Choosing the Key

Choosing the correct cluster key is dependent on the most common types of queries issued against the clustered tables.

For example, consider the `emp` table in a hash cluster. If queries often select rows by employee number, the `empno` column should be the cluster key. If queries often select rows by department number, the `deptno` column should be the cluster key. For hash clusters that contain a single table, the cluster key is typically the entire primary key of the contained table.

The key of a hash cluster, like that of an index cluster, can be a single column or a composite key (multiple column key). A hash cluster with a composite key must use the internal hash function of the database.

23.3.4.2 Setting HASH IS

Specify the `HASH IS` parameter only if the cluster key is a single column of the `NUMBER` data type, and contains uniformly distributed integers.

If these conditions apply, you can distribute rows in the cluster so that each unique cluster key value hashes, with no collisions (two cluster key values having the same hash value), to a unique hash value. If these conditions do not apply, omit this clause so that you use the internal hash function.

23.3.4.3 Setting SIZE

`SIZE` should be set to the average amount of space required to hold all rows for any given hash key.

Therefore, to properly determine `SIZE`, you must be aware of the characteristics of your data:

- If the hash cluster is to contain only a single table and the hash key values of the rows in that table are unique (one row for each value), `SIZE` can be set to the average row size in the cluster.
- If the hash cluster is to contain multiple tables, `SIZE` can be set to the average amount of space required to hold all rows associated with a representative hash value.

Further, once you have determined a (preliminary) value for SIZE, consider the following. If the SIZE value is small (more than four hash keys can be assigned for each data block) you can use this value for SIZE in the CREATE CLUSTER statement. However, if the value of SIZE is large (four or fewer hash keys can be assigned for each data block), then you should also consider the expected frequency of collisions and whether performance of data retrieval or efficiency of space usage is more important to you.

- If the hash cluster does not use the internal hash function (if you specified HASH IS) and you expect few or no collisions, you can use your preliminary value of SIZE. No collisions occur and space is used as efficiently as possible.
- If you expect frequent collisions on inserts, the likelihood of overflow blocks being allocated to store rows is high. To reduce the possibility of overflow blocks and maximize performance when collisions are frequent, you should adjust SIZE as shown in the following chart.

Available Space for each Block / Calculated SIZE	Setting for SIZE
1	SIZE
2	SIZE + 15%
3	SIZE + 12%
4	SIZE + 8%
>4	SIZE

Overestimating the value of SIZE increases the amount of unused space in the cluster. If space efficiency is more important than the performance of data retrieval, disregard the adjustments shown in the preceding table and use the original value for SIZE.

23.3.4.4 Setting HASHKEYS

Specify the HASHKEYS clause to create a hash cluster and specify the number of hash values for the hash cluster.

For maximum distribution of rows in a hash cluster, the database rounds the HASHKEYS value up to the nearest prime number.

23.3.4.5 Controlling Space in Hash Clusters

Examples illustrate how to correctly choose the cluster key and set the HASH IS, SIZE, and HASHKEYS parameters. For all examples, assume that the data block size is 2K and that on average, 1950 bytes of each block is available data space (block size minus overhead).

- [Controlling Space in Hash Clusters: Example 1](#)
An example illustrates controlling space in hash clusters.
- [Controlling Space in Hash Clusters: Example 2](#)
An example illustrates controlling space in hash clusters.

23.3.4.5.1 Controlling Space in Hash Clusters: Example 1

An example illustrates controlling space in hash clusters.

You decide to load the `emp` table into a hash cluster. Most queries retrieve employee records by their employee number. You estimate that the maximum number of rows in the `emp` table at any given time is 10000 and that the average row size is 55 bytes.

In this case, `empno` should be the cluster key. Because this column contains integers that are unique, the internal hash function can be bypassed. `SIZE` can be set to the average row size, 55 bytes. Note that 34 hash keys are assigned for each data block. `HASHKEYS` can be set to the number of rows in the table, 10000. The database rounds this value up to the next highest prime number: 10007.

```
CREATE CLUSTER emp_cluster (empno
NUMBER)
.
.
SIZE 55
HASH IS empno HASHKEYS 10000;
```

23.3.4.5.2 Controlling Space in Hash Clusters: Example 2

An example illustrates controlling space in hash clusters.

In this example, conditions are similar to the example in "[Controlling Space in Hash Clusters: Example 1](#)". In this case, however, rows are usually retrieved by department number. At most, there are 1000 departments with an average of 10 employees for each department. Department numbers increment by 10 (0, 10, 20, 30, . . .).

In this case, `deptno` should be the cluster key. Since this column contains integers that are uniformly distributed, the internal hash function can be bypassed. A preliminary value of `SIZE` (the average amount of space required to hold all rows for each department) is 55 bytes * 10, or 550 bytes. Using this value for `SIZE`, only three hash keys can be assigned for each data block. If you expect some collisions and want maximum performance of data retrieval, slightly alter your estimated `SIZE` to prevent collisions from requiring overflow blocks. By adjusting `SIZE` by 12%, to 620 bytes (see "[Setting SIZE](#)"), there is more space for rows from expected collisions.

`HASHKEYS` can be set to the number of unique department numbers, 1000. The database rounds this value up to the next highest prime number: 1009.

```
CREATE CLUSTER emp_cluster (deptno NUMBER)
.
.
SIZE 620
HASH IS deptno HASHKEYS 1000;
```

23.3.5 Estimating Size Required by Hash Clusters

As with index clusters, it is important to estimate the storage required for the data in a hash cluster.

Oracle Database guarantees that the initial allocation of space is sufficient to store the hash table according to the settings `SIZE` and `HASHKEYS`. If settings for the storage parameters `INITIAL`, `NEXT`, and `MINEXTENTS` do not account for the hash table size, incremental (additional) extents are allocated until at least `SIZE*HASHKEYS` is reached. For example, assume that the data block size is 2K, the available data space for each block is approximately 1900 bytes (data block size minus overhead), and that the

STORAGE and HASH parameters are specified in the CREATE CLUSTER statement as follows:

```
STORAGE (INITIAL 100K
          NEXT 150K
          MINEXTENTS 1
          PCTINCREASE 0)
SIZE 1500
HASHKEYS 100
```

In this example, only one hash key can be assigned for each data block. Therefore, the initial space required for the hash cluster is at least $100*2K$ or 200K. The settings for the storage parameters do not account for this requirement. Therefore, an initial extent of 100K and a second extent of 150K are allocated to the hash cluster.

Alternatively, assume the HASH parameters are specified as follows:

```
SIZE 500 HASHKEYS 100
```

In this case, three hash keys are assigned to each data block. Therefore, the initial space required for the hash cluster is at least $34*2K$ or 68K. The initial settings for the storage parameters are sufficient for this requirement (an initial extent of 100K is allocated to the hash cluster).

23.4 Altering Hash Clusters

You can alter a hash cluster with the ALTER CLUSTER statement.

For example, the following ALTER CLUSTER statement alters the emp_dept cluster:

```
ALTER CLUSTER emp_dept . . . ;
```

The implications for altering a hash cluster are identical to those for altering an index cluster, described in "[Altering Clusters](#)". However, the SIZE, HASHKEYS, and HASH IS parameters cannot be specified in an ALTER CLUSTER statement. To change these parameters, you must re-create the cluster, then copy the data from the original cluster.

23.5 Dropping Hash Clusters

You can drop a hash cluster using the DROP CLUSTER statement.

For example, the following DROP CLUSTER statement drops the emp_dept cluster:

```
DROP CLUSTER emp_dept;
```

A table in a hash cluster is dropped using the DROP TABLE statement. The implications of dropping hash clusters and tables in hash clusters are the same as those for dropping index clusters.

["Dropping Clusters"](#)

23.6 Hash Clusters Data Dictionary Views

You can query a set of data dictionary views for information about hash clusters.

The following views display information about hash clusters:

View	Description
DBA_CLUSTERS	DBA view describes all clusters (including hash clusters) in the database. ALL view describes all clusters accessible to the user. USER view is restricted to clusters owned by the user. Some columns in these views contain statistics that are generated by the DBMS_STATS package or ANALYZE statement.
ALL_CLUSTERS	
USER_CLUSTERS	
DBA_CLU_COLUMNS	These views map table columns to cluster columns.
USER_CLU_COLUMNS	
DBA_CLUSTER_HASH_EXPRESSIONS	These views list hash functions for hash clusters.
ALL_CLUSTER_HASH_EXPRESSIONS	
USER_CLUSTER_HASH_EXPRESSIONS

Managing Views, Sequences, and Synonyms

You can create and manage views, sequences, and synonyms with Oracle Database.

- [Managing Views](#)

You can perform tasks such as creating views, replacing views, altering views, and dropping views.

- [Managing Sequences](#)

You can perform tasks such as creating sequences, altering sequences, using sequences, and dropping sequences.

- [Managing Synonyms](#)

You can perform tasks such as creating synonyms, using synonyms, and dropping synonyms.

- [Views, Synonyms, and Sequences Data Dictionary Views](#)

You can query data dictionary views for information about views, synonyms, and sequences.

24.1 Managing Views

You can perform tasks such as creating views, replacing views, altering views, and dropping views.

[Live SQL:](#)

To view and run examples related to managing views on Oracle Live SQL, go to [Oracle Live SQL: Creating, Replacing, and Dropping a View](#).

- [About Views](#)

A **view** is a logical representation of a table or combination of tables. In essence, a view is a stored query.

- [Creating Views and Join Views](#)

You can create views using the `CREATE VIEW` statement. Each view is defined by a query that references tables, materialized views, or other views. You can also create join views that specify multiple base tables or views in the `FROM` clause.

- [Replacing Views](#)

You can replace a view by dropping it and re-creating it or by issuing a `CREATE VIEW` statement that contains the `OR REPLACE` clause.

- [Using Views in Queries](#)

You can query a view. You can also perform data manipulation language (DML) operations on views, with some restrictions.

- [DML Statements and Join Views](#)
Restrictions apply when issuing DML statements on join views.
- [Altering Views](#)
You use the `ALTER VIEW` statement only to explicitly recompile a view that is invalid.
- [Dropping Views](#)
You can drop a view with the `DROP VIEW` statement.

24.1.1 About Views

A **view** is a logical representation of a table or combination of tables. In essence, a view is a stored query.

A view derives its data from the tables on which it is based. These tables are called **base tables**. Base tables might in turn be actual tables or might be views themselves. All operations performed on a view actually affect the base table of the view. You can use views in almost the same way as tables. You can query, update, insert into, and delete from views, just as you can standard tables.

Views can provide a different representation (such as subsets or supersets) of the data that resides within other tables and views. Views are very powerful because they allow you to tailor the presentation of data to different types of users.

 **Note:**

One special type of view is the editioning view, which is used only to support online upgrade of applications using edition-based redefinition. The remainder of this section on managing views describes all views except editioning views. See *Oracle Database Development Guide* for a discussion of editioning views and edition-based redefinition.

Oracle Database Concepts for an overview of views

24.1.2 Creating Views and Join Views

You can create views using the `CREATE VIEW` statement. Each view is defined by a query that references tables, materialized views, or other views. You can also create join views that specify multiple base tables or views in the `FROM` clause.

- [Creating Views](#)
You can create a view with the `CREATE VIEW` statement.
- [Creating Join Views](#)
You can also create views that specify multiple base tables or views in the `FROM` clause of a `CREATE VIEW` statement. These are called **join views**.

- **Expansion of Defining Queries at View Creation Time**
When a view is created, Oracle Database expands any wildcard (*) in a top-level view query into a column list. The resulting query is stored in the data dictionary; any subqueries are left intact.
- **Creating Views with Errors**
If there are no syntax errors in a CREATE VIEW statement, then the database can create the view even if the defining query of the view cannot be executed. In this case, the view is considered "created with errors."

24.1.2.1 Creating Views

You can create a view with the CREATE VIEW statement.

To create a view, you must meet the following requirements:

- To create a view in your schema, you must have the CREATE VIEW privilege. To create a view in another user's schema, you must have the CREATE ANY VIEW system privilege. You can acquire these privileges explicitly or through a role.
- The owner of the view (whether it is you or another user) must have been explicitly granted privileges to access all objects referenced in the view definition. The owner *cannot* have obtained these privileges through roles. Also, the functionality of the view depends on the privileges of the view owner. For example, if the owner of the view has only the INSERT privilege for Scott's emp table, then the view can be used only to insert new rows into the emp table, not to SELECT, UPDATE, or DELETE rows.
- If the owner of the view intends to grant access to the view to other users, the owner must have received the object privileges to the base objects with the GRANT OPTION or the system privileges with the ADMIN OPTION.

You can create views using the CREATE VIEW statement. Each view is defined by a query that references tables, materialized views, or other views. As with all subqueries, the query that defines a view cannot contain the FOR UPDATE clause.

The following statement creates a view on a subset of data in the hr.departments table:

```
CREATE VIEW departments_hq AS
    SELECT department_id, department_name, location_id
    FROM hr.departments
    WHERE location_id = 1700
    WITH CHECK OPTION CONSTRAINT departments_hq_cnst;
```

The query that defines the departments_hq view references only rows in location 1700. Furthermore, the CHECK OPTION creates the view with the constraint (named departments_hq_cnst) so that INSERT and UPDATE statements issued against the view cannot result in rows that the view cannot select. For example, the following INSERT statement successfully inserts a row into the departments table with the departments_hq view, which contains all rows with location 1700:

```
INSERT INTO departments_hq VALUES (300, 'NETWORKING', 1700);
```

However, the following INSERT statement returns an error because it attempts to insert a row for location 2700, which cannot be selected using the departments_hq view:

```
INSERT INTO departments_hq VALUES (301, 'TRANSPORTATION', 2700);
```

The view could have been constructed specifying the `WITH READ ONLY` clause, which prevents any updates, inserts, or deletes from being done to the base table through the view. If no `WITH` clause is specified, the view, with some restrictions, is inherently updatable.

You can also create views with invisible columns. For example, the following statements creates the `departments_hq_man` view and makes the `manager_id` column invisible:

```
CREATE VIEW departments_hq_man
  (department_id, department_name, manager_id INVISIBLE, location_id)
  AS SELECT department_id, department_name, manager_id, location_id
    FROM hr.departments
   WHERE location_id = 1700
  WITH CHECK OPTION CONSTRAINT departments_hq_man_cnst;
```

See Also:

- *Oracle Database SQL Language Reference* for syntax and semantics of the `CREATE VIEW` statement
- "[Understand Invisible Columns](#)"

24.1.2.2 Creating Join Views

You can also create views that specify multiple base tables or views in the `FROM` clause of a `CREATE VIEW` statement. These are called **join views**.

The following statement creates the `division1_staff` view that joins data from the `emp` and `dept` tables:

```
CREATE VIEW division1_staff AS
  SELECT ename, empno, job, dname
    FROM emp, dept
   WHERE emp.deptno IN (10, 30)
     AND emp.deptno = dept.deptno;
```

An **updatable join view** is a join view where `UPDATE`, `INSERT`, and `DELETE` operations are allowed. See "[Updating a Join View](#)" for further discussion.

24.1.2.3 Expansion of Defining Queries at View Creation Time

When a view is created, Oracle Database expands any wildcard (*) in a top-level view query into a column list. The resulting query is stored in the data dictionary; any subqueries are left intact.

The column names in an expanded column list are enclosed in quotation marks to account for the possibility that the columns of the base object were originally entered with quotes and require them for the query to be syntactically correct.

As an example, assume that the `dept` view is created as follows:

```
CREATE VIEW dept AS SELECT * FROM scott.dept;
```

The database stores the defining query of the `dept` view as:

```
SELECT "DEPTNO", "DNAME", "LOC" FROM scott.dept;
```

Views created with errors do not have wildcards expanded. However, if the view is eventually compiled without errors, wildcards in the defining query are expanded.

24.1.2.4 Creating Views with Errors

If there are no syntax errors in a `CREATE VIEW` statement, then the database can create the view even if the defining query of the view cannot be executed. In this case, the view is considered "created with errors."

For example, when a view is created that refers to a nonexistent table or an invalid column of an existing table, or when the view owner does not have the required privileges, the view can be created anyway and entered into the data dictionary. However, the view is not yet usable.

To create a view with errors, you must include the `FORCE` clause of the `CREATE VIEW` statement.

```
CREATE FORCE VIEW AS ...;
```

By default, views with errors are created as `INVALID`. When you try to create such a view, the database returns a message indicating the view was created with errors. If conditions later change so that the query of an invalid view can be executed, the view can be recompiled and be made valid (usable). For information changing conditions and their impact on views, see "[Managing Object Dependencies](#)".

24.1.3 Replacing Views

You can replace a view by dropping it and re-creating it or by issuing a `CREATE VIEW` statement that contains the `OR REPLACE` clause.

To replace a view, you must have all of the privileges required to drop and create a view. If the definition of a view must change, the view must be replaced; you cannot use an `ALTER VIEW` statement to change the definition of a view. You can replace views in the following ways:

- You can drop and re-create the view.

 **Note:**

When a view is dropped, all grants of corresponding object privileges are revoked from roles and users. After the view is re-created, privileges must be regranted.

- You can redefine the view with a `CREATE VIEW` statement that contains the `OR REPLACE` clause. The `OR REPLACE` clause replaces the current definition of a view and preserves the current security authorizations. For example, assume that you created the `sales_staff` view as shown earlier, and, in addition, you granted several object privileges to roles and other users. However, now you must redefine the `sales_staff` view to change the department number specified in the `WHERE` clause. You can replace the current version of the `sales_staff` view with the following statement:

```
CREATE OR REPLACE VIEW sales_staff AS
    SELECT empno, ename, deptno
    FROM emp
    WHERE deptno = 30
    WITH CHECK OPTION CONSTRAINT sales_staff_cnst;
```

Before replacing a view, consider the following effects:

- Replacing a view replaces the view definition in the data dictionary. All underlying objects referenced by the view are not affected.
- If a constraint in the `CHECK OPTION` was previously defined but not included in the new view definition, the constraint is dropped.
- All views dependent on a replaced view become invalid (not usable). In addition, dependent PL/SQL program units may become invalid, depending on what was changed in the new version of the view. For example, if only the `WHERE` clause of the view changes, dependent PL/SQL program units remain valid. However, if any changes are made to the number of view columns or to the view column names or data types, dependent PL/SQL program units are invalidated. See "[Managing Object Dependencies](#)" for more information on how the database manages such dependencies.

24.1.4 Using Views in Queries

You can query a view. You can also perform data manipulation language (DML) operations on views, with some restrictions.

To issue a query or an `INSERT`, `UPDATE`, or `DELETE` statement against a view, you must have the `SELECT`, `READ`, `INSERT`, `UPDATE`, or `DELETE` object privilege for the view, respectively, either explicitly or through a role.

Views can be queried in the same manner as tables. For example, to query the `Division1_staff` view, enter a valid `SELECT` statement that references the view:

```
SELECT * FROM Division1_staff;
```

ENAME	EMPNO	JOB	DNAME
<hr/>			
CLARK	7782	MANAGER	ACCOUNTING
KING	7839	PRESIDENT	ACCOUNTING
MILLER	7934	CLERK	ACCOUNTING
ALLEN	7499	SALESMAN	SALES
WARD	7521	SALESMAN	SALES
JAMES	7900	CLERK	SALES
TURNER	7844	SALESMAN	SALES
MARTIN	7654	SALESMAN	SALES
BLAKE	7698	MANAGER	SALES

With some restrictions, rows can be inserted into, updated in, or deleted from a base table using a view. The following statement inserts a new row into the `emp` table using the `sales_staff` view:

```
INSERT INTO sales_staff
    VALUES (7954, 'OSTER', 30);
```

Restrictions on DML operations for views use the following criteria in the order listed:

1. If a view is defined by a query that contains SET or DISTINCT operators, a GROUP BY clause, or a group function, then rows cannot be inserted into, updated in, or deleted from the base tables using the view.
2. If a view is defined with WITH CHECK OPTION, a row cannot be inserted into, or updated in, the base table (using the view), if the view cannot select the row from the base table.
3. If a NOT NULL column that does not have a DEFAULT clause is omitted from the view, then a row cannot be inserted into the base table using the view.
4. If the view was created by using an expression, such as DECODE(deptno, 10, "SALES", ...), then rows cannot be inserted into or updated in the base table using the view.

The constraint created by WITH CHECK OPTION of the sales_staff view only allows rows that have a department number of 30 to be inserted into, or updated in, the emp table. Alternatively, assume that the sales_staff view is defined by the following statement (that is, excluding the deptno column):

```
CREATE VIEW sales_staff AS
  SELECT empno, ename
    FROM emp
   WHERE deptno = 10
  WITH CHECK OPTION CONSTRAINT sales_staff_cnst;
```

Considering this view definition, you can update the empno or ename fields of existing records, but you cannot insert rows into the emp table through the sales_staff view because the view does not let you alter the deptno field. If you had defined a DEFAULT value of 10 on the deptno field, then you could perform inserts.

When a user attempts to reference an invalid view, the database returns an error message to the user:

```
ORA-04063: view 'view_name' has errors
```

This error message is returned when a view exists but is unusable due to errors in its query (whether it had errors when originally created or it was created successfully but became unusable later because underlying objects were altered or dropped).

24.1.5 DML Statements and Join Views

Restrictions apply when issuing DML statements on join views.

- **Updating a Join View**

An updatable join view (also referred to as a **modifiable join view**) is a view that contains multiple tables in the top-level FROM clause of the SELECT statement, and is not restricted by the WITH READ ONLY clause.

- **Key-Preserved Tables**

The concept of a **key-preserved table** is fundamental to understanding the restrictions on modifying join views. A table is key-preserved if every key of the table can also be a key of the result of the join. So, a key-preserved table has its keys preserved through a join.

- **Rules for DML Statements and Join Views**

The general rule is that any UPDATE, DELETE, or INSERT statement on a join view can modify only one underlying base table.

- [Updating Views That Involve Outer Joins](#)
Views that involve outer joins are modifiable in some cases.
- [Using the UPDATABLE_COLUMNS Views](#)
A set of views can assist you in identifying inherently updatable join views.

24.1.5.1 Updating a Join View

An updatable join view (also referred to as a **modifiable join view**) is a view that contains multiple tables in the top-level `FROM` clause of the `SELECT` statement, and is not restricted by the `WITH READ ONLY` clause.

The rules for updatable join views are shown in the following table. Views that meet these criteria are said to be inherently updatable.

Rule	Description
General Rule	Any <code>INSERT</code> , <code>UPDATE</code> , or <code>DELETE</code> operation on a join view can modify only one underlying base table at a time.
UPDATE Rule	All updatable columns of a join view must map to columns of a key-preserved table . See " Key-Preserved Tables " for a discussion of key-preserved tables. If the view is defined with the <code>WITH CHECK OPTION</code> clause, then all join columns and all columns of repeated tables are not updatable.
DELETE Rule	Rows from a join view can be deleted as long as there is exactly one key-preserved table in the join. The key preserved table can be repeated in the <code>FROM</code> clause. If the view is defined with the <code>WITH CHECK OPTION</code> clause and the key preserved table is repeated, then the rows cannot be deleted from the view.
INSERT Rule	An <code>INSERT</code> statement must not explicitly or implicitly refer to the columns of a non-key-preserved table . If the join view is defined with the <code>WITH CHECK OPTION</code> clause, <code>INSERT</code> statements are not permitted.

There are data dictionary views that indicate whether the columns in a join view are inherently updatable. See "[Using the UPDATABLE_COLUMNS Views](#)" for descriptions of these views.

 **Note:**

There are some additional restrictions and conditions that can affect whether a join view is inherently updatable. Specifics are listed in the description of the `CREATE VIEW` statement in the *Oracle Database SQL Language Reference*.

If a view is not inherently updatable, it can be made updatable by creating an `INSTEAD OF` trigger on it. See *Oracle Database PL/SQL Language Reference* for information about triggers.

Additionally, if a view is a join on other nested views, then the other nested views must be mergeable into the top level view. For a discussion of mergeable and unmergeable views, and more generally, how the optimizer optimizes statements that reference views, see the *Oracle Database SQL Tuning Guide*.

Examples illustrating the rules for inherently updatable join views, and a discussion of key-preserved tables, are presented in following sections. The examples in these sections work only if you explicitly define the primary and foreign keys in the tables, or define unique indexes. The following statements create the appropriately constrained table definitions for `emp` and `dept`.

```
CREATE TABLE dept (
    deptno      NUMBER(4) PRIMARY KEY,
    dname       VARCHAR2(14),
    loc         VARCHAR2(13));

CREATE TABLE emp (
    empno       NUMBER(4) PRIMARY KEY,
    ename       VARCHAR2(10),
    job         VARCHAR2(9),
    mgr         NUMBER(4),
    sal         NUMBER(7,2),
    comm        NUMBER(7,2),
    deptno     NUMBER(2),
    FOREIGN KEY (DEPTNO) REFERENCES DEPT(DEPTNO));
```

You could also omit the primary and foreign key constraints listed in the preceding example, and create a `UNIQUE INDEX` on `dept` (`deptno`) to make the following examples work.

The following statement created the `emp_dept` join view which is referenced in the examples:

```
CREATE VIEW emp_dept AS
    SELECT emp.empno, emp.ename, emp.deptno, emp.sal, dept.dname, dept.loc
    FROM emp, dept
    WHERE emp.deptno = dept.deptno
        AND dept.loc IN ('DALLAS', 'NEW YORK', 'BOSTON');
```

24.1.5.2 Key-Preserved Tables

The concept of a **key-preserved table** is fundamental to understanding the restrictions on modifying join views. A table is key-preserved if every key of the table can also be a key of the result of the join. So, a key-preserved table has its keys preserved through a join.

 **Note:**

It is not necessary that the key or keys of a table be selected for it to be key preserved. It is sufficient that if the key or keys were selected, then they would also be keys of the result of the join.

The key-preserving property of a table does not depend on the actual data in the table. It is, rather, a property of its schema. For example, if in the `emp` table there was at most one employee in each department, then `deptno` would be unique in the result of a join of `emp` and `dept`, but `dept` would still not be a key-preserved table.

If you select all rows from `emp_dept`, the results are:

EMPNO	ENAME	DEPTNO	DNAME	LOC
-----	-----	-----	-----	-----

```

7782 CLARK      10 ACCOUNTING    NEW YORK
7839 KING       10 ACCOUNTING    NEW YORK
7934 MILLER     10 ACCOUNTING    NEW YORK
7369 SMITH      20 RESEARCH      DALLAS
7876 ADAMS      20 RESEARCH      DALLAS
7902 FORD        20 RESEARCH      DALLAS
7788 SCOTT      20 RESEARCH      DALLAS
7566 JONES      20 RESEARCH      DALLAS
8 rows selected.

```

In this view, `emp` is a key-preserved table, because `empno` is a key of the `emp` table, and also a key of the result of the join. `dept` is *not* a key-preserved table, because although `deptno` is a key of the `dept` table, it is not a key of the join.

24.1.5.3 Rules for DML Statements and Join Views

The general rule is that any `UPDATE`, `DELETE`, or `INSERT` statement on a join view can modify only one underlying base table.

- [UPDATE Statements and Join Views](#)

Examples illustrate `UPDATE` statements that can modify join views.

- [DELETE Statements and Join Views](#)

For most join views, a delete is successful only if there is *one and only one* key-preserved table in the join. The key-preserved table can be repeated in the `FROM` clause.

- [INSERT Statements and Join Views](#)

Examples illustrate `INSERT` statements that can modify join views.

24.1.5.3.1 UPDATE Statements and Join Views

Examples illustrate `UPDATE` statements that can modify join views.

The following example shows an `UPDATE` statement that successfully modifies the `emp_dept` view:

```
UPDATE emp_dept
   SET sal = sal * 1.10
 WHERE deptno = 10;
```

The following `UPDATE` statement would be disallowed on the `emp_dept` view:

```
UPDATE emp_dept
   SET loc = 'BOSTON'
 WHERE ename = 'SMITH';
```

This statement fails with an error (ORA-01779 cannot modify a column which maps to a non key-preserved table), because it attempts to modify the base `dept` table, and the `dept` table is not key-preserved in the `emp_dept` view.

In general, all updatable columns of a join view must map to columns of a key-preserved table. If the view is defined using the `WITH CHECK OPTION` clause, then all join columns and all columns taken from tables that are referenced more than once in the view are not modifiable.

So, for example, if the `emp_dept` view were defined using `WITH CHECK OPTION`, the following `UPDATE` statement would fail:

```
UPDATE emp_dept
   SET deptno = 10
 WHERE ename = 'SMITH';
```

The statement fails because it is trying to update a join column.

 **See Also:**

Oracle Database SQL Language Reference for syntax and additional information about the UPDATE statement

24.1.5.3.2 DELETE Statements and Join Views

For most join views, a delete is successful only if there is *one and only one* key-preserved table in the join. The key-preserved table can be repeated in the FROM clause.

The following DELETE statement works on the emp_dept view:

```
DELETE FROM emp_dept
   WHERE ename = 'SMITH';
```

This DELETE statement on the emp_dept view is legal because it can be translated to a DELETE operation on the base emp table, and because the emp table is the only key-preserved table in the join.

In the following view, a DELETE operation is permitted, because although there are two key-preserved tables, they are the same table. That is, the key-preserved table is repeated. In this case, the delete statement operates on the first table in the FROM clause (e1, in this example):

```
CREATE VIEW emp_emp AS
  SELECT e1.ename, e2.empno, e2.deptno
    FROM emp e1, emp e2
   WHERE e1.empno = e2.empno;
```

If a view is defined using the WITH CHECK OPTION clause and the key-preserved table is repeated, rows cannot be deleted from such a view.

```
CREATE VIEW emp_mgr AS
  SELECT e1.ename, e2.ename mname
    FROM emp e1, emp e2
   WHERE e1.mgr = e2.empno
 WITH CHECK OPTION;
```

 **Note:**

- If the `DELETE` statement uses the same column in its `WHERE` clause that was used to create the view as a join condition, then the delete operation can be successful when there are different key-preserved tables in the join. In this case, the `DELETE` statement operates on the first table in the `FROM` clause, and the tables in the `FROM` clause can be different from the tables in the `WHERE` clause.
- The `DELETE` statement is successful, even if it does not use the `WHERE` clause.
- The `DELETE` statement is successful, even if it uses a different column in its `WHERE` clause than the one that was used to create the view as a join condition.
- The `DELETE` statement operates on the second table in the `FROM` clause in all the cases, because no primary key is defined on the second table.
- If a primary key is defined on the second table, then the `DELETE` statement operates on the first table in the `FROM` clause.

 **See Also:**

Oracle Database SQL Language Reference for syntax and additional information about the `DELETE` statement

24.1.5.3.3 INSERT Statements and Join Views

Examples illustrate `INSERT` statements that can modify join views.

The following `INSERT` statement on the `emp_dept` view succeeds:

```
INSERT INTO emp_dept (ename, empno, deptno)
VALUES ('KURODA', 9010, 40);
```

This statement works because only one key-preserved base table is being modified (`emp`), and 40 is a valid `deptno` in the `dept` table (thus satisfying the `FOREIGN KEY` integrity constraint on the `emp` table).

An `INSERT` statement, such as the following, would fail for the same reason that such an `UPDATE` on the base `emp` table would fail: the `FOREIGN KEY` integrity constraint on the `emp` table is violated (because there is no `deptno` 77).

```
INSERT INTO emp_dept (ename, empno, deptno)
VALUES ('KURODA', 9010, 77);
```

The following `INSERT` statement would fail with an error (ORA-01776 cannot modify more than one base table through a join view):

```
INSERT INTO emp_dept (empno, ename, loc)
VALUES (9010, 'KURODA', 'BOSTON');
```

An `INSERT` cannot implicitly or explicitly refer to columns of a non-key-preserved table. If the join view is defined using the `WITH CHECK OPTION` clause, then you cannot perform an `INSERT` to it.

See Also:

Oracle Database SQL Language Reference for syntax and additional information about the `INSERT` statement

24.1.5.4 Updating Views That Involve Outer Joins

Views that involve outer joins are modifiable in some cases.

For example:

```
CREATE VIEW emp_dept_oj1 AS
  SELECT empno, ename, e.deptno, dname, loc
    FROM emp e, dept d
   WHERE e.deptno = d.deptno (+);
```

The statement:

```
SELECT * FROM emp_dept_oj1;
```

Results in:

EMPNO	ENAME	DEPTNO	DNAME	LOC
7369	SMITH	40	OPERATIONS	BOSTON
7499	ALLEN	30	SALES	CHICAGO
7566	JONES	20	RESEARCH	DALLAS
7654	MARTIN	30	SALES	CHICAGO
7698	BLAKE	30	SALES	CHICAGO
7782	CLARK	10	ACCOUNTING	NEW YORK
7788	SCOTT	20	RESEARCH	DALLAS
7839	KING	10	ACCOUNTING	NEW YORK
7844	TURNER	30	SALES	CHICAGO
7876	ADAMS	20	RESEARCH	DALLAS
7900	JAMES	30	SALES	CHICAGO
7902	FORD	20	RESEARCH	DALLAS
7934	MILLER	10	ACCOUNTING	NEW YORK
7521	WARD	30	SALES	CHICAGO

14 rows selected.

Columns in the base `emp` table of `emp_dept_oj1` are modifiable through the view, because `emp` is a key-preserved table in the join.

The following view also contains an outer join:

```
CREATE VIEW emp_dept_oj2 AS
  SELECT e.empno, e.ename, e.deptno, d.dname, d.loc
    FROM emp e, dept d
   WHERE e.deptno (+) = d.deptno;
```

The following statement:

```
SELECT * FROM emp_dept_oj2;
```

Results in:

EMPNO	ENAME	DEPTNO	DNAME	LOC
7782	CLARK	10	ACCOUNTING	NEW YORK
7839	KING	10	ACCOUNTING	NEW YORK
7934	MILLER	10	ACCOUNTING	NEW YORK
7369	SMITH	20	RESEARCH	DALLAS
7876	ADAMS	20	RESEARCH	DALLAS
7902	FORD	20	RESEARCH	DALLAS
7788	SCOTT	20	RESEARCH	DALLAS
7566	JONES	20	RESEARCH	DALLAS
7499	ALLEN	30	SALES	CHICAGO
7698	BLAKE	30	SALES	CHICAGO
7654	MARTIN	30	SALES	CHICAGO
7900	JAMES	30	SALES	CHICAGO
7844	TURNER	30	SALES	CHICAGO
7521	WARD	30	SALES	CHICAGO
			OPERATIONS	BOSTON

15 rows selected.

In this view, `emp` is no longer a key-preserved table, because the `empno` column in the result of the join can have nulls (the last row in the preceding `SELECT` statement). So, `UPDATE`, `DELETE`, and `INSERT` operations cannot be performed on this view.

In the case of views containing an outer join on other nested views, a table is key preserved if the view or views containing the table are merged into their outer views, all the way to the top. A view which is being outer-joined is currently merged only if it is "simple." For example:

```
SELECT col1, col2, ... FROM T;
```

The select list of the view has no expressions.

If you are in doubt whether a view is modifiable, then you can select from the `USER_UPDATABLE_COLUMNS` view to see if it is. For example:

```
SELECT owner, table_name, column_name, updatable FROM USER_UPDATABLE_COLUMNS
WHERE TABLE_NAME = 'EMP_DEPT_VIEW';
```

This returns output similar to the following:

OWNER	TABLE_NAME	COLUMN_NAM	UPD
SCOTT	EMP_DEPT_V	EMPNO	NO
SCOTT	EMP_DEPT_V	ENAME	NO
SCOTT	EMP_DEPT_V	DEPTNO	NO
SCOTT	EMP_DEPT_V	DNAME	NO
SCOTT	EMP_DEPT_V	LOC	NO

5 rows selected.

24.1.5.5 Using the UPDATABLE_COLUMNS Views

A set of views can assist you in identifying inherently updatable join views.

View	Description
DBA_UPDATABLE_COLUMNS	Shows all columns in all tables and views that are modifiable.

View	Description
ALL_UPDATABLE_COLUMNS	Shows all columns in all tables and views accessible to the user that are modifiable.
USER_UPDATABLE_COLUMNS	Shows all columns in all tables and views in the user's schema that are modifiable.

The updatable columns in view emp_dept are shown below.

```
SELECT COLUMN_NAME, UPDATABLE
      FROM USER_UPDATABLE_COLUMNS
     WHERE TABLE_NAME = 'EMP_DEPT';
```

COLUMN_NAME	UPD
EMPNO	YES
ENAME	YES
DEPTNO	YES
SAL	YES
DNAME	NO
LOC	NO

6 rows selected.

See Also:

Oracle Database Reference for complete descriptions of the updatable column views

24.1.6 Altering Views

You use the `ALTER VIEW` statement only to explicitly recompile a view that is invalid.

To change the definition of a view, see "[Replacing Views](#)".

The `ALTER VIEW` statement lets you locate recompilation errors before run time. To ensure that the alteration does not affect the view or other objects that depend on it, you can explicitly recompile a view after altering one of its base tables.

To use the `ALTER VIEW` statement, the view must be in your schema, or you must have the `ALTER ANY TABLE` system privilege.

See Also:

Oracle Database SQL Language Reference for syntax and additional information about the `ALTER VIEW` statement

24.1.7 Dropping Views

You can drop a view with the `DROP VIEW` statement.

You can drop any view contained in your schema. To drop a view in another user's schema, you must have the `DROP ANY VIEW` system privilege. Drop a view using the `DROP VIEW` statement. For example, the following statement drops the `emp_dept` view:

```
DROP VIEW emp_dept;
```

 **See Also:**

Oracle Database SQL Language Reference for syntax and additional information about the `DROP VIEW` statement

24.2 Managing Sequences

You can perform tasks such as creating sequences, altering sequences, using sequences, and dropping sequences.

- [About Sequences](#)
Sequences are database objects from which multiple users can generate unique integers. The sequence generator generates sequential numbers, which can be used to generate unique primary keys automatically, and to coordinate keys across multiple rows or tables.
- [Creating Sequences](#)
Create a sequence using the `CREATE SEQUENCE` statement.
- [Altering Sequences](#)
Alter a sequence using the `ALTER SEQUENCE` statement.
- [Using Sequences](#)
A sequence can be accessed and incremented by multiple users.
- [Dropping Sequences](#)
If a sequence is no longer required, you can drop the sequence using the `DROP SEQUENCE` statement.

24.2.1 About Sequences

Sequences are database objects from which multiple users can generate unique integers. The sequence generator generates sequential numbers, which can be used to generate unique primary keys automatically, and to coordinate keys across multiple rows or tables.

Without sequences, sequential values can only be produced programmatically. A new primary key value can be obtained by selecting the most recently produced value and incrementing it. This method requires a lock during the transaction and causes multiple users to wait for the next value of the primary key; this waiting is known as **serialization**. If developers have such constructs in applications, then you should

encourage the developers to replace them with access to sequences. Sequences eliminate serialization and improve the concurrency of an application.

 **See Also:**

Oracle Database Concepts for an overview of sequences

24.2.2 Creating Sequences

Create a sequence using the `CREATE SEQUENCE` statement.

To create a sequence in your schema, you must have the `CREATE SEQUENCE` system privilege. To create a sequence in another user's schema, you must have the `CREATE ANY SEQUENCE` privilege.

For example, the following statement creates a sequence used to generate employee numbers for the `empno` column of the `emp` table:

```
CREATE SEQUENCE emp_sequence
    INCREMENT BY 1
    START WITH 1
    NOMAXVALUE
    NOCYCLE
    CACHE 10;
```

Notice that several parameters can be specified to control the function of sequences. You can use these parameters to indicate whether the sequence is ascending or descending, the starting point of the sequence, the minimum and maximum values, and the interval between sequence values. The `NOCYCLE` option indicates that the sequence cannot generate more values after reaching its maximum or minimum value.

The `CACHE` clause preallocates a set of sequence numbers and keeps them in memory so that sequence numbers can be accessed faster. When the last of the sequence numbers in the cache has been used, the database reads another set of numbers into the cache.

The database might skip sequence numbers if you choose to cache a set of sequence numbers. For example, when an instance abnormally shuts down (for example, when an instance failure occurs or a `SHUTDOWN ABORT` statement is issued), sequence numbers that have been cached but not used are lost. Also, sequence numbers that have been used but not saved are lost as well. The database might also skip cached sequence numbers after an export and import. See *Oracle Database Utilities* for details.

 **See Also:**

- *Oracle Database SQL Language Reference* for the CREATE SEQUENCE statement syntax
- *Oracle Real Application Clusters Administration and Deployment Guide* for information about using sequences in an Oracle Real Application Clusters environment

24.2.3 Altering Sequences

Alter a sequence using the ALTER SEQUENCE statement.

To alter a sequence, your schema must contain the sequence, you must have the ALTER object privilege on the sequence, or you must have the ALTER ANY SEQUENCE system privilege. You can alter a sequence to change any of the parameters that define how it generates sequence numbers except the sequence starting number. To change the starting point of a sequence, drop the sequence and then re-create it.

For example, the following statement alters the emp_sequence:

```
ALTER SEQUENCE emp_sequence
    INCREMENT BY 10
    MAXVALUE 10000
    CYCLE
    CACHE 20;
```

 **See Also:**

Oracle Database SQL Language Reference for syntax and additional information about the ALTER SEQUENCE statement

24.2.4 Using Sequences

A sequence can be accessed and incremented by multiple users.

To use a sequence, your schema must contain the sequence or you must have been granted the SELECT object privilege for another user's sequence. Once a sequence is defined, it can be accessed and incremented by multiple users (who have SELECT object privilege for the sequence containing the sequence) with no waiting. The database does not wait for a transaction that has incremented a sequence to complete before that sequence can be incremented again.

The examples outlined in the following sections show how sequences can be used in master/detail table relationships. Assume an order entry system is partially comprised of two tables, `orders_tab` (master table) and `line_items_tab` (detail table), that hold information about customer orders. A sequence named `order_seq` is defined by the following statement:

```
CREATE SEQUENCE Order_seq
    START WITH 1
    INCREMENT BY 1
    NOMAXVALUE
    NOCYCLE
    CACHE 20;
```

- **Referencing a Sequence**

A sequence is referenced in SQL statements with the `NEXTVAL` and `CURRVAL` pseudocolumns; each new sequence number is generated by a reference to the sequence pseudocolumn `NEXTVAL`, while the current sequence number can be repeatedly referenced using the pseudo-column `CURRVAL`.

- **Caching Sequence Numbers**

Caching sequence numbers can improve access time.

24.2.4.1 Referencing a Sequence

A sequence is referenced in SQL statements with the `NEXTVAL` and `CURRVAL` pseudocolumns; each new sequence number is generated by a reference to the sequence pseudocolumn `NEXTVAL`, while the current sequence number can be repeatedly referenced using the pseudo-column `CURRVAL`.

`NEXTVAL` and `CURRVAL` are not reserved words or keywords and can be used as pseudocolumn names in SQL statements such as `SELECT`, `INSERT`, or `UPDATE`.

- **Generating Sequence Numbers with `NEXTVAL`**

To generate and use a sequence number, reference `seq_name.NEXTVAL` in a SQL statement.

- **Using Sequence Numbers with `CURRVAL`**

To use or refer to the current sequence value of your session, reference `seq_name.CURRVAL` in a SQL statement.

- **Uses and Restrictions of `NEXTVAL` and `CURRVAL`**

`CURRVAL` and `NEXTVAL` can be used in specific places, and restrictions apply to their use.

24.2.4.1.1 Generating Sequence Numbers with `NEXTVAL`

To generate and use a sequence number, reference `seq_name.NEXTVAL` in a SQL statement.

For example, assume a customer places an order. The sequence number can be referenced in a values list. For example:

```
INSERT INTO Orders_tab (Orderno, Custno)
    VALUES (Order_seq.NEXTVAL, 1032);
```

Or, the sequence number can be referenced in the `SET` clause of an `UPDATE` statement. For example:

```
UPDATE Orders_tab
    SET Orderno = Order_seq.NEXTVAL
    WHERE Orderno = 10112;
```

The sequence number can also be referenced outermost `SELECT` of a query or subquery. For example:

```
SELECT Order_seq.NEXTVAL FROM dual;
```

As defined, the first reference to `order_seq.NEXTVAL` returns the value 1. Each subsequent statement that references `order_seq.NEXTVAL` generates the next sequence number (2, 3, 4, . . .). The pseudo-column `NEXTVAL` can be used to generate as many new sequence numbers as necessary. However, only a single sequence number can be generated for each row. In other words, if `NEXTVAL` is referenced more than once in a single statement, then the first reference generates the next number, and all subsequent references in the statement return the same number.

Once a sequence number is generated, the sequence number is available only to the session that generated the number. Independent of transactions committing or rolling back, other users referencing `order_seq.NEXTVAL` obtain unique values. If two users are accessing the same sequence concurrently, then the sequence numbers each user receives might have gaps because sequence numbers are also being generated by the other user.

24.2.4.1.2 Using Sequence Numbers with CURRVAL

To use or refer to the current sequence value of your session, reference `seq_name.CURRVAL` in a SQL statement.

`CURRVAL` can only be used if `seq_name.NEXTVAL` has been referenced in the current user session (in the current or a previous transaction). `CURRVAL` can be referenced as many times as necessary, including multiple times within the same statement. The next sequence number is not generated until `NEXTVAL` is referenced. Continuing with the previous example, you would finish placing the customer's order by inserting the line items for the order:

```
INSERT INTO Line_items_tab (Orderno, Partno, Quantity)
    VALUES (Order_seq.CURRVAL, 20321, 3);

INSERT INTO Line_items_tab (Orderno, Partno, Quantity)
    VALUES (Order_seq.CURRVAL, 29374, 1);
```

Assuming the `INSERT` statement given in the previous section generated a new sequence number of 347, both rows inserted by the statements in this section insert rows with order numbers of 347.

24.2.4.1.3 Uses and Restrictions of NEXTVAL and CURRVAL

`CURRVAL` and `NEXTVAL` can be used in specific places, and restrictions apply to their use.

`CURRVAL` and `NEXTVAL` can be used in the following places:

- `VALUES` clause of `INSERT` statements
- The `SELECT` list of a `SELECT` statement
- A view query or materialized view query

However, the use of `CURRVAL` and `NEXTVAL` in a materialized view query makes the materialized view complex. Therefore, it cannot be fast refreshed.

- The `SET` clause of an `UPDATE` statement

`CURRVAL` and `NEXTVAL` cannot be used in these places:

- A subquery

- A SELECT statement with the DISTINCT operator
- A SELECT statement with a GROUP BY or ORDER BY clause
- A SELECT statement that is combined with another SELECT statement with the UNION, INTERSECT, or MINUS set operator
- The WHERE clause of a SELECT statement
- The condition of a CHECK constraint

24.2.4.2 Caching Sequence Numbers

Caching sequence numbers can improve access time.

- [About Caching Sequence Numbers](#)
Sequence numbers can be kept in the sequence cache in the System Global Area (SGA). Sequence numbers can be accessed more quickly in the sequence cache than they can be read from disk.
- [The Number of Entries in the Sequence Cache](#)
When an application accesses a sequence in the sequence cache, the sequence numbers are read quickly. However, if an application accesses a sequence that is not in the cache, then the sequence must be read from disk to the cache before the sequence numbers are used.
- [The Number of Values in Each Sequence Cache Entry](#)
When a sequence is read into the sequence cache, sequence values are generated and stored in a cache entry. These values can then be accessed quickly.

24.2.4.2.1 About Caching Sequence Numbers

Sequence numbers can be kept in the sequence cache in the System Global Area (SGA). Sequence numbers can be accessed more quickly in the sequence cache than they can be read from disk.

The sequence cache consists of entries. Each entry can hold many sequence numbers for a single sequence.

Follow these guidelines for fast access to all sequence numbers:

- Be sure the sequence cache can hold all the sequences used concurrently by your applications.
- Increase the number of values for each sequence held in the sequence cache.

24.2.4.2.2 The Number of Entries in the Sequence Cache

When an application accesses a sequence in the sequence cache, the sequence numbers are read quickly. However, if an application accesses a sequence that is not in the cache, then the sequence must be read from disk to the cache before the sequence numbers are used.

If your applications use many sequences concurrently, then your sequence cache might not be large enough to hold all the sequences. In this case, access to sequence numbers might often require disk reads. For fast access to all sequences, be sure your cache has enough entries to hold all the sequences used concurrently by your applications.

24.2.4.2.3 The Number of Values in Each Sequence Cache Entry

When a sequence is read into the sequence cache, sequence values are generated and stored in a cache entry. These values can then be accessed quickly.

The number of sequence values stored in the cache is determined by the CACHE parameter in the CREATE SEQUENCE statement. The default value for this parameter is 20.

This CREATE SEQUENCE statement creates the seq2 sequence so that 50 values of the sequence are stored in the SEQUENCE cache:

```
CREATE SEQUENCE seq2
    CACHE 50;
```

The first 50 values of seq2 can then be read from the cache. When the 51st value is accessed, the next 50 values will be read from disk.

Choosing a high value for CACHE lets you access more successive sequence numbers with fewer reads from disk to the sequence cache. However, if there is an instance failure, then all sequence values in the cache are lost. Cached sequence numbers also could be skipped after an export and import if transactions continue to access the sequence numbers while the export is running.

If you use the NOCACHE option in the CREATE SEQUENCE statement, then the values of the sequence are not stored in the sequence cache. In this case, every access to the sequence requires a disk read. Such disk reads slow access to the sequence. This CREATE SEQUENCE statement creates the SEQ3 sequence so that its values are never stored in the cache:

```
CREATE SEQUENCE seq3
    NOCACHE;
```

24.2.5 Dropping Sequences

If a sequence is no longer required, you can drop the sequence using the DROP SEQUENCE statement.

You can drop any sequence in your schema. To drop a sequence in another schema, you must have the DROP ANY SEQUENCE system privilege. For example, the following statement drops the order_seq sequence:

```
DROP SEQUENCE order_seq;
```

When a sequence is dropped, its definition is removed from the data dictionary. Any synonyms for the sequence remain, but return an error when referenced.

See Also:

Oracle Database SQL Language Reference for syntax and additional information about the DROP SEQUENCE statement

24.3 Managing Synonyms

You can perform tasks such as creating synonyms, using synonyms, and dropping synonyms.

- [About Synonyms](#)
A synonym is an alias for a schema object.
- [Creating Synonyms](#)
Create a synonym using the `CREATE SYNONYM` statement.
- [Using Synonyms in DML Statements](#)
A synonym can be referenced in a DML statement the same way that the underlying object of the synonym can be referenced.
- [Dropping Synonyms](#)
Drop a synonym that is no longer required using `DROP SYNONYM` statement. To drop a private synonym, omit the `PUBLIC` keyword. To drop a public synonym, include the `PUBLIC` keyword.

24.3.1 About Synonyms

A synonym is an alias for a schema object.

Synonyms can provide a level of security by masking the name and owner of an object and by providing location transparency for remote objects of a distributed database. Also, they are convenient to use and reduce the complexity of SQL statements for database users.

Synonyms allow underlying objects to be renamed or moved, where only the synonym must be redefined and applications based on the synonym continue to function without modification.

You can create both public and private synonyms. A **public** synonym is owned by the special user group named `PUBLIC` and is accessible to every user in a database. A **private** synonym is contained in the schema of a specific user and available only to the user and to grantees for the underlying object.

Synonyms themselves are not securable. When you grant object privileges on a synonym, you are really granting privileges on the underlying object, and the synonym is acting only as an alias for the object in the `GRANT` statement.

See Also:

Oracle Database Concepts for a more complete description of synonyms

24.3.2 Creating Synonyms

Create a synonym using the `CREATE SYNONYM` statement.

To create a private synonym in your own schema, you must have the `CREATE SYNONYM` privilege. To create a private synonym in another user's schema, you must have the

CREATE ANY SYNONYM privilege. To create a public synonym, you must have the CREATE PUBLIC SYNONYM system privilege.

When you create a synonym, the underlying schema object need not exist, nor do you need privileges to access the object for the CREATE SYNONYM statement to succeed.

The following statement creates a public synonym named `public_emp` on the `emp` table contained in the schema of `jward`:

```
CREATE PUBLIC SYNONYM public_emp FOR jward.emp
```

When you create a synonym for a remote procedure or function, you must qualify the remote object with its schema name. Alternatively, you can create a local public synonym on the database where the remote object resides, in which case the database link must be included in all subsequent calls to the procedure or function.

 **See Also:**

Oracle Database SQL Language Reference for syntax and additional information about the CREATE SYNONYM statement

24.3.3 Using Synonyms in DML Statements

A synonym can be referenced in a DML statement the same way that the underlying object of the synonym can be referenced.

You can successfully use any private synonym contained in your schema or any public synonym, assuming that you have the necessary privileges to access the underlying object, either explicitly, from an enabled role, or from PUBLIC. You can also reference any private synonym contained in another schema if you have been granted the necessary object privileges for the underlying object.

You can reference another user's synonym using only the object privileges that you have been granted. For example, if you have only the SELECT privilege on the `jward.emp` table, and the synonym `jward.employee` is created for `jward.emp`, you can query the `jward.employee` synonym, but you cannot insert rows using the `jward.employee` synonym.

For example, if a synonym named `employee` refers to a table or view, then the following statement is valid:

```
INSERT INTO employee (empno, ename, job)
  VALUES (emp_sequence.NEXTVAL, 'SMITH', 'CLERK');
```

If the synonym named `fire_emp` refers to a standalone procedure or package procedure, then you could execute it with the command

```
EXECUTE Fire_emp(7344);
```

24.3.4 Dropping Synonyms

Drop a synonym that is no longer required using `DROP SYNONYM` statement. To drop a private synonym, omit the `PUBLIC` keyword. To drop a public synonym, include the `PUBLIC` keyword.

You can drop any private synonym in your own schema. To drop a private synonym in another user's schema, you must have the `DROP ANY SYNONYM` system privilege. To drop a public synonym, you must have the `DROP PUBLIC SYNONYM` system privilege.

For example, the following statement drops the private synonym named `emp`:

```
DROP SYNONYM emp;
```

The following statement drops the public synonym named `public_emp`:

```
DROP PUBLIC SYNONYM public_emp;
```

When you drop a synonym, its definition is removed from the data dictionary. All objects that reference a dropped synonym remain. However, they become invalid (not usable). For more information about how dropping synonyms can affect other schema objects, see "[Managing Object Dependencies](#)".

 **See Also:**

Oracle Database SQL Language Reference for syntax and additional information about the `DROP SYNONYM` statement

24.4 Views, Synonyms, and Sequences Data Dictionary Views

You can query data dictionary views for information about views, synonyms, and sequences.

The following views display information about views, synonyms, and sequences:

View	Description
DBA_VIEWS	DBA view describes all views in the database. ALL view is restricted to views accessible to the current user. USER view is restricted to views owned by the current user.
ALL_VIEWS	
USER_VIEWS	
DBA_SYNONYMS	These views describe synonyms.
ALL_SYNONYMS	
USER_SYNONYMS	
DBA_SEQUENCES	These views describe sequences.
ALL_SEQUENCES	
USER_SEQUENCES	

View	Description
DBA_UPDATABLE_COLUMNS	These views describe all columns in join views that are updatable.
ALL_UPDATABLE_COLUMNS	
USER_UPDATABLE_COLUMNS	

Repairing Corrupted Data

You can detect and correct data block corruption.

 **Note:**

If you are not familiar with the `DBMS_REPAIR` package, then it is recommended that you work with an Oracle Support Services analyst when performing any of the repair procedures included in this package.

- [Options for Repairing Data Block Corruption](#)
Oracle Database provides different methods for detecting and correcting data block corruption.
- [About the DBMS_REPAIR Package](#)
The `DBMS_REPAIR` package contains data corruption repair procedures that enable you to detect and repair corrupt blocks in tables and indexes.
- [Using the DBMS_REPAIR Package](#)
You can use the `DBMS_REPAIR` package to address data block corruption:
- [DBMS_REPAIR Examples](#)
Examples illustrate how to use the `DBMS_REPAIR` package.

25.1 Options for Repairing Data Block Corruption

Oracle Database provides different methods for detecting and correcting data block corruption.

One method of correction is to drop and re-create an object after the corruption is detected. However, this is not always possible or desirable. If data block corruption is limited to a subset of rows, then another option is to rebuild the table by selecting all data except for the corrupt rows.

Another way to manage data block corruption is to use the `DBMS_REPAIR` package. You can use `DBMS_REPAIR` to detect and repair corrupt blocks in tables and indexes. You can continue to use objects while you attempt to rebuild or repair them.

You can also use the Recovery Manager (RMAN) command `RECOVER BLOCK` to recover a corrupt data block or set of data blocks.

 **Note:**

Any corruption that involves the loss of data requires analysis and understanding of how that data fits into the overall database system. Depending on the nature of the repair, you might lose data, and logical inconsistencies can be introduced. You must determine whether the repair approach provided by this package is the appropriate tool for each specific corruption problem.

 **See Also:**

Oracle Database Backup and Recovery Reference for more information about the RECOVER BLOCK RMAN command

25.2 About the DBMS_REPAIR Package

The DBMS_REPAIR package contains data corruption repair procedures that enable you to detect and repair corrupt blocks in tables and indexes.

- [DBMS_REPAIR Procedures](#)
Procedures in the DBMS_REPAIR package enable you to detect and repair corrupt blocks.
- [Limitations and Restrictions for DBMS_REPAIR Procedures](#)
Some limitations and restrictions apply to DBMS_REPAIR procedures.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for more information on the syntax, restrictions, and exceptions for the DBMS_REPAIR procedures

25.2.1 DBMS_REPAIR Procedures

Procedures in the DBMS_REPAIR package enable you to detect and repair corrupt blocks.

The following table lists the procedures included in the DBMS_REPAIR package.

Procedure Name	Description
ADMIN_TABLES	Provides administrative functions (create, drop, purge) for repair or orphan key tables. Note: These tables are always created in the SYS schema.
CHECK_OBJECT	Detects and reports corruptions in a table or index

Procedure Name	Description
DUMP_ORPHAN_KEYS	Reports on index entries that point to rows in corrupt data blocks
FIX_CORRUPT_BLOCKS	Marks blocks as software corrupt that have been previously identified as corrupt by the CHECK_OBJECT procedure
REBUILD_FREELISTS	Rebuilds the free lists of the object
SEGMENT_FIX_STATUS	Provides the capability to fix the corrupted state of a bitmap entry when segment space management is AUTO
SKIP_CORRUPT_BLOCKS	When used, ignores blocks marked corrupt during table and index scans. If not used, you get error ORA-01578 when encountering blocks marked corrupt.

These procedures are further described, with examples of their use, in "[DBMS_REPAIR Examples](#)".

25.2.2 Limitations and Restrictions for DBMS_REPAIR Procedures

Some limitations and restrictions apply to DBMS_REPAIR procedures.

DBMS_REPAIR procedures have the following limitations:

- Tables with LOB data types, nested tables, and varrays are supported, but the out-of-line columns are ignored.
- Clusters are supported in the SKIP_CORRUPT_BLOCKS and REBUILD_FREELISTS procedures, but not in the CHECK_OBJECT procedure.
- Index-organized tables and LOB indexes are not supported.
- Global temporary tables are not supported.
- The DUMP_ORPHAN_KEYS procedure does not operate on bitmap indexes or function-based indexes.
- The DUMP_ORPHAN_KEYS procedure processes keys that are no more than 3,950 bytes long.

25.3 Using the DBMS_REPAIR Package

You can use the DBMS_REPAIR package to address data block corruption:

- [Task 1: Detect and Report Corruptions](#)
The first task is the detection and reporting of corruptions. Reporting not only indicates what is wrong with a block, but also identifies the associated repair directive.
- [Task 2: Evaluate the Costs and Benefits of Using DBMS_REPAIR](#)
Before using DBMS_REPAIR you must weigh the benefits of its use in relation to the liabilities. You should also examine other options available for addressing corrupt objects.
- [Task 3: Make Objects Usable](#)
DBMS_REPAIR makes the object usable by ignoring corruptions during table and index scans.

- [Task 4: Repair Corruptions and Rebuild Lost Data](#)
After making an object usable, perform the following repair activities.

25.3.1 Task 1: Detect and Report Corruptions

The first task is the detection and reporting of corruptions. Reporting not only indicates what is wrong with a block, but also identifies the associated repair directive.

- [About Detecting and Reporting Corruptions](#)
There are several ways to detect corruptions.
- [DBMS_REPAIR: Using the CHECK_OBJECT and ADMIN_TABLES Procedures](#)
The `CHECK_OBJECT` procedure checks and reports block corruptions for a specified object. The `ADMIN_TABLES` procedure creates a repair table that facilitates correcting corruptions.
- [DB_VERIFY: Performing an Offline Database Check](#)
Use `DB_VERIFY` as an offline diagnostic utility when you encounter data corruption.
- [ANALYZE: Reporting Corruption](#)
The `ANALYZE TABLE...VALIDATE STRUCTURE` statement validates the structure of the analyzed object. If the database encounters corruption in the structure of the object, then an error message is returned. In this case, drop and re-create the object.
- [DB_BLOCK_CHECKING Initialization Parameter](#)
You can enable database block checking by setting the `DB_BLOCK_CHECKING` initialization parameter to `TRUE`.

25.3.1.1 About Detecting and Reporting Corruptions

There are several ways to detect corruptions.

[Table 25-1](#) describes the different detection methodologies.

Table 25-1 Comparison of Corruption Detection Methods

Detection Method	Description
DBMS_REPAIR PL/SQL package	Performs block checking for a specified table, partition, or index. It populates a repair table with results.
DB_VERIFY utility	Performs block checking on an offline database
ANALYZE TABLE SQL statement	Used with the <code>VALIDATE STRUCTURE</code> option, the <code>ANALYZE TABLE</code> statement verifies the integrity of the structure of an index, table, or cluster; checks or verifies that tables and indexes are synchronized.
DB_BLOCK_CHECKING initialization parameter	When <code>DB_BLOCK_CHECKING=TRUE</code> , corrupt blocks are identified before they are marked corrupt. Checks are performed when changes are made to a block.

25.3.1.2 DBMS_REPAIR: Using the CHECK_OBJECT and ADMIN_TABLES Procedures

The `CHECK_OBJECT` procedure checks and reports block corruptions for a specified object. The `ADMIN_TABLES` procedure creates a repair table that facilitates correcting corruptions.

The `CHECK_OBJECT` procedure is similar to the `ANALYZE...VALIDATE STRUCTURE` statement for indexes and tables, block checking is performed for index and data blocks.

Not only does `CHECK_OBJECT` report corruptions, but it also identifies any fixes that would occur if `FIX_CORRUPT_BLOCKS` is subsequently run on the object. This information is made available by populating a repair table, which must first be created by the `ADMIN_TABLES` procedure.

After you run the `CHECK_OBJECT` procedure, a simple query on the repair table shows the corruptions and repair directives for the object. With this information, you can assess how best to address the reported problems.

25.3.1.3 DB_VERIFY: Performing an Offline Database Check

Use `DB_VERIFY` as an offline diagnostic utility when you encounter data corruption.

See Also:

[Oracle Database Utilities](#) for more information about `DB_VERIFY`

25.3.1.4 ANALYZE: Reporting Corruption

The `ANALYZE TABLE...VALIDATE STRUCTURE` statement validates the structure of the analyzed object. If the database encounters corruption in the structure of the object, then an error message is returned. In this case, drop and re-create the object.

You can use the `CASCADE` clause of the `ANALYZE TABLE` statement to check the structure of the table and all of its indexes in one operation. Because this operation can consume significant resources, there is a `FAST` option that performs a lightweight check. See "[Validating Tables, Indexes, Clusters, and Materialized Views](#)" for details.

See Also:

- [Oracle Database SQL Language Reference](#) for more information about the `ANALYZE` statement

25.3.1.5 DB_BLOCK_CHECKING Initialization Parameter

You can enable database block checking by setting the DB_BLOCK_CHECKING initialization parameter to TRUE.

This checks data and index blocks for internal consistency whenever they are modified. DB_BLOCK_CHECKING is a dynamic parameter, modifiable by the ALTER SYSTEM SET statement. Block checking is always enabled for the system tablespace.

 **See Also:**

Oracle Database Reference for more information about the DB_BLOCK_CHECKING initialization parameter

25.3.2 Task 2: Evaluate the Costs and Benefits of Using DBMS_REPAIR

Before using DBMS_REPAIR you must weigh the benefits of its use in relation to the liabilities. You should also examine other options available for addressing corrupt objects.

Begin by answering the following questions:

- What is the extent of the corruption?
To determine if there are corruptions and repair actions, execute the CHECK_OBJECT procedure and query the repair table.
- What other options are available for addressing block corruptions? Consider the following:
 - If the data is available from another source, then drop, re-create, and repopulate the object.
 - Issue the CREATE TABLE...AS SELECT statement from the corrupt table to create a new one.
 - Ignore the corruption by excluding corrupt rows from SELECT statements.
 - Perform media recovery.
- What logical corruptions or side effects are introduced when you use DBMS_REPAIR to make an object usable? Can these be addressed? What is the effort required to do so?

You might not have access to rows in blocks marked corrupt. However, a block can be marked corrupt even if there are rows that you can validly access.

It is also possible that referential integrity constraints are broken when blocks are marked corrupt. If this occurs, then disable and reenable the constraint; any inconsistencies are reported. After fixing all problems, you should be able to reenable the constraint.

Logical corruption can occur when there are triggers defined on the table. For example, if rows are reinserted, should insert triggers be fired or not? You can

address these issues only if you understand triggers and their use in your installation.

If indexes and tables are not synchronized, then execute the `DUMP_ORPHAN_KEYS` procedure to obtain information from the keys that might be useful in rebuilding corrupted data. Then issue the `ALTER INDEX...REBUILD ONLINE` statement to synchronize the table with its indexes.

- If repair involves loss of data, can this data be retrieved?

You can retrieve data from the index when a data block is marked corrupt. The `DUMP_ORPHAN_KEYS` procedure can help you retrieve this information.

25.3.3 Task 3: Make Objects Usable

`DBMS_REPAIR` makes the object usable by ignoring corruptions during table and index scans.

- [Corruption Repair: Using the FIX_CORRUPT_BLOCKS and SKIP_CORRUPT_BLOCKS Procedures](#)

You can make a corrupt object usable by establishing an environment that skips corruptions that remain outside the scope of `DBMS_REPAIR` capabilities.

- [Implications When Skipping Corrupt Blocks](#)

When skipping corrupt blocks, a query can return different results in some situations.

25.3.3.1 Corruption Repair: Using the FIX_CORRUPT_BLOCKS and SKIP_CORRUPT_BLOCKS Procedures

You can make a corrupt object usable by establishing an environment that skips corruptions that remain outside the scope of `DBMS_REPAIR` capabilities.

If corruptions involve a loss of data, such as a bad row in a data block, then all such blocks are marked corrupt by the `FIX_CORRUPT_BLOCKS` procedure. Then you can run the `SKIP_CORRUPT_BLOCKS` procedure, which skips blocks that are marked as corrupt. When the `SKIP_FLAG` parameter in the procedure is set, table and index scans skip all blocks marked corrupt. This applies to both media and software corrupt blocks.

25.3.3.2 Implications When Skipping Corrupt Blocks

When skipping corrupt blocks, a query can return different results in some situations.

If an index and table are not synchronized, then a `SET TRANSACTION READ ONLY` transaction can be inconsistent in situations where one query probes only the index, and a subsequent query probes both the index and the table. If the table block is marked corrupt, then the two queries return different results, thereby breaking the rules of a read-only transaction. One way to approach this is not to skip corruptions in a `SET TRANSACTION READ ONLY` transaction.

A similar issue occurs when selecting rows that are chained. A query of the same row may or may not access the corruption, producing different results.

25.3.4 Task 4: Repair Corruptions and Rebuild Lost Data

After making an object usable, perform the following repair activities.

- [Recover Data Using the DUMP_ORPHAN_KEYS Procedures](#)
The DUMP_ORPHAN_KEYS procedure reports on index entries that point to rows in corrupt data blocks. All such index entries are inserted into an orphan key table that stores the key and rowid of the corruption.
- [Fix Segment Bitmaps Using the SEGMENT_FIX_STATUS Procedure](#)
Use the SEGMENT_FIX_STATUS procedure if free space in segments is being managed by using bitmaps (SEGMENT SPACE MANAGEMENT AUTO).

25.3.4.1 Recover Data Using the DUMP_ORPHAN_KEYS Procedures

The DUMP_ORPHAN_KEYS procedure reports on index entries that point to rows in corrupt data blocks. All such index entries are inserted into an orphan key table that stores the key and rowid of the corruption.

After the index entry information has been retrieved, you can rebuild the index using the ALTER INDEX...REBUILD ONLINE statement.

25.3.4.2 Fix Segment Bitmaps Using the SEGMENT_FIX_STATUS Procedure

Use the SEGMENT_FIX_STATUS procedure if free space in segments is being managed by using bitmaps (SEGMENT SPACE MANAGEMENT AUTO).

This procedure recalculates the state of a bitmap entry based on the current contents of the corresponding block. Alternatively, you can specify that a bitmap entry be set to a specific value. Usually the state is recalculated correctly and there is no need to force a setting.

25.4 DBMS_REPAIR Examples

Examples illustrate how to use the DBMS_REPAIR package.

- [Examples: Building a Repair Table or Orphan Key Table](#)
A repair table provides information about the corruptions. An orphan key table provides information about index entries that point to corrupt rows.
- [Example: Detecting Corruption](#)
An example illustrates detecting corruption with the CHECK_OBJECT procedure.
- [Example: Fixing Corrupt Blocks](#)
An example illustrates fixing corrupt blocks with the FIX_CORRUPT_BLOCKS procedure.
- [Example: Finding Index Entries Pointing to Corrupt Data Blocks](#)
An example illustrates finding index entries pointing to corrupt data blocks using the DUMP_ORPHAN_KEYS procedure.
- [Example: Skipping Corrupt Blocks](#)
An example illustrates skipping corrupt blocks using the SKIP_CORRUPT_BLOCKS procedure.

25.4.1 Examples: Building a Repair Table or Orphan Key Table

A repair table provides information about the corruptions. An orphan key table provides information about index entries that point to corrupt rows.

- [About Repair Tables or Orphan Key Tables](#)
The ADMIN_TABLES procedure is used to create, purge, or drop a repair table or an orphan key table.
- [Example: Creating a Repair Table](#)
An example illustrates creating a repair table using the ADMIN_TABLES procedure.
- [Example: Creating an Orphan Key Table](#)
An example illustrates creating an orphan key table using the ADMIN_TABLES procedure.

25.4.1.1 About Repair Tables or Orphan Key Tables

The ADMIN_TABLES procedure is used to create, purge, or drop a repair table or an orphan key table.

A repair table provides information about the corruptions that were found by the CHECK_OBJECT procedure and how these will be addressed if the FIX_CORRUPT_BLOCKS procedure is run. Further, it is used to drive the execution of the FIX_CORRUPT_BLOCKS procedure.

An orphan key table is used when the DUMP_ORPHAN_KEYS procedure is executed and it discovers index entries that point to corrupt rows. The DUMP_ORPHAN_KEYS procedure populates the orphan key table by logging its activity and providing the index information in a usable manner.

25.4.1.2 Example: Creating a Repair Table

An example illustrates creating a repair table using the ADMIN_TABLES procedure.

The following example creates a repair table for the users tablespace.

```
BEGIN
    DBMS_REPAIR.ADMIN_TABLES (
        TABLE_NAME => 'REPAIR_TABLE',
        TABLE_TYPE => dbms_repair.repair_table,
        ACTION      => dbms_repair.create_action,
        TABLESPACE  => 'USERS');
END;
/
```

For each repair or orphan key table, a view is also created that eliminates any rows that pertain to objects that no longer exist. The name of the view corresponds to the name of the repair or orphan key table and is prefixed by DBA_ (for example, DBA_REPAIR_TABLE or DBA_ORPHAN_KEY_TABLE).

The following query describes the repair table that was created for the users tablespace.

```
DESC REPAIR_TABLE
```

Name	Null?	Type
OBJECT_ID	NOT NULL	NUMBER
TABLESPACE_ID	NOT NULL	NUMBER
RELATIVE_FILE_ID	NOT NULL	NUMBER
BLOCK_ID	NOT NULL	NUMBER
CORRUPT_TYPE	NOT NULL	NUMBER
SCHEMA_NAME		NOT NULL VARCHAR2(128)

OBJECT_NAME	NOT NULL VARCHAR2(128)
BASEOBJECT_NAME	VARCHAR2(128)
PARTITION_NAME	VARCHAR2(128)
CORRUPT_DESCRIPTION	VARCHAR2(2000)
REPAIR_DESCRIPTION	VARCHAR2(200)
MARKED_CORRUPT	NOT NULL VARCHAR2(10)
CHECK_TIMESTAMP	NOT NULL DATE
FIX_TIMESTAMP	DATE
REFORMAT_TIMESTAMP	DATE

25.4.1.3 Example: Creating an Orphan Key Table

An example illustrates creating an orphan key table using the ADMIN_TABLES procedure.

This example illustrates the creation of an orphan key table for the users tablespace.

```
BEGIN
    DBMS_REPAIR.ADMIN_TABLES (
        TABLE_NAME => 'ORPHAN_KEY_TABLE',
        TABLE_TYPE => dbms_repair.orphan_table,
        ACTION      => dbms_repair.create_action,
        TABLESPACE  => 'USERS');
END;
/
```

The orphan key table is described in the following query:

```
DESC ORPHAN_KEY_TABLE
```

Name	Null?	Type
SCHEMA_NAME	NOT NULL	VARCHAR2(128)
INDEX_NAME	NOT NULL	VARCHAR2(128)
IPART_NAME		VARCHAR2(128)
INDEX_ID	NOT NULL	NUMBER
TABLE_NAME	NOT NULL	VARCHAR2(128)
PART_NAME		VARCHAR2(128)
TABLE_ID	NOT NULL	NUMBER
KEYROWID	NOT NULL	ROWID
KEY	NOT NULL	ROWID
DUMP_TIMESTAMP	NOT NULL	DATE

25.4.2 Example: Detecting Corruption

An example illustrates detecting corruption with the CHECK_OBJECT procedure.

The CHECK_OBJECT procedure checks the specified object, and populates the repair table with information about corruptions and repair directives. You can optionally specify a range, partition name, or subpartition name when you want to check a portion of an object.

Validation consists of checking all blocks in the object that have not previously been marked corrupt. For each block, the transaction and data layer portions are checked for self consistency. During CHECK_OBJECT, if a block is encountered that has a corrupt buffer cache header, then that block is skipped.

The following is an example of executing the CHECK_OBJECT procedure for the scott.dept table.

```

SET SERVEROUTPUT ON
DECLARE num_corrupt INT;
BEGIN
    num_corrupt := 0;
    DBMS_REPAIR.CHECK_OBJECT (
        SCHEMA_NAME => 'SCOTT',
        OBJECT_NAME => 'DEPT',
        REPAIR_TABLE_NAME => 'REPAIR_TABLE',
        CORRUPT_COUNT => num_corrupt);
    DBMS_OUTPUT.PUT_LINE('number corrupt: ' || TO_CHAR (num_corrupt));
END;
/

```

SQL*Plus outputs the following line, indicating one corruption:

```
number corrupt: 1
```

Querying the repair table produces information describing the corruption and suggesting a repair action.

```

SELECT OBJECT_NAME, BLOCK_ID, CORRUPT_TYPE, MARKED_CORRUPT,
       CORRUPT_DESCRIPTION, REPAIR_DESCRIPTION
  FROM REPAIR_TABLE;

OBJECT_NAME          BLOCK_ID CORRUPT_TYPE MARKED_COR
-----  -----
CORRUPT_DESCRIPTION
-----  -----
REPAIR_DESCRIPTION
-----
DEPT                  3           1 FALSE
kdbchk: row locked by non-existent transaction
        table=0 slot=0
        lockid=32 ktbbhitc=1
mark block software corrupt

```

The corrupted block has not yet been marked corrupt, so this is the time to extract any meaningful data. After the block is marked corrupt, the entire block must be skipped.

25.4.3 Example: Fixing Corrupt Blocks

An example illustrates fixing corrupt blocks with the `FIX_CORRUPT_BLOCKS` procedure.

Use the `FIX_CORRUPT_BLOCKS` procedure to fix the corrupt blocks in specified objects based on information in the repair table that was generated by the `CHECK_OBJECT` procedure. Before changing a block, the block is checked to ensure that the block is still corrupt. Corrupt blocks are repaired by marking the block software corrupt. When a repair is performed, the associated row in the repair table is updated with a timestamp.

This example fixes the corrupt block in table `scott.dept` that was reported by the `CHECK_OBJECT` procedure.

```

SET SERVEROUTPUT ON
DECLARE num_fix INT;
BEGIN
    num_fix := 0;
    DBMS_REPAIR.FIX_CORRUPT_BLOCKS (
        SCHEMA_NAME => 'SCOTT',
        OBJECT_NAME=> 'DEPT',

```

```

OBJECT_TYPE => dbms_repair.table_object,
REPAIR_TABLE_NAME => 'REPAIR_TABLE',
FIX_COUNT=> num_fix);
DBMS_OUTPUT.PUT_LINE('num fix: ' || TO_CHAR(num_fix));
END;
/

```

SQL*Plus outputs the following line:

```
num fix: 1
```

The following query confirms that the repair was done.

```

SELECT OBJECT_NAME, BLOCK_ID, MARKED_CORRUPT
  FROM REPAIR_TABLE;

OBJECT_NAME          BLOCK_ID MARKED_COR
-----            -----
DEPT                  3      TRUE

```

25.4.4 Example: Finding Index Entries Pointing to Corrupt Data Blocks

An example illustrates finding index entries pointing to corrupt data blocks using the DUMP_ORPHAN_KEYS procedure.

The DUMP_ORPHAN_KEYS procedure reports on index entries that point to rows in corrupt data blocks. For each index entry, a row is inserted into the specified orphan key table. The orphan key table must have been previously created.

This information can be useful for rebuilding lost rows in the table and for diagnostic purposes.

 **Note:**

This should be run for every index associated with a table identified in the repair table.

In this example, pk_dept is an index on the scott.dept table. It is scanned to determine if there are any index entries pointing to rows in the corrupt data block.

```

SET SERVEROUTPUT ON
DECLARE num_orphans INT;
BEGIN
  num_orphans := 0;
  DBMS_REPAIR.DUMP_ORPHAN_KEYS (
    SCHEMA_NAME => 'SCOTT',
    OBJECT_NAME => 'PK_DEPT',
    OBJECT_TYPE => dbms_repair.index_object,
    REPAIR_TABLE_NAME => 'REPAIR_TABLE',
    ORPHAN_TABLE_NAME=> 'ORPHAN_KEY_TABLE',
    KEY_COUNT => num_orphans);
  DBMS_OUTPUT.PUT_LINE('orphan key count: ' || TO_CHAR(num_orphans));
END;
/

```

The following output indicates that there are three orphan keys:

```
orphan key count: 3
```

Index entries in the orphan key table implies that the index should be rebuilt. This guarantees that a table probe and an index probe return the same result set.

25.4.5 Example: Skipping Corrupt Blocks

An example illustrates skipping corrupt blocks using the SKIP_CORRUPT_BLOCKS procedure.

The SKIP_CORRUPT_BLOCKS procedure enables or disables the skipping of corrupt blocks during index and table scans of the specified object. When the object is a table, skipping applies to the table and its indexes. When the object is a cluster, it applies to all of the tables in the cluster, and their respective indexes.

The following example enables the skipping of software corrupt blocks for the scott.dept table:

```
BEGIN
    DBMS_REPAIR.SKIP_CORRUPT_BLOCKS (
        SCHEMA_NAME => 'SCOTT',
        OBJECT_NAME => 'DEPT',
        OBJECT_TYPE => dbms_repair.table_object,
        FLAGS => dbms_repair.skip_flag);
END;
/
```

Querying scott's tables using the DBA_TABLES view shows that SKIP_CORRUPT is enabled for table scott.dept.

```
SELECT OWNER, TABLE_NAME, SKIP_CORRUPT FROM DBA_TABLES
WHERE OWNER = 'SCOTT';
```

OWNER	TABLE_NAME	SKIP_COR
SCOTT	ACCOUNT	DISABLED
SCOTT	BONUS	DISABLED
SCOTT	DEPT	ENABLED
SCOTT	DOCINDEX	DISABLED
SCOTT	EMP	DISABLED
SCOTT	RECEIPT	DISABLED
SCOTT	SALGRADE	DISABLED
SCOTT	SCOTT_EMP	DISABLED
SCOTT	SYS_IOT_OVER_12255	DISABLED
SCOTT	WORK_AREA	DISABLED

```
10 rows selected.
```

Part IV

Database Resource Management and Task Scheduling

You can manage automated database maintenance tasks, database resources, and task scheduling.

- [Managing Automated Database Maintenance Tasks](#)
Oracle Database has automated several common maintenance tasks typically performed by database administrators. These automated maintenance tasks are performed when the system load is expected to be light. You can enable and disable individual maintenance tasks, and can configure when these tasks run and what resource allocations they are allotted.
- [Managing Resources with Oracle Database Resource Manager](#)
Oracle Database Resource Manager (Resource Manager) enables you to manage resource allocation for a database.
- [Oracle Scheduler Concepts](#)
You can schedule tasks with Oracle Scheduler.
- [Scheduling Jobs with Oracle Scheduler](#)
You can create, run, and manage jobs with Oracle Scheduler.
- [Administering Oracle Scheduler](#)
You can configure, manage, monitor, and troubleshoot Oracle Scheduler.

Managing Automated Database Maintenance Tasks

Oracle Database has automated several common maintenance tasks typically performed by database administrators. These automated maintenance tasks are performed when the system load is expected to be light. You can enable and disable individual maintenance tasks, and can configure when these tasks run and what resource allocations they are allotted.

Note:

This chapter explains how to administer automated maintenance tasks using PL/SQL packages. An easier way is to use the graphical interface of Oracle Enterprise Manager Cloud Control (Cloud Control).

To manage automatic maintenance tasks with Cloud Control:

1. Access the Database Home Page.
2. From the Administration menu, select **Oracle Scheduler**, then **Automated Maintenance Tasks**.
3. On the Automated Maintenance Tasks page, click **Configure**.

- [About Automated Maintenance Tasks](#)

Automated maintenance tasks are tasks that are started automatically at regular intervals to perform maintenance operations on the database. An example is a task that gathers statistics on schema objects for the query optimizer.

- [About Maintenance Windows](#)

A **maintenance window** is a contiguous time interval during which automated maintenance tasks are run. Maintenance windows are Oracle Scheduler windows that belong to the window group named `MAINTENANCE_WINDOW_GROUP`.

- [Configuring Automated Maintenance Tasks](#)

To enable or disable specific maintenance tasks in any subset of maintenance windows, you can use the `DBMS_AUTO_TASK_ADMIN` PL/SQL package.

- [Configuring Maintenance Windows](#)

You may want to adjust the predefined maintenance windows to a time suitable to your database environment or create a new maintenance window. You can customize maintenance windows using the `DBMS_SCHEDULER` PL/SQL package.

- [Configuring Resource Allocations for Automated Maintenance Tasks](#)

You can reduce or increase resource allocation to the automated maintenance tasks.

- [Automated Maintenance Tasks Reference](#)

Oracle Database has predefined maintenance windows. It also has data dictionary views that you can query for information about automated maintenance.

26.1 About Automated Maintenance Tasks

Automated maintenance tasks are tasks that are started automatically at regular intervals to perform maintenance operations on the database. An example is a task that gathers statistics on schema objects for the query optimizer.

Automated maintenance tasks run in *maintenance windows*, which are predefined time intervals that are intended to occur during a period of low system load. You can customize maintenance windows based on the resource usage patterns of your database, or disable certain default windows from running. You can also create your own maintenance windows.

Oracle Database has these predefined automated maintenance tasks:

- **Automatic Optimizer Statistics Collection**—Collects optimizer statistics for all schema objects in the database for which there are no statistics or only stale statistics. The statistics gathered by this task are used by the SQL query optimizer to improve the performance of SQL execution.

 **See Also:**

Oracle Database SQL Tuning Guide for more information on automatic statistics collection

- **Optimizer Statistics Advisor**—Analyzes how statistics are being gathered and suggests changes that can be made to fine tune statistics collection.

 **See Also:**

Oracle Database SQL Tuning Guide

- **Automatic Segment Advisor**—Identifies segments that have space available for reclamation, and makes recommendations on how to defragment those segments.

You can also run the Segment Advisor manually to obtain more up-to-the-minute recommendations or to obtain recommendations on segments that the Automatic Segment Advisor did not examine for possible space reclamation.

 **See Also:**

"Using the Segment Advisor" for more information.

- **Automatic SQL Tuning Advisor**—Examines the performance of high-load SQL statements, and makes recommendations on how to tune those statements. You can configure this advisor to automatically implement SQL profile recommendations.

 **See Also:**

Oracle Database SQL Tuning Guide for more information on SQL Tuning Advisor

- **SQL Plan Management (SPM) Evolve Advisor**—Evolves plans that have recently been added to the SQL plan baseline. The advisor simplifies plan evolution by eliminating the requirement to do it manually.

 **See Also:**

Oracle Database SQL Tuning Guide for more information on SPM Evolve Advisor

By default, all of these automated maintenance tasks are configured to run in all maintenance windows.

26.2 About Maintenance Windows

A **maintenance window** is a contiguous time interval during which automated maintenance tasks are run. Maintenance windows are Oracle Scheduler windows that belong to the window group named `MAINTENANCE_WINDOW_GROUP`.

A Scheduler window can be a simple repeating interval (such as "between midnight and 6 a.m., every Saturday"), or a more complex interval (such as "between midnight and 6 a.m., on the last workday of every month, excluding company holidays").

When a maintenance window opens, Oracle Database creates an Oracle Scheduler job for each maintenance task that is scheduled to run in that window. Each job is assigned a job name that is generated at run time. All automated maintenance task job names begin with `ORA$AT`. For example, the job for the Automatic Segment Advisor might be called `ORA$AT_SA_SPC_SY_26`. When an automated maintenance task job finishes, it is deleted from the Oracle Scheduler job system. However, the job can still be found in the Scheduler job history.

 **Note:**

To view job history, you must log in as the `SYS` user.

In the case of a very long maintenance window, all automated maintenance tasks except Automatic SQL Tuning Advisor are restarted every four hours. This feature ensures that maintenance tasks are run regularly, regardless of window size.

The framework of automated maintenance tasks relies on maintenance windows being defined in the database. [Table 26-1](#) lists the maintenance windows that are automatically defined with each new Oracle Database installation.

 **See Also:**

- ["About Jobs and Supporting Scheduler Objects"](#) for more information on windows and groups.

26.3 Configuring Automated Maintenance Tasks

To enable or disable specific maintenance tasks in any subset of maintenance windows, you can use the DBMS_AUTO_TASK_ADMIN PL/SQL package.

- [Enabling and Disabling Maintenance Tasks for all Maintenance Windows](#)
With a single operation, you can disable or enable a particular automated maintenance task for all maintenance windows.
- [Enabling and Disabling Maintenance Tasks for Specific Maintenance Windows](#)
By default, all maintenance tasks run in all predefined maintenance windows. You can disable a maintenance task for a specific window.

26.3.1 Enabling and Disabling Maintenance Tasks for all Maintenance Windows

With a single operation, you can disable or enable a particular automated maintenance task for all maintenance windows.

You can disable a particular automated maintenance task for all maintenance windows with a single operation. You do so by calling the DISABLE procedure of the DBMS_AUTO_TASK_ADMIN PL/SQL package without supplying the window_name argument. For example, you can completely disable the Automatic SQL Tuning Advisor task as follows:

```
BEGIN
    dbms_auto_task_admin.disable(
        client_name => 'sql tuning advisor',
        operation    => NULL,
        window_name  => NULL);
END;
/
```

To enable this maintenance task again, use the ENABLE procedure, as follows:

```
BEGIN
    dbms_auto_task_admin.enable(
        client_name => 'sql tuning advisor',
        operation    => NULL,
        window_name  => NULL);
END;
/
```

The task names to use for the client_name argument are listed in the DBA_AUTOTASK_CLIENT database dictionary view.

To enable or disable all automated maintenance tasks for all windows, call the ENABLE or DISABLE procedure with no arguments.

```
EXECUTE DBMS_AUTO_TASK_ADMIN.DISABLE;
```

See Also:

- ["Automated Maintenance Tasks Database Dictionary Views"](#)
- [Oracle Database PL/SQL Packages and Types Reference](#) for more information on the DBMS_AUTO_TASK_ADMIN PL/SQL package.

26.3.2 Enabling and Disabling Maintenance Tasks for Specific Maintenance Windows

By default, all maintenance tasks run in all predefined maintenance windows. You can disable a maintenance task for a specific window.

The following example disables the Automatic SQL Tuning Advisor from running in the window MONDAY_WINDOW:

```
BEGIN
    dbms_auto_task_admin.disable(
        client_name => 'sql tuning advisor',
        operation    => NULL,
        window_name  => 'MONDAY_WINDOW');
END;
/
```

26.4 Configuring Maintenance Windows

You may want to adjust the predefined maintenance windows to a time suitable to your database environment or create a new maintenance window. You can customize maintenance windows using the DBMS_SCHEDULER PL/SQL package.

- [Modifying a Maintenance Window](#)

The DBMS_SCHEDULER PL/SQL package includes a SET_ATTRIBUTE procedure for modifying the attributes of a window.

- [Creating a New Maintenance Window](#)

To create a new maintenance window, you must create an Oracle Scheduler window object and then add it to the window group MAINTENANCE_WINDOW_GROUP.

- [Removing a Maintenance Window](#)

To remove an existing maintenance window, remove it from the MAINTENANCE_WINDOW_GROUP window group.

26.4.1 Modifying a Maintenance Window

The DBMS_SCHEDULER PL/SQL package includes a SET_ATTRIBUTE procedure for modifying the attributes of a window.

For example, the following script changes the duration of the maintenance window SATURDAY_WINDOW to 4 hours:

```
BEGIN
    dbms_scheduler.disable(
        name => 'SATURDAY_WINDOW');
    dbms_scheduler.set_attribute(
        name      => 'SATURDAY_WINDOW',
        attribute => 'DURATION',
        value     => numtodsinterval(4, 'hour'));
    dbms_scheduler.enable(
        name => 'SATURDAY_WINDOW');
END;
/
```

Note that you must use the DBMS_SCHEDULER.DISABLE subprogram to disable the window before making changes to it, and then re-enable the window with DBMS_SCHEDULER.ENABLE when you are finished. If you change a window when it is currently open, the change does not take effect until the next time the window opens.

 **See Also:**

["Managing Job Scheduling and Job Priorities with Windows"](#) for more information about modifying windows.

26.4.2 Creating a New Maintenance Window

To create a new maintenance window, you must create an Oracle Scheduler window object and then add it to the window group MAINTENANCE_WINDOW_GROUP.

You use the DBMS_SCHEDULER.CREATE_WINDOW package procedure to create the window, and the DBMS_SCHEDULER.ADD_GROUP_MEMBER procedure to add the new window to the window group.

The following example creates a maintenance window named EARLY_MORNING_WINDOW. This window runs for one hour daily between 5 a.m. and 6 a.m.

```
BEGIN
    DBMS_SCHEDULER.CREATE_WINDOW(
        window_name      => 'EARLY_MORNING_WINDOW',
        duration         => NUMTODSINTERVAL(1, 'hour'),
        resource_plan   => 'DEFAULT_MAINTENANCE_PLAN',
        repeat_interval => 'FREQ=DAILY;BYHOUR=5;BYMINUTE=0;BYSECOND=0');
    DBMS_SCHEDULER.ADD_GROUP_MEMBER(
        group_name      => 'MAINTENANCE_WINDOW_GROUP',
        member          => 'EARLY_MORNING_WINDOW');
END;
/
```

 **See Also:**

- ["Creating Windows"](#)
- [Oracle Database PL/SQL Packages and Types Reference](#) for information on the DBMS_SCHEDULER package

26.4.3 Removing a Maintenance Window

To remove an existing maintenance window, remove it from the MAINTENANCE_WINDOW_GROUP window group.

The window continues to exist but no longer runs automated maintenance tasks. Any other Oracle Scheduler jobs assigned to this window continue to run as usual.

The following example removes EARLY_MORNING_WINDOW from the window group:

```
BEGIN
    DBMS_SCHEDULER.REMOVE_GROUP_MEMBER(
        group_name  => 'MAINTENANCE_WINDOW_GROUP',
        member       => 'EARLY_MORNING_WINDOW');
END;
/
```

 **See Also:**

- ["Removing a Member from a Window Group"](#)
- ["Dropping Windows"](#)
- [Oracle Database PL/SQL Packages and Types Reference](#) for information on the DBMS_SCHEDULER package

26.5 Configuring Resource Allocations for Automated Maintenance Tasks

You can reduce or increase resource allocation to the automated maintenance tasks.

- [About Resource Allocations for Automated Maintenance Tasks](#)

By default, all predefined maintenance windows use the resource plan DEFAULT_MAINTENANCE_PLAN. Automated maintenance tasks run under its subplan ORA\$AUTOTASK. This subplan divides its portion of total resource allocation equally among the maintenance tasks.

- [Changing Resource Allocations for Automated Maintenance Tasks](#)

To change the resource allocation for automated maintenance tasks within a maintenance window, you must change the percentage of resources allocated to the subplan ORA\$AUTOTASK in the resource plan for that window.

 See Also:

[Managing Resources with Oracle Database Resource Manager](#)

26.5.1 About Resource Allocations for Automated Maintenance Tasks

By default, all predefined maintenance windows use the resource plan `DEFAULT_MAINTENANCE_PLAN`. Automated maintenance tasks run under its subplan `ORA$AUTOTASK`. This subplan divides its portion of total resource allocation equally among the maintenance tasks.

`DEFAULT_MAINTENANCE_PLAN` defines the following resource allocations:

Consumer Group/subplan	Level 1	Maximum Utilization Limit
ORA\$AUTOTASK	5%	90
OTHER_GROUPS	20%	-
SYS_GROUP	75%	-

In this plan, any sessions in the `SYS_GROUP` consumer group get priority. (Sessions in this group are sessions created by user accounts `SYS` and `SYSTEM`.) Any resource allocation that is unused by sessions in `SYS_GROUP` is then shared by sessions belonging to the other consumer groups and subplans in the plan. Of that allocation, 5% goes to maintenance tasks and 20% goes to user sessions. The maximum utilization limit for `ORA$AUTOTASK` is 90. Therefore, even if the CPU is idle, this group/plan cannot be allocated more than 90% of the CPU resources.

To reduce or increase resource allocation to the automated maintenance tasks, you make adjustments to `DEFAULT_MAINTENANCE_PLAN`. See "[Changing Resource Allocations for Automated Maintenance Tasks](#)" for more information.

Note that as with any resource plan, the portion of an allocation that is not used by a consumer group or subplan is available for other consumer groups or subplans. Note also that the Database Resource Manager does not begin to limit resource allocations according to resource plans until 100% of CPU is being used.

 Note:

Although `DEFAULT_MAINTENANCE_PLAN` is the default, you can assign any resource plan to any maintenance window. If you do change a maintenance window resource plan, ensure that you include the subplan `ORA$AUTOTASK` in the new plan.

 See Also:

[Managing Resources with Oracle Database Resource Manager](#) for more information on resource plans.

26.5.2 Changing Resource Allocations for Automated Maintenance Tasks

To change the resource allocation for automated maintenance tasks within a maintenance window, you must change the percentage of resources allocated to the subplan ORA\$AUTOTASK in the resource plan for that window.

(By default, the resource plan for each predefined maintenance window is DEFAULT_MAINTENANCE_PLAN.) You must also adjust the resource allocation for one or more other subplans or consumer groups in the window's resource plan such that the resource allocation at the top level of the plan adds up to 100%. For information on changing resource allocations, see [Managing Resources with Oracle Database Resource Manager](#).

26.6 Automated Maintenance Tasks Reference

Oracle Database has predefined maintenance windows. It also has data dictionary views that you can query for information about automated maintenance.

- [Predefined Maintenance Windows](#)
By default there are seven predefined maintenance windows, each one representing a day of the week.
- [Automated Maintenance Tasks Database Dictionary Views](#)
You can query a set of data dictionary views for information about automated maintenance tasks.

26.6.1 Predefined Maintenance Windows

By default there are seven predefined maintenance windows, each one representing a day of the week.

The weekend maintenance windows, SATURDAY_WINDOW and SUNDAY_WINDOW, are longer in duration than the weekday maintenance windows. The window group MAINTENANCE_WINDOW_GROUP consists of these seven windows. The list of predefined maintenance windows is given in [Table 26-1](#).

Table 26-1 Predefined Maintenance Windows

Window Name	Description
MONDAY_WINDOW	Starts at 10 p.m. on Monday and ends at 2 a.m.
TUESDAY_WINDOW	Starts at 10 p.m. on Tuesday and ends at 2 a.m.
WEDNESDAY_WINDOW	Starts at 10 p.m. on Wednesday and ends at 2 a.m.
THURSDAY_WINDOW	Starts at 10 p.m. on Thursday and ends at 2 a.m.

Table 26-1 (Cont.) Predefined Maintenance Windows

Window Name	Description
FRIDAY_WINDOW	Starts at 10 p.m. on Friday and ends at 2 a.m.
SATURDAY_WINDOW	Starts at 6 a.m. on Saturday and is 20 hours long.
SUNDAY_WINDOW	Starts at 6 a.m. on Sunday and is 20 hours long.

26.6.2 Automated Maintenance Tasks Database Dictionary Views

You can query a set of data dictionary views for information about automated maintenance tasks.

[Table 26-2](#) displays information about database dictionary views for automated maintenance tasks:

Table 26-2 Automated Maintenance Tasks Database Dictionary Views

View Name	Description
DBA_AUTOTASK_CLIENT_JOB	Contains information about currently running Scheduler jobs created for automated maintenance tasks. It provides information about some objects targeted by those jobs, as well as some additional statistics from previous instantiations of the same task. Some of this additional data is taken from generic Scheduler views.
DBA_AUTOTASK_CLIENT	Provides statistical data for each automated maintenance task over 7-day and 30-day periods.
DBA_AUTOTASK_JOB_HISTORY	Lists the history of automated maintenance task job runs. Jobs are added to this view after they finish executing.
DBA_AUTOTASK_WINDOW_CLIENTS	Lists the windows that belong to MAINTENANCE_WINDOW_GROUP, along with the Enabled or Disabled status for the window for each maintenance task. Primarily used by Cloud Control.
DBA_AUTOTASK_CLIENT_HISTORY	Provides per-window history of job execution counts for each automated maintenance task. This information is viewable in the Job History page of Cloud Control.

See Also:

["Resource Manager Data Dictionary Views"](#) for column descriptions for views.

Managing Resources with Oracle Database Resource Manager

Oracle Database Resource Manager (Resource Manager) enables you to manage resource allocation for a database.

Note:

This chapter discusses using PL/SQL package procedures to administer the Resource Manager. An easier way to administer the Resource Manager is with the graphical user interface of Oracle Enterprise Manager Cloud Control (Cloud Control). For instructions about administering Resource Manager with Cloud Control, see the Cloud Control online help.

To use Resource Manager with Cloud Control:

1. Access the Database Home Page.
2. From the Administration menu, select **Resource Manager**.

- [About Oracle Database Resource Manager](#)

Oracle Database Resource Manager (the Resource Manager) enables you to manage multiple workloads within a database that are contending for system and database resources.

- [Assigning Sessions to Resource Consumer Groups](#)

There are automatic and manual methods that database administrators, users, and applications can use to assign sessions to resource consumer groups. When a session is assigned to a resource consumer group, Oracle Database Resource Manager (the Resource Manager) can manage resource allocation for it.

- [The Types of Resources Managed by the Resource Manager](#)

Resource plan directives specify how resources are allocated to resource consumer groups or subplans. Each directive can specify several different methods for allocating resources to its consumer group or subplan.

- [Creating a Simple Resource Plan](#)

You can quickly create a simple resource plan that is adequate for many situations using the `CREATE_SIMPLE_PLAN` procedure.

- [Creating a Complex Resource Plan](#)

When your situation calls for a more complex resource plan, you must create the plan, with its directives and consumer groups, in a staging area called the pending area, and then validate the plan before storing it in the data dictionary.

- [Enabling Oracle Database Resource Manager and Switching Plans](#)

You enable Oracle Database Resource Manager (the Resource Manager) by setting the `RESOURCE_MANAGER_PLAN` initialization parameter. This parameter specifies the top plan, identifying the plan to be used for the current instance. If no plan is specified with this parameter, the Resource Manager is not enabled.

- [Putting It All Together: Oracle Database Resource Manager Examples](#)
Examples illustrate how to allocate resources with Resource Manager.
- [Managing Multiple Database Instances on a Single Server](#)
Oracle Database provides a method for managing CPU allocations on a multi-CPU server running multiple database instances. This method is called instance caging. Instance caging and Oracle Database Resource Manager (the Resource Manager) work together to support desired levels of service across multiple instances.
- [Maintaining Consumer Groups, Plans, and Directives](#)
You can maintain consumer groups, resource plans, and resource plan directives for Oracle Database Resource Manager (the Resource Manager). You perform maintenance tasks using the DBMS_RESOURCE_MANAGER PL/SQL package.
- [Viewing Database Resource Manager Configuration and Status](#)
You can use several static data dictionary views and dynamic performance views to view the current configuration and status of Oracle Database Resource Manager (the Resource Manager).
- [Monitoring Oracle Database Resource Manager](#)
A set of dynamic performance views enable you to monitor the results of your Oracle Database Resource Manager settings.
- [Interacting with Operating-System Resource Control](#)
Many operating systems provide tools for resource management. These tools often contain "workload manager" or "resource manager" in their names, and are intended to allow multiple applications to share the resources of a single server, using an administrator-defined policy. Examples are Hewlett Packard's Process Resource Manager or Solaris Containers, Zones, and Resource Pools.
- [Oracle Database Resource Manager Reference](#)
Resource Manager includes predefined resource plans, consumer groups, and consumer groups mapping rules. You can query data dictionary views for information about your Resource Manager configuration.

27.1 About Oracle Database Resource Manager

Oracle Database Resource Manager (the Resource Manager) enables you to manage multiple workloads within a database that are contending for system and database resources.

- [What Solutions Does the Resource Manager Provide for Workload Management?](#)
Resource Manager allows the database to have more control over how hardware resources are allocated.
- [The Elements of Resource Manager](#)
Resource Manager includes several elements that you can manage.
- [About Resource Manager Administration Privileges](#)
You must have the required privileges to administer the Resource Manager.

27.1.1 What Solutions Does the Resource Manager Provide for Workload Management?

Resource Manager allows the database to have more control over how hardware resources are allocated.

When database resource allocation decisions are left to the operating system, you may encounter the following problems with workload management:

- Excessive overhead
Excessive overhead results from operating system context switching between Oracle Database server processes when the number of server processes is high.
- Inefficient scheduling
The operating system deschedules database servers while they hold latches, which is inefficient.
- Inappropriate allocation of resources
The operating system distributes resources equally among all active processes and cannot prioritize one task over another.
- Inability to manage database-specific resources, such as parallel execution servers and active sessions

The Resource Manager helps to overcome these problems by allowing the database more control over how hardware resources are allocated. In an environment with multiple concurrent user sessions that run jobs with differing priorities, all sessions should not be treated equally. The Resource Manager enables you to classify sessions into groups based on session attributes, and to then allocate resources to those groups in a way that optimizes hardware utilization for your application environment.

With the Resource Manager, you can:

- Guarantee certain sessions a minimum amount of CPU regardless of the load on the system and the number of users.
- Distribute available CPU by allocating percentages of CPU time to different users and applications. In a data warehouse, a higher percentage can be given to ROLAP (relational online analytical processing) applications than to batch jobs.
- Limit the degree of parallelism of any operation performed by members of a group of users.
- Manage the order of parallel statements in the parallel statement queue. Parallel statements from a critical application can be enqueued ahead of parallel statements from a low priority group of users.
- Limit the number of parallel execution servers that a group of users can use. This ensures that all the available parallel execution servers are not allocated to only one group of users.
- Create an active session pool. An **active session pool** consists of a specified maximum number of user sessions allowed to be concurrently active within a group of users. Additional sessions beyond the maximum are queued for execution, but you can specify a timeout period, after which queued jobs will terminate. The active session pool limits the total number of sessions actively competing for resources, thereby enabling active sessions to make faster progress.
- Monitor resources

When Resource Manager is enabled, Resource Manager automatically records statistics about resource usage, and you can examine these statistics using real-time SQL monitoring and the Resource Manager dynamic performance views (the V\$RSRC_* views). See "[Monitoring Oracle Database Resource Manager](#)" for

information about using real-time SQL monitoring and the Resource Manager dynamic performance views.

- Limit the amount of PGA memory used by each session that belongs to a group of users.
 - Manage runaway sessions or calls in the following ways:
 - By detecting when a session or call consumes more than a specified amount of CPU, physical I/O, logical I/O, or elapsed time, and then automatically either terminating the session or call, or switching to a consumer group with a lower resource allocation or a limit on the percentage of CPU that the group can use
- A logical I/O, also known as a buffer I/O, refers to reads and writes of buffers in the buffer cache. When a requested buffer is not found in memory, the database performs a physical I/O to copy the buffer from either disk or the flash cache into memory, and then a logical I/O to read the cached buffer.
- By recording detailed information about SQL statements that consume more than a specified amount of CPU, physical I/O, logical I/O, or elapsed time with real-time SQL monitoring
 - By using the Automatic Workload Repository (AWR) to analyze a persistent record of SQL statements that consume more than a specified amount of CPU, physical I/O, logical I/O, or elapsed time
 - By logging information about a runaway session without taking any other action related to the session
- Prevent the execution of operations that the optimizer estimates will run for a longer time than a specified limit.
 - Limit the amount of time that a session can be idle. This can be further defined to mean only sessions that are blocking other sessions.
 - Allow a database to use different resource plans, based on changing workload requirements. You can dynamically change the resource plan, for example, from a daytime resource plan to a nighttime resource plan, without having to shut down and restart the instance. You can also schedule a resource plan change with Oracle Scheduler. See [Oracle Scheduler Concepts](#) for more information.

27.1.2 The Elements of Resource Manager

Resource Manager includes several elements that you can manage.

- [About the Elements of Resource Manager](#)
The elements of the Resource Manager include resource consumer groups, resource plans, and resource plan directives.
- [About Resource Consumer Groups](#)
A resource consumer group (consumer group) is a collection of user sessions that are grouped together based on their processing needs.
- [About Resource Plan Directives](#)
The Resource Manager allocates resources to consumer groups according to the set of resource plan directives (directives) that belong to the currently active resource plan.
- [About Resource Plans](#)
A resource plan is a container for directives that specify how resources are allocated to resource consumer groups.

- [Example: A Simple Resource Plan](#)
An example illustrates a simple resource plan.
- [About Subplans](#)
Instead of referencing a consumer group, a resource plan directive (directive) can reference another resource plan. In this case, the plan is referred to as a subplan.
- [Example: A Resource Plan with Subplans](#)
An example illustrates a resource plan with subplans.

27.1.2.1 About the Elements of Resource Manager

The elements of the Resource Manager include resource consumer groups, resource plans, and resource plan directives.

Element	Description
Resource consumer group	A group of sessions that are grouped together based on resource requirements. The Resource Manager allocates resources to resource consumer groups, not to individual sessions.
Resource plan	A container for directives that specify how resources are allocated to resource consumer groups. You specify how the database allocates resources by activating a specific resource plan.
Resource plan directive	Associates a resource consumer group with a particular plan and specifies how resources are to be allocated to that resource consumer group.

You use the `DBMS_RESOURCE_MANAGER` PL/SQL package to create and maintain these elements. The elements are stored in tables in the data dictionary. You can view information about them with data dictionary views.

See Also:

["Resource Manager Data Dictionary Views"](#)

27.1.2.2 About Resource Consumer Groups

A resource consumer group (consumer group) is a collection of user sessions that are grouped together based on their processing needs.

When a session is created, it is automatically mapped to a consumer group based on mapping rules that you set up. As a database administrator (DBA), you can manually switch a session to a different consumer group. Similarly, an application can run a PL/SQL package procedure that switches its session to a particular consumer group.

Because the Resource Manager allocates resources (such as CPU) only to consumer groups, when a session becomes a member of a consumer group, its resource allocation is determined by the allocation for the consumer group.

There are special consumer groups that are always present in the data dictionary. They cannot be modified or deleted. They are:

- `SYS_GROUP`

This is the initial consumer group for all sessions created by user accounts `SYS` or `SYSTEM`. This initial consumer group can be overridden by session-to-consumer group mapping rules.

- `OTHER_GROUPS`

This consumer group contains all sessions that have not been assigned to a consumer group. Every resource plan must contain a directive to `OTHER_GROUPS`.

There can be no more than 28 resource consumer groups in any active plan.

 **See Also:**

- [Table 27-6](#)
- ["Specifying Session-to-Consumer Group Mapping Rules"](#)

27.1.2.3 About Resource Plan Directives

The Resource Manager allocates resources to consumer groups according to the set of resource plan directives (directives) that belong to the currently active resource plan.

There is a parent-child relationship between a resource plan and its resource plan directives. Each directive references one consumer group, and no two directives for the currently active plan can reference the same consumer group.

A directive has several ways in which it can limit resource allocation for a consumer group. For example, it can control how much CPU the consumer group gets as a percentage of total CPU, and it can limit the total number of sessions that can be active in the consumer group. See ["The Types of Resources Managed by the Resource Manager"](#) for more information.

27.1.2.4 About Resource Plans

A resource plan is a container for directives that specify how resources are allocated to resource consumer groups.

In addition to the resource plans that are predefined for each Oracle database, you can create any number of resource plans. However, only one resource plan is active at a time. When a resource plan is active, each of its child resource plan directives controls resource allocation for a different consumer group. Each plan must include a directive that allocates resources to the consumer group named `OTHER_GROUPS`. `OTHER_GROUPS` applies to all sessions that belong to a consumer group that is not part of the currently active plan.

Note:

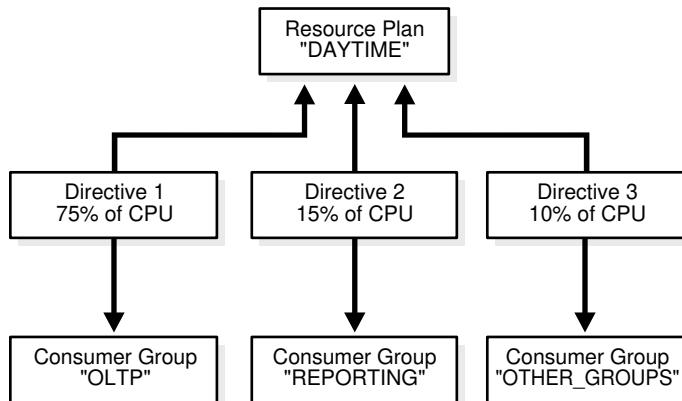

Although the term "resource plan" (or just "plan") denotes one element of the Resource Manager, in this chapter it is also used to refer to a complete *resource plan schema*, which includes the resource plan element itself, its resource plan directives, and the consumer groups that the directives reference. For example, when this chapter refers to the DAYTIME resource plan, it could mean either the resource plan element named DAYTIME, or the particular resource allocation schema that the DAYTIME resource plan and its directives define. Thus, for brevity, it is acceptable to say, "the DAYTIME plan favors interactive applications over batch applications."

27.1.2.5 Example: A Simple Resource Plan

An example illustrates a simple resource plan.

Figure 27-1 shows a simple resource plan for an organization that runs online transaction processing (OLTP) applications and reporting applications simultaneously during the daytime. The currently active plan, DAYTIME, allocates CPU resources among three resource consumer groups. Specifically, OLTP is allotted 75% of the CPU time, REPORTS is allotted 15%, and OTHER_GROUPS receives the remaining 10%. Any group can use more resources than it is guaranteed if there is no resource contention. For example, OLTP is guaranteed 75% of the CPU, but if there is no resource contention, it can use up to 100% of the CPU.

Figure 27-1 A Simple Resource Plan

Oracle Database provides a procedure (`CREATE_SIMPLE_PLAN`) that enables you to quickly create a simple resource plan. This procedure is discussed in "[Creating a Simple Resource Plan](#)".

 **Note:**

The currently active resource plan does not enforce allocations until CPU usage is at 100%. If the CPU usage is below 100%, the database is not CPU-bound and hence there is no need to enforce allocations to ensure that all sessions get their designated resource allocation.

In addition, when allocations are enforced, unused allocation by any consumer group can be used by other consumer groups. In the previous example, if the OLTP group does not use all of its allocation, the Resource Manager permits the REPORTS group or OTHER_GROUPS group to use the unused allocation.

27.1.2.6 About Subplans

Instead of referencing a consumer group, a resource plan directive (directive) can reference another resource plan. In this case, the plan is referred to as a subplan.

The subplan itself has directives that allocate resources to consumer groups and other subplans. The resource allocation scheme then works like this: The *top* resource plan (the currently active plan) divides resources among consumer groups and subplans. Each subplan allocates its portion of the total resource allocation among its consumer groups and subplans. You can create hierarchical plans with any number of subplans.

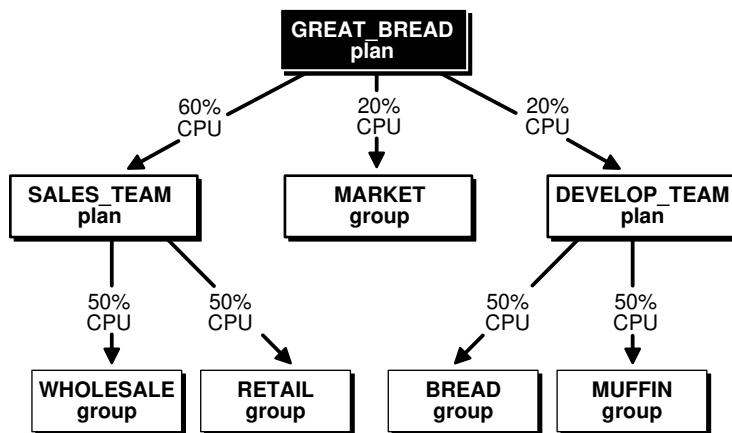

You create a resource subplan in the same way that you create a resource plan. To create a plan that is to be used only as a subplan, you use the SUB_PLAN argument in the package procedure DBMS_RESOURCE_MANAGER.CREATE_PLAN.

In any top level plan, you can reference a subplan only once. A subplan is not required to have a directive to OTHER_GROUPS and cannot be set as a resource plan.

27.1.2.7 Example: A Resource Plan with Subplans

An example illustrates a resource plan with subplans.

In this example, the Great Bread Company allocates the CPU resource as shown in [Figure 27-2](#). The figure illustrates a top plan (GREAT_BREAD) and all of its descendants. For simplicity, the requirement to include the OTHER_GROUPS consumer group is ignored, and resource plan directives are not shown, even though they are part of the plan. Rather, the CPU percentages that the directives allocate are shown along the connecting lines between plans, subplans, and consumer groups.

Figure 27-2 A Resource Plan With Subplans

The GREAT_BREAD plan allocates resources as follows:

- 20% of CPU resources to the consumer group MARKET
- 60% of CPU resources to subplan SALES_TEAM, which in turn divides its share equally between the WHOLESALE and RETAIL consumer groups
- 20% of CPU resources to subplan DEVELOP_TEAM, which in turn divides its resources equally between the BREAD and MUFFIN consumer groups

It is possible for a subplan or consumer group to have multiple parents. An example would be if the MARKET group were included in the SALES_TEAM subplan. However, a plan cannot contain any loops. For example, the SALES_TEAM subplan cannot have a directive that references the GREAT_BREAD plan.

See Also:

["Putting It All Together: Oracle Database Resource Manager Examples"](#) for an example of a more complex resource plan.

27.1.3 About Resource Manager Administration Privileges

You must have the required privileges to administer the Resource Manager.

You must have the system privilege ADMINISTER_RESOURCE_MANAGER to administer the Resource Manager. This privilege (with the ADMIN option) is granted to database administrators through the DBA role.

Being an administrator for the Resource Manager enables you to execute all of the procedures in the DBMS_RESOURCE_MANAGER PL/SQL package.

You may, as an administrator with the ADMIN option, choose to grant the administrative privilege to other users or roles. To do so, use the DBMS_RESOURCE_MANAGER_PRIVS PL/SQL package. The relevant package procedures are listed in the following table.

Procedure	Description
GRANT_SYSTEM_PRIVILEGE	Grants the ADMINISTER_RESOURCE_MANAGER system privilege to a user or role.
REVOKE_SYSTEM_PRIVILEGE	Revokes the ADMINISTER_RESOURCE_MANAGER system privilege from a user or role.

The following PL/SQL block grants the administrative privilege to user `HR`, but does not grant `HR` the `ADMIN` option. Therefore, `HR` can execute all of the procedures in the `DBMS_RESOURCE_MANAGER` package, but `HR` cannot use the `GRANT_SYSTEM_PRIVILEGE` procedure to grant the administrative privilege to others.

```
BEGIN
  DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SYSTEM_PRIVILEGE(
    GRANTEE_NAME    => 'HR',
    PRIVILEGE_NAME  => 'ADMINISTER_RESOURCE_MANAGER',
    ADMIN_OPTION    => FALSE);
END;
/
```

You can revoke this privilege using the `REVOKE_SYSTEM_PRIVILEGE` procedure.

 **Note:**

The `ADMINISTER_RESOURCE_MANAGER` system privilege can only be granted or revoked using the `DBMS_RESOURCE_MANAGER_PRIVS` package. It cannot be granted or revoked through the SQL `GRANT` or `REVOKE` statements.

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference*. for information about the `DBMS_RESOURCE_MANAGER` package
- *Oracle Database PL/SQL Packages and Types Reference*. for information about the `DBMS_RESOURCE_MANAGER_PRIVS` package
- *Oracle Database Security Guide* for information about the `ADMIN` option

27.2 Assigning Sessions to Resource Consumer Groups

There are automatic and manual methods that database administrators, users, and applications can use to assign sessions to resource consumer groups. When a session is assigned to a resource consumer group, Oracle Database Resource Manager (the Resource Manager) can manage resource allocation for it.

 **Note:**

Sessions that are not assigned to a consumer group are placed in the consumer group OTHER_GROUPS.

- [Overview of Assigning Sessions to Resource Consumer Groups](#)
Before you enable the Resource Manager, you must specify how user sessions are assigned to resource consumer groups.
- [Assigning an Initial Resource Consumer Group](#)
The initial consumer group of a session is determined by the mapping rules that you configure.
- [Specifying Session-to–Consumer Group Mapping Rules](#)
You can create and prioritize session-to–consumer group mapping rules.
- [Switching Resource Consumer Groups](#)
You can switch the resource consumer group of a session.
- [Specifying Automatic Consumer Group Switching](#)
You can configure the Resource Manager to automatically switch a session to another consumer group when a certain condition is met.
- [Granting and Revoking the Switch Privilege](#)
A user or application must have the switch privilege to switch a session to a specified resource consumer group.

27.2.1 Overview of Assigning Sessions to Resource Consumer Groups

Before you enable the Resource Manager, you must specify how user sessions are assigned to resource consumer groups.

You do this by creating *mapping rules* that enable the Resource Manager to automatically assign each session to a consumer group upon session startup, based upon session attributes. After a session is assigned to its initial consumer group and is running, you can call a procedure to manually switch the session to a different consumer group. You would typically do this if the session is using excessive resources and must be moved to a consumer group that is more limited in its resource allocation. You can also grant the *switch privilege* to users and to applications so that they can switch their sessions from one consumer group to another.

The database can also automatically switch a session from one consumer group to another (typically lower priority) consumer group when there are changes in session attributes or when a session exceeds designated resource consumption limits.

27.2.2 Assigning an Initial Resource Consumer Group

The initial consumer group of a session is determined by the mapping rules that you configure.

For information on how to configure mapping rules, see "[Specifying Session-to–Consumer Group Mapping Rules](#)".

27.2.3 Specifying Session-to-Consumer Group Mapping Rules

You can create and prioritize session-to-consumer group mapping rules.

- [About Session-to-Consumer Group Mapping Rules](#)

You can specify the initial consumer group for a session and dynamically switch the session to a different consumer group if the session attributes change.

- [Creating Consumer Group Mapping Rules](#)

You use the `SET_CONSUMER_GROUP_MAPPING` procedure to map a session attribute/value pair to a consumer group.

- [Modifying and Deleting Consumer Group Mapping Rules](#)

To modify a consumer group mapping rule, run the `SET_CONSUMER_GROUP_MAPPING` procedure against the desired attribute/value pair, specifying a new consumer group.

- [Creating Mapping Rule Priorities](#)

To resolve conflicting mapping rules, you can establish a priority ordering of the session attributes from most important to least important.

27.2.3.1 About Session-to-Consumer Group Mapping Rules

You can specify the initial consumer group for a session and dynamically switch the session to a different consumer group if the session attributes change.

By creating session-to-consumer group mapping rules, you can:

- Specify the initial consumer group for a session based on session attributes.
- Enable the Resource Manager to dynamically switch a running session to another consumer group based on changing session attributes.

The mapping rules are based on session attributes such as the user name, the service that the session used to connect to the database, or the name of the client program.

To resolve conflicts among mapping rules, the Resource Manager orders the rules by priority. For example, suppose user SCOTT connects to the database with the SALES service. If one mapping rule states that user SCOTT starts in the MED_PRIORITY consumer group, and another states that sessions that connect with the SALES service start in the HIGH_PRIORITY consumer group, mapping rule priorities resolve this conflict.

There are two types of session attributes upon which mapping rules are based: login attributes and run-time attributes. The login attributes are meaningful only at session login time, when the Resource Manager determines the initial consumer group of the session. Run-time attributes apply any time during and after session login. You can reassign a logged in session to another consumer group by changing any of its run-time attributes.

You use the `SET_CONSUMER_GROUP_MAPPING` and `SET_CONSUMER_GROUP_MAPPING_PRI` procedures to configure the automatic assignment of sessions to consumer groups. You must use a pending area for these procedures. (You must create the pending area, run the procedures, optionally validate the pending area, and then submit the pending area. For examples of using the pending area, see "[Creating a Complex Resource Plan](#)".)

A session is automatically switched to a consumer group through mapping rules at distinct points in time:

- When the session first logs in, the mapping rules are evaluated to determine the initial group of the session.
- If a session attribute is dynamically changed to a new value (which is only possible for run-time attributes), then the mapping rules are reevaluated, and the session might be switched to another consumer group.

Predefined Consumer Group Mapping Rules

Each Oracle database comes with a set of predefined consumer group mapping rules:

- As described in "[About Resource Consumer Groups](#)", all sessions created by user accounts SYS or SYSTEM are initially mapped to the SYS_GROUP consumer group.
- Sessions performing a data load with Data Pump or performing backup or copy operations with RMAN are automatically mapped to the predefined consumer groups designated in [Table 27-7](#).

You can use the DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING procedure to modify or delete any of these predefined mapping rules.

See Also:

- "[Assigning an Initial Resource Consumer Group](#)"
- "[Specifying Automatic Switching with Mapping Rules](#)"

27.2.3.2 Creating Consumer Group Mapping Rules

You use the SET_CONSUMER_GROUP_MAPPING procedure to map a session attribute/value pair to a consumer group.

The parameters for this procedure are the following:

Parameter	Description
ATTRIBUTE	The session attribute type, specified as a package constant
VALUE	The value of the attribute
CONSUMER_GROUP	The consumer group to map to for this attribute/value pair

ATTRIBUTE can be one of the following:

Attribute	Type	Description
ORACLE_USER	Login	The Oracle Database user name
SERVICE_NAME	Login	The database service name used by the client to establish a connection
CLIENT_OS_USER	Login	The operating system user name of the client that is logging in

Attribute	Type	Description
CLIENT_PROG	Login	The name of the client program used to log in to the server
RAM		
CLIENT_MACH	Login	The name of the computer from which the client is making the connection
INE		
CLIENT_ID	Login	The client identifier for the session
		The client identifier session attribute is set by the DBMS_SESSION.SET_IDENTIFIER procedure.
MODULE_NAME	Run-time	The module name in the currently running application as set by the DBMS_APPLICATION_INFO.SET_MODULE procedure or the equivalent OCI attribute setting
MODULE_NAME	Run-time	A combination of the current module and the action being performed as set by either of the following procedures or their equivalent OCI attribute setting:
_ACTION		<ul style="list-style-type: none"> • DBMS_APPLICATION_INFO.SET_MODULE • DBMS_APPLICATION_INFO.SET_ACTION <p>The attribute is specified as the module name followed by a period (.), followed by the action name (<i>module_name.action_name</i>).</p>
SERVICE_MOD	Run-time	A combination of service and module names in this form: <i>service_name.module_name</i>
ULE		
SERVICE_MOD	Run-time	A combination of service name, module name, and action name, in this form: <i>service_name.module_name.action_name</i>
ULE_ACTION		
ORACLE_FUNC	Run-time	An RMAN or Data Pump operation. Valid values are DATALOAD, BACKUP, and COPY. There are predefined mappings for each of these values. If your session is performing any of these functions, it is automatically mapped to a predefined consumer group. See Table 27-7 for details.
TION		

For example, the following PL/SQL block causes user SCOTT to map to the DEV_GROUP consumer group every time that he logs in:

```

BEGIN
  DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING
    (DBMS_RESOURCE_MANAGER.ORACLE_USER, 'SCOTT', 'DEV_GROUP');
END;
/

```

Again, you must create a pending area before running the SET_CONSUMER_GROUP_MAPPING procedure.

You can use wildcards for the value of most attributes in the `value` parameter in the SET_CONSUMER_GROUP_MAPPING procedure. To specify values with wildcards, use the same semantics as the SQL LIKE operator. Specifically, wildcards use the following semantics:

- % for a multicharacter wildcard
- _ for a single character wildcard
- \ to escape the wildcards

Wildcards can only be used if the attribute is one of the following:

- CLIENT_OS_USER

- CLIENT_PROGRAM
- CLIENT_MACHINE
- MODULE_NAME
- MODULE_NAME_ACTION
- SERVICE_MODULE
- SERVICE_MODULE_ACTION

27.2.3.3 Modifying and Deleting Consumer Group Mapping Rules

To modify a consumer group mapping rule, run the `SET_CONSUMER_GROUP_MAPPING` procedure against the desired attribute/value pair, specifying a new consumer group.

To delete a rule, run the `SET_CONSUMER_GROUP_MAPPING` procedure against the desired attribute/value pair and specify a `NULL` consumer group.

27.2.3.4 Creating Mapping Rule Priorities

To resolve conflicting mapping rules, you can establish a priority ordering of the session attributes from most important to least important.

You use the `SET_CONSUMER_GROUP_MAPPING_PRI` procedure to set the priority of each attribute to a unique integer from 1 (most important) to 12 (least important). The following example illustrates this setting of priorities:

```
BEGIN
    DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING_PRI(
        EXPLICIT => 1,
        SERVICE_MODULE_ACTION => 2,
        SERVICE_MODULE => 3,
        MODULE_NAME_ACTION => 4,
        MODULE_NAME => 5,
        SERVICE_NAME => 6,
        ORACLE_USER => 7,
        CLIENT_PROGRAM => 8,
        CLIENT_OS_USER => 9,
        CLIENT_MACHINE => 10,
        CLIENT_ID => 11);
END;
/
```

In this example, the priority of the database user name is set to 7 (less important), while the priority of the module name is set to 5 (more important).

 **Note:**

SET_CONSUMER_GROUP_MAPPING_PRI requires that you include the pseudo-attribute EXPLICIT as an argument. It must be set to 1. It indicates that explicit consumer group switches have the highest priority. You explicitly switch consumer groups with these package procedures, which are described in detail in *Oracle Database PL/SQL Packages and Types Reference*:

- DBMS_SESSION.SWITCH_CURRENT_CONSUMER_GROUP
- DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_SESS
- DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_USER

To illustrate how mapping rule priorities work, continuing with the previous example, assume that in addition to the mapping of user SCOTT to the DEV_GROUP consumer group, there is also a module name mapping rule as follows:

```
BEGIN
    DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING
        (DBMS_RESOURCE_MANAGER MODULE_NAME, 'EOD_REPORTS', 'LOW_PRIORITY');
END;
/
```

Now if the application in user SCOTT's session sets its module name to EOD_REPORTS, the session is reassigned to the LOW_PRIORITY consumer group, because module name mapping has a higher priority than database user mapping.

You can query the view DBA_RSRC_MAPPING_PRIORITY to see the current priority ordering of session attributes.

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference* for information about setting the module name with the DBMS_APPLICATION_INFO.SET_MODULE procedure
- "[Granting and Revoking the Switch Privilege](#)"

27.2.4 Switching Resource Consumer Groups

You can switch the resource consumer group of a session.

- [Manually Switching Resource Consumer Groups](#)
You can change the resource consumer group of running sessions.
- [Enabling Users or Applications to Manually Switch Consumer Groups](#)
You can grant a user the switch privilege so that he can switch his current consumer group using the SWITCH_CURRENT_CONSUMER_GROUP procedure in the DBMS_SESSION package.

27.2.4.1 Manually Switching Resource Consumer Groups

You can change the resource consumer group of running sessions.

- [About Manually Switching Resource Consumer Groups](#)

The DBMS_RESOURCE_MANAGER PL/SQL package provides two procedures that enable you to change the resource consumer group of running sessions.

- [Switching a Single Session](#)

The SWITCH_CONSUMER_GROUP_FOR_SESS procedure causes the specified session to immediately be moved into the specified resource consumer group. In effect, this procedure can raise or lower priority of the session.

- [Switching All Sessions for a User](#)

The SWITCH_CONSUMER_GROUP_FOR_USER procedure changes the resource consumer group for all sessions pertaining to the specified user name.

27.2.4.1.1 About Manually Switching Resource Consumer Groups

The DBMS_RESOURCE_MANAGER PL/SQL package provides two procedures that enable you to change the resource consumer group of running sessions.

Both of these procedures can also change the consumer group of any parallel execution server sessions associated with the coordinator session. The changes made by these procedures pertain to current sessions only; they are not persistent. They also do not change the initial consumer groups for users.

Instead of killing (terminating) a session of a user who is using excessive CPU, you can change that user's consumer group to one that is allocated fewer resources.

27.2.4.1.2 Switching a Single Session

The SWITCH_CONSUMER_GROUP_FOR_SESS procedure causes the specified session to immediately be moved into the specified resource consumer group. In effect, this procedure can raise or lower priority of the session.

The following PL/SQL block switches a specific session to a new consumer group. The session identifier (`SID`) is 17, the session serial number (`SERIAL#`) is 12345, and the new consumer group is the `HIGH_PRIORITY` consumer group.

```
BEGIN
    DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_SESS ('17', '12345',
    'HIGH_PRIORITY');
END;
/
```

The `SID`, session serial number, and current resource consumer group for a session are viewable using the `V$SESSION` view.

See Also:

Oracle Database Reference for details about the `V$SESSION` view.

27.2.4.1.3 Switching All Sessions for a User

The `SWITCH_CONSUMER_GROUP_FOR_USER` procedure changes the resource consumer group for all sessions pertaining to the specified user name.

The following PL/SQL block switches all sessions that belong to user `HR` to the `LOW_GROUP` consumer group:

```
BEGIN
  DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_USER ('HR',
  'LOW_GROUP');
END;
/
```

27.2.4.2 Enabling Users or Applications to Manually Switch Consumer Groups

You can grant a user the switch privilege so that he can switch his current consumer group using the `SWITCH_CURRENT_CONSUMER_GROUP` procedure in the `DBMS_SESSION` package.

A user can run this procedure from an interactive session, for example from SQL*Plus, or an application can call this procedure to switch its session, effectively dynamically changing its priority.

The `SWITCH_CURRENT_CONSUMER_GROUP` procedure enables users to switch to only those consumer groups for which they have the switch privilege. If the caller is another procedure, then this procedure enables users to switch to a consumer group for which the owner of that procedure has switch privileges.

The parameters for this procedure are the following:

Parameter	Description
<code>NEW_CONSUMER_GROUP</code>	The consumer group to which the user is switching.
<code>OLD_CONSUMER_GROUP</code>	Returns the name of the consumer group from which the user switched. Can be used to switch back later.
<code>INITIAL_GROUP_ON_ERR</code>	Controls behavior if a switching error occurs.
<code>OR</code>	If TRUE, in the event of an error, the user is switched to the initial consumer group. If FALSE, raises an error.

The following SQL*Plus session illustrates switching to a new consumer group. By printing the value of the output parameter `old_group`, the example illustrates how the old consumer group name is saved.

```
SET serveroutput on
DECLARE
  old_group varchar2(30);
BEGIN
  DBMS_SESSION.SWITCH_CURRENT_CONSUMER_GROUP('BATCH_GROUP', old_group, FALSE);
  DBMS_OUTPUT.PUT_LINE('OLD GROUP = ' || old_group);
END;
/
```

The following line is output:

```
OLD GROUP = OLTP_GROUP
```

Note that the Resource Manager considers a switch to have taken place even if the `SWITCH_CURRENT_CONSUMER_GROUP` procedure is called to switch the session to the consumer group that it is already in.

 **Note:**

The Resource Manager also works in environments where a generic database user name is used to log on to an application. The `DBMS_SESSION` package can be called to switch the consumer group assignment of a session at session startup, or as particular modules are called.

 **See Also:**

- ["Granting and Revoking the Switch Privilege"](#)
- [Oracle Database PL/SQL Packages and Types Reference](#) for additional examples and more information about the `DBMS_SESSION` package

27.2.5 Specifying Automatic Consumer Group Switching

You can configure the Resource Manager to automatically switch a session to another consumer group when a certain condition is met.

Automatic switching can occur when: a session attribute changes, causing a new mapping rule to take effect, or a session exceeds the CPU, physical I/O, or logical I/O resource consumption limits set by its consumer group, or it exceeds the elapsed time limit set by its consumer group.

- [Specifying Automatic Switching with Mapping Rules](#)

If a session attribute changes while the session is running, then the session-to-consumer group mapping rules are reevaluated. If a new rule takes effect, then the session might be moved to a different consumer group.

- [Specifying Automatic Switching by Setting Resource Limits](#)

You can manage runaway sessions or calls that use CPU, physical I/O, or logical I/O resources beyond a specified limit. A runaway session is a SQL query, while a runaway call is a PL/SQL call.

27.2.5.1 Specifying Automatic Switching with Mapping Rules

If a session attribute changes while the session is running, then the session-to-consumer group mapping rules are reevaluated. If a new rule takes effect, then the session might be moved to a different consumer group.

See "[Specifying Session-to–Consumer Group Mapping Rules](#)" for more information.

27.2.5.2 Specifying Automatic Switching by Setting Resource Limits

You can manage runaway sessions or calls that use CPU, physical I/O, or logical I/O resources beyond a specified limit. A runaway session is a SQL query, while a runaway call is a PL/SQL call.

When you create a resource plan directive for a consumer group, you can specify limits for CPU, physical I/O, or logical I/O resource consumption for sessions in that group. You can specify limits for physical I/O and logical I/O separately. You can also specify a limit for elapsed time. If the `SWITCH_FOR_CALL` resource plan directive is set to `FALSE`, then Resource Manager enforces these limits from the start of the session. If the `SWITCH_FOR_CALL` resource plan directive is set to `TRUE`, then Resource Manager enforces these limits from the start of the SQL operation or PL/SQL block.

You can then specify the action that is to be taken if any single session or call exceeds one of these limits. The possible actions are the following:

- The session is dynamically switched to a designated consumer group.
The target consumer group is typically one that has lower resource allocations.
- The session is killed (terminated).
- The session's current SQL statement is aborted.
- Information about the session is logged, but no other action is taken for the session.

The following are the resource plan directive attributes that are involved in this type of automatic session switching.

- `SWITCH_GROUP`
- `SWITCH_TIME`
- `SWITCH_ESTIMATE`
- `SWITCH_IO_MEGABYTES`
- `SWITCH_IO_REQS`
- `SWITCH_FOR_CALL`
- `SWITCH_IO_LOGICAL`
- `SWITCH_ELAPSED_TIME`

See "[Creating Resource Plan Directives](#)" for descriptions of these attributes.

Switches occur for sessions that are running and consuming resources, not waiting for user input or waiting for CPU cycles. After a session is switched, it continues in the target consumer group until it becomes idle, at which point it is switched back to its original consumer group. However, if `SWITCH_FOR_CALL` is set to `TRUE`, then the Resource Manager does not wait until the session is idle to return it to its original resource consumer group. Instead, the session is returned when the current top-level call completes. A **top-level call** in PL/SQL is an entire PL/SQL block treated as one call. A top-level call in SQL is an individual SQL statement.

`SWITCH_FOR_CALL` is useful for three-tier applications where the middle tier server is using session pooling.

A switched session is allowed to continue running even if the active session pool for the new group is full. Under these conditions, a consumer group can have more sessions running than specified by its active session pool.

When `SWITCH_FOR_CALL` is `FALSE`, the Resource Manager views a session as idle if a certain amount of time passes between calls. This time interval is a few seconds and is not configurable.

The following are examples of automatic switching based on resource limits. You must create a pending area before running these examples.

Example 1

The following PL/SQL block creates a resource plan directive for the `OLTP` group that switches any session in that group to the `LOW_GROUP` consumer group if a call in the sessions exceeds 5 seconds of CPU time. This example prevents unexpectedly long queries from consuming too many resources. The switched-to consumer group is typically one with lower resource allocations.

```
BEGIN
  DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'DAYTIME',
    GROUP_OR_SUBPLAN => 'OLTP',
    COMMENT        => 'OLTP group',
    MGMT_P1       => 75,
    SWITCH_GROUP  => 'LOW_GROUP',
    SWITCH_TIME   => 5);
END;
/
```

Example 2

The following PL/SQL block creates a resource plan directive for the `OLTP` group that temporarily switches any session in that group to the `LOW_GROUP` consumer group if the session exceeds 10,000 physical I/O requests or exceeds 2,500 Megabytes of data transferred. The session is returned to its original group after the offending top call is complete.

```
BEGIN
  DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'DAYTIME',
    GROUP_OR_SUBPLAN => 'OLTP',
    COMMENT        => 'OLTP group',
    MGMT_P1       => 75,
    SWITCH_GROUP  => 'LOW_GROUP',
    SWITCH_IO_REQS => 10000,
    SWITCH_IO_MEGABYTES => 2500,
    SWITCH_FOR_CALL => TRUE);
END;
/
```

Example 3

The following PL/SQL block creates a resource plan directive for the `REPORTING` group that kills (terminates) any session that exceeds 60 seconds of CPU time. This example prevents runaway queries from consuming too many resources.

```
BEGIN
  DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'DAYTIME',
```

```

GROUP_OR_SUBPLAN => 'REPORTING',
COMMENT          => 'Reporting group',
MGMT_P1          => 75,
SWITCH_GROUP     => 'KILL_SESSION',
SWITCH_TIME      => 60);
END;
/

```

In this example, the reserved consumer group name `KILL_SESSION` is specified for `SWITCH_GROUP`. Therefore, the session is terminated when the switch criteria is met. Other reserved consumer group names are `CANCEL_SQL` and `LOG_ONLY`. When `CANCEL_SQL` is specified, the current call is canceled when switch criteria are met, but the session is not terminated. When `LOG_ONLY` is specified, information about the session is recorded in real-time SQL monitoring, but no specific action is taken for the session.

Example 4

The following PL/SQL block creates a resource plan directive for the `OLTP` group that temporarily switches any session in that group to the `LOW_GROUP` consumer group if the session exceeds 100 logical I/O requests. The session is returned to its original group after the offending top call is complete.

```

BEGIN
  DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'DAYTIME',
    GROUP_OR_SUBPLAN => 'OLTP',
    COMMENT        => 'OLTP group',
    MGMT_P1        => 75,
    SWITCH_GROUP   => 'LOW_GROUP',
    SWITCH_IO_LOGICAL => 100,
    SWITCH_FOR_CALL => TRUE);
END;
/

```

Example 5

The following PL/SQL block creates a resource plan directive for the `OLTP` group that temporarily switches any session in that group to the `LOW_GROUP` consumer group if a call in a session exceeds five minutes (300 seconds). The session is returned to its original group after the offending top call is complete.

```

BEGIN
  DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'DAYTIME',
    GROUP_OR_SUBPLAN => 'OLTP',
    COMMENT        => 'OLTP group',
    MGMT_P1        => 75,
    SWITCH_GROUP   => 'LOW_GROUP',
    SWITCH_FOR_CALL => TRUE,
    SWITCH_ELAPSED_TIME => 300);
END;
/

```

 See Also:

- "[Creating Resource Plan Directives](#)"
- "[What Solutions Does the Resource Manager Provide for Workload Management?](#)" for information about logical I/O

27.2.6 Granting and Revoking the Switch Privilege

A user or application must have the switch privilege to switch a session to a specified resource consumer group.

- [About Granting and Revoking the Switch Privilege](#)

Using the `DBMS_RESOURCE_MANAGER_PRIVS` PL/SQL package, you can grant or revoke the switch privilege to a user, role, or `PUBLIC`. The switch privilege enables a user or application to switch a session to a specified resource consumer group.

- [Granting the Switch Privilege](#)

You can grant a user the privilege to switch to a specific consumer group using the `GRANT_SWITCH_CONSUMER_GROUP` procedure.

- [Revoking Switch Privileges](#)

You can revoke a user's privilege to switch to a specific consumer group using the `REVOKE_SWITCH_CONSUMER_GROUP` procedure.

27.2.6.1 About Granting and Revoking the Switch Privilege

Using the `DBMS_RESOURCE_MANAGER_PRIVS` PL/SQL package, you can grant or revoke the switch privilege to a user, role, or `PUBLIC`. The switch privilege enables a user or application to switch a session to a specified resource consumer group.

The package also enables you to revoke the switch privilege. The relevant package procedures are listed in the following table.

Procedure	Description
<code>GRANT_SWITCH_CONSUMER_GROUP</code>	Grants permission to a user, role, or <code>PUBLIC</code> to switch to a specified resource consumer group.
<code>REVOKE_SWITCH_CONSUMER_GROUP</code>	Revokes permission for a user, role, or <code>PUBLIC</code> to switch to a specified resource consumer group.

`OTHER_GROUPS` has switch privileges granted to `PUBLIC`. Therefore, all users are automatically granted the switch privilege for this consumer group.

The following switches do not require explicit switch privilege:

- There is a consumer group mapping specified by the `SET_CONSUMER_GROUP_MAPPING` procedure in the `DBMS_RESOURCE_MANAGER` package, and a session is switching to a different consumer group due to the mapping. See "[Creating Consumer Group Mapping Rules](#)".
- There is an automatic consumer group switch when a switch condition is met based on the setting of the `switch_group` parameter of a resource plan directive.

Explicit switch privilege is required for a user to switch a session to a consumer group in all other cases.

 **See Also:**

- "[Enabling Users or Applications to Manually Switch Consumer Groups](#)"
- "[Specifying Automatic Consumer Group Switching](#)"

27.2.6.2 Granting the Switch Privilege

You can grant a user the privilege to switch to a specific consumer group using the `GRANT_SWITCH_CONSUMER_GROUP` procedure.

The following example grants user SCOTT the privilege to switch to consumer group OLTP.

```
BEGIN
    DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SWITCH_CONSUMER_GROUP (
        GRANTEE_NAME    => 'SCOTT',
        CONSUMER_GROUP  => 'OLTP',
        GRANT_OPTION    => TRUE);
END;
/
```

User SCOTT is also granted permission to grant switch privileges for OLTP to others.

If you grant permission to a role to switch to a particular resource consumer group, then any user who is granted that role and has enabled that role can switch his session to that consumer group.

If you grant `PUBLIC` the permission to switch to a particular consumer group, then any user can switch to that group.

If the `GRANT_OPTION` argument is `TRUE`, then users granted switch privilege for the consumer group can also grant switch privileges for that consumer group to others.

27.2.6.3 Revoking Switch Privileges

You can revoke a user's privilege to switch to a specific consumer group using the `REVOKE_SWITCH_CONSUMER_GROUP` procedure.

The following example revokes user SCOTT's privilege to switch to consumer group OLTP.

```
BEGIN
    DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SWITCH_CONSUMER_GROUP (
        REVOKEE_NAME    => 'SCOTT',
        CONSUMER_GROUP  => 'OLTP');
END;
/
```

If you revoke a user's switch privileges for a particular consumer group, any subsequent attempts by that user to switch to that consumer group manually will fail. The user's session will then be automatically assigned to `OTHER_GROUPS`.

If you revoke from a role the switch privileges to a consumer group, any users who had switch privileges for the consumer group only through that role are no longer able to switch to that consumer group.

If you revoke switch privileges to a consumer group from PUBLIC, any users other than those who are explicitly assigned switch privileges either directly or through a role are no longer able to switch to that consumer group.

27.3 The Types of Resources Managed by the Resource Manager

Resource plan directives specify how resources are allocated to resource consumer groups or subplans. Each directive can specify several different methods for allocating resources to its consumer group or subplan.

- **CPU**

To manage CPU resources, Resource Manager allocates resources among consumer groups and redistributes CPU resources that were allocated but were not used. You can also set a limit on the amount of CPU resources that can be allocated to a particular consumer group.

- **Exadata I/O**

Management attributes enable you to specify CPU resource allocation for Exadata I/O.

- **Parallel Execution Servers**

Resource Manager can manage usage of the available parallel execution servers for a database.

- **Program Global Area (PGA)**

To manage PGA resources, Resource Manager can limit the amount of PGA memory that can be allocated to each session in a particular consumer group.

- **Runaway Queries**

Runaway sessions and calls can adversely impact overall performance if they are not managed properly. Resource Manager can take action when a session or call consumes more than a specified amount of CPU, physical I/O, logical I/O, or elapsed time. Resource Manager can either switch the session or call to a consumer group that is allocated a small amount of CPU or terminate the session or call.

- **Active Session Pool with Queuing**

You can control the maximum number of concurrently active sessions allowed within a consumer group. This maximum defines the **active session pool**.

- **Undo Pool**

You can specify an undo pool for each consumer group. An undo pool controls the total amount of undo for uncommitted transactions that can be generated by a consumer group.

- **Idle Time Limit**

You can specify an amount of time that a session can be idle, after which it is terminated.

27.3.1 CPU

To manage CPU resources, Resource Manager allocates resources among consumer groups and redistributes CPU resources that were allocated but were not used. You can also set a limit on the amount of CPU resources that can be allocated to a particular consumer group.

- **Management Attributes**

Management attributes enable you to specify how CPU resources are to be allocated among consumer groups and subplans.

- **Utilization Limit**

Use the `UTILIZATION_LIMIT` attribute to impose an absolute upper limit on CPU utilization for a resource consumer group. This absolute limit overrides any redistribution of CPU within a plan.

27.3.1.1 Management Attributes

Management attributes enable you to specify how CPU resources are to be allocated among consumer groups and subplans.

Multiple levels of CPU resource allocation (up to eight levels) provide a means of prioritizing CPU usage within a plan. Consumer groups and subplans at level 2 get resources that were not allocated at level 1 or that were allocated at level 1 but were not completely consumed by a consumer group or subplan at level 1. Similarly, resource consumers at level 3 are allocated resources only when some allocation remains from levels 1 and 2. The same rules apply to levels 4 through 8. Multiple levels not only provide a way of prioritizing, but they provide a way of explicitly specifying how all primary and leftover resources are to be used.

Use the management attributes `MGMT_Pn`, where *n* is an integer between 1 and 8, to specify multiple levels of CPU resource allocation. For example, use the `MGMT_P1` directive attribute to specify CPU resource allocation at level 1 and `MGMT_P2` directive attribute to specify resource allocation at level 2.

Use management attributes with parallel statement directive attributes, such as [Degree of Parallelism Limit](#) and [Parallel Server Limit](#), to control parallel statement queuing. When parallel statement queuing is used, management attributes are used to determine which consumer group is allowed to issue the next parallel statement. For example, if you set the `MGMT_P1` directive attribute for a consumer group to 80, that group has an 80% chance of issuing the next parallel statement.

 **See Also:**

[Oracle Database VLDB and Partitioning Guide](#) for information about parallel statement queuing

[Table 27-1](#) illustrates a simple resource plan with three levels.

Table 27-1 A Simple Three-Level Resource Plan

Consumer Group	Level 1 CPU Allocation	Level 2 CPU Allocation	Level 3 CPU Allocation
HIGH_GROUP	80%		
LOW_GROUP		50%	
MAINT_SUBPLAN		50%	
OTHER_GROUPS			100%

High priority applications run within `HIGH_GROUP`, which is allocated 80% of CPU. Because `HIGH_GROUP` is at level one, it gets priority for CPU utilization, but only up to 80% of CPU. This leaves a remaining 20% of CPU to be shared 50-50 by `LOW_GROUP` and the `MAINT_SUBPLAN` at level 2. Any unused allocation from levels 1 and 2 are then available to `OTHER_GROUPS` at level 3. Because `OTHER_GROUPS` has no sibling consumer groups or subplans at its level, 100% is specified.

Within a particular level, CPU allocations are not fixed. If there is not sufficient load in a particular consumer group or subplan, residual CPU can be allocated to remaining consumer groups or subplans. Thus, when there is only one level, unused allocation by any consumer group or subplan can be redistributed to other "sibling" consumer groups or subplans. If there are multiple levels, then the unused allocation is distributed to the consumer groups or subplans at the next level. If the last level has unused allocations, these allocations can be redistributed to all other levels in proportion to their designated allocations.

As an example of redistribution of unused allocations from one level to another, if during a particular period, `HIGH_GROUP` consumes only 25% of CPU, then 75% is available to be shared by `LOW_GROUP` and `MAINT_SUBPLAN`. Any unused portion of the 75% at level 2 is then made available to `OTHER_GROUPS` at level 3. However, if `OTHER_GROUPS` has no session activity at level 3, then the 75% at level 2 can be redistributed to all other consumer groups and subplans in the plan proportionally.

27.3.1.2 Utilization Limit

Use the `UTILIZATION_LIMIT` attribute to impose an absolute upper limit on CPU utilization for a resource consumer group. This absolute limit overrides any redistribution of CPU within a plan.

In the previous scenario, suppose that due to inactivity elsewhere, `LOW_GROUP` acquires 90% of CPU. Suppose that you do not want to allow `LOW_GROUP` to use 90% of the server because you do not want non-critical sessions to inundate the CPUs. The `UTILIZATION_LIMIT` attribute of resource plan directives can prevent this situation.

Setting the `UTILIZATION_LIMIT` attribute is optional. If you omit this attribute for a consumer group, there is no limit on the amount of CPU that the consumer group can use. Therefore, if all the other applications are idle, a consumer group that does not have `UTILIZATION_LIMIT` set can be allocated 100% of the CPU resources.

You can also use the `UTILIZATION_LIMIT` attribute as the sole means of limiting CPU utilization for consumer groups, without specifying level limits.

[Table 27-2](#) shows a variation of the previous plan. In this plan, using `UTILIZATION_LIMIT`, CPU utilization is capped at 75% for `LOW_GROUP`, 50% for

MAINT_SUBPLAN, and 75% for OTHER_GROUPS. (Note that the sum of all utilization limits can exceed 100%. Each limit is applied independently.)

Table 27-2 A Three-Level Resource Plan with Utilization Limits

Consumer Group	Level 1 CPU Allocation	Level 2 CPU Allocation	Level 3 CPU Allocation	Utilization Limit
HIGH_GROUP	80%			
LOW_GROUP		50%		75%
MAINT_SUBPLAN		50%		50%
OTHER_GROUPS			100%	75%

In the example described in [Table 27-2](#), if HIGH_GROUP is using only 10% of the CPU at a given time, then the remaining 90% is available to LOW_GROUP and the consumer groups in MAINT_SUBPLAN at level 2. If LOW_GROUP uses only 20% of the CPU, then 70% can be allocated to MAINT_SUBPLAN. However, MAINT_SUBPLAN has a UTILIZATION_LIMIT of 50%. Therefore, even though more CPU resources are available, the server cannot allocate more than 50% of the CPU to the consumer groups that belong to the subplan MAINT_SUBPLAN.

You can set UTILIZATION_LIMIT for both a subplan and the consumer groups that the subplan contains. In such cases, the limit for a consumer group is computed using the limits specified for the subplan and that consumer group. For example, the MAINT_SUBPLAN contains the consumer groups MAINT_GROUP1 and MAINT_GROUP2. MAINT_GROUP1 has UTILIZATION_LIMIT set to 40%. However, the limit for MAINT_SUBPLAN is set to 50%. Therefore, the limit for consumer group MAINT_GROUP1 is computed as 40% of 50%, or 20%. For an example of how to compute UTILIZATION_LIMIT for a consumer group when limits are specified for both the consumer group and the subplan to which the group belongs, see "[Example 4 - Specifying a Utilization Limit for Consumer Groups and Subplans](#)".

 **See Also:**

- ["Creating Resource Plan Directives "](#)
- ["Putting It All Together: Oracle Database Resource Manager Examples"](#)

27.3.2 Exadata I/O

Management attributes enable you to specify CPU resource allocation for Exadata I/O.

 **See Also:**

The Exadata documentation for information about using management attributes for Exadata I/O

27.3.3 Parallel Execution Servers

Resource Manager can manage usage of the available parallel execution servers for a database.

- **Degree of Parallelism Limit**

You can limit the maximum degree of parallelism for any operation within a consumer group. Use the `PARALLEL_DEGREE_LIMIT_P1` directive attribute to specify the degree of parallelism for a consumer group.

- **Parallel Server Limit**

Use the `PARALLEL_SERVER_LIMIT` directive attribute to specify the maximum percentage of the parallel execution server pool that a particular consumer group can use. The number of parallel execution servers used by a particular consumer group is counted as the sum of the parallel execution servers used by all sessions in that consumer group.

- **Parallel Queue Timeout**

The `PARALLEL_QUEUE_TIMEOUT` directive attribute enables you to specify the maximum time, in seconds, that a parallel statement can wait in the parallel statement queue before it is timed out.

27.3.3.1 Degree of Parallelism Limit

You can limit the maximum degree of parallelism for any operation within a consumer group. Use the `PARALLEL_DEGREE_LIMIT_P1` directive attribute to specify the degree of parallelism for a consumer group.

The degree of parallelism limit applies to one operation within a consumer group; it does not limit the total degree of parallelism across all operations within the consumer group. However, you can combine both the `PARALLEL_DEGREE_LIMIT_P1` and the `PARALLEL_SERVER_LIMIT` directive attributes to achieve the desired control. For more information about the `PARALLEL_SERVER_LIMIT` attribute, see "[Parallel Server Limit](#)".

 **See Also:**

Oracle Database VLDB and Partitioning Guide for more information about degree of parallelism in producer/consumer operations

27.3.3.2 Parallel Server Limit

Use the `PARALLEL_SERVER_LIMIT` directive attribute to specify the maximum percentage of the parallel execution server pool that a particular consumer group can use. The number of parallel execution servers used by a particular consumer group is counted as the sum of the parallel execution servers used by all sessions in that consumer group.

It is possible for a single consumer group to launch enough parallel statements to use all of the available parallel execution servers. If this happens when a high-priority parallel statement from a different consumer group is run, then no parallel execution servers are available to allocate to this group. You can avoid such a scenario by

limiting the number of parallel execution servers that can be used by a particular consumer group. You can also set the directive PARALLEL_STMT_CRITICAL to BYPASS_QUEUE for the high-priority consumer group so that parallel statements from the consumer group bypass the parallel statement queue.

For example, assume that the total number of parallel execution servers is 32, as set by the PARALLEL_SERVERS_TARGET initialization parameter, and the PARALLEL_SERVER_LIMIT directive attribute for the consumer group MY_GROUP is set to 50%. This consumer group can use a maximum of 50% of 32, or 16 parallel execution servers.

If your resource plan has management attributes (MGMT_P1, MGMT_P2, and so on), then a separate parallel statement queue is managed as a First In First Out (FIFO) queue for each management attribute.

If your resource plan does not have any management attributes, then a single parallel statement queue is managed as a FIFO queue.

In the case of an Oracle Real Application Clusters (Oracle RAC) environment, the target number of parallel execution servers is the sum of (PARALLEL_SERVER_LIMIT * PARALLEL_SERVERS_TARGET / 100) across all Oracle RAC instances. If a consumer group is using the number of parallel execution servers computed above or more, then it has exceeded its limit, and its parallel statements will be queued.

If a consumer group does not have any parallel statements running within an Oracle RAC database, then the first parallel statement is allowed to exceed the limit specified by PARALLEL_SERVER_LIMIT.

 **Note:**

In an Oracle Real Application Clusters (Oracle RAC) environment, the PARALLEL_SERVER_LIMIT attribute applies to the entire cluster and not to a single instance.

- [Managing Parallel Statement Queuing Using Parallel Server Limit](#)

The PARALLEL_SERVER_LIMIT attribute enables you to specify when parallel statements from a consumer group can be queued. Oracle Database maintains a separate parallel statement queue for each consumer group.

 **See Also:**

- ["Creating Resource Plan Directives "](#)
- ["Managing Parallel Statement Queuing Using Parallel Server Limit"](#)
- *Oracle Database VLDB and Partitioning Guide* for information about parallel statement queuing

27.3.3.2.1 Managing Parallel Statement Queuing Using Parallel Server Limit

The `PARALLEL_SERVER_LIMIT` attribute enables you to specify when parallel statements from a consumer group can be queued. Oracle Database maintains a separate parallel statement queue for each consumer group.

A parallel statement from a consumer group is not run and instead is added to the parallel statement queue of that consumer group if the following conditions are met:

- `PARALLEL_DEGREE_POLICY` is set to `AUTO`.

Setting this initialization parameter to `AUTO` enables automatic degree of parallelism (Auto DOP), parallel statement queuing, and in-memory parallel execution.

Note that parallel statements which have `PARALLEL_DEGREE_POLICY` set to `MANUAL` or `LIMITED` are executed immediately and are not added to the parallel statement queue.

- The number of active parallel execution servers across all consumer groups exceeds the `PARALLEL_SERVERS_TARGET` initialization parameter setting. This condition applies regardless of whether you specify `PARALLEL_SERVER_LIMIT`. If `PARALLEL_SERVER_LIMIT` is not specified, then it defaults to 100%.
- The sum of the number of active parallel execution servers for the consumer group and the degree of parallelism of the parallel statement exceeds the target number of active parallel execution servers.

The target number of active parallel execution servers is computed as follows:

`PARALLEL_SERVER_LIMIT/100 * PARALLEL_SERVERS_TARGET`

See Also:

"[Parallel Server Limit](#)"

27.3.3.3 Parallel Queue Timeout

The `PARALLEL_QUEUE_TIMEOUT` directive attribute enables you to specify the maximum time, in seconds, that a parallel statement can wait in the parallel statement queue before it is timed out.

When you use parallel statement queuing, if the database does not have sufficient resources to execute a parallel statement, the statement is queued until the required resources become available. However, there is a chance that a parallel statement may be waiting in the parallel statement queue for longer than is desired. You can prevent such scenarios by specifying the maximum time a parallel statement can wait in the parallel statement queue.

The `PARALLEL_QUEUE_TIMEOUT` attribute can be set for each consumer group. This attribute is applicable even if you do not specify other management attributes (`MGMT_P1`, `MGMT_P2`, and so on) in your resource plan.

 **See Also:**

Oracle Database VLDB and Partitioning Guide for more information about parallel statement queuing

 **Note:**

Because the parallel statement queue is clusterwide, all directives related to the parallel statement queue are also clusterwide.

When a parallel statement is timed out, the statement execution ends with the following error message:

ORA-07454: queue timeout, n second(s), exceeded

If you want more per-workload management, then you must use the following directive attributes:

- MGMT_Pn
 - Management attributes control how a parallel statement is selected from the parallel statement queue for execution. You can prioritize the parallel statements of one consumer group over another by setting a higher value for the management attributes of that group.
- PARALLEL_SERVER_LIMIT
- PARALLEL_QUEUE_TIMEOUT
- PARALLEL_DEGREE_LIMIT_P1

 **See Also:**

"[Example of Managing Parallel Statements Using Directive Attributes](#)" for more information about the combined use of all the parallel execution server directive attributes

Although parallel execution server usage is monitored for all sessions, the parallel execution server directive attributes you set affect only sessions for which parallel statement queuing is enabled (`PARALLEL_DEGREE_POLICY` is set to `AUTO`). If a session has the `PARALLEL_DEGREE_POLICY` set to `MANUAL`, parallel statements from this session are not queued. However, any parallel execution servers used by such sessions are included in the count that is used to determine the limit for `PARALLEL_SERVER_LIMIT`. Even if this limit is exceeded, parallel statements from this session are not queued.

27.3.4 Program Global Area (PGA)

To manage PGA resources, Resource Manager can limit the amount of PGA memory that can be allocated to each session in a particular consumer group.

To limit the PGA resources for each session in a consumer group, set the `session_pga_limit` parameter in the package procedure `DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE`. The value of this parameter is the maximum amount of PGA memory, in megabytes, allowed for each session in the consumer group. If a session exceeds the limit set for its consumer group, then error ORA-10260 is raised. This limit includes parallel query slaves and job queue processes.

For example, poorly written PL/SQL code can consume an unbounded amount of PGA. You can use the `session_pga_limit` parameter to limit sessions that run PL/SQL code to ensure that those sessions do not use an inordinate amount of PGA resource.

The following table illustrates a simple resource plan with PGA limits.

Table 27-3 A Simple Resource Plan with PGA Limits

Consumer Group	session_pga_limit Value
HIGH_GROUP	20
LOW_GROUP	10
MAINT_SUBPLAN	Null (unlimited)
OTHER_GROUPS	Null (unlimited)

In this resource plan, high priority applications run within `HIGH_GROUP`, and each session in that group is limited to 20 MB of PGA resource. The sessions used by the lower priority applications within `LOW_GROUP` are limited to 10 MB of PGA resource. The sessions used for maintenance jobs within `MAINT_SUBPLAN` and other sessions within `OTHER_GROUPS` can use unlimited PGA resource.

 **Note:**

You can limit the PGA usage of a whole instance with the `PGA_AGGREGATE_LIMIT` initialization parameter.

27.3.5 Runaway Queries

Runaway sessions and calls can adversely impact overall performance if they are not managed properly. Resource Manager can take action when a session or call consumes more than a specified amount of CPU, physical I/O, logical I/O, or elapsed time. Resource Manager can either switch the session or call to a consumer group that is allocated a small amount of CPU or terminate the session or call.

 **Note:**

Starting with Oracle Database 12c Release 2 (12.2.0.1), Resource Manager can also limit the amount of PGA memory that can be allocated to each session in a particular consumer group.

- [Automatic Consumer Group Switching](#)
You can control resource allocation by specifying criteria that, if met, causes the automatic switching of a session to a specified consumer group.
- [Canceling SQL and Terminating Sessions](#)
You can also specify directives to cancel long-running SQL queries or to terminate long-running sessions based on the amount of system resources consumed.
- [Execution Time Limit](#)
You can specify a maximum execution time allowed for an operation.

See Also:

["Program Global Area \(PGA\)"](#)

27.3.5.1 Automatic Consumer Group Switching

You can control resource allocation by specifying criteria that, if met, causes the automatic switching of a session to a specified consumer group.

Typically, this method is used to switch a session from a high-priority consumer group—one that receives a high proportion of system resources—to a lower priority consumer group because that session exceeded the expected resource consumption for a typical session in the group.

See "[Specifying Automatic Switching by Setting Resource Limits](#)" for more information.

27.3.5.2 Canceling SQL and Terminating Sessions

You can also specify directives to cancel long-running SQL queries or to terminate long-running sessions based on the amount of system resources consumed.

See "[Specifying Automatic Switching by Setting Resource Limits](#)" for more information.

27.3.5.3 Execution Time Limit

You can specify a maximum execution time allowed for an operation.

If the database estimates that an operation will run longer than the specified maximum execution time, then the operation is terminated with an error. This error can be trapped and the operation rescheduled.

27.3.6 Active Session Pool with Queuing

You can control the maximum number of concurrently active sessions allowed within a consumer group. This maximum defines the **active session pool**.

An **active session** is a session that is actively processing a transaction or SQL statement. Specifically, an active session is either in a transaction, holding a user enqueue, or has an open cursor and has not been idle for over 5 seconds. An active session is considered active even if it is blocked, for example waiting for an I/O request to complete. When the active session pool is full, a session that is trying to process a call is placed into a queue. When an active session completes, the first session in the queue can then be removed from the queue and scheduled for

execution. You can also specify a period after which a session in the execution queue times out, causing the call to terminate with an error.

Active session limits should not be used for OLTP workloads. In addition, active session limits should not be used to implement connection pooling or parallel statement queuing.

To manage parallel statements, you must use parallel statement queuing with the PARALLEL_SERVER_LIMIT attribute and management attributes (MGMT_P1, MGMT_P2, and so on).

27.3.7 Undo Pool

You can specify an undo pool for each consumer group. An undo pool controls the total amount of undo for uncommitted transactions that can be generated by a consumer group.

When the total undo generated by a consumer group exceeds its undo limit, the current DML statement generating the undo is terminated. No other members of the consumer group can perform further data manipulation until undo space is freed from the pool.

27.3.8 Idle Time Limit

You can specify an amount of time that a session can be idle, after which it is terminated.

You can also specify a more stringent idle time limit that applies to sessions that are idle and blocking other sessions.

27.4 Creating a Simple Resource Plan

You can quickly create a simple resource plan that is adequate for many situations using the CREATE_SIMPLE_PLAN procedure.

This procedure enables you to both create consumer groups and allocate resources to them by executing a single procedure call. Using this procedure, you are not required to invoke the procedures that are described in succeeding sections for creating a pending area, creating each consumer group individually, specifying resource plan directives, and so on.

You specify the following arguments for the CREATE_SIMPLE_PLAN procedure:

Parameter	Description
SIMPLE_PLAN	Name of the plan
CONSUMER_GROUP1	Consumer group name for first group
GROUP1_PERCENT	CPU resource allocated to this group
CONSUMER_GROUP2	Consumer group name for second group
GROUP2_PERCENT	CPU resource allocated to this group
CONSUMER_GROUP3	Consumer group name for third group
GROUP3_PERCENT	CPU resource allocated to this group

Parameter	Description
CONSUMER_GROUP4	Consumer group name for fourth group
GROUP4_PERCENT	CPU resource allocated to this group
CONSUMER_GROUP5	Consumer group name for fifth group
GROUP5_PERCENT	CPU resource allocated to this group
CONSUMER_GROUP6	Consumer group name for sixth group
GROUP6_PERCENT	CPU resource allocated to this group
CONSUMER_GROUP7	Consumer group name for seventh group
GROUP7_PERCENT	CPU resource allocated to this group
CONSUMER_GROUP8	Consumer group name for eighth group
GROUP8_PERCENT	CPU resource allocated to this group

You can specify up to eight consumer groups with this procedure. The only resource allocation method supported is CPU. The plan uses the `EMPHASIS` CPU allocation policy (the default) and each consumer group uses the `ROUND_ROBIN` scheduling policy (also the default). Each consumer group specified in the plan is allocated its CPU percentage at level 2. Also implicitly included in the plan are `SYS_GROUP` (a system-defined group that is the initial consumer group for the users `SYS` and `SYSTEM`) and `OTHER_GROUPS`. The `SYS_GROUP` consumer group is allocated 100% of the CPU at level 1, and `OTHER_GROUPS` is allocated 100% of the CPU at level 3.

Example: Creating a Simple Plan with the `CREATE_SIMPLE_PLAN` Procedure

The following PL/SQL block creates a simple resource plan with two user-specified consumer groups:

```
BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_SIMPLE_PLAN(SIMPLE_PLAN => 'SIMPLE_PLAN1',
                                              CONSUMER_GROUP1 => 'MYGROUP1', GROUP1_PERCENT => 80,
                                              CONSUMER_GROUP2 => 'MYGROUP2', GROUP2_PERCENT => 20);
END;
/
```

Executing the preceding statements creates the following plan:

Consumer Group	Level 1	Level 2	Level 3
SYS_GROUP	100%	-	-
MYGROUP1	-	80%	-
MYGROUP2	-	20%	-
OTHER_GROUPS	-	-	100%

 **See Also:**

- "[Creating a Resource Plan](#)" for more information on the EMPHASIS CPU allocation policy
- "[Creating Resource Consumer Groups](#)" for more information on the ROUND_ROBIN scheduling policy
- "[Elements of the Resource Manager](#)"

27.5 Creating a Complex Resource Plan

When your situation calls for a more complex resource plan, you must create the plan, with its directives and consumer groups, in a staging area called the pending area, and then validate the plan before storing it in the data dictionary.

The following is a summary of the steps required to create a complex resource plan.

 **Note:**

A complex resource plan is any resource plan that is not created with the DBMS_RESOURCE_MANAGER.CREATE_SIMPLE_PLAN procedure.

Step 1: Create a pending area.

Step 2: Create, modify, or delete consumer groups.

Step 3: Map sessions to consumer groups.

Step 4: Create the resource plan.

Step 5: Create resource plan directives.

Step 6: Validate the pending area.

Step 7: Submit the pending area.

You use procedures in the DBMS_RESOURCE_MANAGER PL/SQL package to complete these steps.

- [About the Pending Area](#)

The **pending area** is a staging area where you can create a new resource plan, update an existing plan, or delete a plan without affecting currently running applications.

- [Creating a Pending Area](#)

You create a pending area with the CREATE_PENDING_AREA procedure.

- [Creating Resource Consumer Groups](#)

You create a resource consumer group using the CREATE_CONSUMER_GROUP procedure.

- [Mapping Sessions to Consumer Groups](#)
You can map sessions to consumer groups using the `SET_CONSUMER_GROUP_MAPPING` procedure.
- [Creating a Resource Plan](#)
You create a resource plan with the `CREATE_PLAN` procedure.
- [Creating Resource Plan Directives](#)
You use the `CREATE_PLAN_DIRECTIVE` procedure to create resource plan directives. Each directive belongs to a plan or subplan and allocates resources to either a consumer group or subplan.
- [Validating the Pending Area](#)
At any time when you are making changes in the pending area, you can call `VALIDATE_PENDING_AREA` to ensure that the pending area is valid so far.
- [Submitting the Pending Area](#)
After you have validated your changes, call the `SUBMIT_PENDING_AREA` procedure to make your changes active.
- [Clearing the Pending Area](#)
You can clear the pending area at any time using the `CLEAR_PENDING_AREA` procedure.

 **See Also:**

- [Predefined Consumer Group Mapping Rules](#)
- *Oracle Database PL/SQL Packages and Types Reference* for details on the `DBMS_RESOURCE_MANAGER` PL/SQL package.
- ["Elements of the Resource Manager"](#)

27.5.1 About the Pending Area

The **pending area** is a staging area where you can create a new resource plan, update an existing plan, or delete a plan without affecting currently running applications.

When you create a pending area, the database initializes it and then copies existing plans into the pending area so that they can be updated.

 **Tip:**

After you create the pending area, if you list all plans by querying the `DBA_RSRC_PLANS` data dictionary view, you see two copies of each plan: one with the `PENDING` status, and one without. The plans with the `PENDING` status reflect any changes you made to the plans since creating the pending area. Pending changes can also be viewed for consumer groups using `DBA_RSRC_CONSUMER_GROUPS` and for resource plan directives using `DBA_RSRC_PLAN_DIRECTIVES`. See [Resource Manager Data Dictionary Views](#) for more information.

After you make changes in the pending area, you validate the pending area and then submit it. Upon submission, all pending changes are applied to the data dictionary, and the pending area is cleared and deactivated.

If you attempt to create, update, or delete a plan (or create, update, or delete consumer groups or resource plan directives) without first creating the pending area, you receive an error message.

Submitting the pending area does not activate any new plan that you create; it just stores new or updated plan information in the data dictionary. However, if you modify a plan that is currently active, the plan is reactivated with the new plan definition. See "[Enabling Oracle Database Resource Manager and Switching Plans](#)" for information about activating a resource plan.

When you create a pending area, no other users can create one until you submit or clear the pending area or log out.

27.5.2 Creating a Pending Area

You create a pending area with the `CREATE_PENDING_AREA` procedure.

Example: Creating a pending area:

The following PL/SQL block creates and initializes a pending area:

```
BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
END;
/
```

27.5.3 Creating Resource Consumer Groups

You create a resource consumer group using the `CREATE_CONSUMER_GROUP` procedure.

You can specify the following parameters:

Parameter	Description
<code>CONSUMER_GROUP</code>	Name to assign to the consumer group.
<code>COMMENT</code>	Any comment.
<code>CPU_MTH</code>	Deprecated. Use <code>MGMT_MTH</code> .
<code>MGMT_MTH</code>	The resource allocation method for distributing CPU among sessions in the consumer group. The default is 'ROUND-ROBIN', which uses a round-robin scheduler to ensure that sessions are fairly executed. 'RUN-TO-COMPLETION' specifies that long-running sessions are scheduled ahead of other sessions. This setting helps long-running sessions (such as batch processes) complete sooner.

Example: Creating a Resource Consumer Group

The following PL/SQL block creates a consumer group called `OLTP` with the default (ROUND-ROBIN) method of allocating resources to sessions in the group:

```
BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
        CONSUMER_GROUP => 'OLTP',
        COMMENT         => 'OLTP applications');
```

```
END;  
/
```

 **See Also:**

- ["Updating a Consumer Group"](#)
- ["Deleting a Consumer Group"](#)

27.5.4 Mapping Sessions to Consumer Groups

You can map sessions to consumer groups using the `SET_CONSUMER_GROUP_MAPPING` procedure.

You can specify the following parameters:

Parameter	Description
ATTRIBUTE	Session attribute type, specified as a package constant.
VALUE	Value of the attribute.
CONSUMER_GROUP	Name of the consumer group.

Example: Mapping a Session to a Consumer Group

The following PL/SQL block maps the `oe` user to the `OLTP` consumer group:

```
BEGIN  
    DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING(  
        ATTRIBUTE      => DBMS_RESOURCE_MANAGER.ORACLE_USER,  
        VALUE          => 'OE',  
        CONSUMER_GROUP => 'OLTP' );  
END;  
/
```

 **See Also:**

- ["Creating Consumer Group Mapping Rules"](#)

27.5.5 Creating a Resource Plan

You create a resource plan with the `CREATE_PLAN` procedure.

You can specify the parameters shown in the following table. The first two parameters are required. The remainder are optional.

Parameter	Description
PLAN	Name to assign to the plan.

Parameter	Description
COMMENT	Any descriptive comment.
CPU_MTH	Deprecated. Use MGMT_MTH.
ACTIVE_SESS_POOL_MTH	Active session pool resource allocation method. ACTIVE_SESS_POOL_ABSOLUTE is the default and only method available.
PARALLEL_DEGREE_LIMIT_MTH	Resource allocation method for specifying a limit on the PARALLEL_DEGREE_LIMIT_ABSOLUTE is the default and only method available.
QUEUEING_MTH	Queuing resource allocation method. Controls the order in which queued inactive sessions are removed from the queue and added to the active session pool. FIFO_TIMEOUT is the default and only method available.
MGMT_MTH	Resource allocation method for specifying how much CPU each consumer group or subplan gets. 'EMPHASIS', the default method, is for single-level or multilevel plans that use percentages to specify how CPU is distributed among consumer groups. 'RATIO' is for single-level plans that use ratios to specify how CPU is distributed.
SUB_PLAN	If TRUE, the plan cannot be used as the top plan; it can be used as a subplan only. Default is FALSE.

Example: Creating a Resource Plan

The following PL/SQL block creates a resource plan named DAYTIME:

```
BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_PLAN(
        PLAN      => 'DAYTIME',
        COMMENT  => 'More resources for OLTP applications');
END;
/
```

- [About the RATIO CPU Allocation Method](#)

The RATIO method is an alternate CPU allocation method intended for simple plans that have only a single level of CPU allocation.

27.5.5.1 About the RATIO CPU Allocation Method

The RATIO method is an alternate CPU allocation method intended for simple plans that have only a single level of CPU allocation.

Instead of percentages, you specify numbers corresponding to the ratio of CPU that you want to give to each consumer group. To use the RATIO method, you set the MGMT_MTH argument for the CREATE_PLAN procedure to 'RATIO'. See "[Creating Resource Plan Directives](#)" for an example of a plan that uses this method.

 **See Also:**

- "[Updating a Plan](#)"
- "[Deleting a Plan](#)"

27.5.6 Creating Resource Plan Directives

You use the `CREATE_PLAN_DIRECTIVE` procedure to create resource plan directives. Each directive belongs to a plan or subplan and allocates resources to either a consumer group or subplan.

 **Note:**

The set of directives for a resource plan and its subplans can name a particular subplan only once.

You can specify directives for a particular consumer group in a top plan and its subplans. However, Oracle recommends that the set of directives for a resource plan and its subplans name a particular consumer group only once.

You can specify the following parameters:

Parameter	Description
PLAN	Name of the resource plan to which the directive belongs.
GROUP_OR_SUBPLAN	Name of the consumer group or subplan to which to allocate resources.
COMMENT	Any comment.
CPU_P1	Deprecated. Use MGMT_P1.
CPU_P2	Deprecated. Use MGMT_P2.
CPU_P3	Deprecated. Use MGMT_P3.
CPU_P4	Deprecated. Use MGMT_P4.
CPU_P5	Deprecated. Use MGMT_P5.
CPU_P6	Deprecated. Use MGMT_P6.
CPU_P7	Deprecated. Use MGMT_P7.
CPU_P8	Deprecated. Use MGMT_P8.
ACTIVE_SESS_POOL_P1	Specifies the maximum number of concurrently active sessions for a consumer group. Other sessions await execution in an inactive session queue. Default is UNLIMITED.
QUEUEING_P1	Specifies time (in seconds) after which a session in an inactive session queue (waiting for execution) times out and the call is aborted. Default is UNLIMITED.
PARALLEL_DEGREE_LIMIT_P1	Specifies a limit on the degree of parallelism for any operation. Default is UNLIMITED.

Parameter	Description
SWITCH_GROUP	<p>Specifies the consumer group to which a session is switched if switch criteria are met.</p> <p>If the group name is CANCEL_SQL, then the current call is canceled when switch criteria are met. If the group name is CANCEL_SQL, then the SWITCH_FOR_CALL parameter is always set to TRUE, overriding the user-specified setting.</p> <p>If the group name is KILL_SESSION, then the session is killed when switch criteria are met.</p> <p>If the group name is LOG_ONLY, then information about the session is recorded in real-time SQL monitoring, but no specific action is taken for the session.</p> <p>If NULL, then the session is not switched and no additional logging is performed. The default is NULL. An error is returned if this parameter is set to NULL and any other switch parameter is set to non-NULL.</p> <p>Note: The following consumer group names are reserved: CANCEL_SQL, KILL_SESSION, and LOG_ONLY. An error results if you attempt to create a consumer group with one of these names.</p>
SWITCH_TIME	Specifies the time (in CPU seconds) that a call can execute before an action is taken. Default is UNLIMITED. The action is specified by SWITCH_GROUP.
SWITCH_ESTIMATE	<p>If TRUE, the database estimates the execution time of each call, and if estimated execution time exceeds SWITCH_TIME, the session is switched to the SWITCH_GROUP before beginning the call. Default is FALSE.</p> <p>The execution time estimate is obtained from the optimizer. The accuracy of the estimate is dependent on many factors, especially the quality of the optimizer statistics. In general, you should expect statistics to be no more accurate than ± 10 minutes.</p>
MAX_EST_EXEC_TIME	<p>Specifies the maximum execution time (in CPU seconds) allowed for a call. If the optimizer estimates that a call will take longer than MAX_EST_EXEC_TIME, the call is not allowed to proceed and ORA-07455 is issued. If the optimizer does not provide an estimate, this directive has no effect. Default is UNLIMITED.</p> <p>The accuracy of the estimate is dependent on many factors, especially the quality of the optimizer statistics.</p>
UNDO_POOL	Sets a maximum in kilobytes (K) on the total amount of undo for uncommitted transactions that can be generated by a consumer group. Default is UNLIMITED.
MAX_IDLE_TIME	Indicates the maximum session idle time, in seconds. Default is NULL, which implies unlimited.
MAX_IDLE_BLOCKER_TIME	Indicates the maximum session idle time of a blocking session, in seconds. Default is NULL, which implies unlimited.
SWITCH_TIME_IN_CALL	Deprecated. Use SWITCH_FOR_CALL.

Parameter	Description
MGMT_P1	For a plan with the MGMT_MTH parameter set to EMPHASIS, specifies the CPU percentage to allocate at the first level. For MGMT_MTH set to RATIO, specifies the weight of CPU usage. Default is NULL for all MGMT_Pn parameters.
MGMT_P2	For EMPHASIS, specifies CPU percentage to allocate at the second level. Not applicable for RATIO.
MGMT_P3	For EMPHASIS, specifies CPU percentage to allocate at the third level. Not applicable for RATIO.
MGMT_P4	For EMPHASIS, specifies CPU percentage to allocate at the fourth level. Not applicable for RATIO.
MGMT_P5	For EMPHASIS, specifies CPU percentage to allocate at the fifth level. Not applicable for RATIO.
MGMT_P6	For EMPHASIS, specifies CPU percentage to allocate at the sixth level. Not applicable for RATIO.
MGMT_P7	For EMPHASIS, specifies CPU percentage to allocate at the seventh level. Not applicable for RATIO.
MGMT_P8	For EMPHASIS, specifies CPU percentage to allocate at the eighth level. Not applicable for RATIO.
SWITCH_IO_MEGABYTES	Specifies the number of megabytes of physical I/O that a session can transfer (read and write) before an action is taken. Default is UNLIMITED. The action is specified by SWITCH_GROUP.
SWITCH_IO_REQS	Specifies the number of physical I/O requests that a session can execute before an action is taken. Default is UNLIMITED. The action is specified by SWITCH_GROUP.
SWITCH_FOR_CALL	If TRUE, a session that was automatically switched to another consumer group (according to SWITCH_TIME, SWITCH_IO_MEGABYTES, or SWITCH_IO_REQS) is returned to its original consumer group when the top level call completes. Default is NULL.
PARALLEL_QUEUE_TIMEOUT	Specifies the maximum time, in seconds, that a parallel statement can wait in the parallel statement queue before it is timed out.
PARALLEL_SERVER_LIMIT	Specifies the maximum percentage of the parallel execution server pool that a particular consumer group can use. The number of parallel execution servers used by a particular consumer group is counted as the sum of the parallel execution servers used by all sessions in that consumer group.
UTILIZATION_LIMIT	Specifies the maximum CPU utilization percentage permitted for the consumer group. This value overrides any level allocations for CPU (MGMT_P1 through MGMT_P8), and also imposes a limit on total CPU utilization when unused allocations are redistributed. You can specify this attribute and leave MGMT_P1 through MGMT_P8 NULL.
SWITCH_IO_LOGICAL	Number of logical I/O requests that will trigger the action specified by SWITCH_GROUP. As with other switch directives, if SWITCH_FOR_CALL is TRUE, then the number of logical I/O requests is accumulated from the start of a call. Otherwise, the number of logical I/O requests is accumulated for the length of the session.

Parameter	Description
SWITCH_ELAPSED_TIME	Elapsed time, in seconds, that will trigger the action specified by SWITCH_GROUP. As with other switch directives, if SWITCH_FOR_CALL is TRUE, then the elapsed time is accumulated from the start of a call. Otherwise, the elapsed time is accumulated for the length of the session.
SHARES	Allocates resources among pluggable databases (PDBs) in a multitenant container database (CDB). Also allocates resources among consumer groups in a non-CDB or in a PDB. See " CDB Resource Plans ".
PARALLEL_STMT_CRITICAL	Specifies whether parallel statements from the consumer group are critical. When BYPASS_QUEUE is specified, parallel statements from the consumer group are critical. These statements bypass the parallel queue and are executed immediately. When FALSE or NULL (the default) is specified, parallel statements from the consumer group are not critical. These statements are added to the parallel queue when necessary.
SESSION_PGA_LIMIT	Specifies the maximum amount of PGA memory, in megabytes, that can be allocated to each session in a particular consumer group. If a session exceeds the limit, then its process is terminated with an ORA-10260 error.

Example 1

The following PL/SQL block creates a resource plan directive for plan DAYTIME. (It assumes that the DAYTIME plan and OLTP consumer group are already created in the pending area.)

```
BEGIN
  DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'DAYTIME',
    GROUP_OR_SUBPLAN => 'OLTP',
    COMMENT        => 'OLTP group',
    MGMT_P1        => 75);
END;
/
```

This directive assigns 75% of CPU resources to the OLTP consumer group at level 1.

You can also create the REPORTING consumer group, and then execute the following PL/SQL block:

```
BEGIN
  DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'DAYTIME',
    GROUP_OR_SUBPLAN => 'REPORTING',
    COMMENT        => 'Reporting group',
    MGMT_P1        => 15,
    PARALLEL_DEGREE_LIMIT_P1 => 8,
    ACTIVE_SESS_POOL_P1      => 4,
    SESSION_PGA_LIMIT        => 20);

  DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'DAYTIME',
    GROUP_OR_SUBPLAN => 'OTHER_GROUPS',
```

```

COMMENT          => 'This one is required',
MGMT_P1         => 10);
END;
/

```

In this plan, consumer group REPORTING has a maximum degree of parallelism of 8 for any operation, while none of the other consumer groups are limited in their degree of parallelism. In addition, the REPORTING group has a maximum of 4 concurrently active sessions. Each session can use a maximum of 20 MB of PGA memory.

Example 2

This example uses the RATIO method to allocate CPU, which uses ratios instead of percentages. Suppose your application suite offers three service levels to clients: Gold, Silver, and Bronze. You create three consumer groups named GOLD(CG), SILVER(CG), and BRONZE(CG), and you create the following resource plan:

```

BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_PLAN
    (PLAN          => 'SERVICE_LEVEL_PLAN',
     MGMT_MTH      => 'RATIO',
     COMMENT        => 'Plan that supports three service levels');

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE
    (PLAN          => 'SERVICE_LEVEL_PLAN',
     GROUP_OR_SUBPLAN => 'GOLD(CG',
     COMMENT        => 'Gold service level customers',
     MGMT_P1       => 10);

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE
    (PLAN          => 'SERVICE_LEVEL_PLAN',
     GROUP_OR_SUBPLAN => 'SILVER(CG',
     COMMENT        => 'Silver service level customers',
     MGMT_P1       => 5);

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE
    (PLAN          => 'SERVICE_LEVEL_PLAN',
     GROUP_OR_SUBPLAN => 'BRONZE(CG',
     COMMENT        => 'Bronze service level customers',
     MGMT_P1       => 2);

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE
    (PLAN          => 'SERVICE_LEVEL_PLAN',
     GROUP_OR_SUBPLAN => 'OTHER_GROUPS',
     COMMENT        => 'Lowest priority sessions',
     MGMT_P1       => 1);

END;
/

```

The ratio of CPU allocation is 10:5:2:1 for the GOLD(CG), SILVER(CG), BRONZE(CG), and OTHER_GROUPS consumer groups, respectively.

If sessions exist only in the GOLD(CG) and SILVER(CG) consumer groups, then the ratio of CPU allocation is 10:5 between the two groups.

- [Conflicting Resource Plan Directives](#)

Although this is allowed, Oracle strongly recommends that you avoid referencing the same consumer group from a top plan and any of its subplans.

27.5.6.1 Conflicting Resource Plan Directives

Although this is allowed, Oracle strongly recommends that you avoid referencing the same consumer group from a top plan and any of its subplans.

You may have occasion to reference the same consumer group from the top plan and any number of subplans. This results in multiple resource plan directives referring to the same consumer group.

Similarly, when multiple resource plan directives refer to the same consumer group, they have conflicting directives. Although this is allowed, Oracle strongly recommends that you avoid multiple resource plan directives that refer to the same consumer group.

See Also:

- ["Updating a Resource Plan Directive"](#)
- ["Deleting a Resource Plan Directive"](#)

27.5.7 Validating the Pending Area

At any time when you are making changes in the pending area, you can call `VALIDATE_PENDING_AREA` to ensure that the pending area is valid so far.

The following rules must be adhered to, and are checked by the validate procedure:

- No plan can contain any loops. A loop occurs when a subplan contains a directive that references a plan that is above the subplan in the plan hierarchy. For example, a subplan cannot reference the top plan.
- All plans and resource consumer groups referred to by plan directives must exist.
- All plans must have plan directives that point to either plans or resource consumer groups.
- All percentages in any given level must not add up to greater than 100.
- A plan that is currently being used as a top plan by an active instance cannot be deleted.
- The following parameters can appear only in plan directives that refer to resource consumer groups, not other resource plans:
 - `ACTIVE_SESS_POOL_P1`
 - `MAX_EST_EXEC_TIME`
 - `MAX_IDLE_BLOCKER_TIME`
 - `MAX_IDLE_TIME`
 - `PARALLEL_DEGREE_LIMIT_P1`
 - `QUEUEING_P1`
 - `SESSION_PGA_LIMIT`
 - `SWITCH_ESTIMATE`

- SWITCH_FOR_CALL
- SWITCH_GROUP
- SWITCH_IO_MEGABYTES
- SWITCH_IO_REQS
- SWITCH_TIME
- UNDO_POOL
- UTILIZATION_LIMIT
- There can be no more than 28 resource consumer groups in any active plan. Also, at most, a plan can have 28 children.
- Plans and resource consumer groups cannot have the same name.
- There must be a plan directive for OTHER_GROUPS somewhere in any active plan. This ensures that a session that is not part of any of the consumer groups included in the currently active plan is allocated resources (as specified by the directive for OTHER_GROUPS).

VALIDATE_PENDING_AREA raises an error if any of the preceding rules are violated. You can then make changes to fix any problems and call the procedure again.

It is possible to create "orphan" consumer groups that have no plan directives referring to them. This allows the creation of consumer groups that will not currently be used, but might be part of some plan to be implemented in the future.

Example: Validating the Pending Area:

The following PL/SQL block validates the pending area.

```
BEGIN
    DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA( );
END;
/
```

See Also:

["About the Pending Area"](#)

27.5.8 Submitting the Pending Area

After you have validated your changes, call the SUBMIT_PENDING_AREA procedure to make your changes active.

The submit procedure also performs validation, so you do not necessarily need to make separate calls to the validate procedure. However, if you are making major changes to plans, debugging problems is often easier if you incrementally validate your changes. No changes are submitted (made active) until validation is successful on all of the changes in the pending area.

The SUBMIT_PENDING_AREA procedure clears (deactivates) the pending area after successfully validating and committing the changes.

 **Note:**

A call to `SUBMIT_PENDING_AREA` might fail even if `VALIDATE_PENDING_AREA` succeeds. This can happen if, for example, a plan being deleted is loaded by an instance after a call to `VALIDATE_PENDING_AREA`, but before a call to `SUBMIT_PENDING_AREA`.

Example: Submitting the Pending Area:

The following PL/SQL block submits the pending area:

```
BEGIN
    DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/
```

 **See Also:**

["About the Pending Area"](#)

27.5.9 Clearing the Pending Area

You can clear the pending area at any time using the `CLEAR_PENDING_AREA` procedure.

This PL/SQL block causes all of your changes to be cleared from the pending area and deactivates the pending area:

```
BEGIN
    DBMS_RESOURCE_MANAGER.CLEAR_PENDING_AREA();
END;
/
```

After calling `CLEAR_PENDING_AREA`, you must call the `CREATE_PENDING_AREA` procedure before you can again attempt to make changes.

 **See Also:**

["About the Pending Area"](#)

27.6 Enabling Oracle Database Resource Manager and Switching Plans

You enable Oracle Database Resource Manager (the Resource Manager) by setting the `RESOURCE_MANAGER_PLAN` initialization parameter. This parameter specifies the top

plan, identifying the plan to be used for the current instance. If no plan is specified with this parameter, the Resource Manager is not enabled.

By default the Resource Manager is not enabled, except during preconfigured maintenance windows, described later in this section.

The following statement in a text initialization parameter file activates the Resource Manager upon database startup and sets the top plan as `mydb_plan`.

```
RESOURCE_MANAGER_PLAN = mydb_plan
```

You can also activate or deactivate the Resource Manager, or change the current top plan, using the `DBMS_RESOURCE_MANAGER.SWITCH_PLAN` package procedure or the `ALTER SYSTEM` statement.

The following SQL statement sets the top plan to `mydb_plan`, and activates the Resource Manager if it is not already active:

```
ALTER SYSTEM SET RESOURCE_MANAGER_PLAN = 'mydb_plan';
```

An error message is returned if the specified plan does not exist in the data dictionary.

Automatic Enabling of the Resource Manager by Oracle Scheduler Windows

The Resource Manager automatically activates if an Oracle Scheduler window that specifies a resource plan opens. When the Scheduler window closes, the resource plan associated with the window is disabled, and the resource plan that was running before the Scheduler window opened is reenabled. (If no resource plan was enabled before the window opened, then the Resource Manager is disabled.) In an Oracle Real Application Clusters environment, a Scheduler window applies to all instances, so the window's resource plan is enabled on every instance.

Note that by default a set of automated maintenance tasks run during **maintenance windows**, which are predefined Scheduler windows that are members of the `MAINTENANCE_WINDOW_GROUP` window group and which specify the `DEFAULT_MAINTENANCE_PLAN` resource plan. Thus, the Resource Manager activates by default during maintenance windows. You can modify these maintenance windows to use a different resource plan, if desired.

Note:

If you change the plan associated with maintenance windows, then ensure that you include the subplan `ORA$AUTOTASK` in the new plan.

See Also:

- ["Windows"](#)
- [Managing Automated Database Maintenance Tasks](#)

Disabling Plan Switches by Oracle Scheduler Windows

In some cases, the automatic change of Resource Manager plans at Scheduler window boundaries may be undesirable. For example, if you have an important task to finish, and if you set the Resource Manager plan to give your task priority, then you expect that the plan will remain the same until you change it. However, because a Scheduler window could activate after you have set your plan, the Resource Manager plan might change while your task is running.

To prevent this situation, you can set the `RESOURCE_MANAGER_PLAN` initialization parameter to the name of the plan that you want for the system and prepend "FORCE:" to the name, as shown in the following SQL statement:

```
ALTER SYSTEM SET RESOURCE_MANAGER_PLAN = 'FORCE:mydb_plan';
```

Using the prefix `FORCE:` indicates that the current resource plan can be changed only when the database administrator changes the value of the `RESOURCE_MANAGER_PLAN` initialization parameter. This restriction can be lifted by rerunning the command without preceding the plan name with "`FORCE:`".

The `DBMS_RESOURCE_MANAGER.SWITCH_PLAN` package procedure has a similar capability.

See Also:

Oracle Database PL/SQL Packages and Types Reference for more information on `DBMS_RESOURCE_MANAGER.SWITCH_PLAN`.

Disabling the Resource Manager

To disable the Resource Manager, complete the following steps:

1. Issue the following SQL statement:

```
ALTER SYSTEM SET RESOURCE_MANAGER_PLAN = '';
```

2. Disassociate the Resource Manager from all Oracle Scheduler windows.

To do so, for any Scheduler window that references a resource plan in its `resource_plan` attribute, use the `DBMS_SCHEDULER.SET_ATTRIBUTE` procedure to set `resource_plan` to the empty string (""). Qualify the window name with the `SYS` schema name if you are not logged in as user `SYS`. You can view Scheduler windows with the `DBA_SCHEDULER_WINDOWS` data dictionary view. See "["Altering Windows"](#)" and *Oracle Database PL/SQL Packages and Types Reference* for more information.

 Note:

By default, all maintenance windows reference the DEFAULT_MAINTENANCE_PLAN resource plan. To completely disable the Resource Manager, you must alter all maintenance windows to remove this plan. However, use caution, because resource consumption by automated maintenance tasks will no longer be regulated, which may adversely affect the performance of your other sessions. See [Managing Automated Database Maintenance Tasks](#) for more information on maintenance windows.

27.7 Putting It All Together: Oracle Database Resource Manager Examples

Examples illustrate how to allocate resources with Resource Manager.

- [Multilevel Plan Example](#)
An example illustrates a multilevel plan.
- [Examples of Using the Utilization Limit Attribute](#)
You can use the UTILIZATION_LIMIT directive attribute to limit the CPU utilization for applications. One of the most common scenarios in which this attribute can be used is for database consolidation.
- [Example of Using Several Resource Allocation Methods](#)
An example illustrates using several resource allocation methods.
- [Example of Managing Parallel Statements Using Directive Attributes](#)
An example illustrates managing parallel statements using directive attributes.
- [An Oracle-Supplied Mixed Workload Plan](#)
Oracle Database includes a predefined resource plan, MIXED_WORKLOAD_PLAN, that prioritizes interactive operations over batch operations, and includes the required subplans and consumer groups recommended by Oracle.

27.7.1 Multilevel Plan Example

An example illustrates a multilevel plan.

The following PL/SQL block creates a multilevel plan as illustrated in [Figure 27-3](#). Default resource allocation method settings are used for all plans and resource consumer groups.

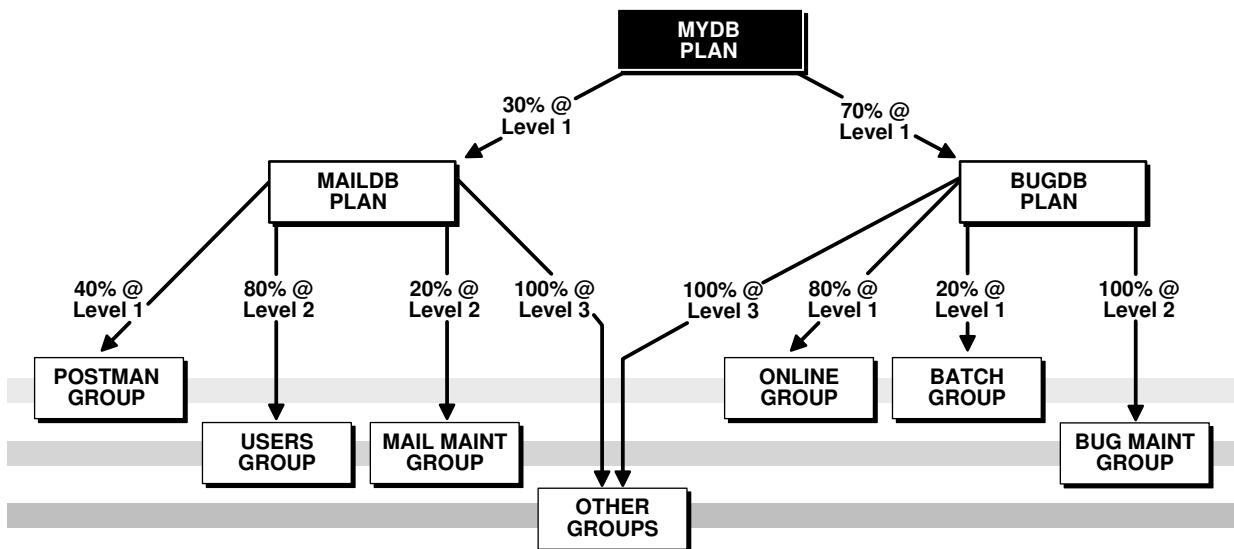

```
BEGIN
DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
DBMS_RESOURCE_MANAGER.CREATE_PLAN(PLAN => 'bugdb_plan',
    COMMENT => 'Resource plan/method for bug users sessions');
DBMS_RESOURCE_MANAGER.CREATE_PLAN(PLAN => 'maildb_plan',
    COMMENT => 'Resource plan/method for mail users sessions');
DBMS_RESOURCE_MANAGER.CREATE_PLAN(PLAN => 'mydb_plan',
    COMMENT => 'Resource plan/method for bug and mail users sessions');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(CONSUMER_GROUP => 'Online_group',
    COMMENT => 'Resource consumer group/method for online bug users sessions');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(CONSUMER_GROUP => 'Batch_group',
    COMMENT => 'Resource consumer group/method for batch job bug users sessions');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(CONSUMER_GROUP => 'Bug_Maint_group',
```

```

COMMENT => 'Resource consumer group/method for users sessions for bug db maint';
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(CONSUMER_GROUP => 'Users_group',
    COMMENT => 'Resource consumer group/method for mail users sessions');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(CONSUMER_GROUP => 'Postman_group',
    COMMENT => 'Resource consumer group/method for mail postman');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(CONSUMER_GROUP => 'Mail_Maint_group',
    COMMENT => 'Resource consumer group/method for users sessions for mail db maint');
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'bugdb_plan',
    GROUP_OR_SUBPLAN => 'Online_group',
    COMMENT => 'online bug users sessions at level 1', MGMT_P1 => 80, MGMT_P2=> 0);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'bugdb_plan',
    GROUP_OR_SUBPLAN => 'Batch_group',
    COMMENT => 'batch bug users sessions at level 1', MGMT_P1 => 20, MGMT_P2 => 0,
    PARALLEL_DEGREE_LIMIT_P1 => 8);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'bugdb_plan',
    GROUP_OR_SUBPLAN => 'Bug_Maint_group',
    COMMENT => 'bug maintenance users sessions at level 2', MGMT_P1 => 0, MGMT_P2 => 100);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'bugdb_plan',
    GROUP_OR_SUBPLAN => 'OTHER_GROUPS',
    COMMENT => 'all other users sessions at level 3', MGMT_P1 => 0, MGMT_P2 => 0,
    MGMT_P3 => 100);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'maildb_plan',
    GROUP_OR_SUBPLAN => 'Postman_group',
    COMMENT => 'mail postman at level 1', MGMT_P1 => 40, MGMT_P2 => 0);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'maildb_plan',
    GROUP_OR_SUBPLAN => 'Users_group',
    COMMENT => 'mail users sessions at level 2', MGMT_P1 => 0, MGMT_P2 => 80);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'maildb_plan',
    GROUP_OR_SUBPLAN => 'Mail_Maint_group',
    COMMENT => 'mail maintenance users sessions at level 2', MGMT_P1 => 0, MGMT_P2 => 20);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'maildb_plan',
    GROUP_OR_SUBPLAN => 'OTHER_GROUPS',
    COMMENT => 'all other users sessions at level 3', MGMT_P1 => 0, MGMT_P2 => 0,
    MGMT_P3 => 100);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'mydb_plan',
    GROUP_OR_SUBPLAN => 'maildb_plan',
    COMMENT=> 'all mail users sessions at level 1', MGMT_P1 => 30);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'mydb_plan',
    GROUP_OR_SUBPLAN => 'bugdb_plan',
    COMMENT => 'all bug users sessions at level 1', MGMT_P1 => 70);
DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/

```

The preceding call to `VALIDATE_PENDING_AREA` is optional because the validation is implicitly performed in `SUBMIT_PENDING_AREA`.

Figure 27-3 Multilevel Plan Schema

In this plan schema, CPU resources are allocated as follows:

- Under `mydb_plan`, 30% of CPU is allocated to the `maildb_plan` subplan, and 70% is allocated to the `bugdb_plan` subplan. Both subplans are at level 1. Because `mydb_plan` itself has no levels below level 1, any resource allocations that are unused by either subplan at level 1 can be used by its sibling subplan. Thus, if `maildb_plan` uses only 20% of CPU, then 80% of CPU is available to `bugdb_plan`.
- `maildb_plan` and `bugdb_plan` define allocations at levels 1, 2, and 3. The levels in these subplans are independent of levels in their parent plan, `mydb_plan`. That is, all plans and subplans in a plan schema have their own level 1, level 2, level 3, and so on.
- Of the 30% of CPU allocated to `maildb_plan`, 40% of that amount (effectively 12% of total CPU) is allocated to `Postman_group` at level 1. Because `Postman_group` has no siblings at level 1, there is an implied 60% remaining at level 1. This 60% is then shared by `Users_group` and `Mail_Maint_group` at level 2, at 80% and 20%, respectively. In addition to this 60%, `Users_group` and `Mail_Maint_group` can also use any of the 40% not used by `Postman_group` at level 1.
- CPU resources not used by either `Users_group` or `Mail_Maint_group` at level 2 are allocated to `OTHER_GROUPS`, because in multilevel plans, unused resources are reallocated to consumer groups or subplans at the next lower level, not to siblings at the same level. Thus, if `Users_group` uses only 70% instead of 80%, the remaining 10% cannot be used by `Mail_Maint_group`. That 10% is available only to `OTHER_GROUPS` at level 3.
- The 70% of CPU allocated to the `bugdb_plan` subplan is allocated to its consumer groups in a similar fashion. If either `Online_group` or `Batch_group` does not use its full allocation, the remainder may be used by `Bug_Maint_group`. If `Bug_Maint_group` does not use all of that allocation, the remainder goes to `OTHER_GROUPS`.

27.7.2 Examples of Using the Utilization Limit Attribute

You can use the UTILIZATION_LIMIT directive attribute to limit the CPU utilization for applications. One of the most common scenarios in which this attribute can be used is for database consolidation.

During database consolidation, you may need to be able to do the following:

- Manage the performance impact that one application can have on another.

One method of managing this performance impact is to create a consumer group for each application and allocate resources to each consumer group.

- Limit the utilization of each application.

Typically, in addition to allocating a specific percentage of the CPU resources to each consumer group, you may need to limit the maximum CPU utilization for each group. This limit prevents a consumer group from using all of the CPU resources when all the other consumer groups are idle.

In some cases, you may want all application users to experience consistent performance regardless of the workload from other applications. This can be achieved by specifying a utilization limit for each consumer group in a resource plan.

The following examples demonstrate how to use the UTILIZATION_LIMIT resource plan directive attribute to:

- Restrict total database CPU utilization
- Quarantine runaway queries
- Limit CPU usage for applications
- Limit CPU utilization during maintenance windows

Example 1 - Restricting Overall Database CPU Utilization

In this example, regardless of database load, system workload from Oracle Database never exceeds 90% of CPU, leaving 10% of CPU for other applications sharing the server.

```
BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();

    DBMS_RESOURCE_MANAGER.CREATE_PLAN(
        PLAN      => 'MAXCAP_PLAN',
        COMMENT  => 'Limit overall database CPU');

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(
        PLAN          => 'MAXCAP_PLAN',
        GROUP_OR_SUBPLAN => 'OTHER_GROUPS',
        COMMENT        => 'This group is mandatory',
        UTILIZATION_LIMIT => 90);

    DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
    DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/
```

Because there is no plan directive other than the one for OTHER_GROUPS, all sessions are mapped to OTHER_GROUPS.

Example 2 - Quarantining Runaway Queries

In this example, runaway queries are switched to a consumer group with a utilization limit of 20%, limiting the amount of resources that they can consume until you can intervene. A runaway query is characterized here as one that takes more than 10 minutes of CPU time. Assume that session mapping rules start all sessions in START_GROUP.

```
BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();

    DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
        CONSUMER_GROUP => 'START_GROUP',
        COMMENT         => 'Sessions start here');

    DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
        CONSUMER_GROUP => 'QUARANTINE_GROUP',
        COMMENT         => 'Sessions switched here to quarantine them');

    DBMS_RESOURCE_MANAGER.CREATE_PLAN(
        PLAN      => 'Quarantine_plan',
        COMMENT   => 'Quarantine runaway queries');

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(
        PLAN          => 'Quarantine_plan',
        GROUP_OR_SUBPLAN => 'START_GROUP',
        COMMENT       => 'Max CPU 10 minutes before switch',
        MGMT_P1       => 75,
        switch_group  => 'QUARANTINE_GROUP',
        switch_time   => 600);

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(
        PLAN          => 'Quarantine_plan',
        GROUP_OR_SUBPLAN => 'OTHER_GROUPS',
        COMMENT       => 'Mandatory',
        MGMT_P1       => 25);

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(
        PLAN          => 'Quarantine_plan',
        GROUP_OR_SUBPLAN => 'QUARANTINE_GROUP',
        COMMENT       => 'Limited CPU',
        MGMT_P2       => 100,
        UTILIZATION_LIMIT => 20);

    DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
    DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/
```

 **Note:**

Although you could set the utilization limit to zero for QUARANTINE_GROUP, thus completely quarantining runaway queries, it is recommended that you avoid doing this. If the runaway query is holding any resources—PGA memory, locks, and so on—required by any other session, then a zero allocation setting could lead to a deadlock.

Example 3 - Limiting CPU for Applications

In this example, assume that mapping rules map application sessions into one of four application groups. Each application group is allocated a utilization limit of 30%. This limits CPU utilization of any one application to 30%. The sum of the UTILIZATION_LIMIT values exceeds 100%, which is permissible and acceptable in a situation where all applications are not active simultaneously.

```

BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();

    DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(
        CONSUMER_GROUP => 'APP1_GROUP',
        COMMENT         => 'Apps group 1');
    DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
        CONSUMER_GROUP => 'APP2_GROUP',
        COMMENT         => 'Apps group 2');
    DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
        CONSUMER_GROUP => 'APP3_GROUP',
        COMMENT         => 'Apps group 3');
    DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
        CONSUMER_GROUP => 'APP4_GROUP',
        COMMENT         => 'Apps group 4');

    DBMS_RESOURCE_MANAGER.CREATE_PLAN(
        PLAN      => 'apps_plan',
        COMMENT   => 'Application consolidation');

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
        PLAN          => 'apps_plan',
        GROUP_OR_SUBPLAN => 'APP1_GROUP',
        COMMENT        => 'Apps group 1',
        UTILIZATION_LIMIT => 30);
    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
        PLAN          => 'apps_plan',
        GROUP_OR_SUBPLAN => 'APP2_GROUP',
        COMMENT        => 'Apps group 2',
        UTILIZATION_LIMIT => 30);
    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
        PLAN          => 'apps_plan',
        GROUP_OR_SUBPLAN => 'APP3_GROUP',
        COMMENT        => 'Apps group 3',
        UTILIZATION_LIMIT => 30);
    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
        PLAN          => 'apps_plan',
        GROUP_OR_SUBPLAN => 'APP4_GROUP',
        COMMENT        => 'Apps group 4',
        UTILIZATION_LIMIT => 30);

    DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (

```

```

PLAN          => 'apps_plan',
GROUP_OR_SUBPLAN => 'OTHER_GROUPS',
COMMENT        => 'Mandatory',
UTILIZATION_LIMIT => 20);

DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/

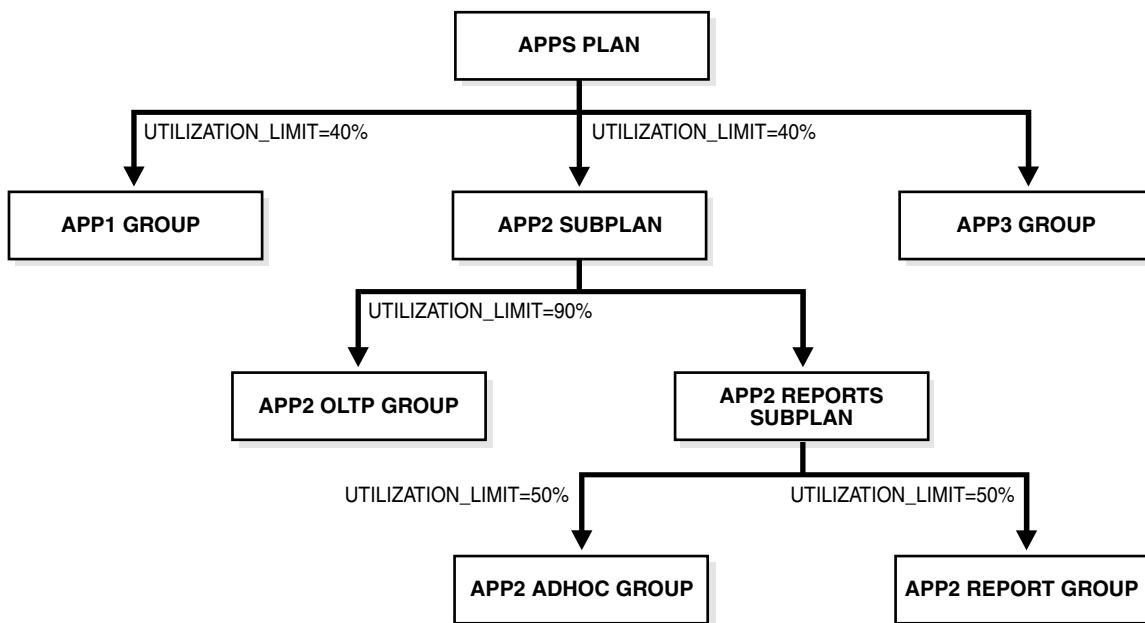

```

If all four application groups can fully use the CPU allocated to them (30% in this case), then the minimum CPU that is allocated to each application group is computed as a ratio of the application group's limit to the total of the limits of all application groups. In this example, all four application groups are allocated a utilization limit of 30%. Therefore, when all four groups fully use their limits, the CPU allocation to each group is $30/(30+30+30+30) = 25\%$.

Example 4 - Specifying a Utilization Limit for Consumer Groups and Subplans

The following example describes how the utilization limit is computed for scenarios, such as the one in [Figure 27-4](#), where you set UTILIZATION_LIMIT for a subplan and for consumer groups within the subplan. For simplicity, the requirement to include the OTHER_GROUPS consumer group is ignored, and resource plan directives are not shown, even though they are part of the plan.

Figure 27-4 Resource Plan with Maximum Utilization for Subplan and Consumer Groups

The following PL/SQL block creates the plan described in [Figure 27-4](#).

```

BEGIN
    DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
    DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
        CONSUMER_GROUP => 'APP1_GROUP',
        COMMENT        => 'Group for application #1');

```

```

DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
    CONSUMER_GROUP => 'APP2_OLTP_GROUP',
    COMMENT        => 'Group for OLTP activity in application #2');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
    CONSUMER_GROUP => 'APP2_ADHOC_GROUP',
    COMMENT        => 'Group for ad-hoc queries in application #2');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
    CONSUMER_GROUP => 'APP2_REPORT_GROUP',
    COMMENT        => 'Group for reports in application #2');
DBMS_RESOURCE_MANAGER.CREATE_PLAN(
    PLAN      => 'APPS_PLAN',
    COMMENT   => 'Plan for managing 3 applications');
DBMS_RESOURCE_MANAGER.CREATE_PLAN(
    PLAN      => 'APP2_SUBPLAN',
    COMMENT   => 'Subplan for managing application #2',
    SUB_PLAN  => TRUE);
DBMS_RESOURCE_MANAGER.CREATE_PLAN(
    PLAN      => 'APP2_REPORTS_SUBPLAN',
    COMMENT   => 'Subplan for managing reports in application #2',
    SUB_PLAN  => TRUE);

DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'APPS_PLAN',
    GROUP_OR_SUBPLAN => 'APP1_GROUP',
    COMMENT        => 'Limit CPU for application #1 to 40%',
    UTILIZATION_LIMIT => 40);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'APPS_PLAN',
    GROUP_OR_SUBPLAN => 'APP2_SUBPLAN',
    COMMENT        => 'Limit CPU for application #2 to 40%',
    UTILIZATION_LIMIT => 40);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'APP2_SUBPLAN',
    GROUP_OR_SUBPLAN => 'APP2_OLTP_GROUP',
    COMMENT        => 'Limit CPU for OLTP to 90% of application #2',
    UTILIZATION_LIMIT => 90);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'APP2_SUBPLAN',
    GROUP_OR_SUBPLAN => 'APP2_REPORTS_SUBPLAN',
    COMMENT        => 'Subplan for ad-hoc and normal reports for application
#2');
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'APP2_REPORTS_SUBPLAN',
    GROUP_OR_SUBPLAN => 'APP2_ADHOC_GROUP',
    COMMENT        => 'Limit CPU for ad-hoc queries to 50% of application #2
reports',
    UTILIZATION_LIMIT => 50);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'APP2_REPORTS_SUBPLAN',
    GROUP_OR_SUBPLAN => 'APP2_REPORT_GROUP',
    COMMENT        => 'Limit CPU for reports to 50% of application #2
reports',
    UTILIZATION_LIMIT => 50);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
    PLAN          => 'APPS_PLAN',
    GROUP_OR_SUBPLAN => 'OTHER_GROUPS',
    COMMENT        => 'No directives for default users');
DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/

```

In this example, the maximum CPU utilization for the consumer group APP1_GROUP and subplan APP2_SUBPLAN is set to 40%. The limit for the consumer groups APP2_ADHOC_GROUP and APP2_REPORT_GROUP is set to 50%.

Because there is no limit specified for the subplan APP2_REPORTS_SUBPLAN, it inherits the limit of its parent subplan APP2_SUBPLAN, which is 40%. The absolute limit for the consumer group APP2_REPORT_GROUP is computed as 50% of its parent subplan, which is 50% of 40%, or 20%.

Similarly, because the consumer group APP2_ADHOC_GROUP is contained in the subplan APP2_REPORTS_SUBPLAN, its limit is computed as a percentage of its parent subplan. The utilization limit for the consumer group APP2_ADHOC_GROUP is 50% of 40%, or 20%.

The maximum CPU utilization for the consumer group APP2_OLTP_GROUP is set to 90%. The parent subplan of APP2_OLTP_GROUP, APP2_SUBPLAN, has a limit of 40%. Therefore, the absolute limit for the group APP2_OLTP_GROUP is 90% of 40%, or 36%.

27.7.3 Example of Using Several Resource Allocation Methods

An example illustrates using several resource allocation methods.

The example presented here could represent a plan for a database supporting a packaged ERP (Enterprise Resource Planning) or CRM (Customer Relationship Management) application. The work in such an environment can be highly varied. There may be a mix of short transactions and quick queries, in combination with longer running batch jobs that include large parallel queries. The goal is to give good response time to OLTP (Online Transaction Processing), while allowing batch jobs to run in parallel.

The plan is summarized in the following table.

Group	CPU Resource Allocation %	Parallel Statement Queuing	Automatic Consumer Group Switching	Maximum Estimated Execution Time	Undo Pool	PGA Limit for Each Session
oltp	60%	--	Switch to group: batch Switch time: 3 secs	-- 3600 secs	200K --	20M --
batch	30%	Parallel server limit: 8 Parallel queue timeout: 600 secs	--	--	--	--
OTHER_GROUP S	10%	--	--	--	--	--

The following statements create the preceding plan, which is named `erp_plan`:

```
BEGIN
DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
DBMS_RESOURCE_MANAGER.CREATE_PLAN(PLAN => 'erp_plan',
    COMMENT => 'Resource plan/method for ERP Database');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(CONSUMER_GROUP => 'oltp',
    COMMENT => 'Resource consumer group/method for OLTP jobs');
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP(CONSUMER_GROUP => 'batch',
```

```

    COMMENT => 'Resource consumer group/method for BATCH jobs');
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'erp_plan',
    GROUP_OR_SUBPLAN => 'oltp', COMMENT => 'OLTP sessions', MGMT_P1 => 60,
    SWITCH_GROUP => 'batch', SWITCH_TIME => 3, UNDO_POOL => 200,
    SWITCH_FOR_CALL => TRUE, SESSION_PGA_LIMIT => 20);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'erp_plan',
    GROUP_OR_SUBPLAN => 'batch', COMMENT => 'BATCH sessions', MGMT_P1 => 30,
    PARALLEL_SERVER_LIMIT => 8, PARALLEL_QUEUE_TIMEOUT => 600,
    MAX_EST_EXEC_TIME => 3600);
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE(PLAN => 'erp_plan',
    GROUP_OR_SUBPLAN => 'OTHER_GROUPS', COMMENT => 'mandatory', MGMT_P1 => 10);
DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/

```

27.7.4 Example of Managing Parallel Statements Using Directive Attributes

An example illustrates managing parallel statements using directive attributes.

A typical data warehousing environment consists of different types of users with varying resource requirements. Users with common processing needs are grouped into a consumer group. The consumer group URGENT_GROUP consists of users who run reports that provide important information to top management. This group generates a large number of parallel queries. Users from the consumer group ETL_GROUP import data from source systems and perform extract, transform, and load (ETL) operations. The group OTHER_GROUPS contains users who execute ad-hoc queries. You must manage the requirements of these diverse groups of users while optimizing performance.

You can use the following directive attributes to manage and optimize the execution of parallel statements:

- MGMT_Pn
- PARALLEL_SERVER_LIMIT
- PARALLEL_STMT_CRITICAL
- PARALLEL_QUEUE_TIMEOUT
- PARALLEL_DEGREE_LIMIT_P1

[Table 27-4](#) describes the resource allocations of the plan DW_PLAN, which can be used to manage the needs of the data warehouse users. This plan contains the consumer groups URGENT_GROUP, ETL_GROUP, and OTHER_GROUPS. This example demonstrates the use of directive attributes in ensuring that one application or consumer group does not use all the available parallel execution servers.

Table 27-4 Resource Plan with Parallel Statement Directives

Consumer Group	Level 1 CPU Allocation	Level 2 CPU Allocation	Level 3 CPU Allocation	PARALLEL_DEGREE_LI	PARALLEL_SERVER_LIMIT_P1	PARALLEL_S	PARALLEL_QUEUE_TIM_EOUT
URGENT_GROUP	100%				12		
ETL_GROUP		100%		8		50%	

Table 27-4 (Cont.) Resource Plan with Parallel Statement Directives

Consumer Group	Level 1 CPU Allocation	Level 2 CPU Allocation	Level 3 CPU Allocation	PARALLEL_DEGREE_LIMIT_P1	PARALLEL_SERVER_LIMIT	PARALLEL_QUEUE_TIMEOUT_EOUT
OTHER_GROUPS		100%		2	50%	360

In this example, the parameter `PARALLEL_SERVERS_TARGET` initialization parameter is set to 64, which means that the number of parallel execution servers available is 64. The total number of parallel execution servers that can be used for parallel statement execution before `URGENT_GROUP` sessions with `PARALLEL_DEGREE_POLICY` set to `AUTO` are added to the parallel statement queue is equal to 64. Because the `PARALLEL_SERVER_LIMIT` attribute of `ETL_GROUP` and `OTHER_GROUPS` is 50%, the maximum number of parallel execution servers that can be used by these groups is 50% of 64, or 32 parallel execution servers each.

Note that parallel statements from a consumer group will only be queued if the `PARALLEL_DEGREE_POLICY` parameter is set to `AUTO` and the total number of active servers for the consumer group is higher than `PARALLEL_SERVERS_TARGET`. If `PARALLEL_DEGREE_POLICY` is set to `MANUAL` or `LIMITED`, then the statements are run provided there are enough parallel execution servers available. The parallel execution servers used by such a statement will count toward the total number of parallel execution servers used by the consumer group. However, the parallel statement will not be added to the parallel statement queue.

Tip:

For low-priority applications, it is a common practice to set low values for `PARALLEL_DEGREE_LIMIT_P1` and `PARALLEL_SERVER_LIMIT`.

Because `URGENT_GROUP` has 100% of the allocation at level 1, its parallel statements will always be dequeued ahead of the other consumer groups from the parallel statement queue. Although `URGENT_GROUP` has no `PARALLEL_SERVER_LIMIT` directive attribute, a statement issued by a session in this group might still be queued if there are not enough available parallel execution servers to run it.

When you create the resource plan directive for the `URGENT_GROUP`, you can set the `PARALLEL_STMT_CRITICAL` parameter to `BYPASS_QUEUE`. With this setting, parallel statements from the consumer group bypass the parallel statements queue and are executed immediately. However, the number of parallel execution servers might exceed the setting of the `PARALLEL_SERVERS_TARGET` initialization parameter, and the degree of parallelism might be lower if the limit set by the `PARALLEL_MAX_SERVERS` initialization parameter is reached.

The degree of parallelism, represented by `PARALLEL_DEGREE_LIMIT_P1`, is set to 12 for `URGENT_GROUP`. Therefore, each parallel statement from `URGENT_GROUP` can use a maximum of 12 parallel execution servers. Similarly, each parallel statement from the `ETL_GROUP` can use a maximum of 8 parallel execution servers and each parallel statement from the `OTHER_GROUPS` can use 2 parallel execution servers.

Suppose, at a given time, the only parallel statements are from the ETL_GROUP, and they are using 26 out of the 32 parallel execution servers available to this group. Sessions from this consumer group have PARALLEL_DEGREE_POLICY set to AUTO. If another parallel statement with the PARALLEL_DEGREE_LIMIT_P1 attribute set to 8 is launched from ETL_GROUP, then this query cannot be run immediately because the available parallel execution servers in the ETL_GROUP is $32-26=6$ parallel execution servers. The new parallel statement is queued until the number of parallel execution servers it requires is available in ETL_GROUP.

While the parallel statements in ETL_GROUP are being executed, suppose a parallel statement is launched from OTHER_GROUPS. This group still has 32 parallel execution servers available and so the parallel statement is executed.

The PARALLEL_QUEUE_TIMEOUT attribute for OTHER_GROUPS is set to 360. Therefore, any parallel statement from this group can remain in the parallel execution server queue for 360 seconds only. After this time, the parallel statement is removed from the queue and the error ORA-07454 is returned.

27.7.5 An Oracle-Supplied Mixed Workload Plan

Oracle Database includes a predefined resource plan, MIXED_WORKLOAD_PLAN, that prioritizes interactive operations over batch operations, and includes the required subplans and consumer groups recommended by Oracle.

MIXED_WORKLOAD_PLAN is defined as follows:

Group or Subplan	CPU Resource Allocation				
	Level 1	Level 2	Level 3	Automatic Consumer Group Switching	Max Degree of Parallelism
BATCH_GROUP					100%
INTERACTIVE_GROUP	85%	Switch to group: BATCH_GROUP Switch time: 60 seconds Switch for call: TRUE			
ORA\$AUTOTASK	5%				
OTHER_GROUP	5%				

Group or Subplan	CPU Resource Allocation				
	Level 1	Level 2	Level 3	Automatic Consumer Group Switching	Max Degree of Parallelism
SYS_GROUP	100%				

In this plan, because `INTERACTIVE_GROUP` is intended for short transactions, any call that consumes more than 60 seconds of CPU time is automatically switched to `BATCH_GROUP`, which is intended for longer batch operations.

You can use this predefined plan if it is appropriate for your environment. (You can modify the plan, or delete it if you do not intend to use it.) Note that there is nothing special about the names `BATCH_GROUP` and `INTERACTIVE_GROUP`. The names reflect only the intended purposes of the groups, and it is up to you to map application sessions to these groups and adjust CPU resource allocation percentages accordingly so that you achieve proper resource management for your interactive and batch applications. For example, to ensure that your interactive applications run under the `INTERACTIVE_GROUP` consumer group, you must map your interactive applications' user sessions to this consumer group based on user name, service name, program name, module name, or action, as described in "[Specifying Session-to–Consumer Group Mapping Rules](#)". You must map your batch applications to the `BATCH_GROUP` in the same way. Finally, you must enable this plan as described in "[Enabling Oracle Database Resource Manager and Switching Plans](#)".

See [Table 27-5](#) and [Table 27-6](#) for explanations of the other resource consumer groups and subplans in this plan.

27.8 Managing Multiple Database Instances on a Single Server

Oracle Database provides a method for managing CPU allocations on a multi-CPU server running multiple database instances. This method is called instance caging. Instance caging and Oracle Database Resource Manager (the Resource Manager) work together to support desired levels of service across multiple instances.

- [About Instance Caging](#)
A simple way to limit CPU consumption for each database instance is to use instance caging. **Instance caging** is a method that uses an initialization parameter to limit the number of CPUs that an instance can use simultaneously.
- [Enabling Instance Caging](#)
You can enable instance caging using by creating a resource plan with CPU directives and setting the `CPU_COUNT` initialization parameter.

27.8.1 About Instance Caging

A simple way to limit CPU consumption for each database instance is to use instance caging. **Instance caging** is a method that uses an initialization parameter to limit the number of CPUs that an instance can use simultaneously.

You might decide to run multiple Oracle database instances on a single multi-CPU server. A typical reason to do so would be server consolidation—using available hardware resources more efficiently. When running multiple instances on a single server, the instances compete for CPU. One resource-intensive database instance could significantly degrade the performance of the other instances. For example, on a 16-CPU system with four database instances, the operating system might be running one database instance on the majority of the CPUs during a period of heavy load for that instance. This could degrade performance in the other three instances. CPU allocation decisions such as this are made solely by the operating system; the user generally has no control over them.

In the previous example, if you use instance caging to limit the number of CPUs to four for each of the four instances, there is less likelihood that one instance can interfere with the others. When constrained to four CPUs, an instance might become CPU-bound. This is when the Resource Manager begins to do its work to allocate CPU among the various database sessions according to the resource plan that you set for the instance. Thus, instance caging and the Resource Manager together provide a simple, effective way to manage multiple instances on a single server.

There are two typical approaches to instance caging for a server:

- Over-subscribing—You would use this approach for non-critical databases such as development and test systems, or low-load non-critical production systems. In this approach, the sum of the CPU limits for each instance exceeds the actual number of CPUs on the system. For example, on a 4-CPU system with four database instances, you might limit each instance to three CPUs. When a server is over-subscribed in this way, the instances can impact each other's performance. However, instance caging limits the impact and helps provide somewhat predictable performance. However, if one of the instances has a period of high load, the CPUs are available to handle it. This is a reasonable approach for non-critical systems, because one or more of the instances may frequently be idle or at a very low load.
- Partitioning—This approach is for critical production systems, where you want to prevent instances from interfering with each other. You allocate CPUs such that the sum of all allocations is equal to the number of CPUs on the server. For example, on a 16-server system, you might allocate 8 CPUs to the first instance, 4 CPUs to the second, and 2 each to the remaining two instances. By dedicating CPU resources to each database instance, the load on one instance cannot affect another's, and each instance performs predictably.

Using Instance Caging with Utilization Limit

If you enable instance caging and set a utilization limit in your resource plan, then the absolute limit is computed as a percentage of the allocated CPU resources.

For example, if you enable instance caging and set the `CPU_COUNT` to 4, and a consumer group has a utilization limit of 50%, then the consumer group can use a maximum of 50% of 4 CPUs, which is 2 CPUs.

27.8.2 Enabling Instance Caging

You can enable instance caging using by creating a resource plan with CPU directives and setting the `CPU_COUNT` initialization parameter.

To enable instance caging, do the following for each instance on the server:

1. Enable the Resource Manager by assigning a resource plan, and ensure that the resource plan has CPU directives, using the MGMT_P1 through MGMT_P8 parameters.

See "[Enabling Oracle Database Resource Manager and Switching Plans](#)" for instructions.

2. Set the `cpu_count` initialization parameter.

This is a dynamic parameter, and can be set with the following statement:

```
ALTER SYSTEM SET CPU_COUNT = 4;
```

27.9 Maintaining Consumer Groups, Plans, and Directives

You can maintain consumer groups, resource plans, and resource plan directives for Oracle Database Resource Manager (the Resource Manager). You perform maintenance tasks using the `DBMS_RESOURCE_MANAGER` PL/SQL package.

- [Updating a Consumer Group](#)

You use the `UPDATE_CONSUMER_GROUP` procedure to update consumer group information.

- [Deleting a Consumer Group](#)

The `DELETE_CONSUMER_GROUP` procedure deletes the specified consumer group.

- [Updating a Plan](#)

You use the `UPDATE_PLAN` procedure to update plan information.

- [Deleting a Plan](#)

The `DELETE_PLAN` procedure deletes the specified plan as well as all the plan directives associated with it.

- [Updating a Resource Plan Directive](#)

Use the `UPDATE_PLAN_DIRECTIVE` procedure to update plan directives.

- [Deleting a Resource Plan Directive](#)

To delete a resource plan directive, use the `DELETE_PLAN_DIRECTIVE` procedure.

 **See Also:**

- [Predefined Consumer Group Mapping Rules](#)
- [*Oracle Database PL/SQL Packages and Types Reference*](#) for details on the `DBMS_RESOURCE_MANAGER` PL/SQL package.

27.9.1 Updating a Consumer Group

You use the `UPDATE_CONSUMER_GROUP` procedure to update consumer group information.

To update a consumer group:

1. Create a pending area.
2. Run the `UPDATE_CONSUMER_GROUP` procedure .

If you do not specify the arguments for the UPDATE_CONSUMER_GROUP procedure, then they remain unchanged in the data dictionary.

3. Submit the pending area.

Related Topics

- [Creating a Pending Area](#)

You create a pending area with the CREATE_PENDING_AREA procedure.

- [Submitting the Pending Area](#)

After you have validated your changes, call the SUBMIT_PENDING_AREA procedure to make your changes active.

27.9.2 Deleting a Consumer Group

The DELETE_CONSUMER_GROUP procedure deletes the specified consumer group.

To delete a consumer group:

1. Create a pending area.
2. Run the DELETE_CONSUMER_GROUP procedure .
3. Submit the pending area.

Upon deletion of a consumer group, all users having the deleted group as their initial consumer group are assigned the OTHER_GROUPS as their initial consumer group. All currently running sessions belonging to a deleted consumer group are assigned to a new consumer group, based on the consumer group mapping rules. If no consumer group is found for a session through mapping, the session is switched to the OTHER_GROUPS.

You cannot delete a consumer group if it is referenced by a resource plan directive.

Related Topics

- [Creating a Pending Area](#)

You create a pending area with the CREATE_PENDING_AREA procedure.

- [Submitting the Pending Area](#)

After you have validated your changes, call the SUBMIT_PENDING_AREA procedure to make your changes active.

27.9.3 Updating a Plan

You use the UPDATE_PLAN procedure to update plan information.

To update a plan:

1. Create a pending area.
2. Run the UPDATE_PLAN procedure. For example, the following PL/SQL block updates the COMMENT parameter:

```
BEGIN
    DBMS_RESOURCE_MANAGER.UPDATE_PLAN(
        PLAN => 'DAYTIME',
        NEW_COMMENT => '50% more resources for OLTP applications');
END;
/
```

If you do not specify the arguments for the `UPDATE_PLAN` procedure, they remain unchanged in the data dictionary.

3. Submit the pending area.

Related Topics

- [Creating a Pending Area](#)

You create a pending area with the `CREATE_PENDING_AREA` procedure.

- [Submitting the Pending Area](#)

After you have validated your changes, call the `SUBMIT_PENDING_AREA` procedure to make your changes active.

27.9.4 Deleting a Plan

The `DELETE_PLAN` procedure deletes the specified plan as well as all the plan directives associated with it.

To delete a plan:

1. Create a pending area.
2. Run the `DELETE_PLAN.Cascade` procedure. For example, the following PL/SQL block deletes the `great_bread` plan and its directives.

```
BEGIN
    DBMS_RESOURCE_MANAGER.DELETE_PLAN(PLAN => 'great_bread');
END;
/
```

If you do not specify the arguments for the `UPDATE_PLAN` procedure, they remain unchanged in the data dictionary.

The resource consumer groups referenced by the deleted directives are not deleted, but they are no longer associated with the `great_bread` plan.

The `DELETE_PLAN.Cascade` procedure deletes the specified plan as well as all its descendants: plan directives and those subplans and resource consumer groups that are not marked by the database as mandatory. If `DELETE_PLAN.Cascade` encounters an error, then it rolls back, leaving the plan unchanged.

You cannot delete the currently active plan.

3. Submit the pending area.

Related Topics

- [Creating a Pending Area](#)

You create a pending area with the `CREATE_PENDING_AREA` procedure.

- [Submitting the Pending Area](#)

After you have validated your changes, call the `SUBMIT_PENDING_AREA` procedure to make your changes active.

27.9.5 Updating a Resource Plan Directive

Use the `UPDATE_PLAN_DIRECTIVE` procedure to update plan directives.

To update a resource plan directive:

1. Create a pending area.

2. Run the `UPDATE_PLAN_DIRECTIVE` procedure.

The following example adds a comment to a directive:

```
BEGIN
    DBMS_RESOURCE_MANAGER.CLEAR_PENDING_AREA();
    DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
    DBMS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(
        PLAN          => 'SIMPLE_PLAN1',
        GROUP_OR_SUBPLAN => 'MYGROUP1',
        NEW_COMMENT      => 'Higher priority'
    );
    DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/
```

To clear (nullify) a comment, pass a null string (''). To clear (zero or nullify) any numeric directive parameter, set its new value to -1:

```
BEGIN
    DBMS_RESOURCE_MANAGER.CLEAR_PENDING_AREA();
    DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
    DBMS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE(
        PLAN          => 'SIMPLE_PLAN1',
        GROUP_OR_SUBPLAN => 'MYGROUP1',
        NEW_MAX_EST_EXEC_TIME => -1
    );
    DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/
```

If you do not specify an argument for the `UPDATE_PLAN_DIRECTIVE` procedure, then its corresponding parameter in the directive remains unchanged.

3. Submit the pending area.

Related Topics

- [Creating a Pending Area](#)

You create a pending area with the `CREATE_PENDING_AREA` procedure.

- [Submitting the Pending Area](#)

After you have validated your changes, call the `SUBMIT_PENDING_AREA` procedure to make your changes active.

27.9.6 Deleting a Resource Plan Directive

To delete a resource plan directive, use the `DELETE_PLAN_DIRECTIVE` procedure.

To delete a resource plan directive:

1. Create a pending area.
2. Run the `DELETE_PLAN_DIRECTIVE` procedure.
3. Submit the pending area.

Related Topics

- [Creating a Pending Area](#)

You create a pending area with the `CREATE_PENDING_AREA` procedure.

- [Submitting the Pending Area](#)

After you have validated your changes, call the `SUBMIT_PENDING_AREA` procedure to make your changes active.

27.10 Viewing Database Resource Manager Configuration and Status

You can use several static data dictionary views and dynamic performance views to view the current configuration and status of Oracle Database Resource Manager (the Resource Manager).

- [Viewing Consumer Groups Granted to Users or Roles](#)

The `DBA_RSRC_CONSUMER_GROUP_PRIVS` view displays the consumer groups granted to users or roles.

- [Viewing Plan Information](#)

An example illustrates using the `DBA_RSRC_PLANS` view to display all of the resource plans defined in the database.

- [Viewing Current Consumer Groups for Sessions](#)

You can use the `V$SESSION` view to display the consumer groups that are currently assigned to sessions.

- [Viewing the Currently Active Plans](#)

The `V$RSRC_PLAN` view displays currently active plans.

 **See Also:**

Oracle Database Reference for details on all static data dictionary views and dynamic performance views

27.10.1 Viewing Consumer Groups Granted to Users or Roles

The `DBA_RSRC_CONSUMER_GROUP_PRIVS` view displays the consumer groups granted to users or roles.

Specifically, it displays the groups to which a user or role is allowed to belong or be switched. For example, in the view shown below, user SCOTT always starts in the SALES consumer group, can switch to the MARKETING group through a specific grant, and can switch to the `DEFAULT_CONSUMER_GROUP` (`OTHER_GROUPS`) and `LOW_GROUP` groups because they are granted to PUBLIC. SCOTT also can grant the SALES group but not the MARKETING group to other users.

```
SELECT * FROM dba_rsrc_consumer_group_privs;
```

GRANTEE	GRANTED_GROUP	GRANT_OPTION	INITIAL_GROUP
PUBLIC	DEFAULT_CONSUMER_GROUP	YES	YES
PUBLIC	LOW_GROUP	NO	NO
SCOTT	MARKETING	NO	NO
SCOTT	SALES	YES	YES
SYSTEM	SYS_GROUP	NO	YES

SCOTT was granted the ability to switch to these groups using the DBMS_RESOURCE_MANAGER_PRIVS package.

27.10.2 Viewing Plan Information

An example illustrates using the DBA_RSRC_PLANS view to display all of the resource plans defined in the database.

All plans have a NULL status, meaning that they are not in the pending area.

 **Note:**

Plans in the pending area have a status of PENDING. Plans in the pending area are being edited.

```
SELECT plan,status,comments FROM dba_rsrc_plans;
```

PLAN	STATUS	COMMENTS
DSS_PLAN		Example plan for DSS workloads that prio...
ETL_CRITICAL_PLAN		Example plan for DSS workloads that prio...
MIXED_WORKLOAD_PLAN		Example plan for a mixed workload that p...
DEFAULT_MAINTENANCE_PLAN		Default plan for maintenance windows tha...
DEFAULT_PLAN		Default, basic, pre-defined plan that pr...
INTERNAL QUIESCE		Plan for quiescing the database. This p...
INTERNAL_PLAN		Internally-used plan for disabling the r...
.		
.		
.		

27.10.3 Viewing Current Consumer Groups for Sessions

You can use the V\$SESSION view to display the consumer groups that are currently assigned to sessions.

The following example queries the V\$SESSION view:

```
SELECT sid,serial#,username,resource_consumer_group FROM v$session;
```

SID	SERIAL#	USERNAME	RESOURCE_CONSUMER_GROUP
11	136	SYS	SYS_GROUP
13	16570	SCOTT	SALES
.			

27.10.4 Viewing the Currently Active Plans

The V\$RSRC_PLAN view displays currently active plans.

This example sets mydb_plan, as created by the example shown in "[Multilevel Plan Example](#)", as the top level plan. It then queries the V\$RSRC_PLAN view to display the currently active plans. The view displays the current top level plan and all of its descendent subplans.

```
ALTER SYSTEM SET RESOURCE_MANAGER_PLAN = mydb_plan;

System altered.

SELECT name, is_top_plan FROM v$rsrc_plan;

NAME          IS_TOP_PLAN
-----
MYDB_PLAN     TRUE
MAILDB_PLAN   FALSE
BUGDB_PLAN    FALSE
```

27.11 Monitoring Oracle Database Resource Manager

A set of dynamic performance views enable you to monitor the results of your Oracle Database Resource Manager settings.

Use the following dynamic performance views to help you monitor the results of your Oracle Database Resource Manager settings:

- [V\\$RSRC_PLAN](#)
- [V\\$RSRC_CONSUMER_GROUP](#)
- [V\\$RSRC_SESSION_INFO](#)
- [V\\$RSRC_PLAN_HISTORY](#)
- [V\\$RSRC_CONS_GROUP_HISTORY](#)
- [V\\$RSRCMGRMETRIC](#)
- [V\\$RSRCMGRMETRIC_HISTORY](#)

These views provide:

- Current status information
- History of resource plan activations
- Current and historical statistics on resource consumption and CPU waits by both resource consumer group and session

In addition, historical statistics are available through the `DBA_HIST_RSRC_PLAN` and `DBA_HIST_RSRC_CONSUMER_GROUP` views, which contain Automatic Workload Repository (AWR) snapshots of the `V$RSRC_PLAN_HISTORY` and `V$RSRC_CONS_GROUP_HISTORY`, respectively.

For assistance with tuning, the views `V$RSRCMGRMETRIC` and `V$RSRCMGRMETRIC_HISTORY` show how much time was spent waiting for CPU and how much CPU was consumed per minute for every consumer group for the past hour. These metrics can also be viewed graphically with Cloud Control, on the Resource Manager Statistics page.

When Resource Manager is enabled, Resource Manager automatically records statistics about resource usage, and you can examine these statistics using real-time SQL monitoring and Resource Manager dynamic performance views.

You can use real-time SQL monitoring by accessing the SQL Monitor page in Cloud Control or by querying the `V$SQL_MONITOR` view and other related views. The `V$SQL_MONITOR` view also includes information about the last action performed by Resource Manager for a consumer group in the following columns:

RM_CONSUMER_GROUP, RM_LAST_ACTION, RM_LAST_ACTION_REASON, and RM_LAST_ACTION_TIME.

In addition, the following dynamic performance views contain statistics about resource usage:

- V\$RSRCMGRMETRIC
- V\$RSRCMGRMETRIC_HISTORY
- V\$RSRC_CONSUMER_GROUP
- V\$RSRC_CONS_GROUP_HISTORY

See Also:

Oracle Database SQL Tuning Guide for more information about real-time SQL monitoring

V\$RSRC_PLAN

This view displays the currently active resource plan and its subplans.

```
SELECT name, is_top_plan FROM v$rsrc_plan;
```

NAME	IS_TOP_PLAN
DEFAULT_PLAN	TRUE
ORA\$AUTOTASK	FALSE
ORA\$AUTOTASK_HIGH_SUB_PLAN	FALSE

The plan for which IS_TOP_PLAN is TRUE is the currently active (top) plan, and the other plans are subplans of either the top plan or of other subplans in the list.

This view also contains other information, including the following:

- The INSTANCE_CAGING column shows whether instance caging is enabled.
- The CPU_MANAGED column shows whether CPU is being managed.
- The PARALLEL_EXECUTION_MANAGED column shows whether parallel statement queuing is enabled.

See Also:

Oracle Database Reference

V\$RSRC_CONSUMER_GROUP

Use the V\$RSRC_CONSUMER_GROUP view to monitor resources consumed, including CPU, I/O, and parallel execution servers. It can also be used to monitor statistics related to CPU resource management, runaway query management, parallel statement queuing, and so on. All of the statistics are cumulative from the time when the plan was activated.

```
SELECT name, active_sessions, queue_length,
       consumed_cpu_time, cpu_waits, cpu_wait_time
  FROM v$rsrc_consumer_group;
```

NAME	ACTIVE_SESSIONS	QUEUE_LENGTH	CONSUMED_CPU_TIME	CPU_WAITS	CPU_WAIT_TIME
OLTP_ORDER_ENTRY	1	0	29690	467	6709
OTHER_GROUPS	0	0	5982366	4089	60425
SYS_GROUP	1	0	2420704	914	19540
DSS_QUERIES	4	2	4594660	3004	55700

In the preceding query results, the DSS_QUERIES consumer group has four sessions in its active session pool and two more sessions queued for activation.

A key measure in this view is CPU_WAIT_TIME. This indicates the total time that sessions in the consumer group waited for CPU because of resource management. Not included in this measure are waits due to latch or enqueue contention, I/O waits, and so on.

Note:

The V\$RSRC_CONSUMER_GROUP view records statistics for resources that are not currently being managed by Resource Manager. When the STATISTICS_LEVEL initialization parameter is set to ALL or TYPICAL.

See Also:

Oracle Database Reference

V\$RSRC_SESSION_INFO

Use this view to monitor the status of one or more sessions. The view shows how the session has been affected by the Resource Manager. It provides information such as:

- The consumer group that the session currently belongs to.
- The consumer group that the session originally belonged to.
- The session attribute that was used to map the session to the consumer group.
- Session state (RUNNING, WAIT_FOR_CPU, QUEUED, and so on).
- Current and cumulative statistics for metrics, such as CPU consumed, wait times, queued time, and number of active parallel servers used. Current statistics reflect statistics for the session since it joined its current consumer group. Cumulative statistics reflect statistics for the session in all consumer groups to which it has belonged since it was created.

```
SELECT se.sid sess_id, co.name consumer_group,
       se.state, se.consumed_cpu_time cpu_time, se.cpu_wait_time, se.queued_time
  FROM v$rsrc_session_info se, v$rsrc_consumer_group co
 WHERE se.current_consumer_group_id = co.id;
```

SESS_ID	CONSUMER_GROUP	STATE	CPU_TIME	CPU_WAIT_TIME	QUEUED_TIME
---------	----------------	-------	----------	---------------	-------------

113	OLTP_ORDER_ENTRY	WAITING	137947	28846	0
135	OTHER_GROUPS	IDLE	785669	11126	0
124	OTHER_GROUPS	WAITING	50401	14326	0
114	SYS_GROUP	RUNNING	495	0	0
102	SYS_GROUP	IDLE	88054	80	0
147	DSS_QUERIES	WAITING	460910	512154	0

CPU_WAIT_TIME in this view has the same meaning as in the V\$RSRC_CONSUMER_GROUP view, but applied to an individual session.

You can join this view with the V\$SESSION view for more information about a session.

See Also:

- *Oracle Database Reference*
- *Oracle Database VLDB and Partitioning Guide*

V\$RSRC_PLAN_HISTORY

This view shows when resource plans were enabled or disabled on the instance. Each resource plan activation or deactivation is assigned a sequence number. For each entry in the view, the V\$RSRC_CONS_GROUP_HISTORY view has a corresponding entry for each consumer group in the plan that shows the cumulative statistics for the consumer group. The two views are joined by the SEQUENCE# column in each.

```
SELECT sequence# seq, name plan_name,
       to_char(start_time, 'DD-MON-YY HH24:MM') start_time,
       to_char(end_time, 'DD-MON-YY HH24:MM') end_time, window_name
  FROM v$rsrc_plan_history;
```

SEQ	PLAN_NAME	START_TIME	END_TIME	WINDOW_NAME
1		29-MAY-07 23:05	29-MAY-07 23:05	
2	DEFAULT_MAINTENANCE_PLAN	29-MAY-07 23:05	30-MAY-07 02:05	TUESDAY_WINDOW
3		30-MAY-07 02:05	30-MAY-07 22:05	
4	DEFAULT_MAINTENANCE_PLAN	30-MAY-07 22:05	31-MAY-07 02:05	WEDNESDAY_WINDOW
5		31-MAY-07 02:05	31-MAY-07 22:05	
6	DEFAULT_MAINTENANCE_PLAN	31-MAY-07 22:05		THURSDAY_WINDOW

A null value under PLAN_NAME indicates that no plan was active.

AWR snapshots of this view are stored in the DBA_HIST_RSRC_PLAN view.

See Also:

- *Oracle Database Reference*

V\$RSRC_CONS_GROUP_HISTORY

This view helps you understand how resources were shared among the consumer groups over time. The sequence# column corresponds to the column of the same

name in the V\$RSRC_PLAN_HISTORY view. Therefore, you can determine the plan that was active for each row of consumer group statistics.

```
SELECT sequence# seq, name, cpu_wait_time, cpu_waits,
consumed_cpu_time FROM v$rsrc_cons_group_history;
```

SEQ	NAME	CPU_WAIT_TIME	CPU_WAITS	CONSUMED_CPU_TIME
2	SYS_GROUP	18133	691	33364431
2	OTHER_GROUPS	51252	825	181058333
2	ORA\$AUTOTASK_MEDIUM_GROUP	21	5	4019709
2	ORA\$AUTOTASK_URGENT_GROUP	35	1	198760
2	ORA\$AUTOTASK_STATS_GROUP	0	0	0
2	ORA\$AUTOTASK_SPACE_GROUP	0	0	0
2	ORA\$AUTOTASK_SQL_GROUP	0	0	0
2	ORA\$AUTOTASK_HEALTH_GROUP	0	0	0
4	SYS_GROUP	40344	85	42519265
4	OTHER_GROUPS	123295	1040	371481422
4	ORA\$AUTOTASK_MEDIUM_GROUP	1	4	7433002
4	ORA\$AUTOTASK_URGENT_GROUP	22959	158	19964703
4	ORA\$AUTOTASK_STATS_GROUP	0	0	0
.				
.				

AWR snapshots of this view are stored in the DBA_HIST_RSRC_CONSUMER_GROUP view. Use DBA_HIST_RSRC_CONSUMER_GROUP with DBA_HIST_RSRC_PLAN to determine the plan that was active for each historical set of consumer group statistics.

Note:

The V\$RSRC_CONS_GROUP_HISTORY view records statistics for resources that are not currently being managed by Resource Manager. when the STATISTICS_LEVEL initialization parameter is set to ALL or TYPICAL.

See Also:

- *Oracle Database Reference*
- *Oracle Database Performance Tuning Guide* for information about the AWR.

V\$RSRCMGRMETRIC

This view enables you to track CPU metrics in milliseconds, in terms of number of sessions, or in terms of utilization for the past one minute. It provides real-time metrics for each consumer group and is very useful in scenarios where you are running workloads and want to continuously monitor CPU resource utilization.

Use this view to compare the maximum possible CPU utilization and average CPU utilization percentage for consumer groups with other consumer group settings such as CPU time used, time waiting for CPU, average number of sessions that are consuming CPU, and number of sessions that are waiting for CPU allocation. For example, you can view the amount of CPU resources a consumer group used and

how long it waited for resource allocation. Or, you can view how many sessions from each consumer group are executed against the total number of active sessions.

To track CPU consumption in terms of CPU utilization, use the `CPU_UTILIZATION_LIMIT` and `AVG_CPU_UTILIZATION` columns. `AVG_CPU_UTILIZATION` lists the average percentage of the server's CPU that is consumed by a consumer group. `CPU_UTILIZATION_LIMIT` represents the maximum percentage of the server's CPU that a consumer group can use. This limit is set using the `UTILIZATION_LIMIT` directive attribute.

```
SELECT consumer_group_name, cpu_utilization_limit,  
avg_cpu_utilization FROM v$rsrcmgrmetric;
```

Use the `CPU_CONSUMED_TIME` and `CPU_TIME_WAIT` columns to track CPU consumption and throttling in milliseconds. The column `NUM_CPUS` represents the number of CPUs that Resource Manager is managing.

```
SELECT consumer_group_name, cpu_consumed_time,  
cpu_wait_time, num_cpus FROM v$rsrcmgrmetric;
```

To track the CPU consumption and throttling in terms of number of sessions, use the `RUNNING_SESSIONS_LIMIT`, `AVG_RUNNING_SESSIONS`, and `AVG_WAITING_SESSIONS` columns. `RUNNING_SESSIONS_LIMIT` lists the maximum number of sessions, from a particular consumer group, that can be running at any time. This limit is defined by the `UTILIZATION_LIMIT` directive attribute that you set either for the consumer group or for a subplan that contains the consumer group. For each consumer group, `AVG_RUNNING_SESSIONS` lists the average number of sessions that are consuming CPU and `AVG_WAITING_SESSIONS` lists the average number of sessions that are waiting for CPU.

```
SELECT sequence#, consumer_group_name, running_sessions_limit,  
avg_running_sessions, avg_waiting_sessions FROM v$rsrcmgrmetric;
```

To track parallel statements and parallel server use for a consumer group, use the `AVG_ACTIVE_PARALLEL_STMTS`, `AVG_QUEUED_PARALLEL_STMTS`, `AVG_ACTIVE_PARALLEL_SERVERS`, `AVG_QUEUED_PARALLEL_SERVERS`, and `PARALLEL_SERVERS_LIMIT` columns. `AVG_ACTIVE_PARALLEL_STMTS` and `AVG_ACTIVE_PARALLEL_SERVERS` list the average number of parallel statements running and the average number of parallel servers used by the parallel statements. `AVG_QUEUED_PARALLEL_STMTS` and `AVG_QUEUED_PARALLEL_SERVERS` list the average number of parallel statements queued and average number of parallel servers that were requested by queued parallel statements. `PARALLEL_SERVERS_LIMIT` lists the number of parallel servers allowed to be used by the consumer group.

```
SELECT avg_active_parallel_stmts, avg_queued_parallel_stmts,  
avg_active_parallel_servers, avg_queued_parallel_servers, parallel_servers_limit  
FROM v$rsrcmgrmetric;
```

 **Note:**

The `V$RSRCMGRMETRIC` view records statistics for resources that are not currently being managed by Resource Manager. When the `STATISTICS_LEVEL` initialization parameter is set to `ALL` or `TYPICAL`.

 **See Also:**

Oracle Database Reference

V\$RSRCMGRMETRIC_HISTORY

The columns in the V\$RSRCMGRMETRIC_HISTORY are the same view as V\$RSRCMGRMETRIC. The only difference between these views is that V\$RSRCMGRMETRIC contains metrics for the past one minute only, whereas V\$RSRCMGRMETRIC_HISTORY contains metrics for the last 60 minutes.

 **Note:**

The V\$RSRCMGRMETRIC_HISTORY view records statistics for resources that are not currently being managed by Resource Manager. when the STATISTICS_LEVEL initialization parameter is set to ALL or TYPICAL.

 **See Also:**

Oracle Database Reference

27.12 Interacting with Operating-System Resource Control

Many operating systems provide tools for resource management. These tools often contain "workload manager" or "resource manager" in their names, and are intended to allow multiple applications to share the resources of a single server, using an administrator-defined policy. Examples are Hewlett Packard's Process Resource Manager or Solaris Containers, Zones, and Resource Pools.

- [Guidelines for Using Operating-System Resource Control](#)
Follow guidelines if you use operating-system resource control.

27.12.1 Guidelines for Using Operating-System Resource Control

Follow guidelines if you use operating-system resource control.

If you choose to use operating-system resource control with Oracle Database, then you must use it judiciously, according to the following guidelines:

- If you have multiple instances on a node, and you want to distribute resources among them, then each instance should be assigned to a dedicated operating-system resource manager group or managed entity. To run multiple instances in the managed entity, use instance caging to manage how the CPU resources within the managed entity should be distributed among the instances. When Oracle Database Resource Manager is managing CPU resources, it expects a fixed amount of CPU resources for the instance. Without instance caging, it expects the

available CPU resources to be equal to the number of CPUs in the managed entity. With instance caging, it expects the available CPU resources to be equal to the value of the `CPU_COUNT` initialization parameter. If there are less CPU resources than expected, then the Oracle Database Resource Manager is not as effective at enforcing the resource allocations in the resource plan. See "[Managing Multiple Database Instances on a Single Server](#)" for information about instance caging.

- The dedicated entity running all the instance's processes must run at one priority (or resource consumption) level.
- The CPU resources assigned to the dedicated entity cannot be changed more frequently than once every few minutes.

If the operating-system resource manager is rapidly changing the CPU resources allocated to an Oracle instance, then the Oracle Database Resource Manager might not manage CPU resources effectively. In particular, if the CPU resources allocated to the Oracle instance changes more frequently than every couple of minutes, then these changes might not be observed by Oracle because it only checks for such changes every couple of minutes. In these cases, Oracle Database Resource Manager can over-schedule processes if it concludes that more CPU resources are available than there actually are, and it can under-schedule processes if it concludes that less CPU resources are available than there actually are. If it over-schedules processes, then the `UTILIZATION_LIMIT` directives might be exceeded, and the CPU directives might not be accurately enforced. If it under-schedules processes, then the Oracle instance might not fully use the server's resources.

- Process priority management must not be enabled.
- Management of individual database processes at different priority levels (for example, using the `nice` command on UNIX platforms) is not supported. Severe consequences, including instance crashes, can result. Similar undesirable results are possible if operating-system resource control is permitted to manage the memory to which an Oracle Database instance is pinned.

27.13 Oracle Database Resource Manager Reference

Resource Manager includes predefined resource plans, consumer groups, and consumer groups mapping rules. You can query data dictionary views for information about your Resource Manager configuration.

- [Predefined Resource Plans and Consumer Groups](#)
Oracle Database includes predefined resource plans.
- [Predefined Consumer Group Mapping Rules](#)
Oracle Database includes predefined consumer group mapping rules.
- [Resource Manager Data Dictionary Views](#)
You can query a set of data dictionary views for information relating to database resource management.

27.13.1 Predefined Resource Plans and Consumer Groups

Oracle Database includes predefined resource plans.

[Table 27-5](#) lists the resource plans and [Table 27-6](#) lists the resource consumer groups that are predefined in each Oracle database. You can verify these by querying the views `DBA_RSRC_PLANS` and `DBA_RSRC_CONSUMER_GROUPS`.

The following query displays the CPU allocations in the example plan DSS_PLAN:

```
SELECT group_or_subplan, mgmt_p1, mgmt_p2, mgmt_p3, mgmt_p4
      FROM dba_rsrc_plan_directives WHERE plan = 'DSS_PLAN';
```

GROUP_OR_SUBPLAN	MGMT_P1	MGMT_P2	MGMT_P3	MGMT_P4
SYS_GROUP	75	0	0	0
DSS_CRITICAL_GROUP	18	0	0	0
DSS_GROUP	3	0	0	0
ETL_GROUP	1	0	0	0
BATCH_GROUP	1	0	0	0
ORA\$AUTOTASK	1	0	0	0
OTHER_GROUPS	1	0	0	0

Table 27-5 Predefined Resource Plans

Resource Plan	Description
DEFAULT_MAINTENANCE_PLAN	Default plan for maintenance windows. See "About Resource Allocations for Automated Maintenance Tasks" for details of this plan. Because maintenance windows are regular Oracle Scheduler windows, you can change the resource plan associated with them, if desired. If you do change a maintenance window resource plan, ensure that you include the subplan ORA\$AUTOTASK in the new plan.
DEFAULT_PLAN	Basic default plan that prioritizes SYS_GROUP operations and allocates minimal resources for automated maintenance and diagnostics operations.
DSS_PLAN	Example plan for a data warehouse that prioritizes critical DSS queries over non-critical DSS queries and ETL operations.
ETL_CRITICAL_PLAN	Example plan for a data warehouse that prioritizes ETL operations over DSS queries.
INTERNAL_PLAN	For disabling the resource manager. For internal use only.
INTERNAL QUIESCE	For quiescing the database. This plan cannot be activated directly. To activate, use the QUIESCE command.
MIXED_WORKLOAD_PLAN	Example plan for a mixed workload that prioritizes interactive operations over batch operations. See "An Oracle-Supplied Mixed Workload Plan" for details.

Table 27-6 Predefined Resource Consumer Groups

Resource Consumer Group	Description
BATCH_GROUP	Consumer group for batch operations. Referenced by the example plan MIXED_WORKLOAD_PLAN.
DSS_CRITICAL_GROUP	Consumer group for critical DSS queries. Referenced by the example plans DSS_PLAN and ETL_CRITICAL_PLAN.
DSS_GROUP	Consumer group for non-critical DSS queries. Referenced by the example plans DSS_PLAN and ETL_CRITICAL_PLAN.
ETL_GROUP	Consumer group for ETL jobs. Referenced by the example plans DSS_PLAN and ETL_CRITICAL_PLAN.

Table 27-6 (Cont.) Predefined Resource Consumer Groups

Resource Consumer Group	Description
INTERACTIVE_GROUP	Consumer group for interactive, OLTP operations. Referenced by the example plan MIXED_WORKLOAD_PLAN.
LOW_GROUP	Consumer group for low-priority sessions.
ORA\$AUTOTASK	Consumer group for maintenance tasks.
OTHER_GROUPS	Default consumer group for all sessions that do not have an explicit initial consumer group, are not mapped to a consumer group with session-to-consumer group mapping rules, or are mapped to a consumer group that is not in the currently active resource plan. OTHER_GROUPS must have a resource plan directive specified in every plan. It cannot be assigned explicitly to sessions through mapping rules.
SYS_GROUP	Consumer group for system administrators. It is the initial consumer group for all sessions created by user accounts SYS or SYSTEM. This initial consumer group can be overridden by session-to-consumer group mapping rules.

27.13.2 Predefined Consumer Group Mapping Rules

Oracle Database includes predefined consumer group mapping rules.

Table 27-7 summarizes the consumer group mapping rules that are predefined in Oracle Database. You can verify these rules by querying the view DBA_RSRC_GROUP_MAPPINGS. You can use the DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING procedure to modify or delete any of these mapping rules.

Table 27-7 Predefined Consumer Group Mapping Rules

Attribute	Value	Mapped Consumer Group	Notes
ORACLE_USER	SYS	SYS_GROUP	
ORACLE_USER	SYSTEM	SYS_GROUP	
ORACLE_FUNCTI ON	BACKUP	BATCH_GROUP	The session is running a backup operation with RMAN. The session is automatically switched to BATCH_GROUP when the operation begins.
ORACLE_FUNCTI ON	COPY	BATCH_GROUP	The session is running a copy operation with RMAN. The session is automatically switched to BATCH_GROUP when the operation begins.

Table 27-7 (Cont.) Predefined Consumer Group Mapping Rules

Attribute	Value	Mapped Consumer Group	Notes
ORACLE_FUNCTION	DATALOAD ON	ETL_GROUP	The session is performing a data load operation with Data Pump. The session is automatically switched to ETL_GROUP when the operation begins.

 **See Also:**

["Specifying Session-to–Consumer Group Mapping Rules"](#)

27.13.3 Resource Manager Data Dictionary Views

You can query a set of data dictionary views for information relating to database resource management.

Table 27-8 lists views that are associated with the Resource Manager.

Table 27-8 Resource Manager Data Dictionary Views

View	Description
DBA_RSRC_CONSUMER_GROUP_P_RIVS	DBA view lists all resource consumer groups and the users and roles to which they have been granted. USER view lists all resource consumer groups granted to the user.
USER_RSRC_CONSUMER_GROUP_PRIVS	
DBA_RSRC_CONSUMER_GROUPS	Lists all resource consumer groups that exist in the database.
DBA_RSRC_MANAGER_SYSTEM_P_RIVS	DBA view lists all users and roles that have been granted Resource Manager system privileges. USER view lists all the users that are granted system privileges for the DBMS_RESOURCE_MANAGER package.
USER_RSRC_MANAGER_SYSTEM_PRIVS	
DBA_RSRC_PLAN_DIRECTIVES	Lists all resource plan directives that exist in the database.
DBA_RSRC_PLANS	Lists all resource plans that exist in the database.
DBA_RSRC_GROUP_MAPPINGS	Lists all of the various mapping pairs for all of the session attributes.
DBA_RSRC_MAPPING_PRIORITY	Lists the current mapping priority of each attribute.
DBA_HIST_RSRC_PLAN	Displays historical information about resource plan activation. This view contains AWR snapshots of V\$RSRC_PLAN_HISTORY.
DBA_HIST_RSRC_CONSUMER_GROUP	Displays historical statistical information about consumer groups. This view contains AWR snapshots of V\$RSRC_CONS_GROUP_HISTORY.

Table 27-8 (Cont.) Resource Manager Data Dictionary Views

View	Description
DBA_USERS	DBA view contains information about all users of the database. It contains the initial resource consumer group for each user.
USER_USERS	USER view contains information about the current user. It contains the current user's initial resource consumer group.
V\$RSRC_CONS_GROUP_HISTORY	For each entry in the view V\$RSRC_PLAN_HISTORY, contains an entry for each consumer group in the plan showing the cumulative statistics for the consumer group.
V\$RSRC_CONSUMER_GROUP	Displays information about active resource consumer groups. This view can be used for tuning.
V\$RSRCMGRMETRIC	Displays a history of resources consumed and cumulative CPU wait time (due to resource management) per consumer group for the past minute.
V\$RSRCMGRMETRIC_HISTORY	Displays a history of resources consumed and cumulative CPU wait time (due to resource management) per consumer group for the past hour on a minute-by-minute basis. If a new resource plan is enabled, the history is cleared.
V\$RSRC_PLAN	Displays the names of all currently active resource plans.
V\$RSRC_PLAN_HISTORY	Shows when Resource Manager plans were enabled or disabled on the instance. It helps you understand how resources were shared among the consumer groups over time.
V\$RSRC_SESSION_INFO	Displays Resource Manager statistics for each session. Shows how the session has been affected by the Resource Manager. Can be used for tuning.
V\$SESSION	Lists session information for each current session. Specifically, lists the name of the resource consumer group of each current session.

28

Oracle Scheduler Concepts

You can schedule tasks with Oracle Scheduler.

- [Overview of Oracle Scheduler](#)

Oracle Database includes Oracle Scheduler, an enterprise job scheduler to help you simplify the scheduling of hundreds or even thousands of tasks. Oracle Scheduler (the Scheduler) is implemented by the procedures and functions in the DBMS_SCHEDULER PL/SQL package.

- [Jobs and Supporting Scheduler Objects](#)

You use jobs and other scheduler objects for task scheduling.

- [More About Jobs](#)

There are different types of jobs. A job instance represents a specific run of a job. You can supply job arguments to override the default program argument values.

- [Scheduler Architecture](#)

Scheduler components handle jobs.

- [Scheduler Support for Oracle Data Guard](#)

Beginning with Oracle Database 11g Release 1 (11.1), the Scheduler can run jobs based on whether a database is a primary database or a logical standby in an Oracle Data Guard environment.

28.1 Overview of Oracle Scheduler

Oracle Database includes Oracle Scheduler, an enterprise job scheduler to help you simplify the scheduling of hundreds or even thousands of tasks. Oracle Scheduler (the Scheduler) is implemented by the procedures and functions in the DBMS_SCHEDULER PL/SQL package.

The Scheduler enables you to control when and where various computing tasks take place in the enterprise environment. The Scheduler helps you effectively manage and plan these tasks. By ensuring that many routine computing tasks occur without manual intervention, you can lower operating costs, implement more reliable routines, minimize human error, and shorten the time windows needed.

The Scheduler provides sophisticated, flexible enterprise scheduling functionality, which you can use to:

- Run **database program units**

You can run program units, that is, PL/SQL anonymous blocks, PL/SQL stored procedures, and Java stored procedures on the local database or on one or more remote Oracle databases.

- Run external executables, (executables that are external to the database)

You can run **external executables**, such as applications, shell scripts, and batch files, on the local system or on one or more remote systems. Remote systems do not require an Oracle Database installation; they require only a Scheduler agent.

Scheduler agents are available for all platforms supported by Oracle Database and some additional platforms.

- Schedule job execution using the following methods:

- Time-based scheduling

You can schedule a job to run at a particular date and time, either once or on a repeating basis. You can define complex repeat intervals, such as "every Monday and Thursday at 3:00 a.m. except on public holidays" or "the last Wednesday of each business quarter." See "[Creating, Running, and Managing Jobs](#)" for more information.

- Event-based scheduling

You can start jobs in response to system or business events. Your applications can detect events and then signal the Scheduler. Depending on the type of signal sent, the Scheduler starts a specific job. Examples of event-based scheduling include starting jobs when a file arrives on a system, when inventory falls below predetermined levels, or when a transaction fails.

Beginning with Oracle Database 11g Release 2 (11.2), a Scheduler object called a file watcher simplifies the task of configuring a job to start when a file arrives on a local or remote system. See "[Using Events to Start Jobs](#)" for more information.

- Dependency scheduling

You can set the Scheduler to run tasks based on the outcome of one or more previous tasks. You can define complex dependency chains that include branching and nested chains. See "[Creating and Managing Job Chains](#)" for more information.

- Prioritize jobs based on business requirements.

The Scheduler provides control over resource allocation among competing jobs, thus aligning job processing with your business needs. This is accomplished in the following ways:

- Controlling Resources by Job Class

You can group jobs that share common characteristics and behavior into larger entities called job classes. You can prioritize among the classes by controlling the resources allocated to each class. Therefore, you can ensure that your critical jobs have priority and enough resources to complete. For example, for a critical project to load a data warehouse, you can combine all the data warehousing jobs into one class and give it priority over other jobs by allocating a high percentage of the available resources to it. You can also assign relative priorities to the jobs within a job class.

- Controlling Job Prioritization based on Schedules

You can change job priorities based on a schedule. Because your definition of a critical job can change over time, the Scheduler also enables you to change the priority among your jobs over that time frame. For example, extract, transfer, and load (ETL) jobs used to load a data warehouse may be critical during non-peak hours but not during peak hours. Additionally, jobs that must run during the close of a business quarter may need to take priority over the ETL jobs. In these cases, you can change the priority among the job classes by changing the resources allocated to each class. See "[Creating Job Classes](#)" and "[Creating Windows](#)" for more information.

- Manage and monitor jobs

You can manage and monitor the multiple states that jobs go through, from creation to completion. The Scheduler logs activity so that you can easily track information such as the status of the job and the last run time of the job by querying views using Oracle Enterprise Manager Cloud Control or SQL. These views provide valuable information about jobs and their execution that can help you schedule and better manage your jobs. For example, a DBA can easily track all jobs that failed for a particular user. See "[Scheduler Data Dictionary Views](#)".

When you create a multiple-destination job, a job that is defined at one database but that runs on multiple remote hosts, you can monitor the status of the job at each destination individually or the overall status of the parent job as a whole.

For advanced job monitoring, your applications can subscribe to job state change notifications that the Scheduler delivers in event queues. The Scheduler can also send e-mail notifications when a job changes state.

See "[Monitoring and Managing the Scheduler](#)".

- Execute and manage jobs in a clustered environment

A cluster is a set of database instances that cooperates to perform the same task. Oracle Real Application Clusters (Oracle RAC) provides scalability and reliability without any change to your applications. The Scheduler fully supports execution of jobs in such a clustered environment. To balance the load on your system and for better performance, you can also specify the database service where you want a job to run. See "[The Scheduler and Real Application Clusters](#)" for more information.

28.2 Jobs and Supporting Scheduler Objects

You use jobs and other scheduler objects for task scheduling.

- [About Jobs and Supporting Scheduler Objects](#)
To use the Scheduler, you create *Scheduler objects*. Schema objects define the what, when, and where for job scheduling. Scheduler objects enable a modular approach to managing tasks. One advantage of the modular approach is that objects can be reused when creating new tasks that are similar to existing tasks.
- [Programs](#)
A program object (program) describes what is to be run by the Scheduler.
- [Schedules](#)
A schedule object (schedule) specifies when and how many times a job is run.
- [Jobs](#)
A job describes a user-defined task.
- [Destinations](#)
You can specify external and database destinations for running a job.
- [File Watchers](#)
A file watcher object (file watcher) defines the location, name, and other properties of a file whose arrival on a system causes the Scheduler to start a job.
- [Credentials](#)
Credentials are user name and password pairs stored in a dedicated database object.
- [Chains](#)
Chains are the means by which you can implement dependency scheduling, in which job starts depend on the outcomes of one or more previous jobs.

- [Job Classes](#)
Job classes enable you to assign the same attributes to member jobs, set resource allocation for member jobs, and group jobs for prioritization.
- [Windows](#)
A window is an interval of time to run a job.
- [Groups](#)
A group designates a list of Scheduler objects.
- [Incompatibilities](#)
An incompatibility definition (or, incompatibility) specifies incompatible jobs or programs, where only one of the group can be running at a time.

28.2.1 About Jobs and Supporting Scheduler Objects

To use the Scheduler, you create *Scheduler objects*. Schema objects define the what, when, and where for job scheduling. Scheduler objects enable a modular approach to managing tasks. One advantage of the modular approach is that objects can be reused when creating new tasks that are similar to existing tasks.

The principal Scheduler object is the job. A **job** defines the action to perform, the schedule for the action, and the location or locations where the action takes place. Most other scheduler objects are created to support jobs.

 **Note:**

The Oracle Scheduler job replaces the DBMS_JOB package, which is still supported for backward compatibility. This chapter assumes that you are only using Scheduler jobs. If you are using both at once, or migrating from DBMS_JOB to Scheduler jobs, see [Support for DBMS_JOB](#).

Each of these objects is described in detail later in this section.

Because Scheduler objects belong to schemas, you can grant object privileges on them. Some Scheduler objects, including job classes, windows, and window groups, are always created in the `SYS` schema, even if the user is not `SYS`. All other objects are created in the user's own schema or in a designated schema.

 **See Also:**

["Scheduler Privileges"](#)

28.2.2 Programs

A program object (program) describes what is to be run by the Scheduler.

A program includes:

- An action: For example, the name of a stored procedure, the name of an executable found in the operating system file system (an "external executable"), or the text of a PL/SQL anonymous block.
- A type: STORED_PROCEDURE, PLSQL_BLOCK, SQL_SCRIPT, EXTERNAL_SCRIPT, BACKUP_SCRIPT, or EXECUTABLE, where EXECUTABLE indicates an external executable.
- Number of arguments: The number of arguments that the stored procedure or external executable accepts.

A program is a separate entity from a job. A job runs at a certain time or because a certain event occurred, and invokes a certain program. You can create jobs that point to existing program objects, which means that different jobs can use the same program and run the program at different times and with different settings. With the right privileges, different users can use the same program without having to redefine it. Therefore, you can create program libraries, where users can select from a list of existing programs.

If a stored procedure or external executable referenced by the program accepts arguments, you define these arguments in a separate step after creating the program. You can optionally define a default value for each argument.

 **See Also:**

- "[Creating Programs](#)"
- "[Jobs](#)" for an overview of jobs

28.2.3 Schedules

A schedule object (schedule) specifies when and how many times a job is run.

Schedules can be shared by multiple jobs. For example, the end of a business quarter may be a common time frame for many jobs. Rather than defining an end-of-quarter schedule each time a new job is defined, job creators can point to a named schedule.

There are two types of schedules:

- time schedules

With time schedules, you can schedule jobs to run immediately or at a later time. Time schedules include a start date and time, optional end date and time, and optional repeat interval.

- event schedules

With event schedules, you can specify that a job executes when a certain event occurs, such as inventory falling below a threshold or a file arriving on a system. For more information on events, see "[Using Events to Start Jobs](#)".

 **See Also:**

["Creating Schedules"](#)

28.2.4 Jobs

A job describes a user-defined task.

- [About Jobs](#)

A job object (job) is a collection of metadata that describes a user-defined task. It defines what must be executed (the action), when (the one-time or recurring schedule or a triggering event), where (the destinations), and with what credentials. A job has an owner, which is the schema in which it is created.

- [Specifying a Job Action](#)

You can specify a job action by specifying the database program unit or external executable to be run or the name of an existing program object (program).

- [Specifying a Job Schedule](#)

You can specify a job schedule by setting attributes of the job object or the name of an existing schedule object (schedule).

- [Specifying a Job Destination](#)

You can specify a job destination in several different ways.

- [Specifying a Job Credential](#)

You can specify a job credential by specifying a named credential object or by allowing the credential attribute of the job to remain `NULL`.

28.2.4.1 About Jobs

A job object (job) is a collection of metadata that describes a user-defined task. It defines what must be executed (the action), when (the one-time or recurring schedule or a triggering event), where (the destinations), and with what credentials. A job has an owner, which is the schema in which it is created.

A job that runs a database program unit is known as a **database job**. A job that runs an external executable is known as an **external job**.

Jobs that run database program units at one or more remote locations are called **remote database jobs**. Jobs that run external executables at one or more remote locations are called **remote external jobs**.

You define where a job runs by specifying one or more destinations. Destinations are also Scheduler objects and are described later in this section. If you do not specify a destination, it is assumed that the job runs on the local database.

28.2.4.2 Specifying a Job Action

You can specify a job action by specifying the database program unit or external executable to be run or the name of an existing program object (program).

You specify the job action in one of the following ways:

- By specifying as a job attribute the database program unit or external executable to be run. This is known as specifying the job action **inline**.
- By specifying as a job attribute the name of an existing program, that specifies the database program unit or external executable to be run. The job owner must have the `EXECUTE` privilege on the program or the `EXECUTE ANY PROGRAM` system privilege.

28.2.4.3 Specifying a Job Schedule

You can specify a job schedule by setting attributes of the job object or the name of an existing schedule object (schedule).

You specify the job schedule in one of the following ways:

- By setting attributes of the job object to define start and end dates and a repeat interval, or to define an event that starts the job. This is known as specifying the schedule **inline**.
- By specifying as a job attribute the name of an existing schedule, which defines start and end dates and a repeat interval, or defines an event.

28.2.4.4 Specifying a Job Destination

You can specify a job destination in several different ways.

You specify the job destinations in one of the following ways:

- By specifying as a job attribute a single named destination object. In this case, the job runs on one remote location.
- By specifying as a job attribute a named destination group, which is equivalent to a list of remote locations. In this case, the job runs on all remote locations.
- By not specifying a destination attribute, in which case the job runs locally. The job runs either of the following:
 - A database program unit on the local database (the database on which the job is created)
 - An external executable on the local host, depending on the job action type

28.2.4.5 Specifying a Job Credential

You can specify a job credential by specifying a named credential object or by allowing the credential attribute of the job to remain `NULL`.

You specify the job credentials in one of the following ways:

- By specifying as a job attribute a named credential object, which contains a database user name and password (for database jobs).

The job runs as the user named in the credential.
- By allowing the credential attribute of the job to remain `NULL`, in which case a local database job runs as the job owner. (See [Table 28-1](#).) The job owner is the schema in which the job was created.

 **Note:**

A local database job always runs as the user is who is the job owner and will ignore any named credential.

After you create a job and enable it, the Scheduler automatically runs the job according to its schedule or when the specified event is detected. You can view the run status of job and its job log by querying data dictionary views. If a job runs on multiple destinations, you can query the status of the job at each destination.

 **See Also:**

- ["Destinations"](#)
- ["More About Jobs"](#)
- ["Creating Jobs"](#)
- ["Scheduler Data Dictionary Views"](#)

28.2.5 Destinations

You can specify external and database destinations for running a job.

- [About Destinations](#)

A destination object (destination) defines a location for running a job.

- [About Destinations and Scheduler Agents](#)

The remote location specified in a destination object must have a Scheduler agent running, and the agent must be registered with the database creating the job.

28.2.5.1 About Destinations

A destination object (destination) defines a location for running a job.

There are two types of destinations:

- External destination: Specifies a remote host name and IP address for running a remote external job.
- Database destination: Specifies a remote database instance for running a remote database job.

Jobs that run external executables (external jobs) must specify external destinations, and jobs that run database program units (database jobs) must specify database destinations.

If you specify a destination when you create a job, the job runs on that destination. If you do not specify a destination, the job runs locally, on the system on which it is created.

You can also create a destination group, which consists of a list of destinations, and reference this destination group when creating a job. In this case, the job runs on all destinations in the group.

 **Note:**

Destination groups can also include the keyword `LOCAL` as a group member, indicating that the job also runs on the local host or local database.

 **See Also:**

"[Groups](#)"

No object privileges are required to use a destination created by another user.

28.2.5.2 About Destinations and Scheduler Agents

The remote location specified in a destination object must have a Scheduler agent running, and the agent must be registered with the database creating the job.

The Scheduler agent enables the local Scheduler to communicate with the remote host, start and stop jobs there, and return remote job status to the local database. For complete details, see "[Specifying Destinations](#)".

- [External Destinations](#)

You cannot explicitly create external destinations. They are created in your local database when you register a Scheduler agent with that database.

- [Database Destinations](#)

You create database destinations with the `DBMS_SCHEDULER.CREATE_DATABASE_DESTINATION` procedure.

28.2.5.2.1 External Destinations

You cannot explicitly create external destinations. They are created in your local database when you register a Scheduler agent with that database.

The name assigned to the external destination is the name of the agent. You can configure an agent name after you install it, or you can accept the default agent name, which is the first part of the host name (before the first dot separator). For example, if you install an agent on the host `dbhost1.us.example.com`, the agent name defaults to `DBHOST1`.

28.2.5.2.2 Database Destinations

You create database destinations with the `DBMS_SCHEDULER.CREATE_DATABASE_DESTINATION` procedure.

 **Note:**

If you have multiple database instances running on the local host, you can run jobs on the other instances by creating database destinations for those instances. Thus, "remote" database instances do not necessarily have to reside on remote hosts. The local host must be running a Scheduler agent to support running remote database jobs on these additional instances.

 **See Also:**

- ["Specifying Destinations"](#)
- ["Installing and Configuring the Scheduler Agent on a Remote Host"](#)

28.2.6 File Watchers

A file watcher object (file watcher) defines the location, name, and other properties of a file whose arrival on a system causes the Scheduler to start a job.

You create a file watcher and then create any number of event-based jobs or event schedules that reference the file watcher. When the file watcher detects the arrival of the designated file, it raises a file arrival event. The job started by the file arrival event can retrieve the event message to learn about the newly arrived file.

A file watcher can watch for a file on the local system (the same host computer running Oracle Database) or a remote system, provided that the remote system is running the Scheduler agent.

To use file watchers, the database Java virtual machine (JVM) component must be installed.

See ["About File Watchers"](#) for more information.

 **See Also:**

- ["Creating File Watchers and File Watcher Jobs"](#)

28.2.7 Credentials

Credentials are user name and password pairs stored in a dedicated database object.

Scheduler jobs use credentials to authenticate themselves with a database instance or the operating system in order to run. You use credentials for:

- Remote database jobs: The credential contains a database user name and password. The stored procedure or PL/SQL block specified in the remote database job runs as this database user.

- External jobs (local or remote): The credential contains a host operating system user name and password. The external executable of the job then runs with this user name and password.
- File watchers: The credential contains a host operating system user name and password. The job that processes the file arrival event uses this user name and password to access the arrived file.

You can query the *_CREDENTIALS views to see a list of credentials in the database. Credential passwords are stored obfuscated, and are not displayed in these views.

 **See Also:**

- "[Specifying Scheduler Job Credentials](#)"
- *Oracle Database Security Guide* for information about creating a credential using the DBMS_CREDENTIAL.CREATE_CREDENTIAL procedure

28.2.8 Chains

Chains are the means by which you can implement dependency scheduling, in which job starts depend on the outcomes of one or more previous jobs.

A chain consists of multiple steps that are combined using dependency rules. The dependency rules define the conditions that can be used to start or stop a step or the chain itself. Conditions can include the success, failure, or completion- or exit-codes of previous steps. Logical expressions, such as AND/OR, can be used in the conditions. In a sense, a chain resembles a decision tree, with many possible paths for selecting which tasks run and when.

In its simplest form, a chain consists of two or more Scheduler program objects (programs) that are linked together for a single, combined objective. An example of a chain might be "run program A followed by program B, and then run program C only if programs A and B complete successfully, otherwise wait an hour and then run program D."

As an example, you might want to create a chain to combine the different programs necessary for a successful financial transaction, such as validating and approving a loan application, and then funding the loan.

A Scheduler job can point to a chain instead of pointing to a single program object. The job then serves to start the chain. This job is referred to as the **chain job**. Multiple chain jobs can point to the same chain, and more than one of these jobs can run simultaneously, thereby creating multiple instances of the same chain, each at a different point of progress in the chain.

Each position within a chain is referred to as a **step**. Typically, after an initial set of chain steps has started, the execution of successive steps depends on the completion of one or more previous steps. Each step can point to one of the following:

- A program object (program)

The program can run a database program unit (such as a stored procedure or PL/SQL anonymous block) or an external executable.

- Another chain (a nested chain)

Chains can be nested to any level.

- An event schedule, inline event, or file watcher

After starting a step that points to an event schedule or that has an inline event specification, the step waits until the specified event is raised. Likewise, a step that references a file watcher inline or that points to an event schedule that references a file watcher waits until the file arrival event is raised. For a file arrival event or any other type of event, when the event occurs, the step completes, and steps that are dependent on the event step can run. A common example of an event in a chain is a user intervention, such as an approval or rejection.

Multiple steps in the chain can invoke the same program or nested chain.

For each step, you can specify either a database destination or an external destination on which the step should run. If a destination is not specified, the step runs on the originating (local) database or the local host. Each step in a chain can run on a different destination.

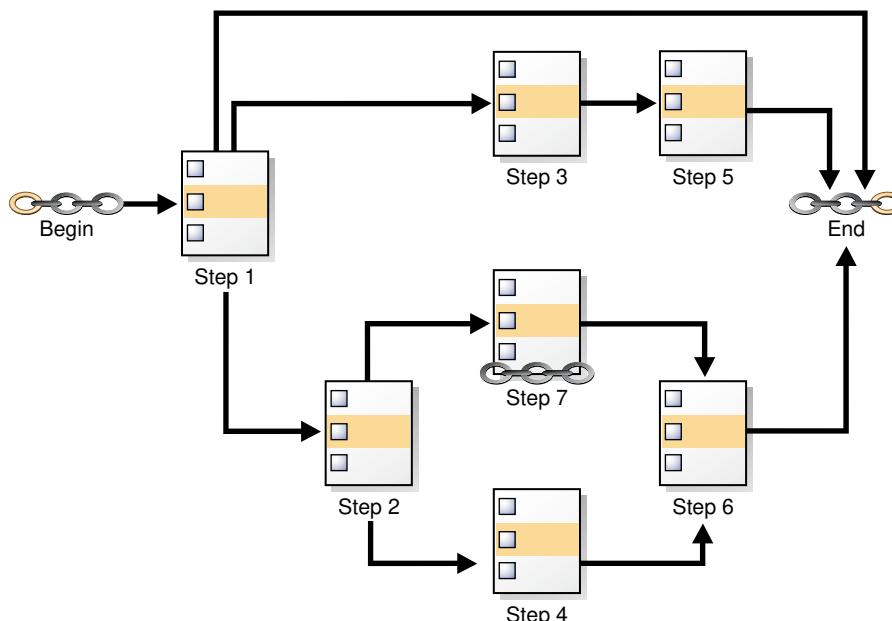

Figure 28-1 shows a chain with multiple branches. The figure makes use of icons to indicate BEGIN, END, and a nested chain, which is Step 7, in the lower subbranch.

In this figure, rules could be defined as follows:

- If Step 1 completes successfully, start Step 2.
- If Step 1 fails with error code 20100, start Step 3.
- If Step 1 fails with any other error code, end the chain.

Additional rules govern the running of steps 4, 5, 6, and 7.

Figure 28-1 Chain with Multiple Branches

While a job pointing to a chain is running, the current state of all steps of the running chain can be monitored. For every step, the Scheduler creates a **step job** with the

same job name and owner as the chain job. Each step job additionally has a step job subname to uniquely identify it. The step job subname is included as the `JOB_SUBNAME` column in the views `*_SCHEDULER_RUNNING_JOBS`, `*_SCHEDULER_JOB_LOG`, and `*_SCHEDULER_JOB_RUN_DETAILS`, and as the `STEP_JOB_SUBNAME` column in the `*_SCHEDULER_RUNNING_CHAINS` views.

 **See Also:**

["Creating and Managing Job Chains"](#)

28.2.9 Job Classes

Job classes enable you to assign the same attributes to member jobs, set resource allocation for member jobs, and group jobs for prioritization.

You typically create job classes only when you are in the role of Scheduler administrator.

Job classes provide a way to:

- Assign the same set of attribute values to member jobs

Each job class specifies a set of attributes, such as logging level. When you assign a job to a job class, the job inherits those attributes. For example, you can specify the same policy for purging log entries for all payroll jobs.

- Set service affinity for member jobs

You can set the `service` attribute of a job class to a desired database service name. This determines the instances in a Real Application Clusters environment that run the member jobs, and optionally, the system resources that are assigned to member jobs. See "[Service Affinity when Using the Scheduler](#)" for more information.

- Set resource allocation for member jobs

Job classes provide the link between the Database Resource Manager and the Scheduler, because each job class can specify a resource consumer group as an attribute. Member jobs then belong to the specified consumer group and are assigned resources according to settings in the current resource plan.

Alternatively, you can leave the `resource_consumer_group` attribute `NULL` and set the `service` attribute of a job class to a desired database service name. That service can in turn be mapped to a resource consumer group. If both the `resource_consumer_group` and `service` attributes are set, and the designated service maps to a resource consumer group, the resource consumer group named in the `resource_consumer_group` attribute takes precedence.

See [Managing Resources with Oracle Database Resource Manager](#) for more information on mapping services to consumer groups.

- Group jobs for prioritization

Within the same job class, you can assign priority values of 1-5 to individual jobs so that if two jobs in the class are scheduled to start at the same time, the one with

the higher priority takes precedence. This ensures that you do not have a less important job preventing the timely completion of a more important one.

If two jobs have the same assigned priority value, the job with the earlier start date takes precedence. If no priority is assigned to a job, its priority defaults to 3.

 **Note:**

Job priorities are used only to prioritize among jobs in the same class.

There is no guarantee that a high priority job in class A will be started before a low priority job in class B, even if they share the same schedule. Prioritizing among jobs of different classes depends on the current resource plan and on the designated resource consumer group or service name of each job class.

When defining job classes, try to classify jobs by functionality. Consider dividing jobs into groups that access similar data, such as marketing, production, sales, finance, and human resources.

Some of the restrictions to keep in mind are:

- A job must be part of exactly one class. When you create a job, you can specify which class the job is part of. If you do not specify a class, the job automatically becomes part of the class `DEFAULT_JOB_CLASS`.
- Dropping a class while there are still jobs in that class results in an error. You can force a class to be dropped even if there are still jobs that are members of that class, but all jobs referring to that class are then automatically disabled and assigned to the class `DEFAULT_JOB_CLASS`. Jobs belonging to the dropped class that are already running continue to run under class settings determined at the start of the job.

- [Oracle Database Reference](#) to view job classes

28.2.10 Windows

A window is an interval of time to run a job.

- [About Windows](#)

You create windows to automatically start jobs or to change resource allocation among jobs during various time periods of the day, week, and so on. A window is represented by an interval of time with a well-defined beginning and end, such as "from 12am-6am".

- [Overlapping Windows](#)

Although Oracle does not recommend it, windows can overlap.

28.2.10.1 About Windows

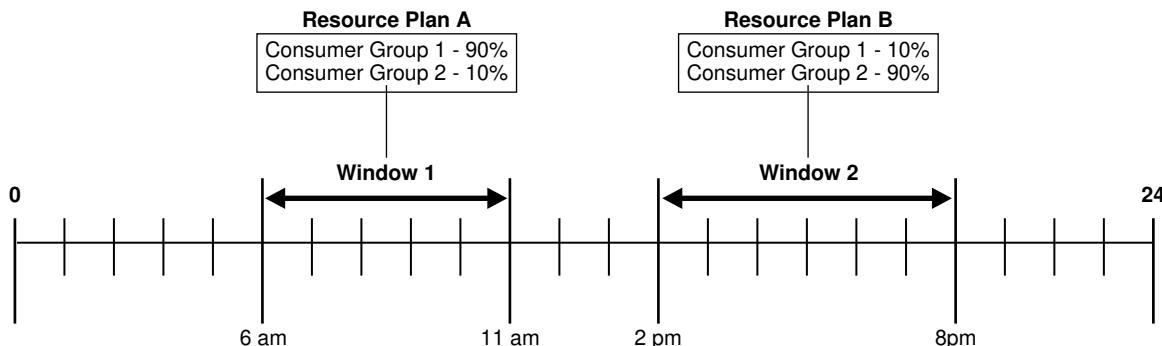

You create windows to automatically start jobs or to change resource allocation among jobs during various time periods of the day, week, and so on. A window is represented by an interval of time with a well-defined beginning and end, such as "from 12am-6am".

You typically create windows only when you are in the role of Scheduler administrator.

Windows work with job classes to control resource allocation. Each window specifies the resource plan to activate when the window **opens** (becomes active), and each job class specifies a resource consumer group or specifies a database service, which can map to a consumer group. A job that runs within a window, therefore, has resources allocated to it according to the consumer group of its job class and the resource plan of the window.

[Figure 28-2](#) shows a workday that includes two windows. In this configuration, jobs belonging to the job class that links to Consumer Group 1 get more resources in the morning than in the afternoon. The opposite is true for jobs in the job class that links to Consumer Group 2.

Figure 28-2 Windows help define the resources that are allocated to jobs

See [Managing Resources with Oracle Database Resource Manager](#) for more information on resource plans and consumer groups.

You can assign a priority to each window. If windows overlap, the window with the highest priority is chosen over other windows with lower priorities. The Scheduler automatically opens and closes windows as window start times and end times come and go.

A job can name a window in its `schedule_name` attribute. The Scheduler then starts the job when the window opens. If a window is already open, and a new job is created that points to that window, the new job does not start until the next time the window opens.

 **Note:**

If necessary, you can temporarily block windows from switching the current resource plan. For more information, see "[Enabling Oracle Database Resource Manager and Switching Plans](#)", or the discussion of the DBMS_RESOURCE_MANAGER.SWITCH_PLAN package procedure in *Oracle Database PL/SQL Packages and Types Reference*.

 **See Also:**

["Creating Windows"](#)

28.2.10.2 Overlapping Windows

Although Oracle does not recommend it, windows can overlap.

Because only one window can be active at one time, the following rules are used to determine which window is active when windows overlap:

- If windows of the same priority overlap, the window that is active will stay open. However, if the overlap is with a window of higher priority, the lower priority window will close and the window with the higher priority will open. Jobs currently running that had a schedule naming the low priority window may be stopped depending on the behavior you assigned when you created the job.
- If, at the end of a window, there are multiple windows defined, the window with the highest priority opens. If all windows have the same priority, the window that has the highest percentage of time remaining opens.
- An open window that is dropped automatically closes. At that point, the previous rule applies.

Whenever two windows overlap, an entry is written in the Scheduler log.

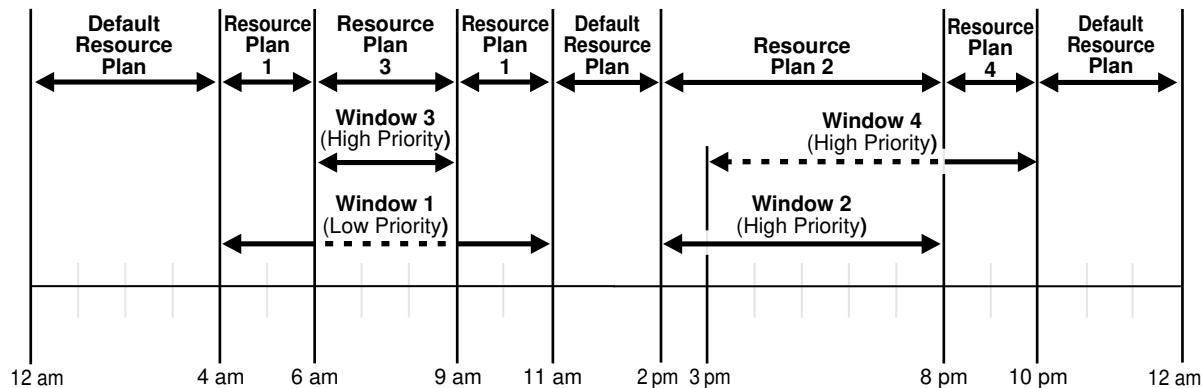

- [Examples of Overlapping Windows](#)
Examples illustrate overlapping windows.

28.2.10.2.1 Examples of Overlapping Windows

Examples illustrate overlapping windows.

Figure 28-3 illustrates a typical example of how windows, resource plans, and priorities might be determined for a 24 hour schedule. In the following two examples, assume that Window1 has been associated with Resource Plan1, Window2 with Resource Plan2, and so on.

Figure 28-3 Windows and Resource Plans (Example 1)

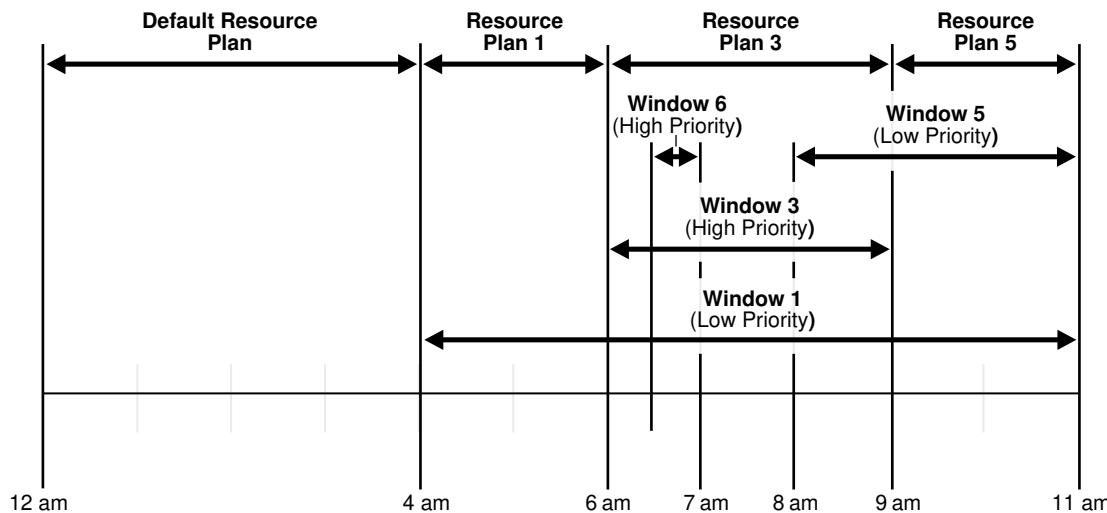

In [Figure 28-3](#), the following occurs:

- From 12AM to 4AM
No windows are open, so a default resource plan is in effect.
- From 4AM to 6AM
Window1 has been assigned a low priority, but it opens because there are no high priority windows. Therefore, Resource Plan 1 is in effect.
- From 6AM to 9AM
Window3 will open because it has a higher priority than Window1, so Resource Plan 3 is in effect. The dotted line indicates Window1 is inactive.
- From 9AM to 11AM
Even though Window1 was closed at 6AM because of a higher priority window opening, at 9AM, this higher priority window is closed and Window1 still has two hours remaining on its original schedule. It will be reopened for these remaining two hours and resource plan will be in effect.
- From 11AM to 2PM
A default resource plan is in effect because no windows are open.
- From 2PM to 3PM
Window2 will open so Resource Plan 2 is in effect.
- From 3PM to 8PM
Window4 is of the same priority as Window2, so it does not interrupt Window2 and Resource Plan 2 is in effect. The dotted line indicates Window4 is inactive.
- From 8PM to 10PM
Window4 will open so Resource Plan 4 is in effect.
- From 10PM to 12AM
A default resource plan is in effect because no windows are open.

[Figure 28-4](#) illustrates another example of how windows, resource plans, and priorities might be determined for a 24 hour schedule.

Figure 28-4 Windows and Resource Plans (Example 2)

In Figure 28-4, the following occurs:

- From 12AM to 4AM
A default resource plan is in effect.
- From 4AM to 6AM
Window1 has been assigned a low priority, but it opens because there are no high priority windows, so Resource Plan 1 is in effect.
- From 6AM to 9AM
Window3 will open because it has a higher priority than Window1. Note that Window6 does not open because another high priority window is already in effect.
- From 9AM to 11AM
At 9AM, Window5 or Window1 are the two possibilities. They both have low priorities, so the choice is made based on which has a greater percentage of its duration remaining. Window5 has a larger percentage of time remaining compared to the total duration than Window1. Even if Window1 were to extend to, say, 11:30AM, Window5 would have $2/3 * 100\%$ of its duration remaining, while Window1 would have only $2.5/7 * 100\%$, which is smaller. Thus, Resource Plan 5 will be in effect.

28.2.11 Groups

A group designates a list of Scheduler objects.

- [About Groups](#)
Instead of passing a list of objects as an argument to a DBMS_SCHEDULER package procedure, you create a group that has those objects as its members, and then pass the group name to the procedure.
- [Destination Groups](#)
When you want a job to run at multiple destinations, you create a database destination group or external destination group and assign it to the destination_name attribute of the job.

- [Window Groups](#)

You can group windows for ease of use in scheduling jobs.

28.2.11.1 About Groups

Instead of passing a list of objects as an argument to a DBMS_SCHEDULER package procedure, you create a group that has those objects as its members, and then pass the group name to the procedure.

There are three types of groups:

- Database destination groups: Members are database destinations, for running remote database jobs.
- External destination groups: Members are external destinations, for running remote external jobs.
- Window groups: Members are Scheduler windows.

All members of a group must be of the same type and each member must be unique.

You create a group with the DBMS_SCHEDULER.CREATE_GROUP procedure.

28.2.11.2 Destination Groups

When you want a job to run at multiple destinations, you create a database destination group or external destination group and assign it to the destination_name attribute of the job.

Specifying a destination group as the destination_name attribute of a job is the only valid way to specify multiple destinations for the job.

28.2.11.3 Window Groups

You can group windows for ease of use in scheduling jobs.

You typically create window groups only when you are in the role of Scheduler administrator.

If a job must run during multiple time periods throughout the day, week, and so on, you can create a window for each time period, and then add the windows to a window group. You can then set the schedule_name attribute of the job to the name of this window group, and the job executes during all the time periods specified by the windows in the window group.

For example, if you had a window called "Weekends" and a window called "Weeknights," you could add these two windows to a window group called "Downtime." The data warehousing staff could then create a job to run queries according to this Downtime window group—on weeknights and weekends—when the queries could be assigned a high percentage of available resources.

If a window in a window group is already open, and a new job is created that points to that window group, the job is not started until the next window in the window group opens.

 **See Also:**

- "[Creating Destination Groups for Multiple-Destination Jobs](#)"
- "[Creating Window Groups](#)"
- "[Windows](#)"

28.2.12 Incompatibilities

An incompatibility definition (or, incompatibility) specifies incompatible jobs or programs, where only one of the group can be running at a time.

For example, if jobs A and B are defined as incompatible, the Scheduler ensures that only one of them can be running at any given time, *even if* their respective job schedules would otherwise cause them to run at the same time.

An incompatibility can be defined at the job level (the default) or the program level. For example, assume the following:

- Jobs J1 and J2 are based on program P1.
- Jobs J3, J4, and J5 are based on program P2.
- Jobs J6 and J7 are based on program P3.

In this scenario:

- If a job-level incompatibility definition specifies J3, J4, and J5, and if job J3 is running, then J4 and J5 cannot be running until J3 finishes.
- If a program-level incompatibility definition specifies P1, P2, and P3, jobs J1 and J2 can run simultaneously (unless a job-level constraint prevents J1 and J2 from running simultaneously); however, no jobs based on programs P2 and P3 can be running until all jobs based on P1 finish.

 **See Also:**

- [Using Incompatibility Definitions](#)

28.3 More About Jobs

There are different types of jobs. A job instance represents a specific run of a job. You can supply job arguments to override the default program argument values.

- [Job Categories](#)
Oracle Scheduler supports several types of jobs.
- [Job Instances](#)
A job instance represents a specific run of a job. Jobs that are scheduled to run only once have only one instance. Jobs that have a repeating schedule or that run

each time an event occurs have multiple instances, each run of the job representing an instance.

- **Job Arguments**

When a job references a program object (program), you can supply job arguments to override the default program argument values, or provide values for program arguments that have no default value. You can also provide argument values to an inline action (for example, a stored procedure) that the job specifies.

- **How Programs, Jobs, and Schedules are Related**

To define what is executed and when, you assign relationships among programs, jobs, and schedules.

 **See Also:**

- "[Creating Jobs](#)"
- "[Viewing the Job Log](#)"

28.3.1 Job Categories

Oracle Scheduler supports several types of jobs.

- **Database Jobs**

Database jobs run Oracle Database program units. You can run local and remote database jobs.

- **External Jobs**

External jobs run executables outside of the database. You can run local and remote external jobs.

- **Multiple-Destination Jobs**

A multiple-destination job is a job whose instances run on multiple target databases or hosts, but can be controlled and monitored from one central database.

- **Chain Jobs**

The **chain** is the Scheduler mechanism that enables dependency-based scheduling.

- **Detached Jobs**

You use a detached job to start a script or application that runs in a separate process, independently and asynchronously to the Scheduler.

- **Lightweight Jobs**

Use lightweight jobs when you have many short-duration jobs that run frequently. Under certain circumstances, using lightweight jobs can deliver a small performance gain.

- **In-Memory Jobs**

Use in-memory jobs when many jobs should be created and run during a short period of time. In-memory jobs have a slightly larger memory footprint, but use memory cache to reduce disk access and the time required for job creation and execution. Performance gains can be significant.

- [Script Jobs](#)
Beginning with Oracle Database 12c, you can use several new script jobs to run custom user scripts with SQL*Plus, the RMAN interpreter, or a command shell such as cmd.exe for Windows and the sh shell or another interpreter for UNIX based systems.

28.3.1.1 Database Jobs

Database jobs run Oracle Database program units. You can run local and remote database jobs.

- [About Database Jobs](#)
Database jobs run Oracle Database program units, including PL/SQL anonymous blocks, PL/SQL stored procedures, and Java stored procedures.
- [Local Database Jobs](#)
A local database job runs on the originating database, as the database user who is the job owner. The job owner is the name of the schema in which the job was created.
- [Remote Database Job](#)
The target database for a remote database job can be an Oracle database on a remote host or another database instance on the same host as the originating database.

28.3.1.1.1 About Database Jobs

Database jobs run Oracle Database program units, including PL/SQL anonymous blocks, PL/SQL stored procedures, and Java stored procedures.

For a database job where the action is specified inline, job_type is set to 'PLSQL_BLOCK' or 'STORED_PROCEDURE', and job_action contains either the text of a PL/SQL anonymous block or the name of a stored procedure. (If a program is a named program object rather than program action specified inline, the corresponding program_type and program_action must be set accordingly.)

Database jobs that run on the originating database—the database on which they were created—are known as **local database jobs**, or just jobs. Database jobs that run on a target database other than the originating database are known as **remote database jobs**.

You can view run results for both local database and remote database jobs in the job log views on the originating database.

28.3.1.1.2 Local Database Jobs

A local database job runs on the originating database, as the database user who is the job owner. The job owner is the name of the schema in which the job was created.

28.3.1.1.3 Remote Database Job

The target database for a remote database job can be an Oracle database on a remote host or another database instance on the same host as the originating database.

You identify a remote database job by specifying the name of an existing database destination object in the destination_name attribute of the job.

Creating a remote database job requires Oracle Database 11g Release 2 (11.2) or later. However, the target database for the job can be any release of Oracle Database. No patch is required for the target database; you only need to install a Scheduler agent on the target database host (even if the target database host is the same as the originating database host) and register the agent with the originating database. The agent must be installed from Oracle Client 11g Release 2 (11.2) or later.

Remote database jobs must run as a user that is valid on the target database. You specify the required user name and password with a credential object that you assign to the remote database job.

 **See Also:**

- "[Credentials](#)"
- "[Creating Jobs](#)"
- "[Using the Oracle Scheduler Agent to Run Remote Jobs](#)"
- "[Viewing the Job Log](#)"

28.3.1.2 External Jobs

External jobs run executables outside of the database. You can run local and remote external jobs.

- [About External Jobs](#)

External jobs run external executables. An **external executable** is an operating system executable that runs outside the database, that is, external to the database.

- [About Local External Jobs](#)

A local external job runs its external executable on the same computer as the Oracle database that schedules the job. For such a job, the `destination_name` job attribute is `NULL`.

- [About Remote External Jobs](#)

A remote external job runs its external executable on a remote host. The remote host may or may not have Oracle Database installed.

28.3.1.2.1 About External Jobs

External jobs run external executables. An **external executable** is an operating system executable that runs outside the database, that is, external to the database.

For an external job, `job_type` is specified as '`EXECUTABLE`'. (If using named programs, the corresponding `program_type` would be '`EXECUTABLE`'.) The `job_action` (or corresponding `program_action`) is the full operating system-dependent path of the desired external executable, excluding any command line arguments. An example might be `/usr/local/bin/perl` or `C:\perl\bin\perl`.

Note that a Windows batch file is not directly executable and must be run a command prompt (`cmd.exe`).

Like a database job, you can assign a schema when you create the external job. That schema then becomes the job owner. Although it is possible to create an external job in the `SYS` schema, Oracle recommends against this practice.

Both the `CREATE JOB` and `CREATE EXTERNAL JOB` privileges are required to create local or remote external jobs.

External executables must run as some operating system user. Thus, the Scheduler enables you to assign operating system credentials to any external job that you create. Like remote database jobs, you specify these credentials with a credential object (a credential) and assign the credential to the external job.

There are two types of external jobs: local external jobs and remote external jobs. A **local external job** runs its external executable on the same computer as the database that schedules the job. A **remote external job** runs its executable on a remote host. The remote host does not need to have an Oracle database; you need only install and register a Scheduler agent.

 **Note:**

On Windows, the host user that runs the external executable must be assigned the `Log on as a batch job` logon privilege.

 **See Also:**

- ["Credentials"](#)
- ["Using the Oracle Scheduler Agent to Run Remote Jobs"](#)

28.3.1.2.2 About Local External Jobs

A local external job runs its external executable on the same computer as the Oracle database that schedules the job. For such a job, the `destination_name` job attribute is `NULL`.

Local external jobs write `stdout` and `stderr` output to log files in the directory `ORACLE_HOME/scheduler/log`. You can retrieve the contents of these files with `DBMS_SCHEDULER.GET_FILE`.

You do not have to assign a credential to a local external job, although Oracle strongly recommends that you do so for improved security. If you do not assign a credential, the job runs with default credentials. [Table 28-1](#) shows the default credentials for different platforms and different job owners.

Table 28-1 Default Credentials for Local External Jobs

Job in SYS Schema?	Platform	Default Credentials
Yes	All	User who installed Oracle Database.

Table 28-1 (Cont.) Default Credentials for Local External Jobs

Job in SYS Schema?	Platform	Default Credentials
No	UNIX and Linux	Values of the <code>run-user</code> and <code>run-group</code> attributes specified in the file <code>ORACLE_HOME/rdbms/admin/externaljob.ora</code>
No	Windows	User that the <code>OracleJobSchedulerSID</code> Windows service runs as (either the Local System account or a named local or domain user). Note: You must manually enable and start this service. For improved security, Oracle recommends using a named user instead of the Local System account.

Note:

Default credentials are included for compatibility with previous releases of Oracle Database, and may be deprecated in a future release. It is, therefore, best to assign a credential to every local external job.

To disable the running of local external jobs that were not assigned credentials, remove the `run_user` attribute from the `ORACLE_HOME/rdbms/admin/externaljob.ora` file (UNIX and Linux) or stop the `OracleJobScheduler` service (Windows). These steps do not disable the running of local external jobs in the `SYS` schema.

See Also:

- Your operating system-specific documentation for any post-installation configuration steps to support local external jobs
- [Example 29-6](#)

28.3.1.2.3 About Remote External Jobs

A remote external job runs its external executable on a remote host. The remote host may or may not have Oracle Database installed.

To enable remote external jobs to run on a specific remote host, you must install a Scheduler agent on the remote host and register it with the local database. The database communicates with the agent to start external executables and to retrieve execution results.

When creating a remote external job, you specify the name of an existing external destination object in the `destination_name` attribute of the job.

Remote external jobs write `stdout` and `stderr` output to log files in the directory `AGENT_HOME/data/log`. You can retrieve the contents of these files with

DBMS_SCHEDULER.GET_FILE. [Example 29-6](#) illustrates how to retrieve stdut output. Although this example is for a local external job, the method is the same for remote external jobs.

 **See Also:**

- ["Credentials"](#)
- ["Using the Oracle Scheduler Agent to Run Remote Jobs"](#)

28.3.1.3 Multiple-Destination Jobs

A multiple-destination job is a job whose instances run on multiple target databases or hosts, but can be controlled and monitored from one central database.

For DBAs or system administrators who must manage multiple databases or multiple hosts, a multiple-destination job can make administration considerably easier. With a multiple-destination job, you can:

- Specify several databases or hosts on which a job must run.
- Modify a job that is scheduled on multiple targets with a single operation.
- Stop jobs running on one or more remote targets.
- Determine the status (running, completed, failed, and so on) of the job instance at each of the remote targets.
- Determine the overall status of the collection of job instances.

A multiple-destination job can be viewed as a single entity for certain purposes and as a collection of independently running jobs for other purposes. When creating or altering the job metadata, the multiple-destination job looks like a single entity. However, when the job instances are running, they are better viewed as a collection of jobs that are nearly identical copies of each other. The job created at the source database is known as the **parent job**, and the job instances that run at the various destinations are known as **child jobs**.

You create a multiple-destination job by assigning a destination group to the `destination_name` attribute of the job. The job runs at all destinations in the group at its scheduled time, or upon the detection of a specified event. The local host can be included as one of the destinations on which the job runs.

For a job whose action is a database program unit, you must specify a database destination group in the `destination_name` attribute. The members of a database destination group include database destinations and the keyword `LOCAL`, which indicates the originating (local) database. For a job whose action is an external executable, you must specify an external destination group in the `destination_name` attribute. The members of an external destination group include external destinations and the keyword `LOCAL`, which indicates the local host.

 **Note:**

Database destinations do not necessarily have to reference remote databases; they can reference additional database instances running on the same host as the database that creates the job.

Multiple-Destination Jobs and Time Zones

Some job destinations might be in time zones that are different from that of the database on which the parent job is created (the *originating database*). In this case, the start time of the job is always based on the time zone of the originating database. So, if you create the parent job in London, England, specify a start time of 8:00 p.m., and specify destinations at Tokyo, Los Angeles, and New York, then all child jobs start at 8:00 p.m. London time. Start times at all destinations may not be exact, due to varying system loads, issues that require retries, and so on.

Event-Based Multiple-Destination Jobs

In the case of a multiple-destination job that is event-based, when the parent job detects the event at its host, it starts all the child jobs at all destinations. The child jobs themselves do not detect events at their respective hosts.

 **See Also:**

- ["Creating Multiple-Destination Jobs"](#)
- ["Monitoring Multiple Destination Jobs"](#)
- ["Destination Groups"](#)
- ["Using Events to Start Jobs "](#)

28.3.1.4 Chain Jobs

The **chain** is the Scheduler mechanism that enables dependency-based scheduling.

In its simplest form, it defines a group of program objects and the dependencies among them. A job can point to a chain instead of pointing to a single program object. The job then serves to start the chain. For a chain job, `job_type` is set to '`CHAIN`'.

 **See Also:**

- ["Chains"](#)
- ["Creating and Managing Job Chains"](#)

28.3.1.5 Detached Jobs

You use a detached job to start a script or application that runs in a separate process, independently and asynchronously to the Scheduler.

A detached job typically starts another process and then exits. Upon exit (when the job action is completed) a detached job remains in the running state. The running state indicates that the asynchronous process that the job started is still active. When the asynchronous process finishes its work, it must connect to the database and call `DBMS_SCHEDULER.END_DETACHED_JOB_RUN`, which ends the job.

Detached jobs cannot be executed using `run_job` to manually trigger execution, when the `use_current_session` parameter set to TRUE.

A job is detached if it points to a program object (program) that has its `detached` attribute set to TRUE (a **detached program**).

You use a detached job under the following two circumstances:

- When it is impractical to wait for the launched asynchronous process to complete because would hold resources unnecessarily.

An example is sending a request to an asynchronous Web service. It could take hours or days for the Web service to respond, and you do not want to hold a Scheduler job slave while waiting for the response. (See "[Scheduler Architecture](#)" for information about job slaves.)

- When it is impossible to wait for the launched asynchronous process to complete because the process shuts down the database.

An example would be using a Scheduler job to launch an RMAN script that shuts down the database, makes a cold backup, and then restarts the database. See "[Creating Detached Jobs](#)."

A detached job works as follows:

1. When it is time for the job to start, the job coordinator assigns a job slave to the job, and the job slave runs the program action defined in the detached program. The program action can be a PL/SQL block, a stored procedure, or an external executable.
2. The program action performs an immediate-return call of another script or executable, referred to here as Process A, and then exits. Because the work of the program action is complete, the job slave exits, but leaves the job in a running state.
3. Process A performs its processing. If it runs any DML against the database, it must commit its work. When processing is complete, Process A logs in to the database and calls `END_DETACHED_JOB_RUN`.
4. The detached job is logged as completed.

You can also call `STOP_JOB` to end a running detached job.

 **See Also:**

["Creating Detached Jobs"](#) for an example of performing a cold backup of the database with a detached job

28.3.1.6 Lightweight Jobs

Use lightweight jobs when you have many short-duration jobs that run frequently. Under certain circumstances, using lightweight jobs can deliver a small performance gain.

Lightweight jobs have the following characteristics:

- Unlike regular jobs, they are not schema objects.
- They have significantly better create and drop times over regular jobs because they do not have the overhead of creating a schema object.
- They have lower average session create time than regular jobs.
- They have a small footprint on disk for job metadata and run-time data.

You designate a lightweight job by setting the `job_style` job attribute to '`LIGHTWEIGHT`'. (The default job style is '`REGULAR`').

Like programs and schedules, regular jobs are schema objects. A regular job offers the maximum flexibility but does entail some overhead when it is created or dropped. The user has fine-grained control of the privileges on the job, and the job can have as its action a program or a stored procedure owned by another user.

If a relatively small number of jobs that run infrequently need to be created, then regular jobs are preferred over lightweight jobs.

A lightweight job must reference a program object (program) to specify a job action. The program must be already enabled when the lightweight job is created, and the program type must be either '`PLSQL_BLOCK`' or '`STORED_PROCEDURE`'. Because lightweight jobs are not schema objects, you cannot grant privileges on them. A lightweight job inherits privileges from its specified program. Thus, any user who has a certain set of privileges on the program has corresponding privileges on the lightweight job.

 **See Also:**

["Creating Jobs Using a Named Program and Job Styles"](#)

28.3.1.7 In-Memory Jobs

Use in-memory jobs when many jobs should be created and run during a short period of time. In-memory jobs have a slightly larger memory footprint, but use memory cache to reduce disk access and the time required for job creation and execution. Performance gains can be significant.

The following types of in-memory jobs are available: runtime (`IN_MEMORY_RUNTIME`) and full (`IN_MEMORY_FULL`).

- **In-memory runtime** jobs are based on [Lightweight Jobs](#), so they are persistent. They can have a repeat interval and run multiple times.

By default, in-memory jobs are associated to the job_class DEFAULT_IN_MEMORY_JOB_CLASS, which has a logging level of NONE. This means that by default, in-memory jobs produce no logging in the views related to Scheduler jobs, thus improving performance.

- **In-memory full** jobs exist only cached in memory, so they are not persistent. They must have a program associated, and they are meant to be run just once and discarded, so they cannot have a repeat interval. Because they do not have a backup on disk, they do not generate redo in creation or at run time, greatly speeding their operation.

In-memory full jobs are only present in the instance where they were created or in one of the RAC instances. They are not propagated to a logical or physical standby instance, and therefore can no longer run (and will be discarded) if the primary instance is switched out for the standby.

 **See Also:**

["Creating Jobs Using a Named Program and Job Styles"](#)

28.3.1.8 Script Jobs

Beginning with Oracle Database 12c, you can use several new script jobs to run custom user scripts with SQL*Plus, the RMAN interpreter, or a command shell such as cmd.exe for Windows and the sh shell or another interpreter for UNIX based systems.

These executables all require OS credentials. These script jobs are:

- **SQL Script Jobs:** Requires a database destination.

SQL script jobs use the SQL*Plus interpreter to run Scheduler jobs. Therefore, you can now use all SQL*Plus features, including query output formatting.

In order to connect to the database after spawning, SQL script jobs need an authentication step. Users can authenticate inline, in the job action, or using the connect_credential functionality provided by the Scheduler. To use the connect_credential functionality, the user sets the connect_credential_name attribute of a job. Then, the job attempts to connect to the database using the username, password, and role of that connect_credential.

- **External Script Jobs:** requires a normal destination

External script jobs spawn a new shell interpreter, allowing a simple way to run command line scripts.

- **Backup Script Jobs:** Requires a database destination.

Backup script jobs provide a more direct way to specify RMAN scripts that create and execute backup tasks.

In order to connect to the database after spawning, backup script jobs need an authentication step. Users can authenticate inline, in the job action, or using the connect_credential functionality provided by the Scheduler. To use the connect_credential functionality, the user sets the connect_credential_name

attribute of a job. Then, the job attempts to connect to the database using the username, password, and role of that `connect_credential`.

Note that job or program actions must point to an appropriate script for each interpreter or have an appropriate inline script. For further details, see the `job_action` parameters for the `CREATE_JOB` subprogram or the `program_action` parameters for the `CREATE_PROGRAM` subprogram.

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference* for the `CREATE_JOB` parameters
- *Oracle Database PL/SQL Packages and Types Reference* for `CREATE_PROGRAM` parameters

28.3.2 Job Instances

A job instance represents a specific run of a job. Jobs that are scheduled to run only once have only one instance. Jobs that have a repeating schedule or that run each time an event occurs have multiple instances, each run of the job representing an instance.

For example, a job that is scheduled to run only on Tuesday, Oct. 8th 2009 has one instance, a job that runs daily at noon for a week has seven instances, and a job that runs when a file arrives on a remote system has one instance for each file arrival event.

Multiple-destination jobs have one instance for each destination. If a multiple-destination job has a repeating schedule, then there is one instance for each run of the job at each destination.

When a job is created, only one entry is added to the Scheduler's job table to represent the job. Depending on the logging level set, each time the job runs, an entry is added to the job log. Therefore, if you create a job that has a repeating schedule, there is one entry in the job views (`*_SCHEDULER_JOBS`) and multiple entries in the job log. Each job instance log entry provides information about a particular run, such as the job completion status and the start and end time. Each run of the job is assigned a unique log id that appears in both the job log and job run details views (`*_SCHEDULER_JOB_LOG` and `*_SCHEDULER_JOB_RUN_DETAILS`).

 **See Also:**

- "[Monitoring Jobs](#)"
- "[Scheduler Data Dictionary Views](#)"

28.3.3 Job Arguments

When a job references a program object (program), you can supply job arguments to override the default program argument values, or provide values for program arguments that have no default value. You can also provide argument values to an inline action (for example, a stored procedure) that the job specifies.

A job cannot be enabled until all required program argument values are defined, either as defaults in a referenced program object, or as job arguments.

A common example of a job is one that runs a set of nightly reports. If different departments require different reports, you can create a program for this task that can be shared among different users from different departments. The program action runs a reports script, and the program has one argument: the department number. Each user can then create a job that points to this program and can specify the department number as a job argument.

 **See Also:**

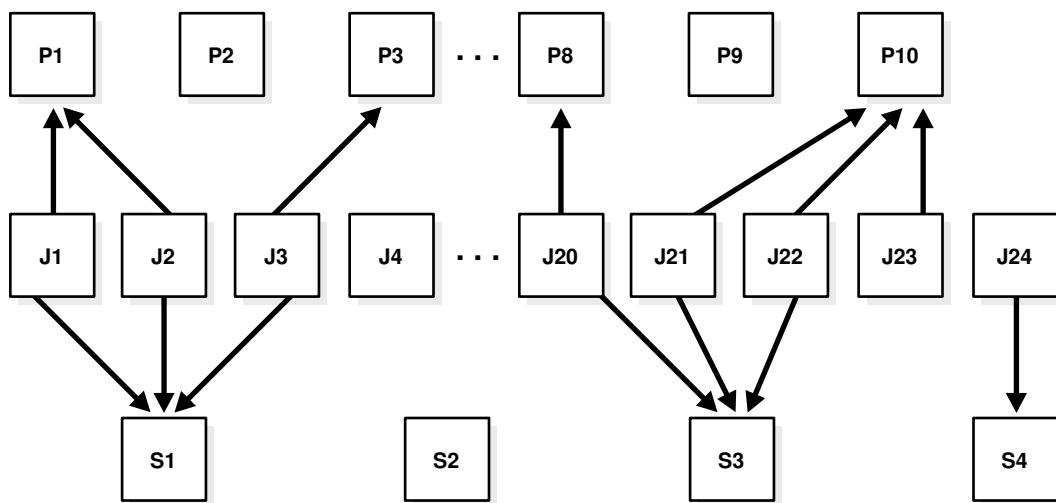

- ["Setting Job Arguments"](#)
- ["Defining Program Arguments"](#)
- ["Creating Jobs"](#)

28.3.4 How Programs, Jobs, and Schedules are Related

To define what is executed and when, you assign relationships among programs, jobs, and schedules.

Figure 28-5 illustrates examples of such relationships.

Figure 28-5 Relationships Among Programs, Jobs, and Schedules

To understand [Figure 28-5](#), consider a situation where tables are being analyzed. In this example, program P1 analyzes a table using the DBMS_STATS package. The program has an input parameter for the table name. Two jobs, J1 and J2, both point to the same program, but each supplies a different table name. Additionally, schedule S1 specifies a run time of 2:00 a.m. every day. The end result is that the two tables named in J1 and J2 are analyzed daily at 2:00 a.m.

Note that J4 points to no other entity, so it is self-contained with all relevant information defined in the job itself. P2, P9 and S2 illustrate that you can leave a program or schedule unassigned if you want. You can, for example, create a program that calculates a year-end inventory and temporarily leave it unassigned to any job.

28.4 Scheduler Architecture

Scheduler components handle jobs.

- [Scheduler Components](#)

Scheduler components include the job table, the job coordinator, and job slaves.

- [The Job Table](#)

The job table is a container for all the jobs, with one table for each database. The job table stores information for all jobs such as the owner name or the level of logging. You can find this information in the *_SCHEDULER_JOBS views.

- [The Job Coordinator](#)

The job coordinator starts job slaves.

- [How Jobs Execute](#)

Job slaves execute the jobs you submit.

- [After Jobs Complete](#)

The slaves perform several operations after a job completes.

- [Using the Scheduler in Real Application Clusters Environments](#)

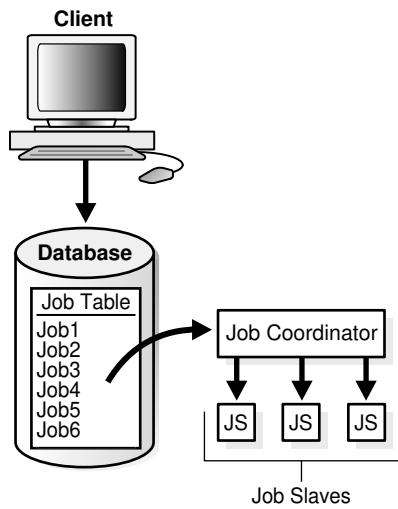

You can use the Scheduler in an Oracle Real Application Clusters environment.

28.4.1 Scheduler Components

Scheduler components include the job table, the job coordinator, and job slaves.

[Figure 28-6](#) illustrates how jobs are handled by the database.

Figure 28-6 Scheduler Components

28.4.2 The Job Table

The job table is a container for all the jobs, with one table for each database. The job table stores information for all jobs such as the owner name or the level of logging. You can find this information in the *_SCHEDULER_JOBS views.

Jobs are database objects, and therefore, can accumulate and take up too much space. To avoid this, job objects are automatically dropped by default after completion. This behavior is controlled by the `auto_drop` job attribute.

See "[Scheduler Data Dictionary Views](#)" for the available job views and administration.

28.4.3 The Job Coordinator

The job coordinator starts job slaves.

- [About The Job Coordinator](#)
The job coordinator, under the control of the database, controls and starts job slaves, making use of the information in the job table.
- [Job Coordinator Actions](#)
The job coordinator performs several actions.
- [Maximum Number of Scheduler Job Processes](#)
The coordinator automatically determines how many job slaves to start based on CPU load and the number of outstanding jobs.

28.4.3.1 About The Job Coordinator

The job coordinator, under the control of the database, controls and starts job slaves, making use of the information in the job table.

The job coordinator background process (`cjqNNN`) starts automatically and stops on an as-needed basis. At database startup, the job coordinator is not started, but the database does monitor whether there are any jobs to be executed, or windows to be opened in the near future. If so, it starts the coordinator.

As long as there are jobs or windows running, the coordinator continues to run. After there has been a certain period of Scheduler inactivity and there are no jobs or windows scheduled in the near future, the coordinator is automatically stopped.

When the database determines whether to start the job coordinator, it takes the service affinity of jobs into account. For example, if there is only one job scheduled in the near future and this job belongs to a job class that has service affinity for only two out of the four Oracle RAC instances, only the job coordinators for those two instances are started. See "[Service Affinity when Using the Scheduler](#)" for more information.

28.4.3.2 Job Coordinator Actions

The job coordinator performs several actions.

The job coordinator:

- Controls and spawns the job slaves
- Queries the job table
- Picks up jobs from the job table on a regular basis and places them in a memory cache. This improves performance by reducing trips to the disk
- Takes jobs from the memory cache and passes them to job slaves for execution
- Cleans up the job slave pool when slaves are no longer needed
- Goes to sleep when no jobs are scheduled
- Wakes up when a new job is about to be executed or a job was created using the CREATE_JOB procedure
- Upon database startup after an abnormal database shutdown, recovers any jobs that were running.

You do not need to set the time that the job coordinator checks the job table; the system chooses the time frame automatically.

One job coordinator is used per instance. This is also the case in Oracle RAC environments.

See Also:

["Scheduler Data Dictionary Views"](#) for job coordinator administration and
["Using the Scheduler in Real Application Clusters Environments"](#) for Oracle RAC information

28.4.3.3 Maximum Number of Scheduler Job Processes

The coordinator automatically determines how many job slaves to start based on CPU load and the number of outstanding jobs.

The JOB_QUEUE_PROCESSES initialization parameter can be used to limit the number of job slaves that the Scheduler can start.

 **See Also:**

Oracle Database Reference for more information about the
JOB_QUEUE_PROCESSES initialization parameter

28.4.4 How Jobs Execute

Job slaves execute the jobs you submit.

They are awakened by the job coordinator when it is time for a job to be executed.
They gather metadata to run the job from the job table.

When a job is picked for processing, the job slave does the following:

1. Gathers all the metadata needed to run the job, for example, program arguments and privilege information.
2. Starts a database session as the owner of the job, starts a transaction, and then starts executing the job.
3. Once the job is complete, the slave commits and ends the transaction.
4. Closes the session.

28.4.5 After Jobs Complete

The slaves perform several operations after a job completes.

When a job is done, the slaves do the following:

- Reschedule the job if required.
- Update the state in the job table to reflect whether the job has completed or is scheduled to run again.
- Insert an entry into the job log table.
- Update the run count, and if necessary, failure and retry counts.
- Clean up.
- Look for new work (if none, they go to sleep).

The Scheduler dynamically sizes the slave pool as required.

28.4.6 Using the Scheduler in Real Application Clusters Environments

You can use the Scheduler in an Oracle Real Application Clusters environment.

- [The Scheduler and Real Application Clusters](#)

In an Oracle Real Application Clusters (Oracle RAC) environment, the Scheduler uses one job table for each database and one job coordinator for each instance.

- [Service Affinity when Using the Scheduler](#)

The Scheduler enables you to specify the database service under which a job should be run (service affinity).

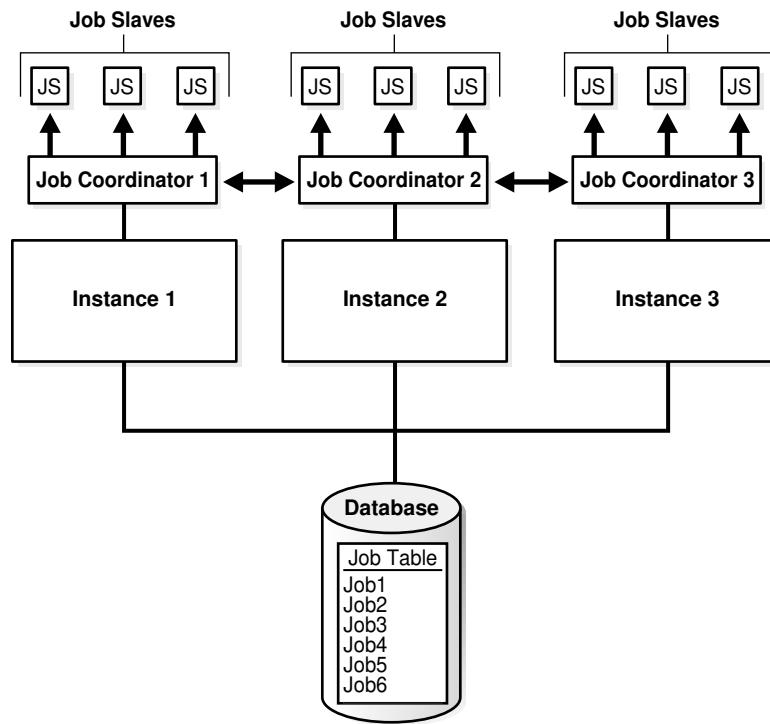

28.4.6.1 The Scheduler and Real Application Clusters

In an Oracle Real Application Clusters (Oracle RAC) environment, the Scheduler uses one job table for each database and one job coordinator for each instance.

The job coordinators communicate with each other to keep information current. The Scheduler attempts to balance the load of the jobs of a job class across all available instances when the job class has no service affinity, or across the instances assigned to a particular service when the job class does have service affinity.

[Figure 28-7](#) illustrates a typical Oracle RAC architecture, with the job coordinator for each instance exchanging information with the others.

Figure 28-7 Oracle RAC Architecture and the Scheduler

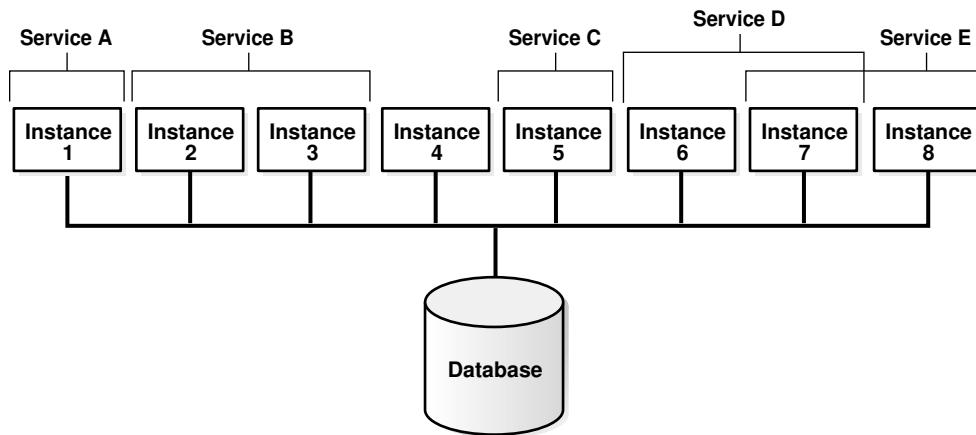

28.4.6.2 Service Affinity when Using the Scheduler

The Scheduler enables you to specify the database service under which a job should be run (service affinity).

This ensures better availability than instance affinity because it guarantees that other nodes can be dynamically assigned to the service if an instance goes down. Instance affinity does not have this capability, so, when an instance goes down, none of the jobs with an affinity to that instance can run until the instance comes back up.

[Figure 28-8](#) illustrates a typical example of how services and instances could be used.

Figure 28-8 Service Affinity and the Scheduler

In [Figure 28-8](#), you could change the properties of the services and the Scheduler automatically recognizes the change.

Each job class can specify a database service. If a service is not specified, the job class belongs to an internal service that is guaranteed to be mapped to every running instance.

28.5 Scheduler Support for Oracle Data Guard

Beginning with Oracle Database 11g Release 1 (11.1), the Scheduler can run jobs based on whether a database is a primary database or a logical standby in an Oracle Data Guard environment.

For a physical standby database, any changes made to Scheduler objects or any database changes made by Scheduler jobs on the primary database are applied to the physical standby like any other database changes.

For the primary database and logical standby databases, there is additional functionality that enables you to specify that a job can run only when the database is in the role of the primary database or a logical standby. You do this using the DBMS_SCHEDULER.SET_ATTRIBUTE procedure to set the database_role job attribute to one of two values: 'PRIMARY' or 'LOGICAL STANDBY'. (To run a job in both roles, you can make a copy of the job and set database_role to 'PRIMARY' for one job and to 'LOGICAL STANDBY' for the other). On switchover or failover, the Scheduler automatically switches to running jobs specific to the new role. DML is replicated to the job event log so that on failover, there is an available record of what ran successfully on the primary database until it failed.

Replication of scheduler jobs from a primary to a logical standby is limited to the upgrade target in a rolling upgrade done using the DBMS_ROLLING package.

 **See Also:**

Scheduling Jobs with Oracle Scheduler

You can create, run, and manage jobs with Oracle Scheduler.

Note:

This chapter describes how to use the `DBMS_SCHEDULER` package to work with Scheduler objects. You can accomplish the same tasks using Oracle Enterprise Manager Cloud Control and many of these tasks with Oracle SQL Developer.

See *Oracle Database PL/SQL Packages and Types Reference* for `DBMS_SCHEDULER` information and the Cloud Control online help for information on Oracle Scheduler pages.

- [About Scheduler Objects and Their Naming](#)

You operate Oracle Scheduler by creating and managing a set of Scheduler objects. Each Scheduler object is a complete database schema object of the form [schema.]name. Scheduler objects follow the naming rules for database objects exactly and share the SQL namespace with other database objects.

- [Creating, Running, and Managing Jobs](#)

A job is the combination of a schedule and a program, along with any additional arguments required by the program.

- [Creating and Managing Programs to Define Jobs](#)

A program is a collection of metadata about a particular task. You optionally use a program to help define a job.

- [Creating and Managing Schedules to Define Jobs](#)

You optionally use a schedule object (a schedule) to define when a job should be run. Schedules can be shared among users by creating and saving them as objects in the database.

- [Using Events to Start Jobs](#)

Oracle Scheduler can start a job when an event is sent. An event is a message one application or system process sends to another.

- [Creating and Managing Job Chains](#)

A job chain is a named series of tasks that are linked together for a combined objective.

- [Using Incompatibility Definitions](#)

An incompatibility definition (or, incompatibility) specifies incompatible jobs or programs, where only one of the group can be running at a time.

- [Managing Job Resources](#)

You can create and alter resources available for use by jobs, and control how many of a specified resource are available to a job.

- [Prioritizing Jobs](#)

You prioritize Oracle Scheduler jobs using three Scheduler objects: job classes, windows, and window groups. These objects prioritize jobs by associating jobs with database resource manager consumer groups. This, in turn, controls the amount of resources allocated to these jobs. In addition, job classes enable you to set relative priorities among a group of jobs if all jobs in the group are allocated identical resource levels.

- [Monitoring Jobs](#)

You can monitor jobs in several different ways.

29.1 About Scheduler Objects and Their Naming

You operate Oracle Scheduler by creating and managing a set of Scheduler objects. Each Scheduler object is a complete database schema object of the form [schema.]name. Scheduler objects follow the naming rules for database objects exactly and share the SQL namespace with other database objects.

Follow SQL naming rules to name Scheduler objects in the DBMS_SCHEDULER package. By default, Scheduler object names are uppercase unless they are surrounded by double quotes. For example, when creating a job, job_name => 'my_job' is the same as job_name => 'My_Job' and job_name => 'MY_JOB', but different from job_name => ' "my_job" '. These naming rules are also followed in those cases where comma-delimited lists of Scheduler object names are used within the DBMS_SCHEDULER package.

 **See Also:**

- [Oracle Database SQL Language Reference](#) for details regarding naming objects
- ["About Jobs and Supporting Scheduler Objects"](#)

29.2 Creating, Running, and Managing Jobs

A job is the combination of a schedule and a program, along with any additional arguments required by the program.

- [Job Tasks and Their Procedures](#)

You use procedures in the DBMS_SCHEDULER package to administer common job tasks.

- [Creating Jobs](#)

You create jobs using the DBMS_SCHEDULER package or Cloud Control.

- [Altering Jobs](#)

You alter a job by modifying its attributes. You do so using the SET_ATTRIBUTE, SET_ATTRIBUTE_NULL, or SET_JOB_ATTRIBUTES procedures in the DBMS_SCHEDULER package or Cloud Control.

- [Running Jobs](#)

A job can be run in several different ways.

- [Stopping Jobs](#)
You stop one or more running jobs using the `STOP_JOB` procedure in the `DBMS_SCHEDULER` package or Cloud Control.
- [Stopping External Jobs](#)
The Scheduler offers implementors of external jobs a mechanism to gracefully clean up after their external jobs when `STOP_JOB` is called with `force` set to `FALSE`.
- [Stopping a Chain Job](#)
If a job that points to a running chain is stopped, then all steps of the chain that are running are stopped.
- [Dropping Jobs](#)
You drop one or more jobs using the `DROP_JOB` procedure in the `DBMS_SCHEDULER` package or Cloud Control.
- [Dropping Running Jobs](#)
If a job is running at the time of the `DROP_JOB` procedure call, then attempting to drop the job fails. You can modify this default behavior by setting either the `force` or `defer` option.
- [Dropping Multiple Jobs](#)
When you specify multiple jobs to drop, the `commit_semantics` argument of the `DBMS_SCHEDULER.DROP_JOB` procedure determines the outcome if an error occurs on one of the jobs.
- [Disabling Jobs](#)
You disable one or more jobs using the `DISABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.
- [Enabling Jobs](#)
You enable one or more jobs by using the `ENABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.
- [Copying Jobs](#)
You copy a job using the `COPY_JOB` procedure in the `DBMS_SCHEDULER` or Cloud Control.

 **See Also:**

["Jobs"](#) for an overview of jobs.

29.2.1 Job Tasks and Their Procedures

You use procedures in the `DBMS_SCHEDULER` package to administer common job tasks.

[Table 29-1](#) illustrates common job tasks and their appropriate procedures and privileges:

Table 29-1 Job Tasks and Their Procedures

Task	Procedure	Privilege Needed
Create a job	<code>CREATE_JOB</code> or <code>CREATE_JOBS</code>	<code>CREATE JOB</code> or <code>CREATE ANY JOB</code>

Table 29-1 (Cont.) Job Tasks and Their Procedures

Task	Procedure	Privilege Needed
Alter a job	SET_ATTRIBUTE or SET_JOB_ATTRIBUTES	ALTER or CREATE ANY JOB or be the owner
Run a job	RUN_JOB	ALTER or CREATE ANY JOB or be the owner
Copy a job	COPY_JOB	ALTER or CREATE ANY JOB or be the owner
Drop a job	DROP_JOB	ALTER or CREATE ANY JOB or be the owner
Stop a job	STOP_JOB	ALTER or CREATE ANY JOB or be the owner
Disable a job	DISABLE	ALTER or CREATE ANY JOB or be the owner
Enable a job	ENABLE	ALTER or CREATE ANY JOB or be the owner

See "[Scheduler Privileges](#)" for further information regarding privileges.

29.2.2 Creating Jobs

You create jobs using the DBMS_SCHEDULER package or Cloud Control.

- [Overview of Creating Jobs](#)
You create one or more jobs using the DBMS_SCHEDULER.CREATE_JOB or DBMS_SCHEDULER.CREATE_JOBS procedures or Cloud Control.
- [Specifying Job Actions, Schedules, Programs, and Styles](#)
Because the CREATE_JOB procedure is overloaded, there are several different ways of using it.
- [Specifying Scheduler Job Credentials](#)
Oracle Scheduler requires job credentials to authenticate with an Oracle database or the operating system before running.
- [Specifying Destinations](#)
For remote external jobs and remote database jobs, you specify the job destination by creating a destination object and assigning it to the destination_name job attribute. A job with a NULL destination_name attribute runs on the host where the job is created.
- [Creating Multiple-Destination Jobs](#)
You can create a job that runs on multiple destinations, but that is managed from a single location.
- [Setting Job Arguments](#)
To set job arguments, use the SET_JOB_ARGUMENT_VALUE or SET_JOB_ANYDATA_VALUE procedures or Cloud Control. SET_JOB_ANYDATA_VALUE is used for complex data types that cannot be represented as a VARCHAR2 string.
- [Setting Additional Job Attributes](#)
After creating a job, you can set additional job attributes or change attribute values by using the SET_ATTRIBUTE or SET_JOB_ATTRIBUTES procedures.
- [Creating Detached Jobs](#)
A detached job must point to a program object (program) that has its detached attribute set to TRUE.

- **Creating Multiple Jobs in a Single Transaction**
If you must create many jobs, then you may be able to reduce transaction overhead and experience a performance gain if you use the CREATE_JOBS procedure.
- **Techniques for External Jobs**
This section contains the following examples, which demonstrate some practical techniques for external jobs.

29.2.2.1 Overview of Creating Jobs

You create one or more jobs using the DBMS_SCHEDULER.CREATE_JOB or DBMS_SCHEDULER.CREATE_JOBS procedures or Cloud Control.

You use the CREATE_JOB procedure to create a single job. This procedure is overloaded to enable you to create different types of jobs that are based on different objects. You can create multiple jobs in a single transaction using the CREATE_JOBS procedure.

You must have the CREATE JOB privilege to create a job in your own schema, and the CREATE ANY JOB privilege to create a job in any schema except SYS.

For each job being created, you specify a job type, an action, and a schedule. You can also optionally specify a credential name, a destination or destination group name, a job class, and other attributes. As soon as you enable a job, it is automatically run by the Scheduler at its next scheduled date and time. By default, jobs are disabled when created and must be enabled with DBMS_SCHEDULER.ENABLE to run. You can also set the enabled argument of the CREATE_JOB procedure to TRUE, in which case the job is ready to be automatically run, according to its schedule, as soon as you create it.

Some job attributes cannot be set with CREATE_JOB, and instead must be set with DBMS_SCHEDULER.SET_ATTRIBUTE. For example, to set the logging_level attribute for a job, you must call SET_ATTRIBUTE after calling CREATE_JOB.

You can create a job in another schema by specifying schema.job_name. The creator of a job is, therefore, not necessarily the job owner. The job owner is the user in whose schema the job is created. The NLS environment of the job, when it runs, is the existing environment at the time the job was created.

The following example demonstrates creating a database job called update_sales, which calls a package procedure in the OPS schema that updates a sales summary table:

```

BEGIN
  DBMS_SCHEDULER.CREATE_JOB (
    job_name      => 'update_sales',
    job_type      => 'STORED_PROCEDURE',
    job_action    => 'OPS.SALES_PKG.UPDATE_SALES_SUMMARY',
    start_date    => '28-APR-08 07.00.00 PM Australia/Sydney',
    repeat_interval => 'FREQ=DAILY;INTERVAL=2', /* every other day */
    end_date      => '20-NOV-08 07.00.00 PM Australia/Sydney',
    auto_drop     => FALSE,
    job_class     => 'batch_update_jobs',
    comments      => 'My new job');
END;
/

```

Because no `destination_name` attribute is specified, the job runs on the originating (local) database. The job runs as the user who created the job.

The `repeat_interval` argument specifies that this job runs every other day until it reaches the end date and time. Another way to limit the number of times that a repeating job runs is to set its `max_runs` attribute to a positive number.

The job is disabled when it is created, by default. You must enable it with `DBMS_SCHEDULER.ENABLE` before the Scheduler will automatically run it.

Jobs are set to be automatically dropped by default after they complete. Setting the `auto_drop` attribute to `FALSE` causes the job to persist. Note that repeating jobs are not auto-dropped unless the job end date passes, the maximum number of runs (`max_runs`) is reached, or the maximum number of failures is reached (`max_failures`).

After a job is created, it can be queried using the `*_SCHEDULER_JOBS` views.

 **See Also:**

"[Specifying Scheduler Job Credentials](#)"

29.2.2.2 Specifying Job Actions, Schedules, Programs, and Styles

Because the `CREATE_JOB` procedure is overloaded, there are several different ways of using it.

In addition to specifying the job action and job repeat interval as job attributes as shown in the example in "[Overview of Creating Jobs](#)", known as specifying the job action and job schedule *inline*, you can create a job that points to a program object (program) to specify the job action, a schedule object (schedule) to specify the repeat interval, or both a program and schedule. You can also create jobs by specifying job programs and job styles.

- [Creating Jobs Using a Named Program](#)
You can create a job by pointing to a named program instead of inlining its action.
- [Creating Jobs Using a Named Program and Job Styles](#)
You can create jobs using named programs and job styles. The following job styles are available: '`REGULAR`', '`LIGHTWEIGHT`', '`IN_MEMORY_RUNTIME`', '`IN_MEMORY_FULL`'.
- [Creating Jobs Using a Named Schedule](#)
You can create a job by pointing to a named schedule instead of inlining its schedule.
- [Creating Jobs Using Named Programs and Schedules](#)
A job can be created by pointing to both a named program and a named schedule.

 See Also:

- ["Programs"](#)
- ["Schedules"](#)

29.2.2.1 Creating Jobs Using a Named Program

You can create a job by pointing to a named program instead of inlining its action.

To create a job using a named program, you specify the value for `program_name` in the `CREATE_JOB` procedure when creating the job and do not specify the values for `job_type`, `job_action`, and `number_of_arguments`.

To use an existing program when creating a job, the owner of the job must be the owner of the program or have `EXECUTE` privileges on it. The following PL/SQL block is an example of a `CREATE_JOB` procedure with a named program that creates a regular job called `my_new_job1`:

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB (
    job_name      => 'my_new_job1',
    program_name   => 'my_saved_program',
    repeat_interval => 'FREQ=DAILY;BYHOUR=12',
    comments       => 'Daily at noon');
END;
/
```

29.2.2.2 Creating Jobs Using a Named Program and Job Styles

You can create jobs using named programs and job styles. The following job styles are available: '`REGULAR`', '`LIGHTWEIGHT`', '`IN_MEMORY_RUNTIME`', '`IN_MEMORY_FULL`'.

The default job style is '`REGULAR`' which is implied if no job style is provided. Examples of the other job types follow.

`LIGHTWEIGHT` Jobs

The following PL/SQL block creates a lightweight job. Lightweight jobs must reference a program, and the program type must be '`PLSQL_BLOCK`' or '`STORED_PROCEDURE`'. In addition, the program must be already enabled when you create the job.

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB (
    job_name      => 'my_lightweight_job1',
    program_name   => 'polling_prog_n2',
    repeat_interval => 'FREQ=SECONDLY;INTERVAL=10',
    end_date       => '30-APR-09 04.00.00 AM Australia/Sydney',
    job_style      => 'LIGHTWEIGHT',
    comments       => 'Job that polls device n2 every 10 seconds');
END;
/
```

`IN_MEMORY_RUNTIME` Jobs

The following PL/SQL block creates an in-memory runtime job. In-memory runtime jobs have the same requirements and restrictions as lightweight jobs.

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB (
    job_name => 'my_repeat_job',
    program_name => 'repeat_prog',
    start_date => systimestamp,
    repeat_interval => 'freq=secondly;interval=10',
    job_style => 'IN_MEMORY_RUNTIME',
    enabled => true);
END;
/
```

IN_MEMORY_FULL Jobs

The following PL/SQL creates an in-memory full job. In-memory full jobs require a program and cannot have a schedule or repeat interval. They run automatically when the job is enabled, and after running they are discarded.

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB (
    job_name => 'my_immediate_job',
    program_name => 'fast_op',
    job_style => 'IN_MEMORY_FULL',
    enabled => true);
END;
/
```

See Also:

["In-Memory Jobs"](#)

29.2.2.2.3 Creating Jobs Using a Named Schedule

You can create a job by pointing to a named schedule instead of inlining its schedule.

To create a job using a named schedule, you specify the value for `schedule_name` in the `CREATE_JOB` procedure when creating the job and do not specify the values for `start_date`, `repeat_interval`, and `end_date`.

You can use any named schedule to create a job because all schedules are created with access to `PUBLIC`. The following `CREATE_JOB` procedure has a named schedule and creates a regular job called `my_new_job2`:

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB (
    job_name          => 'my_new_job2',
    job_type          => 'PLSQL_BLOCK',
    job_action        => 'BEGIN SALES_PKG.UPDATE_SALES_SUMMARY; END;',
    schedule_name     => 'my_saved_schedule');
END;
/
```

29.2.2.2.4 Creating Jobs Using Named Programs and Schedules

A job can be created by pointing to both a named program and a named schedule.

For example, the following `CREATE_JOB` procedure creates a regular job called `my_new_job3`, based on the existing program, `my_saved_program1`, and the existing schedule, `my_saved_schedule1`:

```
BEGIN
    DBMS_SCHEDULER.CREATE_JOB (
        job_name          => 'my_new_job3',
        program_name      => 'my_saved_program1',
        schedule_name     => 'my_saved_schedule1');
END;
/
```

- ["Creating and Managing Programs to Define Jobs"](#)
- ["Creating and Managing Schedules to Define Jobs"](#)
- ["Using Events to Start Jobs "](#)

29.2.2.3 Specifying Scheduler Job Credentials

Oracle Scheduler requires job credentials to authenticate with an Oracle database or the operating system before running.

For local external jobs, remote external jobs, and remote database jobs, you must specify the credentials under which the job runs. You do so by creating a credential object and assigning it to the `credential_name` job attribute.

Note:

A local database job always runs as the user is who is the job owner and will ignore any named credential.

To create a credential, call the `DBMS_CREDENTIAL.CREATE_CREDENTIAL` procedure.

You must have the `CREATE CREDENTIAL` privilege to create a credential in your own schema, and the `CREATE ANY CREDENTIAL` privilege to create a credential in any schema except `SYS`. A credential can be used only by a job whose owner has `EXECUTE` privileges on the credential or whose owner also owns the credential. Because a credential belongs to a schema like any other schema object, you use the `GRANT SQL` statement to grant privileges on a credential.

Example 29-1 Creating a Credential

```
BEGIN
    DBMS_CREDENTIAL.CREATE_CREDENTIAL('DW_CREDENTIAL', 'dwuser', 'dw001515');
```

```
END;  
/  
  
GRANT EXECUTE ON DW_CREDENTIAL TO salesuser;
```

You can query the *_CREDENTIALS views to see a list of credentials in the database. Credential passwords are stored obfuscated and are not displayed in these views.

 **Note:**

*_SCHEDULER_CREDENTIALS is deprecated in Oracle Database 12c, but remains available, for reasons of backward compatibility.

 **See Also:**

Oracle Database Security Guide for information about creating a credential using the DBMS_CREDENTIAL.CREATE_CREDENTIAL procedure

29.2.2.4 Specifying Destinations

For remote external jobs and remote database jobs, you specify the job destination by creating a destination object and assigning it to the destination_name job attribute. A job with a NULL destination_name attribute runs on the host where the job is created.

- [Destination Tasks and Their Procedures](#)
You use procedures in the DBMS_SCHEDULER package to administer destination tasks.
- [Creating Destinations](#)
A **destination** is a Scheduler object that defines a location for running a job.
- [Creating Destination Groups for Multiple-Destination Jobs](#)
To create a job that runs on multiple destinations, you must create a destination group and assign that group to the destination_name attribute of the job.
- [Example: Creating a Remote Database Job](#)
An example illustrates creating a remote database job.

29.2.2.4.1 Destination Tasks and Their Procedures

You use procedures in the DBMS_SCHEDULER package to administer destination tasks.

[Table 29-2](#) illustrates destination tasks and their procedures and privileges:

Table 29-2 Destination Tasks and Their Procedures

Task	Procedure	Privilege Needed
Create an external destination	(none)	See " Creating Destinations "

Table 29-2 (Cont.) Destination Tasks and Their Procedures

Task	Procedure	Privilege Needed
Drop an external destination	DROP_AGENT_DESTINATION	MANAGE SCHEDULER
Create a database destination	CREATE_DATABASE_DESTINATION	CREATE JOB or CREATE ANY JOB
Drop a database destination	DROP_DATABASE_DESTINATION	CREATE ANY JOB or be the owner
Create a destination group	CREATE_GROUP	CREATE JOB or CREATE ANY JOB
Drop a destination group	DROP_GROUP	CREATE ANY JOB or be the owner
Add members to a destination group	ADD_GROUP_MEMBER	ALTER or CREATE ANY JOB or be the owner
Remove members from a destination group	REMOVE_GROUP_MEMBER	ALTER or CREATE ANY JOB or be the owner

29.2.2.4.2 Creating Destinations

A **destination** is a Scheduler object that defines a location for running a job.

You designate the locations where a job runs by specifying either a single destination or a destination group in the `destination_name` attribute of the job. If you leave the `destination_name` attribute `NULL`, the job runs on the local host (the host where the job was created).

Use external destinations to specify locations where remote external jobs run. Use database destinations to specify locations where remote database jobs run.

You do not need object privileges to use a destination created by another user.

To create an external destination, register a remote Scheduler agent with the database.

See "[Installing and Configuring the Scheduler Agent on a Remote Host](#)" for instructions.

 **Note:**

There is no `DBMS_SCHEDULER` package procedure to create an external destination. You create an external destination implicitly by registering a remote agent.

You can also register a local Scheduler agent if you have other database instances on the same host that are targets for remote jobs. This creates an external destination that references the local host.

The external destination name is automatically set to the agent name. To verify that the external destination was created, query the views DBA_SCHEDULER_EXTERNAL_DESTS or ALL_SCHEDULER_EXTERNAL_DESTS.

To create a database destination, call the DBMS_SCHEDULER.CREATE_DATABASE_DESTINATION procedure.

You must specify the name of an external destination as a procedure argument. This designates the remote host that the database destination points to. You also specify a net service name or complete connect descriptor that identifies the database instance being connected to. If you specify a net service name, it must be resolved by the local tnsnames.ora file. If you do not specify a database instance, the remote Scheduler agent connects to its default database, which is specified in the agent configuration file.

To create a database destination, you must have the CREATE JOB system privilege. To create a database destination in a schema other than your own, you must have the CREATE ANY JOB privilege.

Example 29-2 Creating a Database Destination

The following example creates a database destination named DBHOST1_ORCLDW. For this example, assume the following:

- You installed a Scheduler agent on the remote host dbhost1.example.com, and you registered the agent with the local database.
- You did not modify the agent configuration file to set the agent name. Therefore the agent name and the external destination name default to DBHOST1.
- You used Net Configuration Assistant on the local host to create a connect descriptor in tnsnames.ora for the Oracle Database instance named orcldw, which resides on the remote host dbhost1.example.com. You assigned a net service name (alias) of ORCLDW to this connect descriptor.

```
BEGIN
  DBMS_SCHEDULER.CREATE_DATABASE_DESTINATION (
    destination_name      => 'DBHOST1_ORCLDW',
    agent                 => 'DBHOST1',
    tns_name              => 'ORCLDW',
    comments              => 'Instance named orcldw on host dbhost1.example.com');
END;
/
```

To verify that the database destination was created, query the views *_SCHEDULER_DB_DESTS.

See Also:

- "[Destinations](#)" for more information about destinations
- "[Jobs](#)" to learn about remote external jobs and remote database jobs

29.2.2.4.3 Creating Destination Groups for Multiple-Destination Jobs

To create a job that runs on multiple destinations, you must create a destination group and assign that group to the destination_name attribute of the job.

You can specify group members (destinations) when you create the group, or you can add group members at a later time.

To create a destination group, call the DBMS_SCHEDULER.CREATE_GROUP procedure.

For remote external jobs you must specify a group of type 'EXTERNAL_DEST', and all group members must be external destinations. For remote database jobs, you must specify a group of type 'DB_DEST', and all members must be database destinations.

Members of destination groups have the following format:

`[[schema.]credential@[schema.]destination]`

where:

- `credential` is the name of an existing credential.
- `destination` is the name of an existing database destination or external destination

The credential portion of a destination member is optional. If omitted, the job using this destination member uses its default credential.

You can include another group of the same type as a member of a destination group. Upon group creation, the Scheduler expands the included group into its members.

If you want the local host to be one of many destinations on which a job runs, you can include the keyword LOCAL as a group member for either type of destination group. LOCAL can be preceded by a credential only in an external destination group.

A group is owned by the user who creates it. You must have the CREATE JOB system privilege to create a group in your own schema, and the CREATE ANY JOB system privilege to create a group in another schema. You can grant object privileges on a group to other users by granting SELECT on the group.

See Also:

["Groups"](#) for an overview of groups.

Example 29-3 Creating a Database Destination Group

This example creates a database destination group. Because some members do not include a credential, a job using this destination group must have default credentials.

```
BEGIN
    DBMS_SCHEDULER.CREATE_GROUP(
        GROUP_NAME      => 'all_dbs',
        GROUP_TYPE     => 'DB_DEST',
        MEMBER         => 'oltp_admin@orcl, orcldw1, LOCAL',
        COMMENTS       => 'All databases managed by me');
END;
/
```

The following code adds another member to the group.

```
BEGIN
    DBMS_SCHEDULER.ADD_GROUP_MEMBER(
        GROUP_NAME      => 'all_dbs',
        MEMBER          => 'dw_admin@orcldw2');
END;
/
```

29.2.2.4.4 Example: Creating a Remote Database Job

An example illustrates creating a remote database job.

The following example creates a remote database job by specifying a database destination object in the destination_name object of the job. A credential must also be specified so the job can authenticate with the remote database. The example uses the credential created in [Example 29-1](#) and the database destination created in [Example 29-2](#).

```
BEGIN
    DBMS_SCHEDULER.CREATE_JOB (
        job_name          => 'SALES_SUMMARY1',
        job_type          => 'STORED_PROCEDURE',
        job_action         => 'SALES.SALES_REPORT1',
        start_date         => '15-JUL-09 11.00.00 PM Europe/Warsaw',
        repeat_interval   => 'FREQ=DAILY',
        credential_name   => 'DW_CREDENTIAL',
        destination_name  => 'DBHOST1_ORCLDW');
END;
/
```

29.2.2.5 Creating Multiple-Destination Jobs

You can create a job that runs on multiple destinations, but that is managed from a single location.

A typical reason to do this is to run a database maintenance job on all of the databases that you administer. Rather than create the job on each database, you create the job once and designate multiple destinations for the job. From the database where you created the job (the *local database*), you can monitor the state and results of all instances of the job at all locations.

To create a multiple-destination job:

- Call the DBMS_SCHEDULER.CREATE_JOB procedure and set the destination_name attribute of the job to the name of database destination group or external destination group.

If not all destination group members include a credential prefix (the schema), assign a default credential to the job.

To include the local host or local database as one of the destinations on which the job runs, ensure that the keyword LOCAL is one of the members of the destination group.

To obtain a list of destination groups, submit this query:

```
SELECT owner, group_name, group_type, number_of_members FROM all_scheduler_groups
WHERE group_type = 'DB_DEST' or group_type = 'EXTERNAL_DEST';
```

OWNER	GROUP_NAME	GROUP_TYPE	NUMBER_OF_MEMBERS
DBA1	ALL_DBS	DB_DEST	4
DBA1	ALL_HOSTS	EXTERNAL_DEST	4

The following example creates a multiple-destination database job, using the database destination group created in [Example 29-3](#). The user specified in the credential should have sufficient privileges to perform the job action.

```
BEGIN
  DBMS_CREDENTIAL.CREATE_CREDENTIAL('DBA_CREDENTIAL', 'dbal', 'sYs040533');
  DBMS_SCHEDULER.CREATE_JOB (
    job_name      => 'MAINT_SET1',
    job_type      => 'STORED_PROCEDURE',
    job_action    => 'MAINT_PROC1',
    start_date    => '15-JUL-09 11.00.00 PM Europe/Warsaw',
    repeat_interval => 'FREQ=DAILY',
    credential_name => 'DBA_CREDENTIAL',
    destination_name => 'ALL_DBS' );
END;
/
```

- ["Multiple-Destination Jobs"](#)
- ["Monitoring Multiple Destination Jobs"](#)
- ["Groups"](#)

29.2.2.6 Setting Job Arguments

To set job arguments, use the `SET_JOB_ARGUMENT_VALUE` or `SET_JOB_ANYDATA_VALUE` procedures or Cloud Control. `SET_JOB_ANYDATA_VALUE` is used for complex data types that cannot be represented as a `VARCHAR2` string.

After creating a job, you may need to set job arguments if:

- The inline job action is a stored procedure or other executable that requires arguments
- The job references a named program object and you want to override one or more default program arguments
- The job references a named program object and one or more of the program arguments were not assigned a default value

An example of a job that might need arguments is one that starts a reporting program that requires a start date and end date. The following code example sets the end date job argument, which is the second argument expected by the reporting program:

```
BEGIN
  DBMS_SCHEDULER.SET_JOB_ARGUMENT_VALUE (
    job_name      => 'ops_reports',
    argument_position  => 2,
    argument_value   => '12-DEC-03');
```

```
END;  
/
```

If you use this procedure on an argument whose value has already been set, it will be overwritten. You can set argument values using either the argument name or the argument position. To use argument name, the job must reference a named program object, and the argument must have been assigned a name in the program object. If a program is inlined, only setting by position is supported. Arguments are not supported for jobs of type 'PLSQL_BLOCK'.

To remove a value that has been set, use the `RESET_JOB_ARGUMENT` procedure. This procedure can be used for both regular and `ANYDATA` arguments.

`SET_JOB_ARGUMENT_VALUE` only supports arguments of SQL type. Therefore, argument values that are not of SQL type, such as booleans, are not supported as program or job arguments.

 **See Also:**

["Defining Program Arguments"](#)

29.2.2.7 Setting Additional Job Attributes

After creating a job, you can set additional job attributes or change attribute values by using the `SET_ATTRIBUTE` or `SET_JOB_ATTRIBUTES` procedures.

You can also set job attributes with Cloud Control. Although many job attributes can be set with the call to `CREATE_JOB`, some attributes, such as `destination` and `credential_name`, can be set only with `SET_ATTRIBUTE` or `SET_JOB_ATTRIBUTES` after the job has been created.

29.2.2.8 Creating Detached Jobs

A detached job must point to a program object (program) that has its `detached` attribute set to `TRUE`.

The following example for Linux and UNIX creates a nightly job that performs a cold backup of the database. It contains three steps.

Step 1—Create the Script That Invokes RMAN

Create a shell script that calls an RMAN script to perform a cold backup. The shell script is in `$ORACLE_HOME/scripts/coldbackup.sh`. It must be executable by the user who installed Oracle Database (typically the user `oracle`).

```
#!/bin/sh

export ORACLE_HOME=/u01/app/oracle/product/11.2.0/db_1
export ORACLE_SID=orcl
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$ORACLE_HOME/lib

$ORACLE_HOME/bin/rman TARGET / @$ORACLE_HOME/scripts/coldbackup.rman
  trace /u01/app/oracle/backup/coldbackup.out &
exit 0
```

Step 2—Create the RMAN Script

Create an RMAN script that performs the cold backup and then ends the job. The script is in \$ORACLE_HOME/scripts/coldbackup.rman.

```
run {
# Shut down database for backups and put into MOUNT mode
shutdown immediate
startup mount

# Perform full database backup
backup full format "/u01/app/oracle/backup/%d_FULL_%U" (database) ;

# Open database after backup
alter database open;

# Call notification routine to indicate job completed successfully
sql " BEGIN DBMS_SCHEDULER.END_DETACHED_JOB_RUN('sys.backup_job', 0,
      null); END; ";
}
```

Step 3—Create the Job and Use a Detached Program

Submit the following PL/SQL block:

```
BEGIN
    DBMS_SCHEDULER.CREATE_PROGRAM(
        program_name    => 'sys.backup_program',
        program_type   => 'executable',
        program_action => '?/scripts/coldbackup.sh',
        enabled         => TRUE);

    DBMS_SCHEDULER.SET_ATTRIBUTE( 'sys.backup_program' , 'detached' , TRUE );

    DBMS_SCHEDULER.CREATE_JOB(
        job_name         => 'sys.backup_job',
        program_name    => 'sys.backup_program',
        repeat_interval => 'FREQ=DAILY;BYHOUR=1;BYMINUTE=0');

    DBMS_SCHEDULER.ENABLE( 'sys.backup_job' );
END;
/
```

29.2.2.9 Creating Multiple Jobs in a Single Transaction

If you must create many jobs, then you may be able to reduce transaction overhead and experience a performance gain if you use the CREATE_JOBS procedure.

[Example 29-4](#) demonstrates how to use this procedure to create multiple jobs in a single transaction.

Example 29-4 Creating Multiple Jobs in a Single Transaction

```
DECLARE
    newjob sys.job_definition;
    newjobarr sys.job_definition_array;
BEGIN
    -- Create an array of JOB_DEFINITION object types
    newjobarr := sys.job_definition_array();

    -- Allocate sufficient space in the array
    newjobarr.extend(5);

    -- Add definitions for 5 jobs
    FOR i IN 1..5 LOOP
        -- Create a JOB_DEFINITION object type
        newjob := sys.job_definition(job_name => 'TESTJOB' || to_char(i),
                                      job_style => 'REGULAR',
                                      program_name => 'PROG1',
                                      repeat_interval => 'FREQ=HOURLY',
                                      start_date => systimestamp + interval '600' second,
                                      max_runs => 2,
                                      auto_drop => FALSE,
                                      enabled => TRUE
                                    );
        -- Add it to the array
        newjobarr(i) := newjob;
    END LOOP;

    -- Call CREATE_JOBS to create jobs in one transaction
    DBMS_SCHEDULER.CREATE_JOBS(newjobarr, 'TRANSACTIONAL');
END;
/

PL/SQL procedure successfully completed.

SELECT JOB_NAME FROM USER_SCHEDULER_JOBS;

JOB_NAME
-----
TESTJOB1
TESTJOB2
TESTJOB3
TESTJOB4
TESTJOB5

5 rows selected.
```

 **See Also:**

["Lightweight Jobs"](#)

29.2.2.10 Techniques for External Jobs

This section contains the following examples, which demonstrate some practical techniques for external jobs.

Example 29-5 Creating a Local External Job That Runs a Command Interpreter

This example demonstrates how to create a local external job on Windows that runs an interpreter command (in this case, `mkdir`). The job runs `cmd.exe` with the `/c` option.

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB(
    job_name          => 'MKDIR_JOB',
    job_type          => 'EXECUTABLE',
    number_of_arguments => 3,
    job_action        => '\windows\system32\cmd.exe',
    auto_drop         => FALSE,
    credential_name   => 'TESTCRED');

  DBMS_SCHEDULER.SET_JOB_ARGUMENT_VALUE('mkdir_job',1,'/c');
  DBMS_SCHEDULER.SET_JOB_ARGUMENT_VALUE('mkdir_job',2,'mkdir');
  DBMS_SCHEDULER.SET_JOB_ARGUMENT_VALUE('mkdir_job',3,'\temp\extjob_test_dir');
  DBMS_SCHEDULER.ENABLE('MKDIR_JOB');
END;
/
```

Example 29-6 Creating a Local External Job and Viewing the Job Output

This example for Linux and UNIX shows how to create and run a local external job and then view the job output. When an external job runs, the Scheduler automatically retrieves the output from the job and stores it inside the database.

To see the output, query `*_SCHEDULER_JOB_RUN_DETAILS` views.

```
-- User scott must have CREATE JOB, CREATE CREDENTIAL, and CREATE EXTERNAL JOB
-- privileges
GRANT CREATE JOB, CREATE EXTERNAL JOB TO scott ;

CONNECT scott/password
SET SERVEROUTPUT ON

-- Create a credential for the job to use
exec DBMS_CREDENTIAL.CREATE_CREDENTIAL('my_cred','host_username','host_passwd')

-- Create a job that lists a directory. After running, the job is dropped.
BEGIN
  DBMS_SCHEDULER.CREATE_JOB(
    job_name          => 'lsdir',
    job_type          => 'EXECUTABLE',
    job_action        => '/bin/ls',
    number_of_arguments => 1,
    enabled           => false,
    auto_drop         => true,
    credential_name   => 'my_cred');
  DBMS_SCHEDULER.SET_JOB_ARGUMENT_VALUE('lsdir',1,'/tmp');
  DBMS_SCHEDULER.ENABLE('lsdir');
END;
/

-- Wait a bit for the job to run, and then check the job results.
SELECT job_name, status, error#, actual_start_date, additional_info
  FROM user_scheduler_job_run_details WHERE job_name='LSDIR';

-- Now use the external log id from the additional_info column to
-- formulate the log file name and retrieve the output
DECLARE
```

```
my_clob clob;
log_id varchar2(50);
BEGIN
  SELECT regexp_substr(additional_info,'job[_0-9]*') INTO log_id
    FROM user_scheduler_job_run_details WHERE job_name='LSDIR';
  DBMS_LOB.CREATETEMPORARY(my_clob, false);

  SELECT job_name, status, error#, errors, output FROM user_scheduler_job_run_details
  WHERE job_name = 'LSDIR';
END;
/
```

See Also:

- *Oracle Database Security Guide* for more information about external authentication
- "[External Jobs](#)"
- "[Stopping External Jobs](#)"
- "[Troubleshooting Remote Jobs](#)"

29.2.3 Altering Jobs

You alter a job by modifying its attributes. You do so using the `SET_ATTRIBUTE`, `SET_ATTRIBUTE_NULL`, or `SET_JOB_ATTRIBUTES` procedures in the `DBMS_SCHEDULER` package or Cloud Control.

See the `CREATE_JOB` procedure in *Oracle Database PL/SQL Packages and Types Reference* for details on job attributes.

All jobs can be altered, and, except for the job name, all job attributes can be changed. If there is a running instance of the job when the change is made, it is not affected by the call. The change is only seen in future runs of the job.

In general, you should not alter a job that was automatically created for you by the database. Jobs that were created by the database have the column `SYSTEM` set to `TRUE` in job views. The attributes of a job are available in the `*_SCHEDULER_JOBS` views.

It is valid for running jobs to alter their own job attributes. However, these changes do not take effect until the next scheduled run of the job.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `SET_ATTRIBUTE`, `SET_ATTRIBUTE_NULL`, and `SET_JOB_ATTRIBUTES` procedures.

The following example changes the `repeat_interval` of the job `update_sales` to once per week on Wednesday.

```
BEGIN
  DBMS_SCHEDULER.SET_ATTRIBUTE (
    name      => 'update_sales',
    attribute  => 'repeat_interval',
    value      => 'freq=weekly; byday=wed');
END;
/
```

29.2.4 Running Jobs

A job can be run in several different ways.

There are three ways in which a job can be run:

- According to the job schedule—In this case, provided that the job is enabled, the job is automatically picked up by the Scheduler job coordinator and run under the control of a job slave. The job runs as the user who is the job owner, or in the case of a local external job with a credential, as the user named in the credential. To find out whether the job succeeded, you must query the job views (`*_SCHEDULER_JOBS`) or the job log (`*_SCHEDULER_JOB_LOG` and `*_SCHEDULER_JOB_RUN_DETAILS`). See "[How Jobs Execute](#)" for more information job slaves and the Scheduler architecture.
- When an event occurs—Enabled event-based jobs start when a specified event is received on an event queue or when a file watcher raises a file arrival event. (See "[Using Events to Start Jobs](#)".) Event-based jobs also run under the control of a job slave and run as the user who owns the job, or in the case of a local external job with a credential, as the user named in the credential. To find out whether the job succeeded, you must query the job views or the job log.
- By calling `DBMS_SCHEDULER.RUN_JOB`—You can use the `RUN_JOB` procedure to test a job or to run it outside of its specified schedule. You can run the job asynchronously, which is similar to the previous two methods of running a job, or synchronously, in which the job runs in the session that called `RUN_JOB`, and as the user logged in to that session. The `use_current_session` argument of `RUN_JOB` determines whether a job runs synchronously or asynchronously.

`RUN_JOB` accepts a comma-delimited list of job names.

The following example asynchronously runs two jobs:

```
BEGIN
    DBMS_SCHEDULER.RUN_JOB(
        JOB_NAME          => 'DSS.ETLJOB1, DSS.ETLJOB2',
        USE_CURRENT_SESSION => FALSE);
END;
/
```

Note:

It is not necessary to call `RUN_JOB` to run a job according to its schedule. Provided that job is enabled, the Scheduler runs it automatically.

29.2.5 Stopping Jobs

You stop one or more running jobs using the `STOP_JOB` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

`STOP_JOB` accepts a comma-delimited list of jobs, job classes, and job destination IDs. A **job destination ID** is a number, assigned by the Scheduler, that represents a unique combination of a job, a credential, and a destination. It serves as a convenient method for identifying a particular child job of a multiple-destination job and for

stopping just that child. You obtain the job destination ID for a child job from the *_{SCHEDULER_JOB_DESTS} views.

If a job class is supplied, all running jobs in the job class are stopped. For example, the following statement stops job `job1`, all jobs in the job class `dw_jobs`, and two child jobs of a multiple-destination job:

```
BEGIN
    DBMS_SCHEDULER.STOP_JOB('job1, sys.dw_jobs, 984, 1223');
END;
/
```

All instances of the designated jobs are stopped. After stopping a job, the state of a one-time job is set to STOPPED, and the state of a repeating job is set to SCHEDULED (because the next run of the job is scheduled). In addition, an entry is made in the job log with `OPERATION` set to 'STOPPED', and `ADDITIONAL_INFO` set to 'REASON="Stop job called by user: *username*"'.

By default, the Scheduler tries to gracefully stop a job using an interrupt mechanism. This method gives control back to the slave process, which can collect statistics of the job run. If the `force` option is set to `TRUE`, the job is abruptly terminated and certain run-time statistics might not be available for the job run.

Stopping a job that is running a chain automatically stops all running steps (by calling `STOP_JOB` with the `force` option set to `TRUE` on each step).

You can use the `commit_semantics` argument of `STOP_JOB` to control the outcome if multiple jobs are specified and errors occur when trying to stop one or more jobs. If you set this argument to `ABSORB_ERRORS`, the procedure may be able to continue after encountering an error and attempt to stop the remaining jobs. If the procedure indicates that errors occurred, you can query the view `SCHEDULER_BATCH_ERRORS` to determine the nature of the errors. See "[Dropping Jobs](#)" for a more detailed discussion of commit semantics.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `STOP_JOB` procedure.

 **Note:**

When a job is stopped, only the current transaction is rolled back. This can cause data inconsistency.

29.2.6 Stopping External Jobs

The Scheduler offers implementors of external jobs a mechanism to gracefully clean up after their external jobs when `STOP_JOB` is called with `force` set to `FALSE`.

The mechanism described in this section applies only to remote external jobs on the UNIX and Linux platforms.

On UNIX and Linux, a `SIGTERM` signal is sent to the process launched by the Scheduler. The implementor of the external job is expected to trap the `SIGTERM` in an interrupt handler, clean up whatever work the job has done, and exit.

On Windows, `STOP_JOB` with `force` set to `FALSE` is supported. The process launched by the Scheduler is a console process. To stop it, the Scheduler sends a `CTRL+BREAK` to the process. The `CTRL+BREAK` can be handled by registering a handler with the `SetConsoleCtrlHandler()` routine.

29.2.7 Stopping a Chain Job

If a job that points to a running chain is stopped, then all steps of the chain that are running are stopped.

See "[Stopping Individual Chain Steps](#)" for information about stopping individual chain steps.

29.2.8 Dropping Jobs

You drop one or more jobs using the `DROP_JOB` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

`DROP_JOB` accepts a comma-delimited list of jobs and job classes. If a job class is supplied, all jobs in the job class are dropped, although the job class itself is not dropped. You cannot use job destination IDs with `DROP_JOB` to drop the child of a multiple-destination job.

Use the `DROP_JOB_CLASS` procedure to drop a job class, as described in "[Dropping Job Classes](#)".

The following statement drops jobs `job1` and `job3`, and all jobs in job classes `jobclass1` and `jobclass2`:

```
BEGIN
    DBMS_SCHEDULER.DROP_JOB ('job1, job3, sys.jobclass1, sys.jobclass2');
END;
/
```

29.2.9 Dropping Running Jobs

If a job is running at the time of the `DROP_JOB` procedure call, then attempting to drop the job fails. You can modify this default behavior by setting either the `force` or `defer` option.

When you set the `force` option to `TRUE`, the Scheduler first attempts to stop the running job by using an interrupt mechanism, calling `STOP_JOB` with the `force` option set to `FALSE`. If the job stops successfully, it is then dropped. Alternatively, you can first call `STOP_JOB` to stop the job and then call `DROP_JOB`. If `STOP_JOB` fails, you can call `STOP_JOB` with the `force` option, provided you have the `MANAGE_SCHEDULER` privilege. You can then drop the job. By default, `force` is set to `FALSE` for both the `STOP_JOB` and `DROP_JOB` procedures.

When you set the `defer` option to `TRUE`, the running job is allowed to complete and then dropped. The `force` and `defer` options are mutually exclusive; setting both results in an error.

29.2.10 Dropping Multiple Jobs

When you specify multiple jobs to drop, the `commit_semantics` argument of the `DBMS_SCHEDULER.DROP_JOB` procedure determines the outcome if an error occurs on one of the jobs.

Possible values for this argument are:

- `STOP_ON_FIRST_ERROR`, the default—The call returns on the first error and commits previous successful drop operations to disk.
- `TRANSACTIONAL`—The call returns on the first error and rolls back previous drop operations before the error. `force` must be `FALSE`.
- `ABSORB_ERRORS`—The call tries to absorb any errors, attempts to drop the rest of the jobs, and commits all the drops that were successful.

Setting `commit_semantics` is valid only when no job classes are included in the `job_name` list. When you include job classes, default commit semantics (`STOP_ON_FIRST_ERROR`) are in effect.

The following example drops the jobs `myjob1` and `myjob2` with the `defer` option and uses transactional commit semantics:

```
BEGIN
    DBMS_SCHEDULER.DROP_JOB(
        job_name      => 'myjob1, myjob2',
        defer         => TRUE,
        commit_semantics => 'TRANSACTIONAL');
END;
/
```

This next example illustrates the `ABSORB_ERRORS` commit semantics. Assume that `myjob1` is running when the procedure is called and that `myjob2` is not.

```
BEGIN
    DBMS_SCHEDULER.DROP_JOB(
        job_name      => 'myjob1, myjob2',
        commit_semantics => 'ABSORB_ERRORS');
END;
/
Error report:
ORA-27362: batch API call completed with errors
```

You can query the view `SCHEDULER_BATCH_ERRORS` to determine the nature of the errors.

```
SELECT object_name, error_code, error_message FROM scheduler_batch_errors;

OBJECT_NAME      ERROR_CODE ERROR_MESSAGE
-----
STEVE.MYJOB1      27478 "ORA-27478: job "STEVE.MYJOB1" is running
```

Checking `USER_SCHEDULER_JOBS`, you would find that `myjob2` was successfully dropped and that `myjob1` is still present.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DROP_JOB` procedure.

29.2.11 Disabling Jobs

You disable one or more jobs using the `DISABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

Jobs can also become disabled by other means. For example, dropping a job class disables the class jobs. Dropping either the program or the schedule that jobs point to, disables the jobs. However, disabling either the program or the schedule that jobs point to does not disable the jobs, and therefore, results in errors when the Scheduler tries to run them.

Disabling a job means that, although the metadata of the job is there, it should not run and the job coordinator does not pick up these jobs for processing. When a job is disabled, its state in the job table is changed to disabled.

When a currently running job is disabled with the `force` option set to `FALSE`, an error returns. When `force` is set to `TRUE`, the job is disabled, but the currently running instance is allowed to finish.

If `commit_semantics` is set to `STOP_ON_FIRST_ERROR`, then the call returns on the first error and the previous successful disable operations are committed to disk. If `commit_semantics` is set to `TRANSACTIONAL` and `force` is set to `FALSE`, then the call returns on the first error and rolls back the previous disable operations before the error. If `commit_semantics` is set to `ABSORB_ERRORS`, then the call tries to absorb any errors and attempts to disable the rest of the jobs and commits all the successful disable operations. If the procedure indicates that errors occurred, you can query the view `SCHEDULER_BATCH_ERRORS` to determine the nature of the errors.

By default, `commit_semantics` is set to `STOP_ON_FIRST_ERROR`.

You can also disable several jobs in one call by providing a comma-delimited list of job names or job class names to the `DISABLE` procedure call. For example, the following statement combines jobs with job classes:

```
BEGIN
    DBMS_SCHEDULER.DISABLE('job1, job2, job3, sys.jobclass1, sys.jobclass2');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DISABLE` procedure.

29.2.12 Enabling Jobs

You enable one or more jobs by using the `ENABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

The effect of this procedure is that the job will be picked up by the job coordinator for processing. Jobs are created disabled by default, so you must enable them before they can run. When a job is enabled, a validity check is performed. If the check fails, the job is not enabled.

If you enable a disabled job, it begins to run immediately according to its schedule. Enabling a disabled job also resets the job `RUN_COUNT`, `FAILURE_COUNT`, and `RETRY_COUNT` attributes.

If `commit_semantics` is set to `STOP_ON_FIRST_ERROR`, then the call returns on the first error and the previous successful enable operations are committed to disk. If `commit_semantics` is set to `TRANSACTIONAL`, then the call returns on the first error and the previous enable operations before the error are rolled back. If `commit_semantics` is set to `ABSORB_ERRORS`, then the call tries to absorb any errors and attempts to enable the rest of the jobs and commits all the successful enable operations. If the procedure indicates that errors occurred, you can query the view `SCHEDULER_BATCH_ERRORS` to determine the nature of the errors.

By default, `commit_semantics` is set to `STOP_ON_FIRST_ERROR`.

You can enable several jobs in one call by providing a comma-delimited list of job names or job class names to the `ENABLE` procedure call. For example, the following statement combines jobs with job classes:

```
BEGIN
    DBMS_SCHEDULER.ENABLE ('job1, job2, job3,
                           sys.jobclass1, sys.jobclass2, sys.jobclass3');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `ENABLE` procedure.

29.2.13 Copying Jobs

You copy a job using the `COPY_JOB` procedure in the `DBMS_SCHEDULER` or Cloud Control.

This call copies all the attributes of the old job to the new job (except job name). The new job is created disabled.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `COPY_JOB` procedure.

29.3 Creating and Managing Programs to Define Jobs

A program is a collection of metadata about a particular task. You optionally use a program to help define a job.

- [Program Tasks and Their Procedures](#)

You use procedures in the `DBMS_SCHEDULER` package to administer common program tasks.

- [Creating Programs with Scheduler](#)

A program describes what is to be run by the Scheduler.

- [Altering Programs](#)

You alter a program by modifying its attributes. You can use Cloud Control or the `DBMS_SCHEDULER.SET_ATTRIBUTE` and `DBMS_SCHEDULER.SET_ATTRIBUTE_NULL` package procedures to alter programs.

- [Dropping Programs](#)

You drop one or more programs using the `DROP_PROGRAM` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

- [Disabling Programs](#)
You disable one or more programs using the `DISABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.
- [Enabling Programs](#)
You enable one or more programs using the `ENABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

 **See Also:**

["Programs"](#) for an overview of programs.

29.3.1 Program Tasks and Their Procedures

You use procedures in the `DBMS_SCHEDULER` package to administer common program tasks.

[Table 29-3](#) illustrates common program tasks and their appropriate procedures and privileges:

Table 29-3 Program Tasks and Their Procedures

Task	Procedure	Privilege Needed
Create a program	<code>CREATE_PROGRAM</code>	<code>CREATE JOB</code> or <code>CREATE ANY JOB</code>
Alter a program	<code>SET_ATTRIBUTE</code>	<code>ALTER</code> or <code>CREATE ANY JOB</code> or be the owner
Drop a program	<code>DROP_PROGRAM</code>	<code>ALTER</code> or <code>CREATE ANY JOB</code> or be the owner
Disable a program	<code>DISABLE</code>	<code>ALTER</code> or <code>CREATE ANY JOB</code> or be the owner
Enable a program	<code>ENABLE</code>	<code>ALTER</code> or <code>CREATE ANY JOB</code> or be the owner

See "[Scheduler Privileges](#)" for further information regarding privileges.

29.3.2 Creating Programs with Scheduler

A program describes what is to be run by the Scheduler.

- [Creating Programs](#)
You create programs by using the `CREATE_PROGRAM` procedure or Cloud Control.
- [Defining Program Arguments](#)
After creating a program, you can define program arguments.

29.3.2.1 Creating Programs

You create programs by using the `CREATE_PROGRAM` procedure or Cloud Control.

By default, programs are created in the schema of the creator. To create a program in another user's schema, you must qualify the program name with the schema name. For other users to use your programs, they must have `EXECUTE` privileges on the program, therefore, once a program has been created, you must grant the `EXECUTE` privilege on it.

The following example creates a program called `my_program1`:

```
BEGIN
  DBMS_SCHEDULER.CREATE_PROGRAM (
    program_name      => 'my_program1',
    program_action    => '/usr/local/bin/date',
    program_type      => 'EXECUTABLE',
    comments          => 'My comments here');
END;
/
```

Programs are created in the disabled state by default; you must enable them before you can enable jobs that point to them.

Do not attempt to enable a program that requires arguments before you define all program arguments, which you must do in a `DEFINE_XXX_ARGUMENT` procedure as described in "[Defining Program Arguments](#)".

29.3.2.2 Defining Program Arguments

After creating a program, you can define program arguments.

You can define arguments by position in the calling sequence, with an optional argument name and optional default value. If no default value is defined for a program argument, the job that references the program must supply an argument value. (The job can also override a default value.) All argument values must be defined before the job can be enabled.

To set program argument values, use the `DEFINE_PROGRAM_ARGUMENT` or `DEFINE_ANYDATA_ARGUMENT` procedures. Use `DEFINE_ANYDATA_ARGUMENT` for complex types that must be encapsulated in an ANYDATA object. An example of a program that might need arguments is one that starts a reporting program that requires a start date and end date. The following code example sets the end date argument, which is the second argument expected by the reporting program. The example also assigns a name to the argument so that you can refer to the argument by name (instead of position) from other package procedures, including `SET_JOB_ANYDATA_VALUE` and `SET_JOB_ARGUMENT_VALUE`.

```
BEGIN
  DBMS_SCHEDULER.DEFINE_PROGRAM_ARGUMENT (
    program_name      => 'operations_reporting',
    argument_position => 2,
    argument_name     => 'end_date',
    argument_type     => 'VARCHAR2',
    default_value     => '12-DEC-03');
END;
/
```

Valid values for the `argument_type` argument must be SQL data types, therefore booleans are not supported. For external executables, only string types such as `CHAR` or `VARCHAR2` are permitted.

You can drop a program argument either by name or by position, as in the following:

```
BEGIN
  DBMS_SCHEDULER.DROP_PROGRAM_ARGUMENT (
    program_name      => 'operations_reporting',
    argument_position => 2);
```

```

DBMS_SCHEDULER.DROP_PROGRAM_ARGUMENT (
    program_name      => 'operations_reporting',
    argument_name     => 'end_date');
END;
/

```

In some special cases, program logic depends on the Scheduler environment. The Scheduler has some predefined metadata arguments that can be passed as an argument to the program for this purpose. For example, for some jobs whose schedule is a window name, it is useful to know how much longer the window will be open when the job is started. This is possible by defining the window end time as a metadata argument to the program.

If a program needs access to specific job metadata, you can define a special metadata argument using the `DEFINE_METADATA_ARGUMENT` procedure, so values will be filled in by the Scheduler when the program is executed.

See Also:

["Setting Job Arguments"](#)

29.3.3 Altering Programs

You alter a program by modifying its attributes. You can use Cloud Control or the `DBMS_SCHEDULER.SET_ATTRIBUTE` and `DBMS_SCHEDULER.SET_ATTRIBUTE_NULL` package procedures to alter programs.

See the `DBMS_SCHEDULER.CREATE_PROGRAM` procedure in *Oracle Database PL/SQL Packages and Types Reference* for details on program attributes.

If any currently running jobs use the program that you altered, they continue to run with the program as defined before the alter operation.

The following example changes the executable that program `my_program1` runs:

```

BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE (
        name      => 'my_program1',
        attribute => 'program_action',
        value     => '/usr/local/bin/salesreports1');
END;
/

```

29.3.4 Dropping Programs

You drop one or more programs using the `DROP_PROGRAM` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

When the program is dropped, any arguments that pertain to it are also dropped. You can drop several programs in one call by providing a comma-delimited list of program names. For example, the following statement drops three programs:

```

BEGIN
    DBMS_SCHEDULER.DROP_PROGRAM('program1, program2, program3');

```

```
END;  
/
```

Running jobs that point to the program are not affected by the `DROP_PROGRAM` call and are allowed to continue.

If you set the `force` argument to `TRUE`, jobs pointing to this program are disabled and the program is dropped. If you set the `force` argument to `FALSE`, the default, the call fails if there are any jobs pointing to the program.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DROP_PROGRAM` procedure.

29.3.5 Disabling Programs

You disable one or more programs using the `DISABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

When a program is disabled, the status is changed to disabled. A disabled program implies that, although the metadata is still there, jobs that point to this program cannot run.

The `DISABLE` call does not affect running jobs that point to the program and they are allowed to continue. Also, disabling the program does not affect any arguments that pertain to it.

A program can also be disabled by other means, for example, if a program argument is dropped or the `number_of_arguments` is changed so that no arguments are defined.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DISABLE` procedure.

29.3.6 Enabling Programs

You enable one or more programs using the `ENABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

When a program is enabled, the enabled flag is set to `TRUE`. Programs are created disabled by default, therefore, you have to enable them before you can enable jobs that point to them. Before programs are enabled, validity checks are performed to ensure that the action is valid and that all arguments are defined.

You can enable several programs in one call by providing a comma-delimited list of program names to the `ENABLE` procedure call. For example, the following statement enables three programs:

```
BEGIN  
    DBMS_SCHEDULER.ENABLE( 'program1, program2, program3' );  
END;  
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `ENABLE` procedure.

29.4 Creating and Managing Schedules to Define Jobs

You optionally use a schedule object (a schedule) to define when a job should be run. Schedules can be shared among users by creating and saving them as objects in the database.

- [Schedule Tasks and Their Procedures](#)

You use procedures in the `DBMS_SCHEDULER` package to administer common schedule tasks.

- [Creating Schedules](#)

You create schedules by using the `CREATE_SCHEDULE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

- [Altering Schedules](#)

You alter a schedule by using the `SET_ATTRIBUTE` and `SET_ATTRIBUTE_NULL` procedures in the `DBMS_SCHEDULER` package or Cloud Control.

- [Dropping Schedules](#)

You drop a schedule using the `DROP_SCHEDULE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

- [Setting the Repeat Interval](#)

You can control when and how often a job repeats.

 **See Also:**

- "[Schedules](#)" for an overview of schedules.
- "[Managing Job Scheduling and Job Priorities with Windows](#)" and "[Managing Job Scheduling and Job Priorities with Window Groups](#)" to schedule jobs while managing job resource usage

29.4.1 Schedule Tasks and Their Procedures

You use procedures in the `DBMS_SCHEDULER` package to administer common schedule tasks.

[Table 29-4](#) illustrates common schedule tasks and the procedures you use to handle them.

Table 29-4 Schedule Tasks and Their Procedures

Task	Procedure	Privilege Needed
Create a schedule	<code>CREATE_SCHEDULE</code>	<code>CREATE JOB</code> or <code>CREATE ANY JOB</code>
Alter a schedule	<code>SET_ATTRIBUTE</code>	<code>ALTER</code> or <code>CREATE ANY JOB</code> or be the owner
Drop a schedule	<code>DROP_SCHEDULE</code>	<code>ALTER</code> or <code>CREATE ANY JOB</code> or be the owner

See "[Scheduler Privileges](#)" for further information.

29.4.2 Creating Schedules

You create schedules by using the `CREATE_SCHEDULE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

Schedules are created in the schema of the user creating the schedule, and are enabled when first created. You can create a schedule in another user's schema. Once a schedule has been created, it can be used by other users. The schedule is created with access to `PUBLIC`. Therefore, there is no need to explicitly grant access to the schedule. The following example create a schedule:

```
BEGIN
  DBMS_SCHEDULER.CREATE_SCHEDULE (
    schedule_name      => 'my_stats_schedule',
    start_date        => SYSTIMESTAMP,
    end_date          => SYSTIMESTAMP + INTERVAL '30' day,
    repeat_interval   => 'FFREQ=HOURLY; INTERVAL=4',
    comments          => 'Every 4 hours');
END;
/
```

See Also:

- *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `CREATE_SCHEDULE` procedure.
- ["Creating an Event Schedule"](#)

29.4.3 Altering Schedules

You alter a schedule by using the `SET_ATTRIBUTE` and `SET_ATTRIBUTE_NULL` procedures in the `DBMS_SCHEDULER` package or Cloud Control.

Altering a schedule changes the definition of the schedule. With the exception of schedule name, all attributes can be changed. The attributes of a schedule are available in the `*_SCHEDULER_SCHEDULES` views.

If a schedule is altered, the change does not affect running jobs and open windows that use this schedule. The change goes into effect the next time the jobs runs or the window opens.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `SET_ATTRIBUTE` procedure.

29.4.4 Dropping Schedules

You drop a schedule using the `DROP_SCHEDULE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

This procedure call deletes the schedule object from the database.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DROP_SCHEDULE` procedure.

29.4.5 Setting the Repeat Interval

You can control when and how often a job repeats.

- [About Setting the Repeat Interval](#)

You control when and how often a job repeats by setting the `repeat_interval` attribute of the job itself or the named schedule that the job references. You can set `repeat_interval` with `DBMS_SCHEDULER` package procedures or with Cloud Control.

- [Using the Scheduler Calendaring Syntax](#)

The main way to set how often a job repeats is to set the `repeat_interval` attribute with a Scheduler calendaring expression.

- [Using a PL/SQL Expression](#)

When you need more complicated capabilities than the calendaring syntax provides, you can use PL/SQL expressions. You cannot, however, use PL/SQL expressions for windows or in named schedules. The PL/SQL expression must evaluate to a date or a timestamp.

- [Differences Between PL/SQL Expression and Calendaring Syntax Behavior](#)

There are important differences in behavior between a calendaring expression and PL/SQL repeat interval.

- [Repeat Intervals and Daylight Savings](#)

For repeating jobs, the next time a job is scheduled to run is stored in a timestamp with time zone column.

29.4.5.1 About Setting the Repeat Interval

You control when and how often a job repeats by setting the `repeat_interval` attribute of the job itself or the named schedule that the job references. You can set `repeat_interval` with `DBMS_SCHEDULER` package procedures or with Cloud Control.

Evaluating the `repeat_interval` results in a set of timestamps. The Scheduler runs the job at each timestamp. Note that the start date from the job or schedule also helps determine the resulting set of timestamps. If no value for `repeat_interval` is specified, the job runs only once at the specified start date.

Immediately after a job starts, the `repeat_interval` is evaluated to determine the next scheduled execution time of the job. While this might arrive while the job is still running, a new instance of the job does not start until the current one completes.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for more information about `repeat_interval` evaluation

29.4.5.2 Using the Scheduler Calendaring Syntax

The main way to set how often a job repeats is to set the `repeat_interval` attribute with a Scheduler calendaring expression.

See Also:

Oracle Database PL/SQL Packages and Types Reference for a detailed description of the calendaring syntax for `repeat_interval` as well as the `CREATE_SCHEDULE` procedure

Examples of Calendaring Expressions

The following examples illustrate simple repeat intervals. For simplicity, it is assumed that there is no contribution to the evaluation results by the start date.

Run every Friday. (All three examples are equivalent.)

```
FREQ=DAILY; BYDAY=FRI;  
FREQ=WEEKLY; BYDAY=FRI;  
FREQ=YEARLY; BYDAY=FRI;
```

Run every other Friday.

```
FREQ=WEEKLY; INTERVAL=2; BYDAY=FRI;
```

Run on the last day of every month.

```
FREQ=MONTHLY; BYMONTHDAY=-1;
```

Run on the next to last day of every month.

```
FREQ=MONTHLY; BYMONTHDAY=-2;
```

Run on March 10th. (Both examples are equivalent)

```
FREQ=YEARLY; BYMONTH=MAR; BYMONTHDAY=10;  
FREQ=YEARLY; BYDATE=0310;
```

Run every 10 days.

```
FREQ=DAILY; INTERVAL=10;
```

Run daily at 4, 5, and 6PM.

```
FREQ=DAILY; BYHOUR=16,17,18;
```

Run on the 15th day of every other month.

```
FREQ=MONTHLY; INTERVAL=2; BYMONTHDAY=15;
```

Run on the 29th day of every month.

```
FREQ=MONTHLY; BYMONTHDAY=29;
```

Run on the second Wednesday of each month.

```
FREQ=MONTHLY; BYDAY=2WED;
```

Run on the last Friday of the year.

```
FREQ=YEARLY; BYDAY=-1FRI;
```

Run every 50 hours.

```
FREQ=HOURLY; INTERVAL=50;
```

Run on the last day of every other month.

```
FREQ=MONTHLY; INTERVAL=2; BYMONTHDAY=-1;
```

Run hourly for the first three days of every month.

```
FREQ=HOURLY; BYMONTHDAY=1,2,3;
```

Here are some more complex repeat intervals:

Run on the last workday of every month (assuming that workdays are Monday through Friday).

```
FREQ=MONTHLY; BYDAY=MON,TUE,WED,THU,FRI; BYSETPOS=-1
```

Run on the last workday of every month, excluding company holidays. (This example references an existing named schedule called `Company_Holidays`.)

```
FREQ=MONTHLY; BYDAY=MON,TUE,WED,THU,FRI; EXCLUDE=Company_Holidays; BYSETPOS=-1
```

Run at noon every Friday and on company holidays.

```
FREQ=YEARLY;BYDAY=FRI;BYHOUR=12;INCLUDE=Company_Holidays
```

Run on these three holidays: July 4th, Memorial Day, and Labor Day. (This example references three existing named schedules, `JUL4`, `MEM`, and `LAB`, where each defines a single date corresponding to a holiday.)

```
JUL4, MEM, LAB
```

Examples of Calendaring Expression Evaluation

A repeat interval of "FREQ=MINUTELY; INTERVAL=2; BYHOUR=17; BYMINUTE=2,4,5,50,51,7;" with a start date of 28-FEB-2004 23:00:00 will generate the following schedule:

```
SUN 29-FEB-2004 17:02:00
SUN 29-FEB-2004 17:04:00
SUN 29-FEB-2004 17:50:00
MON 01-MAR-2004 17:02:00
MON 01-MAR-2004 17:04:00
MON 01-MAR-2004 17:50:00
...

```

A repeat interval of "FREQ=MONTHLY; BYMONTHDAY=15,-1" with a start date of 29-DEC-2003 9:00:00 will generate the following schedule:

```
WED 31-DEC-2003 09:00:00
THU 15-JAN-2004 09:00:00
SAT 31-JAN-2004 09:00:00
SUN 15-FEB-2004 09:00:00
SUN 29-FEB-2004 09:00:00
```

```
MON 15-MAR-2004 09:00:00
WED 31-MAR-2004 09:00:00
...
```

A repeat interval of "FREQ=MONTHLY;" with a start date of 29-DEC-2003 9:00:00 will generate the following schedule. (Note that because there is no BYMONTHDAY clause, the day of month is retrieved from the start date.)

```
MON 29-DEC-2003 09:00:00
THU 29-JAN-2004 09:00:00
SUN 29-FEB-2004 09:00:00
MON 29-MAR-2004 09:00:00
...
```

Example of Using a Calendaring Expression

As an example of using the calendaring syntax, consider the following statement:

```
BEGIN
    DBMS_SCHEDULER.CREATE_JOB (
        job_name          => 'scott.my_job1',
        start_date        => '15-JUL-04 01.00.00 AM Europe/Warsaw',
        repeat_interval   => 'FREQ=MINUTELY; INTERVAL=30;',
        end_date          => '15-SEP-04 01.00.00 AM Europe/Warsaw',
        comments          => 'My comments here');
END;
/
```

This creates `my_job1` in `scott`. It will run for the first time on July 15th and then run until September 15. The job is run every 30 minutes.

29.4.5.3 Using a PL/SQL Expression

When you need more complicated capabilities than the calendaring syntax provides, you can use PL/SQL expressions. You cannot, however, use PL/SQL expressions for windows or in named schedules. The PL/SQL expression must evaluate to a date or a timestamp.

Other than this restriction, there are no limitations, so with sufficient programming, you can create every possible repeat interval. As an example, consider the following statement:

```
BEGIN
    DBMS_SCHEDULER.CREATE_JOB (
        job_name          => 'scott.my_job2',
        start_date        => '15-JUL-04 01.00.00 AM Europe/Warsaw',
        repeat_interval   => 'SYSTIMESTAMP + INTERVAL '30' MINUTE',
        end_date          => '15-SEP-04 01.00.00 AM Europe/Warsaw',
        comments          => 'My comments here');
END;
/
```

This creates `my_job2` in `scott`. It will run for the first time on July 15th and then every 30 minutes until September 15. The job is run every 30 minutes because `repeat_interval` is set to `SYSTIMESTAMP + INTERVAL '30' MINUTE`, which returns a date 30 minutes into the future.

29.4.5.4 Differences Between PL/SQL Expression and Calendaring Syntax Behavior

There are important differences in behavior between a calendaring expression and PL/SQL repeat interval.

These differences include the following:

- Start date
 - Using the calendaring syntax, the start date is a reference date only. Therefore, the schedule is valid as of this date. It does not mean that the job will start on the start date.
 - Using a PL/SQL expression, the start date represents the actual time that the job will start executing for the first time.
- Next run time
 - Using the calendaring syntax, the next time the job runs is fixed.
 - Using the PL/SQL expression, the next time the job runs depends on the actual start time of the current job run.

As an example of the difference, for a job that is scheduled to start at 2:00 PM and repeat every 2 hours, but actually starts at 2:10:

- If calendaring syntax specified the repeat interval, then it would repeat at 4, 6 and so on.
- If a PL/SQL expression is used, then the job would repeat at 4:10, and if the next job actually started at 4:11, then the subsequent run would be at 6:11.

To illustrate these two points, consider a situation where you have a start date of 15-July-2003 1:45:00 and you want it to repeat every two hours. A calendar expression of "FREQ=HOURLY; INTERVAL=2; BYMINUTE=0;" will generate the following schedule:

```
TUE 15-JUL-2003 03:00:00
TUE 15-JUL-2003 05:00:00
TUE 15-JUL-2003 07:00:00
TUE 15-JUL-2003 09:00:00
TUE 15-JUL-2003 11:00:00
...

```

Note that the calendar expression repeats every two hours on the hour.

A PL/SQL expression of "SYSTIMESTAMP + interval '2' hour", however, might have a run time of the following:

```
TUE 15-JUL-2003 01:45:00
TUE 15-JUL-2003 03:45:05
TUE 15-JUL-2003 05:45:09
TUE 15-JUL-2003 07:45:14
TUE 15-JUL-2003 09:45:20
...

```

29.4.5.5 Repeat Intervals and Daylight Savings

For repeating jobs, the next time a job is scheduled to run is stored in a timestamp with time zone column.

- Using the calendaring syntax, the time zone is retrieved from `start_date`. For more information on what happens when `start_date` is not specified, see *Oracle Database PL/SQL Packages and Types Reference*.
- Using PL/SQL repeat intervals, the time zone is part of the timestamp that the PL/SQL expression returns.

In both cases, it is important to use region names. For example, use "Europe/Istanbul", instead of absolute time zone offsets such as "+2:00". The Scheduler follows daylight savings adjustments that apply to that region only when a time zone is specified as a region name.

29.5 Using Events to Start Jobs

Oracle Scheduler can start a job when an event is sent. An event is a message one application or system process sends to another.

- [About Events](#)

An **event** is a message one application or system process sends to another to indicate that some action or occurrence has been detected. An event is **raised** (sent) by one application or process, and **consumed** (received) by one or more applications or processes.

- [Starting Jobs with Events Raised by Your Application](#)

Oracle Scheduler can start a job when an event is raised by your application.

- [Starting a Job When a File Arrives on a System](#)

You can configure the Scheduler to start a job when a file arrives on the local system or a remote system. The job is an event-based job, and the file arrival event is raised by a file watcher, which is a Scheduler object introduced in Oracle Database 11g Release 2 (11.2).

 **See Also:**

- "[Examples of Creating Jobs and Schedules Based on Events](#)"
- "[Creating and Managing Job Chains](#)" for information about using events with chains to achieve precise control over process flow

29.5.1 About Events

An **event** is a message one application or system process sends to another to indicate that some action or occurrence has been detected. An event is **raised** (sent) by one application or process, and **consumed** (received) by one or more applications or processes.

The Scheduler consumes two kinds of events:

- Events that your application raises

An application can raise an event to be consumed by the Scheduler. The Scheduler reacts to the event by starting a job. For example, when an inventory tracking system notices that the inventory has gone below a certain threshold, it can raise an event that starts an inventory replenishment job.

See "Starting Jobs with Events Raised by Your Application".

- File arrival events that a file watcher raises

You can create a file watcher, a Scheduler object introduced in Oracle Database 11g Release 2 (11.2), to watch for the arrival of a file on a system. You can then configure a job to start when the file watcher detects the presence of the file. For example, a data warehouse for a chain of stores loads data from end-of-day revenue reports which are uploaded from the stores. The data warehouse load job starts each time a new end-of-day report arrives.

See "Starting a Job When a File Arrives on a System"

See Also:

"[Monitoring Job State with Events Raised by the Scheduler](#)" for information about how your application can consume job state change events raised by the Scheduler

29.5.2 Starting Jobs with Events Raised by Your Application

Oracle Scheduler can start a job when an event is raised by your application.

- [About Events Raised by Your Application](#)
Your application can raise an event to notify the Scheduler to start a job. A job started in this way is referred to as an event-based job.
- [Creating an Event-Based Job](#)
You use the `CREATE_JOB` procedure or Cloud Control to create an event-based job. The job can include event information inline as job attributes or can specify event information by pointing to an event schedule. Like jobs based on time schedules, event-based jobs are not auto-dropped unless the job end date passes, `max_runs` is reached, or the maximum number of failures (`max_failures`) is reached.
- [Altering an Event-Based Job](#)
You alter an event-based job by using the `SET_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package.
- [Creating an Event Schedule](#)
You can create a schedule that is based on an event. You can then reuse the schedule for multiple jobs. To do so, use the `CREATE_EVENT_SCHEDULE` procedure, or use Cloud Control.
- [Altering an Event Schedule](#)
You alter the event information in an event schedule in the same way that you alter event information in a job.
- [Passing Event Messages into an Event-Based Job](#)
Through a metadata argument, the Scheduler can pass the message content of the event to the event-based job that started the job.

29.5.2.1 About Events Raised by Your Application

Your application can raise an event to notify the Scheduler to start a job. A job started in this way is referred to as an event-based job.

You can create a named schedule that references an event instead of containing date, time, and recurrence information. If a job is given such a schedule (an **event schedule**), the job runs when the event is raised.

To raise an event to notify the Scheduler to start a job, your application enqueues a message onto an Oracle Database Advanced Queuing queue that was specified when setting up the job. When the job starts, it can optionally retrieve the message content of the event.

To create an event-based job, you must set these two additional attributes:

- `queue_spec`

A queue specification that includes the name of the queue where your application enqueues messages to raise job start events, or in the case of a secure queue, the queue name followed by a comma and the agent name.

- `event_condition`

A conditional expression based on message properties that must evaluate to TRUE for the message to start the job. The expression must have the syntax of an Oracle Database Advanced Queuing rule. Accordingly, you can include user data properties in the expression, provided that the message payload is an object type, and that you prefix object attributes in the expression with `tab.user_data`.

See Also:

- `DBMS_AQADM.ADD_SUBSCRIBER` procedure in *Oracle Database PL/SQL Packages and Types Reference* for more information on queueing rules
- *Oracle Database Advanced Queuing User's Guide* for more information on how to create queues
- *Oracle Database Advanced Queuing User's Guide* for more information on how to enqueue messages

The following example sets `event_condition` to select only low-inventory events that occur after midnight and before 9:00 a.m. Assume that the message payload is an object with two attributes called `event_type` and `event_timestamp`.

```
event_condition = 'tab.user_data.event_type = ''LOW_INVENTORY'' and extract hour from tab.user_data.event_timestamp < 9'
```

You can specify `queue_spec` and `event_condition` as inline job attributes, or you can create an **event schedule** with these attributes and point to this schedule from the job.

Note:

The Scheduler runs the event-based job for each occurrence of an event that matches `event_condition`. However, by default, events that occur while the job is already running are ignored; the event gets consumed, but does not trigger another run of the job. Beginning in Oracle Database 11g Release 1 (11.1), you can change this default behavior by setting the job attribute `PARALLEL_INSTANCES` to TRUE. In this case, an instance of the job is started for every instance of the event, and all job instances are lightweight jobs. See the `SET_ATTRIBUTE` procedure in *Oracle Database PL/SQL Packages and Types Reference* for details.

Table 29-5 describes common administration tasks involving events raised by an application (and consumed by the Scheduler) and the procedures associated with them.

Table 29-5 Event Tasks and Their Procedures for Events Raised by an Application

Task	Procedure	Privilege Needed
Creating an Event-Based Job	<code>CREATE_JOB</code>	<code>CREATE JOB</code> or <code>CREATE ANY JOB</code>
Altering an Event-Based Job	<code>SET_ATTRIBUTE</code>	<code>CREATE ANY JOB</code> or ownership of the job being altered or <code>ALTER</code> privileges on the job
Creating an Event Schedule	<code>CREATE_EVENT_SCHEDULE</code>	<code>CREATE JOB</code> or <code>CREATE ANY JOB</code>
Altering an Event Schedule	<code>SET_ATTRIBUTE</code>	<code>CREATE ANY JOB</code> or ownership of the schedule being altered or <code>ALTER</code> privileges on the schedule

29.5.2.2 Creating an Event-Based Job

You use the `CREATE_JOB` procedure or Cloud Control to create an event-based job. The job can include event information inline as job attributes or can specify event information by pointing to an event schedule. Like jobs based on time schedules, event-based jobs are not auto-dropped unless the job end date passes, `max_runs` is reached, or the maximum number of failures (`max_failures`) is reached.

- [Specifying Event Information as Job Attributes](#)
To specify event information as job attributes, you use an alternate syntax of `CREATE_JOB` that includes the `queue_spec` and `event_condition` attributes.
- [Specifying Event Information in an Event Schedule](#)
To specify event information with an event schedule, you set the `schedule_name` attribute of the job to the name of an event schedule.

29.5.2.2.1 Specifying Event Information as Job Attributes

To specify event information as job attributes, you use an alternate syntax of `CREATE_JOB` that includes the `queue_spec` and `event_condition` attributes.

The following example creates a job that starts when an application signals to the Scheduler that inventory levels for an item have fallen to a low threshold level:

```
BEGIN
DBMS_SCHEDULER.CREATE_JOB (
    job_name          => 'process_lowinv_j1',
    program_name      => 'process_lowinv_p1',
    event_condition   => 'tab.user_data.event_type = ''LOW_INVENTORY'''',
    queue_spec        => 'inv_events_q, inv_agent1',
    enabled           => TRUE,
    comments          => 'Start an inventory replenishment job');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for more information regarding the `CREATE_JOB` procedure.

29.5.2.2.2 Specifying Event Information in an Event Schedule

To specify event information with an event schedule, you set the `schedule_name` attribute of the job to the name of an event schedule.

The following example specifies event information in an event schedule:

```
BEGIN
DBMS_SCHEDULER.CREATE_JOB (
    job_name          => 'process_lowinv_j1',
    program_name      => 'process_lowinv_p1',
    schedule_name     => 'inventory_events_schedule',
    enabled           => TRUE,
    comments          => 'Start an inventory replenishment job');
END;
/
```

See "[Creating an Event Schedule](#)" for more information.

29.5.2.3 Altering an Event-Based Job

You alter an event-based job by using the `SET_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package.

For jobs that specify the event inline, you cannot set the `queue_spec` and `event_condition` attributes individually with `SET_ATTRIBUTE`. Instead, you must set an attribute called `event_spec`, and pass an event condition and queue specification as the third and fourth arguments, respectively, to `SET_ATTRIBUTE`.

The following example uses the `event_spec` attribute:

```
BEGIN
DBMS_SCHEDULER.SET_ATTRIBUTE ('my_job', 'event_spec',
    'tab.user_data.event_type = ''LOW_INVENTORY'''', 'inv_events_q, inv_agent1');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for more information regarding the `SET_ATTRIBUTE` procedure.

29.5.2.4 Creating an Event Schedule

You can create a schedule that is based on an event. You can then reuse the schedule for multiple jobs. To do so, use the `CREATE_EVENT_SCHEDULE` procedure, or use Cloud Control.

The following example creates an event schedule:

```
BEGIN
    DBMS_SCHEDULER.CREATE_EVENT_SCHEDULE (
        schedule_name      => 'inventory_events_schedule',
        start_date         => SYSTIMESTAMP,
        event_condition   => 'tab.user_data.event_type = ''LOW_INVENTORY'''',
        queue_spec         => 'inv_events_q, inv_agent1');
END;
/
```

You can drop an event schedule using the `DROP_SCHEDULE` procedure. See *Oracle Database PL/SQL Packages and Types Reference* for more information on `CREATE_EVENT_SCHEDULE`.

29.5.2.5 Altering an Event Schedule

You alter the event information in an event schedule in the same way that you alter event information in a job.

For more information, see "[Altering an Event-Based Job](#)".

The following example demonstrates how to use the `SET_ATTRIBUTE` procedure and the `event_spec` attribute to alter event information in an event schedule.

```
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE ('inventory_events_schedule', 'event_spec',
        'tab.user_data.event_type = ''LOW_INVENTORY'''', 'inv_events_q, inv_agent1');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for more information regarding the `SET_ATTRIBUTE` procedure.

29.5.2.6 Passing Event Messages into an Event-Based Job

Through a metadata argument, the Scheduler can pass the message content of the event to the event-based job that started the job.

The following rules apply:

- The job must use a named program of type `STORED_PROCEDURE`.
- One of the named program arguments must be a metadata argument with `metadata_attribute` set to `EVENT_MESSAGE`.
- The stored procedure that implements the program must have an argument at the position corresponding to the metadata argument of the named program. The argument type must be the data type of the queue where your application queues the job-start event.

If you use the `RUN_JOB` procedure to manually run a job that has an `EVENT_MESSAGE` metadata argument, the value passed to that argument is `NULL`.

The following example shows how to construct an event-based job that can receive the event message content:

```
CREATE OR REPLACE PROCEDURE my_stored_proc (event_msg IN event_queue_type)
AS
BEGIN
    -- retrieve and process message body
END;
/

BEGIN
    DBMS_SCHEDULER.CREATE_PROGRAM (
        program_name => 'my_prog',
        program_action=> 'my_stored_proc',
        program_type => 'STORED_PROCEDURE',
        number_of_arguments => 1,
        enabled => FALSE) ;

    DBMS_SCHEDULER.DEFINE_METADATA_ARGUMENT (
        program_name => 'my_prog',
        argument_position => 1 ,
        metadata_attribute => 'EVENT_MESSAGE') ;

    DBMS_SCHEDULER.ENABLE ('my_prog');
EXCEPTION
    WHEN others THEN RAISE ;
END ;
/

BEGIN
    DBMS_SCHEDULER.CREATE_JOB (
        job_name => 'my_evt_job' ,
        program_name => 'my_prog',
        schedule_name => 'my_evt_sch',
        enabled => true,
        auto_Drop => false) ;
EXCEPTION
    WHEN others THEN RAISE ;
END ;
/
```

29.5.3 Starting a Job When a File Arrives on a System

You can configure the Scheduler to start a job when a file arrives on the local system or a remote system. The job is an event-based job, and the file arrival event is raised by a file watcher, which is a Scheduler object introduced in Oracle Database 11g Release 2 (11.2).

- [About File Watchers](#)

A **file watcher** is a Scheduler object that defines the location, name, and other properties of a file whose arrival on a system causes the Scheduler to start a job.

- [Enabling File Arrival Events from Remote Systems](#)

To receive file arrival events from a remote system, you must install the Scheduler agent on that system, and you must register the agent with the database.

- [Creating File Watchers and File Watcher Jobs](#)
You complete several steps to create a file watcher and a file watch job.
- [File Arrival Example](#)
An example illustrates file arrival for a file watcher job.
- [Managing File Watchers](#)
The DBMS_SCHEDULER PL/SQL package provides procedures for enabling, disabling, dropping, and setting attributes for file watchers.
- [Viewing File Watcher Information](#)
You can view information about file watchers by querying the views *_SCHEDULER_FILE_WATCHERS.

29.5.3.1 About File Watchers

A **file watcher** is a Scheduler object that defines the location, name, and other properties of a file whose arrival on a system causes the Scheduler to start a job.

You create a file watcher and then create any number of event-based jobs or event schedules that reference the file watcher. When the file watcher detects the arrival of the designated file, a newly arrived file, it raises a file arrival event.

A newly arrived file is a file that has been changed and therefore has a timestamp that is later than either the latest execution or the time that the file watcher job began monitoring the target file directory.

The way the file watcher determines whether a file is a newly arrived one or not is equivalent to repeatedly executing the Unix command `ls -lrt` or the Windows DOS command `dir /od` to watch for new files in a directory. Both these commands ensure that the recently modified file is listed at the end, that is the oldest first and the newest last.

Note:

The following behaviors:

The UNIX `mv` command does not change the file modification time, while the `cp` command does.

The Windows `move/paste` and `copy/paste` commands do not change the file modification time. To do this, execute the following DOS command after the `move` or `copy` command: `copy /b file_name +,,`

The `steady_state_duration` parameter of the `CREATE_FILE_WATCHER` procedure, described in *Oracle Database PL/SQL Packages and Types Reference*, indicates the minimum time interval that the file must remain unchanged before the file watcher considers the file found. This cannot exceed one hour. If the parameter is `NULL`, an internal value is used.

The job started by the file arrival event can retrieve the event message to learn about the newly arrived file. The message contains the information required to find the file, open it, and process it.

A file watcher can watch for a file on the local system (the same host computer running Oracle Database) or a remote system. Remote systems must be running the Scheduler agent, and the agent must be registered with the database.

File watchers check for the arrival of files every 10 minutes. You can adjust this interval. See "[Changing the File Arrival Detection Interval](#)" for details.

To use file watchers, the database Java virtual machine (JVM) component must be installed.

You must have the `CREATE JOB` system privilege to create a file watcher in your own schema. You require the `CREATE ANY JOB` system privilege to create a file watcher in a schema different from your own (except the `SYS` schema, which is disallowed). You can grant the `EXECUTE` object privilege on a file watcher so that jobs in different schemas can reference it. You can also grant the `ALTER` object privilege on a file watcher so that another user can modify it.

29.5.3.2 Enabling File Arrival Events from Remote Systems

To receive file arrival events from a remote system, you must install the Scheduler agent on that system, and you must register the agent with the database.

The remote system does not require a running Oracle Database instance to generate file arrival events.

To enable the raising of file arrival events at remote systems:

1. Set up the local database to run remote external jobs.
See "[Enabling and Disabling Databases for Remote Jobs](#)" for instructions.
2. Install, configure, register, and start the Scheduler agent on the first remote system.

See "[Installing and Configuring the Scheduler Agent on a Remote Host](#)" for instructions.

This adds the remote host to the list of external destinations maintained on the local database.

3. Repeat the previous step for each additional remote system.

29.5.3.3 Creating File Watchers and File Watcher Jobs

You complete several steps to create a file watcher and a file watch job.

You perform the following tasks to create a file watcher and create the event-based job that starts when the designated file arrives.

Task 1 - Create a Credential

The file watcher requires a credential object (a credential) with which to authenticate with the host operating system for access to the file. See "[Credentials](#)" for information on privileges required to create credentials.

Perform these steps:

1. Create a credential for the operating system user that must have access to the watched-for file.

```
BEGIN
  DBMS_CREDENTIAL.CREATE_CREDENTIAL('WATCH_CREDENTIAL', 'salesapps',
    'sa324w1');
END;
/
```

2. Grant the EXECUTE object privilege on the credential to the schema that owns the event-based job that the file watcher will start.

```
GRANT EXECUTE ON WATCH_CREDENTIAL TO DSSUSER;
```

Task 2 - Create a File Watcher

Perform these steps:

1. Create the file watcher, assigning attributes as described in the DBMS_SCHEDULER.CREATE_FILE_WATCHER procedure documentation in *Oracle Database PL/SQL Packages and Types Reference*. You can specify wildcard parameters in the file name. A '?' prefix in the DIRECTORY_PATH attribute denotes the path to the Oracle home directory. A NULL destination indicates the local host. To watch for the file on a remote host, provide a valid external destination name, which you can obtain from the view ALL_SCHEDULER_EXTERNAL_DESTS.

```
BEGIN
  DBMS_SCHEDULER.CREATE_FILE_WATCHER(
    file_watcher_name => 'EOD_FILE_WATCHER',
    directory_path    => '?/eod_reports',
    file_name         => 'eod*.txt',
    credential_name   => 'watch_credential',
    destination       => NULL,
    enabled           => FALSE);
END;
/
```

2. Grant EXECUTE on the file watcher to any schema that owns an event-based job that references the file watcher.

```
GRANT EXECUTE ON EOD_FILE_WATCHER TO dssuser;
```

Task 3 - Create a Program Object with a Metadata Argument

So that your application can retrieve the file arrival event message content, which includes file name, file size, and so on, create a Scheduler program object with a metadata argument that references the event message.

Perform these steps:

1. Create the program.

```
BEGIN
  DBMS_SCHEDULER.CREATE_PROGRAM(
    program_name        => 'dssuser.eod_program',
    program_type        => 'stored_procedure',
    program_action      => 'eod_processor',
    number_of_arguments => 1,
    enabled             => FALSE);
END;
/
```

2. Define the metadata argument using the event_message attribute.

```
BEGIN
  DBMS_SCHEDULER.DEFINE_METADATA_ARGUMENT(
```

```
program_name      => 'DSSUSER.EOD_PROGRAM',
metadata_attribute => 'event_message',
argument_position  => 1);
END;
/
```

3. Create the stored procedure that the program invokes.

The stored procedure that processes the file arrival event must have an argument of type `SYS.SCHEDULER_FILEWATCHER_RESULT`, which is the data type of the event message. The position of that argument must match the position of the defined metadata argument. The procedure can then access attributes of this abstract data type to learn about the arrived file.

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference* for a description of the `DEFINE_METADATA_ARGUMENT` procedure
- *Oracle Database PL/SQL Packages and Types Reference* for a description of the `SYS.SCHEDULER_FILEWATCHER_RESULT` type

Task 4 - Create an Event-Based Job That References the File Watcher

Create the event-based job as described in "[Creating an Event-Based Job](#)", with the following exception: instead of providing a queue specification in the `queue_spec` attribute, provide the name of the file watcher. You would typically leave the `event_condition` job attribute null, but you can provide a condition if desired.

As an alternative to setting the `queue_spec` attribute for the job, you can create an event schedule, reference the file watcher in the `queue_spec` attribute of the event schedule, and reference the event schedule in the `schedule_name` attribute of the job. Perform these steps to prepare the event-based job:

1. Create the job.

```
BEGIN
DBMS_SCHEDULER.CREATE_JOB(
    job_name      => 'dssuser.eod_job',
    program_name   => 'dssuser.eod_program',
    event_condition => NULL,
    queue_spec     => 'eod_file_watcher',
    auto_drop      => FALSE,
    enabled        => FALSE);
END;
/
```

2. If you want the job to run for each instance of the file arrival event, even if the job is already processing a previous event, set the `parallel_instances` attribute to TRUE. With this setting, the job runs as a lightweight job so that multiple instances of the job can be started quickly. To discard file watcher events that occur while the event-based job is already processing another, leave the `parallel_instances` attribute FALSE (the default).

```
BEGIN
DBMS_SCHEDULER.SET_ATTRIBUTE('dssuser.eod_job', 'parallel_instances', TRUE);
```

```
END;
/
```

For more information about this attribute, see the `SET_ATTRIBUTE` description in *Oracle Database PL/SQL Packages and Types Reference*.

See Also:

- ["Creating an Event Schedule"](#)
- ["Creating Jobs Using Named Programs and Schedules"](#)

Task 5 - Enable All Objects

Enable the file watcher, the program, and the job.

```
BEGIN
    DBMS_SCHEDULER.ENABLE( 'DSSUSER.EOD_PROGRAM,DSSUSER.EOD_JOB,EOD_FILE_WATCHER' );
END;
/
```

29.5.3.4 File Arrival Example

An example illustrates file arrival for a file watcher job.

In this example, an event-based job watches for the arrival of end-of-day sales reports onto the local host from various locations. As each report file arrives, a stored procedure captures information about the file and stores the information in a table called `eod_reports`. A regularly scheduled report aggregation job can then query this table, process all unprocessed files, and mark any newly processed files as processed.

It is assumed that the database user running the following code has been granted `EXECUTE` on the `SYS.SCHEDULER_FILEWATCHER_RESULT` data type.

```
BEGIN
    DBMS_CREDENTIAL.CREATE_CREDENTIAL(
        credential_name => 'watch_credential',
        username         => 'pos1',
        password         => 'jk4545st');
END;
/

CREATE TABLE eod_reports (WHEN timestamp, file_name varchar2(100),
    file_size number, processed char(1));

CREATE OR REPLACE PROCEDURE q_eod_report
    (payload IN sys.scheduler_filewatcher_result) AS
BEGIN
    INSERT INTO eod_reports VALUES
        (payload.file_timestamp,
        payload.directory_path || '/' || payload.actual_file_name,
        payload.file_size,
        'N');
END;
/

BEGIN
```

```
DBMS_SCHEDULER.CREATE_PROGRAM(
    program_name      => 'eod_prog',
    program_type      => 'stored_procedure',
    program_action    => 'q_eod_report',
    number_of_arguments => 1,
    enabled           => FALSE);
DBMS_SCHEDULER.DEFINE_METADATA_ARGUMENT(
    program_name      => 'eod_prog',
    metadata_attribute => 'event_message',
    argument_position  => 1);
DBMS_SCHEDULER.ENABLE('eod_prog');
END;
/

BEGIN
    DBMS_SCHEDULER.CREATE_FILE_WATCHER(
        file_watcher_name => 'eod_reports_watcher',
        directory_path     => '?/eod_reports',
        file_name          => 'eod*.txt',
        credential_name    => 'watch_credential',
        destination        => NULL,
        enabled            => FALSE);
END;
/

BEGIN
    DBMS_SCHEDULER.CREATE_JOB(
        job_name          => 'eod_job',
        program_name       => 'eod_prog',
        event_condition   => 'tab.user_data.file_size > 10',
        queue_spec         => 'eod_reports_watcher',
        auto_drop          => FALSE,
        enabled            => FALSE);
    DBMS_SCHEDULER.SET_ATTRIBUTE('EOD_JOB', 'PARALLEL_INSTANCES', TRUE);
END;
/
EXEC DBMS_SCHEDULER.ENABLE('eod_reports_watcher', eod_job');
```

29.5.3.5 Managing File Watchers

The DBMS_SCHEDULER PL/SQL package provides procedures for enabling, disabling, dropping, and setting attributes for file watchers.

- **Enabling File Watchers**

If a file watcher is disabled, then use DBMS_SCHEDULER.ENABLE to enable it.

- **Altering File Watchers**

Use the DBMS_SCHEDULER.SET_ATTRIBUTE and DBMS_SCHEDULER.SET_ATTRIBUTE_NULL package procedures to modify the attributes of a file watcher.

- **Disabling and Dropping File Watchers**

Use the DBMS_SCHEDULER.DISABLE procedure to disable a file watcher and the DBMS_SCHEDULER.DROP_FILE_WATCHER procedure to drop a file watcher.

- **Changing the File Arrival Detection Interval**

File watchers check for the arrival of files every ten minutes by default. You can change this interval.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_SCHEDULER PL/SQL package

29.5.3.5.1 Enabling File Watchers

If a file watcher is disabled, then use DBMS_SCHEDULER.ENABLE to enable it.

This is shown in [Task 5, - Enable All Objects](#).

You can enable a file watcher only if all of its attributes are set to legal values and the file watcher owner has EXECUTE privileges on the specified credential.

29.5.3.5.2 Altering File Watchers

Use the DBMS_SCHEDULER.SET_ATTRIBUTE and DBMS_SCHEDULER.SET_ATTRIBUTE_NULL package procedures to modify the attributes of a file watcher.

See the CREATE_FILE_WATCHER procedure description for information about file watcher attributes.

29.5.3.5.3 Disabling and Dropping File Watchers

Use the DBMS_SCHEDULER.DISABLE procedure to disable a file watcher and the DBMS_SCHEDULER.DROP_FILE_WATCHER procedure to drop a file watcher.

You cannot disable or drop a file watcher if there are jobs that depend on it. To force a disable or drop operation in this case, set the FORCE attribute to TRUE. If you force disabling or dropping a file watcher, jobs that depend on it become disabled.

29.5.3.5.4 Changing the File Arrival Detection Interval

File watchers check for the arrival of files every ten minutes by default. You can change this interval.

To change the file arrival detection interval:

1. Connect to the database as the SYS user.
2. Change the REPEAT_INTERVAL attribute of the predefined schedule SYS.FILE_WATCHER_SCHEDULE. Use any valid calendaring syntax.

Oracle does not recommend setting REPEAT_INTERVAL for file watchers to a value lower than any of the STEADY_STATE_DURATION attribute values.

 **See Also:**

- *Oracle Database PL/SQL Packages and Types Reference* for File Watcher attribute values
- *Oracle Database PL/SQL Packages and Types Reference* for CREATE_FILE_WATCHER parameters

The following example changes the file arrival detection frequency to every two minutes.

```
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE('FILE_WATCHER_SCHEDULE', 'REPEAT_INTERVAL',
        'FREQ=MINUTELY;INTERVAL=2');
END;
/
```

29.5.3.6 Viewing File Watcher Information

You can view information about file watchers by querying the views *_SCHEDULER_FILE_WATCHERS.

For example, run the following query:

```
SELECT file_watcher_name, destination, directory_path, file_name, credential_name
  FROM dba_scheduler_file_watchers;
```

FILE_WATCHER_NAME	DESTINATION	DIRECTORY_PATH	FILE_NAME	CREDENTIAL_NAME
MYFW	dsshost.example.com	/tmp	abc	MYFW_CRED
EOD_FILE_WATCHER		?/eod_reports	eod*.txt	WATCH_CREDENTIAL

 **See Also:**

Oracle Database Reference for details on the *_SCHEDULER_FILE_WATCHERS views

29.6 Creating and Managing Job Chains

A job chain is a named series of tasks that are linked together for a combined objective.

- [About Creating and Managing Job Chains](#)
Using job chains, you can implement dependency-based scheduling, in which jobs start depending on the outcomes of one or more previous jobs.
- [Chain Tasks and Their Procedures](#)
You use procedures in the DBMS_SCHEDULER package to administer common chain tasks.

- **Creating Chains**
You create a chain by using the `CREATE_CHAIN` procedure in the `DBMS_SCHEDULER` package.
- **Defining Chain Steps**
After creating a chain object, you define one or more chain steps.
- **Adding Rules to a Chain**
You add a rule to a chain with the `DEFINE_CHAIN_RULE` procedure in the `DBMS_SCHEDULER` package. You call this procedure once for each rule that you want to add to the chain.
- **Setting an Evaluation Interval for Chain Rules**
The Scheduler evaluates all chain rules at the start of the chain job and at the end of each chain step.
- **Enabling Chains**
You enable a chain with the `ENABLE` procedure in the `DBMS_SCHEDULER` package. A chain must be enabled before it can be run by a job. Enabling an already enabled chain does not return an error.
- **Creating Jobs for Chains**
To run a chain, you must either use the `RUN_CHAIN` procedure in the `DBMS_SCHEDULER` package or create and schedule a job of type 'CHAIN' (a **chain job**).
- **Dropping Chains**
You drop a chain, including its steps and rules, using the `DROP_CHAIN` procedure in the `DBMS_SCHEDULER` package.
- **Running Chains**
To run a chain immediately, use the `RUN_JOB` or `RUN_CHAIN` procedure in the `DBMS_SCHEDULER` package.
- **Dropping Chain Rules**
You drop a rule from a chain by using the `DROP_CHAIN_RULE` procedure in the `DBMS_SCHEDULER` package.
- **Disabling Chains**
You disable a chain using the `DISABLE` procedure in the `DBMS_SCHEDULER` package.
- **Dropping Chain Steps**
You drop a step from a chain using the `DROP_CHAIN_STEP` procedure in the `DBMS_SCHEDULER` package.
- **Stopping Chains**
To stop a running chain, you call the `DBMS_SCHEDULER.STOP_JOB` procedure, passing the name of the chain job (the job that started the chain).
- **Stopping Individual Chain Steps**
You can stop individual chain steps by creating a chain rule that stops one or more steps when the rule condition is met or by calling the `STOP_JOB` procedure.
- **Pausing Chains**
You can pause an entire chain or individual branches of a chain. You do so by setting the `PAUSE` attribute of one or more steps to `TRUE` with the `DBMS_SCHEDULER.ALTER_CHAIN` or `ALTER_RUNNING_CHAIN` procedure.

- [Skipping Chain Steps](#)
You can skip one or more steps in a chain. You do so by setting the SKIP attribute of one or more steps to TRUE with the DBMS_SCHEDULER.ALTER_CHAIN or ALTER_RUNNING_CHAIN procedure.
- [Running Part of a Chain](#)
You can run only part of a chain.
- [Monitoring Running Chains](#)
You can view the status of running chains with the following two views:
*_SCHEDULER_RUNNING_JOBS and *_SCHEDULER_RUNNING_CHAINS.
- [Handling Stalled Chains](#)
At the completion of a step, the chain rules are always evaluated to determine the next steps to run. If none of the rules cause another step to start, none cause the chain to end, and the evaluation_interval for the chain is NULL, the chain enters the **stalled** state.

 **See Also:**

- ["Chains"](#) for an overview of chains
- ["Examples of Creating Chains"](#)

29.6.1 About Creating and Managing Job Chains

Using job chains, you can implement dependency-based scheduling, in which jobs start depending on the outcomes of one or more previous jobs.

To create and use a chain, you complete these tasks in order:

Task	See...
1. Create a chain object	Creating Chains
2. Define the steps in the chain	Defining Chain Steps
3. Add rules	Adding Rules to a Chain
4. Enable the chain	Enabling Chains
5. Create a job (the "chain job") that points to the chain	Creating Jobs for Chains

29.6.2 Chain Tasks and Their Procedures

You use procedures in the DBMS_SCHEDULER package to administer common chain tasks.

[Table 29-6](#) illustrates common tasks involving chains and the procedures associated with them.

Table 29-6 Chain Tasks and Their Procedures

Task	Procedure	Privilege Needed
Create a chain	CREATE_CHAIN	CREATE JOB, CREATE EVALUATION CONTEXT, CREATE RULE, and CREATE RULE SET if the owner. CREATE ANY JOB, CREATE ANY RULE, CREATE ANY RULE SET, and CREATE ANY EVALUATION CONTEXT otherwise
Drop a chain	DROP_CHAIN	Ownership of the chain or ALTER privileges on the chain or CREATE ANY JOB privileges. If not owner, also requires DROP ANY EVALUATION CONTEXT and DROP ANY RULE SET
Alter a chain	SET_ATTRIBUTE	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB
Alter a running chain	ALTER_RUNNING_CHAIN	Ownership of the job, or ALTER privileges on the job or CREATE ANY JOB
Run a chain	RUN_CHAIN	CREATE JOB or CREATE ANY JOB. In addition, the owner of the new job must have EXECUTE privileges on the chain or EXECUTE ANY PROGRAM
Add rules to a chain	DEFINE_CHAIN_RULE	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB privileges. CREATE RULE if the owner of the chain, CREATE ANY RULE otherwise
Alter rules in a chain	DEFINE_CHAIN_RULE	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB privileges. If not owner of the chain, requires ALTER privileges on the rule or ALTER ANY RULE
Drop rules from a chain	DROP_CHAIN_RULE	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB privileges. DROP ANY RULE if not the owner of the chain
Enable a chain	ENABLE	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB
Disable a chain	DISABLE	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB
Create steps	DEFINE_CHAIN_STEP	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB
Drop steps	DROP_CHAIN_STEP	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB
Alter steps (including assigning additional attribute values to steps)	ALTER_CHAIN	Ownership of the chain, or ALTER privileges on the chain or CREATE ANY JOB

29.6.3 Creating Chains

You create a chain by using the `CREATE_CHAIN` procedure in the `DBMS_SCHEDULER` package.

You must ensure that you have the required privileges first. See "[Setting Chain Privileges](#)" for details.

After creating the chain object with `CREATE_CHAIN`, you define chain steps and chain rules separately.

The following example creates a chain:

```
BEGIN
  DBMS_SCHEDULER.CREATE_CHAIN (
    chain_name      => 'my_chain1',
    rule_set_name   => NULL,
    evaluation_interval => NULL,
    comments        => 'My first chain');
END;
/
```

The `rule_set_name` and `evaluation_interval` arguments are typically left `NULL`. `evaluation_interval` can define a repeating interval at which chain rules get evaluated. `rule_set_name` refers to a rule set as defined within Oracle Streams.

 **See Also:**

- ["Adding Rules to a Chain"](#) for more information about the `evaluation_interval` attribute
- See *Oracle Database PL/SQL Packages and Types Reference* for more information on `CREATE_CHAIN`
- See *Oracle Streams Concepts and Administration* for information on rules and rule sets

29.6.4 Defining Chain Steps

After creating a chain object, you define one or more chain steps.

Each step can point to one of the following:

- A Scheduler program object (program)
- Another chain (a nested chain)
- An event schedule, inline event, or file watcher

You define a step that points to a program or nested chain by using the `DEFINE_CHAIN_STEP` procedure. The following example adds two steps to `my_chain1`:

```
BEGIN
  DBMS_SCHEDULER.DEFINE_CHAIN_STEP (
    chain_name      => 'my_chain1',
    step_name       => 'my_step1',
    program_name    => 'my_program1');
  DBMS_SCHEDULER.DEFINE_CHAIN_STEP (
    chain_name      => 'my_chain1',
    step_name       => 'my_step2',
    program_name    => 'my_chain2');
END;
/
```

The named program or chain does not have to exist when you define the step. However, it must exist and be enabled when the chain runs, otherwise an error is generated.

You define a step that waits for an event to occur by using the `DEFINE_CHAIN_EVENT_STEP` procedure. Procedure arguments can point to an event schedule, can include an inline queue specification and event condition, or can include a file watcher name. This example creates a third chain step that waits for the event specified in the named event schedule:

```
BEGIN
  DBMS_SCHEDULER.DEFINE_CHAIN_EVENT_STEP (
    chain_name      => 'my_chain1',
    step_name       => 'my_step3',
    event_schedule_name => 'my_event_schedule');
END;
/
```

An event step does not wait for its event until the step is started.

Steps That Run Local External Executables

After defining a step that runs a local external executable, you must use the `ALTER_CHAIN` procedure to assign a credential to the step, as shown in the following example:

```
BEGIN
  DBMS_SCHEDULER.ALTER_CHAIN('chain1','step1','credential_name','MY_CREDENTIAL');
END;
/
```

Steps That Run on Remote Destinations

After defining a step that is to run an external executable on a remote host or a database program unit on a remote database, you must use the `ALTER_CHAIN` procedure to assign both a credential and a destination to the step, as shown in the following example:

```
BEGIN
  DBMS_SCHEDULER.ALTER_CHAIN('chain1','step2','credential_name','DW_CREDENTIAL');
  DBMS_SCHEDULER.ALTER_CHAIN('chain1','step2','destination_name','DBHOST1_ORCLDW');
END;
/
```

Making Steps Restartable

After a database recovery, by default, steps that were running are marked as `STOPPED` and the chain continues. You can specify the chain steps to restart automatically after a database recovery by using `ALTER_CHAIN` to set the `restart_on_recovery` attribute to `TRUE` for those steps.

See *Oracle Database PL/SQL Packages and Types Reference* for more information regarding the `DEFINE_CHAIN_STEP`, `DEFINE_CHAIN_EVENT_STEP`, and `ALTER_CHAIN` procedures.

 **See Also:**

- ["About Events"](#)
- ["About File Watchers"](#)
- ["Credentials"](#)
- ["Destinations"](#)

29.6.5 Adding Rules to a Chain

You add a rule to a chain with the `DEFINE_CHAIN_RULE` procedure in the `DBMS_SCHEDULER` package. You call this procedure once for each rule that you want to add to the chain.

Chain rules define when steps run and define dependencies between steps. Each rule has a condition and an action. Whenever rules are evaluated, if a condition of a rule evaluates to `TRUE`, its action is performed. The condition can contain Scheduler chain condition syntax or any syntax that is valid in a SQL `WHERE` clause. The syntax can include references to attributes of any chain step, including step completion status. A typical action is to run a specified step or to run a list of steps.

All chain rules work together to define the overall action of the chain. All rules are evaluated to see what action or actions occur next, when the chain job starts and at the end of each step. If more than one rule has a `TRUE` condition, multiple actions can occur. You can also cause rules to be evaluated at regular intervals by setting the `evaluation_interval` attribute of a chain.

Conditions are usually based on the outcome of one or more previous steps. For example, you might want one step to run if the two previous steps succeeded, and another to run if either of the two previous steps failed.

Scheduler chain condition syntax takes one of the following two forms:

```
stepname [NOT] {SUCCEEDED|FAILED|STOPPED|COMPLETED}  
stepname ERROR_CODE {comparision_operator|[NOT] IN} {integer|list_of_integers}
```

You can combine conditions with boolean operators `AND`, `OR`, and `NOT()` to create conditional expressions. You can employ parentheses in your expressions to determine order of evaluation.

`ERROR_CODE` can be set with the `RAISE_APPLICATION_ERROR` PL/SQL statement within the program assigned to the step. Although the error codes that your program sets in this way are negative numbers, when testing `ERROR_CODE` in a chain rule, you test for positive numbers. For example, if your program contains the following statement:

```
RAISE_APPLICATION_ERROR(-20100, errmsg);
```

your chain rule condition must be the following:

```
stepname ERROR_CODE=20100
```

Step Attributes

The following is a list of step attributes that you can include in conditions when using SQL WHERE clause syntax:

```
completed
state
start_date
end_date
error_code
duration
```

The `completed` attribute is boolean and is TRUE when the `state` attribute is either SUCCEEDED, FAILED, or STOPPED.

[Table 29-7](#) shows the possible values for the `state` attribute. These values are visible in the STATE column of the *_SCHEDULER_RUNNING_CHAINS views.

Table 29-7 Values for the State Attribute of a Chain Step

State Attribute Value	Meaning
NOT_STARTED	The chain of a step is running, but the step has not yet started.
SCHEDULED	A rule started the step with an AFTER clause and the designated wait time has not yet expired.
RUNNING	The step is running. For an event step, the step was started and is waiting for an event.
PAUSED	The PAUSE attribute of a step is set to TRUE and the step is paused. It must be unpause before steps that depend on it can start.
SUCCEEDED	The step completed successfully. The ERROR_CODE of the step is 0.
FAILED	The step completed with a failure. ERROR_CODE is nonzero.
STOPPED	The step was stopped with the STOP_JOB procedure.
STALLED	The step is a nested chain that has stalled.

See the `DEFINE_CHAIN_RULE` procedure in *Oracle Database PL/SQL Packages and Types Reference* for rules and examples for SQL WHERE clause syntax.

Condition Examples Using Scheduler Chain Condition Syntax

These examples use Scheduler chain condition syntax.

Steps started by rules containing the following condition starts when the step named `form_validation_step` completes (SUCCEEDED, FAILED, or STOPPED).

```
form_validation_step COMPLETED
```

The following condition is similar, but indicates that the step must succeed for the condition to be met.

```
form_validation_step SUCCEEDED
```

The next condition tests for an error. It is TRUE if the step `form_validation_step` failed with any error code other than 20001.

```
form_validation_step FAILED AND form_validation_step ERROR_CODE != 20001
```

See the `DEFINE_CHAIN_RULE` procedure in *Oracle Database PL/SQL Packages and Types Reference* for more examples.

Condition Examples Using SQL WHERE Syntax

```
':step1.state='SUCCEEDED''
```

Starting the Chain

At least one rule must have a condition that always evaluates to TRUE so that the chain can start when the chain job starts. The easiest way to accomplish this is to set the condition to 'TRUE' if you are using Schedule chain condition syntax, or '1=1' if you are using SQL syntax.

Ending the Chain

At least one chain rule must contain an action of 'END'. A chain job does not complete until one of the rules containing the END action evaluates to TRUE. Several different rules with different END actions are common, some with error codes, and some without.

If a chain has no more running steps, and it is not waiting for an event to occur, and no rules containing the END action evaluate to TRUE (or there are no rules with the END action), the chain job enters the `CHAIN_STALLED` state. See "[Handling Stalled Chains](#)" for more information.

Example of Defining Rules

The following example defines a rule that starts the chain at `step1` and a rule that starts `step2` when `step1` completes. `rule_name` and `comments` are optional and default to NULL. If you do use `rule_name`, you can later redefine that rule with another call to `DEFINE_CHAIN_RULE`. The new definition overwrites the previous one.

```
BEGIN
DBMS_SCHEDULER.DEFINE_CHAIN_RULE (
    chain_name    => 'my_chain1',
    condition     => 'TRUE',
    action        => 'START step1',
    rule_name     => 'my_rule1',
    comments      => 'start the chain');
DBMS_SCHEDULER.DEFINE_CHAIN_RULE (
    chain_name    => 'my_chain1',
    condition     => 'step1 completed',
    action        => 'START step2',
    rule_name     => 'my_rule2');
END;
/
```

 See Also:

- Oracle Database PL/SQL Packages and Types Reference for information on the `DEFINE_CHAIN_RULE` procedure and Scheduler chain condition syntax
- "[Examples of Creating Chains](#)"

29.6.6 Setting an Evaluation Interval for Chain Rules

The Scheduler evaluates all chain rules at the start of the chain job and at the end of each chain step.

You can also configure a chain to have Scheduler evaluate its rules at a repeating time interval, such as once per hour. This capability is useful to start chain steps based on time of day or based on occurrences external to the chain. Here are some examples:

- A chain step is resource-intensive and must therefore run at off-peak hours. You could condition the step on both the completion of another step and on the time of day being after 6:00 p.m and before midnight. The Scheduler would then have to evaluate rules every so often to determine when this condition becomes TRUE.
- A step must wait for data to arrive in a table from some other process that is external to the chain. You could condition this step on both the completion of another step and on a particular table containing rows. The Scheduler would then have to evaluate rules every so often to determine when this condition becomes TRUE. The condition would use SQL WHERE clause syntax, and would be similar to the following:

```
:step1.state='SUCCEEDED' AND select count(*) from oe.sync_table > 0
```

To set an evaluation interval for a chain, you set the `evaluation_interval` attribute when you create the chain. The data type for this attribute is `INTERVAL DAY TO SECOND`.

```
BEGIN
    DBMS_SCHEDULER.CREATE_CHAIN (
        chain_name      => 'my_chain1',
        rule_set_name   => NULL,
        evaluation_interval => INTERVAL '30' MINUTE,
        comments         => 'Chain with 30 minute evaluation interval');
END;
/
```

29.6.7 Enabling Chains

You enable a chain with the `ENABLE` procedure in the `DBMS_SCHEDULER` package. A chain must be enabled before it can be run by a job. Enabling an already enabled chain does not return an error.

This example enables chain `my_chain1`:

```
BEGIN
    DBMS_SCHEDULER.ENABLE ('my_chain1');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for more information regarding the `ENABLE` procedure.

 **Note:**

Chains are automatically disabled by the Scheduler when one of the following is dropped:

- The program that one of the chain steps points to
- The nested chain that one of the chain steps points to
- The event schedule that one of the chain event steps points to

29.6.8 Creating Jobs for Chains

To run a chain, you must either use the `RUN_CHAIN` procedure in the `DBMS_SCHEDULER` package or create and schedule a job of type 'CHAIN' (a **chain job**).

The job action must refer to a previously created chain name, as shown in the following example:

```
BEGIN
    DBMS_SCHEDULER.CREATE_JOB (
        job_name      => 'chain_job_1',
        job_type      => 'CHAIN',
        job_action    => 'my_chain1',
        repeat_interval => 'freq=daily;byhour=13;byminute=0;bysecond=0',
        enabled       => TRUE);
END;
/
```

For every step of a chain job that is running, the Scheduler creates a **step job** with the same job name and owner as the chain job. Each step job additionally has a job subname to uniquely identify it. You can view the job subname as a column in the views `*_SCHEDULER_RUNNING_JOBS`, `*_SCHEDULER_JOB_LOG`, and `*_SCHEDULER_JOB_RUN_DETAILS`. The job subname is normally the same as the step name except in the following cases:

- For nested chains, the current step name may have already been used as a job subname. In this case, the Scheduler appends '`_N`' to the step name, where `N` is an integer that results in a unique job subname.
- If there is a failure when creating a step job, the Scheduler logs a `FAILED` entry in the job log views (`*_SCHEDULER_JOB_LOG` and `*_SCHEDULER_JOB_RUN_DETAILS`) with the job subname set to '`step_name_0`'.

 See Also:

- [Oracle Database PL/SQL Packages and Types Reference](#) for more information on the CREATE_JOB procedure
- "[Running Chains](#)" for another way to run a chain without creating a chain job

29.6.9 Dropping Chains

You drop a chain, including its steps and rules, using the DROP_CHAIN procedure in the DBMS_SCHEDULER package.

The following example drops the chain named my_chain1:

```
BEGIN
    DBMS_SCHEDULER.DROP_CHAIN (
        chain_name    => 'my_chain1',
        force         => TRUE);
END;
/
```

See [Oracle Database PL/SQL Packages and Types Reference](#) for more information regarding the DROP_CHAIN procedure.

29.6.10 Running Chains

To run a chain immediately, use the RUN_JOB or RUN_CHAIN procedure in the DBMS_SCHEDULER package.

If you already created a chain job for a chain, you can use the RUN_JOB procedure to run that job (and thus run the chain), but you must set the use_current_session argument of RUN_JOB to FALSE.

You can use the RUN_CHAIN procedure to run a chain without having to first create a chain job for the chain. You can also use RUN_CHAIN to run only part of a chain.

RUN_CHAIN creates a temporary job to run the specified chain. If you supply a job name, the job is created with that name, otherwise a default job name is assigned.

If you supply a list of *start steps*, only those steps are started when the chain begins running. (Steps that would normally have started do not run if they are not in the list.) If no list of start steps is given, the chain starts normally—that is, an initial evaluation is done to see which steps to start running. The following example immediately runs my_chain1:

```
BEGIN
    DBMS_SCHEDULER.RUN_CHAIN (
        chain_name    => 'my_chain1',
        job_name      => 'partial_chain_job',
        start_steps   => 'my_step2, my_step4');
END;
/
```

 **See Also:**

- "[Running Part of a Chain](#)"
- [Oracle Database PL/SQL Packages and Types Reference](#) for more information regarding the `RUN_CHAIN` procedure

29.6.11 Dropping Chain Rules

You drop a rule from a chain by using the `DROP_CHAIN_RULE` procedure in the `DBMS_SCHEDULER` package.

The following example drops `my_rule1`:

```
BEGIN
    DBMS_SCHEDULER.DROP_CHAIN_RULE (
        chain_name    => 'my_chain1',
        rule_name     => 'my_rule1',
        force         => TRUE);
END;
/
```

See [Oracle Database PL/SQL Packages and Types Reference](#) for more information regarding the `DROP_CHAIN_RULE` procedure.

29.6.12 Disabling Chains

You disable a chain using the `DISABLE` procedure in the `DBMS_SCHEDULER` package.

The following example disables `my_chain1`:

```
BEGIN
    DBMS_SCHEDULER.DISABLE ('my_chain1');
END;
/
```

See [Oracle Database PL/SQL Packages and Types Reference](#) for more information regarding the `DISABLE` procedure.

 **Note:**

Chains are automatically disabled by the Scheduler when one of the following is dropped:

- The program that one of the chain steps points to
- The nested chain that one of the chain steps points to
- The event schedule that one of the chain event steps points to

29.6.13 Dropping Chain Steps

You drop a step from a chain using the `DROP_CHAIN_STEP` procedure in the `DBMS_SCHEDULER` package.

The following example drops `my_step2` from `my_chain2`:

```
BEGIN
  DBMS_SCHEDULER.DROP_CHAIN_STEP (
    chain_name    => 'my_chain2',
    step_name     => 'my_step2',
    force         => TRUE);
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for more information regarding the `DROP_CHAIN_STEP` procedure.

29.6.14 Stopping Chains

To stop a running chain, you call the `DBMS_SCHEDULER.STOP_JOB` procedure, passing the name of the chain job (the job that started the chain).

When you stop a chain job, all steps of the chain that are running are stopped and the chain ends.

See *Oracle Database PL/SQL Packages and Types Reference* for more information regarding the `STOP_JOB` procedure.

29.6.15 Stopping Individual Chain Steps

You can stop individual chain steps by creating a chain rule that stops one or more steps when the rule condition is met or by calling the `STOP_JOB` procedure.

For each step being stopped, you must specify the schema name, chain job name, and step job subname.

```
BEGIN
  DBMS_SCHEDULER.STOP_JOB('oe.chainrunjob.stepa');
END;
/
```

In this example, `chainrunjob` is the chain job name and `stepa` is the step job subname. The step job subname is typically the same as the step name, but not always. You can obtain the step job subname from the `STEP_JOB_SUBNAME` column of the `*_SCHEDULER_RUNNING_CHAINS` views.

When you stop a chain step, its state is set to `STOPPED`, and the chain rules are evaluated to determine the steps to run next.

See *Oracle Database PL/SQL Packages and Types Reference* for more information regarding the `STOP_JOB` procedure.

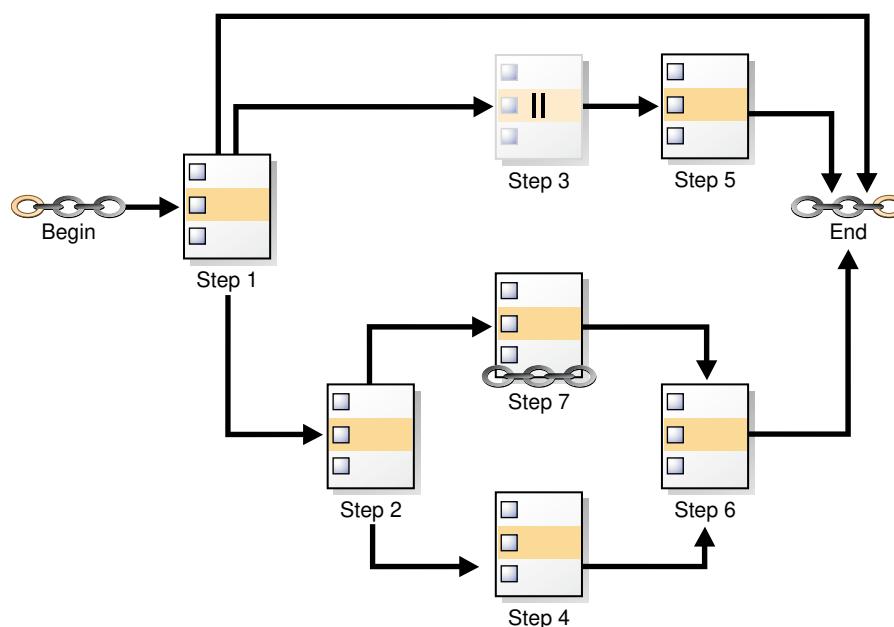

29.6.16 Pausing Chains

You can pause an entire chain or individual branches of a chain. You do so by setting the `PAUSE` attribute of one or more steps to `TRUE` with the `DBMS_SCHEDULER.ALTER_CHAIN` or `ALTER_RUNNING_CHAIN` procedure.

Pausing chain steps enables you to suspend the running of the chain after those steps run.

When you pause a step, after the step runs, its `state` attribute changes to `PAUSED`, and its `completed` attribute remains `FALSE`. Therefore, steps that depend on the completion of the paused step are not run. If you reset the `PAUSE` attribute to `FALSE` for a paused step, its `state` attribute is set to its completion state (`SUCCEEDED`, `FAILED`, or `STOPPED`), and steps that are awaiting the completion of the paused step can then run.

Figure 29-1 Chain with Step 3 Paused

In [Figure 29-1](#), Step 3 is paused. Until Step 3 is unpause, Step 5 will not run. If you were to pause only Step 2, then Steps 4, 6, and 7 would not run. However Steps 1, 3, and 5 could run. In either case, you are suspending only one branch of the chain.

To pause an entire chain, you pause all steps of the chain. To unpause a chain, you unpause one, many, or all of the chain steps. With the chain in [Figure 29-1](#), pausing Step 1 pauses the entire chain after Step 1 runs.

See Also:

The `DBMS_SCHEDULER.ALTER_CHAIN` and `DBMS_SCHEDULER.ALTER_RUNNING_CHAIN` procedures in *Oracle Database PL/SQL Packages and Types Reference*

29.6.17 Skipping Chain Steps

You can skip one or more steps in a chain. You do so by setting the `SKIP` attribute of one or more steps to `TRUE` with the `DBMS_SCHEDULER.ALTER_CHAIN` or `ALTER_RUNNING_CHAIN` procedure.

If a `SKIP` attribute of a step is `TRUE`, then when a chain condition to run that step is met, instead of being run, the step is treated as immediately succeeded. Setting `SKIP` to `TRUE` has no effect on a step that is running, is scheduled to run after a delay, or has already run.

Skipping steps is especially useful when testing chains. For example, when testing the chain shown in [Figure 29-1](#), skipping Step 7 could shorten testing time considerably, because this step is a nested chain.

 **See Also:**

["Skipping Chain Steps"](#)

29.6.18 Running Part of a Chain

You can run only part of a chain.

There are two ways to run only a part of a chain:

- Use the `ALTER_CHAIN` procedure to set the `PAUSE` attribute to `TRUE` for one or more steps, and then either start the chain job with `RUN_JOB` or start the chain with `RUN_CHAIN`. Any steps that depend on the paused steps do not run, but the paused steps do run.

The disadvantage of this method is that you must set the `PAUSE` attribute back to `FALSE` for the affected steps for future runs of the chain.

- Use the `RUN_CHAIN` procedure to start only certain steps of the chain, skipping those steps that you do not want to run.

This is a more straightforward approach, which also allows you to set the initial state of steps before starting them.

You may have to use both of these methods to skip steps both at the beginning and end of a chain.

See the discussion of the `RUN_CHAIN` procedure in *Oracle Database PL/SQL Packages and Types Reference* for more information.

29.6.19 Monitoring Running Chains

You can view the status of running chains with the following two views:

`*_SCHEDULER_RUNNING_JOBS` and `*_SCHEDULER_RUNNING_CHAINS`.

The `*_SCHEDULER_RUNNING_JOBS` views contain one row for the chain job and one row for each running step. The `*_SCHEDULER_RUNNING_CHAINS` views contain one row for

each chain step, including any nested chains, and include run status for each step such as NOT_STARTED, RUNNING, STOPPED, SUCCEEDED, and so on.

 **See Also:**

- *Oracle Database Reference* for details about the *_SCHEDULER_RUNNING_JOBS views
- *Oracle Database Reference* for details about the *_SCHEDULER_RUNNING_CHAINS views

29.6.20 Handling Stalled Chains

At the completion of a step, the chain rules are always evaluated to determine the next steps to run. If none of the rules cause another step to start, none cause the chain to end, and the evaluation_interval for the chain is `NULL`, the chain enters the **stalled** state.

When a chain is stalled, no steps are running, no steps are scheduled to run (after waiting a designated time interval), and no event steps are waiting for an event. The chain can make no further progress unless you manually intervene. In this case, the state of the job that is running the chain is set to `CHAIN_STALLED`. However, the job is still listed in the *_SCHEDULER_RUNNING_JOBS views.

You can troubleshoot a stalled chain with the views `ALL_SCHEDULER_RUNNING_CHAINS`, which shows the state of all steps in the chain (including any nested chains), and `ALL_SCHEDULER_CHAIN_RULES`, which contains all the chain rules.

You can enable the chain to continue by altering the state of one of its steps with the `ALTER_RUNNING_CHAIN` procedure. For example, if step 11 is waiting for step 9 to succeed before it can start, and if it makes sense to do so, you can set the state of step 9 to 'SUCCEEDED'.

Alternatively, if one or more rules are incorrect, you can use the `DEFINE_CHAIN_RULE` procedure to replace them (using the same rule names), or to create new rules. The new and updated rules apply to the running chain and all future chain runs. After adding or updating rules, you must run `EVALUATE_RUNNING_CHAIN` on the stalled chain job to trigger any required actions.

29.7 Using Incompatibility Definitions

An incompatibility definition (or, incompatibility) specifies incompatible jobs or programs, where only one of the group can be running at a time.

- [Creating a Job or Program Incompatibility](#)

You can specify a job-level or program-level incompatibility by using the `CREATE_INCOMPATIBILITY` procedure in the `DBMS_SCHEDULER` package.

- [Adding a Job or Program to an Incompatibility](#)

You can add a job or program to an existing incompatibility definition by using the `ADD_TO_INCOMPATIBILITY` procedure in the `DBMS_SCHEDULER` package.

- [Removing a Job or Program from an Incompatibility](#)
You can remove a job or program from an existing incompatibility definition by using the `REMOVE_FROM_INCOMPATIBILITY` procedure in the `DBMS_SCHEDULER` package.
- [Dropping an Incompatibility](#)
You can drop an existing incompatibility definition by using the `DROP_INCOMPATIBILITY` procedure in the `DBMS_SCHEDULER` package.

 **See Also:**

- [Incompatibilities](#)
- [DBMS_SCHEDULER in Oracle Database PL/SQL Packages and Types Reference](#)

29.7.1 Creating a Job or Program Incompatibility

You can specify a job-level or program-level incompatibility by using the `CREATE_INCOMPATIBILITY` procedure in the `DBMS_SCHEDULER` package.

For example, the following statement creates an incompatibility named `incompat1` specifying that only one of the jobs named `job1`, `job2`, or `job3` can be running at the same time:

```
BEGIN
  dbms_scheduler.create_incompatibility(
    incompatibility_name => 'incompat1',
    object_name => 'job1,job2,job3',
    enabled => true );
END;
/
```

`object_name` contains a comma separated list of either all programs or all jobs that are incompatible with each other (that is, they cannot be run at the same time). In case of jobs the list must consist of two or more jobs and `constraint_level` must be '`JOB_LEVEL`' (the default, and not included in the example). In case of programs, `constraint_level` can be either '`JOB_LEVEL`' or '`PROGRAM_LEVEL`'. When set to the default value '`JOB_LEVEL`', only a single job that is based on the program (or programs) mentioned in `object_name` can run at the same time. When set to '`PROGRAM_LEVEL`', the programs are incompatible, but the jobs based on the same program are not incompatible.

For example, if the value of `object_name` is '`P1,P2,P3`' and `constraint_level` is '`PROGRAM_LEVEL`', many jobs based on `P1` can be running at the same time, but if any `P1` based job is running, none based on `P2` or `P3` can be running. Or similarly, many jobs based on `P3` can be running at the same time, but none based on `P1` or `P2`. If `constraint_level` is set to '`JOB_LEVEL`', then only a single job out of all the jobs based on programs `P1`, `P2`, and `P3` can be running at any given time.

 **See Also:**

CREATE INCOMPATIBILITY Procedure in *Oracle Database PL/SQL Packages and Types Reference*

29.7.2 Adding a Job or Program to an Incompatibility

You can add a job or program to an existing incompatibility definition by using the ADD_TO_INCOMPATIBILITY procedure in the DBMS_SCHEDULER package.

For example, the following statement adds job job1 to the incompatibility named icomp1234:

```
BEGIN
  dbms_scheduler.add_to_incompatibility(
    incompatibility_name => 'icomp1234',
    object_name => 'job1');
END;
/
```

incompatibility_name is the name of an existing incompatibility definition.

object_name contains a comma separated list of jobs or programs.

This procedure does not raise an error if a specified job or program to be added is already included in the specified incompatibility definition.

 **See Also:**

ADD_TO_INCOMPATIBILITY Procedure in *Oracle Database PL/SQL Packages and Types Reference*

29.7.3 Removing a Job or Program from an Incompatibility

You can remove a job or program from an existing incompatibility definition by using the REMOVE_FROM_INCOMPATIBILITY procedure in the DBMS_SCHEDULER package.

For example, the following statement removes job job1 from the incompatibility named icomp1234:

```
BEGIN
  dbms_scheduler.remove_from_incompatibility(
    incompatibility_name => 'icomp1234',
    object_name => 'job1');
END;
/
```

incompatibility_name is the name of an existing incompatibility definition.

object_name contains a comma separated list of jobs or programs.

This procedure does not raise an error if a specified job or program to be removed does not exist in the specified incompatibility definition.

 **See Also:**

[REMOVE_FROM_INCOMPATIBILITY Procedure in Oracle Database PL/SQL Packages and Types Reference](#)

29.7.4 Dropping an Incompatibility

You can drop an existing incompatibility definition by using the `DROP_INCOMPATIBILITY` procedure in the `DBMS_SCHEDULER` package.

For example, the following statement drops the incompatibility named `icomp1234`:

```
BEGIN
  dbms_scheduler.drop_incompatibility(
    incompatibility_name => 'icomp1234';
)
END;
/
```

`incompatibility_name` is the name of an existing incompatibility definition.

 **See Also:**

[DROP_INCOMPATIBILITY Procedure in Oracle Database PL/SQL Packages and Types Reference](#)

29.8 Managing Job Resources

You can create and alter resources available for use by jobs, and control how many of a specified resource are available to a job.

Customers have jobs that need access to resources. A limited number of such resources are available, so the scheduling system needs to keep track of which jobs use which resources and not schedule jobs until the resources that they need are available.

- [Creating or Dropping a Resource](#)

You can create a resource by using the `CREATE_RESOURCE` procedure in the `DBMS_SCHEDULER` package.

- [Altering a Resource](#)

You can alter a resource by using the `SET_ATTRIBUTE` and `SET_ATTRIBUTE_NULL` procedures in the `DBMS_SCHEDULER` package.

- [Setting a Resource Constraint for a Job](#)

You can specify resources for use by jobs or programs by using the `SET_RESOURCE_CONSTRAINT` procedure in the `DBMS_SCHEDULER` package.

 **See Also:**

- DBMS_SCHEDULER in *Oracle Database PL/SQL Packages and Types Reference*

29.8.1 Creating or Dropping a Resource

You can create a resource by using the `CREATE_RESOURCE` procedure in the `DBMS_SCHEDULER` package.

Resources are created in the schema of the user creating the resource.

For example, the following statement creates a resource named `my_resource` specifying that three units of the resource are to be made available initially, and that the Scheduler is manage the constraint so that no more than 3 units can be in use simultaneously by jobs.

```
BEGIN
    DBMS_SCHEDULER.CREATE_RESOURCE(
        resource_name => 'my_resource',
        units          => 3,
        state          => 'ENFORCE_CONSTRAINTS',
        comments       => 'Resource1'
    )
END;
/
```

If you no longer need a resource, you can drop it using the `DROP_RESOURCE` procedure in the `DBMS_SCHEDULER` package. For example:

```
BEGIN
    DBMS_SCHEDULER.DROP_RESOURCE(
        resource_name => 'my_resource',
        force         => true
    )
END;
/
```

 **See Also:**

- `CREATE_RESOURCE` Procedure in *Oracle Database PL/SQL Packages and Types Reference*

29.8.2 Altering a Resource

You can alter a resource by using the `SET_ATTRIBUTE` and `SET_ATTRIBUTE_NULL` procedures in the `DBMS_SCHEDULER` package.

If a resource is altered, the change does not affect currently running jobs that use this resource. The change goes into effect for subsequent jobs that use the resource.

 **See Also:**

SET_ATTRIBUTE Procedure and SET_ATTRIBUTE_NULL Procedure in *Oracle Database PL/SQL Packages and Types Reference*

29.8.3 Setting a Resource Constraint for a Job

You can specify resources for use by jobs or programs by using the SET_RESOURCE_CONSTRAINT procedure in the DBMS_SCHEDULER package.

You can specify the number of units of the resource that a specified job or program can use.

For example, the following statement specifies that the object named `job1` can use one unit of the resource named `resource1`.

```
BEGIN
    DBMS_SCHEDULER.SET_RESOURCE_CONSTRAINT(
        OBJECT_NAME    => 'job1',
        RESOURCE_NAME => 'resource1',
        UNITS          =>1);
END;
/
```

The `object_name` parameter can be the name of a program or a job, or a comma-separated list of names.

The `units` parameter specifies how many units of the resource this program or job can use. If `units` is set to 0, it means that the program or job does not use this resource anymore, and the constraint is deleted. If `units` is set to 0 on a resource for which there was no previous constraint, an error is generated.

If multiple constraints are defined on the same resource, the object types (job or program) must match. For example, if one or more constraints for a resource are based of jobs, and if a new constraint for a program is added for the same resource, an error is generated.

 **See Also:**

SET_RESOURCE_CONSTRAINT Procedure in *Oracle Database PL/SQL Packages and Types Reference*

29.9 Prioritizing Jobs

You prioritize Oracle Scheduler jobs using three Scheduler objects: job classes, windows, and window groups. These objects prioritize jobs by associating jobs with database resource manager consumer groups. This, in turn, controls the amount of resources allocated to these jobs. In addition, job classes enable you to set relative priorities among a group of jobs if all jobs in the group are allocated identical resource levels.

- [Managing Job Priorities with Job Classes](#)
Job classes provide a way to group jobs for prioritization. They also provide a way to easily assign a set of attribute values to member jobs. Job classes influence the priorities of their member jobs through job class attributes that relate to the database resource manager.
- [Setting Relative Job Priorities Within a Job Class](#)
You can change the relative priorities of jobs within the same job class by using the `SET_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package. Job priorities must be in the range of 1-5, where 1 is the highest priority.
- [Managing Job Scheduling and Job Priorities with Windows](#)
You create windows to automatically start jobs or to change resource allocation among jobs during various time periods of the day, week, and so on. A window is represented by an interval of time.
- [Managing Job Scheduling and Job Priorities with Window Groups](#)
Window groups provide an easy way to schedule jobs that must run during multiple time periods throughout the day, week, and so on. If you create a window group, add windows to it, and then name this window group in a job's `schedule_name` attribute, the job runs during all the windows in the window group. Window groups reside in the `SYS` schema.
- [Allocating Resources Among Jobs Using Resource Manager](#)
The Database Resource Manager (Resource Manager) controls how resources are allocated among database sessions. It not only controls asynchronous sessions like Scheduler jobs, but also synchronous sessions like user sessions.
- [Example of Resource Allocation for Jobs](#)
An example illustrates how resources are allocated for jobs.

 **See Also:**

[Managing Resources with Oracle Database Resource Manager](#)

29.9.1 Managing Job Priorities with Job Classes

Job classes provide a way to group jobs for prioritization. They also provide a way to easily assign a set of attribute values to member jobs. Job classes influence the priorities of their member jobs through job class attributes that relate to the database resource manager.

A default job class is created with the database. If you create a job without specifying a job class, the job is assigned to this default job class (`DEFAULT_JOB_CLASS`). The default job class has the `EXECUTE` privilege granted to `PUBLIC` so any database user who has the privilege to create a job can create a job in the default job class.

- [Job Class Tasks and Their Procedures](#)
You use procedures in the `DBMS_SCHEDULER` package to administer common job class tasks.
- [Creating Job Classes](#)
You create a job class using the `CREATE_JOB_CLASS` procedure in the `DBMS_SCHEDULER` package or Cloud Control. Job classes are always created in the `SYS` schema.

- [Altering Job Classes](#)
You alter a job class by using the `SET_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.
- [Dropping Job Classes](#)
You drop one or more job classes using the `DROP_JOB_CLASS` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

 **See Also:**

- [Oracle Database Reference](#) to view job classes
- ["Allocating Resources Among Jobs Using Resource Manager"](#)
- ["Job Classes"](#) for an overview of job classes

29.9.1.1 Job Class Tasks and Their Procedures

You use procedures in the `DBMS_SCHEDULER` package to administer common job class tasks.

[Table 29-8](#) illustrates common job class tasks and their appropriate procedures and privileges:

Table 29-8 Job Class Tasks and Their Procedures

Task	Procedure	Privilege Needed
Create a job class	<code>CREATE_JOB_CLASS</code>	MANAGE SCHEDULER
Alter a job class	<code>SET_ATTRIBUTE</code>	MANAGE SCHEDULER
Drop a job class	<code>DROP_JOB_CLASS</code>	MANAGE SCHEDULER

See "[Scheduler Privileges](#)" for further information regarding privileges.

29.9.1.2 Creating Job Classes

You create a job class using the `CREATE_JOB_CLASS` procedure in the `DBMS_SCHEDULER` package or Cloud Control. Job classes are always created in the `SYS` schema.

The following statement creates a job class for all finance jobs:

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB_CLASS (
    job_class_name      => 'finance_jobs',
    resource_consumer_group  => 'finance_group');
END;
/
```

All jobs in this job class are assigned to the `finance_group` resource consumer group.

To query job classes, use the `*_SCHEDULER_JOB_CLASSES` views.

 See Also:

"[About Resource Consumer Groups](#)"

29.9.1.3 Altering Job Classes

You alter a job class by using the `SET_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

Other than the job class name, all the attributes of a job class can be altered. The attributes of a job class are available in the `*_SCHEDULER_JOB_CLASSES` views.

When a job class is altered, running jobs that belong to the class are not affected. The change only takes effect for jobs that have not started running yet.

29.9.1.4 Dropping Job Classes

You drop one or more job classes using the `DROP_JOB_CLASS` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

Dropping a job class means that all the metadata about the job class is removed from the database.

You can drop several job classes in one call by providing a comma-delimited list of job class names to the `DROP_JOB_CLASS` procedure call. For example, the following statement drops three job classes:

```
BEGIN
    DBMS_SCHEDULER.DROP_JOB_CLASS('jobclass1, jobclass2, jobclass3');
END;
/
```

29.9.2 Setting Relative Job Priorities Within a Job Class

You can change the relative priorities of jobs within the same job class by using the `SET_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package. Job priorities must be in the range of 1-5, where 1 is the highest priority.

For example, the following statement changes the job priority for `my_job1` to a setting of 1:

```
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE (
        name      => 'my_emp_job1',
        attribute => 'job_priority',
        value     => 1);
END;
/
```

You can verify that the attribute was changed by issuing the following statement:

```
SELECT JOB_NAME, JOB_PRIORITY FROM DBA_SCHEDULER_JOBS;
```

JOB_NAME	JOB_PRIORITY
MY_EMP_JOB	3

MY_EMP_JOB1	1
MY_NEW_JOB1	3
MY_NEW_JOB2	3
MY_NEW_JOB3	3

Overall priority of a job within the system is determined first by the combination of the resource consumer group that the job class of the job is assigned to and the current resource plan, and then by relative priority within the job class.

See Also:

- ["Allocating Resources Among Jobs Using Resource Manager"](#)
- *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `SET_ATTRIBUTE` procedure

29.9.3 Managing Job Scheduling and Job Priorities with Windows

You create windows to automatically start jobs or to change resource allocation among jobs during various time periods of the day, week, and so on. A window is represented by an interval of time.

- [About Job Scheduling and Job Priorities with Windows](#)
Windows provide a way to automatically activate different resource plans at different times. Running jobs can then see a change in the resources that are allocated to them when there is a change in resource plan.
- [Window Tasks and Their Procedures](#)
You use procedures in the `DBMS_SCHEDULER` package to administer common window tasks.
- [Creating Windows](#)
You can use Cloud Control or the `DBMS_SCHEDULER.CREATE_WINDOW` procedure to create windows.
- [Altering Windows](#)
You alter a window by modifying its attributes. You do so with the `SET_ATTRIBUTE` and `SET_ATTRIBUTE_NULL` procedures in the `DBMS_SCHEDULER` package or Cloud Control.
- [Opening Windows](#)
When a window opens, the Scheduler switches to the resource plan that has been associated with it during its creation. If there are jobs running when the window opens, the resources allocated to them might change due to the switch in resource plan.
- [Closing Windows](#)
A window can close based on a schedule, or it can be closed manually.
- [Dropping Windows](#)
You drop one or more windows using the `DROP_WINDOW` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

- [Disabling Windows](#)
You disable one or more windows using the `DISABLE` procedure in the `DBMS_SCHEDULER` package or with Cloud Control.
- [Enabling Windows](#)
You enable one or more windows using the `ENABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

29.9.3.1 About Job Scheduling and Job Priorities with Windows

Windows provide a way to automatically activate different resource plans at different times. Running jobs can then see a change in the resources that are allocated to them when there is a change in resource plan.

A job can name a window in its `schedule_name` attribute. The Scheduler then starts the job with the window *opens*. A window has a schedule associated with it, so it can open at various times during your workload cycle.

These are the key attributes of a window:

- Schedule
This controls when the window is in effect.
- Duration
This controls how long the window is open.
- Resource plan
This names the resource plan that activates when the window opens.

Only one window can be in effect at any given time. Windows belong to the `SYS` schema.

All window activity is logged in the `*_SCHEDULER_WINDOW_LOG` views, otherwise known as the **window logs**. See "[Window Log](#)" for examples of window logging.

 **See Also:**

["Windows"](#) for an overview of windows.

29.9.3.2 Window Tasks and Their Procedures

You use procedures in the `DBMS_SCHEDULER` package to administer common window tasks.

[Table 29-9](#) illustrates common window tasks and the procedures you use to handle them.

Table 29-9 Window Tasks and Their Procedures

Task	Procedure	Privilege Needed
Create a window	<code>CREATE_WINDOW</code>	MANAGE SCHEDULER

Table 29-9 (Cont.) Window Tasks and Their Procedures

Task	Procedure	Privilege Needed
Open a window	OPEN_WINDOW	MANAGE SCHEDULER
Close a window	CLOSE_WINDOW	MANAGE SCHEDULER
Alter a window	SET_ATTRIBUTE	MANAGE SCHEDULER
Drop a window	DROP_WINDOW	MANAGE SCHEDULER
Disable a window	DISABLE	MANAGE SCHEDULER
Enable a window	ENABLE	MANAGE SCHEDULER

See "[Scheduler Privileges](#)" for further information regarding privileges.

29.9.3.3 Creating Windows

You can use Cloud Control or the DBMS_SCHEDULER.CREATE_WINDOW procedure to create windows.

Using the procedure, you can leave the resource_plan parameter NULL. In this case, when the window opens, the current plan remains in effect.

You must have the MANAGE SCHEDULER privilege to create windows.

When you specify a schedule for a window, the Scheduler does not check if there is already a window defined for that schedule. Therefore, this may result in windows that overlap. Also, using a named schedule that has a PL/SQL expression as its repeat interval is not supported for windows

See the CREATE_WINDOW procedure in *Oracle Database PL/SQL Packages and Types Reference* for details on window attributes.

The following example creates a window named daytime that enables the mixed_workload_plan resource plan during office hours:

```
BEGIN
    DBMS_SCHEDULER.CREATE_WINDOW (
        window_name      => 'daytime',
        resource_plan    => 'mixed_workload_plan',
        start_date       => '28-APR-09 08.00.00 AM',
        repeat_interval  => 'freq=daily; byday=mon,tue,wed,thu,fri',
        duration         => interval '9' hour,
        window_priority  => 'low',
        comments         => 'OLTP transactions have priority');
END;
/
```

To verify that the window was created properly, query the view DBA_SCHEDULER_WINDOWS. For example, issue the following statement:

```
SELECT WINDOW_NAME, RESOURCE_PLAN, DURATION, REPEAT_INTERVAL FROM DBA_SCHEDULER_WINDOWS;
```

WINDOW_NAME	RESOURCE_PLAN	DURATION	REPEAT_INTERVAL
DAYTIME	MIXED_WORKLOAD_PLAN	+000 09:00:00	freq=daily; byday=mon,tue,wed,thu,fri

29.9.3.4 Altering Windows

You alter a window by modifying its attributes. You do so with the `SET_ATTRIBUTE` and `SET_ATTRIBUTE_NULL` procedures in the `DBMS_SCHEDULER` package or Cloud Control.

With the exception of `WINDOW_NAME`, all the attributes of a window can be changed when it is altered. See the `CREATE_WINDOW` procedure in *Oracle Database PL/SQL Packages and Types Reference* for window attribute details.

When a window is altered, it does not affect an active window. The changes only take effect the next time the window opens.

All windows can be altered. If you alter a window that is disabled, it will remain disabled after it is altered. An enabled window will be automatically disabled, altered, and then reenabled, if the validity checks performed during the enable process are successful.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `SET_ATTRIBUTE` and `SET_ATTRIBUTE_NULL` procedures.

29.9.3.5 Opening Windows

When a window opens, the Scheduler switches to the resource plan that has been associated with it during its creation. If there are jobs running when the window opens, the resources allocated to them might change due to the switch in resource plan.

There are two ways a window can open:

- According to the window's schedule
- Manually, using the `OPEN_WINDOW` procedure

This procedure opens the window independent of its schedule. This window will open and the resource plan associated with it will take effect immediately. Only an enabled window can be manually opened.

In the `OPEN_WINDOW` procedure, you can specify the time interval that the window should be open for, using the `duration` attribute. The duration is of type `interval day to second`. If the duration is not specified, then the window will be opened for the regular duration as stored with the window.

Opening a window manually has no impact on regular scheduled runs of the window.

When a window that was manually opened closes, the rules about overlapping windows are applied to determine which other window should be opened at that time if any at all.

You can force a window to open even if there is one already open by setting the `force` option to `TRUE` in the `OPEN_WINDOW` call or Cloud Control.

When the `force` option is set to `TRUE`, the Scheduler automatically closes any window that is open at that time, even if it has a higher priority. For the duration of this manually opened window, the Scheduler does not open any other scheduled windows even if they have a higher priority. You can open a window that is already open. In this case, the window stays open for the duration specified in the call, from the time the `OPEN_WINDOW` command was issued.

Consider an example to illustrate this. `window1` was created with a duration of four hours. It has now been open for two hours. If at this point you reopen `window1` using the `OPEN_WINDOW` call and do not specify a duration, then `window1` will be open for another four hours because it was created with that duration. If you specified a duration of 30 minutes, the window will close in 30 minutes.

When a window opens, an entry is made in the window log.

A window can fail to switch resource plans if the current resource plan has been manually switched using the `ALTER SYSTEM` statement with the `FORCE` option, or using the `DBMS_RESOURCE_MANAGER.SWITCH_PLAN` package procedure with the `allow_scheduler_plan_switches` argument set to `FALSE`. In this case, the failure to switch resource plans is written to the window log.

See Also:

- *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DBMS_SCHEDULER.OPEN_WINDOW` procedure
- *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DBMS_RESOURCE_MANAGER.SWITCH_PLAN` procedure

29.9.3.6 Closing Windows

A window can close based on a schedule, or it can be closed manually.

There are two ways a window can close:

- Based on a schedule

A window will close based on the schedule defined at creation time.

- Manually, using the `CLOSE_WINDOW` procedure

The `CLOSE_WINDOW` procedure will close an open window prematurely.

A closed window means that it is no longer in effect. When a window is closed, the Scheduler will switch the resource plan to the one that was in effect outside the window or in the case of overlapping windows to another window. If you try to close a window that does not exist or is not open, an error is generated.

A job that is running will not stop when the window it is running in closes unless the attribute `stop_on_window_close` was set to `TRUE` when the job was created. However, the resources allocated to the job may change because the resource plan may change.

When a running job has a window group as its schedule, the job will not be stopped when its window is closed if another window that is also a member of the same window group then becomes active. This is the case even if the job was created with the attribute `stop_on_window_close` set to `TRUE`.

When a window is closed, an entry will be added to the window log `DBA_SCHEDULER_WINDOW_LOG`.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `CLOSE_WINDOW` procedure.

29.9.3.7 Dropping Windows

You drop one or more windows using the `DROP_WINDOW` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

When a window is dropped, all metadata about the window is removed from the `*_SCHEDULER_WINDOWS` views. All references to the window are removed from window groups.

You can drop several windows in one call by providing a comma-delimited list of window names or window group names to the `DROP_WINDOW` procedure. For example, the following statement drops both windows and window groups:

```
BEGIN
    DBMS_SCHEDULER.DROP_WINDOW ('window1, window2, window3,
                                windowgroup1, windowgroup2');
END;
/
```

Note that if a window group name is provided, then the windows in the window group are dropped, but the window group is not dropped. To drop the window group, you must use the `DROP_GROUP` procedure.

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DROP_GROUP` procedure.

29.9.3.8 Disabling Windows

You disable one or more windows using the `DISABLE` procedure in the `DBMS_SCHEDULER` package or with Cloud Control.

Therefore, the window will not open. However, the metadata of the window is still there, so it can be reenabled. Because the `DISABLE` procedure is used for several Scheduler objects, when disabling windows, they must be preceded by `SYS`.

A window can also become disabled for other reasons. For example, a window will become disabled when it is at the end of its schedule. Also, if a window points to a schedule that no longer exists, it becomes disabled.

If there are jobs that have the window as their schedule, you will not be able to disable the window unless you set `force` to `TRUE` in the procedure call. By default, `force` is set to `FALSE`. When the window is disabled, those jobs that have the window as their schedule will not be disabled.

You can disable several windows in one call by providing a comma-delimited list of window names or window group names to the `DISABLE` procedure call. For example, the following statement disables both windows and window groups:

```
BEGIN
    DBMS_SCHEDULER.DISABLE ('sys.window1, sys.window2,
                            sys.window3, sys.windowgroup1, sys.windowgroup2');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `DISABLE` procedure.

29.9.3.9 Enabling Windows

You enable one or more windows using the `ENABLE` procedure in the `DBMS_SCHEDULER` package or Cloud Control.

An enabled window is one that can be opened. Windows are, by default, created enabled. When a window is enabled using the `ENABLE` procedure, a validity check is performed and only if this is successful will the window be enabled. When a window is enabled, it is logged in the window log table. Because the `ENABLE` procedure is used for several Scheduler objects, when enabling windows, they must be preceded by `SYS`.

You can enable several windows in one call by providing a comma-delimited list of window names. For example, the following statement enables three windows:

```
BEGIN
    DBMS_SCHEDULER.ENABLE ('sys.window1, sys.window2, sys.window3');
END;
/
```

See *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `ENABLE` procedure.

29.9.4 Managing Job Scheduling and Job Priorities with Window Groups

Window groups provide an easy way to schedule jobs that must run during multiple time periods throughout the day, week, and so on. If you create a window group, add windows to it, and then name this window group in a job's `schedule_name` attribute, the job runs during all the windows in the window group. Window groups reside in the `SYS` schema.

- [Window Group Tasks and Their Procedures](#)

You use procedures in the `DBMS_SCHEDULER` package to administer common window group tasks.

- [Creating Window Groups](#)

You create a window group by using the `DBMS_SCHEDULER.CREATE_GROUP` procedure, specifying a group type of 'WINDOW'.

- [Dropping Window Groups](#)

You drop one or more window groups by using the `DROP_GROUP` procedure in the `DBMS_SCHEDULER` package.

- [Adding a Member to a Window Group](#)

You add windows to a window group by using the `ADD_GROUP_MEMBER` procedure in the `DBMS_SCHEDULER` package.

- [Removing a Member from a Window Group](#)

You can remove one or more windows from a window group by using the `REMOVE_GROUP_MEMBER` procedure in the `DBMS_SCHEDULER` package.

- [Enabling a Window Group](#)

You enable one or more window groups using the `ENABLE` procedure in the `DBMS_SCHEDULER` package.

- [Disabling a Window Group](#)

You disable a window group using the `DISABLE` procedure in the `DBMS_SCHEDULER` package.

 [See Also:](#)

"[Window Groups](#)" for an overview of window groups.

29.9.4.1 Window Group Tasks and Their Procedures

You use procedures in the `DBMS_SCHEDULER` package to administer common window group tasks.

[Table 29-10](#) illustrates common window group tasks and the procedures you use to handle them.

Table 29-10 Window Group Tasks and Their Procedures

Task	Procedure	Privilege Needed
Create a window group	<code>CREATE_GROUP</code>	MANAGE SCHEDULER
Drop a window group	<code>DROP_GROUP</code>	MANAGE SCHEDULER
Add a member to a window group	<code>ADD_GROUP_MEMBER</code>	MANAGE SCHEDULER
Drop a member from a window group	<code>REMOVE_GROUP_MEMBER</code>	MANAGE SCHEDULER
Enable a window group	<code>ENABLE</code>	MANAGE SCHEDULER
Disable a window group	<code>DISABLE</code>	MANAGE SCHEDULER

See "[Scheduler Privileges](#)" for further information regarding privileges.

29.9.4.2 Creating Window Groups

You create a window group by using the `DBMS_SCHEDULER.CREATE_GROUP` procedure, specifying a group type of 'WINDOW'.

You can specify the member windows of the group when you create the group, or you can add them later using the `ADD_GROUP_MEMBER` procedure. A window group cannot be a member of another window group. You can, however, create a window group that has no members.

If you create a window group and you specify a member window that does not exist, an error is generated and the window group is not created. If a window is already a member of a window group, it is not added again.

Window groups are created in the `SYS` schema. Window groups, like windows, are created with access to `PUBLIC`, therefore, no privileges are required to access window groups.

The following statement creates a window group called `downtime` and adds two windows (`weeknights` and `weekends`) to it:

```
BEGIN
    DBMS_SCHEDULER.CREATE_GROUP (
        group_name    => 'downtime',
        group_type    => 'WINDOW',
        member        => 'weeknights, weekends');
END;
/
```

To verify the window group contents, issue the following queries as a user with the `MANAGE SCHEDULER` privilege:

```
SELECT group_name, enabled, number_of_members FROM dba_scheduler_groups
WHERE group_type = 'WINDOW';

GROUP_NAME      ENABLED  NUMBER_OF_MEMBERS
-----
DOWNTIME        TRUE      2

SELECT group_name, member_name FROM dba_scheduler_group_members;

GROUP_NAME      MEMBER_NAME
-----
DOWNTIME        "SYS"."WEEKENDS"
DOWNTIME        "SYS"."WEEKNIGHTS"
```

29.9.4.3 Dropping Window Groups

You drop one or more window groups by using the `DROP_GROUP` procedure in the `DBMS_SCHEDULER` package.

This call will drop the window group but not the windows that are members of this window group. To drop all the windows that are members of this group but not the window group itself, you can use the `DROP_WINDOW` procedure and provide the name of the window group to the call.

You can drop several window groups in one call by providing a comma-delimited list of window group names to the `DROP_GROUP` procedure call. You must precede each window group name with the `SYS` schema. For example, the following statement drops three window groups:

```
BEGIN
DBMS_SCHEDULER.DROP_GROUP('sys.windowgroup1, sys.windowgroup2, sys.windowgroup3');
END;
/
```

29.9.4.4 Adding a Member to a Window Group

You add windows to a window group by using the `ADD_GROUP_MEMBER` procedure in the `DBMS_SCHEDULER` package.

You can add several members to a window group in one call, by specifying a comma-delimited list of windows. For example, the following statement adds two windows to the window group `window_group1`:

```
BEGIN
DBMS_SCHEDULER.ADD_GROUP_MEMBER ('sys.windowgroup1','window2, window3');
```

```
END;
/
```

If an already open window is added to a window group, the Scheduler will not start jobs that point to this window group until the next window in the window group opens.

29.9.4.5 Removing a Member from a Window Group

You can remove one or more windows from a window group by using the REMOVE_GROUP_MEMBER procedure in the DBMS_SCHEDULER package.

Jobs with the stop_on_window_close flag set will only be stopped when a window closes. Dropping an open window from a window group has no impact on this.

You can remove several members from a window group in one call by specifying a comma-delimited list of windows. For example, the following statement drops two windows:

```
BEGIN
  DBMS_SCHEDULER.REMOVE_GROUP_MEMBER('sys.window_group1', 'window2, window3');
END;
/
```

29.9.4.6 Enabling a Window Group

You enable one or more window groups using the ENABLE procedure in the DBMS_SCHEDULER package.

By default, window groups are created ENABLED. For example:

```
BEGIN
  DBMS_SCHEDULER.ENABLE('sys.windowgroup1, sys.windowgroup2, sys.windowgroup3');
END;
/
```

29.9.4.7 Disabling a Window Group

You disable a window group using the DISABLE procedure in the DBMS_SCHEDULER package.

A job with a disabled window group as its schedule does not run when the member windows open. Disabling a window group does not disable its member windows.

You can also disable several window groups in one call by providing a comma-delimited list of window group names. For example, the following statement disables three window groups:

```
BEGIN
  DBMS_SCHEDULER.DISABLE('sys.windowgroup1, sys.windowgroup2, sys.windowgroup3');
END;
/
```

29.9.5 Allocating Resources Among Jobs Using Resource Manager

The Database Resource Manager (Resource Manager) controls how resources are allocated among database sessions. It not only controls asynchronous sessions like Scheduler jobs, but also synchronous sessions like user sessions.

It groups all "units of work" in the database into resource consumer groups and uses a resource plan to specify how the resources are allocated among the various consumer groups. The primary system resource that the Resource Manager allocates is CPU.

For Scheduler jobs, resources are allocated by first assigning each job to a job class, and then associating a job class with a consumer group. Resources are then distributed among the Scheduler jobs and other sessions within the consumer group. You can also assign relative priorities to the jobs in a job class, and resources are distributed to those jobs accordingly.

You can manually change the current resource plan at any time. Another way to change the current resource plan is by creating Scheduler windows. Windows have a resource plan attribute. When a window opens, the current plan is switched to the window's resource plan.

The Scheduler tries to limit the number of jobs that are running simultaneously so that at least some jobs can complete, rather than running a lot of jobs concurrently but without enough resources for any of them to complete.

The Scheduler and the Resource Manager are tightly integrated. The job coordinator obtains database resource availability from the Resource Manager. Based on that information, the coordinator determines how many jobs to start. It will only start jobs from those job classes that will have enough resources to run. The coordinator will keep starting jobs in a particular job class that maps to a consumer group until the Resource Manager determines that the maximum resource allocated for that consumer group has been reached. Therefore, there might be jobs in the job table that are ready to run but will not be picked up by the job coordinator because there are no resources to run them. Therefore, there is no guarantee that a job will run at the exact time that it was scheduled. The coordinator picks up jobs from the job table on the basis of which consumer groups still have resources available.

The Resource Manager continues to manage the resources that are assigned to each running job based on the specified resource plan. Keep in mind that the Resource Manager can only manage database processes. The active management of resources does not apply to external jobs.

See Also:

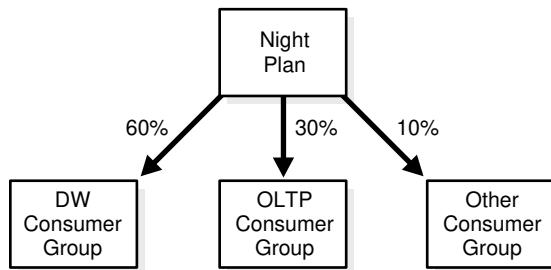

[Managing Resources with Oracle Database Resource Manager](#)

29.9.6 Example of Resource Allocation for Jobs

An example illustrates how resources are allocated for jobs.

Assume that the active resource plan is called "Night Plan" and that there are three job classes: JC1, which maps to consumer group DW; JC2, which maps to consumer group OLTP; and JC3, which maps to the default consumer group. [Figure 29-2](#) offers a simple graphical illustration of this scenario.

Figure 29-2 Sample Resource Plan

This resource plan clearly gives priority to jobs that are part of job class JC1. Consumer group DW gets 60% of the resources, thus jobs that belong to job class JC1 will get 60% of the resources. Consumer group OLTP has 30% of the resources, which implies that jobs in job class JC2 will get 30% of the resources. The consumer group Other specifies that all other consumer groups will be getting 10% of the resources. Therefore, all jobs that belong in job class JC3 will share 10% of the resources and can get a maximum of 10% of the resources.

Note that resources that remain unused by one consumer group are available from use by the other consumer groups. So if the jobs in job class JC1 do not fully use the allocated 60%, the unused portion is available for use by jobs in classes JC2 and JC3. Note also that the Resource Manager does not begin to restrict resource usage at all until CPU usage reaches 100%. See [Managing Resources with Oracle Database Resource Manager](#) for more information.

29.10 Monitoring Jobs

You can monitor jobs in several different ways.

- [About Monitoring Jobs](#)
There are several ways to monitor Scheduler jobs.
- [The Job Log](#)
You can view results for both local and remote jobs in the job log.
- [Monitoring Multiple Destination Jobs](#)
For multiple-destination jobs, the overall parent job state depends on the outcome of the child jobs.
- [Monitoring Job State with Events Raised by the Scheduler](#)
Scheduler can raise an event when a job changes state.
- [Monitoring Job State with E-mail Notifications](#)
Scheduler can send an e-mail when a job changes state.

29.10.1 About Monitoring Jobs

There are several ways to monitor Scheduler jobs.

You can monitor Scheduler jobs in the following ways:

- Viewing the job log

The job log includes the data dictionary views *_SCHEDULER_JOB_LOG and *_SCHEDULER_JOB_RUN_DETAILS, where:

- * = {DBA|ALL|USER}
- See "[Viewing the Job Log](#)".
- Querying additional data dictionary views

Query views such as DBA_SCHEDULER_RUNNING_JOBS and DBA_SCHEDULER_RUNNING_CHAINS to show the status and details of running jobs and chains.
- Writing applications that receive job state events from the Scheduler

See "[Monitoring Job State with Events Raised by the Scheduler](#)"
- Configuring jobs to send e-mail notifications upon a state change

See "[Monitoring Job State with E-mail Notifications](#)"

29.10.2 The Job Log

You can view results for both local and remote jobs in the job log.

- [Viewing the Job Log](#)
You can view information about job runs, job state changes, and job failures in the job log. The job log shows results for both local and remote jobs.
- [Run Details](#)
For every row in *_SCHEDULER_JOB_LOG for which the operation is RUN, RETRY_RUN, or RECOVERY_RUN, there is a corresponding row in the *_SCHEDULER_JOB_RUN_DETAILS view.
- [Precedence of Logging Levels in Jobs and Job Classes](#)
Both jobs and job classes have a logging_level attribute.

29.10.2.1 Viewing the Job Log

You can view information about job runs, job state changes, and job failures in the job log. The job log shows results for both local and remote jobs.

The job log is implemented as the following two data dictionary views:

- *_SCHEDULER_JOB_LOG
- *_SCHEDULER_JOB_RUN_DETAILS

Depending on the logging level that is in effect, the Scheduler can make job log entries whenever a job is run and when a job is created, dropped, enabled, and so on. For a job that has a repeating schedule, the Scheduler makes multiple entries in the job log —one for each job instance. Each log entry provides information about a particular run, such as the job completion status.

The following example shows job log entries for a repeating job that has a value of 4 for the max_runs attribute:

```
SELECT job_name, job_class, operation, status FROM USER_SCHEDULER_JOB_LOG;
```

JOB_NAME	JOB_CLASS	OPERATION	STATUS
JOB1	CLASS1	RUN	SUCCEEDED
JOB1	CLASS1	RUN	SUCCEEDED
JOB1	CLASS1	RUN	SUCCEEDED

JOB1	CLASS1	RUN	SUCCEEDED
JOB1	CLASS1	COMPLETED	

You can control how frequently information is written to the job log by setting the `logging_level` attribute of either a job or a job class. [Table 29-11](#) shows the possible values for `logging_level`.

Table 29-11 Job Logging Levels

Logging Level	Description
DBMS_SCHEDULER.LOGGING_OFF	No logging is performed.
DBMS_SCHEDULER.LOGGING_FAILED_RUNS	A log entry is made only if the job fails.
DBMS_SCHEDULER.LOGGING_RUNS	A log entry is made each time the job is run.
DBMS_SCHEDULER.LOGGING_FULL	A log entry is made every time the job runs and for every operation performed on a job, including create, enable/disable, update (with <code>SET_ATTRIBUTE</code>), stop, and drop.

Log entries for job runs are not made until after the job run completes successfully, fails, or is stopped.

The following example shows job log entries for a complete job lifecycle. In this case, the logging level for the job class is `LOGGING_FULL`, and the job is a non-repeating job. After the first successful run, the job is enabled again, so it runs once more. It is then stopped and dropped.

```
SELECT to_char(log_date, 'DD-MON-YY HH24:MI:SS') TIMESTAMP, job_name,
       job_class, operation, status FROM USER_SCHEDULER_JOB_LOG
      WHERE job_name = 'JOB2' ORDER BY log_date;
```

TIMESTAMP	JOB_NAME	JOB_CLASS	OPERATION	STATUS
18-DEC-07 23:10:56	JOB2	CLASS1	CREATE	
18-DEC-07 23:12:01	JOB2	CLASS1	UPDATE	
18-DEC-07 23:12:31	JOB2	CLASS1	ENABLE	
18-DEC-07 23:12:41	JOB2	CLASS1	RUN	SUCCEEDED
18-DEC-07 23:13:12	JOB2	CLASS1	ENABLE	
18-DEC-07 23:13:18	JOB2		RUN	STOPPED
18-DEC-07 23:19:36	JOB2	CLASS1	DROP	

29.10.2.2 Run Details

For every row in `*_SCHEDULER_JOB_LOG` for which the operation is `RUN`, `RETRY_RUN`, or `RECOVERY_RUN`, there is a corresponding row in the `*_SCHEDULER_JOB_RUN_DETAILS` view.

Rows from the two different views are correlated with their `LOG_ID` columns. You can consult the run details views to determine why a job failed or was stopped.

```
SELECT to_char(log_date, 'DD-MON-YY HH24:MI:SS') TIMESTAMP, job_name, status,
       substr(additional_info, 1, 40) ADDITIONAL_INFO
      FROM user_scheduler_job_run_details ORDER BY log_date;
```

TIMESTAMP	JOB_NAME	STATUS	ADDITIONAL_INFO
18-DEC-07 23:12:41	JOB2	SUCCEEDED	

```
18-DEC-07 23:12:18  JOB2      STOPPED  REASON="Stop job called by user:'SYSTEM'  
19-DEC-07 14:12:20  REMOTE_16  FAILED   ORA-29273: HTTP request failed ORA-06512
```

The run details views also contain actual job start times and durations.

You can also use the attribute `STORE_OUTPUT` to direct the `*_SCHEDULER_JOB_RUN_DETAILS` view to store the output sent to `stdout` for external jobs or `DBMS_OUTPUT` for database jobs. When `STORE_OUTPUT` is set to `TRUE` and the `LOGGING_LEVEL` indicates that the job run should be logged, then all the output is collected and put inside the `BINARY_OUTPUT` column of this view. A `char` representation can be queried from the `OUTPUT` column.

29.10.2.3 Precedence of Logging Levels in Jobs and Job Classes

Both jobs and job classes have a `logging_level` attribute.

The possible values for this attribute are listed in [Table 29-11](#). The default logging level for job classes is `LOGGING_RUNS`, and the default level for individual jobs is `LOGGING_OFF`. If the logging level of the job class is higher than that of a job in the class, then the logging level of the job class takes precedence. Thus, by default, all job runs are recorded in the job log.

For job classes that have very short and highly frequent jobs, the overhead of recording every single run might be too much and you might choose to turn the logging off or set logging to occur only when jobs fail. However, you might prefer to have complete logging of everything that happens with jobs in a specific class, in which case you would enable full logging for that class.

To ensure that there is logging for all jobs, the individual job creator must not be able to turn logging off. The Scheduler supports this by making the class-specified level the minimum level at which job information is logged. A job creator can only enable more logging for an individual job, not less. Thus, leaving all individual job logging levels set to `LOGGING_OFF` ensures that all jobs in a class get logged as specified in the class.

This functionality is provided for debugging purposes. For example, if the class-specific level is set to record job runs and logging is turned off at the job level, the Scheduler still logs job runs. If, however, the job creator turns on full logging and the class-specific level is set to record runs only, the higher logging level of the job takes precedence and all operations on this individual job are logged. This way, an end user can test his job by turning on full logging.

To set the logging level of an individual job, you must use the `SET_ATTRIBUTE` procedure on that job. For example, to turn on full logging for a job called `mytestjob`, issue the following statement:

```
BEGIN  
  DBMS_SCHEDULER.SET_ATTRIBUTE (  
    'mytestjob', 'logging_level', DBMS_SCHEDULER.LOGGING_FULL);  
END;  
/
```

Only a user with the `MANAGE SCHEDULER` privilege can set the logging level of a job class.

 See Also:

["Monitoring and Managing Window and Job Logs"](#) for more information about setting the job class logging level

29.10.3 Monitoring Multiple Destination Jobs

For multiple-destination jobs, the overall parent job state depends on the outcome of the child jobs.

For example, if all child jobs succeed, the parent job state is set to SUCCEEDED. If all fail, the parent job state is set to FAILED. If some fail and some succeed, the parent job state is set to SOME FAILED.

Due to situations that might arise on some destinations that delay the start of child jobs, there might be a significant delay before the parent job state is finalized. For repeating multiple-destination jobs, there might even be a situation in which some child jobs are on their next scheduled run while others are still working on the previous scheduled run. In this case, the parent job state is set to INCOMPLETE. Eventually, however, lagging child jobs may catch up to their siblings, in which case the final state of the parent job can be determined.

[Table 29-12](#) lists the contents of the job monitoring views for multiple-destination jobs.

Table 29-12 Scheduler Data Dictionary View Contents for Multiple-Destination Jobs

View Name	Contents
*_SCHEDULER_JOBS	One entry for the parent job
*_SCHEDULER_RUNNING_JOBS	One entry for the parent job when it starts and an entry for each running child job
*_SCHEDULER_JOB_LOG	One entry for the parent job when it starts (operation = 'MULTIDEST_START'), one entry for each child job when the child job completes, and one entry for the parent job when the last child job completes and thus the parent completes (operation = 'MULTIDEST_RUN')
*_SCHEDULER_JOB_RUN_DETAILS	One entry for each child job when the child job completes, and one entry for the parent job when the last child job completes and thus the parent completes
*_SCHEDULER_JOB_DESTS	One entry for each destination of the parent job

In the *_SCHEDULER_JOB_DESTS views, you can determine the unique job destination ID (job_dest_id) that is assigned to each child job. This ID represents the unique combination of a job, a credential, and a destination. You can use this ID with the STOP_JOB procedure. You can also monitor the job state of each child job with the *_SCHEDULER_JOB_DESTS views.

 See Also:

- "[Multiple-Destination Jobs](#)"
- "[Creating Multiple-Destination Jobs](#)"
- "[Scheduler Data Dictionary Views](#)"

29.10.4 Monitoring Job State with Events Raised by the Scheduler

Scheduler can raise an event when a job changes state.

- [About Job State Events](#)
You can configure a job so that the Scheduler raises an event when the job changes state.
- [Altering a Job to Raise Job State Events](#)
To enable job state events to be raised for a job, you use the `SET_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package to turn on bit flags in the `raise_events` job attribute.
- [Consuming Job State Events with your Application](#)
To consume job state events, your application must subscribe to the Scheduler event queue `SYS.SCHEDULER$_EVENT_QUEUE`. This queue is a secure queue and is owned by `SYS`.

29.10.4.1 About Job State Events

You can configure a job so that the Scheduler raises an event when the job changes state.

The Scheduler can raise an event when a job starts, when a job completes, when a job exceeds its allotted run time, and so on. The consumer of the event is your application, which takes some action in response to the event. For example, if due to a high system load, a job is still not started 30 minutes after its scheduled start time, the Scheduler can raise an event that causes a handler application to stop lower priority jobs to free up system resources. The Scheduler can raise job state events for local (regular) jobs, remote database jobs, local external jobs, and remote external jobs.

[Table 29-13](#) describes the job state event types raised by the Scheduler.

Table 29-13 Job State Event Types Raised by the Scheduler

Event Type	Description
<code>job_all_events</code>	Not an event, but a constant that provides an easy way for you to enable all events
<code>job_broken</code>	The job has been disabled and has changed to the BROKEN state because it exceeded the number of failures defined by the <code>max_failures</code> job attribute

Table 29-13 (Cont.) Job State Event Types Raised by the Scheduler

Event Type	Description
job_chain_stalled	A job running a chain was put into the CHAIN_STALLED state. A running chain becomes stalled if there are no steps running or scheduled to run and the chain evaluation_interval is set to NULL. No progress will be made in the chain unless there is manual intervention.
job_completed	The job completed because it reached its max_runs or end_date
job_disabled	The job was disabled by the Scheduler or by a call to SET_ATTRIBUTE
job_failed	The job failed, either by throwing an error or by abnormally terminating
job_over_max_dur	The job exceeded the maximum run duration specified by its max_run_duration attribute.
job_run_completed	A job run either failed, succeeded, or was stopped
job_sch_lim_reached	The job's schedule limit was reached. The job was not started because the delay in starting the job exceeded the value of the schedule_limit job attribute.
job_started	The job started
job_stopped	The job was stopped by a call to STOP_JOB
job_succeeded	The job completed successfully

You enable the raising of job state events by setting the `raise_events` job attribute. By default, a job does not raise any job state events.

The Scheduler uses Oracle Database Advanced Queuing to raise events. When raising a job state change event, the Scheduler enqueues a message onto a default event queue. Your applications subscribe to this queue, dequeue event messages, and take appropriate actions.

After you enable job state change events for a job, the Scheduler raises these events by enqueueing messages onto the Scheduler event queue `SYS.SCHEDULER$_EVENT_QUEUE`. This queue is a secure queue, so depending on your application, you may have to configure the queue to enable certain users to perform operations on it. See *Oracle Streams Concepts and Administration* for information on secure queues.

To prevent unlimited growth of the Scheduler event queue, events raised by the Scheduler expire in 24 hours by default. (Expired events are deleted from the queue.) You can change this expiry time by setting the `event_expiry_time` Scheduler attribute with the `SET_SCHEDULER_ATTRIBUTE` procedure. See *Oracle Database PL/SQL Packages and Types Reference* for more information.

29.10.4.2 Altering a Job to Raise Job State Events

To enable job state events to be raised for a job, you use the `SET_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package to turn on bit flags in the `raise_events` job attribute.

Each bit flag represents a different job state to raise an event for. For example, turning on the least significant bit enables job started events to be raised. To enable multiple state change event types in one call, you add the desired bit flag values together and supply the result as an argument to `SET_ATTRIBUTE`.

The following example enables multiple state change events for job `dw_reports`. It enables the following event types, both of which indicate some kind of error.

- `JOB_FAILED`
- `JOB_SCH_LIM_REACHED`

```
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE('dw_reports', 'raise_events',
        DBMS_SCHEDULER.JOB_FAILED + DBMS_SCHEDULER.JOB_SCH_LIM_REACHED);
END;
/
```

Note:

You do not need to enable the `JOB_OVER_MAX_DUR` event with the `raise_events` job attribute; it is always enabled.

See Also:

The discussion of `DBMS_SCHEDULER.SET_ATTRIBUTE` in *Oracle Database PL/SQL Packages and Types Reference* for the names and values of job state bit flags

29.10.4.3 Consuming Job State Events with your Application

To consume job state events, your application must subscribe to the Scheduler event queue `SYS.SCHEDULER$_EVENT_QUEUE`. This queue is a secure queue and is owned by `SYS`.

To create a subscription to this queue for a user, do the following:

1. Log in to the database as the `SYS` user or as a user with the `MANAGE ANY QUEUE` privilege.
2. Subscribe to the queue using a new or existing agent.
3. Run the package procedure `DBMS_AQADM.ENABLE_DB_ACCESS` as follows:

```
DBMS_AQADM.ENABLE_DB_ACCESS(agent_name, db_username);
```

where `agent_name` references the agent that you used to subscribe to the events queue, and `db_username` is the user for whom you want to create a subscription.

There is no need to grant dequeue privileges to the user. The dequeue privilege is granted on the Scheduler event queue to PUBLIC.

As an alternative, the user can subscribe to the Scheduler event queue using the `ADD_EVENT_QUEUE_SUBSCRIBER` procedure, as shown in the following example:

```
DBMS_SCHEDULER.ADD_EVENT_QUEUE_SUBSCRIBER(subscriber_name);
```

where `subscriber_name` is the name of the Oracle Database Advanced Queuing (AQ) agent to be used to subscribe to the Scheduler event queue. (If it is NULL, an agent is created whose name is the user name of the calling user.) This call both creates a subscription to the Scheduler event queue and grants the user permission to dequeue using the designated agent. The subscription is rule-based. The rule permits the user to see only events raised by jobs that the user owns, and filters out all other messages. After the subscription is in place, the user can either poll for messages at regular intervals or register with AQ for notification.

See *Oracle Database Advanced Queuing User's Guide* for more information.

Scheduler Event Queue

The Scheduler event queue `SYS.SCHEDULER$_EVENT_QUEUE` is of type `scheduler$_event_info`. See *Oracle Database PL/SQL Packages and Types Reference* for details on this type.

29.10.5 Monitoring Job State with E-mail Notifications

Scheduler can send an e-mail when a job changes state.

- [About E-mail Notifications](#)
You can configure a job to send e-mail notifications when it changes state.
- [Adding E-mail Notifications for a Job](#)
You use the `DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION` package procedure to add e-mail notifications for a job.
- [Removing E-mail Notifications for a Job](#)
You use the `DBMS_SCHEDULER.REMOVE_JOB_EMAIL_NOTIFICATION` package procedure to remove e-mail notifications for a job.
- [Viewing Information About E-mail Notifications](#)
You can view information about current e-mail notifications by querying the views `*_SCHEDULER_NOTIFICATIONS`.

29.10.5.1 About E-mail Notifications

You can configure a job to send e-mail notifications when it changes state.

The job state events for which e-mails can be sent are listed in [Table 29-13](#). E-mail notifications can be sent to multiple recipients, and can be triggered by any event in a list of job state events that you specify. You can also provide a filter condition, and only generate notifications for job state events that match the filter condition. You can include variables such as job owner, job name, event type, error code, and error message in both the subject and body of the message. The Scheduler automatically sets values for these variables before sending the e-mail notification.

You can configure many job state e-mail notifications for a single job. The notifications can differ by job state event list, recipients, and filter conditions.

For example, you can configure a job to send an e-mail to both the principle DBA and one of the senior DBAs whenever the job fails with error code 600 or 700. You can also configure the same job to send a notification to only the principle DBA if the job fails to start at its scheduled time.

Before you can configure jobs to send e-mail notifications, you must set the Scheduler attribute `email_server` to the address of the SMTP server to use to send the e-mail. You may also optionally set the Scheduler attribute `email_sender` to a default sender e-mail address for those jobs that do not specify a sender.

The Scheduler includes support for the SSL and TLS protocols when communicating with the SMTP server. The Scheduler also supports SMTP servers that require authentication.

See Also:

["Setting Scheduler Preferences"](#) for details about setting e-mail notification-related attributes

29.10.5.2 Adding E-mail Notifications for a Job

You use the `DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION` package procedure to add e-mail notifications for a job.

For example, the following procedure adds an e-mail notification for the `EOD_JOB` job:

```
BEGIN
    DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION (
        job_name      => 'EOD_JOB',
        recipients    => 'jsmith@example.com, rjones@example.com',
        sender        => 'do_not_reply@example.com',
        subject       => 'Scheduler Job Notification-%job_owner%-%job_name%-%event_type%',
        body          => '%event_type% occurred at %event_timestamp%. %error_message%',
        events        => 'JOB_FAILED, JOB_BROKEN, JOB_DISABLED, JOB_SCH_LIM_REACHED');
END;
/
```

Note the variables, enclosed in the '%' character, used in the `subject` and `body` arguments. When you specify multiple recipients and multiple events, each recipient is notified when any of the specified events is raised. You can verify this by querying the view `USER_SCHEDULER_NOTIFICATIONS`.

```
SELECT JOB_NAME, RECIPIENT, EVENT FROM USER_SCHEDULER_NOTIFICATIONS;
```

JOB_NAME	RECIPIENT	EVENT
EOD_JOB	jsmith@example.com	JOB_FAILED
EOD_JOB	jsmith@example.com	JOB_BROKEN
EOD_JOB	jsmith@example.com	JOB_SCH_LIM_REACHED
EOD_JOB	jsmith@example.com	JOB_DISABLED
EOD_JOB	rjones@example.com	JOB_FAILED
EOD_JOB	rjones@example.com	JOB_BROKEN

```
EOD_JOB      rjones@example.com    JOB_SCH_LIM_REACHED
EOD_JOB      rjones@example.com    JOB_DISABLED
```

You call `ADD_JOB_EMAIL_NOTIFICATION` once for each different set of notifications that you want to configure for a job. You must specify `job_name` and `recipients`. All other arguments have defaults. The default sender is defined by a Scheduler attribute, as described in the previous section. See the `ADD_JOB_EMAIL_NOTIFICATION` procedure in *Oracle Database PL/SQL Packages and Types Reference* for defaults for the `subject`, `body`, and `events` arguments.

The following example configures an additional e-mail notification for the same job for a different event. This example accepts the defaults for the `sender`, `subject`, and `body` arguments.

```
BEGIN
  DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION (
    job_name      => 'EOD_JOB',
    recipients     => 'jsmith@example.com',
    events        => 'JOB_OVER_MAX_DUR');
END;
/
```

This example could have also omitted the `events` argument to accept event defaults.

The next example is similar to the first, except that it uses a filter condition to specify that an e-mail notification is to be sent only when the error number that causes the job to fail is 600 or 700.

```
BEGIN
  DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION (
    job_name      => 'EOD_JOB',
    recipients     => 'jsmith@example.com, rjones@example.com',
    sender        => 'do_not_reply@example.com',
    subject       => 'Job Notification-%job_owner%.%job_name%-%event_type%',
    body          => '%event_type% at %event_timestamp%. %error_message%',
    events        => 'JOB_FAILED',
    filter_condition => ':event.error_code=600 or :event.error_code=700');
END;
/
```

See Also:

The `ADD_JOB_EMAIL_NOTIFICATION` procedure in *Oracle Database PL/SQL Packages and Types Reference*

29.10.5.3 Removing E-mail Notifications for a Job

You use the `DBMS_SCHEDULER.REMOVE_JOB_EMAIL_NOTIFICATION` package procedure to remove e-mail notifications for a job.

For example, the following procedure removes an e-mail notification for the `OED_JOB` job:

```
BEGIN
  DBMS_SCHEDULER.REMOVE_JOB_EMAIL_NOTIFICATION (
```

```
job_name    => 'EOD_JOB',
recipients => 'jsmith@example.com, rjones@example.com',
events      => 'JOB_DISABLED, JOB_SCH_LIM_REACHED');
END;
/
```

When you specify multiple recipients and multiple events, the notification for each specified event is removed for each recipient. Running the same query as that of the previous section, the results are now the following:

```
SELECT JOB_NAME, RECIPIENT, EVENT FROM USER_SCHEDULER_NOTIFICATIONS;
```

JOB_NAME	RECIPIENT	EVENT
EOD_JOB	jsmith@example.com	JOB_FAILED
EOD_JOB	jsmith@example.com	JOB_BROKEN
EOD_JOB	rjones@example.com	JOB_FAILED
EOD_JOB	rjones@example.com	JOB_BROKEN

Additional rules for specifying `REMOVE_JOB_EMAIL_NOTIFICATION` arguments are as follows:

- If you leave the `events` argument `NULL`, notifications for all events for the specified recipients are removed.
- If you leave `recipients` `NULL`, notifications for all recipients for the specified events are removed.
- If you leave both `recipients` and `events` `NULL`, then all notifications for the job are removed.
- If you include a recipient and event for which you did not previously create a notification, no error is generated.

See Also:

The `REMOVE_JOB_EMAIL_NOTIFICATION` procedure in *Oracle Database PL/SQL Packages and Types Reference*

29.10.5.4 Viewing Information About E-mail Notifications

You can view information about current e-mail notifications by querying the views `*_SCHEDULER_NOTIFICATIONS`.

See Also:

Oracle Database Reference for details on these views

Administering Oracle Scheduler

You can configure, manage, monitor, and troubleshoot Oracle Scheduler.

Note:

This chapter describes how to use the `DBMS_SCHEDULER` package to administer Oracle Scheduler. You can accomplish many of the same tasks using Oracle Enterprise Manager Cloud Control.

See *Oracle Database PL/SQL Packages and Types Reference* for `DBMS_SCHEDULER` information and the Cloud Control online help for information on Oracle Scheduler pages.

See [Using Oracle Scheduler with a CDB](#) for information on using Oracle Scheduler with CDB.

- [Configuring Oracle Scheduler](#)

Configuring Oracle Scheduler includes tasks such as setting privileges and preferences, and using the Oracle Scheduler agent to run remote jobs.

- [Monitoring and Managing the Scheduler](#)

You can view the currently active window and the resource plan associated with it, view information about currently running jobs, monitor and manage window and job logs, and manage Scheduler security.

- [Import/Export and the Scheduler](#)

You must use the Data Pump utilities (`impdp` and `expdp`) to export Scheduler objects.

- [Troubleshooting the Scheduler](#)

You can troubleshoot problems with Scheduler.

- [Examples of Using the Scheduler](#)

Examples illustrate using Scheduler.

- [Scheduler Reference](#)

There are several privileges and data dictionary views related to Scheduler.

30.1 Configuring Oracle Scheduler

Configuring Oracle Scheduler includes tasks such as setting privileges and preferences, and using the Oracle Scheduler agent to run remote jobs.

- [Setting Oracle Scheduler Privileges](#)

You must have the `SCHEDULER_ADMIN` role to perform all Oracle Scheduler administration tasks. Typically, database administrators already have this role with the `ADMIN` option as part of the `DBA` role.

- [Setting Scheduler Preferences](#)
There are several system-wide Scheduler preferences that you can set. You set these preferences by setting Scheduler attributes with the `SET_SCHEDULER_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package.
- [Using the Oracle Scheduler Agent to Run Remote Jobs](#)
The Oracle Scheduler agent can schedule and run remote jobs.

30.1.1 Setting Oracle Scheduler Privileges

You must have the `SCHEDULER_ADMIN` role to perform all Oracle Scheduler administration tasks. Typically, database administrators already have this role with the `ADMIN` option as part of the `DBA` role.

For example, users `SYS` and `SYSTEM` are granted the `DBA` role. You can grant this role to another administrator by issuing the following statement:

```
GRANT SCHEDULER_ADMIN TO username;
```

Because the `SCHEDULER_ADMIN` role is a powerful role allowing a grantee to execute code as any user, you should consider granting individual Scheduler system privileges instead. Object and system privileges are granted using regular SQL grant syntax, for example, if the database administrator issues the following statement:

```
GRANT CREATE JOB TO scott;
```

After this statement is executed, `scott` can create jobs, schedules, programs, and file watchers in his schema. As another example, the database administrator can issue the following statement:

```
GRANT MANAGE SCHEDULER TO adam;
```

After this statement is executed, `adam` can create, alter, or drop windows, job classes, or window groups. `adam` will also be able to set and retrieve Scheduler attributes and purge Scheduler logs.

Setting Chain Privileges

Scheduler chains use underlying Oracle Streams Rules Engine objects along with their associated privileges. To create a chain in their own schema, users must have the `CREATE JOB` privilege in addition to the Rules Engine privileges required to create rules, rule sets, and evaluation contexts in their own schema. These can be granted by issuing the following statement:

```
GRANT CREATE RULE, CREATE RULE SET, CREATE EVALUATION CONTEXT TO user;
```

To create a chain in a different schema, users must have the `CREATE ANY JOB` privilege in addition to the privileges required to create rules, rule sets, and evaluation contexts in schemas other than their own. These can be granted by issuing the following statement:

```
GRANT CREATE ANY RULE, CREATE ANY RULE SET,  
CREATE ANY EVALUATION CONTEXT TO user;
```

Altering or dropping chains in schemas other than the user's schema require corresponding system Rules Engine privileges for rules, rule sets, and evaluation contexts.

 **See Also:**

["Chain Tasks and Their Procedures"](#) for more information regarding chain privileges.

30.1.2 Setting Scheduler Preferences

There are several system-wide Scheduler preferences that you can set. You set these preferences by setting Scheduler attributes with the `SET_SCHEDULER_ATTRIBUTE` procedure in the `DBMS_SCHEDULER` package.

Setting these attributes requires the `MANAGE_SCHEDULER` privilege. The attributes are:

- `default_timezone`

It is very important that you set this attribute. Repeating jobs and windows that use the calendaring syntax need to know which time zone to use for their repeat intervals. See "[Using the Scheduler Calendaring Syntax](#)". They normally retrieve the time zone from `start_date`, but if no `start_date` is provided (which is not uncommon), they retrieve the time zone from the `default_timezone` Scheduler attribute.

The Scheduler derives the value of `default_timezone` from the operating system environment. If the Scheduler can find no compatible value from the operating system, it sets `default_timezone` to `NULL`.

It is crucial that you verify that `default_timezone` is set properly, and if not, that you set it. To verify it, run this query:

```
SELECT DBMS_SCHEDULER.STIME FROM DUAL;  
  
STIME  
-----  
28-FEB-12 09.04.10.308959000 PM UTC
```

To ensure that daylight savings adjustments are followed, it is recommended that you set `default_timezone` to a region name instead of an absolute time zone offset like '`-8:00`'. For example, if your database resides in Miami, Florida, USA, issue the following statement:

```
DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE('default_timezone', 'US/Eastern');
```

Similarly, if your database resides in Paris, you would set this attribute to '`Europe/Warsaw`'. To see a list of valid region names, run this query:

```
SELECT DISTINCT TZNAME FROM V$TIMEZONE_NAMES;
```

If you do not properly set `default_timezone`, the default time zone for repeating jobs and windows will be the absolute offset retrieved from `SYSTIMESTAMP` (the time zone of the operating system environment of the database), which means that repeating jobs and windows that do not have their `start_date` set will not follow daylight savings adjustments.

- `email_server`

This attribute specifies an SMTP server address that the Scheduler uses to send e-mail notifications for job state events. It takes the following format:

`host[:port]`

where:

- `host` is the host name or IP address of the SMTP server.
- `port` is the TCP port on which the SMTP server listens. If not specified, the default port of 25 is used.

If this attribute is not specified, set to `NULL`, or set to an invalid SMTP server address, the Scheduler cannot send job state e-mail notifications.

- `email_sender`

This attribute specifies the default e-mail address of the sender for job state e-mail notifications. It must be a valid e-mail address. If this attribute is not set or set to `NULL`, then job state e-mail notifications that do not specify a sender address do not have a `FROM` address in the e-mail header.

- `email_server_credential`

This attribute specifies the schema and name of an existing credential object. The default is `NULL`.

When an e-mail notification goes out, the Scheduler determines if the `email_server_credential` points to a valid credential object that `sys` has execute object privileges on. If the SMTP server specified in the `email_server` attribute requires authentication, then the Scheduler uses the user name and password stored in the specified credential object to authenticate with the e-mail server.

If the `email_server_credential` is specified, then the `email_server` attribute must specify an SMTP server that requires authentication.

If the `email_server_credential` is not specified, then the Scheduler supports sending notification e-mails through an SMTP server for which authentication is not configured.

- `email_server_encryption`

This attribute indicates whether encryption is enabled for this SMTP server connection, and if so, at what point encryption starts, and with which protocol.

Values for `email_server_encryption` are:

`NONE`: The default, indicates no encryption.

`SSL_TLS`: Indicates that either `SSL` or `TLS` are used, from the beginning of the connection. The two sides determine which protocol is most secure. This is the most common setting for this parameter.

`STARTTLS`: Indicates that the connection starts in an unencrypted state, but then the command `STARTTLS` directs the e-mail server to start encryption using `TLS`.

- `event_expiry_time`

This attribute enables you to set the time in seconds before a job state event generated by the Scheduler expires (is automatically purged from the Scheduler event queue). If `NULL`, job state events expire after 24 hours.

- `log_history`

This attribute controls the number of days that log entries for both the job log and the window log are retained. It helps prevent logs from growing indiscriminately. The range of valid values is 0 through 1000000. If set to 0, no history is kept.

Default value is 30. You can override this value at the job class level by setting a value for the `log_history` attribute of the job class.

See *Oracle Database PL/SQL Packages and Types Reference* for the syntax for the `SET_SCHEDULER_ATTRIBUTE` procedure.

30.1.3 Using the Oracle Scheduler Agent to Run Remote Jobs

The Oracle Scheduler agent can schedule and run remote jobs.

Using the Oracle Scheduler agent, the Scheduler can schedule and run two types of remote jobs:

- Remote database jobs: Remote database jobs must be run through an Oracle Scheduler agent. Oracle recommends that an agent be installed on the same host as the remote database.

If you intend to run remote database jobs, the Scheduler agent must be Oracle Database 11g Release 2 (11.2) or later.

- Remote external jobs: Remote external jobs run on the same host that the Scheduler agent is installed on.

If you intend to run only remote external jobs, Oracle Database 11g Release 1 (11.1) of the Scheduler agent is sufficient.

You must install Scheduler agents on all hosts that remote external jobs will run on. You should install Scheduler agents on all hosts running remote databases that remote database jobs will be run on.

Each database that runs remote jobs requires an initial setup to enable secure communications between databases and remote Scheduler agents, as described in "[Setting up Databases for Remote Jobs](#)".

Enabling remote jobs involves the following steps:

1. [Enabling and Disabling Databases for Remote Jobs](#)
2. [Installing and Configuring the Scheduler Agent on a Remote Host](#)
3. [Performing Tasks with the Scheduler Agent](#)

- [Enabling and Disabling Databases for Remote Jobs](#)

You can set up databases for remote jobs and disable databases for remote jobs.

- [Installing and Configuring the Scheduler Agent on a Remote Host](#)

Before you can run remote jobs on a particular host, you must install and configure the Scheduler agent.

- [Performing Tasks with the Scheduler Agent](#)

The Scheduler agent is a standalone program that enables you to schedule and run external and database jobs on remote hosts. You start and stop the Scheduler agent using the `schagent` utility on UNIX and Linux, and the `OracleSchedulerExecutionAgent` service on Windows.

 **See Also:**

- ["About Remote External Jobs"](#)
- ["Database Jobs"](#) for more information on remote database jobs

30.1.3.1 Enabling and Disabling Databases for Remote Jobs

You can set up databases for remote jobs and disable databases for remote jobs.

- [Setting up Databases for Remote Jobs](#)

Before a database can run jobs using a remote Scheduler agent, the database must be properly configured, and the agent must be registered with the database.

- [Disabling Remote Jobs](#)

You can disable remote jobs on a database by dropping the REMOTE_SCHEDULER_AGENT user.

30.1.3.1.1 Setting up Databases for Remote Jobs

Before a database can run jobs using a remote Scheduler agent, the database must be properly configured, and the agent must be registered with the database.

This section describes the configuration, including the required agent registration password in the database. You will later register the database, as shown in ["Registering Scheduler Agents with Databases"](#).

You can limit the number of Scheduler agents that can register, and you can set the password to expire after a specified duration.

Complete the following steps once for each database that creates and runs remote jobs.

To set up a database to create and run remote jobs:

1. Ensure that shared server is enabled.

See ["Enabling Shared Server"](#).

If several Scheduler agents are being used with the same database, set the value of the SHARED_SERVERS database initialization parameter high enough to avoid errors when all those agents try to work in parallel.

 **Note:**

If you are running in multitenant mode, you must unlock the anonymous account in CDB\$ROOT.

Using SQL*Plus, connect to CDB\$ROOT as SYS user, and enter the following command:

```
SQL> alter session set container = CDB$ROOT;
SQL> alter user anonymous account unlock container=current;
```

2. Using SQL*Plus, connect to the database (specify pluggable database under multitenant mode) as the `SYS` user.
3. Enter the following command to verify that the XML DB option is installed:

```
SQL> DESC RESOURCE_VIEW
```

If XML DB is not installed, this command returns an "object does not exist" error.

 **Note:**

If XML DB is not installed, you must install it before continuing.

4. Enable HTTP connections to the database as follows:
 - a. Determine whether or not the Oracle XML DBM HTTP Server is enabled:

Issue the following command:

```
SQL> SELECT DBMS_XDB.GETHTTPPORT() FROM DUAL;
```

If this statement returns 0, Oracle XML DBM HTTP Server is disabled.

- b. Enable Oracle XML DB HTTP Server on a nonzero port by logging in as `SYS` and issuing the following commands:

```
SQL> EXEC DBMS_XDB.SETHTTPPORT (port);
SQL> COMMIT;
```

where `port` is the TCP port number on which you want the database to listen for HTTP connections.

`port` must be an integer between 1 and 65536, and for UNIX and Linux must be greater than 1023. Choose a port number that is not already in use.

Each pluggable database must use a unique port number so that the scheduler agent can determine the exact pluggable database later during the agent registration procedure.

 **Note:**

This enables HTTP connections on all instances of an Oracle Real Application Clusters database.

5. Run the script `prvtrscl.plb` with following command:

```
SQL> @?/rdbms/admin/prvtrscl.plb
```

6. Set a registration password for the Scheduler agents using the `SET_AGENT_REGISTRATION_PASS` procedure.

The following example sets the agent registration password to `mypassword`.

```
BEGIN
  DBMS_SCHEDULER.SET_AGENT_REGISTRATION_PASS('mypassword');
END;
/
```

 **Note:**

You must have the `MANAGE_SCHEDULER` privilege to set an agent registration password. See *Oracle Database PL/SQL Packages and Types Reference* for more information on the `SET_AGENT_REGISTRATION_PASS` procedure.

You will do the actual registration further on, in "[Registering Scheduler Agents with Databases](#)".

30.1.3.1.2 Disabling Remote Jobs

You can disable remote jobs on a database by dropping the `REMOTE_SCHEDULER_AGENT` user.

To disable remote jobs:

- Submit the following SQL statement:

```
DROP USER REMOTE_SCHEDULER_AGENT CASCADE;
```

Registration of new scheduler agents and execution of remote jobs is disabled until you run `prvtrsch.plb` again.

30.1.3.2 Installing and Configuring the Scheduler Agent on a Remote Host

Before you can run remote jobs on a particular host, you must install and configure the Scheduler agent.

After installing and configuring the Scheduler agent, you must register and start the Scheduler agent on the host, described in "[Performing Tasks with the Scheduler Agent](#)". The Scheduler agent must also be installed in its own Oracle home.

To install and configure the Scheduler agent on a remote host:

1. Download or retrieve the Scheduler agent software, which is available on the Oracle Database Client media included in the Database Media Pack, and online at:

<http://www.oracle.com/technology/software/products/database>

2. Ensure that you have first properly set up any database on which you want to register the agent.

See "[Enabling and Disabling Databases for Remote Jobs](#)" for instructions.

3. Log in to the host you want to install the Scheduler agent on. This host runs remote jobs.

- For Windows, log in as an administrator.
- For UNIX and Linux, log in as the user that you want the Scheduler agent to run as. This user requires no special privileges.

4. Run the Oracle Universal Installer (OUI) from the installation media for Oracle Database Client.

- For Windows, run `setup.exe`.

- For UNIX and Linux, use the following command:

```
/directory_path/runInstaller
```

where *directory_path* is the path to the Oracle Database Client installation media.

5. On the Select Installation Type page, select **Custom**, and then click **Next**.
6. On the Select Product Languages page, select the desired languages, and click **Next**.
7. On the Specify Install Location page, enter the path for a new Oracle home for the agent, and then click **Next**.
8. On the Available Product Components page, select **Oracle Scheduler Agent**, and click **Next**.
9. On the Oracle Database Scheduler Agent page:
 - a. In the Scheduler Agent Hostname field, enter the host name of the computer that the Scheduler agent is installed on.
 - b. In the Scheduler Agent Port Number field, enter the TCP port number that the Scheduler agent is to listen on for connections, or accept the default, and then click **Next**.
Choose an integer between 1 and 65535. On UNIX and Linux, the number must be greater than 1023. Ensure that the port number is not already in use.
OUI performs a series of prerequisite checks. If any of the prerequisite checks fail, resolve the problems, and then click **Next**.
10. On the Summary page, click **Finish**.
11. (UNIX and Linux only) When OUI prompts you to run the script `root.sh`, enter the following command as the `root` user:

```
script_path/root.sh
```

The script is located in the directory that you chose for agent installation.

When the script completes, click **OK** in the Execute Configuration Scripts dialog box.

12. Click **Close** to exit OUI when installation is complete.
13. Use a text editor to review the agent configuration parameter file `schagent.conf`, which is located in the Scheduler agent home directory, and verify the port number in the `PORT=` directive.
14. Ensure that any firewall software on the remote host or any other firewall that protects that host has an exception to accommodate the Scheduler agent.

30.1.3.3 Performing Tasks with the Scheduler Agent

The Scheduler agent is a standalone program that enables you to schedule and run external and database jobs on remote hosts. You start and stop the Scheduler agent using the `schagent` utility on UNIX and Linux, and the `OracleSchedulerExecutionAgent` service on Windows.

- [About the `schagent` Utility](#)

The executable utility `schagent` performs certain tasks for the agent on Windows, UNIX and Linux.

- [Using the Scheduler Agent on Windows](#)
The Windows Scheduler agent service is automatically created and started during installation. The name of the service ends with `OracleSchedulerExecutionAgent`.
- [Starting the Scheduler Agent](#)
Starting the Scheduler agent enables the host on which it resides to run remote jobs.
- [Stopping the Scheduler Agent](#)
Stopping the Scheduler agent prevents the host on which it resides from running remote jobs.
- [Registering Scheduler Agents with Databases](#)
As soon as you have finished configuring the Scheduler Agent, you can register the Agent on one or more databases that are to run remote jobs.

30.1.3.3.1 About the schagent Utility

The executable utility `schagent` performs certain tasks for the agent on Windows, UNIX and Linux.

The options for `schagent` are indicated in [Table 30-1](#).

Use `schagent` with the appropriate syntax and options as follows:

For example:

UNIX and Linux: `AGENT_HOME/bin/schagent -status`

Windows: `AGENT_HOME/bin/schagent.exe -status`

Table 30-1 schagent options

Option	Description
<code>-start</code>	Starts the Scheduler Agent. <i>UNIX and Linux only</i>
<code>-stop</code>	Prompts the Scheduler agent to stop all the currently running jobs and then stop execution gracefully. <i>UNIX and Linux only</i>
<code>-abort</code>	Stops the Scheduler agent forcefully, that is, without stopping jobs first. From Oracle Database 11g Release 2 (11.2). <i>UNIX and Linux only</i>
<code>-status</code>	Returns this information about the Scheduler Agent running locally: version, uptime, total number of jobs run since the agent started, number of jobs currently running, and their descriptions.
<code>-registerdatabase</code>	Register the Scheduler agent with the base database or additional databases that are to run remote jobs on the agent's host computer.
<code>-unregisterdatabase</code>	Unregister an agent from a database.

30.1.3.3.2 Using the Scheduler Agent on Windows

The Windows Scheduler agent service is automatically created and started during installation. The name of the service ends with `OracleSchedulerExecutionAgent`.

 **Note:**

Do not confuse this service with the `OracleJobScheduler` service, which runs on a Windows computer on which an Oracle database is installed, and manages the running of local external jobs without credentials.

30.1.3.3.3 Starting the Scheduler Agent

Starting the Scheduler agent enables the host on which it resides to run remote jobs.

To start the Scheduler agent:

- Do one of the following:
 - On UNIX and Linux, run the following command:
`AGENT_HOME/bin/schagent -start`
 - On Windows, start the service whose name ends with `OracleSchedulerExecutionAgent`.

30.1.3.3.4 Stopping the Scheduler Agent

Stopping the Scheduler agent prevents the host on which it resides from running remote jobs.

To stop the Scheduler agent:

- Do one of the following:
 - On UNIX and Linux, run the `schagent` utility with either the `-stop` or `-abort` option as described in [Table 30-1](#):
`AGENT_HOME/bin/schagent -stop`
 - On Windows, stop the service whose name ends with `OracleSchedulerExecutionAgent`. This is equivalent to the `-abort` option.

30.1.3.3.5 Registering Scheduler Agents with Databases

As soon as you have finished configuring the Scheduler Agent, you can register the Agent on one or more databases that are to run remote jobs.

You can also log in later on and register the agent with additional databases.

1. If you have already logged out, then log in to the host that is running the Scheduler agent, as follows:
 - For Windows, log in as an administrator.
 - For UNIX and Linux, log in as the user with which you installed the Scheduler agent.
2. Use the following command for each database that you want to register the Scheduler agent on:
 - On UNIX and Linux, run this command:
`AGENT_HOME/bin/schagent -registerdatabase db_host db_http_port`

- On Windows, run this command:

```
AGENT_HOME/bin/schagent.exe -registerdatabase db_host db_http_port
```

where:

- *db_host* is the host name or IP address of the host on which the database resides. In an Oracle Real Application Clusters environment, you can specify any node.
- *db_http_port* is the port number that the database listens on for HTTP connections. You set this parameter previously in "[Enabling and Disabling Databases for Remote Jobs](#)". You can check the port number by submitting the following SQL statement to the database:

```
SELECT DBMS_XDB.GETHTTPPORT() FROM DUAL;
```

A port number of 0 means that HTTP connections are disabled.

The agent prompts you to enter the agent registration password that you set in "[Enabling and Disabling Databases for Remote Jobs](#)".

3. Repeat the previous steps for any additional databases to run remote jobs on the agent's host.

30.2 Monitoring and Managing the Scheduler

You can view the currently active window and the resource plan associated with it, view information about currently running jobs, monitor and manage window and job logs, and manage Scheduler security.

- [Viewing the Currently Active Window and Resource Plan](#)

You can view the currently active window and the plan associated with it by querying the `DBA_SCHEDULER_WINDOWS` view.

- [Finding Information About Currently Running Jobs](#)

You can check the state of a job by querying the `DBA_SCHEDULER_JOBS` view.

- [Monitoring and Managing Window and Job Logs](#)

The Scheduler supports two kinds of logs: the job log and the window log.

- [Managing Scheduler Security](#)

You should grant the appropriate privileges to users based on the Scheduler operations they will perform.

30.2.1 Viewing the Currently Active Window and Resource Plan

You can view the currently active window and the plan associated with it by querying the `DBA_SCHEDULER_WINDOWS` view.

For example, issue the following statement:

```
SELECT WINDOW_NAME, RESOURCE_PLAN FROM DBA_SCHEDULER_WINDOWS
WHERE ACTIVE='TRUE';
```

WINDOW_NAME	RESOURCE_PLAN
MY_WINDOW10	MY_RESOURCEPLAN1

If there is no window active, you can view the active resource plan by issuing the following statement:

```
SELECT * FROM V$RSRC_PLAN;
```

30.2.2 Finding Information About Currently Running Jobs

You can check the state of a job by querying the DBA_SCHEDULER_JOBS view.

For example, issue the following statement:

```
SELECT JOB_NAME, STATE FROM DBA_SCHEDULER_JOBS
WHERE JOB_NAME = 'MY_EMP_JOB1';
```

JOB_NAME	STATE
----- MY_EMP_JOB1	----- DISABLED

In this case, you could enable the job using the `ENABLE` procedure. [Table 30-2](#) shows the valid values for job state.

Table 30-2 Job States

Job State	Description
disabled	The job is disabled.
scheduled	The job is scheduled to be executed.
running	The job is currently running.
completed	The job has completed, and is not scheduled to run again.
stopped	The job was scheduled to run once and was stopped while it was running.
broken	The job is broken.
failed	The job was scheduled to run once and failed.
retry scheduled	The job has failed at least once and a retry has been scheduled to be executed.
succeeded	The job was scheduled to run once and completed successfully.
chain_stalled	The job is of type chain and has no steps running, no steps scheduled to run, and no event steps waiting on an event, and the <code>chain_evaluation_interval</code> is set to <code>NULL</code> . No progress will be made in the chain unless there is manual intervention.

You can check the progress of currently running jobs by issuing the following statement:

```
SELECT * FROM ALL_SCHEDULER_RUNNING_JOBS;
```

Note that, for the column `CPU_USED` to show valid data, the initialization parameter `RESOURCE_LIMIT` must be set to `true`.

You can check the status of all jobs at all remote and local destinations by issuing the following statement:

```
SELECT * FROM DBA_SCHEDULER_JOB_DESTS;
```

You can find out information about a job that is part of a running chain by issuing the following statement:

```
SELECT * FROM ALL_SCHEDULER_RUNNING_CHAINS WHERE JOB_NAME='MY_JOB1';
```

You can check whether the job coordinator is running by searching for a process of the form `c_jqNNN`.

 **See Also:**

- ["Multiple-Destination Jobs"](#)
- *Oracle Database Reference* for details regarding the `*_SCHEDULER_RUNNING_JOBS` view
- *Oracle Database Reference* for details regarding the `*_SCHEDULER_JOBS` view

30.2.3 Monitoring and Managing Window and Job Logs

The Scheduler supports two kinds of logs: the job log and the window log.

- [Job Log](#)
You can view information about job runs, job state changes, and job failures in the job log.
- [Window Log](#)
The window log records operations on windows.
- [Purging Logs](#)
To prevent job and window logs from growing indiscriminately, use the `SET_SCHEDULER_ATTRIBUTE` procedure to specify how much history (in days) to keep.

30.2.3.1 Job Log

You can view information about job runs, job state changes, and job failures in the job log.

The job log is implemented as the following two data dictionary views:

- `*_SCHEDULER_JOB_LOG`
- `*_SCHEDULER_JOB_RUN_DETAILS`

You can control the amount of logging that the Scheduler performs on jobs at both the job class and individual job level. Normally, you control logging at the class level, as this offers you more control over logging for the jobs in the class.

See "[Viewing the Job Log](#)" for definitions of the various logging levels and for information about logging level precedence between jobs and their job class. By default, the logging level of job classes is `LOGGING_RUNS`, which causes all job runs to be logged.

You can set the `logging_level` attribute when you create the job class, or you can use the `SET_ATTRIBUTE` procedure to change the logging level at a later time. The following

example sets the logging level of jobs in the `myclass1` job class to `LOGGING_FAILED_RUNS`, which means that only failed runs are logged. Note that all job classes are in the `SYS` schema.

```
BEGIN
  DBMS_SCHEDULER.SET_ATTRIBUTE (
    'sys.myclass1', 'logging_level', DBMS_SCHEDULER.LOGGING_FAILED_RUNS);
END;
/
```

You must be granted the `MANAGE SCHEDULER` privilege to set the logging level of a job class.

See Also:

- "[Viewing the Job Log](#)" for more detailed information about the job log and for examples of queries against the job log views
- *Oracle Database Reference* for details on the `*_SCHEDULER_JOB_LOG` view
- *Oracle Database Reference* for details on the `*_SCHEDULER_JOB_RUN_DETAILS` view
- *Oracle Database PL/SQL Packages and Types Reference* for detailed information about the `CREATE_JOB_CLASS` and `SET_ATTRIBUTE` procedures
- "[Setting Scheduler Preferences](#)" for information about setting retention for log entries

30.2.3.2 Window Log

The window log records operations on windows.

The Scheduler makes an entry in the window log each time that:

- You create or drop a window
- A window opens
- A window closes
- Windows overlap
- You enable or disable a window

There are no logging levels for window activity logging.

To see the contents of the window log, query the `DBA_SCHEDULER_WINDOW_LOG` view. The following statement shows sample output from this view:

```
SELECT log_id, to_char(log_date, 'DD-MON-YY HH24:MI:SS') timestamp,
       window_name, operation FROM DBA_SCHEDULER_WINDOW_LOG;
```

LOG_ID	TIMESTAMP	WINDOW_NAME	OPERATION
4	10/01/2004 15:29:23	WEEKEND_WINDOW	CREATE
5	10/01/2004 15:33:01	WEEKEND_WINDOW	UPDATE

```

22 10/06/2004 22:02:48 WEEKKNIGHT_WINDOW OPEN
25 10/07/2004 06:59:37 WEEKKNIGHT_WINDOW CLOSE
26 10/07/2004 22:01:37 WEEKKNIGHT_WINDOW OPEN
29 10/08/2004 06:59:51 WEEKKNIGHT_WINDOW CLOSE

```

The DBA_SCHEDULER_WINDOWS_DETAILS view provides information about every window that was active and is now closed (completed). The following statement shows sample output from that view:

```
SELECT LOG_ID, WINDOW_NAME, ACTUAL_START_DATE, ACTUAL_DURATION
  FROM DBA_SCHEDULER_WINDOW_DETAILS;
```

LOG_ID	WINDOW_NAME	ACTUAL_START_DATE	ACTUAL_DURATION
25	WEEKKNIGHT_WINDOW	06-OCT-04 10:02.48.832438 PM PST8PDT +000	01:02:32
29	WEEKKNIGHT_WINDOW	07-OCT-04 10.01.37.025704 PM PST8PDT +000	03:02:00

Notice that log IDs correspond in both of these views, and that in this case the rows in the DBA_SCHEDULER_WINDOWS_DETAILS view correspond to the CLOSE operations in the DBA_SCHEDULER_WINDOW_LOG view.

See Also:

- *Oracle Database Reference* for details on the *_SCHEDULER_WINDOW_LOG view
- *Oracle Database Reference* for details on the DBA_SCHEDULER_WINDOWS_DETAILS view

30.2.3.3 Purging Logs

To prevent job and window logs from growing indiscriminately, use the SET_SCHEDULER_ATTRIBUTE procedure to specify how much history (in days) to keep.

Once per day, the Scheduler automatically purges all log entries that are older than the specified history period from both the job log and the window log. The default history period is 30 days. For example, to change the history period to 90 days, issue the following statement:

```
DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE('log_history','90');
```

Some job classes are more important than others. Because of this, you can override this global history setting by using a class-specific setting. For example, suppose that there are three job classes (class1, class2, and class3), and that you want to keep 10 days of history for the window log, class1, and class3, but 30 days for class2. To achieve this, issue the following statements:

```
DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE('log_history','10');
DBMS_SCHEDULER.SET_ATTRIBUTE('class2','log_history','30');
```

You can also set the class-specific history when creating the job class.

Note that log entries pertaining to steps of a chain run are not purged until the entries for the main chain job are purged.

Purging Logs Manually

The PURGE_LOG procedure enables you to manually purge logs. As an example, the following statement purges all entries from both the job and window logs:

```
DBMS_SCHEDULER.PURGE_LOG();
```

Another example is the following, which purges all entries from the job log that are older than three days. The window log is not affected by this statement.

```
DBMS_SCHEDULER.PURGE_LOG(log_history => 3, which_log => 'JOB_LOG');
```

The following statement purges all window log entries older than 10 days and all job log entries older than 10 days that relate to job1 and to the jobs in class2:

```
DBMS_SCHEDULER.PURGE_LOG(log_history => 10, job_name => 'job1, sys.class2');
```

30.2.4 Managing Scheduler Security

You should grant the appropriate privileges to users based on the Scheduler operations they will perform.

You should grant the CREATE JOB system privilege to regular users who need to be able to use the Scheduler to schedule and run jobs. You should grant MANAGE SCHEDULER to any database administrator who needs to manage system resources. Grant any other Scheduler system privilege or role with great caution. In particular, the CREATE ANY JOB system privilege and the SCHEDULER_ADMIN role, which includes it, are very powerful because they allow execution of code as any user. They should only be granted to very powerful roles or users.

Handling external job is a particularly important issue from a security point of view. Only users that need to run jobs outside of the database should be granted the CREATE EXTERNAL JOB system privilege that allows them to do so. Security for the Scheduler has no other special requirements. See *Oracle Database Security Guide* for details regarding security.

If users need to create credentials to authenticate their jobs to the operating system or a remote database, grant them CREATE CREDENTIAL system privilege.

Note:

When upgrading from Oracle Database 10g Release 1 (10.1) to Oracle Database 10g Release 2 (10.2) or later, CREATE EXTERNAL JOB is automatically granted to all users and roles that have the CREATE JOB privilege. Oracle recommends that you revoke this privilege from users that do not need it.

30.3 Import/Export and the Scheduler

You must use the Data Pump utilities (`impdp` and `expdp`) to export Scheduler objects.

You cannot use the earlier import/export utilities (`IMP` and `EXP`) with the Scheduler. Also, Scheduler objects cannot be exported while the database is in read-only mode.

An export generates the DDL that was used to create the Scheduler objects. All attributes are exported. When an import is done, all the database objects are re-created in the new database. All schedules are stored with their time zones, which are maintained in the new database. For example, schedule "Monday at 1 PM PST in a database in San Francisco" would be the same if it was exported and imported to a database in Germany.

Although Scheduler credentials are exported, for security reasons, the passwords in these credentials are not exported. After you import Scheduler credentials, you must reset the passwords using the `SET_ATTRIBUTE` procedure of the `DBMS_SCHEDULER` package.

 **See Also:**

Oracle Database Utilities for details on Data Pump

30.4 Troubleshooting the Scheduler

You can troubleshoot problems with Scheduler.

- [A Job Does Not Run](#)
A job may fail to run for several reasons.
- [A Program Becomes Disabled](#)
A program can become disabled if a program argument is dropped or `number_of_arguments` is changed so that all arguments are no longer defined.
- [A Window Fails to Take Effect](#)
A window can fail to take effect for various reasons.

30.4.1 A Job Does Not Run

A job may fail to run for several reasons.

To begin troubleshooting a job that you suspect did not run, check the job state by issuing the following statement:

```
SELECT JOB_NAME, STATE FROM DBA_SCHEDULER_JOBS;
```

Typical output will resemble the following:

JOB_NAME	STATE

MY_EMP_JOB	DISABLED
MY_EMP_JOB1	FAILED
MY_NEW_JOB1	DISABLED
MY_NEW_JOB2	BROKEN
MY_NEW_JOB3	COMPLETED

- [About Job States](#)
If a job does not run, then it can be in one of the following states: failed, broken, disabled, or completed.
- [Viewing the Job Log](#)
The job log is an important troubleshooting tool.

- [Troubleshooting Remote Jobs](#)
Remote jobs must successfully communicate with a Scheduler agent on the remote host. If a remote job does not run, then check the `DBA_SCHEDULER_JOBS` view and the job log first.
- [About Job Recovery After a Failure](#)
The Scheduler can attempt to recover jobs that are interrupted.

30.4.1.1 About Job States

If a job does not run, then it can be in one of the following states: failed, broken, disabled, or completed.

- [Failed Jobs](#)
If a job has the status of `FAILED` in the job table, then it was scheduled to run once but the execution has failed. If the job was specified as restartable, then all retries have failed.
- [Broken Jobs](#)
A broken job is one that has exceeded a certain number of failures. This number is set in `max_failures`, and can be altered.
- [Disabled Jobs](#)
A job can become disabled for several reasons.
- [Completed Jobs](#)
A job will be completed if `end_date` or `max_runs` is reached.

30.4.1.1.1 Failed Jobs

If a job has the status of `FAILED` in the job table, then it was scheduled to run once but the execution has failed. If the job was specified as restartable, then all retries have failed.

If a job fails in the middle of execution, only the last transaction of that job is rolled back. If your job executes multiple transactions, then you must be careful about setting `restartable` to `TRUE`. You can query failed jobs by querying the `*_SCHEDULER_JOB_RUN_DETAILS` views.

30.4.1.1.2 Broken Jobs

A broken job is one that has exceeded a certain number of failures. This number is set in `max_failures`, and can be altered.

In the case of a broken job, the entire job is broken, and it will not be run until it has been fixed. For debugging and testing, you can use the `RUN_JOB` procedure.

You can query broken jobs by querying the `*_SCHEDULER_JOBS` and `*_SCHEDULER_JOB_LOG` views.

30.4.1.1.3 Disabled Jobs

A job can become disabled for several reasons.

The reasons include the following:

- The job was manually disabled
- The job class it belongs to was dropped

- The program, chain, or schedule that it points to was dropped
- A window or window group is its schedule and the window or window group is dropped

30.4.1.1.4 Completed Jobs

A job will be completed if `end_date` or `max_runs` is reached.

If a job recently completed successfully but is scheduled to run again, then the job state is SCHEDULED.

30.4.1.2 Viewing the Job Log

The job log is an important troubleshooting tool.

For details and instructions, see "[Viewing the Job Log](#)".

30.4.1.3 Troubleshooting Remote Jobs

Remote jobs must successfully communicate with a Scheduler agent on the remote host. If a remote job does not run, then check the `DBA_SCHEDULER_JOBS` view and the job log first.

Then perform the following tasks:

1. Check that the remote system is reachable over the network with tools such as `nslookup` and `ping`.
2. Check the status of the Scheduler agent on the remote host by calling the `GET_AGENT_VERSION` package procedure.

```
DECLARE
    versionnum VARCHAR2(30);
BEGIN
    versionnum := DBMS_SCHEDULER.GET_AGENT_VERSION('remote_host.example.com');
    DBMS_OUTPUT.PUT_LINE(versionnum);
END;
/
```

If an error is generated, the agent may not be installed or may not be registered with your local database. See "[Using the Oracle Scheduler Agent to Run Remote Jobs](#)" for instructions for installing, registering, and starting the Scheduler agent.

30.4.1.4 About Job Recovery After a Failure

The Scheduler can attempt to recover jobs that are interrupted.

The Scheduler attempts to recover jobs that are interrupted when:

- The database abnormally shuts down
- A job slave process is killed or otherwise fails
- For an external job, the external job process that starts the executable or script is killed or otherwise fails. (The external job process is `ext_job` on UNIX. On Windows, it is the external job service.)
- For an external job, the process that runs the end-user executable or script is killed or otherwise fails.

Job recovery proceeds as follows:

- The Scheduler adds an entry to the job log for the instance of the job that was running when the failure occurred. In the log entry, the OPERATION is 'RUN', the STATUS is 'STOPPED', and ADDITIONAL_INFO contains one of the following:
 - REASON="Job slave process was terminated"
 - REASON="ORA-01014: ORACLE shutdown in progress"
- If restartable is set to TRUE for the job, the job is restarted.
- If restartable is set to FALSE for the job:
 - If the job is a run-once job and auto_drop is set to TRUE, the job run is done and the job is dropped.
 - If the job is a run-once job and auto_drop is set to FALSE, the job is disabled and the job state is set to 'STOPPED'.
 - If the job is a repeating job, the Scheduler schedules the next job run and the job state is set to 'SCHEDULED'.

When a job is restarted as a result of this recovery process, the new run is entered into the job log with the operation 'RECOVERY_RUN'.

30.4.2 A Program Becomes Disabled

A program can become disabled if a program argument is dropped or number_of_arguments is changed so that all arguments are no longer defined.

See "[Creating and Managing Programs to Define Jobs](#)" for more information regarding programs.

30.4.3 A Window Fails to Take Effect

A window can fail to take effect for various reasons.

A window can fail to take effect for the following reasons:

- A window becomes disabled when it is at the end of its schedule
- A window that points to a schedule that no longer exists is disabled

See "[Managing Job Scheduling and Job Priorities with Windows](#)" for more information regarding windows.

30.5 Examples of Using the Scheduler

Examples illustrate using Scheduler.

- [Examples of Creating Job Classes](#)
Examples illustrate creating job classes.
- [Examples of Setting Attributes](#)
Examples illustrate setting attributes.
- [Examples of Creating Chains](#)
Examples illustrate creating chains.

- [Examples of Creating Jobs and Schedules Based on Events](#)
Examples illustrate creating event-based jobs and event schedules.
- [Example of Creating a Job In an Oracle Data Guard Environment](#)
In an Oracle Data Guard environment, the Scheduler includes additional support for two database roles: primary and logical standby. You can configure a job to run only when the database is in the primary role or only when the database is in the logical standby role.

30.5.1 Examples of Creating Job Classes

Examples illustrate creating job classes.

To create a job class, you use the `CREATE_JOB_CLASS` procedure.

Example 30-1 Creating a Job Class

The following statement creates a job class:

```
BEGIN
    DBMS_SCHEDULER.CREATE_JOB_CLASS (
        job_class_name          => 'my_class1',
        service                 => 'my_service1',
        comments                => 'This is my first job class');
END;
/
```

This creates `my_class1` in `SYS`. It uses a service called `my_service1`. To verify that the job class was created, issue the following statement:

```
SELECT JOB_CLASS_NAME FROM DBA_SCHEDULER_JOB_CLASSES
WHERE JOB_CLASS_NAME = 'MY_CLASS1';

JOB_CLASS_NAME
-----
MY_CLASS1
```

Example 30-2 Creating a Job Class

The following statement creates a job class:

```
BEGIN
    DBMS_SCHEDULER.CREATE_JOB_CLASS (
        job_class_name          => 'finance_jobs',
        resource_consumer_group  => 'finance_group',
        service                 => 'accounting',
        comments                => 'All finance jobs');
END;
/
```

This creates `finance_jobs` in `SYS`. It assigns a resource consumer group called `finance_group`, and designates service affinity for the `accounting` service. Note that if the `accounting` service is mapped to a resource consumer group other than `finance_group`, jobs in this class run under the `finance_group` consumer group, because the `resource_consumer_group` attribute takes precedence.

 **See Also:**

Oracle Database PL/SQL Packages and Types Reference for detailed information about the CREATE_JOB_CLASS procedure and "[Creating Job Classes](#)" for further information

30.5.2 Examples of Setting Attributes

Examples illustrate setting attributes.

To set attributes, you use SET_ATTRIBUTE and SET_SCHEDULER_ATTRIBUTE procedures.

Example 30-3 Setting the Repeat Interval Attribute

The following example resets the frequency that my_emp_job1 runs daily:

```
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE (
        name      => 'my_emp_job1',
        attribute  => 'repeat_interval',
        value      => 'FREQ=DAILY');
END;
/
```

To verify the change, issue the following statement:

```
SELECT JOB_NAME, REPEAT_INTERVAL FROM DBA_SCHEDULER_JOBS
WHERE JOB_NAME = 'MY_EMP_JOB1';

JOB_NAME          REPEAT_INTERVAL
-----            -----
MY_EMP_JOB1      FREQ=DAILY
```

Example 30-4 Setting Multiple Job Attributes for a Set of Jobs

The following example sets four different attributes for each of five jobs:

```
DECLARE
    newattr sys.jobattr;
    newattrarr sys.jobattr_array;
    j number;
BEGIN
    -- Create new JOBATTR array
    newattrarr := sys.jobattr_array();

    -- Allocate enough space in the array
    newattrarr.extend(20);
    j := 1;
    FOR i IN 1..5 LOOP
        -- Create and initialize a JOBATTR object type
        newattr := sys.jobattr(job_name => 'TESTJOB' || to_char(i),
                               attr_name => 'MAX_FAILURES',
                               attr_value => 5);
        -- Add it to the array.
        newattrarr(j) := newattr;
        j := j + 1;
        newattr := sys.jobattr(job_name => 'TESTJOB' || to_char(i),
                               attr_name => 'COMMENTS',
```

```

        attr_value => 'Test job');
newattrarr(j) := newattr;
j := j + 1;
newattr := sys.jobattr(job_name => 'TESTJOB' || to_char(i),
                      attr_name => 'END_DATE',
                      attr_value => systimestamp + interval '24' hour);
newattrarr(j) := newattr;
j := j + 1;
newattr := sys.jobattr(job_name => 'TESTJOB' || to_char(i),
                      attr_name => 'SC SCHEDULE_LIMIT',
                      attr_value => interval '1' hour);
newattrarr(j) := newattr;
j := j + 1;
END LOOP;

-- Call SET_JOB_ATTRIBUTES to set all 20 set attributes in one transaction
DBMS_SCHEDULER.SET_JOB_ATTRIBUTES(newattrarr, 'TRANSACTIONAL');
END;
/

```

See Also:

Oracle Database PL/SQL Packages and Types Reference for detailed information about the `SET_SCHEDULER_ATTRIBUTE` procedure and "[Setting Scheduler Preferences](#)"

30.5.3 Examples of Creating Chains

Examples illustrate creating chains.

To create chains, you use the `CREATE_CHAIN` procedure. After creating a chain, you add steps to the chain with the `DEFINE_CHAIN_STEP` or `DEFINE_CHAIN_EVENT_STEP` procedures and define the rules with the `DEFINE_CHAIN_RULE` procedure.

Example 30-5 Creating a Chain

The following example creates a chain where `my_program1` runs before `my_program2` and `my_program3`. `my_program2` and `my_program3` run in parallel after `my_program1` has completed.

The user for this example must have the `CREATE EVALUATION CONTEXT`, `CREATE RULE`, and `CREATE RULE SET` privileges. See "[Setting Chain Privileges](#)" for more information.

```

BEGIN
  DBMS_SCHEDULER.CREATE_CHAIN (
    chain_name          => 'my_chain1',
    rule_set_name       => NULL,
    evaluation_interval => NULL,
    comments            => NULL);
END;
/

--- define three steps for this chain. Referenced programs must be enabled.
BEGIN
  DBMS_SCHEDULER.DEFINE_CHAIN_STEP('my_chain1', 'stepA', 'my_program1');
  DBMS_SCHEDULER.DEFINE_CHAIN_STEP('my_chain1', 'stepB', 'my_program2');

```

```

DBMS_SCHEDULER.DEFINE_CHAIN_STEP('my_chain1', 'stepC', 'my_program3');
END;
/

--- define corresponding rules for the chain.
BEGIN
DBMS_SCHEDULER.DEFINE_CHAIN_RULE('my_chain1', 'TRUE', 'START stepA');
DBMS_SCHEDULER.DEFINE_CHAIN_RULE (
    'my_chain1', 'stepA COMPLETED', 'Start stepB, stepC');
DBMS_SCHEDULER.DEFINE_CHAIN_RULE (
    'my_chain1', 'stepB COMPLETED AND stepC COMPLETED', 'END');
END;
/

--- enable the chain
BEGIN
DBMS_SCHEDULER.ENABLE('my_chain1');
END;
/

--- create a chain job to start the chain daily at 1:00 p.m.
BEGIN
DBMS_SCHEDULER.CREATE_JOB (
    job_name      => 'chain_job_1',
    job_type      => 'CHAIN',
    job_action    => 'my_chain1',
    repeat_interval => 'freq=daily;byhour=13;byminute=0;bysecond=0',
    enabled        => TRUE);
END;
/

```

Example 30-6 Creating a Chain

The following example creates a chain where first `my_program1` runs. If it succeeds, `my_program2` runs; otherwise, `my_program3` runs.

```

BEGIN
DBMS_SCHEDULER.CREATE_CHAIN (
    chain_name      => 'my_chain2',
    rule_set_name   => NULL,
    evaluation_interval => NULL,
    comments        => NULL);
END;
/

--- define three steps for this chain.
BEGIN
DBMS_SCHEDULER.DEFINE_CHAIN_STEP('my_chain2', 'step1', 'my_program1');
DBMS_SCHEDULER.DEFINE_CHAIN_STEP('my_chain2', 'step2', 'my_program2');
DBMS_SCHEDULER.DEFINE_CHAIN_STEP('my_chain2', 'step3', 'my_program3');
END;
/

--- define corresponding rules for the chain.
BEGIN
DBMS_SCHEDULER.DEFINE_CHAIN_RULE ('my_chain2', 'TRUE', 'START step1');
DBMS_SCHEDULER.DEFINE_CHAIN_RULE (
    'my_chain2', 'step1 SUCCEEDED', 'Start step2');
DBMS_SCHEDULER.DEFINE_CHAIN_RULE (
    'my_chain2', 'step1 COMPLETED AND step1 NOT SUCCEEDED', 'Start step3');
DBMS_SCHEDULER.DEFINE_CHAIN_RULE (

```

```
'my_chain2', 'step2 COMPLETED OR step3 COMPLETED', 'END');
END;
/
```

30.5.4 Examples of Creating Jobs and Schedules Based on Events

Examples illustrate creating event-based jobs and event schedules.

To create event-based jobs, you use the CREATE_JOB procedure. To create event-based schedules, you use the CREATE_EVENT_SCHEDULE procedure.

These examples assume the existence of an application that, when it detects the arrival of a file on a system, enqueues an event onto the queue `my_events_q`.

Example 30-7 Creating an Event-Based Schedule

The following example illustrates creating a schedule that can be used to start a job whenever the Scheduler receives an event indicating that a file arrived on the system before 9AM:

```
BEGIN
  DBMS_SCHEDULER.CREATE_EVENT_SCHEDULE (
    schedule_name      => 'scott.file_arrival',
    start_date         => systimestamp,
    event_condition   => 'tab.user_data.object_owner = ''SCOTT''
                           and tab.user_data.event_name = ''FILE_ARRIVAL''
                           and extract hour from tab.user_data.event_timestamp < 9',
    queue_spec        => 'my_events_q');
END;
/
```

Example 30-8 Creating an Event-Based Job

The following example creates a job that starts when the Scheduler receives an event indicating that a file arrived on the system:

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB (
    job_name          => my_job,
    program_name      => my_program,
    start_date        => '15-JUL-04 1.00.00AM US/Pacific',
    event_condition   => 'tab.user_data.event_name = ''LOW_INVENTORY''',
    queue_spec        => 'my_events_q',
    enabled           => TRUE,
    comments          => 'my event-based job');
END;
/
```

Oracle Database PL/SQL Packages and Types Reference for detailed information about the CREATE_JOB and CREATE_EVENT_SCHEDULE procedures

30.5.5 Example of Creating a Job In an Oracle Data Guard Environment

In an Oracle Data Guard environment, the Scheduler includes additional support for two database roles: primary and logical standby. You can configure a job to run only when the database is in the primary role or only when the database is in the logical standby role.

To do so, you set the `database_role` attribute. This example explains how to enable a job to run in both database roles. The method used is to create two copies of the job and assign a different `database_role` attribute to each.

By default, a job runs when the database is in the role that it was in when the job was created. You can run the same job in both roles using the following steps:

1. Copy the job
2. Enable the new job
3. Change the `database_role` attribute of the new job to the required role

The example starts by creating a job called `primary_job` on the primary database. It then makes a copy of this job and sets its `database_role` attribute to '`LOGICAL STANDBY`'. If the primary database then becomes a logical standby, the job continues to run according to its schedule.

When you copy a job, the new job is disabled, so you must enable the new job.

```
BEGIN DBMS_SCHEDULER.CREATE_JOB (
    job_name      => 'primary_job',
    program_name   => 'my_prog',
    schedule_name  => 'my_sched');

DBMS_SCHEDULER.COPY_JOB('primary_job','standby_job');
DBMS_SCHEDULER.ENABLE(name=>'standby_job', commit_semantics=>'ABSORB_ERRORS');
DBMS_SCHEDULER.SET_ATTRIBUTE('standby_job','database_role','LOGICAL STANDBY');
END;
/
```

After you execute this example, the data in the `DBA_SCHEDULER_JOB_ROLES` view is as follows:

```
SELECT JOB_NAME, DATABASE_ROLE FROM DBA_SCHEDULER_JOB_ROLES
WHERE JOB_NAME IN ('PRIMARY_JOB', 'STANDBY_JOB');
```

JOB_NAME	DATABASE_ROLE
-----	-----
PRIMARY_JOB	PRIMARY
STANDBY_JOB	LOGICAL STANDBY

 **Note:**

For a physical standby database, any changes made to Scheduler objects or any database changes made by Scheduler jobs on the primary database are applied to the physical standby like any other database changes.

30.6 Scheduler Reference

There are several privileges and data dictionary views related to Scheduler.

- [Scheduler Privileges](#)
Users can be granted various Scheduler privileges.
- [Scheduler Data Dictionary Views](#)
You can query a set of views for information about Scheduler.

30.6.1 Scheduler Privileges

Users can be granted various Scheduler privileges.

[Table 30-3](#) and [Table 30-4](#) describe the various Scheduler privileges.

Table 30-3 Scheduler System Privileges

Privilege Name	Operations Authorized
CREATE JOB	This privilege enables you to create jobs, chains, schedules, programs, file watchers, destinations, and groups in your own schema. You can always alter and drop these objects in your own schema, even if you do not have the CREATE JOB privilege. In this case, the object would have been created in your schema by another user with the CREATE ANY JOB privilege.
CREATE ANY JOB	This privilege enables you to create, alter, and drop jobs, chains, schedules, programs, file watchers, destinations, and groups in any schema except SYS. This privilege is extremely powerful and should be used with care because it allows the grantee to execute any PL/SQL code as any other database user.
CREATE EXTERNAL JOB	This privilege is required to create jobs that run outside of the database. Owners of jobs of type 'EXECUTABLE' or jobs that point to programs of type 'EXECUTABLE' require this privilege. To run a job of type 'EXECUTABLE', you must have this privilege and the CREATE JOB privilege. This privilege is also required to retrieve files from a remote host and to save files to one or more remote hosts.
EXECUTE ANY PROGRAM	This privilege enables your jobs to use programs or chains from any schema.
EXECUTE ANY CLASS	This privilege enables your jobs to run under any job class.
MANAGE SCHEDULER	This is the most important privilege for administering the Scheduler. It enables you to create, alter, and drop job classes, windows, and window groups, and to stop jobs with the force option. It also enables you to set and retrieve Scheduler attributes, purge Scheduler logs, and set the agent password for a database.

Table 30-4 Scheduler Object Privileges

Privilege Name	Operations Authorized
SELECT	You can grant object privileges on a group to other users by granting SELECT on the group.
EXECUTE	You can grant this privilege only on programs, chains, file watchers, credentials, and job classes. The EXECUTE privilege enables you to reference the object in a job. It also enables you to view the object if the object was not created in your schema.
ALTER	This privilege enables you to alter or drop the object it is granted on. Altering includes such operations as enabling, disabling, defining or dropping program arguments, setting or resetting job argument values and running a job. Certain restricted attributes of jobs of job type EXECUTABLE cannot be altered using the ALTER object privilege. These include job_type, job_action, number_of_arguments, event_spec, and setting PL/SQL date functions as schedules. For programs, jobs, chains, file watchers, and credentials, this privilege also enables schemas that do not own these objects to view them. This privilege can be granted on jobs, chains, programs, schedules, file watchers, and credentials. For other types of Scheduler objects, you must grant the MANAGE SCHEDULER system privilege.
ALL	This privilege authorizes operations allowed by all other object privileges possible for a given object. It can be granted on jobs, programs, chains, schedules, file watchers, credentials, and job classes.

Note:

No object privileges are required to use a destination object created by another user.

The SCHEDULER_ADMIN role is created with all of the system privileges shown in [Table 30-3](#) (with the ADMIN option). The SCHEDULER_ADMIN role is granted to DBA (with the ADMIN option).

When calling DBMS_SCHEDULER procedures and functions from a definer's rights PL/SQL block, object privileges must be granted directly to the calling user. As with all PL/SQL stored procedures, DBMS_SCHEDULER ignores privileges granted through roles on database objects when called from a definer's rights PL/SQL block.

The following object privileges are granted to PUBLIC: SELECT ALL_SCHEDULER_* views, SELECT USER_SCHEDULER_* views, SELECT SYS.SCHEDULER\$_JOBSUFFIX_S (for generating a job name), and EXECUTE SYS.DEFAULT_JOB_CLASS.

30.6.2 Scheduler Data Dictionary Views

You can query a set of views for information about Scheduler.

The following example shows information for completed instances of my_job1:

```
SELECT JOB_NAME, STATUS, ERROR#
FROM DBA_SCHEDULER_JOB_RUN_DETAILS WHERE JOB_NAME = 'MY_JOB1';
```

JOB_NAME	STATUS	ERROR#
----------	--------	--------

```
----- ----- -----
MY_JOB1 FAILURE      20000
```

Table 30-5 contains views associated with the Scheduler. The *_SCHEDULER_JOBS, *_SCHEDULER_SCHEDULES, *_SCHEDULER_PROGRAMS, *_SCHEDULER_RUNNING_JOBS, *_SCHEDULER_JOB_LOG, *_SCHEDULER_JOB_RUN_DETAILS views are particularly useful for managing jobs. See *Oracle Database Reference* for details regarding Scheduler views.

 **Note:**

In the following table, the asterisk at the beginning of a view name can be replaced with DBA, ALL, or USER.

Table 30-5 Scheduler Views

View	Description
*_SCHEDULER_CHAIN_RULES	These views show all rules for all chains.
*_SCHEDULER_CHAIN_STEPS	These views show all steps for all chains.
*_SCHEDULER_CHAINS	These views show all chains.
*_SCHEDULER_CREDENTIALS	These views show all credentials. ** *_SCHEDULER_CREDENTIALS is deprecated in Oracle Database 12c, but remains available, for reasons of backward compatibility.
*_CREDENTIALS	The recommended view is *_CREDENTIALS.
*_SCHEDULER_DB_DESTS	These views show all database destinations.
*_SCHEDULER_DESTS	These views show all destinations, both database and external.
*_SCHEDULER_EXTERNAL_DESTS	These views show all external destinations.
*_SCHEDULER_FILE_WATCHERS	These views show all file watchers.
*_SCHEDULER_GLOBAL_ATTRIBUTE	These views show the current values of Scheduler attributes.
*_SCHEDULER_GROUP_MEMBERS	These views show all group members in all groups.
*_SCHEDULER_GROUPS	These views show all groups.
*_SCHEDULER_INCOMPATIBILITY	These views show all programs or jobs that are members of incompatibility definitions.

Table 30-5 (Cont.) Scheduler Views

View	Description
*_SCHEDULER_JOB_ARGS	These views show all set argument values for all jobs.
*_SCHEDULER_JOB_CLASSES	These views show all job classes.
*_SCHEDULER_JOB_DESTS	These views show the state of both local jobs and jobs at remote destinations, including child jobs of multiple-destination jobs. You obtain job destination IDs (<i>job_dest_id</i>) from these views.
*_SCHEDULER_JOB_LOG	These views show job runs and state changes, depending on the logging level set.
*_SCHEDULER_JOB_ROLES	These views show all jobs by Oracle Data Guard database role.
*_SCHEDULER_JOB_RUN_DETAILS	These views show all completed (failed or successful) job runs.
*_SCHEDULER_JOBS	These views show all jobs, enabled as well as disabled.
*_SCHEDULER_NOTIFICATIONS	These views show all job state e-mail notifications.
*_SCHEDULER_PROGRAM_ARGS	These views show all arguments defined for all programs as well as the default values if they exist.
*_SCHEDULER_PROGRAMS	These views show all programs.
*_SCHEDULER_REMOTE_DATABASES	These views show information about the remote databases accessible to the current user that have been registered as sources and destinations for remote database jobs.
*_SCHEDULER_REMOTE_JOB_STATE	These views displays information about the state of the jobs accessible to the current user at remote databases.
*_SCHEDULER_RESOURCES	These views describe the resource metadata.
*_SCHEDULER_RUNNING_CHAINS	These views show all chains that are running.
*_SCHEDULER_RUNNING_JOBS	These views show state information on all jobs that are currently being run.
*_SCHEDULER_RSRC_CONSTRAINTS	These views show the types of resources used by a job or program and the number of units of each resource it needs.
*_SCHEDULER_SCHEDULES	These views show all schedules.
*_SCHEDULER_WINDOW_DETAIL	These views show all completed window runs.
*_SCHEDULER_WINDOW_GROUPS	These views show all window groups.

Table 30-5 (Cont.) Scheduler Views

View	Description
*_SCHEDULER_WINDOW_LOG	These views show all state changes made to windows.
*_SCHEDULER_WINDOWS	These views show all windows.
*_SCHEDULER_WINGROUP_MEMBERS	These views show the members of all window groups, one row for each group member.

Part V

Distributed Database Management

You can manage a distributed database environment.

- **Distributed Database Concepts**

Concepts related to distributed databases include distributed database architecture, database links, transaction processing, application development, and character set support.

- **Managing a Distributed Database**

Managing a distributed database includes tasks such as managing global names, managing database links, and creating location and statement transparency.

- **Developing Applications for a Distributed Database System**

Developing applications for a distributed database system includes tasks such as managing the distribution of application data, controlling connections established by database links, maintaining referential integrity, tuning distributed queries, and handling errors in remote procedures.

- **Distributed Transactions Concepts**

Distributed transactions update data on two or more distinct nodes of a distributed database.

- **Managing Distributed Transactions**

Managing distributed transactions includes tasks such as specifying the comment point strength of a node, naming transactions, and managing in-doubt transactions.

31

Distributed Database Concepts

Concepts related to distributed databases include distributed database architecture, database links, transaction processing, application development, and character set support.

- **Distributed Database Architecture**

A **distributed database system** allows applications to access data from local and remote databases. In a **homogenous distributed database system**, each database is an Oracle Database. In a **heterogeneous distributed database system**, at least one of the databases is not an Oracle Database. Distributed databases use a **client/server** architecture to process information requests.

- **Database Links**

The central concept in distributed database systems is a **database link**. A database link is a connection between two physical database servers that allows a client to access them as one logical database.

- **Distributed Database Administration**

Distributed database administration includes topics related to site autonomy, security, auditing database links, and administration tools.

- **Transaction Processing in a Distributed System**

A transaction is a logical unit of work constituted by one or more SQL statements executed by a single user. A transaction begins with the user's first executable SQL statement and ends when it is committed or rolled back by that user. A **remote transaction** contains only statements that access a single remote node. A **distributed transaction** contains statements that access multiple nodes.

- **Distributed Database Application Development**

Application development in a distributed system raises issues that are not applicable in a non-distributed system.

- **Character Set Support for Distributed Environments**

Different databases and clients can use different character sets in a distributed environment.

31.1 Distributed Database Architecture

A **distributed database system** allows applications to access data from local and remote databases. In a **homogenous distributed database system**, each database is an Oracle Database. In a **heterogeneous distributed database system**, at least one of the databases is not an Oracle Database. Distributed databases use a **client/server** architecture to process information requests.

- **Homogenous Distributed Database Systems**

A homogenous distributed database system includes only Oracle databases.

- **Heterogeneous Distributed Database Systems**

A heterogeneous distributed database system includes both Oracle databases and non-Oracle databases.

- [Client/Server Database Architecture](#)
A database server is the Oracle software managing a database, and a client is an application that requests information from a server. Each computer in a network is a node that can host one or more databases. Each node in a distributed database system can act as a client, a server, or both, depending on the situation.

31.1.1 Homogenous Distributed Database Systems

A homogenous distributed database system includes only Oracle databases.

- [About Homogenous Distributed Database Systems](#)
A homogenous distributed database system is a network of two or more Oracle Databases that reside on one or more systems.
- [Distributed Databases Versus Distributed Processing](#)
The terms **distributed database** and **distributed processing** are closely related, yet have distinct meanings.
- [Distributed Databases Versus Replicated Databases](#)
The terms distributed database system and **database replication** are related, yet distinct.

31.1.1.1 About Homogenous Distributed Database Systems

A homogenous distributed database system is a network of two or more Oracle Databases that reside on one or more systems.

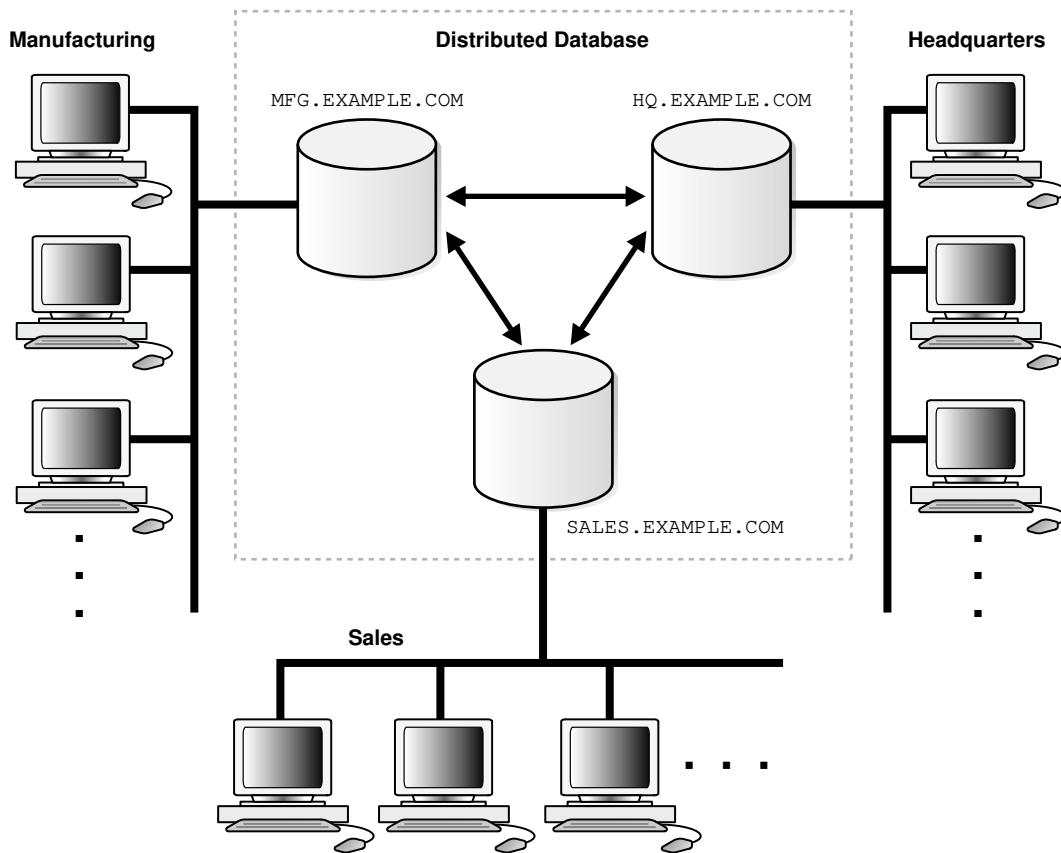

[Figure 31-1](#) illustrates a distributed system that connects three databases: `hq`, `mfg`, and `sales`. An application can simultaneously access or modify the data in several databases in a single distributed environment. For example, a single query from a Manufacturing client on local database `mfg` can retrieve joined data from the `products` table on the local database and the `dept` table on the remote `hq` database.

For a client application, the location and platform of the databases are transparent. You can also create **synonyms** for remote objects in the distributed system so that users can access them with the same syntax as local objects. For example, if you are connected to database `mfg` but want to access data on database `hq`, creating a synonym on `mfg` for the remote `dept` table enables you to issue this query:

```
SELECT * FROM dept;
```

In this way, a distributed system gives the appearance of native data access. Users on `mfg` do not have to know that the data they access resides on remote databases.

Figure 31-1 Homogeneous Distributed Database

An Oracle Database distributed database system can incorporate Oracle Databases of different releases. All supported releases of Oracle Database can participate in a distributed database system. Nevertheless, the applications that work with the distributed database must understand the functionality that is available at each node in the system. A distributed database application cannot expect an Oracle7 database to understand the SQL extensions that are only available with Oracle Database.

31.1.1.2 Distributed Databases Versus Distributed Processing

The terms **distributed database** and **distributed processing** are closely related, yet have distinct meanings.

There definitions are as follows:

- Distributed database

A set of databases in a distributed system that can appear to applications as a single data source.

- Distributed processing

The operations that occurs when an application distributes its tasks among different computers in a network. For example, a database application typically distributes front-end presentation tasks to client computers and allows a back-end database server to manage shared access to a database. Consequently, a

distributed database application processing system is more commonly referred to as a client/server database application system.

Distributed database systems employ a distributed processing architecture. For example, an Oracle Database server acts as a client when it requests data that another Oracle Database server manages.

31.1.1.3 Distributed Databases Versus Replicated Databases

The terms distributed database system and **database replication** are related, yet distinct.

In a **pure** (that is, not replicated) distributed database, the system manages a single copy of all data and supporting database objects. Typically, distributed database applications use distributed transactions to access both local and remote data and modify the global database in real-time.

 **Note:**

This book discusses only pure distributed databases.

The term **replication** refers to the operation of copying and maintaining database objects in multiple databases belonging to a distributed system. While replication relies on distributed database technology, database replication offers applications benefits that are not possible within a pure distributed database environment.

Most commonly, replication is used to improve local database performance and protect the availability of applications because alternate data access options exist. For example, an application may normally access a local database rather than a remote server to minimize network traffic and achieve maximum performance. Furthermore, the application can continue to function if the local server experiences a failure, but other servers with replicated data remain accessible.

31.1.2 Heterogeneous Distributed Database Systems

A heterogeneous distributed database system includes both Oracle databases and non-Oracle databases.

- [About Heterogeneous Distributed Database Systems](#)

In a heterogeneous distributed database system, at least one of the databases is a non-Oracle Database system. To the application, the heterogeneous distributed database system appears as a single, local, Oracle Database. The local Oracle Database server hides the distribution and heterogeneity of the data.

- [Heterogeneous Services](#)

Heterogeneous Services (HS) is an integrated component within the Oracle Database server and the enabling technology for the current suite of Oracle Transparent Gateway products.

- [Transparent Gateway Agents](#)

For each non-Oracle Database system that you access, Heterogeneous Services can use a transparent gateway agent to interface with the specified non-Oracle Database system. The agent is specific to the non-Oracle Database system, so each type of system requires a different agent.

- [Generic Connectivity](#)

Generic connectivity enables you to connect to non-Oracle Database data stores by using either a Heterogeneous Services ODBC agent or a Heterogeneous Services OLE DB agent.

31.1.2.1 About Heterogeneous Distributed Database Systems

In a heterogeneous distributed database system, at least one of the databases is a non-Oracle Database system. To the application, the heterogeneous distributed database system appears as a single, local, Oracle Database. The local Oracle Database server hides the distribution and heterogeneity of the data.

The Oracle Database server accesses the non-Oracle Database system using Oracle Heterogeneous Services with an **agent**. If you access the non-Oracle Database data store using an Oracle Transparent Gateway, then the agent is a system-specific application. For example, if you include a Sybase database in an Oracle Database distributed system, then you must obtain a Sybase-specific transparent gateway so that the Oracle Database in the system can communicate with it.

Alternatively, you can use **generic connectivity** to access non-Oracle Database data stores so long as the non-Oracle Database system supports the ODBC or OLE DB protocols.

 **Note:**

Other than the introductory material presented in this chapter, this book does not discuss Oracle Heterogeneous Services. See *Oracle Database Heterogeneous Connectivity User's Guide* for more detailed information about Heterogeneous Services.

31.1.2.2 Heterogeneous Services

Heterogeneous Services (HS) is an integrated component within the Oracle Database server and the enabling technology for the current suite of Oracle Transparent Gateway products.

HS provides the common architecture and administration mechanisms for Oracle Database gateway products and other heterogeneous access facilities. Also, it provides upwardly compatible functionality for users of most of the earlier Oracle Transparent Gateway releases.

31.1.2.3 Transparent Gateway Agents

For each non-Oracle Database system that you access, Heterogeneous Services can use a transparent gateway agent to interface with the specified non-Oracle Database system. The agent is specific to the non-Oracle Database system, so each type of system requires a different agent.

The transparent gateway agent facilitates communication between Oracle Database and non-Oracle Database systems and uses the Heterogeneous Services component in the Oracle Database server. The agent executes SQL and transactional requests at the non-Oracle Database system on behalf of the Oracle Database server.

 **See Also:**

Your Oracle-supplied gateway-specific documentation for information about transparent gateways

31.1.2.4 Generic Connectivity

Generic connectivity enables you to connect to non-Oracle Database data stores by using either a Heterogeneous Services ODBC agent or a Heterogeneous Services OLE DB agent.

Both are included with your Oracle product as a standard feature. Any data source compatible with the ODBC or OLE DB standards can be accessed using a generic connectivity agent.

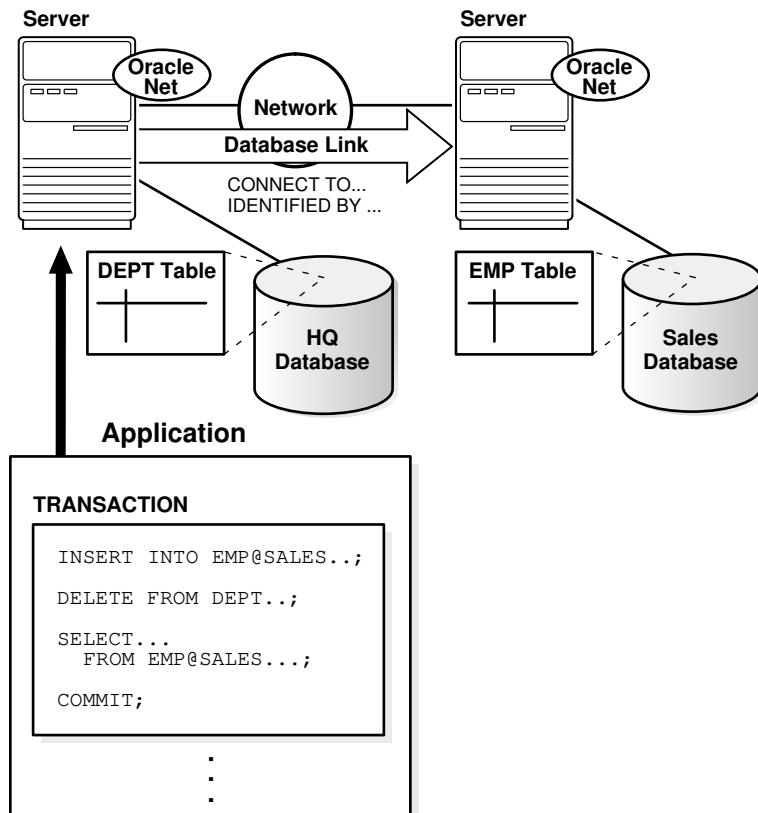

The advantage to generic connectivity is that it may not be required for you to purchase and configure a separate system-specific agent. You use an ODBC or OLE DB driver that can interface with the agent. However, some data access features are only available with transparent gateway agents.

31.1.3 Client/Server Database Architecture

A database server is the Oracle software managing a database, and a client is an application that requests information from a server. Each computer in a network is a node that can host one or more databases. Each node in a distributed database system can act as a client, a server, or both, depending on the situation.

In [Figure 31-2](#), the host for the `hq` database is acting as a database server when a statement is issued against its local data (for example, the second statement in each transaction issues a statement against the local `dept` table), but is acting as a client when it issues a statement against remote data (for example, the first statement in each transaction is issued against the remote table `emp` in the `sales` database).

Figure 31-2 An Oracle Database Distributed Database System

A client can connect **directly** or **indirectly** to a database server. A direct connection occurs when a client connects to a server and accesses information from a database contained on that server. For example, if you connect to the `hq` database and access the `dept` table on this database as in [Figure 31-2](#), you can issue the following:

```
SELECT * FROM dept;
```

This query is direct because you are not accessing an object on a remote database.

In contrast, an indirect connection occurs when a client connects to a server and then accesses information contained in a database on a different server. For example, if you connect to the `hq` database but access the `emp` table on the remote `sales` database as in [Figure 31-2](#), you can issue the following:

```
SELECT * FROM emp@sales;
```

This query is indirect because the object you are accessing is not on the database to which you are directly connected.

31.2 Database Links

The central concept in distributed database systems is a **database link**. A database link is a connection between two physical database servers that allows a client to access them as one logical database.

- [What Are Database Links?](#)
A database link is a pointer that defines a one-way communication path from an Oracle Database server to another database server.
- [What Are Shared Database Links?](#)
A shared database link is a link between a local server process and the remote database. The link is shared because multiple client processes can use the same link simultaneously.
- [Why Use Database Links?](#)
The great advantage of database links is that they allow users to access another user's objects in a remote database so that they are bounded by the privilege set of the object owner. In other words, a local user can access a link to a remote database without having to be a user on the remote database.
- [Global Database Names in Database Links](#)
To understand how a database link works, you must first understand what a global database name is. Each database in a distributed database is uniquely identified by its global database name.
- [Global Name as a Loopback Database Link](#)
You can use the global name of a database as a loopback database link without explicitly creating a database link. When the database link in a SQL statement matches the global name of the current database, the database link is effectively ignored.
- [Names for Database Links](#)
Typically, a database link has the same name as the global database name of the remote database that it references.
- [Types of Database Links](#)
Oracle Database lets you create **private**, **public**, and **global** database links.
- [Users of Database Links](#)
Users of database links include connect user, current user, and fixed user.
- [Creation of Database Links: Examples](#)
Create database links using the `CREATE DATABASE LINK` statement.
- [Schema Objects and Database Links](#)
After you have created a database link, you can execute SQL statements that access objects on the remote database. You must also be authorized in the remote database to access specific remote objects.
- [Database Link Restrictions](#)
Several restrictions apply to database links.

31.2.1 What Are Database Links?

A database link is a pointer that defines a one-way communication path from an Oracle Database server to another database server.

For public and private database links, the link pointer is actually defined as an entry in a data dictionary table. To access the link, you must be connected to the local database that contains the data dictionary entry. For global database links, the link pointer is defined in a directory service. The different types of database links are described in more detail in "[Types of Database Links](#)".

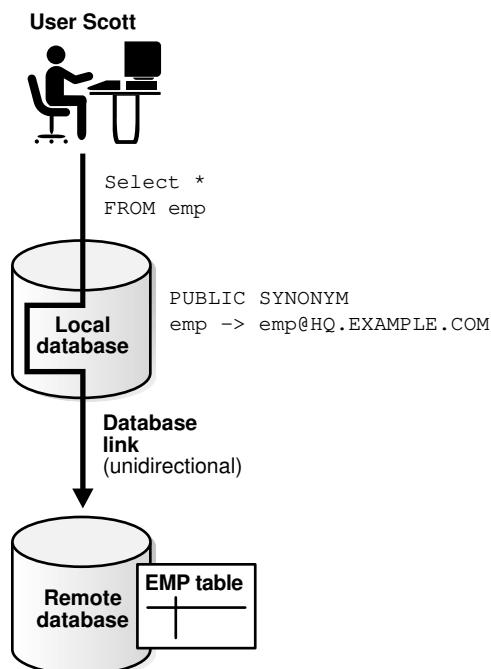

A database link connection is one-way in the sense that a client connected to local database A can use a link stored in database A to access information in remote

database B, but users connected to database B cannot use the same link to access data in database A. If local users on database B want to access data on database A, then they must define a link that is stored in the data dictionary of database B.

A database link connection allows local users to access data on a remote database. For this connection to occur, each database in the distributed system must have a unique **global database name** in the network domain. The global database name uniquely identifies a database server in a distributed system.

Figure 31-3 shows an example of user scott accessing the emp table on the remote database with the global name hq.example.com:

Figure 31-3 Database Link

Database links are either private or public. If they are private, then only the user who created the link has access; if they are public, then all database users have access.

One principal difference among database links is the way that different link definitions determine how the link connection is authenticated. Users access a remote database through the following types of links:

Type of Link	Description
Connected user link	Users connect as themselves, which means that they must have an account on the remote database with the same user name and password as their account on the local database.

Type of Link	Description
Fixed user link	Users connect using the user name and password referenced in the link. For example, if Jane uses a fixed user link that connects to the <code>hq</code> database with the user name and password <code>scott/password</code> , then she connects as <code>scott</code> , Jane has all the privileges in <code>hq</code> granted to <code>scott</code> directly, and all the default roles that <code>scott</code> has been granted in the <code>hq</code> database.
Current user link	A user connects as a global user. A local user can connect as a global user in the context of a stored procedure, without storing the global user's password in a link definition. For example, Jane can access a procedure that Scott wrote, accessing Scott's account and Scott's schema on the <code>hq</code> database.

Create database links using the `CREATE DATABASE LINK` statement. After a link is created, you can use it to specify schema objects in SQL statements.

 **See Also:**

Oracle Database SQL Language Reference for syntax of the `CREATE DATABASE` statement

31.2.2 What Are Shared Database Links?

A shared database link is a link between a local server process and the remote database. The link is shared because multiple client processes can use the same link simultaneously.

When a local database is connected to a remote database through a database link, either database can run in dedicated or shared server mode. The following table illustrates the possibilities:

Local Database Mode	Remote Database Mode
Dedicated	Dedicated
Dedicated	Shared server
Shared server	Dedicated
Shared server	Shared server

A shared database link can exist in any of these four configurations. Shared links differ from standard database links in the following ways:

- Different users accessing the same schema object through a database link can share a network connection.
- When a user must establish a connection to a remote server from a particular server process, the process can reuse connections already established to the remote server. The reuse of the connection can occur if the connection was established on the same server process with the same database link, possibly in a different session. In a non-shared database link, a connection is not shared across multiple sessions.

- When you use a shared database link in a shared server configuration, a network connection is established directly out of the shared server process in the local server. For a non-shared database link on a local shared server, this connection would have been established through the local dispatcher, requiring context switches for the local dispatcher, and requiring data to go through the dispatcher.

 **See Also:**

Oracle Database Net Services Administrator's Guide for information about shared server

31.2.3 Why Use Database Links?

The great advantage of database links is that they allow users to access another user's objects in a remote database so that they are bounded by the privilege set of the object owner. In other words, a local user can access a link to a remote database without having to be a user on the remote database.

For example, assume that employees submit expense reports to Accounts Payable (A/P), and further suppose that a user using an A/P application must retrieve information about employees from the `hq` database. The A/P users should be able to connect to the `hq` database and execute a stored procedure in the remote `hq` database that retrieves the desired information. The A/P users should not need to be `hq` database users to do their jobs; they should only be able to access `hq` information in a controlled way as limited by the procedure.

 **See Also:**

- "[Users of Database Links](#)" for an explanation of database link users
- "[Viewing Information About Database Links](#)" for an explanation of how to hide passwords from non-administrative users

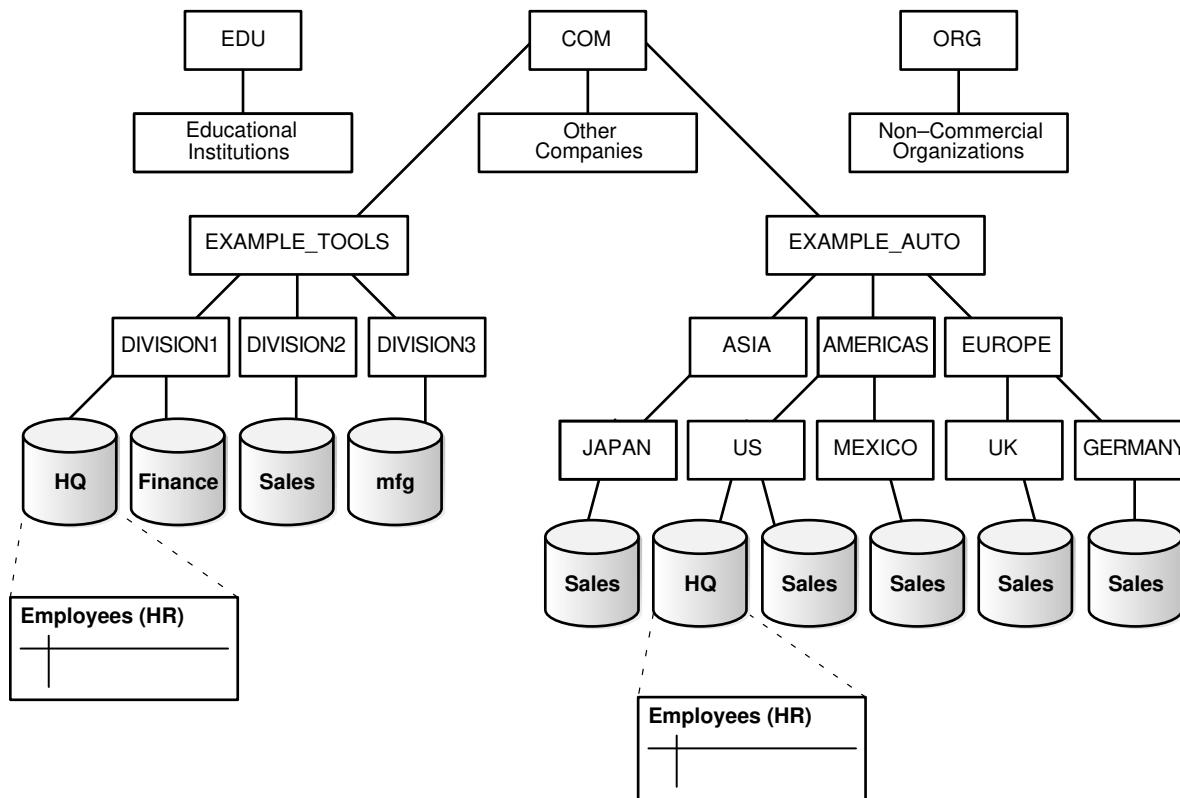

31.2.4 Global Database Names in Database Links

To understand how a database link works, you must first understand what a global database name is. Each database in a distributed database is uniquely identified by its global database name.

The database forms a global database name by prefixing the database network domain, specified by the `DB_DOMAIN` initialization parameter at database creation, with the individual database name, specified by the `DB_NAME` initialization parameter.

For example, [Figure 31-4](#) illustrates a representative hierarchical arrangement of databases throughout a network.

Figure 31-4 Hierarchical Arrangement of Networked Databases

The name of a database is formed by starting at the leaf of the tree and following a path to the root. For example, the `mfg` database is in `division3` of the `example_tools` branch of the `com` domain. The global database name for `mfg` is created by concatenating the nodes in the tree as follows:

- `mfg.division3.example_tools.com`

While several databases can share an individual name, each database must have a unique global database name. For example, the network domains `us.americas.example_auto.com` and `uk.europe.example_auto.com` each contain a `sales` database. The global database naming system distinguishes the `sales` database in the `americas` division from the `sales` database in the `europe` division as follows:

- `sales.us.americas.example_auto.com`
- `sales.uk.europe.example_auto.com`

See Also:

["Managing Global Names in a Distributed System"](#) to learn how to specify and change global database names

31.2.5 Global Name as a Loopback Database Link

You can use the global name of a database as a loopback database link without explicitly creating a database link. When the database link in a SQL statement matches the global name of the current database, the database link is effectively ignored.

For example, assume the global name of a database is db1.example.com. You can run the following SQL statement on this database:

```
SELECT * FROM hr.employees@db1.example.com;
```

In this case, the @db1.example.com portion of the SQL statement is effectively ignored.

31.2.6 Names for Database Links

Typically, a database link has the same name as the global database name of the remote database that it references.

For example, if the global database name of a database is sales.us.example.com, then the database link is also called sales.us.example.com.

When you set the initialization parameter `GLOBAL_NAMES` to `TRUE`, the database ensures that the name of the database link is the same as the global database name of the remote database. For example, if the global database name for `hq` is `hq.example.com`, and `GLOBAL_NAMES` is `TRUE`, then the link name must be called `hq.example.com`. Note that the database checks the domain part of the global database name as stored in the data dictionary, *not* the `DB_DOMAIN` setting in the initialization parameter file (see "[Changing the Domain in a Global Database Name](#)").

If you set the initialization parameter `GLOBAL_NAMES` to `FALSE`, then you are not required to use global naming. You can then name the database link whatever you want. For example, you can name a database link to `hq.example.com` as `foo`.

 **Note:**

Oracle recommends that you use global naming because many useful features require global naming.

After you have enabled global naming, database links are essentially transparent to users of a distributed database because the name of a database link is the same as the global name of the database to which the link points. For example, the following statement creates a database link in the local database to remote database `sales`:

```
CREATE PUBLIC DATABASE LINK sales.division3.example.com USING 'sales1';
```

 See Also:

Oracle Database Reference for more information about specifying the initialization parameter `GLOBAL_NAMES`

31.2.7 Types of Database Links

Oracle Database lets you create **private**, **public**, and **global** database links.

These basic link types differ according to which users are allowed access to the remote database:

Type	Owner	Description
Private	User who created the link. View ownership data through: <ul style="list-style-type: none"> • <code>DBA_DB_LINKS</code> • <code>ALL_DB_LINKS</code> • <code>USER_DB_LINKS</code> 	Creates link in a specific schema of the local database. Only the owner of a private database link or PL/SQL subprograms in the schema can use this link to access database objects in the corresponding remote database.
Public	User called PUBLIC. View ownership data through views shown for private database links.	Creates a database-wide link. All users and PL/SQL subprograms in the database can use the link to access database objects in the corresponding remote database.
Global	No user owns the global database link. The global database link exists in a directory service.	Creates a network-wide link. When an Oracle network uses a directory server and the database is registered in the directory service, this information can be used as a database link. Users and PL/SQL subprograms in any database can use a global database link to access objects in the corresponding remote database. Global database links refer to the use of net service names from the directory server.

Determining the type of database links to employ in a distributed database depends on the specific requirements of the applications using the system. Consider these features when making your choice:

Type of Link	Features
Private database link	This link is more secure than a public or global link, because only the owner of the private link, or subprograms within the same schema, can use the link to access the remote database.
Public database link	When many users require an access path to a remote Oracle Database, you can create a single public database link for all users in a database.
Global database link	When an Oracle network uses a directory server, an administrator can conveniently manage global database links for all databases in the system. Database link management is centralized and simple. There is no user data associated with a global database link definition. A global database link must operate as a connected user database link.

- ["Specifying Link Types"](#) to learn how to create different types of database links
- ["Viewing Information About Database Links"](#) to learn how to access information about links

31.2.8 Users of Database Links

Users of database links include connect user, current user, and fixed user.

- [Overview of Database Link Users](#)

When creating the link, you determine which user should connect to the remote database to access the data.

- [Connected User Database Links](#)

Connected user links have no connect string associated with them. The advantage of a connected user link is that a user referencing the link connects to the remote database as the same user, and credentials do not have to be stored in the link definition in the data dictionary.

- [Fixed User Database Links](#)

A benefit of a fixed user link is that it connects a user in a primary database to a remote database with the security context of the user specified in the connect string.

- [Current User Database Links](#)

Current user database links make use of a global user. A global user must be authenticated by an X.509 certificate or a password, and be a user on both databases involved in the link.

31.2.8.1 Overview of Database Link Users

When creating the link, you determine which user should connect to the remote database to access the data.

The following table explains the differences among the categories of users involved in database links:

User Type	Description	Sample Link Creation Syntax
Connected user	A local user accessing a database link in which no fixed username and password have been specified. If SYSTEM accesses a public link in a query, then the connected user is SYSTEM, and the database connects to the SYSTEM schema in the remote database. Note: A connected user does not have to be the user who created the link, but is any user who is accessing the link.	CREATE PUBLIC DATABASE LINK hq USING 'hq';

User Type	Description	Sample Link Creation Syntax
Current user	A global user in a CURRENT_USER database link. The global user must be authenticated by an X.509 certificate (an SSL-authenticated enterprise user) or a password (a password-authenticated enterprise user), and be a user on both databases involved in the link. See <i>Oracle Database Enterprise User Security Administrator's Guide</i> for information about global security	CREATE PUBLIC DATABASE LINK hq CONNECT TO CURRENT_USER using 'hq';
Fixed user	A user whose username/password is part of the link definition. If a link includes a fixed user, the fixed user's username and password are used to connect to the remote database.	CREATE PUBLIC DATABASE LINK hq CONNECT TO jane IDENTIFIED BY password USING 'hq';

 **Note:**

The following users cannot be target users of database links: SYS and PUBLIC.

 **See Also:**

["Specifying Link Users"](#) to learn how to specify users when creating links

31.2.8.2 Connected User Database Links

Connected user links have no connect string associated with them. The advantage of a connected user link is that a user referencing the link connects to the remote database as the same user, and credentials do not have to be stored in the link definition in the data dictionary.

Connected user links have some disadvantages. Because these links require users to have accounts and privileges on the remote databases to which they are attempting to connect, they require more privilege administration for administrators. Also, giving users more privileges than they need violates the fundamental security concept of least privilege: users should only be given the privileges they need to perform their jobs.

The ability to use a connected user database link depends on several factors, chief among them whether the user is authenticated by the database using a password, or externally authenticated by the operating system or a network authentication service. If the user is externally authenticated, then the ability to use a connected user link also depends on whether the remote database accepts remote authentication of users, which is set by the REMOTE_OS_AUTHENT initialization parameter.

The `REMOTE_OS_AUTHENT` parameter operates as follows:

REMOTE_OS_AUTHENT Value	Consequences
TRUE for the remote database	An externally-authenticated user can connect to the remote database using a connected user database link.
FALSE for the remote database	An externally-authenticated user cannot connect to the remote database using a connected user database link unless a secure protocol or a network authentication service option is used.

If the connected user database link is accessed from within a definer's rights function, procedure, or package, then the definer's authorization ID is used to connect as a remote user. For example, if user `jane` calls procedure `scott.p` (a definer's rights procedure created by `scott`), and the link appears inside procedure `scott.p`, then `scott` is the connected user. To run a definer's rights function, procedure, or package that includes a connected user database link, the user who invokes the function, procedure, or package must be granted the `INHERIT REMOTE PRIVILEGES` privilege.

 **Note:**

The `REMOTE_OS_AUTHENT` initialization parameter is deprecated. It is retained for backward compatibility only.

31.2.8.3 Fixed User Database Links

A benefit of a fixed user link is that it connects a user in a primary database to a remote database with the security context of the user specified in the connect string.

For example, local user `joe` can create a public database link in `joe`'s schema that specifies the fixed user `scott` with password `password`. If `jane` uses the fixed user link in a query, then `jane` is the user on the local database, but she connects to the remote database as `scott/password`.

Fixed user links have a user name and password associated with the connect string. The user name and password are stored with other link information in data dictionary tables.

31.2.8.4 Current User Database Links

Current user database links make use of a global user. A global user must be authenticated by an X.509 certificate or a password, and be a user on both databases involved in the link.

The user invoking the `CURRENT_USER` link does not have to be a global user. For example, if `jane` is authenticated (not as a global user) by password to the Accounts Payable database, she can access a stored procedure to retrieve data from the `hq` database. The procedure uses a current user database link, which connects her to `hq` as global user `scott`. User `scott` is a global user and authenticated through a certificate over SSL, but `jane` is not.

Note that current user database links have these consequences:

- If the current user database link is *not* accessed from within a stored object, then the current user is the same as the connected user accessing the link. For example, if `scott` issues a `SELECT` statement through a current user link, then the current user is `scott`.
- When executing a stored object such as a procedure, view, or trigger that accesses a database link, the current user is the user that *owns* the stored object, and not the user that *calls* the object. For example, if `jane` calls procedure `scott.p` (created by `scott`), and a current user link appears *within* the called procedure, then `scott` is the current user of the link.
- If the stored object is an invoker's rights function, procedure, or package, then the invoker's authorization ID is used to connect as a remote user. For example, if user `jane` calls procedure `scott.p` (an invoker's rights procedure created by `scott`), and the link appears inside procedure `scott.p`, then `jane` is the current user.
- You cannot connect to a database as an enterprise user and then use a current user link in a stored procedure that exists in a shared, global schema. For example, if user `jane` accesses a stored procedure in the shared schema `guest` on database `hq`, she cannot use a current user link in this schema to log on to a remote database.

See Also:

- "[Distributed Database Security](#)" for more information about security issues relating to database links

- *Oracle Database Security Guide* for information about running a definer's rights function, procedure, or package that includes a current user database link

31.2.9 Creation of Database Links: Examples

Create database links using the `CREATE DATABASE LINK` statement.

The table gives examples of SQL statements that create database links in a local database to the remote `sales.us.americas.example_auto.com` database:

SQL Statement	Connects To Database	Connects As	Link Type
<pre>CREATE DATABASE LINK sales.us.americas.example_auto.com USING 'sales_us';</pre>	<code>sales</code> using net service name <code>sales_us</code>	Connected user	Private connected user
<pre>CREATE DATABASE LINK foo CONNECT TO CURRENT_USER USING 'am_sls';</pre>	<code>sales</code> using service name <code>am_sls</code>	Current global user	Private current user

SQL Statement	Connects To Database	Connects As	Link Type
<pre>CREATE DATABASE LINK sales.us.americas .example_auto.com CONNECT TO scott IDENTIFIED BY password USING 'sales_us';</pre>	sales using net service name sales_us	scott using password <i>password</i>	Private fixed user
<pre>CREATE PUBLIC DATABASE LINK sales CONNECT TO scott IDENTIFIED BY <i>password</i> USING 'rev';</pre>	sales using net service name rev	scott using password <i>password</i>	Public fixed user
<pre>CREATE SHARED PUBLIC DATABASE LINK sales.us.americas .example_auto.com CONNECT TO scott IDENTIFIED BY password AUTENTICATED BY anupam IDENTIFIED BY <i>password1</i> USING 'sales';</pre>	sales using net service name sales	scott using password <i>password</i> , authenticated as anupam using <i>password1</i>	Shared public fixed user

See Also:

- "[Creating Database Links](#)" to learn how to create link
- *Oracle Database SQL Language Reference* for information about the CREATE DATABASE LINK statement syntax

31.2.10 Schema Objects and Database Links

After you have created a database link, you can execute SQL statements that access objects on the remote database. You must also be authorized in the remote database to access specific remote objects.

For example, to access remote object `emp` using database link `foo`, you can issue:

```
SELECT * FROM emp@foo;
```

Constructing properly formed object names using database links is an essential aspect of data manipulation in distributed systems.

If you call a procedure using a remote database link, and the procedure contains a ROLLBACK command, only DML operations performed at the remote site are rolled back. Any DML changes made at the originating site are not rolled back.

- [Naming of Schema Objects Using Database Links](#)
Oracle Database uses the global database name to name the schema objects globally.
- [Authorization for Accessing Remote Schema Objects](#)
To access a remote schema object, you must be granted access to the remote object in the remote database.
- [Synonyms for Schema Objects](#)
Oracle Database lets you create synonyms so that you can hide the database link name from the user.
- [Schema Object Name Resolution](#)
To resolve application references to schema objects (a process called **name resolution**), the database forms object names hierarchically.

31.2.10.1 Naming of Schema Objects Using Database Links

Oracle Database uses the global database name to name the schema objects globally.

Global database names are in the following form:

schema.schema_object@global_database_name

where:

- *schema* is a collection of logical structures of data, or schema objects. A schema is owned by a database user and has the same name as that user. Each user owns a single schema.
- *schema_object* is a logical data structure like a table, index, view, synonym, procedure, package, or a database link.
- *global_database_name* is the name that uniquely identifies a remote database. This name must be the same as the concatenation of the remote database initialization parameters DB_NAME and DB_DOMAIN, unless the parameter GLOBAL_NAMES is set to FALSE, in which case any name is acceptable.

For example, using a database link to database sales.division3.example.com, a user or application can reference remote data as follows:

```
SELECT * FROM scott.emp@sales.division3.example.com; # emp table in scott's schema
SELECT loc FROM scott.dept@sales.division3.example.com;
```

If GLOBAL_NAMES is set to FALSE, then you can use any name for the link to sales.division3.example.com. For example, you can call the link foo. Then, you can access the remote database as follows:

```
SELECT name FROM scott.emp@foo; # link name different from global name
```

31.2.10.2 Authorization for Accessing Remote Schema Objects

To access a remote schema object, you must be granted access to the remote object in the remote database.

Further, to perform any updates, inserts, or deletes on the remote object, you must be granted the `READ` or `SELECT` privilege on the object, along with the `UPDATE`, `INSERT`, or `DELETE` privilege. Unlike when accessing a local object, the `READ` or `SELECT` privilege is necessary for accessing a remote object because the database has no remote describe capability. The database must do a `SELECT *` on the remote object to determine its structure.

31.2.10.3 Synonyms for Schema Objects

Oracle Database lets you create synonyms so that you can hide the database link name from the user.

A synonym allows access to a table on a remote database using the same syntax that you would use to access a table on a local database. For example, assume you issue the following query against a table in a remote database:

```
SELECT * FROM emp@hq.example.com;
```

You can create the synonym `emp` for `emp@hq.example.com` so that you can issue the following query instead to access the same data:

```
SELECT * FROM emp;
```

See Also:

"[Using Synonyms to Create Location Transparency](#)" to learn how to create synonyms for objects specified using database links

31.2.10.4 Schema Object Name Resolution

To resolve application references to schema objects (a process called **name resolution**), the database forms object names hierarchically.

For example, the database guarantees that each schema within a database has a unique name, and that within a schema each object has a unique name. As a result, a schema object name is always unique within the database. Furthermore, the database resolves application references to the local name of the object.

In a distributed database, a schema object such as a table is accessible to all applications in the system. The database extends the hierarchical naming model with global database names to effectively create **global object names** and resolve references to the schema objects in a distributed database system. For example, a query can reference a remote table by specifying its fully qualified name, including the database in which it resides.

For example, assume that you connect to the local database as user `SYSTEM`:

```
CONNECT SYSTEM@sales1
```

You then issue the following statements using database link `hq.example.com` to access objects in the `scott` and `jane` schemas on remote database `hq`:

```
SELECT * FROM scott.emp@hq.example.com;
INSERT INTO jane.accounts@hq.example.com (acc_no, acc_name, balance)
```

```
VALUES (5001, 'BOWER', 2000);
UPDATE jane.accounts@hq.example.com
  SET balance = balance + 500;
DELETE FROM jane.accounts@hq.example.com
 WHERE acc_name = 'BOWER';
```

31.2.11 Database Link Restrictions

Several restrictions apply to database links.

You *cannot* perform the following operations using database links:

- Grant privileges on remote objects
- Execute `DESCRIBE` operations on some remote objects. The following remote objects, however, do support `DESCRIBE` operations:
 - Tables
 - Views
 - Procedures
 - Functions
- Analyze remote objects
- Define or enforce referential integrity
- Grant roles to users in a remote database
- Obtain nondefault roles on a remote database. For example, if `jane` connects to the local database and executes a stored procedure that uses a fixed user link connecting as `scott`, `jane` receives `scott`'s default roles on the remote database. `Jane` cannot issue `SET ROLE` to obtain a nondefault role.
- Use a current user link without authentication through SSL, password, or Microsoft Windows native authentication

See Also:

- *Oracle Database Object-Relational Developer's Guide* for information about database link restrictions for user-defined types
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for information about database link restrictions for LOBs

31.3 Distributed Database Administration

Distributed database administration includes topics related to site autonomy, security, auditing database links, and administration tools.

- [Site Autonomy](#)

Site autonomy means that each server participating in a distributed database is administered independently from all other databases.

- [Distributed Database Security](#)
The database supports all of the security features that are available with a non-distributed database environment for distributed database systems, including password authentication for users and roles, some types of external authentication for users and roles including Kerberos version 5 for connected user links, and login packet encryption for client-to-server and server-to-server connections.
- [Auditing Database Links](#)
You must always perform auditing operations locally. That is, if a user acts in a local database and accesses a remote database through a database link, the local actions are audited in the local database, and the remote actions are audited in the remote database, provided appropriate audit options are set in the respective databases.
- [Administration Tools](#)
The database administrator has several choices for tools to use when managing an Oracle Database distributed database system.

 **See Also:**

- [Managing a Distributed Database](#) to learn how to administer homogenous systems
- [*Oracle Database Heterogeneous Connectivity User's Guide*](#) to learn about heterogeneous services concepts

31.3.1 Site Autonomy

Site autonomy means that each server participating in a distributed database is administered independently from all other databases.

Although several databases can work together, each database is a separate repository of data that is managed individually. Some of the benefits of site autonomy in an Oracle Database distributed database include:

- Nodes of the system can mirror the logical organization of companies or groups that need to maintain independence.
- Local administrators control corresponding local data. Therefore, each database administrator's domain of responsibility is smaller and more manageable.
- Independent failures are less likely to disrupt other nodes of the distributed database. No single database failure need halt all distributed operations or be a performance bottleneck.
- Administrators can recover from isolated system failures independently from other nodes in the system.
- A data dictionary exists for each local database. A global catalog is not necessary to access local data.
- Nodes can upgrade software independently.

Although Oracle Database permits you to manage each database in a distributed database system independently, you should not ignore the global requirements of the system. For example, you may need to:

- Create additional user accounts in each database to support the links that you create to facilitate server-to-server connections.
- Set additional initialization parameters such as `COMMIT_POINT_STRENGTH`, and `OPEN_LINKS`.

31.3.2 Distributed Database Security

The database supports all of the security features that are available with a non-distributed database environment for distributed database systems, including password authentication for users and roles, some types of external authentication for users and roles including Kerberos version 5 for connected user links, and login packet encryption for client-to-server and server-to-server connections.

- [Authentication Through Database Links](#)
Database links are either private or public, **authenticated** or **non-authenticated**.
- [Authentication Without Passwords](#)
When using a connected user or current user database link, you can use an external authentication source such as Kerberos to obtain **end-to-end security**.
- [Supporting User Accounts and Roles](#)
In a distributed database system, you must carefully plan the user accounts and roles that are necessary to support applications using the system.
- [Centralized User and Privilege Management](#)
For centralized user and privilege management, you must consider the authentication method. You can also consider schema-dependent global users or schema-independent global users.
- [Data Encryption](#)
The Oracle Advanced Security option also enables Oracle Net and related products to use network data encryption and checksumming so that data cannot be read or altered. It protects data from unauthorized viewing by using the RSA Data Security RC4 or the Data Encryption Standard (DES) encryption algorithm.

 **See Also:**

Oracle Database Enterprise User Security Administrator's Guide for more information about external authentication

31.3.2.1 Authentication Through Database Links

Database links are either private or public, **authenticated** or **non-authenticated**.

You create public links by specifying the `PUBLIC` keyword in the link creation statement. For example, you can issue:

```
CREATE PUBLIC DATABASE LINK foo USING 'sales';
```

You create authenticated links by specifying the `CONNECT TO` clause, `AUTHENTICATED BY` clause, or both clauses together in the database link creation statement. For example, you can issue:

```
CREATE DATABASE LINK sales CONNECT TO scott IDENTIFIED BY password USING 'sales';

CREATE SHARED PUBLIC DATABASE LINK sales CONNECT TO nick IDENTIFIED BY password1
    AUTHENTICATED BY david IDENTIFIED BY password2 USING 'sales';
```

This table describes how users access the remote database through the link:

Link Type	Authenticated	Security Access
Private	No	When connecting to the remote database, the database uses security information (userid/password) taken from the local session. Hence, the link is a connected user database link. Passwords must be synchronized between the two databases.
Private	Yes	The userid/password is taken from the link definition rather than from the local session context. Hence, the link is a fixed user database link. This configuration allows passwords to be different on the two databases, but the local database link password must match the remote database password.
Public	No	Works the same as a private nonauthenticated link, except that all users can reference this pointer to the remote database.
Public	Yes	All users on the local database can access the remote database, and all use the same userid/password to make the connection.

Note:

The following initialization parameters can provide enhanced security for database link connections:

- The `OUTBOUND_DBLINK_PROTOCOLS` initialization parameter can specify Oracle Net transport protocols restricting any outbound database link communication to use only the protocols from the specified list.
- The `ALLOW_GLOBAL_DBLINKS` initialization parameter can allow or disallow LDAP lookup for global database links information.

See Also:

- *Oracle Database Security Guide*
- *Oracle Database Reference* for more information about the `OUTBOUND_DBLINK_PROTOCOLS` initialization parameter
- *Oracle Database Reference* for more information about the `ALLOW_GLOBAL_DBLINKS` initialization parameter

31.3.2.2 Authentication Without Passwords

When using a connected user or current user database link, you can use an external authentication source such as Kerberos to obtain **end-to-end security**.

In end-to-end authentication, credentials are passed from server to server and can be authenticated by a database server belonging to the same domain. For example, if jane is authenticated externally on a local database, and wants to use a connected user link to connect as herself to a remote database, the local server passes the security ticket to the remote database.

31.3.2.3 Supporting User Accounts and Roles

In a distributed database system, you must carefully plan the user accounts and roles that are necessary to support applications using the system.

Note that:

- The user accounts necessary to establish server-to-server connections must be available in all databases of the distributed database system.
- The roles necessary to make available application privileges to distributed database application users must be present in all databases of the distributed database system.

As you create the database links for the nodes in a distributed database system, determine which user accounts and roles each site must support server-to-server connections that use the links.

In a distributed environment, users typically require access to many network services. When you must configure separate authentications for each user to access each network service, security administration can become unwieldy, especially for large systems.

See Also:

["Creating Database Links"](#) for more information about the user accounts that must be available to support different types of database links in the system

31.3.2.4 Centralized User and Privilege Management

For centralized user and privilege management, you must consider the authentication method. You can also consider schema-dependent global users or schema-independent global users.

- [About Centralized User and Privilege Management](#)
The database provides different ways for you to manage the users and privileges involved in a distributed system.
- [Schema-Dependent Global Users](#)
One option for centralizing user and privilege management is to create a global user in a centralized directory and a user in every database to which the global user must connect.

- [Schema-Independent Global Users](#)

The database supports functionality that allows a global user to be centrally managed by an enterprise directory service. Users who are managed in the directory are called **enterprise users**.

31.3.2.4.1 About Centralized User and Privilege Management

The database provides different ways for you to manage the users and privileges involved in a distributed system.

For example, you have these options:

- Enterprise user management. You can create global users who are authenticated through SSL or by using passwords, then manage these users and their privileges in a directory through an independent enterprise directory service.
- Network authentication service. This common technique simplifies security management for distributed environments. You can use the Oracle Advanced Security option to enhance Oracle Net and the security of an Oracle Database distributed database system. Microsoft Windows native authentication is an example of a non-Oracle authentication solution.

31.3.2.4.2 Schema-Dependent Global Users

One option for centralizing user and privilege management is to create a global user in a centralized directory and a user in every database to which the global user must connect.

For example, you can create a global user called fred with the following SQL statement:

```
CREATE USER fred IDENTIFIED GLOBALLY AS 'CN=fred adams,O=Oracle,C=England';
```

This solution allows a single global user to be authenticated by a centralized directory.

The schema-dependent global user solution has the consequence that you must create a user called fred on every database that this user must access. Because most users need permission to access an application schema but do not need their own schemas, the creation of a separate account in each database for every global user creates significant overhead. Because of this problem, the database also supports schema-independent users, which are global users that can access a single, generic schema in every database.

31.3.2.4.3 Schema-Independent Global Users

The database supports functionality that allows a global user to be centrally managed by an enterprise directory service. Users who are managed in the directory are called **enterprise users**.

This directory contains information about:

- Which databases in a distributed system an enterprise user can access
- Which role on each database an enterprise user can use
- Which schema on each database an enterprise user can connect to

The administrator of each database is not required to create a global user account for each enterprise user on each database to which the enterprise user must connect. Instead, multiple enterprise users can connect to the same database schema, called a **shared schema**.

 **Note:**

You cannot access a current user database link in a shared schema.

For example, suppose `jane`, `bill`, and `scott` all use a human resources application. The `hq` application objects are all contained in the `guest` schema on the `hq` database. In this case, you can create a local global user account to be used as a shared schema. This global username, that is, shared schema name, is `guest`. `jane`, `bill`, and `scott` are all created as enterprise users in the directory service. They are also mapped to the `guest` schema in the directory, and can be assigned different authorizations in the `hq` application.

[Figure 31-5](#) illustrates an example of global user security using the enterprise directory service:

Figure 31-5 Global User Security

Assume that the enterprise directory service contains the following information on enterprise users for `hq` and `sales`:

Database	Role	Schema	Enterprise Users
hq	clerk1	guest	bill scott
	clerk2	guest	jane scott

Also, assume that the local administrators for `hq` and `sales` have issued statements as follows:

Databases	CREATE Statements
hq	<pre>CREATE USER guest IDENTIFIED GLOBALLY AS ''; CREATE ROLE clerk1 GRANT select ON emp; CREATE PUBLIC DATABASE LINK sales_link CONNECT AS CURRENT_USER USING 'sales';</pre>
sales	<pre>CREATE USER guest IDENTIFIED GLOBALLY AS ''; CREATE ROLE clerk2 GRANT select ON dept;</pre>

Assume that enterprise user `scott` requests a connection to local database `hq` in order to execute a distributed transaction involving `sales`. The following steps occur (not necessarily in this exact order):

1. Enterprise user `scott` is authenticated using SSL or a password.
 2. User `scott` issues the following statement:
- ```
SELECT e.ename, d.loc
FROM emp e, dept@sales_link d
WHERE e.deptno=d.deptno;
```
3. Databases `hq` and `sales` mutually authenticate one another using SSL.
  4. Database `hq` queries the enterprise directory service to determine whether enterprise user `scott` has access to `hq`, and discovers `scott` can access local schema `guest` using role `clerk1`.
  5. Database `sales` queries the enterprise directory service to determine whether enterprise user `scott` has access to `sales`, and discovers `scott` can access local schema `guest` using role `clerk2`.
  6. Enterprise user `scott` logs into `sales` to schema `guest` with role `clerk2` and issues a `SELECT` to obtain the required information and transfer it to `hq`.
  7. Database `hq` receives the requested data from `sales` and returns it to the client `scott`.

 **See Also:**

*Oracle Database Enterprise User Security Administrator's Guide* for more information about enterprise user security

### 31.3.2.5 Data Encryption

The Oracle Advanced Security option also enables Oracle Net and related products to use network data encryption and checksumming so that data cannot be read or altered. It protects data from unauthorized viewing by using the RSA Data Security RC4 or the Data Encryption Standard (DES) encryption algorithm.

To ensure that data has not been modified, deleted, or replayed during transmission, the security services of the Oracle Advanced Security option can generate a cryptographically secure message digest and include it with each packet sent across the network.

 **See Also:**

*Oracle Database Advanced Security Guide* for more information about these and other features of the Oracle Advanced Security option

### 31.3.3 Auditing Database Links

You must always perform auditing operations locally. That is, if a user acts in a local database and accesses a remote database through a database link, the local actions are audited in the local database, and the remote actions are audited in the remote database, provided appropriate audit options are set in the respective databases.

The remote database cannot determine whether a successful connect request and subsequent SQL statements come from another server or from a locally connected client. For example, assume the following:

- Fixed user link `hq.example.com` connects local user `jane` to the remote `hq` database as remote user `scott`.
- User `scott` is audited on the remote database.

Actions performed during the remote database session are audited as if `scott` were connected locally to `hq` and performing the same actions there. You must set audit options in the remote database to capture the actions of the username--in this case, `scott` on the `hq` database--embedded in the link if the desired effect is to audit what `jane` is doing in the remote database.

 **Note:**

You can audit the global username for global users.

You cannot set local auditing options on remote objects. Therefore, you cannot audit use of a database link, although access to remote objects can be audited on the remote database.

### 31.3.4 Administration Tools

The database administrator has several choices for tools to use when managing an Oracle Database distributed database system.

- [Cloud Control and Distributed Databases](#)  
Oracle Enterprise Manager Cloud Control is the Oracle Database administration tool that provides a graphical user interface (GUI). Cloud Control provides administrative functionality for distributed databases through an easy-to-use interface.
- [Third-Party Administration Tools](#)  
Currently more than 60 companies produce more than 150 products that help manage Oracle Databases and networks, providing a truly open environment.
- [SNMP Support](#)  
Besides its network administration capabilities, Oracle **Simple Network Management Protocol (SNMP)** support allows an Oracle Database server to be located and queried by any SNMP-based network management system.

#### 31.3.4.1 Cloud Control and Distributed Databases

Oracle Enterprise Manager Cloud Control is the Oracle Database administration tool that provides a graphical user interface (GUI). Cloud Control provides administrative functionality for distributed databases through an easy-to-use interface.

You can use Cloud Control to:

- Administer multiple databases. You can use Cloud Control to administer a single database or to simultaneously administer multiple databases.
- Centralize database administration tasks. You can administer both local and remote databases running on any Oracle Database platform in any location worldwide. In addition, these Oracle Database platforms can be connected by any network protocols supported by Oracle Net.
- Dynamically execute SQL, PL/SQL, and Cloud Control commands. You can use Cloud Control to enter, edit, and execute statements. Cloud Control also maintains a history of statements executed.

Thus, you can reexecute statements without retyping them, a particularly useful feature if you must execute lengthy statements repeatedly in a distributed database system.

- Manage security features such as global users, global roles, and the enterprise directory service.

#### 31.3.4.2 Third-Party Administration Tools

Currently more than 60 companies produce more than 150 products that help manage Oracle Databases and networks, providing a truly open environment.

#### 31.3.4.3 SNMP Support

Besides its network administration capabilities, Oracle **Simple Network Management Protocol (SNMP)** support allows an Oracle Database server to be located and queried by any SNMP-based network management system.

SNMP is the accepted standard underlying many popular network management systems such as:

- HP OpenView
- Digital POLYCENTER Manager on NetView
- IBM NetView/6000
- Novell NetWare Management System
- SunSoft SunNet Manager

 **Note:**

Oracle has deprecated SNMP support in Oracle Net Listener. Oracle recommends not using SNMP in new implementations. See *Oracle Database Upgrade Guide* for more information.

## 31.4 Transaction Processing in a Distributed System

A transaction is a logical unit of work constituted by one or more SQL statements executed by a single user. A transaction begins with the user's first executable SQL statement and ends when it is committed or rolled back by that user. A **remote transaction** contains only statements that access a single remote node. A **distributed transaction** contains statements that access multiple nodes.

- [Remote SQL Statements](#)  
A remote SQL statement either queries or modifies one or more remote tables, all of which reside at the same remote node.
- [Distributed SQL Statements](#)  
A distributed SQL statement either queries or modifies data on two or more nodes.
- [Shared SQL for Remote and Distributed Statements](#)  
The mechanics of a remote or distributed statement using shared SQL are essentially the same as those of a local statement.
- [Remote Transactions](#)  
A remote transaction contains one or more remote statements, all of which reference a single remote node.
- [Distributed Transactions](#)  
A distributed transaction is a transaction that includes one or more statements that, individually or as a group, update data on two or more distinct nodes of a distributed database.
- [Two-Phase Commit Mechanism](#)  
The database **two-phase commit** mechanism guarantees that *all* database servers participating in a distributed transaction either all commit or all roll back the statements in the transaction.
- [Database Link Name Resolution](#)  
Whenever a SQL statement includes a reference to a global object name, the database searches for a database link with a name that matches the database name specified in the global object name.

- **Schema Object Name Resolution**  
It is important to understand how the remote schema is determined when a local Oracle Database connects to a remote database.
- **Global Name Resolution in Views, Synonyms, and Procedures**  
A global object name can be complete or partial.

### 31.4.1 Remote SQL Statements

A remote SQL statement either queries or modifies one or more remote tables, all of which reside at the same remote node.

A **remote query** statement is a query that selects information from one or more remote tables, all of which reside at the same remote node. For example, the following query accesses data from the dept table in the scott schema of the remote sales database:

```
SELECT * FROM scott.dept@sales.us.americas.example_auto.com;
```

A **remote update** statement is an update that modifies data in one or more tables, all of which are located at the same remote node. For example, the following query updates the dept table in the scott schema of the remote sales database:

```
UPDATE scott.dept@mktng.us.americas.example_auto.com
SET loc = 'NEW YORK'
WHERE deptno = 10;
```

#### Note:

A remote update can include a subquery that retrieves data from one or more remote nodes, but because the update happens at only a single remote node, the statement is classified as a remote update.

### 31.4.2 Distributed SQL Statements

A distributed SQL statement either queries or modifies data on two or more nodes.

A **distributed query** statement retrieves information from two or more nodes. For example, the following query accesses data from the local database as well as the remote sales database:

```
SELECT ename, dname
 FROM scott.emp e, scott.dept@sales.us.americas.example_auto.com d
 WHERE e.deptno = d.deptno;
```

A **distributed update** statement modifies data on two or more nodes. A distributed update is possible using a PL/SQL subprogram unit such as a procedure or trigger that includes two or more remote updates that access data on different nodes. For example, the following PL/SQL program unit updates tables on the local database and the remote sales database:

```
BEGIN
 UPDATE scott.dept@sales.us.americas.example_auto.com
 SET loc = 'NEW YORK'
 WHERE deptno = 10;
```

```
UPDATE scott.emp
 SET deptno = 11
 WHERE deptno = 10;
END;
COMMIT;
```

The database sends statements in the program to the remote nodes, and their execution succeeds or fails as a unit.

### 31.4.3 Shared SQL for Remote and Distributed Statements

The mechanics of a remote or distributed statement using shared SQL are essentially the same as those of a local statement.

The SQL text must match, and the referenced objects must match. If available, shared SQL areas can be used for the local and remote handling of any statement or decomposed query.

 **See Also:**

*Oracle Database Concepts* for more information about shared SQL

### 31.4.4 Remote Transactions

A remote transaction contains one or more remote statements, all of which reference a single remote node.

For example, the following transaction contains two statements, each of which accesses the remote `sales` database:

```
UPDATE scott.dept@sales.us.americas.example_auto.com
 SET loc = 'NEW YORK'
 WHERE deptno = 10;
UPDATE scott.emp@sales.us.americas.example_auto.com
 SET deptno = 11
 WHERE deptno = 10;
COMMIT;
```

### 31.4.5 Distributed Transactions

A distributed transaction is a transaction that includes one or more statements that, individually or as a group, update data on two or more distinct nodes of a distributed database.

For example, this transaction updates the local database and the remote `sales` database:

```
UPDATE scott.dept@sales.us.americas.example_auto.com
 SET loc = 'NEW YORK'
 WHERE deptno = 10;
UPDATE scott.emp
 SET deptno = 11
 WHERE deptno = 10;
COMMIT;
```

 **Note:**

If all statements of a transaction reference only a single remote node, the transaction is remote, not distributed.

### 31.4.6 Two-Phase Commit Mechanism

The database **two-phase commit** mechanism guarantees that *all* database servers participating in a distributed transaction either all commit or all roll back the statements in the transaction.

A database must guarantee that all statements in a transaction, distributed or non-distributed, either commit or roll back as a unit. The effects of an ongoing transaction should be invisible to all other transactions at all nodes; this transparency should be true for transactions that include any type of operation, including queries, updates, or remote procedure calls.

The general mechanisms of transaction control in a non-distributed database are discussed in the *Oracle Database Concepts*. In a distributed database, the database must coordinate transaction control with the same characteristics over a network and maintain data consistency, even if a network or system failure occurs.

A two-phase commit mechanism also protects implicit DML operations performed by integrity constraints, remote procedure calls, and triggers.

 **See Also:**

[Distributed Transactions Concepts](#) for more information about the Oracle Database two-phase commit mechanism

### 31.4.7 Database Link Name Resolution

Whenever a SQL statement includes a reference to a global object name, the database searches for a database link with a name that matches the database name specified in the global object name.

- [About Database Link Name Resolution](#)  
A **global object name** is an object specified using a database link.
- [Name Resolution When the Global Database Name Is Complete](#)  
For SQL statements with a complete global database name, the database searches only for links that match the specified global database name.
- [Name Resolution When the Global Database Name Is Partial](#)  
If any part of the domain is specified, then the database assumes that a complete global database name is specified.
- [Name Resolution When No Global Database Name Is Specified](#)  
If a global object name references an object in the local database and a database link name is *not* specified using the @ symbol, then the database automatically

detects that the object is local and does not search for or use database links to resolve the object reference.

- **Terminating the Search for Name Resolution**

The database does not necessarily stop searching for matching database links when it finds the first match. The database must search for matching private, public, and network database links until it determines a complete path to the remote database (both a remote account and service name).

### 31.4.7.1 About Database Link Name Resolution

A **global object name** is an object specified using a database link.

The essential components of a global object name are:

- Object name
- Database name
- Domain

The following table shows the components of an explicitly specified global database object name:

| <b>Statement</b>                                 | <b>Object</b> | <b>Database</b> | <b>Domain</b>  |
|--------------------------------------------------|---------------|-----------------|----------------|
| SELECT * FROM<br>joan.dept@sales.example.co<br>m | dept          | sales           | example.com    |
| SELECT * FROM<br>emp@mktg.us.example.com         | emp           | mktg            | us.example.com |

Whenever a SQL statement includes a reference to a global object name, the database searches for a database link with a name that matches the database name specified in the global object name. For example, if you issue the following statement:

```
SELECT * FROM scott.emp@orders.us.example.com;
```

The database searches for a database link called `orders.us.example.com`. The database performs this operation to determine the path to the specified remote database.

The database always searches for matching database links in the following order:

1. Private database links in the schema of the user who issued the SQL statement.
2. Public database links in the local database.
3. Global database links (only if a directory server is available).

### 31.4.7.2 Name Resolution When the Global Database Name Is Complete

For SQL statements with a complete global database name, the database searches only for links that match the specified global database name.

Assume that you issue the following SQL statement, which specifies a complete global database name:

```
SELECT * FROM emp@prod1.us.example.com;
```

In this case, both the database name (`prod1`) and domain components (`us.example.com`) are specified, so the database searches for private, public, and global database links.

### 31.4.7.3 Name Resolution When the Global Database Name Is Partial

If any part of the domain is specified, then the database assumes that a complete global database name is specified.

If a SQL statement specifies a partial global database name (that is, only the database component is specified), the database appends the value in the `DB_DOMAIN` initialization parameter to the value in the `DB_NAME` initialization parameter to construct a complete name. For example, assume you issue the following statements:

```
CONNECT scott@locdb
SELECT * FROM scott.emp@orders;
```

If the network domain for `locdb` is `us.example.com`, then the database appends this domain to `orders` to construct the complete global database name of `orders.us.example.com`. The database searches for database links that match only the constructed global name. If a matching link is not found, the database returns an error and the SQL statement cannot execute.

### 31.4.7.4 Name Resolution When No Global Database Name Is Specified

If a global object name references an object in the local database and a database link name is *not* specified using the @ symbol, then the database automatically detects that the object is local and does not search for or use database links to resolve the object reference.

For example, assume that you issue the following statements:

```
CONNECT scott@locdb
SELECT * from scott.emp;
```

Because the second statement does not specify a global database name using a database link connect string, the database does not search for database links.

### 31.4.7.5 Terminating the Search for Name Resolution

The database does not necessarily stop searching for matching database links when it finds the first match. The database must search for matching private, public, and network database links until it determines a complete path to the remote database (both a remote account and service name).

The first match determines the remote schema as illustrated in the following table:

| User Operation                                     | Database Response                   | Example                                                                                   |
|----------------------------------------------------|-------------------------------------|-------------------------------------------------------------------------------------------|
| Do <i>not</i> specify the CONNECT clause           | Uses a connected user database link | <code>CREATE DATABASE LINK k1 USING 'prod'</code>                                         |
| Do specify the CONNECT TO ... IDENTIFIED BY clause | Uses a fixed user database link     | <code>CREATE DATABASE LINK k2 CONNECT TO scott IDENTIFIED BY password USING 'prod'</code> |

| User Operation                             | Database Response                                                                                                                                                  | Example                                                      |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| Specify the CONNECT TO CURRENT_USER clause | Uses a current user database link                                                                                                                                  | CREATE DATABASE LINK k3 CONNECT TO CURRENT_USER USING 'prod' |
| Do <i>not</i> specify the USING clause     | Searches until it finds a link specifying a database string. If matching database links are found and a string is never identified, the database returns an error. | CREATE DATABASE LINK k4 CONNECT TO CURRENT_USER              |

After the database determines a complete path, it creates a remote session, assuming that an identical connection is not already open on behalf of the same local session. If a session already exists, the database reuses it.

### 31.4.8 Schema Object Name Resolution

It is important to understand how the remote schema is determined when a local Oracle Database connects to a remote database.

- [About Schema Object Name Resolution](#)  
After the local Oracle Database connects to the specified remote database on behalf of the local user that issued the SQL statement, object resolution continues as if the remote user had issued the associated SQL statement.
- [Example of Global Object Name Resolution: Complete Object Name](#)  
An example illustrates how the database resolves a complete global object name and determines the appropriate path to the remote database using both a private and public database link.
- [Example of Global Object Name Resolution: Partial Object Name](#)  
An example illustrates how the database resolves a partial global object name and determines the appropriate path to the remote database using both a private and public database link.

#### 31.4.8.1 About Schema Object Name Resolution

After the local Oracle Database connects to the specified remote database on behalf of the local user that issued the SQL statement, object resolution continues as if the remote user had issued the associated SQL statement.

The first match determines the remote schema according to the following rules:

| Type of Link Specified         | Location of Object Resolution                   |
|--------------------------------|-------------------------------------------------|
| A fixed user database link     | Schema specified in the link creation statement |
| A connected user database link | Connected user's remote schema                  |
| A current user database link   | Current user's schema                           |

If the database cannot find the object, then it checks public objects of the remote database. If it cannot resolve the object, then the established remote session remains but the SQL statement cannot execute and returns an error.

The following are examples of global object name resolution in a distributed database system. For all the following examples, assume that:

### 31.4.8.2 Example of Global Object Name Resolution: Complete Object Name

An example illustrates how the database resolves a complete global object name and determines the appropriate path to the remote database using both a private and public database link.

For this example, assume the following:

- The remote database is named sales.division3.example.com.
- The local database is named hq.division3.example.com.
- A directory server (and therefore, global database links) is not available.
- A remote table emp is contained in the schema tsmith.

Consider the following statements issued by scott at the local database:

```
CONNECT scott@hq

CREATE PUBLIC DATABASE LINK sales.division3.example.com
CONNECT TO guest IDENTIFIED BY network
 USING 'dbstring';
```

Later, jward connects and issues the following statements:

```
CONNECT jward@hq

CREATE DATABASE LINK sales.division3.example.com
CONNECT TO tsmith IDENTIFIED BY radio;

UPDATE tsmith.emp@sales.division3.example.com
 SET deptno = 40
 WHERE deptno = 10;
```

The database processes the final statement as follows:

1. The database determines that a complete global object name is referenced in jward's UPDATE statement. Therefore, the system begins searching in the local database for a database link with a matching name.
2. The database finds a matching private database link in the schema jward. Nevertheless, the private database link jward.sales.division3.example.com does not indicate a complete path to the remote sales database, only a remote account. Therefore, the database now searches for a matching public database link.
3. The database finds the public database link in scott's schema. From this public database link, the database takes the service name dbstring.
4. Combined with the remote account taken from the matching private fixed user database link, the database determines a complete path and proceeds to establish a connection to the remote sales database as user tsmith/radio.
5. The remote database can now resolve the object reference to the emp table. The database searches in the tsmith schema and finds the referenced emp table.
6. The remote database completes the execution of the statement and returns the results to the local database.

### 31.4.8.3 Example of Global Object Name Resolution: Partial Object Name

An example illustrates how the database resolves a partial global object name and determines the appropriate path to the remote database using both a private and public database link.

For this example, assume that:

- The remote database is named sales.division3.example.com.
- The local database is named hq.division3.example.com.
- A directory server (and therefore, global database links) is not available.
- A table `emp` on the remote database `sales` is contained in the schema `tsmith`, but not in schema `scott`.
- A public synonym named `emp` resides at remote database `sales` and points to `tsmith.emp` in the remote database `sales`.
- The public database link in "[Example of Global Object Name Resolution: Complete Object Name](#)" is already created on local database `hq`:

```
CREATE PUBLIC DATABASE LINK sales.division3.example.com
 CONNECT TO guest IDENTIFIED BY network
 USING 'dbstring';
```

Consider the following statements issued at local database `hq`:

```
CONNECT scott@hq

CREATE DATABASE LINK sales.division3.example.com;

DELETE FROM emp@sales
 WHERE empno = 4299;
```

The database processes the final `DELETE` statement as follows:

1. The database notices that a partial global object name is referenced in `scott`'s `DELETE` statement. It expands it to a complete global object name using the domain of the local database as follows:

```
DELETE FROM emp@sales.division3.example.com
 WHERE empno = 4299;
```

2. The database searches the local database for a database link with a matching name.
3. The database finds a matching *private* connected user link in the schema `scott`, but the private database link indicates no path at all. The database uses the connected username/password as the remote account portion of the path and then searches for and finds a matching *public* database link:

```
CREATE PUBLIC DATABASE LINK sales.division3.example.com
 CONNECT TO guest IDENTIFIED BY network
 USING 'dbstring';
```

4. The database takes the database net service name `dbstring` from the public database link. At this point, the database has determined a complete path.
5. The database connects to the remote database as `scott/password` and searches for and does not find an object named `emp` in the schema `scott`.

6. The remote database searches for a public synonym named `emp` and finds it.
7. The remote database executes the statement and returns the results to the local database.

### 31.4.9 Global Name Resolution in Views, Synonyms, and Procedures

A global object name can be complete or partial.

- [About Global Name Resolution in Views, Synonyms, and Procedures](#)  
A view, synonym, or PL/SQL program unit (for example, a procedure, function, or trigger) can reference a remote schema object by its global object name.
- [What Happens When Global Names Change](#)  
Global name changes can affect views, synonyms, and procedures that reference remote data using partial global object names.
- [Scenarios for Global Name Changes](#)  
Scenarios illustrate global name changes.

#### 31.4.9.1 About Global Name Resolution in Views, Synonyms, and Procedures

A view, synonym, or PL/SQL program unit (for example, a procedure, function, or trigger) can reference a remote schema object by its global object name.

If the global object name is complete, then the database stores the definition of the object without expanding the global object name. If the name is partial, however, then the database expands the name using the domain of the local database name.

The following table explains when the database completes the expansion of a partial global object name for views, synonyms, and program units:

| User Operation         | Database Response                                                                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Create a view          | Does <i>not</i> expand partial global names. The data dictionary stores the exact text of the defining query. Instead, the database expands a partial global object name each time a statement that uses the view is parsed. |
| Create a synonym       | Expands partial global names. The definition of the synonym stored in the data dictionary includes the expanded global object name.                                                                                          |
| Compile a program unit | Expands partial global names.                                                                                                                                                                                                |

#### 31.4.9.2 What Happens When Global Names Change

Global name changes can affect views, synonyms, and procedures that reference remote data using partial global object names.

If the global name of the referenced database changes, views and procedures may try to reference a nonexistent or incorrect database. However, synonyms do not expand database link names at run time, so they do not change.

#### 31.4.9.3 Scenarios for Global Name Changes

Scenarios illustrate global name changes.

For example, consider two databases named `sales.uk.example.com` and `hq.uk.example.com`. Also, assume that the `sales` database contains the following view and synonym:

```
CREATE VIEW employee_names AS
 SELECT ename FROM scott.emp@hr;

CREATE SYNONYM employee FOR scott.emp@hr;
```

The database expands the `employee` synonym definition and stores it as:

```
scott.emp@hr.uk.example.com
```

- **Scenario 1: Both Databases Change Names**  
A scenario illustrates a situation in which both global database names change.
- **Scenario 2: One Database Changes Names**  
A scenario illustrates a situation in which one global database name changes.

### 31.4.9.3.1 Scenario 1: Both Databases Change Names

A scenario illustrates a situation in which both global database names change.

First, consider the situation where both the Sales and Human Resources departments are relocated to the United States. Consequently, the corresponding global database names are both changed as follows:

- `sales.uk.example.com` becomes `sales.us.example.com`
- `hq.uk.example.com` becomes `hq.us.example.com`

The following table describes query expansion before and after the change in global names:

| Query on sales                            | Expansion Before Change                                | Expansion After Change                                 |
|-------------------------------------------|--------------------------------------------------------|--------------------------------------------------------|
| <code>SELECT * FROM employee_names</code> | <code>SELECT * FROM scott.emp@hr.uk.example.com</code> | <code>SELECT * FROM scott.emp@hr.us.example.com</code> |
| <code>SELECT * FROM employee</code>       | <code>SELECT * FROM scott.emp@hr.uk.example.com</code> | <code>SELECT * FROM scott.emp@hr.us.example.com</code> |

### 31.4.9.3.2 Scenario 2: One Database Changes Names

A scenario illustrates a situation in which one global database name changes.

Now consider that only the Sales department is moved to the United States; Human Resources remains in the UK. Consequently, the corresponding global database names are both changed as follows:

- `sales.uk.example.com` becomes `sales.us.example.com`
- `hq.uk.example.com` is not changed

The following table describes query expansion before and after the change in global names:

| Query on sales               | Expansion Before Change                   | Expansion After Change                    |
|------------------------------|-------------------------------------------|-------------------------------------------|
| SELECT * FROM employee_names | SELECT * FROM scott.emp@hr.uk.example.com | SELECT * FROM scott.emp@hr.us.example.com |
| SELECT * FROM employee       | SELECT * FROM scott.emp@hr.uk.example.com | SELECT * FROM scott.emp@hr.uk.example.com |

In this case, the defining query of the `employee_names` view expands to a nonexistent global database name. However, the `employee` synonym continues to reference the correct database, `hq.uk.example.com`.

## 31.5 Distributed Database Application Development

Application development in a distributed system raises issues that are not applicable in a non-distributed system.

- **Transparency in a Distributed Database System**

With minimal effort, you can develop applications that make an Oracle Database distributed database system transparent to users that work with the system. The goal of transparency is to make a distributed database system appear as though it is a single Oracle Database. Consequently, the system does not burden developers and users of the system with complexities that would otherwise make distributed database application development challenging and detract from user productivity.

- **PL/SQL and Remote Procedure Calls (RPCs)**

Developers can code PL/SQL packages and procedures to support applications that work with a distributed database. Applications can make local procedure calls to perform work at the local database and **remote procedure calls (RPCs)** to perform work at a remote database.

- **Distributed Query Optimization**

**Distributed query optimization** is an Oracle Database feature that reduces the amount of data transfer required between sites when a transaction retrieves data from remote tables referenced in a distributed SQL statement.

 **See Also:**

[Developing Applications for a Distributed Database System](#) to learn how to develop applications for distributed systems

### 31.5.1 Transparency in a Distributed Database System

With minimal effort, you can develop applications that make an Oracle Database distributed database system transparent to users that work with the system. The goal of transparency is to make a distributed database system appear as though it is a single Oracle Database. Consequently, the system does not burden developers and

users of the system with complexities that would otherwise make distributed database application development challenging and detract from user productivity.

- **Location Transparency**  
An Oracle Database distributed database system has features that allow application developers and administrators to hide the physical location of database objects from applications and users.
- **SQL and COMMIT Transparency**  
The Oracle Database distributed database architecture provides query, update, and transaction transparency.

### 31.5.1.1 Location Transparency

An Oracle Database distributed database system has features that allow application developers and administrators to hide the physical location of database objects from applications and users.

**Location transparency** exists when a user can universally refer to a database object such as a table, regardless of the node to which an application connects. Location transparency has several benefits, including:

- Access to remote data is simple, because database users do not need to know the physical location of database objects.
- Administrators can move database objects with no impact on end-users or existing database applications.

Typically, administrators and developers use synonyms to establish location transparency for the tables and supporting objects in an application schema. For example, the following statements create synonyms in a database for tables in another, remote database.

```
CREATE PUBLIC SYNONYM emp
 FOR scott.emp@sales.us.americas.example_auto.com;
CREATE PUBLIC SYNONYM dept
 FOR scott.dept@sales.us.americas.example_auto.com;
```

Now, rather than access the remote tables with a query such as:

```
SELECT ename, dname
 FROM scott.emp@sales.us.americas.example_auto.com e,
 scott.dept@sales.us.americas.example_auto.com d
 WHERE e.deptno = d.deptno;
```

An application can issue a much simpler query that does not have to account for the location of the remote tables.

```
SELECT ename, dname
 FROM emp e, dept d
 WHERE e.deptno = d.deptno;
```

In addition to synonyms, developers can also use views and stored procedures to establish location transparency for applications that work in a distributed database system.

### 31.5.1.2 SQL and COMMIT Transparency

The Oracle Database distributed database architecture provides query, update, and transaction transparency.

For example, standard SQL statements such as SELECT, INSERT, UPDATE, and DELETE work just as they do in a non-distributed database environment. Additionally, applications control transactions using the standard SQL statements COMMIT, SAVEPOINT, and ROLLBACK. There is no requirement for complex programming or other special operations to provide distributed transaction control.

- The statements in a single transaction can reference any number of local or remote tables.
- The database guarantees that all nodes involved in a distributed transaction take the same action: they either all commit or all roll back the transaction.
- If a network or system failure occurs during the commit of a distributed transaction, the transaction is automatically and transparently resolved globally. Specifically, when the network or system is restored, the nodes either all commit or all roll back the transaction.

Internal to the database, each committed transaction has an associated **system change number (SCN)** to uniquely identify the changes made by the statements within that transaction. In a distributed database, the SCNs of communicating nodes are coordinated when:

- A connection is established using the path described by one or more database links.
- A distributed SQL statement is executed.
- A distributed transaction is committed.

Among other benefits, the coordination of SCNs among the nodes of a distributed database system allows global distributed read-consistency at both the statement and transaction level. If necessary, global distributed time-based recovery can also be completed.

### 31.5.2 PL/SQL and Remote Procedure Calls (RPCs)

Developers can code PL/SQL packages and procedures to support applications that work with a distributed database. Applications can make local procedure calls to perform work at the local database and **remote procedure calls (RPCs)** to perform work at a remote database.

When a program calls a remote procedure, the local server passes all procedure parameters to the remote server in the call. For example, the following PL/SQL program unit calls the packaged procedure del\_emp located at the remote sales database and passes it the parameter 1257:

```
BEGIN
 emp_mgmt.del_emp@sales.us.americas.example_auto.com(1257);
END;
```

In order for the RPC to succeed, the called procedure must exist at the remote site, and the user being connected to must have the proper privileges to execute the procedure.

When developing packages and procedures for distributed database systems, developers must code with an understanding of what program units should do at remote locations, and how to return the results to a calling application.

### 31.5.3 Distributed Query Optimization

**Distributed query optimization** is an Oracle Database feature that reduces the amount of data transfer required between sites when a transaction retrieves data from remote tables referenced in a distributed SQL statement.

Distributed query optimization uses cost-based optimization to find or generate SQL expressions that extract only the necessary data from remote tables, process that data at a remote site or sometimes at the local site, and send the results to the local site for final processing. This operation reduces the amount of required data transfer when compared to the time it takes to transfer all the table data to the local site for processing.

Using various cost-based optimizer hints such as `DRIVING_SITE`, `NO_MERGE`, and `INDEX`, you can control where Oracle Database processes the data and how it accesses the data.

 **See Also:**

"[Using Cost-Based Optimization](#)" for more information about cost-based optimization

## 31.6 Character Set Support for Distributed Environments

Different databases and clients can use different character sets in a distributed environment.

- [About Character Set Support for Distributed Environments](#)  
Oracle Database supports environments in which clients, Oracle Database servers, and non-Oracle Database servers use different character sets. `NCHAR` support is provided for heterogeneous environments.
- [Client/Server Environment](#)  
In a client/server environment, set the client character set to be the same as or a subset of the Oracle Database server character set.
- [Homogeneous Distributed Environment](#)  
In a non-heterogeneous environment, the client and server character sets should be either the same as or subsets of the main server character set.
- [Heterogeneous Distributed Environment](#)  
In a heterogeneous environment, the globalization support parameter settings of the client, the transparent gateway, and the non-Oracle Database data source should be either the same or a subset of the database server character set.

### 31.6.1 About Character Set Support for Distributed Environments

Oracle Database supports environments in which clients, Oracle Database servers, and non-Oracle Database servers use different character sets. `NCHAR` support is provided for heterogeneous environments.

You can set a variety of National Language Support (NLS) and Heterogeneous Services (HS) environment variables and initialization parameters to control data conversion between different character sets.

Character settings are defined by the following NLS and HS parameters:

| Parameters                                    | Environment                   | Defined For                                       |
|-----------------------------------------------|-------------------------------|---------------------------------------------------|
| <code>NLS_LANG</code> (environment variable)  | Client/Server                 | Client                                            |
| <code>NLS_LANGUAGE</code>                     | Client/Server                 | Oracle Database server                            |
| <code>NLS_CHARACTERSET</code>                 | Not Heterogeneous Distributed |                                                   |
| <code>NLS_TERRITORY</code>                    | Heterogeneous Distributed     |                                                   |
| <code>HS_LANGUAGE</code>                      | Heterogeneous Distributed     | Non-Oracle Database server<br>Transparent gateway |
| <code>NLS_NCHAR</code> (environment variable) | Heterogeneous Distributed     | Oracle Database server<br>Transparent gateway     |
| <code>HS_NLS_NCHAR</code>                     |                               |                                                   |

#### See Also:

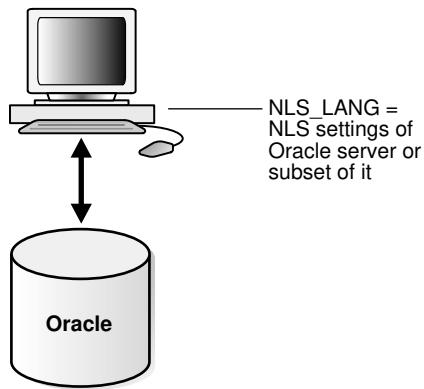

- *Oracle Database Globalization Support Guide* for information about NLS parameters
- *Oracle Database Heterogeneous Connectivity User's Guide* for information about HS parameters

### 31.6.2 Client/Server Environment

In a client/server environment, set the client character set to be the same as or a subset of the Oracle Database server character set.

[Figure 31-6](#) illustrates a client/server environment.

**Figure 31-6 NLS Parameter Settings in a Client/Server Environment**

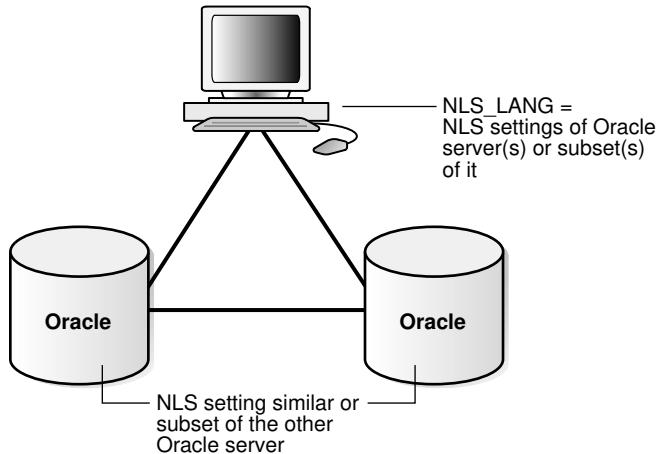

### 31.6.3 Homogeneous Distributed Environment

In a non-heterogeneous environment, the client and server character sets should be either the same as or subsets of the main server character set.

[Figure 31-7](#) illustrates a homogeneous distributed environment:

**Figure 31-7 NLS Parameter Settings in a Homogeneous Environment**

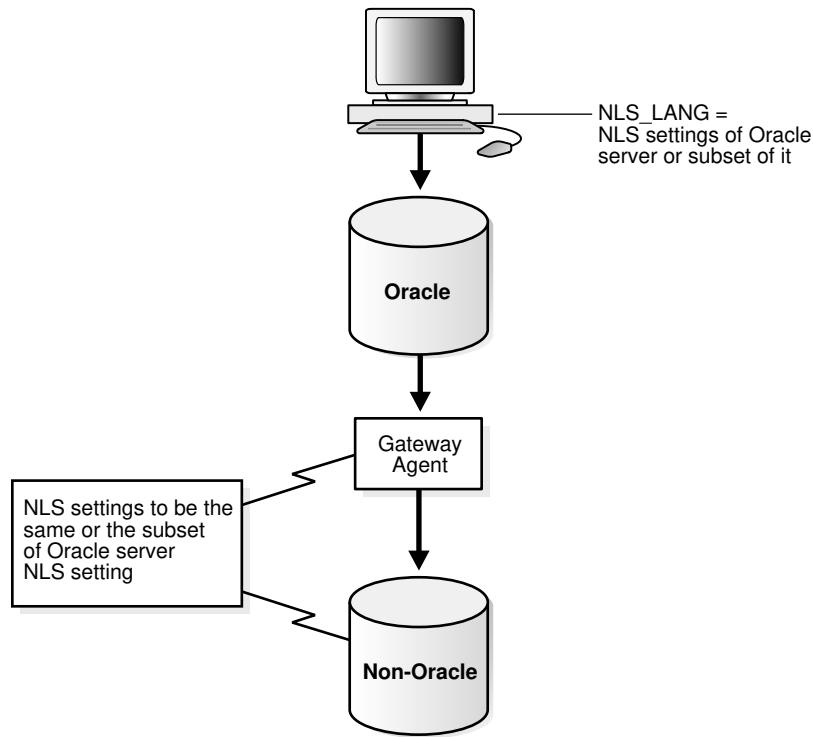

### 31.6.4 Heterogeneous Distributed Environment

In a heterogeneous environment, the globalization support parameter settings of the client, the transparent gateway, and the non-Oracle Database data source should be either the same or a subset of the database server character set.

[Figure 31-8](#) illustrates a heterogeneous distributed environment. Transparent gateways have full globalization support.

Figure 31-8 NLS Parameter Settings in a Heterogeneous Environment

In a heterogeneous environment, only transparent gateways built with HS technology support complete NCHAR capabilities. Whether a specific transparent gateway supports NCHAR depends on the non-Oracle Database data source it is targeting. For information on how a particular transparent gateway handles NCHAR support, consult the system-specific transparent gateway documentation.

# Managing a Distributed Database

Managing a distributed database includes tasks such as managing global names, managing database links, and creating location and statement transparency.

- [Managing Global Names in a Distributed System](#)

In a distributed database system, each database should have a unique **global database name**. Global database names uniquely identify a database in the system. A primary administration task in a distributed system is managing the creation and alteration of global database names.

- [Creating Database Links](#)

To support application access to the data and schema objects throughout a distributed database system, you must create all necessary database links.

- [Using Shared Database Links](#)

Every application that references a remote server using a standard database link establishes a connection between the local database and the remote database. Many users running applications simultaneously can cause a high number of connections between the local and remote databases. Shared database links enable you to limit the number of network connections required between the local server and the remote server.

- [Managing Database Links](#)

Managing database links includes tasks such as closing them, dropping them, and limiting the number of active connections to them.

- [Viewing Information About Database Links](#)

The data dictionary of each database stores the definitions of all the database links in the database. You can use data dictionary tables and views to gain information about the links.

- [Creating Location Transparency](#)

After you have configured the necessary database links, you can use various tools to hide the distributed nature of the database system from users. In other words, users can access remote objects as if they were local objects.

- [Managing Statement Transparency](#)

In a distributed database, some SQL statements can reference remote tables.

- [Managing a Distributed Database: Examples](#)

Examples illustrate managing database links.

## 32.1 Managing Global Names in a Distributed System

In a distributed database system, each database should have a unique **global database name**. Global database names uniquely identify a database in the system. A primary administration task in a distributed system is managing the creation and alteration of global database names.

- [Understanding How Global Database Names Are Formed](#)

A global database name is formed from two components: a database name and a domain.

- [Determining Whether Global Naming Is Enforced](#)  
The name that you give to a link on the local database depends on whether the local database enforces global naming.
- [Viewing a Global Database Name](#)  
Use the data dictionary view `GLOBAL_NAME` to view the database global name.
- [Changing the Domain in a Global Database Name](#)  
Use the `ALTER DATABASE` statement to change the domain in a database global name.
- [Changing a Global Database Name: Scenario](#)  
A scenario illustrates changing a global database name.

### 32.1.1 Understanding How Global Database Names Are Formed

A global database name is formed from two components: a database name and a domain.

The database name and the domain name are determined by the following initialization parameters at database creation:

| Component                      | Parameter              | Requirements                                                                                                                                                      | Example                     |
|--------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|
| Database name                  | <code>DB_NAME</code>   | Must be 30 characters or less.                                                                                                                                    | <code>sales</code>          |
| Domain containing the database | <code>DB_DOMAIN</code> | Must follow standard Internet conventions.<br>Levels in domain names must be separated by dots and the order of domain names is from leaf to root, left to right. | <code>us.example.com</code> |

These are examples of valid global database names:

| <code>DB_NAME</code> | <code>DB_DOMAIN</code>      | Global Database Name              |
|----------------------|-----------------------------|-----------------------------------|
| <code>sales</code>   | <code>example.com</code>    | <code>sales.example.com</code>    |
| <code>sales</code>   | <code>us.example.com</code> | <code>sales.us.example.com</code> |
| <code>mktg</code>    | <code>us.example.com</code> | <code>mktg.us.example.com</code>  |
| <code>payroll</code> | <code>example.org</code>    | <code>payroll.example.org</code>  |

The `DB_DOMAIN` initialization parameter is only important at database creation time when it is used, together with the `DB_NAME` parameter, to form the database global name. At this point, the database global name is stored in the data dictionary. You must change the global name using an `ALTER DATABASE` statement, *not* by altering the `DB_DOMAIN` parameter in the initialization parameter file. It is good practice, however, to change the `DB_DOMAIN` parameter to reflect the change in the domain name before the next database startup.

### 32.1.2 Determining Whether Global Naming Is Enforced

The name that you give to a link on the local database depends on whether the local database enforces global naming.

If the local database enforces global naming, then you must use the remote database global database name as the name of the link. For example, if you are connected to the local `hq` server and want to create a link to the remote `mfg` database, and the local database enforces global naming, then you must use the `mfg` global database name as the link name.

You can also use service names as part of the database link name. For example, if you use the service names `sn1` and `sn2` to connect to database `hq.example.com`, and global naming is enforced, then you can create the following link names to `hq`:

- `HQ.EXAMPLE.COM@SN1`
- `HQ.EXAMPLE.COM@SN2`

 **See Also:**

["Using Connection Qualifiers to Specify Service Names Within Link Names"](#) for more information about using services names in link names

To determine whether global naming is enforced on a database, either examine the database initialization parameter file or query the `V$PARAMETER` view. For example, to see whether global naming is enforced on `mfg`, you could start a session on `mfg` and then create and execute the following `globalnames.sql` script (sample output included):

```
COL NAME FORMAT A12
COL VALUE FORMAT A6
SELECT NAME, VALUE FROM V$PARAMETER
 WHERE NAME = 'global_names'
/
SQL> @globalnames

NAME VALUE

global_names FALSE
```

### 32.1.3 Viewing a Global Database Name

Use the data dictionary view `GLOBAL_NAME` to view the database global name.

For example, issue the following:

```
SELECT * FROM GLOBAL_NAME;

GLOBAL_NAME

SALES.EXAMPLE.COM
```

### 32.1.4 Changing the Domain in a Global Database Name

Use the `ALTER DATABASE` statement to change the domain in a database global name.

After the database is created, changing the initialization parameter `DB_DOMAIN` has no effect on the global database name or on the resolution of database link names.

The following example shows the syntax for the renaming statement, where *database* is a database name and *domain* is the network domain:

```
ALTER DATABASE RENAME GLOBAL_NAME TO database.domain;
```

Use the following procedure to change the domain in a global database name:

1. Determine the current global database name. For example, issue:

```
SELECT * FROM GLOBAL_NAME;
```

```
GLOBAL_NAME
```

```

```

```
SALES.EXAMPLE.COM
```

2. Rename the global database name using an `ALTER DATABASE` statement. For example, enter:

```
ALTER DATABASE RENAME GLOBAL_NAME TO sales.us.example.com;
```

3. Query the `GLOBAL_NAME` table to check the new name. For example, enter:

```
SELECT * FROM GLOBAL_NAME;
```

```
GLOBAL_NAME
```

```

```

```
SALES.US.EXAMPLE.COM
```

### 32.1.5 Changing a Global Database Name: Scenario

A scenario illustrates changing a global database name.

In this scenario, you change the domain part of the global database name of the local database. You also create database links using partially specified global names to test how Oracle Database resolves the names. You discover that the database resolves the partial names using the domain part of the current global database name of the local database, not the value for the initialization parameter `DB_DOMAIN`.

1. You connect to `SALES.US.EXAMPLE.COM` and query the `GLOBAL_NAME` data dictionary view to determine the current database global name:

```
CONNECT SYSTEM@sales.us.example.com
SELECT * FROM GLOBAL_NAME;
```

```
GLOBAL_NAME
```

```

```

```
SALES.US.EXAMPLE.COM
```

2. You query the `V$PARAMETER` view to determine the current setting for the `DB_DOMAIN` initialization parameter:

```
SELECT NAME, VALUE FROM V$PARAMETER WHERE NAME = 'db_domain';
```

| NAME | VALUE |
|------|-------|
|------|-------|

```

db_domain US.EXAMPLE.COM
```

3. You then create a database link to a database called `hq`, using only a partially-specified global name:

```
CREATE DATABASE LINK hq USING 'sales';
```

The database expands the global database name for this link by appending the domain part of the global database name of the *local* database to the name of the database specified in the link.

4. You query `USER_DB_LINKS` to determine which domain name the database uses to resolve the partially specified global database name:

```
SELECT DB_LINK FROM USER_DB_LINKS;
```

```
DB_LINK

HQ.US.EXAMPLE.COM
```

This result indicates that the domain part of the global database name of the local database is `us.example.com`. The database uses this domain in resolving partial database link names when the database link is created.

5. Because you have received word that the `sales` database will move to Japan, you rename the `sales` database to `sales.jp.example.com`:

```
ALTER DATABASE RENAME GLOBAL_NAME TO sales.jp.example.com;
SELECT * FROM GLOBAL_NAME;
```

```
GLOBAL_NAME

SALES.JP.EXAMPLE.COM
```

6. You query `V$PARAMETER` again and discover that the value of `DB_DOMAIN` is *not* changed, although you renamed the domain part of the global database name:

```
SELECT NAME, VALUE FROM V$PARAMETER
WHERE NAME = 'db_domain';
```

```
NAME VALUE

db_domain US.EXAMPLE.COM
```

This result indicates that the value of the `DB_DOMAIN` initialization parameter is independent of the `ALTER DATABASE RENAME GLOBAL_NAME` statement. The `ALTER DATABASE` statement determines the domain of the global database name, not the `DB_DOMAIN` initialization parameter (although it is good practice to alter `DB_DOMAIN` to reflect the new domain name).

7. You create another database link to database `supply`, and then query `USER_DB_LINKS` to see how the database resolves the domain part of the global database name of `supply`:

```
CREATE DATABASE LINK supply USING 'supply';
SELECT DB_LINK FROM USER_DB_LINKS;
```

```
DB_LINK

HQ.US.EXAMPLE.COM
SUPPLY.JP.EXAMPLE.COM
```

This result indicates that the database resolves the partially specified link name by using the domain `jp.example.com`. This domain is used when the link is created because it is the domain part of the global database name of the local database. The database does *not* use the `DB_DOMAIN` initialization parameter setting when resolving the partial link name.

8. You then receive word that your previous information was faulty: `sales` will be in the `ASIA.JP.EXAMPLE.COM` domain, not the `JP.EXAMPLE.COM` domain. Consequently, you rename the global database name as follows:

```
ALTER DATABASE RENAME GLOBAL_NAME TO sales.asia.jp.example.com;
SELECT * FROM GLOBAL_NAME;
```

```
GLOBAL_NAME

SALES.ASIA.JP.EXAMPLE.COM
```

9. You query `V$PARAMETER` to again check the setting for the parameter `DB_DOMAIN`:

```
SELECT NAME, VALUE FROM V$PARAMETER
 WHERE NAME = 'db_domain';
```

```
NAME VALUE

db_domain US.EXAMPLE.COM
```

The result indicates that the domain setting in the parameter file is the same as it was before you issued either of the `ALTER DATABASE RENAME` statements.

10. Finally, you create a link to the `warehouse` database and again query `USER_DB_LINKS` to determine how the database resolves the partially-specified global name:

```
CREATE DATABASE LINK warehouse USING 'warehouse';
SELECT DB_LINK FROM USER_DB_LINKS;
```

```
DB_LINK

HQ.US.EXAMPLE.COM
SUPPLY.JP.EXAMPLE.COM
WAREHOUSE.ASIA.JP.EXAMPLE.COM
```

Again, you see that the database uses the domain part of the global database name of the local database to expand the partial link name during link creation.

 **Note:**

In order to correct the `supply` database link, it must be dropped and re-created.

- *Oracle Database Reference* for more information about specifying the DB\_DOMAIN initialization parameter

## 32.2 Creating Database Links

To support application access to the data and schema objects throughout a distributed database system, you must create all necessary database links.

- [Obtaining Privileges Necessary for Creating Database Links](#)

A database link is a pointer in the local database that lets you access objects on a remote database. To create a private database link, you must have been granted the proper privileges.

- [Specifying Link Types](#)

When you create a database link, you must decide who will have access to it.

- [Specifying Link Users](#)

A database link defines a communication path from one database to another. When an application uses a database link to access a remote database, Oracle Database establishes a database session in the remote database on behalf of the local application request. When you create a private or public database link, you can determine which schema on the remote database the link will establish connections to by creating fixed user, current user, and connected user database links.

- [Using Connection Qualifiers to Specify Service Names Within Link Names](#)

In some situations, you may want to have several database links of the same type (for example, public) that point to the same remote database, yet establish connections to the remote database using different communication pathways.

### 32.2.1 Obtaining Privileges Necessary for Creating Database Links

A database link is a pointer in the local database that lets you access objects on a remote database. To create a private database link, you must have been granted the proper privileges.

The following table illustrates which privileges are required on which database for which type of link:

| Privilege                   | Database | Required For                           |
|-----------------------------|----------|----------------------------------------|
| CREATE DATABASE LINK        | Local    | Creation of a private database link.   |
| CREATE PUBLIC DATABASE LINK | Local    | Creation of a public database link.    |
| CREATE SESSION              | Remote   | Creation of any type of database link. |

To see which privileges you currently have available, query ROLE\_SYS\_PRIVS. For example, you could create and execute the following privs.sql script (sample output included):

```
SELECT DISTINCT PRIVILEGE AS "Database Link Privileges"
FROM ROLE_SYS_PRIVS
WHERE PRIVILEGE IN ('CREATE SESSION', 'CREATE DATABASE LINK',
 'CREATE PUBLIC DATABASE LINK')
/
SQL> @privs

Database Link Privileges

CREATE DATABASE LINK
CREATE PUBLIC DATABASE LINK
CREATE SESSION
```

## 32.2.2 Specifying Link Types

When you create a database link, you must decide who will have access to it.

- [Creating Private Database Links](#)  
Use the CREATE DATABASE LINK statement to create private database links.
- [Creating Public Database Links](#)  
Use the CREATE PUBLIC DATABASE LINK statement to create public database links.
- [Creating Global Database Links](#)  
You can use a directory server in which databases are identified by net service names. In this document, these are referred to as global database links.

### 32.2.2.1 Creating Private Database Links

Use the CREATE DATABASE LINK statement to create private database links.

To create a private database link, specify the following (where *link\_name* is the global database name or an arbitrary link name):

```
CREATE DATABASE LINK link_name ...;
```

Following are examples of private database links:

| SQL Statement                                                                                      | Result                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE DATABASE LINK supply.us.example.com;                                                        | A private link using the global database name to the remote supply database.<br><br>The link uses the userid/password of the connected user. So if scott (identified by <i>password</i> ) uses the link in a query, the link establishes a connection to the remote database as scott/ <i>password</i> . |
| CREATE DATABASE LINK link_2<br>CONNECT TO jane IDENTIFIED BY<br><i>password</i> USING 'us_supply'; | A private fixed user link called link_2 to the database with service name us_supply. The link connects to the remote database with the userid/password of jane/ <i>password</i> regardless of the connected user.                                                                                        |

| SQL Statement                                                                     | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>CREATE DATABASE LINK link_1 CONNECT TO CURRENT_USER USING 'us_supply';</pre> | <p>A private link called <code>link_1</code> to the database with service name <code>us_supply</code>. The link uses the userid/password of the current user to log onto the remote database.</p> <p><b>Note:</b> The current user may not be the same as the connected user, and must be a global user on both databases involved in the link (see "<a href="#">Users of Database Links</a>"). Current user links are part of the Oracle Advanced Security option.</p> |

#### See Also:

*Oracle Database SQL Language Reference* for `CREATE DATABASE LINK` syntax

### 32.2.2.2 Creating Public Database Links

Use the `CREATE PUBLIC DATABASE LINK` statement to create public database links.

To create a public database link, use the keyword `PUBLIC` (where *link\_name* is the global database name or an arbitrary link name):

```
CREATE PUBLIC DATABASE LINK link_name ...;
```

Following are examples of public database links:

| SQL Statement                                                                                       | Result                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>CREATE PUBLIC DATABASE LINK supply.us.example.com;</pre>                                       | <p>A public link to the remote supply database. The link uses the userid/password of the connected user. So if scott (identified by <i>password</i>) uses the link in a query, the link establishes a connection to the remote database as scott/<i>password</i>.</p>                                                                                                                            |
| <pre>CREATE PUBLIC DATABASE LINK pu_link CONNECT TO CURRENT_USER USING 'supply';</pre>              | <p>A public link called <code>pu_link</code> to the database with service name <code>supply</code>. The link uses the userid/password of the current user to log onto the remote database.</p> <p><b>Note:</b> The current user may not be the same as the connected user, and must be a global user on both databases involved in the link (see "<a href="#">Users of Database Links</a>").</p> |
| <pre>CREATE PUBLIC DATABASE LINK sales.us.example.com CONNECT TO jane IDENTIFIED BY password;</pre> | <p>A public fixed user link to the remote sales database. The link connects to the remote database with the userid/password of <code>jane</code>/<i>password</i>.</p>                                                                                                                                                                                                                            |

 **See Also:**

*Oracle Database SQL Language Reference* for CREATE PUBLIC DATABASE LINK syntax

### 32.2.2.3 Creating Global Database Links

You can use a directory server in which databases are identified by net service names. In this document, these are referred to as global database links.

See the *Oracle Database Net Services Administrator's Guide* to learn how to create directory entries that act as global database links.

## 32.2.3 Specifying Link Users

A database link defines a communication path from one database to another. When an application uses a database link to access a remote database, Oracle Database establishes a database session in the remote database on behalf of the local application request. When you create a private or public database link, you can determine which schema on the remote database the link will establish connections to by creating fixed user, current user, and connected user database links.

- [Creating Fixed User Database Links](#)

When an application uses a fixed user database link, the local server always establishes a connection to a fixed remote schema in the remote database. The local server also sends the fixed user's credentials across the network when an application uses the link to access the remote database.

- [Creating Connected User and Current User Database Links](#)

Connected user and current user database links do not include credentials in the definition of the link. The credentials used to connect to the remote database can change depending on the user that references the database link and the operation performed by the application.

### 32.2.3.1 Creating Fixed User Database Links

When an application uses a fixed user database link, the local server always establishes a connection to a fixed remote schema in the remote database. The local server also sends the fixed user's credentials across the network when an application uses the link to access the remote database.

To create a **fixed user database link**, you embed the credentials (in this case, a username and password) required to access the remote database in the definition of the link:

```
CREATE DATABASE LINK ... CONNECT TO username IDENTIFIED BY password ...;
```

Following are examples of fixed user database links:

| SQL Statement                                                                                                  | Result                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>CREATE PUBLIC DATABASE LINK supply.us.example.com CONNECT TO scott IDENTIFIED BY <i>password</i>;</code> | A public link using the global database name to the remote <code>supply</code> database. The link connects to the remote database with the userid/password <code>scott/<i>password</i></code> .                  |
| <code>CREATE DATABASE LINK foo CONNECT TO jane IDENTIFIED BY <i>password</i> USING 'finance';</code>           | A private fixed user link called <code>foo</code> to the database with service name <code>finance</code> . The link connects to the remote database with the userid/password <code>jane/<i>password</i></code> . |

### 32.2.3.2 Creating Connected User and Current User Database Links

Connected user and current user database links do not include credentials in the definition of the link. The credentials used to connect to the remote database can change depending on the user that references the database link and the operation performed by the application.

 **Note:**

For many distributed applications, you do not want a user to have privileges in a remote database. One simple way to achieve this result is to create a procedure that contains a fixed user or current user database link within it. In this way, the user accessing the procedure temporarily assumes someone else's privileges.

- [Creating a Connected User Database Link](#)

To create a connected user database link, omit the `CONNECT TO` clause in the `CREATE DATABASE LINK` statement.

- [Creating a Current User Database Link](#)

To create a current user database link, use the `CONNECT TO CURRENT_USER` clause in the `CREATE DATABASE LINK` statement.

#### Related Topics

- [Users of Database Links](#)

Users of database links include connect user, current user, and fixed user.

#### 32.2.3.2.1 Creating a Connected User Database Link

To create a connected user database link, omit the `CONNECT TO` clause in the `CREATE DATABASE LINK` statement.

The following syntax creates a connected user database link, where `dblink` is the name of the link and `net_service_name` is an optional connect string:

```
CREATE [SHARED] [PUBLIC] DATABASE LINK dblink ... [USING 'net_service_name'];
```

For example, to create a connected user database link, use the following syntax:

```
CREATE DATABASE LINK sales.division3.example.com USING 'sales';
```

### 32.2.3.2.2 Creating a Current User Database Link

To create a current user database link, use the CONNECT TO CURRENT\_USER clause in the CREATE DATABASE LINK statement.

Current user links are only available through the Oracle Advanced Security option.

The following syntax creates a current user database link, where *dblink* is the name of the link and *net\_service\_name* is an optional connect string:

```
CREATE [SHARED] [PUBLIC] DATABASE LINK dblink CONNECT TO CURRENT_USER
[USING 'net_service_name'];
```

For example, to create a connected user database link to the *sales* database, you might use the following syntax:

```
CREATE DATABASE LINK sales CONNECT TO CURRENT_USER USING 'sales';
```

 **Note:**

To use a current user database link, the current user must be a global user on both databases involved in the link.

 **See Also:**

*Oracle Database SQL Language Reference* for more syntax information about creating database links

### 32.2.4 Using Connection Qualifiers to Specify Service Names Within Link Names

In some situations, you may want to have several database links of the same type (for example, public) that point to the same remote database, yet establish connections to the remote database using different communication pathways.

Some cases in which this strategy is useful are:

- A remote database is part of an Oracle Real Application Clusters configuration, so you define several public database links at your local node so that connections can be established to specific instances of the remote database.
- Some clients connect to the Oracle Database server using TCP/IP while others use DECNET.

To facilitate such functionality, the database lets you create a database link with an optional service name in the database link name. When creating a database link, a service name is specified as the trailing portion of the database link name, separated by an @ sign, as in @sales. This string is called a **connection qualifier**.

For example, assume that remote database `hq.example.com` is managed in an Oracle Real Application Clusters environment. The `hq` database has two instances named `hq_1` and `hq_2`. The local database can contain the following public database links to define pathways to the remote instances of the `hq` database:

```
CREATE PUBLIC DATABASE LINK hq.example.com@hq_1
 USING 'string_to_hq_1';
CREATE PUBLIC DATABASE LINK hq.example.com@hq_2
 USING 'string_to_hq_2';
CREATE PUBLIC DATABASE LINK hq.example.com
 USING 'string_to_hq';
```

Notice in the first two examples that a service name is simply a part of the database link name. The text of the service name does not necessarily indicate how a connection is to be established; this information is specified in the service name of the `USING` clause. Also notice that in the third example, a service name is not specified as part of the link name. In this case, just as when a service name is specified as part of the link name, the instance is determined by the `USING` string.

To use a service name to specify a particular instance, include the service name at the end of the global object name:

```
SELECT * FROM scott.emp@hq.example.com@hq_1
```

Note that in this example, there are two @ symbols.

## 32.3 Using Shared Database Links

Every application that references a remote server using a standard database link establishes a connection between the local database and the remote database. Many users running applications simultaneously can cause a high number of connections between the local and remote databases. Shared database links enable you to limit the number of network connections required between the local server and the remote server.

- **Determining Whether to Use Shared Database Links**

Look carefully at your application and shared server configuration to determine whether to use shared links. A simple guideline is to use shared database links when the number of users accessing a database link is expected to be much larger than the number of server processes in the local database.

- **Creating Shared Database Links**

To create a shared database link, use the keyword `SHARED` in the `CREATE DATABASE LINK` statement.

- **Configuring Shared Database Links**

You can configure shared database links in different ways.

### See Also:

["What Are Shared Database Links?"](#) for a conceptual overview of shared database links

### 32.3.1 Determining Whether to Use Shared Database Links

Look carefully at your application and shared server configuration to determine whether to use shared links. A simple guideline is to use shared database links when the number of users accessing a database link is expected to be much larger than the number of server processes in the local database.

The following table illustrates three possible configurations involving database links:

| Link Type | Server Mode             | Consequences                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Nonshared | Dedicated/shared server | If your application uses a standard public database link, and 100 users simultaneously require a connection, then 100 direct network connections to the remote database are required.                                                                                                                      |
| Shared    | Shared server           | If 10 shared server processes exist in the local shared server mode database, then 100 users that use the same database link require 10 or fewer network connections to the remote server. Each local shared server process may only need one connection to the remote server.                             |
| Shared    | Dedicated               | If 10 clients connect to a local dedicated server, and each client has 10 sessions on the same connection (thus establishing 100 sessions overall), and each session references the same remote database, then only 10 connections are needed. With a nonshared database link, 100 connections are needed. |

Shared database links are not useful in all situations. Assume that only one user accesses the remote server. If this user defines a shared database link and 10 shared server processes exist in the local database, then this user can require up to 10 network connections to the remote server. Because the user can use each shared server process, each process can establish a connection to the remote server.

Clearly, a nonshared database link is preferable in this situation because it requires only one network connection. Shared database links lead to more network connections in single-user scenarios, so use shared links only when many users need to use the same link. Typically, shared links are used for public database links, but can also be used for private database links when many clients access the same local schema (and therefore the same private database link).

 **Note:**

In a multitiered environment, there is a restriction that if you use a shared database link to connect to a remote database, then that remote database cannot link to another database with a database link that cannot be migrated. That link must use a shared server, or it must be another shared database link.

### 32.3.2 Creating Shared Database Links

To create a shared database link, use the keyword SHARED in the CREATE DATABASE LINK statement.

Use the following syntax to create a shared database link:

```
CREATE SHARED DATABASE LINK dblink_name
[CONNECT TO username IDENTIFIED BY password] | [CONNECT TO CURRENT_USER]
AUTHENTICATED BY schema_name IDENTIFIED BY password
[USING 'service_name'];
```

Whenever you use the keyword SHARED, the clause AUTHENTICATED BY is required. The schema specified in the AUTHENTICATED BY clause must exist in the remote database and must be granted at least the CREATE SESSION privilege. The credentials of this schema can be considered the authentication method between the local database and the remote database. These credentials are required to protect the remote shared server processes from clients that masquerade as a database link user and attempt to gain unauthorized access to information.

After a connection is made with a shared database link, operations on the remote database proceed with the privileges of the CONNECT TO user or CURRENT\_USER, not the AUTHENTICATED BY schema.

The following example creates a fixed user, shared link to database sales, connecting as scott and authenticated as linkuser:

```
CREATE SHARED DATABASE LINK link2sales
CONNECT TO scott IDENTIFIED BY password
AUTHENTICATED BY linkuser IDENTIFIED BY ostrich
USING 'sales';
```

#### See Also:

*Oracle Database SQL Language Reference* for information about the CREATE DATABASE LINK statement

### 32.3.3 Configuring Shared Database Links

You can configure shared database links in different ways.

- [Creating Shared Links to Dedicated Servers](#)  
A shared server process in the local server can own a dedicated remote server process.
- [Creating Shared Links to Shared Servers](#)  
You can create shared links using shared server processes on the remote server.

#### 32.3.3.1 Creating Shared Links to Dedicated Servers

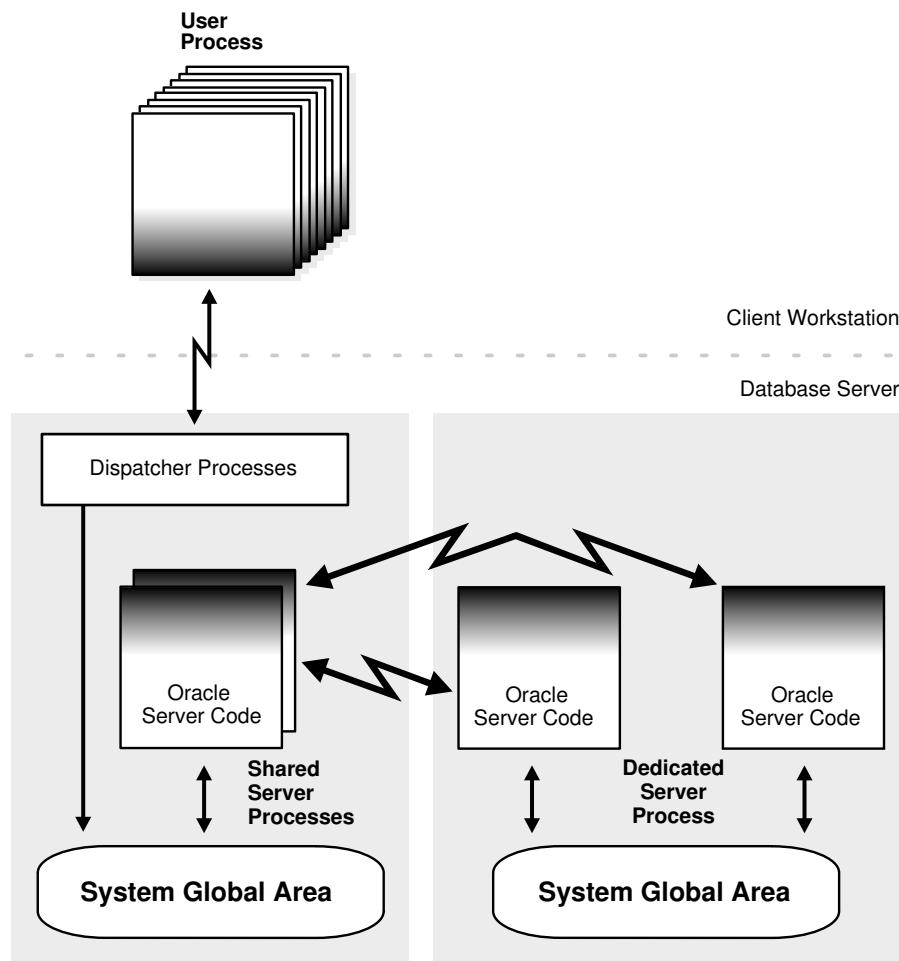

A shared server process in the local server can own a dedicated remote server process.

The advantage is that a direct network transport exists between the local shared server and the remote dedicated server. A disadvantage is that extra back-end server processes are needed.

 **Note:**

The remote server can either be a shared server or dedicated server. There is a dedicated connection between the local and remote servers. When the remote server is a shared server, you can force a dedicated server connection by using the (SERVER=DEDICATED) clause in the definition of the service name.

**Figure 32-1 A Shared Database Link to Dedicated Server Processes**

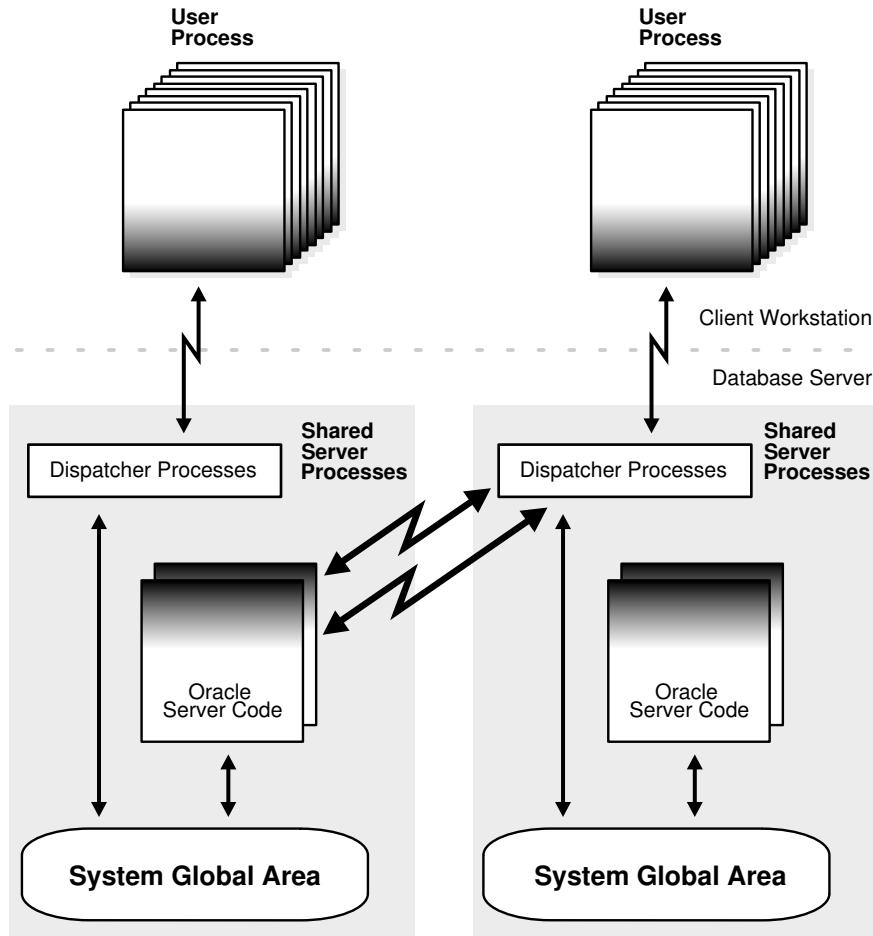

### 32.3.3.2 Creating Shared Links to Shared Servers

You can create shared links using shared server processes on the remote server.

This configuration eliminates the need for more dedicated servers, but requires the connection to go through the dispatcher on the remote server. Note that both the local and the remote server must be configured as shared servers.

**Figure 32-2 Shared Database Link to Shared Server**

**See Also:**

["Shared Server Processes"](#) for information about the shared server option

## 32.4 Managing Database Links

Managing database links includes tasks such as closing them, dropping them, and limiting the number of active connections to them.

- [Closing Database Links](#)

If you access a database link in a session, then the link remains open until you close the session. To close a database link manually, use the `ALTER SESSION CLOSE DATABASE LINK` statement.

- [Dropping Database Links](#)

You can drop a database link just as you can drop a table or view. If the link is private, then it must be in your schema. If the link is public, then you must have the `DROP PUBLIC DATABASE LINK` system privilege.

- [Limiting the Number of Active Database Link Connections](#)

You can limit the number of connections from a user process to remote databases using the static initialization parameter `OPEN_LINKS`.

### 32.4.1 Closing Database Links

If you access a database link in a session, then the link remains open until you close the session. To close a database link manually, use the `ALTER SESSION CLOSE DATABASE LINK` statement.

A link is open in the sense that a process is active on each of the remote databases accessed through the link. This situation has the following consequences:

- If 20 users open sessions and access the same public link in a local database, then 20 database link connections are open.
- If 20 users open sessions and each user accesses a private link, then 20 database link connections are open.
- If one user starts a session and accesses 20 different links, then 20 database link connections are open.

After you close a session, the links that were active in the session are automatically closed. You may have occasion to close the link manually. For example, close links when:

- The network connection established by a link is used infrequently in an application.
- The user session must be terminated.

To close a link, issue the following statement, where *linkname* refers to the name of the link:

```
ALTER SESSION CLOSE DATABASE LINK linkname;
```

Note that this statement only closes the links that are active in your current session.

### 32.4.2 Dropping Database Links

You can drop a database link just as you can drop a table or view. If the link is private, then it must be in your schema. If the link is public, then you must have the `DROP PUBLIC DATABASE LINK` system privilege.

The statement syntax is as follows, where *dblink* is the name of the link:

```
DROP [PUBLIC] DATABASE LINK dblink;
```

- [Dropping a Private Database Link](#)

Use the `DROP DATABASE LINK` statement to drop a private database link.

- [Dropping a Public Database Link](#)

Use the `DROP PUBLIC DATABASE LINK` statement to drop a public database link.

### 32.4.2.1 Dropping a Private Database Link

Use the `DROP DATABASE LINK` statement to drop a private database link.

1. Connect to the local database using SQL\*Plus. For example, enter:

```
CONNECT scott@local_db
```

2. Query `USER_DB_LINKS` to view the links that you own. For example, enter:

```
SELECT DB_LINK FROM USER_DB_LINKS;
```

```
DB_LINK

SALES.US.EXAMPLE.COM
MKTG.US.EXAMPLE.COM
2 rows selected.
```

3. Drop the desired link using the `DROP DATABASE LINK` statement. For example, enter:

```
DROP DATABASE LINK sales.us.example.com;
```

### 32.4.2.2 Dropping a Public Database Link

Use the `DROP PUBLIC DATABASE LINK` statement to drop a public database link.

1. Connect to the local database as a user with the `DROP PUBLIC DATABASE LINK` privilege. For example, enter:

```
CONNECT SYSTEM@local_db AS SYSDBA
```

2. Query `DBA_DB_LINKS` to view the public links. For example, enter:

```
SELECT DB_LINK FROM DBA_DB_LINKS
WHERE OWNER = 'PUBLIC';
```

```
DB_LINK

DBL1.US.EXAMPLE.COM
SALES.US.EXAMPLE.COM
INST2.US.EXAMPLE.COM
RMAN2.US.EXAMPLE.COM
4 rows selected.
```

3. Drop the desired link using the `DROP PUBLIC DATABASE LINK` statement. For example, enter:

```
DROP PUBLIC DATABASE LINK sales.us.example.com;
```

### 32.4.3 Limiting the Number of Active Database Link Connections

You can limit the number of connections from a user process to remote databases using the static initialization parameter `OPEN_LINKS`.

This parameter controls the number of remote connections that a single user session can use concurrently in distributed transactions.

Note the following considerations for setting this parameter:

- The value should be greater than or equal to the number of databases referred to in a single SQL statement that references multiple databases.
- Increase the value if several distributed databases are accessed over time. Thus, if you regularly access three databases, set OPEN\_LINKS to 3 or greater.
- The default value for OPEN\_LINKS is 4. If OPEN\_LINKS is set to 0, then no distributed transactions are allowed.

 **See Also:**

*Oracle Database Reference* for more information about the OPEN\_LINKS initialization parameter

## 32.5 Viewing Information About Database Links

The data dictionary of each database stores the definitions of all the database links in the database. You can use data dictionary tables and views to gain information about the links.

- [Determining Which Links Are in the Database](#)  
A set of views shows the database links that have been defined at the local database and stored in the data dictionary.
- [Determining Which Link Connections Are Open](#)  
You may find it useful to determine which database link connections are currently open in your session.
- [Determining the Host of Outgoing Database Links](#)  
You can use the RESOLVE\_TNSNAME function in the DBMS\_TNS package to determine the host name of an outgoing database link.
- [Determining Information About Incoming Database Links](#)  
You can use the DBA\_DB\_LINK\_SOURCES view to determine information about incoming database links.
- [Determining the Source of High SCN Activity for Incoming Database Links](#)  
You can use the following views to determine the source of high system change number (SCN) activity for incoming database links: DBA\_EXTERNAL\_SCN\_ACTIVITY, DBA\_DB\_LINK\_SOURCES, and DBA\_DB\_LINK.

### 32.5.1 Determining Which Links Are in the Database

A set of views shows the database links that have been defined at the local database and stored in the data dictionary.

:

| View          | Purpose                                                    |
|---------------|------------------------------------------------------------|
| DBA_DB_LINKS  | Lists all database links in the database.                  |
| ALL_DB_LINKS  | Lists all database links accessible to the connected user. |
| USER_DB_LINKS | Lists all database links owned by the connected user.      |

These data dictionary views contain the same basic information about database links, with some exceptions:

| Column   | Which Views?      | Description                                                                                                                                            |
|----------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER    | All except USER_* | The user who created the database link. If the link is public, then the user is listed as PUBLIC.                                                      |
| DB_LINK  | All               | The name of the database link.                                                                                                                         |
| USERNAME | All               | If the link definition includes a fixed user, then this column displays the username of the fixed user. If there is no fixed user, the column is NULL. |
| PASSWORD | Only USER_*       | Not used. Maintained for backward compatibility only.                                                                                                  |
| HOST     | All               | The net service name used to connect to the remote database.                                                                                           |
| CREATED  | All               | Creation time of the database link.                                                                                                                    |

Any user can query `USER_DB_LINKS` to determine which database links are available to that user. Only those with additional privileges can use the `ALL_DB_LINKS` or `DBA_DB_LINKS` view.

The following script queries the `DBA_DB_LINKS` view to access link information:

```
COL OWNER FORMAT A10
COL USERNAME FORMAT A8 HEADING "USER"
COL DB_LINK FORMAT A30
COL HOST FORMAT A7 HEADING "SERVICE"
SELECT * FROM DBA_DB_LINKS
/
```

Here, the script is invoked and the resulting output is shown:

SQL>@link\_script

| OWNER            | DB_LINK               | USER  | SERVICE | CREATED   |
|------------------|-----------------------|-------|---------|-----------|
| SYS              | TARGET.US.EXAMPLE.COM | SYS   | inst1   | 23-JUN-99 |
| PUBLIC           | DBL1.UK.EXAMPLE.COM   | BLAKE | ora51   | 23-JUN-99 |
| PUBLIC           | RMAN2.US.EXAMPLE.COM  |       | inst2   | 23-JUN-99 |
| PUBLIC           | DEPT.US.EXAMPLE.COM   |       | inst2   | 23-JUN-99 |
| JANE             | DBL.UK.EXAMPLE.COM    | BLAKE | ora51   | 23-JUN-99 |
| SCOTT            | EMP.US.EXAMPLE.COM    | SCOTT | inst2   | 23-JUN-99 |
| 6 rows selected. |                       |       |         |           |

## 32.5.2 Determining Which Link Connections Are Open

You may find it useful to determine which database link connections are currently open in your session.

Note that if you connect as `SYSDBA`, you cannot query a view to determine all the links open for all sessions; you can only access the link information in the session within which you are working.

The following views show the database link connections that are currently open in your current session:

| <b>View</b> | <b>Purpose</b>                                                                                                                                                    |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V\$DBLINK   | Lists all open database links in your session, that is, all database links with the IN_TRANSACTION column set to YES.                                             |
| GV\$DBLINK  | Lists all open database links in your session along with their corresponding instances. This view is useful in an Oracle Real Application Clusters configuration. |

These data dictionary views contain the same basic information about database links, with one exception:

| <b>Column</b>         | <b>Which Views?</b> | <b>Description</b>                                                                                     |
|-----------------------|---------------------|--------------------------------------------------------------------------------------------------------|
| DB_LINK               | All                 | The name of the database link.                                                                         |
| OWNER_ID              | All                 | The owner of the database link.                                                                        |
| LOGGED_ON             | All                 | Whether the database link is currently logged on.                                                      |
| HETEROGENEOUS         | All                 | Whether the database link is homogeneous (NO) or heterogeneous (YES).                                  |
| PROTOCOL              | All                 | The communication protocol for the database link.                                                      |
| OPEN_CURSORS          | All                 | Whether cursors are open for the database link.                                                        |
| IN_TRANSACTION        | All                 | Whether the database link is accessed in a transaction that has not yet been committed or rolled back. |
| UPDATE_SENT           | All                 | Whether there was an update on the database link.                                                      |
| COMMIT_POINT_STRENGTH | All                 | The commit point strength of the transactions using the database link.                                 |
| INST_ID               | GV\$DBLINK only     | The instance from which the view information was obtained.                                             |

For example, you can create and execute the script below to determine which links are open (sample output included):

```

COL DB_LINK FORMAT A25
COL OWNER_ID FORMAT 99999 HEADING "OWNID"
COL LOGGED_ON FORMAT A5 HEADING "LOGON"
COL HETEROGENEOUS FORMAT A5 HEADING "HETER"
COL PROTOCOL FORMAT A8
COL OPEN_CURSORS FORMAT 999 HEADING "OPN_CUR"
COL IN_TRANSACTION FORMAT A3 HEADING "TXN"
COL UPDATE_SENT FORMAT A6 HEADING "UPDATE"
COL COMMIT_POINT_STRENGTH FORMAT 99999 HEADING "C_P_S"

SELECT * FROM V$DBLINK
/
SQL> @dblink

DB_LINK OWNID LOGON HETER PROTOCOL OPN_CUR TXN UPDATE C_P_S
----- ----- ----- ----- ----- ----- ----- -----
INST2.EXAMPLE.COM 0 YES YES UNKN 0 YES YES 255

```

### 32.5.3 Determining the Host of Outgoing Database Links

You can use the `RESOLVE_TNSNAME` function in the `DBMS_TNS` package to determine the host name of an outgoing database link.

For outgoing database links, the `HOST` column value in the `DBA_DB_LINKS` view does not resolve the connect data when the database link is created with a connect identifier, such as the network service name. As a result, a tool that requires any part of the connect data, such as the host name, must check the `tnsnames.ora` file to find the information. However, the `tnsnames.ora` file might not be accessible to the tool.

1. Connect to the database that contains the outgoing database link as a user who can run subprograms in the `DBMS_TNS` package.
2. Query the `DBA_DB_LINKS` view.

#### Example 32-1 Determining the Host of Outgoing Database Links

This query results show the connect data, including the host name, for each outgoing database link.

```
SELECT DB_LINK, DBMS_TNS.RESOLVE_TNSNAME(HOST) FROM DBA_DB_LINKS;
```

#### See Also:

- *Oracle Database Reference*
- *Oracle Database PL/SQL Packages and Types Reference* for more information about the `RESOLVE_TNSNAME` function

### 32.5.4 Determining Information About Incoming Database Links

You can use the `DBA_DB_LINK_SOURCES` view to determine information about incoming database links.

The database records details about unique connections for incoming database links in a persistent table and the `DBA_DB_LINK_SOURCES` view. You can query this view for information about the incoming connections on database links.

1. Connect to the database as a user who can query the `DBA_DB_LINK_SOURCES` view.
2. Query the `DBA_DB_LINK_SOURCES` view.

#### Example 32-2 Querying the DBA\_DB\_LINK\_SOURCES View

This example returns the database name and host name of each incoming database link. It also returns the time of the first login and last login to the current database with the database link.

```
SELECT DB_NAME, HOST_NAME, FIRST_LOGON_TIME, LAST_LOGON_TIME
 FROM DBA_DB_LINK_SOURCES;
```

 **See Also:**

*Oracle Database Reference*

### 32.5.5 Determining the Source of High SCN Activity for Incoming Database Links

You can use the following views to determine the source of high system change number (SCN) activity for incoming database links: `DBA_EXTERNAL_SCN_ACTIVITY`, `DBA_DB_LINK_SOURCES`, and `DBA_DB_LINK`.

To implement distributed transactions and distributed read consistency in a distributed database environment, databases synchronize SCNs when calls are made over database links. A high SCN increase rate can cause a database to return errors.

It is often hard to determine the source of unusual increases of SCNs that result from distributed database operations. The `DBA_EXTERNAL_SCN_ACTIVITY` view enables you to determine which databases or clients are causing excessive SCN increases. You join this view in a query with the `DBA_DB_LINK_SOURCES` and `DBA_DB_LINK` views to return the information.

1. Connect to the database as a user who can query the `DBA_EXTERNAL_SCN_ACTIVITY`, `DBA_DB_LINK_SOURCES`, and `DBA_DB_LINK` views.
2. Run the following query to show the recent history of SCN increments and their sources:

```
(SELECT RESULT, OPERATION_TIMESTAMP, EXTERNAL_SCN, SCN_ADJUSTMENT,
HOST_NAME, DB_NAME, SESSION_ID, SESSION_SERIAL#
 FROM DBA_EXTERNAL_SCN_ACTIVITY a, DBA_DB_LINK_SOURCES s
 WHERE a.INBOUND_DB_LINK_SOURCE_ID = s.SOURCE_ID)
UNION
(SELECT RESULT, OPERATION_TIMESTAMP, EXTERNAL_SCN, SCN_ADJUSTMENT,
dbms_tns.resolve_tnsname(HOST) HOST_NAME, NULL DB_NAME, SESSION_ID,
SESSION_SERIAL#
 FROM DBA_EXTERNAL_SCN_ACTIVITY a, DBA_DB_LINKS o
 WHERE a.OUTBOUND_DB_LINK_NAME = o.DB_LINK AND
 a.OUTBOUND_DB_LINK_OWNER = o.OWNER)
UNION
(SELECT RESULT, OPERATION_TIMESTAMP, EXTERNAL_SCN, SCN_ADJUSTMENT,
s.MACHINE HOST_NAME, NULL DB_NAME, SESSION_ID, SESSION_SERIAL#
 FROM DBA_EXTERNAL_SCN_ACTIVITY a, V$SESSION s
 WHERE a.SESSION_ID = s.SID AND
 a.SESSION_SERIAL#=s.SERIAL# AND
 INBOUND_DB_LINK_SOURCE_ID IS NULL AND
 OUTBOUND_DB_LINK_NAME IS NULL AND
 OUTBOUND_DB_LINK_OWNER IS NULL);
```

 **Note:**

If no high SCN activity is recorded in the DBA\_EXTERNAL\_SCN\_ACTIVITY view, then this query returns no results.

 **See Also:**

*Oracle Database Reference*

## 32.6 Creating Location Transparency

After you have configured the necessary database links, you can use various tools to hide the distributed nature of the database system from users. In other words, users can access remote objects as if they were local objects.

- [Using Views to Create Location Transparency](#)  
Local views can provide location transparency for local and remote tables in a distributed database system.
- [Using Synonyms to Create Location Transparency](#)  
Synonyms are useful in both distributed and non-distributed environments because they hide the identity of the underlying object, including its location in a distributed database system. If you must rename or move the underlying object, you only need to redefine the synonym; applications based on the synonym continue to function normally. Synonyms also simplify SQL statements for users in a distributed database system.
- [Using Procedures to Create Location Transparency](#)  
PL/SQL program units called **procedures** can provide location transparency.

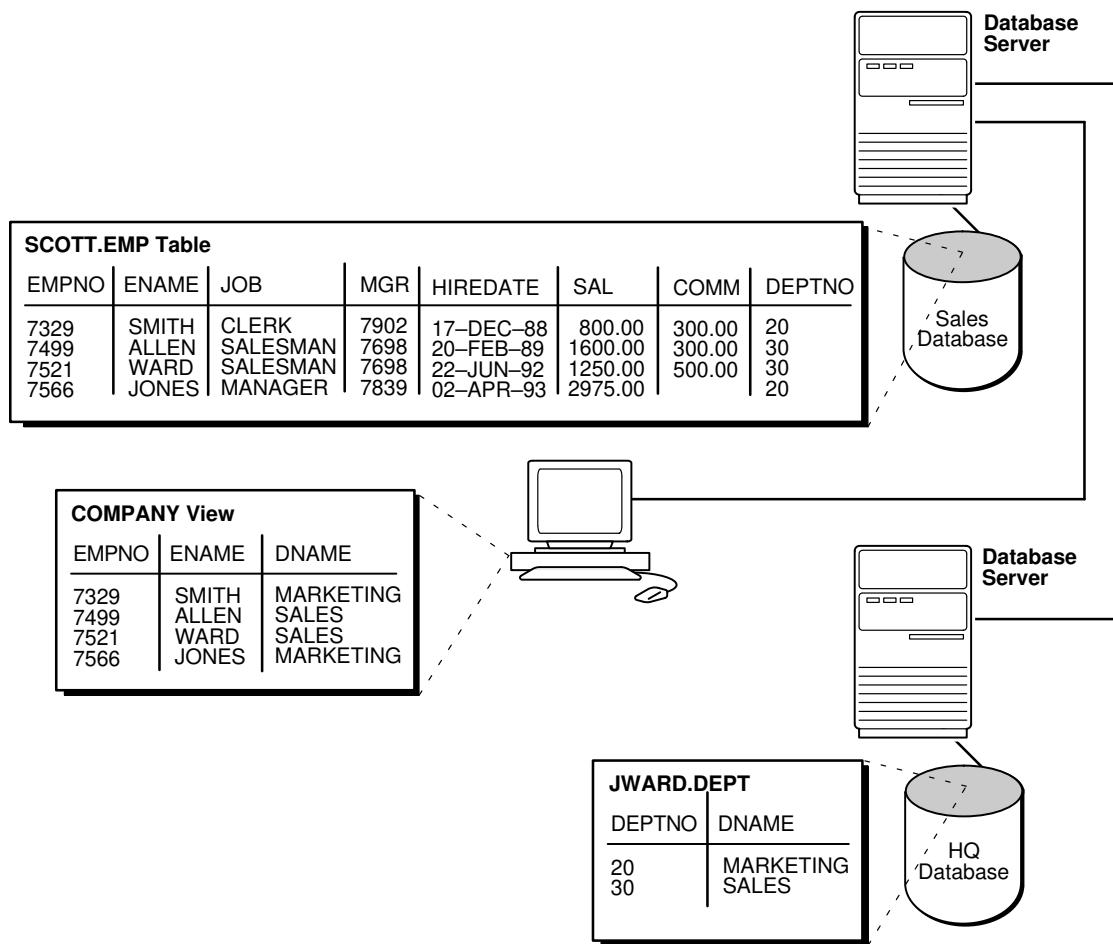

### 32.6.1 Using Views to Create Location Transparency

Local views can provide location transparency for local and remote tables in a distributed database system.

For example, assume that table `emp` is stored in a local database and table `dept` is stored in a remote database. To make these tables transparent to users of the system, you can create a view in the local database that joins local and remote data:

```
CREATE VIEW company AS
 SELECT a.empno, a.ename, b.dname
 FROM scott.emp a, jward.dept@hq.example.com b
 WHERE a.deptno = b.deptno;
```

Figure 32-3 Views and Location Transparency

When users access this view, they do not need to know where the data is physically stored, or if data from more than one table is being accessed. Thus, it is easier for them to get required information. For example, the following query provides data from both the local and remote database table:

```
SELECT * FROM company;
```

The owner of the local view can grant only those object privileges on the local view that have been granted by the remote user. (The remote user is implied by the type of database link). This is similar to privilege management for views that reference local data.

### 32.6.2 Using Synonyms to Create Location Transparency

Synonyms are useful in both distributed and non-distributed environments because they hide the identity of the underlying object, including its location in a distributed database system. If you must rename or move the underlying object, you only need to redefine the synonym; applications based on the synonym continue to function normally. Synonyms also simplify SQL statements for users in a distributed database system.

- [Creating Synonyms](#)  
All synonyms are schema objects that are stored in the data dictionary of the database in which they are created. To simplify remote table access through database links, a synonym can allow single-word access to remote data, hiding the specific object name and the location from users of the synonym.
- [Managing Privileges and Synonyms](#)  
A synonym is a reference to an actual object. A user who has access to a synonym for a particular schema object must also have privileges on the underlying schema object itself.

### 32.6.2.1 Creating Synonyms

All synonyms are schema objects that are stored in the data dictionary of the database in which they are created. To simplify remote table access through database links, a synonym can allow single-word access to remote data, hiding the specific object name and the location from users of the synonym.

You can create synonyms for the following:

- Tables
- Types
- Views
- Materialized views
- Sequences
- Procedures
- Functions
- Packages

The syntax to create a synonym is:

```
CREATE [PUBLIC] SYNONYM synonym_name
FOR [schema.]object_name[@database_link_name];
```

where:

- `PUBLIC` is a keyword specifying that this synonym is available to all users. Omitting this parameter makes a synonym private, and usable only by the creator. Public synonyms can be created only by a user with `CREATE PUBLIC SYNONYM` system privilege.
- `synonym_name` specifies the alternate object name to be referenced by users and applications.
- `schema` specifies the schema of the object specified in `object_name`. Omitting this parameter uses the schema of the creator as the schema of the object.
- `object_name` specifies either a table, view, sequence, materialized view, type, procedure, function or package as appropriate.
- `database_link_name` specifies the database link identifying the remote database and schema in which the object specified in `object_name` is located.

A synonym must be a uniquely named object for its schema. If a schema contains a schema object and a public synonym exists with the same name, then the database

always finds the schema object when the user that owns the schema references that name.

#### Example: Creating a Public Synonym

Assume that in every database in a distributed database system, a public synonym is defined for the scott.emp table stored in the hq database:

```
CREATE PUBLIC SYNONYM emp FOR scott.emp@hq.example.com;
```

You can design an employee management application without regard to where the application is used because the location of the table scott.emp@hq.example.com is hidden by the public synonyms. SQL statements in the application access the table by referencing the public synonym emp.

Furthermore, if you move the emp table from the hq database to the hr database, then you only need to change the public synonyms on the nodes of the system. The employee management application continues to function properly on all nodes.

### 32.6.2.2 Managing Privileges and Synonyms

A synonym is a reference to an actual object. A user who has access to a synonym for a particular schema object must also have privileges on the underlying schema object itself.

For example, if the user attempts to access a synonym but does not have privileges on the table it identifies, an error occurs indicating that the table or view does not exist.

Assume scott creates local synonym emp as an alias for remote object scott.emp@sales.example.com. scott *cannot* grant object privileges on the synonym to another local user. scott cannot grant local privileges for the synonym because this operation amounts to granting privileges for the remote emp table on the sales database, which is not allowed. This behavior is different from privilege management for synonyms that are aliases for local tables or views.

Therefore, you cannot manage local privileges when synonyms are used for location transparency. Security for the base object is controlled entirely at the remote node. For example, user admin cannot grant object privileges for the emp\_syn synonym.

Unlike a database link referenced in a view or procedure definition, a database link referenced in a synonym is resolved by first looking for a private link owned by the schema in effect at the time the reference to the synonym is parsed. Therefore, to ensure the desired object resolution, it is especially important to specify the schema of the underlying object in the definition of a synonym.

### 32.6.3 Using Procedures to Create Location Transparency

PL/SQL program units called **procedures** can provide location transparency.

- [Using Local Procedures to Reference Remote Data](#)

Procedures or functions (either standalone or in packages) can contain SQL statements that reference remote data.

- [Using Local Procedures to Call Remote Procedures](#)

You can use a local procedure to call a remote procedure. The remote procedure can then execute the required DML.

- **Using Local Synonyms to Reference Remote Procedures**  
You can use a local synonym to reference a remote procedure.
- **Managing Procedures and Privileges**  
Assume a local procedure includes a statement that references a remote table or view. The owner of the local procedure can grant the execute privilege to any user, thereby giving that user the ability to execute the procedure and, indirectly, access remote data.

### 32.6.3.1 Using Local Procedures to Reference Remote Data

Procedures or functions (either standalone or in packages) can contain SQL statements that reference remote data.

For example, consider the procedure created by the following statement:

```
CREATE PROCEDURE fire_emp (enum NUMBER) AS
BEGIN
 DELETE FROM emp@hq.example.com
 WHERE empno = enum;
END;
```

When a user or application calls the `fire_emp` procedure, it is not apparent that a remote table is being modified.

A second layer of location transparency is possible when the statements in a procedure indirectly reference remote data using local procedures, views, or synonyms. For example, the following statement defines a local synonym:

```
CREATE SYNONYM emp FOR emp@hq.example.com;
```

Given this synonym, you can create the `fire_emp` procedure using the following statement:

```
CREATE PROCEDURE fire_emp (enum NUMBER) AS
BEGIN
 DELETE FROM emp WHERE empno = enum;
END;
```

If you rename or move the table `emp@hq`, then you only need to modify the local synonym that references the table. None of the procedures and applications that call the procedure require modification.

### 32.6.3.2 Using Local Procedures to Call Remote Procedures

You can use a local procedure to call a remote procedure. The remote procedure can then execute the required DML.

For example, assume that `scott` connects to `local_db` and creates the following procedure:

```
CONNECT scott@local_db

CREATE PROCEDURE fire_emp (enum NUMBER)
AS
BEGIN
 EXECUTE term_emp@hq.example.com;
END;
```

Now, assume that scott connects to the remote database and creates the remote procedure:

```
CONNECT scott@hq.example.com

CREATE PROCEDURE term_emp (enum NUMBER)
AS
BEGIN
 DELETE FROM emp WHERE empno = enum;
END;
```

When a user or application connected to local\_db calls the fire\_emp procedure, this procedure in turn calls the remote term\_emp procedure on hq.example.com.

### 32.6.3.3 Using Local Synonyms to Reference Remote Procedures

You can use a local synonym to reference a remote procedure.

For example, scott connects to the local sales.example.com database and creates the following procedure:

```
CREATE PROCEDURE fire_emp (enum NUMBER) AS
BEGIN
 DELETE FROM emp@hq.example.com
 WHERE empno = enum;
END;
```

User peggy then connects to the supply.example.com database and creates the following synonym for the procedure that scott created on the remote sales database:

```
SQL> CONNECT peggy@supply
SQL> CREATE PUBLIC SYNONYM emp FOR scott.fire_emp@sales.example.com;
```

A local user on supply can use this synonym to execute the procedure on sales.

### 32.6.3.4 Managing Procedures and Privileges

Assume a local procedure includes a statement that references a remote table or view. The owner of the local procedure can grant the execute privilege to any user, thereby giving that user the ability to execute the procedure and, indirectly, access remote data.

In general, procedures aid in security. Privileges for objects referenced within a procedure do not need to be explicitly granted to the calling users.

## 32.7 Managing Statement Transparency

In a distributed database, some SQL statements can reference remote tables.

The database allows the following standard DML statements to reference remote tables:

- SELECT (queries)
- INSERT
- UPDATE

- DELETE
- SELECT...FOR UPDATE (not always supported in Heterogeneous Systems)
- LOCK TABLE

Queries including joins, aggregates, subqueries, and SELECT...FOR UPDATE can reference any number of local and remote tables and views. For example, the following query joins information from two remote tables:

```
SELECT e.empno, e.ename, d.dname
 FROM scott.emp@sales.division3.example.com e, jward.dept@hq.example.com d
 WHERE e.deptno = d.deptno;
```

In a homogeneous environment, UPDATE, INSERT, DELETE, and LOCK TABLE statements can reference both local and remote tables. No programming is necessary to update remote data. For example, the following statement inserts new rows into the remote table `emp` in the `scott.sales` schema by selecting rows from the `emp` table in the `jward` schema in the local database:

```
INSERT INTO scott.emp@sales.division3.example.com
 SELECT * FROM jward.emp;
```

#### **Restrictions for Statement Transparency:**

Several restrictions apply to statement transparency.

- Data manipulation language statements that update objects on a remote non-Oracle Database system cannot reference any objects on the local Oracle Database. For example, a statement such as the following will cause an error to be raised:

```
INSERT INTO remote_table@link as SELECT * FROM local_table;
```

- Within a single SQL statement, all referenced LONG and LONG RAW columns, sequences, updated tables, and locked tables must be located at the same node.
- The database does not allow remote DDL statements (for example, CREATE, ALTER, and DROP) in homogeneous systems except through remote execution of procedures of the DBMS\_SQL package, as in this example:

```
DBMS_SQLPARSE@link_name(crs, 'drop table emp', v7);
```

Note that in Heterogeneous Systems, a pass-through facility lets you execute DDL.

- The LIST CHAINED ROWS clause of an ANALYZE statement cannot reference remote tables.
- In a distributed database system, the database always evaluates environmentally-dependent SQL functions such as SYSDATE, USER, UID, and USERENV with respect to the local server, no matter where the statement (or portion of a statement) executes.

 **Note:**

Oracle Database supports the USERENV function for queries only.

- Several performance restrictions relate to access of remote objects:

- Remote views do not have statistical data.
- Queries on partitioned tables may not be optimized.
- No more than 20 indexes are considered for a remote table.
- No more than 20 columns are used for a composite index.
- There is a restriction in the Oracle Database implementation of distributed read consistency that can cause one node to be in the past with respect to another node. In accordance with read consistency, a query may end up retrieving consistent, but out-of-date data. See "[Managing Read Consistency](#)" to learn how to manage this problem.

 **See Also:**

*Oracle Database PL/SQL Packages and Types Reference* for more information about the `DBMS_SQL` package

## 32.8 Managing a Distributed Database: Examples

Examples illustrate managing database links.

- [Example 1: Creating a Public Fixed User Database Link](#)  
An example illustrates creating a public fixed user database link.
- [Example 2: Creating a Public Fixed User Shared Database Link](#)  
An example illustrates creating a public fixed user shared database link.
- [Example 3: Creating a Public Connected User Database Link](#)  
An example illustrates creating a public connected user database link.
- [Example 4: Creating a Public Connected User Shared Database Link](#)  
An example illustrates creating a public connected user shared database link.
- [Example 5: Creating a Public Current User Database Link](#)  
An example illustrates creating a public current user database link.

### 32.8.1 Example 1: Creating a Public Fixed User Database Link

An example illustrates creating a public fixed user database link.

The following statements connect to the local database as `jane` and create a public fixed user database link to database `sales` for `scott`. The database is accessed through its net service name `sldb`:

```
CONNECT jane@local

CREATE PUBLIC DATABASE LINK sales.division3.example.com
 CONNECT TO scott IDENTIFIED BY password
 USING 'sldb';
```

After executing these statements, any user connected to the local database can use the `sales.division3.example.com` database link to connect to the remote database. Each user connects to the schema `scott` in the remote database.

To access the table `emp` table in `scott`'s remote schema, a user can issue the following SQL query:

```
SELECT * FROM emp@sales.division3.example.com;
```

Note that each application or user session creates a separate connection to the common account on the server. The connection to the remote database remains open for the duration of the application or user session.

## 32.8.2 Example 2: Creating a Public Fixed User Shared Database Link

An example illustrates creating a public fixed user shared database link.

The following example connects to the local database as `dana` and creates a public link to the `sales` database (using its net service name `sldb`). The link allows a connection to the remote database as `scott` and authenticates this user as `scott`:

```
CONNECT dana@local

CREATE SHARED PUBLIC DATABASE LINK sales.division3.example.com
 CONNECT TO scott IDENTIFIED BY password
 AUTHENTICATED BY scott IDENTIFIED BY password
 USING 'sldb';
```

Now, any user connected to the local shared server can use this database link to connect to the remote `sales` database through a shared server process. The user can then query tables in the `scott` schema.

In the preceding example, each local shared server can establish one connection to the remote server. Whenever a local shared server process must access the remote server through the `sales.division3.example.com` database link, the local shared server process reuses established network connections.

## 32.8.3 Example 3: Creating a Public Connected User Database Link

An example illustrates creating a public connected user database link.

The following example connects to the local database as `larry` and creates a public link to the database with the net service name `sldb`:

```
CONNECT larry@local

CREATE PUBLIC DATABASE LINK redwood
 USING 'sldb';
```

Any user connected to the local database can use the `redwood` database link. The connected user in the local database who uses the database link determines the remote schema.

If `scott` is the connected user and uses the database link, then the database link connects to the remote schema `scott`. If `fox` is the connected user and uses the database link, then the database link connects to remote schema `fox`.

The following statement fails for local user `fox` in the local database when the remote schema `fox` cannot resolve the `emp` schema object. That is, if the `fox` schema in the `sales.division3.example.com` does not have `emp` as a table, view, or (public) synonym, an error will be returned.

```
CONNECT fox@local

SELECT * FROM emp@redwood;
```

### 32.8.4 Example 4: Creating a Public Connected User Shared Database Link

An example illustrates creating a public connected user shared database link.

The following example connects to the local database as neil and creates a shared, public link to the sales database (using its net service name sldb). The user is authenticated by the userid/password of crazy/horse. The following statement creates a public, connected user, shared database link:

```
CONNECT neil@local

CREATE SHARED PUBLIC DATABASE LINK sales.division3.example.com
 AUTHENTICATED BY crazy IDENTIFIED BY horse
 USING 'sldb';
```

Each user connected to the local server can use this shared database link to connect to the remote database and query the tables in the corresponding remote schema.

Each local, shared server process establishes one connection to the remote server. Whenever a local server process must access the remote server through the sales.division3.example.com database link, the local process reuses established network connections, even if the connected user is a different user.

If this database link is used frequently, eventually every shared server in the local database will have a remote connection. At this point, no more physical connections are needed to the remote server, even if new users use this shared database link.

### 32.8.5 Example 5: Creating a Public Current User Database Link

An example illustrates creating a public current user database link.

The following example connects to the local database as the connected user and creates a public link to the sales database (using its net service name sldb). The following statement creates a public current user database link:

```
CONNECT bart@local

CREATE PUBLIC DATABASE LINK sales.division3.example.com
 CONNECT TO CURRENT_USER
 USING 'sldb';
```

 **Note:**

To use this link, the current user must be a global user.

The consequences of this database link are as follows:

Assume scott creates local procedure fire\_emp that deletes a row from the remote emp table, and grants execute privilege on fire\_emp to ford.

```
CONNECT scott@local_db

CREATE PROCEDURE fire_emp (enum NUMBER)
AS
BEGIN
 DELETE FROM emp@sales.division3.example.com
 WHERE empno=enum;
END;

GRANT EXECUTE ON fire_emp TO ford;
```

Now, assume that `ford` connects to the local database and runs `scott`'s procedure:

```
CONNECT ford@local_db

EXECUTE PROCEDURE scott.fire_emp (enum 10345);
```

When `ford` executes the procedure `scott.fire_emp`, the procedure runs under `scott`'s privileges. Because a current user database link is used, the connection is established to `scott`'s remote schema, not `ford`'s remote schema. Note that `scott` must be a global user while `ford` does not have to be a global user.

 **Note:**

If a connected user database link were used instead, the connection would be to `ford`'s remote schema. For more information about invoker rights and privileges, see the *Oracle Database PL/SQL Language Reference*.

You can accomplish the same result by using a fixed user database link to `scott`'s remote schema.

# Developing Applications for a Distributed Database System

Developing applications for a distributed database system includes tasks such as managing the distribution of application data, controlling connections established by database links, maintaining referential integrity, tuning distributed queries, and handling errors in remote procedures.

- **Managing the Distribution of Application Data**

In a distributed database environment, coordinate with the database administrator to determine the best location for the data.

- **Controlling Connections Established by Database Links**

When a global object name is referenced in a SQL statement or remote procedure call, database links establish a connection to a session in the remote database on behalf of the local user.

- **Maintaining Referential Integrity in a Distributed System**

Design your application to check for any returned error messages that indicate that a portion of the distributed update has failed. If you detect a failure, then you should roll back the entire transaction before allowing the application to proceed.

- **Tuning Distributed Queries**

The local Oracle Database server breaks the distributed query into a corresponding number of remote queries, which it then sends to the remote nodes for execution. The remote nodes execute the queries and send the results back to the local node. The local node then performs any necessary post-processing and returns the results to the user or application.

- **Handling Errors in Remote Procedures**

Errors can occur when a database executes a procedure.

 **See Also:**

*Oracle Database Development Guide* for more information about application development in an Oracle Database environment

## 33.1 Managing the Distribution of Application Data

In a distributed database environment, coordinate with the database administrator to determine the best location for the data.

Some issues to consider are:

- Number of transactions posted from each location
- Amount of data (portion of table) used by each node

- Performance characteristics and reliability of the network
- Speed of various nodes, capacities of disks
- Importance of a node or link when it is unavailable
- Need for referential integrity among tables

## 33.2 Controlling Connections Established by Database Links

When a global object name is referenced in a SQL statement or remote procedure call, database links establish a connection to a session in the remote database on behalf of the local user.

The remote connection and session are only created if the connection has not already been established previously for the local user session.

The connections and sessions established to remote databases persist for the duration of the local user's session, unless the application or user explicitly terminates them. Note that when you issue a `SELECT` statement across a database link, a transaction lock is placed on the undo segments. To rerelease the segment, you must issue a `COMMIT` or `ROLLBACK` statement.

Terminating remote connections established using database links is useful for disconnecting high cost connections that are no longer required by the application. You can terminate a remote connection and session using the `ALTER SESSION` statement with the `CLOSE DATABASE LINK` clause. For example, assume you issue the following transactions:

```
SELECT * FROM emp@sales;
COMMIT;
```

The following statement terminates the session in the remote database pointed to by the `sales` database link:

```
ALTER SESSION CLOSE DATABASE LINK sales;
```

To close a database link connection in your user session, you must have the `ALTER SESSION` system privilege.

### Note:

Before closing a database link, first close all cursors that use the link and then end your current transaction if it uses the link.

### See Also:

*Oracle Database SQL Language Reference* for more information about the `ALTER SESSION` statement

## 33.3 Maintaining Referential Integrity in a Distributed System

Design your application to check for any returned error messages that indicate that a portion of the distributed update has failed. If you detect a failure, then you should roll back the entire transaction before allowing the application to proceed.

If a part of a distributed statement fails, for example, due to an integrity constraint violation, the database returns error number ORA-02055. Subsequent statements or procedure calls return error number ORA-02067 until a ROLLBACK or ROLLBACK TO SAVEPOINT is issued.

The database does not permit declarative referential integrity constraints to be defined across nodes of a distributed system. In other words, a declarative referential integrity constraint on one table cannot specify a foreign key that references a primary or unique key of a remote table. Nevertheless, you can maintain parent/child table relationships across nodes using triggers.

If you decide to define referential integrity across the nodes of a distributed database using triggers, be aware that network failures can limit the accessibility of not only the parent table, but also the child table. For example, assume that the child table is in the sales database and the parent table is in the hq database. If the network connection between the two databases fails, some DML statements against the child table (those that insert rows into the child table or update a foreign key value in the child table) cannot proceed because the referential integrity triggers must have access to the parent table in the hq database.

### See Also:

*Oracle Database PL/SQL Language Reference* for more information about using triggers to enforce referential integrity

## 33.4 Tuning Distributed Queries

The local Oracle Database server breaks the distributed query into a corresponding number of remote queries, which it then sends to the remote nodes for execution. The remote nodes execute the queries and send the results back to the local node. The local node then performs any necessary post-processing and returns the results to the user or application.

 **Note:**

SQL management objects, such as SQL profiles, SQL plan baselines, and SQL patches, and stored outlines might not always work as expected if your query references remote tables with database links. For example, for SQL plan management, when Oracle uses a SQL plan baseline for the query, the parts of the query that are remotely executed might use a different plan than when the SQL plan baseline was created.

- [Using Collocated Inline Views](#)

The most effective way of optimizing distributed queries is to access the remote databases as little as possible and to retrieve only the required data.

- [Using Cost-Based Optimization](#)

Using cost-based optimization includes completing tasks such as rewriting queries and setting up cost-based optimization.

- [Using Hints](#)

Hints can extend the capability of cost-based optimization.

- [Analyzing the Execution Plan](#)

An important aspect to tuning distributed queries is analyzing the execution plan.

### 33.4.1 Using Collocated Inline Views

The most effective way of optimizing distributed queries is to access the remote databases as little as possible and to retrieve only the required data.

For example, assume you reference five remote tables from two different remote databases in a distributed query and have a complex filter (for example, `WHERE r1.salary + r2.salary > 50000`). You can improve the performance of the query by rewriting the query to access the remote databases once and to apply the filter at the remote site. This rewrite causes less data to be transferred to the query execution site.

Rewriting your query to access the remote database once is achieved by using collocated inline views. The following terms need to be defined:

- **Collocated**

Two or more tables located in the same database.

- **Inline view**

A SELECT statement that is substituted for a table in a parent SELECT statement. The embedded SELECT statement, shown within the parentheses is an example of an inline view:

```
SELECT e.empno, e.ename, d.deptno, d.dname
 FROM (SELECT empno, ename
 FROM emp@orcl.world) e, dept d;
```

- **Collocated inline view**

An inline view that selects data from multiple tables from a single database only. It reduces the amount of times that the remote database is accessed, improving the performance of a distributed query.

Oracle recommends that you form your distributed query using collocated inline views to increase the performance of your distributed query. Oracle Database cost-based

optimization can transparently rewrite many of your distributed queries to take advantage of the performance gains offered by colocated inline views.

### 33.4.2 Using Cost-Based Optimization

Using cost-based optimization includes completing tasks such as rewriting queries and setting up cost-based optimization.

- [How Does Cost-Based Optimization Work?](#)

The main task of optimization is to rewrite a distributed query to use colocated inline views.

- [Rewriting Queries for Cost-Based Optimization](#)

In addition to rewriting your queries with colocated inline views, the cost-based optimization method optimizes distributed queries according to the gathered statistics of the referenced tables and the computations performed by the optimizer.

- [Setting Up Cost-Based Optimization](#)

After you have set up your system to use cost-based optimization to improve the performance of distributed queries, the operation is transparent to the user. In other words, the optimization occurs automatically when the query is issued.

#### 33.4.2.1 How Does Cost-Based Optimization Work?

The main task of optimization is to rewrite a distributed query to use colocated inline views.

This optimization is performed in three steps:

1. All mergeable views are merged.
2. Optimizer performs colocated query block test.
3. Optimizer rewrites query using colocated inline views.

After the query is rewritten, it is executed and the data set is returned to the user.

While cost-based optimization is performed transparently to the user, it cannot improve the performance of several distributed query scenarios. Specifically, if your distributed query contains any of the following, cost-based optimization is not effective:

- Aggregates
- Subqueries
- Complex SQL

If your distributed query contains one of these elements, see "[Using Hints](#)" to learn how you can modify your query and use hints to improve the performance of your distributed query.

### 33.4.2.2 Rewriting Queries for Cost-Based Optimization

In addition to rewriting your queries with colocated inline views, the cost-based optimization method optimizes distributed queries according to the gathered statistics of the referenced tables and the computations performed by the optimizer.

For example, cost-based optimization analyzes the following query. The example assumes that table statistics are available. Note that it analyzes the query inside a `CREATE TABLE` statement:

```
CREATE TABLE AS (
 SELECT l.a, l.b, r1.c, r1.d, r1.e, r2.b, r2.c
 FROM local l, remotel r1, remote2 r2
 WHERE l.c = r.c
 AND r1.c = r2.c
 AND r.e > 300
);
```

and rewrites it as:

```
CREATE TABLE AS (
 SELECT l.a, l.b, v.c, v.d, v.e
 FROM (
 SELECT r1.c, r1.d, r1.e, r2.b, r2.c
 FROM remotel r1, remote2 r2
 WHERE r1.c = r2.c
 AND r1.e > 300
) v, local l
 WHERE l.c = r1.c
);
```

The alias `v` is assigned to the inline view, which can then be referenced as a table in the preceding `SELECT` statement. Creating a colocated inline view reduces the amount of queries performed at a remote site, thereby reducing costly network traffic.

### 33.4.2.3 Setting Up Cost-Based Optimization

After you have set up your system to use cost-based optimization to improve the performance of distributed queries, the operation is transparent to the user. In other words, the optimization occurs automatically when the query is issued.

- [Setting Up the Environment](#)

Set the `OPTIMIZER_MODE` initialization parameter to establish the default behavior for choosing an optimization approach for the instance.

- [Analyzing Tables](#)

For cost-based optimization to select the most efficient path for a distributed query, you must provide accurate statistics for the tables involved. You do this using the `DBMS_STATS` package.

#### 33.4.2.3.1 Setting Up the Environment

Set the `OPTIMIZER_MODE` initialization parameter to establish the default behavior for choosing an optimization approach for the instance.

You can set this parameter by:

- Modifying the `OPTIMIZER_MODE` parameter in the initialization parameter file

- Setting it at session level by issuing an `ALTER SESSION` statement

 **See Also:**

*Oracle Database SQL Tuning Guide* for information on setting the `OPTIMIZER_MODE` initialization parameter in the parameter file and for configuring your system to use a cost-based optimization method

### 33.4.2.3.2 Analyzing Tables

For cost-based optimization to select the most efficient path for a distributed query, you must provide accurate statistics for the tables involved. You do this using the `DBMS_STATS` package.

 **Note:**

You must connect locally with respect to the tables when executing the `DBMS_STATS` procedure.

You must first connect to the remote site and then execute a `DBMS_STATS` procedure.

The following `DBMS_STATS` procedures enable the gathering of certain classes of optimizer statistics:

- `GATHER_INDEX_STATS`
- `GATHER_TABLE_STATS`
- `GATHER_SCHEMA_STATS`
- `GATHER_DATABASE_STATS`

For example, assume that distributed transactions routinely access the `scott.dept` table. To ensure that the cost-based optimizer is still picking the best plan, execute the following:

```
BEGIN
 DBMS_STATS.GATHER_TABLE_STATS ('scott', 'dept');
END;
```

 **See Also:**

- *Oracle Database SQL Tuning Guide* for information about generating statistics
- *Oracle Database PL/SQL Packages and Types Reference* for additional information on using the `DBMS_STATS` package

### 33.4.3 Using Hints

Hints can extend the capability of cost-based optimization.

- [About Using Hints](#)

If a statement is not sufficiently optimized, then you can use hints to extend the capability of cost-based optimization. Specifically, if you write your own query to use collocated inline views, instruct the cost-based optimizer not to rewrite your distributed query.

- [Using the NO\\_MERGE Hint](#)

The `NO_MERGE` hint prevents the database from merging an inline view into a potentially non-collocated SQL statement.

- [Using the DRIVING\\_SITE Hint](#)

The `DRIVING_SITE` hint lets you specify the site where the query execution is performed.

#### 33.4.3.1 About Using Hints

If a statement is not sufficiently optimized, then you can use hints to extend the capability of cost-based optimization. Specifically, if you write your own query to use collocated inline views, instruct the cost-based optimizer not to rewrite your distributed query.

Additionally, if you have special knowledge about the database environment (such as statistics, load, network and CPU limitations, distributed queries, and so forth), you can specify a hint to guide cost-based optimization. For example, if you have written your own optimized query using collocated inline views that are based on your knowledge of the database environment, specify the `NO_MERGE` hint to prevent the optimizer from rewriting your query.

This technique is especially helpful if your distributed query contains an aggregate, subquery, or complex SQL. Because this type of distributed query cannot be rewritten by the optimizer, specifying `NO_MERGE` causes the optimizer to skip the steps described in "[How Does Cost-Based Optimization Work?](#)".

The `DRIVING_SITE` hint lets you define a remote site to act as the query execution site. In this way, the query executes on the remote site, which then returns the data to the local site. This hint is especially helpful when the remote site contains the majority of the data.

 **See Also:**

*Oracle Database SQL Tuning Guide* for more information about using hints

### 33.4.3.2 Using the NO\_MERGE Hint

The `NO_MERGE` hint prevents the database from merging an inline view into a potentially non-collocated SQL statement.

This hint is embedded in the `SELECT` statement and can appear either at the beginning of the `SELECT` statement with the inline view as an argument or in the query block that defines the inline view.

```
/* with argument */

SELECT /*+NO_MERGE(v)*/ t1.x, v.avg_y
 FROM t1, (SELECT x, AVG(y) AS avg_y FROM t2 GROUP BY x) v,
 WHERE t1.x = v.x AND t1.y = 1;

/* in query block */

SELECT t1.x, v.avg_y
 FROM t1, (SELECT /*+NO_MERGE*/ x, AVG(y) AS avg_y FROM t2 GROUP BY x) v,
 WHERE t1.x = v.x AND t1.y = 1;
```

Typically, you use this hint when you have developed an optimized query based on your knowledge of your database environment.

#### Related Topics

- [Using Hints](#)  
Hints can extend the capability of cost-based optimization.

### 33.4.3.3 Using the DRIVING\_SITE Hint

The `DRIVING_SITE` hint lets you specify the site where the query execution is performed.

It is best to let cost-based optimization determine where the execution should be performed, but if you prefer to override the optimizer, you can specify the execution site manually.

Following is an example of a `SELECT` statement with a `DRIVING_SITE` hint:

```
SELECT /*+DRIVING_SITE(dept)*/ * FROM emp, dept@remote.com
 WHERE emp.deptno = dept.deptno;
```

#### Related Topics

- [Using Hints](#)  
Hints can extend the capability of cost-based optimization.

### 33.4.4 Analyzing the Execution Plan

An important aspect to tuning distributed queries is analyzing the execution plan.

The feedback that you receive from your analysis is an important element to testing and verifying your database. Verification becomes especially important when you want to compare plans. For example, comparing the execution plan for a distributed query optimized by cost-based optimization to a plan for a query manually optimized using hints, collocated inline views, and other techniques.

- **Generating the Execution Plan**

After you have prepared the database to store the execution plan, you are ready to view the plan for a specified query. Instead of directly executing a SQL statement, append the statement to the EXPLAIN PLAN FOR clause.

- **Viewing the Execution Plan**

After you have executed the preceding SQL statement, the execution plan is stored temporarily in the PLAN\_TABLE.

 **See Also:**

*Oracle Database SQL Tuning Guide* for detailed information about execution plans, the EXPLAIN PLAN statement, and how to interpret the results

#### 33.4.4.1 Generating the Execution Plan

After you have prepared the database to store the execution plan, you are ready to view the plan for a specified query. Instead of directly executing a SQL statement, append the statement to the EXPLAIN PLAN FOR clause.

For example, you can execute the following:

```
EXPLAIN PLAN FOR
 SELECT d.dname
 FROM dept d
 WHERE d.deptno
 IN (SELECT deptno
 FROM emp@orc2.world
 GROUP BY deptno
 HAVING COUNT (deptno) >3
)
 /
```

#### 33.4.4.2 Viewing the Execution Plan

After you have executed the preceding SQL statement, the execution plan is stored temporarily in the PLAN\_TABLE.

To view the results of the execution plan, execute the following script:

```
@utlxpls.sql
```

 **Note:**

The `utlxpls.sql` can be found in the `$ORACLE_HOME/rdbms/admin` directory.

Executing the `utlxpls.sql` script displays the execution plan for the `SELECT` statement that you specified. The results are formatted as follows:

Plan Table

| Operation | Name | Rows | Bytes | Cost | Pstart | Pstop |
|-----------|------|------|-------|------|--------|-------|
|-----------|------|------|-------|------|--------|-------|

|                          |         |  |  |  |  |  |  |
|--------------------------|---------|--|--|--|--|--|--|
| SELECT STATEMENT         |         |  |  |  |  |  |  |
| NESTED LOOPS             |         |  |  |  |  |  |  |
| VIEW                     |         |  |  |  |  |  |  |
| REMOTE                   |         |  |  |  |  |  |  |
| TABLE ACCESS BY INDEX RO | DEPT    |  |  |  |  |  |  |
| INDEX UNIQUE SCAN        | PK_DEPT |  |  |  |  |  |  |

If you are manually optimizing distributed queries by writing your own colocated inline views or using hints, it is best to generate an execution plan before and after your manual optimization. With both execution plans, you can compare the effectiveness of your manual optimization and make changes as necessary to improve the performance of the distributed query.

To view the SQL statement that will be executed at the remote site, execute the following select statement:

```
SELECT OTHER
FROM PLAN_TABLE
WHERE operation = 'REMOTE';
```

Following is sample output:

```
SELECT DISTINCT "A1"."DEPTNO" FROM "EMP" "A1"
GROUP BY "A1"."DEPTNO" HAVING COUNT("A1"."DEPTNO")>3
```

#### Note:

If you are having difficulty viewing the entire contents of the OTHER column, execute the following SQL\*Plus command:

```
SET LONG 9999999
```

## 33.5 Handling Errors in Remote Procedures

Errors can occur when a database executes a procedure.

When the database executes a procedure locally or at a remote location, four types of exceptions can occur:

- PL/SQL user-defined exceptions, which must be declared using the keyword EXCEPTION
- PL/SQL predefined exceptions such as the NO\_DATA\_FOUND keyword
- SQL errors such as ORA-00900 and ORA-02015
- Application exceptions generated using the RAISE\_APPLICATION\_ERROR() procedure

When using local procedures, you can trap these messages by writing an exception handler such as the following

```
BEGIN
 ...
EXCEPTION
 WHEN ZERO_DIVIDE THEN
```

```
/* ... handle the exception */
END;
```

Notice that the WHEN clause requires an exception name. If the exception does not have a name, for example, exceptions generated with RAISE\_APPLICATION\_ERROR, you can assign one using PRAGMA\_EXCEPTION\_INIT. For example:

```
DECLARE
 null_salary EXCEPTION;
 PRAGMA EXCEPTION_INIT(null_salary, -20101);
BEGIN
 ...
 RAISE_APPLICATION_ERROR(-20101, 'salary is missing');
 ...
EXCEPTION
 WHEN null_salary THEN
 ...
END;
```

When calling a remote procedure, exceptions can be handled by an exception handler in the local procedure. The remote procedure must return an error number to the local, calling procedure, which then handles the exception as shown in the previous example. Note that PL/SQL user-defined exceptions always return ORA-06510 to the local procedure.

Therefore, it is not possible to distinguish between two different user-defined exceptions based on the error number. All other remote exceptions can be handled in the same manner as local exceptions.

 **See Also:**

*Oracle Database PL/SQL Language Reference* for more information about PL/SQL procedures

# Distributed Transactions Concepts

Distributed transactions update data on two or more distinct nodes of a distributed database.

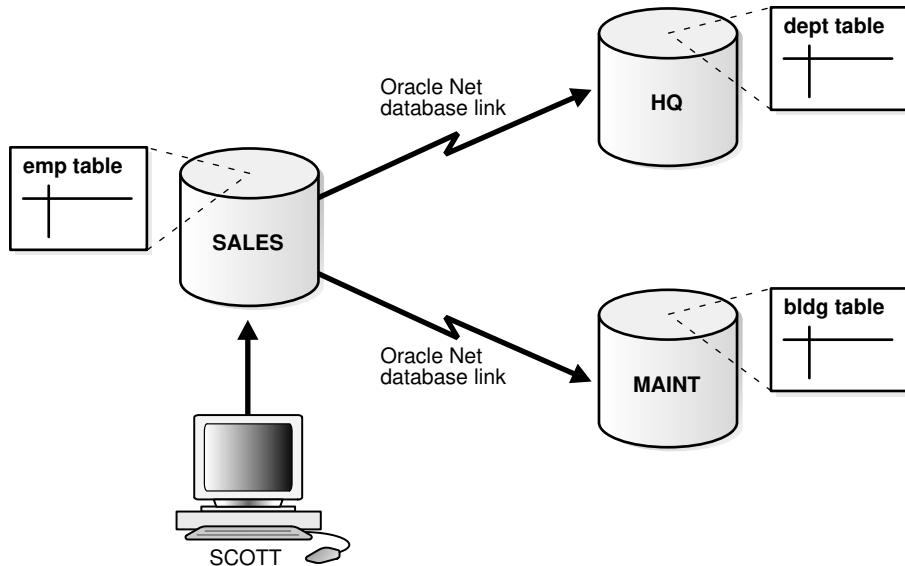

- [What Are Distributed Transactions?](#)  
A **distributed transaction** includes one or more statements that, individually or as a group, update data on two or more distinct nodes of a distributed database.
- [Session Trees for Distributed Transactions](#)  
A session tree is a hierarchical model that describes the relationships among sessions and their roles.
- [Two-Phase Commit Mechanism](#)  
In a distributed database environment, the database must coordinate the committing or rolling back of the changes in a distributed transaction as a self-contained unit.
- [In-Doubt Transactions](#)  
A transaction becomes in-doubt if the two-phase commit mechanism fails.
- [Distributed Transaction Processing: Case Study](#)  
A case study illustrates distributed transaction processing.

## 34.1 What Are Distributed Transactions?

A **distributed transaction** includes one or more statements that, individually or as a group, update data on two or more distinct nodes of a distributed database.

For example, assume the database configuration depicted in [Figure 34-1](#):

**Figure 34-1    Distributed System**

The following distributed transaction executed by scott updates the local sales database, the remote hq database, and the remote maint database:

```
UPDATE scott.dept@hq.us.example.com
 SET loc = 'REDWOOD SHORES'
 WHERE deptno = 10;
UPDATE scott.emp
 SET deptno = 11
 WHERE deptno = 10;
UPDATE scott.bldg@maint.us.example.com
 SET room = 1225
 WHERE room = 1163;
COMMIT;
```

 **Note:**

If all statements of a transaction reference only a single remote node, then the transaction is remote, not distributed.

There are two types of permissible operations in distributed transactions: DML and DDL transactions, and transaction control statement.

- [DML and DDL Transactions](#)  
Some DML and DDL operations are supported in a distributed transaction.
- [Transaction Control Statements](#)  
Some transaction control statements are supported in distributed transactions.

### 34.1.1 DML and DDL Transactions

Some DML and DDL operations are supported in a distributed transaction.

The following are the DML and DDL operations supported in a distributed transaction:

- CREATE TABLE AS SELECT
- DELETE
- INSERT (default and direct load)
- UPDATE
- LOCK TABLE
- SELECT
- SELECT FOR UPDATE

You can execute DML and DDL statements in parallel, and INSERT direct load statements serially, but note the following restrictions:

- All remote operations must be SELECT statements.
- These statements must not be clauses in another distributed transaction.
- If the table referenced in the *table\_expression\_clause* of an INSERT, UPDATE, or DELETE statement is remote, then execution is serial rather than parallel.
- You cannot perform remote operations after issuing parallel DML/DDL or direct load INSERT.

- If the transaction begins using XA or OCI, it executes serially.
- No loopback operations can be performed on the transaction originating the parallel operation. For example, you cannot reference a remote object that is actually a synonym for a local object.
- If you perform a distributed operation other than a `SELECT` in the transaction, no DML is parallelized.

### 34.1.2 Transaction Control Statements

Some transaction control statements are supported in distributed transactions.

The following are the supported transaction control statements:

- `COMMIT`
- `ROLLBACK`
- `SAVEPOINT`

 **See Also:**

*Oracle Database SQL Language Reference* for more information about these SQL statements

## 34.2 Session Trees for Distributed Transactions

A session tree is a hierarchical model that describes the relationships among sessions and their roles.

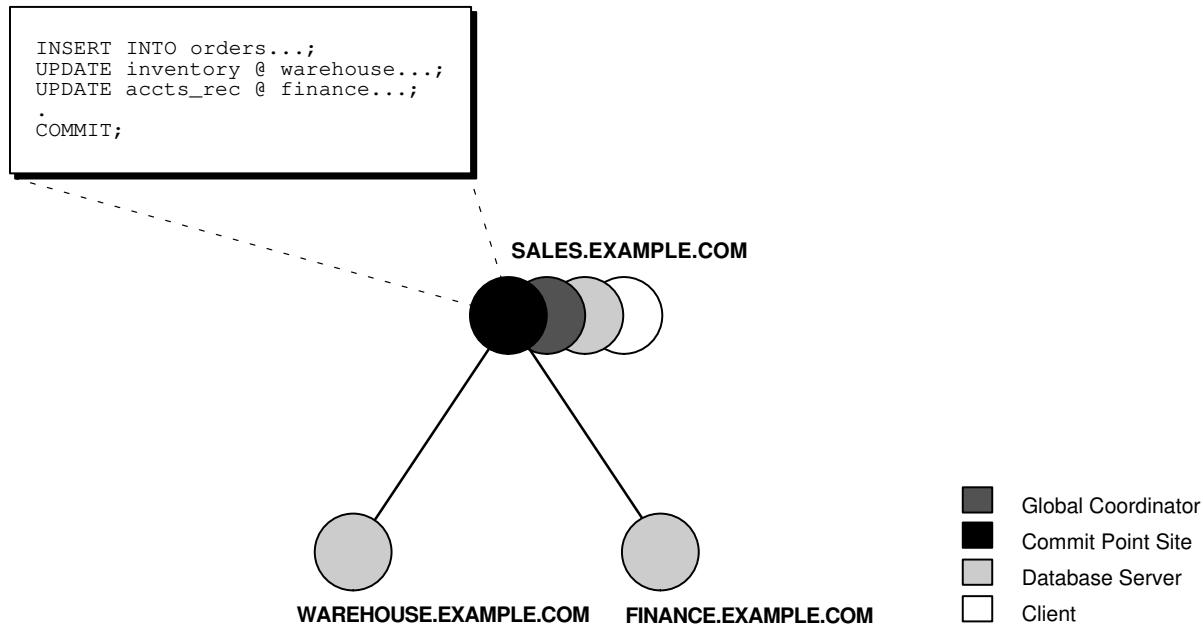

- [About Session Trees for Distributed Transactions](#)  
As the statements in a distributed transaction are issued, the database defines a **session tree** of all nodes participating in the transaction.
- [Clients](#)  
A node acts as a client when it references information from a database on another node.
- [Database Servers](#)  
A database server is a node that hosts a database from which a client requests data.
- [Local Coordinators](#)  
A node that must reference data on other nodes to complete its part in the distributed transaction is called a local coordinator.
- [Global Coordinator](#)  
The node where the distributed transaction originates is called the global coordinator.
- [Commit Point Site](#)  
The system administrator always designates one node to be the commit point site.

### 34.2.1 About Session Trees for Distributed Transactions

As the statements in a distributed transaction are issued, the database defines a **session tree** of all nodes participating in the transaction.

A session tree is a hierarchical model that describes the relationships among sessions and their roles. [Figure 34-2](#) illustrates a session tree:

**Figure 34-2 Example of a Session Tree**

All nodes participating in the session tree of a distributed transaction assume one or more of the following roles:

| Role               | Description                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------|
| Client             | A node that references information in a database belonging to a different node.                 |
| Database server    | A node that receives a request for information from another node.                               |
| Global coordinator | The node that originates the distributed transaction.                                           |
| Local coordinator  | A node that is forced to reference data on other nodes to complete its part of the transaction. |
| Commit point site  | The node that commits or rolls back the transaction as instructed by the global coordinator.    |

The role a node plays in a distributed transaction is determined by:

- Whether the transaction is local or remote
- The **commit point strength** of the node ("Commit Point Site")
- Whether all requested data is available at a node, or whether other nodes need to be referenced to complete the transaction

- Whether the node is read-only

### 34.2.2 Clients

A node acts as a client when it references information from a database on another node.

The referenced node is a database server. In [Figure 34-2](#), the node `sales` is a client of the nodes that host the `warehouse` and `finance` databases.

### 34.2.3 Database Servers

A database server is a node that hosts a database from which a client requests data.

In [Figure 34-2](#), an application at the `sales` node initiates a distributed transaction that accesses data from the `warehouse` and `finance` nodes. Therefore, `sales.example.com` has the role of client node, and `warehouse` and `finance` are both database servers. In this example, `sales` is a database server *and* a client because the application also modifies data in the `sales` database.

### 34.2.4 Local Coordinators

A node that must reference data on other nodes to complete its part in the distributed transaction is called a local coordinator.

In [Figure 34-2](#), `sales` is a local coordinator because it coordinates the nodes it directly references: `warehouse` and `finance`. The node `sales` also happens to be the global coordinator because it coordinates all the nodes involved in the transaction.

A local coordinator is responsible for coordinating the transaction among the nodes it communicates directly with by:

- Receiving and relaying transaction status information to and from those nodes
- Passing queries to those nodes
- Receiving queries from those nodes and passing them on to other nodes
- Returning the results of queries to the nodes that initiated them

### 34.2.5 Global Coordinator

The node where the distributed transaction originates is called the global coordinator.

The database application issuing the distributed transaction is directly connected to the node acting as the global coordinator. For example, in [Figure 34-2](#), the transaction issued at the node `sales` references information from the database servers `warehouse` and `finance`. Therefore, `sales.example.com` is the global coordinator of this distributed transaction.

The global coordinator becomes the parent or root of the session tree. The global coordinator performs the following operations during a distributed transaction:

- Sends all of the distributed transaction SQL statements, remote procedure calls, and so forth to the directly referenced nodes, thus forming the session tree
- Instructs all directly referenced nodes other than the commit point site to prepare the transaction

- Instructs the commit point site to initiate the global commit of the transaction if all nodes prepare successfully
- Instructs all nodes to initiate a global rollback of the transaction if there is an abort response

## 34.2.6 Commit Point Site

The system administrator always designates one node to be the commit point site.

- [About the Commit Point Site](#)  
The job of the commit point site is to initiate a commit or roll back operation as instructed by the global coordinator.
- [How a Distributed Transaction Commits](#)  
A distributed transaction is considered committed after all non-commit-point sites are prepared, and the transaction has been actually committed at the commit point site.
- [Commit Point Strength](#)  
Every database server must be assigned a commit point strength. If a database server is referenced in a distributed transaction, the value of its commit point strength determines which role it plays in the two-phase commit.

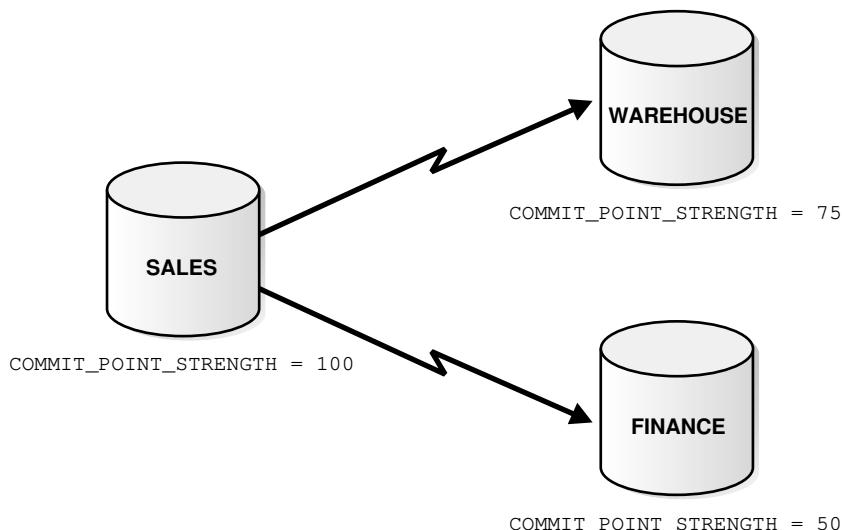

### 34.2.6.1 About the Commit Point Site

The job of the commit point site is to initiate a commit or roll back operation as instructed by the global coordinator.

The system administrator always designates one node to be the commit point site in the session tree by assigning all nodes a commit point strength. The node selected as commit point site should be the node that stores the most critical data.

[Figure 34-3](#) illustrates an example of distributed system, with `SALES` serving as the commit point site:

**Figure 34-3 Commit Point Site**

The commit point site is distinct from all other nodes involved in a distributed transaction in these ways:

- The commit point site never enters the prepared state. Consequently, if the commit point site stores the most critical data, this data never remains in-doubt, even if a failure occurs. In failure situations, failed nodes remain in a prepared state, holding necessary locks on data until in-doubt transactions are resolved.
- The commit point site commits before the other nodes involved in the transaction. In effect, the outcome of a distributed transaction at the commit point site determines whether the transaction at all nodes is committed or rolled back: the other nodes follow the lead of the commit point site. The global coordinator ensures that all nodes complete the transaction in the same manner as the commit point site.

### 34.2.6.2 How a Distributed Transaction Commits

A distributed transaction is considered committed after all non-commit-point sites are prepared, and the transaction has been actually committed at the commit point site.

The redo log at the commit point site is updated as soon as the distributed transaction is committed at this node.

Because the commit point log contains a record of the commit, the transaction is considered committed even though some participating nodes may still be only in the prepared state and the transaction not yet actually committed at these nodes. In the same way, a distributed transaction is considered *not* committed if the commit has not been logged at the commit point site.

### 34.2.6.3 Commit Point Strength

Every database server must be assigned a commit point strength. If a database server is referenced in a distributed transaction, the value of its commit point strength determines which role it plays in the two-phase commit.

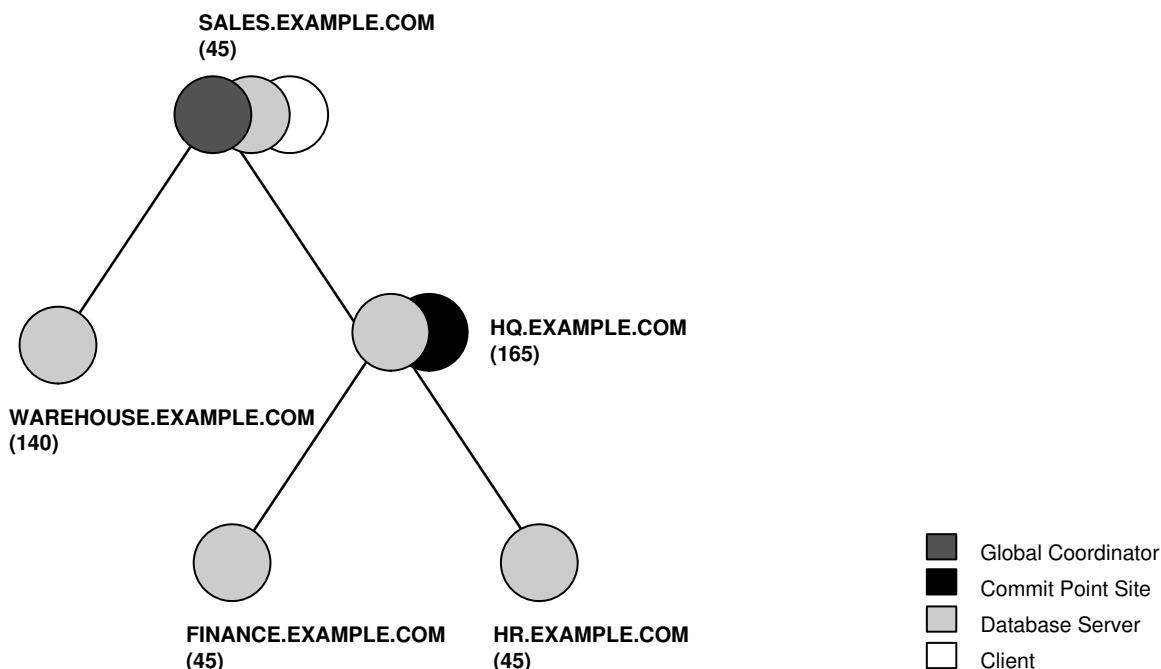

Specifically, the commit point strength determines whether a given node is the commit point site in the distributed transaction and thus commits before all of the other nodes. This value is specified using the initialization parameter `COMMIT_POINT_STRENGTH`. This section explains how the database determines the commit point site.

The commit point site, which is determined at the beginning of the prepare phase, is selected only from the nodes participating in the transaction. The following sequence of events occurs:

1. Of the nodes directly referenced by the global coordinator, the database selects the node with the highest commit point strength as the commit point site.
2. The initially-selected node determines if any of the nodes from which it has to obtain information for this transaction has a higher commit point strength.
3. Either the node with the highest commit point strength directly referenced in the transaction or one of its servers with a higher commit point strength becomes the commit point site.
4. After the final commit point site has been determined, the global coordinator sends prepare responses to all nodes participating in the transaction.

[Figure 34-4](#) shows in a sample session tree the commit point strengths of each node (in parentheses) and shows the node chosen as the commit point site:

**Figure 34-4 Commit Point Strengths and Determination of the Commit Point Site**

The following conditions apply when determining the commit point site:

- A read-only node cannot be the commit point site.
- If multiple nodes directly referenced by the global coordinator have the same commit point strength, then the database designates one of these as the commit point site.
- If a distributed transaction ends with a rollback, then the prepare and commit phases are not needed. Consequently, the database never determines a commit point site. Instead, the global coordinator sends a `ROLLBACK` statement to all nodes and ends the processing of the distributed transaction.

As Figure 34-4 illustrates, the commit point site and the global coordinator can be different nodes of the session tree. The commit point strength of each node is communicated to the coordinators when the initial connections are made. The coordinators retain the commit point strengths of each node they are in direct communication with so that commit point sites can be efficiently selected during two-phase commits. Therefore, it is not necessary for the commit point strength to be exchanged between a coordinator and a node each time a commit occurs.

**See Also:**

- "[Specifying the Commit Point Strength of a Node](#)" to learn how to set the commit point strength of a node
- *Oracle Database Reference* for more information about the initialization parameter `COMMIT_POINT_STRENGTH`

## 34.3 Two-Phase Commit Mechanism

In a distributed database environment, the database must coordinate the committing or rolling back of the changes in a distributed transaction as a self-contained unit.

- **About the Two-Phase Commit Mechanism**

Unlike a transaction on a local database, a distributed transaction involves altering data on multiple databases. Consequently, distributed transaction processing is more complicated, because the database must coordinate the committing or rolling back of the changes in a transaction as a self-contained unit. In other words, the entire transaction commits, or the entire transaction rolls back.

- **Prepare Phase**

Prepare phase is the first phase in committing a distributed transaction.

- **Commit Phase**

The second phase in committing a distributed transaction is the commit phase. Before this phase occurs, *all* nodes other than the commit point site referenced in the distributed transaction have guaranteed that they are prepared, that is, they have the necessary resources to commit the transaction.

- **Forget Phase**

After the participating nodes notify the commit point site that they have committed, the commit point site can forget about the transaction.

### 34.3.1 About the Two-Phase Commit Mechanism

Unlike a transaction on a local database, a distributed transaction involves altering data on multiple databases. Consequently, distributed transaction processing is more complicated, because the database must coordinate the committing or rolling back of the changes in a transaction as a self-contained unit. In other words, the entire transaction commits, or the entire transaction rolls back.

The database ensures the integrity of data in a distributed transaction using the **two-phase commit mechanism**. In the **prepare phase**, the initiating node in the transaction asks the other participating nodes to promise to commit or roll back the transaction. During the **commit phase**, the initiating node asks all participating nodes to commit the transaction. If this outcome is not possible, then all nodes are asked to roll back.

All participating nodes in a distributed transaction should perform the same action: they should either all commit or all perform a rollback of the transaction. The database automatically controls and monitors the commit or rollback of a distributed transaction and maintains the integrity of the **global database** (the collection of databases participating in the transaction) using the two-phase commit mechanism. This mechanism is completely transparent, requiring no programming on the part of the user or application developer.

The commit mechanism has the following distinct phases, which the database performs automatically whenever a user commits a distributed transaction:

| Phase         | Description                                                                                                                                                                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Prepare phase | The initiating node, called the <b>global coordinator</b> , asks participating nodes other than the commit point site to promise to commit or roll back the transaction, even if there is a failure. If any node cannot prepare, the transaction is rolled back. |
| Commit phase  | If all participants respond to the coordinator that they are prepared, then the coordinator asks the commit point site to commit. After it commits, the coordinator asks all other nodes to commit the transaction.                                              |
| Forget phase  | The global coordinator forgets about the transaction.                                                                                                                                                                                                            |

### 34.3.2 Prepare Phase

Prepare phase is the first phase in committing a distributed transaction.

- [About Prepare Phase](#)  
The first phase in committing a distributed transaction is the prepare phase.
- [Types of Responses in the Prepare Phase](#)  
When a node is told to prepare, it can respond in the different ways.
- [Steps in the Prepare Phase](#)  
The prepare phase in the two-phase commit process includes specific steps.

#### 34.3.2.1 About Prepare Phase

The first phase in committing a distributed transaction is the prepare phase.

In this phase, the database does not actually commit or roll back the transaction. Instead, all nodes referenced in a distributed transaction (except the commit point site, described in the "Commit Point Site") are told to prepare to commit. By preparing, a node:

- Records information in the redo logs so that it can subsequently either commit or roll back the transaction, regardless of intervening failures
- Places a distributed lock on modified tables, which prevents reads

When a node responds to the global coordinator that it is prepared to commit, the prepared node *promises* to either commit or roll back the transaction later, but does not make a unilateral decision on whether to commit or roll back the transaction. The promise means that if an instance failure occurs at this point, the node can use the redo records in the online log to recover the database back to the prepare phase.

 **Note:**

Queries that start after a node has prepared cannot access the associated locked data until all phases complete. The time is insignificant unless a failure occurs (see "[Deciding How to Handle In-Doubt Transactions](#)").

### 34.3.2.2 Types of Responses in the Prepare Phase

When a node is told to prepare, it can respond in the different ways.

| Response  | Meaning                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------|
| Prepared  | Data on the node has been modified by a statement in the distributed transaction, and the node has successfully prepared. |
| Read-only | No data on the node has been, or can be, modified (only queried), so no preparation is necessary.                         |
| Abort     | The node cannot successfully prepare.                                                                                     |

- **Prepared Response**

When a node has successfully prepared, it issues a **prepared message**.

- **Read-Only Response**

When a node is asked to prepare, and the SQL statements affecting the database do not change any data on the node, the node responds with a **read-only message**.

- **Abort Response**

The **abort message** results in specific actions.

#### 34.3.2.2.1 Prepared Response

When a node has successfully prepared, it issues a **prepared message**.

The message indicates that the node has records of the changes in the online log, so it is prepared either to commit or perform a rollback. The message also guarantees that locks held for the transaction can survive a failure.

#### 34.3.2.2.2 Read-Only Response

When a node is asked to prepare, and the SQL statements affecting the database do not change any data on the node, the node responds with a **read-only message**.

The message indicates that the node will not participate in the commit phase.

There are three cases in which all or part of a distributed transaction is read-only:

| Case                                    | Conditions                                                                                                                                                                                                                                    | Consequence                                                                                                                                                                                                                                    |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Partially read-only                     | Any of the following occurs: <ul style="list-style-type: none"> <li>• Only queries are issued at one or more nodes.</li> <li>• No data is changed.</li> <li>• Changes rolled back due to triggers firing or constraint violations.</li> </ul> | The read-only nodes recognize their status when asked to prepare. They give their local coordinators a read-only response. Thus, the commit phase completes faster because the database eliminates read-only nodes from subsequent processing. |
| Completely read-only with prepare phase | All of following occur: <ul style="list-style-type: none"> <li>• No data changes.</li> <li>• Transaction is <i>not</i> started with <code>SET TRANSACTION READ ONLY</code> statement.</li> </ul>                                              | All nodes recognize that they are read-only during prepare phase, so no commit phase is required. The global coordinator, not knowing whether all nodes are read-only, must still perform the prepare phase.                                   |

| Case                                          | Conditions                                                                                                                                                                      | Consequence                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completely read-only without two-phase commit | All of following occur: <ul style="list-style-type: none"> <li>• No data changes.</li> <li>• Transaction <i>is</i> started with SET TRANSACTION READ ONLY statement.</li> </ul> | Only queries are allowed in the transaction, so global coordinator does not have to perform two-phase commit. Changes by other transactions do not degrade global transaction-level read consistency because of global SCN coordination among nodes. The transaction does not use undo segments. |

Note that if a distributed transaction is set to read-only, then it does not use undo segments. If many users connect to the database and their transactions are *not* set to READ ONLY, then they allocate undo space even if they are only performing queries.

### 34.3.2.2.3 Abort Response

The **abort message** results in specific actions.

When a node cannot successfully prepare, it performs the following actions:

1. Releases resources currently held by the transaction and rolls back the local portion of the transaction.
2. Responds to the node that referenced it in the distributed transaction with an abort message.

These actions then propagate to the other nodes involved in the distributed transaction so that they can roll back the transaction and guarantee the integrity of the data in the global database. This response enforces the primary rule of a distributed transaction: *all nodes involved in the transaction either all commit or all roll back the transaction at the same logical time*.

### 34.3.2.3 Steps in the Prepare Phase

The prepare phase in the two-phase commit process includes specific steps.

To complete the prepare phase, each node excluding the commit point site performs the following steps:

1. The node requests that its **descendants**, that is, the nodes subsequently referenced, prepare to commit.
2. The node checks to see whether the transaction changes data on itself or its descendants. If there is no change to the data, then the node skips the remaining steps and returns a read-only response (see "[Read-Only Response](#)").
3. The node allocates the resources it must commit the transaction if data is changed.
4. The node saves redo records corresponding to changes made by the transaction to its redo log.
5. The node guarantees that locks held for the transaction are able to survive a failure.

6. The node responds to the initiating node with a prepared response (see "[Prepared Response](#)") or, if its attempt or the attempt of one of its descendants to prepare was unsuccessful, with an abort response (see "[Abort Response](#)").

These actions guarantee that the node can subsequently commit or roll back the transaction on the node. The prepared nodes then wait until a COMMIT or ROLLBACK request is received from the global coordinator.

After the nodes are prepared, the distributed transaction is said to be **in-doubt** (see "[In-Doubt Transactions](#)"). It retains in-doubt status until all changes are either committed or rolled back.

### 34.3.3 Commit Phase

The second phase in committing a distributed transaction is the commit phase. Before this phase occurs, *all* nodes other than the commit point site referenced in the distributed transaction have guaranteed that they are prepared, that is, they have the necessary resources to commit the transaction.

- [Steps in the Commit Phase](#)

The commit phase in the two-phase commit process includes specific steps.

- [Guaranteeing Global Database Consistency](#)

Each committed transaction has an associated system change number (SCN) to uniquely identify the changes made by the SQL statements within that transaction.

#### 34.3.3.1 Steps in the Commit Phase

The commit phase in the two-phase commit process includes specific steps.

The commit phase consists of the following steps:

1. The global coordinator instructs the commit point site to commit.
2. The commit point site commits.
3. The commit point site informs the global coordinator that it has committed.
4. The global and local coordinators send a message to all nodes instructing them to commit the transaction.
5. At each node, the database commits the local portion of the distributed transaction and releases locks.
6. At each node, the database records an additional redo entry in the local redo log, indicating that the transaction has committed.
7. The participating nodes notify the global coordinator that they have committed.

When the commit phase is complete, the data on all nodes of the distributed system is consistent.

#### 34.3.3.2 Guaranteeing Global Database Consistency

Each committed transaction has an associated system change number (SCN) to uniquely identify the changes made by the SQL statements within that transaction.

The SCN functions as an internal timestamp that uniquely identifies a committed version of the database.

In a distributed system, the SCNs of communicating nodes are coordinated when all of the following actions occur:

- A connection occurs using the path described by one or more database links
- A distributed SQL statement executes
- A distributed transaction commits

Among other benefits, the coordination of SCNs among the nodes of a distributed system ensures global read-consistency at both the statement and transaction level. If necessary, global time-based recovery can also be completed.

During the prepare phase, the database determines the highest SCN at all nodes involved in the transaction. The transaction then commits with the high SCN at the commit point site. The commit SCN is then sent to all prepared nodes with the commit decision.

 **See Also:**

["Managing Read Consistency"](#) for information about managing time lag issues in read consistency

### 34.3.4 Forget Phase

After the participating nodes notify the commit point site that they have committed, the commit point site can forget about the transaction.

The following steps occur:

1. After receiving notice from the global coordinator that all nodes have committed, the commit point site erases status information about this transaction.
2. The commit point site informs the global coordinator that it has erased the status information.
3. The global coordinator erases its own information about the transaction.

## 34.4 In-Doubt Transactions

A transaction becomes in-doubt if the two-phase commit mechanism fails.

- [About In-Doubt Transactions](#)  
The two-phase commit mechanism ensures that all nodes either commit or perform a rollback together. What happens if any of the three phases fails because of a system or network error? The transaction becomes in-doubt.
- [Automatic Resolution of In-Doubt Transactions](#)  
In the majority of cases, the database resolves the in-doubt transaction automatically. Assume that there are two nodes, `local` and `remote`, in the following scenarios. The local node is the commit point site. User `scott` connects to `local` and executes and commits a distributed transaction that updates `local` and `remote`.
- [Manual Resolution of In-Doubt Transactions](#)  
In some cases, you must resolve an in-doubt transaction manually.

- [Relevance of System Change Numbers for In-Doubt Transactions](#)  
A **system change number** (SCN) is an internal timestamp for a committed version of the database. The Oracle Database server uses the SCN clock value to guarantee transaction consistency.

### 34.4.1 About In-Doubt Transactions

The two-phase commit mechanism ensures that all nodes either commit or perform a rollback together. What happens if any of the three phases fails because of a system or network error? The transaction becomes in-doubt.

Distributed transactions can become in-doubt in the following ways:

- A server system running Oracle Database software crashes
- A network connection between two or more Oracle Databases involved in distributed processing is disconnected
- An unhandled software error occurs

The RECO process automatically resolves in-doubt transactions when the system, network, or software problem is resolved. Until RECO can resolve the transaction, the data is locked for both reads and writes. The database blocks reads because it cannot determine which version of the data to display for a query.

### 34.4.2 Automatic Resolution of In-Doubt Transactions

In the majority of cases, the database resolves the in-doubt transaction automatically. Assume that there are two nodes, `local` and `remote`, in the following scenarios. The local node is the commit point site. User `scott` connects to `local` and executes and commits a distributed transaction that updates `local` and `remote`.

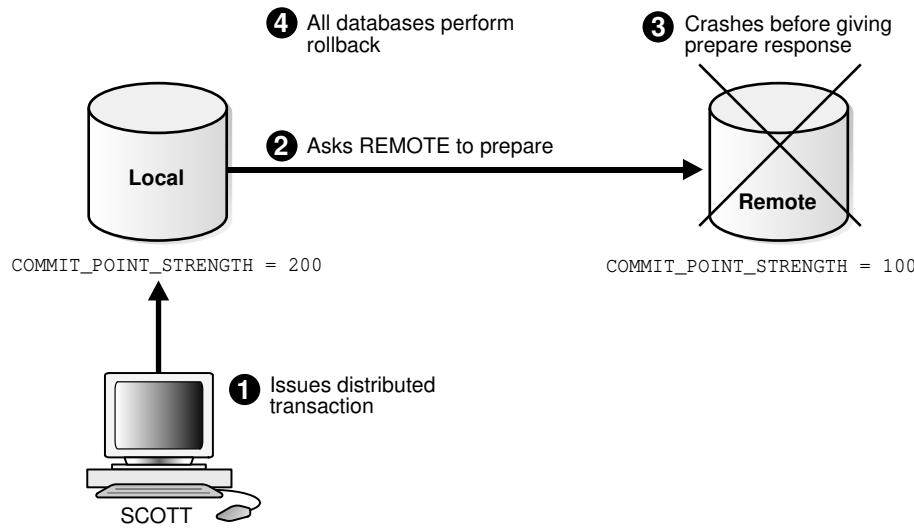

- [Failure During the Prepare Phase](#)  
An example illustrates the steps that are followed when there is a failure during the prepare phase of a two-phase transaction.
- [Failure During the Commit Phase](#)  
An example illustrates the steps that are followed when there is a failure during the commit phase of a two-phase transaction.

#### 34.4.2.1 Failure During the Prepare Phase

An example illustrates the steps that are followed when there is a failure during the prepare phase of a two-phase transaction.

[Figure 34-5](#) illustrates the sequence of events when there is a failure during the prepare phase of a distributed transaction:

**Figure 34-5 Failure During Prepare Phase**

The following steps occur:

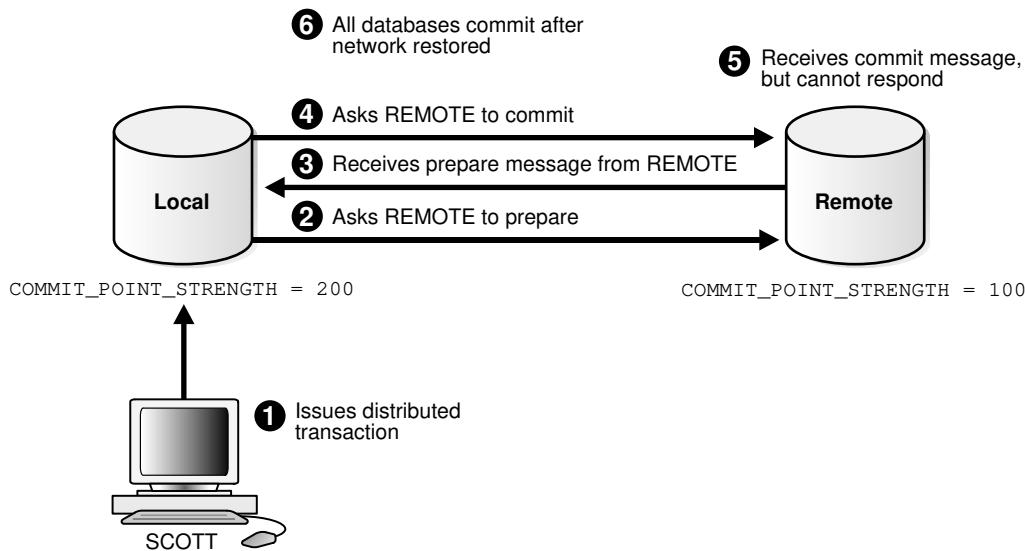

1. User SCOTT connects to Local and executes a distributed transaction.
2. The global coordinator, which in this example is also the commit point site, requests all databases other than the commit point site to promise to commit or roll back when told to do so.
3. The remote database crashes before issuing the prepare response back to local.
4. The transaction is ultimately rolled back on each database by the RECO process when the remote site is restored.

### 34.4.2.2 Failure During the Commit Phase

An example illustrates the steps that are followed when there is a failure during the commit phase of a two-phase transaction.

[Figure 34-6](#) illustrates the sequence of events when there is a failure during the commit phase of a distributed transaction:

**Figure 34-6 Failure During Commit Phase**

The following steps occur:

1. User Scott connects to local and executes a distributed transaction.
2. The global coordinator, which in this case is also the commit point site, requests all databases other than the commit point site to promise to commit or roll back when told to do so.
3. The commit point site receives a prepared message from remote saying that it will commit.
4. The commit point site commits the transaction locally, then sends a commit message to remote asking it to commit.
5. The remote database receives the commit message, but cannot respond because of a network failure.
6. The transaction is ultimately committed on the remote database by the RECO process after the network is restored.

**See Also:**

"[Deciding How to Handle In-Doubt Transactions](#)" for a description of failure situations and how the database resolves intervening failures during two-phase commit

### 34.4.3 Manual Resolution of In-Doubt Transactions

In some cases, you must resolve an in-doubt transaction manually.

You should only need to resolve an in-doubt transaction manually in the following cases:

- The in-doubt transaction has locks on critical data or undo segments.

- The cause of the system, network, or software failure cannot be repaired quickly.

Resolution of in-doubt transactions can be complicated. The procedure requires that you do the following:

- Identify the transaction identification number for the in-doubt transaction.
- Query the DBA\_2PC\_PENDING and DBA\_2PC\_NEIGHBORS views to determine whether the databases involved in the transaction have committed.
- If necessary, force a commit using the COMMIT FORCE statement or a rollback using the ROLLBACK FORCE statement.

 **See Also:**

The following sections explain how to resolve in-doubt transactions:

- ["Deciding How to Handle In-Doubt Transactions"](#)
- ["Manually Overriding In-Doubt Transactions"](#)

#### 34.4.4 Relevance of System Change Numbers for In-Doubt Transactions

A **system change number** (SCN) is an internal timestamp for a committed version of the database. The Oracle Database server uses the SCN clock value to guarantee transaction consistency.

For example, when a user commits a transaction, the database records an SCN for this commit in the redo log.

The database uses SCNs to coordinate distributed transactions among different databases. For example, the database uses SCNs in the following way:

1. An application establishes a connection using a database link.
2. The distributed transaction commits with the highest global SCN among all the databases involved.
3. The commit global SCN is sent to all databases involved in the transaction.

SCNs are important for distributed transactions because they function as a synchronized commit timestamp of a transaction, even if the transaction fails. If a transaction becomes in-doubt, an administrator can use this SCN to coordinate changes made to the global database. The global SCN for the transaction commit can also be used to identify the transaction later, for example, in distributed recovery.

### 34.5 Distributed Transaction Processing: Case Study

A case study illustrates distributed transaction processing.

- [About the Distributed Transaction Processing Case Study](#)

In this scenario, a company has separate Oracle Database servers, sales.example.com and warehouse.example.com. As users insert sales records into the sales database, associated records are being updated at the warehouse database.

- **Stage 1: Client Application Issues DML Statements**  
An example illustrates the first stage in distributed transaction processing.
- **Stage 2: Oracle Database Determines Commit Point Site**  
An example illustrates the second stage in distributed transaction processing.
- **Stage 3: Global Coordinator Sends Prepare Response**  
An example illustrates the third stage in distributed transaction processing.
- **Stage 4: Commit Point Site Commits**  
An example illustrates the fourth stage in distributed transaction processing.
- **Stage 5: Commit Point Site Informs Global Coordinator of Commit**  
An example illustrates the fifth stage in distributed transaction processing.
- **Stage 6: Global and Local Coordinators Tell All Nodes to Commit**  
An example illustrates the sixth stage in distributed transaction processing.
- **Stage 7: Global Coordinator and Commit Point Site Complete the Commit**  
An example illustrates the seventh stage in distributed transaction processing.

### 34.5.1 About the Distributed Transaction Processing Case Study

In this scenario, a company has separate Oracle Database servers, `sales.example.com` and `warehouse.example.com`. As users insert sales records into the `sales` database, associated records are being updated at the `warehouse` database.

This case study of distributed processing illustrates:

- The definition of a session tree
- How a commit point site is determined
- When prepare messages are sent
- When a transaction actually commits
- What information is stored locally about the transaction

### 34.5.2 Stage 1: Client Application Issues DML Statements

An example illustrates the first stage in distributed transaction processing.

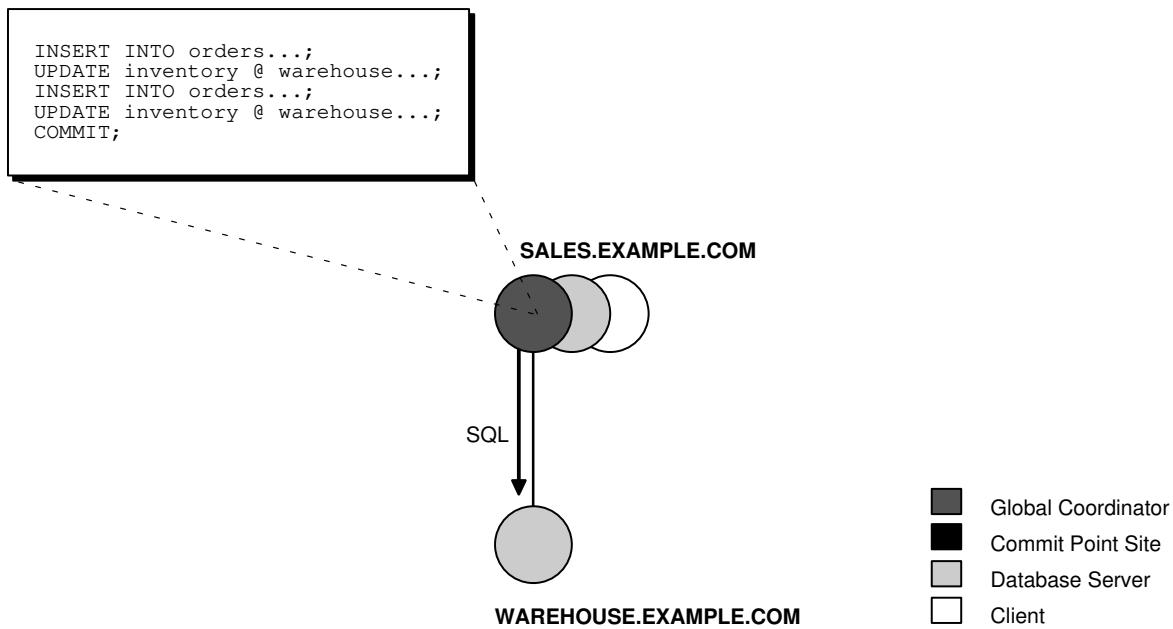

At the Sales department, a salesperson uses SQL\*Plus to enter a sales order and then commit it. The application issues several SQL statements to enter the order into the `sales` database and update the inventory in the `warehouse` database:

```
CONNECT scott@sales.example.com ...;
INSERT INTO orders ...;
UPDATE inventory@warehouse.example.com ...;
INSERT INTO orders ...;
UPDATE inventory@warehouse.example.com ...;
COMMIT;
```

These SQL statements are part of a single distributed transaction, guaranteeing that all issued SQL statements succeed or fail as a unit. Treating the statements as a unit prevents the possibility of an order being placed and then inventory not being updated to reflect the order. In effect, the transaction guarantees the consistency of data in the global database.

As each of the SQL statements in the transaction executes, the session tree is defined, as shown in [Figure 34-7](#).

**Figure 34-7 Defining the Session Tree**

Note the following aspects of the transaction:

- An order entry application running on the sales database initiates the transaction. Therefore, `sales.example.com` is the global coordinator for the distributed transaction.
- The order entry application inserts a new sales record into the sales database and updates the inventory at the warehouse. Therefore, the nodes `sales.example.com` and `warehouse.example.com` are both database servers.
- Because `sales.example.com` updates the inventory, it is a client of `warehouse.example.com`.

This stage completes the definition of the session tree for this distributed transaction. Each node in the tree has acquired the necessary data locks to execute the SQL statements that reference local data. These locks remain even after the SQL statements have been executed until the two-phase commit is completed.

### 34.5.3 Stage 2: Oracle Database Determines Commit Point Site

An example illustrates the second stage in distributed transaction processing.

The database determines the commit point site immediately following the `COMMIT` statement. `sales.example.com`, the global coordinator, is determined to be the commit point site, as shown in [Figure 34-8](#).

 **See Also:**

["Commit Point Strength"](#) for more information about how the commit point site is determined

**Figure 34-8 Determining the Commit Point Site**

### 34.5.4 Stage 3: Global Coordinator Sends Prepare Response

An example illustrates the third stage in distributed transaction processing.

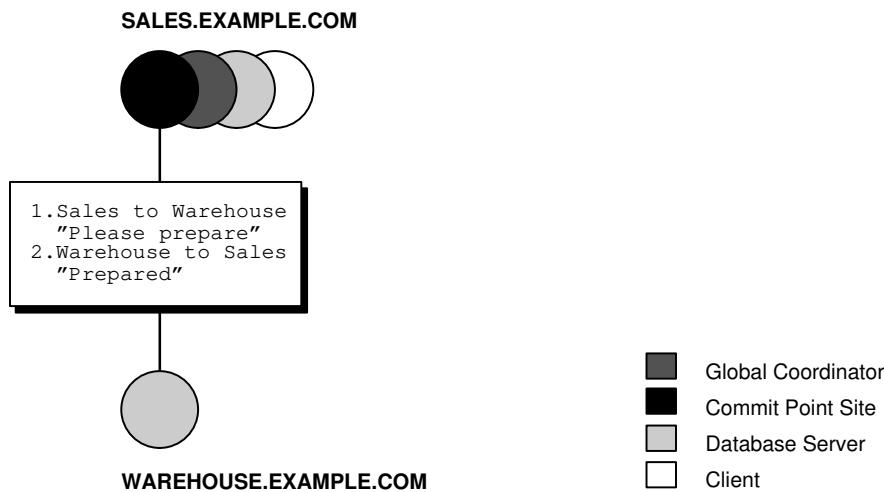

The prepare stage involves the following steps:

1. After the database determines the commit point site, the global coordinator sends the prepare message to all directly referenced nodes of the session tree, *excluding* the commit point site. In this example, `warehouse.example.com` is the only node asked to prepare.
2. Node `warehouse.example.com` tries to prepare. If a node can guarantee that it can commit the locally dependent part of the transaction and can record the commit information in its local redo log, then the node can successfully prepare. In this example, only `warehouse.example.com` receives a prepare message because `sales.example.com` is the commit point site.
3. Node `warehouse.example.com` responds to `sales.example.com` with a prepared message.

As each node prepares, it sends a message back to the node that asked it to prepare. Depending on the responses, one of the following can happen:

- If *any* of the nodes asked to prepare responds with an abort message to the global coordinator, then the global coordinator tells all nodes to roll back the transaction, and the operation is completed.
- If *all* nodes asked to prepare respond with a prepared or a read-only message to the global coordinator, that is, they have successfully prepared, then the global coordinator asks the commit point site to commit the transaction.

**Figure 34-9 Sending and Acknowledging the Prepare Message**

### 34.5.5 Stage 4: Commit Point Site Commits

An example illustrates the fourth stage in distributed transaction processing.

The committing of the transaction by the commit point site involves the following steps:

1. Node `sales.example.com`, receiving acknowledgment that `warehouse.example.com` is prepared, instructs the commit point site to commit the transaction.
2. The commit point site now commits the transaction locally and records this fact in its local redo log.

Even if `warehouse.example.com` has not yet committed, the outcome of this transaction is predetermined. In other words, the transaction *will* be committed at all nodes even if the ability of a given node to commit is delayed.

### 34.5.6 Stage 5: Commit Point Site Informs Global Coordinator of Commit

An example illustrates the fifth stage in distributed transaction processing.

This stage involves the following steps:

1. The commit point site tells the global coordinator that the transaction has committed. Because the commit point site and global coordinator are the same node in this example, no operation is required. The commit point site knows that the transaction is committed because it recorded this fact in its online log.
2. The global coordinator confirms that the transaction has been committed on all other nodes involved in the distributed transaction.

### 34.5.7 Stage 6: Global and Local Coordinators Tell All Nodes to Commit

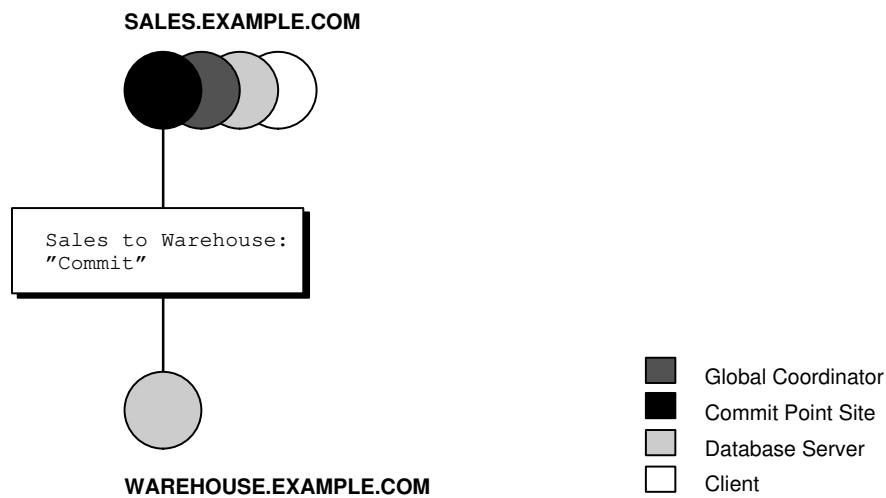

An example illustrates the sixth stage in distributed transaction processing.

The committing of the transaction by all the nodes in the transaction involves the following steps:

1. After the global coordinator has been informed of the commit at the commit point site, it tells all other directly referenced nodes to commit.
2. In turn, any local coordinators instruct their servers to commit, and so on.
3. Each node, including the global coordinator, commits the transaction and records appropriate redo log entries locally. As each node commits, the resource locks that were being held locally for that transaction are released.

In [Figure 34-10](#), sales.example.com, which is both the commit point site and the global coordinator, has already committed the transaction locally. sales now instructs warehouse.example.com to commit the transaction.

**Figure 34-10 Instructing Nodes to Commit**

### 34.5.8 Stage 7: Global Coordinator and Commit Point Site Complete the Commit

An example illustrates the seventh stage in distributed transaction processing.

The completion of the commit of the transaction occurs in the following steps:

1. After all referenced nodes and the global coordinator have committed the transaction, the global coordinator informs the commit point site of this fact.
2. The commit point site, which has been waiting for this message, erases the status information about this distributed transaction.

3. The commit point site informs the global coordinator that it is finished. In other words, the commit point site forgets about committing the distributed transaction. This action is permissible because all nodes involved in the two-phase commit have committed the transaction successfully, so they will never have to determine its status in the future.
4. The global coordinator finalizes the transaction by forgetting about the transaction itself.

After the completion of the COMMIT phase, the distributed transaction is itself complete. The steps described are accomplished automatically and in a fraction of a second.

# Managing Distributed Transactions

Managing distributed transactions includes tasks such as specifying the commit point strength of a node, naming transactions, and managing in-doubt transactions.

- [Specifying the Commit Point Strength of a Node](#)

The database with the highest commit point strength determines which node commits first in a distributed transaction.

- [Naming Transactions](#)

You can name a transaction. This is useful for identifying a specific distributed transaction and replaces the use of the `COMMIT COMMENT` statement for this purpose.

- [Viewing Information About Distributed Transactions](#)

The data dictionary of each database stores information about all open distributed transactions. You can use data dictionary tables and views to gain information about the transactions.

- [Deciding How to Handle In-Doubt Transactions](#)

A transaction is in-doubt when there is a failure during any aspect of the two-phase commit. Distributed transactions become in-doubt in the following ways: a server system running Oracle Database software crashes, a network connection between two or more Oracle Databases involved in distributed processing is disconnected, or an unhandled software error occurs.

- [Manually Overriding In-Doubt Transactions](#)

Use the `COMMIT` or `ROLLBACK` statement with the `FORCE` option and a text string that indicates either the local or global transaction ID of the in-doubt transaction to commit.

- [Purging Pending Rows from the Data Dictionary](#)

You can purge pending rows from the data dictionary for in-doubt transactions.

- [Manually Committing an In-Doubt Transaction: Example](#)

An example illustrates manually committing an in-doubt transaction.

- [Data Access Failures Due to Locks](#)

When you issue a SQL statement, the database attempts to lock the resources needed to successfully execute the statement. If the requested data is currently held by statements of other uncommitted transactions, however, and remains locked for a long time, a timeout occurs.

- [Simulating Distributed Transaction Failure](#)

You can force the failure of a distributed transaction to observe RECO automatically resolving the local portion of the transaction or to practice manually resolving in-doubt distributed transactions and observing the results.

- [Managing Read Consistency](#)

An important restriction exists in the Oracle Database implementation of distributed read consistency.

## 35.1 Specifying the Commit Point Strength of a Node

The database with the highest commit point strength determines which node commits first in a distributed transaction.

When specifying a commit point strength for each node, ensure that the most critical server will be non-blocking if a failure occurs during a prepare or commit phase. The COMMIT\_POINT\_STRENGTH initialization parameter determines the commit point strength of a node.

The default value is operating system-dependent. The range of values is any integer from 0 to 255. For example, to set the commit point strength of a database to 200, include the following line in the database initialization parameter file:

```
COMMIT_POINT_STRENGTH = 200
```

The commit point strength is only used to determine the commit point site in a distributed transaction.

When setting the commit point strength for a database, note the following considerations:

- Because the commit point site stores information about the status of the transaction, the commit point site should not be a node that is frequently unreliable or unavailable in case other nodes need information about transaction status.
- Set the commit point strength for a database relative to the amount of critical shared data in the database. For example, a database on a mainframe computer usually shares more data among users than a database on a PC. Therefore, set the commit point strength of the mainframe to a higher value than the PC.

### See Also:

"[Commit Point Site](#)" for a conceptual overview of commit points

## 35.2 Naming Transactions

You can name a transaction. This is useful for identifying a specific distributed transaction and replaces the use of the COMMIT COMMENT statement for this purpose.

To name a transaction, use the SET TRANSACTION...NAME statement. For example:

```
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE
 NAME 'update inventory checkpoint 0';
```

This example shows that the user started a new transaction with isolation level equal to SERIALIZABLE and named it 'update inventory checkpoint 0'.

For distributed transactions, the name is sent to participating sites when a transaction is committed. If a COMMIT COMMENT exists, it is ignored when a transaction name exists.

The transaction name is displayed in the NAME column of the V\$TRANSACTION view, and in the TRAN\_COMMENT field of the DBA\_2PC\_PENDING view when the transaction is committed.

## 35.3 Viewing Information About Distributed Transactions

The data dictionary of each database stores information about all open distributed transactions. You can use data dictionary tables and views to gain information about the transactions.

- **Determining the ID Number and Status of Prepared Transactions**

Use the `DBA_2PC_PENDING` view to determine the global commit number for a particular transaction ID. You can use this global commit number when manually resolving an in-doubt transaction.

- **Tracing the Session Tree of In-Doubt Transactions**

The `DBA_2PC_NEIGHBORS` view shows which in-doubt transactions are incoming from a remote client and which are outgoing to a remote server.

### 35.3.1 Determining the ID Number and Status of Prepared Transactions

Use the `DBA_2PC_PENDING` view to determine the global commit number for a particular transaction ID. You can use this global commit number when manually resolving an in-doubt transaction.

The following view shows the database links that have been defined at the local database and stored in the data dictionary:

| View                         | Purpose                                                                                                                                                           |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DBA_2PC_PENDING</code> | Lists all in-doubt distributed transactions. The view is empty until populated by an in-doubt transaction. After the transaction is resolved, the view is purged. |

The following table shows the most relevant columns (for a description of all the columns in the view, see *Oracle Database Reference*):

**Table 35-1 DBA\_2PC\_PENDING**

| Column                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>LOCAL_TRAN_ID</code>  | Local transaction identifier in the format <code>integer.integer.integer</code> .<br><b>Note:</b> When the <code>LOCAL_TRAN_ID</code> and the <code>GLOBAL_TRAN_ID</code> for a connection are the same, the node is the global coordinator of the transaction.                                                                                                                                                                                                               |
| <code>GLOBAL_TRAN_ID</code> | Global database identifier in the format <code>global_db_name.db_hex_id.local_tran_id</code> , where <code>db_hex_id</code> is an eight-character hexadecimal value used to uniquely identify the database. This common transaction ID is the same on every node for a distributed transaction.<br><b>Note:</b> When the <code>LOCAL_TRAN_ID</code> and the <code>GLOBAL_TRAN_ID</code> for a connection are the same, the node is the global coordinator of the transaction. |

**Table 35-1 (Cont.) DBA\_2PC\_PENDING**

| Column       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATE        | <p>STATE can have the following values:</p> <ul style="list-style-type: none"> <li>• Collecting<br/>This category normally applies only to the global coordinator or local coordinators. The node is currently collecting information from other database servers before it can decide whether it can prepare.</li> <li>• Prepared<br/>The node has prepared and may or may not have acknowledged this to its local coordinator with a prepared message. However, no commit request has been received. The node remains prepared, holding any local resource locks necessary for the transaction to commit.</li> <li>• Committed<br/>The node (any type) has committed the transaction, but other nodes involved in the transaction may not have done the same. That is, the transaction is still pending at one or more nodes.</li> <li>• Forced Commit<br/>A pending transaction can be forced to commit at the discretion of a database administrator. This entry occurs if a transaction is manually committed at a local node.</li> <li>• Forced termination (rollback)<br/>A pending transaction can be forced to roll back at the discretion of a database administrator. This entry occurs if this transaction is manually rolled back at a local node.</li> </ul> |
| MIXED        | YES means that part of the transaction was committed on one node and rolled back on another node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| TRAN_COMMENT | Transaction comment or, if using transaction naming, the transaction name is placed here when the transaction is committed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| HOST         | Name of the host system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| COMMIT#      | Global commit number for committed transactions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Execute the following script, named `pending_txn_script`, to query pertinent information in `DBA_2PC_PENDING` (sample output included):

```

COL LOCAL_TRAN_ID FORMAT A13
COL GLOBAL_TRAN_ID FORMAT A30
COL STATE FORMAT A8
COL MIXED FORMAT A3
COL HOST FORMAT A10
COL COMMIT# FORMAT A10

SELECT LOCAL_TRAN_ID, GLOBAL_TRAN_ID, STATE, MIXED, HOST, COMMIT#
 FROM DBA_2PC_PENDING
/
SQL> @pending_txn_script

```

| LOCAL_TRAN_ID | GLOBAL_TRAN_ID | STATE | MIX | HOST | COMMIT# |
|---------------|----------------|-------|-----|------|---------|
|---------------|----------------|-------|-----|------|---------|

---

```

1.15.870 HQ.EXAMPLE.COM.ef192da4.1.15.870 commit no dlsun183 115499
```

This output indicates that local transaction 1.15.870 has been committed on this node, but it may be pending on one or more other nodes. Because LOCAL\_TRAN\_ID and the local part of GLOBAL\_TRAN\_ID are the same, the node is the global coordinator of the transaction.

### 35.3.2 Tracing the Session Tree of In-Doubt Transactions

The DBA\_2PC\_NEIGHBORS view shows which in-doubt transactions are incoming from a remote client and which are outgoing to a remote server.

---

| View              | Purpose                                                                                                                                                                                                                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DBA_2PC_NEIGHBORS | <p>Lists all incoming (from remote client) and outgoing (to remote server) in-doubt distributed transactions. It also indicates whether the local node is the commit point site in the transaction.</p> <p>The view is empty until populated by an in-doubt transaction. After the transaction is resolved, the view is purged.</p> |

---

When a transaction is in-doubt, you may need to determine which nodes performed which roles in the session tree. Use this view to determine:

- All the incoming and outgoing connections for a given transaction
- Whether the node is the commit point site in a given transaction
- Whether the node is a global coordinator in a given transaction (because its local transaction ID and global transaction ID are the same)

The following table shows the most relevant columns (for an account of all the columns in the view, see *Oracle Database Reference*):

**Table 35-2 DBA\_2PC\_NEIGHBORS**

---

| Column        | Description                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOCAL_TRAN_ID | Local transaction identifier with the format <i>integer.integer.integer</i> .<br><b>Note:</b> When LOCAL_TRAN_ID and GLOBAL_TRAN_ID.DBA_2PC_PENDING for a connection are the same, the node is the global coordinator of the transaction. |
| IN_OUT        | IN for incoming transactions; OUT for outgoing transactions.                                                                                                                                                                              |
| DATABASE      | For incoming transactions, the name of the client database that requested information from this local node; for outgoing transactions, the name of the database link used to access information on a remote server.                       |
| DBUSER_OWNER  | For incoming transactions, the local account used to connect by the remote database link; for outgoing transactions, the owner of the database link.                                                                                      |

---

**Table 35-2 (Cont.) DBA\_2PC\_NEIGHBORS**

| Column    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INTERFACE | C is a commit message; N is either a message indicating a prepared state or a request for a read-only commit.<br><br>When IN_OUT is OUT, C means that the child at the remote end of the connection is the commit point site and knows whether to commit or terminate. N means that the local node is informing the remote node that it is prepared.<br><br>When IN_OUT is IN, C means that the local node or a database at the remote end of an outgoing connection is the commit point site. N means that the remote node is informing the local node that it is prepared. |

Execute the following script, named `neighbors_script`, to query pertinent information in `DBA_2PC_PENDING` (sample output included):

```

COL LOCAL_TRAN_ID FORMAT A13
COL IN_OUT FORMAT A6
COL DATABASE FORMAT A25
COL DBUSER_OWNER FORMAT A15
COL INTERFACE FORMAT A3
SELECT LOCAL_TRAN_ID, IN_OUT, DATABASE, DBUSER_OWNER, INTERFACE
 FROM DBA_2PC_NEIGHBORS
/
SQL> CONNECT SYS@hq.example.com AS SYSDBA
SQL> @neighbors_script

LOCAL_TRAN_ID IN_OUT DATABASE DBUSER_OWNER INT
----- ----- -----
1.15.870 out SALES.EXAMPLE.COM SYS C

```

This output indicates that the local node sent an outgoing request to remote server sales to commit transaction 1.15.870. If sales committed the transaction but no other node did, then you know that sales is the commit point site, because the commit point site always commits first.

## 35.4 Deciding How to Handle In-Doubt Transactions

A transaction is in-doubt when there is a failure during any aspect of the two-phase commit. Distributed transactions become in-doubt in the following ways: a server system running Oracle Database software crashes, a network connection between two or more Oracle Databases involved in distributed processing is disconnected, or an unhandled software error occurs.

You can manually force the commit or rollback of a local, in-doubt distributed transaction. Because this operation can generate consistency problems, perform it only when specific conditions exist.

- [Discovering Problems with a Two-Phase Commit](#)  
Error messages inform applications when there are problems with distributed transactions.

- [Determining Whether to Perform a Manual Override](#)  
You should override an in-doubt transaction only under certain conditions.
- [Analyzing the Transaction Data](#)  
If you decide to force the transaction to complete, then analyze the available information.

 **See Also:**

[In-Doubt Transactions](#)

### 35.4.1 Discovering Problems with a Two-Phase Commit

Error messages inform applications when there are problems with distributed transactions.

The user application that commits a distributed transaction is informed of a problem by one of the following error messages:

ORA-02050: transaction *ID* rolled back,  
some remote dbs may be in-doubt  
ORA-02053: transaction *ID* committed,  
some remote dbs may be in-doubt  
ORA-02054: transaction *ID* in-doubt

A robust application should save information about a transaction if it receives any of the preceding errors. This information can be used later if manual distributed transaction recovery is desired.

No action is required by the administrator of any node that has one or more in-doubt distributed transactions due to a network or system failure. The automatic recovery features of the database transparently complete any in-doubt transaction so that the same outcome occurs on all nodes of a session tree (that is, all commit or all roll back) after the network or system failure is resolved.

In extended outages, however, you can force the commit or rollback of a transaction to release any locked data. Applications must account for such possibilities.

### 35.4.2 Determining Whether to Perform a Manual Override

You should override an in-doubt transaction only under certain conditions.

Override a specific in-doubt transaction manually *only* when one of the following conditions exists:

- The in-doubt transaction locks data that is required by other transactions. This situation occurs when the ORA-01591 error message interferes with user transactions.
- An in-doubt transaction prevents the extents of an undo segment from being used by other transactions. The first portion of the local transaction ID of an in-doubt distributed transaction corresponds to the ID of the undo segment, as listed by the data dictionary view DBA\_2PC\_PENDING.
- The failure preventing the two-phase commit phases to complete cannot be corrected in an acceptable time period. Examples of such cases include a

telecommunication network that has been damaged or a damaged database that requires a long recovery time.

Normally, you should decide to locally force an in-doubt distributed transaction in consultation with administrators at other locations. A wrong decision can lead to database inconsistencies that can be difficult to trace and that you must manually correct.

If none of these conditions apply, *always* allow the automatic recovery features of the database to complete the transaction. If any of these conditions are met, however, consider a local override of the in-doubt transaction.

### 35.4.3 Analyzing the Transaction Data

If you decide to force the transaction to complete, then analyze the available information.

- [Find a Node that Committed or Rolled Back](#)  
Use the `DBA_2PC_PENDING` view to find a node that has either committed or rolled back the transaction.
- [Look for Transaction Comments](#)  
See if any information is given in the `TRAN_COMMENT` column of `DBA_2PC_PENDING` for the distributed transaction.
- [Look for Transaction Advice](#)  
See if any information is given in the `ADVICE` column of `DBA_2PC_PENDING` for the distributed transaction.

#### 35.4.3.1 Find a Node that Committed or Rolled Back

Use the `DBA_2PC_PENDING` view to find a node that has either committed or rolled back the transaction.

If you can find a node that has already resolved the transaction, then you can follow the action taken at that node.

#### 35.4.3.2 Look for Transaction Comments

See if any information is given in the `TRAN_COMMENT` column of `DBA_2PC_PENDING` for the distributed transaction.

Comments are included in the `COMMENT` clause of the `COMMIT` statement, or if transaction naming is used, the transaction name is placed in the `TRAN_COMMENT` field when the transaction is committed.

For example, the comment of an in-doubt distributed transaction can indicate the origin of the transaction and what type of transaction it is:

```
COMMIT COMMENT 'Finance/Accts_pay/Trans_type 10B';
```

The `SET TRANSACTION...NAME` statement could also have been used (and is preferable) to provide this information in a transaction name.

 **See Also:**

"[Naming Transactions](#)"

### 35.4.3.3 Look for Transaction Advice

See if any information is given in the `ADVICE` column of `DBA_2PC_PENDING` for the distributed transaction.

An application can prescribe advice about whether to force the commit or force the rollback of separate parts of a distributed transaction with the `ADVISE` clause of the `ALTER SESSION` statement.

The advice sent during the prepare phase to each node is the advice in effect at the time the most recent DML statement executed at that database in the current transaction.

For example, consider a distributed transaction that moves an employee record from the `emp` table at one node to the `emp` table at another node. The transaction can protect the record--even when administrators independently force the in-doubt transaction at each node--by including the following sequence of SQL statements:

```
ALTER SESSION ADVISE COMMIT;
INSERT INTO emp@hq ... ; /*advice to commit at HQ */
ALTER SESSION ADVISE ROLLBACK;
DELETE FROM emp@sales ... ; /*advice to roll back at SALES*/
ALTER SESSION ADVISE NOTHING;
```

If you manually force the in-doubt transaction following the given advice, the worst that can happen is that each node has a copy of the employee record; the record cannot disappear.

## 35.5 Manually Overriding In-Doubt Transactions

Use the `COMMIT` or `ROLLBACK` statement with the `FORCE` option and a text string that indicates either the local or global transaction ID of the in-doubt transaction to commit.

 **Note:**

In all examples, the transaction is committed or rolled back on the local node, and the local pending transaction table records a value of forced commit or forced termination for the `STATE` column the row for this transaction.

- [Manually Committing an In-Doubt Transaction](#)  
You can manually commit an in-doubt transaction using a transaction ID or an SCN.
- [Manually Rolling Back an In-Doubt Transaction](#)  
You can roll back an in-doubt transaction using the transaction ID.

## 35.5.1 Manually Committing an In-Doubt Transaction

You can manually commit an in-doubt transaction using a transaction ID or an SCN.

- [Privileges Required to Commit an In-Doubt Transaction](#)

Before attempting to commit the transaction, ensure that you have the proper privileges.

- [Committing Using Only the Transaction ID](#)

You can commit an in-doubt transaction using the transaction ID.

- [Committing Using an SCN](#)

You can commit an in-doubt transaction using an SCN.

### 35.5.1.1 Privileges Required to Commit an In-Doubt Transaction

Before attempting to commit the transaction, ensure that you have the proper privileges.

Note the following requirements:

| User Committing the Transaction | Privilege Required    |
|---------------------------------|-----------------------|
| You                             | FORCE TRANSACTION     |
| Another user                    | FORCE ANY TRANSACTION |

### 35.5.1.2 Committing Using Only the Transaction ID

You can commit an in-doubt transaction using the transaction ID.

The following SQL statement commits an in-doubt transaction:

```
COMMIT FORCE 'transaction_id';
```

The variable *transaction\_id* is the identifier of the transaction as specified in either the LOCAL\_TRAN\_ID or GLOBAL\_TRAN\_ID columns of the DBA\_2PC\_PENDING data dictionary view.

For example, assume that you query DBA\_2PC\_PENDING and determine that LOCAL\_TRAN\_ID for a distributed transaction is 1:45.13.

You then issue the following SQL statement to force the commit of this in-doubt transaction:

```
COMMIT FORCE '1.45.13';
```

### 35.5.1.3 Committing Using an SCN

You can commit an in-doubt transaction using an SCN.

Optionally, you can specify the SCN for the transaction when forcing a transaction to commit. This feature lets you commit an in-doubt transaction with the SCN assigned when it was committed at other nodes.

Consequently, you maintain the synchronized commit time of the distributed transaction even if there is a failure. Specify an SCN only when you can determine the SCN of the same transaction already committed at another node.

For example, assume you want to manually commit a transaction with the following global transaction ID:

```
SALES.EXAMPLE.COM.55d1c563.1.93.29
```

First, query the `DBA_2PC_PENDING` view of a remote database also involved with the transaction in question. Note the SCN used for the commit of the transaction at that node. Specify the SCN when committing the transaction at the local node. For example, if the SCN is 829381993, issue:

```
COMMIT FORCE 'SALES.EXAMPLE.COM.55d1c563.1.93.29', 829381993;
```

 **See Also:**

*Oracle Database SQL Language Reference* for more information about using the `COMMIT` statement

### 35.5.2 Manually Rolling Back an In-Doubt Transaction

You can roll back an in-doubt transaction using the transaction ID.

Before attempting to roll back the in-doubt distributed transaction, ensure that you have the proper privileges. Note the following requirements:

| User Committing the Transaction | Privilege Required    |
|---------------------------------|-----------------------|
| You                             | FORCE TRANSACTION     |
| Another user                    | FORCE ANY TRANSACTION |

The following SQL statement rolls back an in-doubt transaction:

```
ROLLBACK FORCE 'transaction_id';
```

The variable `transaction_id` is the identifier of the transaction as specified in either the `LOCAL_TRAN_ID` or `GLOBAL_TRAN_ID` columns of the `DBA_2PC_PENDING` data dictionary view.

For example, to roll back the in-doubt transaction with the local transaction ID of 2.9.4, use the following statement:

```
ROLLBACK FORCE '2.9.4';
```

 **Note:**

You cannot roll back an in-doubt transaction to a savepoint.

 **See Also:**

*Oracle Database SQL Language Reference* for more information about using the ROLLBACK statement

## 35.6 Purging Pending Rows from the Data Dictionary

You can purge pending rows from the data dictionary for in-doubt transactions.

- [About Purging Pending Rows from the Data Dictionary](#)

You can purge pending rows from the data dictionary for in-doubt transactions using the DBMS\_TRANSACTION.PURGE\_MIXED procedure or the DBMS\_TRANSACTION.PURGE\_LOST\_DB\_ENTRY procedure.

- [Executing the PURGE\\_LOST\\_DB\\_ENTRY Procedure](#)

Use the DBMS\_TRANSACTION.PURGE\_LOST\_DB\_ENTRY procedure to clean up entries for in-doubt transactions in the data dictionary.

- [Determining When to Use DBMS\\_TRANSACTION](#)

You typically should perform a specific action based on the state of a distributed transaction.

### 35.6.1 About Purging Pending Rows from the Data Dictionary

You can purge pending rows from the data dictionary for in-doubt transactions using the DBMS\_TRANSACTION.PURGE\_MIXED procedure or the DBMS\_TRANSACTION.PURGE\_LOST\_DB\_ENTRY procedure.

Before RECO recovers an in-doubt transaction, the transaction appears in DBA\_2PC\_PENDING.STATE as COLLECTING, COMMITTED, or PREPARED. If you force an in-doubt transaction using COMMIT FORCE or ROLLBACK FORCE, then the states FORCED COMMIT or FORCED ROLLBACK may appear.

Automatic recovery normally deletes entries in these states. The only exception is when recovery discovers a forced transaction that is in a state inconsistent with other sites in the transaction. In this case, the entry can be left in the table, and the MIXED column in DBA\_2PC\_PENDING has a value of YES. These entries can be cleaned up with the DBMS\_TRANSACTION.PURGE\_MIXED procedure.

If automatic recovery is not possible because a remote database has been permanently lost, then recovery cannot identify the re-created database because it receives a new database ID when it is re-created. In this case, you must use the PURGE\_LOST\_DB\_ENTRY procedure in the DBMS\_TRANSACTION package to clean up the entries. The entries do not hold up database resources, so there is no urgency in cleaning them up.

 **See Also:**

*Oracle Database PL/SQL Packages and Types Reference* for more information about the DBMS\_TRANSACTION package

## 35.6.2 Executing the PURGE\_LOST\_DB\_ENTRY Procedure

Use the `DBMS_TRANSACTION.PURGE_LOST_DB_ENTRY` procedure to clean up entries for in-doubt transactions in the data dictionary.

To manually remove an entry from the data dictionary, use the following syntax (where `trans_id` is the identifier for the transaction):

```
DBMS_TRANSACTION.PURGE_LOST_DB_ENTRY('trans_id');
```

For example, to purge pending distributed transaction 1.44.99, enter the following statement in SQL\*Plus:

```
EXECUTE DBMS_TRANSACTION.PURGE_LOST_DB_ENTRY('1.44.99');
```

Execute this procedure only if significant reconfiguration has occurred so that automatic recovery cannot resolve the transaction. Examples include:

- Total loss of the remote database
- Reconfiguration in software resulting in loss of two-phase commit capability
- Loss of information from an external transaction coordinator such as a TPMonitor

## 35.6.3 Determining When to Use DBMS\_TRANSACTION

You typically should perform a specific action based on the state of a distributed transaction.

The following tables indicates what the various states indicate about the distributed transaction and what the administrator's action should be:

| STATE Column    | State of Global Transaction | State of Local Transaction | Normal Action | Alternative Action                                                    |
|-----------------|-----------------------------|----------------------------|---------------|-----------------------------------------------------------------------|
| Collecting      | Rolled back                 | Rolled back                | None          | PURGE_LOST_DB_ENTRY (only if autorecovery cannot resolve transaction) |
| Committed       | Committed                   | Committed                  | None          | PURGE_LOST_DB_ENTRY (only if autorecovery cannot resolve transaction) |
| Prepared        | Unknown                     | Prepared                   | None          | Force commit or rollback                                              |
| Forced commit   | Unknown                     | Committed                  | None          | PURGE_LOST_DB_ENTRY (only if autorecovery cannot resolve transaction) |
| Forced rollback | Unknown                     | Rolled back                | None          | PURGE_LOST_DB_ENTRY (only if autorecovery cannot resolve transaction) |

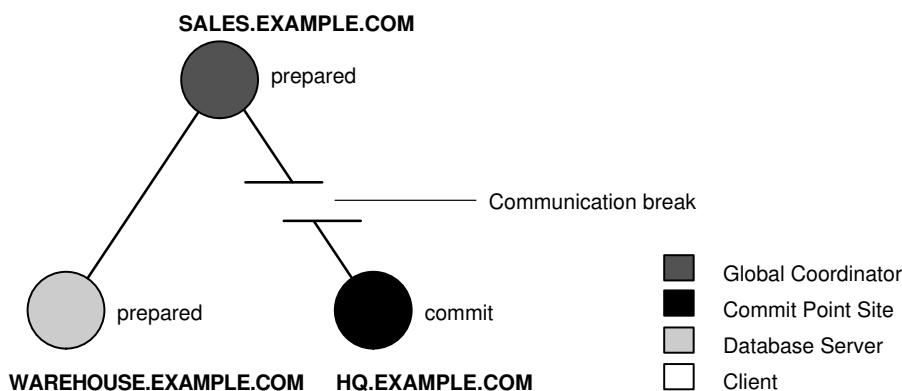

| STATE Column    | State of Global Transaction | State of Local Transaction | Normal Action                                        | Alternative Action |
|-----------------|-----------------------------|----------------------------|------------------------------------------------------|--------------------|
| Forced commit   | Mixed                       | Committed                  | Manually remove inconsistencies then use PURGE_MIXED | -                  |
| Forced rollback | Mixed                       | Rolled back                | Manually remove inconsistencies then use PURGE_MIXED | -                  |

## 35.7 Manually Committing an In-Doubt Transaction: Example

An example illustrates manually committing an in-doubt transaction.

[Figure 35-1](#), illustrates a failure during the commit of a distributed transaction. In this failure case, the prepare phase completes. During the commit phase, however, the commit confirmation of the commit point site never reaches the global coordinator, even though the commit point site committed the transaction. Inventory data is locked and cannot be accessed because the in-doubt transaction is critical to other transactions. Further, the locks must be held until the in-doubt transaction either commits or rolls back.

**Figure 35-1 Example of an In-Doubt Distributed Transaction**

You can manually force the local portion of the in-doubt transaction.

- [Step 1: Record User Feedback](#)  
An example illustrates recording user feedback for an in-doubt transaction.
- [Step 2: Query DBA\\_2PC\\_PENDING](#)  
An example illustrates querying the DBA\_2PC\_PENDING data dictionary view for information about in-doubt transactions.

- **Step 3: Query DBA\_2PC\_NEIGHBORS on Local Node**  
The purpose of this step is to climb the session tree so that you find coordinators, eventually reaching the global coordinator.
- **Step 4: Querying Data Dictionary Views on All Nodes**  
At this point, you can contact the administrator at the located nodes and ask each person to repeat Steps 2 and 3 using the global transaction ID.
- **Step 5: Commit the In-Doubt Transaction**  
Use the global ID to commit the in-doubt transaction.
- **Step 6: Check for Mixed Outcome Using DBA\_2PC\_PENDING**  
After you manually force a transaction to commit or roll back, the corresponding row in the pending transaction table remains. The state of the transaction is changed depending on how you forced the transaction.

### 35.7.1 Step 1: Record User Feedback

An example illustrates recording user feedback for an in-doubt transaction.

The users of the local database system that conflict with the locks of the in-doubt transaction receive the following error message:

```
ORA-01591: lock held by in-doubt distributed transaction 1.21.17
```

In this case, 1.21.17 is the local transaction ID of the in-doubt distributed transaction. You should request and record this ID number from users that report problems to identify which in-doubt transactions should be forced.

### 35.7.2 Step 2: Query DBA\_2PC\_PENDING

An example illustrates querying the DBA\_2PC\_PENDING data dictionary view for information about in-doubt transactions.

After connecting with SQL\*Plus to `warehouse`, query the local DBA\_2PC\_PENDING data dictionary view to gain information about the in-doubt transaction:

```
CONNECT SYS@warehouse.example.com AS SYSDBA
SELECT * FROM DBA_2PC_PENDING WHERE LOCAL_TRAN_ID = '1.21.17';
```

The database returns the following information:

| Column Name    | Value                              |
|----------------|------------------------------------|
| LOCAL_TRAN_ID  | 1.21.17                            |
| GLOBAL_TRAN_ID | SALES.EXAMPLE.COM.55d1c563.1.93.29 |
| STATE          | prepared                           |
| MIXED          | no                                 |
| ADVICE         |                                    |
| TRAN_COMMENT   | Sales/New Order/Trans_type 10B     |
| FAIL_TIME      | 31-MAY-91                          |
| FORCE_TIME     |                                    |
| RETRY_TIME     | 31-MAY-91                          |
| OS_USER        | SWILLIAMS                          |
| OS_TERMINAL    | TWA139:                            |
| HOST           | system1                            |
| DB_USER        | SWILLIAMS                          |
| COMMIT#        |                                    |

- **Determining the Global Transaction ID**  
The global transaction ID is the common transaction ID that is the same on every node for a distributed transaction.
- **Determining the State of the Transaction**  
The STATE column of the DBA\_2PC\_PENDING data dictionary view shows the state of the transaction.
- **Looking for Comments or Advice**  
The TRANS\_COMMENT column of the DBA\_2PC\_PENDING data dictionary view shows the comment included for the transaction, while the ADVICE column provides advice.

### 35.7.2.1 Determining the Global Transaction ID

The global transaction ID is the common transaction ID that is the same on every node for a distributed transaction.

It is of the form:

*global\_database\_name.hhhhhhhh.local\_transaction\_id*

where:

- *global\_database\_name* is the database name of the global coordinator.
- *hhhhhhhh* is the internal database identifier of the global coordinator (in hexadecimal).
- *local\_transaction\_id* is the corresponding local transaction ID assigned on the global coordinator.

Note that the last portion of the global transaction ID and the local transaction ID match at the global coordinator. In the example, you can tell that *warehouse* is *not* the global coordinator because these numbers do not match:

|                |             |
|----------------|-------------|
| LOCAL_TRAN_ID  | 1.21.17     |
| GLOBAL_TRAN_ID | ... 1.93.29 |

### 35.7.2.2 Determining the State of the Transaction

The STATE column of the DBA\_2PC\_PENDING data dictionary view shows the state of the transaction.

The transaction on this node is in a prepared state:

|       |          |
|-------|----------|
| STATE | prepared |
|-------|----------|

Therefore, *warehouse* waits for its coordinator to send either a commit or a rollback request.

### 35.7.2.3 Looking for Comments or Advice

The TRANS\_COMMENT column of the DBA\_2PC\_PENDING data dictionary view shows the comment included for the transaction, while the ADVICE column provides advice.

The transaction comment or advice can include information about this transaction. If so, use this comment to your advantage. In this example, the origin and transaction type is in the transaction comment:

|              |                                |
|--------------|--------------------------------|
| TRAN_COMMENT | Sales/New Order/Trans_type 10B |
|--------------|--------------------------------|

It could also be provided as a transaction name with a `SET TRANSACTION...NAME` statement.

This information can reveal something that helps you decide whether to commit or rollback the local portion of the transaction. If useful comments do not accompany an in-doubt transaction, you must complete some extra administrative work to trace the session tree and find a node that has resolved the transaction.

### 35.7.3 Step 3: Query DBA\_2PC\_NEIGHBORS on Local Node

The purpose of this step is to climb the session tree so that you find coordinators, eventually reaching the global coordinator.

Along the way, you may find a coordinator that has resolved the transaction. If not, you can eventually work your way to the commit point site, which will always have resolved the in-doubt transaction. To trace the session tree, query the `DBA_2PC_NEIGHBORS` view on each node.

In this case, you query this view on the `warehouse` database:

```
CONNECT SYS@warehouse.example.com AS SYSDBA
SELECT * FROM DBA_2PC_NEIGHBORS
WHERE LOCAL_TRAN_ID = '1.21.17'
ORDER BY SESS#, IN_OUT;
```

| Column Name   | Value             |
|---------------|-------------------|
| LOCAL_TRAN_ID | 1.21.17           |
| IN_OUT        | in                |
| DATABASE      | SALES.EXAMPLE.COM |
| DBUSER_OWNER  | SWILLIAMS         |
| INTERFACE     | N                 |
| DBID          | 000003F4          |
| SESS#         | 1                 |
| BRANCH        | 0100              |

- [Obtaining Database Role and Database Link Information](#)

The `DBA_2PC_NEIGHBORS` view provides information about connections associated with an in-doubt transaction.

- [Determining the Commit Point Site](#)

The `INTERFACE` column tells whether the local node or a subordinate node is the commit point site.

#### 35.7.3.1 Obtaining Database Role and Database Link Information

The `DBA_2PC_NEIGHBORS` view provides information about connections associated with an in-doubt transaction.

Information for each connection is different, based on whether the connection is **inbound** (`IN_OUT = in`) or **outbound** (`IN_OUT = out`):

| IN_OUT | Meaning                                 | DATABASE                                                              | DBUSER_OWNER                                                                                           |
|--------|-----------------------------------------|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| in     | Your node is a server of another node.  | Lists the name of the client database that connected to your node.    | Lists the local account for the database link connection that corresponds to the in-doubt transaction. |
| out    | Your node is a client of other servers. | Lists the name of the database link that connects to the remote node. | Lists the owner of the database link for the in-doubt transaction.                                     |

In this example, the IN\_OUT column reveals that the `warehouse` database is a server for the `sales` client, as specified in the DATABASE column:

|          |                   |
|----------|-------------------|
| IN_OUT   | in                |
| DATABASE | SALES.EXAMPLE.COM |

The connection to `warehouse` was established through a database link from the `swilliams` account, as shown by the DBUSER\_OWNER column:

|              |           |
|--------------|-----------|
| DBUSER_OWNER | SWILLIAMS |
|--------------|-----------|

### 35.7.3.2 Determining the Commit Point Site

The INTERFACE column tells whether the local node or a subordinate node is the commit point site.

|           |   |
|-----------|---|
| INTERFACE | N |
|-----------|---|

Neither `warehouse` nor any of its descendants is the commit point site, as shown by the INTERFACE column.

### 35.7.4 Step 4: Querying Data Dictionary Views on All Nodes

At this point, you can contact the administrator at the located nodes and ask each person to repeat Steps 2 and 3 using the global transaction ID.

 **Note:**

If you can directly connect to these nodes with another network, you can repeat Steps 2 and 3 yourself.

For example, the following results are returned when Steps 2 and 3 are performed at `sales` and `hq`.

- [Checking the Status of Pending Transactions at sales](#)

At this stage, the `sales` administrator queries the `DBA_2PC_PENDING` data dictionary view.

- [Determining the Coordinators and Commit Point Site at sales](#)

Next, the `sales` administrator queries `DBA_2PC_NEIGHBORS` to determine the global and local coordinators as well as the commit point site.

- **Checking the Status of Pending Transactions at HQ**  
At this stage, the `hq` administrator queries the `DBA_2PC_PENDING` data dictionary view.

### 35.7.4.1 Checking the Status of Pending Transactions at sales

At this stage, the `sales` administrator queries the `DBA_2PC_PENDING` data dictionary view.

```
SQL> CONNECT SYS@sales.example.com AS SYSDBA
SQL> SELECT * FROM DBA_2PC_PENDING
> WHERE GLOBAL_TRAN_ID = 'SALES.EXAMPLE.COM.55d1c563.1.93.29';
```

| Column Name    | Value                              |
|----------------|------------------------------------|
| LOCAL_TRAN_ID  | 1.93.29                            |
| GLOBAL_TRAN_ID | SALES.EXAMPLE.COM.55d1c563.1.93.29 |
| STATE          | prepared                           |
| MIXED          | no                                 |
| ADVICE         |                                    |
| TRAN_COMMENT   | Sales/New Order/Trans_type 10B     |
| FAIL_TIME      | 31-MAY-91                          |
| FORCE_TIME     |                                    |
| RETRY_TIME     | 31-MAY-91                          |
| OS_USER        | SWILLIAMS                          |
| OS_TERMINAL    | TWA139:                            |
| HOST           | system1                            |
| DB_USER        | SWILLIAMS                          |
| COMMIT#        |                                    |

### 35.7.4.2 Determining the Coordinators and Commit Point Site at sales

Next, the `sales` administrator queries `DBA_2PC_NEIGHBORS` to determine the global and local coordinators as well as the commit point site.

```
SELECT * FROM DBA_2PC_NEIGHBORS
WHERE GLOBAL_TRAN_ID = 'SALES.EXAMPLE.COM.55d1c563.1.93.29'
ORDER BY SESS#, IN_OUT;
```

This query returns three rows:

- The connection to `warehouse`
- The connection to `hq`
- The connection established by the user

Reformatted information corresponding to the rows for the `warehouse` connection appears below:

| Column Name   | Value                 |
|---------------|-----------------------|
| LOCAL_TRAN_ID | 1.93.29               |
| IN_OUT        | OUT                   |
| DATABASE      | WAREHOUSE.EXAMPLE.COM |
| DBUSER_OWNER  | SWILLIAMS             |
| INTERFACE     | N                     |
| DBID          | 55d1c563              |
| SESS#         | 1                     |
| BRANCH        | 1                     |

Reformatted information corresponding to the rows for the `hq` connection appears below:

| Column Name   | Value          |
|---------------|----------------|
| LOCAL_TRAN_ID | 1.93.29        |
| IN_OUT        | OUT            |
| DATABASE      | HQ.EXAMPLE.COM |
| DBUSER_OWNER  | ALLEN          |
| INTERFACE     | C              |
| DBID          | 00000390       |
| SESS#         | 1              |
| BRANCH        | 1              |

The information from the previous queries reveal the following:

- `sales` is the global coordinator because the local transaction ID and global transaction ID match.
- Two outbound connections are established from this node, but no inbound connections. `sales` is not the server of another node.
- `hq` or one of its servers is the commit point site.

### 35.7.4.3 Checking the Status of Pending Transactions at HQ

At this stage, the `hq` administrator queries the `DBA_2PC_PENDING` data dictionary view.

```
SELECT * FROM DBA_2PC_PENDING@hq.example.com
WHERE GLOBAL_TRAN_ID = 'SALES.EXAMPLE.COM.55d1c563.1.93.29';
```

| Column Name    | Value                              |
|----------------|------------------------------------|
| LOCAL_TRAN_ID  | 1.45.13                            |
| GLOBAL_TRAN_ID | SALES.EXAMPLE.COM.55d1c563.1.93.29 |
| STATE          | COMMIT                             |
| MIXED          | NO                                 |
| ACTION         |                                    |
| TRAN_COMMENT   | Sales/New Order/Trans_type 10B     |
| FAIL_TIME      | 31-MAY-91                          |
| FORCE_TIME     |                                    |
| RETRY_TIME     | 31-MAY-91                          |
| OS_USER        | SWILLIAMS                          |
| OS_TERMINAL    | TWA139:                            |
| HOST           | SYSTEM1                            |
| DB_USER        | SWILLIAMS                          |
| COMMIT#        | 129314                             |

At this point, you have found a node that resolved the transaction. As the view reveals, it has been committed and assigned a commit ID number:

|         |        |
|---------|--------|
| STATE   | COMMIT |
| COMMIT# | 129314 |

Therefore, you can force the in-doubt transaction to commit at your local database. It is a good idea to contact any other administrators you know that could also benefit from your investigation.

### 35.7.5 Step 5: Commit the In-Doubt Transaction

Use the global ID to commit the in-doubt transaction.

You contact the administrator of the `sales` database, who manually commits the in-doubt transaction using the global ID:

```
SQL> CONNECT SYS@sales.example.com AS SYSDBA
SQL> COMMIT FORCE 'SALES.EXAMPLE.COM.55d1c563.1.93.29';
```

As administrator of the `warehouse` database, you manually commit the in-doubt transaction using the global ID:

```
SQL> CONNECT SYS@warehouse.example.com AS SYSDBA
SQL> COMMIT FORCE 'SALES.EXAMPLE.COM.55d1c563.1.93.29';
```

### 35.7.6 Step 6: Check for Mixed Outcome Using DBA\_2PC\_PENDING

After you manually force a transaction to commit or roll back, the corresponding row in the pending transaction table remains. The state of the transaction is changed depending on how you forced the transaction.

Every Oracle Database has a **pending transaction table**. This is a special table that stores information about distributed transactions as they proceed through the two-phase commit phases. You can query the pending transaction table of a database through the `DBA_2PC_PENDING` data dictionary view (see "[Determining the ID Number and Status of Prepared Transactions](#)").

Also of particular interest in the pending transaction table is the mixed outcome flag as indicated in `DBA_2PC_PENDING.MIXED`. You can make the wrong choice if a pending transaction is forced to commit or roll back. For example, the local administrator rolls back the transaction, but the other nodes commit it. Incorrect decisions are detected automatically, and the damage flag for the corresponding pending transaction record is set (`MIXED=yes`).

The RECO (Recoverer) background process uses the information in the pending transaction table to finalize the status of in-doubt transactions. You can also use the information in the pending transaction table to manually override the automatic recovery procedures for pending distributed transactions.

All transactions automatically resolved by RECO are removed from the pending transaction table. Additionally, all information about in-doubt transactions correctly resolved by an administrator (as checked when RECO reestablishes communication) are automatically removed from the pending transaction table. However, all rows resolved by an administrator that result in a mixed outcome across nodes remain in the pending transaction table of all involved nodes until they are manually deleted using `DBMS_TRANSACTIONS.PURGE_MIXED`.

## 35.8 Data Access Failures Due to Locks

When you issue a SQL statement, the database attempts to lock the resources needed to successfully execute the statement. If the requested data is currently held by statements of other uncommitted transactions, however, and remains locked for a long time, a timeout occurs.

- **Transaction Timeouts**  
A DML statement that requires locks on a remote database can be blocked if another transaction own locks on the requested data.
- **Locks from In-Doubt Transactions**  
A query or DML statement that requires locks on a local database can be blocked indefinitely due to the locked resources of an in-doubt distributed transaction.

### 35.8.1 Transaction Timeouts

A DML statement that requires locks on a remote database can be blocked if another transaction own locks on the requested data.

If these locks continue to block the requesting SQL statement, then the following sequence of events occurs:

1. A timeout occurs.
2. The database rolls back the statement.
3. The database returns this error message to the user:

`ORA-02049: time-out: distributed transaction waiting for lock`

Because the transaction did not modify data, no actions are necessary as a result of the timeout. Applications should proceed as if a deadlock has been encountered. The user who executed the statement can try to reexecute the statement later. If the lock persists, then the user should contact an administrator to report the problem.

### 35.8.2 Locks from In-Doubt Transactions

A query or DML statement that requires locks on a local database can be blocked indefinitely due to the locked resources of an in-doubt distributed transaction.

In this case, the database issues the following error message:

`ORA-01591: lock held by in-doubt distributed transaction identifier`

In this case, the database rolls back the SQL statement immediately. The user who executed the statement can try to reexecute the statement later. If the lock persists, the user should contact an administrator to report the problem, *including* the ID of the in-doubt distributed transaction.

The chances of these situations occurring are rare considering the low probability of failures during the critical portions of the two-phase commit. Even if such a failure occurs, and assuming quick recovery from a network or system failure, problems are automatically resolved without manual intervention. Thus, problems usually resolve before they can be detected by users or database administrators.

## 35.9 Simulating Distributed Transaction Failure

You can force the failure of a distributed transaction to observe RECO automatically resolving the local portion of the transaction or to practice manually resolving in-doubt distributed transactions and observing the results.

- **Forcing a Distributed Transaction to Fail**  
You can include comments in the `COMMENT` parameter of the `COMMIT` statement.

- **Disabling and Enabling RECO**

The RECO background process of an Oracle Database instance automatically resolves failures involving distributed transactions. At exponentially growing time intervals, the RECO background process of a node attempts to recover the local portion of an in-doubt distributed transaction.

### 35.9.1 Forcing a Distributed Transaction to Fail

You can include comments in the `COMMENT` parameter of the `COMMIT` statement.

To intentionally induce a failure during the two-phase commit phases of a distributed transaction, include the following comment in the `COMMENT` parameter:

```
COMMIT COMMENT 'ORA-2PC-CRASH-TEST-n';
```

where *n* is one of the following integers:

| <b>n</b> | <b>Effect</b>                                |
|----------|----------------------------------------------|
| 1        | Crash commit point after collect             |
| 2        | Crash non-commit-point site after collect    |
| 3        | Crash before prepare (non-commit-point site) |
| 4        | Crash after prepare (non-commit-point site)  |
| 5        | Crash commit point site before commit        |
| 6        | Crash commit point site after commit         |
| 7        | Crash non-commit-point site before commit    |
| 8        | Crash non-commit-point site after commit     |
| 9        | Crash commit point site before forget        |
| 10       | Crash non-commit-point site before forget    |

For example, the following statement returns the following messages if the local commit point strength is greater than the remote commit point strength and both nodes are updated:

```
COMMIT COMMENT 'ORA-2PC-CRASH-TEST-7';

ORA-02054: transaction 1.93.29 in-doubt
ORA-02059: ORA_CRASH_TEST_7 in commit comment
```

At this point, the in-doubt distributed transaction appears in the `DBA_2PC_PENDING` view. If enabled, RECO automatically resolves the transaction.

### 35.9.2 Disabling and Enabling RECO

The RECO background process of an Oracle Database instance automatically resolves failures involving distributed transactions. At exponentially growing time intervals, the RECO background process of a node attempts to recover the local portion of an in-doubt distributed transaction.

RECO can use an existing connection or establish a new connection to other nodes involved in the failed transaction. When a connection is established, RECO automatically resolves all in-doubt transactions. Rows corresponding to any resolved

in-doubt transactions are automatically removed from the pending transaction table of each database.

You can enable and disable RECO using the `ALTER SYSTEM` statement with the `ENABLE/DISABLE DISTRIBUTED RECOVERY` options. For example, you can temporarily disable RECO to force the failure of a two-phase commit and manually resolve the in-doubt transaction.

The following statement disables RECO:

```
ALTER SYSTEM DISABLE DISTRIBUTED RECOVERY;
```

Alternatively, the following statement enables RECO so that in-doubt transactions are automatically resolved:

```
ALTER SYSTEM ENABLE DISTRIBUTED RECOVERY;
```

## 35.10 Managing Read Consistency

An important restriction exists in the Oracle Database implementation of distributed read consistency.

The problem arises because each system has its own SCN, which you can view as the database internal timestamp. The Oracle Database server uses the SCN to decide which version of data is returned from a query.

The SCNs in a distributed transaction are synchronized at the end of each remote SQL statement and at the start and end of each transaction. Between two nodes that have heavy traffic and especially distributed updates, the synchronization is frequent. Nevertheless, no practical way exists to keep SCNs in a distributed system absolutely synchronized: a window always exists in which one node may have an SCN that is somewhat in the past with respect to the SCN of another node.

Because of the SCN gap, you can execute a query that uses a slightly old snapshot, so that the most recent changes to the remote database are not seen. In accordance with read consistency, a query can therefore retrieve consistent, but out-of-date data. Note that all data retrieved by the query will be from the old SCN, so that if a locally executed update transaction updates two tables at a remote node, then data selected from both tables in the next remote access contain data before the update.

One consequence of the SCN gap is that two consecutive `SELECT` statements can retrieve different data even though no DML has been executed between the two statements. For example, you can issue an update statement and then commit the update on the remote database. When you issue a `SELECT` statement on a view based on this remote table, the view does not show the update to the row. The next time that you issue the `SELECT` statement, the update is present.

You can use the following techniques to ensure that the SCNs of the two systems are synchronized just before a query:

- Because SCNs are synchronized at the end of a remote query, precede each remote query with a dummy remote query to the same site, for example, `SELECT * FROM DUAL@REMOTE.`
- Because SCNs are synchronized at the start of every remote transaction, commit or roll back the current transaction before issuing the remote query.

## Managing a Multitenant Environment

You can manage a multitenant environment.

- [Overview of Managing a Multitenant Environment](#)

Become familiar with basic concepts related to a multitenant environment.

- [Creating and Configuring a CDB](#)

Creating and configuring a multitenant container database (CDB) includes tasks such as planning for CDB creation, creating the CDB, and optionally configuring EM Express for the CDB.

- [Creating and Removing PDBs with SQL\\*Plus](#)

You can create PDBs in several different ways, including using the seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove PDBs from a CDB.

- [Creating and Removing PDBs with Cloud Control](#)

You can create, clone, unplug, and remove pluggable databases (PDBs) in a multitenant container database (CDB) using Oracle Enterprise Manager Cloud Control (Cloud Control).

- [Creating and Removing Application Containers and Seeds with SQL\\*Plus](#)

You can create application containers and application seeds in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application containers from a CDB, and you can remove application seeds from application containers.

- [Administering a CDB with SQL\\*Plus](#)

Administering a multitenant container database (CDB) with SQL\*Plus includes tasks such as accessing a container in a CDB, modifying a CDB, executing DDL statements in a CDB, and running Oracle-supplied SQL scripts in a CDB.

- [Administering CDBs and PDBs with Cloud Control](#)

You can administer CDBs and PDBs with Oracle Enterprise Manager Cloud Control.

- [Administering PDBs with SQL\\*Plus](#)

Administering PDBs with SQL\*Plus includes tasks such as connecting to a PDB, modifying a PDB, and managing services associated with PDBs.

- [Administering Application Containers with SQL\\*Plus](#)

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

- [Viewing Information About CDBs and PDBs with SQL\\*Plus](#)

You can view information about CDBs and PDBs with SQL\*Plus.

- [Using Oracle Resource Manager for PDBs with SQL\\*Plus](#)

You can use PL/SQL package procedures to administer Oracle Resource Manager (Resource Manager) to allocate resources to pluggable databases (PDBs) in a multitenant container database (CDB).

- [Using Oracle Resource Manager for PDBs with Cloud Control](#)  
You can use Oracle Resource Manager for a multitenant environment with Oracle Enterprise Manager Cloud Control.
- [Using Oracle Scheduler with a CDB](#)  
You can use Oracle Scheduler to schedule jobs in a multitenant container database (CDB).

## Overview of Managing a Multitenant Environment

Become familiar with basic concepts related to a multitenant environment.

### Video

- [About a Multitenant Environment](#)

You can use the Oracle Multitenant option to configure and manage a multitenant environment. The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB) that includes zero, one, or many customer-created pluggable databases (PDBs). A PDB is a portable collection of schemas, schema objects, and nonschema objects that appears to an Oracle Net client as a non-CDB. All Oracle databases before Oracle Database 12c were non-CDBs.

- [Purpose of a Multitenant Environment](#)

A multitenant environment enables the central management of multiple PDBs in a single installation and enables you to accomplish several goals.

- [Prerequisites for a Multitenant Environment](#)

Prerequisites must be met for a multitenant environment.

- [Tasks and Tools for a Multitenant Environment](#)

There are common tasks you perform for a multitenant environment, and you use tools to complete the tasks.

### 36.1 About a Multitenant Environment

You can use the Oracle Multitenant option to configure and manage a multitenant environment. The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB) that includes zero, one, or many customer-created pluggable databases (PDBs). A PDB is a portable collection of schemas, schema objects, and nonschema objects that appears to an Oracle Net client as a non-CDB. All Oracle databases before Oracle Database 12c were non-CDBs.

- [Components of a CDB](#)

A CDB includes the root, the CDB seed, and PDBs.

- [Common Users and Local Users](#)

A CDB supports common users. A common user is a user that has the same identity in the root and in every existing and future PDB.

- [Separation of Duties in CDB and PDB Administration](#)

Some database administrators manage an entire CDB, while others manage individual PDBs.

- [Application Containers](#)

An application container is an optional component of a CDB that consists of an application root and all of the application PDBs associated with it. An application

container stores data for one or more applications and shares application metadata and common data.

 **See Also:**

*Oracle Database Concepts*

### 36.1.1 Components of a CDB

A CDB includes the root, the CDB seed, and PDBs.

A CDB includes the following components:

- Root

The root, named `CDB$ROOT`, stores Oracle-supplied metadata and common users. An example of metadata is the source code for Oracle-supplied PL/SQL packages. A common user is a database user known in every container. A CDB has exactly one root.

- CDB seed

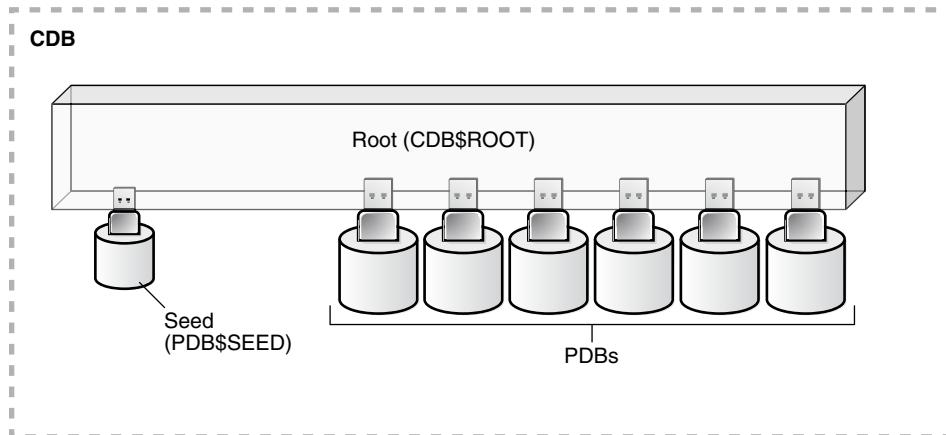

The CDB seed, named `PDB$SEED`, is a template that you can use to create new PDBs. You cannot add objects to or modify objects in the CDB seed. A CDB has exactly one CDB seed.

- PDBs

A PDB appears to users and applications as if it were a non-CDB. For example, a PDB can contain the data and code required to support a specific application. A PDB is fully backward compatible with Oracle Database releases before Oracle Database 12c.

Each of these components is called a container. Therefore, the root is a container, the CDB seed is a container, and each PDB is a container. Each container has a unique container ID and name within a CDB. [Figure 36-1](#) shows a CDB with several PDBs.

**Figure 36-1 CDB with PDBs**

You can easily plug a PDB into a CDB and unplug a PDB from a CDB. When you plug in a PDB, you associate the PDB with a CDB. When you unplug a PDB, you disassociate the PDB from a CDB. An unplugged PDB consists of an XML file that describes the PDB and the PDB's files (such as the data files and wallet file).

You can unplug a PDB from one CDB and plug it into a different CDB without altering your schemas or applications. A PDB can be plugged into only one CDB at a time.

Each PDB has a globally unique identifier (GUID). The PDB GUID is primarily used to generate names for directories that store the PDB's files, including both Oracle Managed Files directories and non-Oracle Managed Files directories.

### 36.1.2 Common Users and Local Users

A CDB supports common users. A common user is a user that has the same identity in the root and in every existing and future PDB.

A common user can log in to the root and any container in which it has been granted `CREATE SESSION` privilege. The operations that a common user can perform depend on the privileges granted to the common user. Some administrative tasks, such as creating a PDB or unplugging a PDB, must be performed by a common user. A CDB also supports local users. A local user is a user that exists in exactly one PDB.

 **See Also:**

*Oracle Database Security Guide* for more information about common users and local users

### 36.1.3 Separation of Duties in CDB and PDB Administration

Some database administrators manage an entire CDB, while others manage individual PDBs.

The database administrators who manage an entire CDB connect to the CDB as common users, and they manage attributes of the entire CDB and the root, as well as some attributes of PDBs. For example, these database administrators can create, unplug, plug in, and drop PDBs. They can also specify the temporary tablespace and the default tablespace for the root, and they can change the open mode of one or more PDBs.

Database administrators can also connect to a specific PDB as a local PDB administrator and then perform a subset of management tasks on the PDB that a database administrator performs on a non-CDB. The subset of tasks are those required for the PDB to support an application. For example, these can include management of tablespaces and schemas in a PDB, specification of storage parameters for that PDB, changing the open mode of the current PDB, and setting PDB-level initialization parameters.

### 36.1.4 Application Containers

An application container is an optional component of a CDB that consists of an application root and all of the application PDBs associated with it. An application

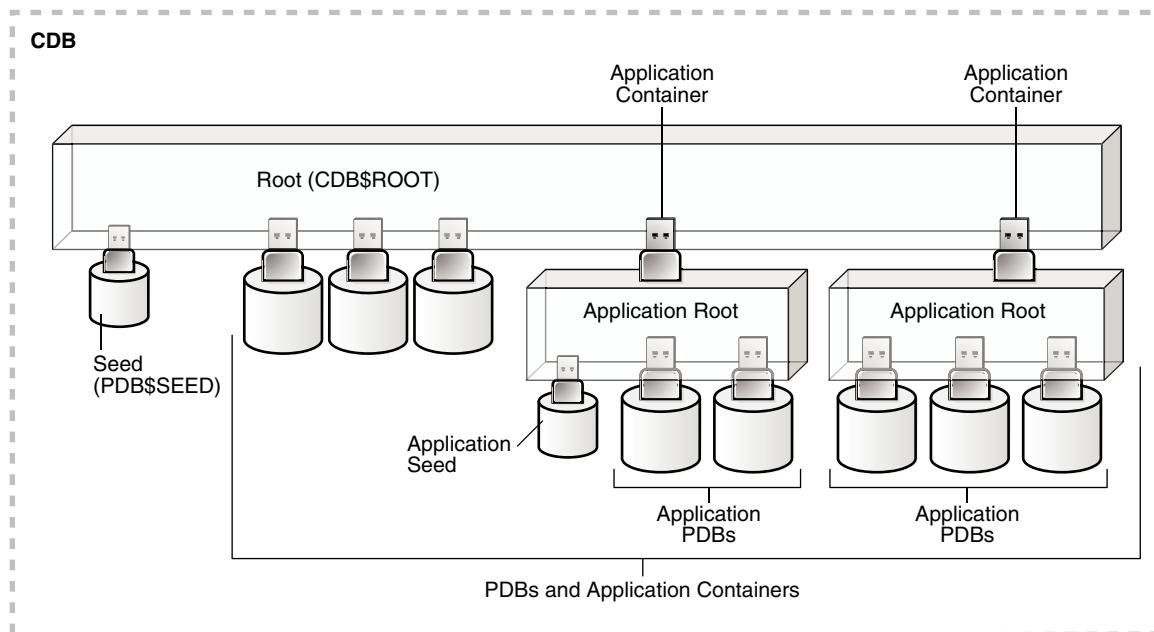

container stores data for one or more applications and shares application metadata and common data.

An application container is a special type of PDB that has an application root that is separate from the root in its CDB, and it can have one or more PDBs. When a PDB belongs to an application root, it is referred to as an application PDB.

An application root is a container to which application PDBs can belong. An application root belongs to its CDB root and shares descriptions of Oracle-supplied common objects in the CDB root. In addition, an application root enables you to create application common objects that are shared only by the application root and the application PDBs that belong to the application root. Application common objects are not visible to the CDB root, other application roots, or PDBs that do not belong to the application root. An application root cannot belong to another application root, and a PDB can belong to either no application roots or to only one application root.

You can create an application seed for an application container. The application seed is optional, but, if it exists, you can use it to create application PDBs quickly that match the requirements of the application container. An application seed enables instant provisioning of application PDBs that are created from it.

**Figure 36-2 Application Containers in a CDB**

You can specify one or more application names for each application container, and each application name has an application version. For an application PDB that is not currently part of the application container, the names and versions of its applications determine whether it can be cloned to, plugged in to, or relocated to the application root. If an application container does not have an application name or application version specified, then only PDBs that also do not have them specified can be plugged into the application container.

You can install an application in the application root. The installation can be script-driven or GUI driven, or a combination of the two. To use this method to install an

application, run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL SQL statement before installing the application and the ALTER PLUGGABLE DATABASE APPLICATION END INSTALL SQL statement after installing the application. After the application is installed in the application root, you can install the application in application PDBs by synchronizing them.

Each application container can have its own application common users, application roles, and application profiles, which can be created only when the current container is the application root. Application common users can connect or switch only to the application root in which they were created and to application PDBs that belong to the application root.

 **Note:**

- Applications cannot be installed in a CDB root or in a PDB plugged into a CDB root.
- In this document, “the root” is a reference to the CDB root (`CDB$ROOT`). Any reference to an application root uses the term “application root.”

## 36.2 Purpose of a Multitenant Environment

A multitenant environment enables the central management of multiple PDBs in a single installation and enables you to accomplish several goals.

By using a multitenant environment, you can accomplish the following goals:

- Cost reduction  
By consolidating hardware and database infrastructure to a single set of background processes, and efficiently sharing computational and memory resources, you reduce costs for hardware and maintenance.
- Easier and more rapid movement of data and code  
By design, you can plug a PDB into a CDB, unplug the PDB from the CDB, and then plug this PDB into a different CDB. Therefore, you can easily move an application's database back end from one server to another.
- Easier management and monitoring of the physical database

The CDB administrator can manage the environment as an aggregate by executing a single operation, such as patching or performing an RMAN backup, for all hosted tenants and the CDB root.

- Separation of data and code

Although consolidated into a single physical CDB, PDBs mimic the behavior of traditional non-CDBs. For example, a PDB administrator can flush the shared pool or buffer cache in the context of a PDB without affecting other PDBs in the CDB.

- Ease of performance tuning

It is easier to collect performance metrics for a CDB than for multiple non-CDBs. It is easier to size one SGA than several SGAs.

- Support for Oracle Database Resource Manager

In any shared resource environment, administrators must manage system resources to provide a predictable environment for users and address unexpected or transient resource contention. To address these issues and to provide resource usage monitoring, you can use Oracle Database Resource Manager (see [Using Oracle Resource Manager for PDBs with SQL\\*Plus](#)).

- Fewer patches and upgrades

It is easier to apply a patch to one CDB than to multiple non-CDBs and to upgrade one CDB than to upgrade several non-CDBs.

A multitenant environment is especially useful when you have many non-CDBs deployed on different hardware in multiple Oracle Database installations. These non-CDBs might use only a fraction of the hardware resources dedicated to them, and each one might not require a full-time database administrator to manage it.

By combining these non-CDBs into a CDB, you can make better use of your hardware resources and database administrator resources. In addition, you can move a PDB from one CDB to another without requiring changes to the applications that depend on the PDB.

## 36.3 Prerequisites for a Multitenant Environment

Prerequisites must be met for a multitenant environment.

The following prerequisites must be met before you can create and use a multitenant environment:

- Install Oracle Database 12c.

The installation includes setting various environment variables unique to your operating system and establishing the directory structure for software and database files.

See *Oracle Database Installation Guide* specific to your operating system.

- Set the database compatibility level to at least 12.0.0.

See *Oracle Database Upgrade Guide* for information about the database compatibility level.

## 36.4 Tasks and Tools for a Multitenant Environment

There are common tasks you perform for a multitenant environment, and you use tools to complete the tasks.

- [Tasks for a Multitenant Environment](#)  
A multitenant environment enables you to achieve several goals. You can complete general tasks to configure and use a multitenant environment.
- [Tools for a Multitenant Environment](#)  
You can use various tools to configure and administer a multitenant environment.

### 36.4.1 Tasks for a Multitenant Environment

A multitenant environment enables you to achieve several goals. You can complete general tasks to configure and use a multitenant environment.

These goals are described in "[Purpose of a Multitenant Environment](#)". To do so, you must complete the following general tasks:

#### **Task 1 Plan for the Multitenant Environment**

Creating and configuring any database requires careful planning. A CDB requires special considerations. For example, consider the following factors when you plan for a CDB:

- The number of PDBs that will be plugged into each CDB
- The resources required to support the planned CDB
- Container management policies executed as an aggregate on the entire CDB or executed locally on individual PDBs
- Container database topology, which could consist of application containers with application PDBs or a CDB with PDBs, or a combination of both

See "[Planning for CDB Creation](#)" for detailed information about planning for a CDB.

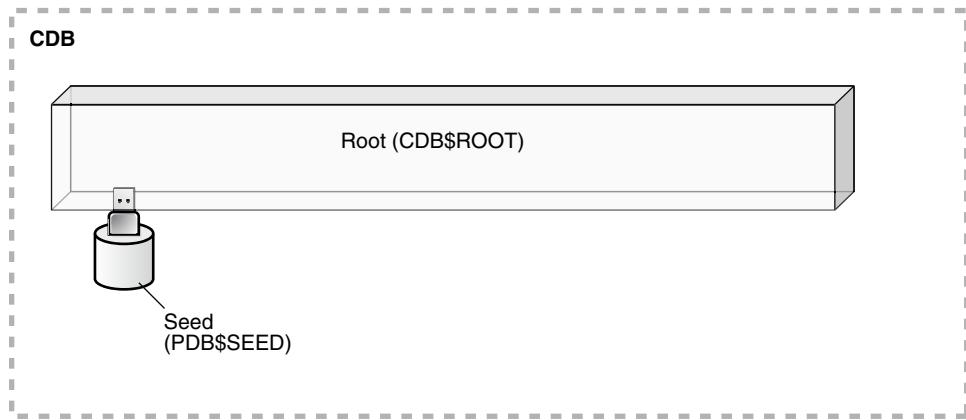

#### **Task 2 Create One or More CDBs**

When you have completed the necessary planning, you can create one or more CDBs using either the Database Configuration Assistant (DBCA) or the `CREATE DATABASE` SQL statement. In either case, you must specify the configuration details for each CDB.

See "[Using DBCA to Create a CDB](#)" and "[Using the CREATE DATABASE Statement to Create a CDB](#)" for detailed information about creating a CDB.

After a CDB is created, it consists of the root and the CDB seed, as shown in [Figure 36-3](#). The CDB root contains only Oracle maintained objects and data structures, and the CDB seed is a generic seed database for cloning purposes.

**Figure 36-3 A Newly Created CDB**

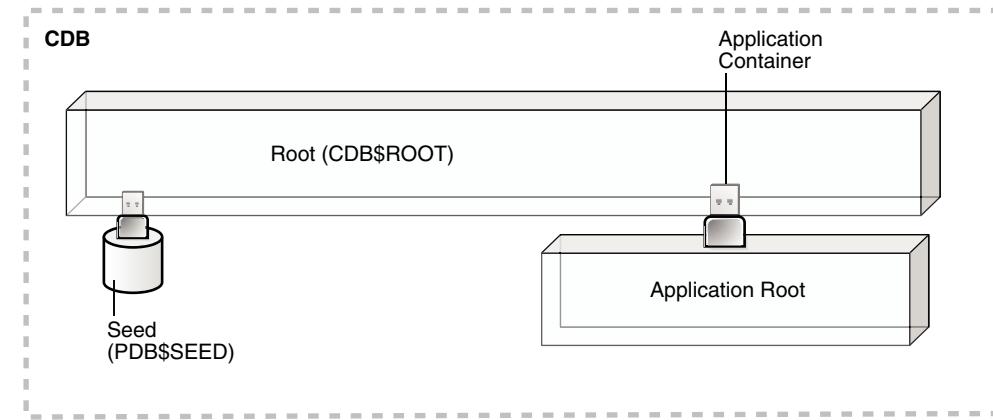

### Task 3 Optionally, Create Application Containers

An application container is an optional component of a CDB that consists of an application root and all of the application PDBs associated with it. An application container stores data for one or more applications.

Figure 36-4 shows a CDB with one empty application container.

**Figure 36-4 An Application Container**

See "[Application Containers](#)".

### Task 4 Create, Plug In, and Unplug PDBs

PDBs contain user data. After creating a CDB, you can create PDBs, plug unplugged PDBs into it, and unplug PDBs from it whenever necessary. You can unplug a PDB from a CDB and plug this PDB into a different CDB. You might move a PDB from one CDB to another if, for example, you want to move the workload for the PDB from one server to another.

See "[Creating and Removing PDBs with SQL\\*Plus](#)" and "[Creating and Removing PDBs with Cloud Control](#)" for information about creating PDBs, plugging in PDBs, and unplugging PDBs.

Figure 36-5 shows a CDB with several PDBs.

**Figure 36-5 A CDB with PDBs**

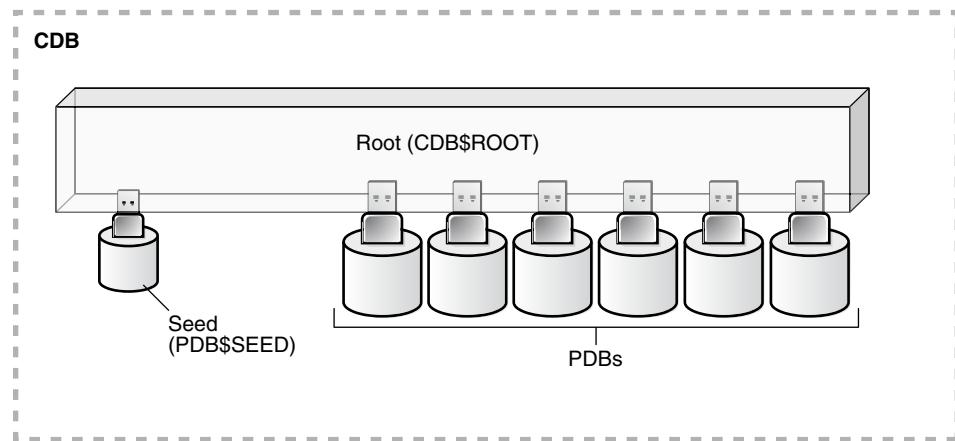

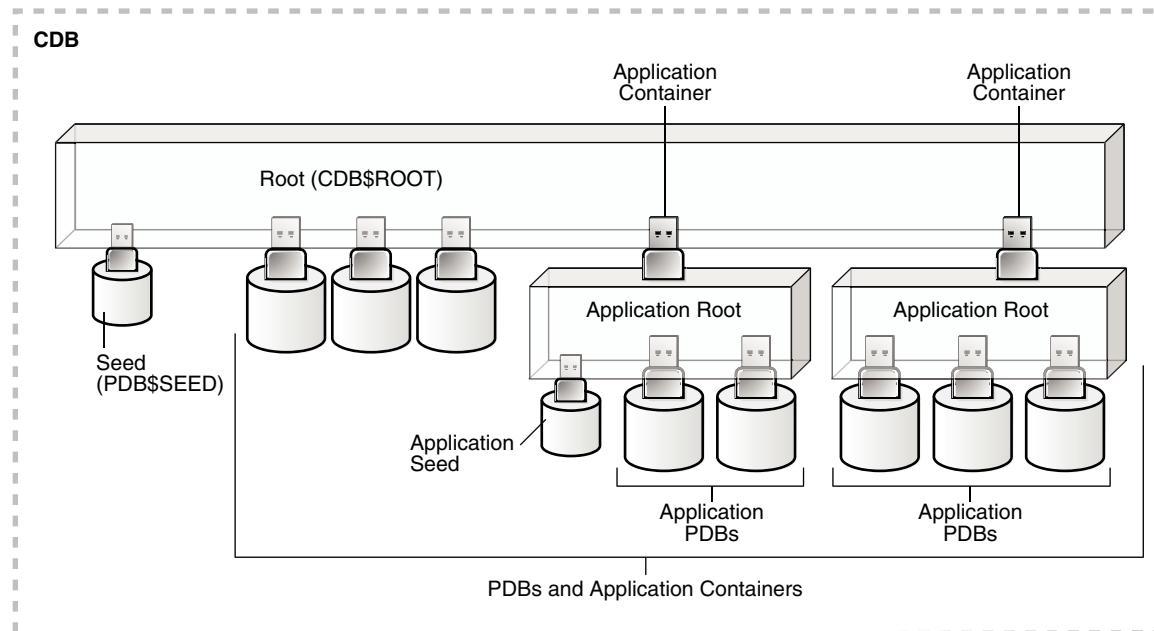

Figure 36-6 shows a CDB with PDBs, application containers, and application PDBs.

**Figure 36-6 A CDB with PDBs, Application Containers, and Application PDBs**

#### Task 5 Administer and Monitor the CDB and Application Containers

Administering and monitoring a CDB involves managing the entire CDB, the root, and some attributes of PDBs. Some management tasks are the same for CDBs and non-CDBs, and some are different.

Administering and monitoring an application container is similar to administering and monitoring a CDB, but your actions only affect the application root and the application PDBs that are part of the application container.

See "[After Creating a CDB](#)" for descriptions of tasks that are similar and tasks that are different. Also, see "[Administering a CDB with SQL\\*Plus](#)", "[Administering CDBs and Non-CDBs with Oracle Database Configuration Assistant](#)", and "[Administering CDBs and Non-CDBs with Oracle Database Control](#)".

PDBs with Cloud Control", and " [Viewing Information About CDBs and PDBs with SQL\\*Plus](#)".

You can use Oracle Resource Manager to allocate and manage resources among PDBs hosted in a CDB, and you can use it to allocate and manage resource use among user processes within a PDB. See " [Using Oracle Resource Manager for PDBs with SQL\\*Plus](#)".

You can also use Oracle Scheduler to schedule jobs in a CDB and in individual PDBs. See " [Using Oracle Scheduler with a CDB](#)".

#### **Task 6 Administer and Monitor PDBs and Application PDBs**

Administering and monitoring a PDB or an application PDB is similar to administering and monitoring a non-CDB, but there are some differences. See " [Administering CDBs and PDBs with Cloud Control](#)", " [Administering PDBs with SQL\\*Plus](#)", and " [Viewing Information About CDBs and PDBs with SQL\\*Plus](#)".

### **36.4.2 Tools for a Multitenant Environment**

You can use various tools to configure and administer a multitenant environment.

Use the following tools to complete tasks for a multitenant environment:

- [SQL\\*Plus](#)

SQL\*Plus is a command-line tool that enables you to create, manage, and monitor CDBs and PDBs. You use SQL statements and Oracle-supplied PL/SQL packages to complete these tasks in SQL\*Plus.

See *SQL\*Plus User's Guide and Reference*.

- [DBCA](#)

Oracle Database Configuration Assistant (DBCA) is a utility with a graphical user interface that enables you to configure a CDB, create PDBs, plug in PDBs, and unplug PDBs.

See *Oracle Database 2 Day DBA*, *Oracle Database Installation Guide*, and the DBCA online help for more information about DBCA.

- [Oracle Enterprise Manager Cloud Control](#)

Cloud Control is a system management tool with a graphical user interface that enables you to manage and monitor a CDB and its PDBs.

See the Cloud Control online help for more information about Cloud Control.

- [Oracle SQL Developer](#)

Oracle SQL Developer is a client application with a graphical user interface that enables you to configure a CDB, create PDBs, plug and unplug PDBs, modify the state of a PDB, clone a PDB to the Oracle Cloud, hot clone/refresh a PDB, relocate a PDB between application roots, and more.

Additionally, Oracle SQL Developer has graphical interfaces for resource management, storage, security, configuration, and reporting of performance metrics on containers and pluggable databases in a CDB.

See *Oracle SQL Developer User's Guide*.

- [The Server Control \(SRVCTL\) utility](#)

The SRVCTL utility can create and manage services for PDBs.

See " [Managing Services Associated with PDBs](#)".

- EM Express

 **Note:**

PDB management with EM Express is available starting with Oracle Database 12c Release 1 (12.1.0.2).

EM Express is a management and monitoring tool with a graphical user interface which ships with Oracle Database. It can be configured for the CDB, individual hosted PDBs, or both. This tool is intended for PDB administrative use, in the context of the PDB, to manage and monitor application development as an application DBA.

See *Oracle Database 2 Day DBA* for more information.

- Oracle Multitenant Self-Service Provisioning application

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

This application enables the self-service provisioning of PDBs. CDB administrators control access to this self-service application and manage quotas on PDBs.

For more information about the application or to download the software, use any browser to access the OTN page for the application:

<http://www.oracle.com/goto/multitenant>

To access the application, click the **Downloads** tab, and select **Oracle Pluggable Database Self-Service Provisioning application** in the Downloads for Oracle Multitenent section.

# Creating and Configuring a CDB

Creating and configuring a multitenant container database (CDB) includes tasks such as planning for CDB creation, creating the CDB, and optionally configuring EM Express for the CDB.

- [About Creating a CDB](#)

The procedure for creating a multitenant container database (CDB) is very similar to the procedure for creating a non-CDB.

- [Planning for CDB Creation](#)

CDB creation prepares several operating system files to work together as a CDB.

- [Using DBCA to Create a CDB](#)

Oracle strongly recommends using the Database Configuration Assistant (DBCA) to create a CDB, because it is a more automated approach, and your CDB is ready to use when DBCA completes. DBCA enables you to specify the number of PDBs in the CDB when it is created.

- [Using the CREATE DATABASE Statement to Create a CDB](#)

You can create a CDB using the `CREATE DATABASE` SQL statement.

- [Configuring EM Express for a CDB](#)

For a CDB, you can configure Oracle Enterprise Manager Database Express (EM Express) for the root and for each PDB by setting a global HTTPS port, or you can set a different port for every container in the CDB.

- [After Creating a CDB](#)

After you create a CDB, it consists of the root and the CDB seed.

## 37.1 About Creating a CDB

The procedure for creating a multitenant container database (CDB) is very similar to the procedure for creating a non-CDB.

The procedure for creating a non-CDB is described in [Creating and Configuring an Oracle Database](#). Before creating a CDB, you must understand the concepts and tasks described in [Creating and Configuring an Oracle Database](#).

This chapter describes special considerations for creating a CDB. This chapter also describes differences between the procedure for creating a non-CDB in [Creating and Configuring an Oracle Database](#) and the procedure for creating a CDB.

After you plan your CDB using some of the guidelines presented in "[Planning for CDB Creation](#)", you can create the CDB either during or after Oracle Database software installation. The following are typical reasons to create a CDB after installation:

- You used Oracle Universal Installer (OUI) to install software only, and did not create a CDB.
- You want to create another CDB on the same host as an existing CDB or an existing non-CDB. In this case, this chapter assumes that the new CDB uses the

same Oracle home as the existing database. You can also create the CDB in a new Oracle home by running OUI again.

The specific methods for creating a CDB are:

- With the Database Configuration Assistant (DBCA), a graphical tool.  
See "[Using DBCA to Create a CDB](#)".
- With the `CREATE DATABASE` SQL statement.  
See "[Using the CREATE DATABASE Statement to Create a CDB](#)".

## 37.2 Planning for CDB Creation

CDB creation prepares several operating system files to work together as a CDB.

 **Note:**

Before planning for CDBs, review the conceptual information about CDBs and PDBs in *Oracle Database Concepts*.

- [Decide How to Configure the CDB](#)  
Prepare to create the CDB by research and careful planning.
- [Prerequisites for CDB Creation](#)  
You must complete prerequisites before creating a new CDB.

### 37.2.1 Decide How to Configure the CDB

Prepare to create the CDB by research and careful planning.

[Table 37-1](#) lists some recommended actions and considerations that apply to CDBs. For more information about many of the actions in [Table 37-1](#), see [Table 2-1](#).

**Table 37-1 Planning for a CDB**

| Action                                                                                                                                                                                                                                                   | Considerations for a CDB                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Additional Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Plan the tables and indexes for the pluggable databases (PDBs) and estimate the amount of space they will require.                                                                                                                                       | <p>In a CDB, most user data is in the PDBs. The root contains no user data or minimal user data. Plan for the PDBs that will be part of the CDB. The disk storage space requirement for a CDB is the space required for the Oracle Database installation plus the sum of the space requirements for all of the PDBs that will be part of the CDB. A CDB can contain up to 4,096 PDBs, but you can limit the CDB to a smaller number of PDBs by setting the <code>MAX_PDBS</code> initialization parameter.</p> <p>You can also create application containers in a CDB. An application container is a collection of application PDBs that store the data for one or more applications. In addition, application containers support user-created application common objects that can be shared by the application PDBs in the application container.</p> | <p>"<a href="#">Oracle Database Structure and Storage</a>"</p> <p><a href="#">Schema Objects</a></p> <p>"<a href="#">Creating and Removing PDBs with SQL*Plus</a>"</p> <p>"<a href="#">Application Containers</a>"</p>                                                                                                                                                                                                                                                                           |
| Plan the layout of the underlying operating system files your CDB will comprise.                                                                                                                                                                         | <p>There are separate data files for the root, the CDB seed, each PDB, each application root, and each application PDB.</p> <p>There is one redo log for a single-instance CDB, or one redo log for each instance of an Oracle Real Application Clusters (Oracle RAC) CDB. Also, for Oracle RAC, all data files and redo log files must be on shared storage.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <p>"<a href="#">Using Oracle Managed Files</a>"</p> <p><i>Oracle Automatic Storage Management Administrator's Guide</i></p> <p><i>Oracle Database Performance Tuning Guide</i></p> <p><i>Oracle Database Backup and Recovery User's Guide</i></p> <p><i>Oracle Grid Infrastructure Installation Guide</i> for information about configuring storage for Oracle RAC</p> <p>Your Oracle operating system-specific documentation, including the appropriate Oracle Database installation guide.</p> |
| Plan for the number of background processes that will be required by the CDB.                                                                                                                                                                            | There is one set of background processes shared by the root and all PDBs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | " <a href="#">Specifying the Maximum Number of Processes</a> "                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Select the global database name, which is the name and location of the CDB within the network structure, and create the global database name for the root by setting both the <code>DB_NAME</code> and <code>DB_DOMAIN</code> initialization parameters. | <p>The global database name of the root is the global database name of the CDB.</p> <p>The global database name of a PDB is defined by the PDB name and the <code>DB_DOMAIN</code> initialization parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | " <a href="#">Determining the Global Database Name</a> "                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 37-1 (Cont.) Planning for a CDB**

| Action                                                                                                                                                                                                                                                                                                                 | Considerations for a CDB                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Additional Information                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Familiarize yourself with the initialization parameters that can be included in an initialization parameter file. Become familiar with the concept and operation of a server parameter file (SPFILE). An SPFILE file lets you store and manage your initialization parameters persistently in a server-side disk file. | <p>A CDB uses a single SPFILE or a single text initialization parameter file (PFILE). Values of initialization parameters set for the root can be inherited by PDBs. You can set some initialization parameters for a PDB by using the ALTER SYSTEM statement.</p> <p>The root must be the current container when you operate on an SPFILE. The user who creates or modifies the SPFILE must be a common user with SYSDBA, SYSOPER, or SYSBACKUP administrative privilege, and the user must exercise the privilege by connecting AS SYSDBA, AS SYSOPER, or AS SYSBACKUP respectively.</p> <p>To create a CDB, the ENABLE_PLUGGABLE_DATABASE initialization parameter must be set to TRUE.</p>                                                                                                                                                                                                                                                                                                                                              | <p>"<a href="#">Specifying Initialization Parameters</a>"</p> <p>"<a href="#">Using the ALTER SYSTEM SET Statement in a CDB</a>"</p> <p>"<a href="#">Listing the Initialization Parameters That Are Modifiable in PDBs</a>"</p> <p>"<a href="#">About the Current Container</a>"</p> <p><i>Oracle Database Reference</i></p> |
| Select the character set.                                                                                                                                                                                                                                                                                              | <p>When the character set of the root is AL32UTF8, PDBs that are plugged into the CDB or cloned can have a different character set than the root. PDBs that are created from the CDB seed inherit the AL32UTF8 from it, but you can migrate the PDB to a different character set.</p> <p>When the character set of the root is not AL32UTF8, all of the PDBs in the CDB use the character set of the root.</p> <p>Oracle recommends AL32UTF8 for the CDB database character set and AL16UTF6 for the CDB national character set because they provide the most flexibility.</p> <p>When selecting the database character set for the CDB, you must consider the current character sets of the databases that you want to consolidate (plug) into this CDB.</p> <p>When moving a non-CDB to a CDB, it is best to migrate the non-CDB to AL32UTF8 first. You can use Oracle Database Migration Assistant for Unicode (DMU) to migrate a non-CDB to AL32UTF8. After a CDB is created, you cannot migrate the CDB's character set using DMU.</p> | <p><i>Oracle Database Globalization Support Guide</i></p>                                                                                                                                                                                                                                                                    |
| Consider which time zones your CDB must support.                                                                                                                                                                                                                                                                       | You can set the time zones for the entire CDB (including all PDBs). You can also set the time zones individually for each PDB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | " <a href="#">Specifying the Database Time Zone and Time Zone File</a> "                                                                                                                                                                                                                                                     |

**Table 37-1 (Cont.) Planning for a CDB**

| Action                                                                                                                                                                                                                              | Considerations for a CDB                                                                                                                                                                                                                                             | Additional Information                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Select the standard database block size. This is specified at CDB creation by the <code>DB_BLOCK_SIZE</code> initialization parameter and cannot be changed after the CDB is created.                                               | The standard block size applies to the entire CDB.                                                                                                                                                                                                                   | <a href="#">"Specifying Database Block Sizes"</a>                                                                                                                                                                                                                   |
| If you plan to store online redo log files on disks with a 4K byte sector size, then determine whether you must manually specify redo log block size. Also, develop a backup and recovery strategy to protect the CDB from failure. | There is a single redo log and a single control file for an entire CDB.                                                                                                                                                                                              | <a href="#">"Planning the Block Size of Redo Log Files"</a><br><a href="#">"Managing the Redo Log"</a><br><a href="#">"Managing Archived Redo Log Files"</a><br><a href="#">"Managing Control Files"</a><br><i>Oracle Database Backup and Recovery User's Guide</i> |
| Determine the appropriate initial sizing for the SYSAUX tablespace.                                                                                                                                                                 | There is a separate SYSAUX tablespace for the root and for each PDB.                                                                                                                                                                                                 | <a href="#">"About the SYSAUX Tablespace"</a>                                                                                                                                                                                                                       |
| Plan to use a default tablespace for non-SYSTEM users to prevent inadvertently saving database objects in the SYSTEM tablespace.                                                                                                    | You can specify a separate default tablespace for the root and for each PDB. Also, there is a separate SYSTEM tablespace for the root and for each PDB.                                                                                                              | <a href="#">"Creating a Default Permanent Tablespace"</a><br><a href="#">"About the Statements That Modify a CDB"</a>                                                                                                                                               |

| Plan to use an undo tablespace to manage your undo data. | <p>A CDB can run in different undo modes. You can configure a CDB to have one active undo tablespace for the entire CDB or a separate undo tablespace for each container in the CDB. You can specify the undo mode during CDB creation, and you can change the undo mode after the CDB is created.</p> <p>When you choose to have one active undo tablespace for the entire CDB, shared undo is used, and local undo is disabled. In this configuration, there is one active undo tablespace for a single-instance CDB. When local undo is enabled, there is one undo tablespace for each container in a single instance configuration. For an Oracle RAC CDB, each PDB has one undo tablespace in each node in which it is open. With shared undo, only a common user who has the appropriate privileges and whose current container is the root can create an undo tablespace.</p> <p>The best practice is to use local undo for a CDB. Shared undo is supported primarily for upgrade and transitional purposes only. Although there is minor overhead associated with local undo when compared with shared undo, the benefits of local undo make it preferable in most environments. Local undo makes unplug operations and point in time recovery faster, and it is required for some features, such as relocating a PDB. By default, DBCA creates new CDBs with local undo enabled.</p> <p>In a CDB, the <code>UNDO_MANAGEMENT</code> initialization parameter must be set to <code>AUTO</code>, and an undo tablespace is required to manage the undo data.</p> <p>When local undo is not enabled, undo tablespaces are visible in static data dictionary views and dynamic performance (V\$) views when the current container is the root. Undo tablespaces are visible only in dynamic performance views when the current container is a PDB.</p> <p>Also, when local undo is disabled, Oracle Database silently ignores undo tablespace and rollback segment operations when the current container is a PDB.</p> | <p>"<a href="#">Managing the CDB Undo Mode</a>"</p> <p>" <a href="#">Managing Undo</a> "</p> <p>"<a href="#">About the Current Container</a>"</p> |

| Plan for the database services required to meet the needs of your applications.                                                   | <p>The root and each PDB might require several services. You can create services for the root or for individual PDBs.</p> <p>Database services have an optional PDB property. You can create services and associate them with a particular PDB by specifying the PDB property. Services with a null PDB property are associated with the CDB root.</p> <p>You can also use the DBMS_SERVICE supplied PL/SQL package to create services and associate them with PDBs. When you run CREATE_SERVICE procedure, the service is associated with the current container.</p> <p>You can manage services with the SRVCTL utility, Oracle Enterprise Manager Cloud Control, and the DBMS_SERVICE supplied PL/SQL package.</p> <p>When you create a PDB, a new default service for the PDB is created automatically. The service has the same name as the PDB. You cannot manage this service with the SRVCTL utility. However, you can create user-defined services and customize them for your applications.</p> | <p>"<a href="#">Managing Application Workloads with Database Services</a>"</p> <p>"<a href="#">Managing Services Associated with PDBs</a>"</p> <p>"<a href="#">SRVCTL Command Reference for Oracle Restart</a>" for information about using the SRVCTL utility with a single-instance database</p> <p><i>Oracle Real Application Clusters Administration and Deployment Guide</i> for information about using the SRVCTL utility with an Oracle RAC database</p> |
| Familiarize yourself with the principles and options of starting up and shutting down an instance and mounting and opening a CDB. | In a CDB, the CDB root and all of the containers share a single instance, or, when using Oracle RAC, multiple concurrent instances. You can start up and shut down an entire CDB, which in turn determines the state of hosted PDBs. When the CDB is open, you can control the open mode of PDBs by using either an ALTER PLUGGABLE DATABASE statement in the context of the CDB or PDB to open or close hosted PDBs. To maintain backward compatibility, ALTER DATABASE OPEN and ALTER DATABASE CLOSE statements are supported when they are executed and a PDB is the current container. You can also use the SQL*Plus STARTUP command and the SQL*Plus SHUTDOWN command when a PDB is the current container. However, the SQL*Plus STARTUP MOUNT command is a CDB-only operation and cannot be used when a PDB is the current container.                                                                                                                                                              | <p>"<a href="#">Starting Up a Database</a>"</p> <p>"<a href="#">Modifying the Open Mode of PDBs</a>"</p> <p>"<a href="#">Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement</a>"</p>                                                                                                                                                                                                                                                                    |

### 37.2.2 Prerequisites for CDB Creation

You must complete prerequisites before creating a new CDB.

Before you can create a new CDB, the following prerequisites must be met:

- Ensure that the prerequisites described in "[Prerequisites for a Multitenant Environment](#)" are met.
- Sufficient memory must be available to start the Oracle Database instance.

The memory required by a CDB should be sized to accommodate the workload of each of its containers and the number of containers.

- Sufficient disk storage space must be available for the planned PDBs on the computer that runs Oracle Database. In an Oracle RAC environment, sufficient shared storage must be available.

The disk storage space required by a CDB is the sum of the space requirements for all of the PDBs that will be part of the CDB.

All of these prerequisites are discussed in the *Oracle Database Installation Guide* or *Oracle Grid Infrastructure Installation Guide* specific to your operating system. If you use the Oracle Universal Installer, then it will guide you through your installation and provide help in setting environment variables and establishing directory structure and authorizations.

## 37.3 Using DBCA to Create a CDB

Oracle strongly recommends using the Database Configuration Assistant (DBCA) to create a CDB, because it is a more automated approach, and your CDB is ready to use when DBCA completes. DBCA enables you to specify the number of PDBs in the CDB when it is created.

DBCA can be launched by the Oracle Universal Installer (OUI), depending upon the type of install that you select. You can also launch DBCA as a standalone tool at any time after Oracle Database installation.

You can use DBCA to create a CDB in interactive mode or noninteractive/silent mode. Interactive mode provides a graphical interface and guided workflow for creating and

configuring a CDB. Noninteractive/silent mode enables you to script a pre-configured CDB template deployment with pre-configured, customized PDB seed databases for cloning purposes. You can run DBCA in noninteractive/silent mode by specifying command-line arguments, a response file, or both.

After a CDB is created, you can use DBCA to plug PDBs into it and unplug PDBs from it.

 **See Also:**

- ["Creating a Database with DBCA"](#)
- [Oracle Database 2 Day DBA](#)
- The DBCA online help

## 37.4 Using the CREATE DATABASE Statement to Create a CDB

You can create a CDB using the `CREATE DATABASE` SQL statement.

 **Note:**

Oracle strongly recommends using the Database Configuration Assistant (DBCA) template deployment instead of the `CREATE DATABASE` SQL statement to create a CDB, because using DBCA is a more automated approach, and your CDB is ready to use when DBCA completes.

- [About Creating a CDB with the CREATE DATABASE Statement](#)

Creating a CDB using the `CREATE DATABASE` SQL statement is very similar to creating a non-CDB. This section describes additional requirements for creating a CDB. When you create a CDB using the `CREATE DATABASE` SQL statement, you must enable PDBs and specify the names and locations of the root's files and the CDB seed's files.

- [Step 1: Specify an Instance Identifier \(SID\)](#)

The `ORACLE_SID` environment variable is used to distinguish this instance from other Oracle Database instances that you may create later and run concurrently on the same host computer.

- [Step 2: Ensure That the Required Environment Variables Are Set](#)

Depending on your platform, before you can start SQL\*Plus (as required in a later step), you may have to set environment variables, or at least verify that they are set properly.

- [Step 3: Choose a Database Administrator Authentication Method](#)

You must be authenticated and granted appropriate system privileges in order to create a database.

- **Step 4: Create the Initialization Parameter File**  
When an Oracle instance starts, it reads an initialization parameter file. This file can be a text file, which can be created and modified with a text editor, or a binary file, which is created and dynamically modified by the database. The binary file, which is preferred, is called a **server parameter file**. In this step, you create a text initialization parameter file. In a later step, you create a server parameter file from the text file.
- **Step 5: (Windows Only) Create an Instance**  
On the Windows platform, before you can connect to an instance, you must manually create it if it does not already exist. The ORADIM command creates an Oracle Database instance by creating a new Windows service.
- **Step 6: Connect to the Instance**  
Start SQL\*Plus and connect to your Oracle Database instance with the SYSDBA administrative privilege.
- **Step 7: Create a Server Parameter File**  
The server parameter file enables you to change initialization parameters with the ALTER SYSTEM command and persist the changes across a database shutdown and startup. You create the server parameter file from your edited text initialization file.
- **Step 8: Start the Instance**  
Start an instance without mounting a database.
- **Step 9: Create a CDB with the CREATE DATABASE Statement**  
When you use the CREATE DATABASE statement to create a CDB, you must complete additional actions before you have an operational CDB.

### 37.4.1 About Creating a CDB with the CREATE DATABASE Statement

Creating a CDB using the CREATE DATABASE SQL statement is very similar to creating a non-CDB. This section describes additional requirements for creating a CDB. When you create a CDB using the CREATE DATABASE SQL statement, you must enable PDBs and specify the names and locations of the root's files and the CDB seed's files.

 **Note:**

Using the CREATE DATABASE SQL statement is a more manual approach to creating a CDB than using DBCA.

- **About Enabling PDBs**  
To create a CDB, the CREATE DATABASE statement must include the ENABLE PLUGGABLE DATABASE clause. When this clause is included, the statement creates a CDB with the root and the CDB seed.
- **About the Names and Locations of the Root's Files and the CDB Seed's Files**  
The CDB seed can be used as a template to create new containers.
- **About the Attributes of the CDB Seed's Data Files**  
Add the *undo\_mode\_clause* to an ENABLE PLUGGABLE DATABASE clause to specify the undo mode of the CDB.
- **About the CDB's Undo Mode**  
Add the *undo\_mode\_clause* to an ENABLE PLUGGABLE DATABASE clause to specify the undo mode of the CDB.

 **See Also:**

*Oracle Database Concepts* for information about a CDB's files

### 37.4.1.1 About Enabling PDBs

To create a CDB, the `CREATE DATABASE` statement must include the `ENABLE PLUGGABLE DATABASE` clause. When this clause is included, the statement creates a CDB with the root and the CDB seed.

When the `ENABLE PLUGGABLE DATABASE` clause is not included in the `CREATE DATABASE` statement, the newly created database is a non-CDB. The statement does not create the root and the CDB seed, and the non-CDB can never contain PDBs.

### 37.4.1.2 About the Names and Locations of the Root's Files and the CDB Seed's Files

The `CREATE DATABASE` statement uses the root's files (such as data files) to generate the names of the CDB seed's files. You must specify the names and locations of the root's files and the CDB seed's files. After the `CREATE DATABASE` statement completes successfully, you can use the CDB seed and its files to create new PDBs. The CDB seed cannot be modified after it is created.

You must specify the names and locations of the CDB seed's files in one of the following ways:

1. The `SEED FILE_NAME_CONVERT` clause
2. Oracle Managed Files
3. The `PDB_FILE_NAME_CONVERT` initialization parameter

If you use more than one of these methods, then the `CREATE DATABASE` statement uses one method in the order of precedence of the previous list. For example, if you use all of the methods, then the `CREATE DATABASE` statement only uses the specifications in the `SEED FILE_NAME_CONVERT` clause.

- [The SEED FILE\\_NAME\\_CONVERT Clause](#)  
The `SEED FILE_NAME_CONVERT` clause of the `CREATE DATABASE` statement specifies how to generate the names of the CDB seed's files using the names of root's files.
- [Oracle Managed Files](#)  
When Oracle Managed Files is enabled, it can determine the names and locations of the CDB seed's files.
- [The PDB\\_FILE\\_NAME\\_CONVERT Initialization Parameter](#)  
The `PDB_FILE_NAME_CONVERT` initialization parameter can specify the names and locations of the seed's files.

 **See Also:**

["Creating a PDB Using the Seed"](#)

### 37.4.1.2.1 The SEED FILE\_NAME\_CONVERT Clause

The `SEED FILE_NAME_CONVERT` clause of the `CREATE DATABASE` statement specifies how to generate the names of the CDB seed's files using the names of root's files.

You can use this clause to specify one of the following options:

- One or more file name patterns and replacement file name patterns, in the following form:

```
'string1' , 'string2' , 'string3' , 'string4' , ...
```

The `string2` file name pattern replaces the `string1` file name pattern, and the `string4` file name pattern replaces the `string3` file name pattern. You can use as many pairs of file name pattern and replacement file name pattern strings as required.

If you specify an odd number of strings (the last string has no corresponding replacement string), then an error is returned. Do not specify more than one pattern/replace string that matches a single file name or directory.

File name patterns cannot match files or directories managed by Oracle Managed Files.

- `NONE` when no file names should be converted. Omitting the `SEED FILE_NAME_CONVERT` clause is the same as specifying `NONE`.

#### **Example 37-1 SEED FILE\_NAME\_CONVERT Clause**

This `SEED FILE_NAME_CONVERT` clause generates file names for the CDB seed's files in the `/oracle/pdbseed/` directory using file names in the `/oracle/dbs` directory.

```
SEED
FILE_NAME_CONVERT = ('/oracle/dbs/' , '/oracle/pdbseed/')
```

#### See Also:

[Oracle Database SQL Language Reference](#) for the syntax of the `SEED FILE_NAME_CONVERT` clause

### 37.4.1.2.2 Oracle Managed Files

When Oracle Managed Files is enabled, it can determine the names and locations of the CDB seed's files.

#### See Also:

[Using Oracle Managed Files](#)

### 37.4.1.2.3 The PDB\_FILE\_NAME\_CONVERT Initialization Parameter

The `PDB_FILE_NAME_CONVERT` initialization parameter can specify the names and locations of the seed's files.

To use this technique, ensure that the `PDB_FILE_NAME_CONVERT` initialization parameter is included in the initialization parameter file when you create the CDB.

File name patterns specified in this initialization parameter cannot match files or directories managed by Oracle Managed Files.

 **See Also:**

*Oracle Database Reference*

### 37.4.1.3 About the Attributes of the CDB Seed's Data Files

The CDB seed can be used as a template to create new containers.

The attributes of the data files for the root's `SYSTEM` and `SYSAUX` tablespaces might not be suitable for the CDB seed. In this case, you can specify different attributes for the CDB seed's data files by using the `tablespace_datafile` clauses. Use these clauses to specify attributes for all data files comprising the `SYSTEM` and `SYSAUX` tablespaces in the CDB seed. The values inherited from the root are used for any attributes whose values have not been provided.

The syntax of the `tablespace_datafile` clauses is the same as the syntax for a data file specification, excluding the name and location of the data file and the `REUSE` attribute. You can use the `tablespace_datafile` clauses with any of the methods for specifying the names and locations of the CDB seed's data files described in "[About the Names and Locations of the Root's Files and the CDB Seed's Files](#)".

The `tablespace_datafile` clauses do not specify the names and locations of the CDB seed's data files. Instead, they specify the attributes of `SYSTEM` and `SYSAUX` data files in the CDB seed that differ from those in the root. If `SIZE` is not specified in the `tablespace_datafile` clause for a tablespace, then data file size for the tablespace is set to a predetermined fraction of the size of a corresponding root data file.

#### Example 37-2 Using the `tablespace_datafile` Clauses

Assume the following `CREATE DATABASE` clauses specify the names, locations, and attributes of the data files that comprise the `SYSTEM` and `SYSAUX` tablespaces in the root.

```
DATAFILE '/u01/app/oracle/oradata/newcdb/system01.dbf' SIZE 325M REUSE
SYSAUX DATAFILE '/u01/app/oracle/oradata/newcdb/sysaux01.dbf' SIZE 325M REUSE
```

You can use the following `tablespace_datafile` clauses to specify different attributes for these data files:

```
SEED
SYSTEM DATAFILES SIZE 125M AUTOEXTEND ON NEXT 10M MAXSIZE UNLIMITED
SYSAUX DATAFILES SIZE 100M
```

In this example, the data files for the CDB seed's SYSTEM and SYSAUX tablespaces inherit the REUSE attribute from the root's data files. However, the following attributes of the CDB seed's data files differ from the root's:

- The data file for the SYSTEM tablespace is 125 MB for the CDB seed and 325 MB for the root.
- AUTOEXTEND is enabled for the CDB seed's SYSTEM data file, and it is disabled by default for the root's SYSTEM data file.
- The data file for the SYSAUX tablespace is 100 MB for the CDB seed and 325 MB for the root.

 **See Also:**

*Oracle Database SQL Language Reference* for information about data file specifications

#### 37.4.1.4 About the CDB's Undo Mode

Add the *undo\_mode\_clause* to an `ENABLE PLUGGABLE DATABASE` clause to specify the undo mode of the CDB.

The *undo\_mode\_clause* specifies whether the CDB undo mode is local or shared. Local undo mode means that every container in the CDB uses local undo. To configure local undo mode for the CDB, specify `LOCAL UNDO ON`. Shared undo mode means that there is one active undo tablespace for a single-instance CDB, or for an Oracle RAC CDB, there is one active undo tablespace for each instance. To configure shared undo mode for the CDB, specify `LOCAL UNDO OFF`. If the *undo\_mode\_clause* is not added to the `ENABLE PLUGGABLE DATABASE` clause, then shared undo mode is the default.

#### 37.4.2 Step 1: Specify an Instance Identifier (SID)

The `ORACLE_SID` environment variable is used to distinguish this instance from other Oracle Database instances that you may create later and run concurrently on the same host computer.

1. Decide on a unique Oracle system identifier (SID) for your instance.
2. Open a command window.

 **Note:**

Use this command window for the subsequent steps.

3. Set the `ORACLE_SID` environment variable.

Restrictions related to the valid characters in an `ORACLE_SID` are platform-specific. On some platforms, the SID is case-sensitive.

 **Note:**

It is common practice to set the SID to be equal to the database name. The maximum number of characters for the database name is eight. For more information, see the discussion of the `DB_NAME` initialization parameter in *Oracle Database Reference*.

The following example for UNIX and Linux operating systems sets the SID for the instance that you will connect to in [Step 6: Connect to the Instance](#):

- Bourne, Bash, or Korn shell:

```
ORACLE_SID=mynewdb
export ORACLE_SID
```

- C shell:

```
setenv ORACLE_SID mynewdb
```

The following example sets the SID for the Windows operating system:

```
set ORACLE_SID=mynewdb
```

 **See Also:**

*Oracle Database Concepts* for background information about the Oracle instance

### 37.4.3 Step 2: Ensure That the Required Environment Variables Are Set

Depending on your platform, before you can start SQL\*Plus (as required in a later step), you may have to set environment variables, or at least verify that they are set properly.

- Set required environment variables.

For example, on most platforms, `ORACLE_SID` and `ORACLE_HOME` must be set. In addition, it is advisable to set the `PATH` variable to include the `ORACLE_HOME/bin` directory. On the UNIX and Linux platforms, you must set these environment variables manually. On the Windows platform, OUI automatically assigns values to `ORACLE_HOME` and `ORACLE_SID` in the Windows registry. If you did not create a database upon installation, OUI does not set `ORACLE_SID` in the registry, and you will have to set the `ORACLE_SID` environment variable when you create your database later.

### 37.4.4 Step 3: Choose a Database Administrator Authentication Method

You must be authenticated and granted appropriate system privileges in order to create a database.

- Decide on an authentication method.

You can be authenticated as an administrator with the required privileges in the following ways:

- With a password file
- With operating system authentication

To be authenticated with a password file, create the password file as described in ["Creating and Maintaining a Database Password File"](#). To be authenticated with operating system authentication, ensure that you log in to the host computer with a user account that is a member of the appropriate operating system user group. On the UNIX and Linux platforms, for example, this is typically the dba user group. On the Windows platform, the user installing the Oracle software is automatically placed in the required user group.

 **See Also:**

- ["About Database Administrator Security and Privileges"](#)
- ["Database Administrator Authentication"](#) for information about password files and operating system authentication

### 37.4.5 Step 4: Create the Initialization Parameter File

When an Oracle instance starts, it reads an initialization parameter file. This file can be a text file, which can be created and modified with a text editor, or a binary file, which is created and dynamically modified by the database. The binary file, which is preferred, is called a **server parameter file**. In this step, you create a text initialization parameter file. In a later step, you create a server parameter file from the text file.

- Create the initialization parameter file.

One way to create the text initialization parameter file is to edit the sample presented in ["Sample Initialization Parameter File"](#).

If you create the initialization parameter file manually, ensure that it contains at least the parameters listed in [Table 37-2](#). All other parameters not listed have default values.

**Table 37-2 Recommended Minimum Initialization Parameters**

| Parameter Name | Mandatory | Notes                                                                                                                                                                                                                                                                                               |
|----------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB_NAME        | Yes       | Database identifier. Must correspond to the value used in the CREATE DATABASE statement. Maximum 8 characters.                                                                                                                                                                                      |
| CONTROL_FILES  | No        | Strongly recommended. If not provided, then the database instance creates one control file in the same location as the initialization parameter file. Providing this parameter enables you to multiplex control files. See " <a href="#">Creating Initial Control Files</a> " for more information. |
| MEMORY_TARGET  | No        | Sets the total amount of memory used by the instance and enables automatic memory management. You can choose other initialization parameters instead of this one for more manual control of memory usage. See " <a href="#">Configuring Memory Manually</a> ".                                      |

For convenience, store your initialization parameter file in the Oracle Database default location, using the default file name. Then when you start your database, it will not be necessary to specify the PFILE clause of the STARTUP command, because Oracle Database automatically looks in the default location for the initialization parameter file.

For more information about initialization parameters and the initialization parameter file, including the default name and location of the initialization parameter file for your platform, see "[About Initialization Parameters and Initialization Parameter Files](#)".

#### See Also:

- ["Specifying Initialization Parameters"](#)
- *Oracle Database Reference* for details on all initialization parameters

### 37.4.6 Step 5: (Windows Only) Create an Instance

On the Windows platform, before you can connect to an instance, you must manually create it if it does not already exist. The ORADIM command creates an Oracle Database instance by creating a new Windows service.

To create an instance:

- Enter the following command at a Windows command prompt:

```
oradim -NEW -SID sid -STARTMODE MANUAL -PFILE file
```

Replace the following placeholders with appropriate values:

- *sid* - The desired SID (for example mynewdb)
- *file* - The full path to the text initialization parameter file

**⚠ Caution:**

Do not set the `-STARTMODE` argument to `AUTO` at this point, because this causes the new instance to start and attempt to mount the database, which does not exist yet. You can change this parameter to `AUTO`, if desired, in [Step 14: \(Optional\) Enable Automatic Instance Startup.](#)

Most Oracle Database services log on to the system using the privileges of the Oracle Home User. The service runs with the privileges of this user. The `ORADIM` command prompts you for the password to this user account. You can specify other options using `ORADIM`.

**✎ See Also:**

- *Oracle Database Platform Guide for Microsoft Windows* for more information on the `ORADIM` command and the Oracle Home User
- *Oracle Database Installation Guide for Microsoft Windows* for more information about the Oracle Home User

### 37.4.7 Step 6: Connect to the Instance

Start SQL\*Plus and connect to your Oracle Database instance with the `SYSDBA` administrative privilege.

- To authenticate with a password file, enter the following commands, and then enter the `SYS` password when prompted:

```
$ sqlplus /nolog
SQL> CONNECT SYS AS SYSDBA
```

- To authenticate with operating system authentication, enter the following commands:

```
$ sqlplus /nolog
SQL> CONNECT / AS SYSDBA
```

SQL\*Plus outputs the following message:

```
Connected to an idle instance.
```

 **Note:**

SQL\*Plus may output a message similar to the following:

```
Connected to:
Oracle Database 12c Enterprise Edition Release 12.1.0.1.0 - 64bit
Production
With the Partitioning, OLAP, Advanced Analytics and Real Application
Testing options
```

If so, the instance is already started. You may have connected to the wrong instance. Exit SQL\*Plus with the `EXIT` command, check that `ORACLE_SID` is set properly, and repeat this step.

### 37.4.8 Step 7: Create a Server Parameter File

The server parameter file enables you to change initialization parameters with the `ALTER SYSTEM` command and persist the changes across a database shutdown and startup. You create the server parameter file from your edited text initialization file.

- Run the following SQL\*Plus command:

```
CREATE SPFILE FROM PFILE;
```

This SQL\*Plus command reads the text initialization parameter file (PFILE) with the default name from the default location, creates a server parameter file (SPFILE) from the text initialization parameter file, and writes the SPFILE to the default location with the default SPFILE name.

You can also supply the file name and path for both the PFILE and SPFILE if you are not using default names and locations.

 **Tip:**

The database must be restarted before the server parameter file takes effect.

 **Note:**

Although creating a server parameter file is optional at this point, it is recommended. If you do not create a server parameter file, the instance continues to read the text initialization parameter file whenever it starts.

**Important**—If you are using Oracle Managed Files and your initialization parameter file does not contain the `CONTROL_FILES` parameter, then you must create a server parameter file now so the database can save the names and locations of the control files that it creates during the `CREATE DATABASE` statement. See "[Specifying Oracle Managed Files at Database Creation](#)" for more information.

 **See Also:**

- "[Managing Initialization Parameters Using a Server Parameter File](#)"
- *Oracle Database SQL Language Reference* for more information on the CREATE SPFILE command

### 37.4.9 Step 8: Start the Instance

Start an instance without mounting a database.

- Run the STARTUP command with the NOMOUNT clause.

Typically, you do this only during database creation or while performing maintenance on the database. In this example, because the initialization parameter file or server parameter file is stored in the default location, you are not required to specify the PFILE clause:

```
STARTUP NOMOUNT
```

At this point, the instance memory is allocated and its processes are started. The database itself does not yet exist.

 **See Also:**

- [Starting Up and Shutting Down](#) for information about using the STARTUP command
- "[Managing Initialization Parameters Using a Server Parameter File](#)"

### 37.4.10 Step 9: Create a CDB with the CREATE DATABASE Statement

When you use the CREATE DATABASE statement to create a CDB, you must complete additional actions before you have an operational CDB.

These actions include building views on the data dictionary tables and installing standard PL/SQL packages in the root. You perform these actions by running the supplied catcdb.sql script.

The instructions in this section apply to *single-instance installations only*. See the Oracle Real Application Clusters (Oracle RAC) installation guide for your platform for instructions for creating an Oracle RAC CDB.

 **Note:**

*Single-instance* does not mean that only one Oracle instance can reside on a single host computer. In fact, multiple Oracle instances (and their associated databases) can run on a single host computer. A single-instance database is a database that is accessed by only one Oracle instance at a time, as opposed to an Oracle RAC database, which is accessed concurrently by multiple Oracle instances on multiple nodes. See *Oracle Real Application Clusters Administration and Deployment Guide* for more information on Oracle RAC.

 **Tip:**

If you are using Oracle ASM to manage your disk storage, then you must start the Oracle ASM instance and configure your disk groups before performing these steps. See *Oracle Automatic Storage Management Administrator's Guide*.

The examples in the following steps create a CDB named newcdb.

**To create a CDB with the CREATE DATABASE statement:**

1. Set the `ENABLE_PLUGGABLE_DATABASE` initialization parameter to TRUE.

Also, in a CDB, the `DB_NAME` initialization parameter specifies the name of the root. It is common practice to set the SID to the name of the root. The maximum number of characters for this name is 30. For more information, see the discussion of the `DB_NAME` initialization parameter in *Oracle Database Reference*.

2. Use the `CREATE DATABASE` statement to create a new CDB.

 **Note:**

If the `CREATE DATABASE` statement fails, and if you did not complete "[Step 7: Create a Server Parameter File](#)", then ensure that there is not a pre-existing server parameter file (SPFILE) for this instance that is setting initialization parameters in an unexpected way. For example, an SPFILE contains a setting for the complete path to all control files, and the `CREATE DATABASE` statement fails if those control files do not exist. Ensure that you shut down and restart the instance (with `STARTUP NOMOUNT`) after removing an unwanted SPFILE. See "[Managing Initialization Parameters Using a Server Parameter File](#)" for more information.

See also the following examples after this procedure that describe how to create a new CDB using the `CREATE DATABASE` statement:

- Example 1: Creating a CDB Without Using Oracle Managed Files
- Example 2: Creating a CDB Using Oracle Managed Files

3. Run the `catcdb.sql` SQL script.

Enter the following in SQL\*Plus to run the script:

```
@?/rdbms/admin/catcdb.sql
```

4. When prompted by the script, enter the log file directory for parameter 1 and the log file name for parameter 2.

The following example enters `/tmp` for the first prompt and `create_cdb.log` for the second prompt:

```
SQL> host perl -I &&rdbms_admin &&rdbms_admin_catcdb --logDirectory &&1
--logFilename &&2
Enter value for 1: /tmp
Enter value for 2: create_cdb.log
```

5. When prompted by the script, enter any other required information.

For example, the scripts prompts for administrator passwords and the temporary tablespace name:

```
Enter new password for SYS: *****
Enter new password for SYSTEM: *****
Enter temporary tablespace name: TEMP
```

6. Back Up the Database

Take a full backup of the database to ensure that you have a complete set of files from which to recover if a media failure occurs.

For information on backing up a database, see *Oracle Database Backup and Recovery User's Guide*.

7. Enable Automatic Instance Startup

You might want to configure the Oracle instance to start automatically when its host computer restarts.

See your operating system documentation for instructions. For example, on Windows, use the following command to configure the database service to start the instance upon computer restart:

```
ORADIM -EDIT -SID sid -STARTMODE AUTO -SRVCSTART SYSTEM [-SPFILE]
```

You must use the `-SPFILE` argument if you want the instance to read an SPFILE upon automatic restart.

- ["Oracle Automatic Storage Management Administrator's Guide"](#)

### Example 1: Creating a CDB Without Using Oracle Managed Files

The following statement creates a CDB named newcldb. This name must agree with the DB\_NAME parameter in the initialization parameter file. This example assumes the following:

- The initialization parameter file specifies the number and location of control files with the CONTROL\_FILES parameter.
- The directory /u01/app/oracle/oradata/newcldb exists.
- The directory /u01/app/oracle/oradata/pdbseed exists.
- The directories /u01/logs/my and /u02/logs/my exist.

This example includes the ENABLE PLUGGABLE DATABASE clause to create a CDB with the root and the CDB seed. This example also includes the SEED FILE\_NAME\_CONVERT clause to specify the names and locations of the CDB seed's files. This example also includes *tablespace\_datafile* clauses that specify attributes of the CDB seed's data files for the SYSTEM and SYSAUX tablespaces that differ from the root's. This example includes the *undo\_mode\_clause* to specify that the CDB undo mode is local.

```

CREATE DATABASE newcldb
 USER SYS IDENTIFIED BY sys_password
 USER SYSTEM IDENTIFIED BY system_password
 LOGFILE GROUP 1 ('/u01/logs/my/redo01a.log','/u02/logs/my/redo01b.log')
 SIZE 100M BLOCKSIZE 512,
 GROUP 2 ('/u01/logs/my/redo02a.log','/u02/logs/my/redo02b.log')
 SIZE 100M BLOCKSIZE 512,
 GROUP 3 ('/u01/logs/my/redo03a.log','/u02/logs/my/redo03b.log')
 SIZE 100M BLOCKSIZE 512

 MAXLOGHISTORY 1
 MAXLOGFILES 16
 MAXLOGMEMBERS 3
 MAXDATAFILES 1024
 CHARACTER SET AL32UTF8
 NATIONAL CHARACTER SET AL16UTF16
 EXTENT MANAGEMENT LOCAL
 DATAFILE '/u01/app/oracle/oradata/newcldb/system01.dbf'
 SIZE 700M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
 SYSAUX DATAFILE '/u01/app/oracle/oradata/newcldb/sysaux01.dbf'
 SIZE 550M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
 DEFAULT TABLESPACE deftbs
 DATAFILE '/u01/app/oracle/oradata/newcldb/deftbs01.dbf'
 SIZE 500M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED
 DEFAULT TEMPORARY TABLESPACE temptbs1
 TEMPFILE '/u01/app/oracle/oradata/newcldb/temp01.dbf'
 SIZE 20M REUSE AUTOEXTEND ON NEXT 640K MAXSIZE UNLIMITED
 UNDO TABLESPACE undotbs1
 DATAFILE '/u01/app/oracle/oradata/newcldb/undotbs01.dbf'
 SIZE 200M REUSE AUTOEXTEND ON NEXT 5120K MAXSIZE UNLIMITED

 ENABLE PLUGGABLE DATABASE
 SEED
 FILE_NAME_CONVERT = ('/u01/app/oracle/oradata/newcldb/',
 '/u01/app/oracle/oradata/pdbseed/')
 LOCAL UNDO ON;

```

A CDB is created with the following characteristics:

- The CDB is named `newcdb`. Its global database name is `newcdb.us.example.com`, where the domain portion (`us.example.com`) is taken from the initialization parameter file. See "[Determining the Global Database Name](#)".
- Three control files are created as specified by the `CONTROL_FILES` initialization parameter, which was set before CDB creation in the initialization parameter file. See "[Sample Initialization Parameter File](#)" and "[Specifying Control Files](#)".
- The passwords for user accounts `SYS` and `SYSTEM` are set to the values that you specified. The passwords are case-sensitive. The two clauses that specify the passwords for `SYS` and `SYSTEM` are not mandatory in this release of Oracle Database. However, if you specify either clause, then you must specify both clauses. For further information about the use of these clauses, see "[Protecting Your Database: Specifying Passwords for Users SYS and SYSTEM](#)".
- The new CDB has three online redo log file groups, each with two members, as specified in the `LOGFILE` clause. `MAXLOGFILES`, `MAXLOGMEMBERS`, and `MAXLOGHISTORY` define limits for the redo log. See "[Choosing the Number of Redo Log Files](#)". The block size for the redo logs is set to 512 bytes, the same size as physical sectors on disk. The `BLOCKSIZE` clause is optional if block size is to be the same as physical sector size (the default). Typical sector size and thus typical block size is 512. Permissible values for `BLOCKSIZE` are 512, 1024, and 4096. For newer disks with a 4K sector size, optionally specify `BLOCKSIZE` as 4096. See "[Planning the Block Size of Redo Log Files](#)" for more information.
- `MAXDATAFILES` specifies the maximum number of data files that can be open in the CDB. This number affects the initial sizing of the control file. For a CDB, set `MAXDATAFILES` to a high number that anticipates the aggregate number of data files for all containers, in addition to the CDB root files.

 **Note:**

You can set several limits during CDB creation. Some of these limits are limited by and affected by operating system limits. For example, if you set `MAXDATAFILES`, then Oracle Database allocates enough space in the control file to store `MAXDATAFILES` file names, even if the CDB has only one data file initially. However, because the maximum control file size is limited and operating system dependent, you might not be able to set all `CREATE DATABASE` parameters at their theoretical maximums.

For more information about setting limits during CDB creation, see the *Oracle Database SQL Language Reference* and your operating system-specific Oracle documentation.

- The `AL32UTF8` character set is used to store data in this CDB.
- The `AL16UTF16` character set is specified as the `NATIONAL CHARACTER SET` used to store data in columns specifically defined as `NCHAR`, `NCLOB`, or `NVARCHAR2`.
- The `SYSTEM` tablespace, consisting of the operating system file `/u01/app/oracle/oradata/newcdb/system01.dbf`, is created as specified by the `DATAFILE` clause. If a file with that name already exists, then it is overwritten.
- The `SYSTEM` tablespace is created as a locally managed tablespace. See "[Creating a Locally Managed SYSTEM Tablespace](#)".

- A SYSAUX tablespace is created, consisting of the operating system file /u01/app/oracle/oradata/newcldb/sysaux01.dbf as specified in the SYSAUX DATAFILE clause. See "[About the SYSAUX Tablespace](#)".
- The DEFAULT TABLESPACE clause creates and names a default permanent tablespace for this CDB.
- The DEFAULT TEMPORARY TABLESPACE clause creates and names a default temporary tablespace for the root of this CDB. See "[Creating a Default Temporary Tablespace](#)".
- The UNDO TABLESPACE clause creates and names an undo tablespace that is used to store undo data for this CDB. In a CDB, an undo tablespace is required to manage the undo data, and the UNDO\_MANAGEMENT initialization parameter must be set to AUTO. If you omit this parameter, then it defaults to AUTO. See "[Using Automatic Undo Management: Creating an Undo Tablespace](#)".
- Redo log files will not initially be archived, because the ARCHIVELOG clause is not specified in this CREATE DATABASE statement. This is customary during CDB creation. You can later use an ALTER DATABASE statement to switch to ARCHIVELOG mode. The initialization parameters in the initialization parameter file for newcldb relating to archiving are LOG\_ARCHIVE\_DEST\_1 and LOG\_ARCHIVE\_FORMAT. See [Managing Archived Redo Log Files](#).
- The ENABLE PLUGGABLE DATABASE clause creates a CDB with the root and the CDB seed.
- SEED is required for the FILE\_NAME\_CONVERT clause and the *tablespace\_datafile* clauses.
- The FILE\_NAME\_CONVERT clause generates file names for the CDB seed's files in the /u01/app/oracle/oradata/pdbseed directory using file names in the /u01/app/oracle/oradata/newcldb directory.
- The LOCAL UNDO ON clause sets the CDB's undo mode to local, which means that each container in the CDB uses local undo.

When the CDB is created in local undo mode, the CDB seed includes an undo tablespace so that any new PDB created from the CDB seed has an undo tablespace. When a PDB is created by plugging it in or cloning a remote PDB, and the source PDB was in shared undo mode, an undo tablespace is created for the PDB automatically the first time the PDB is opened.

 **Note:**

- Ensure that all directories used in the CREATE DATABASE statement exist. The CREATE DATABASE statement does not create directories.
- If you are not using Oracle Managed Files, then every tablespace clause must include a DATAFILE or TEMPFILE clause.
- If CDB creation fails, then you can look at the alert log to determine the reason for the failure and to determine corrective actions. See "[Viewing the Alert Log](#)". If you receive an error message that contains a process number, then examine the trace file for that process. Look for the trace file that contains the process number in the trace file name. See "[Finding Trace Files](#)" for more information.
- To resubmit the CREATE DATABASE statement after a failure, you must first shut down the instance and delete any files created by the previous CREATE DATABASE statement.

### Example 2: Creating a CDB Using Oracle Managed Files

This example illustrates creating a CDB with Oracle Managed Files, which enables you to use a much simpler CREATE DATABASE statement. To use Oracle Managed Files, the initialization parameter DB\_CREATE\_FILE\_DEST must be set. This parameter defines the base directory for the various CDB files that the CDB creates and automatically names.

The following statement is an example of setting this parameter in the initialization parameter file:

```
DB_CREATE_FILE_DEST='/u01/app/oracle/oradata'
```

This example sets the parameter Oracle ASM storage:

```
DB_CREATE_FILE_DEST = +data
```

This example includes the ENABLE PLUGGABLE DATABASE clause to create a CDB with the root and the CDB seed. This example does not include the SEED FILE\_NAME\_CONVERT clause because Oracle Managed Files determines the names and locations of the CDB seed's files. However, this example does include *tablespace\_datafile* clauses that specify attributes of the CDB seed's data files for the SYSTEM and SYSAUX tablespaces that differ from the root's.

With Oracle Managed Files and the following CREATE DATABASE statement, the CDB creates the SYSTEM and SYSAUX tablespaces, creates the additional tablespaces specified in the statement, and chooses default sizes and properties for all data files, control files, and redo log files. Note that these properties and the other default CDB properties set by this method might not be suitable for your production environment, so it is recommended that you examine the resulting configuration and modify it if necessary.

```
CREATE DATABASE newcdb
USER SYS IDENTIFIED BY sys_password
USER SYSTEM IDENTIFIED BY system_password
EXTENT MANAGEMENT LOCAL
DEFAULT TABLESPACE users
```

```
DEFAULT TEMPORARY TABLESPACE temp
UNDO TABLESPACE undotbs1
ENABLE PLUGGABLE DATABASE
SEED
SYSTEM DATAFILES SIZE 125M AUTOEXTEND ON NEXT 10M MAXSIZE UNLIMITED
SYSAUX DATAFILES SIZE 100M;
```

A CDB is created with the following characteristics:

- The CDB is named newcdb. Its global database name is newcdb.us.example.com, where the domain portion (us.example.com) is taken from the initialization parameter file. See "[Determining the Global Database Name](#)".
- The passwords for user accounts SYS and SYSTEM are set to the values that you specified. The passwords are case-sensitive. The two clauses that specify the passwords for SYS and SYSTEM are not mandatory in this release of Oracle Database. However, if you specify either clause, then you must specify both clauses. For further information about the use of these clauses, see "[Protecting Your Database: Specifying Passwords for Users SYS and SYSTEM](#)".
- The DEFAULT TABLESPACE clause creates and names a default permanent tablespace for this CDB.
- The DEFAULT TEMPORARY TABLESPACE clause creates and names a default temporary tablespace for the root of this CDB. See "[Creating a Default Temporary Tablespace](#)".
- The UNDO TABLESPACE clause creates and names an undo tablespace that is used to store undo data for this CDB. In a CDB, an undo tablespace is required to manage the undo data, and the UNDO\_MANAGEMENT initialization parameter must be set to AUTO. If you omit this parameter, then it defaults to AUTO. See "[Using Automatic Undo Management: Creating an Undo Tablespace](#)".
- Redo log files will not initially be archived, because the ARCHIVELOG clause is not specified in this CREATE DATABASE statement. This is customary during CDB creation. You can later use an ALTER DATABASE statement to switch to ARCHIVELOG mode. The initialization parameters in the initialization parameter file for newcdb relating to archiving are LOG\_ARCHIVE\_DEST\_1 and LOG\_ARCHIVE\_FORMAT. See [Managing Archived Redo Log Files](#).
- The ENABLE PLUGGABLE DATABASE clause creates a CDB with the root and the CDB seed.
- SEED is required for the *tablespace\_datafile* clauses.
- The SYSTEM DATAFILES clause specifies attributes of the CDB seed's SYSTEM tablespace data file(s) that differ from the root's.
- The SYSAUX DATAFILES clause specifies attributes of the CDB seed's SYSAUX tablespace data file(s) that differ from the root's.

## 37.5 Configuring EM Express for a CDB

For a CDB, you can configure Oracle Enterprise Manager Database Express (EM Express) for the root and for each PDB by setting a global HTTPS port, or you can set a different port for every container in the CDB.

You can set a global port, which enables you to use EM Express to connect to all of the PDBs in the CDB using the HTTP or HTTPS port for the CDB. Alternatively, you can set a different HTTP or HTTPS port for every container in a CDB.

### To configure EM Express for a CDB:

1. In SQL\*Plus, access a container in a CDB.

The user must have common SYSDBA administrative privilege, and you must exercise this privilege using AS SYSDBA at connect time. The container can be the root or a PDB.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Set the port in one of the following ways:

- To set the global port, connect to the CDB\$ROOT, and issue the following SQL statement to configure the global port for the CDB:

```
exec DBMS_XDB_CONFIG.SETGLOBALPORTENABLED(TRUE);
```

- To set the HTTP port for the current container, run the following procedure:

```
exec DBMS_XDB_CONFIG.SETHTTPPORT(http_port_number);
```

Replace *http\_port\_number* with the appropriate HTTP port number.

- To set the HTTPS port for the current container , run the following procedure:

```
exec DBMS_XDB_CONFIG.SETHTTPSPORT(https_port_number);
```

Replace *https\_port\_number* with the appropriate HTTPS port number.

After the port is set, you can access EM Express in one of the following ways:

- To use the global port, enter the EM Express URL provided by Database Configuration Assistant (DBCA) when it configured the CDB that includes the PDB. When the EM Express login screen appears, specify your administrator credentials, and enter the name of the PDB that you want to connect to in the **Container Name** field.

- The URL for the HTTP port for a container:

```
http://database_hostname:http_port_number/em/
```

Replace *database\_hostname* with the host name of the computer on which the database instance is running, and replace *http\_port\_number* with the appropriate HTTP port number.

- The URL for the HTTPS port for a container:

```
https://database_hostname:https_port_number/em/
```

Replace *database\_hostname* with the host name of the computer on which the database instance is running, and replace *https\_port\_number* with the appropriate HTTPS port number.

When connected to the root, EM Express displays data and enables actions that apply to the entire CDB. When connected to a PDB, EM Express displays data and enables actions that apply to the PDB only.

 **Note:**

If the listener is not configured on port 1521, then you must manually configure the port for EM Express. See *Oracle Database 2 Day DBA* for instructions.

 **See Also:**

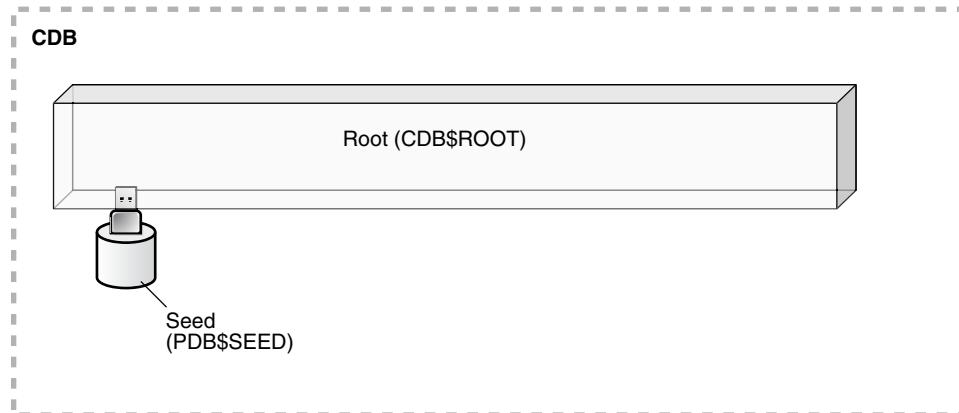

*Oracle Database 2 Day DBA* for more information about EM Express

## 37.6 After Creating a CDB

After you create a CDB, it consists of the root and the CDB seed.

The root contains system-supplied metadata and common users that can administer the PDBs. The CDB seed is a template that you can use to create new PDBs. [Figure 37-1](#) shows a newly created CDB.

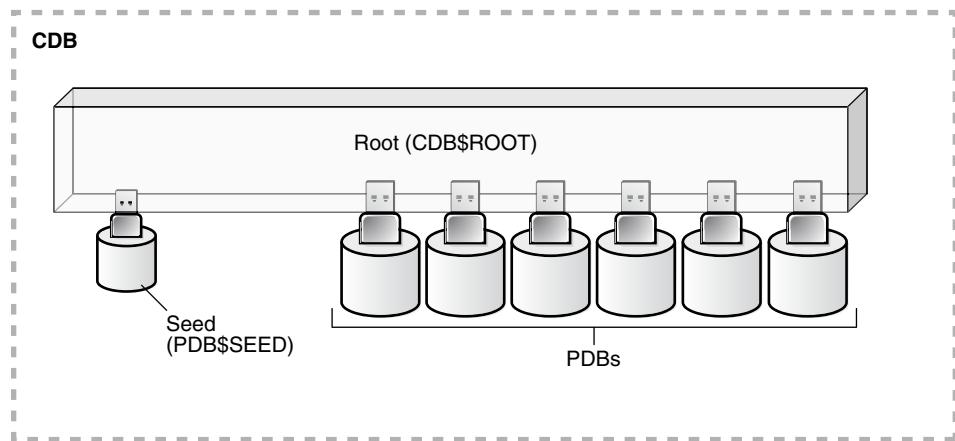

**Figure 37-1 A Newly Created CDB**

In a CDB, the root contains minimal user data or no user data. User data resides in the PDBs. Therefore, after creating a CDB, one of the first tasks is to add the PDBs that will contain the user data. See "[Creating and Removing PDBs with SQL\\*Plus](#)" for instructions.

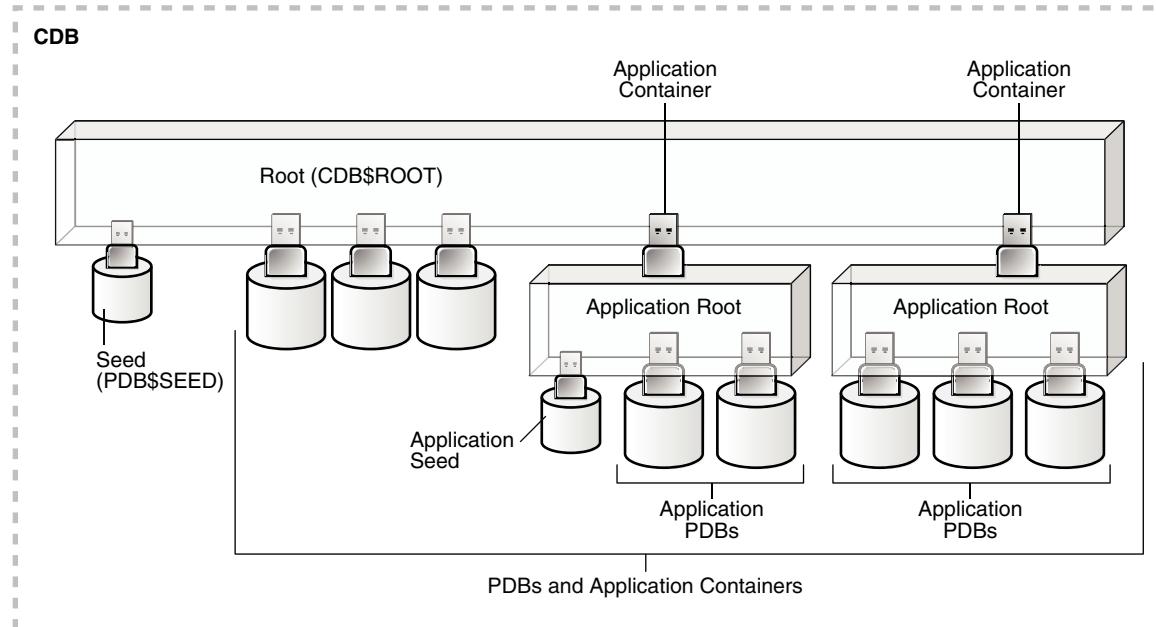

[Figure 37-2](#) shows a CDB with PDBs.

**Figure 37-2 CDB with PDBs**

You have the option of creating one or more application containers. An application container consists of an application root and application PDBs, and it stores data for one or more applications. An application container can store application common objects, which contain user data that can be shared by the application PDBs in the application container. It can also contain an application seed for fast creation of application PDBs in an application container.

**Figure 37-3 Application Containers in a CDB**

When you have added the PDBs and application containers to the CDB, the physical structure of a CDB is very similar to the physical structure of a non-CDB. A CDB contains the following files:

- One control file

- One active online redo log for a single-instance CDB, or one active online redo log for each instance of an Oracle RAC CDB
- Sets of temp files

There is one default temporary tablespace for the root of the CDB and one for each PDB, application root, and application PDB.

- Sets of system data files

The primary physical difference between a CDB and a non-CDB is in the data files. A non-CDB has only one set of system data files. In contrast, a CDB includes one set of system data files for each container in the CDB, including a set of system data files for each PDB, application root, and application PDB. In addition, a CDB has one set of user-created data files for each container. If the CDB is in local undo mode, then each container also has its own undo tablespace and associated data files.

- Sets of user-created data files

Each PDB has its own set of non-system data files. These data files contain the user-defined schemas and database objects for the PDB.

See *Oracle Database Concepts* for more information about the physical architecture of a CDB.

For backup and recovery of a CDB, Recovery Manager (RMAN) is recommended. PDB point-in-time recovery (PDB PITR) must be performed with RMAN. By default, RMAN turns on control file autobackup for a CDB. It is strongly recommended that control file autobackup is enabled for a CDB, to ensure that PDB PITR can undo data file additions or deletions.

Because the physical structure of a CDB and a non-CDB are similar, most management tasks are the same for a CDB and a non-CDB. However, some administrative tasks are specific to CDBs. The following chapters describe these tasks:

- ["Creating and Removing PDBs with SQL\\*Plus"](#)

This chapter documents the following tasks:

- Creating a PDB using the CDB seed with SQL\*Plus
- Creating a PDB by cloning an existing PDB or Non-CDB with SQL\*Plus
- Creating a PDB by relocating it with SQL\*Plus
- Creating a PDB as a proxy PDB with SQL\*Plus
- Plugging in a PDB with SQL\*Plus
- Unplugging a PDB with SQL\*Plus
- Dropping a PDB with SQL\*Plus

- ["Creating and Removing PDBs with Cloud Control "](#)

This chapter documents the following tasks:

- Creating a PDB with Cloud Control
- Plugging in a PDB with Cloud Control
- Unplugging a PDB with Cloud Control

- "[Creating and Removing Application Containers and Seeds with SQL\\*Plus](#)"  
This chapter documents the following tasks:
  - Creating application containers with SQL\*Plus
  - Creating application seeds with SQL\*Plus
  - Unplugging application containers with SQL\*Plus
  - Unplugging application seeds with SQL\*Plus
  - Dropping application containers with SQL\*Plus
  - Dropping application seeds with SQL\*Plus
- "[Administering a CDB with SQL\\*Plus](#)"  
This chapter documents the following tasks:
  - Connecting to a container
  - Switching into a container
  - Modifying a CDB
  - Modifying the root
  - Changing the open mode of a PDB
  - Executing DDL statements in a CDB
  - Shutting down the CDB instance
- "[Administering CDBs and PDBs with Cloud Control](#)"  
This chapter documents the following tasks:
  - Managing CDB storage and schema objects
  - Managing per-container storage and schema objects
  - Monitoring storage and schema alerts
  - Switching into a container
  - Changing the open mode of a PDB
- "[Administering PDBs with SQL\\*Plus](#)"  
This chapter documents the following tasks:
  - Connecting to a PDB
  - Modifying a PDB
  - Managing services associated with PDBs
- "[Administering Application Containers with SQL\\*Plus](#)"  
This chapter documents the following tasks:
  - Managing applications in an application container, including installing, upgrading, and patching applications
  - Managing application common objects
  - Issuing DML statements on containers in an application container
  - Partitioning by PDB with container maps
- "[Viewing Information About CDBs and PDBs with SQL\\*Plus](#)"

This chapter documents the following tasks:

- Querying views for monitoring a CDB and its PDBs
- Running sample queries that provide information about a CDB and its PDBs
- "[Using Oracle Resource Manager for PDBs with SQL\\*Plus](#)"

This chapter documents the following tasks:

- Creating resource plans in a CDB with SQL\*Plus
- Managing resource plans in a CDB with SQL\*Plus
- "[Using Oracle Resource Manager for PDBs with Cloud Control](#)"

This chapter documents the following tasks:

- Creating resource plans in a CDB with Cloud Control
- Monitoring the system performance under a CDB resource plan with Cloud Control
- Creating a PDB resource plan
- "[Using Oracle Scheduler with a CDB](#)"

This chapter documents the following topics:

- DBMS\_SCHEDULER invocations in a CDB
- Job coordinator and slave processes in a CDB
- Using DBMS\_JOB
- Processes to close a PDB
- New and changed views

# Creating and Removing PDBs with SQL\*Plus

You can create PDBs in several different ways, including using the seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove PDBs from a CDB.

## Note:

You can complete the tasks in this chapter using SQL\*Plus or Oracle SQL Developer.

- [About Creating and Removing PDBs](#)

You can create a pluggable database (PDB) in a multitenant container database (CDB) by using the CDB seed or an application seed, cloning an existing PDB or non-CDB, plugging an unplugged PDB into a CDB, or using a non-CDB. You can remove a PDB from a CDB by unplugging the PDB or dropping the PDB. You can also create PDBs in application containers.

- [Preparing for PDBs](#)

Prerequisites must be met before creating a PDB.

- [Creating a PDB Using the Seed](#)

You can use the `CREATE PLUGGABLE DATABASE` statement to create a PDB in a CDB using the files of the CDB seed. You can also use this statement to create an application PDB in an application container using the files of an application seed or a CDB seed.

- [Creating a PDB by Cloning an Existing PDB or Non-CDB](#)

You can create a PDB by cloning a local PDB, a remote PDB, or a non-CDB.

- [Creating a PDB by Relocating It](#)

You can create a PDB by relocating it from one CDB to another.

- [Creating a PDB by Plugging an Unplugged PDB into a CDB](#)

You can create a PDB by plugging an unplugged PDB into a CDB.

- [Creating a PDB as a Proxy PDB](#)

You can create a PDB as a proxy PDB by referencing a PDB in a remote CDB.

- [Creating a PDB Using a Non-CDB](#)

You can create a PDB using a non-CDB in different ways.

- [Unplugging a PDB from a CDB](#)

You can unplug a PDB from a CDB.

- [Dropping a PDB](#)

The `DROP PLUGGABLE DATABASE` statement drops a PDB. You can drop a PDB when you want to move the PDB from one CDB to another or when you no longer need the PDB.

### Related Topics

- [Tools for a Multitenant Environment](#)

You can use various tools to configure and administer a multitenant environment.

## 38.1 About Creating and Removing PDBs

You can create a pluggable database (PDB) in a multitenant container database (CDB) by using the CDB seed or an application seed, cloning an existing PDB or non-CDB, plugging an unplugged PDB into a CDB, or using a non-CDB. You can remove a PDB from a CDB by unplugging the PDB or dropping the PDB. You can also create PDBs in application containers.

### Note:

- This chapter discusses using SQL statements to create and remove PDBs. An easier way to create and remove PDBs is with a graphical user interface, such as of Database Configuration Assistant (DBCA), Oracle Enterprise Manager Cloud Control (Cloud Control), or Oracle Enterprise Manager Database Express (EM Express).
- A CDB can contain up to 4,096 PDBs, including PDBs, application roots, application PDBs, application seeds, and proxy PDBs. This number does not include the CDB root and the CDB seed.

- [Techniques for Creating a PDB](#)

You can use various techniques to create a PDB.

- [The CREATE PLUGGABLE DATABASE Statement](#)

You use the CREATE PLUGGABLE DATABASE statement to create a PDB. To use this statement, you must understand the clauses for the statement and when to use each clause.

- [Summary of Clauses for Creating a PDB](#)

When you create a PDB with the CREATE PLUGGABLE DATABASE statement, various clauses are available to you based on different factors, such as the technique you are using to create the PDB. You can determine which clauses to use by answering a series of questions.

### 38.1.1 Techniques for Creating a PDB

You can use various techniques to create a PDB.

Creating a PDB is the process of associating the PDB with a CDB or an application container. You create a PDB when you want to use the PDB as part of the CDB or application container.

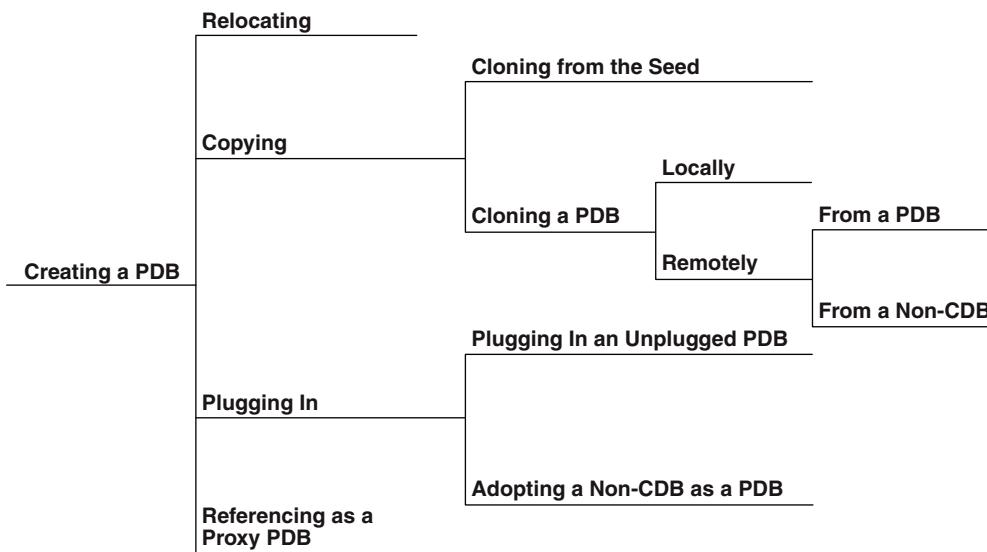

[Table 38-1](#) describes the techniques that you can use to create a PDB.

**Table 38-1 Techniques for Creating a PDB**

| Technique                                            | Description                                                                                                                                                                                                                                                                                                    | More Information                                                         |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Create a PDB by using the seed                       | Create a PDB in a CDB using the files of the CDB seed or application seed. This technique copies the files associated with the seed to a new location and associates the copied files with the new PDB.                                                                                                        | <a href="#">"Creating a PDB Using the Seed"</a>                          |
| Create a PDB by cloning an existing PDB or non-CDB   | Create a PDB by cloning a source PDB or non-CDB. A source can be a PDB in the local CDB, a PDB in a remote CDB, a PDB in a local or remote application container, or a non-CDB. This technique copies the files associated with the source to a new location and associates the copied files with the new PDB. | <a href="#">"Creating a PDB by Cloning an Existing PDB or Non-CDB"</a>   |
| Create a PDB by relocating it to a different CDB     | Create a PDB by relocating it from one CDB to another. This technique moves the files associated with the PDB to a new location.                                                                                                                                                                               | <a href="#">"Creating a PDB by Relocating It"</a>                        |
| Create a PDB by plugging an unplugged PDB into a CDB | Create a PDB by using the XML metadata file that describes the PDB and the files associated with the PDB to plug it into the CDB.                                                                                                                                                                              | <a href="#">"Creating a PDB by Plugging an Unplugged PDB into a CDB"</a> |
| Creating a PDB as a proxy PDB                        | Create a PDB as a proxy PDB by referencing a different PDB with a database link. The referenced PDB can be in the same CDB as the proxy PDB, or it can be in a different CDB.                                                                                                                                  | <a href="#">"Creating a PDB as a Proxy PDB"</a>                          |
| Create a PDB by using a non-CDB                      | Create a PDB by adopting a non-CDB into a PDB. You can use the DBMS_PDB package to create an unplugged PDB from an Oracle Database 12c non-CDB. You can then plug the unplugged PDB into the CDB.                                                                                                              | <a href="#">"About Creating a PDB Using a Non-CDB"</a>                   |

All of the techniques described in [Table 38-1](#) use the CREATE PLUGGABLE DATABASE statement to create a PDB. These techniques fall into four main categories: relocating, copying, plugging in, and referencing as a proxy PDB. [Figure 38-1](#) depicts the options for creating a PDB:

**Figure 38-1 Options for Creating a PDB**

Creating an application container is the process of associating the application container with a CDB. You can use all of these techniques to create an application container by including the AS APPLICATION CONTAINER clause in the CREATE PLUGGABLE DATABASE statement.

When you create a PDB, it can be associated with a CDB or with an application container. When the current container is a CDB root and you create a PDB, the PDB is associated with the CDB root. When the current container is an application root in an application container, and you create a PDB, the PDB is associated with the application root. When cloning a PDB into an application container, relocating a PDB to an application container, or plugging in a PDB into an application container, the PDB's application name and version must match the application container's application name and version.

You can unplug a PDB when you want to plug it into a different CDB. You can unplug or drop a PDB when you no longer need it. An unplugged PDB is not usable until it is plugged into a CDB.

 **Note:**

- Creating a PDB by cloning a non-CDB is available starting with Oracle Database 12c Release 1 (12.1.0.2).
- Creating a PDB by relocating it or as a proxy PDB is available starting with Oracle Database 12c Release 2 (12.2.0.1).

 **See Also:**

- "[Creating and Removing Application Containers with SQL\\*Plus](#)"
- "[Unplugging a PDB from a CDB](#)"
- "[Dropping a PDB](#)"

### 38.1.2 The CREATE PLUGGABLE DATABASE Statement

You use the CREATE PLUGGABLE DATABASE statement to create a PDB. To use this statement, you must understand the clauses for the statement and when to use each clause.

All of the techniques described in [Table 38-1](#) use this statement.

 **Note:**

Starting with Oracle Database 12c Release 2 (12.2.0.1), you can also use the CREATE PLUGGABLE DATABASE statement to create application containers, application seeds, and application PDBs. The SQL statements that create PDBs and application PDBs are exactly the same. When a CREATE PLUGGABLE DATABASE statement is run in the CDB root, the PDB belongs to the CDB root. When a CREATE PLUGGABLE DATABASE statement is run in an application root, the application PDB belongs to the application root. You can create an application root by running a CREATE PLUGGABLE DATABASE statement with the AS APPLICATION CONTAINER clause when the CDB root is the current container.

- [Storage Limits](#)

The optional STORAGE clause of the CREATE PLUGGABLE DATABASE statement specifies storage limits for PDBs.

- [File Location of the New PDB](#)

In the CREATE PLUGGABLE DATABASE statement, you can specify the locations of files used by the new PDB.

- [Restrictions on PDB File Locations](#)

The PATH\_PREFIX clause of the CREATE PLUGGABLE DATABASE statement ensures that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. It also ensures that the following files associated with the PDB are restricted to specified directory: the Oracle XML repository for the PDB, files created with a CREATE PFILE statement, and the export directory for Oracle wallets.

- [Source File Locations When Plugging In an Unplugged PDB](#)

Use the CREATE PLUGGABLE DATABASE ... USING statement to plug an unplugged PDB into a CDB.

- [Renaming a Service](#)  
The SERVICE\_NAME\_CONVERT clause of the CREATE PLUGGABLE DATABASE statement renames the user-defined services of the new PDB based on the service names of the source PDB.
- [Temp File Reuse](#)  
The TEMPFILE REUSE clause of the CREATE PLUGGABLE DATABASE statement specifies that an existing temp file in the target location is reused.
- [Default Tablespace](#)  
The DEFAULT TABLESPACE clause of the CREATE PLUGGABLE DATABASE statement specifies the default tablespace for the new PDB.
- [User Tablespaces](#)  
The USER\_TABLESPACES clause of the CREATE PLUGGABLE DATABASE statement specifies which tablespaces are available in the new PDB.
- [PDB Tablespace Logging](#)  
The *logging\_clause* of the CREATE PLUGGABLE DATABASE statement specifies the logging attribute of the PDB. The logging attribute controls whether certain DML operations are logged in the redo log file (LOGGING) or not (NOLOGGING).
- [PDB Inclusion in Standby CDBs](#)  
The STANDBYS clause of the CREATE PLUGGABLE DATABASE statement specifies whether the new PDB is included in standby CDBs.
- [Excluding Data When Cloning a PDB](#)  
The NO DATA clause of the CREATE PLUGGABLE DATABASE statement specifies that a PDB's data model definition is cloned but not the PDB's data.
- [Parallelize PDB Creation](#)  
The PARALLEL clause of the CREATE PLUGGABLE DATABASE statement specifies whether to use parallel execution servers during PDB creation and, optionally, the degree of parallelism.
- [PDB Refresh](#)  
The REFRESH MODE clause of the CREATE PLUGGABLE DATABASE statement specifies whether a PDB created as a clone can be refreshed periodically. Each PDB refresh propagates changes from the source PDB to the new PDB.
- [Application Container and Application Seed](#)  
With the CREATE PLUGGABLE DATABASE statement, you can create an application container. You can also create an application seed in an application container.
- [PDB Listener Host Name and Port Number](#)  
The host name and port number settings for a PDB are important only if proxy PDBs will reference the PDB. Use the PORT clause to specify the PDB's port number. Use the HOST clause to specify the PDB's host name.

 **See Also:**

- ["Creating and Removing Application Containers and Seeds with SQL\\*Plus"](#)
- [Oracle Database SQL Language Reference](#) for more information about the CREATE PLUGGABLE DATABASE statement

### 38.1.2.1 Storage Limits

The optional `STORAGE` clause of the `CREATE PLUGGABLE DATABASE` statement specifies storage limits for PDBs.

The `STORAGE` clause specifies the following limits:

- The amount of storage that can be used by all tablespaces that belong to the PDB  
Use `MAXSIZE` and a size clause to specify a limit, or set `MAXSIZE` to `UNLIMITED` to indicate no limit.
- The amount of storage that can be used by unified audit OS spillover (.bin format) files in the PDB  
Use `MAX_AUDIT_SIZE` and a size clause to specify a limit, or set `MAX_AUDIT_SIZE` to `UNLIMITED` to indicate no limit.
- The amount of diagnostics (trace files and incident dumps) in the Automatic Diagnostic Repository (ADR) that can be used by the PDB  
Use `MAX_DIAG_SIZE` and a size clause to specify a limit, or set `MAX_DIAG_SIZE` to `UNLIMITED` to indicate no limit.

If `STORAGE UNLIMITED` is set, or if there is no `STORAGE` clause, then there are no storage limits for the PDB.

The following are examples that use the `STORAGE` clause.

#### Example 38-1 `STORAGE` Clause That Specifies a Storage Limit

This `STORAGE` clause specifies that the storage used by all tablespaces that belong to the PDB must not exceed 2 gigabytes.

```
STORAGE (MAXSIZE 2G)
```

#### Example 38-2 `STORAGE` Clause That Specifies Unlimited Storage

This `STORAGE` clause specifies unlimited storage for all tablespaces that belong to the PDB.

```
STORAGE (MAXSIZE UNLIMITED)
```

#### See Also:

*Oracle Database SQL Language Reference* for the syntax of the `STORAGE` clause

### 38.1.2.2 File Location of the New PDB

In the `CREATE PLUGGABLE DATABASE` statement, you can specify the locations of files used by the new PDB.

The term "file name" means both the name and the location of a file. The `CREATE PLUGGABLE DATABASE` statement has the following clauses that indicate the file names of the new PDB being created:

- The `FILE_NAME_CONVERT` clause specifies the names of the PDB's files after the PDB is created.

Use this clause when the files are not yet at their ultimate destination, and you want to copy or move them during PDB creation. You can use this clause in any `CREATE PLUGGABLE DATABASE` statement.

- Starting with Oracle Database 12c Release 1 (12.1.0.2), the `CREATE_FILE_DEST` clause specifies the default Oracle Managed Files file system directory or Oracle ASM disk group for the PDB's files.

Use this clause to enable Oracle Managed Files for the new PDB, independent of any Oracle Managed Files default location specified in the root for the CDB. You can use this clause in any `CREATE PLUGGABLE DATABASE` statement.

When necessary, you can use both of these clauses in the same `CREATE PLUGGABLE DATABASE` statement. In addition, the following initialization parameters can control the location of the new PDB's files:

- The `DB_CREATE_FILE_DEST` initialization parameter set in the root

This initialization parameter specifies the default location for Oracle Managed Files for the CDB. When this parameter is set in a PDB, it specifies the default location for Oracle Managed Files for the PDB.

- The `PDB_FILE_NAME_CONVERT` initialization parameter

This initialization parameter maps names of existing files to new file names when processing a `CREATE PLUGGABLE DATABASE` statement.

The following table shows the precedence order when both clauses are used in the same `CREATE PLUGGABLE DATABASE` statement, and both initialization parameters are set. For each clause and initialization parameter, the table also shows whether the files created by the `CREATE PLUGGABLE DATABASE` statement will use Oracle Managed Files or not.

**Table 38-2 Summary of File Location Clauses and Initialization Parameters**

| Clause or Initialization Parameter                          | Precedence Order | Will the Files Created by <code>CREATE PLUGGABLE DATABASE</code> Use Oracle Managed Files? |
|-------------------------------------------------------------|------------------|--------------------------------------------------------------------------------------------|
| <code>FILE_NAME_CONVERT</code> clause                       | 1                | No                                                                                         |
| <code>CREATE_FILE_DEST</code> clause                        | 2                | Yes                                                                                        |
| <code>DB_CREATE_FILE_DEST</code> initialization parameter   | 3                | Yes                                                                                        |
| <code>PDB_FILE_NAME_CONVERT</code> initialization parameter | 4                | No                                                                                         |

Regarding the use of Oracle Managed Files, the table only applies to files created by the `CREATE PLUGGABLE DATABASE` statement. Files created for the PDB after the PDB has been created might or might not use Oracle Managed Files.

In addition, if `FILE_NAME_CONVERT` and `CREATE_FILE_DEST` are both specified in the `CREATE PLUGGABLE DATABASE` statement, then the `FILE_NAME_CONVERT` setting is used for the files being placed during PDB creation, and the `CREATE_FILE_DEST` setting is used to set the `DB_CREATE_FILE_DEST` initialization parameter in the PDB. In this case, Oracle Managed Files controls the location of the files for the PDB after PDB creation.

 **Note:**

The `PATH_PREFIX` clause does not affect files created by Oracle Managed Files.

- **`FILE_NAME_CONVERT` Clause**

If the PDB will not use Oracle Managed Files, then the `FILE_NAME_CONVERT` clause of the `CREATE PLUGGABLE DATABASE` statement specifies how to generate the names of files (such as data files) using the names of existing files.

- **`CREATE_FILE_DEST` Clause**

The `CREATE_FILE_DEST` clause of the `CREATE PLUGGABLE DATABASE` statement enables Oracle Managed Files for the PDB and specifies the default file system directory or Oracle ASM disk group for the PDB's files. The PDB's data files and temp files are restricted to the specified directory and its subdirectories.

 **See Also:**

- *Oracle Database Reference* for more information about the `DB_CREATE_FILE_DEST` initialization parameter
- *Oracle Database Reference* for more information about the `PDB_FILE_NAME_CONVERT` initialization parameter

### 38.1.2.2.1 `FILE_NAME_CONVERT` Clause

If the PDB will not use Oracle Managed Files, then the `FILE_NAME_CONVERT` clause of the `CREATE PLUGGABLE DATABASE` statement specifies how to generate the names of files (such as data files) using the names of existing files.

You can use this clause to specify one of the following options:

- One or more file name patterns and replacement file name patterns, in the following form:

```
'string1' , 'string2' , 'string3' , 'string4' , ...
```

The `string2` file name pattern replaces the `string1` file name pattern, and the `string4` file name pattern replaces the `string3` file name pattern. You can use as many pairs of file name pattern and replacement file name pattern strings as required.

If you specify an odd number of strings (the last string has no corresponding replacement string), then an error is returned. Do not specify more than one pattern/replace string that matches a single file name or directory.

- `NONE` when no files should be copied or moved during PDB creation. Omitting the `FILE_NAME_CONVERT` clause is the same as specifying `NONE`.

You can use the `FILE_NAME_CONVERT` clause in any `CREATE PLUGGABLE DATABASE` statement.

When the FILE\_NAME\_CONVERT clause is not specified in a CREATE PLUGGABLE DATABASE statement, either Oracle Managed Files or the PDB\_FILE\_NAME\_CONVERT initialization parameter specifies how to generate the names of the files. If you use both Oracle Managed Files and the PDB\_FILE\_NAME\_CONVERT initialization parameter, then Oracle Managed Files takes precedence. The FILE\_NAME\_CONVERT clause takes precedence when it is specified.

File name patterns specified in the FILE\_NAME\_CONVERT clause cannot match files or directories managed by Oracle Managed Files.

#### Example 38-3 FILE\_NAME\_CONVERT Clause

This FILE\_NAME\_CONVERT clause generates file names for the new PDB in the /oracle/pdb5 directory using file names in the /oracle/dbs directory.

```
FILE_NAME_CONVERT = ('/oracle/dbs/', '/oracle/pdb5/')
```

#### See Also:

- [Oracle Database SQL Language Reference](#) for the syntax of the FILE\_NAME\_CONVERT clause
- [Example 45-7](#)
- [Using Oracle Managed Files](#)
- [Oracle Database Reference](#) for information about the PDB\_FILE\_NAME\_CONVERT initialization parameter

### 38.1.2.2 CREATE\_FILE\_DEST Clause

The CREATE\_FILE\_DEST clause of the CREATE PLUGGABLE DATABASE statement enables Oracle Managed Files for the PDB and specifies the default file system directory or Oracle ASM disk group for the PDB's files. The PDB's data files and temp files are restricted to the specified directory and its subdirectories.

If a file system directory is specified as the default location in this clause, then the directory must exist. Also, the user who runs the CREATE PLUGGABLE DATABASE statement must have the appropriate privileges to create files in the specified directory. Alternatively, you can specify the name of a directory object that exists in the CDB root (CDB\$ROOT). The directory object points to the file system directory used by CREATE\_FILE\_DEST.

If there is a default Oracle Managed Files location for the CDB set in the CDB root, then the CREATE\_FILE\_DEST setting overrides the CDB root's setting, and the specified CREATE\_FILE\_DEST setting is used for the PDB.

If CREATE\_FILE\_DEST=NONE is specified, then Oracle Managed Files is disabled for the PDB.

When the CREATE\_FILE\_DEST clause is set to a value other than NONE, the DB\_CREATE\_FILE\_DEST initialization parameter is set implicitly in the PDB with SCOPE=SPFILE.

If the CDB root uses Oracle Managed Files, and this clause is not specified, then the PDB inherits the Oracle Managed Files default location from the CDB root.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

**Example 38-4 CREATE\_FILE\_DEST Clause**

This CREATE\_FILE\_DEST clause specifies /oracle/pdb2/ as the default Oracle Managed Files file system directory for the new PDB.

```
CREATE_FILE_DEST = '/oracle/pdb2/'
```

 **See Also:**

" [Using Oracle Managed Files](#)"

### 38.1.2.3 Restrictions on PDB File Locations

The PATH\_PREFIX clause of the CREATE PLUGGABLE DATABASE statement ensures that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. It also ensures that the following files associated with the PDB are restricted to specified directory: the Oracle XML repository for the PDB, files created with a CREATE PFILE statement, and the export directory for Oracle wallets.

Use this clause when you want to ensure that a PDB's files reside in a specific directory and its subdirectories.

You can use this clause to specify one of the following options:

- An absolute path that is used as a prefix for all file paths associated with the PDB.
- The name of a directory object that exists in the CDB root (CDB\$ROOT). The directory object points to the absolute path to be used for PATH\_PREFIX.
- NONE to indicate that there are no restrictions for the file paths. Omitting the PATH\_PREFIX clause is the same as specifying NONE.

After a PDB is created, its PATH\_PREFIX setting cannot be modified.

You can use the PATH\_PREFIX clause in any CREATE PLUGGABLE DATABASE statement.

**Example 38-5 PATH\_PREFIX Clause**

This PATH\_PREFIX clause ensures that all file paths associated with the PDB are restricted to the /disk1/oracle/dbs/salespdb/ directory.

```
PATH_PREFIX = '/disk1/oracle/dbs/salespdb/'
```

Be sure to specify the path name so that it is properly formed when file names are appended to it. For example, on UNIX systems, be sure to end the path name with a forward slash (/).

 **Note:**

- After the `PATH_PREFIX` clause is specified for a PDB, existing directory objects might not work as expected, since the `PATH_PREFIX` string is always added as a prefix to all local directory objects in the PDB.
- The `PATH_PREFIX` clause does not affect files created by Oracle Managed Files.
- The `PATH_PREFIX` clause only applies to user-created directory objects. It does not apply to Oracle-supplied directory objects.
- The `PATH_PREFIX` clause does not apply to data files or temporary files. If you are using Oracle Managed Files, then use the `CREATE_FILE_DEST` clause to restrict the locations of data files and temporary files.

- ["Viewing Information About the Containers in a CDB"](#)

### 38.1.2.4 Source File Locations When Plugging In an Unplugged PDB

Use the `CREATE PLUGGABLE DATABASE ... USING` statement to plug an unplugged PDB into a CDB.

You can plug in a PDB by specifying the XML metadata file or by specifying a compressed archive file with a .pdb extension. An archive file includes the XML metadata file and the PDB's files (such as the data files and wallet file).

When you use a .pdb archive file when plugging in a PDB, this file is extracted when you plug in the PDB, and the PDB's files are placed in the same directory as the .pdb archive file. Therefore, the clauses that specify the source file locations are not required when you use a .pdb archive file.

When you specify an XML metadata file when plugging in a PDB, this file describes the names and locations of an unplugged PDB's source files. The XML file might not describe the locations of these files accurately if you transported the unplugged files from one storage system to a different one. The files are in a new location, but the file paths in the XML file still indicate the old location.

The `CREATE PLUGGABLE DATABASE` statement has the following clauses that indicate the location of the source files for the new PDB being created:

- The `SOURCE_FILE_NAME_CONVERT` clause specifies how to locate files (such as data files) listed in an XML file describing a PDB if they reside in a location different

from that specified in the XML file. The clause contains information about each file listed in the XML file.

- Starting with Oracle Database 12c Release 1 (12.1.0.2), the SOURCE\_FILE\_DIRECTORY clause specifies the source directory of the files that will be used to create the new PDB. The clause specifies a directory that contains all of the files listed in the XML file. Using this clause is convenient when you have a large number of data files and specifying a SOURCE\_FILE\_NAME\_CONVERT pattern for each file is not feasible.

Use these clauses only when you are plugging in an unplugged PDB with a CREATE PLUGGABLE DATABASE ... USING statement with an XML metadata file (not a .pdb archive file). These clauses are mutually exclusive. You cannot use both clauses in a single CREATE PLUGGABLE DATABASE statement.

- **SOURCE\_FILE\_NAME\_CONVERT Clause**

The SOURCE\_FILE\_NAME\_CONVERT clause of the CREATE PLUGGABLE DATABASE ... USING statement specifies how to locate files (such as data files) listed in an XML file describing a PDB if they reside in a location different from that specified in the XML file.

- **SOURCE\_FILE\_DIRECTORY Clause**

The SOURCE\_FILE\_DIRECTORY clause of the CREATE PLUGGABLE DATABASE statement specifies the source directory of the files that will be used to create the new PDB. The clause specifies a directory that contains all of the files listed in the XML file for the unplugged PDB.

#### 38.1.2.4.1 SOURCE\_FILE\_NAME\_CONVERT Clause

The SOURCE\_FILE\_NAME\_CONVERT clause of the CREATE PLUGGABLE DATABASE ... USING statement specifies how to locate files (such as data files) listed in an XML file describing a PDB if they reside in a location different from that specified in the XML file.

You can use this clause to specify one of the following options:

- One or more file name patterns and replacement file name patterns, in the following form:

```
'string1' , 'string2' , 'string3' , 'string4' , ...
```

The *string2* file name pattern replaces the *string1* file name pattern, and the *string4* file name pattern replaces the *string3* file name pattern. You can use as many pairs of file name pattern and replacement file name pattern strings as required.

When you use this clause, ensure that the files you want to use for the PDB reside in the replacement file name patterns. Move or copy the files to these locations if necessary.

- NONE when no file names need to be located because the PDB's XML file describes the file names accurately. Omitting the SOURCE\_FILE\_NAME\_CONVERT clause is the same as specifying NONE.

You can use the SOURCE\_FILE\_NAME\_CONVERT clause only in a CREATE PLUGGABLE DATABASE statement with a USING clause that specifies an XML metadata file. Therefore, you can use this clause only when you are plugging in an unplugged PDB with an XML metadata file. You cannot use this clause when you are plugging in a PDB with a .pdb archive file.

#### Example 38-6 SOURCE\_FILE\_NAME\_CONVERT Clause

This SOURCE\_FILE\_NAME\_CONVERT clause uses the files in the /disk2/oracle/pdb7 directory instead of the /disk1/oracle/pdb7 directory. In this case, the XML file describing a PDB specifies the /disk1/oracle/pdb7 directory, but the PDB should use the files in the /disk2/oracle/pdb7 directory.

```
SOURCE_FILE_NAME_CONVERT = ('/disk1/oracle/pdb7', '/disk2/oracle/pdb7')
```

 **See Also:**

- [Creating a PDB by Plugging an Unplugged PDB into a CDB](#)
- [Oracle Database SQL Language Reference](#) for the syntax of the SOURCE\_FILE\_NAME\_CONVERT clause

#### 38.1.2.4.2 SOURCE\_FILE\_DIRECTORY Clause

The SOURCE\_FILE\_DIRECTORY clause of the CREATE PLUGGABLE DATABASE statement specifies the source directory of the files that will be used to create the new PDB. The clause specifies a directory that contains all of the files listed in the XML file for the unplugged PDB.

When you plug in a PDB, if the source files are all present in a single directory, then you can specify the directory name in this clause. The directory is scanned to find the appropriate files based on the unplugged PDB's XML file.

You can use this clause to specify one of the following options:

- The absolute path of the source file directory.
- NONE when no files should be copied or moved during PDB creation. Omitting the SOURCE\_FILE\_DIRECTORY clause is the same as specifying NONE.

You can use the SOURCE\_FILE\_DIRECTORY clause only in a CREATE PLUGGABLE DATABASE statement with a USING clause that specifies an XML metadata file. Therefore, you can use this clause only when you are plugging in an unplugged PDB with an XML metadata file. You cannot use this clause when you are plugging in a PDB with a .pdb archive file.

You can specify this clause for configurations that use Oracle Managed Files and for configurations that do not use Oracle Managed Files.

#### Example 38-7 SOURCE\_FILE\_DIRECTORY Clause

This SOURCE\_FILE\_DIRECTORY clause generates file names for the new PDB by using the source files in the /oracle/pdb5/ directory.

```
SOURCE_FILE_DIRECTORY = '/oracle/pdb5/'
```

 **See Also:**

- [Creating a PDB by Plugging an Unplugged PDB into a CDB](#)
- [Oracle Database SQL Language Reference](#) for the syntax of the SOURCE\_FILE\_DIRECTORY clause

### 38.1.2.5 Renaming a Service

The SERVICE\_NAME\_CONVERT clause of the CREATE PLUGGABLE DATABASE statement renames the user-defined services of the new PDB based on the service names of the source PDB.

When the service name of a new PDB conflicts with an existing service name in the CDB, plug-in violations can result. Use the SERVICE\_NAME\_CONVERT clause to rename services and avoid these violations.

You can use this clause to specify one of the following options:

- One or more service names and replacement service names, in the following form:

```
'string1' , 'string2' , 'string3' , 'string4' , ...
```

The *string2* service name replaces the *string1* service name, and the *string4* service name replaces the *string3* service name. You can use as many pairs of service names and replacement service names as required.

If you specify an odd number of strings (the last string has no corresponding replacement string), then an error is returned.

- NONE when no service names need to be renamed. Omitting the SERVICE\_NAME\_CONVERT clause is the same as specifying NONE.

You can use the SERVICE\_NAME\_CONVERT clause in any CREATE PLUGGABLE DATABASE statement, except for a CREATE PLUGGABLE DATABASE statement that creates a PDB from the CDB seed. The CDB seed cannot have user-defined services. However, you can use this statement for a CREATE PLUGGABLE DATABASE statement that creates an application PDB from an application seed in an application container.

 **Note:**

This clause does not apply to the default service for the PDB. The default service has the same name as the PDB.

#### Example 38-8 SERVICE\_NAME\_CONVERT Clause

This SERVICE\_NAME\_CONVERT clause uses renames the salesrep service to salesperson.

```
SERVICE_NAME_CONVERT = ('salesrep','salesperson')
```

 **Note:**

*Oracle Database SQL Language Reference*

### 38.1.2.6 Temp File Reuse

The TEMPFILE REUSE clause of the CREATE PLUGGABLE DATABASE statement specifies that an existing temp file in the target location is reused.

When you specify this clause, Oracle Database formats the temp file and reuses it. The previous contents of the file are lost. If this clause is specified, and there is no temp file in the target location, then Oracle Database creates a new temp file for the PDB.

If you do not specify this clause, then the CREATE PLUGGABLE DATABASE statement creates a new temp file for the PDB. If a file exists with the same name as the new temp file in the target location, then an error is returned, and the PDB is not created. Therefore, if you do not specify the TEMPFILE REUSE clause, then ensure that such a temp file does not exist in the target location.

#### **Example 38-9 TEMPFILE REUSE Clause**

```
TEMPFILE REUSE
```

### 38.1.2.7 Default Tablespace

The DEFAULT TABLESPACE clause of the CREATE PLUGGABLE DATABASE statement specifies the default tablespace for the new PDB.

Oracle Database will assign the default tablespace to any non-SYSTEM users who do not have a different permanent tablespace specified.

When you create the PDB from the CDB seed or an application seed and specify the DEFAULT TABLESPACE clause, Oracle Database creates a smallfile tablespace and sets it as the default tablespace for the PDB. When you create the PDB using a method other than the using the CDB seed or application seed, such as cloning a PDB or plugging in an unplugged PDB, the default tablespace must be a tablespace that already exists in the source PDB.

#### **Example 38-10 DEFAULT TABLESPACE Clause**

```
DEFAULT TABLESPACE sales
```

### 38.1.2.8 User Tablespaces

The USER\_TABLESPACES clause of the CREATE PLUGGABLE DATABASE statement specifies which tablespaces are available in the new PDB.

You can use this clause to separate the data for multiple schemas into different PDBs. For example, when you move a non-CDB to a PDB, and the non-CDB had a number of schemas that each supported a different application, you can use this clause to separate the data belonging to each schema into a separate PDB, assuming that each schema used a separate tablespace in the non-CDB.

You can use this clause to specify one of the following options:

- List one or more tablespaces to include.
- Specify ALL, the default, to include all of the tablespaces.
- Specify ALL EXCEPT to include all of the tablespaces, except for the tablespaces listed.
- Specify NONE to exclude all of the tablespaces.
- If the creation mode of the user tablespaces must be different from the creation mode for the Oracle-supplied tablespaces (such as SYSTEM and SYSAUX), then specify one of the following in the USER\_TABLESPACES clause:
  - COPY: The files of the tablespaces are copied to a new location.
  - MOVE: The files of the tablespaces are moved to a new location.
  - NOCOPY: The files of the tablespaces are not copied or moved.
  - SNAPSHOT COPY: The tablespaces are cloned with storage snapshots.
  - NO DATA: The data model definition of the tablespaces is cloned but not the tablespaces' data.

When the compatibility level of the CDB is 12.2.0 or higher, the tablespaces that are excluded by this clause are created offline in the new PDB, and they have no data files associated with them. When the compatibility level of the CDB is lower than 12.2.0, the tablespaces that are excluded by this clause are offline in the new PDB, and all data files that belong to these tablespaces are unnamed and offline.

This clause does not apply to the SYSTEM, SYSAUX, or TEMP tablespaces. Do not include these tablespaces in a tablespace list for this clause.

The following are examples that use the USER\_TABLESPACES clause.

#### **Example 38-11   USER\_TABLESPACES Clause That Includes One Tablespace**

Assume that the non-CDB or PDB from which a PDB is being created includes the following tablespaces: tbs1, tbs2, and tbs3. This USER\_TABLESPACES clause includes the tbs2 tablespace, but excludes the tbs1 and tbs3 tablespaces.

```
USER_TABLESPACES=('tbs2')
```

#### **Example 38-12   USER\_TABLESPACES Clause That Includes a List of Tablespaces**

Assume that the non-CDB or PDB from which a PDB is being created includes the following tablespaces: tbs1, tbs2, tbs3, tbs4, and tbs5. This USER\_TABLESPACES clause includes the tbs1, tbs4, and tbs5 tablespaces, but excludes the tbs2 and tbs3 tablespaces.

```
USER_TABLESPACES=('tbs1','tbs4','tbs5')
```

#### **Example 38-13   USER\_TABLESPACES Clause That Includes All Tablespaces Except for Listed Ones**

Assume that the non-CDB or PDB from which a PDB is being created includes the following tablespaces: tbs1, tbs2, tbs3, tbs4, and tbs5. This USER\_TABLESPACES clause includes the tbs2 and tbs3 tablespaces, but excludes the tbs1, tbs4, and tbs5 tablespaces.

```
USER_TABLESPACES=ALL EXCEPT('tbs1','tbs4','tbs5')
```

#### Example 38-14 USER\_TABLESPACES in a Different Creation Mode

This example shows a full CREATE PLUGGABLE DATABASE statement that plugs in a non-CDB and only includes the tbs3 user tablespace from the non-CDB. The example copies the files for Oracle-supplied tablespaces (such as SYSTEM and SYSAUX) to a new location, but moves the files of the tbs3 user tablespace.

```
CREATE PLUGGABLE DATABASE ncdb USING '/disk1/oracle/ncdb.xml'
COPY
FILE_NAME_CONVERT = ('/disk1/oracle/dbs/' , '/disk2/oracle/ncdb/')
USER_TABLESPACES=('tbs3') MOVE;
```

#### 38.1.2.9 PDB Tablespace Logging

The *logging\_clause* of the CREATE PLUGGABLE DATABASE statement specifies the logging attribute of the PDB. The logging attribute controls whether certain DML operations are logged in the redo log file (LOGGING) or not (NOLOGGING).

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

You can use this clause to specify one of the following attributes:

- LOGGING, the default, indicates that any future tablespaces created within the PDB will be created with the LOGGING attribute by default.
- NOLOGGING indicates that any future tablespaces created within the PDB will be created with the NOLOGGING attribute by default.

You can override the default logging attribute by specifying either LOGGING or NOLOGGING at the schema object level--for example, in a CREATE TABLE statement.

The specified attribute is used to establish the logging attribute of tablespaces created within the PDB if the *logging\_clause* is not specified in the CREATE TABLESPACE statement.

The DBA\_PDBS view shows the current logging attribute for a PDB.

#### Example 38-15 Specifying the LOGGING Attribute for the PDB

```
LOGGING
```

#### Example 38-16 Specifying the NOLOGGING Attribute for the PDB

```
NOLOGGING
```

 **See Also:**

- "[Controlling the Writing of Redo Records](#)"
- *Oracle Database SQL Language Reference* for more information about the logging attribute

### 38.1.2.10 PDB Inclusion in Standby CDBs

The `STANDBYS` clause of the `CREATE PLUGGABLE DATABASE` statement specifies whether the new PDB is included in standby CDBs.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

You can specify one of the following values for the `STANDBYS` clause:

- `ALL` includes the new PDB in all of the standby CDBs.
- `ALL EXCEPT` includes the new PDB in all of the standby CDBs except the specified standby CDBs. If more than one standby CDB is excluded, use a comma-separated list of the excluded standby CDBs.
- A comma-separated list of the standby CDBs. The new PDB is included in the listed standby CDBs.
- `NONE` excludes the new PDB from all of the standby CDBs.

When a PDB is not included in any of the standby CDBs, the PDB's data files are offline and marked as unnamed on all of the standby CDBs. Any new standby CDBs that are instantiated after the PDB has been created must disable the PDB for recovery explicitly to exclude it from the standby CDB. It is possible to enable a PDB on a standby CDB after it was excluded on that standby CDB.

#### **Example 38-17 STANDBYS Clause That Includes the New PDB on All Standby CDBs**

`STANDBYS=ALL`

#### **Example 38-18 STANDBYS Clause That Includes the New PDB on All Standby CDBs Except the Specified Standby CDBs**

This example shows a `STANDBYS` clause that includes the new PDB in all standby CDBs except standby CDB `standby1` and standby CDB `standby2`.

`STANDBYS=ALL EXCEPT('standby1', 'standby2')`

#### **Example 38-19 STANDBYS Clause That Lists Standby CDBs**

This example shows a `STANDBYS` clause that includes the new PDB in a list of standby CDBs. The list includes the standby CDBs `standby1`, `standby2`, and `standby3`.

```
STANDBYS=('standby1' , 'standby2' , 'standby3')
```

**Example 38-20 STANDBYS Clause That Excludes the New PDB from All Standby CDBs**

```
STANDBYS=NONE
```

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information about configuring PDBs on standby CDBs

### 38.1.2.11 Excluding Data When Cloning a PDB

The NO DATA clause of the CREATE PLUGGABLE DATABASE statement specifies that a PDB's data model definition is cloned but not the PDB's data.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

The dictionary data in the source PDB is cloned, but all user-created table and index data from the source PDB is discarded. This clause is useful for quickly creating clones of a PDB with only the object definitions and no data. Use this clause only when you are cloning a PDB with a CREATE PLUGGABLE DATABASE ... FROM statement.

This clause does not apply to the SYSTEM and SYSAUX tablespaces. If user-created database objects in the source PDB are stored in one of these tablespaces, the database objects will contain data in the cloned PDB.

When the NO DATA clause is included in the CREATE PLUGGABLE DATABASE statement, the source PDB cannot contain the following types of tables:

- Advanced Queue (AQ) tables
- Clustered tables
- Table clusters

**Example 38-21 NO DATA Clause**

```
NO DATA
```

 **See Also:**

*Oracle Database SQL Language Reference*

### 38.1.2.12 Parallelize PDB Creation

The `PARALLEL` clause of the `CREATE PLUGGABLE DATABASE` statement specifies whether to use parallel execution servers during PDB creation and, optionally, the degree of parallelism.

You can use this clause to make the creation of PDBs faster by using more than one parallel execution server to copy the new PDB's data files to a new location. When the compatibility level of the CDB is 12.2.0 or higher, the CDB chooses the degree of parallelism to use for PDB creation by default. Alternatively, you can specify the desired degree of parallelism in the clause, but the CDB can ignore the suggestion, depending on the current database load and the number of available parallel execution servers.

When a value of 0 or 1 is specified, the CDB does not parallelize the creation of the PDB. Specifying 0 or 1 can result in longer PDB creation time.

Use this clause only when you are creating a PDB from the CDB seed or an application seed, or when you are cloning a PDB.

#### Example 38-22 The CDB Chooses the Degree of Parallelism for PDB Creation

Either omit the `PARALLEL` clause or specify the following in the `CREATE PLUGGABLE DATABASE` statement:

```
PARALLEL
```

#### Example 38-23 Specify the Degree of Parallelism for PDB Creation

This example specifies that the PDB is created with a degree of parallelism of four:

```
PARALLEL 4
```

#### Example 38-24 Specify That the CDB Does Not Parallelize PDB Creation

This example specifies that the PDB is created without parallel processing:

```
PARALLEL 1
```

### 38.1.2.13 PDB Refresh

The `REFRESH MODE` clause of the `CREATE PLUGGABLE DATABASE` statement specifies whether a PDB created as a clone can be refreshed periodically. Each PDB refresh propagates changes from the source PDB to the new PDB.

This clause is supported only in a `CREATE PLUGGABLE DATABASE ... FROM` statement. You can use this clause to specify one of the following options:

- Specify `REFRESH MODE NONE`, the default, to create a PDB that is not refreshable.
- Specify `REFRESH MODE MANUAL` to create a refreshable PDB that must be refreshed manually.
- Specify `REFRESH MODE EVERY number_of_minutes MINUTES` to create a refreshable PDB that is refreshed automatically after the specified number of minutes has

passed. A refreshable PDB that uses automatic refresh can also be refreshed manually.

A refreshable PDB can be opened only in open read-only mode. Also, a refreshable PDB must be closed when a refresh is performed. If it is not closed when automatic refresh is attempted, then the refresh is deferred until the next scheduled refresh. If it is not closed when a user attempts to perform manual refresh, then an error is reported.

The refreshable PDB must be kept in read-only mode to prevent out-of-sync changes on the refreshable PDB which do not occur on the source PDB. The refreshable PDB is intended to serve as a clone master and as such must accurately reflect the source PDB at the refreshed point in time.

This clause is also supported in an `ALTER PLUGGABLE DATABASE` statement that modifies the refresh mode of a refreshable PDB. The `ALTER PLUGGABLE DATABASE` statement can switch from manual refresh to automatic refresh, or from automatic refresh to manual refresh. It can also change the number of minutes between automatic refreshes.

 **Note:**

- A refreshable PDB and its source must be in different CDBs. Therefore, a refreshable PDB must be created at a CDB that is remote from the source CDB, and a database link must be specified during the creation.
- A PDB that is not refreshable cannot be changed into a refreshable PDB. However, a PDB that is refreshable can be changed into a PDB that is not refreshable by running an `ALTER PLUGGABLE DATABASE` statement with `REFRESH MODE NONE` for the PDB.
- When you create a refreshable PDB, you can set the `REMOTE_RECOVERY_FILE_DEST` initialization parameter in the PDB. This initialization parameter specifies a directory from which to read archive log files during refresh operations if the source PDB is not available over its database link.
- If new data files are created in the source PDB, then the `PDB_FILE_NAME_CONVERT` initialization parameter must be set in the CDB to convert the data file paths from the source PDB to the clone PDB.

#### Example 38-25 A REFRESH MODE Clause That Specifies Automatic Refresh

This refresh mode clause specifies that a refreshable PDB is refreshed automatically every two hours (120 minutes):

```
REFRESH MODE EVERY 120 MINUTES
```

#### Related Topics

- [About Cloning a PDB](#)

You can use the `CREATE PLUGGABLE DATABASE` statement to clone a PDB from a source PDB or from a non-CDB.

- [Refreshing a PDB](#)  
You can refresh a PDB that was created as a refreshable clone.
- [File Location of the New PDB](#)  
In the CREATE PLUGGABLE DATABASE statement, you can specify the locations of files used by the new PDB.

### 38.1.2.14 Application Container and Application Seed

With the CREATE PLUGGABLE DATABASE statement, you can create an application container. You can also create an application seed in an application container.

- [AS APPLICATION CONTAINER Clause](#)  
To create an application container, specify the AS APPLICATION CONTAINER clause of the CREATE PLUGGABLE DATABASE statement.
- [AS SEED Clause](#)  
To create an application seed in an application container, specify the AS SEED clause of the CREATE PLUGGABLE DATABASE statement.

#### Related Topics

- [Creating and Removing Application Containers and Seeds with SQL\\*Plus](#)  
You can create application containers and application seeds in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application containers from a CDB, and you can remove application seeds from application containers.

#### 38.1.2.14.1 AS APPLICATION CONTAINER Clause

To create an application container, specify the AS APPLICATION CONTAINER clause of the CREATE PLUGGABLE DATABASE statement.

This clause creates an application container (not a PDB). When you include this clause in a CREATE PLUGGABLE DATABASE statement, you can use all of the techniques and clauses that are used for creating a PDB.

When you include this clause, the current container must be a CDB root. It cannot be an application root.

#### Example 38-26 AS APPLICATION CONTAINER Clause

```
AS APPLICATION CONTAINER
```

#### Related Topics

- [Creating and Removing Application Containers with SQL\\*Plus](#)  
You can create application containers in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application containers from a CDB.

#### 38.1.2.14.2 AS SEED Clause

To create an application seed in an application container, specify the AS SEED clause of the CREATE PLUGGABLE DATABASE statement.

This clause creates an application seed in an application container. When you include this clause in a CREATE PLUGGABLE DATABASE statement, you can use all of the techniques and clauses that are used for creating a PDB.

When you include this clause, the current container must be an application root. It cannot be the CDB root.

An application container can have no application seed or one application seed. It cannot have more than one application seed.

After an application seed is created, you can use it to create application PDBs in the application container. The application seed provides a quick way to create application PDBs that meet the requirements of the application container.

#### Example 38-27 AS SEED Clause

```
AS SEED
```

#### Related Topics

- [Creating and Removing Application Seeds with SQL\\*Plus](#)

You can create application seeds in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application seeds from application containers.

### 38.1.2.15 PDB Listener Host Name and Port Number

The host name and port number settings for a PDB are important only if proxy PDBs will reference the PDB. Use the `PORt` clause to specify the PDB's port number. Use the `HOST` clause to specify the PDB's host name.

- [HOST Clause](#)

The `HOST` clause of the `CREATE PLUGGABLE DATABASE` statement specifies the host name of the listener for the PDB being created.

- [PORT Clause](#)

The `PORt` clause of the `CREATE PLUGGABLE DATABASE` statement specifies the port number of the listener for the PDB being created.

#### Related Topics

- [Modifying the Listener Settings of a Referenced PDB](#)

A PDB that is referenced by a proxy PDB is called a referenced PDB. When the port or host name changes for the listener of the referenced PDB, you must modify the listener settings of the referenced PDB so that its proxy PDBs continue to function properly.

### 38.1.2.15.1 HOST Clause

The `HOST` clause of the `CREATE PLUGGABLE DATABASE` statement specifies the host name of the listener for the PDB being created.

By default, the host name of the listener is the same as the host name of the PDB being created. Specify the `HOST` clause when both of the following conditions are true:

- The host name of the listener is different from the host name of the PDB being created.
- You plan to create proxy PDBs that reference the PDB being created.

A proxy PDB uses a database link to establish communication with its referenced PDB. After communication is established, the proxy PDB communicates directly with the referenced PDB without using a database link. The host name of the listener must be correct for the proxy PDB to function properly.

**Example 38-28 HOST Clause**

```
HOST='myhost.example.com'
```

**Related Topics**

- [About Creating a Proxy PDB](#)

A proxy PDB provides access to another PDB in a remote CDB. You can use the CREATE PLUGGABLE DATABASE statement to create a proxy PDB by referencing the other PDB.

- [Altering the Listener Host Name of a Referenced PDB](#)

When the host name of the listener for a referenced PDB changes, you must run an ALTER PLUGGABLE DATABASE CONTAINERS HOST statement to reset the host name of the referenced PDB so that its proxy PDBs continue to function properly.

### 38.1.2.15.2 PORT Clause

The PORT clause of the CREATE PLUGGABLE DATABASE statement specifies the port number of the listener for the PDB being created.

By default, the port number of the listener for the PDB being created is 1521. Specify the PORT clause when both of the following conditions are true:

- The port number of the listener is not 1521.
- You plan to create proxy PDBs that reference the PDB being created.

A proxy PDB uses a database link to establish communication with its referenced PDB. After communication is established, the proxy PDB communicates directly with the referenced PDB without using a database link. The port number of the listener must be correct for the proxy PDB to function properly.

**Example 38-29 PORT Clause**

```
PORT=1599
```

**Related Topics**

- [About Creating a Proxy PDB](#)

A proxy PDB provides access to another PDB in a remote CDB. You can use the CREATE PLUGGABLE DATABASE statement to create a proxy PDB by referencing the other PDB.

- [Altering the Listener Port Number of a Referenced PDB](#)

When the port number of the listener for a referenced PDB changes, you must run an ALTER PLUGGABLE DATABASE CONTAINERS PORT statement to reset the port number of the referenced PDB so that its proxy PDBs continue to function properly.

## 38.1.3 Summary of Clauses for Creating a PDB

When you create a PDB with the CREATE PLUGGABLE DATABASE statement, various clauses are available to you based on different factors, such as the technique you are

using to create the PDB. You can determine which clauses to use by answering a series of questions.

The following table describes which CREATE PLUGGABLE DATABASE clauses you must specify based on different factors.

**Table 38-3 Clauses for Creating a PDB**

| Clause                   | Can Be Used Only When                                                                                                        | Question                                                                                                                                                                                                                                             | Yes                                                                                                                                                                                                                                                                                                                                                | No                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AS APPLICATION CONTAINER | Creating an application container in a CDB                                                                                   | Do you want to create an application container instead of a PDB?                                                                                                                                                                                     | Specify the AS APPLICATION CONTAINER clause.                                                                                                                                                                                                                                                                                                       | Omit the AS APPLICATION CONTAINER clause.                                                                                                                                       |
| AS CLONE                 | Plugging in an unplugged PDB                                                                                                 | Are you plugging a PDB into a CDB that contains one or more PDBs that were created by plugging in the same PDB?                                                                                                                                      | Specify the AS CLONE clause to ensure that Oracle Database generates unique PDB DBID, GUID, and other identifiers expected for the new PDB. The PDB is plugged in as a clone of the unplugged PDB to ensure that all of its identifiers are unique.                                                                                                | Omit the AS CLONE clause.                                                                                                                                                       |
| AS SEED                  | Creating an application seed in an application container                                                                     | Do you want to create an application seed in an application container?                                                                                                                                                                               | Specify the AS SEED clause.                                                                                                                                                                                                                                                                                                                        | Omit the AS SEED clause.                                                                                                                                                        |
| CREATE_FILE_DEST         | Creating a PDB from the CDB seed or an application seed<br>Cloning a PDB<br>Relocating a PDB<br>Plugging in an unplugged PDB | Do you want to use a CREATE_FILE_DEST clause to specify the Oracle Managed Files default location for the PDB's files?<br><br>When creating a PDB from the CDB seed or an application seed, the source files are the files associated with the seed. | Include a CREATE_FILE_DEST clause that specifies the default file system directory or Oracle ASM disk group for the PDB's files.<br><br>• FILE_NAME_CONVERT clause<br>• Enable Oracle Managed Files for the CDB for it to determine the target locations.<br>• Specify the target locations in the PDB_FILE_NAME_CONVERT initialization parameter. | Omit the CREATE_FILE_DEST clause.<br><br>Use one of these techniques to specify the target locations of the files:<br><br>See " <a href="#">File Location of the New PDB</a> ". |

**Table 38-3 (Cont.) Clauses for Creating a PDB**

| Clause             | Can Be Used Only When                                                                                                                                                                                                   | Question                                                                                                                                                                                                                  | Yes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | No                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEFAULT TABLESPACE | Creating a PDB from the CDB seed or an application seed<br>Cloning a PDB<br>Relocating a PDB<br>Plugging in an unplugged PDB                                                                                            | Do you want to specify a default permanent tablespace for the PDB?                                                                                                                                                        | Specify a DEFAULT TABLESPACE clause with the appropriate limits.<br><br>Oracle Database will assign to this tablespace any non-SYSTEM users for whom you do not specify a different permanent tablespace.<br><br>When creating a PDB from the CDB seed or an application seed, Oracle Database creates a smallfile tablespace and sets it as the default tablespace. When using a technique other than creation from the CDB seed or an application seed, the specified tablespace must exist in the source PDB. | Omit the DEFAULT TABLESPACE clause.<br><br>If you do not specify this clause, then the SYSTEM tablespace is the default permanent tablespace for non-SYSTEM users. Using the SYSTEM tablespace for non-SYSTEM users is not recommended.                                                                                                                                                                                                       |
| FILE_NAME_CONVERT  | Creating a PDB from the CDB seed or an application seed<br>Cloning a PDB<br>Relocating a PDB<br>Creating a proxy PDB (Only applies to data files in the SYSTEM and SYSAUX tablespaces.)<br>Plugging in an unplugged PDB | Do you want to use a FILE_NAME_CONVERT clause to specify the target locations of the files?<br><br>When creating a PDB from the CDB seed or an application seed, the source files are the files associated with the seed. | Include a FILE_NAME_CONVERT clause that specifies the target locations of the files based on the names of the source files.                                                                                                                                                                                                                                                                                                                                                                                      | Omit the FILE_NAME_CONVERT clause.<br><br>Use one of these techniques to specify the target locations of the files: <ul style="list-style-type: none"><li>• CREATE_FILE_DEST clause</li><li>• Enable Oracle Managed Files for the CDB for it to determine the target locations.</li><li>• Specify the target locations in the PDB_FILE_NAME_CONVERT initialization parameter.</li></ul> See " <a href="#">File Location of the New PDB</a> ". |

**Table 38-3 (Cont.) Clauses for Creating a PDB**

| Clause                | Can Be Used Only When                                                                                                        | Question                                                                                                                                                                 | Yes                                                                                                                                                                                                                                                                                                                  | No                               |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| HOST                  | Creating a PDB from the CDB seed or an application seed<br>Cloning a PDB<br>Relocating a PDB<br>Plugging in an unplugged PDB | Is the PDB a reference PDB with a dependent proxy PDB, and is the host name of its listener changing?                                                                    | Include a HOST clause and specify the host name of the listener for the PDB being created. For example, you might have a listener network for the physical host name and default port and also have configured a second listener bound to a virtual host name and virtual IP address with a non-default port number. | Omit the HOST clause.            |
| <i>logging_clause</i> | Creating a PDB from the CDB seed or an application seed<br>Cloning a PDB<br>Plugging in an unplugged PDB                     | Do you want to specify the logging attribute of the tablespaces in the new PDB?<br><br>This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2). | Include the <i>logging_clause</i> .                                                                                                                                                                                                                                                                                  | Omit the <i>logging_clause</i> . |

**Table 38-3 (Cont.) Clauses for Creating a PDB**

| Clause                                                                      | Can Be Used Only When        | Question                                                                                                                                                                                                              | Yes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | No                       |
|-----------------------------------------------------------------------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| NOCOPY, COPY, MOVE<br>See " <a href="#">File Location of the New PDB</a> ". | Plugging in an unplugged PDB | Do you want to copy or move the files to a new location?                                                                                                                                                              | <p>Specify COPY to copy the files to a new location. COPY is the default. Specify MOVE to move the files to a new location. Use one of these techniques to specify the target location:</p> <ul style="list-style-type: none"> <li>• Include a FILE_NAME_CONVERT clause that specifies the target locations based on the names of the source files.</li> <li>• Include a CREATE_FILE_DEST clause that specifies the Oracle Managed Files default location for the PDB's files.</li> <li>• Enable Oracle Managed Files for it to determine the target locations.</li> <li>• Specify the target locations in the PDB_FILE_NAME_CONVERT initialization parameter.</li> </ul> | Specify NOCOPY.          |
| NO DATA                                                                     | Cloning a PDB                | <p>Do you want to specify that the data model definition of the source PDB is cloned but not the data of the source PDB?</p> <p>This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).</p> | <p>Include the NO DATA clause.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Omit the NO DATA clause. |

**Table 38-3 (Cont.) Clauses for Creating a PDB**

| Clause      | Can Be Used Only When                                                                                                        | Question                                                                                                                                                                                                                                                                                                                               | Yes                                                                                                                                                                                                                                                                                                                    | No                                             |
|-------------|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| PARALLEL    | Creating a PDB from the CDB seed or an application seed<br>Cloning a PDB                                                     | Do you want to use multiple parallel execution servers to parallelize PDB creation?                                                                                                                                                                                                                                                    | To let the CDB choose the degree of parallelism, include or omit the PARALLEL clause.<br><br>To specify the degree of parallelism, specify the PARALLEL clause with an integer. For example, specify PARALLEL 4 to indicate a degree of parallelism of 4.                                                              | Specify PARALLEL 0 or PARALLEL 1.              |
| PATH_PREFIX | Creating a PDB from the CDB seed or an application seed<br>Cloning a PDB<br>Relocating a PDB<br>Plugging in an unplugged PDB | Do you want to use a PATH_PREFIX clause to restrict file paths for the PDB for the following: directory objects, the Oracle XML repository for the PDB, files created with a CREATE PFILE statement, and the export directory for Oracle wallets?<br><br>The PATH_PREFIX clause does not affect files created by Oracle Managed Files. | Include a PATH_PREFIX clause that specifies an absolute path.                                                                                                                                                                                                                                                          | Set the PATH_PREFIX clause to NONE or omit it. |
| PORT        | Creating a PDB from the CDB seed or an application seed<br>Cloning a PDB<br>Relocating a PDB<br>Plugging in an unplugged PDB | Is the PDB a reference PDB with a dependent proxy PDB, and is the port number of its listener changing to a value other than 1521?                                                                                                                                                                                                     | Include a PORT clause and specify the port number of the listener for the PDB being created. For example, you might have a listener network for the physical host name and default port and also have configured a second listener bound to a virtual host name and virtual IP address with a non-default port number. | Omit the PORT clause.                          |

**Table 38-3 (Cont.) Clauses for Creating a PDB**

| Clause               | Can Be Used Only When                                                                                                                                                                                                                               | Question                                                                                                                                                                                                  | Yes                                                                                                                                                                                                                                                                                                                                                                               | No                                                                  |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| REFRESH MODE         | Cloning a PDB                                                                                                                                                                                                                                       | <p>Do you want to be able to refresh the PDB to propagate changes from the source PDB to the clone PDB?</p> <p>A refreshable PDB must be opened in open read-only mode.</p>                               | Include a REFRESH MODE MANUAL or REFRESH MODE EVERY <i>minutes</i> clause.                                                                                                                                                                                                                                                                                                        | Omit the REFRESH MODE clause or include a REFRESH MODE NONE clause. |
| ROLES                | Creating a PDB from the CDB seed or an application seed                                                                                                                                                                                             | Do you want to grant predefined Oracle roles to the PDB_DBA role locally in the PDB?                                                                                                                      | <p>Include the ROLES clause and specify the predefined Oracle roles to grant to the PDB_DBA role. The specified roles are granted to the PDB_DBA role locally in the PDB. The user who runs the CREATE PLUGGABLE DATABASE statement does not need to be granted the specified roles. See <i>Oracle Database Security Guide</i> for information about predefined Oracle roles.</p> | Omit the ROLES clause.                                              |
|                      | Creating a proxy PDB                                                                                                                                                                                                                                | The new administrator for the PDB is granted the PDB_DBA common role locally in the PDB. By default, the CREATE PLUGGABLE DATABASE statement does not grant the administrator or the role any privileges. |                                                                                                                                                                                                                                                                                                                                                                                   |                                                                     |
| SERVICE_NAME_CONVERT | <p>Creating a PDB from the application seed, but not a CDB seed</p> <p>Cloning a PDB</p> <p>Relocating a PDB</p> <p>Creating a proxy PDB (Only applies to data files in the SYSTEM and SYSAUX tablespaces.)</p> <p>Plugging in an unplugged PDB</p> | Do you want to use a SERVICE_NAME_CONVERT clause to rename the user-defined services of the new PDB based on the service names of the source PDB?                                                         | Include a SERVICE_NAME_CONVERT clause that specifies the new name of a service and the service name it is replacing. Specify multiple service names and replacement service names if necessary.                                                                                                                                                                                   | Omit the SERVICE_NAME_CONVERT clause.                               |

**Table 38-3 (Cont.) Clauses for Creating a PDB**

| Clause                   | Can Be Used Only When                                                                                                                                       | Question                                                                                                                            | Yes                                                                                                                                                                                                                                                                                                                                                                  | No                                                                              |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| SNAPSHOT COPY            | Cloning a PDB                                                                                                                                               | Do you want to clone a PDB using a storage snapshot?                                                                                | <p>Specify a SNAPSHOT COPY clause to indicate that cloning is to be performed using storage snapshots.</p> <p>Creating a PDB clone with storage snapshots makes creating a clone nearly instantaneous because it does not require copying the source PDB's data files. SNAPSHOT COPY is supported only if the underlying file system supports storage snapshots.</p> | Omit the SNAPSHOT COPY clause.                                                  |
| SOURCE_FILE_DIRECTORY    | <p>Plugging in an unplugged PDB using an XML file directly.</p> <p>This clause does not apply to plugging in an unplugged PDB with a .pdb archive file.</p> | Are all of the source files in a single directory with new file names that would require multiple SOURCE_FILE_NAME_CONVERT entries? | Specify the SOURCE_FILE_DIRECTORY with the full absolute path to the source files.                                                                                                                                                                                                                                                                                   | Omit the SOURCE_FILE_DIRECTORY clause.                                          |
| SOURCE_FILE_NAME_CONVERT | <p>Plugging in an unplugged PDB using an XML file directly.</p> <p>This clause does not apply to plugging in an unplugged PDB with a .pdb archive file.</p> | Do the contents of the XML file accurately describe the locations of the source files?                                              | Omit the SOURCE_FILE_NAME_CONVERT clause.                                                                                                                                                                                                                                                                                                                            | Use the SOURCE_FILE_NAME_CONVERT clause to specify the source file locations.   |
| STANDBYS                 | <p>Creating a PDB from the CDB seed or an application seed</p> <p>Cloning a PDB</p> <p>Relocating a PDB</p> <p>Plugging in an unplugged PDB</p>             | Do you want to include the new PDB in one or more standby CDBs?                                                                     | Specify ALL, ALL EXCEPT, or a list of standby CDBs.                                                                                                                                                                                                                                                                                                                  | Omit the STANDBYS clause or specify NONE.                                       |
| STORAGE                  | <p>Creating a PDB from the CDB seed or an application seed</p> <p>Cloning a PDB</p> <p>Relocating a PDB</p> <p>Plugging in an unplugged PDB</p>             | Do you want to limit the amount of storage that the PDB can use?                                                                    | Specify a STORAGE clause with the appropriate limits.                                                                                                                                                                                                                                                                                                                | Omit the STORAGE clause, or specify unlimited storage using the STORAGE clause. |

**Table 38-3 (Cont.) Clauses for Creating a PDB**

| Clause           | Can Be Used Only When                                                                                                                    | Question                                                                                                                                                                                                           | Yes                                                                                               | No                                                                                                                                  |

## 38.2 Preparing for PDBs

Prerequisites must be met before creating a PDB.

Ensure that the following prerequisites are met before creating a PDB:

- The CDB must exist.  
See "[Creating and Configuring a CDB](#)".
- The CDB must be in read/write mode.
- The current user must be a common user whose current container is the CDB root or an application container.
- The current user must have the `CREATE PLUGGABLE DATABASE` system privilege.
- You must decide on a unique container name for each container. Each container name must be unique in a single CDB, and each container name must be unique within the scope of all the CDBs whose instances are reached through a specific listener.

The PDB name is used to distinguish a PDB from other PDBs in the CDB. PDB names follow the same rules as service names, which includes being case-insensitive. See *Oracle Database Net Services Reference* for information about the rules for service names.

- If you are creating a PDB in an Oracle Data Guard configuration with a physical standby database, then additional tasks must be completed before creating a PDB. See *Oracle Data Guard Concepts and Administration* for more information.

- If you are creating a PDB that includes data that was encrypted with Transparent Data Encryption, then follow the instructions in *Oracle Database Advanced Security Guide*.
- If you are creating a Database Vault-enabled PDB, then follow the instructions in *Oracle Database Vault Administrator's Guide*.

**See Also:**

"[About the Current Container](#)"

## 38.3 Creating a PDB Using the Seed

You can use the CREATE PLUGGABLE DATABASE statement to create a PDB in a CDB using the files of the CDB seed. You can also use this statement to create an application PDB in an application container using the files of an application seed or a CDB seed.

- [About Creating a PDB from the Seed](#)

You can use the CREATE PLUGGABLE DATABASE statement to create a new PDB by using the files of the CDB seed or an application PDB from the files of an application seed or the CDB seed.

- [Creating a PDB from the Seed](#)

Using the CREATE PLUGGABLE DATABASE statement, you can create a PDB from the CDB seed, and you can create an application PDB from an application seed or the CDB seed.

**See Also:**

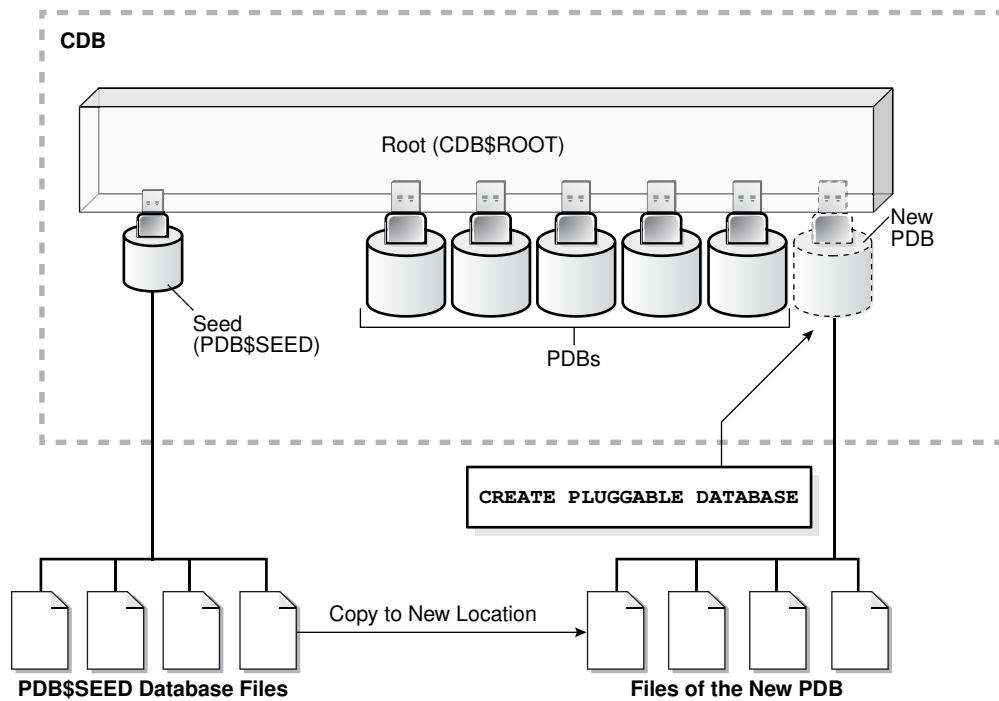

*Oracle Database SQL Language Reference* for more information about the CREATE PLUGGABLE DATABASE statement

### 38.3.1 About Creating a PDB from the Seed

You can use the CREATE PLUGGABLE DATABASE statement to create a new PDB by using the files of the CDB seed or an application PDB from the files of an application seed or the CDB seed.

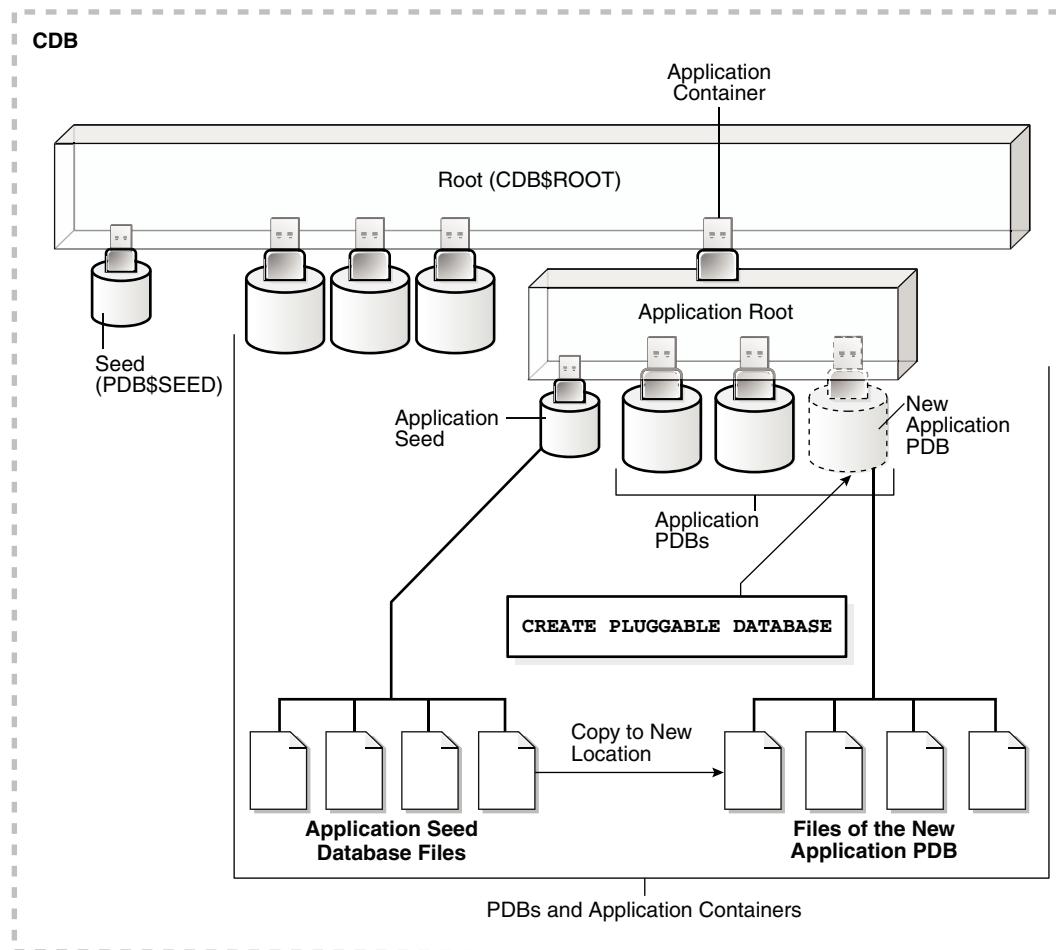

The statement copies these files to a new location and associates them with the new PDB. [Figure 38-2](#) illustrates how this technique creates a new PDB in a CDB with the CDB root as the current container.

Figure 38-2 Create a PDB in the CDB Root Using the CDB Seed Files

[Figure 38-3](#) illustrates how this technique creates a new application PDB in an application container with the application root as the current container.

**Figure 38-3 Create a PDB in an Application Root Using the Application Seed Files**

**See Also:**

["The CREATE PLUGGABLE DATABASE Statement"](#)

When an application container includes an application seed, and a the `CREATE PLUGGABLE DATABASE` statement is run in the application root to create an application PDB from the seed, the application PDB is created using the application seed. However, when an application container does not include an application seed, and a the `CREATE PLUGGABLE DATABASE` statement is run in the application root to create an application PDB from the seed, the application PDB is created using the CDB seed (`PDB$SEED` ).

When you create a new PDB or application PDB from the seed, you must specify an administrator for the PDB or application PDB in the `CREATE PLUGGABLE DATABASE` statement. The statement creates the administrator as a local user in the PDB and grants the `PDB_DBA` role locally to the administrator.

When you create a PDB using the CDB seed or an application seed, you must address the questions that apply to creating a PDB from the seed in [Table 38-3](#). The table describes which `CREATE PLUGGABLE DATABASE` clauses you must specify based on different factors.

 **See Also:**

["Creating an Application PDB"](#)

### 38.3.2 Creating a PDB from the Seed

Using the `CREATE PLUGGABLE DATABASE` statement, you can create a PDB from the CDB seed, and you can create an application PDB from an application seed or the CDB seed.

Before creating a PDB from the CDB seed (`PDB$SEED`) or an application PDB from an application seed or the CDB seed, complete the prerequisites described in "[Preparing for PDBs](#)".

**To create a PDB from the seed:**

1. In SQL\*Plus, ensure that the current container is the CDB root or an application root.

When the current container is the CDB root, the PDB is created in the CDB using the files of the CDB seed.

When the current container is an application root, the application PDB is created in the application container using the files of the application seed. If there is no application seed in the application container, then the application PDB is created in the application container using the files of the CDB seed.

See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Run the `CREATE PLUGGABLE DATABASE` statement, and specify a local administrator for the PDB. Specify other clauses when they are required.

See "[Examples of Creating a PDB from the Seed](#)".

After you create the PDB, it is in mounted mode, and its status is `NEW`. You can view the open mode of a PDB by querying the `OPEN_MODE` column in the `V$PDBS` view. You can view the status of a PDB by querying the `STATUS` column of the `CDB_PDBS` or `DBA_PDBS` view.

A new default service is created for the PDB. The service has the same name as the PDB and can be used to access the PDB. Oracle Net Services must be configured properly for clients to access this service. See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

3. Open the new PDB in read/write mode.

You must open the new PDB in read/write mode for Oracle Database to complete the integration of the new PDB into the CDB. An error is returned if you attempt to open the PDB in read-only mode. After the PDB is opened in read/write mode, its status is `NORMAL`.

See "[Modifying the Open Mode of PDBs](#)" for more information.

**4. Back up the PDB.**

A PDB cannot be recovered unless it is backed up.

*Oracle Database Backup and Recovery User's Guide* for information about backing up a PDB.

A local user with the name of the specified local administrator is created and granted the `PDB_DBA` common role locally in the PDB. If this user was not granted administrator privileges during PDB creation, then use the `SYS` and `SYSTEM` common users to administer to the PDB.

 **Note:**

If an error is returned during PDB creation, then the PDB being created might be in an `UNUSABLE` state. You can check a PDB's state by querying the `CDB_PDBS` or `DBA_PDBS` view, and you can learn more about PDB creation errors by checking the alert log. An unusable PDB can only be dropped, and it must be dropped before a PDB with the same name as the unusable PDB can be created.

### Examples of Creating a PDB from the Seed

The following examples create a new PDB named `salespdb` and a `salesadm` local administrator given different factors.

In addition to creating the `salespdb` PDB, this statement grants the `PDB_DBA` role to the PDB administrator `salesadm` and grants the specified predefined Oracle roles to the `PDB_DBA` role locally in the PDB.

In each example, the root to which the new PDB belongs depends on the current container when the `CREATE PLUGGABLE DATABASE` statement is run:

- When the current container is the CDB root, the new PDB is created in the CDB root.
- When the current container is an application root in an application container, the new PDB is created as an application PDB in the application root.

#### Example 38-30 Creating a PDB Using No Clauses

This example assumes the following factors:

- Storage limits are not required for the PDB. Therefore, the `STORAGE` clause is not required.
- The PDB does not require a default tablespace.
- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled for the CDB, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The files associated with the CDB seed or application seed will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the TEMPFILE REUSE clause is not required.
- No predefined Oracle roles need to be granted to the PDB\_DBA role.

Given the preceding factors, the following statement creates the PDB:

```
CREATE PLUGGABLE DATABASE salespdb ADMIN USER salesadm IDENTIFIED BY password;
```

#### See Also:

- [Using Oracle Managed Files](#)
- *Oracle Database Reference* for information about the PDB\_FILE\_NAME\_CONVERT initialization parameter
- *Oracle Database Security Guide* for guidelines about choosing passwords

### Example 38-31 Creating a PDB and Granting Predefined Oracle Roles to the PDB Administrator

This example assumes the following factors:

- Storage limits are not required for the PDB. Therefore, the STORAGE clause is not required.
- The PDB does not require a default tablespace.
- The PATH\_PREFIX clause is not required.
- The FILE\_NAME\_CONVERT clause and the CREATE\_FILE\_DEST clause are not required.

Either Oracle Managed Files is enabled, or the PDB\_FILE\_NAME\_CONVERT initialization parameter is set. The files associated with the CDB seed or application seed will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the TEMPFILE REUSE clause is not required.
- The PDB\_DBA role should be granted the following predefined Oracle role locally: DBA.

Given the preceding factors, the following statement creates the PDB:

```
CREATE PLUGGABLE DATABASE salespdb ADMIN USER salesadm IDENTIFIED BY password
 ROLES=(DBA);
```

 **See Also:**

- [Using Oracle Managed Files](#)
- *Oracle Database Reference* for information about the `PDB_FILE_NAME_CONVERT` initialization parameter
- *Oracle Database Security Guide* for guidelines about choosing passwords

**Example 38-32 Creating a PDB Using the STORAGE, DEFAULT TABLESPACE, PATH\_PREFIX, and FILE\_NAME\_CONVERT Clauses**

This example assumes the following factors:

- Storage limits must be enforced for the PDB. Therefore, the `STORAGE` clause is required. Specifically, all tablespaces that belong to the PDB must not exceed 2 gigabytes.
- A default permanent tablespace is required for any non-administrative users for which you do not specify a different permanent tablespace. Specifically, this example creates a default permanent tablespace named `sales` with the following characteristics:
  - The single data file for the tablespace is `sales01.dbf`, and the statement creates it in the `/disk1/oracle/dbs/salespdb` directory.
  - The `SIZE` clause specifies that the initial size of the tablespace is 250 megabytes.
  - The `AUTOEXTEND` clause enables automatic extension for the file.
- The path prefix must be added to the PDB's directory object paths. Therefore, the `PATH_PREFIX` clause is required. In this example, the path prefix `/disk1/oracle/dbs/salespdb/` is added to the PDB's directory object paths.
- The `CREATE_FILE_DEST` clause will not be used, Oracle Managed Files is not enabled, and the `PDB_FILE_NAME_CONVERT` initialization parameter is not set. Therefore, the `FILE_NAME_CONVERT` clause is required. Specify the location of the data files for the CDB seed or application seed on your system. In this example, Oracle Database copies the files from `/disk1/oracle/dbs/pdbseed` to `/disk1/oracle/dbs/salespdb`.

To view the location of the data files for the CDB seed or application seed, run the query in [Example 45-7](#).

- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.
- No predefined Oracle roles need to be granted to the `PDB_DBA` role.

Given the preceding factors, the following statement creates the PDB:

```
CREATE PLUGGABLE DATABASE salespdb ADMIN USER salesadm IDENTIFIED BY password
 STORAGE (MAXSIZE 2G)
 DEFAULT TABLESPACE sales
 DATAFILE '/disk1/oracle/dbs/salespdb/sales01.dbf' SIZE 250M AUTOEXTEND ON
 PATH_PREFIX = '/disk1/oracle/dbs/salespdb/'
 FILE_NAME_CONVERT = ('/disk1/oracle/dbs/pdbseed/' , '/disk1/oracle/dbs/salespdb/');
```

 See Also:

- *Oracle Database SQL Language Reference* for more information about the DEFAULT TABLESPACE clause
- *Oracle Database Security Guide* for guidelines about choosing passwords

## 38.4 Creating a PDB by Cloning an Existing PDB or Non-CDB

You can create a PDB by cloning a local PDB, a remote PDB, or a non-CDB.

 Note:

Creating a PDB by cloning a non-CDB is available starting with Oracle Database 12c Release 1 (12.1.0.2).

- [About Cloning a PDB](#)

You can use the CREATE PLUGGABLE DATABASE statement to clone a PDB from a source PDB or from a non-CDB.

- [Cloning a Local PDB](#)

This section describes cloning a local PDB. After cloning a local PDB, the source and target PDBs are in the same CDB.

- [Cloning a Remote PDB or Non-CDB](#)

You can create a PDB by cloning a remote source. The remote source can be a remote PDB or non-CDB. After the cloning operation is complete, the source and the target PDB are in different locations.

- [After Cloning a PDB](#)

Certain rules regarding users and tablespaces apply after cloning a PDB.

### 38.4.1 About Cloning a PDB

You can use the CREATE PLUGGABLE DATABASE statement to clone a PDB from a source PDB or from a non-CDB.

This technique clones a source PDB or non-CDB as a new PDB and automatically plugs the clone into the CDB. To use this technique, you must include a `FROM` clause that specifies the source.

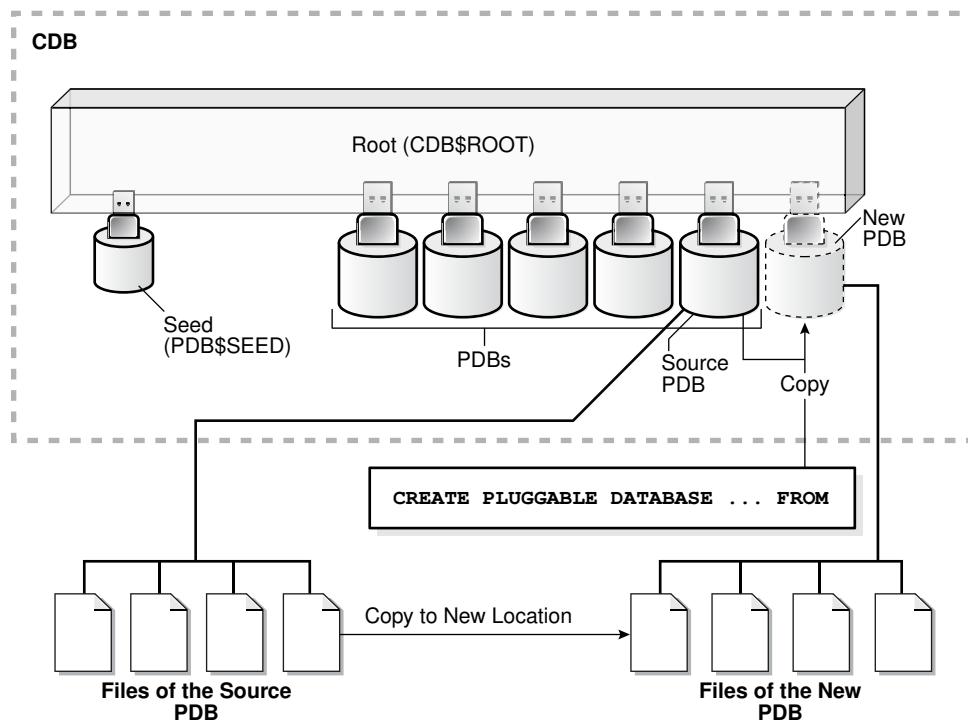

The source is the existing PDB or non-CDB that is copied. The target PDB is the clone of the source. The source can be a PDB in the local CDB, a PDB in a remote CDB, or a non-CDB. The CREATE PLUGGABLE DATABASE statement copies the files associated with the source to a new location and associates the files with the target PDB. When the CDB is in ARCHIVELOG mode and local undo mode, the source PDB can be opened

in read/write mode and fully functional during the operation. Therefore, hot PDB cloning is supported.

One use of cloning is for testing. Cloning enables you to create one or more clones of a PDB or non-CDB and safely test them in isolation. For example, you might test a new or modified application on a cloned PDB before using the application with a production PDB.

[Figure 38-4](#) illustrates how this technique creates a new PDB when the source is a local PDB.

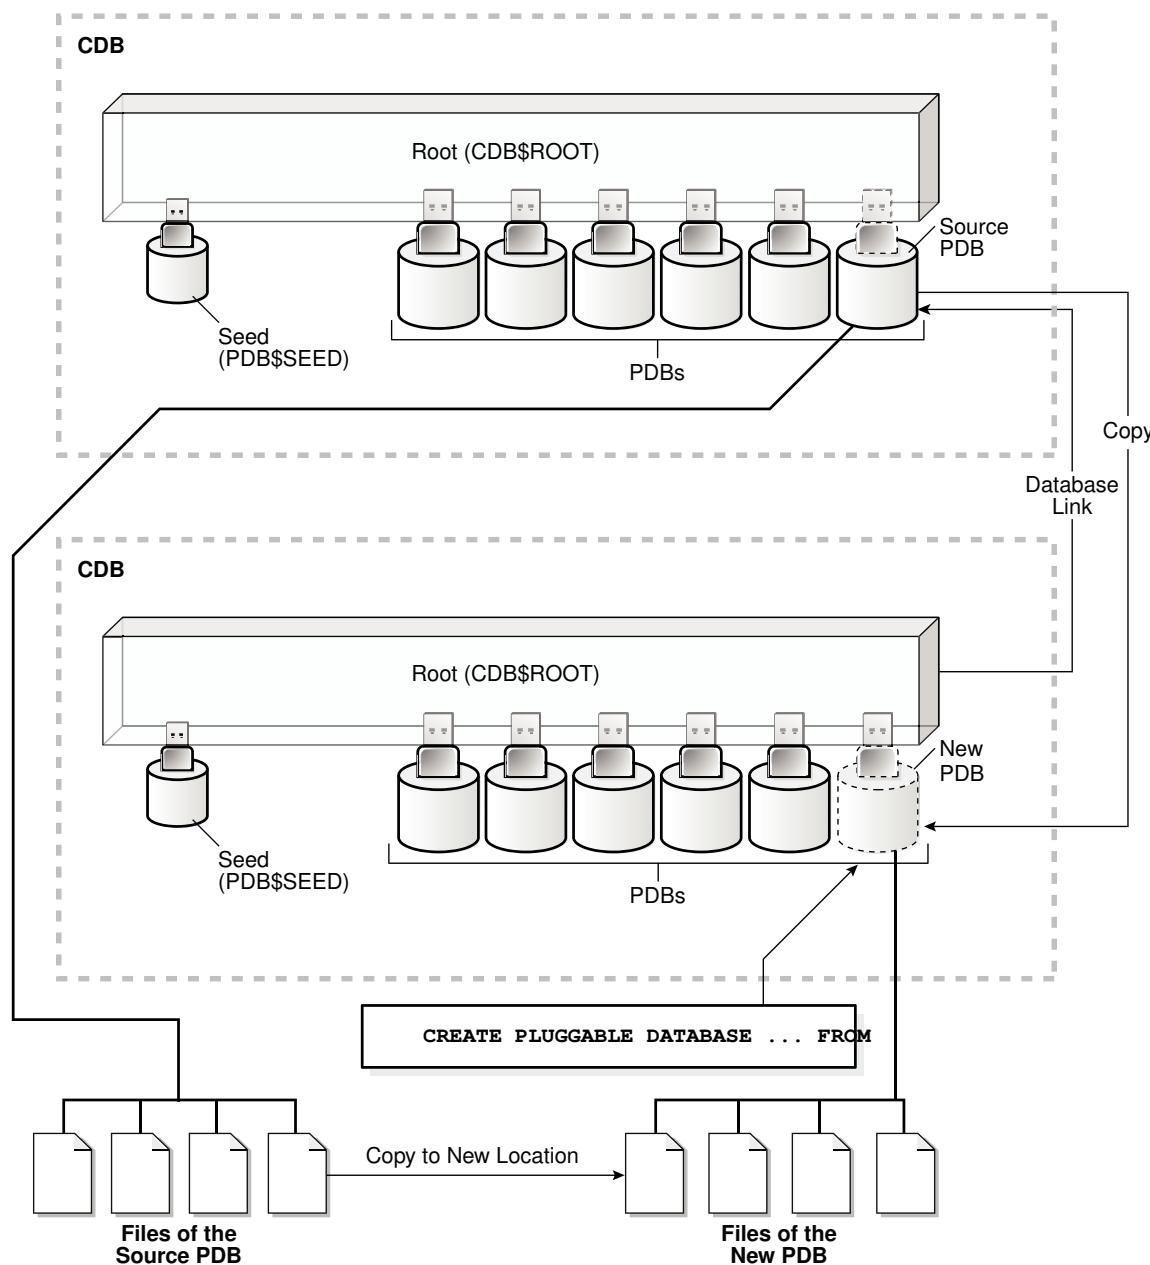

**Figure 38-4 Clone a Local PDB**

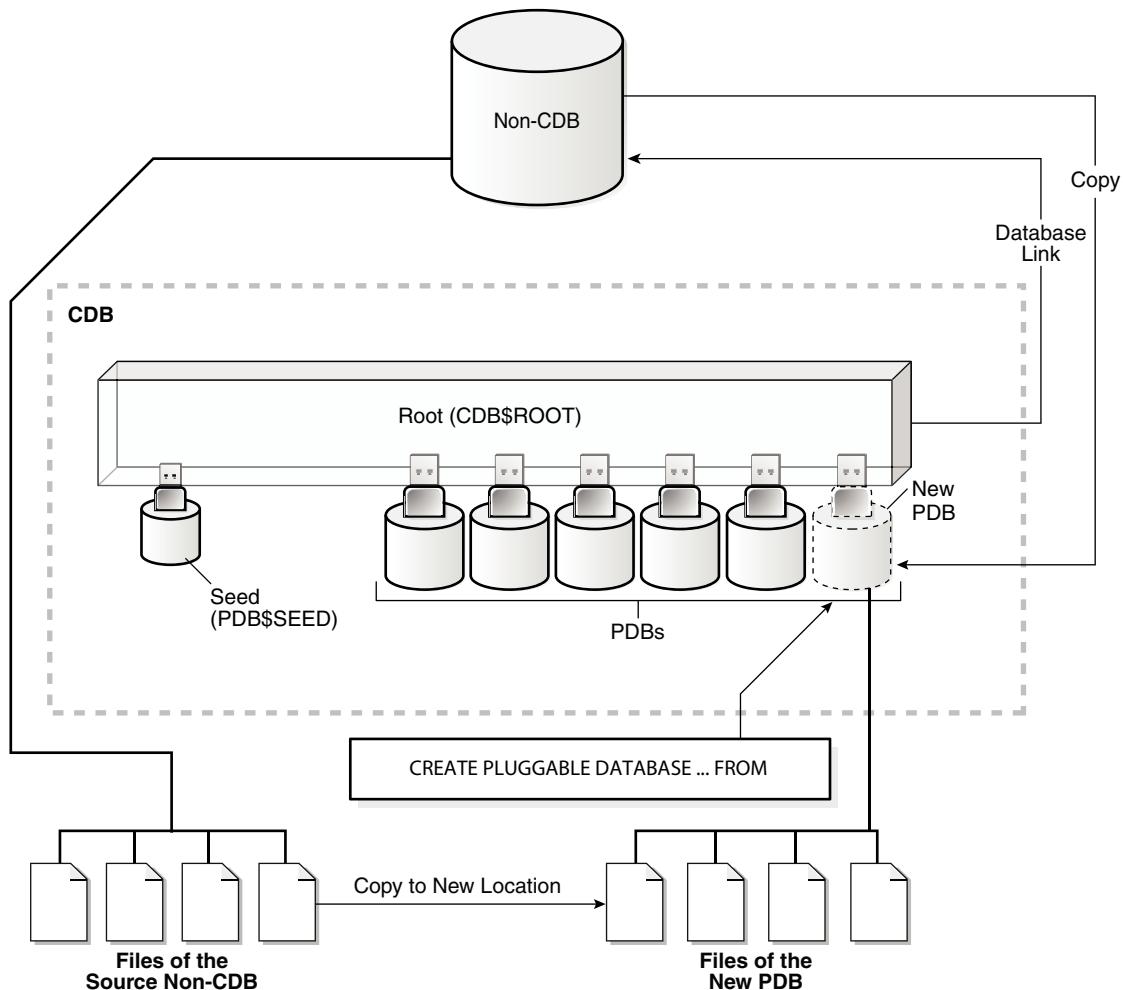

When the source is a PDB in a remote CDB, you must use a database link to clone the PDB. The database link must be created in the CDB that will contain the cloned PDB. When you issue the CREATE PLUGGABLE DATABASE statement from the root of the CDB that will contain the new PDB, you must specify a database link to the remote CDB that contains the PDB being cloned in the FROM clause. The database link connects either to the root of the remote CDB or to the remote source PDB from the CDB that will contain the new PDB.

[Figure 38-5](#) illustrates how this technique creates a new PDB when the source PDB is remote.

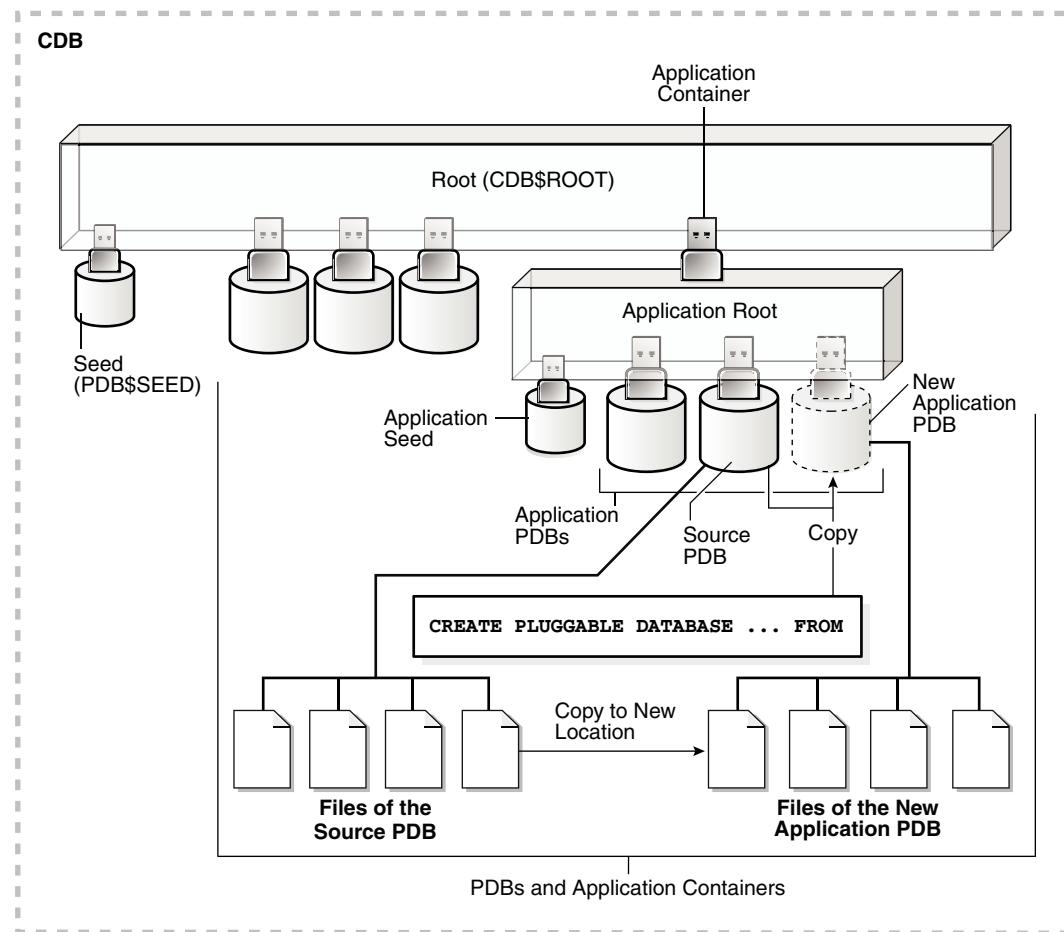

**Figure 38-5 Creating a PDB by Cloning a Remote PDB**

When the source is a non-CDB, you must specify a database link to the non-CDB in the `FROM` clause. [Figure 38-6](#) illustrates how this technique creates a new PDB when the source is a remote non-CDB.

**Figure 38-6** Creating a PDB by Cloning a Non-CDB

In all cloning scenarios (local, remote, and from a non-CDB), when an application root is the current container when you run the `CREATE PLUGGABLE DATABASE` statement, the cloned PDB is created in the application container. In this case, the source PDB's application name and version must match the application name and version of the application container. [Figure 38-7](#) illustrates how this technique creates a new application PDB in an application container by cloning a local source application PDB. The source PDB can also be a PDB plugged into the local CDB root, a PDB plugged into a remote CDB root, or an application PDB plugged into a remote application root.

**Figure 38-7 Clone a PDB in an Application Container****See Also:**

["The CREATE PLUGGABLE DATABASE Statement"](#)

**Note:**

You cannot use the **FROM** clause in the **CREATE PLUGGABLE DATABASE** statement to create a PDB from the CDB seed (**PDB\$SEED**) or from an application seed. See "[Creating a PDB Using the Seed](#)" for information about creating a PDB from the seed.

When you clone a PDB, you must address the questions that apply to cloning a PDB in [Table 38-3](#). The table describes which **CREATE PLUGGABLE DATABASE** clauses you must specify based on different factors.

 **Note:**

If you want to create the PDB by cloning another PDB or from a non-CDB, and if the source database has encrypted data or a keystore set, then you must provide the keystore password by including the keystore identified by `keystore_password` clause in the `CREATE PLUGGABLE DATABASE ... FROM` SQL statement. You must provide this password even if the source database is using an auto-login software keystore. You can determine whether the source database has encrypted data or a keystore by querying the `DBA_ENCRYPTED_COLUMNS` data dictionary view.

 **See Also:**

- ["Creating an Application PDB"](#)
- ["Determining the Current Container ID or Name"](#)
- [Oracle Database Advanced Security Guide](#) for more information about cloning a source with encrypted data or a keystore set

### Refreshable Clone PDB

You can clone a source PDB and configure the clone to be refreshable. To do so, include the `REFRESH MODE` clause of the `CREATE PLUGGABLE DATABASE` statement. When the clone PDB is refreshed, it is updated with any changes made to its source PDB. You can configure the clone PDB to refresh automatically at set intervals, or you can refresh it manually with the `ALTER PLUGGABLE DATABASE REFRESH` statement. The refreshable clone PDB and the source PDB must be in different CDBs.

A refreshable clone PDB must be in either read-only mode or closed. It cannot be in read/write mode. However, you can change a refreshable clone PDB into an ordinary PDB by including the `REFRESH MODE NONE` clause in an `ALTER PLUGGABLE DATABASE` statement and then opening the PDB in read/write mode. An ordinary PDB cannot be changed into a refreshable clone PDB, and after a refreshable clone PDB is converted to an ordinary PDB, it cannot be changed back into a refreshable clone PDB.

 **See Also:**

- ["PDB Refresh"](#)
- ["Cloning a Remote PDB or Non-CDB"](#)
- ["Refreshing a PDB"](#)

### The SNAPSHOT COPY Clause

When you use the `SNAPSHOT COPY` clause, all of the data files of the source PDB must be stored in the same storage type.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB and the `CLONEDB` initialization parameter is set to `FALSE`, the underlying file system for the source PDB's files must support storage snapshots. Such file systems include Oracle Automatic Storage Management Cluster File System (Oracle ACFS) and Direct NFS Client storage. Exadata supports snapshot copy functionality on ASM configured with sparse ASM grid disks.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB and the `CLONEDB` initialization parameter is set to `TRUE`, the underlying file system for the source PDB's files can be any local file system, network file system (NFS), or clustered file system that has Direct NFS enabled and supports sparse files. However, when the `CLONEDB` initialization parameter is set to `TRUE`, the source PDB must remain in open read-only mode as long as any clones exist.

Direct NFS Client enables an Oracle database to access network attached storage (NAS) devices directly, rather than using the operating system kernel NFS client. If the PDB's files are stored on Direct NFS Client storage, then the following additional requirements must be met:

- The source PDB's files must be located on an NFS volume.
- Storage credentials must be stored in a Transparent Data Encryption keystore.
- The storage user must have the privileges required to create and destroy snapshots on the volume that hosts the source PDB's files.
- Credentials must be stored in the keystore using an `ADMINISTER KEY MANAGEMENT ADD SECRET SQL` statement.

The following example configures an Oracle Database secret in a software keystore:

```
ADMINISTER KEY MANAGEMENT
 ADD SECRET 'secret' FOR CLIENT 'client_name'
 USING TAG 'storage_user'
 IDENTIFIED BY keystore_password WITH BACKUP;
```

Run this statement to add a separate entry for each storage server in the configuration. In the previous example, the following values must be specified:

- *secret* is the storage password.
- *client\_name* is the storage server. On a Linux or UNIX platform, it is the name entered in `/etc/hosts` or the IP address of the storage server.
- *tag* is the username passed to the storage server.
- *keystore\_password* is the password for the keystore.

See *Oracle Database Advanced Security Guide* for more information about managing keystores and secrets.

PDB clones created using the `SNAPSHOT COPY` clause cannot be unplugged. They can only be dropped. Attempting to unplug a clone created using the `SNAPSHOT COPY` clause results in an error.

Storage clones are named and tagged using the destination PDB's GUID. You can query the `CLONETAG` column of `DBA_PDB_HISTORY` view to view clone tags for storage clones.

 **Note:**

Snapshot copy behavior and efficiency are vendor specific and may vary between vendors.

### 38.4.2 Cloning a Local PDB

This section describes cloning a local PDB. After cloning a local PDB, the source and target PDBs are in the same CDB.

The following prerequisites must be met:

- Complete the prerequisites described in "[Preparing for PDBs](#)".
- The current user must have the `CREATE PLUGGABLE DATABASE` system privilege in both the root and the source PDB.
- The source PDB cannot be closed.
- If the CDB is not in local undo mode, then the source PDB must be in open read-only mode. This requirement does not apply if the CDB is in local undo mode.

See "[About the CDB Undo Mode](#)".

- If the CDB is not in `ARCHIVELOG` mode, then the source PDB must be in open read-only mode. This requirement does not apply if the CDB is in `ARCHIVELOG` mode.
- If you are creating an application PDB, then the application PDB must have the same character set and national character set as the application container.

If the database character set of the CDB is `AL32UTF8`, then the character set and national character set of the application container can be different from the CDB. However, all application PDBs in an application container must have same character set and national character set, matching that of the application container.

 **Note:**

You cannot use the `REFRESH MODE` clause to create a refreshable clone PDB that is a clone of a local PDB. A refreshable clone PDB must be created in a remote CDB.

**To clone a local PDB:**

1. In SQL\*Plus, ensure that the current container is the CDB root or an application root.

When the current container is the CDB root, the PDB is created in the CDB. When the current container is an application root, the application PDB is created in the application container.

See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Run the `CREATE PLUGGABLE DATABASE` statement, and specify the source PDB in the `FROM` clause. Specify other clauses when they are required.

See "[Examples of Cloning a Local PDB](#)".

After you create the PDB, it is in mounted mode, and its status is `NEW`. You can view the open mode of a PDB by querying the `OPEN_MODE` column in the `V$PDBS` view. You can view the status of a PDB by querying the `STATUS` column of the `CDB_PDBS` or `DBA_PDBS` view.

A new default service is created for the PDB. The service has the same name as the PDB and can be used to access the PDB. Oracle Net Services must be configured properly for clients to access this service. See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

3. Open the new PDB in read/write mode.

You must open the new PDB in read/write mode for Oracle Database to complete the integration of the new PDB into the CDB. An error is returned if you attempt to open the PDB in read-only mode. After the PDB is opened in read/write mode, its status is `NORMAL`.

See "[Modifying the Open Mode of PDBs](#)" for more information.

4. Back up the PDB.

A PDB cannot be recovered unless it is backed up.

*Oracle Database Backup and Recovery User's Guide* for information about backing up a PDB.

 **Note:**

If an error is returned during PDB creation, then the PDB being created might be in an `UNUSABLE` state. You can check a PDB's state by querying the `CDB_PDBS` or `DBA_PDBS` view, and you can learn more about PDB creation errors by checking the alert log. An unusable PDB can only be dropped, and it must be dropped before a PDB with the same name as the unusable PDB can be created.

## Examples of Cloning a Local PDB

The following examples clone a local source PDB named `pdb1` to a target PDB named `pdb2` given different factors.

In each example, the root to which the new PDB belongs depends on the current container when the `CREATE PLUGGABLE DATABASE` statement is run:

- When the current container is the CDB root, the new PDB is created in the CDB root.
- When the current container is an application root in an application container, the new PDB is created as an application PDB in the application root.

### Example 38-33 Cloning a Local PDB Using No Clauses

This example assumes the following factors:

- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. Therefore, the `FILE_NAME_CONVERT` clause is not required. The files will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- Storage limits are not required for the PDB. Therefore, the `STORAGE` clause is not required.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Given the preceding factors, the following statement clones the `pdb2` PDB from the `pdb1` PDB:

```
CREATE PLUGGABLE DATABASE pdb2 FROM pdb1;
```

#### See Also:

- [Using Oracle Managed Files](#)
- *Oracle Database Reference* for information about the `PDB_FILE_NAME_CONVERT` initialization parameter

### Example 38-34 Cloning a Local PDB With the PATH\_PREFIX, FILE\_NAME\_CONVERT, and SERVICE\_NAME\_CONVERT Clauses

This example assumes the following factors:

- The path prefix must be added to the PDB's directory object paths. Therefore, the `PATH_PREFIX` clause is required. In this example, the path prefix `/disk2/oracle/pdb2/` is added to the PDB's directory object paths.
- The `FILE_NAME_CONVERT` clause is required to specify the target locations of the copied files. In this example, the files are copied from `/disk1/oracle/pdb1` to `/disk2/oracle/pdb2`.

The CREATE\_FILE\_DEST clause is not used, and neither Oracle Managed Files nor the PDB\_FILE\_NAME\_CONVERT initialization parameter is used to specify the target locations of the copied files.

To view the location of the data files for a PDB, run the query in [Example 45-7](#).

- Storage limits are not required for the PDB. Therefore, the STORAGE clause is not required.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the TEMPFILE REUSE clause is not required.
- The PDB that is being cloned (pdb1) has two user-defined services: salesrep\_ca and orders\_ca for the sales representatives and order entry personnel in California. The new services will be for the sales representatives and order entry personnel in Oregon, and the service names will be renamed to salesrep\_or and orders\_or, respectively, in the cloned PDB (pdb2).
- Future tablespaces created within the PDB will be created with the NOLOGGING attribute by default. This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

Given the preceding factors, the following statement clones the pdb2 PDB from the pdb1 PDB:

```
CREATE PLUGGABLE DATABASE pdb2 FROM pdb1
PATH_PREFIX = '/disk2/oracle/pdb2/'
FILE_NAME_CONVERT = ('/disk1/oracle/pdb1/', '/disk2/oracle/pdb2/')
SERVICE_NAME_CONVERT = ('salesrep_ca','salesrep_or','orders_ca','orders_or')
NOLOGGING;
```

### **Example 38-35 Cloning a Local PDB Using the FILE\_NAME\_CONVERT, STORAGE, and SERVICE\_NAME\_CONVERT Clauses**

This example assumes the following factors:

- The PATH\_PREFIX clause is not required.
- The FILE\_NAME\_CONVERT clause is required to specify the target locations of the copied files. In this example, the files are copied from /disk1/oracle/pdb1 to /disk2/oracle/pdb2.

The CREATE\_FILE\_DEST clause is not used, and neither Oracle Managed Files nor the PDB\_FILE\_NAME\_CONVERT initialization parameter is used to specify the target locations of the copied files.

To view the location of the data files for a PDB, run the query in [Example 45-7](#).

- Storage limits must be enforced for the PDB. Therefore, the STORAGE clause is required. Specifically, all tablespaces that belong to the PDB must not exceed 2 gigabytes.
- The PDB that is being cloned (pdb1) has two user-defined services: salesrep\_ca and orders\_ca for the sales representatives and order entry personnel in California. The new services will be for the sales representatives and order entry personnel in Oregon, and the service names will be renamed to salesrep\_or and orders\_or, respectively, in the cloned PDB (pdb2).
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the TEMPFILE REUSE clause is not required.

Given the preceding factors, the following statement clones the `pdb2` PDB from the `pdb1` PDB:

```
CREATE PLUGGABLE DATABASE pdb2 FROM pdb1
 FILE_NAME_CONVERT = ('/disk1/oracle/pdb1/', '/disk2/oracle/pdb2/')
 STORAGE (MAXSIZE 2G)
 SERVICE_NAME_CONVERT = ('salesrep_ca','salesrep_or','orders_ca','orders_or');
```

### **Example 38-36 Cloning a Local PDB Without Cloning Its Data**

This example assumes the following factors:

- The `NO DATA` clause is required because the goal is to clone the data model definition of the source PDB without cloning its data.
- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. Therefore, the `FILE_NAME_CONVERT` clause is not required. The files will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- Storage limits are not required for the PDB. Therefore, the `STORAGE` clause is not required.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Assume that the source PDB `pdb1` has a large amount of data. The following steps illustrate how the clone does not contain the source PDB's data when the operation is complete:

1. With the source PDB `pdb1` as the current container, query a table with a large amount of data:

```
SELECT COUNT(*) FROM tpch.lineitem;
COUNT(*)

6001215
```

The table has over six million rows.

2. Clone the source PDB with the `NO DATA` clause:

```
CREATE PLUGGABLE DATABASE pdb2 FROM pdb1 NO DATA;
```

3. Open the cloned PDB:

```
ALTER PLUGGABLE DATABASE pdb2 OPEN;
```

4. With the cloned PDB `pdb2` as the current container, query the table that has a large amount of data in the source PDB:

```
SELECT COUNT(*) FROM tpch.lineitem;
COUNT(*)

0
```

The table in the cloned PDB has no rows.

### 38.4.3 Cloning a Remote PDB or Non-CDB

You can create a PDB by cloning a remote source. The remote source can be a remote PDB or non-CDB. After the cloning operation is complete, the source and the target PDB are in different locations.

The following prerequisites must be met:

- Complete the prerequisites described in "[Preparing for PDBs](#)".
- The current user must have the `CREATE PLUGGABLE DATABASE` system privilege in the root of the CDB that will contain the target PDB.
- The source PDB cannot be closed.
- When cloning a PDB, if the remote CDB is not in local undo mode, then the source PDB must be in open read-only mode. This requirement does not apply if the remote CDB that contains the source PDB is in local undo mode.

See "[About the CDB Undo Mode](#)".

- If the remote CDB or non-CDB is not in `ARCHIVELOG` mode, then the source PDB or non-CDB must be in open read-only mode. This requirement does not apply if the remote CDB that contains the source PDB or the non-CDB is in `ARCHIVELOG` mode.
- The following prerequisites apply for the database link:
  - A database link must enable a connection from the CDB to which the PDB is being cloned to the source PDB's CDB. The database link can connect to either the root of the CDB, to an application PDB if the source is an application PDB, or to the PDB.
  - The user that the database link connects with must have the `CREATE PLUGGABLE DATABASE` system privilege.
  - If the database link connects to the root in the source PDB's CDB, then the user that the database link connects with must be a common user.
- The source and target platforms must meet these requirements:
  - They must have the same endianness.
  - The database options installed on the source platform must be the same as, or a subset of, the database options installed on the target platform.
- If the character set of the CDB to which the PDB is being cloned is not AL32UTF8, then the source and target must have compatible character sets and national character sets. To be compatible, the character sets and national character sets must meet all of the requirements specified in *Oracle Database Globalization Support Guide*.

If the character set of the CDB to which the PDB is being cloned is AL32UTF8, then this requirement does not apply.

- If you create a PDB by cloning a non-CDB, then you must meet the following requirements:
  - The CDB and the non-CDB must be running Oracle Database 12c Release 1 (12.1.0.2) or later.
  - The data block size of the cloned PDB must match the CDB in which the clone PDB will reside.

- If you are creating an application PDB, then the application name and version of the source PDB must match the application name and version of the application container that will contain the target application PDB.
  - If you are creating an application PDB, then the application PDB must have the same character set and national character set as the application container.
- If the database character set of the CDB is AL32UTF8, then the character set and national character set of the application container can different from the CDB. However, all application PDBs in an application container must have same character set and national character set, matching that of the application container.
- If you are creating a refreshable PDB, then the source PDB must be in ARCHIVELOG mode and local undo mode.

#### To clone a remote PDB or non-CDB:

1. In SQL\*Plus, ensure that the current container is the root of the CDB that will contain the new PDB or the application root of the application container that will contain the new PDB.  
See "[About the Current Container](#)" and "[About Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Run the CREATE PLUGGABLE DATABASE statement, and specify the source PDB or the source non-CDB in the FROM clause. Specify other clauses when they are required.  
See "[Creating a PDB by Cloning It From a Remote PDB Using No Clauses](#)".

After you create the PDB, it is in mounted mode, and its status is NEW. You can view the open mode of a PDB by querying the OPEN\_MODE column in the V\$PDBS view. You can view the status of a PDB by querying the STATUS column of the CDB\_PDBS or DBA\_PDBS view.

A new default service is created for the PDB. The service has the same name as the PDB and can be used to access the PDB. Oracle Net Services must be configured properly for clients to access this service. See "[About Accessing a Container in a CDB with SQL\\*Plus](#)".

3. If you created the PDB from a non-CDB, then run the ORACLE\_HOME/rdbms/admin/noncdb\_to\_pdb.sql script. This script must be run before the PDB can be opened for the first time.

If the PDB was not a non-CDB, then running the noncdb\_to\_pdb.sql script is not required.

To run the noncdb\_to\_pdb.sql script, complete the following steps:

- a. Access the PDB.

The current user must have SYSDBA administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using AS SYSDBA at connect time.

See "[About Accessing a Container in a CDB with SQL\\*Plus](#)".

- b. Run the noncdb\_to\_pdb.sql script:

```
@$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql
```

The script opens the PDB, performs changes, and closes the PDB when the changes are complete.

4. Open the new PDB in read/write mode.

You must open the new PDB in read/write mode for Oracle Database to complete the integration of the new PDB into the CDB. An error is returned if you attempt to open the PDB in read-only mode. After the PDB is opened in read/write mode, its status is NORMAL.

See "[Modifying the Open Mode of PDBs](#)" for more information.

5. Back up the PDB.

A PDB cannot be recovered unless it is backed up.

*Oracle Database Backup and Recovery User's Guide* for information about backing up a PDB.

 **Note:**

If an error is returned during PDB creation, then the PDB being created might be in an UNUSABLE state. You can check a PDB's state by querying the CDB\_PDBS or DBA\_PDBS view, and you can learn more about PDB creation errors by checking the alert log. An unusable PDB can only be dropped, and it must be dropped before a PDB with the same name as the unusable PDB can be created.

### Examples of Cloning a Remote PDB or Non-CDB

The following examples clone a remote PDB or non-CDB given different factors.

In each example, the root to which the new PDB belongs depends on the current container when the CREATE PLUGGABLE DATABASE statement is run:

- When the current container is the CDB root, the new PDB is created in the CDB root.
- When the current container is an application root in an application container, the new PDB is created as an application PDB in the application root.

#### **Example 38-37 Creating a PDB by Cloning It From a Remote PDB Using No Clauses**

This example clones a remote source PDB named `pdb1` to a target PDB named `pdb2` given different factors. This example assumes the following factors:

- The database link name to the remote PDB is `pdb1_link`.
- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The files will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- Storage limits are not required for the PDB. Therefore, the `STORAGE` clause is not required.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Given the preceding factors, the following statement clones the `pdb2` PDB from the `pdb1` remote PDB:

```
CREATE PLUGGABLE DATABASE pdb2 FROM pdb1@pdb1_link;
```

#### Example 38-38 Creating a PDB by Cloning a Remote Non-CDB

This example creates a new PDB by cloning a remote source non-CDB named `mydb` to a target PDB named `pdb2` given different factors. This example assumes the following factors:

- The database link name to the remote non-CDB is `mydb_link`.
- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The files will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- Storage limits are not required for the PDB. Therefore, the `STORAGE` clause is not required.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Given the preceding factors, the following statement creates the `pdb2` PDB from the remote non-CDB named `mydb`:

```
CREATE PLUGGABLE DATABASE pdb2 FROM mydb@mydb_link;
```

When the source is a non-CDB, you can substitute `NON$CDB` for the name of the non-CDB. For example, the following statement is equivalent to the previous example:

```
CREATE PLUGGABLE DATABASE pdb2 FROM NON$CDB@mydb_link;
```

#### See Also:

- [Using Oracle Managed Files](#)
- *Oracle Database Reference* for information about the `PDB_FILE_NAME_CONVERT` initialization parameter

#### Example 38-39 Creating a Refreshable Clone

This example clones a remote source PDB named `pdb1` to a target PDB named `pdb2` given different factors. The clone is a refreshable copy of the source PDB, which means that it can be refreshed to update it with any changes made to the source PDB. This example assumes the following factors:

- The database link name to the remote PDB is `pdb1_link`.
- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The files will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- Storage limits are not required for the PDB. Therefore, the `STORAGE` clause is not required.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.
- The refreshable clone will be refreshed automatically every 60 minutes.

Remember that, to create a refreshable PDB, the source PDB must be in `ARCHIVELOG` mode and local undo mode.

Given the preceding factors, the following statement clones the `pdb2` PDB from the `pdb1` remote PDB:

```
CREATE PLUGGABLE DATABASE pdb2 FROM pdb1@pdb1_link REFRESH MODE EVERY 60 MINUTES;
```

#### See Also:

- "[PDB Refresh](#)"
- "[About Cloning a PDB](#)"
- "[Refreshing a PDB](#)"

### 38.4.4 After Cloning a PDB

Certain rules regarding users and tablespaces apply after cloning a PDB.

The following applies after cloning a PDB:

- Users in the PDB who used the default temporary tablespace of the source non-CDB or PDB use the default temporary tablespace of the cloned PDB. Users who used non-default temporary tablespaces in the non-CDB or PDB continue to use the same local temporary tablespaces in the cloned PDB. See "[About Managing Tablespaces in a CDB](#)".
- When cloning a remote PDB, user-created common users that existed in the source CDB but not in the target CDB do not have any privileges granted commonly. However, if the target CDB has a common user with the same name as a common user in the PDB, the latter is linked to the former and has the privileges granted to this common user in the target CDB.

If the cloned or plugged-in PDB has a common user account that does not exist in the target CDB, and if this user does not own objects in the PDB, then Oracle Database drops the user during the synchronization step; otherwise, the user account is locked in the target PDB. You have the following options regarding locked accounts:

- Close the PDB, connect to the root, and create a common user account with the same name. When the PDB is opened in read/write mode, differences in roles and privileges granted commonly to the user account are resolved, and

you can unlock the account. Privileges and roles granted locally to the user account remain unchanged during this process.

- Create a new local user account in the PDB and use Data Pump to export/import the locked user's data into the new local user's schema.
- Leave the user account locked.
- Drop the user account.

 **See Also:**

## 38.5 Creating a PDB by Relocating It

You can create a PDB by relocating it from one CDB to another.

- [About Relocating a PDB](#)

You can use the `CREATE PLUGGABLE DATABASE` statement to relocate a PDB from one CDB to another.

- [Relocating a PDB](#)

You can create a PDB by relocating it. After the operation is complete, the PDB is removed from its current CDB and is added to a different CDB.

### 38.5.1 About Relocating a PDB

You can use the `CREATE PLUGGABLE DATABASE` statement to relocate a PDB from one CDB to another.

This technique moves a PDB from one CDB to another. To use this technique, you run the `CREATE PLUGGABLE DATABASE` statement and include the `FROM` clause and the `RELOCATE` clause.

You must include a `FROM` clause that specifies the current location of the PDB. You must also include the `RELOCATE` clause to specify that the PDB is being moved instead of cloned. After the operation is complete, the PDB is added to the CDB to which the PDB is relocated. The `CREATE PLUGGABLE DATABASE` statement also moves the files associated with the PDB to a new location. Using this technique is the fastest way to relocate a PDB with minimal down time.

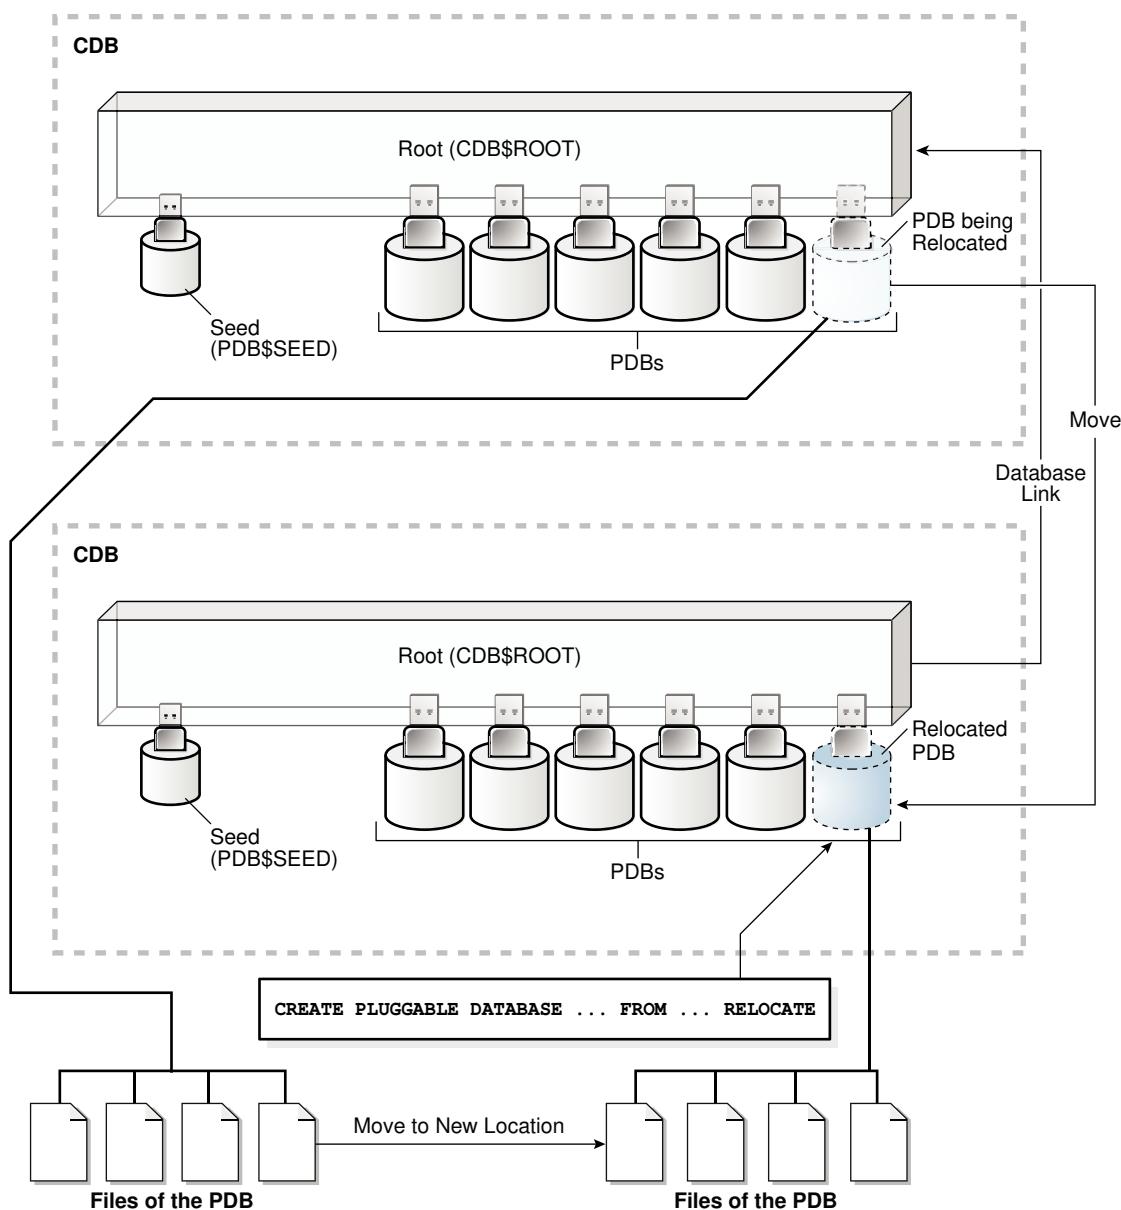

In addition, the PDB being relocated can be opened in read/write mode and fully functional during the relocation process. This technique automatically quiesces the

PDB in its old location while transporting and applying redo data to the PDB in its new location. Finally, when the PDB is ready, this technique brings it online in its new location. While the PDB is being relocated, current DML and DDL operations will pause while they are redirected to the PDB's new location. Queries continue to run with no pause.

You must use a database link to relocate the PDB. The database link must be created in the CDB that will contain the relocated PDB. When you issue the `CREATE PLUGGABLE DATABASE` statement from the root of the CDB that will contain the relocated PDB, you must specify a database link to the remote CDB that contains the PDB being relocated in the `FROM` clause. The database link must connect to the root of the remote CDB from the CDB that will contain the new PDB.

Figure 38-8 illustrates how this technique relocates a PDB.

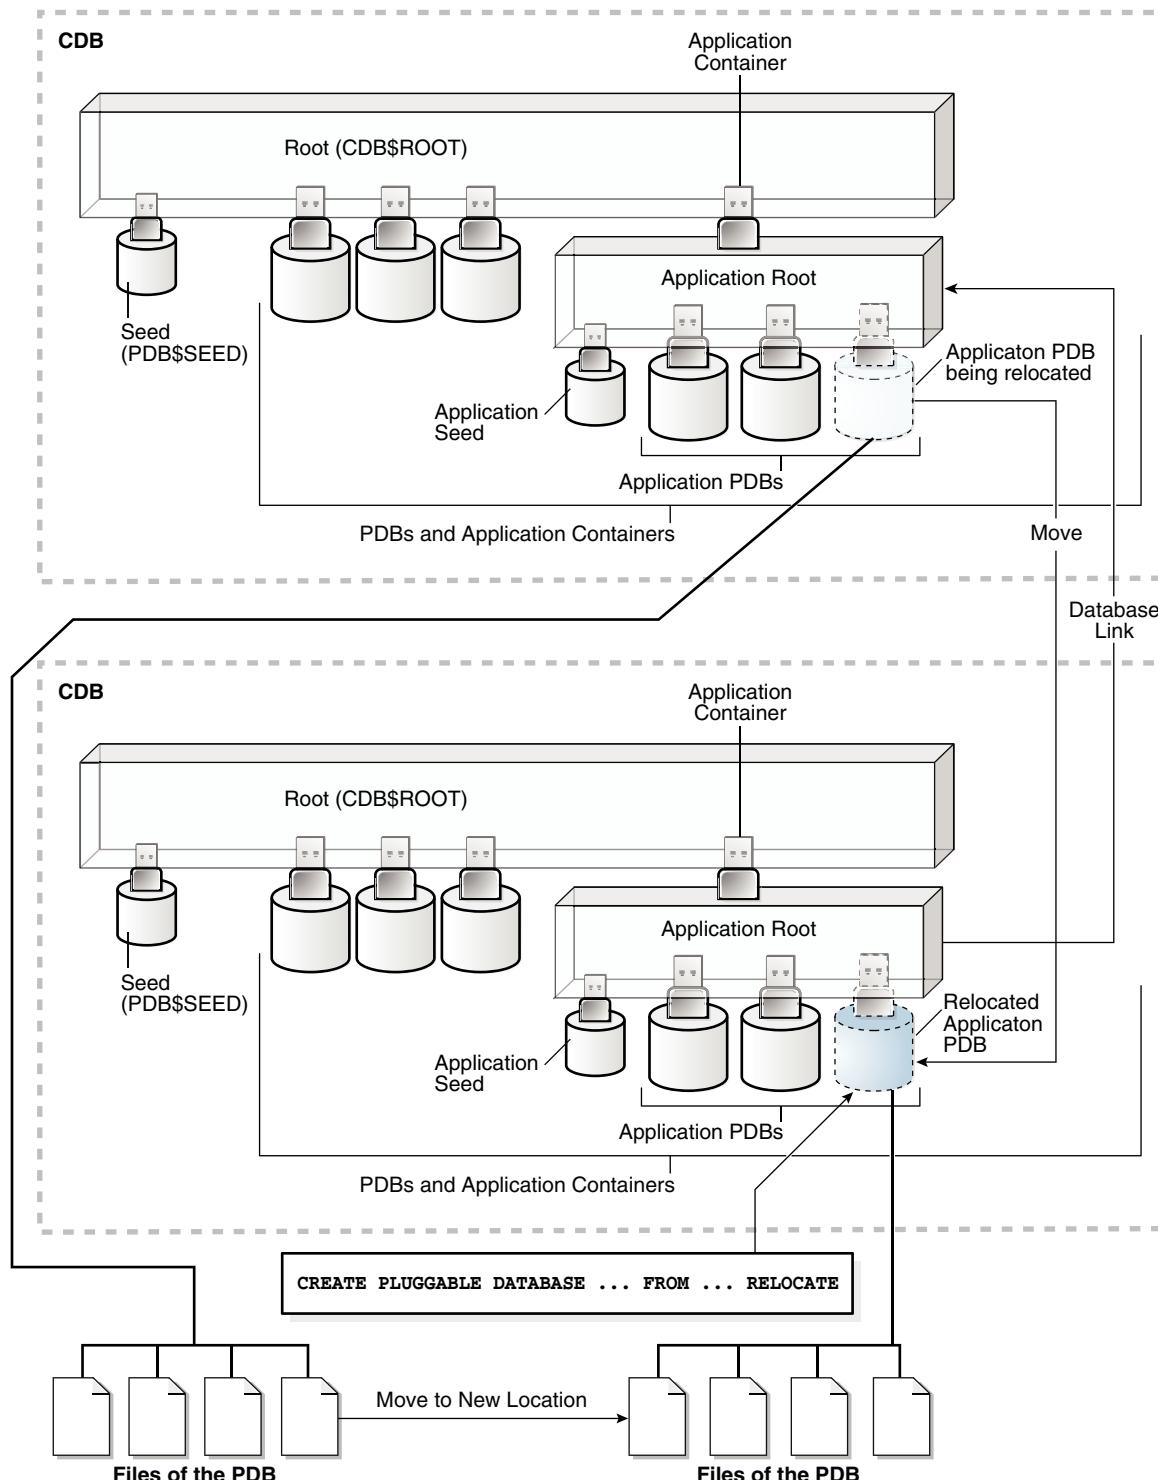

**Figure 38-8 Relocate a PDB**

 See Also:

"[The CREATE PLUGGABLE DATABASE Statement](#)"

You can relocate a PDB into an application container as an application PDB, and you can relocate an application PDB from one application root to another. You can also relocate an empty application root from one CDB to another, but the application root must not have any hosted application PDBs. [Figure 38-9](#) illustrates how this technique creates a new application PDB in an application container.

**Figure 38-9 Relocate a PDB Into an Application Container**

When you relocate a PDB, you must address the questions that apply to relocating a PDB in [Table 38-3](#). The table describes which CREATE PLUGGABLE DATABASE clauses you must specify based on different factors.

When a PDB is relocated, you have two options regarding connections to the PDB: `AVAILABILITY MAX` and `AVAILABILITY NORMAL`. You optionally can use the `AVAILABILITY MAX` clause to redirect connections from the old location of the PDB to the new location. When the `AVAILABILITY MAX` clause is specified, the relocate operation configures the listener to relocate connections to the new location.

You have the following options for redirecting connections from the PDB's old location to the PDB's new location:

- If your system is using Oracle Internet Directory (Oracle's LDAP directory service), then connection information can be updated in a central location rather than in multiple client configuration files.
- If you use the same listener for the PDB in its old and new locations, then new connections are automatically routed to the PDB's new location when relocation is complete.
- If the PDBs use different listeners, and you employ cross-registration of their respective listeners through configuration of the `local_listener` and `remote_listener` parameters, then relocation is seamless because the availability and location of the PDB's services are automatically registered with the listeners.

 **Note:**

In an Oracle Clusterware environment, when relocating a PDB between different CDBs (not CDB instances of the same database), the non-default service resource must be recreated using SRVCTL.

When the source and target CDBs for the relocate operation do not share a common listener network, use the `AVAILABILITY MAX` clause to automatically configure the original listener to forward connections to the new listener that is handling the relocated PDB's connections. This configuration is intended to be transient while the Oracle Internet Directory (OID) is updated or the client connections are modified. A "tombstone" PDB remains in the source CDB to protect the PDB's namespace and preserve the listener forwarding configuration until the OID server or the client connections are updated. After that is completed, the source PDB can be dropped with a `DROP PLUGGABLE DATABASE` statement.

If the source CDB and target CDB for the relocation operation share a common listener network, forwarding client connections is not necessary as it is handled implicitly by the common listener network. In this case, use the `AVAILABILITY NORMAL` clause for the relocate operation. After the PDB is relocated to the target CDB and opened, the PDB on the source CDB is dropped.

If a local listener redirects to a Single Client Access Name (SCAN) listener in an Oracle RAC configuration, then this listener may need to further redirect the client connection request to another cluster node. Multiple redirects are not supported by Oracle Net listeners by default. Because any SCAN listener can route the connection request to any node, set the `ALLOW_MULTIPLE_REDIRECTS_listener_name` parameter to the `listener_name` of every SCAN listener, and set it in every `listener.ora` file in the cluster. For example, if the SCAN listeners are named `listener_scan1`,

listener\_scan2, and listener\_scan3, then the `listener.ora` file on every destination host should have the following settings:

```
ALLOW_MULTIPLE_REDIRECTS_LISTENER_SCAN1=YES
ALLOW_MULTIPLE_REDIRECTS_LISTENER_SCAN2=YES
ALLOW_MULTIPLE_REDIRECTS_LISTENER_SCAN3=YES
```

 **Caution:**

Do not set the `ALLOW_MULTIPLE_REDIRECTS_listener_name` parameter for node listeners because it may allow infinite redirection loops in certain network configurations.

 **See Also:**

- ["Creating an Application PDB"](#)
- *Oracle Database Net Services Administrator's Guide* for more information about listener redirects

### 38.5.2 Relocating a PDB

You can create a PDB by relocating it. After the operation is complete, the PDB is removed from its current CDB and is added to a different CDB.

The following prerequisites must be met:

- Complete the prerequisites described in ["Preparing for PDBs"](#).
- The current user must have the `CREATE PLUGGABLE DATABASE` system privilege in the root of the CDB to which the PDB is being relocated.
- The CDB that contains the PDB before relocation must be in local undo mode.  
See ["About the CDB Undo Mode"](#).
- If the CDB to which the PDB is being relocated is not in `ARCHIVELOG` mode, then the PDB must be in open read-only mode during the operation. This requirement does not apply if the CDB to which the PDB is being relocated is in `ARCHIVELOG` mode.
- The following prerequisites apply to the database link:
  - A database link must enable a connection from the CDB to which the PDB is being relocated to the PDB's current CDB. The database link must connect to the root of the CDB. If the PDB is an application PDB, then the database link must connect to its application root.
  - The user that the database link connects with in the PDB's current CDB must have either the `CREATE PLUGGABLE DATABASE` system privilege or the `SYSOPER` administrative privilege.

- If the database link connects to the CDB root in the PDB's current CDB, then the user that the database link connects with must be a common user.
- The platforms of the PDB's current CDB and the CDB to which it is being relocated must meet these requirements:
  - They must have the same endianness.
  - The database options installed on the source platform must be the same as, or a subset of, the database options installed on the target platform.
- If the character set of the CDB to which the PDB is being relocated is not AL32UTF8, then the PDB's current CDB and the CDB to which it is being relocated must have compatible character sets and national character sets. To be compatible, the character sets and national character sets must meet all of the requirements specified in *Oracle Database Globalization Support Guide*.  
If the character set of the CDB to which the PDB is being relocated is AL32UTF8, then this requirement does not apply.
- If you are creating an application PDB, then the application name and version of the PDB being relocated must match the application name and version of the application container that will contain the application PDB after it is relocated.

#### To relocate a PDB:

1. In SQL\*Plus, ensure that the current container is the root of the CDB that will contain the new PDB or the application root of the application container that will contain the new PDB.  
See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Run the `CREATE PLUGGABLE DATABASE` statement. Specify the PDB in the `FROM` clause, and include the `RELOCATE` clause. Specify the `AVAILABILITY MAX` clause to redirect connections from the old location of the PDB to the new location. Specify other clauses when they are required.

After you relocate the PDB, it is in mounted mode, and its status is `RELOCATING`. You can view the open mode of a PDB by querying the `OPEN_MODE` column in the `V$PDBS` view. You can view the status of a PDB by querying the `STATUS` column of the `CDB_PDBS` or `DBA_PDBS` view.

A new default service is created for the PDB. The service has the same name as the PDB and can be used to access the PDB. Oracle Net Services must be configured properly for clients to access this service. See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

3. Open the new PDB in read/write mode.

You must open the new PDB in read/write mode for Oracle Database to complete the integration of the new PDB into the CDB. An error is returned if you attempt to open the PDB in read-only mode. After the PDB is opened in read/write mode, its status is `NORMAL`.

See "[Modifying the Open Mode of PDBs](#)" for more information.

4. Back up the PDB.

A PDB cannot be recovered unless it is backed up.

*Oracle Database Backup and Recovery User's Guide* for information about backing up a PDB.

 **Note:**

If an error is returned during PDB relocation, then the PDB being created might be in an `UNUSABLE` state. You can check a PDB's state by querying the `CDB_PDBS` or `DBA_PDBS` view, and you can learn more about PDB creation errors by checking the alert log. An unusable PDB can only be dropped, and it must be dropped before a PDB with the same name as the unusable PDB can be created.

**Example 38-40 Relocating a PDB From a Remote CDB**

In this example, the root to which the new PDB belongs depends on the current container when the `CREATE PLUGGABLE DATABASE` statement is run:

- When the current container is the CDB root, the new PDB is created in the CDB root.
- When the current container is an application root in an application container, the new PDB is created as an application PDB in the application root.

This example relocates a PDB named `pdb1` from a remote CDB given different factors. This example assumes the following factors:

- The current user has the `CREATE PLUGGABLE DATABASE` system privilege in the root of the CDB to which the PDB is being relocated.
- The database link name to the PDB's current CDB is `mycdb`. This database link was created with the following SQL statement:

```
CREATE PUBLIC DATABASE LINK mycdb CONNECT TO c##myadmin IDENTIFIED BY
password USING 'MYCDB';
```

The common user `c##myadmin` has `SYSOPER` administrative privilege and `CREATE PLUGGABLE DATABASE` system privilege in the CDB that currently contains the PDB.

- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The files will be moved to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- Storage limits are not required for the PDB. Therefore, the `STORAGE` clause is not required.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.
- Connections should be relocated automatically from the source PDB to the relocated PDB. Therefore, the `AVAILABILITY MAX` clause is included.

Given the preceding factors, the following statement relocates the `pdb1` PDB from a remote CDB to the current CDB:

```
CREATE PLUGGABLE DATABASE pdb1 FROM pdb1@mycdb RELOCATE AVAILABILITY MAX;
```

## 38.6 Creating a PDB by Plugging an Unplugged PDB into a CDB

You can create a PDB by plugging an unplugged PDB into a CDB.

- [About Plugging In an Unplugged PDB](#)

This technique plugs in an unplugged PDB. This technique uses the XML metadata file that describes the PDB and the files associated with the PDB to plug it into the CDB. These files can be separate, or they can be included in a single, compressed .pdb archive file.

- [Plugging In an Unplugged PDB](#)

You must meet prerequisites before plugging in an unplugged PDB.

- [After Plugging in an Unplugged PDB](#)

Certain rules regarding users and tablespaces apply after plugging in an unplugged PDB.

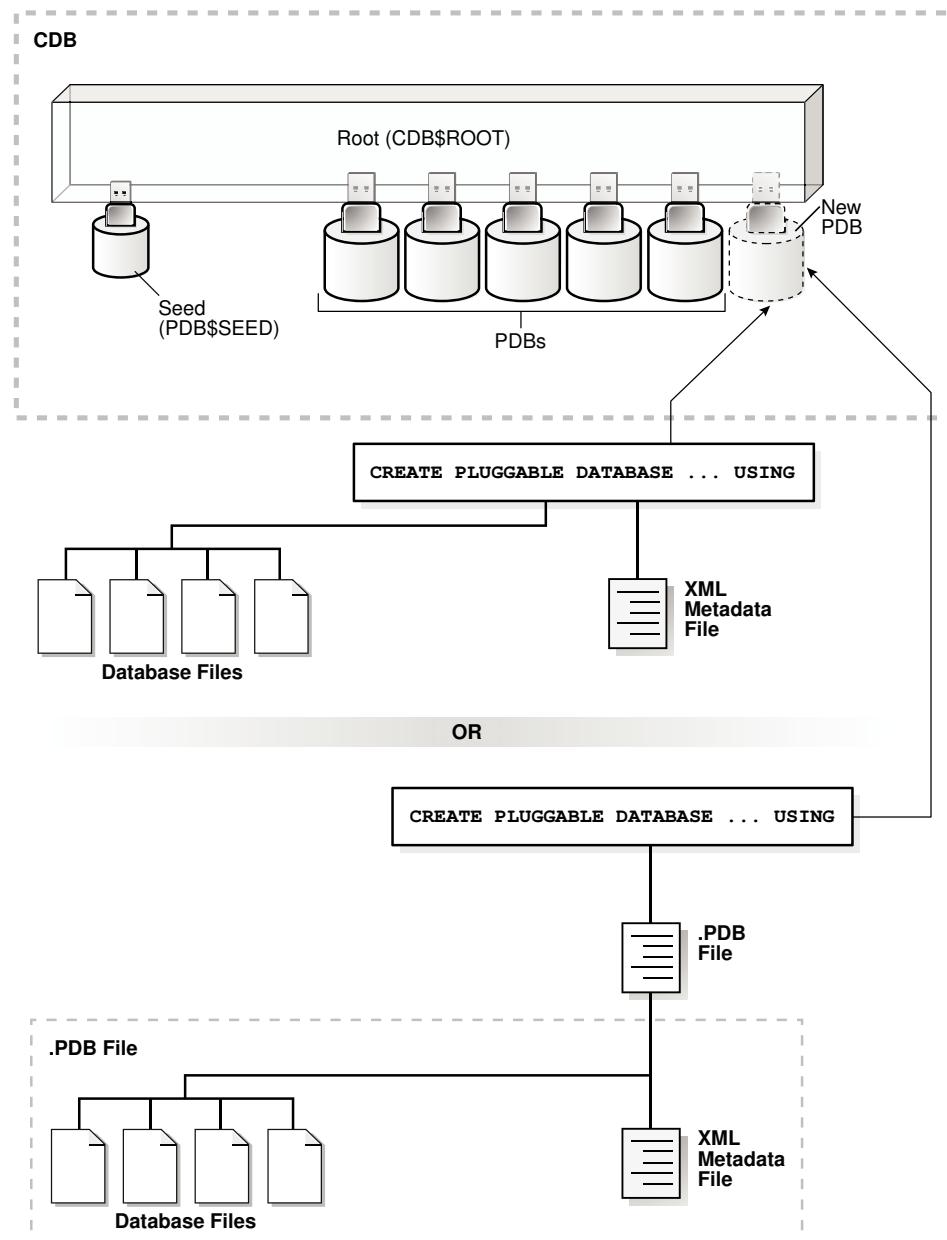

### 38.6.1 About Plugging In an Unplugged PDB

This technique plugs in an unplugged PDB. This technique uses the XML metadata file that describes the PDB and the files associated with the PDB to plug it into the CDB. These files can be separate, or they can be included in a single, compressed .pdb archive file.

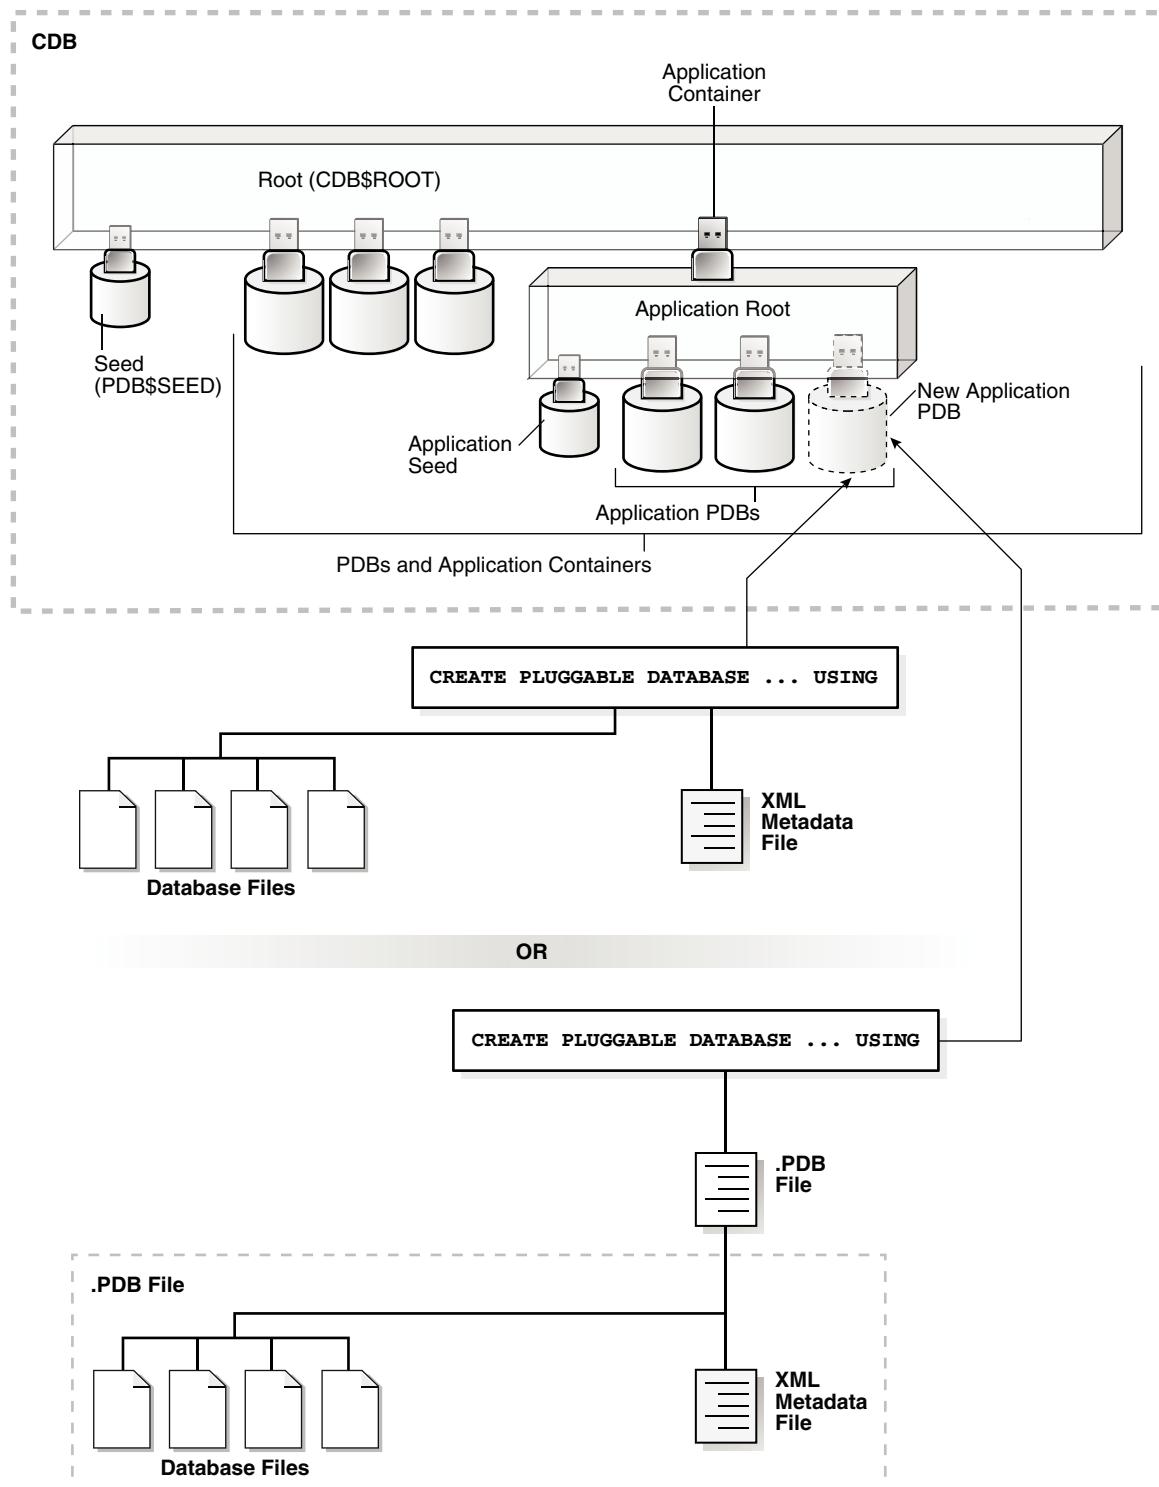

You can plug in a PDB by specifying the XML metadata file or by specifying a compressed archive file with a .pdb extension. An archive file includes the XML metadata file and the PDB's files (such as the data files and wallet file). The `USING` clause of the `CREATE PLUGGABLE DATABASE` statement specifies the XML metadata file or the .pdb archive file. When a .pdb archive file is not used and the XML metadata file is specified in the `USING` clause, the XML metadata file includes the full paths to the locations of the PDB's files. When the .pdb archive file is specified in the `USING` clause and the XML file is included in the .pdb archive file, the XML metadata file contains the file names only.

[Figure 38-10](#) illustrates how this technique creates a new PDB.

Figure 38-10 Plugging an Unplugged PDB Into a CDB Root

[Figure 38-11](#) illustrates how this technique creates a new application PDB in an application container.

**Figure 38-11 Plugging an Unplugged PDB Into an Application Root**

 **See Also:**

"[The CREATE PLUGGABLE DATABASE Statement](#)"

An unplugged PDB consists of an XML file that describes the PDB and the PDB's files (such as the data files and wallet file). You can use the `CREATE PLUGGABLE DATABASE` statement to plug in an unplugged PDB. To do so, you must include a `USING` clause that specifies the XML file that describes the PDB or a .pdb archive file.

The source CDB is the CDB from which the PDB was unplugged. The target CDB is the CDB into which you are plugging the PDB. The source CDB and target CDB can be the same CDB or different CDBs.

 **Note:**

Automatic downgrade of a PDB is not supported. Therefore, you cannot plug in a PDB if the source CDB is a higher Oracle Database release than the target CDB.

When you plug in an unplugged PDB, you must address the questions that apply to plugging in an unplugged PDB in [Table 38-3](#). The table describes which `CREATE PLUGGABLE DATABASE` clauses you must specify based on different factors.

 **See Also:**

"[Creating an Application PDB](#)"

### 38.6.2 Plugging In an Unplugged PDB

You must meet prerequisites before plugging in an unplugged PDB.

To plug in an unplugged PDB, the following prerequisites must be met:

- Complete the prerequisites described in "[Preparing for PDBs](#)".
- Either the XML file that describes the PDB or the .pdb archive file must exist in a location that is accessible to the CDB.

The `USING` clause must specify the XML file or the .pdb archive file.

If the PDB's XML file is unusable or cannot be located, then you can use the `DBMS_PDB.RECOVER` procedure to generate an XML file using the PDB's data files. See *Oracle Database PL/SQL Packages and Types Reference* for more information about this procedure.

- If an XML file is specified in the `USING` clause (not a .pdb file), then the files associated with the PDB (such as the data files and wallet file) must exist in a location that is accessible to the CDB.
- The source and target CDB platforms must meet the following requirements:

- They must have the same endianness.
  - The database options installed on the source platform must be the same as, or a subset of, the database options installed on the target platform.
  - If the character set of the CDB into which the PDB is being plugged is not AL32UTF8, then the CDB that contained the unplugged PDB and the target CDB must have compatible character sets and national character sets. To be compatible, the character sets and national character sets must meet all of the requirements specified in *Oracle Database Globalization Support Guide*.
- If the character set of the CDB into which the PDB is being plugged is AL32UTF8, then this requirement does not apply.
- If you are creating an application PDB, then the application name and version of the unplugged PDB must match the application name and version of the application container into which the application PDB is being plugged.
  - If you are creating an application PDB, then the application PDB must have the same character set and national character set as the application container.
- If the database character set of the CDB is AL32UTF8, then the character set and national character set of the application container can be different from the CDB. However, all application PDBs in an application container must have same character set and national character set, matching that of the application container.

You can use the DBMS\_PDB.CHECK\_PLUG\_COMPATIBILITY function to determine whether these requirements are met. Step 2 in the following procedure describes using this function.

#### To plug in a PDB:

1. In SQL\*Plus, ensure that the current container is the root of the CDB into which you want to plug the PDB or an application root.  
When the current container is the CDB root, the PDB is created in the CDB. When the current container is an application root, the application PDB is created in the application container.  
See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. (Optional) Run the DBMS\_PDB.CHECK\_PLUG\_COMPATIBILITY function to determine whether the unplugged PDB is compatible with the CDB.
  - a. If the PDB is not yet unplugged, then run the DBMS\_PDB.DESCRIBE procedure to produce an XML file that describes the PDB.  
If the PDB is already unplugged, then proceed to Step 2.b.

For example, to generate an XML file named salespdb.xml in the /disk1/oracle directory, run the following procedure:

```
BEGIN
 DBMS_PDB.DESCRIBE(
 pdb_descr_file => '/disk1/oracle/salespdb.xml',
 pdb_name => 'SALESPDB');
END;
/
```

If the PDB is in a remote CDB, then you can include @database\_link\_name in the pdb\_name parameter, where database\_link\_name is the name of a valid

database link to the remote CDB or to the PDB. For example, if the database link name to the remote CDB is `rcdb`, then set the `pdb_name` value to `SALESPDB@rcdb`.

- b.** Run the `DBMS_PDB.CHECK_PLUG_COMPATIBILITY` function.

When you run the function, set the following parameters:

- `pdb_descr_file` - Set this parameter to the full path to the XML file.
- `pdb_name` - Specify the name of the new PDB. If this parameter is omitted, then the PDB name in the XML file is used.

For example, to determine whether a PDB described by the `/disk1/usr/salespdb.xml` file is compatible with the current CDB, run the following PL/SQL block:

```
SET SERVEROUTPUT ON
DECLARE
 compatible CONSTANT VARCHAR2(3) :=
 CASE DBMS_PDB.CHECK_PLUG_COMPATIBILITY(
 pdb_descr_file => '/disk1/usr/salespdb.xml',
 pdb_name => 'SALESPDB')
 WHEN TRUE THEN 'YES'
 ELSE 'NO'
 END;
BEGIN
 DBMS_OUTPUT.PUT_LINE(compatible);
END;
/
```

If the output is YES, then the PDB is compatible, and you can continue with the next step.

If the output is NO, then the PDB is not compatible, and you can check the `PDB_PLUG_IN_VIOLATIONS` view to see why it is not compatible.

### Note:

You can specify a .pdb archive file in the `pdb_descr_file` parameter.

- 3.** If the PDB is not unplugged, then unplug it.

See "[Unplugging a PDB from a CDB](#)".

- 4.** Run the `CREATE PLUGGABLE DATABASE` statement, and specify the XML file or the .pdb archive file in the `USING` clause. Specify other clauses when they are required.

See "[Examples of Plugging In an Unplugged PDB](#)".

After you create the PDB, it is in mounted mode, and its status is `NEW`. You can view the open mode of a PDB by querying the `OPEN_MODE` column in the `V$PDBS` view. You can view the status of a PDB by querying the `STATUS` column of the `CDB_PDBS` or `DBA_PDBS` view.

A new default service is created for the PDB. The service has the same name as the PDB and can be used to access the PDB. Oracle Net Services must be configured properly for clients to access this service. See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

**5.** Open the new PDB in read/write mode.

You must open the new PDB in read/write mode for Oracle Database to complete the integration of the new PDB into the CDB. An error is returned if you attempt to open the PDB in read-only mode. After the PDB is opened in read/write mode, its status is NORMAL.

See "[Modifying the Open Mode of PDBs](#)" for more information.

**6.** Back up the PDB.

A PDB cannot be recovered unless it is backed up.

*Oracle Database Backup and Recovery User's Guide* for information about backing up a PDB.

 **Note:**

If an error is returned during PDB creation, then the PDB being created might be in an UNUSABLE state. You can check a PDB's state by querying the CDB\_PDBS or DBA\_PDBS view, and you can learn more about PDB creation errors by checking the alert log. An unusable PDB can only be dropped, and it must be dropped before a PDB with the same name as the unusable PDB can be created.

### Examples of Plugging In an Unplugged PDB

The following examples plug in an unplugged PDB named salespdb using the /disk1/usr/salespdb.xml file or the /disk1/usr/sales.pdb file given different factors.

In each example, the root to which the new PDB belongs depends on the current container when the CREATE PLUGGABLE DATABASE statement is run:

- When the current container is the CDB root, the new PDB is created in the CDB.
- When the current container is an application root, the new application PDB is created in the application root's application container.

#### **Example 38-41 Plugging In an Unplugged PDB Using the NOCOPY Clause**

This example assumes the following factors:

- The new PDB is not based on the same unplugged PDB that was used to create an existing PDB in the CDB. Therefore, the AS CLONE clause is not required.
- The PATH\_PREFIX clause is not required.
- The XML file accurately describes the current locations of the files. Therefore, the SOURCE\_FILE\_NAME\_CONVERT clause or SOURCE\_FILE\_DIRECTORY clause is not required.
- The files are in the correct location. Therefore, NOCOPY is included.
- Storage limits are not required for the PDB. Therefore, the STORAGE clause is not required.
- A file with the same name as the temp file specified in the XML file exists in the target location. Therefore, the TEMPFILE REUSE clause is required.

Given the preceding factors, the following statement plugs in the PDB:

---

```
CREATE PLUGGABLE DATABASE salespdb USING '/disk1/usr/salespdb.xml'
 NOCOPY
 TEMPFILE REUSE;
```

#### **Example 38-42 Plugging In an Unplugged PDB Using the AS CLONE and NOCOPY Clauses**

This example assumes the following factors:

- The new PDB is based on the same unplugged PDB that was used to create an existing PDB in the CDB. Therefore, the AS CLONE clause is required. The AS CLONE clause ensures that the new PDB has unique identifiers.
- The PATH\_PREFIX clause is not required.
- The XML file accurately describes the current locations of the files. Therefore, the SOURCE\_FILE\_NAME\_CONVERT clause or SOURCE\_FILE\_DIRECTORY clause is not required.
- The files are in the correct location. Therefore, NOCOPY is included.
- Storage limits are not required for the PDB. Therefore, the STORAGE clause is not required.
- A file with the same name as the temp file specified in the XML file exists in the target location. Therefore, the TEMPFILE REUSE clause is required.

Given the preceding factors, the following statement plugs in the PDB:

```
CREATE PLUGGABLE DATABASE salespdb AS CLONE USING '/disk1/usr/salespdb.xml'
 NOCOPY
 TEMPFILE REUSE;
```

#### **Example 38-43 Plugging In an Unplugged PDB Using the SOURCE\_FILE\_NAME\_CONVERT, NOCOPY, and STORAGE Clauses**

This example assumes the following factors:

- The new PDB is not based on the same unplugged PDB that was used to create an existing PDB in the CDB. Therefore, the AS CLONE clause is not required.
- The PATH\_PREFIX clause is not required.
- The XML file does not accurately describe the current locations of the files. Therefore, the SOURCE\_FILE\_NAME\_CONVERT clause or SOURCE\_FILE\_DIRECTORY clause is required. In this example, the XML file indicates that the files are in /disk1/oracle/sales, but the files are in /disk2/oracle/sales, and the SOURCE\_FILE\_NAME\_CONVERT clause is used.
- The files are in the correct location. Therefore, NOCOPY is included.
- Storage limits must be enforced for the PDB. Therefore, the STORAGE clause is required. Specifically, all tablespaces that belong to the PDB must not exceed 2 gigabytes.
- A file with the same name as the temp file specified in the XML file exists in the target location. Therefore, the TEMPFILE REUSE clause is required.

Given the preceding factors, the following statement plugs in the PDB:

```
CREATE PLUGGABLE DATABASE salespdb USING '/disk1/usr/salespdb.xml'
 SOURCE_FILE_NAME_CONVERT = ('/disk1/oracle/sales/', '/disk2/oracle/sales/')
 NOCOPY
```

```
STORAGE (MAXSIZE 2G)
TEMPFILE REUSE;
```

**Example 38-44 Plugging In an Unplugged PDB With the COPY, PATH\_PREFIX, and FILE\_NAME\_CONVERT Clauses**

This example assumes the following factors:

- The new PDB is not based on the same unplugged PDB that was used to create an existing PDB in the CDB. Therefore, the AS CLONE clause is not required.
- The path prefix must be added to the PDB's directory object paths. Therefore, the PATH\_PREFIX clause is required. In this example, the path prefix /disk2/oracle/sales/ is added to the PDB's directory object paths.
- The XML file accurately describes the current locations of the files. Therefore, the SOURCE\_FILE\_NAME\_CONVERT clause or SOURCE\_FILE\_DIRECTORY clause is not required.
- The files are not in the correct location. Therefore, COPY or MOVE must be included. In this example, the files are copied.

The CREATE\_FILE\_DEST clause is not used, Oracle Managed Files is not enabled, and the PDB\_FILE\_NAME\_CONVERT initialization parameter is not set. Therefore, the FILE\_NAME\_CONVERT clause is required. In this example, the files are copied from /disk1/oracle/sales to /disk2/oracle/sales.

- Storage limits are not required for the PDB. Therefore, the STORAGE clause is not required.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the TEMPFILE REUSE clause is not required.

Given the preceding factors, the following statement plugs in the PDB:

```
CREATE PLUGGABLE DATABASE salespdb USING '/disk1/usr/salespdb.xml'
COPY
PATH_PREFIX = '/disk2/oracle/sales/'
FILE_NAME_CONVERT = ('/disk1/oracle/sales/', '/disk2/oracle/sales/');
```

**Example 38-45 Plugging In an Unplugged PDB Using the SOURCE\_FILE\_NAME\_CONVERT, MOVE, FILE\_NAME\_CONVERT, and STORAGE Clauses**

This example assumes the following factors:

- The new PDB is not based on the same unplugged PDB that was used to create an existing PDB in the CDB. Therefore, the AS CLONE clause is not required.
- The PATH\_PREFIX clause is not required.
- The XML file does not accurately describe the current locations of the files. Therefore, the SOURCE\_FILE\_NAME\_CONVERT clause or SOURCE\_FILE\_DIRECTORY clause is required. In this example, the XML file indicates that the files are in /disk1/oracle/sales, but the files are in /disk2/oracle/sales, and the SOURCE\_FILE\_NAME\_CONVERT clause is used.
- The files are not in the correct final location for the PDB. Therefore, COPY or MOVE must be included. In this example, MOVE is specified to move the files.

The CREATE\_FILE\_DEST clause is not used, Oracle Managed Files is not enabled, and the PDB\_FILE\_NAME\_CONVERT initialization parameter is not set. Therefore, the

`FILE_NAME_CONVERT` clause is required. In this example, the files are moved from `/disk2/oracle/sales` to `/disk3/oracle/sales`.

- Storage limits must be enforced for the PDB. Therefore, the `STORAGE` clause is required. Specifically, all tablespaces that belong to the PDB must not exceed 2 gigabytes.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Given the preceding factors, the following statement plugs in the PDB:

```
CREATE PLUGGABLE DATABASE salespdb USING '/disk1/usr/salespdb.xml'
 SOURCE_FILE_NAME_CONVERT = ('/disk1/oracle/sales/', '/disk2/oracle/sales/')
 MOVE
 FILE_NAME_CONVERT = ('/disk2/oracle/sales/', '/disk3/oracle/sales/')
 STORAGE (MAXSIZE 2G);
```

#### **Example 38-46 Plugging In an Unplugged PDB Using the `SOURCE_FILE_DIRECTORY`, `MOVE`, `FILE_NAME_CONVERT`, and `STORAGE` Clauses**

This example assumes the following factors:

- The new PDB is not based on the same unplugged PDB that was used to create an existing PDB in the CDB. Therefore, the `AS CLONE` clause is not required.
- The `PATH_PREFIX` clause is not required.
- The XML file does not accurately describe the current locations of the files. Therefore, the `SOURCE_FILE_NAME_CONVERT` clause or `SOURCE_FILE_DIRECTORY` clause is required. In this example, the XML file indicates that the files are in `/disk1/oracle/sales`, but the files are in `/disk2/oracle/sales`, and the `SOURCE_FILE_DIRECTORY` clause is used.
- The files are not in the correct final location for the PDB. Therefore, `COPY` or `MOVE` must be included. In this example, `MOVE` is specified to move the files.

The `CREATE_FILE_DEST` clause is not used, Oracle Managed Files is not enabled, and the `PDB_FILE_NAME_CONVERT` initialization parameter is not set. Therefore, the `FILE_NAME_CONVERT` clause is required. In this example, the files are moved from `/disk2/oracle/sales` to `/disk3/oracle/sales`.

- Storage limits must be enforced for the PDB. Therefore, the `STORAGE` clause is required. Specifically, all tablespaces that belong to the PDB must not exceed 2 gigabytes.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Given the preceding factors, the following statement plugs in the PDB:

```
CREATE PLUGGABLE DATABASE salespdb USING '/disk1/usr/salespdb.xml'
 SOURCE_FILE_DIRECTORY = '/disk2/oracle/sales/'
 MOVE
 FILE_NAME_CONVERT = ('/disk2/oracle/sales/', '/disk3/oracle/sales/')
 STORAGE (MAXSIZE 2G);
```

#### **Example 38-47 Plugging In an Unplugged PDB Using an Archive File**

This example assumes the following factors:

- The unplugged PDB is in a .pdb archive file named sales.pdb. The archive file includes the XML metadata file and the PDB's files (such as the data files and wallet file) in compressed form, and these files are extracted to the current directory of the .pdb archive file when the CREATE PLUGGABLE DATABASE statement is run.
- The new PDB is not based on the same unplugged PDB that was used to create an existing PDB in the CDB. Therefore, the AS CLONE clause is not required.
- The PATH\_PREFIX clause is not required.
- Storage limits must be enforced for the PDB. Therefore, the STORAGE clause is required. Specifically, all tablespaces that belong to the PDB must not exceed 2 gigabytes.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the TEMPFILE REUSE clause is not required.

Given the preceding factors, the following statement plugs in the PDB using an archive file:

```
CREATE PLUGGABLE DATABASE salespdb USING '/disk1/usr/sales.pdb'
 STORAGE (MAXSIZE 2G);
```

### 38.6.3 After Plugging in an Unplugged PDB

Certain rules regarding users and tablespaces apply after plugging in an unplugged PDB.

The following applies after plugging in an unplugged PDB:

- Users in the PDB who used the default temporary tablespace of the source PDB use the default temporary tablespace of the target PDB. Users who used non-default temporary tablespaces in the source PDB continue to use the same local temporary tablespaces in the target PDB. See "[About Managing Tablespaces in a CDB](#)".
- User-created common users that existed in the source CDB but not in the target CDB do not have any privileges granted commonly. However, if the target CDB has a common user with the same name as a common user in the PDB, the latter is linked to the former and has the privileges granted to this common user in the target CDB.

If the cloned or plugged-in PDB has a common user account that does not exist in the target CDB, and if this user does not own objects in the PDB, then Oracle Database drops the user during the synchronization step; otherwise, the user account is locked in the target PDB. You have the following options regarding locked accounts:

- Close the PDB, connect to the root, and create a common user account with the same name. When the PDB is opened in read/write mode, differences in roles and privileges granted commonly to the user account are resolved, and you can unlock the account. Privileges and roles granted locally to the user account remain unchanged during this process.
- Create a new local user account in the PDB and use Data Pump to export/import the locked user's data into the new local user's schema.
- Leave the user account locked.
- Drop the user account.

## 38.7 Creating a PDB as a Proxy PDB

You can create a PDB as a proxy PDB by referencing a PDB in a remote CDB.

- [About Creating a Proxy PDB](#)

A proxy PDB provides access to another PDB in a remote CDB. You can use the CREATE PLUGGABLE DATABASE statement to create a proxy PDB by referencing the other PDB.

- [Creating a Proxy PDB](#)

You can create a proxy PDB by referencing a PDB in a different CDB.

### 38.7.1 About Creating a Proxy PDB

A proxy PDB provides access to another PDB in a remote CDB. You can use the CREATE PLUGGABLE DATABASE statement to create a proxy PDB by referencing the other PDB.

This technique creates a proxy PDB by referencing a PDB in a different CDB, which is referred to as the **referenced PDB**. You can use a proxy PDB when you want a local context for a remote PDB. In addition, when application containers in different CDBs have the same application, their application roots can be kept synchronized with a proxy PDB.

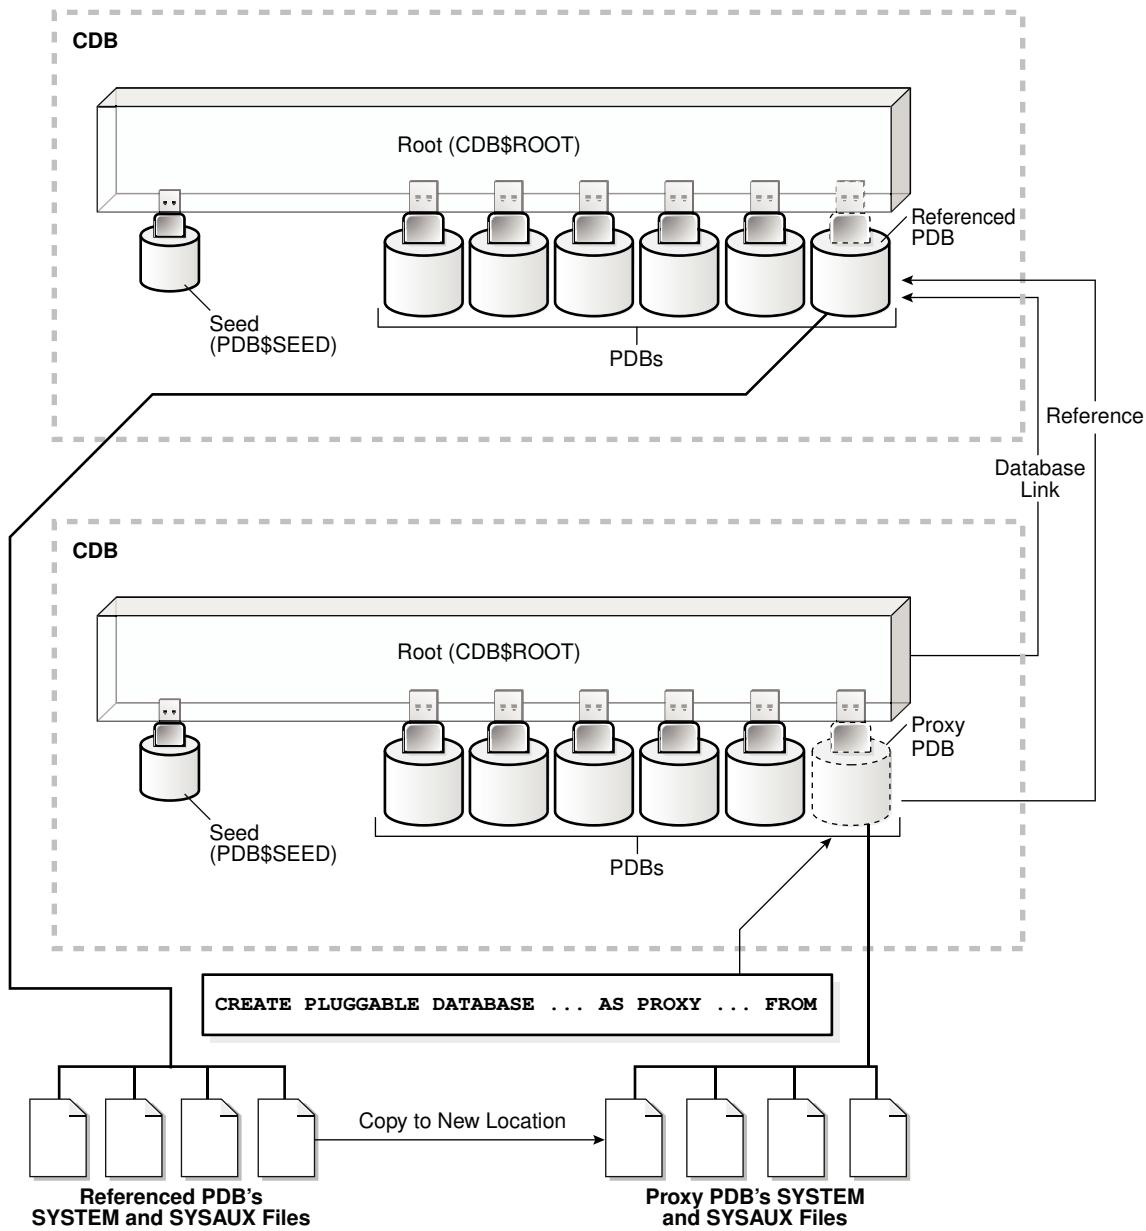

To use this technique, you run the CREATE PLUGGABLE DATABASE statement in the CDB that will contain the proxy PDB. You must include the AS PROXY clause to specify that

you are creating a proxy PDB. You must also include a `FROM` clause that specifies the PDB that the proxy PDB is referencing.

You must specify a database link to the current location of the referenced PDB in the `FROM` clause of the `CREATE PLUGGABLE DATABASE` statement. The database link must be created in the root of the CDB that will contain the proxy PDB, and the database link connects either to the root of remote CDB or to the remote referenced PDB.

[Figure 38-12](#) illustrates how this technique creates a proxy PDB that references a PDB in a remote CDB.

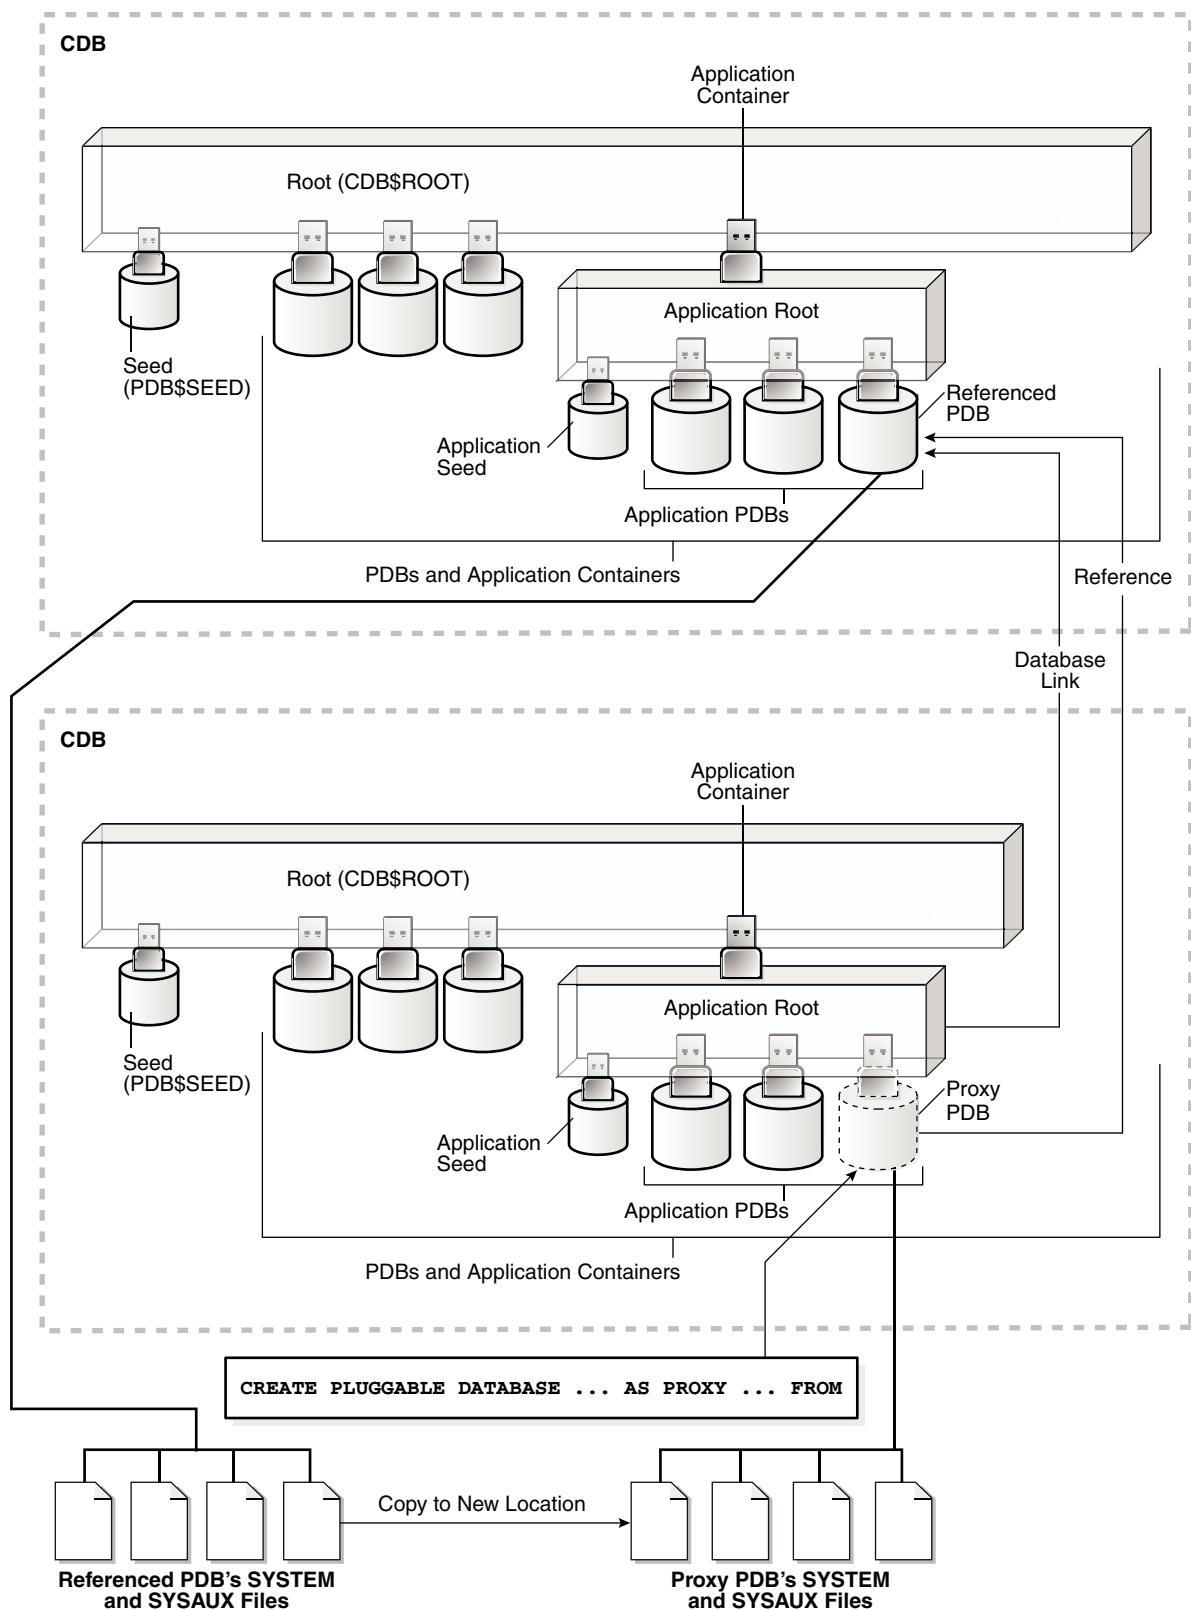

**Figure 38-12 Create a Remote Proxy PDB**

You can create a proxy PDB in an application container. To do so, the referenced PDB must be an application root or an application PDB in an application container in a different CDB. The database link must be created in the root of the application container that will contain the proxy PDB, and the database link connects either to the root of remote application container or to the remote referenced application PDB.

[Figure 38-13](#) illustrates how this technique creates a proxy PDB in an application container based on a remote referenced PDB in an application container.

Figure 38-13 Create a Remote Proxy PDB in an Application Container

When you create a proxy PDB, you must address the questions that apply to creating a proxy PDB in [Table 38-3](#). The table describes which CREATE PLUGGABLE DATABASE clauses you must specify based on different factors.

#### See Also:

- ["The CREATE PLUGGABLE DATABASE Statement"](#)
- ["Synchronizing an Application Root Replica with a Proxy PDB"](#)

### SQL Statements and Proxy PDBs

Excluding ALTER PLUGGABLE DATABASE and ALTER DATABASE statements, when the proxy PDB is the current container, all SQL statements submitted for execution in the proxy PDB are sent to the referenced PDB and executed in the referenced PDB. The results of the remote execution are returned to the proxy PDB. For example, data definition language (DDL) statements, data manipulation language (DML) statements, and queries executed in the proxy PDB are sent to the referenced PDB for execution, and the results are returned to the proxy PDB.

When the proxy PDB is the current container and ALTER PLUGGABLE DATABASE and ALTER DATABASE statements are executed, these statements only affect the proxy PDB. They are not sent to the referenced PDB for execution. Similarly, when the current container is the root to which the proxy PDB belongs, ALTER PLUGGABLE DATABASE statements only affect the proxy PDB. For example, an ALTER PLUGGABLE DATABASE statement executed in a CDB root, application root, or proxy PDB can open or close a proxy PDB, but this statement does not open or close the referenced PDB.

### Proxy PDBs and Database Links

As described previously, a database link is always required when you create a proxy PDB. However, after the proxy PDB is created, the database link specified during creation is no longer used by the proxy PDB. Instead, the proxy PDB communicates directly with the referenced PDB.

This direct communication requires the port number and host name of the listener of the CDB that contains the referenced PDB. During proxy PDB creation, the proxy PDB uses the following values by default:

- **Listener port number:** 1521

If the referenced PDB's listener does not use the default port number, then you must use the `PORT` clause to specify the listener's port number. You can specify the port number when you create the proxy PDB, or you can alter the proxy PDB to change the port number.

- **Listener host name:** The host name of the CDB that contains the referenced PDB

If the referenced PDB's listener does not use the default host name, then you must use the `HOST` clause to specify the listener's host name. You can specify the host name when you create the proxy PDB, or you can alter the proxy PDB to change the host name.

### Proxy PDBs and Authentication

Only password authentication is supported for sessions in a proxy PDB.

#### Related Topics

- [PDB Listener Host Name and Port Number](#)

The host name and port number settings for a PDB are important only if proxy PDBs will reference the PDB. Use the `PORT` clause to specify the PDB's port number. Use the `HOST` clause to specify the PDB's host name.

- [Modifying the Listener Settings of a Referenced PDB](#)

A PDB that is referenced by a proxy PDB is called a referenced PDB. When the port or host name changes for the listener of the referenced PDB, you must modify the listener settings of the referenced PDB so that its proxy PDBs continue to function properly.

- [Creating an Application PDB](#)

You create an application PDB by running the `CREATE PLUGGABLE DATABASE` statement with an application root as the current container.

## 38.7.2 Creating a Proxy PDB

You can create a proxy PDB by referencing a PDB in a different CDB.

The following prerequisites must be met:

- Complete the prerequisites described in "[Preparing for PDBs](#)".
- The current user must have the `CREATE PLUGGABLE DATABASE` system privilege in the root of the CDB in which the proxy PDB is being created.
- The CDB that contains the referenced PDB must be in local undo mode.  
See "[About the CDB Undo Mode](#)".
- The CDB that contains the referenced PDB must be in `ARCHIVELOG` mode.
- The referenced PDB must be in open read/write mode when the proxy PDB is created. The open mode of the referenced PDB can be changed after the proxy PDB is created.
- A database link must enable a connection from the root of the CDB in which the proxy PDB is being created to the location of the referenced PDB. The database link can connect to either the root of the remote CDB or to the remote PDB.
- If the database link connects to the root in a remote CDB that contains the referenced PDB, then the user that the database link connects with must be a common user.
- If the database link connects to the referenced PDB, then the user that the database link connects with in the referenced PDB must have the `CREATE PLUGGABLE DATABASE` system privilege.
- If you are creating a proxy PDB in an application container, then the following prerequisites apply:
  - The referenced PDB must be an application root or an application PDB in an application container.

- The application name and version of the proxy PDB's application container must match the application name and version of the referenced PDB.
- When the proxy PDB is being created in an application container, a database link must enable a connection from the root of the application container in which the proxy PDB is being created to the location of the referenced PDB. The database link can connect to either the root of the remote application container or to the remote application PDB.
- If the database link connects to the root in a remote application container that contains the referenced PDB, then the user that the database link connects with must be an application common user.
- If the database link connects to the referenced application PDB, then the user that the database link connects with in the referenced application PDB must have the CREATE PLUGGABLE DATABASE system privilege.

 **Note:**

You can create a proxy PDB in a CDB root that is based on a referenced PDB in an application container.

**To create a proxy PDB:**

1. In SQL\*Plus, ensure that the current container is the CDB root or application root in which the proxy PDB is being created.

When the current container is the CDB root, the proxy PDB is created in the CDB. When the current container is an application root, the proxy PDB is created in the application container.

See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Run the `CREATE PLUGGABLE DATABASE` statement. Specify the `AS PROXY` clause, and specify the referenced PDB with the database link name in the `FROM` clause. Specify other clauses when they are required.

After you create the proxy PDB, it is in mounted mode, and its status is `NEW`. You can view the open mode of a PDB by querying the `OPEN_MODE` column in the `V$PDBS` view. You can view the status of a PDB by querying the `STATUS` column of the `CDB_PDBS` or `DBA_PDBS` view.

A new default service is created for the PDB. The service has the same name as the PDB and can be used to access the PDB. Oracle Net Services must be configured properly for clients to access this service. See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

3. Open the new PDB in read/write mode.

You must open the new PDB in read/write mode for Oracle Database to complete the integration of the new PDB into the CDB. An error is returned if you attempt to open the PDB in read-only mode. After the PDB is opened in read/write mode, its status is `NORMAL`.

See "[Modifying the Open Mode of PDBs](#)" for more information.

4. Back up the PDB.

A PDB cannot be recovered unless it is backed up.

*Oracle Database Backup and Recovery User's Guide* for information about backing up a PDB.

 **Note:**

If an error is returned during creation of the proxy PDB, then the PDB being created might be in an `UNUSABLE` state. You can check a PDB's state by querying the `CDB_PDBS` or `DBA_PDBS` view, and you can learn more about PDB creation errors by checking the alert log. An unusable PDB can only be dropped, and it must be dropped before a PDB with the same name as the unusable PDB can be created.

#### Example 38-48 Creating a Remote Proxy PDB

In this example, the root to which the new PDB belongs depends on the current container when the `CREATE PLUGGABLE DATABASE` statement is run:

- When the current container is the CDB root, the new PDB is created in the CDB root.
- When the current container is an application root in an application container, the new PDB is created as an application PDB in the application root.

This example creates a remote proxy PDB named `pdb1` given different factors. This example assumes the following factors:

- The database link name to the referenced PDB's CDB is `pdb1_link`.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The `SYSTEM` and `SYSAUX` files will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

Given the preceding factors, the following statement creates the `pdb1` proxy PDB:

```
CREATE PLUGGABLE DATABASE pdb1 AS PROXY FROM pdb1@pdb1_link;
```

## 38.8 Creating a PDB Using a Non-CDB

You can create a PDB using a non-CDB in different ways.

- [About Creating a PDB Using a Non-CDB](#)  
You can move a non-CDB into a PDB.
- [Using the DBMS\\_PDB Package on a Non-CDB](#)  
You can use the `DBMS_PDB` package on a non-CDB to enable you to plug the non-CDB into a CDB.

### 38.8.1 About Creating a PDB Using a Non-CDB

You can move a non-CDB into a PDB.

You can accomplish this task in the following ways:

- Creating a PDB by cloning a non-CDB

Starting with Oracle Database 12c Release 1 (12.1.0.2), you can create a PDB by cloning a non-CDB. This method is the simplest way to create a PDB using a non-CDB, but it requires copying the files of the non-CDB to a new location.

See "[Creating a PDB by Cloning an Existing PDB or Non-CDB](#)" for instructions.

Both the CDB and the non-CDB must be running Oracle Database 12c Release 1 (12.1.0.2) or later. If your current non-CDB uses an Oracle Database release before Oracle Database 12c Release 1 (12.1.0.2), then you must upgrade the non-CDB to Oracle Database 12c Release 1 (12.1.0.2) to use this technique. See *Oracle Database Upgrade Guide* for information about upgrading.

- Use the DBMS\_PDB package to generate an XML metadata file.

The XML metadata file describes the database files of the non-CDB so that you can plug it into a CDB.

This method requires more steps than creating a PDB by cloning a non-CDB, but it enables you to create a PDB using a non-CDB without moving the non-CDB files in some situations.

["Using the DBMS\\_PDB Package on a Non-CDB"](#) describes using this technique.

To use this technique, the non-CDB must be an Oracle Database 12c non-CDB. If your current non-CDB uses an Oracle Database release before Oracle Database 12c, then you must upgrade the non-CDB to Oracle Database 12c to use this technique. See *Oracle Database Upgrade Guide* for information about upgrading.

- Use Oracle Data Pump export/import.

You export the data from the non-CDB and import it into a PDB.

When you import, specify the connect identifier for the PDB after the user name. For example, if the connect identifier for the PDB is hrpdb, then enter the following when you run the Oracle Data Pump Import utility:

```
impdp user_name@hrpdb ...
```

If the Oracle Database release of the non-CDB is Oracle Database 11g Release 2 (11.2.0.3) or later, then you can use full transportable export/import to move the data. When transporting a non-CDB from an Oracle Database 11g Release 2 (11.2.0.3) or later Oracle Database 11g database to Oracle Database 12c, the VERSION Data Pump export parameter must be set to 12.0.0.0.0 or higher.

If the Oracle Database release of the non-CDB is before Oracle Database 11g Release 2 (11.2.0.3), then you can use transportable tablespaces to move the data, or you can perform a full database export/import.

See [Transporting Data](#).

- Use GoldenGate replication.

You replicate the data from the non-CDB to a PDB. When the PDB catches up with the non-CDB, you fail over to the PDB.

See the Oracle GoldenGate documentation.

### 38.8.2 Using the DBMS\_PDB Package on a Non-CDB

You can use the DBMS\_PDB package on a non-CDB to enable you to plug the non-CDB into a CDB.

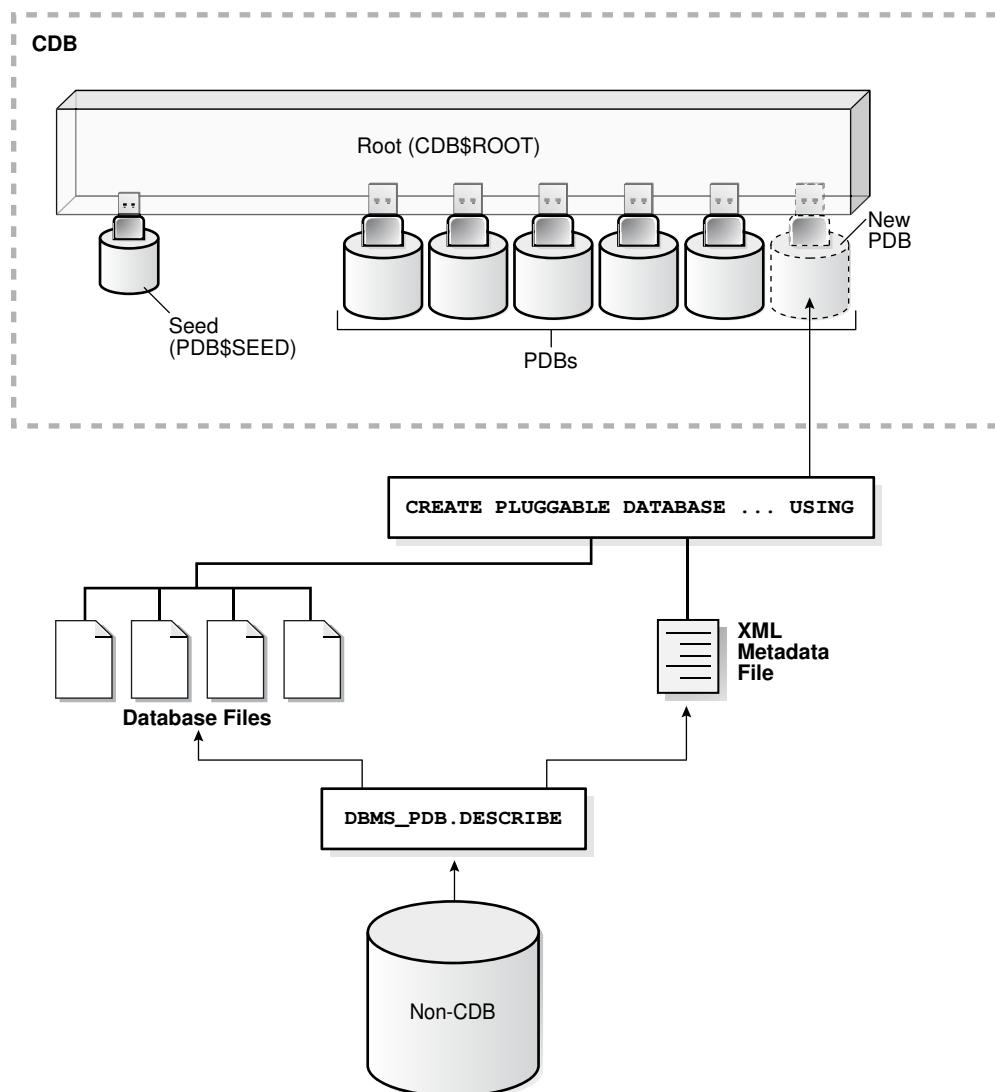

- [About Using the DBMS\\_PDB Package on a Non-CDB](#)  
This technique creates a PDB from a non-CDB using the `DBMS_PDB.DESCRIBE` procedure.
- [Using the DBMS\\_PDB Package to Create an Unplugged PDB](#)  
You can move a non-CDB into a PDB by using the `DBMS_PDB.DESCRIBE` procedure.

### 38.8.2.1 About Using the DBMS\_PDB Package on a Non-CDB

This technique creates a PDB from a non-CDB using the `DBMS_PDB.DESCRIBE` procedure.

You run the `DBMS_PDB.DESCRIBE` procedure on the non-CDB to generate the XML file that describes the database files of the non-CDB. After the XML file is generated, you can plug in the non-CDB in the same way that you can plug in an unplugged PDB. Specifically, you specify the `USING` clause in the `CREATE PLUGGABLE DATABASE` statement. When the non-CDB is plugged in to a CDB, it is a PDB.

**Figure 38-14 Plug In a Non-CDB Using the DBMS\_PDB.DESCRIBE Procedure**

You can use the same technique to create a new application PDB in an application container.

 **Note:**

To use this technique, the non-CDB must be an Oracle Database 12c non-CDB.

 **See Also:**

["Creating a PDB by Plugging an Unplugged PDB into a CDB"](#)

### 38.8.2.2 Using the DBMS\_PDB Package to Create an Unplugged PDB

You can move a non-CDB into a PDB by using the `DBMS_PDB.DESCRIBE` procedure.

**To move a non-CDB into a PDB using the `DBMS_PDB` package:**

1. Create the CDB if it does not exist.

See [Creating and Configuring a CDB](#).

2. Ensure that the non-CDB is in a transactionally-consistent state and place it in read-only mode.

See ["Opening a Database in Read-Only Mode"](#).

3. Connect to the non-CDB, and run the `DBMS_PDB.DESCRIBE` procedure to construct an XML file that describes the non-CDB.

The current user must have `SYSDBA` administrative privilege. The user must exercise the privilege using `AS SYSDBA` at connect time.

For example, to generate an XML file named `ncdb.xml` in the `/disk1/oracle` directory, run the following procedure:

```
BEGIN
 DBMS_PDB.DESCRIBE(
 pdb_descr_file => '/disk1/oracle/ncdb.xml');
END;
/
```

After the procedure completes successfully, you can use the XML file and the non-CDB's database files to plug the non-CDB into a CDB.

4. Run the `DBMS_PDB.CHECK_PLUG_COMPATIBILITY` function to determine whether the non-CDB is compatible with the CDB.

When you run the function, set the following parameters:

- `pdb_descr_file` - Set this parameter to the full path to the XML file.
- `pdb_name` - Specify the name of the new PDB. If this parameter is omitted, then the PDB name in the XML file is used.

For example, to determine whether a non-CDB described by the /disk1/oracle/ncdb.xml file is compatible with the current CDB, run the following PL/SQL block:

```
SET SERVEROUTPUT ON
DECLARE
 compatible CONSTANT VARCHAR2(3) :=
 CASE DBMS_PDB.CHECK_PLUG_COMPATIBILITY(
 pdb_descr_file => '/disk1/oracle/ncdb.xml',
 pdb_name => 'NCDB')
 WHEN TRUE THEN 'YES'
 ELSE 'NO'
 END;
BEGIN
 DBMS_OUTPUT.PUT_LINE(compatible);
END;
/
```

If the output is YES, then the non-CDB is compatible, and you can continue with the next step.

If the output is NO, then the non-CDB is not compatible, and you can check the PDB\_PLUG\_IN\_VIOLATIONS view to see why it is not compatible. All violations must be corrected before you continue. For example, any version or patch mismatches should be resolved by running an upgrade or the datapatch utility. After correcting the violations, run DBMS\_PDB.CHECK\_PLUG\_COMPATIBILITY again to ensure that the non-CDB is compatible with the CDB.

5. Shut down the non-CDB.

See "[Shutting Down a Database](#)".

6. Plug in the non-CDB.

Follow the instructions in "[Creating a PDB by Plugging an Unplugged PDB into a CDB](#)" to plug in the non-CDB.

For example, the following SQL statement plugs in a non-CDB, copies its files to a new location, and includes only the tbs3 user tablespace from the non-CDB:

```
CREATE PLUGGABLE DATABASE ncdb USING '/disk1/oracle/ncdb.xml'
COPY
FILE_NAME_CONVERT = ('/disk1/oracle/dbs', '/disk2/oracle/ncdb/')
USER_TABLESPACES=('tbs3');
```

If there are no violations, then do not open the new PDB. You will open it in step 8.

The USER\_TABLESPACES clause enables you to separate data that was used for multiple tenants in a non-CDB into different PDBs. You can use multiple CREATE PLUGGABLE DATABASE statements with this clause to create other PDBs that include the data from other tablespaces that existed in the non-CDB.

7. Run the ORACLE\_HOME/rdbms/admin/noncdb\_to\_pdb.sql script. This script must be run before the PDB can be opened for the first time. See "[Creating a PDB Using a Non-CDB](#)".

If the PDB was not a non-CDB, then running the noncdb\_to\_pdb.sql script is not required.

To run the noncdb\_to\_pdb.sql script, complete the following steps:

- a. Access the PDB.

The current user must have SYSDBA administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using AS SYSDBA at connect time.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

**b.** Run the `noncdb_to_pdb.sql` script:

```
@$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql
```

The script opens the PDB, performs changes, and closes the PDB when the changes are complete.

**8.** Open the new PDB in read/write mode.

You must open the new PDB in read/write mode for Oracle Database to complete the integration of the new PDB into the CDB. An error is returned if you attempt to open the PDB in read-only mode. After the PDB is opened in read/write mode, its status is NORMAL.

See "[Modifying the Open Mode of PDBs](#)" for more information.

**9.** Back up the PDB.

A PDB cannot be recovered unless it is backed up.

*Oracle Database Backup and Recovery User's Guide* for information about backing up a PDB.

 **Note:**

If an error is returned during PDB creation, then the PDB being created might be in an UNUSABLE state. You can check a PDB's state by querying the `CDB_PDBS` or `DBA_PDBS` view, and you can learn more about PDB creation errors by checking the alert log. An unusable PDB can only be dropped, and it must be dropped before a PDB with the same name as the unusable PDB can be created.

 **See Also:**

- ["After Plugging in an Unplugged PDB"](#)
- ["User Tablespaces"](#)

## 38.9 Unplugging a PDB from a CDB

You can unplug a PDB from a CDB.

**• [About Unplugging a PDB](#)**

Unplugging a PDB disassociates the PDB from a CDB. You unplug a PDB when you want to move the PDB to a different CDB, when you want to archive the PDB for later use, or when you no longer want the PDB to be available.

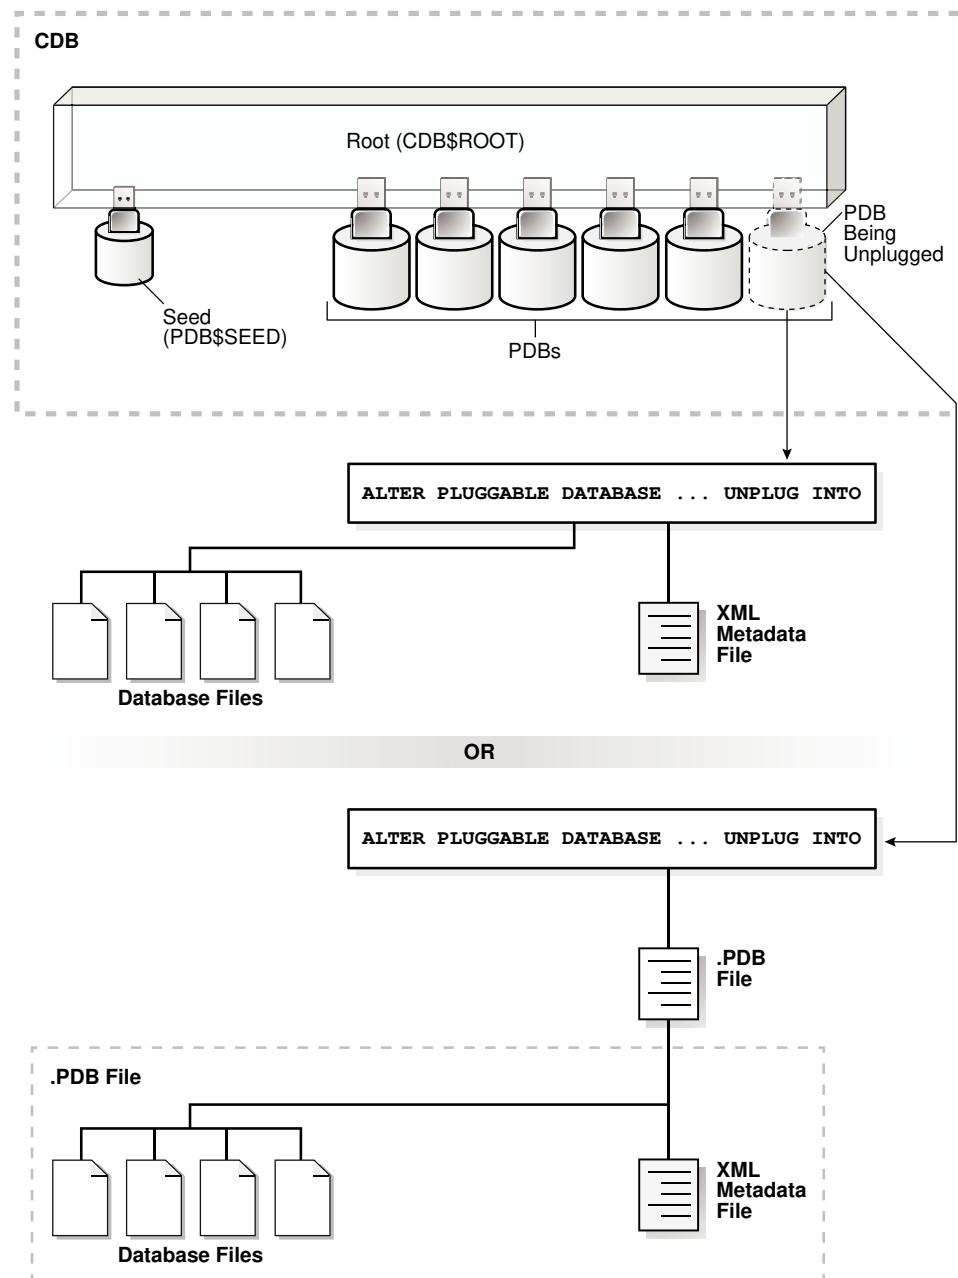

- [Unplugging a PDB](#)  
You must meet prerequisites when unplugging a PDB.

### 38.9.1 About Unplugging a PDB

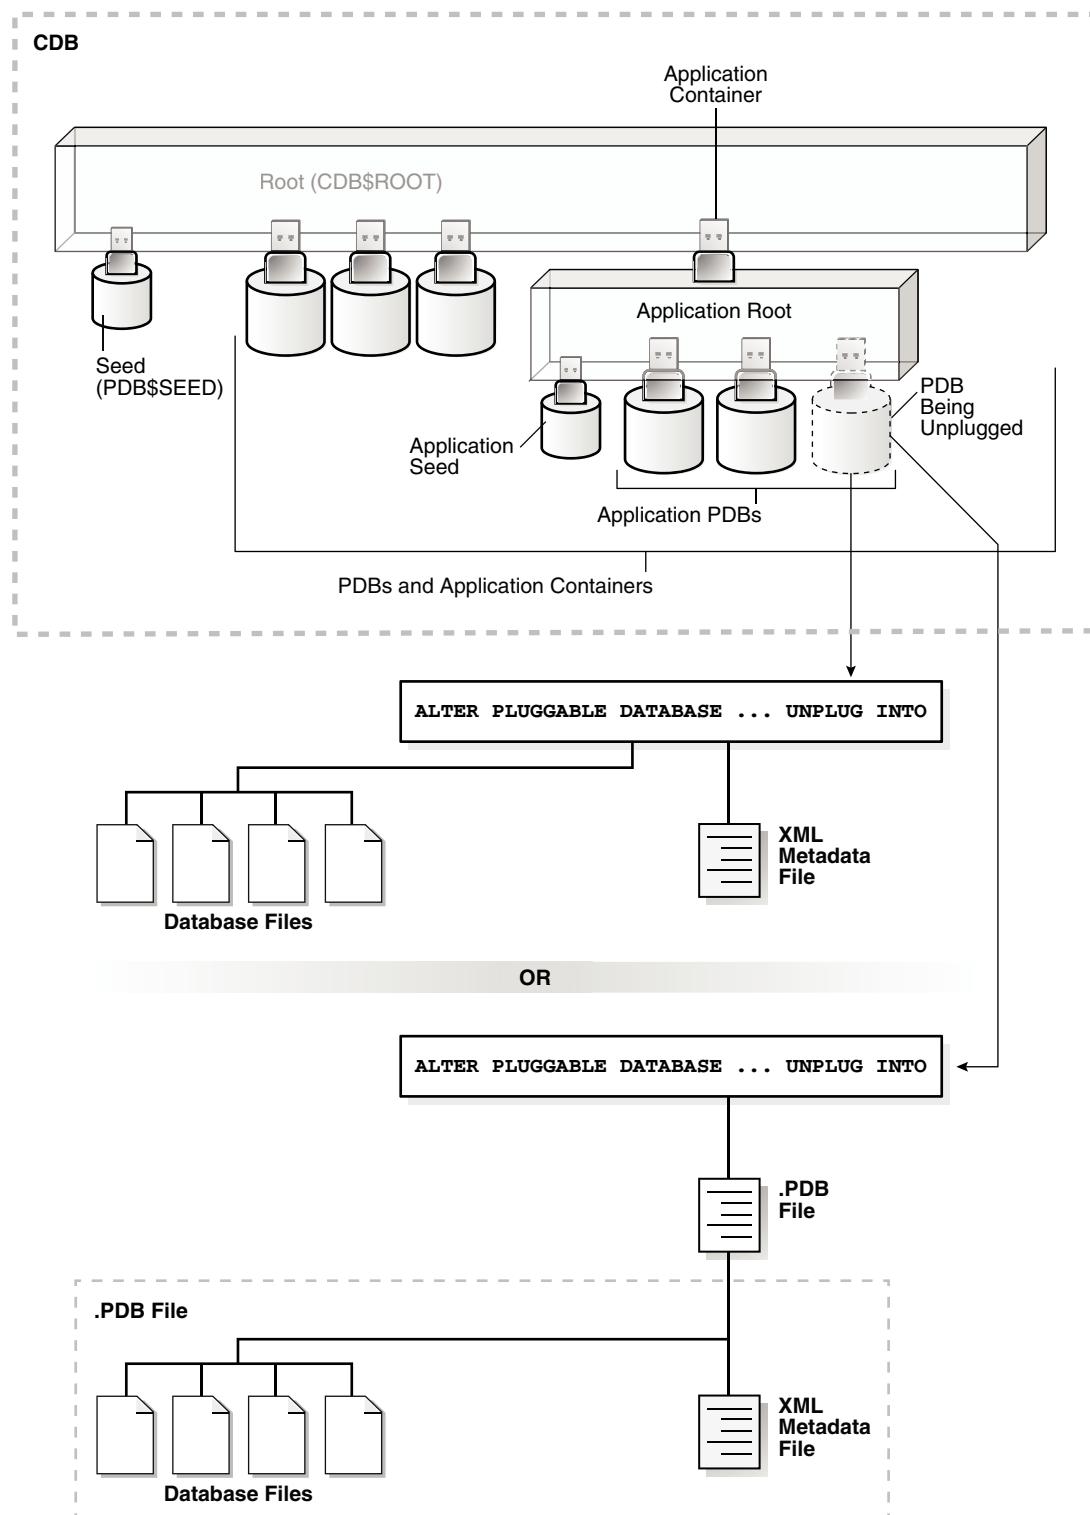

Unplugging a PDB disassociates the PDB from a CDB. You unplug a PDB when you want to move the PDB to a different CDB, when you want to archive the PDB for later use, or when you no longer want the PDB to be available.

To unplug a PDB, connect to its CDB root or application root and use the `ALTER PLUGGABLE DATABASE` statement to specify an XML file or a .pdb file. When you specify an XML file (.xml extension), it will contain metadata about the PDB after it is unplugged. The SQL statement creates the XML file, and it contains the required information to enable a `CREATE PLUGGABLE DATABASE` statement on a target CDB to plug in the PDB. When you specify a .pdb file, it contains a compressed archive of the XML file that describes the PDB and the files used by the PDB (such as the data files and wallet file). A .pdb file enables you to copy a single, compressed file (instead of multiple files) to a new location to plug the PDB into a CDB.

**Figure 38-15 Unplug a PDB**

The following illustration shows how this technique unplugs an application PDB from an application container.

The PDB must be closed before it can be unplugged. When you unplug a PDB, the unplugged PDB is in mounted mode. The unplug operation makes some changes in the PDB's data files to record, for example, that the PDB was successfully unplugged. Because it is still part of the CDB, the unplugged PDB is included in an RMAN backup.

of the entire CDB. Such a backup provides a convenient way to archive the unplugged PDB in case it is needed in the future.

To completely remove the PDB from the CDB, you can drop the PDB. The only operation supported on an unplugged PDB is dropping the PDB. The PDB must be dropped from the CDB before it can be plugged back into the same CDB. A PDB is usable only when it is plugged into a CDB.

 **Note:**

You can unplug an application container only if no application PDBs belong to it.

 **See Also:**

- ["Dropping a PDB"](#)
- ["Modifying the Open Mode of PDBs"](#) for information about closing a PDB
- ["Using the ALTER SYSTEM Statement to Modify a PDB"](#) for information about initialization parameters and unplugged PDBs
- [Oracle Database Security Guide](#) for information about common users and local users

### 38.9.2 Unplugging a PDB

You must meet prerequisites when unplugging a PDB.

The following prerequisites must be met:

- The current user must have SYSDBA or SYSOPER administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using AS SYSDBA or AS SYSOPER at connect time.
- The PDB must have been opened at least once.

 **Note:**

If you are unplugging a PDB that includes data that was encrypted with Transparent Data Encryption, then follow the instructions in *Oracle Database Advanced Security Guide*.

#### To unplug a PDB:

1. In SQL\*Plus, ensure that the current container is the root of the PDB.

If the PDB is plugged into the CDB root, then the current container must be the CDB root. If the PDB is plugged into an application root, then the current container must be the application root.

If you are unplugging an application container, then the current container must be the CDB root, and the application container must not have any application PDBs plugged into it.

See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".

**2. Close the PDB.**

In an Oracle Real Application Clusters (Oracle RAC) environment, the PDB must be closed on all instances.

**3. Run the ALTER PLUGGABLE DATABASE statement with the UNPLUG INTO clause, and specify the PDB to unplug and the name and location of the PDB's XML metadata file or .pdb file.**

**Example 38-49 Unplugging PDB salespdb Into an XML Metadata File**

This ALTER PLUGGABLE DATABASE statement unplugs the PDB `salespdb` and creates the `salespdb.xml` metadata file in the `/oracle/data/` directory:

```
ALTER PLUGGABLE DATABASE salespdb UNPLUG INTO '/oracle/data/salespdb.xml';
```

**Example 38-50 Unplugging PDB salespdb Into an Archive File**

This ALTER PLUGGABLE DATABASE statement unplugs the PDB `salespdb` and creates the `sales.pdb` archive file in the `/oracle/data/` directory. The `sales.pdb` archive file is a compressed file that includes the XML metadata file and the PDB's files (such as the data files and wallet file).

```
ALTER PLUGGABLE DATABASE salespdb UNPLUG INTO '/oracle/data/sales.pdb';
```

## 38.10 Dropping a PDB

The `DROP PLUGGABLE DATABASE` statement drops a PDB. You can drop a PDB when you want to move the PDB from one CDB to another or when you no longer need the PDB.

When you drop a PDB, the control file of the CDB is modified to eliminate all references to the dropped PDB. Archived redo log files and backups associated with the PDB are not removed, but you can use Oracle Recovery Manager (RMAN) to remove them.

When dropping a PDB, you can either keep or delete the PDB's data files by using one of the following clauses:

- `KEEP DATAFILES`, the default, retains the data files.

The PDB's temp file is removed even when `KEEP DATAFILES` is specified because the temp file is no longer needed.

When `KEEP DATAFILES` is specified, the PDB must be unplugged.

- `INCLUDING DATAFILES` removes the data files from disk.

If a PDB was created with the `SNAPSHOT COPY` clause, then you must specify `INCLUDING DATAFILES` when you drop the PDB.

The following prerequisites must be met:

- The PDB must be in mounted mode, or it must be unplugged.

See "[Modifying the Open Mode of PDBs](#)".

See "Unplugging a PDB from a CDB".

- The current user must have SYSDBA or SYSOPER administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using AS SYSDBA or AS SYSOPER at connect time.

 **Note:**

This operation is destructive.

**To drop a PDB:**

1. In SQL\*Plus, ensure that the current container is the CDB root, or, for an application PDB, the application root that contains the application PDB.

If the PDB is plugged into the CDB root, then the current container must be the CDB root. If the PDB is plugged into an application root, then the current container must be that application root or the CDB root.

If you are dropping an application container, then the current container must be the CDB root, and the application container must not have any application PDBs plugged into it.

See "About the Current Container" and "Accessing a Container in a CDB with SQL\*Plus".

2. Run the DROP PLUGGABLE DATABASE statement and specify the PDB to drop.

**Example 38-51 Dropping PDB salespdb While Keeping Its Data Files**

```
DROP PLUGGABLE DATABASE salespdb
KEEP DATAFILES;
```

**Example 38-52 Dropping PDB salespdb and Its Data Files**

```
DROP PLUGGABLE DATABASE salespdb
INCLUDING DATAFILES;
```

# Creating and Removing PDBs with Cloud Control

You can create, clone, unplug, and remove pluggable databases (PDBs) in a multitenant container database (CDB) using Oracle Enterprise Manager Cloud Control (Cloud Control).

- [Getting Started with Creating and Removing PDBs with Cloud Control](#)  
You follow specific steps when you create a new PDB, clone a PDB, migrate a non-CDB as a PDB, unplug a PDB, and delete a PDB.
- [Overview of Creating and Removing PDBs with Cloud Control](#)  
An Oracle Database can contain a portable collection of schemas, schema objects, and nonschema objects, that appear to an Oracle Net client as a separate database. This self-contained collection is called a PDB. A CDB can include one or more PDBs.
- [Provisioning a PDB with Cloud Control](#)  
You can provision PDBs by creating a new PDB within a CDB, by cloning an existing PDB, or by migrating existing non-CDBs to a CDB as PDBs. You can also use unplugged PDBs for provisioning, by plugging them into a CDB.
- [Removing PDBs with Cloud Control](#)  
You can unplug and delete PDBs.
- [Viewing PDB Job Details with Cloud Control](#)  
You can view the details of the jobs that are created by the Enterprise Manager job system when you create a PDB, unplug a PDB, or delete a PDB.

## See Also:

- ["About Creating and Removing PDBs"](#)
- ["Preparing for PDBs"](#)

## 39.1 Getting Started with Creating and Removing PDBs with Cloud Control

You follow specific steps when you create a new PDB, clone a PDB, migrate a non-CDB as a PDB, unplug a PDB, and delete a PDB.

The following table provides a documentation map to understand the sequence of actions you must perform to successfully complete these tasks using Cloud Control. Click the reference links provided against the steps to reach the relevant topics that provide more information.

**Table 39-1 Getting Started with PDBs**

| Step          | Description                                                                                                                                                                                                                                                                                                                                                          | Reference Links                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>Obtaining an Overview</b><br>Obtain a conceptual overview of PDBs.                                                                                                                                                                                                                                                                                                | To obtain a conceptual overview of PDBs, see " <a href="#">Overview</a> ".<br>For detailed conceptual information, see " <a href="#">Overview of Managing a Multitenant Environment</a> " and <i>Oracle Database Concepts</i>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 2</b> | <b>Selecting the Use Case</b><br>Among the following use cases, select the one that best matches your requirement: <ul style="list-style-type: none"> <li>• Creating a new PDB</li> <li>• Plugging in an unplugged PDB</li> <li>• Cloning a PDB</li> <li>• Migrating a non-CDB as a PDB</li> <li>• Unplugging and dropping a PDB</li> <li>• Deleting PDBs</li> </ul> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 3</b> | <b>Meeting the Prerequisites</b><br>Meet the prerequisites for the selected use case.                                                                                                                                                                                                                                                                                | <ul style="list-style-type: none"> <li>• To meet the prerequisites for creating a new PDB, see "<a href="#">Prerequisites</a>".</li> <li>• To meet the prerequisites for plugging in an unplugged PDB, see "<a href="#">Prerequisites</a>".</li> <li>• To meet the prerequisites for cloning a PDB, see "<a href="#">Prerequisites</a>".</li> <li>• To meet the prerequisites for migrating a non-CDB to a PDB, see "<a href="#">Prerequisites</a>".</li> <li>• To meet the prerequisites for unplugging and dropping a PDB, see "<a href="#">Prerequisites</a>".</li> <li>• To meet the prerequisites for deleting PDBs, see "<a href="#">Prerequisites</a>".</li> </ul> |
| <b>Step 4</b> | <b>Following the Procedure</b><br>Follow the procedure for the selected use case.                                                                                                                                                                                                                                                                                    | <ul style="list-style-type: none"> <li>• To create a new PDB, see "<a href="#">Procedure</a>".</li> <li>• To plug in an unplugged PDB, see "<a href="#">Procedure</a>".</li> <li>• To clone a PDB, see "<a href="#">Procedure</a>".</li> <li>• To migrate a non-CDB to a PDB, see "<a href="#">Procedure</a>".</li> <li>• To unplug and drop a PDB, see "<a href="#">Procedure</a>".</li> <li>• To delete PDBs, see "<a href="#">Procedure</a>".</li> </ul>                                                                                                                                                                                                               |

## 39.2 Overview of Creating and Removing PDBs with Cloud Control

An Oracle Database can contain a portable collection of schemas, schema objects, and nonschema objects, that appear to an Oracle Net client as a separate database. This self-contained collection is called a PDB. A CDB can include one or more PDBs.

Oracle Database 12c allows you to create many PDBs within a single CDB. Applications that connect to databases view PDBs and earlier versions of Oracle Database in the same manner.

Cloud Control enables administrators to manage the entire PDB lifecycle, including provisioning CDBs, provisioning PDBs (from the seed or from an unplugged PDB), cloning existing PDBs, migrating non-CDBs as PDBs, unplugging PDBs, and deleting PDBs.

 **Note:**

To manage the PDB lifecycle using Cloud Control, you must have the 12.1.0.3 Enterprise Manager for Oracle Database plug-in, or a later version, deployed. To delete PDBs using Cloud Control, you must have the 12.1.0.5 Enterprise Manager for Oracle Database plug-in deployed.

For information on how to deploy a plug-in and upgrade an existing plug-in, see *Oracle Enterprise Manager Cloud Control Administrator's Guide*.

[Figure 39-1](#) provides a graphical overview of how you can manage the PDB lifecycle in Cloud Control.

**Figure 39-1 Managing PDBs**

## 39.3 Provisioning a PDB with Cloud Control

You can provision PDBs by creating a new PDB within a CDB, by cloning an existing PDB, or by migrating existing non-CDBs to a CDB as PDBs. You can also use unplugged PDBs for provisioning, by plugging them into a CDB.

 **Note:**

As an alternative to using the methods described in this section, you can use Enterprise Manager Command Line Interface (EM CLI) to provision PDBs. For more information, see *Oracle® Enterprise Manager Lifecycle Management Administrator's Guide*.

- [Creating a New PDB with Cloud Control](#)  
You can create a new PDB in a CDB.
- [Plugging In an Unplugged PDB with Cloud Control](#)  
You can plug an unplugged PDB into a CDB.
- [Cloning a PDB with Cloud Control](#)  
You can clone a PDB using either the Full Clone method, or the Snap Clone method.
- [Migrating a Non-CDB to a PDB with Cloud Control](#)  
You can migrate a non-CDB to a PDB.

### 39.3.1 Creating a New PDB with Cloud Control

You can create a new PDB in a CDB.

- [Prerequisites](#)  
Prerequisites must be met when creating a new PDB.
- [Procedure](#)  
Follow these steps to create a new PDB in a CDB.

#### 39.3.1.1 Prerequisites

Prerequisites must be met when creating a new PDB.

- Oracle Software Library (Software Library) must be set up in Cloud Control.  
For information on how to set up Software Library in Cloud Control, see *Oracle Enterprise Manager Lifecycle Management Administrator's Guide*.
- The CDB within which you want to create a PDB must exist, and must be a Cloud Control target.
- The CDB (within which you want to create a PDB) must be in read/write mode.
- The target host user must be the owner of the Oracle Home that the CDB (within which you want to create the PDB) belongs to.

#### 39.3.1.2 Procedure

Follow these steps to create a new PDB in a CDB.

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Database Provisioning**. In the Database Provisioning page, in the Related Links section of the left menu pane, click **Provision Pluggable Databases**.

 **Note:**

You can also access the Provision Pluggable Database Console from the Home page of the CDB. To do so, in the CDB's Home page, from the **Oracle Database** menu, select **Provisioning**, then select **Provision Pluggable Database**.

2. In the Provision Pluggable Database Console, in the Container Database section, select the CDB within which you want to create new PDBs.

 **Note:**

Skip this step if you have accessed the Provision Pluggable Database Console from the CDB's Home page.

3. In the PDB Operations section, select **Create New Pluggable Databases**.
4. Click **Launch**.

 **Note:**

You will be prompted to log in to the database if you have not already logged in to it through Enterprise Manager. Make sure you log in using SYSDBA user account credentials.

5. In the Creation Options page of the Create Pluggable Database Wizard, in the Pluggable Database Creation Options section, select **Create a New PDB**.
6. In the Container Database Host Credentials section, select or specify the target CDB Oracle Home owner host credentials. If you have already registered the credentials with Enterprise Manager, then you can select **Preferred** or **Named**. Otherwise, you can select **New** and enter the credentials.
7. Click **Next**.
8. In the Identification page, enter a unique name for the PDB you are creating.

If you prefer to create more than one PDB in this procedure, then select **Create Multiple Copies**, and set the number of PDBs you want to create. Note that you can create a maximum of 252 PDBs.

 **Note:**

If you choose to create multiple PDBs, then the unique name you enter here is used as a prefix for all PDBs, and the suffix is a numeric value that indicates the count of PDBs.

For example, if you create five PDBs with the name `accountsPDB`, then the PDBs are created with the names `accountsPDB1`, `accountsPDB2`, `accountsPDB3`, `accountsPDB4`, and `accountsPDB5`.

9. In the PDB Administrator section, enter the credentials of the admin user account you need to create for administering the PDB.

 **Note:**

If you choose to create multiple PDBs, then an admin user account is created for each PDB that you create, with the same set of the specified credentials.

10. Click **Next**.
11. In the Storage page, in the PDB Datafile Locations section, select the type of location where you want to store the datafiles.
  - If the target CDB (*CDB in which you are creating the PDB*) is enabled with Oracle Managed Files and if you want to use the same, then select **Use Oracle Managed Files (OMF)**.
  - If you want to enter a custom location, then select **Use Common Location for PDB Datafiles**. Select the storage type and the location where the datafiles can be stored.
12. In the Temporary Working Directory section, enter a location where the temporary files generated during the PDB creation process can be stored.
13. In the Post-Creation Scripts section, select a custom SQL script you want to run as part of this procedure, once the PDB is created.
14. Click **Next**.
15. In the Schedule page, enter a unique deployment procedure instance name and a schedule for the deployment. The instance name you enter here helps you identify and track the progress of this procedure on the Procedure Activity page.  
  
If you want to run the procedure immediately, then retain the default selection, that is, **Immediately**. Otherwise, select **Later** and provide time zone, start date, and start time details.  
  
You can optionally set a grace period for this schedule. A grace period is a period of time that defines the maximum permissible delay when attempting to run a scheduled procedure. If the procedure does not start within the grace period you have set, then the procedure skips running. To set a grace period, select **Grace Period**, and set the permissible delay time.

16. Click **Next**.

17. In the Review page, review the details you have provided for the deployment procedure. If you are satisfied with the details, click **Submit**.

If you want to modify the details, then click **Back** repeatedly to reach the page where you want to make the changes.

18. In the Procedure Activity page, view the status of the procedure. From the **Procedure Actions** menu, you can select **Debug** to set the logging level to Debug, and select **Stop** to stop the procedure execution.

When you create a new PDB, the Enterprise Manager job system creates a Create Pluggable Database job. For information about viewing the details of this job, refer "[Viewing Create PDB Job Details](#)".

### 39.3.2 Plugging In an Unplugged PDB with Cloud Control

You can plug an unplugged PDB into a CDB.

- [Prerequisites](#)

Prerequisites must be met when plugging an unplugged PDB.

- [Procedure](#)

Follow these steps to plug an unplugged PDB into a CDB.

#### 39.3.2.1 Prerequisites

Prerequisites must be met when plugging an unplugged PDB.

- Oracle Software Library (Software Library) must be set up in Cloud Control.  
For information on how to set up Software Library in Cloud Control, see *Oracle Enterprise Manager Lifecycle Management Administrator's Guide*.
- The target CDB (the CDB within which you want to plug in the unplugged PDB) must exist, and must be a Cloud Control target.
- The target CDB must be in read/write mode.
- The XML file that describes the unplugged PDB, and the other files associated with the unplugged PDB, such as the data files, must exist and must be readable.
- The target host user must be the owner of the Oracle Home that the CDB (into which you want to plug the unplugged PDB) belongs to.
- The platforms of the source CDB host (the host on which the CDB that previously contained the unplugged PDB is installed) and the target CDB host (the host on which the target CDB is installed) must have the same endianness.
- The database options installed on the source platform must be the same as, or a subset of, the database options installed on the target platform.
- If the character set of the CDB to which the PDB is being cloned is not AL32UTF8, then the CDB that contained the unplugged PDB and the target CDB must have compatible character sets and national character sets. To be compatible, the character sets and national character sets must meet all of the requirements specified in *Oracle Database Globalization Support Guide*.

If the character set of the CDB to which the PDB is being cloned is AL32UTF8, then this requirement does not apply.

- If you are creating an application PDB, then the application name and version of the unplugged PDB must match the application name and version of the application container that will contain the application PDB when it is plugged in.
- If you are creating an application PDB, then the application PDB must have the same character set and national character set as the application container.

If the database character set of the CDB is AL32UTF8, then the character set and national character set of the application container can different from the CDB. However, all application PDBs in an application container must have same character set and national character set, matching that of the application container.

### 39.3.2.2 Procedure

Follow these steps to plug an unplugged PDB into a CDB.

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Database Provisioning**. In the Database Provisioning page, in the Related Links section of the left menu pane, click **Provision Pluggable Databases**.

 **Note:**

You can also access the Provision Pluggable Database Console from the Home page of the CDB. To do so, in the CDB's Home page, from the **Oracle Database** menu, select **Provisioning**, then select **Provision Pluggable Database**.

2. In the Provision Pluggable Database Console, in the Container Database section, select the CDB to which you want to add the unplugged PDBs.

 **Note:**

Skip this step if you have accessed the Provision Pluggable Database Console from the CDB's Home page.

3. In the PDB Operations section, select **Create New Pluggable Databases**.
4. Click **Launch**.

 **Note:**

You will be prompted to log in to the database if you have not already logged in to it through Enterprise Manager. Make sure you log in using **SYSDBA** user account credentials.

5. In the Creation Options page of the Create Pluggable Database Wizard, in the Pluggable Database Creation Options section, select **Plug an Unplugged PDB**.
6. In the Container Database Host Credentials section, select or specify the target CDB Oracle Home owner host credentials. If you have already registered the credentials with Enterprise Manager, then you can select **Preferred** or **Named**. Otherwise, you can select **New** and enter the credentials.
7. Click **Next**.
8. In the Identification page, enter a unique name for the PDB you are plugging in.

Select **Create As Clone** if you are plugging a PDB into a CDB that contains one or more PDBs that were created by plugging in the same PDB. Selecting this option ensures that Oracle Database generates unique PDB DBID, GUID, and other identifiers expected for the new PDB.

If you prefer to create more than one PDB in this procedure, then select **Create Multiple Copies**, and set the number of PDBs you want to create. Note that you can create a maximum of 252 PDBs.

 **Note:**

If you choose to create multiple PDBs, then the unique name you enter here is used as a prefix for all PDBs, and the suffix is a numeric value that indicates the count of PDBs.

For example, if you create five PDBs with the name `accountsPDB`, then the PDBs are created with the names `accountsPDB1`, `accountsPDB2`, `accountsPDB3`, `accountsPDB4`, and `accountsPDB5`.

9. In the PDB Administrator section, do one of the following to administer the PDB:

- If you prefer to use the admin user account that was created as part of the source PDB that you are plugging in, then deselect **Create PDB Administrator**.
- If you want to create a brand new admin user account for the PDB you are plugging in, then select **Create PDB Administrator**, and enter the desired credentials.

 **Note:**

If you choose to create multiple PDBs, then an admin user account is created for each PDB that you create, with the same set of the specified credentials.

To lock and expire all the users in the newly created PDB, (except the newly created Admin), select **Lock All Existing PDB Users**.

10. In the PDB Template Location section, select the location where the source PDB's template is available, and then select the type of PDB template.
- If the PDB template is available on your CDB host (*CDB to which you are plugging in the unplugged PDB*), then select **Target Host File System**.
    - If the PDB template is a single archive file—a TAR file with data files and metadata XML file included in it, then select **Create Pluggable Database from Pluggable Database Archive**, then select the PDB template.
    - If the PDB template is a PDB file set—a separate DBF file with all the data files and a separate metadata XML file, then select **Create the PDB using PDB File Set**, then select the DBF and XML files.
    - If you want to plug in a PDB using the PDB metadata XML file and the existing data files, then select **Create PDB using Metadata file**.
  - If the PDB template is available in Oracle Software Library (Software Library), then select **Software Library**, then select the component in the Software Library that contains the PDB template.
11. Click **Next**.

**12.** In the Storage page, do one of the following:

- In the previous page, if you chose to create the PDB from a PDB archive (single TAR file) or using a PDB file set (DFB file and an XML file), then select the type of location where you want to store the target data files for the PDB you are plugging in.
  - If the target CDB (*CDB to which you are plugging in the unplugged PDB*) is enabled with Oracle Managed Files and if you want to use the same, then select **Use Oracle Managed Files (OMF)**.
  - If you want to enter a common custom location, then select **Use Common Location for PDB datafiles**. Select the storage type and the location where the data files can be stored.
- In the previous page, if you chose to create the PDB using a PDB template (XML file only), then do the following:

In the PDB Datafile Locations section, validate the locations mapped for the data files. If they are incorrect, correct the paths. Alternatively, if you have a single location where the data files are all available, then enter the absolute path in the **Set Common Source File Mapping Location** field, and click **Set**.

You can choose to store the target data files for the PDB you are plugging in, in the same location as the source data files. However, if you want the target data files to be stored in a different location, then select **Copy Datafiles**, and select the type of location:

- If the target CDB (*CDB to which you are plugging in the unplugged PDB*) is enabled with Oracle Managed Files and if you want to use the same, then select **Use Oracle Managed Files (OMF)**.
- If you want to enter a common custom location, then select **Use Common Location for Pluggable Database Files**. Select the storage type and the location where the data files can be stored.
- If you prefer to use different custom locations for different data files, then select **Customized Location**, and enter the custom location paths.

**13.** In the Temporary Working Directory section, enter a location where the temporary files generated during the PDB creation process can be stored.

**14.** In the Post-Creation Scripts section, select a custom SQL script you want to run as part of this procedure, once the PDB is plugged in.

If the script is available in the Software Library, select **Select from Software Library**, then select the component that contains the custom script.

**15.** Click **Next**.

**16.** In the Schedule page, enter a unique deployment procedure instance name and a schedule for the deployment. The instance name you enter here helps you identify and track the progress of this procedure on the Procedure Activity page.

If you want to run the procedure immediately, then retain the default selection, that is, **Immediately**. Otherwise, select **Later** and provide time zone, start date, and start time details.

You can optionally set a grace period for this schedule. A grace period is a period of time that defines the maximum permissible delay when attempting to run a scheduled procedure. If the procedure does not start within the grace period you have set, then the procedure skips running. To set a grace period, select **Grace Period**, then set the permissible delay time.

17. Click **Next**.
18. In the Review page, review the details you have provided for the deployment procedure. If you are satisfied with the details, click **Submit**.  
If you want to modify the details, then click **Back** repeatedly to reach the page where you want to make the changes.
19. In the Procedure Activity page, view the status of the procedure. From the **Procedure Actions** menu, you can select **Debug** to set the logging level to Debug, and select **Stop** to stop the procedure execution.  
When you plug in an unplugged PDB, the Enterprise Manager job system creates a Create Pluggable Database job. For information about viewing the details of this job, refer "[Viewing Create PDB Job Details](#)".

### 39.3.3 Cloning a PDB with Cloud Control

You can clone a PDB using either the Full Clone method, or the Snap Clone method.

- [Prerequisites](#)  
Prerequisites must be met when cloning a PDB.
- [Procedure](#)  
Follow these steps to clone an existing PDB.

#### 39.3.3.1 Prerequisites

Prerequisites must be met when cloning a PDB.

- Oracle Software Library (Software Library) must be set up in Cloud Control.  
For information on how to set up Software Library in Cloud Control, see *Oracle Enterprise Manager Lifecycle Management Administrator's Guide*.
- The source PDB (the PDB that you want to clone) must exist, and must be a Cloud Control target.

 **Note:**

For information on how to create a new PDB, refer to "[Creating a New PDB](#)".

- The source PDB must be open.
- The target CDB (the CDB into which you want to plug in the cloned PDB) must exist, and must be a Cloud Control target.
- The target CDB must be in read/write mode.
- The target host user must be the owner of the Oracle Home that the source CDB belongs to.

To clone a PDB using the Snap Clone method, you must meet the following additional prerequisites:

- The 12.1.0.5 Enterprise Manager for Oracle Database plug-in must be downloaded and deployed. Also, the 12.1.0.3 SMF plug-in or higher must be downloaded and deployed.

- The PDB that you want to clone must reside on a registered storage server. This storage server must be synchronized.

For information on how to register a storage server and synchronize storage servers, see *Oracle Enterprise Manager Cloud Administration Guide*.

- All the datafiles of the PDB that you want to clone must reside on the storage volumes of the storage server, and not on the local disk.
- Metric collections must be run on the source CDB (the CDB containing the PDB that you want to clone), the source CDB host, and the PDB that you want to clone.
- The Snap Clone feature must be enabled for the PDB that you want to clone.

For information on how to enable the Snap Clone feature, see *Oracle Enterprise Manager Cloud Administration Guide*.

### 39.3.3.2 Procedure

Follow these steps to clone an existing PDB.

 **Note:**

If you use the Full Clone method to clone a PDB, you can clone the PDB only to the source CDB (the CDB containing the PDB that you are cloning).

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Database Provisioning**. In the Database Provisioning page, in the Related Links section of the left menu pane, click **Provision Pluggable Databases**.

 **Note:**

You can also access the Provision Pluggable Database Console from the Home page of the CDB. To do so, in the CDB's Home page, from the **Oracle Database** menu, select **Provisioning**, then select **Provision Pluggable Database**.

2. In the Provision Pluggable Database Console, in the CDB section, select the source CDB, that is, the CDB containing the PDB that you want to clone.

 **Note:**

Skip this step if you have accessed the Provision Pluggable Database Console from the CDB's Home page.

3. In the PDB Operations section, select **Create New Pluggable Databases**.
4. Click **Launch**.

 **Note:**

You will be prompted to log in to the database if you have not already logged in to it through Enterprise Manager. Make sure you log in using SYSDBA user account credentials.

5. In the Creation Options page of the Create Pluggable Database Wizard, in the PDB Creation Options section, select **Clone an Existing PDB**.

To clone a PDB using the traditional method of cloning the PDB datafiles, select **Full Clone**. Use this method if you want to clone a PDB for long term usage. This method is ideal for load testing, when you plan to make significant data updates to the PDB clone. However, this method takes a longer period of time, and a clone that is created using this method occupies a fairly large amount of space, as compared to the Snap Clone method.

To clone a PDB using the Storage Management Framework (SMF) Snap Clone feature, select **Snap Clone**. Use this method if you want to clone a PDB for short term purposes. This method is ideal for functional testing, as the cloning process is quick, and a PDB clone that is created using this method occupies very little space. However, this method is not suitable if you plan to make significant data updates to the PDB clone.

For **Source PDB**, select the PDB that you want to clone.

6. In the CDB Host Credentials section, select or specify the source CDB Oracle Home owner host credentials. If you have already registered the credentials with Enterprise Manager, you can select **Preferred** or **Named**. Otherwise, you can select **New** and enter the credentials.
7. Click **Next**.
8. In the Identification page, enter a unique name for the PDB you are cloning.

If you prefer to create more than one PDB in this procedure, then select **Create Multiple Copies**, and set the number of PDBs you want to create. Note that you can create a maximum of 252 PDBs.

 **Note:**

If you choose to create multiple PDBs, then the unique name you enter here is used as a prefix for all the cloned PDBs, and the suffix is a numeric value that indicates the count of PDBs.

For example, if you create five PDBs with the name `accountsPDB`, then the PDBs are created with the names `accountsPDB1`, `accountsPDB2`, `accountsPDB3`, `accountsPDB4`, and `accountsPDB5`.

9. In the PDB Administrator section, do one of the following to administer the PDB:
  - If you prefer to use the admin user account that was created as part of the source PDB that you are cloning, then deselect **Create PDB Administrator**.
  - If you want to create a brand new admin user account for the PDB you are cloning, then select **Create PDB Administrator**, and enter the desired credentials.

 **Note:**

If you choose to create multiple PDBs, then an admin user account is created for each PDB that you create, with the same set of the specified credentials.

- 10.** In the Source CDB Login Credentials section, select or specify the login credentials of the source CDB. If you have already registered the credentials with Enterprise Manager, you can select **Preferred** or **Named**. Otherwise, you can select **New** and enter the credentials.

The credentials are used to bring the source PDB to read-only mode before the cloning operation begins, and to restore it to the original state after the cloning operation ends.

If you chose the Snap Clone method (on the Source page of the Create Pluggable Database Wizard) to clone the PDB, specify the host credentials for the source CDB.

 **Note:**

If you are cloning the source PDB to the source CDB itself, then the Source CDB Login Credentials section is not displayed, that is, you do not need to provide the source CDB login credentials or the source CDB host credentials.

If you are cloning the source PDB to a CDB different from the source CDB, and this CDB resides on the source CDB host, then you must provide the source CDB login credentials. You do not need to provide the source CDB host credentials.

If you are cloning the source PDB to a CDB different from the source CDB, and this CDB resides on a host different from the source CDB host, then you must provide the source CDB login credentials and the source CDB host credentials.

- 11.** Click **Next**.

- 12.** In the Storage page, specify the storage information.

If you chose the Full Clone method to clone the PDB, select the type of location where you want to store the PDB datafiles in the following manner:

- If the source CDB is enabled with Oracle Managed Files and if you want to use the same, then select **Use Oracle Managed Files (OMF)**.
- If you want to enter a custom location, then select **Use Common Location for PDB datafiles**. Select the storage type and the location where the datafiles can be stored.

If you chose the Snap Clone method to clone the PDB, do the following:

- In the PDB Datafile Locations section, specify a value for **Mount Point Prefix**, that is, the mount location for the storage volumes. You can choose to specify the same prefix for all the volumes, or a different prefix for each volume. Also, specify a value for **Writable Space**, that is, the space that you want to allocate for writing the changes made to the PDB clone. You can choose to specify the

same writable space value for all the volumes, or a different value for each volume.

- In the Privileged Host Credentials section, select or specify the credentials of the root user. These credentials are used for mounting the cloned volumes on the destination host.  
If you have already registered the credentials with Enterprise Manager, you can select **Preferred** or **Named**. Otherwise, you can select **New** and enter the credentials.
- 13.** In the Temporary Working Directory section, enter a location where the temporary files generated during the PDB creation process can be stored.
- 14.** In the Post-Creation Scripts section, select a custom SQL script you want to run as part of this procedure, once the PDB is cloned.
- 15.** Click **Next**.
- 16.** In the Schedule page, enter a unique deployment procedure instance name and a schedule for the deployment. The instance name you enter here helps you identify and track the progress of this procedure on the Procedure Activity page.  
If you want to run the procedure immediately, then retain the default selection, that is, **Immediately**. Otherwise, select **Later** and provide time zone, start date, and start time details.  
You can optionally set a grace period for this schedule. A grace period is a period of time that defines the maximum permissible delay when attempting to run a scheduled procedure. If the procedure does not start within the grace period you have set, then the procedure skips running. To set a grace period, select **Grace Period**, and set the permissible delay time.

**17.** Click **Next**.

**18.** In the Review page, review the details you have provided for the deployment procedure. If you are satisfied with the details, click **Submit**.

If you want to modify the details, then click **Back** repeatedly to reach the page where you want to make the changes.

**19.** In the Procedure Activity page, view the status of the procedure. From the **Procedure Actions** menu, you can select **Debug** to set the logging level to Debug, and select **Stop** to stop the procedure execution.

When you clone a PDB, the Enterprise Manager job system creates a Create Pluggable Database job. For information about viewing the details of this job, refer "[Viewing Create PDB Job Details](#)".

### 39.3.4 Migrating a Non-CDB to a PDB with Cloud Control

You can migrate a non-CDB to a PDB.

- [Prerequisites](#)  
Prerequisites must be met when migrating a non-CDB to a PDB.
- [Procedure](#)  
Follow these steps to migrate a non-CDB to a PDB.

#### 39.3.4.1 Prerequisites

Prerequisites must be met when migrating a non-CDB to a PDB.

- Oracle Software Library (Software Library) must be set up in Cloud Control.  
For information on how to set up Software Library in Cloud Control, see *Oracle Enterprise Manager Lifecycle Management Administrator's Guide*.
- The target CDB (the CDB to which you want to migrate a non-CDB to a PDB) must exist, and must be a Cloud Control target.
- The target CDB must be in read/write mode.
- The non-CDB that you want to migrate and the target CDB must be running in ARCHIVELOG mode.
- The database administrators of the database you want to migrate and the target CDB must have SYSDBA privileges.
- The target host user must be the owner of the Oracle Home that the target CDB belongs to.

### 39.3.4.2 Procedure

Follow these steps to migrate a non-CDB to a PDB.

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Database Provisioning**. In the Database Provisioning page, in the Related Links section of the left menu pane, click **Provision Pluggable Databases**.

 **Note:**

You can also access the Provision Pluggable Database Console from the Home page of the CDB. To do so, in the CDB's Home page, from the **Oracle Database** menu, select **Provisioning**, then select **Provision Pluggable Database**.

2. In the Provision Pluggable Database Console, in the Container Database section, select the CDB to which you want to migrate a non-CDB to a PDB.

 **Note:**

Skip this step if you have accessed the Provision Pluggable Database Console from the CDB's Home page.

3. In the PDB Operations section of the Provision Pluggable Database page, select the **Migrate Existing Databases** option and click **Launch**.
4. On the Database Login page, select the Credential Name from the drop-down list. Click **Login**.
5. On the Migrate Non-CDBs launch page, select a data migration method, that is, **Export/Import** or **Plug as a PDB**. If you select **Plug as a PDB**, ensure that the non-CDB that you want to migrate is open, and is in read-only mode.

Enter the appropriate credentials for the Oracle Home Credential section.

Click **Next**.

6. On the Database page, select a Non-CDB to be migrated. You can select more than one. Click **Add**. In the database pane, provide the appropriate credential, properties, export, import, and datafile location information. Click **Next**.
7. On the Schedule page, enter the appropriate job and scheduling details. Click **Next**.
8. On the Review page, review all details entered. If there are no changes required, click **Submit**.

## 39.4 Removing PDBs with Cloud Control

You can unplug and delete PDBs.

- [Unplugging and Dropping a PDB with Cloud Control](#)  
You can unplug or drop a PDB.
- [Deleting PDBs with Cloud Control](#)  
You can delete a PDB from a CDB.

### 39.4.1 Unplugging and Dropping a PDB with Cloud Control

You can unplug or drop a PDB.

#### Note:

As an alternative to using the method described in this section, you can use Enterprise Manager Command Line Interface (EM CLI) to unplug and drop PDBs. For more information, see *Oracle® Enterprise Manager Lifecycle Management Administrator's Guide*.

- [Prerequisites](#)  
Prerequisites must be met when unplugging and dropping a PDB.
- [Procedure](#)  
Follow these steps to create unplug a PDB from its CDB.

#### 39.4.1.1 Prerequisites

Prerequisites must be met when unplugging and dropping a PDB.

- Oracle Software Library (Software Library) must be set up in Cloud Control.  
For information on how to set up Software Library in Cloud Control, see *Oracle Enterprise Manager Lifecycle Management Administrator's Guide*.
- The PDB that you want to unplug and drop must have been opened at least once.
- The target host user must be the owner of the Oracle Home that the CDB (containing the PDB that you want to unplug and drop) belongs to.

#### 39.4.1.2 Procedure

Follow these steps to create unplug a PDB from its CDB.

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Database Provisioning**. In the Database Provisioning page, in the Related Links section of the left menu pane, click **Provision Pluggable Databases**.

 **Note:**

You can also access the Provision Pluggable Database Console from the Home page of the CDB. To do so, in the CDB's Home page, from the **Oracle Database** menu, select **Provisioning**, then select **Provision Pluggable Database**.

2. In the Provision Pluggable Database Console, in the Container Database section, select the CDB from which you want to unplug the PDBs.

 **Note:**

Skip this step if you have accessed the Provision Pluggable Database Console from the CDB's Home page.

3. In the PDB Operations section, select **Unplug Pluggable Database**.
4. Click **Launch**.

 **Note:**

You will be prompted to log in to the database if you have not already logged in to it through Enterprise Manager. Make sure you log in using SYSDBA user account credentials.

5. In the Select PDB page of the Unplug Pluggable Database Wizard, in the Select Pluggable Database section, select the PDB you want to unplug. Note that the PDB once unplugged will be stopped and dropped.
6. In the Container Database Host Credentials section, select or specify the target CDB Oracle Home owner host credentials. If you have already registered the credentials with Enterprise Manager, you can select **Preferred** or **Named**. Otherwise, you can select **New** and enter the credentials.
7. In the Destination page, select the type of PDB template you want to generate for unplugging the PDB, and the location where you want to store it. The PDB template consists of all data files as well as the metadata XML file.
  - If you want to store the PDB template on your CDB host (*CDB from which you are unplugging the PDB*), then select **Target Host File System**.
    - If you want to generate a single archive file—a TAR file with the data files and the metadata XML file included in it, then select **Generate PDB Archive**. Select a location where the archive file can be created.

 **Note:**

Oracle recommends that you select this option if the source and target CDBs are using file system for storage. This option is not supported for PDBs using ASM as storage.

- If you want to generate an archive file set—a separate DBF file with all the data files and a separate metadata XML file, then select **Generate PDB File Set**. Select the locations where the DBF and XML files can be created.

 **Note:**

Oracle recommends that you select this option if the source and target CDBs are using ASM for storage.

- If you want to generate only a metadata XML file, leaving the data files in their current location, then select **Generate PDB Metadata File**. Select a location where the metadata XML file can be created.
- If you want to store the PDB template in Oracle Software Library (Software Library), then select **Software Library**.
  - If you want to generate a single archive file—a TAR file with the data files and the metadata XML file included in it, then select **Generate PDB Archive**. If you want to generate an archive file set—a separate DBF file with all the data files and a separate metadata XML file, then select **Generate PDB File Set**. If you want to generate only a metadata XML file, leaving the data files in their current location, then select **Generate PDB Metadata File**.
  - Enter a unique PDB template name.

The template is created in the default location that has the following format:

Database Configuration/db\_release/platform/Database Templates  
For example,

Database Configuration/12.1.0.0.2/unix/Database Templates

- Enter a temporary location where the archive can be created by Enterprise Manager before it is uploaded to the Software Library.

8. In the Schedule page, enter a unique deployment procedure instance name and a schedule for the deployment. The instance name you enter here helps you identify and track the progress of this procedure on the Procedure Activity page.

If you want to run the procedure immediately, then retain the default selection, that is, **Immediately**. Otherwise, select **Later** and provide time zone, start date, and start time details.

You can optionally set a grace period for this schedule. A grace period is a period of time that defines the maximum permissible delay when attempting to run a scheduled procedure. If the procedure does not start within the grace period you

have set, then the procedure skips running. To set a grace period, select **Grace Period**, and set the permissible delay time.

9. Click **Next**.
10. In the Review page, review the details you have provided for the deployment procedure. If you are satisfied with the details, click **Submit**.  
If you want to modify the details, then click **Back** repeatedly to reach the page where you want to make the changes.
11. In the Procedure Activity page, view the status of the procedure. From the **Procedure Actions** menu, you can select **Debug** to set the logging level to Debug, and select **Stop** to stop the procedure execution.  
When you unplug and drop a PDB, the Enterprise Manager job system creates an Unplug Pluggable Database job. For information about viewing the details of this job, refer "[Viewing Unplug PDB Job Details](#)".

## 39.4.2 Deleting PDBs with Cloud Control

You can delete a PDB from a CDB.

- [Prerequisites](#)  
Prerequisites must be met when permanently deleting a set of PDBs from a CDB.
- [Procedure](#)  
Follow these steps to permanently delete a set of PDBs from a CDB.

### 39.4.2.1 Prerequisites

Prerequisites must be met when permanently deleting a set of PDBs from a CDB.

- The 12.1.0.5 Enterprise Manager for Oracle Database plug-in must be downloaded and deployed.  
For information on how to download and deploy a plug-in, see *Oracle Enterprise Manager Cloud Control Administrator's Guide*.
- Oracle Software Library (Software Library) must be set up in Cloud Control.  
For information on how to set up Software Library in Cloud Control, see *Oracle Enterprise Manager Lifecycle Management Administrator's Guide*.
- The PDBs that you want to delete must have been opened at least once.
- The target host user must be the owner of the Oracle home that the CDB (containing the PDBs that you want to delete) belongs to.

### 39.4.2.2 Procedure

Follow these steps to permanently delete a set of PDBs from a CDB.

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Database Provisioning**. In the Database Provisioning page, in the Related Links section of the left menu pane, click **Provision Pluggable Databases**.

 **Note:**

You can also access the Provision Pluggable Database Console from the Home page of the CDB. To do so, in the CDB's Home page, from the **Oracle Database** menu, select **Provisioning**, then select **Provision Pluggable Database**.

2. In the Provision Pluggable Database Console, in the CDB section, select the CDB from which you want to delete the PDBs.

 **Note:**

Skip this step if you have accessed the Provision Pluggable Database Console from the CDB's home page.

3. In the PDB Operations section, select **Delete Pluggable Databases**.
4. Click **Launch**.

 **Note:**

You will be prompted to log in to the database if you have not already logged in to it through Enterprise Manager. Make sure you log in using SYSDBA user account credentials.

5. In the Select PDBs page of the Delete Pluggable Databases Wizard, click **Add**. Select the PDBs that you want to delete, then click **Select**.

 **Note:**

If you choose to delete a PDB that was created using the Snap Clone method, the PDB mount points on the CDB host are cleaned up. The corresponding storage volumes on the storage server are also deleted. This action is irreversible.

6. In the CDB Host Credentials section, select or specify the target CDB Oracle Home owner host credentials. If you have already registered the credentials with Enterprise Manager, you can select **Preferred** or **Named**. Otherwise, you can select **New** and enter the credentials.

If one (or more) of the PDBs that you selected for deletion is the Snap Clone of another PDB, you must also provide the privileged host credentials, that is, the credentials of the root user. If you have already registered the credentials with Enterprise Manager, you can select **Preferred** or **Named**. Otherwise, you can select **New** and enter the credentials.

7. In the Schedule page, enter a unique deployment procedure instance name and a schedule for the deployment. The instance name you enter here helps you identify and track the progress of this procedure on the Procedure Activity page.

If you want to run the procedure immediately, then retain the default selection, that is, **Immediately**. Otherwise, select **Later** and provide time zone, start date, and start time details.

You can optionally set a grace period for this schedule. A grace period is a period of time that defines the maximum permissible delay when attempting to run a scheduled procedure. If the procedure does not start within the grace period you have set, then the procedure skips running. To set a grace period, select **Grace Period**, and set the permissible delay time.

8. Click **Next**.
9. In the Review page, review the details you have provided for the deployment procedure. If you are satisfied with the details, click **Submit**.

If you want to modify the details, then click **Back** repeatedly to reach the page where you want to make the changes.

10. In the Procedure Activity page, view the status of the procedure. From the **Procedure Actions** menu, you can select **Debug** to set the logging level to Debug, and select **Stop** to stop the procedure execution.

When you delete a PDB, the Enterprise Manager job system creates a Delete Pluggable Database job. For information about viewing the details of this job, refer "[Viewing Delete PDB Job Details](#)".

## 39.5 Viewing PDB Job Details with Cloud Control

You can view the details of the jobs that are created by the Enterprise Manager job system when you create a PDB, unplug a PDB, or delete a PDB.

- [Viewing Create PDB Job Details with Cloud Control](#)  
Follow these steps to view the details of a create PDB job.
- [Viewing Unplug PDB Job Details with Cloud Control](#)  
Follow these steps to view the details of an unplug PDB job.
- [Viewing Delete PDB Job Details with Cloud Control](#)  
Follow these steps to view the details of a delete PDB job.

### 39.5.1 Viewing Create PDB Job Details with Cloud Control

Follow these steps to view the details of a create PDB job.

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Procedure Activity**.
2. Click the deployment procedure that contains the required create PDB job.
3. Expand the deployment procedure steps. Select the PDB creation job.
4. Click **Job Summary**.
5. To view a summary of the job details, click **Summary**.

In the Prepare Configuration Data step, the system prepares for PDB creation.

In the Check Prerequisites step, the system checks the prerequisites for PDB creation.

In the Verify and Prepare step, the system runs tasks prior to PDB creation.

In the Perform Configuration step, the PDB creation is performed. For details of the performed tasks and their status, refer to the remote log files present on the host.

In the Post Configuration step, Enterprise Manager is updated with the newly created PDB details, and the custom scripts are run.

6. To view a visual representation of the create PDB job progress, click **Results**.

In the Configuration Progress section, you can view the completion percentage of the job, and a list of pending, currently running, and completed job steps. You can also view errors, warnings, and logs. The tail of the log for the currently running job step is displayed.

### 39.5.2 Viewing Unplug PDB Job Details with Cloud Control

Follow these steps to view the details of an unplug PDB job.

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Procedure Activity**.
2. Click the deployment procedure that contains the required unplug PDB job.
3. Expand the deployment procedure steps. Select the unplug PDB job.
4. Click **Job Summary**.
5. To view a summary of the job details, click **Summary**.

In the Prepare Configuration Data step, the system prepares for unplugging a PDB.

In the Check Prerequisites step, the system checks the prerequisites for unplugging a PDB.

In the Verify and Prepare step, the system runs tasks prior to unplugging the PDB.

In the Perform Configuration step, the PDB unplugging is performed. For details of the performed tasks and their status, refer to the remote log files present on the host.

In the Post Configuration step, Enterprise Manager is updated with the unplugged PDB details.

6. To view a visual representation of the unplug PDB job progress, click **Results**.

In the Configuration Progress section, you can view the completion percentage of the job, and a list of pending, currently running, and completed job steps. You can also view errors, warnings, and logs. The tail of the log for the currently running job step is displayed.

### 39.5.3 Viewing Delete PDB Job Details with Cloud Control

Follow these steps to view the details of a delete PDB job.

1. From the **Enterprise** menu, select **Provisioning and Patching**, then select **Procedure Activity**.
2. Click the deployment procedure that contains the required delete PDB job.
3. Expand the deployment procedure steps. Select the delete PDB job.
4. Click **Job Summary**.

5. To view a summary of the job details, click **Summary**.

In the Prepare Configuration Data step, the system prepares for deleting the PDBs.

In the Verify and Prepare step, the system runs tasks prior to deleting the PDBs.

In the Perform Configuration step, the PDB deletion is performed. For details of the performed tasks and their status, refer to the remote log files present on the host.

In the Post Configuration step, Enterprise Manager is updated with the deleted PDB details.

6. To view a visual representation of the delete PDB job progress, click **Results**.

In the Configuration Progress section, you can view the completion percentage of the job, and a list of pending, currently running, and completed job steps. You can also view errors, warnings, and logs. The tail of the log for the currently running job step is displayed.

# Creating and Removing Application Containers and Seeds with SQL\*Plus

You can create application containers and application seeds in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application containers from a CDB, and you can remove application seeds from application containers.

- [Creating and Removing Application Containers with SQL\\*Plus](#)

You can create application containers in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application containers from a CDB.

- [Creating and Removing Application Seeds with SQL\\*Plus](#)

You can create application seeds in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application seeds from application containers.

- [Creating an Application PDB](#)

You create an application PDB by running the `CREATE PLUGGABLE DATABASE` statement with an application root as the current container.

## Related Topics

- [Administering Application Containers with SQL\\*Plus](#)

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

- [Oracle Database Concepts](#)

## 40.1 Creating and Removing Application Containers with SQL\*Plus

You can create application containers in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application containers from a CDB.

- [Creating Application Containers](#)

You can use the `CREATE PLUGGABLE DATABASE` statement to create an application container in a CDB.

- [Unplugging an Application Container from a CDB](#)

You can unplug an application container from a CDB.

- [Dropping an Application Container](#)

You can use the `DROP PLUGGABLE DATABASE` statement to drop an application container. You can drop an application container when you want to move the application container from one CDB to another or when you no longer need the application container.

## 40.1.1 Creating Application Containers

You can use the CREATE PLUGGABLE DATABASE statement to create an application container in a CDB.

- [About Creating an Application Container](#)  
When you include the AS APPLICATION CONTAINER clause in the CREATE PLUGGABLE DATABASE statement, the statement creates a new application container.
- [Preparing for Application Containers](#)  
Prerequisites must be met before creating an application container.
- [Creating an Application Container](#)  
You can create an application container using the CREATE PLUGGABLE DATABASE statement with the AS APPLICATION CONTAINER clause.

### 40.1.1.1 About Creating an Application Container

When you include the AS APPLICATION CONTAINER clause in the CREATE PLUGGABLE DATABASE statement, the statement creates a new application container.

An application container consists of an application root and a collection of application PDBs that store data for one or more applications. The application PDBs are plugged into the application root, and you can optionally create an application seed for quick and easy creation of new application PDBs. The application PDBs and application root can share application common objects.

There are three types of application common objects:

- Metadata-linked application common objects store the metadata for specific objects, such as tables, so that the containers that share the application common object have the same structure but different data.
- Data-linked application common objects are defined once in the application root and shared as read-only objects in the context of hosted application PDBs.
- Extended data-linked application common objects store shared data in the application root but also allow application PDBs to store data appended to that object. The appended data is local data that is unique to each application PDB.

You create an application container by including the AS APPLICATION CONTAINER clause in the CREATE PLUGGABLE DATABASE statement. You can use the following techniques to create an application container:

- Using the CDB seed
- Cloning an existing PDB or non-CDB
- Relocating a PDB
- Plugging in an unplugged PDB

When the current container is the CDB root and the AS APPLICATION CONTAINER clause is included in the CREATE PLUGGABLE DATABASE statement, an application container is created.

 **Note:**

An application container cannot be unplugged or dropped if any application PDBs belong to it.

### Migrating Existing Applications to an Application Container

You can migrate an application to an application container by creating an application container using an existing PDB. You must complete additional tasks when you are migrating an existing application to an application container. The PDBs that you plug in must contain the application's database objects, including their data, and you must run procedures in the DBMS\_PDB package to associate database objects with the application. Also, when application common users, roles, or profiles exist in the application root, you must run procedures in the DBMS\_PDB package to associate them with the application.

After the application is migrated to the application container, you can create application PDBs in the application container, and you can create an application PDB using an existing PDB.

 **See Also:**

"[Migrating an Existing Application to an Application Container](#)"

#### 40.1.1.2 Preparing for Application Containers

Prerequisites must be met before creating an application container.

- The CDB must exist.  
See [Creating and Configuring a CDB](#).
- The CDB must be in read/write mode.
- The current user must be a common user whose current container is the CDB root.
- The current user must have the CREATE PLUGGABLE DATABASE system privilege.
- You must decide on a unique application container name for each application container. Each application container name must be unique with regards to all of the containers in a single CDB, and each application container name must be unique within the scope of all the CDBs whose instances are reached through a specific listener.

The application container name is used to distinguish an application container from other containers in the CDB. Application container names follow the same rules as service names, which includes being case-insensitive. See *Oracle Database Net Services Reference* for information about the rules for service names.

- If you are creating an application container in an Oracle Data Guard configuration with a physical standby database, then additional tasks must be completed before

creating an application container. See *Oracle Data Guard Concepts and Administration* for more information.

- If you are migrating an existing application to an application container using a PDB, then it must be possible to clone the PDB to the application root, relocate the PDB to the application root, or plug the PDB into the application root.

 **See Also:**

- "[About the Current Container](#)"
- "[Migrating an Existing Application to an Application Container](#)"

### 40.1.1.3 Creating an Application Container

You can create an application container using the `CREATE PLUGGABLE DATABASE` statement with the `AS APPLICATION CONTAINER` clause.

Before creating an application container, complete the prerequisites described in "[Preparing for Application Containers](#)".

1. In SQL\*Plus, ensure that the current container is the CDB root.
2. Run the `CREATE PLUGGABLE DATABASE` statement, and include the `AS APPLICATION CONTAINER` clause. Specify other clauses when they are required.

After you create the application container, it is in mounted mode, and its status is `NEW`. You can view the open mode of an application container by querying the `OPEN_MODE` column in the `V$PDBS` view. You can view the status of an application container by querying the `STATUS` column of the `CDB_PDBS` or `DBA_PDBS` view.

A new default service is created for the application container. The service has the same name as the application container and can be used to access the application container. Oracle Net Services must be configured properly for clients to access this service.

3. Open the new application container in read/write mode.

You must open the new application container in read/write mode for Oracle Database to complete the integration of the new application container into the CDB. An error is returned if you attempt to open the application container in read-only mode. After the application container is opened in read/write mode, its status is `NORMAL`.

4. Back up the application container.

A application container cannot be recovered unless it is backed up.

 **Note:**

If an error is returned during application container creation, then the application container being created might be in an `UNUSABLE` state. You can check a application container's state by querying the `CDB_PDBS` or `DBA_PDBS` view, and you can learn more about application container creation errors by checking the alert log. An unusable application container can only be dropped, and it must be dropped before an application container or PDB with the same name as the unusable application container can be created.

5. If you are migrating an existing application to the application container, then follow the instructions in "[Migrating an Existing Application to an Application Container](#)".

The application container is created with an application root. You can create application PDBs in the application container.

#### Example 40-1 Creating an Application Container Using the CDB Seed

This example assumes the following factors:

- Storage limits are not required for the application container. Therefore, the `STORAGE` clause is not required.
- The application container does not require a default tablespace.
- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled for the CDB, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The files associated with the CDB seed will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.
- No predefined Oracle roles need to be granted to the `PDB_DBA` role.

Given the preceding factors, the following statement creates the application container from the CDB seed:

```
CREATE PLUGGABLE DATABASE salesact AS APPLICATION CONTAINER ADMIN USER salesadm
IDENTIFIED BY password;
```

#### Example 40-2 Creating an Application Container by Cloning a Local PDB

This example assumes the following factors:

- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause is required to specify the target locations of the copied files. In this example, the files are copied from `/disk1/oracle/pdb1/` to `/disk2/oracle/hract/`.

The `CREATE_FILE_DEST` clause is not used, and neither Oracle Managed Files nor the `PDB_FILE_NAME_CONVERT` initialization parameter is used to specify the target locations of the copied files.

To view the location of the data files for a PDB, run the query in [Example 45-7](#).

- Storage limits must be enforced for the application root. Therefore, the `STORAGE` clause is required. Specifically, all tablespaces that belong to the application root must not exceed 2 gigabytes. This storage limit does not apply to the application PDBs that are plugged into the application root.
- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Given the preceding factors, the following statement clones `hract` as an application container from the `pdb1` PDB:

```
CREATE PLUGGABLE DATABASE hract AS APPLICATION CONTAINER FROM pdb1
 FILE_NAME_CONVERT = ('/disk1/oracle/pdb1/', '/disk2/oracle/hract/')
 STORAGE (MAXSIZE 2G);
```

 **Note:**

If you are migrating an existing application to the new application container, then follow the instructions in "[Migrating an Existing Application to an Application Container](#)".

### Example 40-3 Creating an Application Container by Plugging In an Unplugged PDB

This example assumes the following factors:

- The new application container is not based on the same unplugged PDB that was used to create an existing PDB or application container in the CDB. Therefore, the `AS CLONE` clause is not required.
- The `PATH_PREFIX` clause is not required.
- The XML file does not accurately describe the current locations of the files. Therefore, the `SOURCE_FILE_NAME_CONVERT` clause or `SOURCE_FILE_DIRECTORY` clause is required. In this example, the XML file indicates that the files are in `/disk1/oracle/payroll/`, but the files are in `/disk2/oracle/payroll/`, and the `SOURCE_FILE_NAME_CONVERT` clause is used.
- The files are in the correct location. Therefore, `NOCOPY` is included.
- Storage limits must be enforced for the application container. Therefore, the `STORAGE` clause is required. Specifically, all tablespaces that belong to the application container must not exceed 2 gigabytes.
- A file with the same name as the temp file specified in the XML file exists in the target location. Therefore, the `TEMPFILE REUSE` clause is required.

Given the preceding factors, the following statement plugs in the PDB:

```
CREATE PLUGGABLE DATABASE payrollact AS APPLICATION CONTAINER USING '/disk1/usr/
payrollpdb.xml'
 SOURCE_FILE_NAME_CONVERT = ('/disk1/oracle/payroll/', '/disk2/oracle/payroll/')
 NOCOPY
 STORAGE (MAXSIZE 2G)
 TEMPFILE REUSE;
```

 **Note:**

If you are migrating an existing application to the new application container, then follow the instructions in "[Migrating an Existing Application to an Application Container](#)".

### Related Topics

- [Administering Application Containers with SQL\\*Plus](#)  
You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.
- [About the Current Container](#)  
The data dictionary in each container in a CDB is separate, and the current container is the container whose data dictionary is used for name resolution and for privilege authorization. The current container can be the CDB root, an application root, a PDB, or an application PDB. Each session has exactly one current container at any point in time, but it is possible for a session to switch from one container to another.
- [Accessing a Container in a CDB with SQL\\*Plus](#)  
You can access a container in a CDB with SQL\*Plus.
- [Modifying the Open Mode of PDBs](#)  
You can modify the open mode of a PDB by using the `ALTER PLUGGABLE DATABASE` SQL statement or the SQL\*Plus `STARTUP` command.

## 40.1.2 Unplugging an Application Container from a CDB

You can unplug an application container from a CDB.

- [About Unplugging an Application Container](#)  
Unplugging an application container disassociates the application container from a CDB. You unplug an application container when you want to move the application container to a different CDB or when you no longer want the application container to be available.
- [Unplugging an Application Container](#)  
You must meet prerequisites when unplugging an application container.

### 40.1.2.1 About Unplugging an Application Container

Unplugging an application container disassociates the application container from a CDB. You unplug an application container when you want to move the application container to a different CDB or when you no longer want the application container to be available.

Unplugging an application container is similar to unplugging a PDB. To unplug a application container, connect to its CDB root and use the `ALTER PLUGGABLE DATABASE` statement to specify an XML file or a .pdb file. When you specify an XML file (.xml extension), it will contain metadata about the application container after it is unplugged. The SQL statement creates the XML file, and it contains the required information to enable a `CREATE PLUGGABLE DATABASE` statement on a target CDB to plug in the application container. When you specify a .pdb file, it contains a compressed

archive of the XML file that describes the application container and the files used by the application container (such as the data files and wallet file). A .pdb file enables you to copy a single, compressed file (instead of multiple files) to a new location to plug the application container into a CDB.

Before it can be unplugged, the application container must not have any application PDBs plugged into it, and it must be closed. When you unplug an application container, the unplugged application container is in mounted mode. The unplug operation makes some changes in the application container's data files to record, for example, that the application container was successfully unplugged. Because it is still part of the CDB, the unplugged application container is included in an RMAN backup of the entire CDB. Such a backup provides a convenient way to archive the unplugged application container in case it is needed in the future.

To completely remove the application container from the CDB, you can drop it. The only operation supported on an unplugged application container is dropping the application container. The application container must be dropped from the CDB before it can be plugged back into the same CDB. An application container is usable only when it is plugged into a CDB.

 **See Also:**

- ["Unplugging a PDB from a CDB"](#)
- ["Dropping an Application Container"](#)
- ["Modifying the Open Mode of PDBs"](#) for information about closing a PDB
- ["Using the ALTER SYSTEM Statement to Modify a PDB"](#) for information about initialization parameters and unplugged PDBs
- [Oracle Database Security Guide](#) for information about common users and local users

#### 40.1.2.2 Unplugging an Application Container

You must meet prerequisites when unplugging an application container.

- The current user must have SYSDBA or SYSOPER administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using AS SYSDBA or AS SYSOPER at connect time.
- The application container must have been opened at least once.
- The application container must not have any application PDBs plugged into it.
- The application container must not have an application seed plugged into it.

 **Note:**

If you are unplugging an application container that includes data that was encrypted with Transparent Data Encryption, then follow the instructions in *Oracle Database Advanced Security Guide*.

**To unplug an application container:**

1. In SQL\*Plus, ensure that the current container is the root of the CDB.

See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Close the application container.

In an Oracle Real Application Clusters (Oracle RAC) environment, the application container must be closed on all instances.

3. Run the ALTER PLUGGABLE DATABASE statement with the UNPLUG INTO clause, and specify the application container to unplug and the name and location of the application container's XML metadata file or .pdb file.

**Example 40-4 Unplugging Application Container salesact**

This ALTER PLUGGABLE DATABASE statement unplugs the application container salesact and creates the salesact.xml metadata file in the /oracle/data/ directory:

```
ALTER PLUGGABLE DATABASE salesact UNPLUG INTO '/oracle/data/saleact.xml';
```

### 40.1.3 Dropping an Application Container

You can use the DROP PLUGGABLE DATABASE statement to drop an application container. You can drop an application container when you want to move the application container from one CDB to another or when you no longer need the application container.

Dropping an application container is very similar to dropping a PDB. When you drop an application container, the control file of the CDB is modified to eliminate all references to the dropped application container. Archived redo log files and backups associated with the application container are not removed, but you can use Oracle Recovery Manager (RMAN) to remove them.

When dropping an application container, you can either keep or delete the application container's data files by using one of the following clauses:

- `KEEP DATAFILES`, the default, retains the data files.

The application container's temp file is removed even when `KEEP DATAFILES` is specified because the temp file is no longer needed.

- `INCLUDING DATAFILES` removes the data files from disk.

If an application container was created with the `SNAPSHOT COPY` clause, then you must specify `INCLUDING DATAFILES` when you drop the application container.

The following prerequisites must be met:

- The application container must be in mounted mode, or it must be unplugged.

See "[Modifying the Open Mode of PDBs](#)".

See "[Unplugging an Application Container](#)".

- The current user must have `SYSDBA` or `SYSOPER` administrative privilege, and the privilege must be either commonly granted or locally granted in the application container. The user must exercise the privilege using `AS SYSDBA` or `AS SYSOPER` at connect time.

- The application container must not have any application PDBs plugged into it.
- The application container must not have an application seed plugged into it.

 **Note:**

This operation is destructive.

**To drop an application container:**

1. In SQL\*Plus, ensure that the current container is the CDB root.  
See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Run the `DROP PLUGGABLE DATABASE` statement and specify the application container to drop.

**Example 40-5 Dropping Application Container salesact While Keeping Its Data Files**

```
DROP PLUGGABLE DATABASE salesact
 KEEP DATAFILES;
```

**Example 40-6 Dropping Application Container salesact and Its Data Files**

```
DROP PLUGGABLE DATABASE saleact
 INCLUDING DATAFILES;
```

 **See Also:**

## 40.2 Creating and Removing Application Seeds with SQL\*Plus

You can create application seeds in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application seeds from application containers.

- [Creating Application Seeds](#)

You can use the `CREATE PLUGGABLE DATABASE` statement to create an application seed in an application container.

- [Unplugging an Application Seed from an Application Container](#)  
You can unplug an application seed from an application container.
- [Dropping an Application Seed](#)  
You can use the `DROP PLUGGABLE DATABASE` statement to drop an application seed.  
You can drop an application seed when you no longer need it.

## 40.2.1 Creating Application Seeds

You can use the `CREATE PLUGGABLE DATABASE` statement to create an application seed in an application container.

- [About Creating an Application Seed](#)  
You can use the `CREATE PLUGGABLE DATABASE` statement with the `AS SEED` clause to create a new application seed in an application container.
- [Preparing for an Application Seed](#)  
Prerequisites must be met before creating an application seed.
- [Creating an Application Seed](#)  
You create an application seed by including the `AS SEED` clause in the `CREATE PLUGGABLE DATABASE` statement.

### 40.2.1.1 About Creating an Application Seed

You can use the `CREATE PLUGGABLE DATABASE` statement with the `AS SEED` clause to create a new application seed in an application container.

You can use an application seed to provision an application container with application PDBs that have the application root's applications installed. Typically, the application container's applications are installed in the application root before the application seed is created. After the application seed is created, it is synchronized with the application root so that the applications are installed in the application seed. When that is complete, any PDBs created using the application seed have the applications installed. When an application in the application root is upgraded or patched, the application seed must be synchronized with the application root to apply these changes.

You create an application seed by including the `AS SEED` clause in the `CREATE PLUGGABLE DATABASE` statement.

An application container can have zero or one application seed. When you create an application seed using the `AS SEED` clause, you do not specify its name. The application seed name is always `application_container_name$SEED`, where `application_container_name` is the name of the application seed's application container. For example, an application seed in the `salesact` application container must be named `salesact$SEED`.

When you create a new application seed, you must specify an administrator for the application container in the `CREATE PLUGGABLE DATABASE` statement. The statement creates the administrator as a local user in the application container and grants the `PDB_DBA` role locally to the administrator.

#### Related Topics

- [Creating a PDB Using the Seed](#)  
You can use the `CREATE PLUGGABLE DATABASE` statement to create a PDB in a CDB using the files of the CDB seed. You can also use this statement to create an

application PDB in an application container using the files of an application seed or a CDB seed.

- [Managing Applications in an Application Container](#)

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- [Synchronizing Applications in an Application PDB](#)

When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

#### 40.2.1.2 Preparing for an Application Seed

Prerequisites must be met before creating an application seed.

Ensure that the following prerequisites are met before creating an application seed:

- The CDB must exist.  
See [Creating and Configuring a CDB](#).
- The CDB must be in read/write mode.
- The application container to which the application seed will belong must be in read/write mode.
- The current user must be a common user whose current container is the application root to which the application seed will belong.
- The current user must have the CREATE PLUGGABLE DATABASE system privilege.
- For the application seed to include the application for the application container, the application must be installed in the application root.

 **See Also:**

- ["About the Current Container"](#)
- [Managing Applications in an Application Container](#)

#### 40.2.1.3 Creating an Application Seed

You create an application seed by including the AS SEED clause in the CREATE PLUGGABLE DATABASE statement.

An application seed in an application container is similar to the seed in a CDB. An application seed enables you to create application PDBs that meet the requirements of an application container quickly and easily.

Before creating an application seed, complete the prerequisites described in ["Preparing for an Application Seed"](#).

1. In SQL\*Plus, ensure that the current container is the application root.
2. Run the CREATE PLUGGABLE DATABASE statement, and include the AS SEED clause, to create the application seed. Specify other clauses when they are required.

After you create the application seed, it is in mounted mode, and its status is NEW. You can view the open mode of an application seed by querying the OPEN\_MODE column in the V\$PDBS view. You can view the status of an application seed by querying the STATUS column of the CDB\_PDBS or DBA\_PDBS view.

A new default service is created for the application seed. The service has the same name as the application seed and can be used to access the application seed. Oracle Net Services must be configured properly for clients to access this service.

3. Open the new application seed in read/write mode.
4. You must open the new application seed in read/write mode for Oracle Database to complete the integration of the new application seed into the application container. An error is returned if you attempt to open the application seed in read-only mode. After the application seed is opened in read/write mode, its status is NORMAL.
5. Perform one or more of the following actions:
  - If the application seed was created from the CDB seed, then switch container to the application seed, and use an ALTER PLUGGABLE DATABASE statement with the SYNC clause to synchronize the application seed. Synchronizing with the application root instantiates one or more of the application root's applications in the application seed.
  - If the application seed was created from an application root, then switch container to the application seed, and run the pdb\_to\_appdb.sql script to convert the application root to an application PDB.

These actions are not required when the application seed is created by cloning an application PDB.

6. Close the application seed, and then open it in open read-only mode.
7. Back up the application seed.

An application seed cannot be recovered unless it is backed up.

 **Note:**

- If an error is returned during application seed creation, then the application seed being created might be in an UNUSABLE state. You can check an application seed's state by querying the CDB\_PDBS or DBA\_PDBS view, and you can learn more about application seed creation errors by checking the alert log. An unusable application seed can only be dropped.
- When an application in the application root is upgraded or patched in the application root, the application seed must synchronize with the application root to include the changes.

### Example 40-7 Creating an Application Seed From the CDB Seed

This example assumes the following factors:

- The application seed is being created in an application container named salesact.
- Storage limits are not required for the application seed. Therefore, the STORAGE clause is not required.
- The application seed does not require a default tablespace.
- The PATH\_PREFIX clause is not required.
- The FILE\_NAME\_CONVERT clause and the CREATE\_FILE\_DEST clause are not required.

Either Oracle Managed Files is enabled for the CDB, or the PDB\_FILE\_NAME\_CONVERT initialization parameter is set. The files associated with the CDB seed will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the TEMPFILE REUSE clause is not required.
- No predefined Oracle roles need to be granted to the PDB\_DBA role.

Given the preceding factors, the following statement creates the application seed from the CDB seed, opens the application seed, switches containers to the application seed, synchronizes the application seed with all of the applications in the application root, closes the application seed, and opens the application seed in open read-only mode:

```
CREATE PLUGGABLE DATABASE AS SEED ADMIN USER actseedadm IDENTIFIED BY password;
ALTER PLUGGABLE DATABASE salesact$SEED OPEN;
ALTER SESSION SET CONTAINER=salesact$SEED;
ALTER PLUGGABLE DATABASE APPLICATION ALL SYNC;
ALTER PLUGGABLE DATABASE CLOSE IMMEDIATE;
ALTER PLUGGABLE DATABASE OPEN READ ONLY;
```

Because the application container name is salesact, the application seed name is salesact\$SEED.

A local user with the name of the specified local administrator is created and granted the PDB\_DBA common role locally in the application seed. If this user was not granted administrator privileges during application seed creation, then use the SYS and SYSTEM common users to administer to the application seed.

The application seed was synchronized with the application root when it was created. Therefore, the application seed includes the applications installed in the application root and the application common objects that are part of those applications. When a new application PDB is created using the application seed, the application PDB also includes the installed applications and application common objects.

### Example 40-8 Creating an Application Seed From an Application PDB

This example assumes the following factors:

- The application seed is being created in an application container named salesact.
- The application seed is being created in an application PDB in the application container named salesappdb.

- Storage limits are not required for the application seed. Therefore, the `STORAGE` clause is not required.
- The application seed does not require a default tablespace.
- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled for the CDB, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The files associated with the application root will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Given the preceding factors, the following statement creates the application seed from the application root, opens the application seed, closes the application seed, and opens the application seed in open read-only mode:

```
CREATE PLUGGABLE DATABASE AS SEED FROM salesappdb;
ALTER PLUGGABLE DATABASE salesact$SEED OPEN;
ALTER PLUGGABLE DATABASE CLOSE IMMEDIATE;
ALTER PLUGGABLE DATABASE OPEN READ ONLY;
```

Because the application container name is `salesact`, the application seed name is `salesact$SEED`.

The application seed was created from an application PDB. Therefore, the application seed includes the applications installed in the application root and the application common objects that are part of those applications. When a new application PDB is created using the application seed, the application PDB also includes the installed applications and application common objects.

### **Example 40-9 Creating an Application Seed From an Application Root**

This example assumes the following factors:

- The application seed is being created in an application container named `salesact`. The application seed is cloned from the root of the application container.
- Storage limits are not required for the application seed. Therefore, the `STORAGE` clause is not required.
- The application seed does not require a default tablespace.
- The `PATH_PREFIX` clause is not required.
- The `FILE_NAME_CONVERT` clause and the `CREATE_FILE_DEST` clause are not required.

Either Oracle Managed Files is enabled for the CDB, or the `PDB_FILE_NAME_CONVERT` initialization parameter is set. The files associated with the application root will be copied to a new location based on the Oracle Managed Files configuration or the initialization parameter setting.

- There is no file with the same name as the new temp file that will be created in the target location. Therefore, the `TEMPFILE REUSE` clause is not required.

Given the preceding factors, the following statement creates the application seed from the application root, opens the application seed, switches containers to the application

seed, runs the `pdb_to_appdb.sql` script to convert the application root to an application PDB, closes the application seed, and opens the application seed in open read-only mode:

```
CREATE PLUGGABLE DATABASE AS SEED FROM salesact;
ALTER PLUGGABLE DATABASE salesact$SEED OPEN;
ALTER SESSION SET CONTAINER=salesact$SEED;
@$ORACLE_HOME/rdbms/admin/pdb_to_appdb.sql
ALTER PLUGGABLE DATABASE CLOSE IMMEDIATE;
ALTER PLUGGABLE DATABASE OPEN READ ONLY;
```

Because the application container name is `salesact`, the application seed name is `salesact$SEED`.

The application seed was created from the application root. Therefore, the application seed includes the applications installed in the application root and the application common objects that are part of those applications. When a new application PDB is created using the application seed, the application PDB also includes the installed applications and application common objects.

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

### 40.2.2 Unplugging an Application Seed from an Application Container

You can unplug an application seed from an application container.

- [About Unplugging an Application Seed](#)

Unplugging an application seed disassociates the application seed from an application container. You unplug an application seed when you no longer want the application seed to be available.

- [Unplugging an Application Seed](#)

You must meet prerequisites when unplugging an application seed.

#### 40.2.2.1 About Unplugging an Application Seed

Unplugging an application seed disassociates the application seed from an application container. You unplug an application seed when you no longer want the application seed to be available.

Unplugging an application seed is similar to unplugging a PDB. To unplug a application seed, connect to its application root and use the `ALTER PLUGGABLE DATABASE` statement to specify an XML file or a .pdb file. When you specify an XML file (.xml extension), it will contain metadata about the application seed after it is unplugged. The SQL statement creates the XML file, and it contains the required information to enable a `CREATE PLUGGABLE DATABASE` statement on a target CDB to plug it in as a PDB or an application PDB. When you specify a .pdb file, it contains a compressed archive of the XML file that describes the application seed and the files used by the application seed (such as the data files and wallet file). A .pdb file enables you to copy a single, compressed file (instead of multiple files) to a new location to plug in as a PDB or an application PDB.

Before it can be unplugged, the application seed must be closed. When you unplug an application seed, the unplugged application seed is in mounted mode. The unplug operation makes some changes in the application seed's data files to record, for example, that the application seed was successfully unplugged. Because it is still part of the application container, the unplugged application seed is included in an RMAN backup of the entire CDB. Such a backup provides a convenient way to archive the unplugged application seed in case it is needed in the future.

To completely remove the application seed from the application container, you can drop it. The only operation supported on an unplugged application seed is dropping the application seed. The application seed must be dropped from the application container before it can be plugged back into the same application container. An application seed is usable only when it is plugged into an application container.

- [Oracle Database Security Guide](#) for information about common users and local users

### 40.2.2.2 Unplugging an Application Seed

You must meet prerequisites when unplugging an application seed.

The following prerequisites must be met:

- The current user must have SYSDBA or SYSOPER administrative privilege, and the privilege must be either commonly granted or locally granted in the application container. The user must exercise the privilege using AS SYSDBA or AS SYSOPER at connect time.
- The application seed must have been opened at least once.

#### Note:

If you are unplugging an application seed that includes data that was encrypted with Transparent Data Encryption, then follow the instructions in *Oracle Database Advanced Security Guide*.

#### To unplug an application seed:

1. In SQL\*Plus, ensure that the current container is the application root of the application container to which the application seed belongs.

See "About the Current Container" and "Accessing a Container in a CDB with SQL\*Plus".

2. Close the application seed.

In an Oracle Real Application Clusters (Oracle RAC) environment, the application seed must be closed on all instances.

3. Run the ALTER PLUGGABLE DATABASE statement with the UNPLUG INTO clause, and specify the application seed to unplug and the name and location of the application seed's XML metadata file or .pdb file.

#### **Example 40-10 Unplugging Application Seed salesact\$SEED**

This ALTER PLUGGABLE DATABASE statement unplugs the application seed salesact\$SEED and creates the salesact\$SEED.xml metadata file in the /oracle/data/ directory:

```
ALTER PLUGGABLE DATABASE salesact$SEED UNPLUG INTO '/oracle/data/saleact$SEED.xml';
```

### 40.2.3 Dropping an Application Seed

You can use the DROP PLUGGABLE DATABASE statement to drop an application seed. You can drop an application seed when you no longer need it.

When you drop an application seed, the control file of the CDB is modified to eliminate all references to the dropped application seed. Archived redo log files and backups associated with the application seed are not removed, but you can use Oracle Recovery Manager (RMAN) to remove them.

When dropping an application seed, you can either keep or delete the application seed's data files by using one of the following clauses:

- KEEP DATAFILES, the default, retains the data files.

The application seed's temp file is removed even when KEEP DATAFILES is specified because the temp file is no longer needed.

- INCLUDING DATAFILES removes the data files from disk.

If an application seed was created with the SNAPSHOT COPY clause, then you must specify INCLUDING DATAFILES when you drop the application seed.

The following prerequisites must be met:

- The application seed must be in mounted mode, or it must be unplugged.

See "Modifying the Open Mode of PDBs".

See "Unplugging an Application Seed".

- The current user must have SYSDBA or SYSOPER administrative privilege, and the privilege must be either commonly granted or locally granted in the application container. The user must exercise the privilege using AS SYSDBA or AS SYSOPER at connect time.

#### **Note:**

This operation is destructive.

**To drop an application seed:**

1. In SQL\*Plus, ensure that the current container is the application root of the application container to which the application seed belongs.

See "[About the Current Container](#)" and "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Run the DROP PLUGGABLE DATABASE statement and specify the application seed.

**Example 40-11 Dropping Application Seed salesact\$SEED While Keeping Its Data Files**

```
DROP PLUGGABLE DATABASE salesact$SEED
KEEP DATAFILES;
```

**Example 40-12 Dropping Application Seed salesact\$SEED and Its Data Files**

```
DROP PLUGGABLE DATABASE salesact$SEED
INCLUDING DATAFILES;
```

## 40.3 Creating an Application PDB

You create an application PDB by running the CREATE PLUGGABLE DATABASE statement with an application root as the current container.

You can create application PDBs using the same SQL statements that you use to create PDBs in the CDB root. The newly created PDB is an application PDB when the CREATE PLUGGABLE DATABASE statement is run in an application root. The statement must be run in an application root and has an explicit dependency on the application database defined in that application root.

Before creating an application PDB, complete the prerequisites described in "[Preparing for PDBs](#)". You must also complete the prerequisites for the specific type of PDB you are creating. For example, if you are cloning a PDB, then you must meet the prerequisites PDB cloning.

1. In SQL\*Plus, ensure that the current container is the application root.
2. Run a CREATE PLUGGABLE DATABASE statement.

After you create the application PDB, it is in mounted mode, and its status is NEW. You can view the open mode of an application PDB by querying the OPEN\_MODE

column in the V\$PDBS view. You can view the status of an application PDB by querying the STATUS column of the CDB\_PDBS or DBA\_PDBS view.

A new default service is created for the application PDB. The service has the same name as the application PDB and can be used to access the application PDB. Oracle Net Services must be configured properly for clients to access this service.

3. Open the new application PDB in read/write mode.
4. You must open the new application PDB in read/write mode for Oracle Database to complete the integration of the new application PDB into the application container. An error is returned if you attempt to open the application PDB in read-only mode. After the application PDB is opened in read/write mode, its status is NORMAL.
5. Switch container to the application PDB.
6. Use an ALTER PLUGGABLE DATABASE statement with the SYNC clause to synchronize the application PDB.

Synchronizing with the application PDB instantiates one or more of the application root's applications in the application PDB.

7. Close the application PDB, and then open it in open read-only mode.
8. Back up the application PDB.

An application PDB cannot be recovered unless it is backed up.

 **Note:**

- If an error is returned during application PDB creation, then the application PDB being created might be in an UNUSABLE state. You can check an application PDB's state by querying the CDB\_PDBS or DBA\_PDBS view, and you can learn more about application PDB creation errors by checking the alert log. An unusable application PDB can only be dropped.
- When an application in the application root is upgraded or patched in the application root, the application PDB must synchronize with the application root to include the changes.

#### Related Topics

- [Creating and Removing PDBs with SQL\\*Plus](#)

You can create PDBs in several different ways, including using the seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove PDBs from a CDB.

- [Administering Application Containers with SQL\\*Plus](#)

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

# Administering a CDB with SQL\*Plus

Administering a multitenant container database (CDB) with SQL\*Plus includes tasks such as accessing a container in a CDB, modifying a CDB, executing DDL statements in a CDB, and running Oracle-supplied SQL scripts in a CDB.

## Note:

You can complete the tasks in this chapter using SQL\*Plus or Oracle SQL Developer.

- [About Administering a CDB](#)

Administering a CDB is similar to administering a non-CDB, but there are some differences. Most of the differences are because some administrative tasks apply to the entire CDB, while others apply to the CDB root, application containers, application roots, and specific pluggable databases (PDBs) and application PDBs.

- [Accessing a Container in a CDB with SQL\\*Plus](#)

You can access a container in a CDB with SQL\*Plus.

- [Executing Code in Containers Using the DBMS\\_SQL Package](#)

When you are executing PL/SQL code in a container in a CDB, and you want to execute one or more SQL statements in a different container, use the `DBMS_SQL` package to switch containers.

- [Modifying a CDB](#)

You can modify the entire CDB, the root, or one or more PDBs.

- [Using the ALTER SYSTEM SET Statement in a CDB](#)

The `ALTER SYSTEM SET` statement can dynamically set an initialization parameter in one or more containers in a CDB.

- [Issuing DML Statements on Containers in a CDB](#)

A DML (data manipulation language) statement issued in a CDB root can modify one or more containers in the CDB. In addition, you can specify one or more default container targets for DML statements.

- [Executing DDL Statements in a CDB](#)

In a CDB, you can execute a data definition language (DDL) statement in the current container or in all containers.

- [Managing the CDB Undo Mode](#)

When local undo is enabled, each container has its own undo tablespace for every instance in which it is open. When local undo is disabled, there is one undo tablespace for the entire CDB.

- [Running Oracle-Supplied SQL Scripts in a CDB](#)

You can use the `catcon.pl` script to run Oracle-supplied SQL scripts in a CDB.

- [Shutting Down a CDB Instance](#)

You can shut down a CDB instance in the same way that you shut down a non-CDB instance.

### Related Topics

- [Tools for a Multitenant Environment](#)

You can use various tools to configure and administer a multitenant environment.

## 41.1 About Administering a CDB

Administering a CDB is similar to administering a non-CDB, but there are some differences. Most of the differences are because some administrative tasks apply to the entire CDB, while others apply to the CDB root, application containers, application roots, and specific pluggable databases (PDBs) and application PDBs.

- [About the Current Container](#)

The data dictionary in each container in a CDB is separate, and the current container is the container whose data dictionary is used for name resolution and for privilege authorization. The current container can be the CDB root, an application root, a PDB, or an application PDB. Each session has exactly one current container at any point in time, but it is possible for a session to switch from one container to another.

- [About Administrative Tasks in a CDB](#)

Common users perform administrative tasks for a CDB.

- [About Using Manageability Features in a CDB](#)

For each of Oracle Database's manageability features in a CDB, it is important to understand the data location and the data visibility.

- [About Managing Database Objects in a CDB](#)

In a CDB, different containers can contain different database objects.

- [About Flashing Back a PDB](#)

You can use the `FLASHBACK PLUGGABLE DATABASE` statement to return a PDB to a past time or system change number (SCN).

- [About Restricting PDB Users for Enhanced Security](#)

There are several ways to restrict PDB users for enhanced security. A PDB lockdown profile restricts the features and options available to users in a particular PDB. The `PDB_OS_CREDENTIAL` initialization parameter can specify a unique operating system user for a PDB to limit operating system access. Also, when the `PATH_PREFIX` and `CREATE_FILE_DEST` clauses are specified during PDB creation, they limit file system access.

### 41.1.1 About the Current Container

The data dictionary in each container in a CDB is separate, and the current container is the container whose data dictionary is used for name resolution and for privilege authorization. The current container can be the CDB root, an application root, a PDB, or an application PDB. Each session has exactly one current container at any point in time, but it is possible for a session to switch from one container to another.

Each container has a unique ID and name in a CDB. You can use the `CON_ID` and `CON_NAME` parameters in the `USERENV` namespace to determine the current container ID and name with the `SYS_CONTEXT` function. For example, the following query returns the current container name:

```
SELECT SYS_CONTEXT ('USERENV', 'CON_NAME') FROM DUAL;
```

You can access a container in various ways in a CDB. For example, you can use the SQL\*Plus CONNECT command, and you can use an ALTER SESSION SET CONTAINER statement to switch the container of the current session.

The following rules apply to the current container in a CDB:

- The current container can be CDB\$ROOT (CDB root) only for common users.
- The current container can be a particular PDB for common users and local users.
- The current container can be an application root only for common users or for application common users created in the application root.
- The current container can be a particular application PDB for common users, application common users, and local users.
- The current container must be the CDB root or an application root when a SQL statement includes CONTAINER = ALL.

You can include the CONTAINER clause in several SQL statements, such as the CREATE USER, ALTER USER, CREATE ROLE, GRANT, REVOKE, and ALTER SYSTEM statements.

- When a SQL statement includes CONTAINER = ALL and the current container is the CDB root, the SQL statement affects all containers in the CDB, including all PDBs, application roots, and application PDBs.
- When a SQL statement includes CONTAINER = ALL and the current container is an application root, the SQL statement affects all containers in the application container, including the application root and all of the application PDBs that belong to the application root. The SQL statement does not affect the CDB root or any PDBs or application PDBs that do not belong to the current application root.
- Only a common user or application common user with the commonly granted SET CONTAINER privilege can run a SQL statement that includes CONTAINER = ALL.

### 41.1.2 About Administrative Tasks in a CDB

Common users perform administrative tasks for a CDB.

A common user has a single identity and can log in to the CDB root, any application root, PDB, or application PDB in which it has privileges. Some tasks, such as starting up a CDB instance, can be performed only by a common user.

Other administrative tasks are the same for a CDB and a non-CDB. [Table 41-1](#) describes some of these tasks and provides pointers to the relevant documentation.

**Table 41-1 Administrative Tasks Common to CDBs and Non-CDBs**

| Task                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Additional Information                                                                                                                                                                         |

| Managing processes                                           | A CDB has one set of background processes shared by the CDB root and all containers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | " <a href="#">Managing Processes</a> "                                                                                                                                                         |
| Managing memory                                              | A CDB has a single system global area (SGA) and a single aggregate program global area (PGA). The memory required by a CDB is the sum of the memory requirements for all of the containers that will be part of the CDB.                                                                                                                                                                                                                                                                                                                                                              | " <a href="#">Managing Memory</a> "                                                                                                                                                            |
| Managing security                                            | You can create and drop common users, application common users, and local users in a CDB. You can also grant privileges to and revoke privileges from these users. You can also manage the <code>CONTAINER_DATA</code> attributes of common users and application common users.<br><br>In addition, grant the following roles to the appropriate users: <ul style="list-style-type: none"> <li>• Grant the <code>CDB_DBA</code> role to CDB administrators.</li> <li>• Grant the <code>PDB_DBA</code> role to application container administrators and PDB administrators.</li> </ul> | <i>Oracle Database Security Guide</i>                                                                                                                                                          |
| Monitoring errors and alerts                                 | A CDB has one alert log for the entire CDB. The name of an application container, PDB, or application PDB is included in records in trace files, when appropriate.                                                                                                                                                                                                                                                                                                                                                                                                                    | " <a href="#">Monitoring Errors and Alerts</a> "                                                                                                                                               |
| Managing diagnostic data                                     | In a CDB, you can use the Oracle Database fault diagnosability infrastructure and the Automatic Diagnostic Repository (ADR).                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <a href="#">Managing Diagnostic Data</a>                                                                                                                                                       |
| Managing control files                                       | A CDB has one control file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | " <a href="#">Managing Control Files</a> "                                                                                                                                                     |
| Managing the online redo log and the archived redo log files | A CDB has one online redo log and one set of archived redo log files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | " <a href="#">Managing the Redo Log</a> "<br>" <a href="#">Managing Archived Redo Log Files</a> "                                                                                              |
| Managing tablespaces                                         | You can create, modify, and drop tablespaces and temporary tablespaces for the CDB root and for individual containers. You can also specify a default tablespace, default tablespace type, and a default temporary tablespace for the CDB root. The CDB root has its own set of Oracle-supplied tablespaces, such as the <code>SYSTEM</code> tablespace, and other containers have their own set of Oracle-supplied tablespaces.                                                                                                                                                      | " <a href="#">Managing Tablespaces</a> "<br>" <a href="#">Modifying a CDB</a> "                                                                                                                |

**Table 41-1 (Cont.) Administrative Tasks Common to CDBs and Non-CDBs**

| Task                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Additional Information                                                                                                                                                     |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Managing data files and temp files | The CDB root has its own data files, and other containers have their own data files. In a CDB, you can manage data files and temp files in basically the same way you would manage them for a non-CDB. However, the following exceptions apply to CDBs: <ul style="list-style-type: none"> <li>You can limit the amount of storage used by the data files for a container by using the <code>STORAGE</code> clause in a <code>CREATE PLUGGABLE DATABASE</code> or <code>ALTER PLUGGABLE DATABASE</code> statement.</li> <li>There is a default temporary tablespace for the CDB root and for individual containers.</li> </ul> | " <a href="#">Managing Data Files and Temp Files</a> "<br>" <a href="#">Modifying a CDB</a> "<br>" <a href="#">Storage Limits</a> "<br>" <a href="#">Modifying a PDB</a> " |
| Managing undo                      | A CDB can run in local undo mode or shared undo mode. Local undo mode means that every container in the CDB uses local undo. Shared undo mode means that there is one active undo tablespace for a single-instance CDB, or for an Oracle RAC CDB, there is one active undo tablespace for each instance. <p>In a CDB, the <code>UNDO_MANAGEMENT</code> initialization parameter must be set to <code>AUTO</code>, and an undo tablespace is required to manage the undo data.</p>                                                                                                                                              | " <a href="#">Managing the CDB Undo Mode</a> "<br>" <a href="#">Managing Undo</a> "<br>" <a href="#">About the Current Container</a> "                                     |
| Moving data between containers     | You can move data between containers using the same methods that you would use to move data between non-CDBs. For example, you can transport the data or use Data Pump export/import to move the data.                                                                                                                                                                                                                                                                                                                                                                                                                         | " <a href="#">Transporting Data</a> "<br><i>Oracle Database Utilities</i>                                                                                                  |
| Using Oracle Managed Files         | Using Oracle Managed files can simplify administration for both a CDB and a non-CDB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | " <a href="#">Using Oracle Managed Files</a> "                                                                                                                             |
| Using Transparent Data Encryption  | Transparent Data Encryption is a feature that enables encryption of individual table columns before storing them in the data file, or enables encryption of entire tablespaces. In a CDB, each container has its own master key for Transparent Data Encryption, and, where applicable, the <code>ADMINISTER KEY MANAGEMENT</code> SQL statement enables key management at the CDB level and for individual containers.                                                                                                                                                                                                        | <i>Oracle Database Advanced Security Guide</i><br>" <a href="#">About the Current Container</a> "                                                                          |
| Using a standby database           | Oracle Data Guard can configure a physical standby or a logical standby of a CDB. Data Guard operates on the entire CDB, not on individual containers in a CDB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <i>Oracle Data Guard Concepts and Administration</i>                                                                                                                       |
| Using Oracle Database Vault        | Oracle Database Vault common realms can be scoped to an application root on common objects. Database Vault common command rules can be scoped to either the CDB or an application root. Local realms and command rules can be locally scoped to individual PDBs or application PDBs. When Oracle Database Vault security objects are in the CDB root or an application root, enforcement of the security objects only applies to the containers that have Oracle Database Vault enabled.                                                                                                                                       | <i>Oracle Database Vault Administrator's Guide</i>                                                                                                                         |

**Table 41-1 (Cont.) Administrative Tasks Common to CDBs and Non-CDBs**

| Task                | Description                                                                                                                                                                                                                                                                                                                                                                                                 | Additional Information                                                    |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| Dropping a database | <p>When you drop a CDB, all of the containers in the CDB are dropped along with their data. These containers include the CDB root and CDB seed and all of the application containers, application seeds, PDBs, and application PDBs.</p> <p>You can also drop individual application containers, application seeds, PDBs, and application PDBs with the <code>DROP PLUGGABLE DATABASE</code> statement.</p> | <a href="#">"Dropping a Database"</a><br><a href="#">"Dropping a PDB"</a> |

### 41.1.3 About Using Manageability Features in a CDB

For each of Oracle Database's manageability features in a CDB, it is important to understand the data location and the data visibility.

It is important to understand where the data is stored for Oracle Database's manageability features in a CDB. When the data for a feature is stored in the CDB root only, the data related to a PDB is not included if the PDB is unplugged. However, when the data for a feature is stored in the PDB, the data related to the PDB is included if the PDB is unplugged, and this data remains part of the PDB if it is plugged into the same CDB or a different CDB.

It is also important to understand which data is visible to different users. Generally, in a CDB, a common user can view data for the CDB root and for multiple PDBs when the common user's current container is the CDB root. A common user can view this data by querying container data objects. The specific data that is visible varies for the manageability features. A user whose current container is a PDB can view data for that PDB only.

[Table 41-2](#) describes how the manageability features work in a CDB.

**Table 41-2 Manageability Features in a CDB**

| Manageability Feature                                                                                                             | Data Location                                                                                                    | Data Visibility                                                                                                                                                                    | Additional Information                                  |
|-----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| Active Session History (ASH)                                                                                                      | Most of the ASH data is stored in memory. A small percentage of the ASH data samples are stored in the CDB root. | A common user whose current container is the CDB root can view ASH data for the CDB root and for PDBs. A user whose current container is a PDB can view ASH data for the PDB only. | <i>Oracle Database 2 Day + Performance Tuning Guide</i> |
| ASH collects information about active database sessions. You can use this information to analyze and identify performance issues. | ASH data related to a PDB is not included if the PDB is unplugged.                                               |                                                                                                                                                                                    | <i>Oracle Database Performance Tuning Guide</i>         |

**Table 41-2 (Cont.) Manageability Features in a CDB**

| Manageability Feature                                                                                                                                                                                                                                                                                                                                                                                    | Data Location                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Data Visibility                                                                                                                                                                                                                                         | Additional Information                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Alerts<br><br>An alert is a notification of a possible problem.                                                                                                                                                                                                                                                                                                                                          | Threshold settings that pertain to a PDB are stored in the PDB.<br><br>Alerts posted when thresholds are violated are enqueued into the alert queue in the CDB root.<br><br>Threshold settings that pertain to a PDB are included if the PDB is unplugged. Alerts related to a PDB are not included if the PDB is unplugged.                                                                                                                                        | A common user whose current container is the CDB root can view alerts for the CDB root and for PDBs.<br><br>A user whose current container is a PDB can view alert thresholds and alerts for the PDB only.                                              | " <a href="#">Monitoring Errors and Alerts</a> "                                                                                                                                                                                                                                                                                            |
| Automated Database Maintenance Tasks<br><br>Automated database maintenance tasks are tasks that are started automatically at regular intervals to perform maintenance operations on the database.<br><br>Automated tasks include automatic optimizer statistics collection, Automatic Segment Advisor tasks, and Automatic SQL Tuning Advisor tasks.                                                     | A user can schedule maintenance windows and enable or disable maintenance tasks for the current container only. If the current container is the CDB root, then the changes only apply to the CDB root. If the current container is a PDB, then the changes only apply to the PDB.<br><br>Data related to a PDB is stored in the PDB for automatic optimizer statistics collection and the Automatic Segment Advisor. This data is included if the PDB is unplugged. | See the appropriate row in this table for data visibility information about the following manageability features: automatic optimizer statistics collection, Optimizer Statistics Advisor, Automatic Segment Advisor, and Automatic SQL Tuning Advisor. | " <a href="#">Managing Automated Database Maintenance Tasks</a> "<br><br><i>Oracle Database Reference</i> for information about the <code>ENABLE_AUTOMATIC_MAINTENANCE_PDB</code> initialization parameter<br><br><i>Oracle Database Reference</i> for information about the <code>AUTOTASK_MAX_ACTIVE_PDBS</code> initialization parameter |
| The <code>ENABLE_AUTOMATIC_MAINTENANCE_PDB</code> initialization parameter can enable or disable the running of automated maintenance tasks for all the PDBs in a CDB or for individual PDBs in a CDB.<br><br>The <code>AUTOTASK_MAX_ACTIVE_PDBS</code> initialization parameter limits the number of PDBs that can schedule automated maintenance tasks at the same time (during a maintenance window). | Automatic SQL Tuning Advisor runs only in the CDB root. See the SQL Tuning Advisor row in this table for information about data collected by Automatic SQL Tuning Advisor.                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                             |

**Table 41-2 (Cont.) Manageability Features in a CDB**

| Manageability Feature                                                                                                                                                                                                                                                                           | Data Location                                                                                                                                                                                                                                                                                                                                        | Data Visibility                                                                                                                                                                                                              | Additional Information                                                                                                      |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Automatic Database Diagnostic Monitor (ADDM)                                                                                                                                                                                                                                                    | All ADDM runs must be performed in the CDB root. All ADDM results are stored in the CDB root.                                                                                                                                                                                                                                                        | ADDM results are visible only to a common user whose current container is the CDB root. The ADDM results can include information about multiple PDBs. The ADDM results cannot be viewed when the current container is a PDB. | <i>Oracle Database 2 Day DBA</i><br><i>Oracle Database Performance Tuning Guide</i>                                         |
| ADDM can diagnose a database's performance and determine how identified problems can be resolved.                                                                                                                                                                                               | ADDM analyzes activity in a PDB within the context of the current analysis target. ADDM does not analyze one PDB at a time. As in previous releases, ADDM runs with a target of either the entire instance or Oracle Real Application Clusters (Oracle RAC) database.<br><br>ADDM results related to a PDB are not included if the PDB is unplugged. |                                                                                                                                                                                                                              |                                                                                                                             |
| Automatic Optimizer Statistics Collection                                                                                                                                                                                                                                                       | When an automatic optimizer statistics collection task gathers data for a PDB, it stores this data in the PDB. This data is included if the PDB is unplugged.                                                                                                                                                                                        | A common user whose current container is the CDB root can view optimizer statistics data for PDBs.<br><br>A user whose current container is a PDB can view optimizer statistics data for the PDB only.                       | " <a href="#">Using Oracle Resource Manager for PDBs with SQL*Plus</a> "<br><br><i>Oracle Database SQL Tuning Guide</i>     |
| Automatic optimizer statistics collection gathers optimizer statistics for all schema objects in the database for which there are no statistics or only stale statistics. The statistics gathered by this task are used by the SQL query optimizer to improve the performance of SQL execution. |                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                              |                                                                                                                             |
| Automatic Segment Advisor                                                                                                                                                                                                                                                                       | When Automatic Segment Advisor gathers data for a PDB, it stores this data in the PDB. This data is included if the PDB is unplugged.                                                                                                                                                                                                                | A common user whose current container is the CDB root can view Automatic Segment Advisor data for PDBs.<br><br>A user whose current container is a PDB can view the Automatic Segment Advisor data for the PDB only.         | " <a href="#">Reclaiming Unused Space</a> "<br><br>" <a href="#">Using Oracle Resource Manager for PDBs with SQL*Plus</a> " |

## 41.1.4 About Managing Database Objects in a CDB

In a CDB, different containers can contain different database objects.

An Oracle database stores database objects, such as tables, indexes, and directories. Database objects that are owned by a schema are called schema objects, while database objects that are not owned by a schema are called nonschema objects. The root and PDBs contain schemas, and schemas contain schema objects. The root and PDBs can also contain nonschema objects, such as users, roles, tablespaces, directories, and editions.

In a CDB, the root contains Oracle-supplied schemas and database objects. Oracle-supplied common users, such as `SYS` and `SYSTEM`, own these schemas and common database objects. They can also own local objects, both in the root and in a PDB.

You can create common users in the root to administer containers in the CDB. User-created common users can create database objects in the root. Oracle recommends that, in the root, schemas owned by user-created common users contain only database triggers and the objects used in their definitions. A user-created common user can also own any type of local object in a PDB.

You can create local users in a PDB. A local user in a PDB can create schema objects and nonschema objects in the PDB. You cannot create local users in the root.

Name resolution in a CDB is similar to name resolution in a non-CDB, except that names are resolved in the context of the dictionary of the user's current container.

## 41.1.5 About Flashing Back a PDB

You can use the `FLASHBACK PLUGGABLE DATABASE` statement to return a PDB to a past time or system change number (SCN).

You can create restore points for a PDB and flash back the PDB to the restore point without affecting the CDB or other PDBs.

## 41.1.6 About Restricting PDB Users for Enhanced Security

There are several ways to restrict PDB users for enhanced security. A PDB lockdown profile restricts the features and options available to users in a particular PDB. The `PDB_OS_CREDENTIAL` initialization parameter can specify a unique operating system user for a PDB to limit operating system access. Also, when the `PATH_PREFIX` and `CREATE_FILE_DEST` clauses are specified during PDB creation, they limit file system access.

### PDB Lockdown Profiles

When identities are shared between PDBs, elevated privileges might exist. You can use lockdown profiles to prevent this elevation of privileges. Identities can be shared in the following situations:

- At the operating system level, when the database interacts with operating system resources such as files or processes
- At the network level, when the database communicates with other systems
- Inside the database, as PDBs access or create common objects or communicate across container boundaries using features such as database links

To increase security, a CDB administrator might want to use PDB lockdown profiles to restrict users in particular PDBs. A PDB lockdown profile can disable users from running specified SQL statements, such as `ALTER SYSTEM` statements, or disable access to a package that can access the network, such as the `UTL_SMTP` package. A PDB lockdown profile can also restrict access to common users, common objects, and administrative tools, such as Oracle XML DB, administrative features, such as cursor sharing, and database options, such as Oracle Database Advanced Queuing. PDB lockdown profiles can prohibit the use of the XDB protocols (FTP, HTTP, HTTPS) by a PDB with the `XDB_PROTOCOLS` feature.

You create a PDB lockdown profile in a CDB with the `CREATE LOCKDOWN PROFILE` statement. You can add and remove restrictions with the `ALTER LOCKDOWN PROFILE` statement. Only a common user with common `SYSDBA` or common `ALTER SYSTEM` privileges can create or alter a lockdown profile.

You specify a PDB lockdown profile by using the `PDB_LOCKDOWN` initialization parameter. You can set this parameter at the PDB level, in which case the profile applies only to the PDB in which it is set, or at the CDB level, in which case the profile applies to all PDBs. A common user can override a CDB-wide setting for a specific PDB, but only if the user has common `SYSDBA` or common `ALTER SYSTEM` privileges.

### The PDB\_OS\_CREDENTIAL Initialization Parameter

When the database accesses an external procedure with the extproc agent, the PDB\_OS\_CREDENTIAL initialization parameter determines the identity of the operating system user (OS user) employed when interacting with the operating system from a PDB. Using an OS user described by a credential whose name is specified as a value of the PDB\_OS\_CREDENTIAL initialization parameter can ensure that operating system interactions are performed as a less powerful user and provides the ability to protect data belonging to one PDB from being accessed by users connected to another PDB. A credential is an object that is created using the CREATE\_CREDENTIAL procedure in the DBMS\_CREDENTIAL package.

The Oracle OS user is usually a highly privileged user, and using that user for operating system interactions is not recommended. Also, using the same OS user for operating system interactions from different PDBs might compromise data belonging to a given PDB.

#### See Also:

- ["Managing Processes for External Procedures"](#)
- [Oracle Database Reference](#) for more information about the PDB\_OS\_CREDENTIAL initialization parameter

### The PATH\_PREFIX and CREATE\_FILE\_DEST PDB Creation Clauses

The PATH\_PREFIX clause of the CREATE PLUGGABLE DATABASE statement ensures that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. It also ensures that the following files associated with the PDB are restricted to specified directory: the Oracle XML repository for the PDB, files created with a CREATE PFILE statement, and the export directory for Oracle wallets.

The CREATE\_FILE\_DEST clause of the CREATE PLUGGABLE DATABASE statement ensures that all the database files belonging to the PDB are restricted to the specified directory and its subdirectories. The clause enables Oracle Managed Files for the PDB and specifies the default file system directory or Oracle ASM disk group for the PDB's files.

## 41.2 Accessing a Container in a CDB with SQL\*Plus

You can access a container in a CDB with SQL\*Plus.

- [About Accessing a Container in a CDB with SQL\\*Plus](#)  
You can use SQL\*Plus to access the root or a PDB in a CDB. You can connect to a container by using the SQL\*Plus CONNECT command, or you can switch into a container with an ALTER SESSION SET CONTAINER SQL statement.
- [Connecting to a Container Using the SQL\\*Plus CONNECT Command](#)  
You can use the SQL\*Plus CONNECT command to connect to the root or to a PDB.
- [Switching to a Container Using the ALTER SESSION Statement](#)  
When you are connected to a container as a common user, you can switch to a different container and application service using the ALTER SESSION statement.

### 41.2.1 About Accessing a Container in a CDB with SQL\*Plus

You can use SQL\*Plus to access the root or a PDB in a CDB. You can connect to a container by using the SQL\*Plus CONNECT command, or you can switch into a container with an ALTER SESSION SET CONTAINER SQL statement.

This section assumes that you understand how to connect to a non-CDB in SQL\*Plus. See "[Submitting Commands and SQL to the Database](#)" for information.

Clients access the root or a PDB through database services. Database services have an optional `PDB` property. When a PDB is created, a new default service for the PDB is created automatically. The service has the same name as the PDB. With the service name, you can access the PDB using the easy connect syntax or the net service name from the `tnsnames.ora` file. Oracle Net Services must be configured properly for clients to access this service.

When a user connects using a service with a non-null `PDB` property, the user name is resolved in the context of the specified PDB. When a user connects without specifying a service or using a service name with a null `PDB` property, the user name is resolved in the context of the root. You can view the `PDB` property for a service by querying the `CDB_SERVICES` data dictionary view or by running the `config service` command in the `SRVCTL` utility.

The setting for the `SESSIONS` initialization parameter limits the total number of sessions available in a CDB, including the sessions connected to PDBs. If the limit is reached for the CDB, then users cannot connect to PDBs. To ensure that one PDB does not use too many sessions, you can limit the number of sessions available to a PDB by setting the `SESSIONS` initialization parameter in the PDB.

 **Note:**

When two or more CDBs on the same computer system use the same listener and two or more PDBs have the same service name in these CDBs, a connection that specifies this service name connects randomly to one of the PDBs with the service name. To avoid incorrect connections, ensure that all service names for PDBs are unique on the computer system, or configure a separate listener for each CDB on the computer system.

 **See Also:**

## 41.2.2 Connecting to a Container Using the SQL\*Plus CONNECT Command

You can use the SQL\*Plus CONNECT command to connect to the root or to a PDB.

- [Connecting to the Root Using the SQL\\*Plus CONNECT Command](#)  
You can connect to the root in the same way that you connect to a non-CDB.
- [Connecting to a PDB Using the SQL\\*Plus CONNECT Command](#)  
To connect to a PDB with the SQL\*Plus CONNECT command, you can use easy connect or a net service name.

### 41.2.2.1 Connecting to the Root Using the SQL\*Plus CONNECT Command

You can connect to the root in the same way that you connect to a non-CDB.

Specifically, you can use the following techniques to connect to the root with the SQL\*Plus CONNECT command:

- Local connection
- Local connection with operating system authentication
- Database connection using easy connect
- Database connection using a net service name
- Remote database connection using external authentication

The following prerequisites must be met for the user connecting to the root:

- The user must be a common user.
- The user must be granted CREATE SESSION privilege in the root.

**To connect to the root using the SQL\*Plus CONNECT command:**

1. Configure your environment so that you can open SQL\*Plus.  
See "[Connecting to the Database with SQL\\*Plus](#)".
2. Start SQL\*Plus with the /NOLOG argument:

```
sqlplus /nolog
```

3. Issue a SQL\*Plus CONNECT command to connect to the root, as shown in the following examples.

#### Example 41-1 Connecting to the Root with a Local Connection

This example connects to the root in the local CDB as user SYSTEM. SQL\*Plus prompts for the SYSTEM user password.

```
connect system
```

#### Example 41-2 Connecting to the Root with Operating System Authentication

This example connects locally to the root with the SYSDBA administrative privilege with operating system authentication.

```
connect / as sysdba
```

#### Example 41-3 Connecting to the Root with a Net Service Name

Assume that clients are configured to have a net service name for the root in the CDB. For example, the net service name can be part of an entry in a tnsnames.ora file.

This example connects as common user c##dba to the database service designated by the net service name mycldb. SQL\*Plus prompts for the c##dba user password.

```
connect c##dba@mycldb
```

 **See Also:**

["Submitting Commands and SQL to the Database"](#)

### 41.2.2.2 Connecting to a PDB Using the SQL\*Plus CONNECT Command

To connect to a PDB with the SQL\*Plus CONNECT command, you can use easy connect or a net service name.

To connect to a PDB, a user must be one of the following:

- A common user with a CREATE SESSION privilege granted commonly or granted locally in the PDB
- A local user defined in the PDB with CREATE SESSION privilege

Only a user with SYSDBA, SYSOPER, SYSBACKUP, or SYSDG privilege can connect to a PDB that is in mounted mode. To change the open mode of a PDB, see "["Modifying the Open Mode of PDBs"](#)".

#### To connect to a PDB using the SQL\*Plus CONNECT command:

1. Configure your environment so that you can open SQL\*Plus.  
See "["Connecting to the Database with SQL\\*Plus"](#)".
2. Start SQL\*Plus with the /NOLOG argument:

```
sqlplus /nolog
```

3. Issue a SQL\*Plus CONNECT command using easy connect or a net service name to connect to the PDB.

#### Example 41-4 Connecting to a PDB

Assume that clients are configured to have a net service name for each PDB that matches each PDB name. For example, the net service name can be part of an entry in a tnsnames.ora file.

The following command connects to the `sh` local user in the `salespdb` PDB:

```
CONNECT sh@salespdb
```

The following command connects to the `SYSTEM` common user in the `salespdb` PDB:

```
CONNECT system@salespdb
```

See "[Step 4: Submit the SQL\\*Plus CONNECT Command](#)" for more examples.

### 41.2.3 Switching to a Container Using the ALTER SESSION Statement

When you are connected to a container as a common user, you can switch to a different container and application service using the `ALTER SESSION` statement.

You can use the following statement to switch to a different container and application service:

```
ALTER SESSION SET CONTAINER = container_name [SERVICE = service_name]
```

For `container_name`, specify one of the following:

- `CDB$ROOT` to switch to the CDB root
- `PDB$SEED` to switch to the CDB seed
- A PDB name to switch to the PDB

When the current container is the root, you can view the names of the PDBs in a CDB by querying the `DBA_PDBS` view.

For `service_name`, specify a service that is running in the PDB. You can list the services running in the containers of a CDB, excluding the CDB root, by issuing the following query with the CDB root as the current container:

```
COL NAME FORMAT A30
COL CON_NAME FORMAT A20

SELECT NAME,CON_NAME, CON_ID
 FROM V$ACTIVE_SERVICES
 WHERE UPPER(NAME) != CON_NAME
 AND CON_ID !=1
 ORDER BY CON_ID;
```

By default, when you switch to a container, the session uses the default service for the container. However, the default PDB service does not support all of the service attributes and features such as service metrics, Fast Application Notification (FAN), load balancing, Resource Manager, Transaction Guard, Application Continuity, and so

on. It is best practice to use a non-default service for the container by specifying `SERVICE = service_name`, where `service_name` is the name of the service.

With this new capability, connection pools can switch the service, and, when needed the PDB, on a connection when a connection is borrowed from the pool. Starting with Oracle Database 12c Release 2 (12.2.0.1), connection pools support more than one database service with universal connection pools (UCPs). It can also be used standalone.

When switching to a service, applications are able to consolidate to a CDB, while keeping the database services identified, prioritized, measured, and highly available. Switching to a non-default service provides the following benefits:

- It preserves the service attributes and features.
- It eliminates too many connection pools with too many connections serving these tenants.
- It allows applications to use more database services for workload control without consuming too many connection pools. Customers are able to identify and prioritize workloads using services without over sizing the database connections.

The following are considerations for using the `ALTER SESSION SET CONTAINER` statement:

- After the statement completes successfully, the current schema of the session is set to the schema owned by the common user in the specified container.
- After the statement completes successfully, the security context is reset to that of the schema owned by the common user in the specified container.
- After the statement completes successfully, login triggers for the specified container do not fire.

If you require a trigger, then you can define a before or after `SET CONTAINER` trigger in a PDB to fire before or after the `ALTER SESSION SET CONTAINER` statement is executed.

- After the statement completes successfully and the `SERVICE` clause specifies a non-default service for the PDB, the session is using a new service with attributes set, including metrics, FAN, TAF, Application Continuity, Transaction Guard, `drain_timeout`, and `stop_option` for the new service.
- Package states are not shared across containers.
- When closing a PDB, sessions that switched into the PDB and sessions that connected directly to the PDB are handled identically.
- A transaction cannot span multiple containers. If you start a transaction and use `ALTER SESSION SET CONTAINER` to switch to a different container, then you cannot issue DML, DDL, COMMIT, or ROLLBACK statements until you switch back to the container in which you started the transaction.
- If you open a cursor and use `ALTER SESSION SET CONTAINER` to switch to different container, then you cannot fetch data from that cursor until you switch back to the container in which the cursor was opened.
- You can use the `ALTER SESSION SET CONTAINER` statement with the `SERVICE` clause for connection pooling as well as advanced CDB administration.

For example, you can use this statement for connection pooling with PDBs for a multitenancy application. A multitenancy application uses a single instance of the software on a server to serve multiple customers (tenants). In a non-CDB,

multitenancy is typically supported by adding an extra column that identifies the tenant to every table used by the application, and tenants check out connections from a connection pool. In a CDB with PDBs, each tenant can have its own PDB, and you can use the `ALTER SESSION SET CONTAINER` statement in a connection pooling configuration.

- When working with connection pools that serve applications, the applications may be using data sources with different services. Using the `ALTER SESSION SET CONTAINER` statement with the `SERVICE` clause enables the connection pool to use the same connections for many applications, sharing the services.

The following prerequisites must be met to use the `ALTER SESSION SET CONTAINER` statement:

- The current user must be a common user. The initial connection must be made using the SQL\*Plus `CONNECT` command.
- When altering a session to switch to a PDB as a common user that was not supplied with Oracle Database, the current user must be granted the `SET CONTAINER` privilege commonly or must be granted this privilege locally in the PDB.

 **Note:**

When an `ALTER SESSION SET CONTAINER` statement is used to switch to the current container, these prerequisites are not enforced, and no error message is returned if they are not met.

Before issuing an `ALTER SESSION SET CONTAINER` statement with the `SERVICE` clause, the following prerequisites must be met:

- The service switched to must be active. You cannot switch to a service that is not running.
- When switching between services, the service attributes of the service being switched from and the service being switched to must match. For example, the services switched from and to must all have TAF, or must all use Application Continuity, or must all have `drain_timeout` set.

**To switch to a container using the `ALTER SESSION` statement:**

- In SQL\*Plus, connect to a container as a common user with the required privileges.  
See "[Connecting to a Container Using the SQL\\*Plus CONNECT Command](#)".
- Check the current open mode of the container to which you are switching.

To check the current open mode of the root or a PDB, query the `OPEN_MODE` column in the `V$CONTAINERS` view when the current container is the root.

If the open mode of the root should be changed, then follow the instructions in "[Altering Database Availability](#)" to change the open mode.

If the open mode of the PDB should be changed, then follow the instructions in "[Modifying the Open Mode of PDBs](#)" to change the open mode.

The open mode of the root imposes limitations on the open mode of PDBs. For example, the root must be open before any PDBs can be open. Therefore, you

might need to change the open mode of the root before changing the open mode of a PDB.

3. If you are switching to a specific service, then ensure that the service is running.

To check the active status of the service, query the V\$ACTIVE\_SERVICES view when the current container is the CDB root.

If the service is not running, then use the SRVCTL utility or the DBMS\_SERVICE package to start the service.

4. Run the ALTER SESSION SET CONTAINER statement and specify the container to which you want to switch.

Include the SERVICE clause to switch to a specific application service.

The following examples switch to various containers using ALTER SESSION.

#### **Example 41-5 Switching to the PDB salespdb and Using the salesrep Service**

```
ALTER SESSION SET CONTAINER = salespdb SERVICE = salesrep;
```

#### **Example 41-6 Switching to the PDB salespdb and Using the Default Service**

```
ALTER SESSION SET CONTAINER = salespdb;
```

#### **Example 41-7 Switching to the CDB Root**

```
ALTER SESSION SET CONTAINER = CDB$ROOT;
```

#### **Example 41-8 Switching to the CDB Seed**

```
ALTER SESSION SET CONTAINER = PDB$SEED;
```

#### **Example 41-9 Switching Services Using a Dummy Service in the CDB Root**

To design connection pooling that switches the container and the service, one method is to create a dummy service in the CDB root and set all required service attributes on this dummy service (for example, drain\_timeout, TAF or Application Continuity). The service attributes must match across the CDB root and the PDB. To use this method, complete the following steps:

1. Connect to the dummy service when first creating the connection pool and when creating new connections.
2. As services are added to each PDB, set the same attributes on these real services.
3. When an application requires a connection, complete one of the following actions:
  - Create a new connection to the dummy service, and switch to the PDB and service.
  - Borrow a free connection in the pool and switch to the PDB and service.

You do not need to return to the CDB root when switching across PDBs.

You do not need to return to the CDB root when switching across PDBs.

 **See Also:**

- "[About Database Resident Connection Pooling](#)"
- *Oracle Universal Connection Pool Developer's Guide* for more information about universal connection pools

## 41.3 Executing Code in Containers Using the DBMS\_SQL Package

When you are executing PL/SQL code in a container in a CDB, and you want to execute one or more SQL statements in a different container, use the `DBMS_SQL` package to switch containers.

For example, you can use the `DBMS_SQL` package to switch containers when you need to perform identical actions in more than one container.

The following are considerations for using `DBMS_SQL` to switch containers:

- A transaction cannot span multiple containers.  
If the set of actions you must perform in the target container requires a transaction, then consider using an autonomous transaction and perform a commit or rollback as the last action.
- `SET ROLE` statements are not allowed.

### Example 41-10 Performing Identical Actions in More Than One Container

This example includes a PL/SQL block that creates the `identact` table in the `hr` schema in two PDBs (`pdb1` and `pdb2`). The example also inserts a row into the `identact` table in both PDBs.

```
DECLARE
 c1 INTEGER;
 rowcount INTEGER;
 taskList VARCHAR2(32767) :=
 'DECLARE
 PRAGMA AUTONOMOUS TRANSACTION;
 BEGIN
 -- Create the hr.identact table.
 EXECUTE IMMEDIATE
 ''CREATE TABLE hr.identact
 (actionno NUMBER(4) NOT NULL,
 action VARCHAR2 (10))''';
 EXECUTE IMMEDIATE
 ''INSERT INTO identact VALUES(1, 'ACTION1')''';
 -- A commit is required if the tasks include DML.
 COMMIT;
 EXCEPTION
 WHEN OTHERS THEN
 -- If there are errors, then drop the table.
 BEGIN
 EXECUTE IMMEDIATE ''DROP TABLE identact'';
 EXCEPTION
 WHEN OTHERS THEN
```

```
 NULL;
 END;
 END;';
TYPE containerListType IS TABLE OF VARCHAR2(128) INDEX BY PLS_INTEGER;
containerList containerListType;
BEGIN
 containerList(1) := 'PDB1';
 containerList(2) := 'PDB2';
 c1 := DBMS_SQL.OPEN_CURSOR;
FOR conIndex IN containerList.first..containerList.last LOOP
 DBMS_OUTPUT.PUT_LINE('Creating in container: ' || containerList(conIndex));
 DBMS_SQLPARSE(c => c1 ,
 statement => taskList,
 language_flag => DBMS_SQL.NATIVE,
 edition=> NULL,
 apply_crossedition_trigger => NULL,

## 41.4 Modifying a CDB

You can modify the entire CDB, the root, or one or more PDBs.

- [About Modifying a CDB](#)

The `ALTER DATABASE` statement modifies a CDB. The `ALTER PLUGGABLE DATABASE` statement can modify the open mode of one or more PDBs.

- [About the Statements That Modify a CDB](#)

When connected as a common user whose current container is the root, the `ALTER DATABASE` statement works the same in a CDB and a non-CDB.

- [Managing Tablespaces in a CDB](#)

You can manage tablespaces in a CDB.

- [Modifying an Entire CDB](#)

You can use the `ALTER DATABASE` statement to modify an entire CDB, including the root and all of the PDBs. Most `ALTER DATABASE` statements modify the entire CDB.

- [Modifying the Root](#)

You can use the `ALTER DATABASE` statement to modify only the root of a CDB.

- [Modifying the Open Mode of PDBs](#)  
You can modify the open mode of a PDB by using the `ALTER PLUGGABLE DATABASE` SQL statement or the `SQL*Plus STARTUP` command.
- [Preserving or Discarding the Open Mode of PDBs When the CDB Restarts](#)  
You can preserve the open mode of one or more PDBs when the CDB restarts by using the `ALTER PLUGGABLE DATABASE` SQL statement with a `pdb_save_or_discard_state` clause.

## 41.4.1 About Modifying a CDB

The `ALTER DATABASE` statement modifies a CDB. The `ALTER PLUGGABLE DATABASE` statement can modify the open mode of one or more PDBs.

[Table 41-3](#) lists which containers are modified by clauses in `ALTER DATABASE` and `ALTER PLUGGABLE DATABASE` statements.

**Table 41-3 Statements That Modify Containers in a CDB**

| Modify Entire CDB                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Modify Root Only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Modify One or More PDBs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

#### 41.4.2 About the Statements That Modify a CDB

When connected as a common user whose current container is the root, the `ALTER DATABASE` statement works the same in a CDB and a non-CDB.

Most `ALTER DATABASE` statements affect the entire CDB. The exceptions are listed in the "Modify Root Only" column of [Table 41-3](#).

When an `ALTER DATABASE` statement with the `RENAME GLOBAL_NAME` clause modifies the domain of a CDB, it affects the domain of each PDB with a domain that defaults to that of the CDB.

When connected as a common user whose current container is the root, the `ALTER PLUGGABLE DATABASE` statement with the `pdb_change_state` clause modifies the open mode of one or more PDBs.

When the current container is a PDB, `ALTER DATABASE` and `ALTER PLUGGABLE DATABASE` statements modify the current PDB only.

 **See Also:**

- [Oracle Database SQL Language Reference](#)
- ["Modifying a PDB"](#)

#### 41.4.3 Managing Tablespaces in a CDB

You can manage tablespaces in a CDB.

- [\*\*About Managing Tablespaces in a CDB\*\*](#)

A tablespace is a logical storage container for database objects, such as tables and indexes, that consume storage space. At the physical level, a tablespace stores data in one or more data files or temp files. You can use the `ALTER DATABASE` statement to manage tablespaces in a CDB.

- [\*\*About Managing Permanent Tablespaces in a CDB\*\*](#)

A permanent tablespace can be associated with only one container. Therefore, a permanent tablespace can be associated with the root or with one PDB.

- [\*\*About Managing Temporary Tablespaces in a CDB\*\*](#)

Each container in a CDB has its own default temporary tablespace (or tablespace group).

#### 41.4.3.1 About Managing Tablespaces in a CDB

A tablespace is a logical storage container for database objects, such as tables and indexes, that consume storage space. At the physical level, a tablespace stores data in one or more data files or temp files. You can use the `ALTER DATABASE` statement to manage tablespaces in a CDB.

The following are considerations for tablespaces in a CDB:

- A permanent tablespace can be associated with only one container.
- When you create a tablespace in a container, the tablespace is associated with that container.
- When local undo is disabled for a CDB, the CDB has only one active undo tablespace, or one active undo tablespace for each instance of an Oracle RAC CDB. When local undo is enabled for a CDB, each container in the CDB has its own undo tablespace.
- A local undo tablespace is required for each node in an Oracle Real Application Clusters (Oracle RAC) cluster in which the PDB is open.
- There is one default temporary tablespace each container in the CDB, including the CDB root, each PDB, each application root, and each application PDB.

#### 41.4.3.2 About Managing Permanent Tablespaces in a CDB

A permanent tablespace can be associated with only one container. Therefore, a permanent tablespace can be associated with the root or with one PDB.

Each container in a CDB must have its own default permanent tablespace, and default permanent tablespaces cannot be shared between containers. Users connected to the container who are not explicitly assigned a tablespace use the default permanent tablespace for the container.

#### 41.4.3.3 About Managing Temporary Tablespaces in a CDB

Each container in a CDB has its own default temporary tablespace (or tablespace group).

You also can create additional temporary tablespaces for individual containers, and you can assign specific users in containers to these temporary tablespaces. When you unplug a PDB, its temporary tablespaces are also unplugged.

When a user is not assigned a temporary tablespace explicitly in a container, the user's temporary tablespace is the default temporary tablespace for the container.

 **See Also:**

- [Managing Tablespaces](#)
- ["Unplugging a PDB from a CDB"](#)
- ["Modifying an Entire CDB"](#)
- ["Modifying the Root"](#)

#### 41.4.4 Modifying an Entire CDB

You can use the `ALTER DATABASE` statement to modify an entire CDB, including the root and all of the PDBs. Most `ALTER DATABASE` statements modify the entire CDB.

See the "Modify Entire CDB" column of [Table 41-3](#) for a list of these statements.

To modify an entire CDB, the following prerequisites must be met:

- The current user must be a common user with the `ALTER DATABASE` privilege.
- To run an `ALTER DATABASE` statement with a *recovery\_clause*, the current user must have the `SYSDBA` administrative privilege commonly granted. In this case, you must exercise this privilege using `AS SYSDBA` at connect time.

**To modify an entire CDB:**

1. In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Run an `ALTER DATABASE` statement with a clause that modifies an entire CDB.

**Example 41-11 Backing Up the Control File for a CDB**

This `ALTER DATABASE` statement uses a *recovery\_clause* to back up a control file.

```
ALTER DATABASE BACKUP CONTROLFILE TO '+DATA/dbs/backup/control.bkp';
```

**Example 41-12 Adding a Redo Log File to a CDB**

This `ALTER DATABASE` statement uses a *logfile\_clause* to add redo log files.

```
ALTER DATABASE cdb ADD LOGFILE
 GROUP 4 ('/u01/logs/orcl/redo04a.log','/u02/logs/orcl/redo04b.log')
 SIZE 100M BLOCKSIZE 512 REUSE;
```

 **See Also:**

[Oracle Database SQL Language Reference](#)

## 41.4.5 Modifying the Root

You can use the `ALTER DATABASE` statement to modify only the root of a CDB.

When the current container is the root, these `ALTER DATABASE` statements modify the root without directly modifying any of the PDBs. See the "Modify Root Only" column of [Table 41-3](#) for a list of these statements.

Some of these statements set the defaults for the PDBs in the CDB. You can overwrite these defaults for a PDB by using the `ALTER PLUGGABLE DATABASE` statement.

To modify the root, the current user must have the `ALTER DATABASE` privilege in the root.

### To modify the root:

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Run an `ALTER DATABASE` statement with a clause that modifies the root.

The following examples modify the root.

A user whose current container is the root that is not explicitly assigned a tablespace uses the default permanent tablespace for the root. The tablespace specified in the `ALTER DATABASE` statement must exist in the root.

After executing this statement, the default type of subsequently created tablespaces in the root is bigfile. This setting is also the default for PDBs.

The tablespace or tablespace group specified in the `ALTER DATABASE` statement must exist in the root.

### Example 41-13 Changing the Default Permanent Tablespace for the Root

This `ALTER DATABASE` statement uses a `DEFAULT TABLESPACE` clause to set the default permanent tablespace to `root_tbs` for the root.

```
ALTER DATABASE DEFAULT TABLESPACE root_tbs;
```

### Example 41-14 Bringing a Data File Online for the Root

This `ALTER DATABASE` statement uses a `database_file_clause` to bring the `/u02/oracle/cdb_01.dbf` data file online.

```
ALTER DATABASE DATAFILE '/u02/oracle/cdb_01.dbf' ONLINE;
```

### Example 41-15 Changing the Default Tablespace Type for the Root

This `ALTER DATABASE` statement uses a `SET DEFAULT TABLESPACE` clause to change the default tablespace type to bigfile for the root.

```
ALTER DATABASE SET DEFAULT BIGFILE TABLESPACE;
```

### Example 41-16 Changing the Default Temporary Tablespace for the Root

This `ALTER DATABASE` statement uses a `DEFAULT TEMPORARY TABLESPACE` clause to set the default temporary tablespace to `root_temp` for the root.

```
ALTER DATABASE DEFAULT TEMPORARY TABLESPACE root_temp;
```

## 41.4.6 Modifying the Open Mode of PDBs

You can modify the open mode of a PDB by using the `ALTER PLUGGABLE DATABASE` SQL statement or the SQL\*Plus `STARTUP` command.

- [About the Open Mode of a PDB](#)  
A PDB can be in various modes.
- [About Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE](#)  
When the current container is the root, an `ALTER PLUGGABLE DATABASE` statement with a `pdb_change_state` clause modifies the open mode of the specified PDBs.
- [About Modifying the Open Mode of PDBs with the SQL\\*Plus STARTUP Command](#)  
When the current container is the root, the `STARTUP PLUGGABLE DATABASE` command can open a single PDB.
- [Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE](#)  
You can modify the open mode of PDBs with the `ALTER PLUGGABLE DATABASE` statement with a `pdb_change_state` clause.
- [Modifying the Open Mode of PDBs with the SQL\\*Plus STARTUP Command](#)  
You can use the `STARTUP PLUGGABLE DATABASE` command to open a single PDB.

### 41.4.6.1 About the Open Mode of a PDB

A PDB can be in various modes.

[Table 41-4](#) describes the possible PDB modes.

**Table 41-4 PDB Modes**

| Mode            | Description                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OPEN READ WRITE | A PDB in open read/write mode allows queries and user transactions to proceed and allows users to generate redo logs.                                                                                                                                                                                                |
| OPEN READ ONLY  | A PDB in open read-only mode allows queries but does not allow user changes.                                                                                                                                                                                                                                         |
| OPEN MIGRATE    | When a PDB is in open migrate mode, you can run database upgrade scripts on the PDB.<br><br>A PDB is in this mode after an <code>ALTER DATABASE OPEN UPGRADE</code> is run.                                                                                                                                          |
| MOUNTED         | When a PDB is in mounted mode, it behaves like a non-CDB in mounted mode. It does not allow changes to any objects, and it is accessible only to database administrators. It cannot read from or write to data files. Information about the PDB is removed from memory caches. Cold backups of the PDB are possible. |

The open read/write, read-only, and migrate modes can be restricted to users with RESTRICTED SESSION privilege in the PDB.

While a PDB is in mounted or read-only mode, database administrators can create, modify, or drop common users and roles in the CDB. The CDB applies these changes to the PDB when its open mode is changed to open in read/write mode. Before the changes are applied, descriptions of common users and roles in the PDB might be different from the descriptions in the rest of the CDB.

When a PDB is opened, Oracle Database checks the compatibility of the PDB with the CDB. Each compatibility violation is either a warning or an error. If a compatibility violation is a warning, then the warning is recorded in the alert log, but the PDB is opened normally without displaying a warning message. If a compatibility violation is an error, then a message is displayed when the PDB is opened stating that the PDB was altered with errors, and the errors are recorded in the alert log. You must correct the condition that caused each error. When there are errors, the PDB is opened, but access to the PDB is limited to users with RESTRICTED SESSION privilege so that the compatibility violations can be addressed. You can view descriptions of violations by querying `PDB_PLUG_IN_VIOLATIONS` view.

#### 41.4.6.2 About Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE

When the current container is the root, an `ALTER PLUGGABLE DATABASE` statement with a `pdb_change_state` clause modifies the open mode of the specified PDBs.

The following table describes the clauses of the `ALTER PLUGGABLE DATABASE` statement that modify the mode of a PDB.

**Table 41-5 ALTER PLUGGABLE DATABASE Clauses That Modify the Mode of a PDB**

| Clause                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OPEN READ WRITE<br>[RESTRICTED] [FORCE] | Opens the PDB in read/write mode.<br>When RESTRICTED is specified, the PDB is accessible only to users with RESTRICTED SESSION privilege in the PDB. All sessions connected to the PDB that do not have RESTRICTED SESSION privilege on it are terminated, and their transactions are rolled back.<br>When FORCE is specified, the statement opens a PDB that is currently closed and changes the open mode of a PDB that is in open read-only mode.                                                                                                                                                                                                                                                                                                                          |
| OPEN READ ONLY<br>[RESTRICTED] [FORCE]  | Opens the PDB in read-only mode.<br>When RESTRICTED is specified, the PDB is accessible only to users with RESTRICTED SESSION privilege in the PDB. All sessions connected to the PDB that do not have RESTRICTED SESSION privilege on it are terminated.<br>When FORCE is specified, the statement opens a PDB that is currently closed and changes the open mode of a PDB that is in open read/write mode.                                                                                                                                                                                                                                                                                                                                                                  |
| OPEN UPGRADE<br>[RESTRICTED]            | Opens the PDB in migrate mode.<br>When RESTRICTED is specified, the PDB is accessible only to users with RESTRICTED SESSION privilege in the PDB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| CLOSE [ IMMEDIATE  <br>ABORT ]          | Places the PDB in mounted mode.<br>The CLOSE statement is the PDB equivalent of the SQL*Plus SHUTDOWN command. If you do not specify IMMEDIATE or ABORT, then the PDB is shut down with the normal mode. See " <a href="#">Shutting Down with the Normal Mode</a> ".<br>When IMMEDIATE is specified, this statement is the PDB equivalent of the SQL*Plus SHUTDOWN command with the immediate mode. See " <a href="#">Shutting Down with the Immediate Mode</a> ".<br>When ABORT is specified, the PDB is forcefully closed. For a single-instance CDB, PDB media recovery is required when you specify SHUTDOWN ABORT. For an Oracle Real Application Clusters (Oracle RAC) CDB, PDB media recovery is required if the SHUTDOWN ABORT command closes the last open instance. |

When you issue an ALTER PLUGGABLE DATABASE OPEN statement, READ WRITE is the default unless a PDB being opened belongs to a CDB that is used as a physical standby database, in which case READ ONLY is the default.

You can specify which PDBs to modify in the following ways:

- List one or more PDBs.
- Specify ALL to modify all of the PDBs.
- Specify ALL EXCEPT to modify all of the PDBs, except for the PDBs listed.

### The *services* Clause

You can use the *services* clause to specify the services that are started when a single PDB is opened in the following ways:

- List one or more services in the *services* clause in the following form:

```
SERVICES = ('service_name' [, 'service_name'] ...)
```

- Specify **ALL** in the *services* clause to start all of the PDB's services, as in the following example:

```
SERVICES = ALL
```

- Specify **ALL EXCEPT** in the *services* clause to start all of the PDB's services, except for the services listed, in the following form:

```
SERVICES = ALL EXCEPT('service_name' [, 'service_name'] ...)
```

- Specify **NONE** in the *services* clause to start only the PDB's default service and none of the other PDB's services, as in the following example:

```
SERVICES = NONE
```

**NONE** is the default setting for the *services* clause. A PDB's default service is always started, regardless of the setting for the *services* clause.

### The *instances* Clause

For an Oracle Real Application Clusters (Oracle RAC) CDB, you can use the *instances* clause to specify the instances on which the PDB is modified in the following ways:

- List one or more instances in the *instances* clause in the following form:

```
INSTANCES = ('instance_name' [, 'instance_name'] ...)
```

- Specify **ALL** in the *instances* clause to modify the PDB in all running instances, as in the following example:

```
INSTANCES = ALL
```

- Specify **ALL EXCEPT** in the *instances* clause to modify the PDB in all of the instances, except for the instances listed, in the following form:

```
INSTANCES = ALL EXCEPT('instance_name' [, 'instance_name'] ...)
```

Also, when you are closing a PDB in an Oracle RAC CDB, you can use the *relocate* clause, which includes the following options:

- Specify **NORELOCATE**, the default, to close the PDB in the current instance.
- Specify **RELOCATE TO** and specify an instance name to reopen the PDB in the specified instance.
- Specify **RELOCATE** to reopen the PDB on a different instance that is selected by Oracle Database.

 **Note:**

If both the `services` clause and the `instances` clause are specified in the same `ALTER PLUGGABLE DATABASE` statement, then the specified services are started on the specified instances.

### The `relocate` Clause

When you are closing a PDB in an Oracle RAC CDB, you can use the `relocate` clause, which includes the following options:

- Specify `NORELOCATE`, the default, to close the PDB in the current instance.
- Specify `RELOCATE TO` and specify an instance name to reopen the PDB in the specified instance.
- Specify `RELOCATE` to reopen the PDB on a different instance that is selected by Oracle Database.

To modify the open mode of PDBs with the `ALTER PLUGGABLE DATABASE` statement, the following prerequisites must be met:

- The current user must have `SYSDBA`, `SYSOPER`, `SYSBACKUP`, or `SYSDG` administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using `AS SYSDBA`, `AS SYSOPER`, `AS SYSBACKUP`, or `AS SYSDG`, respectively, at connect time.
- When `RESTRICTED SESSION` is enabled, `RESTRICTED` must be specified when a PDB is opened.
- In an Oracle RAC CDB, if a PDB is open in one or more Oracle RAC instances, then it can be opened in additional instances, but it must be opened in the same mode as in the instances in which it is already open. A PDB can be closed in some instances and opened on others.

### Summary of Requirements for the `ALTER PLUGGABLE DATABASE` Statement

To modify the open mode of PDBs with the `ALTER PLUGGABLE DATABASE` statement, the following prerequisites must be met:

- The current user must have `SYSDBA`, `SYSOPER`, `SYSBACKUP`, or `SYSDG` administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using `AS SYSDBA`, `AS SYSOPER`, `AS SYSBACKUP`, or `AS SYSDG`, respectively, at connect time.
- When `RESTRICTED SESSION` is enabled, `RESTRICTED` must be specified when a PDB is opened.
- In an Oracle RAC CDB, if a PDB is open in one or more Oracle RAC instances, then it can be opened in additional instances, but it must be opened in the same mode as in the instances in which it is already open. A PDB can be closed in some instances and opened on others.

To place PDBs in a particular target mode with the `ALTER PLUGGABLE DATABASE` statement, you must meet the requirements described in the following table.

**Table 41-6 Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE**

| Target Mode of PDBs | ALL Keyword Included | FORCE Keyword Included | Required Mode for the Root | Required Mode for Each PDB Being Modified  |
|---------------------|----------------------|------------------------|----------------------------|--------------------------------------------|
| Read/write          | Yes                  | Yes                    | Read/write                 | Mounted, read-only, or read/write          |
| Read/write          | Yes                  | No                     | Read/write                 | Mounted or read/write                      |
| Read/write          | No                   | Yes                    | Read/write                 | Mounted, read-only, or read/write          |
| Read/write          | No                   | No                     | Read/write                 | Mounted                                    |
| Read-only           | Yes                  | Yes                    | Read-only or read/write    | Mounted, read-only, or read/write          |
| Read-only           | Yes                  | No                     | Read-only or read/write    | Mounted or read-only                       |
| Read-only           | No                   | Yes                    | Read-only or read/write    | Mounted, read-only, or read/write          |
| Read-only           | No                   | No                     | Read-only or read/write    | Mounted                                    |
| Migrate             | Yes                  | Not applicable         | Read-only or read/write    | Mounted                                    |
| Migrate             | No                   | Not applicable         | Read-only or read/write    | Mounted                                    |
| Mounted             | Yes                  | Not applicable         | Read-only or read/write    | Mounted, read-only, migrate, or read/write |
| Mounted             | No                   | Not applicable         | Read-only or read/write    | Read-only, migrate, or read/write          |

 **Note:**

You can also modify the open mode of a PDB when the current container is the PDB. See "["Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement"](#)".

### Related Topics

- [Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE](#)

You can modify the open mode of PDBs with the `ALTER PLUGGABLE DATABASE` statement with a `pdb_change_state` clause.

### 41.4.6.3 About Modifying the Open Mode of PDBs with the SQL\*Plus STARTUP Command

When the current container is the root, the `STARTUP PLUGGABLE DATABASE` command can open a single PDB.

Use the following options of the `STARTUP PLUGGABLE DATABASE` command to open a PDB:

- `FORCE`

Closes an open PDB before re-opening it in read/write mode. When this option is specified, no other options are allowed.

- `RESTRICT`

Enables only users with the `RESTRICTED SESSION` system privilege in the PDB to access the PDB.

If neither `OPEN READ WRITE` nor `OPEN READ ONLY` is specified, then the PDB is opened in read-only mode when the CDB to which it belongs is a physical standby database. Otherwise, the PDB is opened in read/write mode.

- `OPEN open_pdb_options`

Opens the PDB in either read/write mode or read-only mode. You can specify `OPEN READ WRITE` or `OPEN READ ONLY`. When you specify `OPEN` without any other options, `READ WRITE` is the default.

The following prerequisites must be met:

- The current user must have `SYSDBA`, `SYSOPER`, `SYSBACKUP`, or `SYSdg` administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using `AS SYSDBA`, `AS SYSOPER`, `AS SYSBACKUP`, or `AS SYSdg`, respectively, at connect time.
- When `RESTRICTED SESSION` is enabled, `RESTRICT` must be specified when a PDB is opened.

In addition, to place PDBs in a particular target mode with the `STARTUP PLUGGABLE DATABASE` command, you must meet the requirements described in the following table.

**Table 41-7 Modifying the Open Mode of a PDB with STARTUP PLUGGABLE DATABASE**

| Target Mode of the PDB | FORCE Option Included | Required Mode for the Root | Required Mode of the PDB Being Modified |
|------------------------|-----------------------|----------------------------|-----------------------------------------|
| Read/write             | Yes                   | Read/write                 | Mounted, read-only, or read/write       |
| Read/write             | No                    | Read/write                 | Mounted                                 |
| Read-only              | No                    | Read-only or read/write    | Mounted                                 |

 **Note:**

You can also use the `STARTUP` command to modify the open mode of a PDB when the current container is the PDB. See "[Using the STARTUP SQL\\*Plus Command on a PDB](#)".

**Related Topics**

- [Modifying the Open Mode of PDBs with the SQL\\*Plus STARTUP Command](#)  
You can use the `STARTUP PLUGGABLE DATABASE` command to open a single PDB.

#### 41.4.6.4 Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE

You can modify the open mode of PDBs with the `ALTER PLUGGABLE DATABASE` statement with a `pdb_change_state` clause.

1. In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Run an `ALTER PLUGGABLE DATABASE` statement with a `pdb_change_state` clause.

**Example 41-17 Changing the Open Mode of Listed PDBs**

This statement changes the open mode of PDBs `salespdb` and `hrpdb` to open in read/write mode.

```
ALTER PLUGGABLE DATABASE salespdb, hrpdb
 OPEN READ WRITE;
```

This statement changes the open mode of PDB `salespdb` to open in read-only mode. `RESTRICTED` specifies that the PDB is accessible only to users with `RESTRICTED SESSION` privilege in the PDB.

```
ALTER PLUGGABLE DATABASE salespdb
 OPEN READ ONLY RESTRICTED;
```

This statement changes the open mode of PDB `salespdb` to open in migrate mode:

```
ALTER PLUGGABLE DATABASE salespdb
 OPEN UPGRADE;
```

**Example 41-18 Changing the Open Mode of All PDBs**

Run the following query to display the open mode of each PDB associated with a CDB:

```
SELECT NAME, OPEN_MODE FROM V$PDBS WHERE CON_ID > 2;
```

| NAME     | OPEN_MODE  |
|----------|------------|
| HRPDB    | READ WRITE |
| SALESPDB | MOUNTED    |
| DWPDB    | MOUNTED    |

Notice that `hrpdb` is already in read/write mode. To change the open mode of `salespdb` and `dwpdb` to open in read/write mode, use the following statement:

```
ALTER PLUGGABLE DATABASE ALL
OPEN READ WRITE;
```

The `hrpdb` PDB is not modified because it is already in open read/write mode. The statement does not return an error because two PDBs are in mounted mode and one PDB (`hrpdb`) is in the specified mode (read/write). Similarly, the statement does not return an error if all PDBs are in mounted mode.

However, if any PDB is in read-only mode, then the statement returns an error. To avoid an error and open all PDBs in the CDB in read/write mode, specify the `FORCE` keyword:

```
ALTER PLUGGABLE DATABASE ALL
OPEN READ WRITE FORCE;
```

With the `FORCE` keyword included, all PDBs are opened in read/write mode, including PDBs in read-only mode.

#### Example 41-19 Changing the Open Mode of All PDBs Except for Listed Ones

This statement changes the mode of all PDBs except for `salespdb` and `hrpdb` to mounted mode.

```
ALTER PLUGGABLE DATABASE ALL EXCEPT salespdb, hrpdb
CLOSE IMMEDIATE;
```

##### Note:

An `ALTER PLUGGABLE DATABASE` statement modifying the open mode of a PDB is instance-specific. Therefore, if this statement is issued when connected to an Oracle RAC instance, then it affects the open mode of the PDB only in that instance.

##### See Also:

- ["About Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE"](#)
- ["Modifying a PDB"](#) for information about modifying the other attributes of a PDB
- ["Altering Database Availability"](#) for information about database modes and their uses

- *Oracle Database Concepts* for more information about shutdown modes

#### 41.4.6.5 Modifying the Open Mode of PDBs with the SQL\*Plus STARTUP Command

You can use the STARTUP PLUGGABLE DATABASE command to open a single PDB.

**To modify a PDB with the STARTUP PLUGGABLE DATABASE command:**

1. In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Run the STARTUP PLUGGABLE DATABASE command.

 **Note:**

When the current container is the root, the SQL\*Plus SHUTDOWN command always shuts down the CDB instance. It cannot be used to close individual PDBs.

**Example 41-20 Opening a PDB in Read/Write Mode with the STARTUP Command**

```
STARTUP PLUGGABLE DATABASE hrpdb OPEN
```

**Example 41-21 Opening a PDB in Read/Write Restricted Mode with the STARTUP Command**

```
STARTUP PLUGGABLE DATABASE hrpdb RESTRICT
```

**Example 41-22 Opening a PDB in Read-Only Restricted Mode with the STARTUP Command**

```
STARTUP PLUGGABLE DATABASE hrpdb OPEN READ ONLY RESTRICT
```

**Example 41-23 Opening a PDB in Read-Only Mode with the STARTUP Command**

```
STARTUP PLUGGABLE DATABASE hrpdb OPEN READ ONLY
```

**Example 41-24 Opening a PDB in Read/Write Mode with the STARTUP Command and the FORCE Option**

This example assumes that the hrpdb PDB is currently open. The FORCE option closes the PDB and then opens it in the read/write mode.

```
STARTUP PLUGGABLE DATABASE hrpdb FORCE
```

#### 41.4.7 Preserving or Discarding the Open Mode of PDBs When the CDB Restarts

You can preserve the open mode of one or more PDBs when the CDB restarts by using the `ALTER PLUGGABLE DATABASE` SQL statement with a `pdb_save_or_discard_state` clause.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

You can do this in the following way:

- Specify `SAVE STATE` to preserve the PDBs' mode when the CDB is restarted.

For example, if a PDB is in open read/write mode before the CDB is restarted, then the PDB is in open read/write mode after the CDB is restarted; if a PDB is in mounted mode before the CDB is restarted, then the PDB is in mounted mode after the CDB is restarted.

- Specify `DISCARD STATE` to ignore the PDBs' open mode when the CDB is restarted.

When `DISCARD STATE` is specified for a PDB, the PDB is always mounted after the CDB is restarted.

You can specify which PDBs to modify in the following ways:

- List one or more PDBs.
- Specify `ALL` to modify all of the PDBs.
- Specify `ALL EXCEPT` to modify all of the PDBs, except for the PDBs listed.

For an Oracle RAC CDB, you can use the `instances` clause in the `pdb_save_or_discard_state` clause to specify the instances on which a PDB's open mode is preserved in the following ways:

- List one or more instances in the `instances` clause in the following form:

```
INSTANCES = ('instance_name' [, 'instance_name'] ...)
```

- Specify ALL in the *instances* clause to modify the PDB in all running instances, as in the following example:

```
INSTANCES = ALL
```

- Specify ALL EXCEPT in the *instances* clause to modify the PDB in all of the instances, except for the instances listed, in the following form:

```
INSTANCES = ALL EXCEPT('instance_name' [, 'instance_name'] ...)
```

For a PDB in an Oracle RAC CDB, SAVE STATE and DISCARD STATE only affect the mode of the current instance. They do not affect the mode of other instances, even if more than one instance is specified in the *instances* clause.

To issue an ALTER PLUGGABLE DATABASE SQL statement with a *pdb\_save\_or\_discard\_state* clause, the current user must have the ALTER DATABASE privilege in the root.

You can check the saved states for the PDBs in a CDB by querying the DBA\_PDB\_SAVED\_STATES view.

#### To preserve or discard a PDB's open mode when the CDB restarts:

- In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
- Run an ALTER PLUGGABLE DATABASE statement with a *pdb\_save\_or\_discard\_state* clause.

The following examples either preserve or discard the open mode of one or more PDBs when the CDB restarts.

#### **Example 41-25 Preserving the Open Mode of a PDB When the CDB Restarts**

This statement preserves the open mode of the salespdb when the CDB restarts.

```
ALTER PLUGGABLE DATABASE salespdb SAVE STATE;
```

#### **Example 41-26 Discarding the Open Mode of a PDB When the CDB Restarts**

This statement discards the open mode of the salespdb when the CDB restarts.

```
ALTER PLUGGABLE DATABASE salespdb DISCARD STATE;
```

#### **Example 41-27 Preserving the Open Mode of All PDBs When the CDB Restarts**

This statement preserves the open mode of all of the PDBs when the CDB restarts.

```
ALTER PLUGGABLE DATABASE ALL SAVE STATE;
```

#### **Example 41-28 Preserving the Open Mode of Listed PDBs When the CDB Restarts**

This statement preserves the open mode of the salespdb and hrpdb when the CDB restarts.

```
ALTER PLUGGABLE DATABASE salespdb, hrpdb SAVE STATE;
```

### Example 41-29 Preserving the Open Mode of All PDBs Except for Listed Ones When the CDB Restarts

This statement preserves the open mode of all PDBs except for salespdb and hrpdb.

```
ALTER PLUGGABLE DATABASE ALL EXCEPT salespdb, hrpdb SAVE STATE;
```

## 41.5 Using the ALTER SYSTEM SET Statement in a CDB

The ALTER SYSTEM SET statement can dynamically set an initialization parameter in one or more containers in a CDB.

A CDB uses an inheritance model for initialization parameters in which PDBs inherit initialization parameter values from the root. In this case, inheritance means that the value of a particular parameter in the root applies to a particular PDB.

A PDB can override the root's setting for some parameters, which means that a PDB has an inheritance property for each initialization parameter that is either true or false. The inheritance property is true for a parameter when the PDB inherits the root's value for the parameter. The inheritance property is false for a parameter when the PDB does not inherit the root's value for the parameter.

The inheritance property for some parameters must be true. For other parameters, you can change the inheritance property by running the ALTER SYSTEM SET statement to set the parameter when the current container is the PDB. If `ISPDB_MODIFIABLE` is TRUE for an initialization parameter in the `V$SYSTEM_PARAMETER` view, then the inheritance property can be false for the parameter.

When the current container is the root, the `COUNTAINER` clause of the ALTER SYSTEM SET statement controls which PDBs inherit the parameter value being set. The `COUNTAINER` clause has the following syntax:

```
COUNTAINER = { CURRENT | ALL }
```

The following settings are possible:

- `CURRENT`, the default, means that the parameter setting applies only to the current container.

When the current container is the root, the parameter setting applies to the root and to any PDB with an inheritance property of true for the parameter.

- `ALL` means that the parameter setting applies to all containers in the CDB, including the root and all of the PDBs.

Specifying `ALL` sets the inheritance property to true for the parameter in all PDBs.

See "[About the Current Container](#)" for more information about the `COUNTAINER` clause and rules that apply to it.

#### To use ALTER SYSTEM SET in the root in a CDB:

1. In SQL\*Plus, ensure that the current container is the root.

The current user must have the commonly granted `ALTER SYSTEM` privilege.

[See "Accessing a Container in a CDB with SQL\\*Plus".](#)

2. Run the `ALTER SYSTEM SET` statement.

 **Note:**

If you want to change the inheritance property for a particular parameter in a particular PDB from false to true, then you can run the `ALTER SYSTEM RESET` statement to reset the parameter when the current container is the PDB. The following example resets the `OPEN_CURSORS` parameter:

```
ALTER SYSTEM RESET OPEN_CURSORS SCOPE = SPFILE;
```

**Example 41-30 Setting an Initialization Parameter for All Containers**

This `ALTER SYSTEM SET` statement sets the `OPEN_CURSORS` initialization parameter to 200 for the all containers and sets the inheritance property to TRUE in each PDB.

```
ALTER SYSTEM SET OPEN_CURSORS = 200 CONTAINER = ALL;
```

**Example 41-31 Setting an Initialization Parameter for the Root**

This `ALTER SYSTEM SET` statement sets the `OPEN_CURSORS` initialization parameter to 200 for the root and for PDBs with an inheritance property of true for the parameter.

```
ALTER SYSTEM SET OPEN_CURSORS = 200 CONTAINER = CURRENT;
```

 **See Also:**

- ["Using the ALTER SYSTEM Statement to Modify a PDB"](#)
- [Oracle Database SQL Language Reference](#) for more information about the `ALTER SYSTEM SET` statement

## 41.6 Issuing DML Statements on Containers in a CDB

A DML (data manipulation language) statement issued in a CDB root can modify one or more containers in the CDB. In addition, you can specify one or more default container targets for DML statements.

- [About Issuing DML Statements on Containers in a CDB](#)  
DML statements can affect database objects in more than one container in a CDB.
- [Specifying the Default Container for DML Statements in a CDB](#)  
To specify the default container for DML statements in a CDB, issue the `ALTER DATABASE` statement with the `CONTAINERS DEFAULT TARGET` clause.

### 41.6.1 About Issuing DML Statements on Containers in a CDB

DML statements can affect database objects in more than one container in a CDB.

In a CDB root or an application root, a single DML statement that includes the `CONTAINERS` clause can modify a table or view in one or more containers in that CDB or application container. To use the `CONTAINERS` clause, specify the table or view being

modified in the CONTAINERS clause and the containers affected in the WHERE clause. A target container can be specified in an INSERT VALUES statement by specifying a value for CON\_ID in the VALUES clause. Also, a target container can be specified in an UPDATE or DELETE statement by specifying a CON\_ID predicate in the WHERE clause.

For example, the following DML statement updates the sales.customers table in the containers with a CON\_ID of 7 or 8:

```
UPDATE CONTAINERS(sales.customers) ctab
 SET ctab.city_name='MIAMI'
 WHERE ctab.CON_ID IN(7,8) AND
 CUSTOMER_ID=3425;
```

The values specified for the CON\_ID in the WHERE clause must be for containers that are part of the CDB, including PDBs, application roots, and application PDBs.

You can also specify default target containers for DML operations. If a DML statement does not specify values for the CON\_ID in the WHERE clause, then the target containers of the DML operation are those specified in the database property CONTAINERS\_DEFAULT\_TARGET in the CDB root. When issued in a CDB root, the following DML statement modifies the default target containers for the CDB:

```
UPDATE CONTAINERS(sales.customers) ctab
 SET ctab.city_name='MIAMI'
 WHERE CUSTOMER_ID=3425;
```

A target container can be specified in an INSERT VALUES statement by specifying a value for CON\_ID in the VALUES clause. Also, a target container can be specified in an UPDATE or DELETE statement by specifying a CON\_ID predicate in the WHERE clause.

By default, the default target containers in a CDB include all of its PDBs, application roots, application seeds, and application PDBs, but not its CDB root or CDB seed. You can determine the default target containers for a CDB by running the following query:

```
SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE
PROPERTY_NAME='CONTAINERS_DEFAULT_TARGET';
```

The following restrictions apply to the CONTAINERS clause:

- INSERT AS SELECT statements where the target of the INSERT is in CONTAINERS() is not supported.
- A multi-table INSERT statement where the target of the INSERT is in CONTAINERS() is not supported.
- DML statements using the CONTAINERS clause require that the database listener is configured using TCP (instead of IPC) and that the PORT and HOST values are specified for each target PDB using the PORT and HOST clauses, respectively.

## 41.6.2 Specifying the Default Container for DML Statements in a CDB

To specify the default container for DML statements in a CDB, issue the `ALTER DATABASE` statement with the `CONTAINERS DEFAULT TARGET` clause.

When a DML statement is issued in a CDB root without specifying containers in the `WHERE` clause, the DML statement affects the default container for the CDB. The default container can be any container in the CDB, including the CDB root, a PDB, an application root, or an application PDB. Only one default container is allowed.

1. In SQL\*Plus, ensure that the current container is the CDB root.  
The current user must have the commonly granted `ALTER DATABASE` privilege.
2. Run the `ALTER DATABASE` statement with the `CONTAINERS DEFAULT TARGET` clause.

### Example 41-32 Specifying the Default Container for DML Statements in a CDB

This example specifies that `PDB1` is the default container for DML statements in the CDB.

```
ALTER DATABASE CONTAINERS DEFAULT TARGET = (PDB1);
```

### Example 41-33 Clearing the Default Container

This example clears the default container setting. When it is not set, the default container is the CDB root.

```
ALTER DATABASE CONTAINERS DEFAULT TARGET = NONE;
```

## 41.7 Executing DDL Statements in a CDB

In a CDB, you can execute a data definition language (DDL) statement in the current container or in all containers.

- [About Executing DDL Statements in a CDB](#)  
In a CDB, some DDL statements can apply to all containers or to the current container only.
- [Executing a DDL Statement in the Current Container](#)  
Specify `CURRENT` in the `CONTAINER` clause of a DDL statement to execute the statement in the current container.
- [Executing a DDL Statement in All Containers in a CDB](#)  
Specify `ALL` in the `CONTAINER` clause of a DDL statement to execute the statement in all of the containers in a CDB.

### 41.7.1 About Executing DDL Statements in a CDB

In a CDB, some DDL statements can apply to all containers or to the current container only.

To specify which containers are affected, use the `CONTAINER` clause:

```
CONTAINER = { CURRENT | ALL }
```

The following settings are possible:

- CURRENT means that the statement applies only to the current container.
- ALL means that the statement applies to all containers in the CDB, including the root and all of the PDBs.

The following restrictions apply to the CONTAINER clause in DDL statements:

- The restrictions described in "[About the Current Container](#)".
- You can use the CONTAINER clause only with the DDL statements listed in [Table 41-8](#).

**Table 41-8 DDL Statements and the CONTAINER Clause in a CDB**

| DDL Statement | CONTAINER = CURRENT                                                                                                                                                                                                                                                                                                                                                                                                                                           | CONTAINER = ALL                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE USER   | Creates a local user in the current PDB.                                                                                                                                                                                                                                                                                                                                                                                                                      | Creates a common user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ALTER USER    | Alters a local user in the current PDB.                                                                                                                                                                                                                                                                                                                                                                                                                       | Alters a common user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| CREATE ROLE   | Creates a local role in the current PDB.                                                                                                                                                                                                                                                                                                                                                                                                                      | Creates a common role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| GRANT         | Grants a privilege in the local container to a local user, common user, or local role.<br><br>The SET CONTAINER privilege can be granted to a user-created common user in the current PDB.                                                                                                                                                                                                                                                                    | Grants a system privilege or object privilege on a common object to a common user or common role. The specified privilege is granted to the user or role across the entire CDB.                                                                                                                                                                                                                                                                                                                                                                                         |
| REVOKE        | Revokes a privilege in the local container from a local user, common user, or local role.<br><br>This statement can revoke only a privilege granted with CURRENT specified in the CONTAINER clause from the specified user or role in the local container. The statement does not affect privileges granted with ALL specified in the CONTAINER clause.<br><br>The SET CONTAINER privilege can be revoked from a user-created common user in the current PDB. | Revokes a system privilege or object privilege on a common object from a common user or common role. The specified privilege is revoked from the user or role across the entire CDB.<br><br>This statement can revoke only a privilege granted with ALL specified in the CONTAINER clause from the specified common user or common role. The statement does not affect privileges granted with CURRENT specified in the CONTAINER clause. However, any privileges granted locally that depend on the privilege granted commonly that is being revoked are also revoked. |

All other DDL statements apply to the current container only.

In addition to the usual rules for user, role, and profile names, the following rules and best practices apply when you create a user, role, or profile in a CDB:

- It is best practice for common user, role, and profile names to start with a prefix to avoid naming conflicts between common users, roles, and profiles and local users, roles, and profiles. You specify this prefix with the COMMON\_USER\_PREFIX initialization parameter in the CDB root. By default, the prefix is C## or c## in the CDB root.
- In an application container, it is best practice for application common user, role, and profile names to start with a prefix to avoid naming conflicts between application common users, roles, and profiles and local users, roles, and profiles. You specify this prefix with the COMMON\_USER\_PREFIX initialization parameter in the application root. By default, the prefix is NULL in an application root.

- When the `COMMON_USER_PREFIX` initialization parameter is set in an application root, the setting applies to the application common user, role, and profile names in the application container. The prefix can be different in the CDB root and in an application root, and the prefix can be different in different application containers.
- Common user, role, and profile names must consist only of ASCII characters. This restriction does not apply to application common user, role, and profile names.
- Local user, role, and profile names cannot start with the prefix specified for common users with the `COMMON_USER_PREFIX` initialization parameter.
- Local user, role, and profile names cannot start with `C##` or `c##`.
- Regardless of the value of `COMMON_USER_PREFIX` in the CDB root, application common user, role, and profile names cannot start with `C##` or `c##`.
- Application common user, role, and profile names cannot start with the prefix specified for common users with the `COMMON_USER_PREFIX` initialization parameter.

### 41.7.2 Executing a DDL Statement in the Current Container

Specify `CURRENT` in the `CONTAINER` clause of a DDL statement to execute the statement in the current container.

The supported DDL statements are listed in [Table 41-8](#).

The current user must be granted the required privileges to execute the DDL statement in the current container. For example, to create a user, the current user must be granted the `CREATE USER` system privilege in the current container.

To execute a DDL statement in the current container:

1. In SQL\*Plus, access a container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Execute the DDL statement with `CONTAINER` set to `CURRENT`.

A local user's user name cannot start with the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, in the CDB root, the prefix is `C##` or `c##`. An application root can specify its own prefix for an application container. In addition, a common user's name must consist only of ASCII characters. The specified tablespace must exist in the PDB.

**Example 41-34 Creating Local User in a PDB**

This example creates the local user testpdb in the current PDB.

```
CREATE USER testpdb IDENTIFIED BY password
 DEFAULT TABLESPACE pdb1_tbs
 QUOTA UNLIMITED ON pdb1_tbs
 CONTAINER = CURRENT;
```

### 41.7.3 Executing a DDL Statement in All Containers in a CDB

Specify `ALL` in the `CONTAINER` clause of a DDL statement to execute the statement in all of the containers in a CDB.

The supported DDL statements are listed in [Table 41-8](#).

The following prerequisites must be met:

- The current user must be a common user.
- The current user must be granted the required privileges commonly to execute the DDL statement. For example, to create a user, the current user must be granted the `CREATE USER` system privilege commonly.

To execute a DDL statement in all containers in a CDB:

1. In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Execute the DDL statement with `CONTAINER` set to `ALL`.

A common user's user name must start with the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, in the CDB root, the prefix is `C##` or `c##`. An application root can specify its own prefix for an application container. In addition, a common user's name must consist only of ASCII characters. The specified tablespace must exist in the root and in all PDBs.

**Example 41-35 Creating Common User in a CDB**

This example creates the common user `c##testcdb`.

```
CREATE USER c##testcdb IDENTIFIED BY password
 DEFAULT TABLESPACE cdb_tbs
 QUOTA UNLIMITED ON cdb_tbs
 CONTAINER = ALL;
```

## 41.8 Managing the CDB Undo Mode

When local undo is enabled, each container has its own undo tablespace for every instance in which it is open. When local undo is disabled, there is one undo tablespace for the entire CDB.

- [About the CDB Undo Mode](#)  
You can configure a CDB to use local undo in every container or to use shared undo for the entire CDB.
- [Configuring a CDB to Use Local Undo Mode](#)  
When a CDB is in shared undo mode, you can change it to use local undo mode by issuing an `ALTER DATABASE LOCAL UNDO ON` statement and restarting the database.

- [Configuring a CDB to Use Shared Undo Mode](#)

When a CDB is in local undo mode, you can change it to use shared undo mode by issuing an `ALTER DATABASE LOCAL UNDO OFF` statement and restarting the database.

## 41.8.1 About the CDB Undo Mode

You can configure a CDB to use local undo in every container or to use shared undo for the entire CDB.

A CDB can run in local undo mode or shared undo mode. You can specify the undo mode of a CDB during CDB creation in the `ENABLE PLUGGABLE DATABASE` clause of the `CREATE DATABASE` statement. You can change the undo mode of a CDB after it is created by issuing an `ALTER DATABASE` statement and restarting the CDB. The undo mode applies to the entire CDB. Therefore, every container either uses shared undo or local undo.

To determine the current CDB undo mode, run the following query in the CDB root:

```
SELECT PROPERTY_NAME, PROPERTY_VALUE
 FROM DATABASE_PROPERTIES
 WHERE PROPERTY_NAME = 'LOCAL_UNDO_ENABLED';
```

If the query returns `TRUE` for the `PROPERTY_VALUE`, then the CDB is in local undo mode. Otherwise, the CDB is in shared undo mode.

### Local Undo Mode

Local undo mode means that each container has its own undo tablespace for every instance in which it is open. In this mode, Oracle Database automatically creates an undo tablespace for every container in the CDB. For an Oracle RAC CDB, there is one active undo tablespace for each instance for each PDB in local undo mode.

Local undo mode provides increased isolation for each container and improves the efficiency of some operations, such as unplugging the container or performing point-in-time recovery on the container. In addition, local undo mode is required for some operations to be supported, such as relocating a PDB or cloning a PDB that is in open read/write mode.

When a CDB is in local undo mode, the following applies:

- Any user who has the appropriate privileges for the current container can create an undo tablespace for the container.

See *Oracle Database SQL Language Reference* for information about the required privileges.

- Undo tablespaces are visible in static data dictionary views and dynamic performance (`V$`) views in every container in the CDB.

### Shared Undo Mode

Shared undo mode means that there is one active undo tablespace for a single-instance CDB. For an Oracle RAC CDB, there is one active undo tablespace for each instance.

When a CDB is in shared undo mode, the following applies:

- Only a common user who has the appropriate privileges and whose current container is the CDB root can create an undo tablespace.
- When the current container is not the CDB root, an attempt to create an undo tablespace fails and returns an error.
- Undo tablespaces are visible in static data dictionary views and dynamic performance (V\$) views when the current container is the CDB root. Undo tablespaces are visible only in dynamic performance views when the current container is a PDB, an application root, or an application PDB.

 **Note:**

- When you change the undo mode of a CDB, the new undo mode applies to an individual container the first time the container is opened after the change.
- When you change the undo mode of a CDB, containers in the CDB cannot flash back to a time or SCN that is prior to the change.

#### Related Topics

- [About Flashing Back a PDB](#)

You can use the `FLASHBACK PLUGGABLE DATABASE` statement to return a PDB to a past time or system change number (SCN).

### 41.8.2 Configuring a CDB to Use Local Undo Mode

When a CDB is in shared undo mode, you can change it to use local undo mode by issuing an `ALTER DATABASE LOCAL UNDO ON` statement and restarting the database.

When a CDB is in local undo mode, each container has its own undo tablespace for every instance in which it is open. Oracle Database automatically creates an undo tablespace in any container in the CDB that does not have one. If a PDB without an undo tablespace is cloned, relocated, or plugged into a CDB that is configured to use local undo mode, then Oracle Database automatically creates an undo tablespace for the PDB the first time it is opened.

When a CDB is changed from shared undo mode to local undo mode, Oracle Database creates the required undo tablespaces automatically.

1. Shut down the CDB instance if it is open.
2. Start up the CDB instance in `OPEN UPGRADE` mode. For example:  
`STARTUP UPGRADE`
3. In SQL\*Plus, ensure that the current container is the CDB root. For example, enter the following:

```
SHOW CON_NAME
```

```
CON_NAME
```

```

```

```
CDB$ROOT
```

4. Issue the following SQL statement:

```
ALTER DATABASE LOCAL UNDO ON;
```

5. Shut down and restart the CDB instance.

6. Optional: Manually create an undo tablespace in the CDB seed.

While Oracle Database creates an undo tablespace in the CDB seed automatically in local undo mode, you might want to control the size and configuration of the undo tablespace by creating an undo tablespace manually. To ensure the PDBs created from the CDB seed use the manually-created undo tablespace and not the automatically-created undo tablespace, you must set the `UNDO_TABLESPACE` initialization parameter to the manually-created undo tablespace, or drop the automatically-created undo tablespace.

- a. In SQL\*Plus, ensure that the current container is the root.

- b. Place the CDB seed in open read/write mode:

```
ALTER PLUGGABLE DATABASE PDB$SEED OPEN READ WRITE FORCE;
```

- c. Switch container to the CDB seed:

```
ALTER SESSION SET CONTAINER=PDB$SEED;
```

- d. Create an undo tablespace in the CDB seed. For example:

```
CREATE UNDO TABLESPACE seedundots1
 DATAFILE 'seedundotbs_1a.dbf'
 SIZE 10M AUTOEXTEND ON
 RETENTION GUARANTEE;
```

- e. Switch container to the root:

```
ALTER SESSION SET CONTAINER=CDB$ROOT;
```

- f. Place the CDB seed in open read-only mode:

```
ALTER PLUGGABLE DATABASE PDB$SEED OPEN READ ONLY FORCE;
```

### 41.8.3 Configuring a CDB to Use Shared Undo Mode

When a CDB is in local undo mode, you can change it to use shared undo mode by issuing an `ALTER DATABASE LOCAL UNDO OFF` statement and restarting the database.

1. Shut down the CDB instance if it is open.

2. Start up the CDB instance in `OPEN UPGRADE` mode. For example:

```
STARTUP UPGRADE
```

3. In SQL\*Plus, ensure that the current container is the CDB root. For example, enter the following:

```
SHOW CON_NAME
```

```
CON_NAME
```

```

```

```
CDB$ROOT
```

4. Issue the following SQL statement:

```
ALTER DATABASE LOCAL UNDO OFF;

5. Shut down and restart the CDB instance.
```

When it is in shared undo mode, the CDB ignores any local undo tablespaces that were created when it was in local undo mode. Oracle recommends that you delete these local undo tablespaces.

## 41.9 Running Oracle-Supplied SQL Scripts in a CDB

You can use the catcon.pl script to run Oracle-supplied SQL scripts in a CDB.

- [About Running Oracle-Supplied SQL Scripts in a CDB](#)  
In a CDB, the catcon.pl script is the best way to run SQL scripts and SQL statements.
- [Syntax and Parameters for catcon.pl](#)  
The catcon.pl script is a Perl script that must be run at an operating system prompt.
- [Running the catcon.pl Script](#)  
Examples illustrate running the catcon.pl script.

### 41.9.1 About Running Oracle-Supplied SQL Scripts in a CDB

In a CDB, the catcon.pl script is the best way to run SQL scripts and SQL statements.

An Oracle Database installation includes several SQL scripts. These scripts perform operations such as creating data dictionary views and installing options.

The catcon.pl script can run scripts in the root and in specified PDBs in the correct order, and it generates log files that you can view to confirm that the SQL script or SQL statement did not generate unexpected errors. It also starts multiple processes and assigns new scripts to them as they finish running scripts previously assigned to them.

 **Note:**

- Unless you exclude the CDB seed when you run catcon.pl, the SQL script or SQL statement is run on the CDB seed.
- You can use the catcon.pl script to run scripts on both CDBs and non-CDBs.

### 41.9.2 Syntax and Parameters for catcon.pl

The catcon.pl script is a Perl script that must be run at an operating system prompt.

The catcon.pl script has the following syntax and parameters:

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl
[--usr username[/password]] [--int_usr username[/password]] [--script_dir directory]
[--log_dir directory] [{--incl_con|--excl_con} container] [--echo] [--spool]
[--error_logging { ON | errorlogging-table-other-than-SPERRORLOG }] [--app_con
application_root]
```

```
[--no_set_errlog_ident] [--diag] [-ignore_unavailable_pdbs] [--verbose] [--force_pdb_mode pdb_mode]
[--recover] --log_file_base log_file_name_base
-- { SQL_script [arguments] | --x'SQL_statement' }
```

Ensure that `--xSQL_statement` is preceded by `--` if it follows any single-letter parameter. If `--xSQL_statement` is preceded by a script name or another `--xSQL_statement`, then do not precede it with `--`. Also, note that the SQL statement must be inside single quotation marks.

Command line parameters to SQL scripts can be introduced using `--p`. Interactive (or secret) parameters to SQL scripts can be introduced using `--P`.

To view the help for the `catcon.pl` script, run the following command:

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl --help
```

**Table 41-9** describes the `catcon.pl` parameters. A parameter is optional unless it is indicated that it is required.

The short parameter names in the following table are for backward compatibility. Some parameters do not have short names.

**Table 41-9 catcon.pl Parameters**

| Parameter                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--usr</code><br>Short name: <code>-u</code>                         | Specifies the username and password to connect to the root and the specified PDBs. Specify a common user with the required privileges to run the SQL script or the SQL statement. The default is <code>/ AS SYSDBA</code> . If no password is supplied, then <code>catcon.pl</code> prompts for a password.                                                                                                                                                                                                                                                                 |
| <code>--int_usr</code><br>Short name: <code>-U</code>                     | Specifies the username and password to connect to the root and the specified PDBs. Specify a common user with the required privileges to perform internal tasks, such as running queries on the CDB's metadata. The default is <code>/ AS SYSDBA</code> . If no password is supplied, then <code>catcon.pl</code> prompts for a password.                                                                                                                                                                                                                                   |
| <code>--script_dir</code><br>Short name: <code>-d</code>                  | Directory that contains the SQL script. The default is the current directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>--log_dir</code><br>Short name: <code>-l</code>                     | Directory into which <code>catcon.pl</code> writes log files. The default is the current directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>{--incl_con --excl_con}</code><br>Short names: <code>{-c -C}</code> | <p>The containers in which the SQL script is run or is not run.</p> <p>The <code>--incl_con</code> parameter lists the containers in which the SQL script is run.</p> <p>The <code>--excl_con</code> parameter lists the containers in which the SQL script is not run.</p> <p>Specify containers in a space-delimited list of PDB names enclosed in single quotation marks.</p> <p>The <code>--incl_con</code> and <code>--excl_con</code> parameters are mutually exclusive.</p> <p>When this parameter is used, the <code>--app_con</code> parameter cannot be used.</p> |

**Table 41-9 (Cont.) catcon.pl Parameters**

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --echo<br>Short name: -e                    | Sets echo ON while running the script. The default is echo OFF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| --spool<br>Short name: -s                   | Spools the output of every script into a file with the following name:<br><br><i>log-file-name-base_script-name-without-extension_[container-name-if-any].default-extension</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| --error_logging<br>Short name: -E           | When set to ON, the default error logging table is used. ON is the default setting. When set to ON, errors are written to the table SPERRORLOG in the current schema in each container in which the SQL script runs. If this table does not exist in a container, then it is created automatically.<br><br>When a table other than SPERRORLOG is specified, errors are written to the specified table. The table must exist in each container in which the SQL script runs, and the current user must have the necessary privileges to perform DML operations on the table in each of these containers.<br><br>See <i>SQL*Plus User's Guide and Reference</i> for more information about the error logging table. |
| --app_con<br>Short name: -F                 | Specify an application root. The scripts are run in the application root and in the application PDBs that are plugged into the application root.<br><br>When this parameter is used, the --incl_con and --excl_con parameters cannot be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| --no_set_errlog_ident<br>Short name: -I     | Do not issue a SET ERRORLOGGING identifier. This option is intended for cases in which the SET ERRORLOGGING identifier is already set and should not be overwritten.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| --diag<br>Short name: -g                    | Turns on the generation of debugging information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| --verbose<br>Short name: -v                 | Turns on verbose output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --ignore_unavailable_pdbs<br>Short name: -f | Ignore PDBs that are closed or, if the --incl_con or --excl_con option is used, do not exist and process only open PDBs that were specified explicitly or implicitly.<br><br>When this option is not specified and some specified PDBs do not exist or are not open, an error is returned and none of the containers are processed.                                                                                                                                                                                                                                                                                                                                                                               |

**Table 41-9 (Cont.) catcon.pl Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --force_pdb_mode | The required open mode for all PDBs against which the scripts are run. Specify one of the following values: <ul style="list-style-type: none"> <li>• UNCHANGED</li> <li>• READ WRITE</li> <li>• READ ONLY</li> <li>• UPGRADE</li> <li>• DOWNGRADE</li> </ul>                                                                |
|                  | When a value other than UNCHANGED is specified, all of the PDBs against which the script is run are changed to the specified open mode. If a PDB is open in a different mode, then the PDB is closed and re-opened in the specified mode. After all of the scripts are run, each PDB is restored to its original open mode. |
|                  | When UNCHANGED, the default, is specified, the open mode of the PDBs is not changed.                                                                                                                                                                                                                                        |
| --recover        | Causes catcon.pl to attempt to recover if a SQL*Plus process that it spawned ends unexpectedly. When this parameter is not specified, catcon.pl does not attempt to recover the process and closes.                                                                                                                         |
| Short name: -R   |                                                                                                                                                                                                                                                                                                                             |
| --log_file_base  | (Required) The base name for log file names.                                                                                                                                                                                                                                                                                |
| Short name: -b   |                                                                                                                                                                                                                                                                                                                             |

### 41.9.3 Running the catcon.pl Script

Examples illustrate running the catcon.pl script.

If a SQL script or SQL statement run by catcon.pl performs data manipulation language (DML) or data definition language (DDL) operations, then the containers being modified must be in read/write mode. See "[Modifying the Open Mode of PDBs](#)".

To run the catcon.pl script:

1. Open a command line prompt.
2. Run the catcon.pl script and specify one or more SQL scripts or SQL statements:

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl parameters
SQL_script
```

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl parameters -- --
xSQL_statement
```

#### Examples That Run the catcon.pl Script

The following examples run the catcon.pl script.

##### Example 41-36 Running the catblock.sql Script in All Containers in a CDB

This example runs the catblock.sql script in all of the containers of a CDB.

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl --usr SYS
--script_dir $ORACLE_HOME/rdbms/admin --log_file_base catblock_output catblock.sql
```

The following parameters are specified:

- The --usr parameter specifies that SYS user runs the script in each container.
- The --script\_dir parameter specifies that the SQL script is in the \$ORACLE\_HOME/rdbms/admin directory.
- The --log\_file\_base parameter specifies that the base name for log file names is catblock\_output.

Default parameter values are used for all other parameters. Neither the --incl\_con nor the --excl\_con parameter is specified. Therefore, catcon.pl runs the script in all containers by default.

#### Example 41-37 Running the catblock.sql Script in Specific PDBs

This example runs the catblock.sql script in the hrpdb and salespdb PDBs in a CDB.

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl --usr SYS --int_usr
SYS
--script_dir $ORACLE_HOME/rdbms/admin --log_dir '/disk1/script_output' --incl_con
'HRPDB SALESPDB'
--log_file_base catblock_output catblock.sql
```

The following parameters are specified:

- The --usr parameter specifies that SYS user runs the script in each container.
- The --int\_usr parameter specifies that SYS user performs internal tasks.
- The --script\_dir parameter specifies that the SQL script is in the \$ORACLE\_HOME/rdbms/admin directory.
- The --log\_dir parameter specifies that the output files are placed in the /disk1/script\_output directory.
- The --incl\_con parameter specifies that the SQL script is run in the hrpdb and salespdb PDBs. The script is not run in any other containers in the CDB.
- The --log\_file\_base parameter specifies that the base name for log file names is catblock\_output.

#### Example 41-38 Running the catblock.sql Script in All Containers Except for Specific PDBs

This example runs the catblock.sql script in all of the containers in a CDB except for the hrpdb and salespdb PDBs.

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl --usr SYS
--script_dir $ORACLE_HOME/rdbms/admin --log_dir '/disk1/script_output' --excl_con
'HRPDB SALESPDB'
--log_file_base catblock_output catblock.sql
```

The following parameters are specified:

- The --usr parameter specifies that SYS user runs the script in each container.
- The --script\_dir parameter specifies that the SQL script is in the \$ORACLE\_HOME/rdbms/admin directory.
- The --log\_dir parameter specifies that the output files are placed in the /disk1/script\_output directory.

- The `--excl_con` parameter specifies that the SQL script is run in all of the containers in the CDB except for the `hrpdb` and `salespdb` PDBs.
- The `--log_file_base` parameter specifies that the base name for log file names is `catblock_output`.

#### **Example 41-39 Running a SQL Script with Command Line Parameters**

This example runs the `custom_script.sql` script in all of the containers of a CDB.

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl --usr SYS
--script_dir /u01/scripts --log_file_base custom_script_output custom_script.sql
'--phr' '--PEnter password for user hr:'
```

The following parameters are specified:

- The `--usr` parameter specifies that `SYS` user runs the script in each container.
- The `--script_dir` parameter specifies that the SQL script is in the `/u01/scripts` directory.
- The `--log_file_base` parameter specifies that the base name for log file names is `custom_script_output`.
- The `--p` parameter specifies `hr` for a command line parameter
- The `--p` parameter specifies an interactive parameter that prompts for the password of user `hr`.

Default parameter values are used for all other parameters. Neither the `-incl_con` nor the `-excl_con` parameter is specified. Therefore, `catcon.pl` runs the script in all containers by default.

#### **Example 41-40 Running a SQL Statement in All Containers in a CDB**

This example runs a SQL statement in all of the containers of a CDB.

```
$ORACLE_HOME/perl/bin/perl $ORACLE_HOME/rdbms/admin/catcon.pl --usr SYS --echo
--log_file_base select_output -- --x"SELECT * FROM DUAL"
```

The following parameters are specified:

- The `--usr` parameter specifies that `SYS` user runs the script in each container.
- The `--echo` parameter shows output for the SQL statement.
- The `--log_file_base` parameter specifies that the base name for log file names is `select_output`.
- The SQL statement `SELECT * FROM DUAL` is inside quotation marks and is preceded by `--x`. Because `--x` is preceded by a parameter (`--log_file_base`), it must be preceded by `--`.

Default parameter values are used for all other parameters. Neither the `-incl_con` nor the `-excl_con` parameter is specified. Therefore, `catcon.pl` runs the SQL statement in all containers by default.

## 41.10 Shutting Down a CDB Instance

You can shut down a CDB instance in the same way that you shut down a non-CDB instance.

The following prerequisites must be met:

- The CDB instance must be mounted or open.
- The current user must be a common user with SYSDBA, SYSOPER, SYSBACKUP, or SYSDG administrative privilege. To shut down a CDB, you must exercise this privilege using AS SYSDBA, AS SYSOPER, AS SYSBACKUP, or AS SYSDG, respectively, at connect time.

**To shut down a CDB:**

1. In SQL\*Plus, ensure that the current container is the root.

See "[Connecting to a Container Using the SQL\\*Plus CONNECT Command](#)".

2. Shut down the CDB instance.

["Shutting Down a Database"](#)

# Administering CDBs and PDBs with Cloud Control

You can administer CDBs and PDBs with Oracle Enterprise Manager Cloud Control.

- [Administering CDB Storage and Schema Objects with Cloud Control](#)  
You can administer CDB storage and schema objects with Oracle Enterprise Manager Cloud Control.
- [Administering PDBs with Cloud Control](#)  
You can use Oracle Enterprise Manager Cloud Control to switch between PDBs and alter the open mode of a PDB.

## See Also:

["About Administering a CDB"](#)

## 42.1 Administering CDB Storage and Schema Objects with Cloud Control

You can administer CDB storage and schema objects with Oracle Enterprise Manager Cloud Control.

- [About Managing and Monitoring CDB Storage and Schema Objects](#)  
You can use Enterprise Manager to manage and monitor CDB storage and schema objects.
- [Managing CDB Storage and Schema Objects](#)  
You can manage CDB storage and schema objects with Oracle Enterprise Manager Cloud Control.
- [Managing Per-Container Storage and Schema Objects](#)  
You can manager per-container storage and schema objects with Oracle Enterprise Manager Cloud Control.
- [Monitoring Storage and Schema Alerts](#)  
You can monitor storage and schema alerts with Oracle Enterprise Manager Cloud Control.

### 42.1.1 About Managing and Monitoring CDB Storage and Schema Objects

You can use Enterprise Manager to manage and monitor CDB storage and schema objects.

With Enterprise Manager you can:

- View database storage objects, such as tablespaces, and schema objects, such as tables, across the CDB. You can also view objects belonging to the CDB\$ROOT container.
- View and manage database storage and schema objects at the container level.
- Use storage metrics to gather data across the CDB and generate Enterprise Manager incidents (alerts) at the container level.
- Run Storage and Undo Advisors for the CDB and view related storage advice.
- Support configuration metric collection for CDB/PDB.

The Database Object Search pages are displayed when you select certain menu items from either the Schema or Administration menus. These pages conduct searches for database objects based on criteria you enter, such as schema name, object name, or container name, which is only available if you are viewing from the CDB level. The Database Object Search page features are supported at both the CDB level and PDB level. The Container column displays on the Search page at both the CDB level and container level.

Undo tablespaces can only be managed from the CDB\$ROOT container.

## 42.1.2 Managing CDB Storage and Schema Objects

You can manage CDB storage and schema objects with Oracle Enterprise Manager Cloud Control.

To manage CDB storage and schema objects, follow these steps:

1. Navigate to the CDB database home page.
2. From the CDB menu, access a feature supporting the CDB level view, such as accessing the Tablespaces Search page.
3. Log in as a common user. The Tablespaces Search page displays in the CDB context.
4. Perform a search. In the above example, the Tablespace page displays all tablespaces within the CDB including those belonging to the CDB\$ROOT container. An additional column displays the container name.
5. Perform any management feature if you have the proper privilege associated with that operation.

## 42.1.3 Managing Per-Container Storage and Schema Objects

You can manager per-container storage and schema objects with Oracle Enterprise Manager Cloud Control.

To manage per-container storage and schema objects, follow these steps:

1. Navigate to a CDB target.
2. From the Administration menu, select Storage, then, select Tablespaces.
3. Log in as a common user. The Tablespaces Search page is displayed using CDB as its context.

4. Switch to a specific container. Once context switcher is used to switch containers, the pages automatically refresh and show container-only data.
5. Perform a search. The Tablespace page displays all tablespaces within the selected container.
6. You can perform any management feature for which you have the proper privilege associated with that operation.

#### 42.1.4 Monitoring Storage and Schema Alerts

You can monitor storage and schema alerts with Oracle Enterprise Manager Cloud Control.

To monitor storage and schema alerts, follow these steps:

1. Navigate to a Pluggable Database target.
2. From the Oracle Database menu, select **Monitoring**, then select **Incident Manager**.

Open incidents for Storage and Schema area metrics are displayed. The container name is part of the incident message.

### 42.2 Administering PDBs with Cloud Control

You can use Oracle Enterprise Manager Cloud Control to switch between PDBs and alter the open mode of a PDB.

- [Switching Between PDBs](#)

If you are performing a task such as granting user privileges or performance reporting, and you need to perform the same task on another PDB, then you can use Oracle Enterprise Manager Cloud Control to switch to another PDB.

- [Altering the Open Mode of a PDB](#)

You can change the open mode of a PDB with Oracle Enterprise Manager Cloud Control.

#### 42.2.1 Switching Between PDBs

If you are performing a task such as granting user privileges or performance reporting, and you need to perform the same task on another PDB, then you can use Oracle Enterprise Manager Cloud Control to switch to another PDB.

To switch between PDBs while staying on the same feature page:

1. From the current PDB, select any PDB scope page (such as, Manage Advanced Queues).

In the upper-left corner of the window, the name of the PDB will update to display a context switcher as a drop-down menu.

2. Click the context switcher to display the drop-down menu. This menu shows the PDBs most recently used.

Select a PDB from this list.

3. The page will update to show the System Queues.

4. Click the context switcher to display the drop-down menu. If the menu does not show the PDBs you want, then select **All Containers**.
5. A Switch Container window will pop up to display all available PDBs for the monitored target.  
Select a PDB from this list and click **OK**.
6. The page will update to show data for the selected PDB.

## 42.2.2 Altering the Open Mode of a PDB

You can change the open mode of a PDB with Oracle Enterprise Manager Cloud Control.

To change the open mode of a single-instance PDB to Open or Close:

1. From the **Oracle Database** menu, select **Control**, then select **Open/Close Pluggable Database**.
2. From the Open/Close Pluggable Database page, select a PDB from the list.
3. Click on **Open**, **Open Read Only**, or **Close**.
4. In the Confirmation dialog window, click **Yes** to complete the change. A Processing dialog window appears to show you the progress of your choice.
5. Once the open mode change completes, the Open/Close PDB page will update to show the new open mode of the PDB.

To change the open mode of a PDB in a Cluster/RAC to Open or Close:

1. From the **Oracle Database** menu, select **Control**, then **Open/Close Pluggable Database**.
2. From the Open/Close Pluggable Database page, select a PDB from the list. The RAC instances are shown along with the PDB's current open mode on those instances.
3. Once you select a PDB, a panel appears below the list to show the open mode of the PDBs on the different RAC instances. The open and close options apply to the PDBs on the RAC instance's panel. You can open or close a PDB on any number of available RAC instances.
4. In the Confirmation dialog window, click **Yes** to complete the change. A Processing dialog window appears to show you the progress of your choice.
5. Once the open mode change completes, the Open/Close Pluggable Database page will update to show the new open mode of the PDB.

# Administering PDBs with SQL\*Plus

Administering PDBs with SQL\*Plus includes tasks such as connecting to a PDB, modifying a PDB, and managing services associated with PDBs.

 **Note:**

You can complete the tasks in this chapter using SQL\*Plus or Oracle SQL Developer.

- [About Administering PDBs](#)

Administering a pluggable database (PDB) involves a subset of the tasks required to administer a non-CDB.

- [Connecting to a PDB with SQL\\*Plus](#)

You can use several techniques to connect to a PDB with the SQL\*Plus CONNECT command.

- [Modifying a PDB](#)

You can modify a PDB using the ALTER PLUGGABLE DATABASE statement and with the SQL\*Plus STARTUP and SHUTDOWN commands.

- [Using the ALTER SYSTEM Statement to Modify a PDB](#)

You can use the ALTER SYSTEM statement to modify a PDB.

- [Managing Services Associated with PDBs](#)

You can create, modify, or remove services for a PDB.

- [Refreshing a PDB](#)

You can refresh a PDB that was created as a refreshable clone.

- [Modifying the Listener Settings of a Referenced PDB](#)

A PDB that is referenced by a proxy PDB is called a referenced PDB. When the port or host name changes for the listener of the referenced PDB, you must modify the listener settings of the referenced PDB so that its proxy PDBs continue to function properly.

## Related Topics

- [Tools for a Multitenant Environment](#)

You can use various tools to configure and administer a multitenant environment.

## 43.1 About Administering PDBs

Administering a pluggable database (PDB) involves a subset of the tasks required to administer a non-CDB.

In this subset of tasks, most are the same for a PDB and a non-CDB, but there are some differences. For example, there are differences when you modify the open mode of a PDB. Also, a PDB administrator is limited to managing a single PDB and cannot affect other PDBs in the multitenant container database (CDB).

Other administrative tasks are the same for a PDB and a non-CDB. [Table 43-1](#) describes some of these tasks.

**Table 43-1 Administrative Tasks Common to PDBs and Non-CDBs**

| Task                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Additional Information                                                                                                                                                                 |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Managing tablespaces               | You can create, modify, and drop tablespaces for a PDB. You can specify a default tablespace and default tablespace type for each PDB. Also, there is a default temporary tablespace for each PDB. You optionally can create additional temporary tablespaces for use by individual PDBs.                                                                                                                                                                                                                                                                  | " <a href="#">Managing Tablespaces</a> "<br>" <a href="#">Modifying a PDB</a> "                                                                                                        |
| Managing data files and temp files | Each PDB has its own data files. You can manage data files and temp files in the same way that you would manage them for a non-CDB. You can also limit the amount of storage used by the data files for a PDB by using the STORAGE clause in a CREATE PLUGGABLE DATABASE or ALTER PLUGGABLE DATABASE statement.                                                                                                                                                                                                                                            | " <a href="#">Managing Data Files and Temp Files</a> "<br>" <a href="#">Storage Limits</a> "<br>" <a href="#">Modifying a PDB</a> "                                                    |
| Managing schema objects            | You can create, modify, and drop schema objects in a PDB in the same way that you would in a non-CDB. You can also create triggers that fire for a specific PDB. When you manage database links in a CDB, the root has a unique global database name, and so does each PDB. The global name of the root is defined by the DB_NAME and DB_DOMAIN initialization parameters. The global database name of a PDB is defined by the PDB name and the DB_DOMAIN initialization parameter. The global database name of each PDB must be unique within the domain. | " <a href="#">Schema Objects</a> "<br><i>Oracle Database PL/SQL Language Reference</i> for information about creating triggers in a CDB<br>" <a href="#">Creating Database Links</a> " |

When you are administering a PDB, you can modify the PDB with an `ALTER DATABASE`, `ALTER PLUGGABLE DATABASE`, or `ALTER SYSTEM` statement. You can also execute DDL statements on the PDB.

It is also important to understand which administrative tasks cannot be performed when the current container is a PDB. The following are some administrative tasks that are performed by a common user for the entire CDB or for the root when the current container is the root:

- Starting up and shutting down a CDB instance
- Modifying the CDB or the root with an `ALTER DATABASE` statement
- Modifying the CDB or the root with an `ALTER SYSTEM` statement
- Executing data definition language (DDL) statements on a CDB or the root
- Managing the following components:
  - Processes
  - Memory
  - Errors and alerts
  - Diagnostic data
  - Control files

- The online redo log and the archived redo log files
- Undo
- Creating, plugging in, unplugging, and dropping PDBs

A common user whose current container is the root can also change the open mode of one or more PDBs. See [Administering a CDB with SQL\\*Plus](#) for more information about this task and other tasks related to administering a CDB or the root.

A common user or local user whose current container is a PDB can change the open mode of the current PDB. See "[Modifying a PDB](#)" for more information about this task.

 **See Also:**

["About the Current Container"](#)

## 43.2 Connecting to a PDB with SQL\*Plus

You can use several techniques to connect to a PDB with the SQL\*Plus CONNECT command.

This section assumes that you understand how to connect to a non-CDB in SQL\*Plus. See "[Connecting to the Database with SQL\\*Plus](#)" for information.

You can use the following techniques to connect to a PDB with the SQL\*Plus CONNECT command:

- Local connection with operating system authentication
- Database connection using easy connect
- Database connection using a net service name

The following prerequisites must be met:

- The user connecting to the PDB must be granted the CREATE SESSION privilege in the PDB.
- To connect to a PDB as a user that does not have SYSDBA, SYSOPER, SYSBACKUP, or SYSDG administrative privilege, the PDB must be open. See "[Modifying the Open Mode of PDBs](#)" and "[Modifying a PDB](#)" for information about changing the open mode of a PDB.

 **Note:**

This section assumes that the user connecting to the PDB is a local user. You can also connect to the PDB as a common user, and you can connect to the root as a common user and switch to the PDB.

To connect to a PDB using the SQL\*Plus CONNECT command:

1. Configure your environment so that you can open SQL\*Plus.

See "[Connecting to the Database with SQL\\*Plus](#)".

2. Start SQL\*Plus with the `/NLOG` argument:

```
sqlplus /nolog
```

3. Issue a `CONNECT` command using easy connect or a net service name to connect to the PDB.

To connect to a PDB, connect to a service with a `PDB` property.

#### **Example 43-1 Connecting to a PDB in SQL\*Plus Using the PDB's Net Service Name**

The following command connects to the `hr` user using the `hrapp` service. The `hrapp` service has a `PDB` property for the `hrpdb` PDB. This example assumes that the client is configured to have a net service name for the `hrapp` service.

```
CONNECT hr@hrapp
```

See "[Step 4: Submit the SQL\\*Plus CONNECT Command](#)" for more examples.

#### **See Also:**

- "[Accessing a Container in a CDB with SQL\\*Plus](#)" for information about connecting to a PDB as a common user
- "[Managing Services Associated with PDBs](#)"

## 43.3 Modifying a PDB

You can modify a PDB using the `ALTER PLUGGABLE DATABASE` statement and with the SQL\*Plus `STARTUP` and `SHUTDOWN` commands.

- [Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement](#)  
You can modify a PDB with the `ALTER PLUGGABLE DATABASE` SQL statement.
- [Modifying a PDB with the SQL\\*Plus STARTUP and SHUTDOWN Commands](#)  
When the current container is a PDB, you can use the SQL\*Plus `STARTUP` command to open the PDB and the SQL\*Plus `SHUTDOWN` command to close the PDB.

### 43.3.1 Modifying a PDB with the `ALTER PLUGGABLE DATABASE` Statement

You can modify a PDB with the `ALTER PLUGGABLE DATABASE` SQL statement.

- [About Modifying a PDB with the `ALTER PLUGGABLE DATABASE` Statement](#)  
An `ALTER PLUGGABLE DATABASE` statement can modify a PDB.
- [Modifying a PDB with the `ALTER PLUGGABLE DATABASE` Statement](#)  
You can use the `ALTER PLUGGABLE DATABASE` statement to modify the attributes of a single PDB.

- [Changing the Global Database Name of a PDB](#)

You can change the global database name of a PDB with the `ALTER PLUGGABLE DATABASE RENAME GLOBAL_NAME TO` statement.

### 43.3.1.1 About Modifying a PDB with the `ALTER PLUGGABLE DATABASE` Statement

An `ALTER PLUGGABLE DATABASE` statement can modify a PDB.

When the current container is a PDB, an `ALTER PLUGGABLE DATABASE` statement with any of the following clauses modifies the PDB:

- *database\_file\_clauses*

These clauses work the same as they would in an `ALTER DATABASE` statement, but the statement applies to the current PDB.

- *set\_time\_zone\_clause*

This clause works the same as it would in an `ALTER DATABASE` statement, but it applies to the current PDB.

- `DEFAULT TABLESPACE` clause

For users created while the current container is a PDB, this clause specifies the default tablespace for the user if the default tablespace is not specified in the `CREATE USER` statement.

- `DEFAULT TEMPORARY TABLESPACE` clause

For users created while the current container is a PDB, this clause specifies the default temporary tablespace for the user if the default temporary tablespace is not specified in the `CREATE USER` statement.

- `RENAME GLOBAL_NAME` clause

This clause changes the unique global database name for the PDB. The new global database name must be different from that of any container in the CDB. When you change the global database name of a PDB, the PDB name is changed to the name before the first period in the global database name.

You must change the `PDB` property of database services used to connect to the PDB when you change the global database name. See "[Managing Services Associated with PDBs](#)".

- `SET DEFAULT { BIGFILE | SMALLFILE } TABLESPACE` clause

This clause changes the default type of subsequently created tablespaces in the PDB to either bigfile or smallfile. This clause works the same as it would in an `ALTER DATABASE` statement, but it applies to the current PDB.

- `DEFAULT EDITION` clause

This clause works the same as it would in an `ALTER DATABASE` statement, but it applies to the current PDB. Each PDB can use edition-based redefinition, and editions in one PDB do not affect editions in other PDBs. In a multitenant environment in which each PDB has its own application, you can use edition-based redefinition independently for each distinct application.

- *pdb\_storage\_clause*

This clause sets a limit on the amount of storage used by all tablespaces that belong to a PDB. This limit applies to the total size of all data files and temp files comprising tablespaces that belong to the PDB.

This clause can also set a limit on the amount of storage that can be used by unified audit OS spillover (.bin format) files in the PDB. If the limit is reached, then no additional storage is available for these files.

This clause can also set a limit on the amount of storage in a shared temporary tablespace that can be used by sessions connected to the PDB. If the limit is reached, then no additional storage in the shared temporary tablespace is available to sessions connected to the PDB.

- *pdb\_change\_state\_clause*

This clause changes the open mode of the current PDB.

If you specify the optional RESTRICTED keyword, then the PDB is accessible only to users with the RESTRICTED SESSION privilege in the PDB.

Specifying FORCE in this clause changes semantics of the ALTER PLUGGABLE DATABASE statement so that, in addition to opening a PDB that is currently closed, it can be used to change the open mode of a PDB that is already open.

See "["Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE"](#)".

- *logging\_clause*

 **Note:**

This clause is available starting with Oracle Database 12c Release 1 (12.1.0.2).

This clause specifies the logging attribute of the PDB. The logging attribute controls whether certain DML operations are logged in the redo log file (`LOGGING`) or not (`NOLOGGING`).

You can use this clause to specify one of the following attributes:

- `LOGGING` indicates that any future tablespaces created within the PDB will be created with the `LOGGING` attribute by default. You can override this default logging attribute by specifying `NOLOGGING` at the schema object level, in a `CREATE TABLE` statement for example.
- `NOLOGGING` indicates that any future tablespaces created within the PDB will be created with the `NOLOGGING` attribute by default. You can override this default logging attribute by specifying `LOGGING` at the schema object level, in a `CREATE TABLE` statement for example.

The specified attribute is used to establish the logging attribute of tablespaces created within the PDB if the *logging\_clause* is not specified in the `CREATE TABLESPACE` statement.

The `DBA_PDBS` view shows the current logging attribute for a PDB.

 **Note:**

The PDB must be open in restricted mode to use this clause.

 **See Also:**

- ["Controlling the Writing of Redo Records"](#)
- *Oracle Database SQL Language Reference* for more information about the logging attribute

- `pdb_force_logging_clause`

 **Note:**

This clause is available starting with Oracle Database 12c Release 1 (12.1.0.2).

This clause places a PDB into force logging or force nologging mode or takes a PDB out of force logging or force nologging mode.

You can use this clause to specify one of the following attributes:

- `ENABLE FORCE LOGGING` places the PDB in force logging mode, which causes all changes in the PDB, except changes in temporary tablespaces and temporary segments, to be logged. Force logging mode cannot be overridden at the schema object level.  
  
PDB-level force logging mode takes precedence over and is independent of any `NOLOGGING` or `FORCE LOGGING` settings you specify for individual tablespaces in the PDB and any `NOLOGGING` settings you specify for individual database objects in the PDB.  
  
`ENABLE FORCE LOGGING` cannot be specified if a PDB is in force nologging mode. `DISABLE FORCE NOLOGGING` must be specified first.
- `DISABLE FORCE LOGGING` takes a PDB which is currently in force logging mode out of that mode. If the PDB is not in force logging mode currently, then specifying `DISABLE FORCE LOGGING` results in an error.
- `ENABLE FORCE NOLOGGING` places the PDB in force nologging mode, which causes no changes in the PDB to be logged. Force nologging mode cannot be overridden at the schema object level.  
  
CDB-wide force logging mode supersedes PDB-level force nologging mode. PDB-level force nologging mode takes precedence over and is independent of any `LOGGING` or `FORCE LOGGING` settings you specify for individual tablespaces in the PDB and any `LOGGING` settings you specify for individual database objects in the PDB.  
  
`ENABLE FORCE NOLOGGING` cannot be specified if a PDB is in force logging mode. `DISABLE FORCE LOGGING` must be specified first.

- DISABLE FORCE NOLOGGING takes a PDB that is currently in force nologging mode out of that mode. If the PDB is not in force nologging mode currently, then specifying DISABLE FORCE NOLOGGING results in an error.

The DBA\_PDBS view shows whether a PDB is in force logging or force nologging mode.

 **Note:**

The PDB must be open in restricted mode to use this clause.

 **See Also:**

- ["Controlling the Writing of Redo Records"](#)
- [Oracle Database SQL Language Reference](#) for more information about force logging mode and force nologging mode

- *pdb\_recovery\_clause*

 **Note:**

This clause is available starting with Oracle Database 12c Release 1 (12.1.0.2).

ALTER PLUGGABLE DATABASE DISABLE RECOVERY takes the data files that belong to the PDB offline and disables recovery of the PDB. The PDB's data files are not part of any recovery session until it is enabled again. Any new data files created while recovery is disabled are created as unnamed files for the PDB.

ALTER PLUGGABLE DATABASE ENABLE RECOVERY brings the data files that belong to the PDB online and marks the PDB for active recovery. Recovery sessions include these files.

You can check the recovery status of a PDB by querying the RECOVERY\_STATUS column in the V\$PDBS view.

See [Oracle Data Guard Concepts and Administration](#) for more information about the *pdb\_recovery\_clause*.

An ALTER DATABASE statement issued when the current container is a PDB that includes clauses that are supported for an ALTER PLUGGABLE DATABASE statement have the same effect as the corresponding ALTER PLUGGABLE DATABASE statement. However, these statements cannot include clauses that are specific to PDBs, such as the *pdb\_storage\_clause*, the *pdb\_change\_state\_clause*, the *logging\_clause*, and the *pdb\_recovery\_clause*.

 **See Also:**

["About the Current Container"](#)

### 43.3.1.2 Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement

You can use the `ALTER PLUGGABLE DATABASE` statement to modify the attributes of a single PDB.

See "[About Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement](#)" for information about the clauses that modify the attributes of a single PDB. When the current container is a PDB, an `ALTER PLUGGABLE DATABASE` statement with one of these clauses modifies the PDB. The modifications overwrite the defaults set for the root in the PDB. The modifications do not affect the root or other PDBs.

The following prerequisites must be met:

- To change the open mode of the PDB from mounted to opened or from opened to mounted, the current user must have `SYSDBA`, `SYSOPER`, `SYSBACKUP`, or `SYSDG` administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using `AS SYSDBA`, `AS SYSOPER`, `AS SYSBACKUP`, or `AS SYSDG`, respectively, at connect time.
- For all other operations performed using the `ALTER PLUGGABLE DATABASE` statement, the current user must have the `ALTER DATABASE` system privilege, and the privilege must be either commonly granted or locally granted in the PDB.
- To close a PDB, the PDB must be open.

 **Note:**

This section does not cover changing the global database name of a PDB using the `ALTER PLUGGABLE DATABASE` statement. To do so, see "[Changing the Global Database Name of a PDB](#)".

To modify a PDB with the `ALTER PLUGGABLE DATABASE` statement:

1. In SQL\*Plus, ensure that the current container is a PDB.  
See "[Connecting to a PDB with SQL\\*Plus](#)".
2. Run an `ALTER PLUGGABLE DATABASE` statement.

The following examples modify a single PDB.

#### **Example 43-2 Changing the Open Mode of a PDB**

This `ALTER PLUGGABLE DATABASE` statement changes the open mode of the current PDB to mounted.

```
ALTER PLUGGABLE DATABASE CLOSE IMMEDIATE;
```

The following statement changes the open mode of the current PDB to open read-only.

```
ALTER PLUGGABLE DATABASE OPEN READ ONLY;
```

A PDB must be in mounted mode to change its open mode to read-only or read/write unless you specify the `FORCE` keyword.

The following statement changes the open mode of the current PDB from mounted or open read-only to open read-write.

```
ALTER PLUGGABLE DATABASE OPEN FORCE;
```

The following statement changes the open mode of the current PDB from mounted to migrate.

```
ALTER PLUGGABLE DATABASE OPEN UPGRADE;
```

### **Example 43-3 Bringing a Data File Online for a PDB**

This `ALTER PLUGGABLE DATABASE` statement uses a `database_file_clause` to bring the `/u03/oracle/pdb1_01.dbf` data file online.

```
ALTER PLUGGABLE DATABASE DATAFILE '/u03/oracle/pdb1_01.dbf' ONLINE;
```

### **Example 43-4 Changing the Default Tablespaces for a PDB**

This `ALTER PLUGGABLE DATABASE` statement uses a `DEFAULT TABLESPACE` clause to set the default permanent tablespace to `pdb1_tbs` for the PDB.

```
ALTER PLUGGABLE DATABASE DEFAULT TABLESPACE pdb1_tbs;
```

This `ALTER PLUGGABLE DATABASE` statement uses a `DEFAULT TEMPORARY TABLESPACE` clause to set the default temporary tablespace to `pdb1_temp` for the PDB.

```
ALTER PLUGGABLE DATABASE DEFAULT TEMPORARY TABLESPACE pdb1_temp;
```

The tablespace or tablespace group specified in the `ALTER PLUGGABLE DATABASE` statement must exist in the PDB. Users whose current container is a PDB that are not explicitly assigned a default tablespace or default temporary tablespace use the default tablespace or default temporary tablespace for the PDB.

### **Example 43-5 Changing the Default Tablespace Type for a PDB**

This `ALTER DATABASE` statement uses a `SET DEFAULT TABLESPACE` clause to change the default tablespace type to bigfile for the PDB.

```
ALTER PLUGGABLE DATABASE SET DEFAULT BIGFILE TABLESPACE;
```

### **Example 43-6 Setting Storage Limits for a PDB**

This statement sets the storage limit for all tablespaces that belong to a PDB to two gigabytes.

```
ALTER PLUGGABLE DATABASE STORAGE(MAXSIZE 2G);
```

This statement specifies that there is no storage limit for the tablespaces that belong to the PDB.

```
ALTER PLUGGABLE DATABASE STORAGE(MAXSIZE UNLIMITED);
```

This statement specifies that there is no storage limit for the tablespaces that belong to the PDB and that there is no storage limit for the shared temporary tablespace that can be used by sessions connected to the PDB.

```
ALTER PLUGGABLE DATABASE STORAGE UNLIMITED;
```

#### Example 43-7 Setting the Logging Attribute of a PDB

With the PDB open in restricted mode, this statement specifies the NOLOGGING attribute for the PDB:

```
ALTER PLUGGABLE DATABASE NOLOGGING;
```

 **Note:**

This example requires Oracle Database 12c Release 1 (12.1.0.2) or later.

#### Example 43-8 Setting the Force Logging Mode of a PDB

This statement enables force logging mode for the PDB:

```
ALTER PLUGGABLE DATABASE ENABLE FORCE LOGGING;
```

 **Note:**

This example requires Oracle Database 12c Release 1 (12.1.0.2) or later.

#### Example 43-9 Setting the Default Edition for a PDB

This example sets the default edition for the current PDB to PDB1E3.

```
ALTER PLUGGABLE DATABASE DEFAULT EDITION = PDB1E3;
```

 **See Also:**

- *Oracle Database SQL Language Reference* for more information about the ALTER PLUGGABLE DATABASE statement
- *Oracle Database Development Guide* for a complete discussion of edition-based redefinition

### 43.3.1.3 Changing the Global Database Name of a PDB

You can change the global database name of a PDB with the ALTER PLUGGABLE DATABASE RENAME GLOBAL\_NAME TO statement.

When you change the global database name of a PDB, the new global database name must be different from that of any container in the CDB.

The following prerequisites must be met:

- The current user must have the ALTER DATABASE system privilege, and the privilege must be either commonly granted or locally granted in the PDB.
- For an Oracle Real Application Clusters (Oracle RAC) database, the PDB must be open on the current instance only. The PDB must be closed on all other instances.
- The PDB being modified must be opened on the current instance in read/write mode with RESTRICTED specified so that it is accessible only to users with RESTRICTED SESSION privilege in the PDB.

To change the global database name of a PDB:

1. In SQL\*Plus, ensure that the current container is a PDB.  
See "[Connecting to a PDB with SQL\\*Plus](#)".
2. Run an ALTER PLUGGABLE DATABASE RENAME GLOBAL\_NAME TO statement.

The following example changes the global database name of the PDB to salespdb.example.com:

```
ALTER PLUGGABLE DATABASE RENAME GLOBAL_NAME TO salespdb.example.com;
```

3. Close the PDB.
4. Open the PDB in read/write mode.

When you change the global database name of a PDB, the PDB name is changed to the first part of the new global name, which is the part before the first period. Also, Oracle Database changes the name of the default database service for the PDB automatically. Oracle Database also changes the PDB property of all database services in the PDB to the new global name of the PDB. You must close the PDB and open it in read/write mode for Oracle Database to complete the integration of the new PDB service name into the CDB, as shown in steps 3 and 4.

Oracle Net Services must be configured properly for clients to access database services. You might need to alter your Oracle Net Services configuration as a result of the PDB name change.

 **See Also:**

- "[Modifying a PDB](#)" for more information about modifying the open mode of a PDB
- "[Managing Services Associated with PDBs](#)" for information about PDBs and database services
- "[Connecting to a PDB with SQL\\*Plus](#)"

### 43.3.2 Modifying a PDB with the SQL\*Plus STARTUP and SHUTDOWN Commands

When the current container is a PDB, you can use the SQL\*Plus STARTUP command to open the PDB and the SQL\*Plus SHUTDOWN command to close the PDB.

- [Using the STARTUP SQL\\*Plus Command on a PDB](#)  
When the current container is a PDB, the SQL\*Plus STARTUP command opens the PDB.
- [Using the SQL\\*Plus SHUTDOWN Command on a PDB](#)  
When the current container is a PDB, the SQL\*Plus SHUTDOWN command closes the PDB.

### 43.3.2.1 Using the STARTUP SQL\*Plus Command on a PDB

When the current container is a PDB, the SQL\*Plus STARTUP command opens the PDB.

Use the following options of the STARTUP command to open a PDB:

- **FORCE**  
Closes an open PDB before re-opening it in read/write mode. When this option is specified, no other options are allowed.
- **RESTRICT**  
Enables only users with the RESTRICTED SESSION system privilege in the PDB to access the PDB.  
  
If neither OPEN READ WRITE nor OPEN READ ONLY is specified and RESTRICT is specified, then the PDB is opened in read-only mode when the CDB to which it belongs is a physical standby database. Otherwise, the PDB is opened in read/write mode.
- **OPEN *open\_pdb\_options***  
Opens the PDB in either read/write mode or read-only mode. Specify OPEN READ WRITE or OPEN READ ONLY. When RESTRICT is not specified, READ WRITE is always the default.

To issue the STARTUP command when the current container is a PDB, the following prerequisites must be met:

- The current user must have SYSDBA, SYSOPER, SYSBACKUP, or SYSDG administrative privilege, and the privilege must be either commonly granted or locally granted in the PDB. The user must exercise the privilege using AS SYSDBA, AS SYSOPER, AS SYSBACKUP, or AS SYSDG, respectively, at connect time.
- Excluding the use of the FORCE option, the PDB must be in mounted mode to open it.
- To place a PDB in mounted mode, the PDB must be in open read-only or open read/write mode.

To modify a PDB with the STARTUP command:

1. In SQL\*Plus, ensure that the current container is a PDB.  
See "[Connecting to a PDB with SQL\\*Plus](#)".
2. Run the STARTUP command.

 **See Also:**

- ["Starting Up a Database"](#)
- ["About the Current Container"](#)
- [SQL\\*Plus User's Guide and Reference](#)

**Example 43-10 Opening a PDB in Read/Write Mode with the STARTUP Command**

```
STARTUP OPEN
```

**Example 43-11 Opening a PDB in Read-Only Mode with the STARTUP Command**

```
STARTUP OPEN READ ONLY
```

**Example 43-12 Opening a PDB in Read-Only Restricted Mode with the STARTUP Command**

```
STARTUP RESTRICT OPEN READ ONLY
```

**Example 43-13 Opening a PDB in Read/Write Mode with the STARTUP Command and the FORCE Option**

This example assumes that the PDB is currently open. The `FORCE` option closes the PDB and then opens it in the read/write mode.

```
STARTUP FORCE
```

### 43.3.2.2 Using the SQL\*Plus SHUTDOWN Command on a PDB

When the current container is a PDB, the SQL\*Plus `SHUTDOWN` command closes the PDB.

After the `SHUTDOWN` command is issued on a PDB successfully, it is in mounted mode.

The following `SHUTDOWN` modes are possible:

- When you specify `SHUTDOWN` only, then the PDB is shut down with the normal mode.
- When you specify `SHUTDOWN IMMEDIATE`, the PDB is shut down with the immediate mode.
- When you specify `SHUTDOWN ABORT`, the PDB is forcefully closed.

For a single-instance CDB, PDB media recovery is required when you specify `SHUTDOWN ABORT`. For an Oracle Real Application Clusters (Oracle RAC) CDB, PDB media recovery is required if the `SHUTDOWN ABORT` command closes the last open instance.

To issue the `SHUTDOWN` command when the current container is a PDB, the following prerequisites must be met:

- The current user must have `SYSDBA`, `SYSOPER`, `SYSBACKUP`, or `SYSDG` administrative privilege, and the privilege must be either commonly granted or locally granted in

the PDB. The user must exercise the privilege using AS SYSDBA, AS SYSOPER, AS SYSBACKUP, or AS SYSDG, respectively, at connect time.

- To close a PDB, the PDB must be open.

To modify a PDB with the `SHUTDOWN` command:

1. In SQL\*Plus, ensure that the current container is a PDB.  
See "[Connecting to a PDB with SQL\\*Plus](#)".
2. Run the `SHUTDOWN` command.

 **Note:**

- When the current container is a PDB, the `SHUTDOWN` command only closes the PDB, not the CDB instance.
- There is no `SHUTDOWN` command for a PDB that is equivalent to `SHUTDOWN TRANSACTIONAL` for a non-CDB.

 **See Also:**

- "[Modifying the Open Mode of PDBs with ALTER PLUGGABLE DATABASE](#)"
- "[Shutting Down a Database](#)" for more information about shutdown modes
- "[About the Current Container](#)"
- *SQL\*Plus User's Guide and Reference*

**Example 43-14 Closing a PDB with the SHUTDOWN IMMEDIATE Command**

`SHUTDOWN IMMEDIATE`

## 43.4 Using the ALTER SYSTEM Statement to Modify a PDB

You can use the `ALTER SYSTEM` statement to modify a PDB.

- [About Using the ALTER SYSTEM Statement on a PDB](#)

The `ALTER SYSTEM` statement can dynamically alter a PDB. You can issue an `ALTER SYSTEM` statement when you want to change the way a PDB operates.

- [Using the ALTER SYSTEM Statement on a PDB](#)

You can use the `ALTER SYSTEM` statement to modify a PDB.

### 43.4.1 About Using the ALTER SYSTEM Statement on a PDB

The `ALTER SYSTEM` statement can dynamically alter a PDB. You can issue an `ALTER SYSTEM` statement when you want to change the way a PDB operates.

When the current container is a PDB, you can run the following ALTER SYSTEM statements:

- ALTER SYSTEM FLUSH SHARED\_POOL
- ALTER SYSTEM FLUSH BUFFER\_CACHE
- ALTER SYSTEM FLUSH FLASH\_CACHE
- ALTER SYSTEM ENABLE RESTRICTED SESSION
- ALTER SYSTEM DISABLE RESTRICTED SESSION
- ALTER SYSTEM SET USE\_STORED\_OUTLINES
- ALTER SYSTEM SUSPEND
- ALTER SYSTEM RESUME
- ALTER SYSTEM CHECKPOINT
- ALTER SYSTEM CHECK DATAFILES
- ALTER SYSTEM REGISTER
- ALTER SYSTEM KILL SESSION
- ALTER SYSTEM DISCONNECT SESSION
- ALTER SYSTEM SET *initialization\_parameter* (for a subset of initialization parameters)

All other ALTER SYSTEM statements affect the entire CDB and must be run by a common user in the root.

The ALTER SYSTEM SET *initialization\_parameter* statement can modify only some initialization parameters for PDBs. All initialization parameters can be set for the root. For any initialization parameter that is not set explicitly for a PDB, the PDB inherits the root's parameter value.

You can modify an initialization parameter for a PDB when the `ISPDB_MODIFIABLE` column is `TRUE` for the parameter in the `V$SYSTEM_PARAMETER` view. The following query lists all of the initialization parameters that are modifiable for a PDB:

```
SELECT NAME FROM V$SYSTEM_PARAMETER WHERE ISPDB_MODIFIABLE='TRUE' ORDER BY NAME;
```

When the current container is a PDB, run the ALTER SYSTEM SET *initialization\_parameter* statement to modify the PDB. The statement does not affect the root or other PDBs. The following table describes the behavior of the `SCOPE` clause when you use a server parameter file (SPFILE) and run the ALTER SYSTEM SET statement on a PDB.

---

**SCOPE Setting Behavior**

---

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MEMORY | <p>The initialization parameter setting is changed in memory and takes effect immediately in the PDB. The new setting affects only the PDB.</p> <p>The setting reverts to the value set in the root in any of the following cases:</p> <ul style="list-style-type: none"> <li>An ALTER SYSTEM SET statement sets the value of the parameter in the root with SCOPE equal to BOTH or MEMORY, and the PDB is closed and re-opened. The parameter value in the PDB is not changed if SCOPE is equal to SPFILE, and the PDB is closed and re-opened.</li> <li>The PDB is closed and re-opened.</li> <li>The CDB is shut down and re-opened.</li> </ul> |
| SPFILE | <p>The initialization parameter setting is changed for the PDB and stored persistently. The new setting takes effect in any of the following cases:</p> <ul style="list-style-type: none"> <li>The PDB is closed and re-opened.</li> <li>The CDB is shut down and re-opened.</li> </ul> <p>In these cases, the new setting affects only the PDB.</p>                                                                                                                                                                                                                                                                                               |
| BOTH   | <p>The initialization parameter setting is changed in memory, and it is changed for the PDB and stored persistently. The new setting takes effect immediately in the PDB and persists after the PDB is closed and re-opened or the CDB is shut down and re-opened. The new setting affects only the PDB.</p>                                                                                                                                                                                                                                                                                                                                       |

---

When a PDB is unplugged from a CDB, the values of the initialization parameters that were specified for the PDB with SCOPE=BOTH or SCOPE=SPFILE are added to the PDB's XML metadata file. These values are restored for the PDB when it is plugged in to a CDB.

 **Note:**

A text initialization parameter file (PFILE) cannot contain PDB-specific parameter values.

 **See Also:**

- ["Unplugging a PDB from a CDB"](#)
- ["About the Current Container"](#)
- ["Using the ALTER SYSTEM SET Statement in a CDB"](#)
- [Oracle Database SQL Language Reference](#)

## 43.4.2 Using the ALTER SYSTEM Statement on a PDB

You can use the `ALTER SYSTEM` statement to modify a PDB.

The current user must be granted the following privileges, and the privileges must be either commonly granted or locally granted in the PDB:

- `CREATE SESSION`
- `ALTER SYSTEM`

To use `ALTER SYSTEM` to modify a PDB:

1. In SQL\*Plus, ensure that the current container is a PDB.  
See "[Connecting to a PDB with SQL\\*Plus](#)".
2. Run the `ALTER SYSTEM` statement.

### Example 43-15 Enable Restricted Sessions in a PDB

To restrict sessions in a PDB, issue the following statement:

```
ALTER SYSTEM ENABLE RESTRICTED SESSION;
```

### Example 43-16 Changing the Statistics Gathering Level for the PDB

This `ALTER SYSTEM` statement sets the `STATISTICS_LEVEL` initialization parameter to `ALL` for the current PDB:

```
ALTER SYSTEM SET STATISTICS_LEVEL = ALL SCOPE = MEMORY;
```

#### See Also:

- "[Using the ALTER SYSTEM SET Statement in a CDB](#)"
- [Oracle Database SQL Language Reference](#)

## 43.5 Managing Services Associated with PDBs

You can create, modify, or remove services for a PDB.

- [About Services Associated with PDBs](#)

Database services have an optional `PDB` property. You can set a `PDB` property when you create a service, and you can modify the `PDB` property of a service.

- [Creating, Modifying, or Removing a Service for a PDB](#)

You can create, modify, or remove a service with a `PDB` property.

#### See Also:

- "[Managing Application Workloads with Database Services](#)"

### 43.5.1 About Services Associated with PDBs

Database services have an optional `PDB` property. You can set a `PDB` property when you create a service, and you can modify the `PDB` property of a service.

The `PDB` property associates the service with the PDB. When a client connects to a service with a `PDB` property, the current container for the connection is the PDB. You can view the `PDB` property for a service by querying the `ALL_SERVICES` data dictionary view or, when using the `SRVCTL` utility, by using the `srvctl config` service command.

The `PDB` property is required only when you are creating a service or modifying the `PDB` property of a service. For example, you do not specify a `PDB` property when you start, stop, or remove a service, and you do not need to specify a `PDB` property when you modify a service without modifying its `PDB` property.

When a PDB is created, a new default service for the PDB is created automatically, and this service has the same name as the PDB. You cannot manage this service, and it should only be used for administrative tasks. Do not use this default PDB service for applications. Always use user-defined services for applications because you can customize user-defined services to fit the requirements of your applications.

 **Note:**

- Each database service name must be unique in a CDB, and each database service name must be unique within the scope of all the CDBs whose instances are reached through a specific listener.
- In an Oracle Clusterware environment, an Oracle Clusterware resource must be created for each service that is created for the PDB.
- When your database is being managed by Oracle Restart or Oracle Clusterware, and you use the `SRVCTL` utility to start a service with a `PDB` property for a PDB that is closed, the PDB is opened in read/write mode on the nodes where the service is started. However, stopping a PDB service does not change the open mode of the PDB. See ["Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement"](#) for information about changing the open mode of a PDB.
- When you unplug or drop a PDB, the services of the unplugged or dropped PDB are not removed automatically. You can remove these services manually.
- Do not associate a service with a proxy PDB.

 **See Also:**

- ["About the Current Container"](#)
- ["Creating a PDB as a Proxy PDB"](#)

## 43.5.2 Creating, Modifying, or Removing a Service for a PDB

You can create, modify, or remove a service with a `PDB` property.

You can do so in the following ways:

- If your single-instance database is being managed by Oracle Restart or your Oracle RAC database is being managed by Oracle Clusterware, then use the Server Control (SRVCTL) utility to create, modify, or remove the service.

To create a service for a PDB using the SRVCTL utility, use the `add service` command and specify the PDB in the `-pdb` parameter. If you do not specify a PDB in the `-pdb` parameter when you create a service, then the service is associated with the root.

To modify the `PDB` property of a service using the SRVCTL utility, use the `modify service` command and specify the PDB in the `-pdb` parameter. To remove a service for a PDB using the SRVCTL utility, use the `remove service` command.

You can use other SRVCTL commands to manage the service, such as the `start service` and `stop service` commands, even if they do not include the `-pdb` parameter.

The PDB name is not validated when you create or modify a service with the SRVCTL utility. However, an attempt to start a service with invalid PDB name results in an error.

- If your database is not being managed by Oracle Restart or Oracle Clusterware, then use the `DBMS_SERVICE` package to create or remove a database service.

When you create a service with the `DBMS_SERVICE` package, the `PDB` property of the service is set to the current container. Therefore, to create a service with a `PDB` property set to a specific PDB using the `DBMS_SERVICE` package, run the `CREATE_SERVICE` procedure when the current container is that PDB. If you create a service using the `CREATE_SERVICE` procedure when the current container is the root, then the service is associated with the root.

You cannot modify the `PDB` property of a service with the `DBMS_SERVICE` package. However, you can remove a service in one PDB and create a similar service in a different PDB. In this case, the new service has the `PDB` property of the PDB in which it was created.

You can also use other `DBMS_SERVICE` subprograms to manage the service, such as the `START_SERVICE` and `STOP_SERVICE` procedures. Use the `DELETE_SERVICE` procedure to remove a service.

Oracle recommends using the SRVCTL utility to create and modify services. However, if you do not use the SRVCTL utility, then you can use the `DBMS_SERVICE` package.

To create, modify, or remove a service with a `PDB` property using the SRVCTL utility:

1. Log in to the host computer with the correct user account, and ensure that you run SRVCTL from the correct Oracle home.
2. To create or modify a service, run the `add service` command, and specify the PDB in the `-pdb` parameter. To modify the `PDB` property of a service, run the `modify service` command, and specify the PDB in the `-pdb` parameter. To remove a service, run the `remove service` command.

To create or remove a service for a PDB using the `DBMS_SERVICE` package:

1. In SQL\*Plus, ensure that the current container is a PDB.  
See "[Connecting to a PDB with SQL\\*Plus](#)".
2. Run the appropriate subprogram in the DBMS\_SERVICE package.

 **Note:**

If your database is being managed by Oracle Restart or Oracle Clusterware, then use the SRVCTL utility to manage services. Do not use the DBMS\_SERVICE package.

#### **Example 43-17 Creating a Service for a PDB Using the SRVCTL Utility**

This example adds the salesrep service for the PDB salespdb in the CDB with DB\_UNIQUE\_NAME mycldb:

```
srvctl add service -db mycldb -service salesrep -pdb salespdb
```

#### **Example 43-18 Modifying the PDB Property of a Service Using the SRVCTL Utility**

This example modifies the salesrep service in the CDB with DB\_UNIQUE\_NAME mycldb to associate the service with the hrpdb PDB:

```
srvctl modify service -db mycldb -service salesrep -pdb hrpdb
```

#### **Example 43-19 Removing a Service Using the SRVCTL Utility**

This example removes the salesrep service in the CDB with DB\_UNIQUE\_NAME mycldb:

```
srvctl remove service -db mycldb -service salesrep
```

#### **Example 43-20 Creating a Service for a PDB Using the DBMS\_SERVICE Package**

This example creates the salesrep service for the current PDB:

```
BEGIN
 DBMS_SERVICE.CREATE_SERVICE(
 service_name => 'salesrep',
 network_name => 'salesrep.example.com');
END;
/
```

The PDB property of the service is set to the current container. For example, if the current container is the salespdb PDB, then the PDB property of the service is salespdb.

#### **Example 43-21 Removing a Service Using the DBMS\_SERVICE Package**

This example removes the salesrep service in the current PDB.

```
BEGIN
 DBMS_SERVICE.DELETE_SERVICE(
 service_name => 'salesrep');
END;
/
```

 **See Also:**

## 43.6 Refreshing a PDB

You can refresh a PDB that was created as a refreshable clone.

When you refresh a PDB manually, changes made to the source PDB since the last refresh are propagated to the PDB being refreshed. You can manually refresh a PDB that is configured for automatic refresh.

To refresh a PDB, the PDB must have been created as a clone with the `REFRESH MODE MANUAL` or `REFRESH MODE EVERY minutes` clause included.

1. In SQL\*Plus, ensure that the current container is the PDB you want to refresh.
2. If the PDB is not closed, then close the PDB. For example, issue the following SQL statement:

```
ALTER PLUGGABLE DATABASE CLOSE IMMEDIATE;
```

3. Issue the following SQL statement:

```
ALTER PLUGGABLE DATABASE REFRESH;
```

### Related Topics

- [PDB Refresh](#)

The `REFRESH MODE` clause of the `CREATE PLUGGABLE DATABASE` statement specifies whether a PDB created as a clone can be refreshed periodically. Each PDB refresh propagates changes from the source PDB to the new PDB.

- [Cloning a Remote PDB or Non-CDB](#)

You can create a PDB by cloning a remote source. The remote source can be a remote PDB or non-CDB. After the cloning operation is complete, the source and the target PDB are in different locations.

## 43.7 Modifying the Listener Settings of a Referenced PDB

A PDB that is referenced by a proxy PDB is called a referenced PDB. When the port or host name changes for the listener of the referenced PDB, you must modify the listener settings of the referenced PDB so that its proxy PDBs continue to function properly.

- [Altering the Listener Host Name of a Referenced PDB](#)  
When the host name of the listener for a referenced PDB changes, you must run an `ALTER PLUGGABLE DATABASE CONTAINERS HOST` statement to reset the host name of the referenced PDB so that its proxy PDBs continue to function properly.
- [Altering the Listener Port Number of a Referenced PDB](#)  
When the port number of the listener for a referenced PDB changes, you must run an `ALTER PLUGGABLE DATABASE CONTAINERS PORT` statement to reset the port number of the referenced PDB so that its proxy PDBs continue to function properly.

#### Related Topics

- [Creating a PDB as a Proxy PDB](#)

You can create a PDB as a proxy PDB by referencing a PDB in a remote CDB.

### 43.7.1 Altering the Listener Host Name of a Referenced PDB

When the host name of the listener for a referenced PDB changes, you must run an `ALTER PLUGGABLE DATABASE CONTAINERS HOST` statement to reset the host name of the referenced PDB so that its proxy PDBs continue to function properly.

A proxy PDB uses a database link to establish communication with its referenced PDB during PDB creation. After communication is established, the proxy PDB communicates directly with the referenced PDB without using a database link, and the database link can be dropped. When the listener host name changes for the referenced PDB, each proxy PDB must re-establish communication with its referenced PDB.

The listener host name of a referenced PDB is a database property. When it is set, you can view the current setting by querying the `DATABASE_PROPERTIES` data dictionary view.

The current user must have the `ALTER DATABASE` system privilege, and the privilege must be either commonly granted or locally granted in the PDB.

1. In SQL\*Plus, ensure that the current container is the referenced PDB.  
See "[Connecting to a PDB with SQL\\*Plus](#)".
2. Run an `ALTER PLUGGABLE DATABASE CONTAINERS HOST` statement and specify the new host name, or include the `RESET` keyword to return the host name to its default setting, which is the host name of the referenced PDB.
3. Drop and re-create the proxy PDBs that reference the referenced PDB to re-establish communication for each proxy PDB and its referenced PDB.

#### Example 43-22 Altering the Listener Host Name of a Referenced PDB

This example changes the host name for the referenced PDB to `myhost.example.com`.

```
ALTER PLUGGABLE DATABASE CONTAINERS HOST='myhost.example.com';
```

#### Example 43-23 Resetting the Listener Host Name to the Default Value

This example resets the host name for the referenced PDB to its default value. The default value is the host name of the referenced PDB.

```
ALTER PLUGGABLE DATABASE CONTAINERS HOST RESET;
```

### Related Topics

- [Creating a PDB as a Proxy PDB](#)  
You can create a PDB as a proxy PDB by referencing a PDB in a remote CDB.
- [HOST Clause](#)  
The HOST clause of the CREATE PLUGGABLE DATABASE statement specifies the host name of the listener for the PDB being created.

## 43.7.2 Altering the Listener Port Number of a Referenced PDB

When the port number of the listener for a referenced PDB changes, you must run an ALTER PLUGGABLE DATABASE CONTAINERS PORT statement to reset the port number of the referenced PDB so that its proxy PDBs continue to function properly.

A proxy PDB uses a database link to establish communication with its referenced PDB during PDB creation. After communication is established, the proxy PDB communicates directly with the referenced PDB without using a database link, and the database link can be dropped. When the listener port number changes for the referenced PDB, each proxy PDB must re-establish communication with its referenced PDB.

The listener port number of a referenced PDB is a database property. When it is set, you can view the current setting by querying the DATABASE\_PROPERTIES data dictionary view.

The current user must have the ALTER DATABASE system privilege, and the privilege must be either commonly granted or locally granted in the PDB.

1. In SQL\*Plus, ensure that the current container is the referenced PDB.  
See "[Connecting to a PDB with SQL\\*Plus](#)".
2. Run an ALTER PLUGGABLE DATABASE CONTAINERS PORT statement and specify the new port number, or include the RESET keyword to return the port number to its default setting, which is 1521.
3. Drop and re-create the proxy PDBs that reference the referenced PDB to re-establish communication for each proxy PDB and its referenced PDB.

### Example 43-24 Altering the Listener Port Number of a Referenced PDB

This example changes the port number for the referenced PDB to 1543.

```
ALTER PLUGGABLE DATABASE CONTAINERS PORT=1543;
```

### Example 43-25 Resetting the Listener Port Number to the Default Value

This example resets the port number for the referenced PDB to its default value. The default value for the port number is 1521.

```
ALTER PLUGGABLE DATABASE CONTAINERS PORT RESET;
```

### Related Topics

- [Creating a PDB as a Proxy PDB](#)  
You can create a PDB as a proxy PDB by referencing a PDB in a remote CDB.

- **PORT Clause**

The `PORT` clause of the `CREATE PLUGGABLE DATABASE` statement specifies the port number of the listener for the PDB being created.

# Administering Application Containers with SQL\*Plus

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

## Note:

You can complete the tasks in this chapter using SQL\*Plus or Oracle SQL Developer.

- [About Administering Application Containers with SQL\\*Plus](#)

Some aspects of administering an application container are similar to administering the CDB root and the CDB as a whole, while other aspects of administering an application container are similar to administering a PDB.

- [About Modifying an Application Root](#)

The `ALTER DATABASE` statement can modify an application root. The `ALTER PLUGGABLE DATABASE` statement can modify the open mode of one or more application PDBs.

- [Managing Applications in an Application Container](#)

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- [Managing Application Common Objects](#)

Application common objects are shared, user-created database objects in an application container. Application common objects are created in an application root.

- [Issuing DML Statements on Containers in an Application Container](#)

A DML statement issued in an application root can modify one or more containers in the application container. In addition, you can specify one or more default container targets for DML statements.

- [Partitioning by PDB with Container Maps](#)

Container maps enable the partitioning of data at the application PDB level when the data is not physically partitioned at the table level.

## Related Topics

- [Creating and Removing Application Containers and Seeds with SQL\\*Plus](#)

You can create application containers and application seeds in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application containers from a CDB, and you can remove application seeds from application containers.

- [Tools for a Multitenant Environment](#)

You can use various tools to configure and administer a multitenant environment.

## 44.1 About Administering Application Containers with SQL\*Plus

Some aspects of administering an application container are similar to administering the CDB root and the CDB as a whole, while other aspects of administering an application container are similar to administering a PDB.

Administering an application container is similar to administering a CDB because you can manage both the application root and the application PDBs that are plugged into the application root. However, administering an application container is also similar to managing a PDB because changes to the application container do not affect other application containers or PDBs in the CDB.

The following table describes administrative tasks for application containers that are similar to administrative tasks that manage a CDB or CDB root.

**Table 44-1 Application Container Administrative Tasks Similar to Those of a CDB**

| Administrative Task                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                  | More Information                                             |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| Configuring application common users and commonly granted privileges | Application common users and privileges are similar to common users and commonly granted privileges in a CDB root, but in an application container, common users and commonly granted privileges only exist within the containers of the application container, including the application root, application PDBs that belong to the application root, and an optional application seed that belongs to the application root. | <i>Oracle Database Concepts</i>                              |
| Creating application containers                                      | A common user whose current container is the CDB root can create application containers that are plugged into the CDB root. To do so, include the AS APPLICATION CONTAINER clause in the CREATE PLUGGABLE DATABASE statement                                                                                                                                                                                                 | " <a href="#">Creating Application Containers</a> "          |
| Creating application PDBs                                            | A common user whose current container is the application root can create application PDBs that are plugged into the application root.                                                                                                                                                                                                                                                                                        | " <a href="#">Creating and Removing PDBs with SQL*Plus</a> " |

**Table 44-1 (Cont.) Application Container Administrative Tasks Similar to Those of a CDB**

| Administrative Task                               | Description                                                                                                                                                                                                                                                      | More Information                                                               |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Switching to containers                           | A common user with the proper privileges can switch between containers in an application container, including the application root, application PDBs that belong to the application root, and an optional application seed that belongs to the application root. | " <a href="#">Switching to a Container Using the ALTER SESSION Statement</a> " |
| Issuing ALTER SYSTEM SET statements               | The ALTER SYSTEM SET statement can dynamically set an initialization parameter in one or more containers in an application container.                                                                                                                            | " <a href="#">Using the ALTER SYSTEM SET Statement in a CDB</a> "              |
| Issuing data definition language (DDL) statements | In an application container, some DDL statements can apply to all containers in the application container or to the current container only.                                                                                                                      | " <a href="#">Modifying Application Common Objects with DDL Statements</a> "   |

The following table describes administrative tasks for application containers that are similar to administrative tasks that manage a PDB.

**Table 44-2 Application Container Administrative Tasks Similar to Those of a PDB**

| Administrative Task                            | Description                                                                                                                                                                                                                                                    | More Information                                                           |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Connecting to the application root             | The application root has its own service name, and users can connect to the application root in the same way that they connect to a PDB. Similarly, each application PDB has its own service name, and the application seed has its own service name.          | " <a href="#">Accessing a Container in a CDB with SQL*Plus</a> "           |
| Issuing the ALTER PLUGGABLE DATABASE statement | An ALTER PLUGGABLE DATABASE statement can modify an application root, application PDB, and application seed in the same way it modifies a PDB. For example, an administrator can open or close an application root with an ALTER PLUGGABLE DATABASE statement. | " <a href="#">Modifying a CDB</a> "<br>" <a href="#">Modifying a PDB</a> " |

**Table 44-2 (Cont.) Application Container Administrative Tasks Similar to Those of a PDB**

| Administrative Task                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       | More Information                                                                                                                          |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Issuing the SQL*Plus STARTUP and SHUTDOWN commands | SQL*Plus STARTUP and SHUTDOWN commands operate on an application root, application PDB, and application seed in the same way that they operate on a PDB.                                                                                                                                                                                                                                                                                          | " <a href="#">Modifying the Open Mode of PDBs</a> "                                                                                       |
| Issuing the ALTER SYSTEM statements                | An ALTER SYSTEM statement operates on an application root, application PDB, and application seed in the same way that it operates on a PDB.                                                                                                                                                                                                                                                                                                       | " <a href="#">Using the ALTER SYSTEM SET Statement in a CDB</a> "<br>" <a href="#">Using the ALTER SYSTEM Statement to Modify a PDB</a> " |
| Managing tablespaces                               | Administrators can create, modify, and drop tablespaces for an application root and for application PDBs. Each container has its own tablespaces.                                                                                                                                                                                                                                                                                                 | " <a href="#">Managing Tablespaces in a CDB</a> "                                                                                         |
| Managing data files and temp files                 | Administrators can create, modify, and drop data files and temp files for an application root and for application PDBs. Each container has its own files.                                                                                                                                                                                                                                                                                         | " <a href="#">Managing Data Files and Temp Files</a> "                                                                                    |
| Managing schema objects                            | You can create, modify, and drop schema objects in a an application root and in each application PDB in the same way that you would in a PDB. You can also create triggers that fire for a specific application root or application PDB.<br><br>However, application containers support application common objects, which can be shared between the containers in an application container. Application common objects cannot be created in PDBs. | " <a href="#">Managing Application Common Objects</a> "                                                                                   |

## 44.2 About Modifying an Application Root

The `ALTER DATABASE` statement can modify an application root. The `ALTER PLUGGABLE DATABASE` statement can modify the open mode of one or more application PDBs.

**Table 44-3** lists which containers are modified by clauses in `ALTER DATABASE` and `ALTER PLUGGABLE DATABASE` statements issued in an application root. The table also lists statements that are not allowed in an application root.

 **Note:**

Statements issued when the current container is the application root never affect the CDB root or PDBs that do not belong to the current application root.

**Table 44-3 Statements That Modify Containers in an Application Root**

| Modify Application Root Only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Modify One or More Application PDBs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Cannot Be Issued in an Application Root                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## 44.3 Managing Applications in an Application Container

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- [About Managing Applications in an Application Container](#)  
In an application container, an application is a named, versioned set of application metadata and common data. A typical application installs application common users and application common objects.
- [Installing Applications in an Application Container](#)  
You can install an application in an application container.
- [Upgrading Applications in an Application Container](#)  
Major changes to an application constitute application upgrades. You can upgrade an application in an application container.
- [Patching Applications in an Application Container](#)  
Minor changes to an application constitute application patches. Examples of minor changes can include bug fixes and security patches. You can patch an application in an application container.
- [Migrating an Existing Application to an Application Container](#)  
You can migrate an application that is installed in a PDB to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12c Release 1 (12.1) CDB to an application container in an Oracle Database 12c Release 2 (12.2) CDB.
- [Synchronizing Applications in an Application PDB](#)  
When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.
- [Synchronizing an Application Root Replica with a Proxy PDB](#)  
When application containers in different CDBs have the same application, their application roots can be kept synchronized by creating a master application root, a replica application root, and a proxy PDB.
- [Setting the Compatibility Version of an Application](#)  
The compatibility version of an application is the earliest version of the application possible for the application PDBs that belong to the application container.
- [Performing Bulk Inserts During Application Install, Upgrade, and Patch Operations](#)  
SQL\*Loader is the only supported utility for bulk inserts into tables during application install, upgrade, and patch operations. Only conventional path loads are supported for bulk inserts during application install, upgrade, and patch operations.

### 44.3.1 About Managing Applications in an Application Container

In an application container, an application is a named, versioned set of application metadata and common data. A typical application installs application common users and application common objects.

Within an application container, an application is the named, versioned set of application common objects stored in the application root. In this context, “application” means “application back-end.” Application common objects include user accounts, tables, packages, and so on. An application can be shared with the application PDBs that belong to the application root.

An application can be installed, upgraded, and patched in an application root. When an application is installed, upgraded, or patched, you must issue an `ALTER PLUGGABLE DATABASE ... BEGIN` statement to start the operation and an `ALTER PLUGGABLE DATABASE ... END` statement to end the operation. These statements can be issued in the same user session or in different user sessions.

When application changes are performed in this way, application PDBs can synchronize with the application in the application root to apply the changes. The application container also manages the versions of the application and the patches to the application:

- When you install an application, you must specify the application version number.
- When you upgrade an application, you must specify the old application version number and the new application version number.
- When you patch an application, you must specify the minimum application version number for the patch and the patch number.

As the application evolves, the application container maintains all of the versions and patch changes you apply. You can also configure the application container so that different application PDBs use different versions of the application. For example, if you provide an application to various customers, and each customer has its own application PDB, some customers might wait longer to upgrade the application. In this case, some application PDBs can use the latest version of the application, while other application PDBs can use an older version of the application.

The following is the typical process for creating and maintaining an application in an application container:

1. Create the application container.
2. Install the application in the application root.  
This step includes creating the application data model and configuring the application common users and application common objects.
3. Create the application PDBs in the application root.
4. Synchronize each application PDB that should install the application with the application in the application root.
5. Load the data for each application PDB.
6. Maintain the application by upgrading it and patching it in the application root.
7. Synchronize application PDBs that should apply changes from upgrades and patches.
8. Add new application PDBs whenever necessary.

 **Note:**

SQL\*Loader is the only supported utility for bulk inserts into tables during application install, upgrade, and patch operations.

- **Application Module Names**

The application module name is set by the `DBMS_APPLICATION_INFO.SET_MODULE` procedure or the equivalent OCI attribute setting.

 **See Also:**

- [Creating Application Containers](#)*Oracle Database Security Guide* for information about auditing install, upgrade, and patch operations for an application container
- [Oracle Database PL/SQL Packages and Types Reference](#) for more information about setting the application module name

#### 44.3.1.1 Application Module Names

The application module name is set by the `DBMS_APPLICATION_INFO.SET_MODULE` procedure or the equivalent OCI attribute setting.

The module name is necessary during application maintenance because of other activity that might be occurring in the database. For example, statements issued by background processes should not be captured in the application capture tables. Also, other users might execute statements that are unrelated to the application. A module name check distinguishes what should be captured from what should not be captured. Only sessions whose module name matches the module name of the session where `APPLICATION BEGIN` was issued are considered for capture.

Some clauses, such as the `SHARING` clause, are valid only when issued between an `ALTER PLUGGABLE DATABASE ... BEGIN` statement and an `ALTER PLUGGABLE DATABASE ... END` statement. For these clauses, if the module name for a session does not match, then this session is not included in between the `BEGIN` and `END` statements, causing statements that include the clause to fail with `ORA-65021` or other errors.

The most common cause for a module name mismatch is the default module name. For example, SQL\*Plus sets a default module name when a connection is made to the database. A connection as a `SYSDBA` user results in one default module name (for example, `sqlplus@host1 (TNS V1-V3)`), whereas a connection as a non-`SYSDBA` user results in a different default module name (for example, `SQL*Plus`). When `SYSDBA` and non-`SYSDBA` users are both performing maintenance, you must explicitly set the module name in each session to the same value, and not rely on the default settings in SQL\*Plus.

### Example 44-1 Checking the Application Module Name

This example shows how the default module name changes depending on whether the connected user has SYSDBA privileges.

```
SQL> CONNECT / AS SYSDBA
Connected.

SQL> select module from v$session where audsid =
SYS_CONTEXT('USERENV', 'sessionid');

MODULE

sqlplus@host1 (TNS V1-V3)

SQL> CONNECT dba1
Password: *****
Connected.

SQL> select module from v$session where audsid =
SYS_CONTEXT('USERENV', 'sessionid');

MODULE

SQL*Plus
```

 **See Also:**

## 44.3.2 Installing Applications in an Application Container

You can install an application in an application container.

- [About Installing Applications in an Application Container](#)  
You issue ALTER PLUGGABLE DATABASE APPLICATION statements to install an application in the application root.
- [Installing an Application in an Application Container with Automated Propagation](#)  
To install an application in an application container, run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL statement to begin the installation and the ALTER PLUGGABLE DATABASE APPLICATION END INSTALL statement to end the installation. The application is installed in the application PDBs that synchronize with the application in the application root.

### 44.3.2.1 About Installing Applications in an Application Container

You issue ALTER PLUGGABLE DATABASE APPLICATION statements to install an application in the application root.

You install the application in the application root only, and application PDBs that synchronize with the application install the application automatically. With the automated method, the installation can be done with one or more of the following: scripts, SQL statements, and graphical user interface tools.

You must indicate the start of the installation with an `ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL` statement and the end of the install with an `ALTER PLUGGABLE DATABASE APPLICATION END INSTALL` statement. Each installation must be associated with an application name and version number, which are specified in the `ALTER PLUGGABLE DATABASE APPLICATION` statements.

#### Related Topics

- [Running Oracle-Supplied SQL Scripts in a CDB](#)

You can use the `catcon.pl` script to run Oracle-supplied SQL scripts in a CDB.

### 44.3.2.2 Installing an Application in an Application Container with Automated Propagation

To install an application in an application container, run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL` statement to begin the installation and the `ALTER PLUGGABLE DATABASE APPLICATION END INSTALL` statement to end the installation. The application is installed in the application PDBs that synchronize with the application in the application root.

The following prerequisites must be met:

- The current user must have the `ALTER PLUGGABLE DATABASE` system privilege, and the privilege must be commonly granted in the application root.
  - The application root must be in open read/write mode.
1. In SQL\*Plus, ensure that the current container is the application root.
  2. Run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL` statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name BEGIN INSTALL
'application_version_number';
```

For example, run the following statement if the `application_name` is `salesapp` and the `application_version_number` is `4.2`:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN INSTALL '4.2';
```

3. Install the application using scripts, SQL statements, or graphical user interface tools.
4. Run the `ALTER PLUGGABLE DATABASE APPLICATION END INSTALL` statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name END INSTALL
'application_version_number';
```

For example, run the following statement if the `application_name` is `salesapp` and the `application_version_number` is `4.2`:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp END INSTALL '4.2';
```

 **Note:**

Ensure that the *application\_name* and *application\_version\_number* match in the ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL statement and the ALTER PLUGGABLE DATABASE APPLICATION END INSTALL statement.

5. Synchronize all of the application PDBs that must install the application by issuing an ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause.

**Related Topics**

You can access a container in a CDB with SQL\*Plus.

- [Synchronizing Applications in an Application PDB](#)  
When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

### 44.3.3 Upgrading Applications in an Application Container

Major changes to an application constitute application upgrades. You can upgrade an application in an application container.

- [About Upgrading Applications in an Application Container](#)  
You issue ALTER PLUGGABLE DATABASE APPLICATION statements to upgrade an application in the application root.
- [Upgrading an Application in an Application Container](#)  
To upgrade an application in an application container, run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE statement to begin the upgrade and the ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE statement to end the upgrade. Application changes related to the upgrade are propagated to the application PDBs that synchronize with the application in the application root.

#### 44.3.3.1 About Upgrading Applications in an Application Container

You issue ALTER PLUGGABLE DATABASE APPLICATION statements to upgrade an application in the application root.

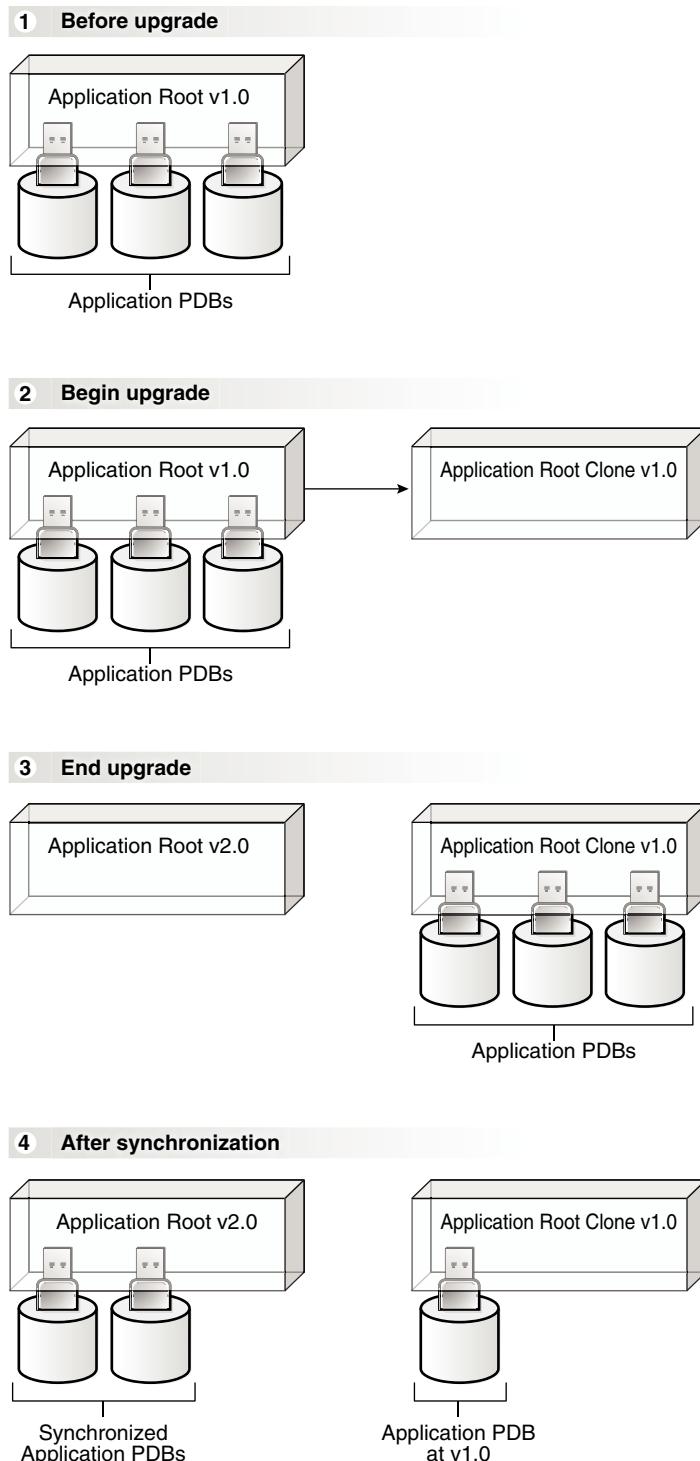

You upgrade the application in the application root only, and application PDBs apply the changes in the upgrade when they synchronize with the application. Application PDBs synchronize with an application by running an ALTER PLUGGABLE DATABASE statement with the SYNC clause. The upgrade can be done with one or more of the following: scripts, SQL statements, and graphical user interface tools.

You must indicate the start of the upgrade with an ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE statement and the end of the upgrade with an ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE statement. Each upgrade must be associated with an application name, starting version number, and ending version number, which are specified in the ALTER PLUGGABLE DATABASE APPLICATION statements.

When an application is upgraded, Oracle Database automatically creates a clone of the application root. During the upgrade operation, application PDBs are pointed to the clone. Applications continue to run during the upgrade operation. Application PDBs can perform DML operations on metadata-linked and extended data-linked tables and views, and application PDBs can query metadata-linked objects, extended data-linked objects, and data-linked objects. After the upgrade operation is complete, the application root clone remains and continues to support any application PDB that uses the version of the application in the clone. Application PDBs that upgrade are pointed to the upgraded application root. Application PDBs that do not upgrade might continue to use the clone, and application PDBs that are plugged into the application root might also use the same application version as the clone.

[Figure 44-1](#) illustrates the upgrade process.

**Figure 44-1 Upgrading Applications in an Application Container**

 **Note:**

When the application root is in any open mode, the application root clone is in read-only mode. When the application root is closed, the application root clone is also closed.

### 44.3.3.2 Upgrading an Application in an Application Container

To upgrade an application in an application container, run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE` statement to begin the upgrade and the `ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE` statement to end the upgrade.

Application changes related to the upgrade are propagated to the application PDBs that synchronize with the application in the application root.

The following prerequisites must be met:

- The CDB must be in local undo mode.
  - The current user must have the `ALTER PLUGGABLE DATABASE` system privilege, and the privilege must be commonly granted in the application root.
  - The application root must be in open read/write mode.
1. In SQL\*Plus, ensure that the current container is the application root.
  2. Run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE` statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name BEGIN UPGRADE
'application_start_version_number' TO
'application_end_version_number';
```

For example, run the following statement if the `application_name` is `salesapp`, the `application_start_version_number` is `4.2`, and the `application_end_version_number` is `4.3`:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN UPGRADE '4.2' TO
'4.3';
```

3. Upgrade the application using scripts, SQL statements, or graphical user interface tools.
4. Run the `ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE` statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name END UPGRADE TO
'application_end_version_number';
```

For example, run the following statement if the `application_name` is `salesapp` and the `application_end_version_number` is `4.3`:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp END UPGRADE TO '4.3';
```

 **Note:**

Ensure that the *application\_name* and *application\_end\_version\_number* match in the ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE statement and the ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE statement.

5. Synchronize all of the application PDBs that must upgrade the application by issuing an ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause.

**Related Topics**

- [Accessing a Container in a CDB with SQL\\*Plus](#)  
You can access a container in a CDB with SQL\*Plus.
- [Synchronizing Applications in an Application PDB](#)  
When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.
- [Managing the CDB Undo Mode](#)  
When local undo is enabled, each container has its own undo tablespace for every instance in which it is open. When local undo is disabled, there is one undo tablespace for the entire CDB.

## 44.3.4 Patching Applications in an Application Container

Minor changes to an application constitute application patches. Examples of minor changes can include bug fixes and security patches. You can patch an application in an application container.

- [About Patching Applications in an Application Container](#)  
You issue ALTER PLUGGABLE DATABASE APPLICATION statements to patch an application in the application root.
- [Patching an Application in an Application Container with Automated Propagation](#)  
To patch an application in an application container, run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN PATCH statement to begin the patch operation and the ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE statement to end the patch operation. Application changes for the patch are propagated to the application PDBs that synchronize with the application in the application root.

### 44.3.4.1 About Patching Applications in an Application Container

You issue ALTER PLUGGABLE DATABASE APPLICATION statements to patch an application in the application root.

You patch the application in the application root only, and the application PDBs that synchronize with the application apply the changes. The patch can be done with one or more of the following: scripts, SQL statements, and graphical user interface tools.

You must indicate the start of the patch operation with an ALTER PLUGGABLE DATABASE APPLICATION BEGIN PATCH statement and the end of the patch operation with an ALTER

PLUGGABLE DATABASE APPLICATION END PATCH statement. Each patch must be associated with an application name, starting version number, and ending version number, which are specified in the ALTER PLUGGABLE DATABASE APPLICATION statements.

 **Note:**

The patch process is restricted to a small set of operations. In general, destructive operations, such as dropping a table, are not allowed in a patch. If you attempt to patch an application, and the operation raises an “operation not supported in an application patch” error, then upgrade the application instead of patching it to make the necessary changes.

#### Related Topics

- [Running Oracle-Supplied SQL Scripts in a CDB](#)  
You can use the catcon.pl script to run Oracle-supplied SQL scripts in a CDB.
- [Upgrading Applications in an Application Container](#)  
Major changes to an application constitute application upgrades. You can upgrade an application in an application container.

### 44.3.4.2 Patching an Application in an Application Container with Automated Propagation

To patch an application in an application container, run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN PATCH statement to begin the patch operation and the ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE statement to end the patch operation. Application changes for the patch are propagated to the application PDBs that synchronize with the application in the application root.

The following prerequisites must be met:

- The current user must have the ALTER PLUGGABLE DATABASE system privilege, and the privilege must be commonly granted in the application root.
  - The application root must be in open read/write mode.
1. In SQL\*Plus, ensure that the current container is the application root.
  2. Run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN PATCH statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name BEGIN PATCH
patch_number MINIMUM VERSION 'minimum_application_version_number';
```

For example, run the following statement if the *application\_name* is salesapp, the *patch\_number* is 987654, and the *minimum\_application\_version\_number* is 4.2:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN PATCH 987654
MINIMUM VERSION '4.2';
```

The *minimum\_application\_version\_number* indicates the minimum application version at which an application installation must be before the patch can be applied to it.

3. Patch the application using scripts, SQL statements, and graphical user interface tools.

4. Run the ALTER PLUGGABLE DATABASE APPLICATION END PATCH statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name END PATCH
patch_number;
```

For example, run the following statement if the *application\_name* is `salesapp` and the *patch\_number* is `987654`:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp END PATCH 987654;
```

 **Note:**

Ensure that the *application\_name* and *patch\_number* match in the ALTER PLUGGABLE DATABASE APPLICATION BEGIN PATCH statement and the ALTER PLUGGABLE DATABASE APPLICATION END PATCH statement.

5. Synchronize all of the application PDBs that must patch the application by issuing an ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause.

You can access a container in a CDB with SQL\*Plus.
- [Synchronizing Applications in an Application PDB](#)  
When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

### 44.3.5 Migrating an Existing Application to an Application Container

You can migrate an application that is installed in a PDB to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12c Release 1 (12.1) CDB to an application container in an Oracle Database 12c Release 2 (12.2) CDB.

- [About Migrating an Existing Application to an Application Container](#)  
You can migrate an application to an application root by creating an application root using an existing PDB.
- [Creating an Application Root Using an Existing PDB](#)  
You can migrate an application that is installed in a PDB by copying the PDB to an application container.
- [Creating an Application PDB Using an Existing PDB](#)  
After migrating an existing application to an application root, you can use an existing PDB that uses the application to create an application PDB.

#### 44.3.5.1 About Migrating an Existing Application to an Application Container

You can migrate an application to an application root by creating an application root using an existing PDB.

If the application is installed in more than one PDB, then you can use one of the PDBs to create the application root. You can use one of the methods available for copying a PDB to an application root, such as cloning the PDB or plugging in the PDB as an application root.

When common users, roles, or profiles exist in the PDB used to create the application root, you must run procedures in the DBMS\_PDB package to associate them with the application. When an application root created from a PDB is first opened, each local user, role, and profile is marked as common. The procedures in the DBMS\_PDB package associate the user, role, or profile with the application. Therefore, all DDL operations on the user, role, or profile must subsequently be done within an application BEGIN...END block of this application.

When shared database objects exist in the application root, you must run procedures in the DBMS\_PDB package to associate the database objects with the application as application common objects. Therefore, all DDL operations on the application common objects must subsequently be done within an application BEGIN...END block of this application.

After the application root is in place, you can create application PDBs in the new application container using the existing PDBs. The application PDBs that you create must contain the application's database objects, including their data. Additional steps are necessary to synchronize the application version and patch number and to establish shared database objects in the application PDBs.

### Scenario with One Hundred PDBs Running the Same Application

Assume that you currently have one hundred PDBs that are running the same application, and you want to migrate these PDBs to an application container. These PDBs have the application common objects and common users, roles, and profiles required by the application. To migrate the PDBs to an application container, follow these steps:

1. Choose one of the PDBs, and use the instructions in "[Creating an Application Root Using an Existing PDB](#)" to create the application root with this PDB.

As part of this step, you associate the database objects, users, roles, and profiles with the application by running procedures in the DBMS\_PDB package.
2. Use the instructions in "[Creating an Application PDB Using an Existing PDB](#)" to create one hundred application PDBs using the PDBs that are running the application.

#### Related Topics

- [Creating an Application Container](#)

You can create an application container using the CREATE PLUGGABLE DATABASE statement with the AS APPLICATION CONTAINER clause.

### 44.3.5.2 Creating an Application Root Using an Existing PDB

You can migrate an application that is installed in a PDB by copying the PDB to an application container.

An Oracle Database 12c Release 2 (12.2) CDB must exist.

1. In the Oracle Database 12c Release 2 (12.2) CDB, create the application root by cloning the existing PDB, relocating the existing PDB, or by unplugging and plugging in the existing PDB.

The new application root must contain all of the database objects used by the application.

2. With the application root as the current container, start an application installation operation by issuing an `ALTER PLUGGABLE DATABASE ... BEGIN INSTALL` statement.
  3. Optional: Query the `COMMON` column in the `DBA_USERS`, `DBA_ROLES`, and `DBA_PROFILES` views to determine which users, roles, and profiles are common.
  4. Run the following procedures in the `DBMS_PDB` package to associate users, roles, and profiles with the application:
    - Run the `SET_USER_EXPLICIT` procedure to set application common users.
    - Run the `SET_ROLE_EXPLICIT` procedure to set application common roles.
    - Run the `SET_PROFILE_EXPLICIT` procedure to set application common profiles.
- If you do not have `EXECUTE` privilege on the `DBMS_PDB` package, then you can run these procedures in the `DBMS_PDB_ALTER_SHARING` package.
5. Optional: With the application root as the current container, query the `SHARING` column in the `DBA_OBJECTS` view to determine which database objects are shared.
  6. Run the following procedures in the `DBMS_PDB` package to associate database objects with the application:
    - Run the `SET_DATA_LINKED` procedure to set data-linked application common objects.
    - Run the `SET_METADATA_LINKED` procedure to set metadata-linked application common objects.
    - Run the `SET_EXT_DATA_LINKED` procedure to set extended data-linked application common objects.

If you do not have `EXECUTE` privilege on the `DBMS_PDB` package, then you can run these procedures in the `DBMS_PDB_ALTER_SHARING` package.

7. End the application installation operation by issuing an `ALTER PLUGGABLE DATABASE ... END INSTALL` statement.
8. Optional: Rerun the queries that you ran previously to ensure that the sharing properties of the database objects are correct and that the common properties of the users, roles, and profiles are correct.
9. Optional: If existing PDBs use the application, then create application PDBs using these existing PDBs.

See "[Creating an Application PDB Using an Existing PDB](#)".

## Related Topics

- [Creating an Application Container](#)

You can create an application container using the `CREATE PLUGGABLE DATABASE` statement with the `AS APPLICATION CONTAINER` clause.

- [Managing Applications in an Application Container](#)

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- *Oracle Database PL/SQL Packages and Types Reference*

### 44.3.5.3 Creating an Application PDB Using an Existing PDB

After migrating an existing application to an application root, you can use an existing PDB that uses the application to create an application PDB.

An Oracle Database 12c Release 2 (12.2) CDB must exist, and the application root to which the application PDB will belong must exist.

The PDB must contain all of the application common objects used by the application.

The application must be installed in the application root.

1. In the application root, create the application PDB by cloning the existing PDB, relocating the existing PDB, or by unplugging and plugging in the existing PDB.  
Violations will be reported during PDB creation.
2. Connect to or switch to the new PDB as a user with the required privileges.
3. Run the `pdb_to_appdb.sql` script in the `ORACLE_HOME/rdbms/admin` directory.  
The script automatically synchronizes the application PDB with the application root.
4. Optional: Query the `COMMON` column in the `DBA_USERS`, `DBA_ROLES`, and `DBA_PROFILES` views to ensure that the common properties of the users, roles, and profiles are correct.
5. Optional: Query the `SHARING` column in the `DBA_OBJECTS` view to ensure that the sharing properties of the database objects are correct.

#### Related Topics

- [Creating and Removing PDBs with SQL\\*Plus](#)

You can create PDBs in several different ways, including using the seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove PDBs from a CDB.

### 44.3.6 Synchronizing Applications in an Application PDB

When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

In addition to user-created applications, application containers can also contain implicitly created applications. An application is created implicitly in an application root when an application common user operation is issued with a `CONTAINER=ALL` clause outside of `ALTER PLUGGABLE DATABASE BEGIN/END` statements. Application common user operations include operations such as creating a common user with a `CREATE USER` statement or altering a common user with an `ALTER USER` statement. There are several other application common user operations. An implicit application is named `APP$guid`, where `guid` is the GUID of the application root. An implicit application is created when the application root is opened for the first time.

You synchronize one application in an application PDB by issuing the following SQL statement when the application PDB is the current container:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name SYNC;
```

Enter the name of the application for *application\_name*.

You synchronize all of the applications in an application PDB, including implicitly created applications, by issuing the following SQL statement when the application PDB is the current container:

```
ALTER PLUGGABLE DATABASE APPLICATION ALL SYNC;
```

You synchronize implicitly created applications in an application PDB by issuing one of the following SQL statement when the application PDB is the current container:

- `ALTER PLUGGABLE DATABASE APPLICATION APP$guid SYNC;`  
*guid* is the GUID of the application root.
  - `ALTER PLUGGABLE DATABASE APPLICATION APP$CON SYNC;`  
`APP$CON` is a logical application name that Oracle Database automatically translates to the real name of the implicit application.
1. In SQL\*Plus, ensure that the current container is the application PDB.  
The current user must have `ALTER PLUGGABLE DATABASE` system privilege.
  2. Run an `ALTER PLUGGABLE DATABASE APPLICATION` statement with the `SYNC` clause.

#### **Example 44-2 Synchronizing a Specific Application in an Application PDB**

This example synchronizes an application named `salesapp` with the latest application changes in the application root.

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp SYNC;
```

#### **Example 44-3 Synchronizing All of the Applications in an Application PDB**

This example synchronizes all of the applications in an application PDB with the latest application changes in the application root.

```
ALTER PLUGGABLE DATABASE APPLICATION ALL SYNC;
```

#### **Example 44-4 Synchronizing Implicitly-Created Applications in an Application PDB**

This example synchronizes all of the implicitly-created applications in an application PDB with the latest application changes to the implicitly created applications in the application root.

```
ALTER PLUGGABLE DATABASE APPLICATION APP$CON SYNC;
```

### 44.3.7 Synchronizing an Application Root Replica with a Proxy PDB

When application containers in different CDBs have the same application, their application roots can be kept synchronized by creating a master application root, a replica application root, and a proxy PDB.

- [About Synchronizing an Application Root Replica with a Proxy PDB](#)  
A proxy PDB can synchronize an application root and a replica based on the application root. When multiple application containers have the same application, you can use this technique to keep the application synchronized in all of the application containers. The application root and the application root replica can be in different CDBs.
- [Creating a Proxy PDB That References an Application Root Replica](#)  
When multiple application containers must run the same application, the application in the application containers can be kept in using proxy PDBs.

#### 44.3.7.1 About Synchronizing an Application Root Replica with a Proxy PDB

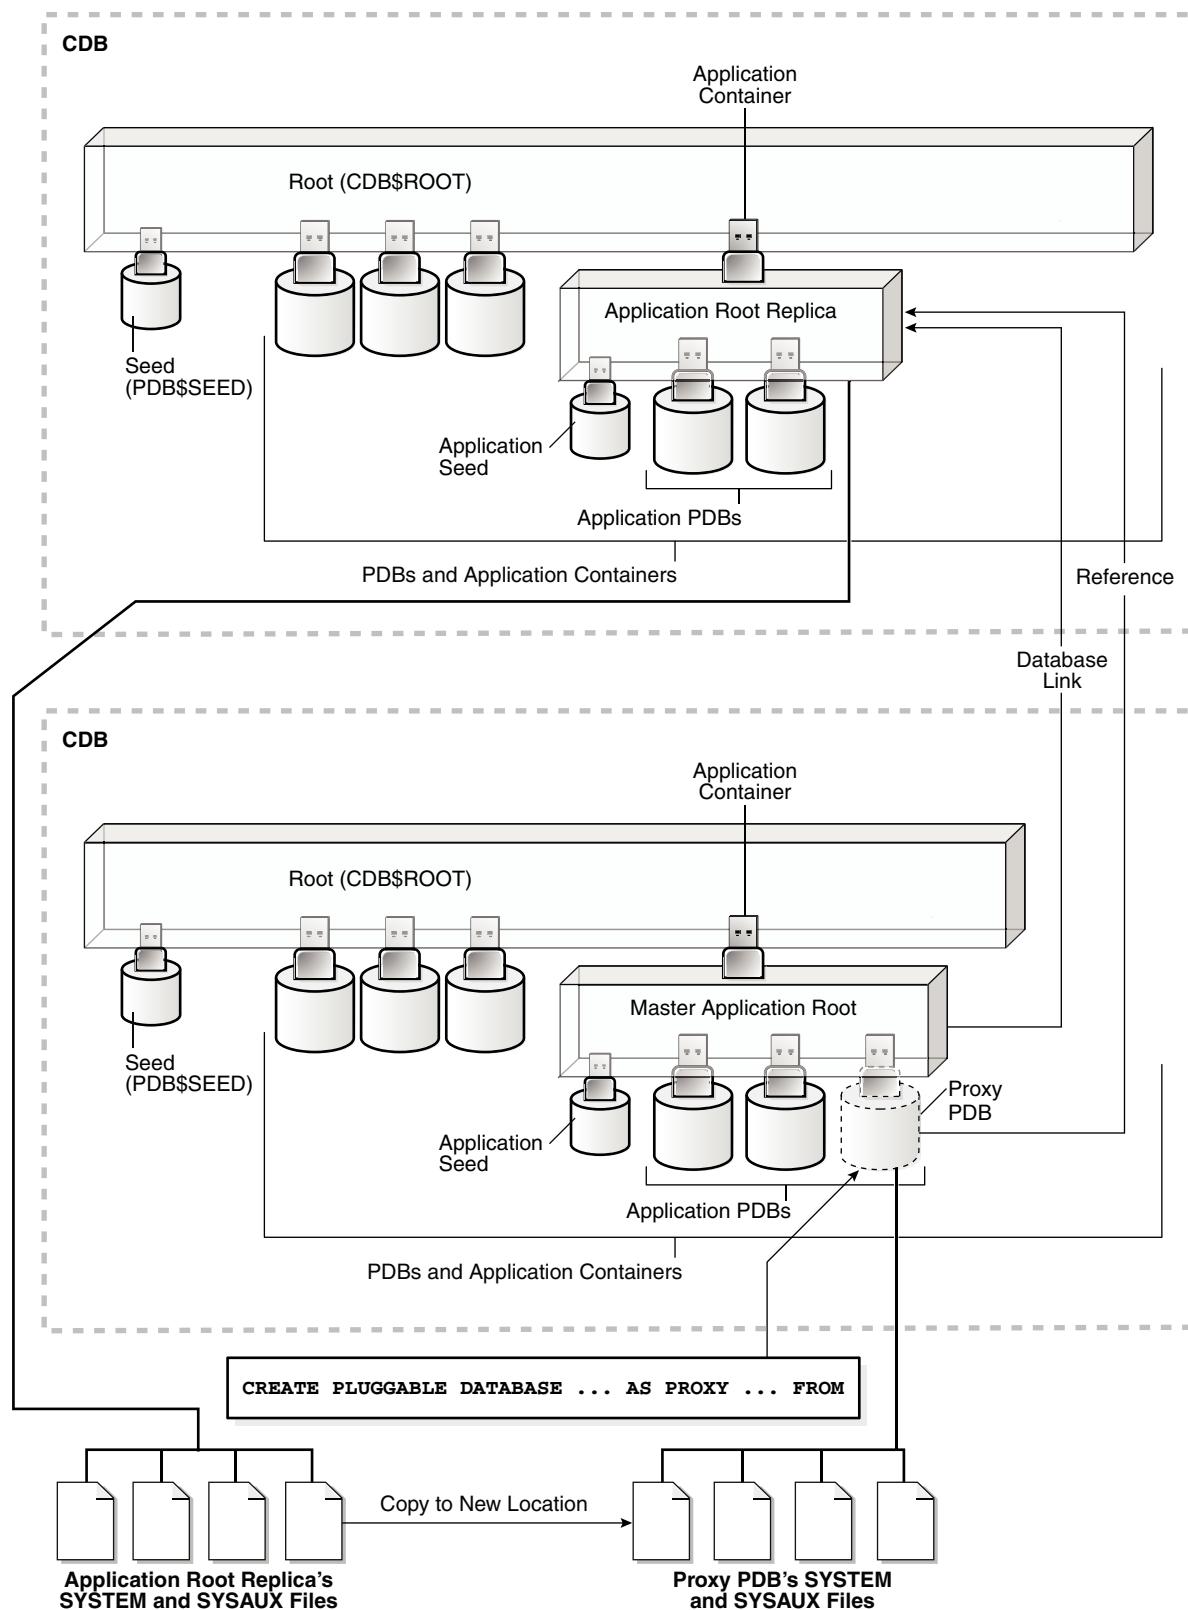

A proxy PDB can synchronize an application root and a replica based on the application root. When multiple application containers have the same application, you can use this technique to keep the application synchronized in all of the application containers. The application root and the application root replica can be in different CDBs.

A particular application might be installed in several application containers. You can make installing, upgrading, and patching the application more efficient by using proxy PDBs.

In this configuration, one application container has the master application root. The master application root is where the application is installed, upgraded, and patched. One or more application root replicas are copies of the master application root. Each application root replica will be referenced by a proxy PDB in the master application root.

Whenever a proxy PDB is synchronized with the application changes in the master application root, it propagates those changes to its referenced application root replica. After an application root replica is synchronized with the changes from the master application root, application PDBs that are plugged into the application root replica can synchronize with it to get the changes also.

[Figure 44-2](#) shows a configuration that synchronizes an application root replica using a proxy PDB.

**Figure 44-2 Synchronizing an Application Root Replica with a Proxy PDB**

In addition, when an application root replica is configured and has its own application PDBs, a query that includes the CONTAINERS clause in the master application root can return data from the current application container and from the application container with the application root replica. The query can show results from the application root replica and from any open application PDBs plugged into it.

#### Related Topics

- [Querying Application Common Objects Across Application PDBs](#)

The CONTAINERS clause enables you to query application common objects, such as tables and views, across all application PDBs in an application container. This clause enables queries from the application root to display data in tables or views that exist in all of the open application PDBs in the application container.

### 44.3.7.2 Creating a Proxy PDB That References an Application Root Replica

When multiple application containers must run the same application, the application in the application containers can be kept in using proxy PDBs.

1. Use a CREATE PLUGGABLE DATABASE statement to create the application container with the master application root.

You can install the application in the application container now or at a later time.

2. Use a CREATE PLUGGABLE DATABASE statement to create the application container with the application root replica in one of the following ways:

- Create an empty application container using any supported method.
- Clone the master application root.

If the port of the listener used by the application root replica is not 1521, then a PORT clause is required during creation. If the host of the application root replica is different from the host of the master application root, then a HOST clause is required during creation.

This application root replica will be referenced by the proxy PDB.

3. In the master application root, create a proxy PDB that references the application root replica you created in the previous step.

4. Open and synchronize the proxy PDB.

When the proxy PDB is synchronized, it propagates the changes in the master application root to the application root replica.

5. Optional: In the master application root, modify the application by installing, upgrading, or patching it.

6. Optional: Synchronize the proxy PDB with the application changes in the master application root by running the ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause.

When the proxy PDB is synchronized, it propagates the changes in the master application root to the application root replica.

#### Example 44-5 Synchronizing an Application Root Replica with a Proxy PDB

This example assumes that two CDBs exist. One CDB is named hgdb and the other is named depdb. The goal is to keep the same application synchronized in an application container in each CDB. To accomplish this goal, this example configures the following application containers:

- The `hqdb` CDB contains the application container with the master application root called `msappcon`.
  - An application called `sampleapp` is installed in the `msappcon` master application root.
  - The `msappcon` application root contains two application PDBs named `mspdb1` and `mspdb2`.
  - The `msappcon` application root also contains a proxy PDB named `prxy` that references the application root replica in the other CDB.
- The `depdb` CDB contains the application container with the application root replica called `depappcon`.
  - An application called `sampleapp` is propagated from the proxy PDB `prxy` in the `msappcon` master application root and installed in the `depappcon` master application root.
  - The `depappcon` application root contains two application PDBs named `deppdb1` and `deppdb2`.

This example shows how changes to the `sampleapp` application in the `msappcon` master application root are applied to the application PDBs in both CDBs when the application PDBs are synchronized.

1. Create the application container with the master application root in the `hqdb` CDB.
  - a. In SQL\*Plus, ensure that the current container is the `hqdb` CDB root.
  - b. Create the application container from the CDB seed with the following statement:

```
CREATE PLUGGABLE DATABASE msappcon
 AS APPLICATION CONTAINER
 ADMIN USER msappconadm IDENTIFIED BY password STORAGE (MAXSIZE
2G)
 DEFAULT TABLESPACE appcontbs
 DATAFILE '/disk1/oracle/dbs/mssappcon/msappcon01.dbf' SIZE 250M
 AUTOEXTEND ON
 FILE_NAME_CONVERT = ('/disk1/oracle/dbs/pdbseed/' , '/disk1/
oracle/dbs/msappcon/');
```

2. Open the new master application root in read/write mode:
  - c. Open the new master application root in read/write mode:

```
ALTER PLUGGABLE DATABASE msappcon OPEN;
```

2. Install an application in the master application root.
  - a. Change container to the master application root:

```
ALTER SESSION SET CONTAINER=msappcon;
```

2. Begin the application installation:

```
ALTER PLUGGABLE DATABASE APPLICATION sampleapp BEGIN INSTALL '1.0';
```

2. Install the application.

For example, you can create database objects:

```
CREATE TABLE apptb SHARING=METADATA
 (id NUMBER(6),
 widget_name VARCHAR2(20));
```

- d. End the application installation:

```
ALTER PLUGGABLE DATABASE APPLICATION sampleapp END INSTALL '1.0';
```

- 3. Create and synchronize one or more application PDBs in the master application root.
  - a. In SQL\*Plus, ensure that the current container is the master application root.
  - b. Create application PDBs in the master application root.

For example, create two application PDBs from the CDB seed:

```
CREATE PLUGGABLE DATABASE mspdb1 ADMIN USER mspdb1admin IDENTIFIED
BY password
 STORAGE (MAXSIZE 2G)
 DEFAULT TABLESPACE mspdbltsb
 DATAFILE '/disk1/oracle/dbs/mspdbl/mspdbl01.dbf' SIZE 250M
 AUTOEXTEND ON
 FILE_NAME_CONVERT = ('/disk1/oracle/dbs/pdbseed/', '/disk1/
oracle/dbs/mspdbl/');
```

```
CREATE PLUGGABLE DATABASE mspdb2 ADMIN USER mspdb2admin IDENTIFIED
BY password
 STORAGE (MAXSIZE 2G)
 DEFAULT TABLESPACE mspdb2tbs
 DATAFILE '/disk1/oracle/dbs/mspdbl/mspdbl01.dbf' SIZE 250M
 AUTOEXTEND ON
 FILE_NAME_CONVERT = ('/disk1/oracle/dbs/pdbseed/', '/disk1/
oracle/dbs/mspdbl/');
```

- c. Open both application PDBs:

```
ALTER PLUGGABLE DATABASE mspdb1 OPEN;
ALTER PLUGGABLE DATABASE mspdb2 OPEN;
```

- d. Synchronize the application PDBs with the master application root:

```
ALTER SESSION SET CONTAINER=mspdbl;
ALTER PLUGGABLE DATABASE APPLICATION sampleapp SYNC;

ALTER SESSION SET CONTAINER=mspdbl2;
ALTER PLUGGABLE DATABASE APPLICATION sampleapp SYNC;
```

- 4. Create the application container with the application root replica in the depdb CDB.
  - a. In SQL\*Plus, ensure that the current container is the depdb CDB root.

- b. Create the application container from the CDB seed with the following statement:

```
CREATE PLUGGABLE DATABASE depappcon
 AS APPLICATION CONTAINER
 ADMIN USER depappconadm IDENTIFIED BY password
 STORAGE (MAXSIZE 2G)
 DEFAULT TABLESPACE appcontbs
 DATAFILE '/disk2/oracle/dbs/depsappcon/depappcon01.dbf' SIZE
250M AUTOEXTEND ON
 FILE_NAME_CONVERT = ('/disk2/oracle/dbs/pdbseed/' , '/disk2/
oracle/dbs/depappcon/');
```

 **Note:**

- If the port of the listener used by the application root replica is not 1521, then a `PORT` clause is required.
- If the host of the application root replica is different from the host of the master application root, then a `HOST` clause is required.

- c. Open the new application root replica in read/write mode:

```
ALTER PLUGGABLE DATABASE depappcon OPEN;
```

5. Create and synchronize the proxy PDB in the master application root.
- In SQL\*Plus, ensure that the current container is the master application root.
  - Create a database link to the application root replica:

```
CREATE PUBLIC DATABASE LINK depappcon CONNECT TO depappconadm
 IDENTIFIED BY password USING 'depappcon';
```

- c. Create the proxy PDB:

```
CREATE PLUGGABLE DATABASE prxy AS PROXY FROM depappcon@depappcon
 FILE_NAME_CONVERT = ('/disk2/oracle/dbs/depsappcon/' , '/disk1/
oracle/dbs/prxy/');
```

- d. Open the proxy PDB:

```
ALTER PLUGGABLE DATABASE prxy OPEN;
```

- e. Synchronize the proxy PDB with the master application root:

```
ALTER SESSION SET CONTAINER=prxy;
ALTER PLUGGABLE DATABASE APPLICATION sampleapp SYNC;
```

6. Create and synchronize one or more application PDBs in the application root replica.

- a. Change container to the application root replica:

```
ALTER SESSION SET CONTAINER=depappcon;
```

- b. Create application PDBs in the application root replica.

For example, create two application PDBs from the CDB seed:

```
CREATE PLUGGABLE DATABASE deppdb1 ADMIN USER depdb1admin
IDENTIFIED BY password
 STORAGE (MAXSIZE 2G)
 DEFAULT TABLESPACE depdb1tbs
 DATAFILE '/disk2/oracle/dbs/deppdb1/deppdb101.dbf' SIZE 250M
 AUTOEXTEND ON
 FILE_NAME_CONVERT = ('/disk2/oracle/dbs/pdbseed/', '/disk2/
oracle/dbs/deppdb1/');

CREATE PLUGGABLE DATABASE deppdb2 ADMIN USER depdb2admin
IDENTIFIED BY password
 STORAGE (MAXSIZE 2G)
 DEFAULT TABLESPACE depdb2tbs
 DATAFILE '/disk2/oracle/dbs/deppdb2/deppdb201.dbf' SIZE 250M
 AUTOEXTEND ON
 FILE_NAME_CONVERT = ('/disk2/oracle/dbs/pdbseed/', '/disk2/
oracle/dbs/deppdb2/');
```

- c. Open both application PDBs:

```
ALTER PLUGGABLE DATABASE deppdb1 OPEN;
ALTER PLUGGABLE DATABASE deppdb2 OPEN;
```

- d. Synchronize the application PDBs with the master application root:

```
ALTER SESSION SET CONTAINER=deppdb1;
ALTER PLUGGABLE DATABASE APPLICATION sampleapp SYNC;

ALTER SESSION SET CONTAINER=deppdb2;
ALTER PLUGGABLE DATABASE APPLICATION sampleapp SYNC;
```

7. Check the structure of the `apptb` table in an application PDB in the application root replica.

- a. From the application root replica, switch containers to the `deppdb1` application PDB:

```
ALTER SESSION SET CONTAINER=deppdb1;
```

- b. Describe the `apptb` table:

```
desc apptb
```

Your output is similar to the following:

| Name        | Null? | Type         |
|-------------|-------|--------------|
| ID          |       | NUMBER(6)    |
| WIDGET_NAME |       | VARCHAR2(20) |

- 8.** In the master application root, upgrade the application.

- a.** Change container to the master application root:

```
ALTER SESSION SET CONTAINER=msappcon;
```

- b.** Begin the application upgrade.

```
ALTER PLUGGABLE DATABASE APPLICATION sampleapp BEGIN UPGRADE '1.0'
TO '1.1';
```

- c.** Modify the application.

For example, add a row to the apptb table:

```
ALTER TABLE apptb ADD (widget_type VARCHAR2(30));
```

- d.** End the application upgrade:

```
ALTER PLUGGABLE DATABASE APPLICATION sampleapp END UPGRADE TO '1.1';
```

- 9.** Synchronize the proxy PDB with the master application root:

```
ALTER SESSION SET CONTAINER=prxy;
ALTER PLUGGABLE DATABASE APPLICATION sampleapp SYNC;
```

- 10.** Synchronize the application PDBs in the application root replica and check for the application upgrade.

- a.** Synchronize the application PDBs:

```
ALTER SESSION SET CONTAINER=deppdb1;
ALTER PLUGGABLE DATABASE APPLICATION sampleapp SYNC;
```

```
ALTER SESSION SET CONTAINER=deppdb2;
ALTER PLUGGABLE DATABASE APPLICATION sampleapp SYNC;
```

- b.** From the application root replica, switch containers to the deppdb1 application PDB:

```
ALTER SESSION SET CONTAINER=deppdb1;
```

- c.** Describe the apptb table:

```
desc apptb
```

Your output is similar to the following:

| Name        | Null? | Type           |
|-------------|-------|----------------|
| ID          |       | NUMBER( 6 )    |
| WIDGET_NAME |       | VARCHAR2( 20 ) |
| WIDGET_TYPE |       | VARCHAR2( 30 ) |

Notice that the change in the application upgrade is reflected in the output because the `widget_type` column has been added to the `apptb` table.

### Related Topics

- [Creating Application Containers](#)

You can use the `CREATE PLUGGABLE DATABASE` statement to create an application container in a CDB.

- [Creating a PDB as a Proxy PDB](#)

You can create a PDB as a proxy PDB by referencing a PDB in a remote CDB.

- [Managing Applications in an Application Container](#)

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- [Synchronizing Applications in an Application PDB](#)

When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

## 44.3.8 Setting the Compatibility Version of an Application

The compatibility version of an application is the earliest version of the application possible for the application PDBs that belong to the application container.

The compatibility version is enforced when the compatibility version is set and when an application PDB is created. If there are application root clones that resulted from application upgrades, then all application root clones that correspond to versions earlier than the compatibility version are implicitly dropped.

You specify the compatibility version of an application by issuing one of the following SQL statements when the application root is the current container:

- `ALTER PLUGGABLE DATABASE APPLICATION application_name SET COMPATIBILITY VERSION 'application_version_number';`

*application\_name* is the name of the application, and *application\_version\_number* is the earliest compatible version.

- `ALTER PLUGGABLE DATABASE APPLICATION application_name SET COMPATIBILITY VERSION CURRENT;`

*application\_name* is the name of the application. The current version is the version of the application in the application root.

1. In SQL\*Plus, ensure that the current container is the application root.
2. Run an ALTER PLUGGABLE DATABASE APPLICATION SET COMPATIBILITY VERSION statement.

#### Example 44-6 Setting the Compatibility Version to a Specific Version Number

This example sets the compatibility version for an application named `salesapp` to version 4.2.

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp SET COMPATIBILITY VERSION
'4.2';
```

#### Example 44-7 Setting the Compatibility Version to the Current Application Version

This example sets the compatibility version for an application named `salesapp` to the current application version.

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp SET COMPATIBILITY VERSION
CURRENT;
```

["About Upgrading Applications in an Application Container"](#) for information about application root clones

### 44.3.9 Performing Bulk Inserts During Application Install, Upgrade, and Patch Operations

SQL\*Loader is the only supported utility for bulk inserts into tables during application install, upgrade, and patch operations. Only conventional path loads are supported for bulk inserts during application install, upgrade, and patch operations.

The correct SQL\*Loader module name must be specified between the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN` and `ALTER PLUGGABLE DATABASE APPLICATION END` statements. The module name is SQL Loader Conventional Path Load.

1. In SQL\*Plus, ensure that the current container is the application root.
2. Set the correct module by running the following procedure:

```
exec DBMS_APPLICATION_INFO.SET_MODULE('SQL Loader Conventional Path
Load', ''');
```

This module must remain set for the entire application install, upgrade, or patch operation.

3. Run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN` statement for beginning an application installation, upgrade, or patch.

For example, if you are performing the bulk insert as part of an application installation, then run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name BEGIN INSTALL
'application_version_number';
```

4. Perform the conventional path load with SQL\*Loader.
5. Run the ALTER PLUGGABLE DATABASE APPLICATION END statement for ending an application installation, upgrade, or patch.

For example, if you are performing the bulk insert as part of an application installation, then run the ALTER PLUGGABLE DATABASE APPLICATION END INSTALL statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name END INSTALL
'application_version_number';
```

 **Note:**

Ensure that the *application\_name* and *application\_version\_number* match in the ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL statement and the ALTER PLUGGABLE DATABASE APPLICATION END INSTALL statement.

6. Synchronize all of the application PDBs that must include these application changes by issuing an ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause.

#### **Example 44-8 Performing a Conventional Path Load During an Application Installation**

In this example, the conventional path load is performed in an application root.

1. In SQL\*Plus, switch to the application root.

```
ALTER SESSION SET CONTAINER=cdb1_aproot1;
```

2. Set the correct module.

```
exec DBMS_APPLICATION_INFO.SET_MODULE('SQL Loader Conventional Path
Load', ''');
```

3. Start the application installation.

```
ALTER PLUGGABLE DATABASE APPLICATION APP1 BEGIN INSTALL '1';
```

4. Use SQL\*Loader to perform the conventional path load.

```
host sqlldr u1/u1@cdb1_aproot1 control=my_bulk_load.ctl rows=3
log=my_bulk_load.log
```

5. End the application installation.

```
ALTER PLUGGABLE DATABASE APPLICATION APP1 END INSTALL '1';
```

## 44.3.10 Uninstalling Applications from an Application Container

You can uninstall an application in an application container.

- [About Uninstalling Applications from an Application Container](#)

You issue `ALTER PLUGGABLE DATABASE APPLICATION` statements to uninstall an application from the application root.

- [Uninstalling an Application from an Application Container](#)

To uninstall an application in from application container, run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UNINSTALL` statement to begin the uninstallation and the `ALTER PLUGGABLE DATABASE APPLICATION END UNINSTALL` statement to end the uninstallation. The application uninstalled from the application PDBs that synchronize with the application in the application root.

### 44.3.10.1 About Uninstalling Applications from an Application Container

You issue `ALTER PLUGGABLE DATABASE APPLICATION` statements to uninstall an application from the application root.

You uninstall the application from the application root only, and application PDBs that synchronize with the application uninstall the application automatically. The uninstall operation can be done with one or more of the following: scripts, SQL statements, and graphical user interface tools.

You must indicate the start of the uninstallation with an `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UNINSTALL` statement and the end of the uninstallation with an `ALTER PLUGGABLE DATABASE APPLICATION END UNINSTALL` statement. Each uninstallation must be associated with an application name and version number, which are specified in the `ALTER PLUGGABLE DATABASE APPLICATION` statements.

Uninstalling an application does not remove the application from the data dictionary. It marks the application as `UNINSTALLED` so that upgrade, patch, and uninstall of the application is disallowed.

Destructive changes to application objects are allowed during application uninstallation. Applications running in an application PDB continue to function during uninstallation and after the application is uninstalled from the application root. The application can continue to function in the application PDB because the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UNINSTALL` statement creates a clone of the application root called an application root clone. An application root clone serves as a metadata repository for old versions of application objects, so that application PDBs that have not been synchronized with latest version of the application can continue to function. Because the clone is created while the application PDB is open, local undo must be configured at the CDB level before an application can be uninstalled.

 **Note:**

An application upgrade also creates an application root clone.

 **See Also:**

- "[About Upgrading Applications in an Application Container](#)" for information about application root clones
- "[Running Oracle-Supplied SQL Scripts in a CDB](#)"

#### 44.3.10.2 Uninstalling an Application from an Application Container

To uninstall an application in from application container, run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UNINSTALL` statement to begin the uninstallation and the `ALTER PLUGGABLE DATABASE APPLICATION END UNINSTALL` statement to end the uninstallation. The application uninstalled from the application PDBs that synchronize with the application in the application root.

The following prerequisites must be met:

- The CDB must be in local undo mode.
  - The current user must have the `ALTER PLUGGABLE DATABASE` system privilege, and the privilege must be commonly granted in the application root.
  - The application root must be in open read/write mode.
1. In SQL\*Plus, ensure that the current container is the application root.
  2. Run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UNINSTALL` statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name BEGIN UNINSTALL;
```

For example, run the following statement if the *application\_name* is salesapp:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN UNINSTALL;
```

3. Uninstall the application using scripts, SQL statements, or graphical user interface tools.
4. Run the `ALTER PLUGGABLE DATABASE APPLICATION END UNINSTALL` statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name END UNINSTALL;
```

For example, run the following statement if the *application\_name* is salesapp:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp END UNINSTALL;
```

 **Note:**

Ensure that the *application\_name* matches in the ALTER PLUGGABLE DATABASE APPLICATION BEGIN UNINSTALL statement and the ALTER PLUGGABLE DATABASE APPLICATION END UNINSTALL statement.

5. Synchronize all of the application PDBs that must uninstall the application by issuing an ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause.

**Related Topics**

- [Accessing a Container in a CDB with SQL\\*Plus](#)  
You can access a container in a CDB with SQL\*Plus.
- [Synchronizing Applications in an Application PDB](#)  
When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.
- [Managing the CDB Undo Mode](#)  
When local undo is enabled, each container has its own undo tablespace for every instance in which it is open. When local undo is disabled, there is one undo tablespace for the entire CDB.

## 44.4 Managing Application Common Objects

Application common objects are shared, user-created database objects in an application container. Application common objects are created in an application root.

- [About Application Common Objects](#)  
Application common objects are created in an application root and are shared with the application PDBs that belong to the application root. There are three types of application common object: metadata-linked, data-linked, and extended data-linked.
- [Restrictions for Application Common Objects](#)  
Some restrictions apply to application common objects.
- [Creating Application Common Objects](#)  
You create an application common object in an application root either by ensuring that the DEFAULT\_SHARING initialization parameter is set to the correct value or by including the SHARING clause in the CREATE SQL statement.
- [Issuing DML Statements on Application Common Objects](#)  
The rules are different for issuing DML statements on metadata-linked, data-linked, and extended data-linked application common objects.
- [Modifying Application Common Objects with DDL Statements](#)  
When you modify an application common object in an application root with certain DDL statements, you must modify the object between ALTER PLUGGABLE DATABASE APPLICATION BEGIN and ALTER PLUGGABLE DATABASE APPLICATION END statements, and application PDBs must synchronize with the application to apply the changes.

## 44.4.1 About Application Common Objects

Application common objects are created in an application root and are shared with the application PDBs that belong to the application root. There are three types of application common object: metadata-linked, data-linked, and extended data-linked.

The following types of database objects can be application common objects:

- Analytic views
- Attribute dimensions
- Directories
- External procedure libraries
- Hierarchies
- Java classes, Java resources, Java sources
- Packages
- Object tables
- Object types
- Object views
- Sequences
- Stored functions
- Stored procedures
- Synonyms
- Tables (including temporary tables)
- Triggers
- Views

You can create these types of database objects as application common objects by issuing the `CREATE` statement when the current container is the application root and specifying the `sharing` attribute for it. You can specify the `sharing` attribute by including the `SHARING` clause in the `CREATE` statement or by setting the `DEFAULT_SHARING` initialization parameter in the application root. When you set the `DEFAULT_SHARING` initialization parameter, the setting is the default sharing attribute for all database objects of a supported type created in the application root. However, when a `SHARING` clause is included in a `CREATE` statement, its setting overrides the setting for the `DEFAULT_SHARING` initialization parameter.

You can specify one of the following for the `sharing` attribute:

- **METADATA:** A metadata link shares the database object's metadata, but its data is unique to each container. These database objects are referred to as metadata-linked application common objects. This setting is the default.
- **DATA:** A data link shares the database object, and its data is the same for all containers in the application container. Its data is stored only in the application root. These database objects are referred to as data-linked application common objects.

- EXTENDED DATA: An extended data link shares the database object, and its data in the application root is the same for all containers in the application container. However, each application PDB in the application container can store data that is unique to the application PDB. For this type of database object, data is stored in the application root and, optionally, in each application PDB. These database objects are referred to as extended data-linked application common objects.
- NONE: The database object is not shared.

For most types of application common objects, the only valid settings for the SHARING clause are METADATA and NONE. The following types of application common objects allow additional settings for the SHARING clause:

- For tables (excluding object tables), the SHARING clause can be set to METADATA, DATA, EXTENDED DATA, or NONE. For object tables, only METADATA or NONE is valid.
- For views (excluding object views), the SHARING clause can be set to METADATA, DATA, EXTENDED DATA, or NONE. For object views, only METADATA or NONE is valid.
- For sequences, the SHARING clause can be set to METADATA, DATA, or NONE.

With a metadata-linked sequence, each application PDB has its own sequence. When the metadata-linked sequence is incremented using the NEXTVAL pseudocolumn in one application PDB, it does not affect the value of the sequence in the other application PDBs in the application container.

With a data-linked sequence, each application PDB shares the same sequence in the application root. When the metadata-linked sequence is incremented using the NEXTVAL pseudocolumn in one application PDB, all of the other application PDBs in the same application container also see the change.

Application common objects can be created or changed only as part of an application installation, upgrade, or patch. An application PDB applies changes to application common objects when it synchronizes with the application that made the changes. If an application PDB is closed when an application common object is created, dropped, or modified, then the appropriate changes are applied in the application PDB when it is opened and synchronized with the application.

The names of application common objects must not conflict with those of local database objects in any of the application PDBs that belong to the application root or Oracle-supplied common objects in the CDB root. If a newly opened application PDB contains a local database object whose name conflicts with that of an application common object, then the application PDB is opened in RESTRICTED mode. In this case, you must resolve the naming conflict before the application PDB can be opened in normal mode.

### Metadata-Linked Application Common Objects

For metadata-linked application common objects, the metadata for the object is stored once in the application root. A metadata link in each application PDB that belongs to the application root enables the application PDBs to share the metadata for the object, including the object name and structure. The data for the object is unique to each container, including the application root and each application PDB that belongs to the application root.

Data definition language (DDL) operations on a metadata-linked application common object can be run in the application root only as part of an application installation, upgrade, or patch. However, the data can be modified in an application PDB using normal data manipulation language (DML) operations.

For example, consider a company with several regional offices. The company wants the structure of the information about employees to be consistent, but each office has different employees. If this company has a human resources application in an application container, it can create a separate application PDB for each regional office and use a metadata-linked table to store employee information. The data structure of the table, such as the columns, is the same in the application PDB for each regional office, but the employee data is different.

Another example might involve a company that builds and maintains a sales application that is used by several different businesses. Each business uses the same sales application, but the data for each business is different. For example, each business has different customers and therefore different customer data. To ensure that each client uses the same data structure for its application, the company might create an application container with metadata-linked application common objects. Each business that uses the sales application has its own application PDB, and the data structure is the same in each application PDB, but the data is different.

### Data-Linked Application Common Objects

For data-linked application common objects, both the metadata and the data for the object is stored once in the application root. A data link in each application PDB that belongs to the application root enables the application PDBs to share the metadata and data of the object.

DDL operations on a data-linked application common object can be run in the application root only as part of an application installation, upgrade, or patch. In addition, the data can be modified using normal DML operations only in the application root. The data cannot be modified in application PDBs.

For example, consider a company with several regional offices. The company wants the information about the products they sell, such as the product names and descriptions, to be consistent at all of the regional offices. If this company has a sales application in an application container, then it can create a separate application PDB for each regional office and use a data-linked table to store product information. Each application PDB can query the product information, and the product information is consistent at each regional office.

Data-linked application common objects are also useful for data that is standard and does not change. For example, a table that stores the postal codes for a country might be a data-linked application common object in an application container. All of the application PDBs access the same postal code data in the application root.

#### Note:

If the data-linked application common object is part of a configuration that synchronizes an application root replica with a proxy PDB, then DML operations on a data-linked object in the application root can be done outside of an application action, but the DML operation is not automatically propagated to the application root replication through the proxy PDB. If you want the DML operation to be propagated to the application root replica, then the DML operation on a data-linked object in the application root must be done within an application installation, upgrade, or patch.

### Extended Data-Linked Application Common Objects

For an extended data-linked object, each application PDB can create its own specific data while sharing the common data in the application root. Therefore, only the data stored in the application root is common for all application PDBs.

DDL operations on an extended data-linked application common object can be run in the application root only as part of an application installation, upgrade, or patch. However, the data can be modified in the application root or in an application PDB using normal DML operations.

For example, a sales application in an application container might support several application PDBs, and all of the application PDBs need the postal codes in the United States for shipping purposes. In this case the postal codes can be stored in the application root so that all of the application PDBs can access it. However, one application PDB also makes sales in Canada, and this application PDB requires the postal codes for the United States and Canada. This one application PDB can store the postal codes for Canada in an extended data-linked object in the application PDB instead of in the application root.

#### Note:

- Tables and views are the only types of database objects that can be extended data-linked objects.
- If the extended data-linked application common object is part of a configuration that synchronizes an application root replica with a proxy PDB, then DML operations on an extended data-linked object in the application root can be done outside of an application action, but the DML operation is not automatically propagated to the application root replication through the proxy PDB. If you want the DML operation to be propagated to the application root replica, then the DML operation on an extended data-linked object in the application root must be done within an application installation, upgrade, or patch.

#### Related Topics

- [Oracle Database Concepts](#)

### 44.4.2 Restrictions for Application Common Objects

Some restrictions apply to application common objects.

Queries on application common objects can return data from a container that is not the current container. For example, when the current container is an application root, queries that include the CONTAINERS clause can return data from application PDBs for metadata-linked application common objects. Also, when the current container is an application PDB, queries on data-linked and extended data-linked application common objects return data that resides in the application root.

Columns of the following types return no data in queries that return data from a container other than the current container:

- The following user-defined types: object types, varrays, REFs, and nested tables

- The following Oracle-supplied types: ANYTYPE, ANYDATASET, URI types, SDO\_TOPO\_GEOMETRY, SDO\_GEOASTER, and Expression

In addition, queries on object tables and object views return no data from containers other than the current container.

#### Related Topics

- [Querying Application Common Objects Across Application PDBs](#)

The CONTAINERS clause enables you to query application common objects, such as tables and views, across all application PDBs in an application container. This clause enables queries from the application root to display data in tables or views that exist in all of the open application PDBs in the application container.

### 44.4.3 Creating Application Common Objects

You create an application common object in an application root either by ensuring that the DEFAULT\_SHARING initialization parameter is set to the correct value or by including the SHARING clause in the CREATE SQL statement.

You can create a metadata-linked object, an extended data-linked, or a data-linked object in an application root as part of an application installation, upgrade, or patch. An application PDB applies changes to application common objects when it synchronizes with the application in the application root.

1. In SQL\*Plus, ensure that the current container is the application root.

The current user must have the privileges required to create the database object.

2. Run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN statement for beginning an application installation, upgrade, or patch.

For example, if you are creating the application common object as part of an application installation, then run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name BEGIN INSTALL
'application_version_number';
```

3. Create the application common object and specify its sharing attribute in one of the following ways:

- Ensure that the DEFAULT\_SHARING initialization parameter is set to the desired sharing attribute in the application root, and issue the CREATE SQL statement to create the database object.
- Issue the CREATE SQL statement, and include the SHARING clause set to METADATA, DATA, or EXTENDED DATA.

When a SHARING clause is included in a SQL statement, it takes precedence over the value specified in the DEFAULT\_SHARING initialization parameter. For example, if the DEFAULT\_SHARING initialization parameter is set to METADATA in the application root, and a database object is created with SHARING set to DATA, then the database object is created as a data-linked database object.

 **Note:**

Once a database object is created, its sharing attribute cannot be changed.

4. Run the ALTER PLUGGABLE DATABASE APPLICATION END statement for ending an application installation, upgrade, or patch.

For example, if you are creating the application common object as part of an application installation, then run the ALTER PLUGGABLE DATABASE APPLICATION END INSTALL statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name END INSTALL
'application_version_number';
```

 **Note:**

Ensure that the *application\_name* and *application\_version\_number* match in the ALTER PLUGGABLE DATABASE APPLICATION BEGIN INSTALL statement and the ALTER PLUGGABLE DATABASE APPLICATION END INSTALL statement.

5. Synchronize all of the application PDBs that must apply these changes by issuing an ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause with the application PDB as the current container.

#### **Example 44-9 Setting the DEFAULT\_SHARING Initialization Parameter**

This example sets the DEFAULT\_SHARING initialization parameter to DATA both in memory and in the SPFILE. When a database object that supports sharing is created in the application root, and no SHARING clause is included in the CREATE SQL statement, the database object uses the sharing attribute specified in the DEFAULT\_SHARING initialization parameter.

```
ALTER SYSTEM SET DEFAULT_SHARING=DATA SCOPE=BOTH;
```

#### **Example 44-10 Creating a Metadata-Linked Object**

This example creates the employees\_md metadata-linked table by including the SHARING=METADATA clause. The *application\_name* is salesapp and the *application\_version\_number* is 4.2, and the object is created during application installation.

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN INSTALL '4.2';
CREATE TABLE employees_md SHARING=METADATA
 (employee_id NUMBER(6),
 first_name VARCHAR2(20),
 last_name VARCHAR2(25) CONSTRAINT emp_last_name_nn_demo NOT
 NULL,
 email VARCHAR2(25) CONSTRAINT emp_email_nn_demo NOT
 NULL,
 phone_number VARCHAR2(20),
 hire_date DATE DEFAULT SYSDATE CONSTRAINT
```

```

emp_hire_date_nn_demo NOT NULL,
 job_id VARCHAR2(10) CONSTRAINT emp_job_nn_demo NOT NULL,
 salary NUMBER(8,2) CONSTRAINT emp_salary_nn_demo NOT
NULL,
 commission_pct NUMBER(2,2),
 manager_id NUMBER(6),
 department_id NUMBER(4),
 dn VARCHAR2(300),
 CONSTRAINT emp_salary_min_demo CHECK (salary > 0),
 CONSTRAINT emp_email_uk_demo UNIQUE (email));
ALTER PLUGGABLE DATABASE APPLICATION salesapp END INSTALL '4.2';

```

### Example 44-11 Creating a Data-Linked Object

This example creates the product\_descriptions\_ob data-linked table by including the SHARING=DATA clause. The *application\_name* is salesapp and the *application\_version\_number* is 4.2, and the object is created during application installation.

```

ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN INSTALL '4.2';
CREATE TABLE product_descriptions_ob SHARING=DATA
 (product_id NUMBER(6),
 language_id VARCHAR2(3),
 translated_name NVARCHAR2(50) CONSTRAINT translated_name_nn
NOT NULL,
 translated_description NVARCHAR2(2000) CONSTRAINT translated_desc_nn
NOT NULL);
ALTER PLUGGABLE DATABASE APPLICATION salesapp END INSTALL '4.2';

```

### Example 44-12 Creating an Extended Data-Linked Object

This example creates the postalcodes extended data-linked table by including the EXTENDED keyword and the SHARING clause. The *application\_name* is salesapp and the *application\_version\_number* is 4.2, and the object is created during application installation.

```

ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN INSTALL '4.2';
CREATE TABLE postalcodes SHARING=EXTENDED DATA
 (code VARCHAR2(7),
 country_id NUMBER,
 place_name VARCHAR2(20));
ALTER PLUGGABLE DATABASE APPLICATION salesapp END INSTALL '4.2';

```

### Example 44-13 Creating an Object That Is Not Shared in an Application Root

This example creates the departments\_ns table and specifies that it is not a shared common application object by including the SHARING=NONE clause. After creation, this database object can be accessed only in the application root.

```

CREATE TABLE departments_ns SHARING=NONE
 (department_id NUMBER(4),
 department_name VARCHAR2(30) CONSTRAINT dept_name_nn NOT NULL,
 manager_id NUMBER(6),

```

```
location_id NUMBER(4),
dn VARCHAR2(300));
```

 **Note:**

The `ALTER PLUGGABLE DATABASE APPLICATION BEGIN` and `END` statements are not required when you create an object that is not a shared common object. However, if you create an object that is not shared in between `ALTER PLUGGABLE DATABASE APPLICATION BEGIN` and `END` statements, then the object is created in application PDBs that synchronize with the application.

#### Related Topics

- [Managing Applications in an Application Container](#)

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- [Synchronizing Applications in an Application PDB](#)

When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

### 44.4.4 Issuing DML Statements on Application Common Objects

The rules are different for issuing DML statements on metadata-linked, data-linked, and extended data-linked application common objects.

The following rules apply for issuing DML statements on application common objects:

- **Metadata-linked application common objects:** DML statements can be issued on metadata-linked application objects normally. For metadata-linked application common objects, the structure is the same in all containers in an application container, but the data is different. Users and applications can issue DML statements on these objects in the same way that they would for ordinary database objects, and the DML statements only affect the current container.

For metadata-linked objects, the `CONTAINERS` clause is useful when the DML statement is run in the application root. This clause lets you query data in the specified table or view across all application PDBs in an application container. It also lets you perform DML changes on the data in the specified table or view across all application PDBs in an application container. To use the `CONTAINERS` clause, you wrap a table in the clause in the SQL statement, as in the following example:

```
SELECT * FROM CONTAINERS(sales.customers);
```

In addition, you can specify that a table or view must always be wrapped in the CONTAINERS clause by issuing an ALTER TABLE or ALTER VIEW statement with the ENABLE CONTAINERS\_DEFAULT clause in the application root, as in the following example:

```
ALTER TABLE sales.customers ENABLE CONTAINERS_DEFAULT;
```

After setting this attribute, queries and DML statements issued in the application root use the CONTAINERS clause by default for the database object. The CONTAINERS\_DEFAULT column in the DBA\_TABLES and DBA\_VIEWS views shows whether the database object is enabled for the CONTAINERS clause by default.

- **Data-linked application common objects:** DML statements can be issued on data-linked application objects normally in the application root. DML changes in the application root affect the data available to all of the application PDBs in the application container. DML statement cannot be issued on data-linked application objects in application PDBs.
- **Extended data-linked application common objects:** DML statements can be issued on extended data-linked application objects normally in the application root and in application PDBs. DML changes in the application root affect the data available to all of the application PDBs in the application container. DML changes in an application PDB only affect the data that is unique to the application PDB.

Consider an application root that has data-linked or extended data-linked objects, and assume that this application root is the master application root for one or more application root replicas that are synchronized with proxy PDBs. In this configuration, DML changes are only synchronized with the application root replicas when the DML statements are issued during an application installation, upgrade, or patch.

Specifically, DML changes must be issued in the application root between ALTER PLUGGABLE DATABASE APPLICATION BEGIN and ALTER PLUGGABLE DATABASE APPLICATION END statements. DML changes made outside of an application installation, upgrade, or patch only apply to the current application root and are not synchronized with application root replicas.

To issue DML statements on a data-linked or extended data-linked application common object:

- Complete the appropriate steps:

For an application common object that is not part of an application root replica configuration:

1. Connect to the appropriate container in the application container as a user with the privileges required to issue DML statements on the database object.
2. Issue DML statements normally.

For a data-linked or extended data-linked object that is part of an application root replica configuration:

1. In SQL\*Plus, ensure that the current container is the master application root in the application root replica in the configuration.

The current user must have the privileges required to issue the DML statements on the database object.

2. Run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN statement for beginning an application installation, upgrade, or patch.

For example, if you are modifying the application common object as part of an application upgrade, then run the ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name BEGIN UPGRADE
'application_start_version_number' TO
'application_end_version_number';
```

For example, run the following statement if the *application\_name* is salesapp, the *application\_start\_version\_number* is 4.2, and the *application\_end\_version\_number* is 4.3:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN UPGRADE '4.2'
TO '4.3';
```

3. Issue the DML statements on the data-linked application common object.
4. Run the ALTER PLUGGABLE DATABASE APPLICATION END statement for ending an application installation, upgrade, or patch.

For example, if you are modifying the application common object as part of an application upgrade, then run the ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name END UPGRADE
TO 'application_end_version_number';
```

For example, run the following statement if the *application\_name* is salesapp and the *application\_end\_version\_number* is 4.3:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp END UPGRADE TO '4.3';
```

#### Note:

Ensure that the *application\_name* and *application\_end\_version\_number* match in the ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE statement and ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE statements.

5. Synchronize all of the application PDBs that must apply these changes by issuing an ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause when the application PDB is the current container.

#### Related Topics

- [Managing Applications in an Application Container](#)

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- [Synchronizing Applications in an Application PDB](#)

When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

- [Synchronizing an Application Root Replica with a Proxy PDB](#)  
When application containers in different CDBs have the same application, their application roots can be kept synchronized by creating a master application root, a replica application root, and a proxy PDB.

#### 44.4.5 Modifying Application Common Objects with DDL Statements

When you modify an application common object in an application root with certain DDL statements, you must modify the object between `ALTER PLUGGABLE DATABASE APPLICATION BEGIN` and `ALTER PLUGGABLE DATABASE APPLICATION END` statements, and application PDBs must synchronize with the application to apply the changes.

You can alter a metadata-linked object or a data-linked object in an application root. You run an `ALTER`, `RENAME`, or `DROP` SQL statement on the database object to perform a DDL change.

1. In SQL\*Plus, ensure that the current container is the application root.

The current user must have the privileges required to make the planned changes to the database object.

2. Run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN` statement for beginning an application installation, upgrade, or patch.

For example, if you are modifying the application common object as part of an application upgrade, then run the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE` statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name BEGIN UPGRADE
'application_start_version_number' TO
'application_end_version_number';
```

For example, run the following statement if the `application_name` is `salesapp`, the `application_start_version_number` is `4.2`, and the `application_end_version_number` is `4.3`:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN UPGRADE '4.2' TO
'4.3';
```

3. Modify the application common object with the DDL statement.

For example, an `ALTER TABLE` statement might add a column to a table.

4. Run the `ALTER PLUGGABLE DATABASE APPLICATION END` statement for ending an application installation, upgrade, or patch.

For example, if you are modifying the application common object as part of an application upgrade, then run the `ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE` statement in the following form:

```
ALTER PLUGGABLE DATABASE APPLICATION application_name END UPGRADE TO
'application_end_version_number';
```

For example, run the following statement if the `application_name` is `salesapp` and the `application_end_version_number` is `4.3`:

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp END UPGRADE TO '4.3';
```

 **Note:**

Ensure that the `application_name` and `application_end_version_number` match in the `ALTER PLUGGABLE DATABASE APPLICATION BEGIN UPGRADE` statement and the `ALTER PLUGGABLE DATABASE APPLICATION END UPGRADE` statement.

5. Synchronize all of the application PDBs that must apply these changes by issuing an `ALTER PLUGGABLE DATABASE APPLICATION` statement with the `SYNC` clause with the application PDB as the current container.

**Related Topics**

- [Managing Applications in an Application Container](#)

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- [Synchronizing Applications in an Application PDB](#)

When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

## 44.5 Issuing DML Statements on Containers in an Application Container

A DML statement issued in an application root can modify one or more containers in the application container. In addition, you can specify one or more default container targets for DML statements.

- [About Issuing DML Statements on Containers in an Application Container](#)  
DML statements can affect database objects in more than one container in an application container.
- [Specifying the Default Container for DML Statements in an Application Container](#)  
To specify the default container for DML statements in an application container, issue the `ALTER PLUGGABLE DATABASE` statement with the `CONTAINERS DEFAULT TARGET` clause.

### 44.5.1 About Issuing DML Statements on Containers in an Application Container

DML statements can affect database objects in more than one container in an application container.

In an application root, a single DML statement that includes the `CONTAINERS` clause can modify a table or view in one or more containers in the application container. To use the `CONTAINERS` clause, specify the table or view being modified in the `CONTAINERS` clause and the containers in the `WHERE` clause. A target container can be specified in

an `INSERT VALUES` statement by specifying a value for `CON_ID` in the `VALUES` clause. Also, a target container can be specified in an `UPDATE` or `DELETE` statement by specifying a `CON_ID` predicate in the `WHERE` clause.

For example, the following DML statement updates the `sales.customers` table in the containers with a `CON_ID` of 7 or 8:

```
UPDATE CONTAINERS(sales.customers) ctab
 SET ctab.city_name='MIAMI'
 WHERE ctab.CON_ID IN(7,8) AND
 CUSTOMER_ID=3425;
```

The values specified for the `CON_ID` in the `WHERE` clause must be for containers in the current application container.

You can specify default target containers for DML operations. If a DML statement does not specify values for the `CON_ID` in the `WHERE` clause, then the target containers of the DML operation are those specified in the database property `CONTAINERS_DEFAULT_TARGET` in the application root. When issued in an application root, the following DML statement modifies the default target containers for the application container:

```
UPDATE CONTAINERS(sales.customers) ctab
 SET ctab.city_name='MIAMI'
 WHERE CUSTOMER_ID=3425;
```

By default, the default target containers in an application container include all of its application PDBs but not its application root or application seed. You can determine the default target containers for an application container by running the following query:

```
SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE
PROPERTY_NAME='CONTAINERS_DEFAULT_TARGET' ;
```

In addition, you can enable the `CONTAINERS_DEFAULT` attribute for a table or view in an application root. When this attribute is enabled, the `CONTAINERS` clause is used for queries and DML statements on the database object by default, and the `CONTAINERS` clause does not need to be specified in the SQL statements. To enable the `CONTAINERS_DEFAULT` attribute for a table or view in an application root, run the an `ALTER TABLE` or `ALTER VIEW` statement with the `ENABLE CONTAINERS_DEFAULT` clause.

The following restrictions apply to the `CONTAINERS` clause:

- `INSERT AS SELECT` statements where the target of the `INSERT` is in `CONTAINERS()` is not supported.
- A multi-table `INSERT` statement where the target of the `INSERT` is in `CONTAINERS()` is not supported.
- DML statements using the `CONTAINERS` clause require that the database listener is configured using TCP (instead of IPC) and that the `PORT` and `HOST` values are specified for each target PDB using the `PORT` and `HOST` clauses, respectively.

### Related Topics

- [About Application Common Objects](#)

Application common objects are created in an application root and are shared with the application PDBs that belong to the application root. There are three types of application common object: metadata-linked, data-linked, and extended data-linked.

## 44.5.2 Specifying the Default Container for DML Statements in an Application Container

To specify the default container for DML statements in an application container, issue the `ALTER PLUGGABLE DATABASE` statement with the `CONTAINERS DEFAULT TARGET` clause.

When a DML statement is issued in an application root without specifying containers in the `WHERE` clause, the DML statement affects the default container for the application container. The default container can be any container in the application container, including the application root or an application PDB. Only one default container is allowed.

1. In SQL\*Plus, ensure that the current container is the application root.

The current user must have the commonly granted `ALTER PLUGGABLE DATABASE` privilege.

2. Run the `ALTER PLUGGABLE DATABASE` statement with the `CONTAINERS DEFAULT TARGET` clause.

### Example 44-14 Specifying the Default Container for DML Statements in an Application Container

This example specifies that `APDB1` is the default container for DML statements in the application container.

```
ALTER PLUGGABLE DATABASE CONTAINERS DEFAULT TARGET = (APDB1);
```

### Example 44-15 Clearing the Default Container

This example clears the default container setting. When it is not set, the default container is the application root.

```
ALTER PLUGGABLE DATABASE CONTAINERS DEFAULT TARGET = NONE;
```

## 44.6 Partitioning by PDB with Container Maps

Container maps enable the partitioning of data at the application PDB level when the data is not physically partitioned at the table level.

- [About Partitioning by PDB with Container Maps](#)

A container map is a database property that specifies a partitioned map table that is defined in an application root. A container map can be used to partition the data in metadata-linked objects in an application container. Container maps partition data in application PDBs based on a commonly-used column.

- [Creating a Container Map](#)

You create a container map by creating a map object and setting the CONTAINER\_MAP database property to the map object.

#### 44.6.1 About Partitioning by PDB with Container Maps

A container map is a database property that specifies a partitioned map table that is defined in an application root. A container map can be used to partition the data in metadata-linked objects in an application container. Container maps partition data in application PDBs based on a commonly-used column.

A container map can define a logical partition key on a column for a common object. This mapping removes the requirements for defining a query with a CON\_ID predicate and the need to use the CONTAINERS clause because the container is resolved internally based on the container map. Container maps are often useful when you are migrating from row based consolidation that uses a tenant ID with multiple tenants in a single PDB to a configuration that uses a different PDB for each tenant.

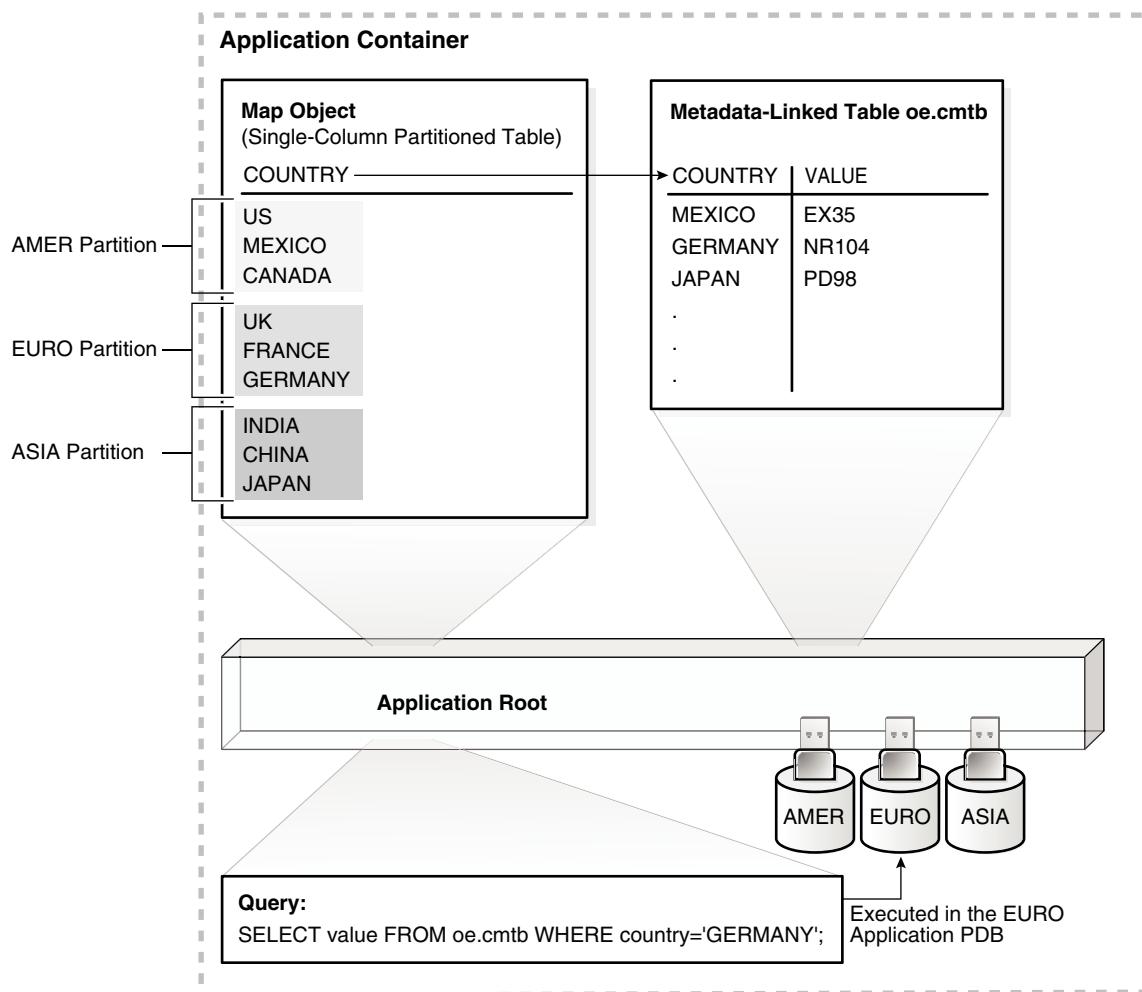

To use a container map in an application container, you use an `ALTER DATABASE` statement in the application root to specify a partitioned table for the CONTAINER\_MAP database property. The partitioned table is called the map object. The map object specifies one of the following partitioning strategies for the data in a metadata-linked table based on a commonly-used column:

- Range partitioning
- List partitioning
- Hash partitioning

The names of the partitions in the map object match the names of the application PDBs in the application container. The column used in partitioning the map object must match a column in the metadata-linked object. The metadata-linked object is not physically partitioned at the table level, but it can be queried using the partitioning strategy that is enabled by the container map.

The following illustration shows, in an application root, a map object, a metadata-linked table, and a query on the metadata-linked table. The query is executed in the appropriate application PDB.

Figure 44-3 Container Map

The illustration shows an application container with three application PDBs named AMER, EURO, and ASIA. The application PDBs store data for the different regions (America, Europe, and Asia, respectively). A metadata-linked table named `oe.cmtb` stores information for an application, and this table has a `COUNTRY` column. For this partitioning strategy, partition by list is used to create a map object that creates a partition for each region, and the country value is used to determine the region. This example is described in detail in "Creating a Container Map".

Consider another example that uses a range-partitioned table for the map object. The following SQL statement creates the map object in the application root:

```
CREATE TABLE app_con_admin.conmap (
 department_id NUMBER NOT NULL)
PARTITION BY RANGE (department_id) (
 PARTITION apppdb1 VALUES LESS THAN (100),
 PARTITION apppdb2 VALUES LESS THAN (200),
 PARTITION apppdb3 VALUES LESS THAN (300));
```

This map object partitions data in the application PDBs apppdb1, apppdb2, and apppdb3 based on the commonly-used column department\_id. The following SQL statement sets the CONTAINER\_MAP database property to the app\_con\_admin.conmap table in the application root:

```
ALTER PLUGGABLE DATABASE SET CONTAINER_MAP='app_con_admin.conmap';
```

Queries that use container maps produce results that are similar to queries that use the CONTAINERS clause. For example, the following queries return similar results:

```
SELECT employee_id
 FROM CONTAINERS(hr.employees)
 WHERE department_id = 10 AND CON_ID IN (44);

SELECT employee_id
 FROM hr.employees
 WHERE department_id = 10;
```

The CONTAINERS clause is unnecessary when a container map is defined. As shown in the first query with the CONTAINERS clause, when the query only pertains to a single application PDB, the query must specify the container ID of this application PDB in the WHERE clause, and this requirement might cause application changes. The second query that uses the container map, replacing the CONTAINERS clause, does not specify the container, because the container map directs the query to the correct application PDB. In addition, queries that use container maps are generally more efficient than queries that use the CONTAINERS clause. The container map must be created by a common user with ALTER DATABASE system privilege. Queries run against an object that is enabled for container map, and query privileges are determined by privileges granted on the object.

 **Note:**

- Container maps cannot be created in the CDB root.
- There is a limit of one container map for each application container.
- Data must be loaded into the PDBs' tables in a manner that is consistent with the partitions defined in map object.
- When there are changes to the application PDBs in an application container, the map object is not synchronized automatically to account for these changes. For example, an application PDB that is referenced in a map object can be unplugged, renamed, or dropped. The map object must be updated manually to account for such changes.

### Related Topics

- [Managing Applications in an Application Container](#)

You install, upgrade, or patch an application in an application container. You can also uninstall an application from an application container. You perform these operations in the application root, and the application container propagates the

application changes to the application PDBs when the application PDBs synchronize with the application in the application root.

- **Managing Application Common Objects**

Application common objects are shared, user-created database objects in an application container. Application common objects are created in an application root.

- **Querying Application Common Objects Across Application PDBs**

The CONTAINERS clause enables you to query application common objects, such as tables and views, across all application PDBs in an application container. This clause enables queries from the application root to display data in tables or views that exist in all of the open application PDBs in the application container.

## 44.6.2 Creating a Container Map

You create a container map by creating a map object and setting the CONTAINER\_MAP database property to the map object.

The map object is a partitioned table in which each partition name matches the name of an application PDB in an application container.

Before creating a container map, an application container with application PDBs must exist in the CDB.

The application container must have at least one application installed in it.

The tables that will be queried using the container map must have a common column.

1. In SQL\*Plus, ensure that the current container is the application root.
2. Create the map object.
3. Set the CONTAINER\_MAP database property to the map object.

```
ALTER DATABASE SET CONTAINER_MAP = 'map_table_schema.map_table_name';
```

Replace *map\_table\_schema* with the owner of the table, and replace *map\_table\_name* with the name of the table.

4. Start an application installation, upgrade, or patch.
5. If the metadata-linked table that will be used by the container map does not exist, then create it.
6. Enable the container map for the table to be queried by issuing an ALTER TABLE statement with the ENABLE CONTAINER\_MAP clause.
7. Ensure that the table to be queried is enabled for the CONTAINERS clause by issuing an ALTER TABLE statement with the ENABLE CONTAINERS\_DEFAULT clause.
8. End the application installation, upgrade, or patch started previously.

### Example 44-16 Creating and Using a Container Map

This example creates a simple application that uses a container map. Assume that an application container has three application PDBs named AMER, EURO, and ASIA. The application PDBs store data for the different regions (America, Europe, and Asia, respectively). A metadata-linked table stores information for an application and has a COUNTRY column. For this partitioning strategy, partition by list is used to create a map object that creates a partition for each region, and the country value is used to determine the region.

1. In SQL\*Plus, ensure that the current container is the application root.
2. Create the map object.

```
CREATE TABLE salesadm.conmap (
 country VARCHAR2(30) NOT NULL)
PARTITION BY LIST (country) (
 PARTITION AMER VALUES ('US','MEXICO','CANADA'),
 PARTITION EURO VALUES ('UK','FRANCE','GERMANY'),
 PARTITION ASIA VALUES ('INDIA','CHINA','JAPAN'));
```

3. Set the `CONTAINER_MAP` database property to the map object.

```
ALTER PLUGGABLE DATABASE SET CONTAINER_MAP='salesadm.conmap';
```

4. Begin an application installation.

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp BEGIN INSTALL '1.0';
```

5. Create a metadata-linked table that will be queried using the container map.

```
CREATE TABLE oe.cmtb SHARING=METADATA (
 value VARCHAR2(30),
 country VARCHAR2(30));
```

6. Enable the container map for the table to be queried.

```
ALTER TABLE oe.cmtb ENABLE CONTAINER_MAP;
```

7. Ensure that the table to be queried is enabled for the `CONTAINERS` clause.

```
ALTER TABLE oe.cmtb ENABLE CONTAINERS_DEFAULT;
```

8. End the application installation.

```
ALTER PLUGGABLE DATABASE APPLICATION salesapp END INSTALL '1.0';
```

9. Switch session into each application PDB and synchronize it.

```
ALTER SESSION SET CONTAINER=amer;
ALTER PLUGGABLE DATABASE APPLICATION salesapp SYNC;
```

```
ALTER SESSION SET CONTAINER=euro;
ALTER PLUGGABLE DATABASE APPLICATION salesapp SYNC;
```

```
ALTER SESSION SET CONTAINER=asia;
ALTER PLUGGABLE DATABASE APPLICATION salesapp SYNC;
```

10. Insert values into the `oe.cmtb` table in each application PDB based on the partitioning strategy.

```
ALTER SESSION SET CONTAINER=amer;
INSERT INTO oe.cmtb VALUES ('AMER VALUE','US');
INSERT INTO oe.cmtb VALUES ('AMER VALUE','MEXICO');
```

```
INSERT INTO oe.cmtb VALUES ('AMER VALUE', 'CANADA');
COMMIT;

ALTER SESSION SET CONTAINER=euro;
INSERT INTO oe.cmtb VALUES ('EURO VALUE', 'UK');
INSERT INTO oe.cmtb VALUES ('EURO VALUE', 'FRANCE');
INSERT INTO oe.cmtb VALUES ('EURO VALUE', 'GERMANY');
COMMIT;

ALTER SESSION SET CONTAINER=asia;
INSERT INTO oe.cmtb VALUES ('ASIA VALUE', 'INDIA');
INSERT INTO oe.cmtb VALUES ('ASIA VALUE', 'CHINA');
INSERT INTO oe.cmtb VALUES ('ASIA VALUE', 'JAPAN');
COMMIT;
```

11. Switch session into the application root and query the data using the container map.

```
ALTER SESSION SET CONTAINER=sales;

SELECT value FROM oe.cmtb WHERE country='MEXICO';

SELECT value FROM oe.cmtb WHERE country='GERMANY';

SELECT value FROM oe.cmtb WHERE country='JAPAN';
```

The output for the first query should be AMER VALUE, the output for the second query should be EURO VALUE, and the output for the third query should be ASIA VALUE. These values illustrate that the container map is working correctly.

# Viewing Information About CDBs and PDBs with SQL\*Plus

You can view information about CDBs and PDBs with SQL\*Plus.

## Note:

You can complete the tasks in this chapter using SQL\*Plus or Oracle SQL Developer.

- [About CDB and Container Information in Views](#)

In a multitenant container database (CDB), the metadata for data dictionary tables and view definitions is stored only in the root. However, each container, including each pluggable database (PDB), application root, and application PDB, has its own set of data dictionary tables and views for the database objects contained in the container.

- [About Viewing Information When the Current Container Is a Not the CDB Root](#)

When the current container is a PDB, an application root, or an application PDB, a user can view data dictionary information for the current container only.

- [About Viewing Information When the Current Container Is the CDB Root](#)

When the current container is the CDB root, a common user can view data dictionary information for the CDB root and for PDBs, application roots, and application PDBs by querying container data objects.

- [Views for a CDB](#)

You can query a set of views for information about a CDB and its PDBs.

- [Determining Whether a Database Is a CDB](#)

You can query the `CDB` column in the `V$DATABASE` view to determine whether a database is a CDB or a non-CDB. The `CDB` column returns `YES` if the current database is a CDB or `NO` if the current database is a non-CDB.

- [Viewing Information About the Containers in a CDB](#)

The `V$CONTAINERS` view provides information about all of the containers in a CDB, including the root and all PDBs.

- [Viewing Information About PDBs](#)

The `CDB_PDBS` view and `DBA_PDBS` view provide information about the PDBs associated with a CDB, including the status of each PDB.

- [Viewing the Open Mode of Each PDB](#)

The `V$PDBS` view provides information about the PDBs associated with the current database instance.

- [Querying Container Data Objects](#)

In the root, container data objects can show information about database objects (such as tables and users) contained in the root and in PDBs. Access to PDB information is controlled by the common user's `CONTAINER_DATA` attribute.

- [Querying Across Containers with the CONTAINERS Clause](#)  
The CONTAINERS clause enables you to query tables and views across all containers in a CDB. It also enables you to query application common objects across all containers in an application container.
- [Determining the Current Container ID or Name](#)  
You can determine your current container ID or container name in a CDB.
- [Listing the Initialization Parameters That Are Modifiable in PDBs](#)  
In a CDB, some initialization parameters apply to the root and to all of the PDBs. When such an initialization parameter is changed, it affects the entire CDB. You can set other initialization parameters to different values in each container.
- [Viewing the History of PDBs](#)  
The CDB\_PDB\_HISTORY view shows the history of the PDBs in a CDB. It provides information about when and how each PDB was created and other information about each PDB's history.
- [Viewing Information About Applications in Application Containers](#)  
Several views provide information about the applications in application containers in a CDB.

#### Related Topics

- [Tools for a Multitenant Environment](#)  
You can use various tools to configure and administer a multitenant environment.

## 45.1 About CDB and Container Information in Views

In a multitenant container database (CDB), the metadata for data dictionary tables and view definitions is stored only in the root. However, each container, including each pluggable database (PDB), application root, and application PDB, has its own set of data dictionary tables and views for the database objects contained in the container.

Because each container can contain different data and schema objects, containers can display different information in data dictionary views, even when querying the same data dictionary view in each container. For example, the information about tables displayed in the DBA\_TABLES view can be different in two different containers, because the containers can contain different tables. An internal mechanism called a metadata link enables a container to access the metadata for these views in the root.

If a dictionary table stores information that pertains to the CDB as a whole, instead of for each container, then both the metadata and the data displayed in a data dictionary view are stored in the root. For example, Automatic Workload Repository (AWR) data can be stored in the root, and this data is displayed in some data dictionary views, such as the DBA\_HIST\_ACTIVE\_SESS\_HISTORY view. An internal mechanism called a data link enables a container to access both the metadata and the data for these types of views in the root.

#### See Also:

*Oracle Database Concepts* for more information about dictionary access in containers, metadata links, and data links

## 45.2 About Viewing Information When the Current Container Is a Not the CDB Root

When the current container is a PDB, an application root, or an application PDB, a user can view data dictionary information for the current container only.

To an application connected to a particular PDB, application root, or application PDB, the data dictionary appears as it would for a non-CDB. The data dictionary only shows information related to the current container. Also, in a container that is not the CDB root, `CDB_` views only show information about database objects visible through the corresponding `DBA_` view.

## 45.3 About Viewing Information When the Current Container Is the CDB Root

When the current container is the CDB root, a common user can view data dictionary information for the CDB root and for PDBs, application roots, and application PDBs by querying container data objects.

A container data object is a table or view that can contain data pertaining to the following:

- One or more containers
- The CDB as a whole
- One or more containers and the CDB as a whole

Container data objects include `V$`, `GV$`, `CDB_`, and some Automatic Workload Repository `DBA_HIST*` views. A common user's `CONTAINER_DATA` attribute determines which containers are visible in container data objects.

In a CDB, for every `DBA_` view, there is a corresponding `CDB_` view. All `CDB_` views are container data objects, but most `DBA_` views are not.

Each container data object contains a `CON_ID` column that identifies the container for each row returned. [Table 45-1](#) describes the meanings of the values in the `CON_ID` column.

**Table 45-1 CON\_ID Column in Container Data Objects**

| Value in CON_ID Column | Description                                                            |
|------------------------|------------------------------------------------------------------------|
| 0                      | The data pertains to the entire CDB                                    |
| 1                      | The data pertains to the CDB root                                      |
| 2                      | The data pertains to the CDB seed                                      |
| 3 - 4,098              | The data pertains to a PDB, an application root, or an application PDB |
|                        | Each container has its own container ID.                               |

The following views behave differently from other `[G]V$` views:

- [G]V\$SYSSTAT
- [G]V\$SYS\_TIME\_MODEL
- [G]V\$SYSTEM\_EVENT
- [G]V\$SYSTEM\_WAIT\_CLASS

When queried from the CDB root, these views return instance-wide data, with 0 in the CON\_ID column for each row returned. However, you can query equivalent views that behave the same as other container data objects. The following views can return specific data for each container in a CDB: [G]V\$CON\_SYSSTAT, [G]V\$CON\_SYS\_TIME\_MODEL, [G]V\$CON\_SYSTEM\_EVENT, and [G]V\$CON\_SYSTEM\_WAIT\_CLASS.

 **Note:**

- When querying a container data object, the data returned depends on whether containers are open and on the privileges granted to the user running the query.
- In an Oracle Real Application Clusters (Oracle RAC) environment, the data returned by container data objects might vary based on the instance to which a session is connected.
- In a non-CDB, all CON\_ID columns in container data objects are 0 (zero).
- When a container is opened in restricted mode, it is ignored in queries on CDB\_views.

 **See Also:**

- "[About the Current Container](#)"
- *Oracle Database Concepts* for a conceptual overview of container data objects
- *Oracle Database Security Guide* for detailed information about container data objects

## 45.4 Views for a CDB

You can query a set of views for information about a CDB and its PDBs.

[Table 45-2](#) describes data dictionary views that are useful for monitoring a CDB and its PDBs.

**Table 45-2 Views for a CDB**

| View                                                                                                                                                                 | Description                                                                                                                                                                                          | More Information                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Container data objects, including:<br><ul style="list-style-type: none"><li>• V\$ views</li><li>• GV\$ views</li><li>• CDB_views</li><li>• DBA_HIST* views</li></ul> | Container data objects can display information about multiple PDBs. Each container data object includes a CON_ID column to identify containers. There is a CDB_view for each corresponding DBA_view. | " <a href="#">Querying Container Data Objects</a> "<br><i>Oracle Database Security Guide</i>                                 |

| V\$DIAG INCIDENT               | Displays information about problems and incidents for the current container in a CDB.                                                      | <i>Oracle Database Reference</i>                                                                                          |
| V\$DIAG_PROBLEM                |                                                                                                                                            |                                                                                                                           |

## 45.5 Determining Whether a Database Is a CDB

You can query the CDB column in the V\$DATABASE view to determine whether a database is a CDB or a non-CDB. The CDB column returns YES if the current database is a CDB or NO if the current database is a non-CDB.

To determine whether a database is a CDB:

1. In SQL\*Plus, connect to the database as an administrative user.
2. Query the V\$DATABASE view.

### Example 45-1 Determining Whether a Database is a CDB

```
SELECT CDB FROM V$DATABASE;
```

Sample output:

```
CDB

YES
```

 **See Also:**

*Oracle Database Reference*

## 45.6 Viewing Information About the Containers in a CDB

The V\$CONTAINERS view provides information about all of the containers in a CDB, including the root and all PDBs.

To view this information, the query must be run by a common user whose current container is the root. When the current container is a PDB, this view only shows information about the current PDB.

To view information about the containers in a CDB:

1. In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the V\$CONTAINERS view.

### Example 45-2 Viewing Identifying Information About Each Container in a CDB

```
COLUMN NAME FORMAT A8

SELECT NAME, CON_ID, DBID, CON_UID, GUID FROM V$CONTAINERS ORDER BY CON_ID;
```

Sample output:

| NAME      | CON_ID | DBID       | CON_UID    | GUID                             |
|-----------|--------|------------|------------|----------------------------------|
| CDB\$ROOT | 1      | 659189539  | 1          | C091A6F89C7572A1E0436797E40AC78D |
| PDB\$SEED | 2      | 4026479912 | 4026479912 | C091AE9C00377591E0436797E40AC138 |
| HRPDB     | 3      | 3718888687 | 3718888687 | C091B6B3B53E7834E0436797E40A9040 |
| SALESPDB  | 4      | 2228741407 | 2228741407 | C091FA64EF8F0577E0436797E40ABE9F |

 **See Also:**

- ["About a Multitenant Environment"](#)
- ["About the Current Container"](#)
- ["Determining the Current Container ID or Name"](#)
- *Oracle Database Reference*

## 45.7 Viewing Information About PDBs

The `CDB_PDBS` view and `DBA_PDBS` view provide information about the PDBs associated with a CDB, including the status of each PDB.

To view this information, the query must be run by a common user whose current container is the root. When the current container is a PDB, all queries on these views return no results.

To view information about PDBs:

1. In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the `CDB_PDBS` or `DBA_PDBS` view.

### Example 45-3 Viewing Container ID, Name, and Status of Each PDB

```
COLUMN PDB_NAME FORMAT A15

SELECT PDB_ID, PDB_NAME, STATUS FROM DBA_PDBS ORDER BY PDB_ID;
```

Sample output:

| PDB_ID | PDB_NAME  | STATUS |
|--------|-----------|--------|
| 2      | PDB\$SEED | NORMAL |
| 3      | HRPDB     | NORMAL |
| 4      | SALESPDB  | NORMAL |

#### See Also:

["About the Current Container"](#)

## 45.8 Viewing the Open Mode of Each PDB

The `V$PDBS` view provides information about the PDBs associated with the current database instance.

You can query this view to determine the open mode of each PDB. For each PDB that is open, this view can also show when the PDB was last opened. A common user can query this view when the current container is the root or a PDB. When the current container is a PDB, this view only shows information about the current PDB.

To view the open status of each PDB:

1. In SQL\*Plus, access a container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the `V$PDBS` view.

**Example 45-4 Viewing the Name and Open Mode of Each PDB**

```
COLUMN NAME FORMAT A15
COLUMN RESTRICTED FORMAT A10
COLUMN OPEN_TIME FORMAT A30

SELECT NAME, OPEN_MODE, RESTRICTED, OPEN_TIME FROM V$PDBS;
```

Sample output:

| NAME      | OPEN_MODE  | RESTRICTED | OPEN_TIME                 |
|-----------|------------|------------|---------------------------|
| PDB\$SEED | READ ONLY  | NO         | 21-MAY-12 12.19.54.465 PM |
| HRPDB     | READ WRITE | NO         | 21-MAY-12 12.34.05.078 PM |
| SALESPDB  | MOUNTED    | NO         | 22-MAY-12 10.37.20.534 AM |

 **See Also:**

- "[Modifying the Open Mode of PDBs](#)"
- "[Modifying a PDB with the ALTER PLUGGABLE DATABASE Statement](#)"
- "[About the Current Container](#)"

## 45.9 Querying Container Data Objects

In the root, container data objects can show information about database objects (such as tables and users) contained in the root and in PDBs. Access to PDB information is controlled by the common user's `CONTAINER_DATA` attribute.

For example, `CDB_` views are container data objects. See "[About Viewing Information When the Current Container Is the Root](#)" and *Oracle Database Security Guide* for more information about container data objects.

Each container data object contains a `CON_ID` column that shows the container ID of each PDB in the query results. You can view the PDB name for a container ID by querying the `DBA_PDBS` view.

To use container data objects to show information about multiple PDBs:

1. In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the container data object to show the desired information.

**Note:**

When a query contains a join of a container data object and a non-container data object, and the current container is the root, the query returns data for the entire CDB only (`CON_ID = 0`).

**See Also:**

- ["About the Current Container"](#)
- *Oracle Database Concepts* for a conceptual overview of container data objects
- *Oracle Database Security Guide* for detailed information about container data objects

### Example 45-5 Showing the Tables Owned by Specific Schemas in Multiple PDBs

This example queries the `DBA_PDBS` view and the `CDB_TABLES` view from the root to show the tables owned by `hr` user and `oe` user in the PDBs associated with the CDB. This query returns only rows where the PDB has an ID greater than 2 (`p.PDB_ID > 2`) to avoid showing the users in the CDB root and CDB seed.

```
COLUMN PDB_NAME FORMAT A15
COLUMN OWNER FORMAT A15
COLUMN TABLE_NAME FORMAT A30

SELECT p.PDB_ID, p.PDB_NAME, t.OWNER, t.TABLE_NAME
 FROM DBA_PDBS p, CDB_TABLES t
 WHERE p.PDB_ID > 2 AND
 t.OWNER IN('HR','OE') AND
 p.PDB_ID = t.CON_ID
 ORDER BY p.PDB_ID;
```

Sample output:

| PDB_ID | PDB_NAME | OWNER | TABLE_NAME                     |
|--------|----------|-------|--------------------------------|
| 3      | HRPDB    | HR    | COUNTRIES                      |
| 3      | HRPDB    | HR    | JOB_HISTORY                    |
| 3      | HRPDB    | HR    | EMPLOYEES                      |
| 3      | HRPDB    | HR    | JOBS                           |
| 3      | HRPDB    | HR    | DEPARTMENTS                    |
| 3      | HRPDB    | HR    | LOCATIONS                      |
| 3      | HRPDB    | HR    | REGIONS                        |
| 4      | SALESPDB | OE    | PRODUCT_INFORMATION            |
| 4      | SALESPDB | OE    | INVENTORIES                    |
| 4      | SALESPDB | OE    | ORDERS                         |
| 4      | SALESPDB | OE    | ORDER_ITEMS                    |
| 4      | SALESPDB | OE    | WAREHOUSES                     |
| 4      | SALESPDB | OE    | CUSTOMERS                      |
| 4      | SALESPDB | OE    | SUBCATEGORY_REF_LIST_NESTEDTAB |
| 4      | SALESPDB | OE    | PRODUCT_REF_LIST_NESTEDTAB     |

```

4 SALES PDB OE PROMOTIONS
4 SALES PDB OE PRODUCT_DESCRIPTIONS

```

This sample output shows the PDB hrpdb has tables in the hr schema and the PDB salespdb has tables in the oe schema.

### **Example 45-6 Showing the Users in Multiple PDBs**

This example queries the DBA\_PDBS view and the CDB\_USERS view from the root to show the users in each PDB. The query uses p.PDB\_ID > 2 to avoid showing the users in the CDB root and the CDB seed.

```

COLUMN PDB_NAME FORMAT A15
COLUMN USERNAME FORMAT A30

SELECT p.PDB_ID, p.PDB_NAME, u.USERNAME
 FROM DBA_PDBS p, CDB_USERS u
 WHERE p.PDB_ID > 2 AND
 p.PDB_ID = u.CON_ID
 ORDER BY p.PDB_ID;

```

Sample output:

| PDB_ID | PDB_NAME  | USERNAME |
|--------|-----------|----------|
| .      | .         | .        |
| .      | .         | .        |
| 3      | HRPDB     | HR       |
| 3      | HRPDB     | OLAPSYS  |
| 3      | HRPDB     | MDSYS    |
| 3      | HRPDB     | ORDSYS   |
| .      | .         | .        |
| .      | .         | .        |
| 4      | SALES PDB | OE       |
| 4      | SALES PDB | CTXSYS   |
| 4      | SALES PDB | MDSYS    |
| 4      | SALES PDB | EXFSYS   |
| 4      | SALES PDB | OLAPSYS  |
| .      | .         | .        |
| .      | .         | .        |

### **Example 45-7 Showing the Data Files for Each PDB in a CDB**

This example queries the DBA\_PDBS and CDB\_DATA\_FILES views to show the name and location of each data file for all of the PDBs in a CDB, including the CDB seed.

```

COLUMN PDB_ID FORMAT 999
COLUMN PDB_NAME FORMAT A8
COLUMN FILE_ID FORMAT 9999
COLUMN TABLESPACE_NAME FORMAT A10
COLUMN FILE_NAME FORMAT A45

SELECT p.PDB_ID, p.PDB_NAME, d.FILE_ID, d.TABLESPACE_NAME, d.FILE_NAME
 FROM DBA_PDBS p, CDB_DATA_FILES d
 WHERE p.PDB_ID = d.CON_ID
 ORDER BY p.PDB_ID;

```

Sample output:

| PDB_ID | PDB_NAME  | FILE_ID | TABLESPACE | FILE_NAME                                   |
|--------|-----------|---------|------------|---------------------------------------------|
| 2      | PDB\$SEED | 6       | SYSAUX     | /disk1/oracle/dbs/pdbseed/cdb1_ax.f         |
| 2      | PDB\$SEED | 5       | SYSTEM     | /disk1/oracle/dbs/pdbseed/cdb1_db.f         |
| 3      | HRPDB     | 9       | SYSAUX     | /disk1/oracle/dbs/hrpdb/hrpdb_ax.f          |
| 3      | HRPDB     | 8       | SYSTEM     | /disk1/oracle/dbs/hrpdb/hrpdb_db.f          |
| 3      | HRPDB     | 13      | USER       | /disk1/oracle/dbs/hrpdb/hrpdb_usr.dbf       |
| 4      | SALESPDB  | 15      | SYSTEM     | /disk1/oracle/dbs/salespdb/salespdb_db.f    |
| 4      | SALESPDB  | 16      | SYSAUX     | /disk1/oracle/dbs/salespdb/salespdb_ax.f    |
| 4      | SALESPDB  | 18      | USER       | /disk1/oracle/dbs/salespdb/salespdb_usr.dbf |

**Example 45-8 Showing the Temp Files in a CDB**

This example queries the `CDB_TEMP_FILES` view to show the name and location of each temp file in a CDB, as well as the tablespace that uses the temp file.

```

COLUMN CON_ID FORMAT 999
COLUMN FILE_ID FORMAT 9999
COLUMN TABLESPACE_NAME FORMAT A15
COLUMN FILE_NAME FORMAT A45

SELECT CON_ID, FILE_ID, TABLESPACE_NAME, FILE_NAME
 FROM CDB_TEMP_FILES
 ORDER BY CON_ID;

```

Sample output:

| CON_ID | FILE_ID | TABLESPACE_NAME | FILE_NAME                                    |
|--------|---------|-----------------|----------------------------------------------|
| 1      | 1       | TEMP            | /disk1/oracle/dbs/t_tmp1.f                   |
| 2      | 2       | TEMP            | /disk1/oracle/dbs/pdbseed/t_tmp1.f           |
| 3      | 3       | TEMP            | /disk1/oracle/dbs/hrpdb/t_hrpdb_tmp1.f       |
| 4      | 4       | TEMP            | /disk1/oracle/dbs/salespdb/t_salespdb_tmp1.f |

**Example 45-9 Showing the Services Associated with PDBs**

This example queries the `CDB_SERVICES` view to show the PDB name, network name, and container ID of each service associated with a PDB.

```

COLUMN NETWORK_NAME FORMAT A30
COLUMN PDB FORMAT A15
COLUMN CON_ID FORMAT 999

SELECT PDB, NETWORK_NAME, CON_ID FROM CDB_SERVICES
 WHERE PDB IS NOT NULL AND
 CON_ID > 2
 ORDER BY PDB;

```

Sample output:

| PDB      | NETWORK_NAME         | CON_ID |
|----------|----------------------|--------|
| HRPDB    | hrpdb.example.com    | 3      |
| SALESPDB | salespdb.example.com | 4      |

## 45.10 Querying Across Containers with the CONTAINERS Clause

The CONTAINERS clause enables you to query tables and views across all containers in a CDB. It also enables you to query application common objects across all containers in an application container.

- [About Querying Across Containers with the CONTAINERS Clause](#)  
The CONTAINERS clause enables you to query across containers in a CDB.
- [Querying User-Created Tables and Views Across All Containers](#)  
The CONTAINERS clause enables you to query user-created tables and views across all containers in a CDB. This clause enables queries from the CDB root to display data in tables or views that exist in all of the open PDBs in a CDB.
- [Querying Application Common Objects Across Application PDBs](#)  
The CONTAINERS clause enables you to query application common objects, such as tables and views, across all application PDBs in an application container. This clause enables queries from the application root to display data in tables or views that exist in all of the open application PDBs in the application container.

### 45.10.1 About Querying Across Containers with the CONTAINERS Clause

The CONTAINERS clause enables you to query across containers in a CDB.

The CONTAINERS clause enables you to query user-created tables and views across all containers in a CDB. This clause enables queries from the CDB root to display data in tables or views that exist in all of the open containers in a CDB.

The CONTAINERS clause also enables you to query application common objects, such as tables and views, across all application PDBs in an application container. This clause enables queries from the application root to display data in tables or views that exist in all of the open application PDBs in the application container.

The CONTAINERS\_PARALLEL\_DEGREE initialization parameter can control the degree of parallelism of a query involving the CONTAINERS clause. If the value of CONTAINERS\_PARALLEL\_DEGREE is lower than 65535 (the default), then the specified value is used.

When the CONTAINERS\_PARALLEL\_DEGREE initialization parameter is set to the default value (65535), queries that use the CONTAINERS clause are parallel by default. The default degree of parallelism is calculated with the following formula:

```
max(min(cpu_count, number_of_open_containers), #instances)
```

In addition, you can pass a DEFAULT\_PDB\_HINT hint in the CONTAINERS clause. The hint is passed in the query that is run in each container.

You can force the recursive SQL that results from a query that includes the CONTAINERS clause to be parallel by using the DEFAULT\_PDB\_HINT clause of a CONTAINERS hint or by using automatic degree of parallelism. However, parallel

statement queuing is not possible for recursive SQL that results from a query that includes the CONTAINERS clause.

Columns of the following types are removed if they exist in a table specified in a CONTAINERS clause:

- The following user-defined types: object types, varrays, REFs, and nested tables
- The following Oracle-supplied types: ANYTYPE, ANYDATASET, URI types, SDO\_TOPO\_GEOMETRY, SDO\_GEOASTER, and Expression

#### Note:

- When a container is opened in restricted mode, it is ignored by the CONTAINERS clause.
- When the CONTAINERS clause is used and an error is returned by a container, the query does not return results from the container that raised the error, and the error is not returned. For example, you cannot select a BFILE column from a remote table into a local variable. If a query that does this uses the CONTAINERS clause and includes local and remote containers, then the query returns results for the local containers, but not the remote containers, and no error is returned.

## 45.10.2 Querying User-Created Tables and Views Across All Containers

The CONTAINERS clause enables you to query user-created tables and views across all containers in a CDB. This clause enables queries from the CDB root to display data in tables or views that exist in all of the open PDBs in a CDB.

 **Note:**

This feature is available starting with Oracle Database 12c Release 1 (12.1.0.2).

### Prerequisites

The tables and views, or synonyms of them, specified in the CONTAINERS clause must exist in the CDB root and in all other containers.

#### To use the CONTAINERS clause to query tables and views across all containers:

1. In SQL\*Plus, access a container.

To view data in multiple containers, ensure that the current container is the CDB root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Run a query that includes the CONTAINERS clause.

#### Example 45-10 Querying a Table Owned by a Common User Across All Containers

This example makes the following assumptions:

- An organization has several PDBs, and each PDB is for a different department in the organization.
- Each PDB has an `employees` table that tracks the employees in the department, but the table in each PDB contains different employees.
- The CDB root also has an empty `employees` table.
- The `employees` table in each container is owned by the same common user.

With the CDB root as the current container and the common user that owns the table as the current user, run the following query with the CONTAINERS clause to return all of the employees in the `employees` table in all PDBs:

```
SELECT * FROM CONTAINERS(employees);
```

#### Example 45-11 Querying a Table Owned by Local Users Across All Containers

This example makes the following assumptions:

- An organization has several PDBs, and each PDB is for a different department in the organization.

- Each PDB has an `hr.employees` table that tracks the employees in the department, but the table in each PDB contains different employees.
- The CDB root also has an empty `employees` table owned by a common user.

To run a query that returns all of the employees in all of the PDBs, first connect to each PDB as a common user, and create a view with the following statement:

```
CREATE OR REPLACE VIEW employees AS SELECT * FROM hr.employees;
```

The common user that owns the view must be the same common user that owns the `employees` table in the CDB root. After you run this statement in each PDB, the common user has a view named `employees` in each PDB.

With the CDB root as the current container and the common user as the current user, run the following query with the `CONTAINERS` clause to return all of the employees in the `hr.employees` table in all PDBs:

```
SELECT * FROM CONTAINERS(employees);
```

You can also query the view in specific containers. For example, the following SQL statement queries the view in the containers with a `CON_ID` of 3 and 4:

```
SELECT * FROM CONTAINERS(employees) WHERE CON_ID IN(3,4);
```

#### Note:

You can also use the `CONTAINERS` clause to query Oracle-supplied tables and views. When running the query, ensure that the current user is the owner of the table or view, or create a view using the `CONTAINERS` clause and grant `SELECT` privilege on the view to the appropriate users.

#### See Also:

- ["About the Current Container"](#)
- *Oracle Database SQL Language Reference* for more information about the `CONTAINERS` clause

- *Oracle Database Security Guide* for detailed information about container data objects

### 45.10.3 Querying Application Common Objects Across Application PDBs

The `CONTAINERS` clause enables you to query application common objects, such as tables and views, across all application PDBs in an application container. This clause

enables queries from the application root to display data in tables or views that exist in all of the open application PDBs in the application container.

The CONTAINERS clause is most useful for metadata-linked application common objects. With metadata-linked application common objects, the structure is the same in all of the containers in an application container, but the data is different. You can use the CONTAINERS clause to view the data in a metadata-linked application common object in multiple application PDBs. The benefits are similar for extended data-linked objects. The CONTAINERS clause uses parallel execution to execute the query across the distinct application PDBs hosted in the application root.

To use the CONTAINERS clause to query tables and views across all application PDBs:

1. In SQL\*Plus, access the application root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Run a query that includes the CONTAINERS clause.

 **Note:**

You can enable the CONTAINERS\_DEFAULT attribute for a table or view in an application root. When this attribute is enabled, the CONTAINERS clause is used for queries and DML statements on the database object by default, and the CONTAINERS clause is not required in the SQL statements. To enable the CONTAINERS\_DEFAULT attribute for a table or view in an application root, run the `ALTER TABLE OR CREATE OR REPLACE VIEW` statement with the `ENABLE CONTAINERS_DEFAULT` clause.

### **Example 45-12 Querying an Application Common Object Across All Application PDBs**

This example makes the following assumptions:

- An organization has several application PDBs, and each application PDB is for a different department in the organization.
- Each application PDB has an `employees` table that tracks the employees in the department, but the table in each application PDB contains different employees.
- The application root also has an empty `employees` table.
- The `employees` table in each container is owned by the same common user.
- A company has multiple tenants that use an application in an application container, and each tenant has its own application PDB.
- The company uses metadata-linked application common objects to keep the structure of the data the same in all of the application PDBs, but the data is different in each application PDB.
- Each application PDB has a metadata-linked `sales.customers` table that stores information about each tenant's customers.

With the application root as the current container and the application common user that owns the table as the current user, run the following query with the CONTAINERS clause to return all of the customers in the `sales.customers` table in all application PDBs:

```
SELECT * FROM CONTAINERS(sales.customers);
```

 **See Also:**

- ["About Application Common Objects"](#)
- ["About the Current Container"](#)
- *Oracle Database SQL Language Reference* for more information about the CONTAINERS clause
- *Oracle Database Security Guide* for detailed information about container data objects

## 45.11 Determining the Current Container ID or Name

You can determine your current container ID or container name in a CDB.

To determine the current container ID:

- Run the following SQL\*Plus command:

```
SHOW CON_ID
```

To determine the current container name:

- Run the following SQL\*Plus command:

```
SHOW CON_NAME
```

In addition, you can use the functions listed in [Table 45-3](#) to determine the container ID of a container.

**Table 45-3 Functions That Return the Container ID of a Container**

| Function                         | Description                                                                          |
|----------------------------------|--------------------------------------------------------------------------------------|
| CON_NAME_TO_ID('container_name') | Returns the container ID based on the container's name.                              |
| CON_DBID_TO_ID(container_dbid)   | Returns the container ID based on the container's DBID.                              |
| CON_UID_TO_ID(container_uid)     | Returns the container ID based on the container's unique identifier (UID).           |
| CON_GUID_TO_ID(container_guid)   | Returns the container ID based on the container's globally unique identifier (GUID). |

The V\$CONTAINERS view shows the name, DBID, UID, and GUID for each container in a CDB.

### Example 45-13 Returning the Container ID Based on the Container Name

```
SELECT CON_NAME_TO_ID('HRPDB') FROM DUAL;
```

#### Example 45-14 Returning the Container ID Based on the Container DBID

```
SELECT CON_DBID_TO_ID(2226957846) FROM DUAL;
```

 **See Also:**

- ["About a Multitenant Environment"](#)
- ["About the Current Container"](#)
- ["Viewing Information About the Containers in a CDB"](#)
- [Oracle Database Reference](#) for more information about the V\$CONTAINERS view

## 45.12 Listing the Initialization Parameters That Are Modifiable in PDBs

In a CDB, some initialization parameters apply to the root and to all of the PDBs. When such an initialization parameter is changed, it affects the entire CDB. You can set other initialization parameters to different values in each container.

For example, you might have a parameter set to one value in the root, set to another value in one PDB, and set to yet another value in a second PDB.

The query in this section lists the initialization parameters that you can set independently in each PDB.

To list the initialization parameters that are modifiable in each container:

1. In SQL\*Plus, access a container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Run the following query:

```
SELECT NAME FROM V$SYSTEM_PARAMETER
 WHERE ISPDB_MODIFIABLE = 'TRUE'
 ORDER BY NAME;
```

If an initialization parameter listed by this query is not set independently for a PDB, then the PDB inherits the parameter value of the root.

 **See Also:**

- ["Using the ALTER SYSTEM SET Statement in a CDB"](#)
- ["Using the ALTER SYSTEM Statement to Modify a PDB"](#)

## 45.13 Viewing the History of PDBs

The `CDB_PDB_HISTORY` view shows the history of the PDBs in a CDB. It provides information about when and how each PDB was created and other information about each PDB's history.

To view the history of each PDB:

1. In SQL\*Plus, ensure that the current container is the root.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query `CDB_PDB_HISTORY` view.

### Example 45-15 Viewing the History of PDBs

This example shows the following information about each PDB's history:

- The `DB_NAME` field shows the CDB that contained the PDB.
- The `CON_ID` field shows the container ID of the PDB.
- The `PDB_NAME` field shows the name of the PDB in one of its incarnations.
- The `OPERATION` field shows the operation performed in the PDB's history.
- The `OP_TIMESTAMP` field shows the date on which the operation was performed.
- If the PDB was cloned in an operation, then the `CLONED_FROM_PDB` field shows the PDB from which the PDB was cloned.

```
COLUMN DB_NAME FORMAT A10
COLUMN CON_ID FORMAT 999
COLUMN PDB_NAME FORMAT A15
COLUMN OPERATION FORMAT A16
COLUMN OP_TIMESTAMP FORMAT A10
COLUMN CLONED_FROM_PDB_NAME FORMAT A15

SELECT DB_NAME, CON_ID, PDB_NAME, OPERATION, OP_TIMESTAMP, CLONED_FROM_PDB_NAME
 FROM CDB_PDB_HISTORY
 WHERE CON_ID > 2
 ORDER BY CON_ID;
```

Sample output:

| DB_NAME | CON_ID | PDB_NAME | OPERATION | OP_TIMESTAMP | CLONED_FROM_PDB |
|---------|--------|----------|-----------|--------------|-----------------|
| NEWCDB  | 3      | HRPDB    | CREATE    | 10-APR-12    | PDB\$SEED       |
| NEWCDB  | 4      | SALESPDB | CREATE    | 17-APR-12    | PDB\$SEED       |
| NEWCDB  | 5      | TESTPDB  | CLONE     | 30-APR-12    | SALESPDB        |

#### Note:

When the current container is a PDB, the `CDB_PDB_HISTORY` view shows the history of the current PDB only. A local user whose current container is a PDB can query the `DBA_PDB_HISTORY` view and exclude the `CON_ID` column from the query to view the history of the current PDB.

"About the Current Container"

## 45.14 Viewing Information About Applications in Application Containers

Several views provide information about the applications in application containers in a CDB.

- [Viewing Information About Applications](#)  
The DBA\_APPLICATIONS view provides information about the applications in an application container.
- [Viewing Information About Application Status](#)  
The DBA\_APP\_PDB\_STATUS view provides information about the status of the applications in an application container. It can show the status of each application in each application PDB.
- [Viewing Information About Application Statements](#)  
The DBA\_APP\_STATEMENTS view provides information about SQL statements issued during application installation, upgrade, and patch operations
- [Viewing Information About Application Versions](#)  
The DBA\_APP VERSIONS view provides information about the versions for applications in an application container.
- [Viewing Information About Application Patches](#)  
The DBA\_APP\_PATCHES view provides information about the patches for applications in an application container.
- [Viewing Information About Application Errors](#)  
The DBA\_APP\_ERRORS view provides information errors raised when an application PDB synchronizes with an application in the application root. An application PDB issues the ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause.
- [Listing the Shared Database Objects in an Application Container](#)  
The DBA\_OBJECTS view can list the shared database objects in an application container. Shared database objects are metadata-linked application common objects, data-linked application common objects, and extended data-linked application common objects.
- [Listing the Extended Data-Linked Objects in an Application Container](#)  
The DBA\_TABLES and DBA\_VIEWS views can list the extended data-linked objects in an application container.

### Related Topics

- [Creating and Removing Application Containers with SQL\\*Plus](#)  
You can create application containers in several different ways, including using the CDB seed, cloning an existing PDB or non-CDB, and plugging in an unplugged PDB. You can also remove application containers from a CDB.

- [Administering Application Containers with SQL\\*Plus](#)

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

### 45.14.1 Viewing Information About Applications

The `DBA_APPLICATIONS` view provides information about the applications in an application container.

 **Note:**

The `DBA_APPLICATIONS` view provides information about the application in the current container only. To view information about applications in all of the application PDBs in the current application container, query the `DBA_APP_PDB_STATUS` with the application root as the current container.

To view information about the applications in an application container:

1. In SQL\*Plus, access the application root of the application container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the `DBA_APPLICATIONS` view.

#### Example 45-16 Viewing Details About the Applications in an Application Container

This query shows the name, the latest version, and the status of each user-created application in the application container.

```
COLUMN APP_NAME FORMAT A15
COLUMN APP_VERSOIN FORMAT A15
COLUMN APP_STATUS FORMAT A15

SELECT APP_NAME, APP_VERSION, APP_STATUS
 FROM DBA_APPLICATIONS
 WHERE APP_IMPLICIT='N';
```

Your output is similar to the following:

| APP_NAME | APP_VERSION | APP_STATUS |
|----------|-------------|------------|
| SALESAPP | 1.2         | NORMAL     |

 **Note:**

Oracle Database creates some applications implicitly when an application common user operation is issued with a `CONTAINER=ALL` clause outside of `ALTER PLUGGABLE DATABASE APPLICATION BEGIN/END` statements. The sample query excludes implicitly-created applications by specifying `APP_IMPLICIT='N'` in the `WHERE` clause.

### Related Topics

- [Administering Application Containers with SQL\\*Plus](#)  
You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.
- [Synchronizing Applications in an Application PDB](#)  
When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

## 45.14.2 Viewing Information About Application Status

The DBA\_APP\_PDB\_STATUS view provides information about the status of the applications in an application container. It can show the status of each application in each application PDB.

The view can show the status of an application in an application PDB even if the application PDB is closed.

 **Note:**

When queried from the application root, the DBA\_APP\_PDB\_STATUS view provides information about the applications in all of the application PDBs in the current application container. To view information about the application in the current container only, query the DBA\_APPLICATIONS view.

To view information about the application status in an application container:

1. In SQL\*Plus, access the application root of the application container.  
See "[About Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the DBA\_APP\_PDB\_STATUS view.

### Example 45-17 Viewing Information About Application Status

This query shows the name of the application PDB, the name of the application, the version number of the application, and the status of the application.

```
COLUMN PDB_NAME FORMAT A15
COLUMN APP_NAME FORMAT A15
COLUMN APP_VERSION FORMAT A20
COLUMN APP_STATUS FORMAT A12

SELECT p.PDB_NAME, s.APP_NAME, s.APP_VERSION, s.APP_STATUS
 FROM DBA_PDBS p, DBA_APP_PDB_STATUS s
 WHERE p.CON_UID = s.CON_UID;
```

Your output is similar to the following:

| PDB_NAME | APP_NAME | APP_VERSION | APP_STATUS |
|----------|----------|-------------|------------|
| SALES1   | SALESAPP | 4.2         | NORMAL     |

 **Note:**

The status of an application can be `NORMAL` in an application PDB even when the application has not been synchronized to the latest version. Other statuses might indicate that an operation is in progress or that an operation encountered a problem. For example, the status `UPGRADING` might indicate that an upgrade of the application is in progress in the application PDB, or it might indicate that an error was encountered when the application PDB tried to upgrade an application.

### Related Topics

- [Administering Application Containers with SQL\\*Plus](#)

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

## 45.14.3 Viewing Information About Application Statements

The `DBA_APP_STATEMENTS` view provides information about SQL statements issued during application installation, upgrade, and patch operations

Oracle Database records all of the SQL statements issued during application installation, upgrade, and patch operations, and you can view the history of these statements by querying the `DBA_APP_STATEMENTS` view.

To view information about the SQL statements issued during application operations:

1. In SQL\*Plus, access the application root of the application container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the `DBA_APP_STATEMENTS` view.

### Example 45-18 Viewing Information About Application Statements

This query shows the statement ID, capture time, SQL statement, and application name for the SQL statements for applications in the application container.

```
SET LONG 8000
SET PAGES 8000
COLUMN STATEMENT_ID FORMAT NNNNN
COLUMN CAPTURE_TIME FORMAT A12
COLUMN APP_STATEMENT FORMAT A36
COLUMN APP_NAME FORMAT A15

SELECT STATEMENT_ID, CAPTURE_TIME, APP_STATEMENT, APP_NAME
 FROM DBA_APP_STATEMENTS
 ORDER BY STATEMENT_ID;
```

Your output is similar to the following:

| STATEMENT_ID | CAPTURE_TIME | APP_STATEMENT | APP_NAME                                      |
|--------------|--------------|---------------|-----------------------------------------------|
| 1            | 30-AUG-15    | SYS           | APP\$1E87C094764<br>1142FE0534018F8<br>0AA6C5 |

```

2 30-AUG-15 ALTER PLUGGABLE DATABASE APPLICATION APP$1E87C094764
 APP$CON BEGIN INSTALL '1.0' 1142FE0534018F8
 0AA6C5
3 30-AUG-15 ALTER PLUGGABLE DATABASE APPLICATION APP$1E87C094764
 APP$CON END INSTALL '1.0' 1142FE0534018F8
 0AA6C5
4 30-AUG-15 SYS SALESAPP
5 30-AUG-15 ALTER PLUGGABLE DATABASE APPLICATION SALESAPP
 salesapp BEGIN INSTALL '1.0'
6 30-AUG-15 CREATE TABLE oe.cmtb SHARING=METADAT SALESAPP
 A (
 value VARCHAR2(30),
 country VARCHAR2(30))
7 30-AUG-15 CREATE TABLE cormap (SALESAPP
 country VARCHAR2(30) NOT NULL)
 PARTITION BY LIST (country) (
 PARTITION AMER VALUES ('US','MEXICO'
 , 'CANADA'),
 PARTITION EURO VALUES ('UK','FRANCE'
 , 'GERMANY'),
 PARTITION ASIA VALUES ('INDIA','CHIN
 A','JAPAN'))
8 30-AUG-15 ALTER TABLE oe.cmtb ENABLE CONTAINER SALESAPP
 _MAP
9 30-AUG-15 ALTER PLUGGABLE DATABASE APPLICATION SALESAPP
 salesapp END INSTALL '1.0'
.
.
.
.
.
.
```

 **Note:**

Oracle Database creates some applications implicitly when an application common user operation is issued with a CONTAINER=ALL clause outside of ALTER PLUGGABLE DATABASE APPLICATION BEGIN/END statements. The names of these applications begin with APP\$, and the sample output shows these applications.

### Related Topics

- [Administering Application Containers with SQL\\*Plus](#)  
You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.
- [Synchronizing Applications in an Application PDB](#)  
When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the application in the application PDB to the latest version and patch in the application root.

## 45.14.4 Viewing Information About Application Versions

The `DBA_APP_VERSIONS` view provides information about the versions for applications in an application container.

Oracle Database records the versions for each application in an application container.

To view information about the application versions in an application container:

1. In SQL\*Plus, access the application root of the application container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the `DBA_APP_VERSIONS` view.

### **Example 45-19 Viewing Information About Application Versions**

This query shows the name of the application that was versioned, the version number, and the comment for the version.

```
COLUMN APP_NAME FORMAT A15
COLUMN APP_VERSION FORMAT A20
COLUMN APP_VERSION_COMMENT FORMAT A25

SELECT APP_NAME, APP_VERSION, APP_VERSION_COMMENT
FROM DBA_APP_VERSIONS;
```

Your output is similar to the following:

| APP_NAME | APP_VERSION | APP_VERSION_COMMENT |
|----------|-------------|---------------------|
| SALESAPP | 1.0         | Sales Application   |

### **Related Topics**

- [Administering Application Containers with SQL\\*Plus](#)

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

## 45.14.5 Viewing Information About Application Patches

The `DBA_APP_PATCHES` view provides information about the patches for applications in an application container.

Oracle Database records the patches for each application in an application container.

To view information about the application patches in an application container:

1. In SQL\*Plus, access the application root of the application container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the `DBA_APP_PATCHES` view.

### **Example 45-20 Viewing Information About Application Patches**

This query shows the name of the application that was patched, the patch number, the minimum application version for the patch, and the status of the patch for each patch in the application container.

```

COLUMN APP_NAME FORMAT A15
COLUMN PATCH_NUMBER FORMAT NNNNNNNNNN
COLUMN PATCH_MIN_VERSION FORMAT A10
COLUMN PATCH_STATUS FORMAT A15

SELECT APP_NAME, PATCH_NUMBER, PATCH_MIN_VERSION, PATCH_STATUS
 FROM DBA_APP_PATCHES;

```

Your output is similar to the following:

| APP_NAME | PATCH_NUMBER | PATCH_MIN_ | PATCH_STATUS |
|----------|--------------|------------|--------------|
| SALESAPP | 1 1.2        |            | INSTALLED    |

### Related Topics

- [Administering Application Containers with SQL\\*Plus](#)

You can administer application containers, including application roots and application PDBs. You can also administer the applications installed in application containers.

## 45.14.6 Viewing Information About Application Errors

The DBA\_APP\_ERRORS view provides information errors raised when an application PDB synchronizes with an application in the application root. An application PDB issues the ALTER PLUGGABLE DATABASE APPLICATION statement with the SYNC clause.

You can view the history of application errors during application synchronization by querying the DBA\_APP\_ERRORS view.

To view information about errors raised during application synchronization:

1. In SQL\*Plus, access the application root of the application container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the DBA\_APP\_ERRORS view.

### Example 45-21 Viewing Details About Errors Raised During Application Synchronization

This query shows the application name, the SQL statement that raised the error, the error number, and the error message for errors raised during application synchronization.

```

SET LONG 8000
SET PAGES 8000
COLUMN APP_NAME FORMAT A15
COLUMN APP_STATEMENT FORMAT A36
COLUMN ERRORNUM FORMAT NNNNNNNNNN
COLUMN ERRORMSG FORMAT A20

SELECT APP_NAME, APP_STATEMENT, ERRORNUM, ERRORMSG
 FROM DBA_APP_ERRORS;

```

### Related Topics

- [Synchronizing Applications in an Application PDB](#)

When an application is installed, upgraded, patched, or uninstalled in an application root, an application PDB that belongs to the application root is not changed until it is synchronized. Synchronizing an application updates the

application in the application PDB to the latest version and patch in the application root.

## 45.14.7 Listing the Shared Database Objects in an Application Container

The `DBA_OBJECTS` view can list the shared database objects in an application container. Shared database objects are metadata-linked application common objects, data-linked application common objects, and extended data-linked application common objects.

To list the shared database objects in an application container:

1. In SQL\*Plus, access the application root of the application container.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Query the `DBA_OBJECTS` view and specify the `SHARING` column.

### **Example 45-22 Listing the User-Created Shared Database Objects in an Application Container**

This query shows the owner and name of the user-created shared database objects in the application container. It also shows whether each shared database object is a metadata-linked application common object or a data-linked application common object. The query excludes Oracle-supplied shared database objects.

```
COLUMN OWNER FORMAT A15
COLUMN OBJECT_NAME FORMAT A25
COLUMN SHARING FORMAT A13

SELECT OWNER, OBJECT_NAME, SHARING
 FROM DBA_OBJECTS WHERE SHARING != 'NONE'
 AND ORACLE_MAINTAINED = 'N';
```

Your output is similar to the following:

| OWNER    | OBJECT_NAME             | SHARING       |
|----------|-------------------------|---------------|
| SALESADM | CONMAP                  | METADATA LINK |
| OE       | PRODUCT_DESCRIPTIONS_OB | DATA LINK     |
| OE       | CMTB                    | METADATA LINK |

#### **Related Topics**

- [Managing Application Common Objects](#)

Application common objects are shared, user-created database objects in an application container. Application common objects are created in an application root.

## 45.14.8 Listing the Extended Data-Linked Objects in an Application Container

The `DBA_TABLES` and `DBA_VIEWS` views can list the extended data-linked objects in an application container.

An extended data-linked object is a special type of data-linked object for which each application PDB can create its own specific data while sharing the common data in the

application root. Only the data stored in the application root is common for all application PDBs.

To list the extended data-linked objects in an application container:

1. In SQL\*Plus, access the application root of the application container.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Query the DBA\_TABLES or DBA\_VIEWS view and specify the EXTENDED\_DATA\_LINK='YES' in the WHERE clause.

**Example 45-23 Listing the Extended Data-Linked Tables in an Application Container**

This query shows the owner and name of the extended data-linked tables in the application container.

```
COLUMN OWNER FORMAT A20
COLUMN TABLE_NAME FORMAT A30

SELECT OWNER, TABLE_NAME FROM DBA_TABLES WHERE EXTENDED_DATA_LINK='YES';
```

Your output is similar to the following:

| OWNER    | TABLE_NAME |
|----------|------------|
| SALESADM | ZIPCODES   |

Application common objects are shared, user-created database objects in an application container. Application common objects are created in an application root.

# Using Oracle Resource Manager for PDBs with SQL\*Plus

You can use PL/SQL package procedures to administer Oracle Resource Manager (Resource Manager) to allocate resources to pluggable databases (PDBs) in a multitenant container database (CDB).

Before using Resource Manager for PDBs, meet the following requirements:

- You understand how to configure and manage a CDB. See "[Managing a Multitenant Environment](#)" for information.
- You understand how to use Oracle Resource Manager to allocate resources in a non-CDB. See "[Managing Resources with Oracle Database Resource Manager](#)" for information.

## Note:

- You can complete the tasks in this chapter using SQL\*Plus or Oracle SQL Developer.
- You can also administer the Resource Manager with the graphical user interface of Oracle Enterprise Manager Cloud Control (Cloud Control). For instructions about administering Resource Manager in a CDB with Cloud Control, see "[Using Oracle Resource Manager for PDBs with Cloud Control](#)" and the Cloud Control online help.
- For simplicity, this chapter refers to PDBs, application roots, and application PDBs as "PDBs."

### [About Using Oracle Resource Manager with CDBs and PDBs](#)

You can create CDB resource plans and PDB resource plans to manage resources for CDBs and PDBs.

### [Prerequisites for Using Resource Manager with a CDB](#)

You must meet prerequisites before using Resource Manager with a CDB.

### [Creating a CDB Resource Plan for Individual PDBs](#)

You use the `DBMS_RESOURCE_MANAGER` package to create a CDB resource plan for individual PDBs and define the directives for the plan.

### [Creating a CDB Resource Plan with PDB Performance Profiles](#)

You use the `DBMS_RESOURCE_MANAGER` package to create a CDB resource plan for PDB performance profiles and define the directives for the plan. Each PDB that uses a profile adopts the CDB resource plan for that profile.

- [Enabling and Disabling a CDB Resource Plan](#)  
A CDB resource plan manages the workloads for multiple PDBs that are contending for system and CDB resources. You can enable or disable a CDB resource plan.
- [Creating a PDB Resource Plan](#)  
You create a PDB resource plan in the same way that you create a resource plan for a non-CDB. You use procedures in the DBMS\_RESOURCE\_MANAGER PL/SQL package to create the plan.
- [Enabling and Disabling a PDB Resource Plan](#)  
A PDB resource plan manages the workloads within a single PDB. You can enable or disable a PDB resource plan.
- [Maintaining Plans and Directives in a CDB](#)  
This section provides instructions for maintaining CDB resource plans, the default directive for PDBs, the autotask directive, and PDB resource plans. You perform maintenance tasks using the DBMS\_RESOURCE\_MANAGER PL/SQL package.
- [Viewing Information About Plans and Directives in a CDB](#)  
You can view information about CDB resource plans, CDB resource plan directives, and predefined resource plans in a CDB.
- [Monitoring PDBs Managed by Oracle Database Resource Manager](#)  
A set of dynamic performance views enables you to monitor the results of your Oracle Database Resource Manager settings for PDBs.

You can use various tools to configure and administer a multitenant environment.
- [Application Containers](#)  
An application container is an optional component of a CDB that consists of an application root and all of the application PDBs associated with it. An application container stores data for one or more applications and shares application metadata and common data.

## 46.1 About Using Oracle Resource Manager with CDBs and PDBs

You can create CDB resource plans and PDB resource plans to manage resources for CDBs and PDBs.

- [About Managing Resources at the CDB Level and PDB Level](#)  
In a non-CDB, you can use Resource Manager to manage multiple workloads that are contending for system and database resources. However, in a CDB, you can have multiple workloads within multiple PDBs competing for system and CDB resources.
- [What Solutions Does Resource Manager Provide for a CDB?](#)  
Resource Manager can provide more efficient use of resources for a CDB.
- [CDB Resource Plans](#)  
In a CDB, PDBs might have different levels of priority. You can create CDB resource plans to distribute resources to different PDBs based on these priorities.

- **PDB Resource Plans**  
A CDB resource plan determines the amount of resources allocated to each PDB. A PDB resource plan determines how the resources allocated to a specific PDB are allocated to consumer groups within that PDB.
- **Background and Administrative Tasks and Consumer Groups**  
In a CDB, background and administrative tasks are mapped to the Resource Manager consumer groups that run them optimally.
- **Initialization Parameters That Control Memory for PDBs**  
Several initialization parameters can control the memory usage of a PDB.
- **Initialization Parameters That Limit I/O for PDBs**  
You can set the `MAX_IOPS` initialization parameter and the `MAX_MBPS` initialization parameter to limit the disk I/O generated by a PDB.

### 46.1.1 About Managing Resources at the CDB Level and PDB Level

In a non-CDB, you can use Resource Manager to manage multiple workloads that are contending for system and database resources. However, in a CDB, you can have multiple workloads within multiple PDBs competing for system and CDB resources.

In a CDB, Resource Manager can manage resources on two basic levels:

- **CDB level** - Resource Manager can manage the workloads for multiple PDBs that are contending for system and CDB resources. You can specify how resources are allocated to PDBs, and you can limit the resource utilization of specific PDBs.
- **PDB level** - Resource Manager can manage the workloads within each PDB.

Resource Manager allocates the resources in two steps:

1. It allocates a portion of the system's resources to each PDB.
2. In a specific PDB, it allocates a portion of system resources obtained in Step 1 to each session connected to the PDB.

 **Note:**

All activity in the root is automatically managed by Resource Manager.

### 46.1.2 What Solutions Does Resource Manager Provide for a CDB?

Resource Manager can provide more efficient use of resources for a CDB.

When resource allocation decisions for a CDB are left to the operating system, you may encounter the following problems with workload management:

- Inappropriate allocation of resources among PDBs

The operating system distributes resources equally among all active processes and cannot prioritize one task over another. Therefore, one or more PDBs might use an inordinate amount of the system resources, leaving the other PDBs starved for resources.

- Inappropriate allocation of resources within a single PDB

One or more sessions connected to a single PDB might use an inordinate amount of the system resources, leaving other sessions connected to the same PDB starved for resources.

- Inconsistent performance of PDBs

A single PDB might perform inconsistently when other PDBs are competing for more system resources or less system resources at various times.

- Lack of resource usage data for PDBs

Resource usage data is critical for monitoring and tuning PDBs. It might be possible to use operating system monitoring tools to gather the resource usage data for a non-CDB if it is the only database running on the system. However, in a CDB, operating system monitoring tools are no longer as useful because there are multiple PDBs running on the system.

Resource Manager helps to overcome these problems by allowing the CDB more control over how hardware resources are allocated among the PDBs and within PDBs.

In a CDB with multiple PDBs, some PDBs typically are more important than others. The Resource Manager enables you to prioritize and limit the resource usage of specific PDBs.

With the Resource Manager, you can:

- Specify that different PDBs should receive different shares of the system resources so that more resources are allocated to the more important PDBs
- Limit the CPU usage of a particular PDB
- Limit the number of parallel execution servers that a particular PDB can use
- Limit the memory usage of a particular PDB
- Specify the amount of memory guaranteed for a particular PDB
- Specify the maximum amount of memory a particular PDB can use
- Use PDB performance profiles for different sets of PDB

A performance profile for a set of PDBs can specify shares of system resources, CPU usage, and number of parallel execution servers. PDB performance profiles enable you to manage resources for large numbers of PDBs by specifying Resource Manager directives for profiles instead of individual PDBs.

- Limit the resource usage of different sessions connected to a single PDB
- Limit the I/O generated by specific PDBs
- Monitor the resource usage of PDBs

### 46.1.3 CDB Resource Plans

In a CDB, PDBs might have different levels of priority. You can create CDB resource plans to distribute resources to different PDBs based on these priorities.

- [About CDB Resource Plans](#)

A CDB resource plan allocates resources to its PDBs according to its set of resource plan directives (directives).

- [Shares for Allocating Resources to PDBs](#)  
To allocate resources among PDBs, you assign a share value to each PDB or to each PDB performance profile. A higher share value results in more guaranteed resources for a PDB or the PDBs that use the PDB performance profile.
- [Utilization Limits for PDBs](#)  
A utilization limit restrains the system resource usage of a specific PDB or a specific PDB performance profile. You can specify utilization limits for CPU, parallel execution servers, and memory.
- [The Default Directive for PDBs](#)  
When you do not explicitly define directives for a PDB, the PDB uses the default directive for PDBs.

#### 46.1.3.1 About CDB Resource Plans

A CDB resource plan allocates resources to its PDBs according to its set of resource plan directives (directives).

There is a parent-child relationship between a CDB resource plan and its directives. Each directive references one of the following:

- A single PDB
- A set of PDBs in a PDB performance profile

PDB performance profiles are a good way to configure CDB resource plan directives for a group of PDBs. For example, you might create a performance profile for "gold" PDBs, "silver" PDBs, and "bronze" PDBs. A PDB specifies its performance profile with the `DB_PERFORMANCE_PROFILE` initialization parameter. You can specify PDB initialization parameters that control resources, such as `SGA_TARGET` and `PGA_AGGREGATE_LIMIT`, for a group of PDBs using PDB lockdown profiles. It is best practice to use matching names for PDB performance profiles and PDB lockdown profiles. In addition, it is best practice to put the PDB's performance profile in the PDB's lockdown profile to prevent PDB owners from switching profiles.

You can specify directives for both individual PDBs and for PDB performance profiles in the same CDB. No two directives for the currently active plan can reference the same PDB or the same PDB performance profile.

The directives control allocation of the following resources to the PDBs:

- CPU
- Parallel execution servers

A directive can control the allocation of resources to PDBs based on the share value that you specify for each PDB or PDB performance profile. A higher share value results in more resources. For example, you can specify that one PDB is allocated double the resources allocated to a second PDB by setting the share value for the first PDB twice as high as the share value for the second PDB. Similarly, you can specify that one PDB performance profile is allocated double the resources allocated to a second PDB performance profile by setting the share value for the first PDB performance profile twice as high as the share value for the second PDB performance profile. The settings apply to the set of PDBs that use each profile.

You can also specify utilization limits for PDBs and PDB performance profiles. The utilization limit limits resource allocation to the PDB or PDB performance profile. For example, it can control how much CPU a PDB gets as a percentage of the total CPU available to the CDB.

You can use both shares and utilization limits together for precise control over the resources allocated to each PDB and PDB performance profile in a CDB.

 **See Also:**

["About Restricting PDB Users for Enhanced Security"](#) for more information about PDB lockdown profiles

#### 46.1.3.2 Shares for Allocating Resources to PDBs

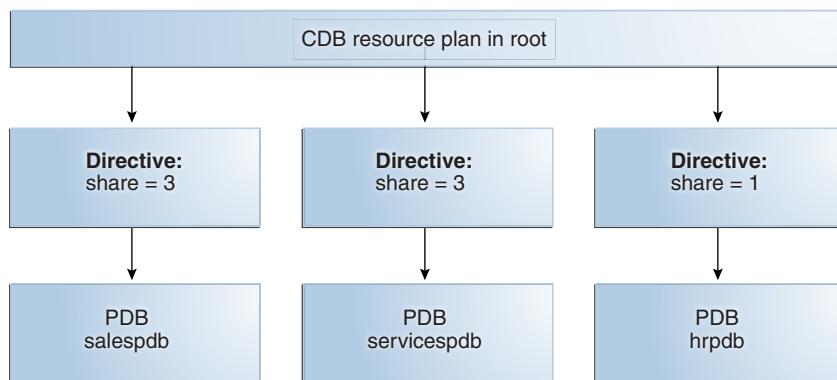

To allocate resources among PDBs, you assign a share value to each PDB or to each PDB performance profile. A higher share value results in more guaranteed resources for a PDB or the PDBs that use the PDB performance profile.

You specify a share value for a PDB using the `CREATE_CDB_PLAN_DIRECTIVE` procedure in the `DBMS_RESOURCE_MANAGER` package. The `shares` parameter in this procedure specifies the share value for the PDB.

You specify a share value for a PDB performance profile using the `CREATE_CDB_PROFILE_DIRECTIVE` procedure in the `DBMS_RESOURCE_MANAGER` package. The `shares` parameter in this procedure specifies the share value for the PDB performance profile. Multiple PDBs can use the same PDB performance profile.

[Figure 46-1](#) shows an example of three PDBs with share values specified for them in a CDB resource plan.

**Figure 46-1 Shares in a CDB Resource Plan**

[Figure 46-1](#) shows that the total number of shares is seven (3 plus 3 plus 1). The `salespdb` and the `servicespdb` PDB are each guaranteed 3/7th of the resources, while the `hrpdb` PDB is guaranteed 1/7th of the resources. However, any PDB can use more than the guaranteed amount of a resource if there is no resource contention.

[Table 46-1](#) shows the resources allocation to the PDBs in [Figure 46-1](#) based on the share values, assuming that loads of the PDBs consume all of the system resources allocated.

**Table 46-1 Resource Allocation for Sample PDBs**

| Resource                   | Resource Allocation                                                                                                                                                                                                                                                                                                                       |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPU                        | The salespdb and servicespdb PDBs can consume the same amount of CPU resources. The salespdb and servicespdb PDBs are each guaranteed three times more CPU resource than the hrpdb PDB.<br><br>See " <a href="#">CPU</a> " for more information about this resource.                                                                      |
| Parallel execution servers | Queued parallel queries from the salespdb and servicespdb PDBs are selected equally. Queued parallel queries from the salespdb and servicespdb PDBs are selected three times as often as queued parallel queries from the hrpdb PDB.<br><br>See " <a href="#">Degree of Parallelism Limit</a> " for more information about this resource. |

### 46.1.3.3 Utilization Limits for PDBs

A utilization limit restrains the system resource usage of a specific PDB or a specific PDB performance profile. You can specify utilization limits for CPU, parallel execution servers, and memory.

Utilization limits for a PDB are set either by the CDB resource plan or by PDB initialization parameters. [Table 46-2](#) describes utilization limits for PDBs and the Resource Manager action taken when a PDB reaches a utilization limit. For limits specified with a PDB performance profile, each limit applies to each PDB that uses the PDB performance profile.

**Table 46-2 Utilization Limits for PDBs**

| Resource | Resource Utilization Limit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Resource Manager Action                                                                                                    |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| CPU      | <p>The sessions connected to a PDB reach the CPU utilization limit for the PDB.</p> <p>This utilization limit for CPU is set by the <code>utilization_limit</code> parameter in subprograms of the <code>DBMS_RESOURCE_MANAGER</code> package. The <code>utilization_limit</code> parameter specifies the percentage of the system resources that a PDB can use. The value ranges from 0 to 100.</p> <p>You can also limit CPU for a PDB by setting the initialization parameter <code>CPU_COUNT</code>. For example, if you set the <code>CPU_COUNT</code> to 8, then the PDB cannot use more than 8 CPUs at any time. If both <code>utilization_limit</code> and <code>CPU_COUNT</code> are specified, then the more restrictive (lower) value is enforced.</p> | Resource Manager throttles the PDB sessions so that the CPU utilization for the PDB does not exceed the utilization limit. |

**Table 46-2 (Cont.) Utilization Limits for PDBs**

| Resource                   | Resource Utilization Limit                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Resource Manager Action                                                                                                                                                                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parallel execution servers | <p>A PDB uses more than the value of the PARALLEL_SERVERS_TARGET initialization parameter multiplied by the value of the parallel_server_limit parameter in subprograms of the DBMS_RESOURCE_MANAGER package.</p> <p>For example, if the PARALLEL_SERVERS_TARGET initialization parameter is set to 200 and the parallel_server_limit parameter for a PDB is set to 10%, then utilization limit for the PDB is 20 parallel execution servers (<math>200 \times .10</math>).</p> | Resource Manager queues parallel queries if the number of parallel execution servers used by the PDB would exceed the limit specified by the PARALLEL_SERVERS_TARGET initialization parameter value multiplied by the value of the parallel_server_limit parameter. |
| Memory                     | <p>Several initialization parameters can control the memory usage of a PDB. For example, the SGA_TARGET initialization parameter limits the PDB's SGA usage, and the PGA_AGGREGATE_LIMIT initialization parameter limits the PDB's PGA usage.</p> <p>See "<a href="#">Initialization Parameters That Control Memory for PDBs</a>" for more information about this resource.</p>                                                                                                 | Oracle Database prevents the PDB from using more memory than the amount specified in a limiting initialization parameter.                                                                                                                                           |

Figure 46-2 shows an example of three PDBs with shares and utilization limits specified for them in a CDB resource plan.

**Figure 46-2 Shares and Utilization Limits in a CDB Resource Plan**

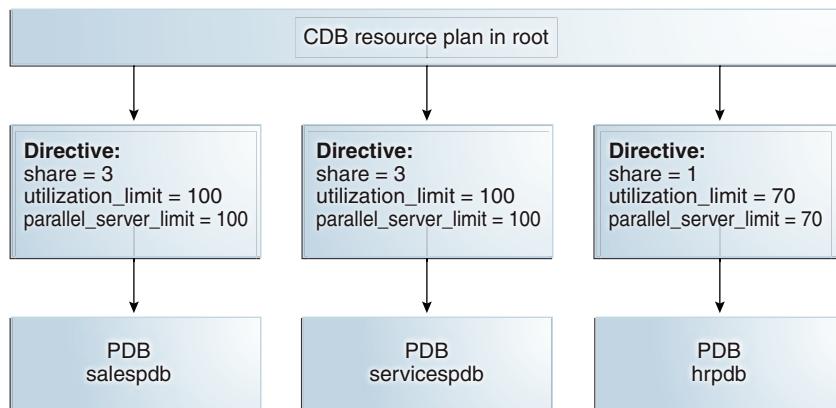

Figure 46-2 shows that there are no utilization limits on the salespdb and servicespdb PDBs because utilization\_limit and parallel\_server\_limit are both set to 100% for them. However, the hrpdb PDB is limited to 70% of the applicable system resources because utilization\_limit and parallel\_server\_limit are both set to 70%.

#### 46.1.3.4 The Default Directive for PDBs

When you do not explicitly define directives for a PDB, the PDB uses the default directive for PDBs.

[Table 46-3](#) shows the attributes of the initial default directive for PDBs.

**Table 46-3 Initial Default Directive Attributes for PDBs**

| Directive Attribute   | Value |
|-----------------------|-------|
| shares                | 1     |
| utilization_limit     | 100   |
| parallel_server_limit | 100   |

When a PDB is plugged into a CDB and no directive is defined for it, the PDB uses the default directive for PDBs.

You can create new directives for the new PDB. You can also change the default directive attribute values for PDBs by using the `UPDATE_CDB_DEFAULT_DIRECTIVE` procedure in the `DBMS_RESOURCE_MANAGER` package.

When a PDB is unplugged from a CDB, the directive for the PDB is retained. If the same PDB is plugged back into the CDB, then it uses the directive defined for it if the directive was not deleted manually.

[Figure 46-3](#) shows an example of the default directive in a CDB resource plan.

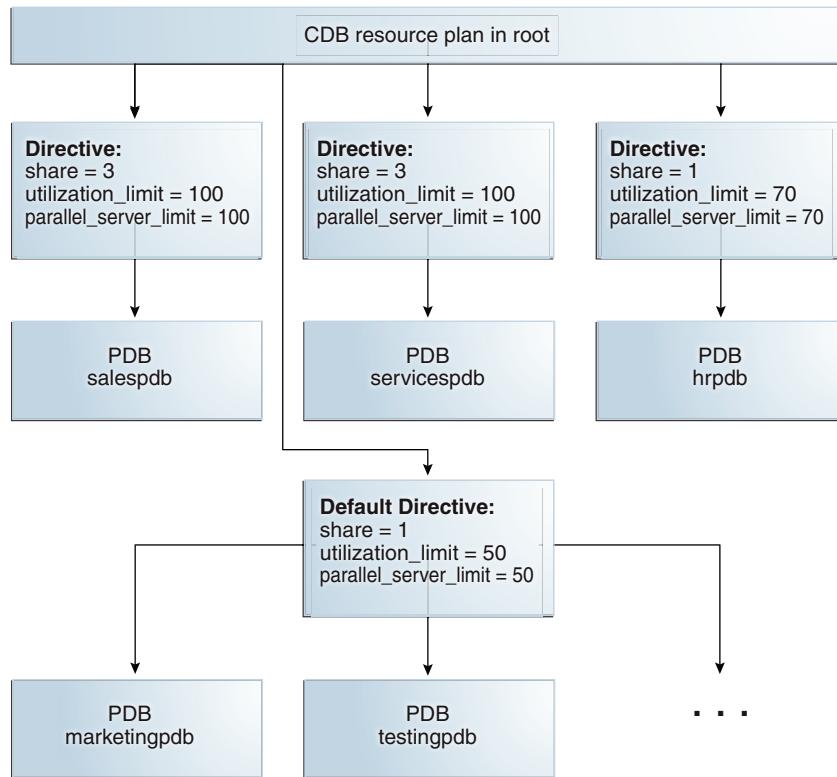

**Figure 46-3 Default Directive in a CDB Resource Plan**

Figure 46-3 shows that the default PDB directive specifies that the `share` is 1, the `utilization_limit` is 50%, and the `parallel_server_limit` is 50%. Any PDB that is part of the CDB and does not have directives defined for it uses the default PDB directive. Figure 46-3 shows the PDBs `marketingpdb` and `testingpdb` using the default PDB directive. Therefore, `marketingpdb` and `testingpdb` each get 1 share and utilization limits of 50.

## 46.1.4 PDB Resource Plans

A CDB resource plan determines the amount of resources allocated to each PDB. A PDB resource plan determines how the resources allocated to a specific PDB are allocated to consumer groups within that PDB.

A PDB resource plan is similar to a resource plan for a non-CDB. Specifically, a PDB resource plan allocates resource among the consumer groups within a PDB. You can use a PDB resource plan to allocate the resources described in "[The Types of Resources Managed by the Resource Manager](#)".

When you create one or more PDB resource plans, the CDB resource plan for the PDB's CDB should meet certain requirements. [Table 46-4](#) describes the requirements for the CDB resource plan and the results when the requirements are not met.

You create directives for a CDB resource plan by using the `CREATE_CDB_PLAN_DIRECTIVE` procedure in the `DBMS_RESOURCE_MANAGER` package. You create directives for a PDB resource plan using the `CREATE_PLAN_DIRECTIVE` procedure in the same package. When you create one or more PDB resource plans and there is no CDB resource plan, the CDB uses the `DEFAULT_CDB_PLAN` that is supplied with Oracle Database.

 **Note:**

[Table 46-4](#) describes parameter values for PL/SQL procedures. The parameter values described in the "CDB Resource Plan Requirements" column are for the `CREATE_CDB_PLAN_DIRECTIVE` procedure. The parameter values described in the "Results When Requirements Are Not Met" column are for the `CREATE_PLAN_DIRECTIVE` procedure.

**Table 46-4 CDB Resource Plan Requirements for PDB Resource Plans**

| Resource | CDB Resource Plan Requirements                                                                                                                                                                                                                                                                                                                                                                                                  | Results When Requirements Are Not Met                                                                                                                                                               |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Figure 46-4 shows an example of a CDB resource plan and a PDB resource plan.

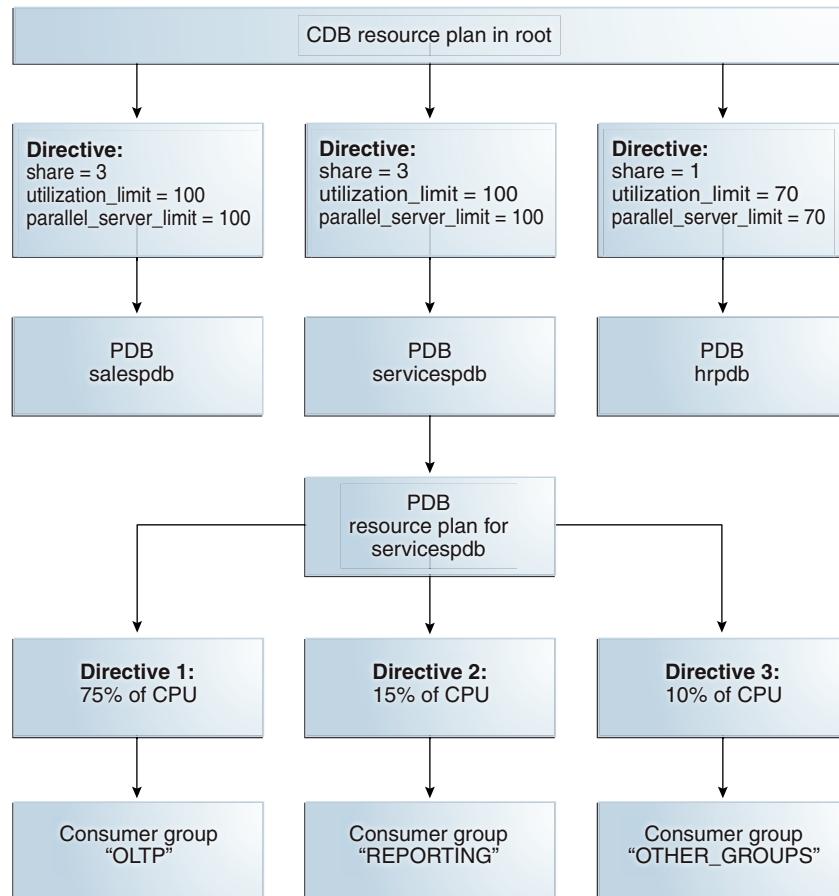

**Figure 46-4 A CDB Resource Plan and a PDB Resource Plan**

Figure 46-4 shows some of the directives in a PDB resource plan for the `servicespdb` PDB. Other PDBs in the CDB can also have PDB resource plans.

In a CDB, the following restrictions apply to PDB resource plans:

- A PDB resource plan cannot have subplans.
- A PDB resource plan can have a maximum of eight consumer groups.
- A PDB resource plan cannot have a multiple-level scheduling policy.

If you create a PDB using a non-CDB, and the non-CDB contains resource plans, then these resource plans might not conform to these restrictions. In this case, Oracle Database automatically transforms these resource plans into equivalent PDB resource plans that meet these requirements. The original resource plans and directives are recorded in the `DBA_RSRC_PLANS` and `DBA_RSRC_PLAN_DIRECTIVES` views with the `LEGACY` status.

#### 46.1.5 Background and Administrative Tasks and Consumer Groups

In a CDB, background and administrative tasks are mapped to the Resource Manager consumer groups that run them optimally.

Resource Manager uses the following rules to map a task to a consumer group:

- A task is mapped to a consumer group in the container that starts the task. If a task starts in the root, then the task is mapped to a consumer group in the root. If the task starts in a PDB, then the task is mapped to a consumer group in the PDB.
- When a task is started by an internal client using an internal API, the internal API determines the consumer group to which the task is mapped.

For example, a backup task uses an internal Oracle function. When `SYS` starts a backup task in the root, the backup task is mapped based on the Oracle function to the `SYS_GROUP` consumer group in the root.

- When a task is started without using an internal API, the task is mapped to a consumer group based on the user-defined mapping rules.

For example, when `SYS` is mapped to the `SYS_GROUP` consumer group, a task started by `SYS` is mapped to the `SYS_GROUP` consumer group.

The following background and administrative tasks follow these rules:

- Backup and recovery
- Auditing
- Replication and Advanced Queuing
- Unplugging a PDB
- Maintenance windows

## 46.1.6 Initialization Parameters That Control Memory for PDBs

Several initialization parameters can control the memory usage of a PDB.

When you set the following initialization parameters with the PDB as the current container, the parameters control the memory usage of the current PDB. When one or more of these parameters is set for a PDB, ensure that the CDB and the other PDBs have sufficient memory for their operations.

**Table 46-5 Initialization Parameters That Control the Memory Usage of PDBs**

| Initialization Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB_CACHE_SIZE            | <p>Sets the minimum, guaranteed buffer cache space for the PDB.</p> <p>The following requirements must be met:</p> <ul style="list-style-type: none"> <li>• It must be less than or equal to 50% of the setting for the DB_CACHE_SIZE in the CDB root.</li> <li>• The sum of the DB_CACHE_SIZE settings for all PDBs must be less than or equal to 50% of the setting for the DB_CACHE_SIZE in the CDB root.</li> </ul> <p>These requirements do not apply if the SGA_TARGET initialization parameter is set to a non-zero value in the CDB root.</p> <p>When the SGA_TARGET initialization parameter is set to a non-zero, the following requirements must be met:</p> <ul style="list-style-type: none"> <li>• The values of DB_CACHE_SIZE plus SHARED_POOL_SIZE in a PDB must be less than or equal to 50% of the PDB's SGA_TARGET value.</li> <li>• The values of DB_CACHE_SIZE plus SHARED_POOL_SIZE in a PDB must be less than or equal to 50% of the SGA_TARGET value at the CDB level.</li> <li>• The sum of DB_CACHE_SIZE plus SHARED_POOL_SIZE across all the PDBs in a CDB must be less than or equal to 50% of the SGA_TARGET value at the CDB level.</li> </ul> |

**Table 46-5 (Cont.) Initialization Parameters That Control the Memory Usage of PDBs**

| Initialization Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| PGA_AGGREGATE_TARGET     | <p>Sets the target aggregate PGA size for the PDB.</p> <p>The following requirements must be met:</p> <ul style="list-style-type: none"> <li>It must be less than or equal to the PGA_AGGREGATE_TARGET value set at the CDB level.</li> <li>It must be less than or equal to 50% of the PGA_AGGREGATE_LIMIT initialization parameter value set at the CDB level.</li> <li>It must be less than or equal to 50% of the PGA_AGGREGATE_LIMIT value set in the PDB.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 46-5 (Cont.) Initialization Parameters That Control the Memory Usage of PDBs**

| Initialization Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SGA_MIN_SIZE             | <p>Sets the minimum SGA size for the PDB. The following requirements must be met:</p> <ul style="list-style-type: none"> <li>• It must be less than or equal to 50% of the setting for the SGA_TARGET in the CDB root.</li> <li>• It must be less than or equal to 50% of the setting for the SGA_TARGET in the PDB.</li> <li>• The sum of the SGA_MIN_SIZE settings for all PDBs must be less than or equal to 50% of the setting for the SGA_TARGET in the CDB root.</li> </ul> <p>These requirements do not apply if the SGA_TARGET initialization parameter is not set or is set to 0 (zero) in the CDB root. The best practice is to limit the sum of the SGA_MIN_SIZE values for all PDBs to 50% or less of the SGA size of the CDB.</p> |
| SGA_TARGET               | <p>Sets the maximum SGA size for the PDB. The SGA_TARGET setting in the PDB is enforced only if the SGA_TARGET initialization parameter is set to a non-zero value in the CDB root. The SGA_TARGET setting in the PDB must be less than or equal to the SGA_TARGET setting in the CDB root.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |

These initialization parameters control the memory usage of PDBs only if the following conditions are met:

- The NONCDB\_COMPATIBLE initialization parameter is set to `false` in the CDB root.
- The MEMORY\_TARGET initialization parameter is not set or is set to 0 (zero) in the CDB root.

#### **Example 46-1 Setting the Maximum Aggregate PGA Memory Available for a PDB**

With the PDB as the current container, run the following SQL statement to set the PGA\_AGGREGATE\_LIMIT initialization parameter both in memory and in the spfile to 90 megabytes:

```
ALTER SYSTEM SET PGA_AGGREGATE_LIMIT = 90M SCOPE = BOTH;
```

#### **Example 46-2 Setting the Minimum SGA Size for a PDB**

With the PDB as the current container, run the following SQL statement to set the SGA\_MIN\_SIZE initialization parameter both in memory and in the spfile to 500 megabytes:

```
ALTER SYSTEM SET SGA_MIN_SIZE = 500M SCOPE = BOTH;
```

You can use the `ALTER SYSTEM` statement to modify a PDB.

## 46.1.7 Initialization Parameters That Limit I/O for PDBs

You can set the `MAX_IOPS` initialization parameter and the `MAX_MBPS` initialization parameter to limit the disk I/O generated by a PDB.

A large amount of disk I/O can cause poor performance. Several factors can result in excess disk I/O, such as poorly designed SQL or index and table scans in high-volume transactions. If one PDB is generating a large amount of disk I/O, then it can degrade the performance of other PDBs in the same CDB.

Use one or both of the following initialization parameters to limit the I/O generated by a particular PDB:

- The `MAX_IOPS` initialization parameter limits the number of I/O operations for each second.
- The `MAX_MBPS` initialization parameter limits the megabytes for I/O operations for each second.

Both limits are enforced if you set both initialization parameters for a single PDB.

If these initialization parameters are set with the CDB root as the current container, then the values become the default values for all of the containers in the CDB. If they are set with an application root as the current container, then the values become the default values for all of the application PDBs in the application container. When they are set with a PDB or application PDB as the current container, then the settings take precedence over the default settings in the CDB root or the application root. These parameters cannot be set in a non-CDB.

The default for both of these initialization parameters is 0 (zero). If these initialization parameters are set to 0 (zero) in a PDB, and the CDB root is set to 0, then there is no I/O limit for the PDB. If these initialization parameters are set to 0 (zero) in an application PDB, and its application root is set to 0, then there is no I/O limit for the application PDB.

Critical I/O operations, such as ones for the control file and password file are exempted from the limit and continue to run even if the limit is reached. However, all I/O operations, including critical I/O operations, are counted when the number of I/O operations and the megabytes for I/O operations are calculated.

You can use the `DBA_HIST_RSRC_PDB_METRIC` view to calculate a reasonable I/O limit for a PDB. Consider the values in the following columns when calculating a limit: `IOPS`, `IOMBPS`, `IOPS_THROTTLE_EXEMPT`, and `IOMBPS_THROTTLE_EXEMPT`. The "rsmgr:io rate limit" wait event indicates that a limit was reached.

### Example 46-3 Limiting the I/O Generated by a PDB

With the PDB as the current container, run the following SQL statement to set the `MAX_IOPS` initialization parameter both in memory and in the spfile to a limit of 1,000 I/O operations for each second:

```
ALTER SYSTEM SET MAX_IOPS = 1000 SCOPE = BOTH;
```

#### Example 46-4 Limiting the Megabytes of I/O Generated by a PDB

With the PDB as the current container, run the following SQL statement to set the MAX\_MBPS initialization parameter both in memory and in the spfile to a limit of 5 megabytes of I/O for each second:

```
ALTER SYSTEM SET MAX_MBPS = 5 SCOPE = BOTH;
```

## 46.2 Prerequisites for Using Resource Manager with a CDB

You must meet prerequisites before using Resource Manager with a CDB.

Before you can use Resource Manager with a CDB, the following prerequisites must be met:

- The CDB must exist and must contain PDBs.  
See [Creating and Configuring a CDB](#) and [Creating and Removing PDBs with SQL\\*Plus](#).
- To complete a task that uses the DBMS\_RESOURCE\_MANAGER package, a user must have ADMINISTER\_RESOURCE\_MANAGER system privilege.  
See "About Resource Manager Administration Privileges".

## 46.3 Creating a CDB Resource Plan for Individual PDBs

You use the DBMS\_RESOURCE\_MANAGER package to create a CDB resource plan for individual PDBs and define the directives for the plan.

The general steps for creating a CDB resource plan for individual PDBs are the following:

1. Create the pending area using the CREATE\_PENDING\_AREA procedure.
2. Create the CDB resource plan using the CREATE\_CDB\_PLAN procedure.
3. Create directives for the PDBs using the CREATE\_CDB\_PLAN\_DIRECTIVE procedure.
4. (Optional) Update the default PDB directive using the UPDATE\_CDB\_DEFAULT\_DIRECTIVE procedure.
5. (Optional) Update the default autotask directive using the UPDATE\_CDB\_AUTOTASK\_DIRECTIVE procedure.
6. Validate the pending area using the VALIDATE\_PENDING\_AREA procedure.

7. Submit the pending area using the SUBMIT\_PENDING\_AREA procedure.
- [Creating a CDB Resource Plan for Individual PDBs: A Scenario](#)  
A scenario illustrates each of the steps involved in creating a CDB resource plan for individual PDBs.

### 46.3.1 Creating a CDB Resource Plan for Individual PDBs: A Scenario

A scenario illustrates each of the steps involved in creating a CDB resource plan for individual PDBs.

The scenario assumes that you want to create a CDB resource plan for a CDB named newcdb. The plan includes a directive for each PDB. In this scenario, you also update the default directive and the autotask directive.

The directives are defined using various procedures in the DBMS\_RESOURCE\_MANAGER package. The attributes of each directive are defined using parameters in these procedures. [Table 46-6](#) describes the types of directives in the plan.

**Table 46-6 Attributes for PDB Directives in a CDB Resource Plan**

| Directive Attribute   | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| shares                | Resource allocation share for CPU and parallel execution server resources. See " <a href="#">Shares for Allocating Resources to PDBs</a> ".                                                                                                                                                                                                                                                 |
| utilization_limit     | Resource utilization limit for CPU. See " <a href="#">Utilization Limits for PDBs</a> ".                                                                                                                                                                                                                                                                                                    |
| parallel_server_limit | Maximum percentage of parallel execution servers that a PDB can use.<br><br>When the parallel_server_limit directive is specified for a PDB, the limit is the value of the PARALLEL_SERVERS_TARGET initialization parameter multiplied by the value of the parallel_server_limit parameter in the CREATE_CDB_PLAN_DIRECTIVE procedure. See " <a href="#">Utilization Limits for PDBs</a> ". |

[Table 46-7](#) describes how the CDB resource plan allocates resources to its PDBs using the directive attributes described in [Table 46-6](#).

**Table 46-7 Sample Directives for PDBs in a CDB Resource Plan**

| PDB         | shares Directive | utilization_limit Directive | parallel_server_limit Directive |
|-------------|------------------|-----------------------------|---------------------------------|
| salespdb    | 3                | Unlimited                   | Unlimited                       |
| servicespdb | 3                | Unlimited                   | Unlimited                       |
| hrpdb       | 1                | 70                          | 70                              |
| Default     | 1                | 50                          | 50                              |
| Autotask    | 1                | 75                          | 75                              |

The salespdb and servicespdb PDBs are more important than the other PDBs in the CDB. Therefore, they get a higher share (3), unlimited CPU utilization resource, unlimited parallel execution server resource, and unlimited memory resource.

The default directive applies to PDBs for which specific directives have not been defined. For this scenario, assume that the CDB has several PDBs that use the default directive. This scenario updates the default directive.

In addition, this scenario updates the autotask directive. The autotask directive applies to automatic maintenance tasks that are run in the root maintenance window.

The following tasks use the `DBMS_RESOURCE_MANAGER` package to create the CDB resource plan and update the default and autotask directives for this scenario:

1. Create a pending area using the `CREATE_PENDING_AREA` procedure:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

2. Create a CDB resource plan named `newcdb_plan` using the `CREATE_CDB_PLAN` procedure:

```
BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PLAN(
 plan => 'newcdb_plan',
 comment => 'CDB resource plan for newcdb');
END;
/
```

3. Create the CDB resource plan directives for the PDBs using the `CREATE_CDB_PLAN_DIRECTIVE` procedure. Each directive specifies how resources are allocated to a specific PDB.

[Table 46-7](#) describes the directives for the `salespdb`, `servicespdb`, and `hrpdb` PDBs in this scenario. Run the following procedures to create these directives:

```
BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PLAN_DIRECTIVE(
 plan => 'newcdb_plan',
 pluggable_database => 'salespdb',
 shares => 3,
 utilization_limit => 100,
 parallel_server_limit => 100);
END;
/

BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PLAN_DIRECTIVE(
 plan => 'newcdb_plan',
 pluggable_database => 'servicespdb',
 shares => 3,
 utilization_limit => 100,
 parallel_server_limit => 100);
END;
/

BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PLAN_DIRECTIVE(
 plan => 'newcdb_plan',
 pluggable_database => 'hrpdb',
 shares => 1,
 utilization_limit => 70,
 parallel_server_limit => 70);
END;
/
```

All other PDBs in this CDB use the default PDB directive.

4. If the current default CDB resource plan directive for PDBs does not meet your requirements, then update the directive using the `UPDATE_CDB_DEFAULT_DIRECTIVE` procedure.

The default directive applies to PDBs for which specific directives have not been defined. See "[The Default Directive for PDBs](#)" for more information.

[Table 46-7](#) describes the default directive that PDBs use in this scenario. Run the following procedure to update the default directive:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_DEFAULT_DIRECTIVE(
 plan => 'newcdb_plan',
 new_shares => 1,
 new_utilization_limit => 50,
 new_parallel_server_limit => 50);
END;
/
```

5. If the current autotask CDB resource plan directive does not meet your requirements, then update the directive using the `UPDATE_CDB_AUTOTASK_DIRECTIVE` procedure.

The autotask directive applies to automatic maintenance tasks that are run in the root maintenance window.

[Table 46-7](#) describes the autotask directive in this scenario. Run the following procedure to update the autotask directive:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_AUTOTASK_DIRECTIVE(
 plan => 'newcdb_plan',
 new_shares => 1,
 new_utilization_limit => 75,
 new_parallel_server_limit => 75);
END;
/
```

6. Validate the pending area using the `VALIDATE_PENDING_AREA` procedure:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

7. Submit the pending area using the `SUBMIT_PENDING_AREA` procedure:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

## 46.4 Creating a CDB Resource Plan with PDB Performance Profiles

You use the `DBMS_RESOURCE_MANAGER` package to create a CDB resource plan for PDB performance profiles and define the directives for the plan. Each PDB that uses a profile adopts the CDB resource plan for that profile.

The general steps for creating a CDB resource plan with PDB performance profiles are the following:

1. For each PDB that will use a profile, set the `DB_PERFORMANCE_PROFILE` initialization parameter and specify the profile name.
2. Create the pending area using the `CREATE_PENDING_AREA` procedure.

3. Create the CDB resource plan using the CREATE\_CDB\_PLAN procedure.
  4. Create directives for the PDB performance profiles using the CREATE\_CDB\_PROFILE\_DIRECTIVE procedure.
  5. (Optional) Update the default PDB directive using the UPDATE\_CDB\_DEFAULT\_DIRECTIVE procedure.
  6. (Optional) Update the default autotask directive using the UPDATE\_CDB\_AUTOTASK\_DIRECTIVE procedure.
  7. Validate the pending area using the VALIDATE\_PENDING\_AREA procedure.
  8. Submit the pending area using the SUBMIT\_PENDING\_AREA procedure.
- [Creating a CDB Resource Plan for PDB Performance Profiles: A Scenario](#)  
A scenario illustrates each of the steps involved in creating a CDB resource plan for PDB performance profiles.

## 46.4.1 Creating a CDB Resource Plan for PDB Performance Profiles: A Scenario

A scenario illustrates each of the steps involved in creating a CDB resource plan for PDB performance profiles.

The scenario assumes that you want to create a CDB resource plan for a CDB named newcdb. The plan includes a directive for each PDB performance profile. In this scenario, you also update the default directive and the autotask directive.

In the CDB resource plan, you give each profile a name. In each PDB, you set the DB\_PERFORMANCE\_PROFILE initialization parameter to specify which PDB performance profile the PDB uses.

The directives are defined using various procedures in the DBMS\_RESOURCE\_MANAGER package. The attributes of each directive are defined using parameters in these procedures. [Table 46-8](#) describes the types of directives in the plan.

**Table 46-8 Attributes for PDB Performance Profile Directives in a CDB Resource Plan**

| Directive Attribute   | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| shares                | Resource allocation share for CPU and parallel execution server resources. See " <a href="#">Shares for Allocating Resources to PDBs</a> ".                                                                                                                                                                                                                                                                      |
| utilization_limit     | Resource utilization limit for CPU. See " <a href="#">Utilization Limits for PDBs</a> ".                                                                                                                                                                                                                                                                                                                         |
| parallel_server_limit | Maximum percentage of parallel execution servers that a PDB can use.<br><br>When the parallel_server_limit directive is specified for a PDB performance profile, the limit is the value of the PARALLEL_SERVERS_TARGET initialization parameter multiplied by the value of the parallel_server_limit parameter in the CREATE_CDB_PFILE_DIRECTIVE procedure. See " <a href="#">Utilization Limits for PDBs</a> ". |

[Table 46-9](#) describes how the CDB resource plan allocates resources to its PDB performance profiles using the directive attributes described in [Table 46-8](#).

**Table 46-9 Sample Directives for PDB Performance Profiles in a CDB Resource Plan**

| PDB      | shares Directive | utilization_limit Directive | parallel_server_limit Directive |
|----------|------------------|-----------------------------|---------------------------------|
| gold     | 3                | Unlimited                   | Unlimited                       |
| silver   | 2                | 40                          | 40                              |
| bronze   | 1                | 20                          | 20                              |
| Default  | 1                | 10                          | 10                              |
| Autotask | 2                | 60                          | 60                              |

The PDBs that use the `gold` PDB performance profile are more important than the other PDBs in the CDB. Therefore, they get a higher share (3), unlimited CPU utilization resource, and unlimited parallel execution server resource.

The PDBs that use the `silver` PDB performance profile are of moderate importance. Therefore, they get a share of 2. They are guaranteed a minimum of 40 percent of the CPU utilization resource and parallel execution server resource.

The PDBs that use the `bronze` PDB performance profile are the least important PDBs in the CDB. Therefore, they get the lowest share (1). They are guaranteed a minimum of 20 percent of the CPU utilization resource and parallel execution server resource.

The default directive applies to PDBs for which specific directives have not been defined. For this scenario, assume that the CDB has several PDBs that use the default directive. This scenario updates the default directive.

In addition, this scenario updates the autotask directive. The autotask directive applies to automatic maintenance tasks that are run in the root maintenance window.

Complete the following steps to create the CDB resource plan for PDB performance profiles and update the default and autotask directives for this scenario:

1. For each PDB that will use a profile, set the `DB_PERFORMANCE_PROFILE` initialization parameter to the name of the profile that the PDB will use.
  - a. Run an `ALTER SYSTEM` statement to set the parameter.

For example, with the PDB as the current container, run the following SQL statement:

```
ALTER SYSTEM SET DB_PERFORMANCE_PROFILE=gold SCOPE=spfile;
```

- b. Close the PDB:

```
ALTER PLUGGABLE DATABASE CLOSE IMMEDIATE;
```

- c. Open the PDB:

```
ALTER PLUGGABLE DATABASE OPEN;
```

2. Create a pending area using the `CREATE_PENDING_AREA` procedure:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Create a CDB resource plan named `newcdb_plan` using the `CREATE_CDB_PLAN` procedure:

```
BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PLAN(
 plan => 'newcdb_plan',
 comment => 'CDB resource plan for newcdb');
END;
/
```

4. Create the CDB resource plan directives for the PDBs using the `CREATE_CDB_PLAN_DIRECTIVE` procedure. Each directive specifies how resources are allocated to a specific PDB.

[Table 46-7](#) describes the directives for the `gold`, `silver`, and `bronze` profiles in this scenario. Run the following procedures to create these directives:

```
BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PROFILE_DIRECTIVE(
 plan => 'newcdb_plan',
 profile => 'gold',
 shares => 3,
 utilization_limit => 100,
 parallel_server_limit => 100);
END;
/

BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PROFILE_DIRECTIVE(
 plan => 'newcdb_plan',
 profile => 'silver',
 shares => 2,
 utilization_limit => 40,
 parallel_server_limit => 40);
END;
/

BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PROFILE_DIRECTIVE(
 plan => 'newcdb_plan',
 profile => 'bronze',
 shares => 1,
 utilization_limit => 20,
 parallel_server_limit => 20);
END;
/
```

All other PDBs in this CDB use the default PDB directive.

5. If the current default CDB resource plan directive for PDBs does not meet your requirements, then update the directive using the `UPDATE_CDB_DEFAULT_DIRECTIVE` procedure.

The default directive applies to PDBs for which specific directives have not been defined. See "[The Default Directive for PDBs](#)" for more information.

[Table 46-7](#) describes the default directive that PDBs use in this scenario. Run the following procedure to update the default directive:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_DEFAULT_DIRECTIVE(
 plan => 'newcdb_plan',
 new_shares => 1,
```

```
 new_utilization_limit => 10,
 new_parallel_server_limit => 10);
END;
/
```

6. If the current autotask CDB resource plan directive does not meet your requirements, then update the directive using the UPDATE\_CDB\_AUTOTASK\_DIRECTIVE procedure.

The autotask directive applies to automatic maintenance tasks that are run in the root maintenance window.

Table 46-7 describes the autotask directive in this scenario. Run the following procedure to update the autotask directive:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_AUTOTASK_DIRECTIVE(
 plan => 'newcdb_plan',
 new_shares => 1,
 new_utilization_limit => 60,
 new_parallel_server_limit => 60);
END;
/
```

7. Validate the pending area using the VALIDATE\_PENDING\_AREA procedure:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

8. Submit the pending area using the SUBMIT\_PENDING\_AREA procedure:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

## 46.5 Enabling and Disabling a CDB Resource Plan

A CDB resource plan manages the workloads for multiple PDBs that are contending for system and CDB resources. You can enable or disable a CDB resource plan.

- [Enabling a CDB Resource Plan](#)

You enable the Resource Manager for a CDB by setting the RESOURCE\_MANAGER\_PLAN initialization parameter in the root.

- [Disabling a CDB Resource Plan](#)

You disable the Resource Manager for a CDB by unsetting the RESOURCE\_MANAGER\_PLAN initialization parameter in the root.

### 46.5.1 Enabling a CDB Resource Plan

You enable the Resource Manager for a CDB by setting the RESOURCE\_MANAGER\_PLAN initialization parameter in the root.

This parameter specifies the top plan, which is the plan to be used for the current CDB instance. If no plan is specified with this parameter, then the Resource Manager is not enabled.

Before enabling a CDB resource plan, complete the prerequisites described in ["Prerequisites for Using Resource Manager with a CDB"](#).

**To enable a CDB resource plan:**

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

**2.** Perform one of the following actions:

- Use an ALTER SYSTEM statement to set the RESOURCE\_MANAGER\_PLAN initialization parameter to the CDB resource plan.

The following example sets the CDB resource plan to newcdb\_plan using an ALTER SYSTEM statement:

```
ALTER SYSTEM SET RESOURCE_MANAGER_PLAN = 'newcdb_plan';
```

- In a text initialization parameter file, set the RESOURCE\_MANAGER\_PLAN initialization parameter to the CDB resource plan, and restart the CDB.

The following example sets the CDB resource plan to newcdb\_plan in an initialization parameter file:

```
RESOURCE_MANAGER_PLAN = 'newcdb_plan'
```

You can also schedule a CDB resource plan change with Oracle Scheduler.

#### Related Topics

- [Enabling Oracle Database Resource Manager and Switching Plans](#)

You enable Oracle Database Resource Manager (the Resource Manager) by setting the RESOURCE\_MANAGER\_PLAN initialization parameter. This parameter specifies the top plan, identifying the plan to be used for the current instance. If no plan is specified with this parameter, the Resource Manager is not enabled.

- [Oracle Scheduler Concepts](#)

You can schedule tasks with Oracle Scheduler.

## 46.5.2 Disabling a CDB Resource Plan

You disable the Resource Manager for a CDB by unsetting the RESOURCE\_MANAGER\_PLAN initialization parameter in the root.

If you disable a CDB resource plan, then some directives in PDB resource plans become disabled. See "[PDB Resource Plans](#)" for information about the CDB resource plan requirements for PDB resource plans.

Before disabling a CDB resource plan, complete the prerequisites described in "[Prerequisites for Using Resource Manager with a CDB](#)".

#### To disable a CDB resource plan:

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

**2.** Perform one of the following actions:

- Use an ALTER SYSTEM statement to unset the RESOURCE\_MANAGER\_PLAN initialization parameter for the CDB.

The following example unsets the RESOURCE\_MANAGER\_PLAN initialization parameter using an ALTER SYSTEM statement:

```
ALTER SYSTEM SET RESOURCE_MANAGER_PLAN = '';
```

- In an initialization parameter file, unset the RESOURCE\_MANAGER\_PLAN initialization parameter, and restart the CDB.

The following example unsets the RESOURCE\_MANAGER\_PLAN initialization parameter in an initialization parameter file:

```
RESOURCE_MANAGER_PLAN =
```

To shut down and restart a CDB, see "[Shutting Down a CDB Instance](#)" and "[Starting Up a Database](#)".

## 46.6 Creating a PDB Resource Plan

You create a PDB resource plan in the same way that you create a resource plan for a non-CDB. You use procedures in the DBMS\_RESOURCE\_MANAGER PL/SQL package to create the plan.

A CDB resource plan allocates a portion of the system's resources to a PDB. A PDB resource plan determines how this portion is allocated within the PDB.

The following is a summary of the steps required to create a PDB resource plan:

1. In SQL\*Plus, ensure that the current container is a PDB.
2. Create a pending area using the CREATE\_PENDING\_AREA procedure.
3. Create, modify, or delete consumer groups using the CREATE\_CONSUMER\_GROUP procedure.
4. Map sessions to consumer groups using the SET\_CONSUMER\_GROUP\_MAPPING procedure.
5. Create the PDB resource plan using the CREATE\_PLAN procedure.
6. Create PDB resource plan directives using the CREATE\_PLAN\_DIRECTIVE procedure.
7. Validate the pending area using the VALIDATE\_PENDING\_AREA procedure.
8. Submit the pending area using the SUBMIT\_PENDING\_AREA procedure.

Ensure that the current container is a PDB and that the user has the required privileges when you complete these steps. See "[Creating a Complex Resource Plan](#)" for detailed information about completing these steps.

You also have the option of creating a simple resource plan that is adequate for many situations using the CREATE\_SIMPLE\_PLAN procedure. See "[Creating a Simple Resource Plan](#)".

 **Note:**

Some restrictions apply to PDB resource plans. See "[PDB Resource Plans](#)" for information.

## 46.7 Enabling and Disabling a PDB Resource Plan

A PDB resource plan manages the workloads within a single PDB. You can enable or disable a PDB resource plan.

- [Enabling a PDB Resource Plan](#)  
You enable a PDB resource plan by setting the RESOURCE\_MANAGER\_PLAN initialization parameter to the plan with an ALTER SYSTEM statement when the current container is the PDB.
- [Disabling a PDB Resource Plan](#)  
You disable a PDB resource plan by unsetting the RESOURCE\_MANAGER\_PLAN initialization parameter in the PDB.

## 46.7.1 Enabling a PDB Resource Plan

You enable a PDB resource plan by setting the RESOURCE\_MANAGER\_PLAN initialization parameter to the plan with an ALTER SYSTEM statement when the current container is the PDB.

If no plan is specified with this parameter, then no PDB resource plan is enabled for the PDB.

Before enabling a PDB resource plan, complete the prerequisites described in ["Prerequisites for Using Resource Manager with a CDB"](#).

### To enable a PDB resource plan:

1. In SQL\*Plus, ensure that the current container is a PDB.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Use an ALTER SYSTEM statement to set the RESOURCE\_MANAGER\_PLAN initialization parameter to the PDB resource plan.

You can also schedule a PDB resource plan change with Oracle Scheduler.

### Example 46-5 Enabling a PDB Resource Plan

The following example sets the PDB resource plan to salespdb\_plan.

```
ALTER SYSTEM SET RESOURCE_MANAGER_PLAN = 'salespdb_plan';
```

#### See Also:

- "[Enabling Oracle Database Resource Manager and Switching Plans](#)"
- "[Oracle Scheduler Concepts](#)"
- "[Using the ALTER SYSTEM Statement to Modify a PDB](#)"

## 46.7.2 Disabling a PDB Resource Plan

You disable a PDB resource plan by unsetting the RESOURCE\_MANAGER\_PLAN initialization parameter in the PDB.

Before disabling a PDB resource plan, complete the prerequisites described in ["Prerequisites for Using Resource Manager with a CDB"](#).

**To disable a PDB resource plan:**

1. In SQL\*Plus, ensure that the current container is a PDB.  
See "[Accessing a Container in a CDB with SQL\\*Plus](#)".
2. Use an ALTER SYSTEM statement to unset the RESOURCE\_MANAGER\_PLAN initialization parameter for the PDB.

**Example 46-6 Disabling a PDB Resource Plan**

The following example disables the PDB resource plan.

```
ALTER SYSTEM SET RESOURCE_MANAGER_PLAN = '';
```

 **See Also:**

["Using the ALTER SYSTEM Statement to Modify a PDB"](#)

## 46.8 Maintaining Plans and Directives in a CDB

This section provides instructions for maintaining CDB resource plans, the default directive for PDBs, the autotask directive, and PDB resource plans. You perform maintenance tasks using the DBMS\_RESOURCE\_MANAGER PL/SQL package.

- [Managing a CDB Resource Plan](#)

Managing a CDB resource plan includes tasks such as updating the plan, creating, updating, or deleting plan directives for PDBs, and updating default directives.

- [Modifying a PDB Resource Plan](#)

You can use the DBMS\_RESOURCE\_MANAGER package to modify a PDB resource plan in the same way you would modify the resource plan for a non-CDB.

### 46.8.1 Managing a CDB Resource Plan

Managing a CDB resource plan includes tasks such as updating the plan, creating, updating, or deleting plan directives for PDBs, and updating default directives.

- [Updating a CDB Resource Plan](#)

You can update a CDB resource plan to change its comment using the UPDATE\_CDB\_PLAN procedure.

- [Managing CDB Resource Plan Directives for a PDB](#)

You can create, update, and delete CDB resource plan directives for a PDB.

- [Managing CDB Resource Plan Directives for a PDB Performance Profile](#)

You can create, update, and delete CDB resource plan directives for a PDB performance profile.

- [Updating the Default Directive for PDBs in a CDB Resource Plan](#)

You can update the default directive for PDBs in a CDB resource plan using the UPDATE\_CDB\_DEFAULT\_DIRECTIVE procedure. The default directive applies to PDBs for which specific directives have not been defined.

- [Updating the Default Directive for Maintenance Tasks in a CDB Resource Plan](#)  
You can update the autotask directive in a CDB resource plan using the `UPDATE_CDB_AUTOTASK_DIRECTIVE` procedure. The autotask directive applies to automatic maintenance tasks that are run in the root maintenance window.
- [Deleting a CDB Resource Plan](#)  
You can delete a CDB resource plan using the `DELETE_CDB_PLAN` procedure.

#### 46.8.1.1 Updating a CDB Resource Plan

You can update a CDB resource plan to change its comment using the `UPDATE_CDB_PLAN` procedure.

Before updating a CDB resource plan, complete the prerequisites described in "[Prerequisites for Using Resource Manager with a CDB](#)".

To update a CDB resource plan:

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `UPDATE_CDB_PLAN` procedure, and enter a new comment in the `new_comment` parameter.

For example, the following procedure changes the comment for the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_PLAN(
 plan => 'newcdb_plan',
 new_comment => 'CDB plan for PDBs in newcdb');
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

 **See Also:**

["CDB Resource Plans"](#)

#### 46.8.1.2 Managing CDB Resource Plan Directives for a PDB

You can create, update, and delete CDB resource plan directives for a PDB.

- [Creating New CDB Resource Plan Directives for a PDB](#)  
When you create a PDB in a CDB, you can create a CDB resource plan directive for the PDB using the `CREATE_CDB_PLAN_DIRECTIVE` procedure. The directive specifies how resources are allocated to the new PDB.
- [Updating CDB Resource Plan Directives for a PDB](#)  
You can update the CDB resource plan directive for a PDB using the `UPDATE_CDB_PLAN_DIRECTIVE` procedure. The directive specifies how resources are allocated to the PDB.
- [Deleting CDB Resource Plan Directives for a PDB](#)  
You can delete the CDB resource plan directive for a PDB using the `DELETE_CDB_PLAN_DIRECTIVE` procedure.

#### 46.8.1.2.1 Creating New CDB Resource Plan Directives for a PDB

When you create a PDB in a CDB, you can create a CDB resource plan directive for the PDB using the `CREATE_CDB_PLAN_DIRECTIVE` procedure. The directive specifies how resources are allocated to the new PDB.

Before creating a new CDB resource plan directive for a PDB, complete the prerequisites described in "[Prerequisites for Using Resource Manager with a CDB](#)".

To create a new CDB resource plan directive for a PDB:

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `CREATE_CDB_PLAN_DIRECTIVE` procedure, and specify the appropriate values for the new PDB.

For example, the following procedure allocates resources to a PDB named `operpdb` in the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PLAN_DIRECTIVE(
 plan => 'newcdb_plan',
 pluggable_database => 'operpdb',
 shares => 1,
 utilization_limit => 20,
 parallel_server_limit => 30);
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

#### See Also:

["CDB Resource Plans"](#)

#### 46.8.1.2.2 Updating CDB Resource Plan Directives for a PDB

You can update the CDB resource plan directive for a PDB using the `UPDATE_CDB_PLAN_DIRECTIVE` procedure. The directive specifies how resources are allocated to the PDB.

Before updating a CDB resource plan directive for a PDB, complete the prerequisites described in "[Prerequisites for Using Resource Manager with a CDB](#)".

To update a CDB resource plan directive for a PDB:

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `UPDATE_CDB_PLAN_DIRECTIVE` procedure, and specify the new resource allocation values for the PDB.

For example, the following procedure updates the resource allocation to a PDB named `operpdb` in the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_PLAN_DIRECTIVE(
 plan => 'newcdb_plan',
 pluggable_database => 'operpdb',
 new_shares => 1,
 new_utilization_limit => 10,
 new_parallel_server_limit => 20);
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

#### See Also:

["CDB Resource Plans"](#)

#### 46.8.1.2.3 Deleting CDB Resource Plan Directives for a PDB

You can delete the CDB resource plan directive for a PDB using the `DELETE_CDB_PLAN_DIRECTIVE` procedure.

You might delete the directive for a PDB if you unplug or drop the PDB. However, you can retain the directive, and if the PDB is plugged into the CDB in the future, the existing directive applies to the PDB.

Before deleting a CDB resource plan directive for a PDB, complete the prerequisites described in "[Prerequisites for Using Resource Manager with a CDB](#)".

**To delete a CDB resource plan directive for a PDB:**

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `DELETE_CDB_PLAN_DIRECTIVE` procedure, and specify the CDB resource plan and the PDB.

For example, the following procedure deletes the directive for a PDB named `operpdb` in the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.DELETE_CDB_PLAN_DIRECTIVE(
 plan => 'newcdb_plan',
 pluggable_database => 'operpdb');
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

 **See Also:**

["CDB Resource Plans"](#)

### 46.8.1.3 Managing CDB Resource Plan Directives for a PDB Performance Profile

You can create, update, and delete CDB resource plan directives for a PDB performance profile.

- [Creating New CDB Resource Plan Directives for a PDB Performance Profile](#)

You can create a CDB resource plan directive for the a new PDB performance profile using the `CREATE_CDB_PROFILE_DIRECTIVE` procedure. The directive specifies how resources are allocated to the all PDBs that use the new profile.

- [Updating CDB Resource Plan Directives for a PDB Performance Profile](#)

You can update the CDB resource plan directive for a PDB performance profile using the `UPDATE_CDB_PROFILE_DIRECTIVE` procedure. The directive specifies how resources are allocated to the PDBs that use the PDB performance profile.

- [Deleting CDB Resource Plan Directives for a PDB Performance Profile](#)

You can delete the CDB resource plan directive for a PDB performance profile using the `DELETE_CDB_PROFILE_DIRECTIVE` procedure.

#### 46.8.1.3.1 Creating New CDB Resource Plan Directives for a PDB Performance Profile

You can create a CDB resource plan directive for the a new PDB performance profile using the `CREATE_CDB_PROFILE_DIRECTIVE` procedure. The directive specifies how resources are allocated to the all PDBs that use the new profile.

Before creating a new CDB resource plan directive for a PDB performance profile, complete the prerequisites described in "[Prerequisites for Using Resource Manager with a CDB](#)".

To create a new CDB resource plan directive for a PDB performance profile:

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `CREATE_CDB_PROFILE_DIRECTIVE` procedure, and specify the appropriate values for the new PDB performance profile.

For example, the following procedure allocates resources to a PDB performance profile named `copper` in the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.CREATE_CDB_PROFILE_DIRECTIVE(
 plan => 'newcdb_plan',
 profile => 'copper',
 shares => 1,
 utilization_limit => 20,
 parallel_server_limit => 30);
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

##### Note:

For a PDB to use the new profile, the PDB must have the `DB_PERFORMANCE_PROFILE` initialization parameter set to the profile name.

##### See Also:

["CDB Resource Plans"](#)

### 46.8.1.3.2 Updating CDB Resource Plan Directives for a PDB Performance Profile

You can update the CDB resource plan directive for a PDB performance profile using the `UPDATE_CDB_PROFILE_DIRECTIVE` procedure. The directive specifies how resources are allocated to the PDBs that use the PDB performance profile.

Before updating a CDB resource plan directive for a PDB performance profile, complete the prerequisites described in "[Prerequisites for Using Resource Manager with a CDB](#)".

To update a CDB resource plan directive for a PDB performance profile:

1. In SQL\*Plus, ensure that the current container is the root.

See "[Accessing a Container in a CDB with SQL\\*Plus](#)".

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `UPDATE_CDB_PROFILE_DIRECTIVE` procedure, and specify the new resource allocation values for the PDB performance profile.

For example, the following procedure updates the resource allocation for a PDB performance profile named `copper` in the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_PROFILE_DIRECTIVE(
 plan => 'newcdb_plan',
 profile => 'copper',
 new_shares => 1,
 new_utilization_limit => 10,
 new_parallel_server_limit => 20);
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

#### See Also:

["CDB Resource Plans"](#)

### 46.8.1.3.3 Deleting CDB Resource Plan Directives for a PDB Performance Profile

You can delete the CDB resource plan directive for a PDB performance profile using the `DELETE_CDB_PROFILE_DIRECTIVE` procedure.

You might delete the directive for a PDB performance profile if no PDBs use the profile.

Before deleting a CDB resource plan directive for a PDB performance profile, complete the prerequisites described in "Prerequisites for Using Resource Manager with a CDB".

**To delete a CDB resource plan directive for a PDB performance profile:**

1. In SQL\*Plus, ensure that the current container is the root.

See "Accessing a Container in a CDB with SQL\*Plus".

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the DELETE\_CDB\_PROFILE\_DIRECTIVE procedure, and specify the CDB resource plan and the PDB performance profile.

For example, the following procedure deletes the directive for a PDB named operpdb in the newcdb\_plan CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.DELETE_CDB_PLAN_DIRECTIVE(
 plan => 'newcdb_plan',
 profile => 'operpdb');
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

**See Also:**

"CDB Resource Plans"

#### 46.8.1.4 Updating the Default Directive for PDBs in a CDB Resource Plan

You can update the default directive for PDBs in a CDB resource plan using the UPDATE\_CDB\_DEFAULT\_DIRECTIVE procedure. The default directive applies to PDBs for which specific directives have not been defined.

See "The Default Directive for PDBs" for more information.

Before updating the default directive for PDBs in a CDB resource plan, complete the prerequisites described in "Prerequisites for Using Resource Manager with a CDB".

**To update the default directive for PDBs in a CDB resource plan:**

1. In SQL\*Plus, ensure that the current container is the root.

See "Accessing a Container in a CDB with SQL\*Plus".

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `UPDATE_CDB_DEFAULT_DIRECTIVE` procedure, and specify the appropriate default resource allocation values.

For example, the following procedure updates the default directive for PDBs in the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_DEFAULT_DIRECTIVE(
 plan => 'newcdb_plan',
 new_shares => 2,
 new_utilization_limit => 40);
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

 **See Also:**

["CDB Resource Plans"](#)

#### 46.8.1.5 Updating the Default Directive for Maintenance Tasks in a CDB Resource Plan

You can update the autotask directive in a CDB resource plan using the `UPDATE_CDB_AUTOTASK_DIRECTIVE` procedure. The autotask directive applies to automatic maintenance tasks that are run in the root maintenance window.

Before updating the default directive for maintenance tasks in a CDB resource plan, complete the prerequisites described in ["Prerequisites for Using Resource Manager with a CDB"](#).

**To update the autotask directive for maintenance tasks in a CDB resource plan:**

1. In SQL\*Plus, ensure that the current container is the root.

See ["Accessing a Container in a CDB with SQL\\*Plus"](#).

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `UPDATE_CDB_AUTOTASK_DIRECTIVE` procedure, and specify the appropriate autotask resource allocation values.

For example, the following procedure updates the autotask directive for maintenance tasks in the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.UPDATE_CDB_AUTOTASK_DIRECTIVE(
 plan => 'newcdb_plan',
 new_shares => 2,
 new_utilization_limit => 60);
```

```
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

 **See Also:**

["CDB Resource Plans"](#)

#### 46.8.1.6 Deleting a CDB Resource Plan

You can delete a CDB resource plan using the `DELETE_CDB_PLAN` procedure.

The resource plan must be disabled. You might delete a CDB resource plan if the plan is no longer needed. You can enable a different CDB resource plan, or you can disable Resource Manager for the CDB.

Before deleting a CDB resource plan, complete the prerequisites described in ["Prerequisites for Using Resource Manager with a CDB"](#).

**To delete a CDB resource plan:**

1. In SQL\*Plus, ensure that the current container is the root.

See ["Accessing a Container in a CDB with SQL\\*Plus"](#).

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Run the `DELETE_CDB_PLAN` procedure, and specify the CDB resource plan.

For example, the following procedure deletes the `newcdb_plan` CDB resource plan:

```
BEGIN
 DBMS_RESOURCE_MANAGER.DELETE_CDB_PLAN(
 plan => 'newcdb_plan');
END;
/
```

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

 **See Also:**

- ["CDB Resource Plans"](#)
- ["Enabling a CDB Resource Plan"](#)
- ["Disabling a CDB Resource Plan"](#)

## 46.8.2 Modifying a PDB Resource Plan

You can use the `DBMS_RESOURCE_MANAGER` package to modify a PDB resource plan in the same way you would modify the resource plan for a non-CDB.

Before modifying a PDB resource plan, complete the prerequisites described in ["Prerequisites for Using Resource Manager with a CDB"](#).

**To modify a PDB resource plan:**

1. In SQL\*Plus, ensure that the current container is a PDB.

See ["About Accessing a Container in a CDB with SQL\\*Plus"](#).

2. Create a pending area:

```
exec DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
```

3. Modify the PDB resource plan by completing one or more of the following tasks:

- Update a consumer group using the `UPDATE_CONSUMER_GROUP` procedure.
- Delete a consumer group using the `DELETE_CONSUMER_GROUP` procedure.
- Update a resource plan using the `UPDATE_PLAN` procedure.
- Delete a resource plan using the `DELETE_PLAN` procedure.
- Update a resource plan directive using the `UPDATE_PLAN_DIRECTIVE` procedure.
- Delete a resource plan directive using the `DELETE_PLAN_DIRECTIVE` procedure.

See ["Maintaining Consumer Groups, Plans, and Directives"](#) for instructions about completing these tasks.

4. Validate the pending area:

```
exec DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA();
```

5. Submit the pending area:

```
exec DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
```

 **See Also:**

- ["PDB Resource Plans"](#)

## 46.9 Viewing Information About Plans and Directives in a CDB

You can view information about CDB resource plans, CDB resource plan directives, and predefined resource plans in a CDB.

- [Viewing CDB Resource Plans](#)

An example illustrates using the `DBA_CDB_RSRC_PLANS` view to display all of the CDB resource plans defined in the CDB.

- [Viewing CDB Resource Plan Directives](#)

An example illustrates using the `DBA_CDB_RSRC_PLAN_DIRECTIVES` view to display all of the directives defined in all of the CDB resource plans in the CDB.

 **See Also:**

["Monitoring Oracle Database Resource Manager"](#)

### 46.9.1 Viewing CDB Resource Plans

An example illustrates using the `DBA_CDB_RSRC_PLANS` view to display all of the CDB resource plans defined in the CDB.

Run the following query in the root:

```
COLUMN PLAN FORMAT A30
COLUMN STATUS FORMAT A10
COLUMN COMMENTS FORMAT A35

SELECT PLAN, STATUS, COMMENTS FROM DBA_CDB_RSRC_PLANS ORDER BY PLAN;
```

Your output looks similar to the following:

| PLAN                     | STATUS | COMMENTS                     |
|--------------------------|--------|------------------------------|
| DEFAULT_CDB_PLAN         |        | Default CDB plan             |
| DEFAULT_MAINTENANCE_PLAN |        | Default CDB maintenance plan |
| NEWCDB_PLAN              |        | CDB plan for PDBs in newcdb  |
| ORA\$INTERNAL_CDB_PLAN   |        | Internal CDB plan            |

The `DEFAULT_CDB_PLAN` is a default CDB plan that is supplied with Oracle Database. You can use this default plan if it meets your requirements.

 **Note:**

Plans in the pending area have a status of `PENDING`. Plans in the pending area are being edited. Any plan that is not in the pending area has a `NULL` status.

 See Also:

["CDB Resource Plans"](#)

## 46.9.2 Viewing CDB Resource Plan Directives

An example illustrates using the `DBA_CDB_RSRC_PLAN_DIRECTIVES` view to display all of the directives defined in all of the CDB resource plans in the CDB.

Run the following query in the root:

```

COLUMN PLAN HEADING 'Plan' FORMAT A11
COLUMN PLUGGABLE_DATABASE HEADING 'Pluggable|Database' FORMAT A13
COLUMN SHARES HEADING 'Shares' FORMAT 999
COLUMN UTILIZATION_LIMIT HEADING 'Utilization|Limit' FORMAT 999
COLUMN PARALLEL_SERVER_LIMIT HEADING 'Parallel|Server|Limit' FORMAT 999

SELECT PLAN,
 PLUGGABLE_DATABASE,
 SHARES,
 UTILIZATION_LIMIT,
 PARALLEL_SERVER_LIMIT
 FROM DBA_CDB_RSRC_PLAN_DIRECTIVES
 ORDER BY PLAN;

```

Your output looks similar to the following:

| Plan             | Pluggable Database | Shares | Utilization Limit | Parallel Server Limit |
|------------------|--------------------|--------|-------------------|-----------------------|
| DEFAULT_CDB_PLAN | ORA\$DEFAULT_P     | 1      | 100               | 100                   |
| DEFAULT_CDB_PLAN | ORA\$AUTOTASK      |        | 90                | 100                   |
| DEFAULT_MAI_PLAN | ORA\$AUTOTASK      |        | 90                | 100                   |
| NTENANCE_PLAN    |                    |        |                   |                       |
| AN               |                    |        |                   |                       |
| DEFAULT_MAI_PLAN | ORA\$DEFAULT_P     | 1      | 100               | 100                   |
| NTENANCE_PLAN    | DB_DIRECTIVE       |        |                   |                       |
| AN               |                    |        |                   |                       |
| NEWCDB_PLAN      | HRPDB              | 1      | 70                | 70                    |
| NEWCDB_PLAN      | SALESPDB           | 3      | 100               | 100                   |
| NEWCDB_PLAN      | ORA\$DEFAULT_P     | 1      | 50                | 50                    |
|                  | DB_DIRECTIVE       |        |                   |                       |
| NEWCDB_PLAN      | ORA\$AUTOTASK      | 1      | 75                | 75                    |
| NEWCDB_PLAN      | SERVICESPDB        | 3      | 100               | 100                   |

The `DEFAULT_CDB_PLAN` is a default CDB plan that is supplied with Oracle Database. You can use this default plan if it meets your requirements.

This output shows the directives for the `newcdb_plan` created in "[Creating a CDB Resource Plan: A Scenario](#)" and modified in "[Managing a CDB Resource Plan](#)".

 **Note:**

The ORA\$DEFAULT\_PDB\_DIRECTIVE is the default directive for PDBs. See "[The Default Directive for PDBs](#)".

 **See Also:**

"[CDB Resource Plans](#)"

## 46.10 Monitoring PDBs Managed by Oracle Database Resource Manager

A set of dynamic performance views enables you to monitor the results of your Oracle Database Resource Manager settings for PDBs.

Use the following dynamic performance views to help you monitor the results of your Oracle Database Resource Manager settings for PDBs:

- V\$RSRCPDBMETRIC
- V\$RSRCPDBMETRIC\_HISTORY

The V\$RSRCPDBMETRIC view provides current statistics on resource consumption for PDBs, including CPU usage, parallel execution, I/O generated, and memory usage.

In addition, historical statistics are available through the DBA\_HIST\_RSRC\_PDB\_METRIC view, which contains Automatic Workload Repository (AWR) snapshots.

The columns in the V\$RSRCPDBMETRIC\_HISTORY view are the same as the columns in the V\$RSRCPDBMETRIC view. The only difference between these views is that the V\$RSRCPDBMETRIC view contains metrics for the past one minute only, whereas the V\$RSRCPDBMETRIC\_HISTORY view contains metrics for the last 60 minutes.

 **Note:**

The V\$RSRCPDBMETRIC and V\$RSRCPDBMETRIC\_HISTORY views record statistics for resources that are not currently being managed by Resource Manager when the STATISTICS\_LEVEL initialization parameter is set to ALL or TYPICAL.

- [Monitoring CPU Usage for PDBs](#)

The V\$RSRCPDBMETRIC view enables you to track CPU metrics in milliseconds, in terms of number of sessions, or in terms of utilization for the past one minute. It provides real-time metrics for each PDB and is very useful in scenarios where you are running workloads and want to continuously monitor CPU resource utilization.

- [Monitoring Parallel Execution for PDBs](#)  
The V\$RSRCPDBMETRIC view enables you to track parallel statements and parallel server use for PDBs.
- [Monitoring the I/O Generated by PDBs](#)  
The V\$RSRCPDBMETRIC view enables you to track the amount of I/O generated by PDBs.
- [Monitoring Memory Usage for PDBs](#)  
The V\$RSRCPDBMETRIC view enables you to track the amount memory used by PDBs.

 **See Also:**

- [Oracle Database Reference](#)
- [Oracle Database SQL Tuning Guide](#) for more information about real-time SQL monitoring

### 46.10.1 Monitoring CPU Usage for PDBs

The V\$RSRCPDBMETRIC view enables you to track CPU metrics in milliseconds, in terms of number of sessions, or in terms of utilization for the past one minute. It provides real-time metrics for each PDB and is very useful in scenarios where you are running workloads and want to continuously monitor CPU resource utilization.

CPU usage for a PDB is managed with the active CDB resource plan of the PDB's CDB. You can use this view to compare the maximum possible CPU utilization and average CPU utilization percentage for PDBs with other PDB settings such as CPU time used, time waiting for CPU, average number of sessions that are consuming CPU, and number of sessions that are waiting for CPU allocation. For example, you can view the amount of CPU resources a PDB used and how long it waited for resource allocation. Or, you can view how many sessions from each PDB are executed against the total number of active sessions.

#### Tracking CPU Consumption in Terms of CPU Utilization for PDBs

To track CPU consumption in terms of CPU utilization, use the CPU\_UTILIZATION\_LIMIT and AVG\_CPU\_UTILIZATION columns. AVG\_CPU\_UTILIZATION lists the average percentage of the server's CPU that is consumed by a PDB. CPU\_UTILIZATION\_LIMIT represents the maximum percentage of the server's CPU that a PDB can use. This limit is set using the UTILIZATION\_LIMIT directive attribute.

The following query displays this information by showing the container ID (CON\_ID) and name of each PDB:

```
COLUMN PDB_NAME FORMAT A10

SELECT r.CON_ID, p.PDB_NAME, r.CPU_UTILIZATION_LIMIT, r.AVG_CPU_UTILIZATION
 FROM V$RSRCPDBMETRIC r, CDB_PDBS p
 WHERE r.CON_ID = p.CON_ID;
```

### Tracking CPU Consumption and Throttling for PDBs

Use the `CPU_CONSUMED_TIME` and `CPU_WAIT_TIME` columns to track CPU consumption and throttling in milliseconds for each PDB. The column `NUM_CPUS` represents the number of CPUs that Resource Manager is managing.

The following query displays this information by showing the container ID (`CON_ID`) and name of each PDB:

```
COLUMN PDB_NAME FORMAT A10

SELECT r.CON_ID, p.PDB_NAME, r.CPU_CONSUMED_TIME, r.CPU_WAIT_TIME, r.NUM_CPUS
 FROM V$RSRCPDBMETRIC r, CDB_PDBS p
 WHERE r.CON_ID = p.CON_ID;
```

### Tracking CPU Consumption and Throttling in Terms of Number of Sessions for PDBs

To track the CPU consumption and throttling in terms of number of sessions, use the `RUNNING_SESSIONS_LIMIT`, `AVG_RUNNING_SESSIONS`, and `AVG_WAITING_SESSIONS` columns. `RUNNING_SESSIONS_LIMIT` lists the maximum number of sessions from a particular PDB that can be running at any time. This limit is defined by the `UTILIZATION_LIMIT` directive attribute that you set for the PDB. `AVG_RUNNING_SESSIONS` lists the average number of sessions that are consuming CPU, and `AVG_WAITING_SESSIONS` lists the average number of sessions that are waiting for CPU.

The following query displays this information by showing the container ID (`CON_ID`) and name of each PDB:

```
COLUMN PDB_NAME FORMAT A10

SELECT r.CON_ID, p.PDB_NAME, r.RUNNING_SESSIONS_LIMIT, r.AVG_RUNNING_SESSIONS,
r.AVG_WAITING_SESSIONS
 FROM V$RSRCPDBMETRIC r, CDB_PDBS p
 WHERE r.CON_ID = p.CON_ID;
```

## 46.10.2 Monitoring Parallel Execution for PDBs

The `V$RSRCPDBMETRIC` view enables you to track parallel statements and parallel server use for PDBs.

Parallel execution servers for a PDB are managed with the active CDB resource plan of the PDB's CDB. To track parallel statements and parallel server use for PDBs, use the `AVG_ACTIVE_PARALLEL_STMTS`, `AVG_QUEUED_PARALLEL_STMTS`, `AVG_ACTIVE_PARALLEL_SERVERS`, `AVG_QUEUED_PARALLEL_SERVERS`, and `PARALLEL_SERVERS_LIMIT` columns.

`AVG_ACTIVE_PARALLEL_STMTS` and `AVG_ACTIVE_PARALLEL_SERVERS` list the average number of parallel statements running and the average number of parallel servers used by the parallel statements. `AVG_QUEUED_PARALLEL_STMTS` and `AVG_QUEUED_PARALLEL_SERVERS` list the average number of parallel statements queued and average number of parallel servers that were requested by queued parallel statements. `PARALLEL_SERVERS_LIMIT` lists the number of parallel servers allowed to be used by the PDB.

The following query displays this information by showing the container ID (CON\_ID) and name of each PDB:

```
COLUMN PDB_NAME FORMAT A10

SELECT r.CON_ID, p.PDB_NAME, r.AVG_ACTIVE_PARALLEL_STMTS,
 r.AVG_QUEUED_PARALLEL_STMTS,
 r.AVG_ACTIVE_PARALLEL_SERVERS, r.AVG_QUEUED_PARALLEL_SERVERS,
 r.PARALLEL_SERVERS_LIMIT
 FROM V$RSRCPDBMETRIC r, CDB_PDBS p
 WHERE r.CON_ID = p.CON_ID;
```

### 46.10.3 Monitoring the I/O Generated by PDBs

The V\$RSRCPDBMETRIC view enables you to track the amount of I/O generated by PDBs.

I/O is limited for a PDB by setting the MAX\_IOPS initialization parameter or the MAX\_MBPS initialization parameter in the PDB. Use this view to compare the I/O generated by PDBs in terms of the number of operations each second and the number of megabytes each second.

#### Tracking the Number of I/O Operations Generated Each Second by PDBs

To track the I/O operations generated each second by PDBs during the previous minute, use the IOPS column.

The following query displays this information by showing the container ID (CON\_ID) and name of each PDB:

```
COLUMN PDB_NAME FORMAT A10

SELECT r.CON_ID, p.PDB_NAME, r.IOPS
 FROM V$RSRCPDBMETRIC r, CDB_PDBS p
 WHERE r.CON_ID = p.CON_ID;
```

#### Tracking the Number Megabytes Generated for I/O Operations Each Second by PDBs

To track number of megabytes generated for I/O operations each second by PDBs during the previous minute, use the IOMBPS column.

The following query displays this information by showing the container ID (CON\_ID) and name of each PDB:

```
COLUMN PDB_NAME FORMAT A10

SELECT r.CON_ID, p.PDB_NAME, r.IOMBPS
 FROM V$RSRCPDBMETRIC r, CDB_PDBS p
 WHERE r.CON_ID = p.CON_ID;
```

### 46.10.4 Monitoring Memory Usage for PDBs

The V\$RSRCPDBMETRIC view enables you to track the amount memory used by PDBs.

Use this view to track the amount of SGA, PGA, buffer cache, and shared pool memory currently used by PDBs.

To track the current memory usage, in bytes, for specific PDBs, use the SGA\_BYT<sub>S</sub>, PGA\_BYT<sub>S</sub>, BUFFER\_CACHE\_BYT<sub>S</sub>, and SHARED\_POOL\_BYT<sub>S</sub> columns.

The following query displays this information by showing the container ID (CON\_ID) and name of each PDB:

```
COLUMN PDB_NAME FORMAT A10

SELECT r.CON_ID, p.PDB_NAME, r.SGA_BYTES, r.PGA_BYTES, r.BUFFER_CACHE_BYTES,
r.SHARED_POOL_BYTES
 FROM V$RSRCPDBMETRIC r, CDB_PDBS p
 WHERE r.CON_ID = p.CON_ID;
```

# Using Oracle Resource Manager for PDBs with Cloud Control

You can use Oracle Resource Manager for a multitenant environment with Oracle Enterprise Manager Cloud Control.

- [About CDB Resource Manager and Cloud Control](#)

You can use Enterprise Manager to manage multitenant container database (CDB) resource plans. Resource Manager provides CDB and pluggable database (PDB) resource management. At the CDB level, Enterprise Manager provides new resource plan creation and resource plan monitoring functionality.

- [Creating a CDB Resource Plan with Cloud Control](#)

You can create a CDB resource plan with Oracle Enterprise Manager Cloud Control that allocates shares of system resources to all PDBs within a CDB.

- [Creating a PDB Resource Plan with Cloud Control](#)

You can create a PDB resource plan with Oracle Enterprise Manager Cloud Control.

 **See Also:**

- ["About Using Oracle Resource Manager with CDBs and PDBs"](#)
- ["Prerequisites for Using Resource Manager with a CDB"](#)

## 47.1 About CDB Resource Manager and Cloud Control

You can use Enterprise Manager to manage multitenant container database (CDB) resource plans. Resource Manager provides CDB and pluggable database (PDB) resource management. At the CDB level, Enterprise Manager provides new resource plan creation and resource plan monitoring functionality.

The CDB Resource Plans page lists all CDB plans available in the system. Each row displays information about the specific CDB plan while the PDB Resource Plans page displays the PDB plans, one row for each PDB plan. Each plan is selectable and you can click on the plan name to drill down for more detailed information. You can edit or view a selected plan or you can create a new plan.

## 47.2 Creating a CDB Resource Plan with Cloud Control

You can create a CDB resource plan with Oracle Enterprise Manager Cloud Control that allocates shares of system resources to all PDBs within a CDB.

To create a CDB resource plan, follow these steps:

1. From the **Administration** menu, choose **Resource Manager**.  
Enterprise Manager displays the Resource Manager home page.
2. On the Resource Manager home page, click the **Resource Plan** link.  
If the current target is a CDB, then a CDB top level Resource Plans page displays. The page lists CDB plans that are available in the system, one row per CDB plan. Each row displays information about the CDB plan, such as Plan Name and whether it is active. You can drill-down for more information about each plan.
3. Click **Create** to create a new resource plan.  
Enterprise Manager displays the CDB Resource Plan detail page. The page contains CDB Resource plan settings on the top, such as the Plan Name. You can add or remove PDBs to this plan by clicking the **Add/Remove** button. A select PDB page appears that allows you to choose PDBs. When you add a PDB, each PDB displays the Share Allocation and Utilization Limit.
4. Fill in the required information and click **Apply**.  
A new resource plan is created and all fields are updated.

## 47.3 Creating a PDB Resource Plan with Cloud Control

You can create a PDB resource plan with Oracle Enterprise Manager Cloud Control.

To create a PDB resource plan, follow these steps:

1. From the **Administration** menu, choose **Resource Manager**.  
Enterprise Manager displays the Resource Manager home page.
2. Click on the **Plans** link under the Pluggable Database section.  
If you are currently connected to a PDB or Single Instance database target, you see the PDB Resource Plan page. This page displays a list of resource plans that are available in the database. Each row displays information about the plan, such as plan name and whether the plan is active. You can drill down for more information about each plan.  
The Advanced radio button is only shown when an existing advanced plan is displayed. When creating or editing a new plan, Advanced mode is not supported.
3. Click **Create** to create a new resource plan.  
Enterprise Manager displays the PDB Resource Plan detail page. The page contains PDB Resource plan settings. The page lists consumer groups that do not have default settings. Click the **Add/Remove** button to add or remove consumer groups and set the value.
4. Enter the required information in all fields and click **Apply**.

# Using Oracle Scheduler with a CDB

You can use Oracle Scheduler to schedule jobs in a multitenant container database (CDB).

Before using Oracle Scheduler with a CDB, meet the following requirements:

- You understand how to configure and manage a CDB. See [Managing a Multitenant Environment](#) for an overview and related information.
- You understand how to use Oracle Scheduler to schedule jobs in a non-CDB. See [Oracle Scheduler Concepts](#), [Scheduling Jobs with Oracle Scheduler](#), and [Administering Oracle Scheduler](#) for information.
- [DBMS\\_SCHEDULER Invocations in a CDB](#)  
Most scheduler calls work exactly the same way as they did in non-CDBs, with the exception of two scheduler global attributes.
- [Job Coordinator and Slave Processes in a CDB](#)  
The major CDB-related changes are to the job coordinator process.
- [Using DBMS\\_JOB](#)  
You can create a job using `DBMS_JOB` within a PDB, and it will work as before. However, `DBMS_JOB` has been desupported and using it is not recommended. Oracle plans to remove `DBMS_JOB` completely in the version after Oracle Database 12c Release 2 (12.2). You should switch from `DBMS_JOB` to `DBMS_SCHEDULER`.
- [Processes to Close a PDB](#)  
If a PDB is closed with the immediate option, then the coordinator terminates jobs running in the PDB, and the jobs must be recovered before they can run again.
- [New and Changed Views](#)  
With the CDB, changes have been made to existing views and new views have been added.

## 48.1 DBMS\_SCHEDULER Invocations in a CDB

Most scheduler calls work exactly the same way as they did in non-CDBs, with the exception of two scheduler global attributes.

To limit job slaves, set the value of the `JOB_QUEUE_PROCESSES` initialization parameter. In the CDB root, set `JOB_QUEUE_PROCESSES` to the maximum number of job slaves that can be used simultaneously in the entire CDB. If `JOB_QUEUE_PROCESSES` is set to 0 in the CDB root, then `DBMS_JOBS` and Oracle Scheduler jobs cannot run in the CDB root, regardless of the `JOB_QUEUE_PROCESSES` setting at the PDB level. In a PDB, set `JOB_QUEUE_PROCESSES` to the maximum number of job slaves that can be used simultaneously in the PDB. The actual number depends on the resources assigned by Resource Manager and the demand in other containers. If `JOB_QUEUE_PROCESSES` is 0 in a PDB, then `DBMS_JOBS` and Oracle Scheduler jobs cannot run in the PDB, regardless of the `JOB_QUEUE_PROCESSES` setting in the CDB root.

For all other global attribute settings, you must be at the pluggable database (PDB) level only. For example, if you set the `EMAIL_SENDER` attribute in the root database, it applies to the jobs that run in the root, not the jobs running in a specific PDB. If you want to pick a new `EMAIL_SENDER` for a PDB, then you must set the global attribute in that PDB.

## 48.2 Job Coordinator and Slave Processes in a CDB

The major CDB-related changes are to the job coordinator process.

In a non-CDB, the coordinator looks at all jobs that are ready to run, picks a subset of them to run, and assigns them to job slaves. It also opens and closes windows, which changes the resource plan in effect for the database.

That is essentially what happens inside a CDB except for the following:

- Jobs are selected from all PDBs

The coordinator looks at the root database and all the child PDBs and selects jobs based on the job priority, the job scheduled start time, and the availability of resources to run the job. The latter criterion depends on the consumer group of the job and the resource plan currently in effect. The coordinator makes no attempt to be fair to every PDB. The only way to ensure that jobs from a PDB are not starved is to allocate enough resources to it.

- Windows are open in the PDB and root database levels

In a non-CDB, only one window can be open at any given time. In a CDB, there are two levels of windows. At the PDB level, windows can be used to set resource plans that allocate resources among consumer groups belonging to that PDB. At the root database level, windows can be used to allocate resources to various different PDBs. Therefore, at any time, there can be a window open in the root database and one in each PDB.

- Job slave switches to the specific PDB it belongs to

The job slaves are essentially the same as in a non-CDB, except that when a slave executes a job, it switches to the PDB that the job belongs to and then executes it. The rest of the code is essentially unchanged.

## 48.3 Using DBMS\_JOB

You can create a job using `DBMS_JOB` within a PDB, and it will work as before. However, `DBMS_JOB` has been desupported and using it is not recommended. Oracle plans to remove `DBMS_JOB` completely in the version after Oracle Database 12c Release 2 (12.2). You should switch from `DBMS_JOB` to `DBMS_SCHEDULER`.

For the scheduler, the coordinator now selects jobs to run from every single PDB and not just a single database as was the case before. Also, for the scheduler, the slave will switch into a PDB before executing a job; otherwise, the code is essentially unchanged.

 **See Also:**

[Support for DBMS\\_JOB](#)

## 48.4 Processes to Close a PDB

If a PDB is closed with the immediate option, then the coordinator terminates jobs running in the PDB, and the jobs must be recovered before they can run again.

In an Oracle RAC database, the coordinator can, in most cases, recover the jobs on another instance where that PDB is open. So, if the coordinator on the first instance can find another instance where the PDB is still open, it moves the jobs there. In certain cases, moving the jobs to another instance may not be possible. For example, if the PDB in question is not open anywhere else, the jobs cannot be moved. Also, moving a job to another instance is not possible when the job has the `INSTANCE_ID` attribute set. In this case the job cannot run until the PDB on that instance is open again.

In a non-Oracle RAC case, the question of moving jobs does not arise. Terminated jobs can only be recovered after the PDB is opened again.

## 48.5 New and Changed Views

With the CDB, changes have been made to existing views and new views have been added.

See *Oracle Database Reference* for details.

- `v$` and `gv$` views now have an additional column (`CON_ID`) which identifies a container whose data a given `CDB_*` row represents. In non-CDBs, this column is `NULL`.
- There are `CDB_*` views corresponding to all Scheduler `DBA_*` views.

In a PDB, these views only show objects visible through a corresponding `DBA_*` view, but all objects can be viewed by the root database. The `CDB_*` view contains all columns found in a given `DBA_*` view and the column (`CON_ID`). In non-CDBs, this column is `NULL`.

## Sharded Database Management

Sharding is a data tier architecture in which data is horizontally partitioned across independent databases.

The following topics discuss sharded database design, deployment, schema creation, and management with Oracle Sharding:

- [Overview of Oracle Sharding](#)

Become familiar with the concepts related to managing a sharded database with Oracle Sharding.

- [Sharded Database Schema Design](#)

To obtain the benefits of sharding, the schema of a sharded database (SDB) should be designed in a way that maximizes the number of database requests executed on a single shard.

- [Physical Organization of a Sharded Database](#)

Learn about the physical organization of a sharded database.

- [Sharding Methods](#)

This chapter discusses the sharding methods supported by Oracle Sharding, how to choose a method, and how to use subpartitioning.

- [Design Considerations for Sharded Database Applications](#)

To obtain the benefits of sharding, a schema of an SDB should be designed in a way that maximizes the number of database requests executed on a single shard.

- [Routing in an SDB Environment](#)

Oracle Sharding supports two types of routing.

- [Shard-Level High Availability](#)

Oracle Sharding is integrated with Oracle Database replication technologies for high availability and disaster recovery at the shard level.

- [Sharded Database Deployment](#)

Sharded database deployment includes the prerequisites and instructions for installing the required software components, creating the catalog, roles, and the sharded database, configuring replication for high availability, and creating the schema for the sharded database.

- [Sharded Database Lifecycle Management](#)

Oracle Sharding provides tools and some automation for lifecycle management of a sharded database.

# Overview of Oracle Sharding

Become familiar with the concepts related to managing a sharded database with Oracle Sharding.

Oracle Sharding terminology, concepts, and benefits are described in the following topics:

- [About Sharding](#)

*Sharding* is a data tier architecture in which data is horizontally partitioned across independent databases.

- [Benefits of Sharding](#)

Sharding provides linear scalability and complete fault isolation for the most demanding OLTP applications.

- [Components of the Oracle Sharding Architecture](#)

Oracle Sharding is a scalability and availability feature for suitable OLTP applications. It enables distribution and replication of data across a pool of Oracle databases that share no hardware or software.

- [Application Suitability for Sharding](#)

Oracle Sharding is for OLTP applications that are suitable for a sharded database.

## 49.1 About Sharding

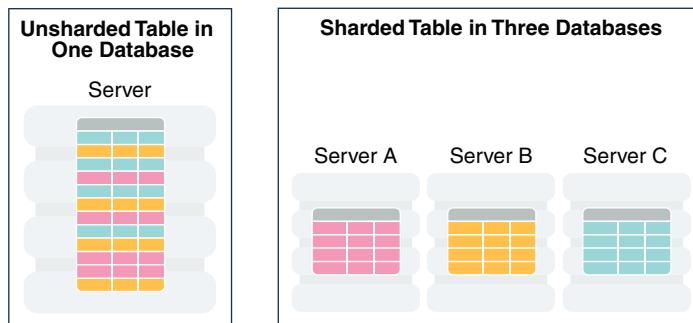

*Sharding* is a data tier architecture in which data is horizontally partitioned across independent databases.

Each database is hosted on dedicated server with its own local resources - CPU, memory, flash, or disk. Each database in such configuration is called a *shard*. All of the shards together make up a single logical database, which is referred to as a *sharded database (SDB)*.

Horizontal partitioning involves splitting a database table across shards so that each shard contains the table with the same columns but a different subset of rows. A table split up in this manner is also known as a *sharded table*.

The following figure shows a table horizontally partitioned across three shards.

Figure 49-1 Horizontal Partitioning of a Table Across Shards

Sharding is based on shared-nothing hardware infrastructure and it eliminates single points of failure because shards do not share physical resources such as CPU, memory, or storage devices. Shards are also loosely coupled in terms of software; they do not run clusterware.

Shards are typically hosted on dedicated servers. These servers can be commodity hardware or engineered systems. The shards can run on single instance or Oracle RAC databases. They can be placed on-premises, in a cloud, or in a hybrid on-premises and cloud configuration.

From the perspective of a database administrator, an SDB consists of multiple databases that can be managed either collectively or individually. However, from the perspective of the application, an SDB looks like a single database: the number of shards and distribution of data across those shards are completely transparent to database applications.

Sharding is intended for custom OLTP applications that are suitable for a sharded database architecture. Applications that use sharding must have a well-defined data model and data distribution strategy (consistent hash, range, list, or composite) that primarily accesses data using a sharding key. Examples of a sharding key include `customer_id`, `account_no`, or `country_id`.

## 49.2 Benefits of Sharding

Sharding provides linear scalability and complete fault isolation for the most demanding OLTP applications.

Key benefits of sharding include:

- **Linear Scalability.** Sharding eliminates performance bottlenecks and makes it possible to linearly scale performance and capacity by adding shards.
- **Fault Containment.** Sharding is a shared nothing hardware infrastructure that eliminates single points of failure, such as shared disk, SAN, and clusterware, and provides strong fault isolation—the failure or slow-down of one shard does not affect the performance or availability of other shards.
- **Geographical Distribution of Data.** Sharding makes it possible to store particular data close to its consumers and satisfy regulatory requirements when data must be located in a particular jurisdiction.

- **Rolling Upgrades.** Applying configuration changes on one shard at a time does not affect other shards, and allows administrators to first test the changes on a small subset of data.
- **Simplicity of Cloud Deployment.** Sharding is well suited to deployment in the cloud. Shards may be sized as required to accommodate whatever cloud infrastructure is available and still achieve required service levels. Oracle Sharding supports on-premises, cloud, and hybrid deployment models.

Unlike NoSQL data stores that implement sharding, Oracle Sharding provides the benefits of sharding *without* sacrificing the capabilities of an enterprise RDBMS. For example, Oracle Sharding supports:

- Relational schemas
- Database partitioning
- ACID properties and read consistency
- SQL and other programmatic interfaces
- Complex data types
- Online schema changes
- Multi-core scalability
- Advanced security
- Compression
- High Availability features
- Enterprise-scale backup and recovery

## 49.3 Components of the Oracle Sharding Architecture

Oracle Sharding is a scalability and availability feature for suitable OLTP applications. It enables distribution and replication of data across a pool of Oracle databases that share no hardware or software.

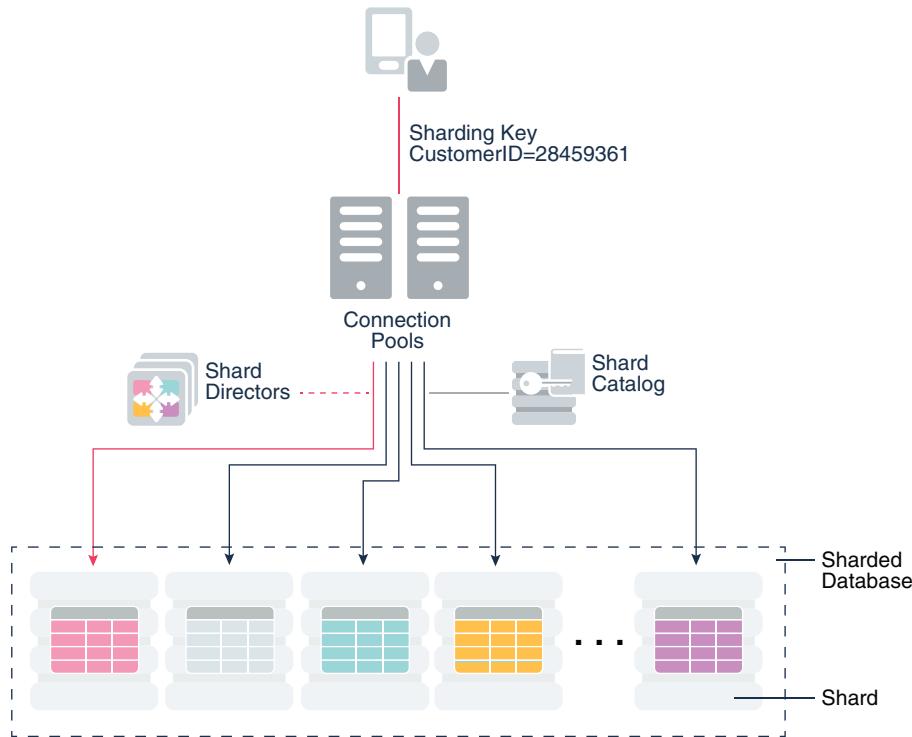

Applications perceive the pool of databases as a single logical database. Applications can elastically scale data, transactions, and users to any level, on any platform, by adding databases (shards) to the pool. Oracle Database 12c Release 2 (12.2.0.1) supports scaling up to 1000 shards.

The following figure illustrates the major architectural components of Oracle Sharding:

- Sharded database (SDB) – a single logical Oracle Database that is horizontally partitioned across a pool of physical Oracle Databases (shards) that share no hardware or software
- Shards - independent physical Oracle databases that host a subset of the sharded database
- Global service - database services that provide access to data in an SDB
- Shard catalog – an Oracle Database that supports automated shard deployment, centralized management of a sharded database, and multi-shard queries
- Shard directors – network listeners that enable high performance connection routing based on a sharding key

- Connection pools - at runtime, act as shard directors by routing database requests across pooled connections
- Management interfaces - GDSCTL (command-line utility) and Oracle Enterprise Manager (GUI)

**Figure 49-2 Oracle Sharding Architecture**

### Sharded Database and Shards

Shards are independent Oracle databases that are hosted on database servers which have their own local resources: CPU, memory, and disk. No shared storage is required across the shards.

A sharded database is a collection of shards. Shards can all be placed in one region or can be placed in different regions. A region in the context of Oracle Sharding represents a data center or multiple data centers that are in close network proximity.

Shards are replicated for High Availability (HA) and Disaster Recovery (DR) with Oracle replication technologies such as Data Guard. For HA, the standby shards can be placed in the same region where the primary shards are placed. For DR, the standby shards are located in another region.

### Global Service

A global service is an extension to the notion of the traditional database service. All of the properties of traditional database services are supported for global services. For sharded databases additional properties are set for global services — for example, database role, replication lag tolerance, region affinity between clients and shards, and so on. For a read-write transactional workload, a single global service is created

to access data from any primary shard in an SDB. For highly available shards using Active Data Guard, a separate read-only global service can be created.

### Shard Catalog

The shard catalog is a special-purpose Oracle Database that is a persistent store for SDB configuration data and plays a key role in centralized management of a sharded database. All configuration changes, such as adding and removing shards and global services, are initiated on the shard catalog. All DDLs in an SDB are executed by connecting to the shard catalog.

The shard catalog also contains the master copy of all duplicated tables in an SDB. The shard catalog uses materialized views to automatically replicate changes to duplicated tables in all shards. The shard catalog database also acts as a query coordinator used to process multi-shard queries and queries that do not specify a sharding key.

Using Oracle Data Guard for shard catalog high availability is a recommended best practice. The availability of the shard catalog has no impact on the availability of the SDB. An outage of the shard catalog only affects the ability to perform maintenance operations or multi-shard queries during the brief period required to complete an automatic failover to a standby shard catalog. OLTP transactions continue to be routed and executed by the SDB and are unaffected by a catalog outage.

### Shard Director

Oracle Database 12c introduced the global service manager to route connections based on database role, load, replication lag, and locality. In support of Oracle Sharding, global service managers support routing of connections based on data location. A global service manager, in the context of Oracle Sharding, is known as a shard director.

A shard director is a specific implementation of a global service manager that acts as a regional listener for clients that connect to an SDB. The director maintains a current topology map of the SDB. Based on the sharding key passed during a connection request, the director routes the connections to the appropriate shard.

For a typical SDB, a set of shard directors are installed on dedicated low-end commodity servers in each region. To achieve high availability, deploy multiple shard directors. In Oracle Database 12c Release 2, you can deploy up to 5 shard directors in a given region.

The following are the key capabilities of shard directors:

- Maintain runtime data about SDB configuration and availability of shards
- Measure network latency between its own and other regions
- Act as a regional listener for clients to connect to an SDB
- Manage global services
- Perform connection load balancing

### Connection Pools

Oracle Database supports connection-pooling in data access drivers such as OCI, JDBC, and ODP.NET. In Oracle 12c Release 2, these drivers can recognize sharding keys specified as part of a connection request. Similarly, the Oracle Universal Connection Pool (UCP) for JDBC clients can recognize sharding keys specified in a

connection URL. Oracle UCP also enables non-Oracle application clients such as Apache Tomcat and WebSphere to work with Oracle Sharding.

Oracle clients use UCP cache routing information to directly route a database request to the appropriate shard, based on the sharding keys provided by the application. Such data-dependent routing of database requests eliminates an extra network hop, decreasing the transactional latency for high volume OLTP applications.

Routing information is cached during an initial connection to a shard, which is established using a shard director. Subsequent database requests for sharding keys within the cached range are routed directly to the shard, bypassing the shard director.

Like UCP, a shard director can process a sharding key specified in a connect string and cache routing information. However, UCP routes database requests using an already established connection, while a shard director routes connection requests to a shard. The routing cache automatically refreshes when a shard becomes unavailable or changes occur to the sharding topology. For high-performance, data-dependent routing, Oracle recommends using a connection pool when accessing data in the SDB.

### Management Interfaces for an SDB

You can deploy, manage, and monitor Oracle Sharded databases with two interfaces: Oracle Enterprise Manager Cloud Control and GDSCTL.

Cloud Control enables life cycle management of a sharded database with a graphical user interface. You can manage and monitor an SDB for availability and performance, and you can do tasks such as add and deploy shards, services, shard directors, and other sharding components.

GDSCTL is a command-line interface that provides a simple declarative way of specifying the configuration of an SDB and automating its deployment. Only a few GDSCTL commands are required to create an SDB, for example:

- CREATE SHARDCATALOG
- ADD GSM and START GSM (create and start shard directors)
- CREATE SHARD (for each shard)
- DEPLOY

The GDSCTL DEPLOY command automatically creates the shards and their respective listeners. In addition, this command automatically deploys the replication configuration used for shard-level high availability specified by the administrator.

## 49.4 Application Suitability for Sharding

Oracle Sharding is for OLTP applications that are suitable for a sharded database.

Existing applications that were never intended to be sharded will require some level of redesign to achieve the benefits of a sharded architecture. In some cases it may be as simple as providing the sharding key, in other cases it may be impossible to horizontally partition data and workload as required by a sharded database.

Many customer-facing web applications, such as e-commerce, mobile, and social media are well suited to sharding. Such applications have a well defined data model and data distribution strategy (hash, range, list, or composite) and primarily access data using a sharding key. Examples of sharding keys include customer ID, account number, and country\_id. Applications will also usually require partial de-normalization of data to perform well with sharding.

OLTP transactions that access data associated with a single value of the sharding key are the primary use-case for a sharded database. For example, lookup and update of a customer's records, subscriber documents, financial transactions, e-commerce transactions, and the like. Because all of the rows that have the same value of the sharding key are guaranteed to be on the same shard, such transactions are always single-shard and executed with the highest performance and provide the highest level of consistency. Multi-shard operations are supported, but with a reduced level of performance and consistency. Such transactions include simple aggregations, reporting, and the like, and play a minor role in a sharded application relative to workloads dominated by single-shard OLTP transactions.

[Design Considerations for Sharded Database Applications](#)

# Sharded Database Schema Design

To obtain the benefits of sharding, the schema of a sharded database (SDB) should be designed in a way that maximizes the number of database requests executed on a single shard.

The following topics describe the objects used for this purpose:

- [Sharded Table](#)

A sharded table is a table that is partitioned into smaller and more manageable pieces among multiple databases, called shards.

- [Sharded Table Family](#)

A sharded table family is a set of tables that are sharded in the same way.

- [Duplicated Tables](#)

In addition to sharded tables, an SDB can contain tables that are duplicated on all shards.

- [Non-Table Objects Created on All Shards](#)

In addition to duplicated tables, other schema objects, such as users, roles, views, indexes, synonyms, functions, procedures, and packages, and non-schema database objects, such as tablespaces, tablespace sets, directories, and contexts, can be created on all shards.

- [DDL Execution in a Sharded Database](#)

- [DDL Syntax Extensions for the Sharded Database](#)

Oracle Sharding introduces changes to the SQL DDL statements. DDL statements with this syntax can only be executed against a sharded database.

## 50.1 Sharded Table

A sharded table is a table that is partitioned into smaller and more manageable pieces among multiple databases, called shards.

Oracle Sharding is implemented based on the Oracle Database partitioning feature. Oracle Sharding is essentially distributed partitioning because it extends partitioning by supporting the distribution of table partitions across shards.

Partitions are distributed across shards at the tablespace level, based on a sharding key. Examples of keys include customer ID, account number, and country ID. The following data types are supported for the sharding key:

- NUMBER
- INTEGER
- SMALLINT
- RAW
- (N)VARCHAR
- (N)CHAR

- DATE
- TIMESTAMP

Each partition of a sharded table resides in a separate tablespace, and each tablespace is associated with a specific shard. Depending on the sharding method, the association can be established automatically or defined by the administrator.

Even though the partitions of a sharded table reside in multiple shards, to the application the table looks and behaves exactly the same as a partitioned table in a single database. SQL statements issued by an application never have to refer to shards or depend on the number of shards and their configuration.

To specify how rows should be partitioned across shards, use the familiar SQL syntax for table partitioning. For example, the following SQL statement creates a sharded table, horizontally partitioning the table across shards based on sharding key `cust_id`:

```
CREATE SHARDED TABLE customers
(cust_id NUMBER NOT NULL
, name VARCHAR2(50)
, address VARCHAR2(250)
, region VARCHAR2(20)
, class VARCHAR2(3)
, signup DATE
CONSTRAINT cust_pk PRIMARY KEY(cust_id)
)
PARTITION BY CONSISTENT HASH (cust_id)
PARTITIONS AUTO
TABLESPACE SET ts1
;
```

## Tablespace Sets

The preceding table is partitioned by consistent hash, a special type of hash partitioning commonly used in scalable distributed systems. This technique automatically spreads tablespaces across shards to provide an even distribution of data and workload. Oracle Sharding creates and manages tablespaces as a unit called a *tablespace set*. The `PARTITIONS AUTO` clause specifies that the number of partitions should be automatically determined. This type of hashing provides more flexibility and efficiency in migrating data between shards, which is important for elastic scalability.

A tablespace is a logical unit of data distribution in an SDB. The distribution of partitions across shards is achieved by automatically creating partitions in tablespaces that reside on different shards. To minimize the number of multi-shard joins, the corresponding partitions of related tables are always stored in the same shard. Each partition of a sharded table is stored in a separate tablespace.

## Chunks

The unit of data migration between shards is a *chunk*. A chunk is a set of tablespaces that store corresponding partitions of all tables in a table family. A chunk contains a single partition from each table of a set of related tables. This guarantees that related data from different sharded tables can be moved together. The number of chunks within each shard is specified when the SDB is created.

## 50.2 Sharded Table Family

A sharded table family is a set of tables that are sharded in the same way.

Often there is a parent-child relationship between database tables with a referential constraint in a child table (foreign key) referring to the primary key of the parent table. Multiple tables linked by such relationships typically form a tree-like structure where every child has a single parent. A set of such tables is referred to as a *table family*. A table in a table family that has no parent is called the *root table*. There can be only one root table in a table family.

 **Note:**

In Oracle Database 12c Release 2, only a single table family is supported in an SDB.

### How a Table Family Is Sharded

To illustrate sharding of a table family, consider the example of the Customers–Orders–LineItems schema. The tables in this schema may look as shown in the examples below. The three tables have a parent-child relationship, with `customers` being the root table.

`Customers` table:

| CustNo | Name  | Address       | Location | Class  |
|--------|-------|---------------|----------|--------|
| 123    | Brown | 100 Main St   | us3      | Gold   |
| 456    | Jones | 300 Pine Ave  | us1      | Silver |
| 999    | Smith | 453 Cherry St | us2      | Bronze |

`Orders` table:

| OrderNo | CustNo | OrderDate   |
|---------|--------|-------------|
| 4001    | 123    | 14-FEB-2013 |
| 4002    | 456    | 09-MAR-2013 |
| 4003    | 456    | 05-APR-2013 |
| 4004    | 123    | 27-MAY-2013 |
| 4005    | 999    | 01-SEP-2013 |

`LineItems` table:

| LineNo | OrderNo | CustNo | StockNo  | Quantity |
|--------|---------|--------|----------|----------|
| 40011  | 4001    | 123    | 05683022 | 1        |
| 40012  | 4001    | 123    | 45423609 | 4        |
| 40013  | 4001    | 123    | 68584904 | 1        |
| 40021  | 4002    | 456    | 05683022 | 1        |
| 40022  | 4002    | 456    | 45423509 | 3        |
| 40022  | 4003    | 456    | 80345330 | 16       |
| 40041  | 4004    | 123    | 45423509 | 1        |
| 40042  | 4004    | 123    | 68584904 | 2        |
| 40051  | 4005    | 999    | 80345330 | 12       |

The tables can be sharded by the customer number, `CustNo`, in the `Customers` table, which is the root. The shard containing data pertaining to customer 123 is shown in the following example tables.

**Customers table:**

| CustNo | Name  | Address     | Location | Class |
|--------|-------|-------------|----------|-------|
| 123    | Brown | 100 Main St | us3      | Gold  |

**Orders table:**

| OrderNo | CustNo | OrderDate   |
|---------|--------|-------------|
| 4001    | 123    | 14-FEB-2013 |
| 4004    | 123    | 27-MAY-2013 |

**LineItems table:**

| LineNo | OrderNo | CustNo | StockNo  | Quantity |
|--------|---------|--------|----------|----------|
| 40011  | 4001    | 123    | 05683022 | 1        |
| 40012  | 4001    | 123    | 45423609 | 4        |
| 40013  | 4001    | 123    | 68584904 | 1        |
| 40041  | 4004    | 123    | 45423509 | 1        |
| 40042  | 4004    | 123    | 68584904 | 2        |

### Creating a Sharded Table Family Using CREATE TABLE

The recommended way to create a sharded table family is to specify parent-child relationships between tables using reference partitioning.

The appropriate `CREATE TABLE` statements for `Customers`–`Orders`–`LineItems` schema are shown below. The first statement creates the root table of the table family – `Customers`.

```
CREATE SHARDED TABLE Customers
(CustNo NUMBER NOT NULL
, Name VARCHAR2(50)
, Address VARCHAR2(250)
, CONSTRAINT RootPK PRIMARY KEY(CustNo)
)
PARTITION BY CONSISTENT HASH (CustNo)
PARTITIONS AUTO
TABLESPACE SET ts1
;
```

The following two statements create `Orders` and `LineItems` tables which are a child and grandchild of `Customers`.

```
CREATE SHARDED TABLE Orders
(OrderNo NUMBER NOT NULL
, CustNo NUMBER NOT NULL
, OrderDate DATE
, CONSTRAINT OrderPK PRIMARY KEY (CustNo, OrderNo)
, CONSTRAINT CustFK FOREIGN KEY (CustNo) REFERENCES Customers(CustNo)
)
```

```
PARTITION BY REFERENCE (CustFK)
;

CREATE SHARDED TABLE LineItems
(CustNo NUMBER NOT NULL
, LineNo NUMBER(2) NOT NULL
, OrderNo NUMBER(5) NOT NULL
, StockNo NUMBER(4)
, Quantity NUMBER(2)
, CONSTRAINT LinePK PRIMARY KEY (CustNo, OrderNo, LineNo)
, CONSTRAINT LineFK FOREIGN KEY (CustNo, OrderNo) REFERENCES
Orders(CustNo, OrderNo)
)
PARTITION BY REFERENCE (LineFK)
;
```

In the example statements above, corresponding partitions of all tables in the family are stored in the same tablespace set – TS1. However, it is possible to specify separate tablespace sets for each table.

Partitioning by reference simplifies the syntax since the partitioning scheme is only specified for the root table. Also, partition management operations that are performed on the root table are automatically propagated to its descendants. For example, when adding a partition to the root table, a new partition is created on all its descendants.

Note that in the example statements above, the partitioning column CustNo used as the sharding key is present in all three tables. This is despite the fact that reference partitioning, in general, allows a child table to be equi-partitioned with the parent table without having to duplicate the key columns in the child table. The reason for this is that reference partitioning requires a primary key in a parent table because the primary key must be specified in the foreign key constraint of a child table used to link the child to its parent. However, a primary key on a sharded table must either be the same as the sharding key, or contain the sharding key as the leading column. This makes it possible to enforce global uniqueness of a primary key without coordination with other shards – a critical requirement for linear scalability.

To summarize, the use of reference-partitioned tables in a sharded database requires adhering to the following rules:

- A primary key on a sharded table must either be the same as the sharding key, or another column(s) prefixed by the sharding key. This is required to enforce global uniqueness of a primary key without coordination with other shards.
- Reference partitioning requires a primary key in a parent table, because the primary key must be specified in the foreign key constraint of a child table to link the child to its parent. For example, to link the LineItems (child) table to the Orders (parent) table, you need a primary key in Orders. The second rule implies that the primary key in Orders is prefixed by the CustNo value. (This is an existing partitioning rule not specific to Oracle Sharding.)

In some cases it is impossible or undesirable to create primary and foreign key constraints that are required for reference partitioning. For such cases, specifying parent-child relationships in a table family requires that all tables are explicitly equi-

partitioned and each child table is created with the `PARENT` clause in `CREATE SHARDED TABLE` that contains the name of its parent. An example of the syntax is shown below.

```
CREATE SHARDED TABLE Customers
(CustNo NUMBER NOT NULL
, Name VARCHAR2(50)
, Address VARCHAR2(250)
, region VARCHAR2(20)
, class VARCHAR2(3)
, signup DATE
)
PARTITION BY CONSISTENT HASH (CustNo)
PARTITIONS AUTO
TABLESPACE SET ts1
;

CREATE SHARDED TABLE Orders
(OrderNo NUMBER
, CustNo NUMBER
, OrderDate DATE
)
PARENT Customers
PARTITION BY CONSISTENT HASH (CustNo)
PARTITIONS AUTO
TABLESPACE SET ts1
;

CREATE SHARDED TABLE LineItems
(LineNo NUMBER
, OrderNo NUMBER
, CustNo NUMBER
, StockNo NUMBER
, Quantity NUMBER
)
)
PARENT Customers
PARTITION BY CONSISTENT HASH (CustNo)
PARTITIONS AUTO
TABLESPACE SET ts1
;
```

Because the partitioning scheme is fully specified in all of the `CREATE SHARDED TABLE` statements, any table can be independently subpartitioned. This is not permitted with reference partitioning where subpartitions can only be specified for the root table and the subpartitioning scheme is the same for all tables in a table family.

Note that this method only supports two-level table families, that is, all children must have the same parent and grandchildren cannot exist. This is not a limitation as long as the partitioning column from the parent table exists in all of the child tables.

 **Note:**

In Oracle Database 12c Release 2, only a single table family is supported in an SDB.

## 50.3 Duplicated Tables

In addition to sharded tables, an SDB can contain tables that are duplicated on all shards.

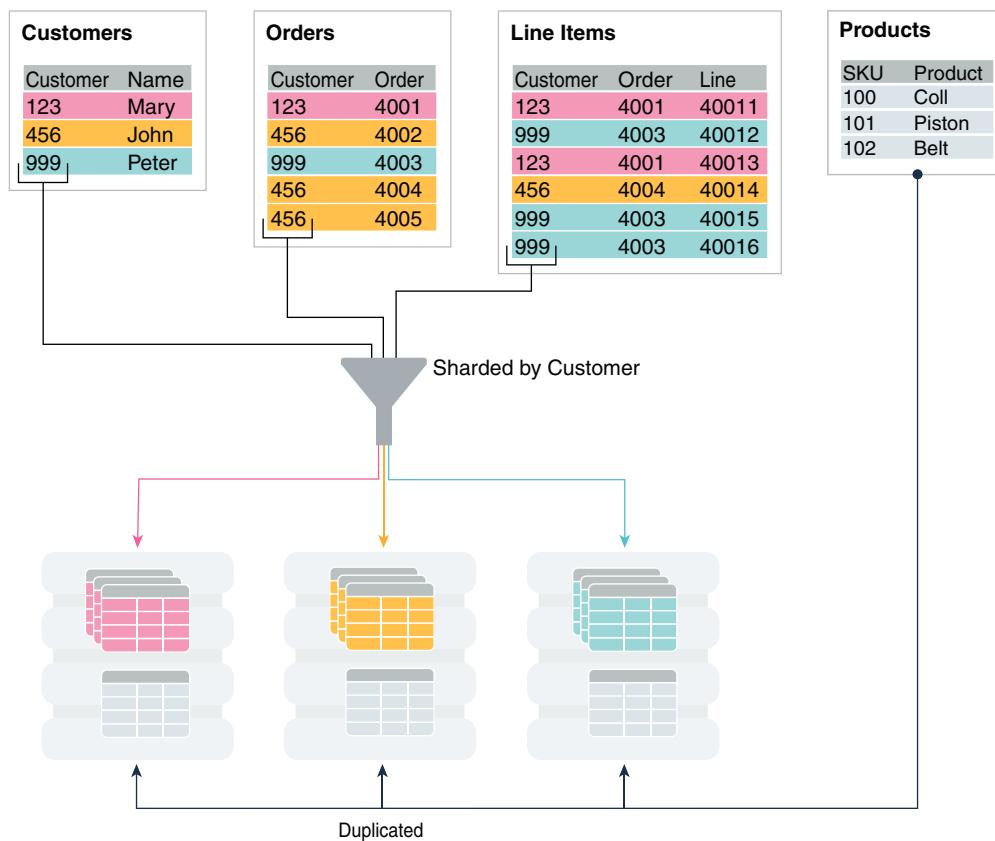

For many applications, the number of database requests handled by a single shard can be maximized by duplicating read-only or read-mostly tables across all shards. This strategy is a good choice for relatively small tables that are often accessed together with sharded tables. A table with the same contents in each shard is called a *duplicated table*.

An SDB includes both sharded tables that are horizontally partitioned across shards, and duplicated tables that are replicated to all shards. Duplicated tables contain reference information, for example, a Stock Items table that is common to each shard. The combination of sharded and duplicated tables enables all transactions associated with a sharding key to be processed by a single shard. This technique enables linear scalability and fault isolation.

As an example of the need for a duplicated table, consider the table family that is described in [Sharded Table Family](#). The database schema might also include a Products table which contains data that is shared by all the customers in the shards that were created for this table family, and it cannot be sharded by the customer number. To prevent multi-shard queries during order processing, the entire table must be duplicated on all shards.

The difference between sharded tables (Customers, Orders, and LineItems) and a duplicated table (Products) is shown in the following figure.

**Figure 50-1 Sharded Tables and a Duplicated Table in an SDB**

### Creating a Duplicated Table Using CREATE TABLE

The duplicated Products table can be created using the following statement.

```
CREATE DUPLICATED TABLE Products
(StockNo NUMBER PRIMARY KEY
, Description VARCHAR2(20)
, Price NUMBER(6,2))
;
```

### Synchronizing the Contents of Duplicated Tables

Oracle Sharding synchronizes the contents of duplicated tables using Materialized View Replication. A duplicated table on each shard is represented by a read-only materialized view. The master table for the materialized views is located in the shard catalog. The `CREATE DUPLICATED TABLE` statement automatically creates the master table, materialized views, and other objects required for materialized view replication.

The materialized views on all of the shards are automatically refreshed at a configurable frequency. The refresh frequency of all duplicated tables is controlled by the database initialization parameter `SHRD_DUPL_TABLE_REFRESH_RATE`. The default value for the parameter is 60 seconds.

 **See Also:**

[Read-Only Materialized View Concepts](#)

## 50.4 Non-Table Objects Created on All Shards

In addition to duplicated tables, other schema objects, such as users, roles, views, indexes, synonyms, functions, procedures, and packages, and non-schema database objects, such as tablespaces, tablespace sets, directories, and contexts, can be created on all shards.

Unlike tables, which require an extra keyword in the `CREATE` statement—`SHARDED` or `DUPLICATED`—other objects are created on all shards using existing syntax. The only requirement is that the `SHARD_DDL` session property must be enabled.

Note that *automatic* creation on all shards of the following objects is not supported in this release. These objects can be created by connecting to individual shards.

- Cluster
- Control file
- Database link
- Disk group
- Edition
- Flashback archive
- Materialized log
- Materialized view
- Materialized zone map
- Outline
- Pfile
- Profile
- Restore point
- Rollback segment
- Summary

## 50.5 DDL Execution in a Sharded Database

To create a schema in an SDB, you must issue DDL commands on the shard catalog database, which validates the DDLs and executes them locally first. Therefore, the shard catalog database contains local copies of all of the objects that exist in the sharded database, and serves as the master copy of the SDB schema. If the catalog validation and execution of DDLs are successful, the DDLs are automatically propagated to all of the shards and applied in the order in which they were issued on the shard catalog.

If a shard is down or not accessible during DDL propagation, the catalog keeps track of DDLs that could not be applied to the shard, and then applies them when the shard is back up. When a new shard is added to an SDB, all of the DDLs that have been

executed in the SDB are applied in the same order to the shard before it becomes accessible to clients.

There are two ways you can issue DDLs in an SDB:

- Use the GDSCTL sql command.

When you issue a DDL this way, GDSCTL waits until all of the shards have finished executing the DDL and returns the status of the execution. For example

```
GDSCTL> sql "create tablespace set tbsset"
```

- Connect to the shard catalog database using SQL\*Plus using the GDS\$CATALOG.sdbname service. For example

```
SQL> create tablespace set tbsset;
```

When you issue a DDL command on the shard catalog database, it returns the status when it finishes executing locally, but the propagation of the DDL to all of the shards happens in the background asynchronously.

### Verifying DDL Propagation

You can check the status of the DDL propagation to the shards by using the GDSCTL show ddl and config shard commands. This check is mandatory when a DDL is executed using SQL\*Plus on the shard catalog, because this method does not return the execution status on all of the shards. When a DDL fails on a shard, all further DDLs on that shard are blocked until the failure is resolved and the GDSCTL recover shard command is executed. Note that the user must have GSM\_ADMIN privileges to execute these GDSCTL commands.

### Creating Objects Locally and Globally

When a DDL to create an object is issued using the GDSCTL sql command, the object is created on all of the shards. A master copy of the object is also created in the shard catalog database. An object that exists on all shards, and the catalog database, is called an *SDB object*.

When connecting to the shard catalog using SQL\*Plus, two types of objects can be created: SDB objects and local objects. *Local objects* are traditional objects that exist only in the shard catalog. Local objects can be used for administrative purposes, or they can be used by multi-shard queries originated from the catalog database, to generate and store a report, for example.

The type of object (SDB or local) that is created in a SQL\*Plus session depends on whether the SHARD DDL mode is enabled in the session. This mode is enabled by default on the shard catalog database for the SDB user – a user that exists on all of the shards and the shard catalog database. All of the objects created while SHARD DDL is enabled in a session are SDB objects. To create a local object, the SDB user must first run alter session disable shard ddl. All of the objects created while SHARD DDL is disabled are local objects. To enable SHARD DDL in the session, the SDB user must run alter session enable shard ddl.

See [ALTER SESSION](#) for more information about the SHARD DDL session parameter.

### Creating the SDB User to Create Schema Objects

Local users that only exist in the shard catalog database do not have the privileges to create schema objects in the SDB. Therefore, the first step of creating the SDB schema is to create the SDB user, by connecting to the shard catalog database as SYSDBA, enabling SHARD DDL, and executing the CREATE USER command. When the SDB user connects to the catalog database, the SHARD DDL mode is enabled by default.

 **Note:**

Local users can create non-schema SDB objects, such as tablespaces, directories, and contexts, if they enable SHARD DDL mode; however, they cannot create schema SDB objects, such as tables, views, indexes, functions, procedures, and so on.

### DDL Execution Examples

The following examples demonstrate the steps to issue a DDL, check its execution status, and what to do when errors are encountered. The examples are given for the case when a DDL is issued using SQL\*Plus, but the same status checking and corrective actions apply when using the GDSCTL sql command.

#### Example 50-1 A DDL execution error on the shard catalog

In this example the user makes a typo in the CREATE USER command.

```
SQL> alter session enable shard ddl;
Session altered.

SQL> CREATE USER example_user IDENTRIFIED BY out_standing1;
CREATE USER example_user IDENTRIFIED BY out_Standing1
*
ERROR at line 1:
ORA-00922: missing or invalid option
```

The DDL fails to execute on the shard catalog and, as expected, the GDSCTL show ddl command shows that no DDL was executed on any of the shards:

```
GDSCTL> show ddl
id DDL Text Failed shards
-- -----

```

Then the user repeats the command with the correct spelling. Note that there is no need to run alter session enable shard ddlagain because the same session is used.

```
SQL> CREATE USER example_user IDENTIFIED BY out_Standng1;
User created.
```

Now show ddl shows that the DDL has been successfully executed on the shard catalog database and it did not fail on any shards that are online.

```
GDSCTL> show ddl
id DDL Text Failed shards
-- -----
1 create user example_user identified by ****
```

 **Note:**

For any shard that is down at the time of the DDL execution, the DDL is automatically applied when the shard is back up.

#### Example 50-2 Recovery from an error on a shard by executing a corrective action on that shard

In this example, the user attempts to create a tablespace set for system-managed sharded tables. But the datafile directory on one of the shards is not writable, so the DDL is successfully executed on the catalog, but fails on the shard.

```
SQL> connect example_user/ out_Standing1
Connected

SQL> create tablespace set tbsset;
Tablespace created.
```

Note that there is no need to run alter session enable shard ddl because the user example\_user was created as the SDB user and shard ddl is enabled by default.

Check status using GDSCTL show ddl:

```
GDSCTL> show ddl
id DDL Text Failed shards
-- -----
1 create user example_user identified by ****
2 create tablespace set tbsset shard01
```

The command output shows that the DDL failed on the shard shard01. Run the GDSCTL config shard command to get detailed information:

```
GDSCTL> config shard -shard shard01
Conversion = ':Name: shard01
Shard Group: dbs1
Status: Ok
State: Deployed
Region: east
Connection string: (DESCRIPTION=(ADDRESS=(HOST=shard01-host)(PORT=1521)
(PROTOCOL=tcp))(CONNECT_DATA=(SID=shard01)))
SCAN address:
ONS remote port: 0
Disk Threshold, ms: 20
```

```
CPU Threshold, %: 75
Version: 12.2.0.0
Failed DDL: create tablespace set tbsset
DDL Error: ORA-02585: create tablepsace set failure, one of its
tablespaces not created
ORA-01119: error in creating database file '/ade/b/3667445372/oracle/
rdbms/dbs/SHARD01/datafile/o1_mf_tbsset_%u_.dbf'
ORA-27040: file create error, unable to create file
Linux-x86_64 Error: 13: Permission denied
Additional information: 1 \(\ngsmoci_execute\)
Failed DDL id: 2
Availability: ONLINE
```

The text beginning with “Failed DDL:” indicates the problem. To resolve it, the user must log in to the shard database host and make the directory writable.

Display the permissions on the directory:

```
cd $ORACLE_HOME/rdbms/dbs
ls -l .. | grep dbs
dr-xr-xr-x 4 oracle dba 102400 Jul 20 15:41 dbs/
```

Change the directory to writable:

```
chmod +w .
ls -l .. | grep dbs
drwxrwxr-x 4 oracle dba 102400 Jul 20 15:41 dbs/
```

Go back to the GDSCTL console and issue the recover shard command:

```
GDSCTL> recover shard -shard shard01
```

Check the status again:

```
GDSCTL> show ddl
id DDL Text Failed shards
-- -----
1 create user example_user identified by *****
2 create tablespace set tbsset

GDSCTL> config shard -shard shard01
Conversion = ':Name: shard01
Shard Group: dbs1
Status: Ok
State: Deployed
Region: east
Connection string: (DESCRIPTION=(ADDRESS=(HOST=shard01-host)(PORT=1521)
(PROTOCOL=tcp))(CONNECT_DATA=(SID=shard01)))
SCAN address:
ONS remote port: 0
Disk Threshold, ms: 20
CPU Threshold, %: 75
Version: 12.2.0.0
```

```
Last Failed DDL:
DDL Error: ---
DDL id:
Availability: ONLINE
```

As shown above, the failed DDL error no longer appears.

### **Example 50-3 Recovery from an error on a shard by executing a corrective action on all other shards**

In this example, the user attempts to create another tablespace set, tbs\_set, but the DDL fails on a shard because there is already an existing local tablespace with the same name.

On the shard catalog:

```
SQL> create tablespace set tbs_set;
Tablespace created.
```

Check status using the GDSCTL show ddl command:

```
GDSCTL> show ddl
id DDL Text Failed shards
-- -----
1 create user example_user identified by *****
2 create tablespace set tbsset
3 create tablespace set tbs_set shard01

GDSCTL> config shard -shard shard01
Conversion = ':'Name: shard01
.....
Failed DDL: create tablespace set tbs_set
DDL Error: ORA-02585: create tablespace set failure, one of its
tablespaces not created
ORA-01543: tablespace \'TBS_SET\' already exists \(\ngsmoci_execute\)
```

A solution to this problem is to login to shard01 as a local database administrator, drop the tablespace TBS\_SET, and then run GDSCTL recover shard -shard shard01. But suppose you want to keep this tablespace, and instead choose to drop the newly created tablespace set that has the name conflict and create another tablespace set with a different name, such as tbsset2. The following example shows how to do that on the shard catalog:

```
SQL> drop tablespace set tbs_set;
SQL> create tablespace set tbs_set2;
```

Check status using GDSCTL:

```
GDSCTL> show ddl
id DDL Text Failed shards
-- -----
1 create user example_user identified by *****
2 create tablespace set tbsset
```

```
3 create tablespace set tbs_set shard01
4 drop tablespace set tbs_set
5 create tablespace set tbsset2
```

You can see that DDLs 4 and 5 are not attempted on shard01 because DDL 3 failed there. To make this shard consistent with the shard catalog, you must run the `GDSCTL recover shard` command. However, it does not make sense to execute DDL 3 on this shard because it will fail again and you actually do not want to create tablespace set `tbs_set` anymore. To skip DDL 3 run `recover shard` with the `-ignore_first` option:

```
GDSCTL> recover shard -shard shard01 -ignore_first
GSM Errors: dbs1 shard01:ORA-00959: tablespace \'TBS_SET\' does not exist
(ngsmoci_execute)

GDSCTL> show ddl
id DDL Text Failed shards
-- -----
1 create user sidney identified by *****
2 create tablespace set tbsset
3 create tablespace set tbs_set
4 drop tablespace set tbs_set shard01
5 create tablespace set tbsset2
```

There is no failure with DDL 3 this time because it was skipped. However, the next DDL (4 - drop tablespace set `tbs_set`) was applied and resulted in the error because the tablespace set to be dropped does not exist on the shard.

Because the `-ignore_first` option only skips the first DDL, you need to execute `recover shard` again to skip the `drop` statement as well:

```
GDSCTL> recover shard -shard shard01 -ignore_first

GDSCTL> show ddl
id DDL Text Failed shards
-- -----
1 create user sidney identified by *****
2 create tablespace set tbsset
3 create tablespace set tbs_set
4 drop tablespace set tbs_set
5 create tablespace set tbsset2
```

Note that there are no longer any failures shown, and all of the DDLs were applied successfully on the shards.

When `recover shard` is run with the `-ignore_first` option, the failed DDL is marked to be ignored during incremental deployment. Therefore, DDL numbers 3 and 4 are skipped when a new shard is added to the SDB, and only DDL numbers 1 and 5 are applied.

## 50.6 DDL Syntax Extensions for the Sharded Database

Oracle Sharding introduces changes to the SQL DDL statements. DDL statements with this syntax can only be executed against a sharded database.

Note that no changes to query and DML statements are required to support Oracle Sharding, and the changes to the DDL statement are very limited. Most existing DDL statements will work the same way on a sharded database with the same syntax and semantics as they do on a regular Oracle Database.

### CREATE TABLESPACE SET

This is a new statement introduced for Oracle Sharding. Its syntax is similar to CREATE TABLESPACE.

```
CREATE TABLESPACE SET tablespace_set
 [IN SHARDSPACE shardspace]
 [USING TEMPLATE (
 { MINIMUM EXTENT size_clause
 | BLOCKSIZE integer [K]
 | logging_clause
 | FORCE LOGGING
 | ENCRYPTION tablespace_encryption_spec
 | DEFAULT [table_compression] storage_clause
 | { ONLINE | OFFLINE }
 | extent_management_clause
 | segment_management_clause
 | flashback_mode_clause
 }...
)];
```

The statement creates a tablespace set that can be used as a logical storage unit for one or more sharded tables and indexes. A tablespace set consists of multiple Oracle tablespaces distributed across shards in a shardspace.

Note that in system-managed sharding there is only one default shardspace in the sharded database. The number of tablespaces in a tablespace set is determined automatically and is equal to the number of chunks in the corresponding shardspace.

All tablespaces in a tablespace set are bigfile and have the same properties. The properties are specified in the USING TEMPLATE clause. This clause is the same as permanent\_tablespace\_clause for a typical tablespace, with the exception that a datafile name cannot be specified in the datafile\_tempfile\_spec clause. The datafile name for each tablespace in a tablespace set is generated automatically.

Note that a tablespace set can only consist of permanent tablespaces, there is no system, undo, or temporary tablespace set.

#### Example

```
CREATE TABLESPACE SET TSP_SET_1 IN SHARDSPACE sgr1
USING TEMPLATE
(DATAFILE SIZE 100m
 EXTEND MANAGEMENT LOCAL
```

```
SEGMENT SPACE MANAGEMENT AUTO
);
```

## ALTER TABLESPACE SET

The shardspace property of a tablespace set cannot be modified. All other attributes of a tablespace set can be altered just as for a regular permanent tablespace. Because tablespaces in a tablespace set are bigfile, the ADD DATAFILE and DROP DATAFILE clauses are not supported.

## DROP TABLESPACE SET and PURGE TABLESPACE SET

The syntax and semantics for these statements are similar to DROP and PURGE TABLESPACE statements.

## CREATE TABLE

This statement has been extended to allow for creation of sharded and duplicated tables and specification of a table family.

### Syntax

```
CREATE [{ GLOBAL TEMPORARY | SHARDED | DUPLICATED }]
 TABLE [schema.] table
 { relational_table | object_table | XMLType_table }
 [PARENT [schema.] table] ;
```

The following parts of the CREATE TABLE statement are intended to support Oracle Sharding:

- The SHARDED and DUPLICATED keywords indicate that the table content is either partitioned across shards or duplicated on all shards respectively. The DUPLICATED keyword is the only syntax change to create duplicated tables. All other changes described below apply only to sharded tables.
- The PARENT clause links a sharded table to the root table of its table family.
- To create a sharded table, TABLESPACE SET is used instead of TABLESPACE. All clauses that contain TABLESPACE are extended to contain TABLESPACE SET.
- Three clauses: consistent\_hash\_partitions, consistent\_hash\_with\_subpartitions, and partition\_set\_clause in the table\_partitioning\_clauses.

```
table_partitioning_clauses ::=
{range_partitions
| hash_partitions
| list_partitions
| composite_range_partitions
| composite_hash_partitions
| composite_list_partitions
| reference_partitioning
| system_partitioning
| consistent_hash_partitions
| consistent_hash_with_subpartitions}
```

```
| partition_set_clause
}
```

Limitations for sharded tables in the current release:

- There is no default tablespace set for sharded tables.
- A temporary table cannot be sharded or duplicated.
- Index-organized sharded tables are not supported.
- A sharded table cannot contain a nested table column or an identity column.
- A primary key constraint defined on a sharded table must contain the sharding column(s). A foreign key constraint on a column of a sharded table referencing a duplicated table column is not supported.
- System partitioning and interval range partitioning are not supported for sharded tables. Specification of individual hash partitions is not supported for partitioning by consistent hash.
- A column in a sharded table used in PARTITION BY or PARTITIONSET BY clauses cannot be a virtual column.

Duplicated tables in the current release are not supported with the following:

- System and reference partitioned tables
- LONG data type
- Maximum number of columns without primary key is 999
- The nologging, parallel, inmemory options
- XMLType column in a duplicated table cannot be used in non-ASSM tablespace

### **Example**

```
CREATE SHARDED TABLE customers
(cust_id NUMBER NOT NULL
, name VARCHAR2(50)
, address VARCHAR2(250)
, location_id VARCHAR2(20)
, class VARCHAR2(3)
, signup_date DATE
,
CONSTRAINT cust_pk PRIMARY KEY(cust_id)
)
PARTITIONSET BY LIST (class)
PARTITION BY CONSISTENT HASH (cust_id)
PARTITIONS AUTO
(PARTITIONSET gold VALUES ('gld') TABLESPACE SET ts2,
 PARTITIONSET silver VALUES ('slv') TABLESPACE SET ts1)
;
```

### **ALTER TABLE**

The following options are not supported for a sharded table:

- rename
- add foreign key constraint

- all operations on individual partitions
- all partition-related operations on the shard except:

The following are not supported for duplicated tables:

- rename table
- rename column/column type
- add/modify column
- add/modify constraint
- drop column
- modify/rename column type
- truncate table
- truncate partition
- drop partition/subpartition
- enabling nologging, parallel and inmemory options

### ALTER SESSION

The session-level SHARD DDL parameter sets the scope for DDLs issued against the shard catalog database.

```
ALTER SESSION { ENABLE | DISABLE } SHARD DDL
```

When SHARD DDL is enabled, all DDLs issued in the session are executed on the shard catalog and all shards. When SHARD DDL is disabled, a DDL is executed only against the shard catalog database. SHARD DDL is enabled by default for an SDB user (the user that exists on all shards and the catalog). To create an SDB user, the SHARD DDL parameter must be enabled before running CREATE USER.

# 51

## Physical Organization of a Sharded Database

Learn about the physical organization of a sharded database.

The following topics describe the physical organization of a sharded database:

- [Sharding as Distributed Partitioning](#)

Sharding is a database scaling technique based on horizontal partitioning of data across multiple independent physical databases. Each physical database in such a configuration is called a shard.

- [Partitions, Tablespaces, and Chunks](#)

Distribution of partitions across shards is achieved by creating partitions in tablespaces that reside on different shards.

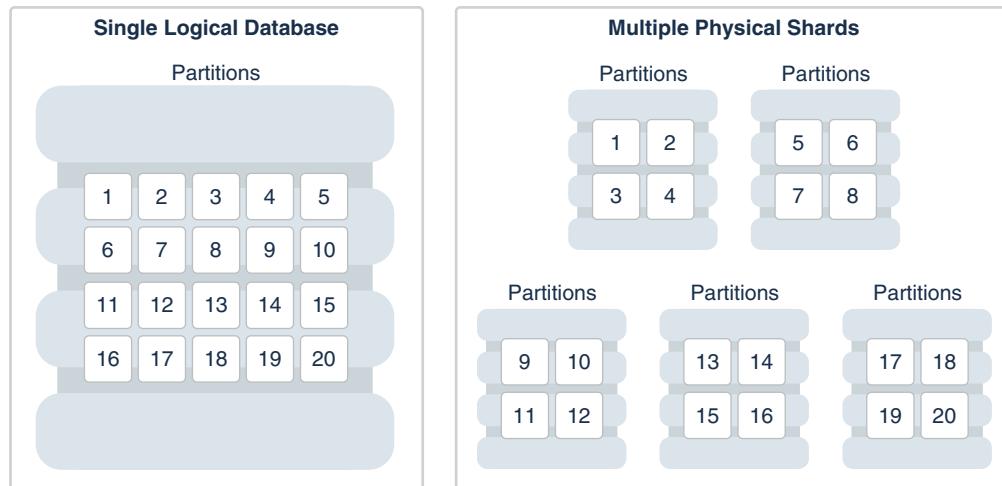

### 51.1 Sharding as Distributed Partitioning

Sharding is a database scaling technique based on horizontal partitioning of data across multiple independent physical databases. Each physical database in such a configuration is called a shard.

Even though a sharded database (SDB) looks like a single database to applications and application developers, from the perspective of a database administrator, it is a set of discrete Oracle databases, each of which is called a *shard*. A sharded table is partitioned across all shards of the SDB. Table partitions on each shard are not different from partitions that could be used in an Oracle database that is not sharded.

The following figure shows the difference between partitioning on a single logical database and partitions distributed across multiple shards.

**Figure 51-1 Sharding as Distributed Partitioning**

Oracle Sharding automatically distributes the partitions across shards when you execute the `CREATE SHARDED TABLE` statement, and the distribution of partitions is transparent to applications. The figure above shows the logical view of a sharded table and its physical implementation.

## 51.2 Partitions, Tablespaces, and Chunks

Distribution of partitions across shards is achieved by creating partitions in tablespaces that reside on different shards.

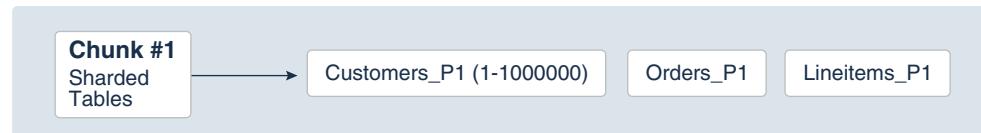

Each partition of a sharded table is stored in a separate tablespace, making the tablespace the unit of data distribution in an SDB.

As described in [Sharded Table Family](#), to minimize the number of multi-shard joins, corresponding partitions of all tables in a table family are always stored in the same shard. This is guaranteed when tables in a table family are created in the same set of distributed tablespaces as shown in the syntax examples where tablespace set `ts1` is used for all tables.

However, it is possible to create different tables from a table family in different tablespace sets, for example the `Customers` table in tablespace set `ts1` and `Orders` in tablespace set `ts2`. In this case, it must be guaranteed that the tablespace that stores partition 1 of `Customers` always resides in the same shard as the tablespace that stores partition 1 of `Orders`. To support this functionality, a set of corresponding partitions from all of the tables in a table family, called a *chunk*, is formed. A chunk contains a single partition from each table of a table family.

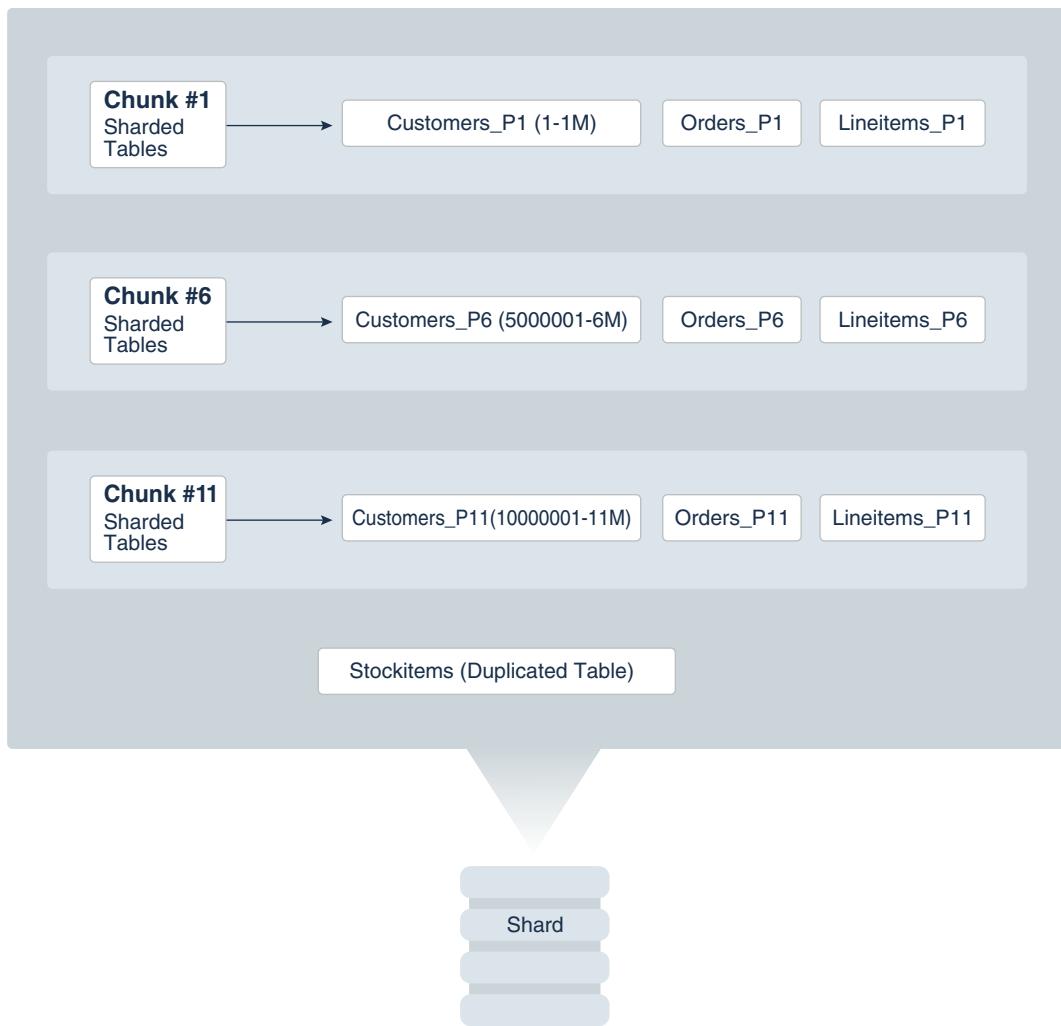

A chunk that contains corresponding partitions from the tables of `Cutomers-Orders-LineItems` schema is shown in the following figure.

**Figure 51-2 Chunk as a Set of Partitions**

Each shard contains multiple chunks as shown in the following figure.

Figure 51-3 Contents of a Shard

In addition to sharded tables, a shard can also contain one or more duplicated tables. Duplicated tables cannot be stored in tablespaces that are used for sharded tables.

# Sharding Methods

This chapter discusses the sharding methods supported by Oracle Sharding, how to choose a method, and how to use subpartitioning.

The following topics describe the sharding methods supported by Oracle Sharding:

- [System-Managed Sharding](#)

System-managed sharding is a sharding method which does not require the user to specify mapping of data to shards. Data is automatically distributed across shards using partitioning by consistent hash. The partitioning algorithm evenly and randomly distributes data across shards.

- [Composite Sharding](#)

The composite sharding method allows you to create multiple shardspaces for different subsets of data in a table partitioned by consistent hash. A *shardspace* is set of shards that store data that corresponds to a range or list of key values.

- [Using Subpartitions with Sharding](#)

Because Oracle Sharding is based on table partitioning, all of the subpartitioning methods provided by Oracle Database are also supported for sharding.

## 52.1 System-Managed Sharding

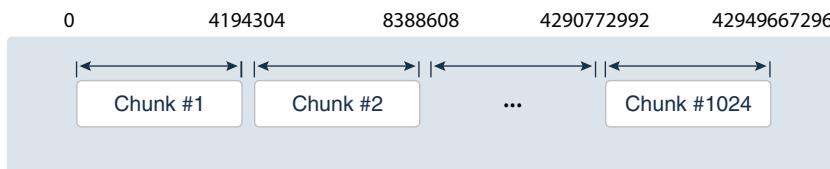

System-managed sharding is a sharding method which does not require the user to specify mapping of data to shards. Data is automatically distributed across shards using partitioning by consistent hash. The partitioning algorithm evenly and randomly distributes data across shards.

The distribution used in system-managed sharding is intended to eliminate hot spots and provide uniform performance across shards. Oracle Sharding automatically maintains the balanced distribution of chunks when shards are added to or removed from an SDB.

Consistent hash is a partitioning strategy commonly used in scalable distributed systems. It is different from traditional hash partitioning. With traditional hashing, the bucket number is calculated as  $\text{HF}(\text{key}) \% N$  where HF is a hash function and N is the number of buckets. This approach works fine if N is constant, but requires reshuffling of all data when N changes.

More advanced algorithms, such as linear hashing, do not require rehashing of the entire table to add a hash bucket, but they impose restrictions on the number of buckets, such as the number of buckets can only be a power of 2, and on the order in which the buckets can be split.

The implementation of consistent hashing used in Oracle Sharding avoids these limitations by dividing the possible range of values of the hash function (for example, from 0 to  $2^{32}$ ) into a set of N adjacent intervals, and assigning each interval to a chunk, as shown in the figure below. In this example, the SDB contains 1024 chunks, and each chunk gets assigned a range of  $2^{22}$  hash values. Therefore partitioning by consistent hash is essentially partitioning by the range of hash values.

**Figure 52-1 Ranges of Hash Values Assigned to Chunks**

Assuming that all of the shards have the same computing power, an equal number of chunks is assigned to each shard in the SDB. For example, if 1024 chunks are created in an SDB that contains 16 shards, each shard will contain 64 chunks.

In the event of resharding, when shards are added to or removed from an SDB, some of the chunks are relocated among the shards to maintain an even distribution of chunks across the shards. The contents of the chunks does not change during this process; no rehashing takes place.

When a chunk is split, its range of hash values is divided into two ranges, but nothing needs to be done for the rest of the chunks. Any chunk can be independently split at any time.

All of the components of an SDB that are involved in directing connection requests to shards maintain a routing table that contains a list of chunks hosted by each shard and ranges of hash values associated with each chunk. To determine where to route a particular database request, the routing algorithm applies the hash function to the provided value of the sharding key, and maps the calculated hash value to the appropriate chunk, and then to a shard that contains the chunk.

The number of chunks in an SDB with system-managed sharding can be specified in the `CREATE SHARDCATALOG` command. If not specified, the default value, 120 chunks per shard, is used. Once an SDB is deployed, the number of chunks can only be changed by splitting chunks.

Before creating a sharded table partitioned by consistent hash, a set of tablespaces (one tablespace per chunk) has to be created to store the table partitions. The tablespaces are automatically created by executing the SQL statement, `CREATE TABLESPACE SET`.

All of the tablespaces in a tablespace set have the same physical attributes and can only contain Oracle Managed Files (OMF). In its simplest form, the `CREATE TABLESPACE SET` statement has only one parameter, the name of the tablespace set, for example:

```
CREATE TABLESPACE SET ts1;
```

In this case each tablespace in the set contains a single OMF file with default attributes. To customize tablespace attributes, the `USING TEMPLATE` clause (shown in the example below) is added to the statement. The `USING TEMPLATE` clause specifies attributes that apply to each tablespace in the set.

```
CREATE TABLESPACE SET ts1
USING TEMPLATE
(
 DATAFILE SIZE 10M
```

```
EXTENT MANAGEMENT LOCAL UNIFORM SIZE 256K
SEGMENT SPACE MANAGEMENT AUTO
ONLINE
)
;
```

After a tablespace set has been created, a table partitioned by consistent hash can be created with partitions stored in the tablespaces that belong to the set. The `CREATE TABLE` statement might look as follows:

```
CREATE SHARDED TABLE customers
(cust_id NUMBER NOT NULL
, name VARCHAR2(50)
, address VARCHAR2(250)
, location_id VARCHAR2(20)
, class VARCHAR2(3)
, signup DATE
, CONSTRAINT cust_pk PRIMARY KEY(cust_id)
)
PARTITION BY CONSISTENT HASH (cust_id)
PARTITIONS AUTO
TABLESPACE SET ts1
;
```

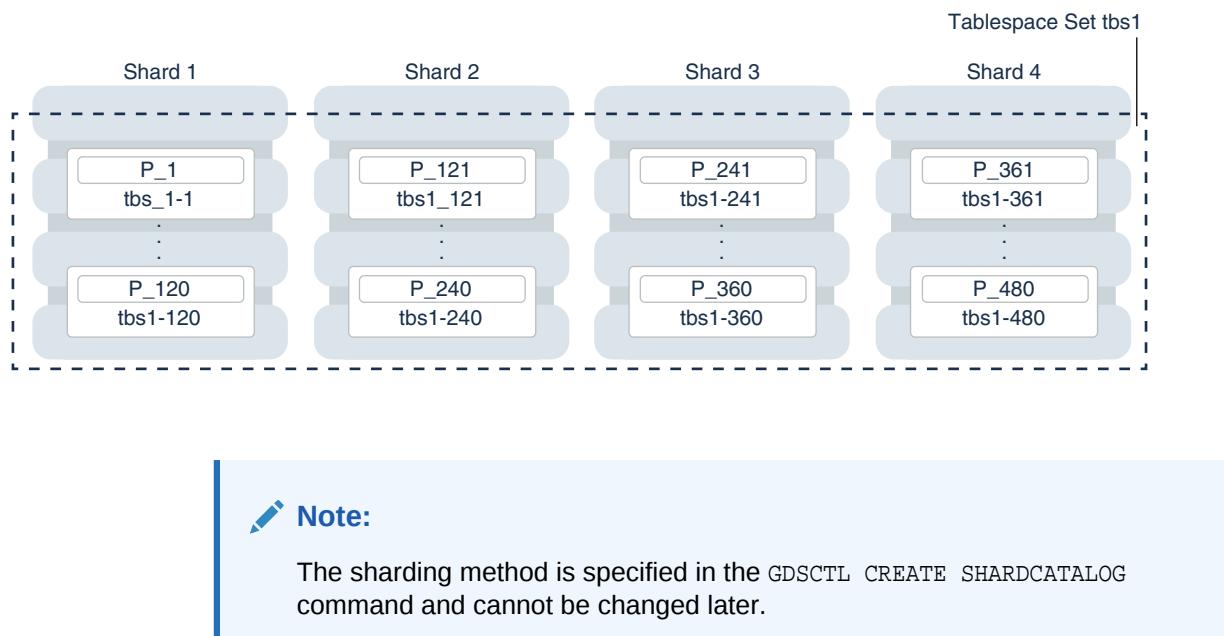

`PARTITIONS AUTO` in this statement means that the number of partitions is automatically set to the number of tablespaces in the tablespace set `ts1` (which is equal to the number of chunks) and each partition will be stored in a separate tablespace.

Each tablespace in a tablespace set belongs to a distinct chunk. In the other words, a chunk can contain only one tablespace from a given tablespace set. However, the same tablespace set can be used for multiple tables that belong to the same table family. In this case, each tablespace in the set will store multiple partitions, one from each table.

Alternatively, each table in a table family can be stored in a separate tablespace set. In this case, a chunk contains multiple tablespaces, one from each tablespace set with each tablespace storing a single partition.

The following figure illustrates the relationship between partitions, tablespaces, and shards for a use case with a single sharded table. In this case, each chunk contains a single tablespace, and each tablespace stores a single partition.

Figure 52-2 System-Managed Sharding

## 52.2 Composite Sharding

The composite sharding method allows you to create multiple shardspaces for different subsets of data in a table partitioned by consistent hash. A *shardspace* is set of shards that store data that corresponds to a range or list of key values.

System-managed sharding uses partitioning by consistent hash to distribute rows across shards in a shardgroup. However, system-managed sharding does not give you any control over the assignment of data to shards.

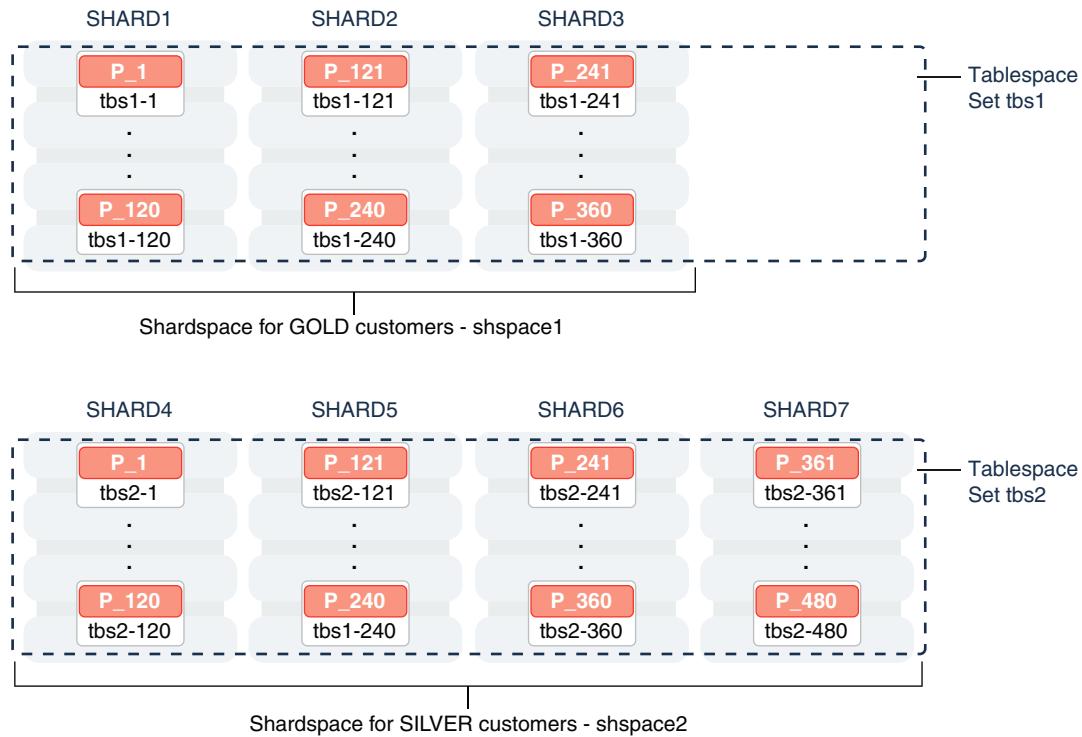

When sharding by consistent hash on a primary key, there is often a requirement to differentiate subsets of data within an SDB in order to store them in different geographic locations, allocate to them different hardware resources, or configure high availability and disaster recovery differently. Usually this differentiation is done based on the value of another (non-primary) column, for example, customer location or a class of service.

With composite sharding, data is first partitioned by list or range across multiple shardspaces, and then further partitioned by consistent hash across multiple shards in each shardspace.

The two levels of sharding make it possible to automatically maintain balanced distribution of chunks across shards in each shardspace, and, at the same time, partition data across shardspaces.

For example, suppose you want to allocate three shards hosted on faster servers to “gold” customers and four shards hosted on slower machines to “silver” customers. Within each set of shards, customers have to be distributed using partitioning by consistent hash on customer ID.

**Figure 52-3 Composite Sharding**

Two shardspaces need to be created for such a configuration, using the following GDSCTL commands:

```

ADD SHARDSPACE -SHARDSPACE shspace1;
ADD SHARDSPACE -SHARDSPACE shspace2;

ADD SHARD -CONNECT shard1 -SHARDSPACE shspace1;
ADD SHARD -CONNECT shard2 -SHARDSPACE shspace1;
ADD SHARD -CONNECT shard3 -SHARDSPACE shspace1;

ADD SHARD -CONNECT shard4 -SHARDSPACE shspace2;
ADD SHARD -CONNECT shard5 -SHARDSPACE shspace2;
ADD SHARD -CONNECT shard6 -SHARDSPACE shspace2;
ADD SHARD -CONNECT shard7 -SHARDSPACE shspace2;

```

With composite sharding, as with the other sharding methods, tablespaces are used to specify the mapping of partitions to shards. To place subsets of data in a sharded table into different shardspaces, a separate tablespace set must be created in each shardspace as shown in the following example.

```

CREATE TABLESPACE SET tbs1 IN SHARDSPACE shspace1;
CREATE TABLESPACE SET tbs2 IN SHARDSPACE shspace2;

```

To store user-defined subsets of data in different tablespaces, Oracle Sharding provides syntax to group partitions into sets and associate each set of partitions with a tablespace set. Support for partition sets can be considered a logical equivalent of a

higher level of partitioning which is implemented on top of partitioning by consistent hash.

The statement in the following example partitions a sharded table into two partition sets: gold and silver, based on class of service. Each partition set is stored in a separate tablespace. Then data in each partition set is further partitioned by consistent hash on customer ID.

```
CREATE SHARDED TABLE customers
(cust_id NUMBER NOT NULL
, name VARCHAR2(50)
, address VARCHAR2(250)
, location_id VARCHAR2(20)
, class VARCHAR2(3)
, signup_date DATE
, CONSTRAINT cust_pk PRIMARY KEY(class, cust_id)
)
PARTITIONSET BY LIST (class)
 PARTITION BY CONSISTENT HASH (cust_id)
 PARTITIONS AUTO
(PARTITIONSET gold VALUES ('gld') TABLESPACE SET tbs1,
 PARTITIONSET silver VALUES ('slv') TABLESPACE SET tbs2)
;
```

#### Note:

In Oracle Database 12c Release 2 only a single partition set from a table can be stored in a shardspace.

The sharding method is specified in the GDSCTL CREATE SHARDCATALOG command and cannot be changed later.

## 52.3 Using Subpartitions with Sharding

Because Oracle Sharding is based on table partitioning, all of the subpartitioning methods provided by Oracle Database are also supported for sharding.

Subpartitioning splits each partition into smaller parts and may be beneficial for efficient parallel execution within a shard, especially in the case of sharding by range or list when the number of partitions per shard may be small.

From a manageability perspective, subpartitioning makes it possible to support the tiered storage approach by putting subpartitions into separate tablespaces and moving them between storage tiers. Migration of subpartitions between storage tiers can be done without sacrificing the scalability and availability benefits of sharding and the ability to perform partition pruning and partition-wise joins on a primary key.

The following example shows system-managed sharding by consistent hash combined with subpartitioning by range.

```
CREATE SHARDED TABLE customers
(cust_id NUMBER NOT NULL
, name VARCHAR2(50)
```

```

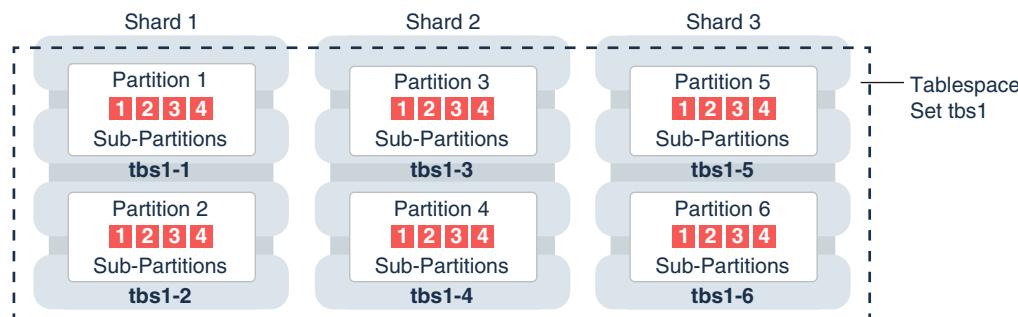

, address VARCHAR2(250)
, location_id VARCHAR2(20)
, class VARCHAR2(3)
, signup_date DATE
, CONSTRAINT cust_pk PRIMARY KEY(cust_id, signup_date)
)

TABLESPACE SET ts1
PARTITION BY CONSISTENT HASH (cust_id)
SUBPARTITION BY RANGE (signup_date)
SUBPARTITION TEMPLATE
(SUBPARTITION per1 VALUES LESS THAN (TO_DATE('01/01/2000','DD/MM/YYYY')),
 SUBPARTITION per2 VALUES LESS THAN (TO_DATE('01/01/2010','DD/MM/YYYY')),
 SUBPARTITION per3 VALUES LESS THAN (TO_DATE('01/01/2020','DD/MM/YYYY')),
 SUBPARTITION future VALUES LESS THAN (MAXVALUE))
)
PARTITIONS AUTO
;

```

The following figure offers a graphical view of the table created by this statement.

**Figure 52-4 Subpartitions Stored in the Tablespace of the Parent Partition**

In this example each subpartition is stored in the parent partition's tablespace. Because subpartitioning is done by date, it makes more sense to store subpartitions in separate tablespaces to provide the ability to archive older data or move it to a read-only storage. The appropriate syntax is shown here.

```

CREATE SHARDED TABLE customers
(cust_id NUMBER NOT NULL
, name VARCHAR2(50)
, address VARCHAR2(250)
, location_id VARCHAR2(20)
, class VARCHAR2(3)
, signup_date DATE NOT NULL
, CONSTRAINT cust_pk PRIMARY KEY(cust_id, signup_date)
)
PARTITION BY CONSISTENT HASH (cust_id)
SUBPARTITION BY RANGE(signup_date)
SUBPARTITION TEMPLATE
(SUBPARTITION per1 VALUES LESS THAN (TO_DATE('01/01/2000','DD/MM/YYYY'))
 TABLESPACE SET ts1,

```

```

 SUBPARTITION per2 VALUES LESS THAN (TO_DATE('01/01/2010','DD/MM/YYYY'))
 TABLESPACE SET ts2,
 SUBPARTITION per3 VALUES LESS THAN (TO_DATE('01/01/2020','DD/MM/YYYY'))
 TABLESPACE SET ts3,
 SUBPARTITION future VALUES LESS THAN (MAXVALUE)
 TABLESPACE SET ts4
)
PARTITIONS AUTO
;

```

Note that in the case of a database that is not sharded, when tablespaces are specified in the subpartition template it means that subpartition N from every partition is stored in the same tablespace. This is different in case of sharding when subpartitions that belong to the different partitions must be stored in separate tablespaces so that they can be moved in the event of resharding.

Subpartitioning can be used with composite sharding, too. In this case data in a table is organized in three levels: partition sets, partitions, and subpartitions. Examples of the three levels of data organization are shown below.

```

CREATE SHARDED TABLE customers
(
 cust_id NUMBER NOT NULL
, name VARCHAR2(50)
, address VARCHAR2(250)
, location_id VARCHAR2(20)
, class VARCHAR2(3) NOT NULL
, signup_date DATE NOT NULL
, CONSTRAINT cust_pk PRIMARY KEY(class, cust_id, signup_date)
)
PARTITIONSET BY LIST (class)
PARTITION BY CONSISTENT HASH (cust_id)
SUBPARTITION BY RANGE (signup_date)
SUBPARTITION TEMPLATE /* applies to both SHARDSPACES */
(
 SUBPARTITION per1 VALUES LESS THAN (TO_DATE('01/01/2000','DD/MM/YYYY'))
, SUBPARTITION per2 VALUES LESS THAN (TO_DATE('01/01/2010','DD/MM/YYYY'))
, SUBPARTITION per3 VALUES LESS THAN (TO_DATE('01/01/2020','DD/MM/YYYY'))
, SUBPARTITION future VALUES LESS THAN (MAXVALUE)
)
PARTITIONS AUTO
(
 PARTITIONSET gold VALUES ('gld') TABLESPACE SET tbs1
, PARTITIONSET silver VALUES ('slv') TABLESPACE SET tbs2
)
;

```

In this example, subpartitions are stored in the tablespace of the parent partition, and the subpartition template is the same for each PARTITIONSET. To store subpartitions in separate tablespaces the following syntax can be used.

```

CREATE SHARDED TABLE customers
(
 cust_id NUMBER NOT NULL
, name VARCHAR2(50)
, address VARCHAR2(250)
, location_id VARCHAR2(20)
,
```

```
, class VARCHAR2(3) NOT NULL
, signup_date DATE NOT NULL
, CONSTRAINT cust_pk PRIMARY KEY(class, cust_id, signup_date)
)
PARTITIONSET BY LIST (class)
PARTITION BY CONSISTENT HASH (cust_id)
SUBPARTITION BY RANGE (signup_date)
PARTITIONS AUTO
(
 PARTITIONSET gold VALUES ('gld')
 SUBPARTITION TEMPLATE
 (SUBPARTITION perl VALUES LESS THAN (TO_DATE('01/01/2000','DD/MM/
YYYY'))
 TABLESPACE SET tbs1
 , SUBPARTITION per2 VALUES LESS THAN (TO_DATE('01/01/2010','DD/MM/
YYYY'))
 TABLESPACE SET tbs2
 , SUBPARTITION per3 VALUES LESS THAN (TO_DATE('01/01/2020','DD/MM/
YYYY'))
 TABLESPACE SET tbs3
 , SUBPARTITION future VALUES LESS THAN (MAXVALUE)
 TABLESPACE SET tbs4
)
 , PARTITIONSET silver VALUES ('slv') TABLESPACE SET ts1
 SUBPARTITION TEMPLATE
 (SUBPARTITION perl VALUES LESS THAN (TO_DATE('01/01/2000','DD/MM/
YYYY'))
 TABLESPACE SET tbs5
 , SUBPARTITION per2 VALUES LESS THAN (TO_DATE('01/01/2010','DD/MM/
YYYY'))
 TABLESPACE SET tbs6
 , SUBPARTITION per3 VALUES LESS THAN (TO_DATE('01/01/2020','DD/MM/
YYYY'))
 TABLESPACE SET tbs7
 , SUBPARTITION future VALUES LESS THAN (MAXVALUE)
 TABLESPACE SET tbs8
)
)
;
;
```

# Design Considerations for Sharded Database Applications

To obtain the benefits of sharding, a schema of an SDB should be designed in a way that maximizes the number of database requests executed on a single shard.

The following topics describe the terminology and concepts you will need to manage a sharded database schema:

- [Considerations for Sharded Database Schema Design](#)  
Design of the database schema has a big impact on the performance and scalability of a sharded database (SDB). An improperly designed schema can lead to unbalanced distribution of data and workload across shards and large percentage of multi-shard operations.
- [Developing Applications for Oracle Sharding](#)  
Sharding provides linear scalability and complete fault isolation for the most demanding OLTP applications without compromising on the enterprise qualities of Oracle Database: strict consistency, the full power of SQL, developer agility with JSON, security, high availability, backup and recovery, life-cycle management, and more.

## 53.1 Considerations for Sharded Database Schema Design

Design of the database schema has a big impact on the performance and scalability of a sharded database (SDB). An improperly designed schema can lead to unbalanced distribution of data and workload across shards and large percentage of multi-shard operations.

Once the SDB is populated with data, it is impossible to change many attributes of the schema, such as whether a table is sharded or duplicated, sharding key, and so on. Therefore, the following points should be carefully considered before deploying an SDB:

- Which tables should be sharded?
- Which tables should be duplicated?
- Which sharded table should be the root table?
- What method should be used to link other tables to the root table?
- Which sharding method should be used?
- Which sharding key should be used?
- Which super sharding key should be used (if the sharding method is composite)?

## 53.2 Developing Applications for Oracle Sharding

Sharding provides linear scalability and complete fault isolation for the most demanding OLTP applications without compromising on the enterprise qualities of

Oracle Database: strict consistency, the full power of SQL, developer agility with JSON, security, high availability, backup and recovery, life-cycle management, and more.

Sharding is a data tier architecture in which data is horizontally partitioned across independent databases. Each database in such a configuration is called a shard. All of the shards together make up a single logical database, which is referred to as a sharded database (SDB).

There are two methods of sharding available to developers.

- System-managed sharding is a sharding method which does not require the user to specify mapping of data to shards. Data is automatically distributed across shards using partitioning by consistent hash. The partitioning algorithm evenly and randomly distributes data across shards for linear scalability.
- Composite sharding is a sharding method that allows the creation of multiple shardspaces for different subsets of data in a table partitioned by consistent hash. Composite sharding is unique to Oracle and offers developers the ability to differentiate subsets of data within an SDB in order to store them in different geographic locations, allocate to them different hardware resources, etc, and then elastically scale performance within each subset.

Oracle Sharding is based on table partitioning; all of the subpartitioning methods provided by Oracle Database are also supported for sharding.

Sharding is intended for OLTP applications that are suitable for a sharded database architecture. Specifically:

- Applications must have a well-defined data model and data distribution strategy, system-managed (consistent hash) or composite, and must primarily access data using a sharding key. Examples of sharding keys include customer ID, account number, country\_id, and so on.
- The data model should be a hierarchical tree structure with a single root table. Oracle Sharding supports any number of levels within the hierarchy.
- For the system-managed sharding method, the sharding key must be based on a column that has high cardinality; the number of unique values in this column must be much bigger than the number of shards. Customer ID, for example, is a good candidate for the sharding key, while a United States state name is not.
- The sharding key should be very stable; its value should almost never change.
- The sharding key must be present in all of the sharded tables. This allows the creation of a family of equi-partitioned tables based on the sharding key. The sharding key must be the leading column of the primary key of the root table.
- Joins between tables in a table family should be performed using the sharding key.
- Composite sharding enables two levels of sharding - one by list or range and another by consistent hash. This is accomplished by the application providing two keys: a super sharding key and a sharding key.
- All database requests that require high performance and fault isolation must only access data associated with a single value of the sharding key. The application must provide the sharding key when establishing a database connection. If this is the case, the request is routed directly to the appropriate shard.

Multiple requests can be executed in the same session as long as they all are related to the same sharding key. Such transactions typically access 10s or 100s of rows. Examples of single-shard transactions include order entry, lookup and

update of a customer's billing record, and lookup and update of a subscriber's documents.

- Database requests that must access data associated with multiple values of the sharding key, or for which the value of the sharding key is unknown, must be executed from the query coordinator which orchestrates parallel execution of the query across multiple shards.
- Applications use Oracle integrated connection pools (UCP, OCI, ODP.NET, JDBC) to connect to a sharded database.
- Separate connection pools must be used for direct routing and proxy routing. For direct routing, separate global services must be created for read-write and read-only workloads. For proxy routing, use the GDS\$CATALOG service on the shard catalog database.

 **See Also:**

- [Direct Routing to a Shard](#)
- [Queries and DMLs via Proxy Routing in an SDB](#)

# Routing in an SDB Environment

Oracle Sharding supports two types of routing.

The following topics describe routing in an SDB environment.

- [Direct Routing to a Shard](#)

Oracle clients and connections pools are able to recognize sharding keys specified in the connection string for high performance data dependent routing. A shard routing cache in the connection layer is used to route database requests directly to the shard where the data resides.

- [Queries and DMLs via Proxy Routing in an SDB](#)

Sharding supports routing for queries that do not specify a sharding key. This allows the flexibility for any database application to execute SQL statements (including SELECT and DML) in a system where tables are sharded or duplicated without the need to specify the shards where the query should be executed.

## 54.1 Direct Routing to a Shard

Oracle clients and connections pools are able to recognize sharding keys specified in the connection string for high performance data dependent routing. A shard routing cache in the connection layer is used to route database requests directly to the shard where the data resides.

The following topics describe direct routing to a shard:

- [About Direct Routing to a Shard](#)

In direct routing to a shard, a connection is established to a single, relevant shard which contains the data pertinent to the required transaction using a sharding key.

- [Sharding APIs](#)

Oracle connection pools and drivers support Oracle Sharding.

### 54.1.1 About Direct Routing to a Shard

In direct routing to a shard, a connection is established to a single, relevant shard which contains the data pertinent to the required transaction using a sharding key.

A sharding key is used to route database connection requests at a user session level during connection checkout. The composite sharding method requires both a sharding key and a super sharding key. Direct routing requires the sharding key (or super sharding key) be passed as part of the connection. Based on this information, a connection is established to the relevant shard which contains the data pertinent to the given sharding key or super sharding key.

Once the session is established with a shard, all SQL queries and DMLs are supported and executed in the scope of the given shard. This routing is fast and is used for all OLTP workloads that perform intra-shard transactions. It is recommended that direct routing be employed for all OLTP workloads that require the highest performance and availability.

In support of Oracle Sharding, key enhancements have been made to Oracle connection pools and drivers. Starting in Oracle Database 12c Release 2, JDBC, Universal Connection Pool (UCP), OCI Session Pool (OCI), and Oracle Data Provider for .NET (ODP.NET) provide new APIs to pass sharding keys during the connection creation. Apache Tomcat, IBM Websphere, Oracle WebLogic Server, and JBOSS can leverage JDBC/UCP support and use sharding. PHP, Python, Perl, and Node.js can leverage OCI support.

A shard topology cache is a mapping of the sharding key ranges to the shards. Oracle Integrated Connection Pools maintain this shard topology cache in their memory. Upon the first connection to a given shard (during pool initialization or when the pool connects to newer shards), the sharding key range mapping is collected from the shards to dynamically build the shard topology cache.

Caching the shard topology creates a fast path to the shards and expedites the process of creating a connection to a shard. When a connection request is made with a sharding key, the connection pool looks up the corresponding shard on which this particular sharding key exists (from its topology cache). If a matching connection is available in the pool then the pool returns a connection to the shard by applying its internal connection selection algorithm.

A database connection request for a given sharding key that is in any of the cached topology map, goes directly to the shard (that is, bypassing the shard director). Connection Pool also subscribes to RLB notifications from the SDB and dispenses the best connection based on runtime load balancing advisory. Once the connection is established, the client executes transactions directly on the shard. After all transactions for the given sharding key have been executed, the application must return the connection to the pool and obtain a connection for another key.

If a matching connection is not available in the pool, then a new connection is created by forwarding the connection request with the sharding key to the shard director.

Once the pools are initialized and the shard topology cache is built based on all shards, a shard director outage has no impact on direct routing.

 **See Also:**

[Direct Routing to a Shard](#)

## 54.1.2 Sharding APIs

Oracle connection pools and drivers support Oracle Sharding.

JDBC, UCP, OCI, and Oracle Data Provider for .NET (ODP.NET) recognize sharding keys as part of the connection check. Apache Tomcat, Websphere, and WebLogic leverage UCP support for sharding and PHP, Python, Perl, and Node.js leverage OCI support.

### Sharding APIs for Oracle UCP

A shard-aware application gets a connection to a given shard by specifying the sharding key using the enhanced sharding API calls `createShardingKeyBuilder` and `createConnectionBuilder`.

At a high-level, the following steps have to be followed in making an application work with a Sharded Database:

1. Update the URL to reflect the Shard Directors and Global Service.
2. Set the pool parameters at the pool level and the shard level:
  - Initial number of connections to be created when UCP is started using `setInitialPoolSize`
  - Minimum number of connections maintained by pool at runtime using `setMinPoolSize`
  - UCP property to set maximum number of connections allowed on connection pool using `setMaxPoolSize`
  - Set max connections per shard with `setMaxConnectionsPerShard`
3. Build a sharding key object with `createShardingKeyBuilder`.
4. Establish a connection using `createConnectionBuilder`.
5. Execute transactions within the scope of the given shard.

#### **Example 54-1 Establishing a Connection Using UCP Sharding API**

The following is a code fragment which illustrates how the sharding keys are built and connections established using UCP Sharding API calls.

```
...

PoolDataSource pds =
 PoolDataSourceFactory.getPoolDataSource();

 // Set Connection Pool properties
 pds.setURL(DB_URL);
 pds.setUser("hr");
 pds.setPassword("*****");
 pds.setInitialPoolSize(10);
 pds.setMinPoolSize(20);
 pds.setMaxPoolSize(30);

 // build the sharding key object

 OracleShardingKey shardingKey =
 pds.createShardingKeyBuilder()
 .subkey("mary.smith@example.com", OracleType.VARCHAR2)
 .build();

 // Get an UCP connection for a shard
 Connection conn =
 pds.createConnectionBuilder()
 .shardingKey(shardingKey)
 .build();
 ...
```

### Example 54-2 Sample Shard-Aware Application Code Using UCP Connection Pool

In this example the pool settings are defined at the pool level and at the shard level.

```

import java.sql.Connection;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

import oracle.jdbc.OracleShardingKey;
import oracle.jdbc.OracleType;
import oracle.jdbc.pool.OracleDataSource;
import oracle.ucp.jdbc.PoolDataSource;
import oracle.ucp.jdbc.PoolDataSourceFactory;

public class MaxConnPerShard
{
 public static void main(String[] args) throws SQLException
 {
 String url = "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(HOST=shard-dir1)
(PORT=3216)(PROTOCOL=tcp))
(CONNECT_DATA=(SERVICE_NAME=shsvc.shpool.oradbcloud)(REGION=east)))";
 String user="testuser1", pwd = "testuser1";

 int maxPerShard = 100, initPoolSize = 20;

 PoolDataSource pds = PoolDataSourceFactory.getPoolDataSource();
 pds.setConnectionFactoryClassName(OracleDataSource.class.getName());
 pds.setURL(url);
 pds.setUser(user);
 pds.setPassword(pwd);
 pds.setConnectionPoolName("testpool");
 pds.setInitialPoolSize(initPoolSize);

 // set max connection per shard
 pds.setMaxConnectionsPerShard(maxPerShard);
 System.out.println("Max-connections per shard is:
"+pds.getMaxConnectionsPerShard());

 // build the sharding key object
 int shardingKeyVal = 123;
 OracleShardingKey sdkey = pds.createShardingKeyBuilder()
 .subkey(shardingKeyVal, OracleType.NUMBER)
 .build();

 // try to build maxPerShard connections with the sharding key
 Connection[] conns = new Connection[maxPerShard];
 for (int i=0; i<maxPerShard; i++)
 {
 conns[i] = pds.createConnectionBuilder()
 .shardingKey(sdkey)
 .build();
 }

 Statement stmt = conns[i].createStatement();
 }
}

```

```
 ResultSet rs = stmt.executeQuery("select sys_context('userenv',
'instance_name'), sys_context('userenv', 'chunk_id') from dual");
 while (rs.next()) {
 System.out.println((i+1)+" - inst:"+rs.getString(1)+",
chunk:"+rs.getString(2));
 }
 rs.close();
 stmt.close();
 }

System.out.println("Try to build "+(maxPerShard+1)+" connection ...");
try {
 Connection conn = pds.createConnectionBuilder()
 .shardingKey(sdkey)
 .build();

 Statement stmt = conn.createStatement();
 ResultSet rs = stmt.executeQuery("select sys_context('userenv',
'instance_name'), sys_context('userenv', 'chunk_id') from dual");
 while (rs.next()) {
 System.out.println((maxPerShard+1)+" - inst:"+rs.getString(1)+",
chunk:"+rs.getString(2));
 }
 rs.close();
 stmt.close();

 System.out.println("Problem!!! could not build connection as max-
connections per shard exceeded");
 conn.close();
} catch (SQLException e) {
 System.out.println("Max-connections per shard met, could not build
connection any more, expected exception: "+e.getMessage());
}
for (int i=0; i<conns.length; i++)
{
 conns[i].close();
}
}
```

## ODP.NET Sharding APIs

A shard-aware application gets a connection to a given shard by specifying the sharding key and super sharding key using ODP.NET APIs, such as the `SetShardingKey(OracleShardingKey shardingKey, OracleShardingKey superShardingKey)` instance method on the `OracleConnection` class.

At a high level, the following steps are necessary for a .NET application to work with a Sharded Database:

1. Use ODP.NET, Unmanaged Driver.

Sharding is supported with or without ODP.NET connection pooling. Each pool can maintain connections to different shards of the sharded database.

2. Use an `OracleShardingKey` class to set the sharding key and another instance for the super sharding key.
3. Invoke the `OracleConnection.SetShardingKey()` method prior to calling `OracleConnection.Open()` so that ODP.NET can return a connection with the specified sharding key and super sharding key.

These keys must be set while the `OracleConnection` is in a `Closed` state, otherwise an exception is thrown.

### Example 54-3 Sample Shard-Aware Application Code Using ODP.NET

```
using System;
using Oracle.DataAccess.Client;

class Sharding
{
 static void Main()
 {
 OracleConnection con = new OracleConnection("user
id=hr;password=hr;Data Source=orcl;");
 //Setting a shard key
 OracleShardingKey shardingKey = new
OracleShardingKey(OracleDbType.Int32, 123);
 //Setting a second shard key value for a composite key
 shardingKey.SetShardingKey(OracleDbType.Varchar2, "gold");
 //Creating and setting the super shard key
 OracleShardingKey superShardingKey = new OracleShardingKey();
 superShardingKey.SetShardingKey(OracleDbType.Int32, 1000);

 //Setting super sharding key and sharding key on the connection
 con.SetShardingKey(shardingKey, superShardingKey);
 con.Open();

 //perform SQL query
 }
}
```

## 54.2 Queries and DMLs via Proxy Routing in an SDB

Sharding supports routing for queries that do not specify a sharding key. This allows the flexibility for any database application to execute SQL statements (including SELECT and DML) in a system where tables are sharded or duplicated without the need to specify the shards where the query should be executed.

The following topics describe proxy routing in detail:

- [About Proxy Routing in a Sharded Database](#)  
Proxy routing is an ancillary usage pattern targeted for developer convenience. This requires connection be established to the coordinator.
- [Oracle Sharding Coordinator](#)  
The Oracle Sharding coordinator database contains the metadata of the sharded topology and provides query processing support for sharded databases.
- [Querying and DMLs Using Proxy Routing](#)  
Proxy routing enables aggregation of data and reporting across shards. It also allows the flexibility for any database application to execute SQL statements (including SELECT and DML) in a system where tables are sharded or duplicated without the need to specify the sharding key (during connect) where the query should execute.
- [Proxy Routing for Single-Shard Queries](#)  
Single shard query (SSQ) is the query which needs to scan data only from one shard and need not look at any other shard.
- [Proxy Routing for Multi-Shard Queries](#)  
A multi-shard query must scan data from more than one shard, and the processing on each shard is independent of any other shard.
- [Resiliency of Proxy Routing](#)  
It is highly recommended that the coordinator be protected with Data Guard with fast-start failover and optionally be Oracle RAC-enabled for availability and scalability
- [Supported Query Shapes in Proxy Routing](#)  
In Oracle Database 12c Release 2, multi-shard query support has several restrictions. Some restrictions are based on the type of tables involved in the query and some are based on the SQL constructs used.

### 54.2.1 About Proxy Routing in a Sharded Database

Proxy routing is an ancillary usage pattern targeted for developer convenience. This requires connection be established to the coordinator.

In Oracle Database 12.2, the shard catalog database assumes the role of the coordinator database. The coordinator uses the metadata of the sharded topology and provides query processing support for sharded databases. The SQL compiler identifies the relevant shards automatically and coordinates the query execution across all the participating shards. Once the session is made to the coordinator, SQL queries and DMLs are executed and require no modification.

Proxy routing is suitable for the following scenarios:

- When the application cannot pass the sharding key during connect

- When the application needs to access data from sharded tables residing on multiple shards
- SQL queries typically used in reporting such as - Aggregates on sales data

Routing using the coordinator allows your application to submit SQL statements without a sharding key value passed during connect. The Coordinator's SQL compiler analyzes and rewrites the query into query fragments that are sent and executed by the participating shards. The queries are rewritten so that most of the query processing is done on the participating shards and then aggregated by the coordinator. In essence, the shards act as compute nodes for the queries executed by coordinator. Because the computation is pushed to the data, there is reduced movement of data between shards and the coordinator. It also enables the effective utilization of the resources of the shards as much as possible to offload processing from the coordinator.

It is recommended that applications separate their workloads for direct routing and proxy routing. Separate connection pools must be created for these workloads.

 **See Also:**

[Queries and DMLs via Proxy Routing in an SDB](#)

## 54.2.2 Oracle Sharding Coordinator

The Oracle Sharding coordinator database contains the metadata of the sharded topology and provides query processing support for sharded databases.

### Connecting to the Coordinator

To perform multi-shard queries, connect to the coordinator using the GDS\$CATALOG service on the shard catalog database:

```
sqlplus app_schema/app_schema@shardcatvm:1521/GDS\$CATALOG.oradbccloud
```

### Coordinator High Availability

The unavailability of the coordinator impacts proxy-routing based workloads. So it is highly recommended that the coordinator be protected with Data Guard in Maximum Availability protection mode (zero data loss failover) with fast-start failover enabled. The coordinator may optionally be Oracle RAC-enabled for additional availability and scalability.

Unavailability of the coordinator has zero impact on workloads utilizing direct routing.

### Coordinator Database Sizing

The shard catalog and coordinator host the following key information:

- Metadata of the sharded database topology
- Schema of the sharded application
- Master copies of the duplicated tables

The size of the metadata and the schema is nominal; however, the number of duplicated tables and the space they occupy should be planned for when sizing the coordinator.

In addition to the above, the coordinator should also be sized to handle proxy routing, which can be CPU, I/O, and memory intensive based on the SQL queries and the amount of data being processed.

### 54.2.3 Querying and DMLs Using Proxy Routing

Proxy routing enables aggregation of data and reporting across shards. It also allows the flexibility for any database application to execute SQL statements (including SELECT and DML) in a system where tables are sharded or duplicated without the need to specify the sharding key (during connect) where the query should execute.

In both use-cases the user accepts a reduced level of performance compared to direct routing.

In a sharded database (SDB), there are two types of tables: sharded tables and duplicated tables.

Sharded tables are equi-partitioned on a sharding key.

$S = S_1 \cup S_2 \cup \dots \cup S_n$

Duplicated tables are identical on all shards.

$R = R_1 = \dots = R_n$

Proxy routing in an SDB provides a transparent mechanism to execute typical SQL queries that access data from sharded and duplicated tables without requiring the application to specify the relevant shards. The SQL compiler identifies the relevant shards automatically and coordinates the query execution across all the participating shards. Database links are used for the communication between the coordinator and the shards.

At a high level the coordinator rewrites each incoming query, Q, into a distributive form composed of two queries, CQ and SQ, where SQ (Shard Query) is the portion of Q that executes on each participating shard and CQ (Coordinator Query) is the portion that executes on the coordinator shard.

$Q \Rightarrow CQ ( \text{Shard\_Iterator}(SQ) )$

The following is an example of an aggregate query Q1 rewritten into Q1' for an inter shard execution:

Q1 : `SELECT COUNT(*) FROM customers`

Q1' : `SELECT SUM(sc) FROM (Shard_Iterator(SELECT COUNT(*) sc FROM s1 (i)))`

There are two key elements in this process: (1) identifying the relevant shards (2) rewriting the query into a distributive form, and shard iteration.

During the compilation of a query on the coordinator database, the query compiler analyzes the predicates on the sharding key and extracts the ones that can be used to identify the participating shards, i.e. shards that will contribute rows for the sharded tables referenced in the query. The rest of the shards are referred to as pruned shards.

In the case where only one participating shard was identified, the full query is routed to that shard for full execution. This is termed as a Single Shard Query. If there is more than one participating shard the query is known as multi-shard query and is rewritten. The rewriting process takes into account the expressions computed by the query as well as the query shape.

#### 54.2.4 Proxy Routing for Single-Shard Queries

Single shard query (SSQ) is the query which needs to scan data only from one shard and need not look at any other shard.

The SSQ is similar to a client connecting to a specific shard and issuing a query on that shard. In this scenario, the entire query will be executed on the single participating shard, and the coordinator just passes processed rows back to the client. The plan on coordinator would be similar to the remote mapped cursor.

For example, the following query is fully mapped to shard1 because the data for customer 123 is located on shard1. The unit of execution on the shard is entire query.

```
Q1: SELECT count(*)
 FROM customers c, orders o
 WHERE c.custno = o.custno and
 c.custno = 123;
```

The SSQ contains a condition on the shard key that maps to one and only one shard which is known at query compilation time (literals) or query start time (bind). The query is fully executed on the qualifying shard. SSQs can be SELECT, UPDATE, DELETE and INSERT. MERGE/UPSERT are not supported.

SSQs are supported for:

- Equality and In-list, such as `Area = 'West'`
- Conditions containing literal, bind, or expression of literals and binds, such as

```
Area = :bind
```

```
Area = CASE :bind <10 THEN 'West' ELSE 'East' END
```

- `SELECT, UPDATE, DELETE and INSERT`

#### 54.2.5 Proxy Routing for Multi-Shard Queries

A multi-shard query must scan data from more than one shard, and the processing on each shard is independent of any other shard.

A multi-shard query maps to more than one shard and the coordinator may need to do some processing before sending the result to the client. For example, the following query fetches the number of orders placed by each customer.

```
Q2: SELECT count(*), c.custno
 FROM customers c, orders o
 WHERE c.custno = o.custno
 GROUP BY c.custno;
```

The query is transformed to the following by the coordinator.

```
Q3: SELECT sum(count_col), custno
 FROM (SELECT count(*) count_col, c.custno
 FROM customers c, orders o
 WHERE c.custno = o.custno
 GROUP BY c.custno)
 GROUP BY custno;
```

The inline query block is mapped to every shard just as a remote mapped query block. The coordinator performs further aggregation and `GROUP BY` on top of the result set from all shards. The unit of execution on every shard is the inline query block.

In Oracle Database 12c Release 2 multi-shard queries are supported for `SELECT` statements only. A query can either access a single shard (in case of equality filter), or ALL shards (in case of no filter predicate on sharding key).

## 54.2.6 Resiliency of Proxy Routing

It is highly recommended that the coordinator be protected with Data Guard with fast-start failover and optionally be Oracle RAC-enabled for availability and scalability.

Failure of the coordinator affects multi- and single-shard queries that are routed through the coordinator. The following are failure scenarios while querying and the expected behavior of proxy routing:

- If a participating shard is down, then the coordinator sends the query to another shard with same data.
- If failure happens during execution of the query on a participating shard, then the user will receive an error.

## 54.2.7 Supported Query Shapes in Proxy Routing

In Oracle Database 12c Release 2, multi-shard query support has several restrictions. Some restrictions are based on the type of tables involved in the query and some are based on the SQL constructs used.

A query with a join between e.g. two sharded tables must satisfy one of the following two conditions to complete successfully:

- All tables should be joined using equality on sharding key.
- All tables have a filter on sharding key that qualifies the same shard.

A query with a join between a sharded and a duplicated table can be on any column using any comparison operator (`= < > <= >=`) or even arbitrary join expression.

### Query Involves Only Duplicated Tables

For queries involving only duplicated tables there are no restrictions on the query shape. The query is executed on the coordinator.

### Query Involves Only Sharded Tables

For single table query, the query may have an equality filter on sharding key that qualifies a shard. For join queries, all tables should be joined using equality on sharding key. Here are various supported and unsupported join patterns.

#### Supported

- Inner join where equi-join is only on sharding key

```
SELECT ... FROM s1 INNER JOIN s2 ON s1.sk=s2.sk
WHERE any_filter(s1) AND any_filter(s2)
```

- Left outer join only on sharding key

```
SELECT ... FROM s1 LEFT OUTER JOIN s2 ON s1.sk=s2.sk
```

- Right outer join, same as left outer join

```
SELECT ... FROM s1 RIGHT OUTER JOIN s2 ON s1.sk=s2.sk
```

- Full outer join only on sharding key , but only if Native is valid which requires equi-join.

```
SELECT ... FROM s1 FULL OUTER JOIN s2 ON s1.sk=s2.sk
WHERE any_filter(s1) AND any_filter(s2)
```

#### Not Supported

- Semi-join (`EXISTS`) on non sharding key
- Anti-join (`NOT EXISTS`)

### Query Involves Sharded and Duplicated Tables

This type of query will be either SSQ or MSQ based on the predicates on the sharding key. The only difference is that the query will contain a non sharded table which is duplicated on each shard.

Joins between a sharded and a duplicated table can be on any column using any comparison operator (`= < > <= >=`) or even arbitrary join expression. The following are various supported and unsupported join patterns.

#### Supported

- Inner join

```
SELECT ... FROM s1 INNER JOIN r1 ON any_join_condition(s1,r1)
WHERE any_filter(s1) AND any_filter(r1)
```

- Left/Right outer join

**Condition:** sharded table has to be the null augmented table, that is

- Sharded table is the first table in LEFT OUTER JOIN

```
SELECT ... FROM s1 LEFT OUTER JOIN r1 ON any_join_condition(s1,r1)
WHERE any_filter(s1) AND any_filter(r1)
```

```
SELECT ... FROM r1 LEFT OUTER JOIN s1 ON any_join_condition(s1,s2)
AND any_filter(r1) AND filter_one_shard(s1)
```

- Sharded table is second table in RIGHT OUTER JOIN

```
SELECT ... FROM r1 RIGHT OUTER JOIN s1 ON any_join_condition(s1,r1)
WHERE any_filter(s1) AND any_filter(r1)
```

```
SELECT ... FROM s1 RIGHT OUTER JOIN r1 ON any_join_condition(s1,s2)
AND filter_one_shard(s1) AND any_filter(r1)
```

- Full outer join

**Condition:** Sharded table pruned to single shard via filter predicate on sharding key AND Native Full outer join

```
SELECT ... FROM s1 FULL OUTER JOIN r1 ON s1.sk=s2.sk
WHERE any_filter(s1) AND any_filter(s2)
```

- Semi-join (EXISTS)

**Condition:** Duplicated table should be in the sub-query OR sharded table in subquery and it prunes to single shard using filter on sharding key

```
SELECT ... FROM s1 EXISTS
(SELECT 1 FROM r1 WHERE r1.anykey=s1.anykey)
```

```
SELECT ... FROM r1 EXISTS
(SELECT 1 FROM s1 WHERE r1.anykey=s1.anykey AND filter_one_shard(s1))
```

- Anti-join (NOT EXISTS)

**Condition:** Duplicated table should be in the sub-query

```
SELECT ... FROM s1 NOT EXISTS
(SELECT 1 FROM r1 WHERE r1.anykey=s1.anykey)
```

### Not Supported

- Left/Right outer join

Duplicated table is first table in LEFT OUTER JOIN OR Sharded table is first and it maps to single shard based on filter predicate on sharding key.

```
SELECT ... FROM r1 LEFT OUTER JOIN s1 ON any_join_condition(s1,s2)
AND any_filter(r1) AND any_filter(s1)
```

Duplicated table is second table in RIGHT OUTER JOIN OR Sharded table is second and it maps to single shard based on filter predicate on sharding key.

```
SELECT ... FROM s1 RIGHT OUTER JOIN r1 ON any_join_condition(s1,s2)
AND any_filter (s1) AND any_filter(r1)
```

- Full Outer Join

Sharded table requiring access to multiple shards

```
SELECT ... FROM s1 FULL OUTER JOIN r1 ON s1.non_sk=s2.non_sk
WHERE any_filter(s1) AND any_filter(s2)
```

- Semi-join (EXISTS)

Sharded table in subquery that requires access of multiple shards.

```
SELECT ... FROM r1 EXISTS
(SELECT 1 FROM s1 WHERE r1.anykey=s1.anykey)
```

- Anti-join (NOT EXISTS)

Sharded table is in the sub-query

```
SELECT ... FROM r1 NOT EXISTS
(SELECT 1 FROM s1 WHERE r1.anykey=s1.anykey)
```

## Aggregate Functions

The following aggregations are supported by proxy routing.

- COUNT
- SUM
- MIN
- MAX
- AVG

## Multi-shard Queries and Global CR

A multi-shard query must maintain global read consistency (CR) by issuing the query at the highest common SCN across all the shards.

## Transactions

A DML statement that affects only one shard is supported. For example,

```
update S1 set col = ... where sk = <constant>;
```

A DML statement that affects more than one shard is not supported. For example,

```
update S1 set col = ...;
```

Within a transaction, multiple single shard DMLs can be performed on different shards. For example,

```
insert into S1 values (...);
Update S1 set col = ... where sk = constant;
Delete S1 where sk = constant;
Commit;
```

For multi-shard DML, the coordinator uses database link, starts a distributed transaction and performs two phase commit to guarantee the consistency of the distributed transaction. In the case of an in-doubt transaction, the database administrator has to recover it manually.

### Execution Plans for Proxy Routing

In Oracle Database 12c Release 2 (12.2.0.1) the plan of the shard query shows the coordinator plan only. You must connect to a shard to see the shard plan for the query. The SQL ID of the query on the shard is different from the SQL ID of the original query on the coordinator, so the shard query text is embedded with the SQL ID of the coordinator and the shard user must look for the SQL with the SQL ID of the original SQL as a comment in the SQL text.

```
SQL> explain plan for select count(*) from employees;

| Id | Operation | Name |

0	SELECT STATEMENT	
1	SORT AGGREGATE	
2	VIEW	VW_SHARD_B4851255
3	SHARD ITERATOR	
4	REMOTE	

Remote SQL Information (identified by operation id):

4 - EXPLAIN PLAN INTO PLAN_TABLE@! FOR
 SELECT COUNT(*) FROM "EMPLOYEES" "A1" /* coord_sql_id=3g18nvrpt0a8p
*/
```

### Passing Hints in Cross Shard Queries

Any hint specified in original query on the coordinator is propagated to the shards.

### Tracing and Troubleshooting Slow Running Cross Shard Queries

Set the trace event `shard_sql` on the coordinator to trace the query rewrite and shard pruning. One of the common performance issue observed is when the group by is not pushed to the shards because of certain limitations of the sharding. Check if all of the possible operations are pushed to shards and the coordinator has minimal work to consolidate the results from shards.

# Shard-Level High Availability

Oracle Sharding is integrated with Oracle Database replication technologies for high availability and disaster recovery at the shard level.

The following topics describe how to use Oracle's replication technologies to make your sharded databases highly available:

- [About Sharding and Replication](#)

Oracle Sharding is tightly integrated with Oracle Data Guard.

- [Using Oracle Data Guard with an SDB](#)

Oracle Data Guard replication maintains one or more synchronized copies (standbys) of a shard (the primary) for high availability and data protection.

Standbys may be deployed locally or remotely, and when using Oracle Active Data Guard can also be open for read-only access.

## 55.1 About Sharding and Replication

Oracle Sharding is tightly integrated with Oracle Data Guard.

Replication provides high availability, disaster recovery, and additional scalability for reads.

Replication topology in a sharded database (SDB) is declaratively specified using GDSCTL command syntax. Oracle Sharding automatically deploys the specified replication topology and enables data replication.

The availability of an SDB is not affected by an outage or slowdown of one or more shards. Replication is used to provide individual shard-level high availability (Oracle Active Data Guard). Replication is automatically configured and deployed when the SDB is created. Optionally, you can use Oracle RAC for shard-level high availability, complemented by replication, to maintain shard-level data availability in the event of a cluster outage. Oracle Sharding automatically fails over database connections from a shard to its replica in the event of an unplanned outage.

## 55.2 Using Oracle Data Guard with an SDB

Oracle Data Guard replication maintains one or more synchronized copies (standbys) of a shard (the primary) for high availability and data protection. Standbys may be deployed locally or remotely, and when using Oracle Active Data Guard can also be open for read-only access.

Oracle Data Guard can be used as the replication technology for SDBs using the system-managed or composite method of sharding.

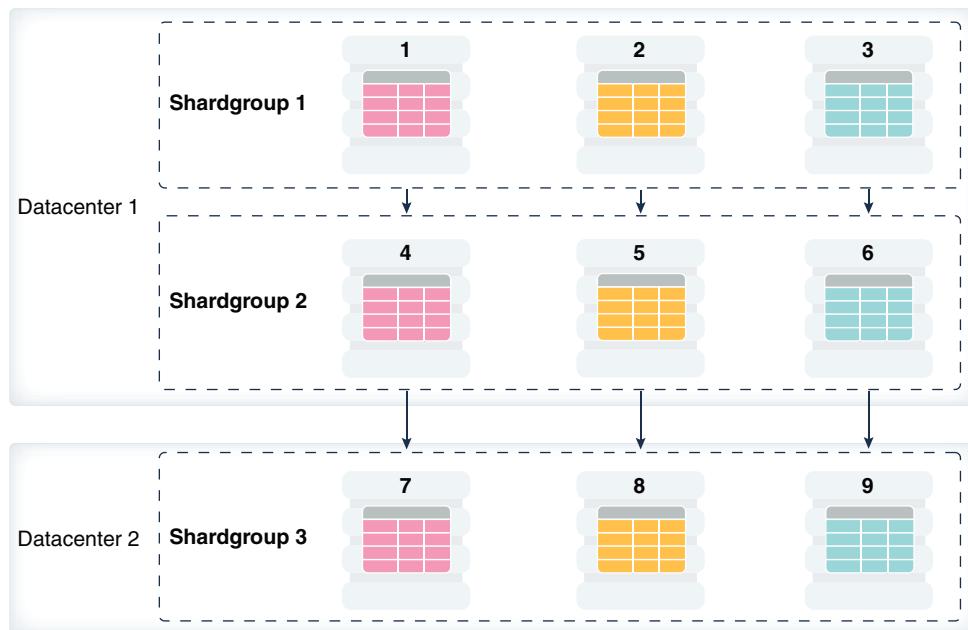

### Using Oracle Data Guard with a System-Managed SDB

In system-managed and composite sharding, the logical unit of replication is a group of shards called a *shardgroup*. In system-managed sharding, a shardgroup contains all of the data stored in the SDB. The data is sharded by consistent hash across shards that

make up the shardgroup. Shards that belong to a shardgroup are usually located in the same data center. An entire shardgroup can be fully replicated to one or more shardgroups in the same or different data centers.

The following figure illustrates how Data Guard replication is used with system-managed sharding. In the example in the figure there is a primary shardgroup, Shardgroup 1, and two standby shardgroups, Shardgroup 2 and Shardgroup 3. Shardgroup 1 consists of Data Guard primary databases (shards 1-3). Shardgroup 2 consists of local standby databases (shards 4-6) which are located in the same datacenter and configured for synchronous replication. And Shardgroup 3 consists of remote standbys (shards 7-9) located in a different datacenter and configured for asynchronous replication. Oracle Active Data Guard is enabled in this configuration, so each standby is open read-only.

**Figure 55-1 System-Managed Sharding with Data Guard Replication**

The concept of shardgroup as a logical unit of replication hides from the user the implementation details of replication. With Data Guard, replication is done at the shard (database) level. The SDB in the figure above consists of three sets of replicated shards: {1, 4, 7}, {2, 5, 8} and {3, 6, 9}. Each set of replicated shards is managed as a Data Guard Broker configuration with fast-start failover (FSFO) enabled.

To deploy replication, specify the properties of the shardgroups (region, role, and so on) and add shards to them. Oracle Sharding automatically configures Data Guard and starts an FSFO observer for each set of replicated shards. It also provides load balancing of the read-only workload, role based global services and replication lag, and locality based routing.

Run the following GDSCTL commands to deploy the example configuration shown in the figure above.

```
CREATE SHARDCATALOG -database host00:1521:shardcat -region dc1, dc2
```

```
ADD GSM -gsm gsm1 -listener 1571 -catalog host00:1521:shardcat -region dc1
ADD GSM -gsm gsm2 -listener 1571 -catalog host00:1521:shardcat -region dc2

ADD SHARDGROUP -shardgroup shardgroup1 -region dc1 -deploy_as primary
ADD SHARDGROUP -shardgroup shardgroup2 -region dc1 -deploy_as
active_standby
ADD SHARDGROUP -shardgroup shardgroup3 -region dc2 -deploy_as
active_standby

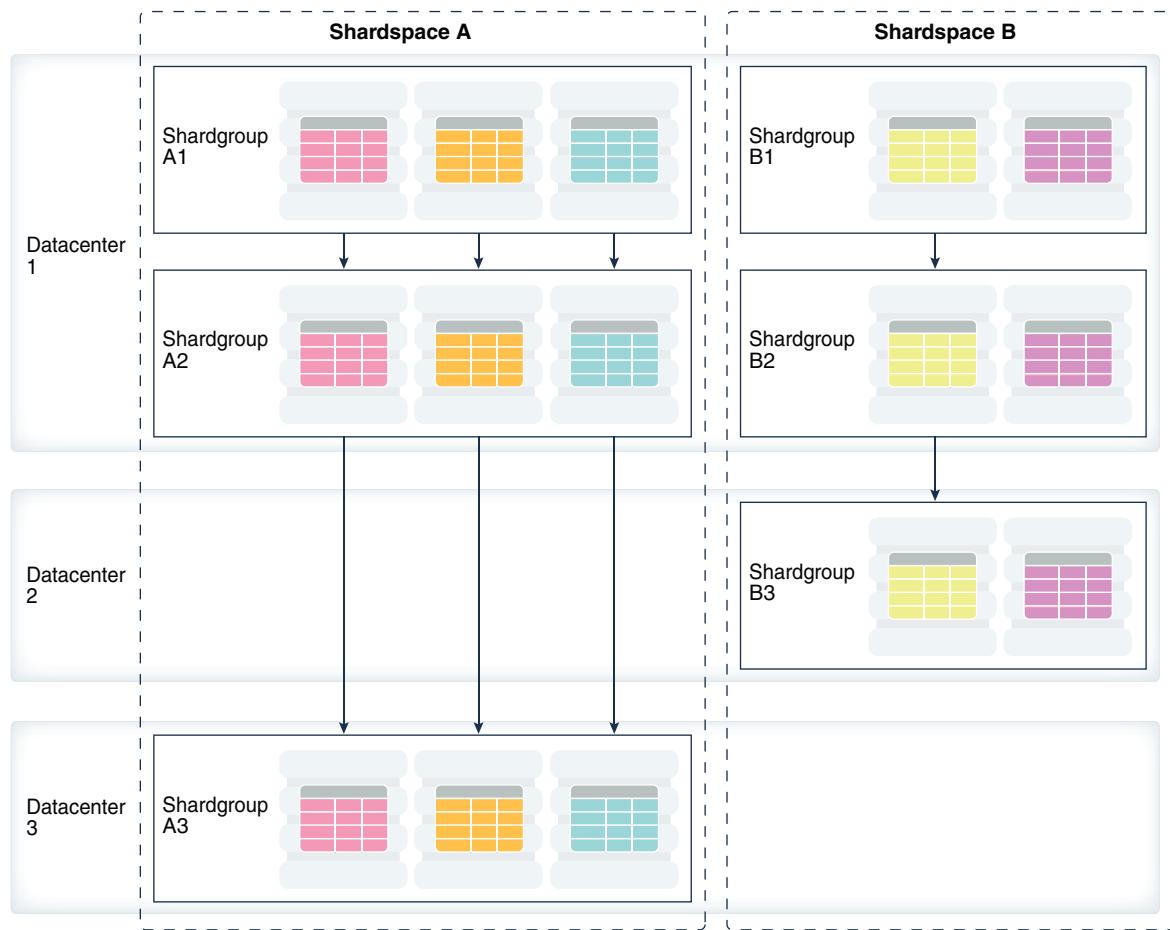

CREATE SHARD -shardgroup shardgroup1 -destination host01 -credential
oracle_cred
CREATE SHARD -shardgroup shardgroup1 -destination host02 -credential
oracle_cred
CREATE SHARD -shardgroup shardgroup1 -destination host03 -credential
oracle_cred
...
CREATE SHARD -shardgroup shardgroup3 -destination host09 -credential
oracle_cred

DEPLOY
```

### Using Oracle Data Guard with a Composite SDB

In composite sharding an SDB consists of multiple shardspaces. However, each shardspace, instead of replicated shards, contains replicated shardgroups.

**Figure 55-2 Composite Sharding with Data Guard Replication**

Run the following GDSCTL commands to deploy the example configuration shown in the previous figure.

```

CREATE SHARDCATALOG -sharding composite -database host00:1521:cat -region
dc1,
dc2, dc3

ADD GSM -gsm gsm1 -listener 1571 -catalog host00:1521:cat -region dc1
ADD GSM -gsm gsm2 -listener 1571 -catalog host00:1521:cat -region dc2
ADD GSM -gsm gsm3 -listener 1571 -catalog host00:1521:cat -region dc3

ADD SHARDSPACE -shardspace shardspace_a
ADD SHARDSPACE -shardspace shardspace_b

ADD SHARDGROUP -shardgroup shardgroup_a1 -shardspace shardspace_a -region
dc1
-deploy_as primary
ADD SHARDGROUP -shardgroup shardgroup_a2 -shardspace shardspace_a -region
dc1
-deploy_as active_standby
ADD SHARDGROUP -shardgroup shardgroup_a3 -shardspace shardspace_a -region

```

```
dc3
-deploy_as active_standby
ADD SHARDGROUP -shardgroup shardgroup_b1 -shardspace shardspace_b -region
dc1
-deploy_as primary
ADD SHARDGROUP -shardgroup shardgroup_b2 -shardspace shardspace_b -region
dc1
-deploy_as active_standby
ADD SHARDGROUP -shardgroup shardgroup_b3 -shardspace shardspace_b -region
dc2
-deploy_as active_standby

CREATE SHARD -shardgroup shardgroup_a1 -destination host01 -credential
orcl_cred
...
CREATE SHARD -shardgroup shardgroup_b3 -destination host09 -credential
orcl_cred

DEPLOY
```

# Sharded Database Deployment

Sharded database deployment includes the prerequisites and instructions for installing the required software components, creating the catalog, roles, and the sharded database, configuring replication for high availability, and creating the schema for the sharded database.

The following topics contain the concepts and tasks you need to deploy a sharded database:

- [Introduction to SDB Deployment](#)  
Oracle Sharding provides the capability to automatically deploy the sharded database (SDB), which includes both the shards and the replicas.
- [Oracle Sharding Prerequisites](#)  
Before you install any software, review these hardware, network, and operating system requirements for Oracle Sharding.
- [Installing Oracle Database Software](#)  
Install Oracle Database on each system that will host the shard catalog or database shards.
- [Installing the Shard Director Software](#)  
Install the global service manager software on each system that you want to host a shard director.
- [Creating the Shard Catalog Database](#)  
Create a non-CDB Oracle Database using DBCA to host the shard catalog.
- [Setting Up the Oracle Sharding Management and Routing Tier](#)  
The shard catalog, shard directors and shards must be configured to communicate with each other.
- [Creating a System-Managed SDB](#)
- [Deploying a Composite SDB](#)  
To deploy a composite SDB you must install the required Oracle Sharding software components, configure the objects for a composite SDB, and create the schema.

## 56.1 Introduction to SDB Deployment

Oracle Sharding provides the capability to automatically deploy the sharded database (SDB), which includes both the shards and the replicas.

The SDB administrator defines the topology (regions, shard hosts, replication technology) and invokes the DEPLOY command with a declarative specification using the GDSCTL command-line interface.

At a high level, the deployment steps are:

1. Set up the components.

 **Note:**

In Oracle Database 12c Release 1 (12.2.0.1) all shards and shard catalog must be non-CDB databases.

- Create a non-CDB database that hosts the shard catalog.
- Install Oracle Database software on the shard nodes.
- Install shard director (GSM) software on the shard director nodes.

 **Note:**

For production deployments, it is highly recommended that you configure Data Guard for the shard catalog database.

2. Specify the topology layout using the following commands.
  - CREATE SHARDCATALOG
  - ADD GSM
  - START GSM
  - ADD CREDENTIAL (if using CREATE SHARD)
  - ADD SHARDGROUP
  - ADD INVITEDNODE
  - CREATE SHARD (or ADD SHARD) for each shard
3. Run DEPLOY and add the global service to access any shard in the SDB.
  - DEPLOY
  - ADD SERVICE

In Oracle Database 12c Release 1 (12.2.0.1) two replication schemes are supported. The SDB administrator can select either Data Guard or Active Data Guard while specifying the topology.

#### Deployment Methods: CREATE SHARD

Oracle Sharding supports two deployment methods. The first method is with the CREATE SHARD command, where the creation of shards and the replication configuration are automatically done by the Oracle Sharding management tier.

The DEPLOY command creates the shards. This is done using the DBMS\_SCHEDULER package (executed on the shard catalog), which communicates with the Scheduler agents on the remote shard hosts.

Agents then invoke DBCA and NETCA to create the shards and the local listeners. After the primary shards are created the corresponding standby shards are built using the RMAN DUPLICATE command. Once the primary and standby shards are built, the DEPLOY command configures the Data Guard Broker with Fast-Start Failover (FSFO) enabled. The FSFO observers are automatically started on the regional shard director.

 **Note:**

Archivelog and flashback are enabled for all of the shards. This is required for the FSFO observer to perform standby auto-reinstantiation upon failover.

#### Deployment Methods: ADD SHARD

The second deployment method is with the `ADD SHARD` command. If your database creation standards require that you deploy the SDB using your own pre-created databases, the `ADD SHARD` deployment method supports this requirement by simply adding your prebuilt database shards.

When the `ADD SHARD` command is used for deployment, the `DEPLOY` command handles the configuration of the Data Guard, Broker, and Fast-start Failover. It also handles the scenario where you have pre-configured Data Guard for the shard that is being added.

## 56.2 Oracle Sharding Prerequisites

Before you install any software, review these hardware, network, and operating system requirements for Oracle Sharding.

- Hardware and operating system requirements for the shards are the same as that on which Oracle Database 12c Release 2 is supported. See your Oracle Database installation documentation for these requirements.
- Hardware, software, and operating system requirements for the shard catalog and shard directors are the same as for the Global Data Services catalog and global service manager. See *Oracle Database Global Data Services Concepts and Administration Guide* for these requirements.
- Network requirements are Low Latency GigE

## 56.3 Installing Oracle Database Software

Install Oracle Database on each system that will host the shard catalog or database shards.

Before installing Oracle Database, create an operating system user on all of the systems where you will be hosting the sharded database, shard catalog, and shard directors, and assign them to the DBA group. Allow the user to run `su`, and make note of the credentials so that you can use them in later procedures.

See *Oracle Database Installation Guide for Linux*, or your platform's installation guide, for information about configuring operating system users.

1. Download the Oracle Database installer on all of the systems that will host the shard catalog or the database shards.
2. Install Oracle Database on all of the systems where you intend to host the shard catalog and sharded database.
  - a. Run the installer on the first system.

```
$ cd /u01/stage/database
$./runInstaller
```

As you step through the Oracle Database installation, be sure to select the following options on the noted screens:

- On the Installation Option page, select **Install database software only**.
  - On the Grid Installation Options page, select **Single instance database installation**. Oracle RAC and Oracle RAC One Node are not supported in this release.
  - On the Database Edition page, select **Enterprise Edition**.
  - On the Installation Location page, use the same **Oracle base** and **Software location** values that you used when creating the environment scripts in the steps above.
  - On the Create Inventory page, accept the defaults.
  - On the Operating System Groups page, accept the defaults or make changes as appropriate for your environment.
  - On the Summary page, you can click **Save Response File** to create a file for silent installation of the Oracle Database software on the remaining hosts.
  - During installation, execute the `orainstRoot.sh` and `root.sh` scripts as `root` in a separate terminal when prompted.
- b. Optionally, using the response file you created in the first installation, run a silent install on each of the remaining hosts.

Note that, after performing a silent install using a response file, when you run the database `root.sh` script its execution might not prompt you interactively for any values and uses only default values (for example, for the local user `bin` directory). If any non-default values are desired, specify just the `-responseFile` location when invoking the Installer and omit the `-silent` option. Click through the Installer screens, accepting the response file values, and then run the root script(s) when prompted. During root script execution, any user prompts are presented to you and non-default values can be entered.

#### See Also:

*Oracle Database Installation Guide for Linux* for more information about using the response file for silent installation of Oracle Database

## 56.4 Installing the Shard Director Software

Install the global service manager software on each system that you want to host a shard director.

1. Download the Oracle Global Service Manager installer on all of the systems that will host the shard directors.
2. See *Oracle Database Global Data Services Concepts and Administration Guide* for information about installing a global service manager.

3. Optionally, using the response file you created in the first installation, run a silent install on each of the remaining shard director hosts.

Note that, after performing a silent install using a response file, when you run the database `root.sh` script its execution might not prompt you interactively for any values and uses only default values (for example, for the local user `bin` directory). If any non-default values are desired, specify just the `-responseFile` location when invoking the Installer and omit the `-silent` option. Click through the Installer screens, accepting the response file values, and then run the root script(s) when prompted. During root script execution, any user prompts are presented to you and non-default values can be entered.

## 56.5 Creating the Shard Catalog Database

Create a non-CDB Oracle Database using DBCA to host the shard catalog.

1. Connect to the host where you will host the shard catalog, and verify that the expected environment variables are set to the correct values.

```
$ env |grep ORA
ORACLE_BASE=/u01/app/oracle
ORACLE_HOME=/u01/app/oracle/product/12.2.0/dbhome_1
```

2. Create the `oradata` and `fast_recovery_area` directories.

```
$ mkdir /u01/app/oracle/oradata
$ mkdir /u01/app/oracle/fast_recovery_area
```

3. Run DBCA to create the shard catalog database.

```
$ dbca
```

The Database Configuration Assistant opens.

4. On the Database Operation page, select **Create a database**, and click **Next**.
5. On the Creation Mode page, select **Advanced configuration**, and click **Next**.
6. On the Deployment Type page, select the **Oracle Single Instance database** database type, select the **General Purpose or Transaction Processing** template, and click **Next**.
7. On the Database Identification page, enter the **Global Database name** and the shard catalog **SID** that you configured in the shard catalog host environment script, uncheck the **Create as Container Database** option, and click **Next**.

**! Important:**

Container databases are not supported in this release of Oracle Sharding. Be sure to uncheck this option before you continue.

8. On the Storage Option page, select the **Use following for the database storage attributes** option, select **File System**, select the **Use Oracle-Managed Files (OMF)** option, and click **Next**.

9. On the Select Fast Recovery Option page, select **Specify Fast Recovery Area**, select **Enable archiving**, and click **Next**.
10. On the Specify Network Configuration Details page, select **Create a new listener**, set the listener name and port number, and click **Next**.

Make note of the listener name so that you can connect to the database later.
11. Skip the Data Vault Option page.
12. On the Configuration Options page **Memory** tab, select **Use Automatic Shared Memory Management**.
13. On the Configuration Options page **Character sets** tab, select **Use Unicode (AL32UTF8)**, and click **Next**.
14. On the Management Option page, uncheck the **Configure Enterprise Manager (EM) database express** option, and click **Next**.
15. On the User Credentials page, select the appropriate option for your business needs, enter the passwords, and click **Next**.

Make a note of the passwords you entered because you will need them later.
16. On the Creation Option page, select **Create database**, and click **Next**.
17. On the Summary page, click **Finish**.
18. After the database has been created, make a note of the Global Database Name, SID, and spfile values.
19. If you plan to use Oracle Data Guard to protect the shard catalog database, click **Password Management**, unlock the SYSDG account, and make a note of the password you enter for this account.
20. Click **Close** to exit DBCA.

## 56.6 Setting Up the Oracle Sharding Management and Routing Tier

The shard catalog, shard directors and shards must be configured to communicate with each other.

1. On the shard catalog host, verify that the expected environment values are set to the correct values.

```
$ env |grep ORA
ORACLE_SID=shardcat
ORACLE_BASE=/u01/app/oracle
ORACLE_HOME=/u01/app/oracle/product/12.2.0/dbhome_1
```

2. If the shard catalog listener is not already started, start the shard catalog listener.

```
$ lsnrctl start
```

3. Verify that `DB_CREATE_FILE_DEST` parameter is set on the shard catalog database.

If the parameter is not set, then set it as shown in the following example. Note that `open_links` and `open_links_per_instance` are set to 16 for the purposes of the Oracle Sharding demo application.

```
$ sqlplus / as sysdba

SQL> alter system set db_create_file_dest='/u01/app/oracle/oradata'
scope=both;
SQL> alter system set open_links=16 scope=spfile;
SQL> alter system set open_links_per_instance=16 scope=spfile;
```

**4.** Shut down and restart the shard catalog database.

```
SQL> shutdown immediate
Database closed.
Database dismounted.
```

```
SQL> startup
ORACLE instance started.
```

```
Total System Global Area 4798283776 bytes
Fixed Size 4430760 bytes
Variable Size 1006634072 bytes
Database Buffers 3774873600 bytes
Redo Buffers 12345344 bytes
Database mounted.
Database opened.
```

**5.** Grant roles and privileges on the shard catalog database.

```
SQL> set echo on
SQL> set termout on
SQL> spool setup_grants_privs.lst
```

**a.** Unlock and set the password for the `GSMCATUSER` schema.

This schema is used by the shard director when connecting to the shard catalog database.

```
SQL> alter user gsmcatuser account unlock;
SQL> alter user gsmcatuser identified by gsmcatuser_password;
```

**b.** Create the administrator schema and grant privileges to it.

The `mysdbadmin` account is an account in the shard catalog database which stores information on the sharding environment. The `mysdbadmin` account is the database administrator schema for making administrative changes to the sharded database environment. GDSCTL connects through this user to the database when GDSCTL commands are run, and the `mysdbadmin` user makes the necessary changes in the database.

```
SQL> create user mysdbadmin identified by mysdbadmin_password;
SQL> grant connect, create session, gsmadmin_role to mysdbadmin;
```

---

```
SQL> grant inherit privileges on user SYS to GSMADMIN_INTERNAL;
SQL> spool off
```

**6.** Connect to a shard director host and start GDSCTL.

The commands in the following steps are executed from a shard director host because the GDSCTL command line interface is installed there.

The following example includes a sanity check that environment variables have been set properly.

```
$ env |grep ORA
ORACLE_BASE=/u01/app/oracle
ORACLE_HOME=/u01/app/oracle/product/12.2.0/gsmhome_1

$ gdsctl
```

**7.** Create the shard catalog and configure the remote scheduler agent on the shard catalog.

In this example, the sharded database is given the name cust\_sdb, and two regions are created: region1 and region2. The regions are used as local availability domains for failover of the shards from the primary to physical standby. The regions are not meant to represent geographical regions in this example.

```
GDSCTL> create shardcatalog -database shard_catalog_host:
1521:shard_catalog_name -chunks 12 -user mysdbadmin/mysdbadmin_password
-sdb cust_sdb -region region1, region2 -agent_port port_num -
agent_password rsa_password
```

**8.** While you are connected to the shard director host, create and start the shard director.

```
GDSCTL> add gsm -gsm sharddirector1 -listener listener_port -pwd
gsmcatuser_password
-catalog shard_catalog_host:1521:shardcat -region region1
```

```
GDSCTL> start gsm -gsm sharddirector1
```

Repeat steps 6 and 8 on each shard director host. Replace the shard director name and region name with appropriate values for each host.

**9.** Using GDSCTL, set the operating system credentials.

```
GDSCTL> add credential -credential credential_name -osaccount
os_account_name -ospassword os_password
```

```
GDSCTL> exit
```

These credentials are the operating system user name and password on the shard hosts (not the catalog host), and the credentials are used by the remote scheduler agent to run jobs on the hosts to set up the shards using DBCA, NETCA, and the like.

Repeat this step if a different operating system credential will be used for each host.

10. Connect to each of the shard hosts, register remote scheduler agents on them, and create directories for oradata and fast\_recovery\_area on them.

 **Note:**

This step is only required if you are using the CREATE SHARD method described in [Introduction to SDB Deployment](#). If you are using the ADD SHARD method you can skip this step.

Execute the following statements on each of the machines that will host a shard.

Note that the `os_account_name` is the account used for Oracle software installation, `shard_host` is the host name or IP address of the machine hosting the shard, the `shard_catalog_host` is the host name or IP address of the shard catalog host, and `port_num` is the remote scheduler agent port number as specified in the `-agent_port` parameter for `create shardcatalog` in step 7 above. The remote scheduler agent prompts you for the agent registration password specified in the `-agent_password` parameter of `create shardcatalog` in step 7 above.

```
$ ssh os_account_name@shard_host
passwd: os_password

$ schagent -start
$ schagent -status
$ schagent -registerdatabase shard_catalog_host port_num

$ mkdir /u01/app/oracle/oradata
$ mkdir /u01/app/oracle/fast_recovery_area
```

## 56.7 Creating a System-Managed SDB

The following topics describe the tasks for creating a system-managed SDB.

- [Deploying a System-Managed SDB](#)

To deploy a system-managed SDB you create shardgroups and shards, create and configure the databases to be used as shards, execute the DEPLOY command, and create role-based global services.

- [Creating a Schema for a System-Managed SDB](#)

Create the schema user, tablespace set, sharded tables, and duplicated tables for the SDB. Verify that the DDLs are propagated to all of the shards, and, while connected to the shards, verify the automatic Data Guard Broker configuration with Fast-Start Failover.

- [System-Managed SDB Demo Application](#)

The system-managed sharded database (SDB) demo application simulates the workload of an online retail store. Use it to validate the setup of any system-managed (automatic sharding) SDB configuration. The demo application also provides a practical example of sharding concepts for administrators and developers new to database sharding.

## 56.7.1 Deploying a System-Managed SDB

To deploy a system-managed SDB you create shardgroups and shards, create and configure the databases to be used as shards, execute the `DEPLOY` command, and create role-based global services.

System-managed sharding does not require the user to map data to shards. Data is automatically distributed across shards using partitioning by consistent hash. The partitioning algorithm evenly and randomly distributes data across shards. For more conceptual information about the system-managed SDB, see [System-Managed Sharding](#).

1. If you are using the `ADD SHARD` method described in [Introduction to SDB Deployment](#) you must first create the databases to be used as shards on their respective hosts.

The shard databases must have the following characteristics:

- They must not be container databases (CDBs)
- They must have an associated TNS Listener on port 1521 on each host
- The `GSMUSER` account must be unlocked with a known password
- The primary and standby databases must be configured as such
- Redo apply should be set up between the corresponding primary and standby databases
- Flashback and force logging should be enabled
- The `compatible` parameter must be set to at least 12.2.0
- A server parameter file (SPFILE) must be in use
- A `DATA_PUMP_DIR` directory object must be created in each database and must point to a valid directory

You must then validate that a database is correctly set up for sharding. Execute the following against each database before adding it to the configuration.

```
SQL> set serveroutput on
SQL> execute DBMS_GSM_FIX.validateShard
```

Screen output will include INFO, WARNING, and ERROR information that needs to be analyzed for any issues. All WARNING and ERROR messages must be resolved. Re-run `validateShard()` after making changes to confirm the configuration.

2. Connect to the shard director host.

```
$ ssh os_user@shard_director1_host
```

3. Set the global service manager for the current session, and specify the credentials to administer it.

```
$ gdsctl
GDSCTL> set gsm -gsm sharddirector1
GDSCTL> connect mysdbadmin/mysdbadmin_password
```

4. Add a shardgroup for the primary shards.

In this example the shardgroup is named `primary_shardgroup`. You can choose your own name.

```
GDSCTL> add shardgroup -shardgroup primary_shardgroup -deploy_as primary -region region1
```

5. Add a shardgroup for the Active Data Guard standby shards.

In this example the shardgroup is named `standby_shardgroup`. You can choose your own name.

```
GDSCTL> add shardgroup -shardgroup standby_shardgroup -deploy_as active_standby -region region2
```

6. Add each shard's host address to the valid node checking for registration (VNCR) list in the catalog, then create the shard in either the primary or standby shardgroup, as shown in the following example.

 **Note:**

The valid node checking for registration (VNCR) feature provides the ability to configure and dynamically update a set of IP addresses, host names, or subnets from which registration requests are allowed by the shard directors. Database instance registration with a shard director succeeds only when the request originates from a valid node. By default, the shard management tier (based on Oracle Global Data Services framework) automatically adds a VNCR entry for the host on which a remote database is running each time `create shard` or `add shard` is executed. The automation (called auto-VNCR) finds the public IP address of the target host, and automatically adds a VNCR entry for that IP address. If the host has multiple public IP addresses, then the address on which the database registers may not be the same as the address which was added using auto-VNCR and, as a result, registration may be rejected. If the target database host has multiple public IP addresses, it is advisable that you configure VNCR manually for this host using the `add invitednode` or `add invitedsubnet` commands in GDSCTL.

If there are multiple net-cards on the target host (`/sbin/ifconfig` returns more than one public interface), use `add invitednode` to be safe (after finding out which interface will be used to route packets).

If there is any doubt about registration, then use `config vncr` and use `add invitednode` as necessary. There is no harm in doing this, because if the node is added already, auto-VNCR ignores it, and if you try to add it after auto-VNCR already added it, you will get a warning stating that it already exists.

The following example shows how to create four shards using the `CREATE SHARD` command, two of which are in the primary shardgroup and two in the standby shardgroup. The `credential_name` is the operating system credential you created on each host.

While creating the shards, you can also set the SYS password in the create shard using `-sys_password` as shown in the following example. This sets the SYS password after the shards are created when running DEPLOY.

```
GDSCTL> add invitednode shard_host_1
GDSCTL> create shard -shardgroup primary_shardgroup -destination
shard_host_1 -credential credential_name -sys_password sys_password

GDSCTL> add invitednode shard_host_2
GDSCTL> create shard -shardgroup standby_shardgroup -destination
shard_host_2 -credential credential_name -sys_password sys_password
GDSCTL> add invitednode shard_host_3
GDSCTL> create shard -shardgroup primary_shardgroup -destination
shard_host_3 -credential credential_name -sys_password sys_password
GDSCTL> add invitednode shard_host_4
GDSCTL> create shard -shardgroup standby_shardgroup -destination
shard_host_4 -credential credential_name -sys_password sys_password
```

If you are using the ADD SHARD method described in [Introduction to SDB Deployment](#), use the following command instead of the CREATE SHARD commands in the example above.

```
GDSCTL> add shard -shardgroup shgrp1 -connect shard_host:1521/
shard_database_name -pwd GSMUSER_password
```

7. Check the configuration from a shard director.

Note that the shard names, sh1, sh2, sh3, and sh4, are system generated shard names when the CREATE SHARD method is used.

```
GDSCTL> config
Regions

region1
region2

GSMs

sharddirector1
sharddirector2

Sharded Database

cust_sdb

Databases

sh1
sh2
sh3
sh4

Shard Groups

```

```

primary_shardgroup
standby_shardgroup

Shard spaces

shardspaceora

Services

GDSCTL pending requests

Command Object Status
----- ----- -----
Global properties

Name: oradbcloud
Master GSM: sharddirector1
DDL sequence #: 0

GDSCTL> config shardspace
SHARDSPACE Chunks
----- -----
shardspaceora 12

GDSCTL> config shardgroup
Shard Group Chunks Region SHARDSPACE
----- ----- ----- -----
primary_shardgroup 12 region1 shardspaceora
standby_shardgroup 12 region2 shardspaceora

GDSCTL> config vncr
Name Group ID
----- -----
shard_host_1

----- ----- ----- ----- ----- -----
sh1 primary_shardgroup U none region1 -
sh2 standby_shardgroup U none region2 -
sh3 primary_shardgroup U none region1 -
sh4 standby_shardgroup U none region2 -

```

8. Run the DEPLOY command to create the shards and the replicas.

The DEPLOY command takes some time to run, approximately 15 to 30 minutes.

```
GDSCTL> deploy
```

When the CREATE SHARD method is used to create the shards, the DEPLOY command creates the primary and standby shards using DBCA. Archivelog and flashback, which is required for the Fast-Start Failover observers to perform standby reinstatement, are enabled for all of the shards.

Once the primary and standby shards are built, the DEPLOY command configures the Data Guard Broker with Fast-Start Failover enabled. The Fast-Start Failover observers are automatically started on the standby group's shard director (sharddirector2 in this example).

**9.** Verify that all of the shards are deployed.

```
GDSCTL> config shard
Name Shard Group Status State Region
Availability
----- -----
----- -----
sh1 primary_shardgroup Ok Deployed region1 ONLINE
sh2 standby_shardgroup Ok Deployed region2 READ_ONLY
sh3 primary_shardgroup Ok Deployed region1 ONLINE
sh4 standby_shardgroup Ok Deployed region2 READ_ONLY
```

**10.** Verify that all of the shards are registered.

```
GDSCTL> databases
Database: "sh1" Registered: Y State: Ok ONS: N. Role: PRIMARY
Instances: 1 Region: region1
 Registered instances:
 cust_sdb%1
Database: "sh2" Registered: Y State: Ok ONS: N. Role: PH_STNDBY
Instances: 1 Region: region2
 Registered instances:

CPU Threshold, %: 75
```

```
Version: 12.2.0.1
Last Failed DDL:
DDL Error: ---
Failed DDL id:
Availability: ONLINE
```

```
Supported services

Name Preferred Status

```

**12.** Add a global service that runs on all of the primary shards.

The oltp\_rw\_srvc global service is a global data service that a client can use to connect to the sharded database. The oltp\_rw\_srvc service runs the OLTP transactions on the primary shards. Likewise, the oltp\_ro\_srvc global service is created to run read-only workload on the standby shards.

```
GDSCTL> add service -service oltp_rw_srvc -role primary
```

```
GDSCTL> config service
```

| Name          | Network name                      | Pool     | Started |
|---------------|-----------------------------------|----------|---------|
| Preferred all | -----                             | ---      | -----   |
| oltp_rw_srvc  | oltp_rw_srvc.cust_sdb.oracelcloud | cust_sdb | No Yes  |

**13.** Start the oltp\_rw\_srvc global service.

```
GDSCTL> start service -service oltp_rw_srvc
```

```
GDSCTL> status service
Service "oltp_rw_srvc.cust_sdb.oracelcloud" has 2 instance(s). Affinity: ANYWHERE
Instance "cust_sdb%1", name: "sh1", db: "sh1", region: "region1",
status: ready.
Instance "cust_sdb%21", name: "sh3", db: "sh3", region: "region1",
status: ready.
```

**14.** Add a global service for the read-only workload to run on the standby shards.

```
GDSCTL> add service -service oltp_ro_srvc -role physical_standby
```

```
GDSCTL> config service
```

| Name          | Network name                      | Pool     | Started |
|---------------|-----------------------------------|----------|---------|
| Preferred all | -----                             | ---      | -----   |
| oltp_rw_srvc  | oltp_rw_srvc.cust_sdb.oracelcloud | cust_sdb | Yes Yes |
| oltp_ro_srvc  | oltp_ro_srvc.cust_sdb.oracelcloud | cust_sdb | No Yes  |

15. Start the read-only service, and verify the status of the global services.

```
GDSCTL> start service -service oltp_ro_srvc

GDSCTL> status service
Service "oltp_ro_srvc.cust_sdb.oradbcloud" has 2 instance(s). Affinity:
ANYWHERE
 Instance "cust_sdb%11", name: "sh2", db: "sh2", region: "region2",
status: ready.
 Instance "cust_sdb%31", name: "sh4", db: "sh4", region: "region2",
status: ready.
Service "oltp_rw_srvc.cust_sdb.oradbcloud" has 2 instance(s). Affinity:
ANYWHERE
 Instance "cust_sdb%1", name: "sh1", db: "sh1", region: "region1",
status: ready.
 Instance "cust_sdb%21", name: "sh3", db: "sh3", region: "region1",
status: ready.
```

[Creating a Schema for a System-Managed SDB](#)

*Oracle Database Global Data Services Concepts and Administration Guide*  
for more information about GDSCTL command usage

## 56.7.2 Creating a Schema for a System-Managed SDB

Create the schema user, tablespace set, sharded tables, and duplicated tables for the SDB. Verify that the DDLs are propagated to all of the shards, and, while connected to the shards, verify the automatic Data Guard Broker configuration with Fast-Start Failover.

1. Connect to the shard catalog database, create the application schema user, and grant privileges and roles to the user.

In this example, the application schema user is called app\_schema.

```
$ sqlplus / as sysdba

SQL> alter session enable shard ddl;
SQL> create user app_schema identified by app_schema_password;
SQL> grant all privileges to app_schema;
SQL> grant gsmadmin_role to app_schema;
SQL> grant select_catalog_role to app_schema;
SQL> grant connect, resource to app_schema;
SQL> grant dba to app_schema;
SQL> grant execute on dbms_crypto to app_schema;
```

2. Create a tablespace set for the sharded tables.

```
SQL> CREATE TABLESPACE SET TSP_SET_1 using template (datafile size 100m
autoextend on next 10M
```

```
maxsize unlimited extent management local segment space management
auto);
```

Specifying the shardspace is optional when creating the tablespace set. If the shardspace is not specified in the command, the default shardspace is used.

**3. Create a tablespace for the duplicated tables.**

In this example the duplicated table is the Products table in the sample Customers-Orders-Products schema.

```
SQL> CREATE TABLESPACE products_tsp datafile size 100m autoextend on
next 10M maxsize unlimited extent management local uniform size 1m;
```

**4. Create a sharded table for the root table.**

In this example, the root table is the Customers table in the sample Customers-Orders-Products schema.

```
SQL> CONNECT app_schema/app_schema_password

SQL> ALTER SESSION ENABLE SHARD DDL;

SQL> CREATE SHARDED TABLE Customers
(
 CustId VARCHAR2(60) NOT NULL,
 FirstName VARCHAR2(60),
 LastName VARCHAR2(60),
 Class VARCHAR2(10),
 Geo VARCHAR2(8),
 CustProfile VARCHAR2(4000),
 Passwd RAW(60),
 CONSTRAINT pk_customers PRIMARY KEY (CustId),
 CONSTRAINT json_customers CHECK (CustProfile IS JSON)
) TABLESPACE SET TSP_SET_1
PARTITION BY CONSISTENT HASH (CustId) PARTITIONS AUTO;
```

**5. Create a sharded table for the other tables in the table family.**

In this example, sharded tables are created for the Orders and LineItems tables in the sample Customers-Orders-Products schema.

The Orders sharded table is created first:

```
SQL> CREATE SHARDED TABLE Orders
(
 OrderId INTEGER NOT NULL,
 CustId VARCHAR2(60) NOT NULL,
 OrderDate TIMESTAMP NOT NULL,
 SumTotal NUMBER(19,4),
 Status CHAR(4),
 CONSTRAINT pk_orders PRIMARY KEY (CustId, OrderId),
 CONSTRAINT fk_orders_parent FOREIGN KEY (CustId)
 REFERENCES Customers ON DELETE CASCADE
) PARTITION BY REFERENCE (fk_orders_parent);
```

Create the sequence used for the OrderId column.

```
SQL> CREATE SEQUENCE Orders_Seq;
```

Create a sharded table for LineItems

```
SQL> CREATE SHARDED TABLE LineItems
(
 OrderId INTEGER NOT NULL,
 CustId VARCHAR2(60) NOT NULL,
 ProductId INTEGER NOT NULL,
 Price NUMBER(19,4),
 Qty NUMBER,
 CONSTRAINT pk_items PRIMARY KEY (CustId, OrderId, ProductId),
 CONSTRAINT fk_items_parent FOREIGN KEY (CustId, OrderId)
 REFERENCES Orders ON DELETE CASCADE
) PARTITION BY REFERENCE (fk_items_parent);
```

**6.** Create any required duplicated tables.

In this example, the Products table is a duplicated object.

```
SQL> CREATE DUPLICATED TABLE Products
(
 ProductId INTEGER GENERATED BY DEFAULT AS IDENTITY PRIMARY KEY,
 Name VARCHAR2(128),
 DescrUri VARCHAR2(128),
 LastPrice NUMBER(19,4)
) TABLESPACE products_tsp;
```

**7.** From the shard director host, verify that there were no failures during the creation of the tablespaces.

```
GDSCTL> show ddl
id DDL Text Failed shards
-- -----
5 grant connect, resource to app_schema
6 grant dba to app_schema
7 grant execute on dbms_crypto to app_s...
8 CREATE TABLESPACE SET TSP_SET_1 usin...
9 CREATE TABLESPACE products_tsp datafi...
10 CREATE SHARDED TABLE Customers (Cu...
11 CREATE SHARDED TABLE Orders (Order...
12 CREATE SEQUENCE Orders_Seq;
13 CREATE SHARDED TABLE LineItems (Or...
14 CREATE MATERIALIZED VIEW "APP_SCHEMA"...
```

 **Note:**

The `show ddl` command output might be truncated. You can run `SELECT ddl_text FROM gsmadmin_internal.ddl_requests` on the catalog to see the full text of the statements.

8. Verify that there were no DDL errors on each of the shards.

Run the `config shard` and `config chunks` commands on each shard in your configuration.

```
GDSCTL> config shard -shard sh1
Name: sh1
Shard Group: primary_shardgroup
Status: Ok
State: Deployed
Region: region1
Connection string: shard_host_1:1521/sh1_host:dedicated
SCAN address:
ONS remote port: 0
Disk Threshold, ms: 20
CPU Threshold, %: 75
Version: 12.2.0.0
Last Failed DDL:
DDL Error: ---
Failed DDL id:
Availability: ONLINE

Supported services

Name Preferred Status
----- -----
oltp_ro_srvc Yes Enabled
oltp_rw_srvc Yes Enabled

GDSCTL> config chunks
Chunks

Database From To
----- --
sh1 1 6
sh2 1 6
sh3 7 12
sh4 7 12
```

9. Verify that the tablespaces of the tablespace set you created for the sharded table family and the tablespaces you created for the duplicated tables are created on all of the shards.

The number of tablespaces in the tablespace set is based on the number of chunks you specified in the `create shardcatalog` command.

The tablespace set with the first 6 chunks of the 12 that were specified in the shard catalog creation example, and the duplicated Products tablespace is shown in the following example.

```
$ sqlplus / as sysdba

SQL> select TABLESPACE_NAME, BYTES/1024/1024 MB from sys.dba_data_files
order by tablespace_name;

TABLESPACE_NAME MB
```

```

| C001TSP_SET_1 | 100
| C002TSP_SET_1 | 100
| C003TSP_SET_1 | 100
| C004TSP_SET_1 | 100
| C005TSP_SET_1 | 100
| C006TSP_SET_1 | 100
| PRODUCTS_TSP | 100
| SYSAUX | 650
| SYSTEM | 890
| SYS_SHARD_TS | 100
| TSP_SET_1 | 100

| TABLESPACE_NAME | MB

| UNDOTBS1 | 105
| USERS | 5

```

13 rows selected.

Repeat this step on all of the shards in your configuration.

- Verify that the chunks and chunk tablespaces were created on all of the shards.

```
SQL> set linesize 140
SQL> column table_name format a20
SQL> column tablespace_name format a20
SQL> column partition_name format a20
SQL> show parameter db_unique_name

NAME TYPE VALUE

db_unique_name string sh1

SQL> select table_name, partition_name, tablespace_name from
dba_tab_partitions where tablespace_name like 'C%TSP_SET_1' order by
tablespace_name;
```

| TABLE_NAME | PARTITION_NAME | TABLESPACE_NAME |
|------------|----------------|-----------------|
| ORDERS     | CUSTOMERS_P1   | C001TSP_SET_1   |
| CUSTOMERS  | CUSTOMERS_P1   | C001TSP_SET_1   |
| LINEITEM   | CUSTOMERS_P1   | C001TSP_SET_1   |
| CUSTOMERS  | CUSTOMERS_P2   | C002TSP_SET_1   |
| LINEITEMS  | CUSTOMERS_P2   | C002TSP_SET_1   |
| ORDERS     | CUSTOMERS_P2   | C002TSP_SET_1   |
| CUSTOMERS  | CUSTOMERS_P3   | C003TSP_SET_1   |

CUSTOMERS CUSTOMERS_P6 C006TSP_SET_1
LINEITEMS CUSTOMERS_P6 C006TSP_SET_1
ORDERS CUSTOMERS_P6 C006TSP_SET_1
18 rows selected.

```

Repeat this step on all of the shards in your configuration.

11. Connect to the shard catalog database and verify that the chunks are uniformly distributed.

```

$ sqlplus / as sysdba

SQL> set echo off
SQL> SELECT a.name Shard, COUNT(b.chunk_number) Number_of_Chunks
 FROM gsmadmin_internal.database a, gsmadmin_internal.chunk_loc b
 WHERE a.database_num=b.database_num
 GROUP BY a.name
 ORDER BY a.name;

SHARD NUMBER_OF_CHUNKS

sh1 6
sh2 6
sh3 6
sh4 6

```

12. Verify that the sharded and duplicated tables were created.

Log in as the application schema user on the shard catalog database and each of the shards.

The following example shows querying the tables on a database shard as the app\_schema user.

```

$ sqlplus app_schema/app_schema_password
Connected.

SQL> select table_name from user_tables;

TABLE_NAME

CUSTOMERS
ORDERS
LINEITEMS
PRODUCTS

4 rows selected.

```

13. Verify that the Data Guard Broker automatic Fast-Start Failover configuration was done.

```
$ ssh os_username@shard_host_1
$ dgmgrl

### 56.7.3 System-Managed SDB Demo Application

The system-managed sharded database (SDB) demo application simulates the workload of an online retail store. Use it to validate the setup of any system-managed (automatic sharding) SDB configuration. The demo application also provides a practical example of sharding concepts for administrators and developers new to database sharding.

The demo application assumes that a system-managed SDB environment was already created along with the CUSTOMER table-family. The environment may have any number of chunks and shards (database nodes). When run, the application will first populate the Products table and then start a one-hour workload that can be paused at any time by the administrator. The workload includes four types of transactions: create a customer order, lookup the list of orders, create a new product, and multi-shard query with report generation. All aspects of a sharded database configuration are exercised.

You can download the demo application, along with a README file that describes how to run and monitor it, from [My Oracle Support Document 2184500.1](#).

## 56.8 Deploying a Composite SDB

To deploy a composite SDB you must install the required Oracle Sharding software components, configure the objects for a composite SDB, and create the schema.

The composite sharding method allows you to create multiple shardspaces for different subsets of data in a table partitioned by consistent hash. A *shardspace* is set of shards that store data that corresponds to a range or list of key values.

The following topics describe the tasks for deploying a composite SDB.

- [Deploying a Composite SDB](#)

To deploy a composite SDB you create shardgroups and shards, execute the DEPLOY command, and create role-based global services.

- [Creating a Schema for a Composite SDB](#)

Create the schema user, tablespace set, sharded tables, and duplicated tables for the SDB. Verify that the DDLs are propagated to all of the shards, and, while connected to the shards, verify the automatic Data Guard Broker configuration with Fast-Start Failover.

### 56.8.1 Deploying a Composite SDB

To deploy a composite SDB you create shardgroups and shards, execute the DEPLOY command, and create role-based global services.

The examples used in this deployment procedure are based on a global distribution scenario where separate shardspaces and shardgroups are created for America and Europe.

1. Connect to a shard director host, and verify the environment variables.

```
$ ssh os_user@shard_director_home
$ env | grep ORA
```

```
ORACLE_BASE=/u01/app/oracle
ORACLE_HOME=/u01/app/oracle/product/12.2.0/gsmhome_1
```

2. Set the global service manager for the current session, and specify the credentials to administer it.

```
$ gdsctl
GDSCTL> set gsm -gsm sharddirector1
GDSCTL> connect mysdbadmin/mysdbadmin_password
```

3. Add shardspaces and shardgroups for each customized grouping of shards your business case requires.

In this example the shardspaces and shardgroups are created for the America and Europe customers. You can choose your own names.

```
GDSCTL> add shardspace -shardspace cust_america
GDSCTL> add shardgroup -shardspace cust_america -shardgroup
america_shgrp1 -deploy_as primary -region region1
```

```
GDSCTL> add shardspace -shardspace cust_europe
GDSCTL> add shardgroup -shardspace cust_europe -shardgroup
europe_shgrp1 -deploy_as primary -region region2
```

 **Note:**

For production deployments, additional shardgroups must be created for high availability using the `add shardgroup` command

4. Verify the shardspace and shardgroup configurations.

```
GDSCTL> config shardspace
SHARDSPACE Chunks

cust_america 12
cust_europe 12
shardspaceora 12

GDSCTL>config shardgroup
Shard Group Chunks Region SHARDSPACE
----- ----- -----
america_shgrp1 12 region1 cust_america
europe_shgrp1 12 region2 cust_europe
```

5. Verify the sharded database configuration.

```
GDSCTL> config

Regions

region1
region2
```

```
GSMs

sharddirector1
sharddirector2

Sharded Database

cust_sdb_comp

Databases

Shard Groups

america_shgrp1
europe_shgrp1

Shard spaces

cust_america
cust_europe
shardspaceora

Services

GDSCTL pending requests

Command Object
Status

Global properties

Name: oradbcloud
Master GSM: sharddirector1
DDL sequence #: 0
```

6. Add each shard's host address to the valid node checking for registration (VNCR) list in the catalog, then create the shard in either the primary or standby shardgroup, as shown in the following example.

 **Note:**

The valid node checking for registration (VNCR) feature provides the ability to configure and dynamically update a set of IP addresses, host names, or subnets from which registration requests are allowed by the shard directors. Database instance registration with a shard director succeeds only when the request originates from a valid node. By default, the shard management tier (based on Oracle Global Data Services framework) automatically adds a VNCR entry for the host on which a remote database is running each time `create shard` or `add shard` is executed. The automation (called auto-VNCR) finds the public IP address of the target host, and automatically adds a VNCR entry for that IP address. If the host has multiple public IP addresses, then the address on which the database registers may not be the same as the address which was added using auto-VNCR and, as a result, registration may be rejected. If the target database host has multiple public IP addresses, it is advisable that you configure VNCR manually for this host using the `add invitednode` or `add invitedsubnet` commands in GDSCTL.

If there are multiple net-cards on the target host (`/sbin/ifconfig` returns more than one public interface), use `add invitednode` to be safe (after finding out which interface will be used to route packets).

If there is any doubt about registration, then use `config vncr` and use `add invitednode` as necessary. There is no harm in doing this, because if the node is added already, auto-VNCR ignores it, and if you try to add it after auto-VNCR already added it, you will get a warning stating that it already exists.

The example shows how to create four shards, two of which are in the America shardgroup and two in the Europe shardgroup. The `os_credential` is the operating system credential you created on each host.

While creating the shards, you can also set the SYS password in the `create shard` using `-sys_password` as shown in the following example. This sets the SYS password after the shards are created when running DEPLOY.

```
GDSCTL> add invitednode shard_host_1
GDSCTL> create shard -shardgroup america_shgrp1 -destination
shard_host_1 -credential os_credential-sys_password

GDSCTL> add invitednode shard_host_2
GDSCTL> create shard -shardgroup america_shgrp1 -destination
shard_host_2 -credential os_credential-sys_password

GDSCTL> add invitednode shard_host_3
GDSCTL> create shard -shardgroup europe_shgrp1 -destination
shard_host_3 -credential os_credential-sys_password

GDSCTL> add invitednode shard_host_4
GDSCTL> create shard -shardgroup europe_shgrp1 -destination
shard_host_4 -credential os_credential-sys_password
```

**7.** Check the configuration from a shard director.

Note that the shard names, sh1, sh2, sh3, and sh4, are system generated shard names.

```
GDSCTL> config shard
Name Shard Group Status State Region
Availability

sh1 america_shgrp1 U none region1
-
sh2 america_shgrp1 U none region1
-
sh3 europe_shgrp1 U none region2
-
sh4 europe_shgrp1 U none region2
-
```

```
GDSCTL> config vncr
Name Group ID

shard_host_1
shard_host_2
shard_host_3
shard_host_4
shard_catalog_host_IP
```

**8.** Run the DEPLOY command to create the shards.

```
GDSCTL> deploy
```

The DEPLOY command takes some time to run, approximately 15 to 30 minutes. The DEPLOY command creates the shards using DBCA.

**9.** Verify that all of the shards are deployed.

```
GDSCTL> config shard
Name Shard Group Status State Region
Availability

sh1 america_shgrp1 Ok Deployed region1
ONLINE
sh2 america_shgrp1 Ok Deployed region1
ONLINE
sh3 europe_shgrp1 Ok Deployed region2
ONLINE
sh4 europe_shgrp1 Ok Deployed region2
ONLINE
```

**10.** Verify that all of the shards are registered.

```
GDSCTL> databases
Database: "sh1" Registered: Y State: Ok ONS: N. Role: PRIMARY
```

```

Instances: 1 Region: region1
 Registered instances:
 cust_sdb_comp%1
Database: "sh2" Registered: Y State: Ok ONS: N. Role: PRIMARY
Instances: 1 Region: region1
 Registered instances:
 cust_sdb_comp%11
Database: "sh3" Registered: Y State: Ok ONS: N. Role: PRIMARY
Instances: 1 Region: region2
 Registered instances:
 cust_sdb_comp%21
Database: "sh4" Registered: Y State: Ok ONS: N. Role: PRIMARY
Instances: 1 Region: region2
 Registered instances:
 cust_sdb_comp%31

```

**11.** Check the configuration of a shard.

```

GDSCTL> config shard -shard sh1
Name: sh1
Shard Group: america_shgrp1
Status: Ok
State: Deployed
Region: region1
Connection string: shard1:1521/sh1:dedicated
SCAN address:
ONS remote port: 0
Disk Threshold, ms: 20
CPU Threshold, %: 75
Version: 12.2.0.0
Last Failed DDL:
DDL Error: ---
Failed DDL id:
Availability: ONLINE

```

```

Supported services

Name
Preferred Status

----- -----

```

**12.** Add a global service that runs on all of the primary shards.

The `oltp_rw_srvc` global service is the global data services listener that helps route a connection from the client to the actual database. The `oltp_rw_srvc` service runs the OLTP transactions on the primary shards.

```

GDSCTL> add service -service oltp_rw_srvc
GDSCTL> config service

```

| Name          | Network name | Pool  | Started |
|---------------|--------------|-------|---------|
| Preferred all | -----        | ----- | -----   |

```

oltp_rw_srvc oltp_rw_srvc.cust_sdb_comp.or cust_sdb_comp No
Yes
 adbcloud
```

**13.** Start the `oltp_rw_srvc` global service.

```
GDSCTL> start service -service oltp_rw_srvc

GDSCTL> status service
Service "oltp_rw_srvc.cust_sdb_comp.oradbcloud" has 4 instance(s).
Affinity: ANYWHERE
 Instance "cust_sdb_comp%1", name: "sh1", db: "sh1", region:
"region1", status: ready.
 Instance "cust_sdb_comp%11", name: "sh2", db: "sh2", region:
"region1", status: ready.
 Instance "cust_sdb_comp%21", name: "sh3", db: "sh3", region:
"region2", status: ready.
 Instance "cust_sdb_comp%31", name: "sh4", db: "sh4", region:
"region2", status: ready.
```

## 56.8.2 Creating a Schema for a Composite SDB

Create the schema user, tablespace set, sharded tables, and duplicated tables for the SDB. Verify that the DDLs are propagated to all of the shards, and, while connected to the shards, verify the automatic Data Guard Broker configuration with Fast-Start Failover.

1. Connect to the shard catalog host, and set the `ORACLE_SID` to the shard catalog name.
2. Connect to the shard catalog database, create the application schema user, and grant privileges and roles to the user.

In this example, the application schema user is called `app_schema`.

```
$ sqlplus / as sysdba

SQL> connect / as sysdba
SQL> alter session enable shard ddl;
SQL> create user app_schema identified by app_schema_password;
SQL> grant connect, resource, alter session to app_schema;
SQL> grant execute on dbms_crypto to app_schema;
SQL> grant create table, create procedure, create tablespace, create
materialized view to app_schema;
SQL> grant unlimited tablespace to app_schema;
SQL> grant select_catalog_role to app_schema;
SQL> grant all privileges to app_schema;
```

```
SQL> grant gsmadmin_role to app_schema;
SQL> grant dba to app_schema;
```

**3. Create tablespace sets for the sharded tables.**

```
SQL> CREATE TABLESPACE SET
 TSP_SET_1 in shardspace cust_america using template
 (datafile size 100m autoextend on next 10M maxsize
 unlimited extent management
 local segment space management auto);

SQL> CREATE TABLESPACE SET
 TSP_SET_2 in shardspace cust_europe using template
 (datafile size 100m autoextend on next 10M maxsize
 unlimited extent management
 local segment space management auto);
```

Specifying the shardspace is optional when creating the tablespace set. If the shardspace is not specified in the command, the default shardspace is used.

**4. Create a tablespace for the duplicated tables.**

In this example the duplicated table is the Products table in the sample Customers-Orders-Products schema.

```
CREATE TABLESPACE products_tsp datafile size 100m autoextend on next
10M maxsize unlimited extent management local uniform size 1m;
```

**5. Create a sharded table for the root table.**

In this example, the root table is the Customers table in the sample Customers-Orders-Products schema.

```
connect app_schema/app_schema_password
alter session enable shard ddl;

CREATE SHARDED TABLE Customers
(
 CustId VARCHAR2(60) NOT NULL,
 FirstName VARCHAR2(60),
 LastName VARCHAR2(60),
 Class VARCHAR2(10),
 Geo VARCHAR2(8),
 CustProfile VARCHAR2(4000),
 Passwd RAW(60),
 CONSTRAINT pk_customers PRIMARY KEY (CustId),
 CONSTRAINT json_customers CHECK (CustProfile IS JSON)
) partitionset by list(GEO)
partition by consistent hash(CustId)
partitions auto
(partitionset america values ('AMERICA') tablespace set tsp_set_1,
partitionset europe values ('EUROPE') tablespace set tsp_set_2
);
```

**6. Create a sharded table for the other tables in the table family.**

In this example, sharded tables are created for the Orders and LineItems tables in the sample Customers-Orders-Products schema.

Create the sequence used for the OrderId column.

```
CREATE SEQUENCE Orders_Seq;
```

The Orders sharded table is created first:

```
CREATE SHARDED TABLE Orders
(
 OrderId INTEGER NOT NULL,
 CustId VARCHAR2(60) NOT NULL,
 OrderDate TIMESTAMP NOT NULL,
 SumTotal NUMBER(19,4),
 Status CHAR(4),
 constraint pk_orders primary key (CustId, OrderId),
 constraint fk_orders_parent foreign key (CustId)
 references Customers on delete cascade
) partition by reference (fk_orders_parent);
```

Create a sharded table for LineItems

```
CREATE SHARDED TABLE LineItems
(
 OrderId INTEGER NOT NULL,
 CustId VARCHAR2(60) NOT NULL,
 ProductId INTEGER NOT NULL,
 Price NUMBER(19,4),
 Qty NUMBER,
 constraint pk_items primary key (CustId, OrderId, ProductId),
 constraint fk_items_parent foreign key (CustId, OrderId)
 references Orders on delete cascade
) partition by reference (fk_items_parent);
```

#### 7. Create any required duplicated tables.

In this example, the Products table is a duplicated object.

```
CREATE DUPLICATED TABLE Products
(
 ProductId INTEGER GENERATED BY DEFAULT AS IDENTITY PRIMARY KEY,
 Name VARCHAR2(128),
 DescrUri VARCHAR2(128),
 LastPrice NUMBER(19,4)
) tablespace products_tsp;
```

#### 8. From the shard director host, verify that there were no failures during the creation of the tablespaces.

```
GDSCTL> show ddl
id DDL Text Failed shards
-- -----
11 CREATE TABLESPACE SET TSP_SET_2 in s...
```

```

12 CREATE TABLESPACE products_tsp datafi...
13 CREATE SHARDED TABLE Customers (Cu...
14 CREATE SEQUENCE Orders_Seq;
15 CREATE SHARDED TABLE Orders (Order...
16 CREATE SHARDED TABLE LineItems (Or...
17 create database link "PRODUCTSDBLINK@...
18 CREATE MATERIALIZED VIEW "PRODUCTS" ...
19 CREATE OR REPLACE FUNCTION PasswCreat...
20 CREATE OR REPLACE FUNCTION PasswCheck...

```

9. Verify that there were no DDL errors on each of the shards.

Run the config shard and config chunks commands on each shard in your configuration.

```

GDSCTL> config shard -shard sh1
Name: sh1
Shard Group: america_shgrp1
Status: Ok
State: Deployed
Region: region1
Connection string: shard1:1521/sh1:dedicated
SCAN address:
ONS remote port: 0
Disk Threshold, ms: 20
CPU Threshold, %: 75
Version: 12.2.0.0
Last Failed DDL:
DDL Error: ---
Failed DDL id:
Availability: ONLINE

```

```

Supported services

Name
Preferred Status

oltp_rw_srvc
Yes Enabled

GDSCTL> config chunks
Chunks

Database From To
----- --- --
sh1 1 6
sh2 7 12
sh3 1 6
sh4 7 12

```

10. Verify that the tablespaces of the tablespace set you created for the sharded table family and the tablespaces you created for the duplicated tables are created on all of the shards.

The number of tablespaces in the tablespace set is based on the number of chunks you specified in the `create shardcatalog` command.

The tablespace set with the first 6 chunks of the 12 that were specified in the shard catalog creation example, and the duplicated Products tablespace is shown in the following example on the `shard_host_1`.

```
$ sqlplus / as sysdba

SQL> select TABLESPACE_NAME, BYTES/1024/1024 MB from sys.dba_data_files
order by tablespace_name;

TABLESPACE_NAME MB

C001TSP_SET_1 100
C002TSP_SET_1 100
C003TSP_SET_1 100
C004TSP_SET_1 100
C005TSP_SET_1 100
C006TSP_SET_1 100
PRODUCTS_TSP 100
SYSAUX 650
SYSTEM 890
SYS_SHARD_TS 100
TSP_SET_1 100

TABLESPACE_NAME MB

TSP_SET_2 100
UNDOTBS1 110
USERS 5

14 rows selected.
```

Repeat this step on all of the shards in your configuration.

11. Verify that the chunks and chunk tablespaces were created on all of the shards.

```
SQL> set linesize 140
SQL> column table_name format a20
SQL> column tablespace_name format a20
SQL> column partition_name format a20
SQL> show parameter db_unique_name
NAME TYPE VALUE

db_unique_name string sh2

SQL> select table_name, partition_name, tablespace_name from
dba_tab_partitions where tablespace_name like 'C%TSP_SET_1' order by
tablespace_name;

TABLE_NAME PARTITION_NAME TABLESPACE_NAME

```

| LINEITEMS  | CUSTOMERS_P7   | C007TSP_SET_1   |

| CUSTOMERS  | CUSTOMERS_P12  | C00CTSP_SET_1   |
| LINEITEMS  | CUSTOMERS_P12  | C00CTSP_SET_1   |
| ORDERS     | CUSTOMERS_P12  | C00CTSP_SET_1   |

18 rows selected.

Repeat this step on all of the shards in your configuration.

12. Connect to the shard catalog database and verify that the chunks are uniformly distributed.

```
$ sqlplus / as sysdba

SQL> set echo off
SQL> select a.name Shard, count(b.chunk_number) Number_of_Chunks
from gsmadmin_internal.database a, gsmadmin_internal.chunk_loc b where
a.database_num=b.database_num group by a.name;

SHARD NUMBER_OF_CHUNKS

sh1 6
sh2 6
sh3 6
sh4 6
```

13. Verify that the sharded and duplicated tables were created.

Log in as the application schema user on the shard catalog database and each of the shards.

The following example shows querying the tables on a database shard as the app\_schema user.

```
$ sqlplus app_schema/app_schema_password
Connected.
SQL> select table_name from user_tables;

TABLE_NAME
```

# Sharded Database Lifecycle Management

Oracle Sharding provides tools and some automation for lifecycle management of a sharded database.

The following topics describe sharded database lifecycle management in detail:

- [Monitoring a Sharded Database](#)

Sharded databases can be monitored using Enterprise Manager Cloud Control or GDSCTL.

- [Backing Up and Recovering a Sharded Database](#)

Because shards are hosted on individual Oracle databases, you can use Oracle Maximum Availability best practices to back up and restore shards individually.

- [Patching a Sharded Database](#)

Applying an Oracle patch to a sharded database environment can be done on a single shard or all shards; however, the method you use depends on the replication option used for the environment and the type of patch being applied.

- [Modifying a Sharded Database Schema](#)

When making changes to duplicated tables or sharded tables in a sharded database, these changes should be done from the shard catalog database.

- [Shard Management](#)

You can manage shards in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control and GDSCTL.

- [Chunk Management](#)

You can manage chunks in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control and GDSCTL.

- [Shard Director Management](#)

You can add, edit, and remove shard directors in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

- [Region Management](#)

You can add, edit, and remove regions in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

- [Shardspace Management](#)

You can add, edit, and remove shardspaces in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

- [Shardgroup Management](#)

You can add, edit, and remove shardgroups in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

- [Services Management](#)

You can manage services in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

## 57.1 Monitoring a Sharded Database

Sharded databases can be monitored using Enterprise Manager Cloud Control or GDSCTL.

See the following topics to use Enterprise Manager Cloud Control or GDSCTL to monitor sharded databases.

- [Monitoring a Sharded Database with GDSCTL](#)

There are numerous GDSCTL CONFIG commands that you can use to obtain the health status of individual shards, shardgroups, shardspaces, and shard directors.

- [Monitoring a Sharded Database with Enterprise Manager Cloud Control](#)

Oracle Enterprise Manager Cloud Control lets you discover, monitor, and manage the components of a sharded database.

### 57.1.1 Monitoring a Sharded Database with GDSCTL

There are numerous GDSCTL CONFIG commands that you can use to obtain the health status of individual shards, shardgroups, shardspaces, and shard directors.

Monitoring a shard is just like monitoring a normal database, and standard Oracle best practices should be used to monitor the individual health of a single shard. However, it is also important to monitor the overall health of the entire sharded environment. The GDSCTL commands can also be scripted and through the use of a scheduler and can be done at regular intervals to help ensure that everything is running smoothly.

*Oracle Database Global Data Services Concepts and Administration Guide* for information about using the GDSCTL CONFIG commands

### 57.1.2 Monitoring a Sharded Database with Enterprise Manager Cloud Control

Oracle Enterprise Manager Cloud Control lets you discover, monitor, and manage the components of a sharded database.

Sharded database targets are found in the All Targets page.

**Figure 57-1** Sharded Databases in the All Targets Refine Search pane

The target home page for a sharded database shows you a summary of the sharded database components and their statuses.

To monitor sharded database components you must first discover them. See [Discovering Sharded Database Components](#) for more information.

### Summary

The Summary pane, in the top left of the page, shows the following information:

- Sharded database name
- Sharded database domain name
- Shard catalog name. You can click the name to view more information about the shard catalog.
- Shard catalog database version
- Sharding method used to shard the database
- Replication technology used for high availability
- Number and status of the shard directors
- Master shard director name. You can click the name to view more information about the master shard director.

**Figure 57-2 Sharded Database Summary pane**

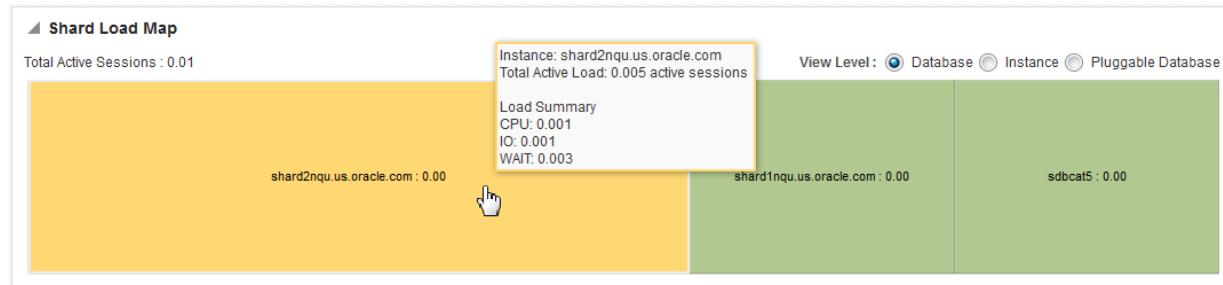

The screenshot shows the 'Summary' section of the Sharded Database Summary pane. It displays the following information:

- Sharded Database Name: employees\_sdb
- Sharded Database Domain Name: oraclecorp
- Catalog Database: sdbcatalog5
- Catalog Version: 12.2.0.1.0
- Sharding Type: System-managed
- Replication Type: Data Guard
- Shard Directors: 1 (1)
- Master Shard Director: sharddirector5

### Shard Load Map

The Shard Load Map, in the upper right of the page, shows a pictorial graph illustrating how transactions are distributed among the shards.

**Figure 57-3 Sharded Database Shard Load Map**

You can select different View Levels above the graph.

- Database

The database view aggregates database instances in Oracle RAC cluster databases into a single cell labeled with the Oracle RAC cluster database target name. This enables you to easily compare the total database load in Oracle RAC environments.

- Instance

The instance view displays all database instances separately, but Oracle RAC instances are grouped together as sub-cells of the Oracle RAC database target. This view is essentially a two-level tree map, where the database level is the primary division, and the instance within the database is the secondary division. This allows load comparison of instances within Oracle RAC databases; for instance, to easily spot load imbalances across instances.

- Pluggable Database

Although the PDB option is shown, PDB is not supported for Oracle Sharding in the current release.

Notice that the cells of the graph are not identical in size. Each cell corresponds to a shard target, either an instance or a cluster database. The cell size (its area) is proportional to the target database's load measured in average active sessions, so that targets with a higher load have larger cell sizes. Cells are ordered by size from left to right and top to bottom. Therefore, the target with the highest load always appears as the upper leftmost cell in the graph.

You can hover your mouse pointer over a particular cell of the graph to view the total active load (I/O to CPU ration), CPU, I/O, and wait times. Segments of the graph are colored to indicate the dominant load:

- Green indicates that CPU time dominates the load
- Blue indicates that I/O dominates the load
- Yellow indicates that WAIT dominates the load

### Members

The Members pane, in the lower left of the page, shows some relevant information about each of the components.

**Figure 57-4 Sharded Database Members pane**

| Name                   | Status | Shardspace    | Shardgroup      | Data Guard Role | Region | Deployed |
|------------------------|--------|---------------|-----------------|-----------------|--------|----------|
| shard1nq.us.oracle.com | ▲      | shardspaceora | shardgroup_east | Primary         | east   | ✓        |
| shard2nq.us.oracle.co  | ▲      | shardspaceora | shardgroup_west | Standby         | west   | ✓        |

The pane is divided into tabs for each component: Shardspaces, Shardgroups, Shard Directors, and Shards. Click on a tab to view the information about each type of component

- Shardspaces

The Shardspaces tab displays the shardspace names, status, number of chunks, and Data Guard protection mode. The shardspace names can be clicked to reveal more details about the selected shardspace.

- Shardgroups

The Shardgroups tab displays the shardgroup names, status, the shardspace to which it belongs, the number of chunks, Data Guard role, and the region to which

it belongs. You can click the shardgroup and shardspace names to reveal more details about the selected component.

- **Shard Directors**

The Shard Directors tab displays the shard director names, status, region, host, and Oracle home. You can click the shard director names can be clicked to reveal more details about the selected shard director.

- **Shards**

The Shards tab displays the shard names, deploy status, status, the shardspaces and shardgroups to which they belong, Data Guard roles, and the regions to which they belong. In the Names column, you can expand the Primary shards to display the information about its corresponding Standby shard. You can hover the mouse over the Deployed column icon and the deployment status details are displayed. You can click on the shard, shardspace, and shardgroup names to reveal more details about the selected component.

## Services

The Services pane, in the lower right of the page, shows the names, status, and Data Guard role of the sharded database services. Above the list is shown the total number of services and an icon showing how many services are in a particular status. You can hover your mouse pointer over the icon to read a description of the status icon.

**Figure 57-5 Sharded Database Services pane**

| Name                       | Status | Data Guard Role  |
|----------------------------|--------|------------------|
| employees_report_year_2015 | ▲      | Physical Stan... |
| employees_report_year_2016 | ▲      | Primary          |

## Incidents

The Incidents pane displays messages and warnings about the various components in the sharded database environment. More information about how to use this pane is in the Cloud Control online help.

## Sharded Database Menu

The Sharded Database menu, located in the top left corner, provides you with access to administrate the sharded database components.

## Target Navigation

The Target Navigation pane gives you easy access to more details about any of the components in the sharded database.

Clicking the navigation tree icon on the upper left corner of the page opens the Target Navigation pane. This pane shows all of the discovered components in the sharded database in tree form.

Expanding a shardspace reveals the shardgroups in them. Expanding a shardgroup reveals the shards in that shardgroup.

Any of the component names can be clicked to view more details about them.

- [Discovering Sharded Database Components](#)

In Enterprise Manager Cloud Control, you can discover the shard catalog and shard databases, then add the shard directors, sharded databases, shardspaces, and shardgroups using guided discovery.

### 57.1.2.1 Discovering Sharded Database Components

In Enterprise Manager Cloud Control, you can discover the shard catalog and shard databases, then add the shard directors, sharded databases, shardspaces, and shardgroups using guided discovery.

As a prerequisite, you must use Cloud Control to discover the shard director hosts and the shard catalog database. Because the catalog database and each of the shards is a database itself, you can use standard database discovery procedures.

Monitoring the shards is only possible when the individual shards are discovered using database discovery. Discovering the shards is optional to discovering a sharded database, because you can have a sharded database configuration without the shards.

1. In Enterprise Manager Cloud Control, select **Setup**, choose **Add Target**, then choose **Add Target Manually**.
2. In the Add Targets Manually page, click **Add Using Guided Process** in the Add Non-Host Target Using Guided Process panel.
3. In the Add Using Guided Process dialog, locate and select **Sharded Database**, and click **Add**.
4. In the Add Sharded Database: Catalog Database page, click the browse icon next to **Catalog Database** to locate the SDB catalog database.
5. In the Select Targets dialog, click the target name corresponding to the catalog database and click **Select**.

The Catalog Database and Monitoring Credentials fields are filled in if they exist. The monitoring credential is used to query the catalog database to get the configuration information. The monitoring user is granted **GDS\_CATALOG\_SELECT** role and has read only privileges on the catalog repository tables.

Click **Next** to proceed to the next step.

In the Add Sharded Database: Components page you are shown information about the sharded database that is managed by the catalog database, including the sharded database name, its domain name, the sharding method employed on the sharded database, and a list of discovered shard directors.

6. To set monitoring credentials on a shard director, click the plus sign icon on the right side of the list entry.

A dialog opens allowing you to set the credentials.

Click **OK** to close the dialog, and click **Next** to proceed to the next step.

7. In the Add Sharded Database: Review page, verify that all of the shard directors, shardspaces, and shardgroups were discovered.

8. Click **Submit** to finalize the steps.

An Enterprise Manager Deployment Procedure is submitted and you are returned to the Add Targets Manually page.

At the top of the page you will see information about the script that was submitted to add all of the discovered components to Cloud Control.

9. Click the link to view the provisioning status of the sharded database components.

In another browser window you can go to the Cloud Control All Targets page to observe the status of the sharded database.

When the target discovery procedure is finished, sharded database targets are added in Cloud Control. You can open the sharded database in Cloud Control to monitor and manage the components.

## 57.2 Backing Up and Recovering a Sharded Database

Because shards are hosted on individual Oracle databases, you can use Oracle Maximum Availability best practices to back up and restore shards individually.

If you are using Data Guard and Oracle Active Data Guard for SDB high availability, be sure to take observers offline and disable Fast Start Failover before taking a primary or standby database offline.

Contact Oracle Support for specific steps to recover a shard in the event of a disaster.

### See Also:

[Oracle Maximum Availability Architecture](#) for MAA best practices white papers

## 57.3 Patching a Sharded Database

Applying an Oracle patch to a sharded database environment can be done on a single shard or all shards; however, the method you use depends on the replication option used for the environment and the type of patch being applied.

Most patches can be applied to a single shard at a time; however, some patches should be applied across all shards. Use Oracle's best practices for applying patches

to single shards just as you would a non-sharded database, keeping in mind the replication method that is being used with the SDB. Oracle `opatchauto` can be used to apply patches to multiple shards at a time, and can be done in a rolling manner. Data Guard configurations are applied one after another, and in some cases (depending on the patch) you can use Standby First patching. If a patch addresses an issue with multi-shard queries, replication, or the sharding infrastructure, it should be applied to all of the shards in the SDB.

## 57.4 Modifying a Sharded Database Schema

When making changes to duplicated tables or sharded tables in a sharded database, these changes should be done from the shard catalog database.

Before executing any DDL operations on a sharded database, enable sharded DDL with

```
ALTER SESSION ENABLE SHARD DDL;
```

This statement ensures that the DDL changes will be propagated to each shard in the sharded database.

The DDL changes that are propagated are commands that are defined as “schema related,” which include operations such as `ALTER TABLE` and `CREATE TRIGGER`. There are other operations that are propagated to each shard, such as the `CREATE`, `ALTER`, `DROP` user commands for simplified user management, and `TABLESPACE` operations to simplify the creation of tablespaces on multiple shards.

`GRANT` and `REVOKE` operations can be done from the shard catalog and are propagated to each shard, providing you have enabled shard DDL for the session. If more granular control is needed you can issue the command directly on each shard.

Operations such as DBMS package calls or similar operations are not propagated. For example, operations gathering statistics on the shard catalog are not propagated to each shard.

If you perform an operation that requires a lock on a table, such as adding a not null column, it is important to remember that each shard needs to obtain the lock on the table in order to perform the DDL operation. Oracle’s best practices for applying DDL in a single instance apply to sharded environments.

Multi-shard queries, which are executed on the shard catalog, issue remote queries across database connections on each shard. In this case it is important to ensure that the user has the appropriate privileges on each of the shards, whether or not the query will return data from that shard.

### See Also:

## 57.5 Shard Management

You can manage shards in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control and GDSCTL.

The following topics describe shard management concepts and tasks:

- [About Adding Shards](#)  
New shards can be added to an existing sharded database environment to scale out and to improve fault tolerance.
- [Resharding and Hot Spot Elimination](#)  
The process of redistributing data between shards, triggered by a change in the number of shards, is called resharding. Automatic resharding is a feature of the system-managed sharding method that provides elastic scalability of an SDB.
- [Removing a Shard From the Pool](#)  
It may become necessary to remove a shard from the sharded database environment, either temporarily or permanently, without losing any data that resides on that shard.
- [Adding Standby Shards](#)  
You can add Data Guard standby shards to an Oracle Sharding environment; however there are some limitations.
- [Managing Shards with Oracle Enterprise Manager Cloud Control](#)  
You can manage database shards using Oracle Enterprise Manager Cloud Control
- [Managing Shards with GDSCTL](#)  
You can manage shards in your Oracle Sharding deployment using the GDSCTL command-line utility.

### 57.5.1 About Adding Shards

New shards can be added to an existing sharded database environment to scale out and to improve fault tolerance.

For fault tolerance, it is beneficial to have many smaller shards than a few very large ones. As an application matures and the amount of data increases, you can add an entire shard or multiple shards to the SDB to increase capacity.

When you add a shard to a sharded database, if the environment is sharded by consistent hash, then chunks from existing shards are automatically moved to the new shard to rebalance the sharded environment.

Oracle Enterprise Manager Cloud Control can be used to help identify chunks that would be good candidates to move, or split and move to the new shard.

When you add a shard to the environment, verify that the standby server is ready, and after the new shard is in place take backups of any shards that have been involved in a `move chunk` operation.

### 57.5.2 Resharding and Hot Spot Elimination

The process of redistributing data between shards, triggered by a change in the number of shards, is called resharding. Automatic resharding is a feature of the system-managed sharding method that provides elastic scalability of an SDB.

Sometimes data in an SDB needs to be migrated from one shard to another. Data migration across shards is required in the following cases:

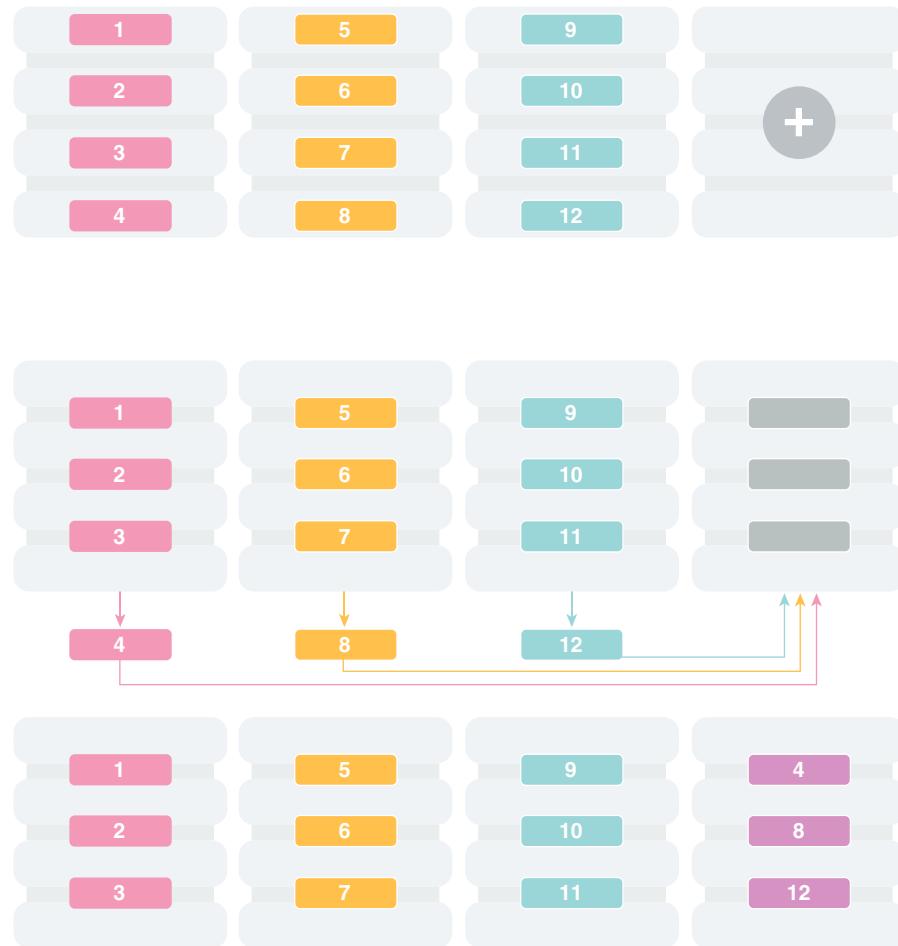

- When one or multiple shards are added to or removed from an SDB
- When there is skew in the data or workload distribution across shards

The unit of data migration between shards is the chunk. Migrating data in chunks guarantees that related data from different sharded tables are moved together.

When a shard is added to or removed from an SDB, multiple chunks are migrated to maintain a balanced distribution of chunks and workload across shards.

Depending on the sharding method, resharding happens automatically (system-managed) or is directed by the user (composite). The following figure shows the stages of automatic resharding when a shard is added to an SDB with three shards.

**Figure 57-6 Resharding an SDB**

A particular chunk can also be moved from one shard to another, when data or workload skew occurs, without any change in the number of shards. In this case, chunk migration can be initiated by the database administrator to eliminate the hot spot.

RMAN Incremental Backup, Transportable Tablespace, and Oracle Notification Service technologies are used to minimize impact of chunk migration on application availability. A chunk is kept online during chunk migration. There is a short period of time (a few seconds) when data stored in the chunk is available for read-only access only.

FAN-enabled clients receive a notification when a chunk is about to become read-only in the source shard, and again when the chunk is fully available in the destination shard on completion of chunk migration. When clients receive the `chunk read-only` event, they can either repeat connection attempts until the chunk migration is completed, or access the read-only chunk in the source chunk. In the latter case, an attempt to write to the chunk will result in a run-time error.

 **See Also:**

[Adding Shards to a System-Managed SDB](#)

[Sharding Methods](#)

### 57.5.3 Removing a Shard From the Pool

It may become necessary to remove a shard from the sharded database environment, either temporarily or permanently, without losing any data that resides on that shard.

For example, removing a shard might become necessary if a sharded environment is scaled down after a busy holiday, or to replace a server or infrastructure within the data center. Prior to decommissioning the shard, you must move all of the chunks from the shard to other shards that will remain online. As you move them, try to maintain a balance of data and activity across all of the shards.

If the shard is only temporarily removed, keep track of the chunks moved to each shard so that they can be easily identified and moved back once the maintenance is complete.

 **See Also:**

[About Moving Chunks](#)

*Oracle Database Global Data Services Concepts and Administration Guide*  
for information about using the `GDSCTL REMOVE SHARD` command

### 57.5.4 Adding Standby Shards

You can add Data Guard standby shards to an Oracle Sharding environment; however there are some limitations.

When using Data Guard as the replication method for a sharded database, Oracle Sharding supports only the addition of a primary or physical standby shard; other types of Data Guard standby databases are not supported when adding a new standby to

the sharded database. However, a shard that is already part of the sharded database can be converted from a physical standby to a snapshot standby. When converting a physical standby to a snapshot standby, the following steps should be followed:

1. Stop all global services on the shard using the GDSCTL command `STOP SERVICE`.
2. Disable all global services on the shard using the GDSCTL command `DISABLE SERVICE`.
3. Convert the shard to a snapshot standby using the procedure described in the Data Guard documentation.

At this point, the shard remains part of the sharded database, but will not accept connections which use the sharding key.

If the database is converted back to a physical standby, the global services can be enabled and started again, and the shard becomes an active member of the sharded database.

 **See Also:**

*Oracle Data Guard Concepts and Administration*

## 57.5.5 Managing Shards with Oracle Enterprise Manager Cloud Control

You can manage database shards using Oracle Enterprise Manager Cloud Control

To manage shards using Cloud Control, they must first be discovered. Because each database shard is a database itself, you can use standard Cloud Control database discovery procedures.

The following topics describe shard management using Oracle Enterprise Manager Cloud Control:

- [Validating a Shard](#)  
Validate a shard prior to adding it to your Oracle Sharding deployment.
- [Adding Primary Shards](#)  
Use Oracle Enterprise Manager Cloud Control to add a primary shards to your Oracle Sharding deployment.
- [Adding Standby Shards](#)  
Use Oracle Enterprise Manager Cloud Control to add a standby shards to your Oracle Sharding deployment.
- [Deploying Shards](#)  
Use Oracle Enterprise Manager Cloud Control to deploy shards that have been added to your Oracle Sharding environment.

### 57.5.5.1 Validating a Shard

Validate a shard prior to adding it to your Oracle Sharding deployment.

You can use Oracle Enterprise Manager Cloud Control to validate shards before adding them to your Oracle Sharding deployment. You can also validate a shard after deployment to confirm that the settings are still valid later in the shard lifecycle. For example, after a software upgrade you can validate existing shards to confirm correctness of their parameters and configuration.

To validate shards with Cloud Control, they should be existing targets that are being monitored by Cloud Control.

1. From a shardgroup management page, open the **Shardgroup** menu, located in the top left corner of the shardgroup target page, and choose **Manage Shards**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select a shard from the list and click **Validate**.
4. Click OK to confirm you want to validate the shard.
5. Click the link in the **Information** box at the top of the page to view the provisioning status of the shard.

When the shard validation script runs successfully check for errors reported in the output.

### 57.5.5.2 Adding Primary Shards

Use Oracle Enterprise Manager Cloud Control to add a primary shards to your Oracle Sharding deployment.

Primary shards should be existing targets that are being monitored by Cloud Control.

It is highly recommended that you validate a shard before adding it to your Oracle Sharding environment. You can either use Cloud Control to validate the shard (see [Validating a Shard](#)), or run the DBMS\_GSM\_FIX.validateShard procedure against the shard using SQL\*Plus (see [Validating a Shard](#)).

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Add Primary Shards**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select **Deploy All Shards in the sharded database** to deploy all shards added to the sharded database configuration.

The deployment operation validates the configuration of the shards and performs final configuration steps. Shards can be used only after they are deployed.

4. Click **Add**.
5. In the **Database** field of the Shard Details dialog, select a shard and click **Select**.
6. In a composite Oracle Sharding environment you can select the shardspace to which to add the shard.

7. Click **OK**.
8. Enter the GSMUSER credentials if necessary, then click **Next**.
9. Indicate when the ADD SHARD operation should occur, then click **Next**.
  - **Immediately**: the shard is provisioned upon confirmation
  - **Later**: schedule the timing of the shard addition using the calendar tool in the adjacent field
10. Review the configuration of the shard to be added and click **Submit**.
11. Click the link in the **Information** box at the top of the page to view the provisioning status of the shard.

If you did not select **Deploy All Shards in the sharded database** in the procedure above, deploy the shard in your Oracle Sharding deployment using the [Deploying Shards](#) task.

### 57.5.5.3 Adding Standby Shards

Use Oracle Enterprise Manager Cloud Control to add a standby shards to your Oracle Sharding deployment.

Standby shards should be existing targets that are being monitored by Cloud Control.

It is highly recommended that you validate a shard before adding it to your Oracle Sharding environment. You can either use Cloud Control to validate the shard (see [Validating a Shard](#)), or run the DBMS\_GSM\_FIX.validateShard procedure against the shard using SQL\*Plus (see [Validating a Shard](#)).

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Add Standby Shards**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select **Deploy All Shards in the sharded database** to deploy all shards added to the sharded database configuration.

The deployment operation validates the configuration of the shards and performs final configuration steps. Shards can be used only after they are deployed.

4. Choose a primary shard for which the new shard will act as a standby in the **Primary Shards** list.
5. Click **Add**.
6. In the **Database** field of the Shard Details dialog, select the standby shard.
7. Select the shardgroup to which to add the shard.

Only shardgroups that do not already contain a standby for the selected primary are shown.

8. Click **OK**.
9. Enter the GSMUSER credentials if necessary, then click **Next**.
10. Indicate when the ADD SHARD operation should occur, then click **Next**.
  - **Immediately**: the shard is provisioned upon confirmation

- **Later:** schedule the timing of the shard addition using the calendar tool in the adjacent field
11. Review the configuration of the shard to be added and click **Submit**.
  12. Click the link in the **Information** box at the top of the page to view the provisioning status of the shard.

If you did not select **Deploy All Shards in the sharded database** in the procedure above, deploy the shard in your Oracle Sharding deployment using the [Deploying Shards](#) task.

#### 57.5.5.4 Deploying Shards

Use Oracle Enterprise Manager Cloud Control to deploy shards that have been added to your Oracle Sharding environment.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Deploy Shards**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select the **Perform Rebalance** check box to redistribute data between shards automatically after the shard is deployed.  
If you want to move chunks to the shard manually, uncheck this box.
4. Click **Submit**.
5. Click the link in the **Information** box at the top of the page to view the provisioning status of the shard.

#### 57.5.6 Managing Shards with GDSCTL

You can manage shards in your Oracle Sharding deployment using the GDSCTL command-line utility.

The following topics describe shard management using GDSCTL:

- [Validating a Shard](#)  
Before adding a newly created shard to a sharding configuration, you must validate that the shard has been configured correctly for the sharding environment.
- [Adding Shards to a System-Managed SDB](#)  
Adding shards to a system-managed SDB elastically scales the SDB. In a system-managed SDB chunks are automatically rebalanced after the new shards are added.

#### 57.5.6.1 Validating a Shard

Before adding a newly created shard to a sharding configuration, you must validate that the shard has been configured correctly for the sharding environment.

Before you run ADD SHARD, run the validateShard procedure against the database that will be added as a shard. The validateShard procedure verifies that the target database has the initialization parameters and characteristics needed to act successfully as a shard.

The validateShard procedure analyzes the target database and reports any issues that need to be addressed prior to running GDSCTL ADD SHARD on that database. The validateShard procedure does not make any changes to the database or its parameters; it only reports information and possible issues.

The validateShard procedure can also be run after the deployment of a shard to confirm that the settings are still valid later in the shard lifecycle. For example, after a software upgrade or after shard deployment, validateShard can be run on existing shards to confirm correctness of their parameters and configuration.

Run validateShard as follows:

```
sqlplus / as sysdba
SQL> set serveroutput on
SQL> execute dbms_gsm_fix.validateShard
```

The following is an example of the output.

```
INFO: Data Guard shard validation requested.
INFO: Database role is PRIMARY.
INFO: Database name is DEN27B.
INFO: Database unique name is den27b.
INFO: Database ID is 718463507.
INFO: Database open mode is READ WRITE.
INFO: Database in archivelog mode.
INFO: Flashback is on.
INFO: Force logging is on.
INFO: Database platform is Linux x86 64-bit.
INFO: Database character set is WE8DEC. This value must match the
character set of the catalog database.
INFO: 'compatible' initialization parameter validated successfully.
INFO: Database is not a multitenant container database.
INFO: Database is using a server parameter file (spfile).
INFO: db_create_file_dest set to: '<ORACLE_BASE>/oracle/dbs2'
INFO: db_recovery_file_dest set to: '<ORACLE_BASE>/oracle/dbs2'
INFO: db_files=1000. Must be greater than the number of chunks and/or
tablespaces to be created in the shard.
INFO: dg_broker_start set to TRUE.
INFO: remote_login_passwordfile set to EXCLUSIVE.
INFO: db_file_name_convert set to: '/dbs/dt, /dbs/bt, dbs2/DEN27D/, dbs2/
DEN27B/'
INFO: GSMUSER account validated successfully.
INFO: DATA_PUMP_DIR is '<ORACLE_BASE>//oracle/dbs2'.
```

Any lines tagged with INFO are informational in nature and confirm correct settings. Lines tagged with WARNING may or may not be issues depending on your configuration. For example, issues related to Data Guard parameters are reported, but if your configuration will only include primary databases, then any Data Guard issues can be ignored. Finally, any output with the ERROR tag must be corrected for the shard to deploy and operate correctly in a sharding configuration.

## 57.5.6.2 Adding Shards to a System-Managed SDB

Adding shards to a system-managed SDB elastically scales the SDB. In a system-managed SDB chunks are automatically rebalanced after the new shards are added.

To prepare a new shard host, do all of the setup procedures as you did for the initial sharded database environment including:

- [Installing Oracle Database Software](#)
  - Registering remote scheduler agents as described in [Setting Up the Oracle Sharding Management and Routing Tier](#)
1. Connect to a shard director host, and verify the environment variables.

```
$ ssh os_user@shard_director_home
$ env |grep ORA
ORACLE_BASE=/u01/app/oracle
ORACLE_HOME=/u01/app/oracle/product/12.2.0/gsmhome_1
```

2. Set the global service manager for the current session, and specify the credentials to administer it.

```
$ gdsctl
GDSCTL> set gsm -gsm sharddirector1
GDSCTL> connect mysdbadmin/mysdbadmin_password
```

3. Verify the current shard configuration.

```
GDSCTL> config shard
Name Shard Group Status State Region
Availability

sh1 primary_shardgroup Ok Deployed region1
ONLINE
sh2 standby_shardgroup Ok Deployed region2
READ_ONLY
sh3 primary_shardgroup Ok Deployed region1
ONLINE
sh4 standby_shardgroup Ok Deployed region2
READ_ONLY
```

4. Specify the shard group, destination, and the credentials for each new shard.

In the examples the new shard hosts are called shard5 and shard6, and they are using the default templates for NETCA and DBCA.

```
GDSCTL> add invitednode shard5
GDSCTL> create shard -shardgroup primary_shardgroup -destination shard5
-credential
os_credential -sys_password
GDSCTL> add invitednode shard6
GDSCTL> create shard -shardgroup standby_shardgroup -destination shard6
-credential os_credential -sys_password
```

While creating the shards, you can also set the SYS password in the `create shard` using `-sys_password` as shown in the above example. This sets the SYS password after the shards are created during DEPLOY.

 **Note:**

See this [note](#) for information about automatic VNCR registration.

5. Run the `DEPLOY` command to create the shards and the replicas.

```
GDSCTL> deploy
```

6. Verify that the new shards are deployed.

```
GDSCTL> config shard
Name Shard Group Status State Region
Availability

sh1 primary_shardgroup Ok Deployed region1
ONLINE
sh2 standby_shardgroup Ok Deployed region2
READ_ONLY
sh3 primary_shardgroup Ok Deployed region1
ONLINE
sh4 standby_shardgroup Ok Deployed region2
READ_ONLY
sh5 primary_shardgroup Ok Deployed region1
ONLINE
sh6 standby_shardgroup Ok Deployed region2
READ_ONLY
```

7. Check the chunk configuration every minute or two to see the progress of automatic rebalancing of chunks.

```
$ gdsctl config chunks -show_Reshard
```

```
Chunks

Database From To

sh1 1 4
sh2 1 4
sh3 7 10
sh4 7 10
sh5 5 6
sh5 11 12
sh6 5 6

## 57.6 Chunk Management

You can manage chunks in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control and GDSCTL.

The following topics describe chunk management concepts and tasks:

- [About Moving Chunks](#)

Sometimes it becomes necessary to move a chunk from one shard to another. To maintain scalability of the sharded environment, it is important to attempt to maintain an equal distribution of the load and activity across all shards.

- [Moving Chunks](#)

You can move chunks from one shard to another in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

- [About Splitting Chunks](#)

Splitting a chunk in a sharded database is required when chunks become too big, or only part of a chunk must be migrated to another shard.

- [Splitting Chunks](#)

You can split chunks in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

## 57.6.1 About Moving Chunks

Sometimes it becomes necessary to move a chunk from one shard to another. To maintain scalability of the sharded environment, it is important to attempt to maintain an equal distribution of the load and activity across all shards.

As the environment matures in a composite SDB, some shards may become more active and have more data than other shards. In order to keep a balance within the environment you must move chunks from more active servers to less active servers. There are other reasons for moving chunks:

- When a shard becomes more active than other shards, you can move a chunk to a less active shard to help redistribute the load evenly across the environment.
- When using range, list, or composite sharding, and you are adding a shard to a shardgroup.
- When using range, list, or composite sharding, and you are removing a shard from a shardgroup.
- After splitting a chunk it is often advisable to move one of the resulting chunks to a new shard.

When moving shards to maintain scalability, the ideal targets of the chunks are shards that are less active, or have a smaller portion of data. Oracle Enterprise Manager and AWR reports can help you identify the distribution of activity across the shards, and help identify shards that are good candidates for chunk movement.

 **Note:**

Any time a chunk is moved from one shard to another, you should make a full backup of the databases involved in the operation (both the source of the chunk move, and the target of the chunk move.)

 **See Also:**

*Oracle Database Global Data Services Concepts and Administration Guide*  
for information about using the GDSCTL MOVE CHUNK command

## 57.6.2 Moving Chunks

You can move chunks from one shard to another in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

1. From a shardspace management page, open the **Shardspace** menu, located in the top left corner of the Sharded Database target page, and choose **Manage Shardgroups**.
2. Select a shardgroup in the list and click **Move Chunks**.

3. In the Move Chunks dialog, select the source and destination shards between which to move the chunks.
4. Select the chunks that you want to move by choosing one of the options.
  - **Enter ID List:** enter a comma separates list of chunk ID numbers
  - **Select IDs From Table:** click the chunk IDs in the table
5. Indicate when the chunk move should occur.
  - **Immediately:** the chunk move is provisioned upon confirmation
  - **Later:** schedule the timing of the chunk move using the calendar tool in the adjacent field
6. Click **OK**.
7. Click the link in the **Information** box at the top of the page to view the provisioning status of the chunk move.

### 57.6.3 About Splitting Chunks

Splitting a chunk in a sharded database is required when chunks become too big, or only part of a chunk must be migrated to another shard.

Oracle Sharding supports the online split of a chunk. Theoretically it is possible to have a single chunk for each shard and split it every time data migration is required. However, even though a chunk split does not affect data availability, the split is a time-consuming and CPU-intensive operation because it scans all of the rows of the partition being split, and then inserts them one by one into the new partitions. For composite sharding, it is time consuming and may require downtime to redefine new values for the shard key or super shard key.

Therefore, it is recommended that you pre-create multiple chunks on each shard and split them either when the number of chunks is not big enough for balanced redistribution of data during re-sharding, or a particular chunk has become a hot spot.

Even with system-managed sharding, a single chunk may grow larger than other chunks or may become more active. In this case, splitting that chunk and allowing automatic resharding to move one of the resulting chunks to another shard maintains a more equal balanced distribution of data and activity across the environment.

 **See Also:**

*Oracle Database Global Data Services Concepts and Administration Guide*  
for information about using the GDSCTL SPLIT CHUNK command

### 57.6.4 Splitting Chunks

You can split chunks in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Shardspaces**.

2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select a shardspace in the list and click **Split Chunks**.
4. Select the chunks that you want to split by choosing one of the options.
  - **Enter ID List**: enter a comma separate list of chunk ID numbers
  - **Select IDs From Table**: click the chunk IDs in the table
5. Indicate when the chunk split should occur.
  - **Immediately**: the chunk split is provisioned upon confirmation
  - **Later**: schedule the timing of the chunk split using the calendar tool in the adjacent field
6. Click **OK**.
7. Click the link in the **Information** box at the top of the page to view the provisioning status of the chunk split.

When the chunk is split successfully the number of chunks is updated in the **Shardspaces** list. You might need to refresh the page to see the updates.

## 57.7 Shard Director Management

You can add, edit, and remove shard directors in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

The following topics describe shard director management tasks:

- [Creating a Shard Director](#)  
Use Oracle Enterprise Manager Cloud Control to create and add a shard director to your Oracle Sharding deployment.
- [Editing a Shard Director Configuration](#)  
Use Oracle Enterprise Manager Cloud Control to edit a shard director configuration in your Oracle Sharding deployment.
- [Removing a Shard Director](#)  
Use Oracle Enterprise Manager Cloud Control to remove shard directors from your Oracle Sharding deployment.

### 57.7.1 Creating a Shard Director

Use Oracle Enterprise Manager Cloud Control to create and add a shard director to your Oracle Sharding deployment.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Shard Directors**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Click **Create**, or select a shard director from the list and click **Create Like**.

Choosing **Create** opens the Add Shard Director dialog with default configuration values in the fields.

Choosing **Create Like** opens the Add Shard Director dialog with configuration values from the selected shard director in the fields. You must select a shard director from the list to enable the **Create Like** option.

4. Enter the required information in the Add Shard Director dialog, and click **OK**.

 **Note:**

If you do not want the shard director to start running immediately upon creation, you must uncheck the **Start Shard Director After Creation** checkbox.

5. Click **OK** on the confirmation dialog.
6. Click the link in the **Information** box at the top of the page to view the provisioning status of the shard director.

When the shard director is created successfully it appears in the **Shard Directors** list. You might need to refresh the page to see the updates.

## 57.7.2 Editing a Shard Director Configuration

Use Oracle Enterprise Manager Cloud Control to edit a shard director configuration in your Oracle Sharding deployment.

You can change the region, ports, local endpoint, and host credentials for a shard director in Cloud Control. You cannot edit the shard director name, host, or Oracle home.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Shard Directors**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select a shard director from the list and click **Edit**.  
Note that you cannot edit the shard director name, host, or Oracle home.
4. Edit the fields, enter the GSMCATUSER password, and click **OK**.
5. Click the link in the **Information** box at the top of the page to view the provisioning status of the shard director configuration changes.

## 57.7.3 Removing a Shard Director

Use Oracle Enterprise Manager Cloud Control to remove shard directors from your Oracle Sharding deployment.

If the shard director you want to remove is the administrative shard director, as indicated by a check mark in that column of the **Shard Directors** list, you must choose another shard director to be the administrative shard director before removing it.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Shard Directors**.

2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select a shard director from the list and click **Delete**.
4. Click the link in the **Information** box at the top of the page to view the provisioning status of the shard director removal.

When the shard director is removed successfully it no longer appears in the **Shard Directors** list. You might need to refresh the page to see the changes.

## 57.8 Region Management

You can add, edit, and remove regions in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

The following topics describe region management tasks:

- [Creating a Region](#)  
Create sharded database regions in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.
- [Editing a Region Configuration](#)  
Edit sharded database region configurations in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.
- [Removing a Region](#)  
Remove sharded database regions in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

### 57.8.1 Creating a Region

Create sharded database regions in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Regions**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Click **Create**.
4. Enter a unique name for the region in the Create Region dialog.
5. Optionally, select a buddy region from among the existing regions.
6. Click **OK**.
7. Click the link in the **Information** box at the top of the page to view the provisioning status of the region.

When the region is created successfully it appears in the **Regions** list. You might need to refresh the page to see the updates.

## 57.8.2 Editing a Region Configuration

Edit sharded database region configurations in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

You can change the buddy region for a sharded database region in Cloud Control. You cannot edit the region name.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Regions**.
2. If prompted, enter the shard catalog credentials, select the shard director under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select a region from the list and click **Edit**.
4. Select or remove a buddy region, and click **OK**.
5. Click the link in the **Information** box at the top of the page to view the provisioning status of the region configuration changes.

When the region configuration is successfully updated the changes appear in the **Regions** list. You might need to refresh the page to see the updates.

## 57.8.3 Removing a Region

Remove sharded database regions in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Regions**.
2. If prompted, enter the shard catalog credentials, select the shard director under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Select a region from the list and click **Delete**.
4. Click the link in the **Information** box at the top of the page to view the provisioning status of the region removal.

When the region configuration is successfully removed the changes appear in the **Regions** list. You might need to refresh the page to see the updates.

## 57.9 Shardspace Management

You can add, edit, and remove shardspaces in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

The following topics describe shardspace management tasks:

- [Creating a Shardspace](#)  
Create shardspaces in your composite Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

## 57.9.1 Creating a Shardspace

Create shardspaces in your composite Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

Only databases that are sharded using the composite method can have more than one shardspace. A system-managed sharded database can have only one shardspace.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Shardspaces**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Click **Create**.

 **Note:**

This option is disabled in the Shardspaces page for a system-managed sharded database.

4. Enter the values in the fields in the Add Shardspace dialog, and click **OK**.
  - **Name**: enter a unique name for the shardspace (required)
  - **Chunks**: Enter the number of chunks that should be created in the shardspace (default 120)
  - **Protection Mode**: select the Data Guard protection mode (default Maximum Performance)
5. Click the link in the **Information** box at the top of the page to view the provisioning status of the shardspace.

When the shardspace is created successfully it appears in the **Shardspaces** list. You might need to refresh the page to see the updates.

## 57.10 Shardgroup Management

You can add, edit, and remove shardgroups in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

The following topics describe shardgroup management tasks:

- [Creating a Shardgroup](#)  
Create shardgroups in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

## 57.10.1 Creating a Shardgroup

Create shardgroups in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

1. Select a shardspace to which to add the shardgroup.

2. Open the **Shardspace** menu, located in the top left corner of the shardspace target page, and choose **Manage Shardgroups**.
3. Click **Create**.
4. Enter values in the Create Shardgroup dialog, and click **OK**.
5. Click the link in the **Information** box at the top of the page to view the provisioning status of the shardgroup.

For example, with the values entered in the screenshots above, the following command is run:

```
GDSCTL Command: ADD SHARDGROUP -SHARDGROUP 'north' -SHARDSPACE
'shardspaceora' -REGION 'north' -DEPLOY_AS 'STANDBY'
```

When the shardgroup is created successfully it appears in the **Manage Shardgroups** list. You might need to refresh the page to see the updates.

## 57.11 Services Management

You can manage services in your Oracle Sharding deployment with Oracle Enterprise Manager Cloud Control.

To manage Oracle Sharding services, open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Services**. On the Services page, using the controls at the top of the list of services, you can start, stop, enable, disable, create, edit, and delete services.

Selecting a service opens a service details list which displays the hosts and shards on which the service is running, and the status, state, and Data Guard role of each of those instances. Selecting a shard in this list allows you to enable, disable, start, and stop the service on the individual shards.

The following topics describe services management tasks:

- [Creating a Service](#)  
Create services in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

### 57.11.1 Creating a Service

Create services in your Oracle Sharding deployment using Oracle Enterprise Manager Cloud Control.

1. Open the **Sharded Database** menu, located in the top left corner of the Sharded Database target page, and choose **Services**.
2. If prompted, enter the shard catalog credentials, select the shard director to manage under **Shard Director Credentials**, select the shard director host credentials, and log in.
3. Click **Create**, or select a service from the list and click **Create Like**.

Choosing **Create** opens the Create Service dialog with default configuration values in the fields.

Choosing **Create Like** opens the Create Like Service dialog with configuration values from the selected service in the fields. You must select a service from the list to enable the **Create Like** option.

4. Enter the required information in the dialog, and click **OK**.

 **Note:**

If you do not want the service to start running immediately upon creation, you must uncheck the **Start service on all shards after creation** checkbox.

5. Click the link in the **Information** box at the top of the page to view the provisioning status of the service.

When the service is created successfully it appears in the **Services** list. You might need to refresh the page to see the updates.

# Part VIII

## Managing Read-Only Materialized Views

Read-only materialized views can provide read-only access to the master table's data. You can create and manage read-only materialized views.

- [Read-Only Materialized View Concepts](#)  
Understand the concepts related to read-only materialized views.
- [Read-Only Materialized View Architecture](#)  
Several objects are used in materialized view replication. Some of these objects are optional and are used only as needed to support the created materialized view environment. For example, if you have a complex materialized view that cannot be fast refreshed, then you might not have a materialized view log at the master database.
- [Planning for Read-Only Materialized Views](#)  
Before you begin to plan your read-only materialized view environment, it is important to understand the concepts and architecture related to materialized views. After you understand concepts and architecture of read-only materialized views, there are important considerations for planning a read-only materialized view environment.
- [Creating and Managing Read-Only Materialized Views](#)  
You can create and manage read-only materialized views and refresh groups. You can also refresh materialized views.
- [Troubleshooting Problems with Read-Only Materialized Views](#)  
You can diagnose and solve problems with database links, materialized view creation, and materialized view refresh.

# Read-Only Materialized View Concepts

Understand the concepts related to read-only materialized views.

- **Replication Databases**

**Replication** is the process of copying and maintaining database objects, such as tables, in multiple databases that comprise a distributed database system. One method that supports replication is read-only materialized views.

- **Read-Only Materialized Views**

A **read-only materialized view** contains a complete or partial copy of a target master table from a single point in time. A partial copy can include a subset of row, a subset of columns, or both.

- **The Uses of Materialized Views**

You can use materialized views to achieve goals such as easing network loads, enabling data subsetting, and enabling disconnected computing.

- **Available Materialized Views**

Available materialized views include primary key materialized views, object materialized views, ROWID materialized views, and complex materialized views.

- **Users and Privileges Related to Materialized Views**

The users related to materialized views include the creator, the refresher, and the owner. The privileges required to perform operations on materialized views depend on the type of user performing the operation.

- **Data Subsetting with Materialized Views**

You can use row subsetting and column subsetting to configure materialized views reflect a subset of the data in the master table.

- **Materialized View Refresh**

To ensure that a materialized view is consistent with its master table, you must **refresh** the materialized view periodically.

- **Refresh Groups**

When it is important for materialized views to be transactionally consistent with each other, you can organize them into **refresh groups**.

- **Materialized View Log**

A **materialized view log** is a table at the database that contains materialized view's master table. It records all of the DML changes to the master table.

- **Materialized Views and User-Defined Data Types**

There are special considerations for materialized views with user-defined data types.

- **Materialized View Registration at a Master Database**

At the master database, an Oracle Database automatically registers information about a materialized view based on its master table(s).

## 58.1 Replication Databases

**Replication** is the process of copying and maintaining database objects, such as tables, in multiple databases that comprise a distributed database system. One method that supports replication is read-only materialized views.

Replication environments support two basic types of databases: **master databases** and **materialized view databases**. Materialized view databases contain an image, or materialized view, of the table data from a certain point in time. The table on which a materialized view is defined is the **master table** for the materialized view. Typically, a materialized view is refreshed periodically to synchronize it with its master table.

You can organize materialized views into **refresh groups**. Materialized views in a refresh group are refreshed at the same time to ensure that the data in all materialized views in the refresh group correspond to the same transactionally consistent point in time.

 **Note:**

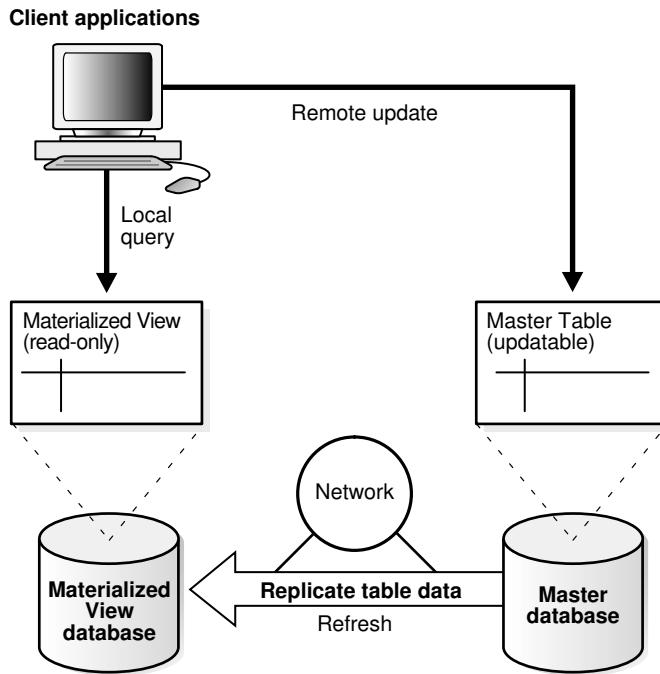

Oracle GoldenGate is Oracle's full-featured solution for replication. See the Oracle GoldenGate documentation for more information.

## 58.2 Read-Only Materialized Views

A **read-only materialized view** contains a complete or partial copy of a target master table from a single point in time. A partial copy can include a subset of row, a subset of columns, or both.

Read-only materialized views can provide read-only access to the master table's data. Applications can query data from read-only materialized views to avoid network access to the master database, regardless of network availability. However, applications throughout the system must access data at the master database to perform data manipulation language changes (DML). [Figure 58-1](#) illustrates basic, read-only replication.

**Figure 58-1 Read-Only Materialized View**

Materialized views provide the following benefits:

- Enable local access, which improves response times and availability
- When the materialized view is in a different database than its source, offload queries from the master database, because users can query the local materialized view instead
- Increase data security by enabling you to replicate only a selected subset of the target master's data set

Users can synchronize (refresh) read-only materialized views on demand. When users refresh read-only materialized views, they receive any changes that happened on the master table since the last refresh.

## 58.3 The Uses of Materialized Views

You can use materialized views to achieve goals such as easing network loads, enabling data subsetting, and enabling disconnected computing.

- **Ease Network Loads**  
If one of your goals is to reduce network loads, then you can use materialized views to distribute your corporate database to regional databases.
- **Enable Data Subsetting**  
Materialized views enable you to replicate data based on column- and row-level subsetting.
- **Enable Disconnected Computing**  
Materialized views do not require a dedicated network connection.

### 58.3.1 Ease Network Loads

If one of your goals is to reduce network loads, then you can use materialized views to distribute your corporate database to regional databases.

Instead of the entire company accessing a single database server, user load is distributed across multiple database servers. To decrease the amount of data that is replicated, a materialized view can be a subset of a master table.

### 58.3.2 Enable Data Subsetting

Materialized views enable you to replicate data based on column- and row-level subsetting.

Data subsetting enables you to replicate information that pertains only to a particular database. For example, if you have a regional sales office, then you might replicate only the data that is needed in that region, thereby cutting down on unnecessary network traffic.

Both row and column subsetting enable you to create materialized views that contain a partial copy of the data at a master table. Row subsetting enables you to include only the rows that are needed from the masters in the materialized views by using a `WHERE` clause. Column subsetting enables you to include only the columns that are needed from the masters in the materialized views. You do this by specifying particular columns in the `SELECT` statement during materialized view creation.

### 58.3.3 Enable Disconnected Computing

Materialized views do not require a dedicated network connection.

Though you have the option of automating the refresh process by scheduling a job, you can manually refresh your materialized view on-demand, which is an ideal solution for queries running on a laptop computer.

## 58.4 Available Materialized Views

Available materialized views include primary key materialized views, object materialized views, `ROWID` materialized views, and complex materialized views.

- [About the Available Materialized Views](#)  
Oracle offers several types of read-only materialized views to meet the needs of many different replication (and nonreplication) situations.
- [Primary Key Materialized Views](#)  
Primary key materialized views are the default type of materialized view.
- [Object Materialized Views](#)  
If a materialized view is based on an object table and is created using the `OF` type clause, then the materialized view is called an object materialized view.
- [ROWID Materialized Views](#)  
`ROWID` materialized view is based on the physical row identifiers (rowids) of the rows in a master table.

- [Complex Materialized Views](#)  
Complex materialized views cannot be fast refreshed.

### 58.4.1 About the Available Materialized Views

Oracle offers several types of read-only materialized views to meet the needs of many different replication (and nonreplication) situations.

Whenever you create a materialized view, regardless of its type, always specify the schema name of the table owner in the query for the materialized view. For example, consider the following CREATE MATERIALIZED VIEW statement:

```
CREATE MATERIALIZED VIEW hr.employees
 AS SELECT * FROM hr.employees@orcl.example.com;
```

Here, the schema `hr` is specified in the query.

### 58.4.2 Primary Key Materialized Views

Primary key materialized views are the default type of materialized view.

The following is an example of a SQL statement for creating a primary key materialized view:

```
CREATE MATERIALIZED VIEW oe.customers WITH PRIMARY KEY
 AS SELECT * FROM oe.customers@orcl.example.com;
```

Because primary key materialized views are the default, the following statement also results in a primary key materialized view:

```
CREATE MATERIALIZED VIEW oe.customers
 AS SELECT * FROM oe.customers@orcl.example.com;
```

Primary key materialized views can contain a subquery so that you can create a subset of rows at the remote materialized view database. A subquery is a query imbedded within the primary query, so that you have multiple `SELECT` statements in the `CREATE MATERIALIZED VIEW` statement. This subquery can be as simple as a basic `WHERE` clause or as complex as a multilevel `WHERE EXISTS` clause. Primary key materialized views that contain a selected class of subqueries can still be incrementally (or fast) refreshed, if each master referenced has a materialized view log. A fast refresh uses materialized view logs to update only the rows that have changed since the last refresh.

The following materialized view is created with a `WHERE` clause containing a subquery:

```
CREATE MATERIALIZED VIEW oe.orders REFRESH FAST AS
 SELECT * FROM oe.orders@orcl.example.com o
 WHERE EXISTS
 (SELECT * FROM oe.customers@orcl.example.com c
 WHERE o.customer_id = c.customer_id AND c.credit_limit > 10000);
```

This type of materialized view is called a subquery materialized view.

 **Note:**

To create this `oe.orders` materialized view, `credit_limit` must be logged in the master table's materialized view log. See "[Logging Columns in a Materialized View Log](#)" for more information.

 **See Also:**

- "[Materialized Views with Subqueries](#)" for more information about materialized views with subqueries
- "[Refresh Types](#)" for more information about fast refresh
- "[Materialized View Log](#)" for more information about materialized view logs
- *Oracle Database SQL Language Reference* for more information about subqueries

### 58.4.3 Object Materialized Views

If a materialized view is based on an object table and is created using the `OF type` clause, then the materialized view is called an object materialized view.

An object materialized view is structured in the same way as an object table. That is, an object materialized view is composed of row objects, and each row object is identified by an object identifier (OID) column.

 **See Also:**

- "[Materialized Views Based on Object Tables](#)"
- "[Creating Read-Only Materialized Views](#)" for an example that creates an object materialized view

### 58.4.4 ROWID Materialized Views

A ROWID materialized view is based on the physical row identifiers (rowids) of the rows in a master table.

ROWID materialized views can be used for materialized views based on master tables that do not have a primary key, or for materialized views that do not include all primary key columns of the master tables.

The following is an example of a `CREATE MATERIALIZED VIEW` statement that creates a ROWID materialized view:

```
CREATE MATERIALIZED VIEW oe.orders REFRESH WITH ROWID AS
SELECT * FROM oe.orders@orcl.example.com;
```

 **See Also:**

- "[Materialized View Log](#)" for more information about the differences between a ROWID and primary key materialized view
- *Oracle Database SQL Language Reference* for more information about the WITH ROWID clause in the CREATE MATERIALIZED VIEW statement

## 58.4.5 Complex Materialized Views

Complex materialized views cannot be fast refreshed.

- [About Complex Materialized Views](#)  
To be fast refreshed, the defining query for a materialized view must observe certain restrictions.
- [A Comparison of Simple and Complex Materialized Views](#)  
For certain applications, you might want to consider using a complex materialized view.

### 58.4.5.1 About Complex Materialized Views

To be fast refreshed, the defining query for a materialized view must observe certain restrictions.

If you require a materialized view whose defining query is more general and cannot observe the restrictions, then the materialized view is complex and cannot be fast refreshed.

Specifically, a materialized view is considered complex when the defining query of the materialized view contains any of the following:

- A CONNECT BY clause

For example, the following statement creates a complex materialized view:

```
CREATE MATERIALIZED VIEW hr.emp_hierarchy AS
 SELECT LPAD(' ', 4*(LEVEL-1))||email USERNAME
 FROM hr.employees@orcl.example.com START WITH manager_id IS NULL
 CONNECT BY PRIOR employee_id = manager_id;
```

- An INTERSECT, MINUS, or UNION ALL set operation

For example, the following statement creates a complex materialized view because it has a UNION ALL set operation:

```
CREATE MATERIALIZED VIEW hr.mview_employees AS
 SELECT employees.employee_id, employees.email
 FROM hr.employees@orcl.example.com
 UNION ALL
 SELECT new_employees.employee_id, new_employees.email
 FROM hr.new_employees@orcl.example.com;
```

- The DISTINCT or UNIQUE keyword

For example, the following statement creates a complex materialized view:

```
CREATE MATERIALIZED VIEW hr.employee_depts AS
 SELECT DISTINCT department_id FROM hr.employees@orc1.example.com
 ORDER BY department_id;
```

- In some cases, an aggregate function, although it is possible to have an aggregate function in the defining query and still have a simple materialized view

For example, the following statement creates a complex materialized view:

```
CREATE MATERIALIZED VIEW hr.average_sal AS
 SELECT AVG(salary) "Average" FROM hr.employees@orc1.example.com;
```

- In some cases, joins other than those in a subquery, although it is possible to have joins in the defining query and still have a simple materialized view

For example, the following statement creates a complex materialized view:

```
CREATE MATERIALIZED VIEW hr.emp_join_dep AS
 SELECT last_name
 FROM hr.employees@orc1.example.com e, hr.departments@orc1.example.com d
 WHERE e.department_id = d.department_id;
```

- In some cases, a UNION operation

Specifically, a materialized view with a UNION operation is complex if any one of these conditions is true:

- Any query within the UNION is complex. The previous bullet items specify when a query makes a materialized view complex.
- The outermost SELECT list columns do not match for the queries in the UNION. In the following example, the first query only has order\_total in the outermost SELECT list while the second query has customer\_id in the outermost SELECT list. Therefore, the materialized view is complex.

```
CREATE MATERIALIZED VIEW oe.orders AS
 SELECT order_total
 FROM oe.orders@orc1.example.com o
 WHERE EXISTS
 (SELECT cust_first_name, cust_last_name
 FROM oe.customers@orc1.example.com c
 WHERE o.customer_id = c.customer_id
 AND c.credit_limit > 50)
UNION
 SELECT customer_id
 FROM oe.orders@orc1.example.com o
 WHERE EXISTS
 (SELECT cust_first_name, cust_last_name
 FROM oe.customers@orc1.example.com c
 WHERE o.customer_id = c.customer_id
 AND c.account_mgr_id = 30);
```

The innermost SELECT list has no bearing on whether a materialized view is complex. In the previous example, the innermost SELECT list is cust\_first\_name and cust\_last\_name for both queries in the UNION.

- Clauses that do not follow the requirements detailed in "[Restrictions for Materialized Views with Subqueries](#)"

 **Note:**

If possible, you should avoid using complex materialized views because they cannot be fast refreshed, which might degrade performance.

 **See Also:**

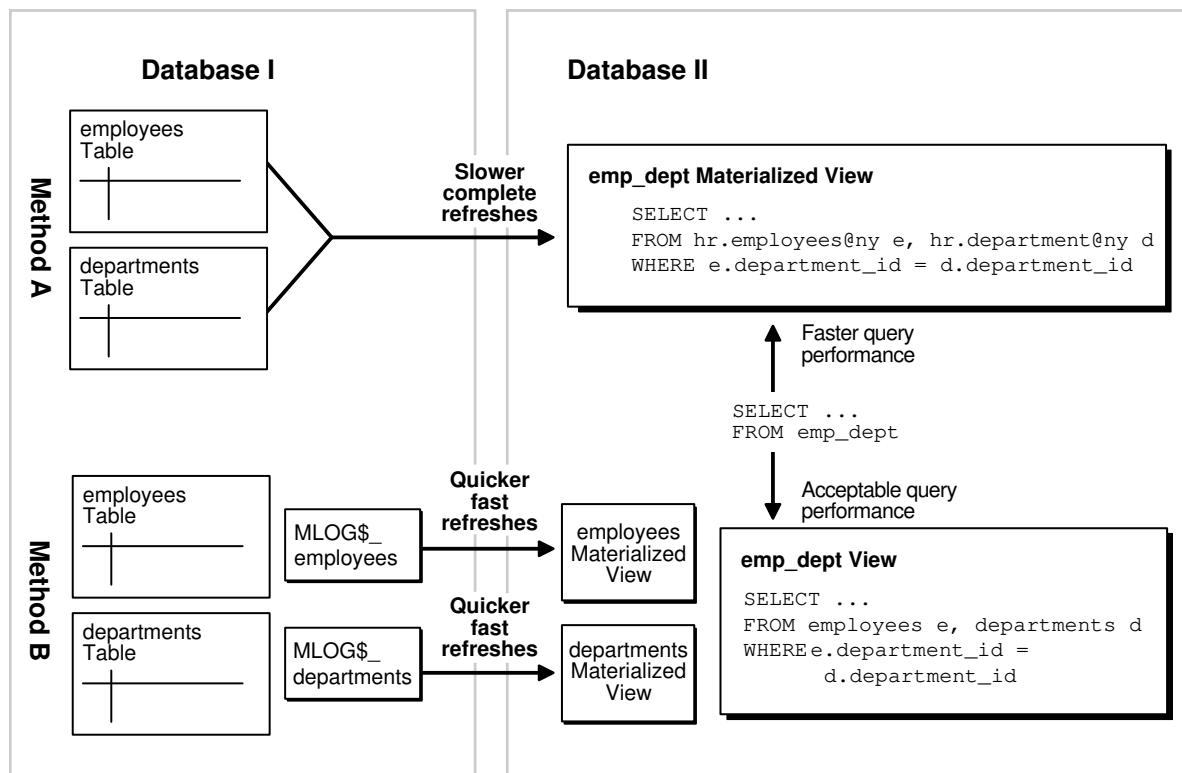

- ["Refresh Process"](#)
- *Oracle Database Data Warehousing Guide* for information about materialized views with aggregate functions and joins
- *Oracle Database SQL Language Reference* for more information about the CONNECT BY clause, set operations, the DISTINCT keyword, and aggregate functions

### 58.4.5.2 A Comparison of Simple and Complex Materialized Views

For certain applications, you might want to consider using a complex materialized view.

[Figure 58-2](#) and the following text discuss some issues that you should consider.

**Figure 58-2 Comparison of Simple and Complex Materialized Views**

- **Complex Materialized View:** Method A in [Figure 58-2](#) shows a complex materialized view. The materialized view in Database II exhibits efficient query performance because the join operation was completed during the materialized view's refresh. However, complete refreshes must be performed because the materialized view is complex, and these refreshes will probably be slower than fast refreshes.
- **Simple Materialized Views with a Joined View:** Method B in [Figure 58-2](#) shows two simple materialized views in Database II, as well as a view that performs the join in the materialized view's database. Query performance against the view would not be as good as the query performance against the complex materialized view in Method A. However, the simple materialized views can be refreshed more efficiently using fast refresh and materialized view logs.

In summary, to decide which method to use:

- If you refresh rarely and want faster query performance, then use Method A (complex materialized view).
- If you refresh regularly and can sacrifice query performance, then use Method B (simple materialized view).

## 58.5 Users and Privileges Related to Materialized Views

The users related to materialized views include the creator, the refresher, and the owner. The privileges required to perform operations on materialized views depend on the type of user performing the operation.

- [Required Privileges for Materialized View Operations](#)  
Three distinct types of users perform operations on materialized views.
- [Creator Is Owner](#)  
If the creator of a materialized view also owns the materialized view, then this user must have the required privileges to create a materialized view.
- [Creator Is Not Owner](#)  
If the creator of a materialized view is not the owner, then certain privileges must be granted to the creator and to the owner to create a materialized view.
- [Refresher Is Owner](#)  
If the refresher of a materialized view also owns the materialized view, then this user must have the required privileges to create the materialized view.
- [Refresher Is Not Owner](#)  
If the refresher of a materialized view is not the owner, certain privileges must be granted to the refresher and to the owner.

### 58.5.1 Required Privileges for Materialized View Operations

Three distinct types of users perform operations on materialized views.

These users are:

- **Creator:** The user who creates the materialized view.
- **Refresher:** The user who refreshes the materialized view.
- **Owner:** The user who owns the materialized view. The materialized view resides in this user's schema.

One user can perform all of these operations on a particular materialized view. However, in some replication environments, different users perform these operations on a particular materialized view. The privileges required to perform these operations depend on whether the same user performs them or different users perform them.

If the owner of a materialized view at the materialized view database has a private database link to the master database, then the database link connects to the owner of the master table at the master database. Otherwise, the normal rules for connections through database links apply.

 **Note:**

The following sections do not cover the requirements necessary to create materialized views with query rewrite enabled. See the *Oracle Database SQL Language Reference* for information.

 **See Also:**

The following sections discuss database links. See [Distributed Database Concepts](#) for more information about using database links.

## 58.5.2 Creator Is Owner

If the creator of a materialized view also owns the materialized view, then this user must have the required privileges to create a materialized view.

The following privileges must be granted explicitly rather than through a role:

- CREATE MATERIALIZED VIEW or CREATE ANY MATERIALIZED VIEW
- CREATE TABLE or CREATE ANY TABLE
- READ or SELECT object privilege on the master table and the master table's materialized view log or either READ ANY TABLE or SELECT ANY TABLE system privilege

If the master database is remote, then the READ or SELECT object privilege must be granted to the user at the master database to which the user at the materialized view database connects through a database link.

## 58.5.3 Creator Is Not Owner

If the creator of a materialized view is not the owner, then certain privileges must be granted to the creator and to the owner to create a materialized view.

Both the creator's privileges and the owner's privileges must be granted explicitly rather than through a role.

[Table 58-1](#) shows the required privileges when the creator of the materialized view is not the owner.

**Table 58-1 Required Privileges for Creating Materialized Views (Creator != Owner)**

| Creator                      | Owner                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE ANY MATERIALIZED VIEW | <p>CREATE TABLE or CREATE ANY TABLE</p> <p>READ or SELECT object privilege on the master table and the master table's materialized view log or either READ ANY TABLE or SELECT ANY TABLE system privilege</p> <p>If the master database is remote, then the READ or SELECT object privilege must be granted to the user at the master database to which the user at the materialized view database connects through a database link.</p> |

## 58.5.4 Refresher Is Owner

If the refresher of a materialized view also owns the materialized view, then this user must have the required privileges to create the materialized view.

Specifically, this user must have READ or SELECT object privilege on the master table and the master table's materialized view log or either READ ANY TABLE or SELECT ANY TABLE system privilege. If the master database is remote, then the READ or SELECT object privilege must be granted to the user at the master database to which the user at the materialized view database connects through a database link. This privilege can be granted either explicitly or through a role.

## 58.5.5 Refresher Is Not Owner

If the refresher of a materialized view is not the owner, certain privileges must be granted to the refresher and to the owner.

These privileges can be granted either explicitly or through a role.

[Table 58-2](#) shows the required privileges when the refresher of the materialized view is not the owner.

**Table 58-2 Required Privileges for Refreshing Materialized Views (Refresher != Owner)**

| Refresher                   | Owner                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALTER ANY MATERIALIZED VIEW | <p>If the master database is local, then READ or SELECT object privilege must be granted on the master table and master table's materialized view log or either READ ANY TABLE or SELECT ANY TABLE system privilege.</p> <p>If the master database is remote, then the READ or SELECT object privilege must be granted to the user at the master database to which the user at the materialized view database connects through a database link.</p> |

## 58.6 Data Subsetting with Materialized Views

You can use row subsetting and column subsetting to configure materialized views reflect a subset of the data in the master table.

- [About Data Subsetting with Materialized Views](#)  
In certain situations, you might want your materialized view to reflect a subset of the data in the master table.
- [Materialized Views with Subqueries](#)  
If you want to replicate data based on the information in multiple tables, then maintaining and defining these materialized views can be difficult.
- [Restrictions for Materialized Views with Subqueries](#)  
The defining query of a materialized view with a subquery is subject to several restrictions to preserve the materialized view's fast refresh capability.
- [Restrictions for Materialized Views with Unions Containing Subqueries](#)  
There are restrictions for fast refresh materialized views with unions containing subqueries.

### 58.6.1 About Data Subsetting with Materialized Views

In certain situations, you might want your materialized view to reflect a subset of the data in the master table.

Row subsetting enables you to include only the rows that are needed from the master table in the materialized views by using a `WHERE` clause. Column subsetting enables you to include only the columns that are needed from the master table in the materialized views. You do this by specifying certain select columns in the `SELECT` statement during materialized view creation.

Some reasons to use data subsetting are to:

- **Reduce Network Traffic:** In a column-subsetted materialized view, only changes that satisfy the `WHERE` clause of the materialized view's defining query are applied to the materialized view database, thereby reducing the amount of data transferred and reducing network traffic.
- **Secure Sensitive Data:** Users can only view data that satisfies the defining query for the materialized view.
- **Reduce Resource Requirements:** If the materialized view is located on a laptop, then hard disks are generally significantly smaller than the hard disks on a corporate server. Subsetted materialized views might require significantly less storage space.
- **Improve Refresh Times:** Because less data is applied to the materialized view database, the refresh process is faster, which might be essential for those who need to refresh materialized views using a network connection from a laptop.

For example, the following statement creates a materialized view based on the `oe.orders@orc1.example.com` master table and includes only the rows for the sales representative with a `sales_rep_id` number of 173:

```
CREATE MATERIALIZED VIEW oe.orders REFRESH FAST AS
 SELECT * FROM oe.orders@orc1.example.com
 WHERE sales_rep_id = 173;
```

Rows of the orders table with a `sales_rep_id` number other than 173 are excluded from this materialized view.

## 58.6.2 Materialized Views with Subqueries

If you want to replicate data based on the information in multiple tables, then maintaining and defining these materialized views can be difficult.

- [Many to One Subqueries](#)

You can create a materialized view with a subquery with a many to one relationship.

- [One to Many Subqueries](#)

You can create a materialized view with a subquery with a one to many relationship.

- [Many to Many Subqueries](#)

You can create a materialized view with a subquery with a many to many relationship.

- [Materialized Views with Subqueries and Unions](#)

You can create a materialized view with subqueries and unions.

### 58.6.2.1 Many to One Subqueries

You can create a materialized view with a subquery with a many to one relationship.

Consider a scenario where you have the `customers` table and `orders` table in the `oe` schema, and you want to create a materialized view of the `orders` table based on data in both the `orders` table and the `customers` table. For example, suppose a salesperson wants to see all of the orders for the customers with a credit limit greater than \$10,000. In this case, the `CREATE MATERIALIZED VIEW` statement that creates the `orders` materialized view has a subquery with a many to one relationship, because there can be many orders for each customer.

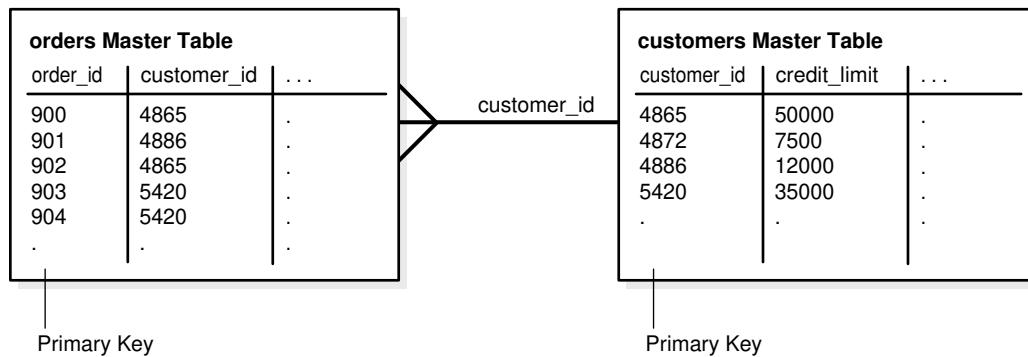

Look at the relationships in [Figure 58-3](#), and notice that the `customers` and `orders` tables are related through the `customer_id` column. The following statement satisfies the original goal of the salesperson. That is, the following statement creates a materialized view that contains orders for customers whose credit limit is greater than \$10,000:

```
CREATE MATERIALIZED VIEW oe.orders REFRESH FAST AS
 SELECT * FROM oe.orders@orc1.example.com o
 WHERE EXISTS
 (SELECT * FROM oe.customers@orc1.example.com c
 WHERE o.customer_id = c.customer_id AND c.credit_limit > 10000);
```

 **Note:**

To create this `oe.orders` materialized view, `credit_limit` must be logged in the master table's materialized view log. See "[Logging Columns in a Materialized View Log](#)" for more information.

**Figure 58-3 Row Subsetting with Many to One Subqueries**

As you can see, the materialized view created by this statement is fast refreshable. If new customers are identified that have a credit limit greater than \$10,000, then the new data will be propagated to the materialized view database during the subsequent refresh process. Similarly, if a customer's credit limit drops to less than \$10,000, then the customer's data will be removed from the materialized view during the subsequent refresh process.

### 58.6.2.2 One to Many Subqueries

You can create a materialized view with a subquery with a one to many relationship.

Consider a scenario where you have the `customers` table and `orders` table in the `oe` schema, and you want to create a materialized view of the `customers` table based on data in both the `customers` table and the `orders` table. For example, suppose a salesperson wants to see all of the customers who have an order with an order total greater than \$20,000. In this case, the most efficient method is to create a materialized view with a one to many subquery in the defining query of a materialized view.

Here, the defining query in the `CREATE MATERIALIZED VIEW` statement on the `customers` table has a subquery with a one to many relationship. That is, one customer can have many orders.

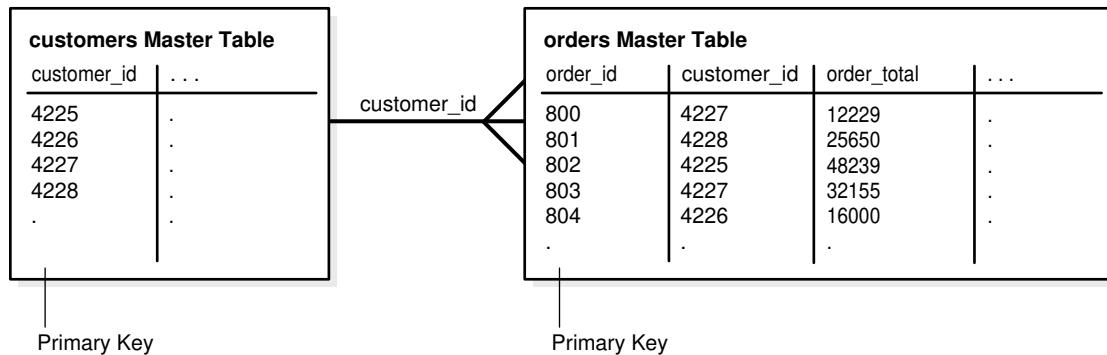

Look at the relationships in [Figure 58-4](#), and notice that the `orders` table and `customers` table are related through the `customer_id` column. The following statement satisfies the original goal of the salesperson. That is, this statement creates a materialized view that contains customers who have an order with an order total greater than \$20,000:

```
CREATE MATERIALIZED VIEW oe.customers REFRESH FAST AS
 SELECT * FROM oe.customers@orc1.example.com c
 WHERE EXISTS
 (SELECT * FROM oe.orders@orc1.example.com o
 WHERE c.customer_id = o.customer_id AND o.order_total > 20000);
```

To create this oe.customers materialized view, customer\_id and order\_total must be logged in the materialized view log for the orders master table. See "[Logging Columns in a Materialized View Log](#)" for more information.

**Figure 58-4** Row Subsetting with One to Many Subqueries

The materialized view created by this statement is fast refreshable. If new customers are identified that have an order total greater than \$20,000, then the new data will be propagated to the materialized view database during the subsequent refresh process. Similarly, if a customer cancels an order with an order total greater than \$20,000 and has no other order totals greater than \$20,000, then the customer's data will be removed from the materialized view during the subsequent refresh process.

### 58.6.2.3 Many to Many Subqueries

You can create a materialized view with a subquery with a many to many relationship.

Consider a scenario where you have the `order_items` table and `inventories` table in the `oe` schema, and you want to create a materialized view of the `inventories` table based on data in both the `inventories` table and the `order_items` table. For example, suppose a salesperson wants to see all of the inventories with a quantity on hand greater than 0 (zero) for each product whose `product_id` is in the `order_items` table. In other words, the salesperson wants to see the inventories that are greater than zero for all of the products that customers have ordered. Here, an inventory is a certain quantity of a product at a particular warehouse. So, a certain product can be in many order items and in many inventories.

To accomplish the salesperson's goal, you can create a materialized view with a subquery on the many to many relationship between the `order_items` table and the `inventories` table.

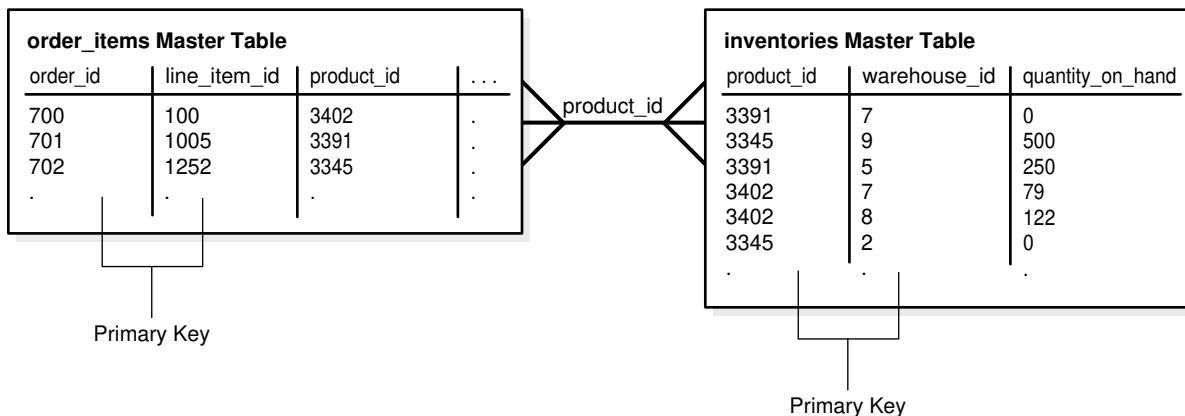

When you create the inventories materialized view, you want to retrieve the inventories with the quantity on hand greater than zero for the products that appear in the `order_items` table. Look at the relationships in [Figure 58-5](#), and note that the `inventories` table and `order_items` table are related through the `product_id` column. The following statement creates the materialized view:

```
CREATE MATERIALIZED VIEW oe.inventories REFRESH FAST AS
 SELECT * FROM oe.inventories@orcl.example.com i
 WHERE i.quantity_on_hand > 0 AND EXISTS
 (SELECT * FROM oe.order_items@orcl.example.com o
 WHERE i.product_id = o.product_id);
```

**Note:**

To create this `oe.inventories` materialized view, the `product_id` column in the `order_items` master table must be logged in the master table's materialized view log. See "[Logging Columns in a Materialized View Log](#)" for more information.

**Figure 58-5 Row Subsetting with Many to Many Subqueries**

The materialized view created by this statement is fast refreshable. If new inventories that are greater than zero are identified for products in the `order_items` table, then the new data will be propagated to the materialized view database during the subsequent refresh process. Similarly, if a customer cancels an order for a product and there are no other orders for the product in the `order_items` table, then the inventories for the product will be removed from the materialized view during the subsequent refresh process.

#### 58.6.2.4 Materialized Views with Subqueries and Unions

You can create a materialized view with subqueries and unions.

In situations where you want a single materialized view to contain data that matches the complete results of two or more different queries, you can use the `UNION` operator. When you use the `UNION` operator to create a materialized view, you have two `SELECT` statements around each `UNION` operator; one is above it and one is below it. The resulting materialized view contains rows selected by either query.

You can use the `UNION` operator as a way to create fast refreshable materialized views that satisfy "or" conditions without using the `OR` expression in the `WHERE` clause of a subquery. Under some conditions, using an `OR` expression in the `WHERE` clause of a subquery causes the resulting materialized view to be complex, and therefore not fast refreshable.

 **See Also:**

"[Restrictions for Materialized Views with Subqueries](#)" for more information about the OR expressions in subqueries

For example, suppose a salesperson wants the product information for the products in a particular category\_id that are *either* in a warehouse in California *or* contain the word "Rouge" in their translated product descriptions (for the French translation). The following statement uses the UNION operator and subqueries to capture this data in a materialized view for products in category\_id 29:

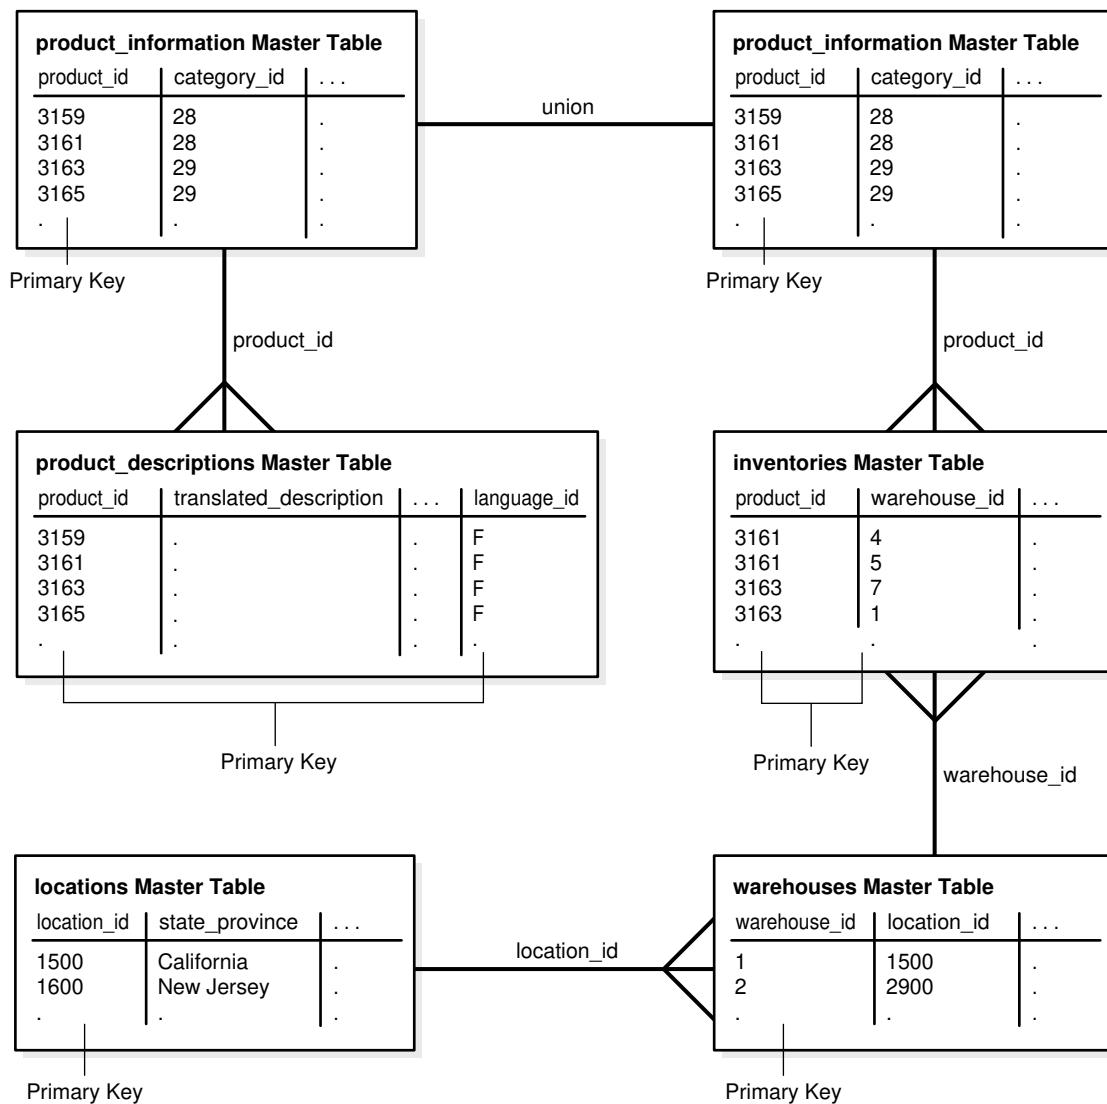

```
CREATE MATERIALIZED VIEW oe.product_information REFRESH FAST AS
 SELECT * FROM oe.product_information@orc1.example.com pi
 WHERE pi.category_id = 29 AND EXISTS
 (SELECT * FROM oe.product_descriptions@orc1.example.com pd
 WHERE pi.product_id = pd.product_id AND
 pd.translated_description LIKE '%Rouge%')
UNION
 SELECT * FROM oe.product_information@orc1.example.com pi
 WHERE pi.category_id = 29 AND EXISTS
 (SELECT * FROM oe.inventories@orc1.example.com i
 WHERE pi.product_id = i.product_id AND EXISTS
 (SELECT * FROM oe.warehouses@orc1.example.com w
 WHERE i.warehouse_id = w.warehouse_id AND EXISTS
 (SELECT * FROM hr.locations@orc1.example.com l
 WHERE w.location_id = l.location_id
 AND l.state_province = 'California')));
```

 **Note:**

To create the oe.product\_information materialized view, translated\_description in the oe.product\_descriptions master table, the state\_province in the hr.locations master table, and the location\_id column in the oe.warehouses master table must be logged in each master's materialized view log. See "[Logging Columns in a Materialized View Log](#)" for more information.

Figure 58-6 shows the relationships of the master tables involved in this statement.

**Figure 58-6 Row Subsetting with Subqueries and Unions**

In addition to the `UNION` operation, this statement contains the following subqueries:

- A subquery referencing the `product_information` table and the `product_descriptions` table. This subquery is one to many because one product can have multiple product descriptions (for different languages).
- A subquery referencing the `product_information` table and the `inventories` table. This subquery is one to many because a product can be in many inventories.
- A subquery referencing the `inventories` table and the `warehouses` table. This subquery is many to one because many inventories can be stored in one warehouse.
- A subquery referencing the `warehouses` table and the `locations` table. This subquery is many to one because many warehouses can be in one location.

The materialized view created by this statement is fast refreshable. If a new product is added that is stored in a warehouse in California or that has the string "Rouge" in the

translated product description, then the new data will be propagated to the `product_information` materialized view during the subsequent refresh process.

### 58.6.3 Restrictions for Materialized Views with Subqueries

The defining query of a materialized view with a subquery is subject to several restrictions to preserve the materialized view's fast refresh capability.

The following are restrictions for fast refresh materialized views with subqueries:

- Materialized views must be primary key materialized views.
- The master table's materialized view log must include certain columns referenced in the subquery. For information about which columns must be included, see "[Logging Columns in a Materialized View Log](#)".
- If the subquery is many to many or one to many, then join columns that are not part of a primary key must be included in the materialized view log of the master table. This restriction does not apply to many to one subqueries.
- The subquery must be a positive subquery. For example, you can use the `EXISTS` condition, but not the `NOT EXISTS` condition.
- The subquery must use `EXISTS` to connect each nested level (`IN` is not allowed).
- Each table can be in only one `EXISTS` expression.
- The join expression must use exact match or equality comparisons (that is, equijoins).
- Each table can be joined only once within the subquery.
- A primary key must exist for each table at each nested level.
- Each nested level can only reference the table in the level above it.
- Subqueries can include `AND` conditions, but each `OR` condition can only reference columns contained within one row. Multiple `OR` conditions within a subquery can be connected with an `AND` condition.
- All tables referenced in a subquery must reside in the same master database.

 **Note:**

If the `CREATE MATERIALIZED VIEW` statement includes an `ON PREBUILT TABLE` clause and a subquery, then the subquery is treated as many to many. Therefore, in this case, the join columns must be recorded in the materialized view log. See the *Oracle Database SQL Language Reference* for more information about the `ON PREBUILT TABLE` clause in the `CREATE MATERIALIZED VIEW` statement.

 See Also:

- ["Primary Key Materialized Views"](#) for more information about primary key materialized views
- ["Determining the Fast Refresh Capabilities of a Materialized View"](#)

## 58.6.4 Restrictions for Materialized Views with Unions Containing Subqueries

There are restrictions for fast refresh materialized views with unions containing subqueries.

The following are restrictions for fast refresh materialized views with unions containing subqueries:

- All of the restrictions described in ["Restrictions for Materialized Views with Subqueries"](#) apply to the subqueries in each union block.
- All join columns must be included in the materialized view log of the master table, even if the subquery is many to one.
- All of the restrictions described in ["Complex Materialized Views"](#) apply for clauses with UNIONs.
- [Examples of Materialized Views with Unions Containing Subqueries](#)  
Examples illustrate creating materialized views with unions containing subqueries.

### 58.6.4.1 Examples of Materialized Views with Unions Containing Subqueries

Examples illustrate creating materialized views with unions containing subqueries.

The following statement creates the oe.orders materialized view. This materialized view is fast refreshable because the subquery in each union block satisfies the restrictions for subqueries described in ["Restrictions for Materialized Views with Subqueries"](#).

```
CREATE MATERIALIZED VIEW oe.orders REFRESH FAST AS
 SELECT * FROM oe.orders@orc1.example.com o
 WHERE EXISTS
 (SELECT * FROM oe.customers@orc1.example.com c
 WHERE o.customer_id = c.customer_id
 AND c.credit_limit > 50)
 UNION
 SELECT *
 FROM oe.orders@orc1.example.com o
 WHERE EXISTS
 (SELECT * FROM oe.customers@orc1.example.com c
 WHERE o.customer_id = c.customer_id
 AND c.account_mgr_id = 30);
```

Notice that one of the restrictions for subqueries states that each table can be in only one EXISTS expression. Here, the customers table appears in two EXISTS expressions, but the EXISTS expressions are in separate UNION blocks. Because the restrictions described in ["Restrictions for Materialized Views with Subqueries"](#) only apply to each

UNION block, not to the entire CREATE MATERIALIZED VIEW statement, the materialized view is fast refreshable.

In contrast, the materialized view created with the following statement cannot be fast refreshed because the `orders` table is referenced in two different EXISTS expressions within the same UNION block:

```
CREATE MATERIALIZED VIEW oe.orders AS
 SELECT * FROM oe.orders@orcl.example.com o
 WHERE EXISTS
 (SELECT * FROM oe.customers@orcl.example.com c
 WHERE o.customer_id = c.customer_id -- first reference to orders table
 AND c.credit_limit > 50
 AND EXISTS
 (SELECT * FROM oe.orders@orcl.example.com o
 WHERE order_total > 5000
 AND o.customer_id = c.customer_id)) -- second reference to orders table
UNION
 SELECT *
 FROM oe.orders@orcl.example.com o
 WHERE EXISTS
 (SELECT * FROM oe.customers@orcl.example.com c
 WHERE o.customer_id = c.customer_id
 AND c.account_mgr_id = 30);
```

["Determining the Fast Refresh Capabilities of a Materialized View"](#)

## 58.7 Materialized View Refresh

To ensure that a materialized view is consistent with its master table, you must **refresh** the materialized view periodically.

Oracle provides the following three methods to refresh materialized views:

- **Fast refresh** uses materialized view logs to update only the rows that have changed since the last refresh.
- **Complete refresh** updates the entire materialized view.
- **Force refresh** performs a fast refresh when possible. When a fast refresh is not possible, force refresh performs a complete refresh.

## 58.8 Refresh Groups

When it is important for materialized views to be transactionally consistent with each other, you can organize them into **refresh groups**.

By refreshing the refresh group, you can ensure that the data in all of the materialized views in the refresh group correspond to the same transactionally consistent point in time. A materialized view in a refresh group still can be refreshed individually, but doing so nullifies the benefits of the refresh group because refreshing the materialized view individually does not refresh the other materialized views in the refresh group.

## 58.9 Materialized View Log

A **materialized view log** is a table at the database that contains materialized view's master table. It records all of the DML changes to the master table.

A materialized view log is associated with a single master table, and each of those has only one materialized view log, regardless of how many materialized views refresh from the master table. A fast refresh of a materialized view is possible only if the materialized view's master table has a materialized view log. When a materialized view is fast refreshed, entries in the materialized view's associated materialized view log that have appeared since the materialized view was last refreshed are applied to the materialized view.

## 58.10 Materialized Views and User-Defined Data Types

There are special considerations for materialized views with user-defined data types.

- [How Materialized Views Work with Object Types and Collections](#)  
You can replicate object types and objects between master databases and materialized view databases in a replication environment.
- [Type Agreement at Replication Databases](#)  
User-defined types include all types created using the CREATE TYPE statement, including object, nested table, VARRAY, and indextype. To replicate schema objects based on user-defined types, the user-defined types themselves must exist, and must be the same, at the master database and the materialized view database.
- [Column Subsetting of Masters with Column Objects](#)  
A read-only materialized view can replicate specific attributes of a column object without replicating other attributes.
- [Materialized Views Based on Object Tables](#)  
You can create a materialized view based on an object table.
- [Materialized Views with Collection Columns](#)  
Collection columns are columns based on varray and nested table data types. Oracle supports the creation of materialized views with collection columns.
- [Materialized Views with REF Columns](#)  
Materialized views can contain REF columns.

### 58.10.1 How Materialized Views Work with Object Types and Collections

You can replicate object types and objects between master databases and materialized view databases in a replication environment.

Oracle **object types** are user-defined data types that make it possible to model complex real-world entities such as customers and orders as single entities, called **objects**, in the database. You create object types using the CREATE TYPE ... AS OBJECT statement.

An Oracle object that occupies a single column in a table is called a **column object**. Typically, tables that contain column objects also contain other columns, which can be built-in data types, such as VARCHAR2 and NUMBER. An **object table** is a special kind of

table in which each row represents an object. Each row in an object table is a **row object**.

You can also replicate **collections**. Collections are user-defined data types that are based on VARRAY and nested table data types. You create varrays with the CREATE TYPE ... AS VARRAY statement, and you create nested tables with the CREATE TYPE ... AS TABLE statement.

 **Note:**

- You cannot create refresh-on-commit materialized views based on a master table with user-defined types or Oracle-supplied types. Refresh-on-commit materialized views are those created using the ON COMMIT REFRESH clause in the CREATE MATERIALIZED VIEW statement.
- Type inheritance and types created with the NOT FINAL clause are not supported.

 **See Also:**

- *Oracle Database Object-Relational Developer's Guide* for detailed information about user-defined types, Oracle objects, and collections. This section assumes a basic understanding of those concepts.
- *Oracle Database SQL Language Reference* for more information about user-defined types and Oracle-supplied types

## 58.10.2 Type Agreement at Replication Databases

User-defined types include all types created using the CREATE TYPE statement, including object, nested table, VARRAY, and indextype. To replicate schema objects based on user-defined types, the user-defined types themselves must exist, and must be the same, at the master database and the materialized view database.

When replicating user-defined types and the schema objects on which they are based, the following conditions apply:

- The user-defined types replicated at the master database and materialized view database must be created at the materialized view database before you create any materialized views that depend on these types.
- All of the master tables on which a materialized view is based must be at the same master database to create a materialized view with user-defined types.
- A user-defined type must be the same at all databases:
  - All replication databases must have the same object identifier (OID), schema owner, and type name for each replicated user-defined type.
  - If the user-defined type is an object type, then all databases must agree on the order and data type of the attributes in the object type. You establish the order

and data types of the attributes when you create the object type. For example, consider the following object type:

```
CREATE TYPE cust_address_typ AS OBJECT
 (street_address VARCHAR2(40),
 postal_code VARCHAR2(10),
 city VARCHAR2(30),
 state_province VARCHAR2(10),
 country_id CHAR(2));
 /
```

At all databases, `street_address` must be the first attribute for this type and must be `VARCHAR2(40)`, `postal_code` must be the second attribute and must be `VARCHAR2(10)`, `city` must be the third attribute and must be `VARCHAR2(30)`, and so on.

- All databases must agree on the hashcode of the user-defined type. Oracle examines a user-defined type and assigns the hashcode. This examination includes the type attributes, order of attributes, and type name. When all of these items are the same for two or more types, the types have the same hashcode. You can view the hashcode for a type by querying the `DBA_TYPE_VERSIONS` data dictionary view.

You can use a `CREATE TYPE` statement at the materialized view database to create the type. It might be necessary to do this to create a read-only materialized view that uses the type.

If you choose this option, then you must ensure the following:

- The type is in the same schema at both the materialized view database and the master database.
- The type has the same attributes in the same order at both the materialized view database and the master database.
- The type has the same data type for each attribute at both the materialized view database and the master database.
- The type has the same object identifier at both the materialized view database and the master database.

You can find the object identifier for a type by querying the `DBA_TYPES` data dictionary view. For example, to find the object identifier (OID) for the `cust_address_typ`, enter the following query:

```
SELECT TYPE_OID FROM DBA_TYPES WHERE TYPE_NAME = 'CUST_ADDRESS_TYP';

TYPE_OID

6F9BC33653681B7CE03400400B40A607
```

For example, now that you know the OID for the type at the master database, you can complete the following steps to create the type at the materialized view database:

1. Log in to the materialized view database as the user who owns the type at the master database. If this user does not exist at the materialized view database, then create the user.
2. Issue the `CREATE TYPE` statement and specify the OID:

```
CREATE TYPE oe.cust_address_typ OID '6F9BC33653681B7CE03400400B40A607'
 AS OBJECT (
```

```

 street_address VARCHAR2(40),
 postal_code VARCHAR2(10),
 city VARCHAR2(30),
 state_province VARCHAR2(10),
 country_id CHAR(2));
/

```

The type is now ready for use at the materialized view database.

### 58.10.3 Column Subsetting of Masters with Column Objects

A read-only materialized view can replicate specific attributes of a column object without replicating other attributes.

For example, using the `cust_address_typ` user-defined data type described in the previous section, suppose a `customers_sub` master table is created at master database `orcl.example.com`:

```

CREATE TABLE oe.customers_sub (
 customer_id NUMBER(6) PRIMARY KEY,
 cust_first_name VARCHAR2(20),
 cust_last_name VARCHAR2(20),
 cust_address oe.cust_address_typ);

```

You can create the following read-only materialized view at a remote materialized view database:

```

CREATE MATERIALIZED VIEW oe.customers_mv1 AS
 SELECT customer_id, cust_last_name, c.cust_address.postal_code
 FROM oe.customers_sub@orcl.example.com c;

```

Notice that the `postal_code` attribute is specified in the `cust_address` column object.

### 58.10.4 Materialized Views Based on Object Tables

You can create a materialized view based on an object table.

- [About Materialized Views Based on Object Tables](#)  
If a materialized view is based on an object table and is created using the `OF type` clause, then the materialized view is called an **object materialized view**.
- [Materialized Views Based on Object Tables Created Without Using the OF type Clause](#)  
If you create a materialized view based on an object table without using the `OF type` clause, then the materialized view loses the object properties of the object table on which it is based.
- [OID Preservation in Object Materialized Views](#)  
An object materialized view inherits the object identifier (OID) specifications of its master.

#### 58.10.4.1 About Materialized Views Based on Object Tables

If a materialized view is based on an object table and is created using the `OF type` clause, then the materialized view is called an **object materialized view**.

An object materialized view is structured in the same way as an object table. That is, an object materialized view is composed of row objects.

If a materialized view that is based on an object table is created without using the `OF type` clause, then the materialized view is not an object materialized view. That is, such a materialized view has regular rows, not row objects.

To create a materialized view based on an object table, the types on which the materialized view depends must exist at the materialized view database, and each type must have the same object identifier as it does at the master database.

 **See Also:**

["Creating Read-Only Materialized Views"](#) for an example that creates an object materialized view

#### 58.10.4.2 Materialized Views Based on Object Tables Created Without Using the `OF type` Clause

If you create a materialized view based on an object table without using the `OF type` clause, then the materialized view loses the object properties of the object table on which it is based.

That is, the resulting read-only materialized view contains one or more of the columns of the master table, but each row functions as a row in a relational table. The rows are not row objects.

For example, you can create a materialized view based on the `categories_tab` master by using the following SQL statement:

```
CREATE MATERIALIZED VIEW oe.categories_relmv
 AS SELECT * FROM oe.categories_tab@orc1.example.com;
```

In this case, the rows in this materialized view function in the same way as rows in a relational table.

#### 58.10.4.3 OID Preservation in Object Materialized Views

An object materialized view inherits the object identifier (OID) specifications of its master.

If the master table has a primary key-based OID, then the OIDs of row objects in the materialized view are primary key-based. If the master table has a system generated OID, then the OIDs of row objects in the materialized view are system generated. Also, the OID of each row in the object materialized view matches the OID of the same row in the master table, and the OIDs are preserved during refresh of the materialized view. Consequently, `REFS` to the rows in the object table remain valid at the materialized view database.

#### 58.10.5 Materialized Views with Collection Columns

Collection columns are columns based on varray and nested table data types. Oracle supports the creation of materialized views with collection columns.

If the collection column is a nested table, then you can optionally specify the *nested\_table\_storage\_clause* during materialized view creation. The *nested\_table\_storage\_clause* lets you specify the name of the storage table for the nested table in the materialized view.

For example, suppose you create the master table `people_reltab` at the master database `orcl.example.com` that contains the nested table `phones_ntab`:

```
CREATE TYPE oe.phone_typ AS OBJECT (
 location VARCHAR2(15),
 num VARCHAR2(14));
/
CREATE TYPE oe.phone_ntabtyp AS TABLE OF oe.phone_typ;
/
CREATE TABLE oe.people_reltab (
 id NUMBER(4) CONSTRAINT pk_people_reltab PRIMARY KEY,
 first_name VARCHAR2(20),
 last_name VARCHAR2(20),
 phones_ntab oe.phone_ntabtyp
 NESTED TABLE phones_ntab STORE AS phone_store_ntab
 ((PRIMARY KEY (NESTED_TABLE_ID, location)));
```

Notice the `PRIMARY KEY` specification in the last line of the preceding SQL statement. You must specify a primary key for the storage table if you plan to create materialized views based on its parent table. In this case, the storage table is `phone_store_ntab` and the parent table is `people_reltab`.

To create materialized views that can be fast refreshed, create a materialized view log on both the parent table and the storage table, specifying the nested table column as a filter column for the parent table's materialized view log:

```
CREATE MATERIALIZED VIEW LOG ON oe.people_reltab;
ALTER MATERIALIZED VIEW LOG ON oe.people_reltab ADD(phones_ntab);
CREATE MATERIALIZED VIEW LOG ON oe.phone_store_ntab WITH PRIMARY KEY;
```

At the materialized view database, create the required types, ensuring that the object identifier for each type is the same as the object identifier at the master database. Then, you can create a materialized view based on `people_reltab` and specify its storage table using the following statement:

```
CREATE MATERIALIZED VIEW oe.people_reltab_mv
 NESTED TABLE phones_ntab STORE AS phone_store_ntab_mv
 REFRESH FAST AS SELECT * FROM oe.people_reltab@orcl.example.com;
```

In this case, the *nested\_table\_storage\_clause* is the line that begins with "NESTED TABLE" in the previous example, and it specifies that the storage table's name is `phone_store_ntab_mv`. The *nested\_table\_storage\_clause* is optional. If you do not specify this clause, then Oracle Database automatically names the storage table. To view the name of a storage table, query the `DBA_NESTED_TABLES` data dictionary table.

The storage table:

- Is a separate, secondary materialized view
- Is refreshed automatically when you refresh the materialized view containing the nested table

- Is dropped automatically when you drop the materialized view containing the nested table
- Inherits the primary key constraint of the master's storage table

Because the storage table inherits the primary key constraint of the master table's storage table, do not specify PRIMARY KEY in the STORE AS clause.

The following actions are not allowed directly on the storage table of a nested table in a materialized view:

- Refreshing the storage table
- Altering the storage table
- Dropping the storage table
- Generating replication support on the storage table

These actions can occur indirectly when they are performed on the materialized view that contains the nested table. In addition, you cannot replicate a subset of the columns in a storage table.

- [Restrictions for Materialized Views with Collection Columns](#)  
Restrictions apply to materialized views with collection columns.

 **See Also:**

*Oracle Database SQL Language Reference* for more information about the `nested_table_col_properties`, which is fully documented in the CREATE TABLE statement

#### 58.10.5.1 Restrictions for Materialized Views with Collection Columns

Restrictions apply to materialized views with collection columns.

The following restrictions apply:

- Row subsetting of collection columns is not allowed. However, you can use row subsetting on the parent table of a nested table and doing so can result in a subset of the nested tables in the materialized view.
- Column subsetting of collection columns is not allowed.
- A nested table's storage table must have a primary key.
- For the parent table of a nested table to be fast refreshed, both the parent table and the nested table's storage table must have a materialized view log.

#### 58.10.6 Materialized Views with REF Columns

Materialized views can contain REF columns.

- [About Materialized Views with REF Columns](#)

You can create materialized views with REF columns. A REF is an Oracle built-in data type that is a logical "pointer" to a row object in an object table.

- **Scoped REF Columns**  
If you are creating a materialized view based on a master table that has a scoped REF column, then you can rescope the REF to a different object table or object materialized view at the materialized view database.
- **Unscoped REF Columns**  
If you create a materialized view based on a remote master table with an unscoped REF column, then the REF column is created in the materialized view, but the REFS are considered dangling because they point to a remote database.
- **Logging REF Columns in the Materialized View Log**  
If necessary, you can log REF columns in the materialized view log.
- **REFs Created Using the WITH ROWID Clause**  
If the WITH ROWID clause is specified for a REF column, then Oracle Database maintains the rowid of the object referenced in the REF.

### 58.10.6.1 About Materialized Views with REF Columns

You can create materialized views with REF columns. A REF is an Oracle built-in data type that is a logical "pointer" to a row object in an object table.

A scoped REF is a REF that can contain references only to a specified object table, while an unscoped REF can contain references to any object table in the database that is based on the corresponding object type. A scoped REF requires less storage space and provides more efficient access than an unscoped REF.

You can rescope a REF column to a local materialized view or table at the materialized view database during creation of the materialized view. If you do not rescope the REF column, then it continues to point to the remote master table. Unscoped REF columns always continue to point to the master table. When a REF column at a materialized view database points to a remote master table, the REFS are considered dangling. In SQL, dereferencing a dangling REF returns a NULL. Also, PL/SQL only supports dereferencing REFS by using the UTL\_OBJECT package and raises an exception for dangling REFS.

### 58.10.6.2 Scoped REF Columns

If you are creating a materialized view based on a master table that has a scoped REF column, then you can rescope the REF to a different object table or object materialized view at the materialized view database.

Typically, you would rescope the REF column to the local object materialized view instead of the original remote object table. To rescope a materialized view, you can either use the SCOPE FOR clause in the CREATE MATERIALIZED VIEW statement, or you can use the ALTER MATERIALIZED VIEW statement after creating the materialized view. If you do not rescope the REF column, then the materialized view retains the REF scope of the master table.

For example, suppose you create the `customers_with_ref` master table at the `orc1.example.com` master database using the following statements:

```
-- Create the user-defined data type cust_address_typ.
CREATE TYPE oe.cust_address_typ AS OBJECT
 (street_address VARCHAR2(40),
 postal_code VARCHAR2(10),
 city VARCHAR2(30),
```

```

state_province VARCHAR2(10),
country_id CHAR(2));
/

-- Create the object table cust_address_objtab.
CREATE TABLE oe.cust_address_objtab OF oe.cust_address_typ;

-- Create table with REF to cust_address_typ.
CREATE TABLE oe.customers_with_ref (
 customer_id NUMBER(6) PRIMARY KEY,
 cust_first_name VARCHAR2(20),
 cust_last_name VARCHAR2(20),
 cust_address REF oe.cust_address_typ
 SCOPE IS oe.cust_address_objtab);

```

Assuming the `cust_address_typ` exists at the materialized view database with the same object identifier as the type at the master database, you can create a `cust_address_objtab_mv` object materialized view using the following statement:

```

CREATE MATERIALIZED VIEW oe.cust_address_objtab_mv OF oe.cust_address_typ AS
 SELECT * FROM oe.cust_address_objtab@orcl.example.com;

```

Now, you can create a materialized view of the `customers_with_ref` master table and rescope the `REF` to the `cust_address_objtab_mv` materialized view using the following statement:

```

CREATE MATERIALIZED VIEW oe.customers_with_ref_mv
(SCOPE FOR (cust_address) IS oe.cust_address_objtab_mv)
AS SELECT * FROM oe.customers_with_ref@orcl.example.com;

```

To use the `SCOPE FOR` clause when you create a materialized view, remember to create the materialized view or table specified in the `SCOPE FOR` clause first. Otherwise, you cannot specify the `SCOPE FOR` clause during materialized view creation. For example, if you had created the `customers_with_ref_mv` materialized view before you created the `cust_address_objtab_mv` materialized view, then you could not use the `SCOPE FOR` clause when you created the `customers_with_ref_mv` materialized view. In this case, the `REFs` are considered dangling because they point back to the object table at the remote master database.

However, even if you do not use the `SCOPE FOR` clause when you are creating a materialized view, you can alter the materialized view to specify a `SCOPE FOR` clause. For example, you can alter the `customers_with_ref_mv` materialized view with the following statement:

```

ALTER MATERIALIZED VIEW oe.customers_with_ref_mv
MODIFY SCOPE FOR (cust_address) IS oe.cust_address_objtab_mv;

```

### 58.10.6.3 Unscoped REF Columns

If you create a materialized view based on a remote master table with an unscoped `REF` column, then the `REF` column is created in the materialized view, but the `REFs` are considered dangling because they point to a remote database.

### 58.10.6.4 Logging REF Columns in the Materialized View Log

If necessary, you can log `REF` columns in the materialized view log.

 **See Also:**

["Logging Columns in a Materialized View Log"](#)

### 58.10.6.5 REFs Created Using the WITH ROWID Clause

If the `WITH ROWID` clause is specified for a `REF` column, then Oracle Database maintains the `rowid` of the object referenced in the `REF`.

Oracle Database can find the object referenced directly using the `rowid` contained in the `REF`, without the need to fetch the `rowid` from the `OID` index. Therefore, you use the `WITH ROWID` clause to specify a `rowid` hint. The `WITH ROWID` clause is not supported for scoped `REFS`.

Replicating a `REF` created using the `WITH ROWID` clause results in an incorrect `rowid` hint at each replication database except the database where the `REF` was first created or modified. The `ROWID` information in the `REF` is meaningless at the other databases, and Oracle Database does not correct the `rowid` hint automatically. Invalid `rowid` hints can cause performance problems. In this case, you can use the `VALIDATE STRUCTURE` option of the `ANALYZE TABLE` statement to determine which `rowid` hints at each replication database are incorrect.

 **See Also:**

*Oracle Database SQL Language Reference* for more information about the `ANALYZE TABLE` statement

## 58.11 Materialized View Registration at a Master Database

At the master database, an Oracle Database automatically registers information about a materialized view based on its master table(s).

- [Viewing Information about Registered Materialized Views](#)  
A materialized view is registered at its master database.
- [Internal Mechanisms](#)  
Oracle Database automatically registers a materialized view at its master database when you create the materialized view, and unregisters the materialized view when you drop it.
- [Manual Materialized View Registration](#)  
If necessary, you can maintain registration manually.

### 58.11.1 Viewing Information about Registered Materialized Views

A materialized view is registered at its master database.

You can query the `DBA_REGISTERED_MVIEWS` data dictionary view at a master database to list the following information about a remote materialized view:

- The owner, name, and database that contains the materialized view
- The materialized view's defining query
- Other materialized view characteristics, such as its refresh method

You can also query the `DBA_MVIEW_REFRESH_TIMES` view at a master database to obtain the last refresh times for each materialized view. Administrators can use this information to monitor materialized view activity and coordinate changes to materialized view databases if a master table must be dropped, altered, or relocated.

## 58.11.2 Internal Mechanisms

Oracle Database automatically registers a materialized view at its master database when you create the materialized view, and unregisters the materialized view when you drop it.

### Note:

Oracle Database cannot guarantee the registration or unregistration of a materialized view at its master database during the creation or drop of the materialized view, respectively. If Oracle Database cannot successfully register a materialized view during creation, then you must complete the registration manually using the `REGISTER_MVIEW` procedure in the `DBMS_MVIEW` package. If Oracle Database cannot successfully unregister a materialized view when you drop the materialized view, then the registration information for the materialized view persists in the master database until it is manually unregistered. It is possible that complex materialized views might not be registered.

## 58.11.3 Manual Materialized View Registration

If necessary, you can maintain registration manually.

Use the `REGISTER_MVIEW` and `UNREGISTER_MVIEW` procedures of the `DBMS_MVIEW` package at the master database to add, modify, or remove materialized view registration information.

### See Also:

The `REGISTER_MVIEW` and `UNREGISTER_MVIEW` procedures are described in the *Oracle Database PL/SQL Packages and Types Reference*

# Read-Only Materialized View Architecture

Several objects are used in materialized view replication. Some of these objects are optional and are used only as needed to support the created materialized view environment. For example, if you have a complex materialized view that cannot be fast refreshed, then you might not have a materialized view log at the master database.

- **Master Database Mechanisms**  
There are mechanisms that support materialized views at the master database.
- **Materialized View Database Mechanisms**  
When a materialized view is created, additional mechanisms are created at the materialized view database to support the materialized view. Specifically, at least one index is created.
- **Organizational Mechanisms**  
Several mechanisms organize the materialized views at the materialized view database. These mechanisms maintain organizational consistency between the materialized view database and its master database.
- **Refresh Process**  
To ensure that a materialized view is consistent with its master table, you must refresh the materialized view periodically.

## 59.1 Master Database Mechanisms

There are mechanisms that support materialized views at the master database.

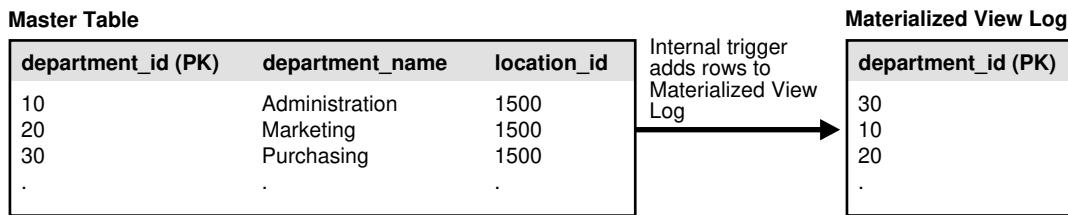

- **Master Database Objects**  
Specific database objects are required at a master database to support fast refreshing of materialized views.
- **Master Table**  
The master table is the basis for the materialized view.
- **Internal Trigger for the Materialized View Log**  
When changes are made to the master table using DML, an internal trigger records information about the affected rows in the materialized view log.
- **Materialized View Logs**  
Materialized view logs enable fast refreshes of materialized views.

### 59.1.1 Master Database Objects

Specific database objects are required at a master database to support fast refreshing of materialized views.

The three database objects displayed in [Figure 59-1](#) are required at a master database to support fast refreshing of materialized views.

**Figure 59-1 Master Database Objects**

## 59.1.2 Master Table

The master table is the basis for the materialized view.

A master table is located at the target master database. Remember that a materialized view points to only one master database. Data manipulation language (DML) changes made to the master table, as recorded by the materialized view log, are propagated to the materialized view during the refresh process.

 **Note:**

Fast refreshable materialized views must be based on master tables or synonyms of master tables. Complete refresh must be used for a materialized view based on a view.

## 59.1.3 Internal Trigger for the Materialized View Log

When changes are made to the master table using DML, an internal trigger records information about the affected rows in the materialized view log.

This information includes the values of the primary key, rowid, or object id, or both, as well as the values of the other columns logged in the materialized view log. This is an internal AFTER ROW trigger that is automatically activated when you create a materialized view log for the target master table. It inserts a row into the materialized view log whenever an INSERT, UPDATE, or DELETE statement modifies the table's data. This trigger is always the last trigger to fire.

 **Note:**

When the materialized view contains a subquery, you might need to log columns referenced in a subquery. See "[Data Subsetting with Materialized Views](#)" for information about subquery materialized views and "[Logging Columns in a Materialized View Log](#)" for more information about the columns that must be logged.

## 59.1.4 Materialized View Logs

Materialized view logs enable fast refreshes of materialized views.

- [About Materialized View Logs](#)  
A materialized view log is required on a master table to perform a fast refresh on materialized views based on the master table.
- [Columns Logged in the Materialized View Log](#)  
When you create a materialized view log, you can add columns to the log when necessary.
- [Restriction on Import of Materialized View Logs to a Different Schema](#)  
Materialized view logs are exported with the schema name explicitly given in the DDL statements. Therefore, materialized view logs cannot be imported into a schema that is different than the schema from which they were exported.

### 59.1.4.1 About Materialized View Logs

A materialized view log is required on a master table to perform a fast refresh on materialized views based on the master table.

When you create a materialized view log for a master table, Oracle Database creates an underlying table as the materialized view log. A materialized view log can hold the primary keys, rowids, or object identifiers of rows that have been updated in the master table. A materialized view log can also contain other columns to support fast refreshes of materialized views with subqueries.

The name of a materialized view log's table is `MLOG$_master_table_name`. The materialized view log is created in the same schema as the target master table. One materialized view log can support multiple materialized views on its master table. As described in the previous section, the internal trigger adds change information to the materialized view log whenever a DML transaction has taken place on the target master table.

Following are the types of materialized view logs:

- **Primary Key:** The materialized view records changes to the master table based on the primary key of the affected rows.
- **Row ID:** The materialized view records changes to the master table based on the rowid of the affected rows.
- **Object ID:** The materialized view records changes to the master object table based on the object identifier of the affected row objects.
- **Combination:** The materialized view records changes to the master table based any combination of the three options. It is possible to record changes based on the primary key, the ROWID, and the object identifier of the affected rows. Such a materialized view log supports primary key, ROWID, and object materialized views, which is helpful for environments that have all three types of materialized views based on a master table.

A combination materialized view log works in the same manner as a materialized view log that tracks only one type of value, except that more than one type of value is recorded. For example, a combination materialized view log can track both the primary key and the rowid of the affected row.

Though the difference between materialized view logs based on primary keys and rowids is small (one records affected rows using the primary key, while the other records affected rows using the physical rowid), the practical impact is large. Using rowid materialized views and materialized view logs makes reorganizing and truncating your master tables difficult because it prevents your `ROWID` materialized views from being fast refreshed. If you reorganize or truncate your master table, then your rowid materialized view must be `COMPLETE` refreshed because the rowids of the master table have changed.

 **Note:**

- You use the `BEGIN_TABLE_REORGANIZATION` and `END_TABLE_REORGANIZATION` procedures in the `DBMS_MVIEW` package to reorganize a master table. See the *Oracle Database PL/SQL Packages and Types Reference* for more information.
- Online redefinition of tables is another possible way to reorganize master tables, but online redefinition is not allowed on master tables with materialized view logs and materialized views. Online redefinition is allowed on master tables that do not have materialized view logs. See "Redefining Tables Online".

 **See Also:**

"[Creating Materialized View Logs](#)"

#### 59.1.4.2 Columns Logged in the Materialized View Log

When you create a materialized view log, you can add columns to the log when necessary.

To perform a fast refresh on a materialized view, the following types of columns must be added to the materialized view log:

- A column referenced in the `WHERE` clause of a subquery that is not part of an equi-join and is not a primary key column. These columns are called filter columns.
- A column in an equi-join that is not a primary key column, if the subquery is either many to many or one to many. If the subquery is many to one, then you do not need to add the join column to the materialized view log.

A collection column cannot be added to a materialized view log. Also, materialized view logs are not required for materialized views that use complete refresh.

For example, consider the following DDL:

```
1) CREATE MATERIALIZED VIEW oe.customers REFRESH FAST AS
2) SELECT * FROM oe.customers@orcl.example.com c
3) WHERE EXISTS
4) (SELECT * FROM oe.orders@orcl.example.com o
5) WHERE c.customer_id = o.customer_id AND o.order_total > 20000);
```

Notice in line 5 of the preceding DDL that three columns are referenced in the WHERE clause. Columns `orders.customer_id` and `customers.customer_id` are referenced as part of the equi-join clause. Because `customers.customer_id` is a primary key column, it is logged by default, but `orders.customer_id` is not a primary key column and so must be added to the materialized view log. Also, the column `orders.order_total` is an additional filter column and so must be logged.

Therefore, add `orders.customer_id` and `orders.order_total` to the materialized view log for the `oe.orders` table.

You are encouraged to analyze the defining queries of your planned materialized views and identify which columns must be added to your materialized view logs. If you try to create or refresh a materialized view that requires an added column without adding the column to the materialized view log, then your materialized view creation or refresh might fail.

 **Note:**

To perform a fast refresh on a materialized view, you must add join columns in subqueries to the materialized view log if the join column is not a primary key and the subquery is either many to many or one to many. If the subquery is many to one, then you do not need to add the join column to the materialized view log.

 **See Also:**

- ["Creating Materialized View Logs"](#) for information about creating a materialized view log
- ["Logging Columns in a Materialized View Log"](#)
- ["Data Subsetting with Materialized Views"](#) for information about materialized views with subqueries
- ["Restrictions for Materialized Views with Subqueries"](#) for additional information about materialized views with subqueries

#### 59.1.4.3 Restriction on Import of Materialized View Logs to a Different Schema

Materialized view logs are exported with the schema name explicitly given in the DDL statements. Therefore, materialized view logs cannot be imported into a schema that is different than the schema from which they were exported.

An error is written to the import log file and the items are not imported if you attempt an import using the Data Pump Import utility that specifies the `REMAP_SCHEMA` import parameter to import an export dump file that contains materialized view logs in the specified schema.

## 59.2 Materialized View Database Mechanisms

When a materialized view is created, additional mechanisms are created at the materialized view database to support the materialized view. Specifically, at least one index is created.

 **Note:**

The size limit for a materialized view name is 30 bytes. If you try to create a materialized view with a name larger than 30 bytes, Oracle Database returns an error.

- [Indexes for Materialized Views](#)

At least one index is created at the remote materialized view database for each primary key and ROWID materialized view.

### 59.2.1 Indexes for Materialized Views

At least one index is created at the remote materialized view database for each primary key and ROWID materialized view.

For a primary key materialized view, the index corresponds to the primary key of the target master table and includes `_PK` in its name. A number is appended if an index with the same name already exists at the materialized view database. For a ROWID materialized view, the index is on the `ROWID` column and includes `I_SNAP$` in its name. Additional indexes can be created by Oracle Database at the remote materialized view database to support fast refreshing of materialized views with subqueries.

## 59.3 Organizational Mechanisms

Several mechanisms organize the materialized views at the materialized view database. These mechanisms maintain organizational consistency between the materialized view database and its master database.

- [Refresh Groups](#)

To preserve referential integrity and transactional (read) consistency among multiple materialized views, Oracle Database can refresh individual materialized views as part of a refresh group.

- [Refresh Group Size](#)

There are a few trade-offs to consider when you are deciding on the size of your refresh groups.

### 59.3.1 Refresh Groups

To preserve referential integrity and transactional (read) consistency among multiple materialized views, Oracle Database can refresh individual materialized views as part of a refresh group.

After refreshing all of the materialized views in a refresh group, the data of all materialized views in the group correspond to the same transactionally consistent point in time.

### 59.3.2 Refresh Group Size

There are a few trade-offs to consider when you are deciding on the size of your refresh groups.

Oracle Database is optimized for large refresh groups. So, large refresh groups refresh faster than an equal number of materialized views in small refresh groups, if the materialized views in the groups are similar. For example, refreshing a refresh group with 100 materialized views is faster than refreshing five refresh groups with 20 materialized views each. Also, large refresh groups enable you to refresh a greater number of materialized views with only one call to a PL/SQL subprogram.

Network connectivity must be maintained while performing a refresh. If the connectivity is lost or interrupted during the refresh, then all changes are rolled back so that the database remains consistent. Therefore, in cases where the network connectivity is difficult to maintain, consider using smaller refresh groups.

There is also an optimization for null refresh. That is, if there were no changes to the master tables since the last refresh for a particular materialized view, then almost no extra time is required for the materialized view during refresh.

## 59.4 Refresh Process

To ensure that a materialized view is consistent with its master table, you must refresh the materialized view periodically.

- [About the Refresh Process](#)  
A **materialized view refresh** is an efficient batch operation that makes a materialized view reflect a more current state of its master table.
- [Refresh Types](#)  
Oracle Database can refresh a materialized view using either a fast, complete, or force refresh.
- [Initiating a Refresh](#)  
When creating a refresh group, you can configure the group so that Oracle Database automatically refreshes the group's materialized views at scheduled intervals. Conversely, you can omit scheduling information so that the refresh group must be refreshed manually or "on-demand." Manual refresh is an ideal solution when the refresh is performed on a system that does not always have a network connection.
- [Constraints and Refresh](#)  
To avoid any integrity constraint violations during refresh of materialized views, make non primary key integrity constraints on each materialized view deferrable.

### 59.4.1 About the Refresh Process

A **materialized view refresh** is an efficient batch operation that makes a materialized view reflect a more current state of its master table.

A materialized view's data does not necessarily match the current data of its master table at all times. A materialized view is a transactionally (read) consistent reflection of

its master table as the data existed at a specific point in time (that is, at creation or when a refresh occurs). To keep a materialized view's data relatively current with the data of its master table, the materialized view must be refreshed periodically.

A row in a master table can be updated many times between refreshes of a materialized view, but the refresh updates the row in the materialized view only once with the current data. For example, a row in a master table might be updated 10 times since the last refresh of a materialized view, but the result is still only one update of the corresponding row in the materialized view during the next refresh.

Decide how and when to refresh each materialized view to make it more current. For example, materialized views based on master tables that applications update often might require frequent refreshes. In contrast, materialized views based on relatively static master tables usually require infrequent refreshes. In summary, analyze application characteristics and requirements to determine appropriate materialized view refresh intervals.

To refresh materialized views, Oracle Database supports several refresh types and methods of initiating a refresh.

## 59.4.2 Refresh Types

Oracle Database can refresh a materialized view using either a fast, complete, or force refresh.

- **Complete Refresh**

To perform a **complete refresh** of a materialized view, the server that manages the materialized view executes the materialized view's defining query, which essentially re-creates the materialized view.

- **Fast Refresh**

To perform a **fast refresh**, the master table that manages the materialized view first identifies the changes that occurred in the master table since the most recent refresh of the materialized view and then applies these changes to the materialized view.

- **Force Refresh**

To perform a **force refresh** of a materialized view, the server that manages the materialized view attempts to perform a fast refresh. If a fast refresh is not possible, then Oracle Database performs a complete refresh.

### 59.4.2.1 Complete Refresh

To perform a **complete refresh** of a materialized view, the server that manages the materialized view executes the materialized view's defining query, which essentially re-creates the materialized view.

To refresh the materialized view, the result set of the query replaces the existing materialized view data. Oracle Database can perform a complete refresh for any materialized view. Depending on the amount of data that satisfies the defining query, a complete refresh can take a substantially longer amount of time to perform than a fast refresh.

 **Note:**

If complete refresh is used for a materialized view, then set its PCTFREE to 0 and PCTUSED to 99 for maximum efficiency.

### 59.4.2.2 Fast Refresh

To perform a **fast refresh**, the master table that manages the materialized view first identifies the changes that occurred in the master table since the most recent refresh of the materialized view and then applies these changes to the materialized view.

Fast refreshes are more efficient than complete refreshes when there are few changes to the master table because the participating server and network replicate a smaller amount of data. You can perform fast refreshes of materialized views only when the master table has a materialized view log. Also, for fast refreshes to be faster than complete refreshes, each join column in the `CREATE MATERIALIZED VIEW` statement must have an index on it.

After a direct path load on a master table using SQL\*Loader, a fast refresh does not apply the changes that occurred during the direct path load. Also, fast refresh does not apply changes that result from other types of bulk load operations on master tables. Examples of these operations include `INSERT` statements with an `APPEND` hint and `INSERT ... SELECT * FROM` statements.

If you have materialized views based on partitioned master tables, then you might be able to use Partition Change Tracking (PCT) to identify which materialized view rows correspond to a particular partition. PCT is also used to support fast refresh after partition maintenance operations on a materialized view's master table. PCT-based refresh on a materialized view is possible only if several conditions are satisfied.

 **See Also:**

*Oracle Database Data Warehousing Guide* for information about PCT and about PCT-based refresh

### 59.4.2.3 Force Refresh

To perform a **force refresh** of a materialized view, the server that manages the materialized view attempts to perform a fast refresh. If a fast refresh is not possible, then Oracle Database performs a complete refresh.

Use the force setting when you want a materialized view to refresh if a fast refresh is not possible.

## 59.4.3 Initiating a Refresh

When creating a refresh group, you can configure the group so that Oracle Database automatically refreshes the group's materialized views at scheduled intervals. Conversely, you can omit scheduling information so that the refresh group must be

refreshed manually or "on-demand." Manual refresh is an ideal solution when the refresh is performed on a system that does not always have a network connection.

- **Scheduled Refresh**  
When you create a refresh group for automatic refreshing, you must specify a scheduled refresh interval for the group during the creation process.
- **On-Demand Refresh**  
On-demand refresh means that the materialized view is refreshed with an explicit procedure call.

#### 59.4.3.1 Scheduled Refresh

When you create a refresh group for automatic refreshing, you must specify a scheduled refresh interval for the group during the creation process.

When setting a group's refresh interval, consider the following characteristics:

- The dates or date expressions specifying the refresh interval must evaluate to a future point in time.
- The refresh interval must be greater than the length of time necessary to perform a refresh.
- Relative date expressions evaluate to a point in time relative to the most recent refresh date. If a network or system failure interferes with a scheduled group refresh, then the evaluation of a relative date expression could change accordingly.
- Explicit date expressions evaluate to specific points in time, regardless of the most recent refresh date.
- Consider your environment's tolerance for stale data: if there is a low tolerance, then refresh often; whereas if there is a high tolerance, then refresh less often.

The following are examples of simple date expressions that you can use to specify an interval:

- An interval of one hour is specified as:  
`SYSDATE + 1/24`
- An interval of seven days is specified as:  
`SYSDATE + 7`

##### See Also:

*Oracle Database SQL Language Reference* for more information about date arithmetic

#### 59.4.3.2 On-Demand Refresh

On-demand refresh means that the materialized view is refreshed with an explicit procedure call.

Scheduled materialized view refreshes might not always be the appropriate solution for your environment. For example, immediately following a bulk data load into a

master table, dependent materialized views no longer represent the master table's data.

You might also want to refresh your materialized views on-demand when your materialized views are integrated with a sales force automation system located on a disconnected laptop. Developers designing the sales force automation software can create an application control, such as a button, that a salesperson can use to refresh the materialized views when they are ready to transfer the day's orders to the server after establishing a network connection.

The following example illustrates an on-demand refresh of the `hr_refg` refresh group:

```
EXECUTE DBMS_REFRESH.REFRESH('hr_refg');
```

 **Note:**

Do not use the `DBMS_MVIEW.REFRESH_ALL_MVIEWS` or the `DBMS_MVIEW.REFRESH_DEPENDENT` procedure to refresh materialized views used in a replication environment. Instead, use the `DBMS_REFRESH.REFRESH` or the `DBMS_MVIEW.REFRESH` procedure to refresh materialized views in a replication environment.

#### 59.4.4 Constraints and Refresh

To avoid any integrity constraint violations during refresh of materialized views, make non primary key integrity constraints on each materialized view deferrable.

This requirement includes LOB columns with `NOT NULL` constraints. In addition, all materialized views that are related by foreign key constraints should be refreshed together or in the same refresh group.

 **Note:**

Primary key constraints on materialized views might or might not be deferrable.

 **See Also:**

*Oracle Database SQL Language Reference* for information about making constraints deferrable

# Planning for Read-Only Materialized Views

Before you begin to plan your read-only materialized view environment, it is important to understand the concepts and architecture related to materialized views. After you understand concepts and architecture of read-only materialized views, there are important considerations for planning a read-only materialized view environment.

- [Considerations for Master Tables](#)  
For master tables, you must consider primary keys, foreign keys, and data types.
- [Planning for Master Databases and Materialized View Databases](#)  
Planning databases in a read-only materialized view environment includes preparing for materialized views and configuring materialized view logs.

## 60.1 Considerations for Master Tables

For master tables, you must consider primary keys, foreign keys, and data types.

- [Primary Keys and Master Tables](#)  
If possible, each master table should have a primary key.
- [Foreign Keys and Master Tables](#)  
When replicating tables with foreign key referential constraints, Oracle recommends that you always index foreign key columns and replicate these indexes, unless no updates and deletes are allowed in the parent table. Indexes are not replicated automatically.
- [Data Type Considerations for Master Tables](#)  
There are several considerations for data types and master tables.
- [Unsupported Table Types](#)  
Materialized views cannot be based on certain types of tables.

### 60.1.1 Primary Keys and Master Tables

If possible, each master table should have a primary key.

Where a primary key is not possible, each master table must have a set of columns that can be used as a unique identifier for each row of the table. If the tables that you plan to use in your replication environment do not have a primary key or a set of unique columns, then alter these tables accordingly. In addition, if you plan to create any primary key materialized views based on a master table, then that master must have a primary key.

### 60.1.2 Foreign Keys and Master Tables

When replicating tables with foreign key referential constraints, Oracle recommends that you always index foreign key columns and replicate these indexes, unless no updates and deletes are allowed in the parent table. Indexes are not replicated automatically.

### 60.1.3 Data Type Considerations for Master Tables

There are several considerations for data types and master tables.

You can create read-only materialized views based on master tables with columns that use the following data types:

- VARCHAR2
- NVARCHAR2
- NUMBER
- DATE
- TIMESTAMP
- TIMESTAMP WITH TIME ZONE
- TIMESTAMP LOCAL TIME ZONE
- INTERVAL YEAR TO MONTH
- INTERVAL DAY TO SECOND
- RAW
- ROWID
- CHAR
- NCHAR
- CLOB with BASICFILE storage
- NCLOB with BASICFILE storage
- BLOB with BASICFILE storage
- XMLType stored as CLOB
- User-defined types that do not use type inheritance or type evolution
- Oracle-supplied types that do not use type inheritance or type evolution

 **Note:**

XMLType stored as a CLOB is deprecated.

You cannot reference LOB columns in a WHERE clause of a materialized view's defining query.

You can create materialized views that use user-defined types, including column objects, object tables, REFS, varrays, and nested tables.

You cannot create materialized views based on master tables with columns that use the following data types:

- FLOAT
- BINARY\_FLOAT

- BINARY\_DOUBLE
- LONG
- LONG RAW
- CLOB with SECUREFILE storage
- NCLOB with SECUREFILE storage
- BLOB with SECUREFILE storage
- BFILE
- XMLType stored object relationally or as binary XML
- Expression type
- User-defined types that use type inheritance or type evolution
- Oracle-supplied types that use type inheritance or type evolution

You should convert LONG data types to LOBs with BASICFILE storage.

 **See Also:**

*Oracle Database SQL Language Reference* for information about data types

#### 60.1.4 Unsupported Table Types

Materialized views cannot be based on certain types of tables.

You cannot create materialized views based on these types of tables:

- Tables that have been compressed with the table compression feature
- Tables with virtual columns
- Temporary tables
- Tables in a flashback data archive

### 60.2 Planning for Master Databases and Materialized View Databases

Planning databases in a read-only materialized view environment includes preparing for materialized views and configuring materialized view logs.

- [Characteristics of Master Databases and Materialized View Databases](#)  
When you are planning your replication environment, you must decide whether the databases participating in the replication environment will be master databases or materialized view databases.
- [Advantages of Master Databases](#)  
Master databases have several advantages.
- [Advantages of Materialized View Databases](#)  
Materialized view databases have certain advantages.

- [Preparing for Materialized Views](#)  
Most problems encountered with materialized view replication result from not preparing the environment properly.
- [Creating Materialized View Logs](#)  
Create a materialized view log on a master table so that materialized views based on the master table can be fast refreshed.
- [Logging Columns in a Materialized View Log](#)  
When you create a materialized view log, you can add columns to the log to enable fast refreshes of materialized views.

## 60.2.1 Characteristics of Master Databases and Materialized View Databases

When you are planning your replication environment, you must decide whether the databases participating in the replication environment will be master databases or materialized view databases.

Consider the characteristics and advantages of both types of databases when you are deciding whether a particular database in your environment should be a master database or a materialized view database. One replication environment can support both master databases and materialized view databases.

**Table 60-1 Characteristics of Master Databases and Materialized View Databases**

| Master Databases                                                     | Materialized View Databases                                                     |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Might communicate with a large number of materialized view databases | Communicate with one master database                                            |
| Contain large amounts of data                                        | Contain small amounts of data that can be subsets of the master database's data |

## 60.2.2 Advantages of Master Databases

Master databases have several advantages.

Master databases have the following advantages:

- Support for highly available data access by remote databases
- Provide support data manipulation language (DML) changes
- Can provide failover protection

## 60.2.3 Advantages of Materialized View Databases

Materialized view databases have certain advantages.

Materialized view databases have the following advantages:

- Support disconnected computing
- Can contain a subset of its master database's data

## 60.2.4 Preparing for Materialized Views

Most problems encountered with materialized view replication result from not preparing the environment properly.

Ensure that the following prerequisites are met before creating your materialized view environment:

- Ensure that the required schemas exist.
- Ensure that the required database links exist.
- Ensure that the required privileges are granted.
- Ensure that the sufficient job processes exist.

- **Required Schemas at Materialized View Database**

A schema containing a materialized view in a remote database must correspond to the schema that contains the master table in the master database.

- **Required Database Links for Materialized Views**

The defining query of a materialized view can use one or more database links to reference remote table data.

- **Required Privileges**

Both the creator and the owner of the materialized view must be able to issue the defining SELECT statement of the materialized view.

- **Sufficient Job Processes**

It is important that you have allocated sufficient job processes to handle the automation of your replication environment. The job processes automatically refresh materialized views.

### 60.2.4.1 Required Schemas at Materialized View Database

A schema containing a materialized view in a remote database must correspond to the schema that contains the master table in the master database.

Therefore, identify the schemas that contain the master tables that you want to replicate with materialized views. After you have identified the target schemas at the master database, create the corresponding accounts with the same names at the remote database. For example, if all master tables are in the `sales` schema of the `ny.example.com` database, then create a corresponding `sales` schema in the materialized view database `sf.example.com`.

 **See Also:**

["Required Privileges for Materialized View Operations"](#)

### 60.2.4.2 Required Database Links for Materialized Views

The defining query of a materialized view can use one or more database links to reference remote table data.

Before creating materialized views, the database links you plan to use must be available. Furthermore, the account that a database link uses to access a remote database defines the security context under which Oracle Database creates and subsequently refreshes a materialized view.

To ensure proper behavior, a materialized view's defining query must use a database link that includes an embedded user name and password in its definition; you cannot use a public database link when creating a materialized view. A database link with an embedded name and password always establishes connections to the remote database using the specified account. Additionally, the remote account that the link uses must have the `SELECT` privileges necessary to access the data referenced in the materialized view's defining query.

Before creating your materialized views, you must create several administrative database links. Specifically, you should create a `PUBLIC` database link from the materialized view database to the master database. Doing so makes defining your private database links easier because you do not need to include the `USING` clause in each link.

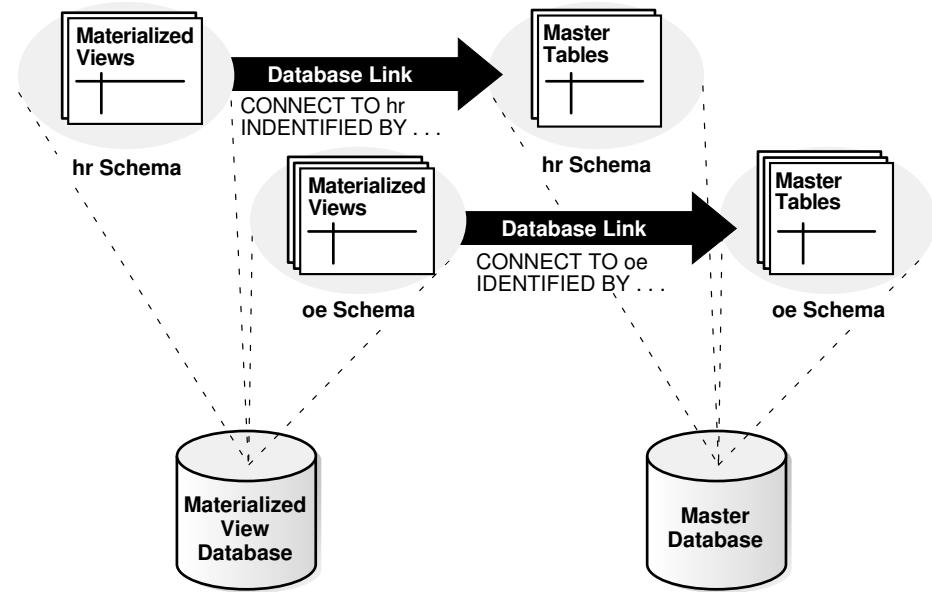

For example, the following statement creates a public database link from a materialized view database to a master database:

```
CREATE PUBLIC DATABASE LINK orcl.example.com USING 'orcl.example.com';
```

After the administrative database links have been created, a private database link must be created connecting each replicated materialized view schema at the materialized view database to the corresponding schema at the master database. Be sure to embed the associated master database account information in each private database link at the materialized view database. For example, the `hr` schema at a materialized view database should have a private database link to the master database that connects using the `hr` user name and password.

For example, the following statement creates a private database link from a materialized view database to a master database:

```
CREATE DATABASE LINK orcl.example.com
 CONNECT TO myuser IDENTIFIED BY password;
```

**Figure 60-1 Recommended Schema and Database Link Configuration**

The defining query for the materialized view cannot be modified by Virtual Private Database (VPD). VPD must return a `NULL` policy for the schema that performs both the create and refresh of the materialized view. Creating a materialized view with a non-`NULL` VPD policy is allowed when the `USING TRUSTED CONSTRAINTS` clause is specified. In this case, ensure that the materialized view behaves correctly. Materialized view results are computed based on the rows and columns filtered by VPD policy. Therefore, you must coordinate the materialized view definition with the VPD policy to ensure the correct results.

#### See Also:

- [Distributed Database Concepts](#) for more information about database links
- [Oracle Database Security Guide](#) for more information about VPD
- [Oracle Label Security Administrator's Guide](#) for information about Oracle Label Security

#### 60.2.4.3 Required Privileges

Both the creator and the owner of the materialized view must be able to issue the defining `SELECT` statement of the materialized view.

The owner is the schema that contains the materialized view.

 **See Also:**

["Required Privileges for Materialized View Operations"](#)

#### 60.2.4.4 Sufficient Job Processes

It is important that you have allocated sufficient job processes to handle the automation of your replication environment. The job processes automatically refresh materialized views.

By the nature of materialized view replication, each materialized view database typically has one scheduled link to the master database and requires at least one job process. Materialized view databases typically require between one and three job processes, depending on user-defined jobs and the scheduled link. Also, you need at least one job process for each degree of parallelism.

Alternatively, if your users are responsible for manually refreshing the materialized view through an application interface, then you do not need to create a scheduled link and your materialized view database requires one less job process.

The job processes are defined using the `JOB_QUEUE_PROCESSES` initialization parameter. This initialization parameter is modifiable. Therefore, you can modify it while an instance is running. Oracle Database automatically determines the interval for job processes. That is, Oracle Database determines when the job processes should "wake up" to execute jobs.

 **See Also:**

[Oracle Database Reference](#)

#### 60.2.5 Creating Materialized View Logs

Create a materialized view log on a master table so that materialized views based on the master table can be fast refreshed.

Before creating materialized views for a remote materialized view database, ensure that you create the necessary materialized view logs at the master database. A materialized view log is necessary for every master table that supports at least one materialized view with fast refreshes.

To create a materialized view log, you need the following privileges:

- `CREATE ANY TABLE`
- `CREATE ANY TRIGGER`
- `SELECT` (on the materialized view log's master table)
- `COMMENT ANY TABLE`

To create a materialized view log:

1. Connect to the master database as a user with the required privileges to create a materialized view log on the intended table.
2. Run the CREATE MATERIALIZED VIEW LOG statement.

When you create a materialized view log on an object table, you must log the object identifier by specifying the WITH OBJECT ID clause, but you can also specify that the primary key is logged if the object identifier is primary key-based.

#### Example 60-1 Creating a Materialized View Log

```
CREATE MATERIALIZED VIEW LOG ON hr.employees;
```

#### Example 60-2 Creating a Materialized View Log on an Object Table

The following SQL statement creates the categories\_typ user-defined type:

```
CREATE TYPE oe.category_typ AS OBJECT
 (category_name VARCHAR2(50),
 category_description VARCHAR2(1000),
 category_id NUMBER(2));
/
```

When you create an object table based on this type, you can either specify that the object identifier should be system-generated or primary key-based:

```
CREATE TABLE oe.categories_tab_sys OF oe.category_typ
 (category_id PRIMARY KEY)
 OBJECT ID SYSTEM GENERATED;

CREATE TABLE oe.categories_tab_pkbased OF oe.category_typ
 (category_id PRIMARY KEY)
 OBJECT ID PRIMARY KEY;
```

For example, the following statement creates a materialized view log for the categories\_tab\_sys object table and specifies that the object identifier column be logged:

```
CREATE MATERIALIZED VIEW LOG ON oe.categories_tab_sys
 WITH OBJECT ID;
```

The following statement creates a materialized view log for the categories\_tab\_pkbased object table and specifies that the primary key column be logged along with the object identifier column:

```
CREATE MATERIALIZED VIEW LOG ON oe.categories_tab_pkbased
 WITH OBJECT ID, PRIMARY KEY;
```

#### See Also:

- ["Materialized View Log"](#)
- [Oracle Database SQL Language Reference](#)

## 60.2.6 Logging Columns in a Materialized View Log

When you create a materialized view log, you can add columns to the log to enable fast refreshes of materialized views.

1. Connect to the master database as a user with the required privileges to create or alter a materialized view log on the intended table.
2. Do one of the following:
  - Run the CREATE MATERIALIZED VIEW LOG statement and specify the columns to log.
  - Run the ALTER MATERIALIZED VIEW LOG statement and specify the columns to log.

### Example 60-3 Logging Columns When Creating a Materialized View

To create the materialized view log on the oe.orders table with the orders.customer\_id and orders.order\_total columns added, issue the following statement:

```
CREATE MATERIALIZED VIEW LOG ON oe.orders
 WITH PRIMARY KEY (customer_id,order_total);
```

### Example 60-4 Logging Columns of an Existing Materialized View

You can add the orders.customer\_id and orders.order\_total columns to the materialized view log on the oe.orders table by issuing the following statement:

```
ALTER MATERIALIZED VIEW LOG ON oe.orders ADD (customer_id,order_total);
```

### Example 60-5 Logging the Attributes of Column Objects

If you are using user-defined data types, then the attributes of column objects can be logged in the materialized view log. For example, the oe.customers table has the cust\_address.postal\_code attribute, which can be logged in the materialized view log by issuing the following statement:

```
ALTER MATERIALIZED VIEW LOG ON oe.customers ADD (cust_address.postal_code);
```

## Creating and Managing Read-Only Materialized Views

You can create and manage read-only materialized views and refresh groups. You can also refresh materialized views.

- [Creating Read-Only Materialized Views](#)  
Create a read-only materialized view to replicate a master table's data in a materialized view database.
- [Creating Refresh Groups](#)  
Add materialized views to a refresh group to ensure transactional consistency between the related materialized views in the refresh group.
- [Refreshing Materialized Views](#)  
Refreshing a materialized view synchronizes the data in the materialized view's master(s) and the data in the materialized view.
- [Determining the Fast Refresh Capabilities of a Materialized View](#)  
You can determine whether a materialized view is fast refreshable by attempting to create the materialized view with the `REFRESH FAST` clause or by using the `DBMS_MVIEW.EXPLAIN_MVIEW` procedure.
- [Adding a New Materialized View Database](#)  
After you have created a materialized view environment with one or more materialized view databases, you might need to add new materialized view databases.
- [Monitoring Materialized View Logs](#)  
You can run queries to display information about the materialized view logs at a master database.
- [Monitoring Materialized Views](#)  
You can run queries to display information about the materialized views and refresh groups.

### 61.1 Creating Read-Only Materialized Views

Create a read-only materialized view to replicate a master table's data in a materialized view database.

Before creating a materialized view to replicate data between a master database and a materialized view database, the database links you plan to use must be available.

1. Connect to the database as a user with the required privileges to create a materialized view.
2. Run the `CREATE MATERIALIZED VIEW` statement.

#### Example 61-1 Creating a Primary Key Materialized View

```
CREATE MATERIALIZED VIEW hr.employees_mv1 WITH PRIMARY KEY
 AS SELECT * FROM hr.employees@orcl.example.com;
```

**Example 61-2 Creating a ROWID Materialized View**

```
CREATE MATERIALIZED VIEW oe.orders REFRESH WITH ROWID AS
 SELECT * FROM oe.orders@orcl.example.com;
```

**Example 61-3 Creating an Object Materialized View**

After the required types are created at the materialized view database, you can create an object materialized view by specifying the `OF type` clause.

For example, suppose the following SQL statements create the `oe.categories_tab` object table at the `orcl.example.com` master database:

```
CREATE TYPE oe.category_typ AS OBJECT
 (category_name VARCHAR2(50),
 category_description VARCHAR2(1000),
 category_id NUMBER(2));
/
CREATE TABLE oe.categories_tab OF oe.category_typ
 (category_id PRIMARY KEY);
```

To create materialized views that can be fast refreshed based on the `oe.categories_tab` master table, create a materialized view log for this table:

```
CREATE MATERIALIZED VIEW LOG ON oe.categories_tab WITH OBJECT ID;
```

The `WITH OBJECT ID` clause is required when you create a materialized view log on an object table.

After you create the `oe.category_typ` type at the materialized view database with the same object identifier as the same type at the master database, you can create an object materialized view based on the `oe.categories_tab` object table using the `OF type` clause, as in the following SQL statement:

```
CREATE MATERIALIZED VIEW oe.categories_objmv OF oe.category_typ
 REFRESH FAST
 AS SELECT * FROM oe.categories_tab@orcl.example.com;
```

Here, `type` is `oe.category_typ`.

 **Note:**

The types must be the same at the materialized view database and master database. See "[Type Agreement at Replication Databases](#)" for more information.

- [Read-Only Materialized View Concepts](#) for several examples that create materialized views
- ["Required Privileges for Materialized View Operations"](#) for information about the privileges required to create materialized views
- ["Required Database Links for Materialized Views"](#)
- ["Materialized Views Based on Object Tables"](#)
- [Oracle Database SQL Language Reference](#)

## 61.2 Creating Refresh Groups

Add materialized views to a refresh group to ensure transactional consistency between the related materialized views in the refresh group.

When a refresh group is refreshed, all materialized views that are added to a particular refresh group are refreshed at the same time.

1. Connect to the materialized view database as an administrative user with the required privileges to create a refresh group and add materialized views to it.
2. Run the `DBMS_REFRESH.MAKE` procedure to create the refresh group.
3. Run the `DBMS_REFRESH.ADD` procedure one or more times to add materialized views to the refresh group.

### Example 61-4 Creating a Refresh Group

This example creates a refresh group and adds two materialized views to it.

```
BEGIN
 DBMS_REFRESH.MAKE (
 name => 'mviewadmin.hr_refg',
 list => '',
 next_date => SYSDATE,
 interval => 'SYSDATE + 1/24',
 implicit_destroy => FALSE,
 rollback_seg => '',
 push_deferred_rpc => TRUE,
 refresh_after_errors => FALSE);
END;
/

BEGIN
 DBMS_REFRESH.ADD (
 name => 'mviewadmin.hr_refg',
 list => 'hr.countries_mv1',
 lax => TRUE);
END;
/

BEGIN
 DBMS_REFRESH.ADD (
 name => 'mviewadmin.hr_refg',
 list => 'hr.departments_mv1',
```

```
 lax => TRUE);
END;
/
```

 **See Also:**

"Refresh Groups"

## 61.3 Refreshing Materialized Views

Refreshing a materialized view synchronizes the data in the materialized view's master(s) and the data in the materialized view.

You can either refresh all of the materialized views in a refresh group at once, or you can refresh materialized views individually. If you have applications that depend on multiple materialized views at a materialized view database, then Oracle recommends using refresh groups so that the data is transactionally consistent in all of the materialized views used by the application.

1. Connect to the materialized view database as a user with the required privileges to refresh a refresh group or an individual materialized view.
2. Do one of the following:
  - Run the DBMS\_REFRESH.REFRESH procedure to refresh a refresh group.
  - Run the DBMS\_MVIEW.REFRESH procedure to refresh an individual materialized view.

### Example 61-5 Refreshing a Refresh Group

The following example refreshes the hr\_refg refresh group:

```
EXECUTE DBMS_REFRESH.REFRESH ('hr_refg');
```

### Example 61-6 Refreshing an Individual Materialized View

The following example refreshes the hr.departments\_mv materialized view:

```
BEGIN
 DBMS_MVIEW.REFRESH (
 list => 'hr.departments_mv',
 method => '?');
END;
/
```

 **Note:**

Do not use the DBMS\_MVIEW.REFRESH\_ALL\_MVIEWS or the DBMS\_MVIEW.REFRESH\_DEPENDENT procedure to refresh materialized views. Instead, use the DBMS\_REFRESH.REFRESH or the DBMS\_MVIEW.REFRESH procedure to refresh materialized views in a replication environment.

### See Also:

- ["Required Privileges for Materialized View Operations"](#) for information about the privileges required to create materialized views
- *Oracle Database PL/SQL Packages and Types Reference* for more information about the `DBMS_MVIEW` package

## 61.4 Determining the Fast Refresh Capabilities of a Materialized View

You can determine whether a materialized view is fast refreshable by attempting to create the materialized view with the `REFRESH FAST` clause or by using the `DBMS_MVIEW.EXPLAIN_MVIEW` procedure.

A fast refresh uses materialized view logs to update only the rows that have changed since the last refresh. To determine whether a materialized view is fast refreshable, create the materialized view with the `REFRESH FAST` clause. Oracle Database returns errors if the materialized view violates any restrictions for subquery materialized views. If you specify force refresh, then you might not receive any errors because, when a force refresh is requested, Oracle Database automatically performs a complete refresh if it cannot perform a fast refresh.

You can also use the `EXPLAIN_MVIEW` procedure in the `DBMS_MVIEW` package to determine the following information about an existing materialized view or a proposed materialized view that does not yet exist:

- The capabilities of a materialized view
- Whether each capability is possible
- If a capability is not possible, then why it is not possible

This information can be stored in a varray or in the `MV_CAPABILITIES_TABLE`. To store the information in the table, before you run the `EXPLAIN_MVIEW` procedure, you must build this table by running the `utlxmv.sql` script in the `Oracle_home/rdbms/admin` directory.

To determine the fast refresh capabilities of a materialized view:

1. Connect to the materialized view database as an administrative user.
2. Do one of the following:
  - Create the materialized view with the `REFRESH FAST` clause.
  - Run the `DBMS_MVIEW.EXPLAIN_MVIEW` procedure.

#### **Example 61-7 Creating a Materialized View with the FAST REFRESH Clause**

```
CREATE MATERIALIZED VIEW oe.orders REFRESH FAST AS
 SELECT * FROM oe.orders@orc1.example.com o
 WHERE EXISTS
 (SELECT * FROM oe.customers@orc1.example.com c
 WHERE o.customer_id = c.customer_id AND c.credit_limit > 10000);
```

### Example 61-8 Determining the Refresh Capabilities of an Existing Materialized View

For example, to determine the capabilities of the oe.orders materialized view, enter:

```
EXECUTE DBMS_MVIEW.EXPLAIN_MVIEW ('oe.orders');
```

### Example 61-9 Determining the Refresh Capabilities of a Materialized View That Does Not Yet Exist

Or, if the materialized view does not yet exist, then you can supply the query that you want to use to create it:

```
BEGIN
 DBMS_MVIEW.EXPLAIN_MVIEW ('SELECT * FROM oe.orders@orc1.example.com o
 WHERE EXISTS (SELECT * FROM oe.customers@orc1.example.com c
 WHERE o.customer_id = c.customer_id AND c.credit_limit > 500)');
END;
/
```

Query the MV\_CAPABILITIES\_TABLE to see the results.

Query the MV\_CAPABILITIES\_TABLE to see the results.

#### Note:

The MV\_CAPABILITIES\_TABLE does not show materialized view refresh capabilities that depend on prebuilt container tables. For example, complete refresh is required after a partition maintenance operation on a prebuilt container table, but the MV\_CAPABILITIES\_TABLE does not show this limitation.

#### See Also:

- ["Restrictions for Materialized Views with Subqueries"](#)
- ["Materialized View Log"](#)
- [Oracle Database Data Warehousing Guide](#) for more information about the EXPLAIN\_MVIEW procedure

## 61.5 Adding a New Materialized View Database

After you have created a materialized view environment with one or more materialized view databases, you might need to add new materialized view databases.

You might encounter problems when you try to perform a fast refresh on the materialized views you create at a new materialized view database if both of the following conditions are true:

- Materialized views at the new materialized view database and existing materialized views at other materialized view databases are based on the same master table.
- Existing materialized views can be refreshed while you create the new materialized views at the new materialized view database.

The problem arises when the materialized view logs for the master tables are purged before a new materialized view can perform its first fast refresh. If this happens and you try to perform a fast refresh on the materialized views at the new materialized view database, then you might encounter the following errors:

```
ORA-12004 REFRESH FAST cannot be used for materialized view materialized_view_name
ORA-12034 materialized view log on materialized_view_name younger than last refresh
```

If you receive these errors, then the only solution is to perform a complete refresh of the new materialized view. To avoid this problem, create a dummy materialized view at the new materialized view database before you create your production materialized views. The dummy materialized view ensures that the materialized view log will not be purged while your production materialized views are being created.

If you choose to create a dummy materialized view at the materialized view database, complete the following steps:

1. Create a dummy materialized view called `dummy_mvview` based on the master table. For example, to create a dummy materialized view based on a master table named `sales`, issue the following statement at the new materialized view database:

```
CREATE MATERIALIZED VIEW dummy_mvview REFRESH FAST AS
 SELECT * FROM pr.sales@orc1.example.com WHERE 1=0;
```

2. Create your production materialized views at the new materialized view database.
3. Perform fast refresh of your production materialized views at the new materialized view database.
4. Drop the dummy materialized view.

## 61.6 Monitoring Materialized View Logs

You can run queries to display information about the materialized view logs at a master database.

- [Listing Information About the Materialized View Logs at a Master Database](#)  
A materialized view log enables you to perform a fast refresh on materialized views based on a master. A master can be a master table or a master materialized view.
- [Listing the Materialized Views that Use a Materialized View Log](#)  
More than one materialized view can use a materialized view log.

## 61.6.1 Listing Information About the Materialized View Logs at a Master Database

A materialized view log enables you to perform a fast refresh on materialized views based on a master. A master can be a master table or a master materialized view.

If you have materialized view logs based at a master, then you can use the query in this section to list the following information about them:

- The name of each log table that stores the materialized view log data
- The owner of each materialized view log
- The master on which each materialized view log is based
- Whether a materialized view log is a row id materialized view log
- Whether a materialized view log is a primary key materialized view log
- Whether the materialized view log is an object id materialized view log
- Whether a materialized view log has filter columns

To view this information, complete the following steps:

1. Connect to the master database as an administrative user.
2. Run the following query:

```
COLUMN LOG_TABLE HEADING 'Log Table' FORMAT A20
COLUMN LOG_OWNER HEADING 'Log|Owner' FORMAT A5
COLUMN MASTER HEADING 'Master' FORMAT A15
COLUMN ROWIDS HEADING 'Row|ID?' FORMAT A3
COLUMN PRIMARY_KEY HEADING 'Primary|Key?' FORMAT A7
COLUMN OBJECT_ID HEADING 'Object|ID?' FORMAT A6
COLUMN FILTER_COLUMNS HEADING 'Filter|Columns?' FORMAT A8

SELECT DISTINCT LOG_TABLE,
 LOG_OWNER,
 MASTER,
 ROWIDS,
 PRIMARY_KEY,
 OBJECT_ID,
 FILTER_COLUMNS
 FROM DBA_MVIEW_LOGS
 ORDER BY 1;
```

Your output looks similar to the following:

| Log Table          | Log Owner | Master      | Row ID? | Primary Key? | Object ID? | Filter Columns? |
|--------------------|-----------|-------------|---------|--------------|------------|-----------------|
| MLOG\$_COUNTRIES   | HR        | COUNTRIES   | NO      | YES          | NO         | NO              |
| MLOG\$_DEPARTMENTS | HR        | DEPARTMENTS | NO      | YES          | NO         | NO              |
| MLOG\$_EMPLOYEES   | HR        | EMPLOYEES   | NO      | YES          | NO         | NO              |
| MLOG\$_JOBS        | HR        | JOBS        | NO      | YES          | NO         | NO              |
| MLOG\$_JOB_HISTORY | HR        | JOB_HISTORY | NO      | YES          | NO         | NO              |
| MLOG\$_LOCATIONS   | HR        | LOCATIONS   | NO      | YES          | NO         | NO              |
| MLOG\$_REGIONS     | HR        | REGIONS     | NO      | YES          | NO         | NO              |

## 61.6.2 Listing the Materialized Views that Use a Materialized View Log

More than one materialized view can use a materialized view log.

If you have materialized view logs based at a master, then you can use the query in this section to list the following the materialized views that use each log:

- The name of each log table that stores the materialized view log data
- The owner of each materialized view log
- The master on which each materialized view log is based
- The materialized view identification number of each materialized view that uses the materialized view log
- The name of each materialized view that uses the materialized view log

To view this information, complete the following steps:

1. Connect to the master database as an administrative user.
2. Run the following query:

```
COLUMN LOG_TABLE HEADING 'Mview|Log Table' FORMAT A20
COLUMN LOG_OWNER HEADING 'Mview|Log Owner' FORMAT A10
COLUMN MASTER HEADING 'Master' FORMAT A20
COLUMN MVVIEW_ID HEADING 'Mview|ID' FORMAT 9999
COLUMN NAME HEADING 'Mview Name' FORMAT A20

SELECT L.LOG_TABLE, L.LOG_OWNER, B.MASTER, B.MVVIEW_ID, R.NAME
FROM ALL_MVIEW_LOGS L, ALL_BASE_TABLE_MVIEWS B, ALL_REGISTERED_MVIEWS R
WHERE B.MVVIEW_ID = R.MVVIEW_ID
AND B.OWNER = L.LOG_OWNER
AND B.MASTER = L.MASTER;
```

Your output looks similar to the following:

| Mview<br>Log Table | Mview<br>Log Owner | Mview<br>Master | Mview<br>ID Mview Name |
|--------------------|--------------------|-----------------|------------------------|
| MLOG\$_COUNTRIES   | HR                 | COUNTRIES       | 21 COUNTRIES_MV1       |
| MLOG\$_DEPARTMENTS | HR                 | DEPARTMENTS     | 22 DEPARTMENTS_MV1     |
| MLOG\$_EMPLOYEES   | HR                 | EMPLOYEES       | 23 EMPLOYEES_MV1       |
| MLOG\$_JOBS        | HR                 | JOBS            | 24 JOBS_MV1            |
| MLOG\$_JOB_HISTORY | HR                 | JOB_HISTORY     | 25 JOB_HISTORY_MV1     |
| MLOG\$_LOCATIONS   | HR                 | LOCATIONS       | 26 LOCATIONS_MV1       |
| MLOG\$_REGIONS     | HR                 | REGIONS         | 27 REGIONS_MV1         |

## 61.7 Monitoring Materialized Views

You can run queries to display information about the materialized views and refresh groups.

- [Listing Information About Materialized Views](#)  
You can run queries to display information about the materialized views.
- [Listing Information About the Refresh Groups at a Materialized View Database](#)  
Each refresh group at a materialized view database is associated with a refresh job that refreshes the materialized views in the refresh group at a set interval.

- [Determining the Job ID for Each Refresh Job at a Materialized View Database](#)  
Query the DBA\_REFRESH and DBA\_JOBS views to determine the job identification number for each refresh job at a materialized view database.
- [Determining Which Materialized Views Are Currently Refreshing](#)  
Query the V\$MVREFRESH view to determine which materialized views are currently refreshing.

## 61.7.1 Listing Information About Materialized Views

You can run queries to display information about the materialized views.

- [Listing Master Database Information For Materialized Views](#)  
Query the DBA\_MVIEWS view to list the master database information for materialized views.
- [Listing the Properties of Materialized Views](#)  
Query the DBA\_MVIEWS view to list the properties of materialized views.

### 61.7.1.1 Listing Master Database Information For Materialized Views

Query the DBA\_MVIEWS view to list the master database information for materialized views.

Complete the following steps to show the master database for each materialized view at a replication database and whether the materialized view can be fast refreshed:

1. Connect to the materialized view database as an administrative user.
2. Run the following query:

```
COLUMN MVVIEW_NAME HEADING 'Materialized|View Name' FORMAT A15
COLUMN OWNER HEADING 'Owner' FORMAT A10
COLUMN MASTER_LINK HEADING 'Master Link' FORMAT A30
COLUMN Fast_Refresh HEADING 'Fast|Refreshable?' FORMAT A16

SELECT MVVIEW_NAME,
 OWNER,
 MASTER_LINK,
 DECODE(FAST_REFRESHABLE,
 'NO', 'NO',
 'DML', 'YES',
 'DIRLOAD', 'DIRECT LOAD ONLY',
 'DIRLOAD_DML', 'YES',
 'DIRLOAD_LIMITEDDML', 'LIMITED') Fast_Refresh
 FROM DBA_MVIEWS;
```

Your output looks similar to the following:

| Materialized<br>View Name | Owner | Master Link       | Fast<br>Refreshable? |
|---------------------------|-------|-------------------|----------------------|
| COUNTRIES_MV1             | HR    | @ORC1.EXAMPLE.COM | YES                  |
| DEPARTMENTS_MV1           | HR    | @ORC1.EXAMPLE.COM | YES                  |
| EMPLOYEES_MV1             | HR    | @ORC1.EXAMPLE.COM | YES                  |
| JOB_HISTORY_MV1           | HR    | @ORC1.EXAMPLE.COM | YES                  |
| LOCATIONS_MV1             | HR    | @ORC1.EXAMPLE.COM | YES                  |
| REGIONS_MV1               | HR    | @ORC1.EXAMPLE.COM | YES                  |

### 61.7.1.2 Listing the Properties of Materialized Views

Query the DBA\_MVIEWS view to list the properties of materialized views.

You can use the query in this section to list the following information about the materialized views at the current replication database:

- The name of each materialized view
- The owner of each materialized view
- The refresh method used by each materialized view: COMPLETE, FORCE, FAST, or NEVER
- The last date on which each materialized view was refreshed

To view this information, complete the following steps:

1. Connect to the materialized view database as an administrative user.
2. Run the following query to list this information:

To view this information, complete the following steps:

1. Connect to the materialized view database as an administrative user.
2. Run the following query:

```
COLUMN MVVIEW_NAME HEADING 'Materialized|View Name' FORMAT A15
COLUMN OWNER HEADING 'Owner' FORMAT A10
COLUMN REFRESH_METHOD HEADING 'Refresh|Method' FORMAT A10
COLUMN LAST_REFRESH_DATE HEADING 'Last|Refresh|Date'
COLUMN LAST_REFRESH_TYPE HEADING 'Last|Refresh|Type' FORMAT A15

SELECT MVVIEW_NAME,
 OWNER,
 REFRESH_METHOD,
 LAST_REFRESH_DATE,
 LAST_REFRESH_TYPE
 FROM DBA_MVIEWS;
```

Your output looks similar to the following:

| Materialized View Name | Owner | Refresh Method | Last Refresh Date | Last Refresh Type |
|------------------------|-------|----------------|-------------------|-------------------|
| COUNTRIES_MV1          | HR    | FAST           | 21-OCT-03         | FAST              |
| DEPARTMENTS_MV1        | HR    | FAST           | 21-OCT-03         | FAST              |
| EMPLOYEES_MV1          | HR    | FAST           | 21-OCT-03         | FAST              |
| JOBS_MV1               | HR    | FAST           | 21-OCT-03         | FAST              |
| JOB_HISTORY_MV1        | HR    | FAST           | 21-OCT-03         | FAST              |
| LOCATIONS_MV1          | HR    | FAST           | 21-OCT-03         | FAST              |
| REGIONS_MV1            | HR    | FAST           | 21-OCT-03         | FAST              |

## 61.7.2 Listing Information About the Refresh Groups at a Materialized View Database

Each refresh group at a materialized view database is associated with a refresh job that refreshes the materialized views in the refresh group at a set interval.

You can query the `DBA_REFRESH` data dictionary view to list the following information about the refresh jobs at a materialized view database:

- The name of the refresh group.
- The owner of the refresh group.
- Whether the refresh job is broken.
- The next date and time when the refresh job will run.
- The current interval setting for the refresh job. The interval setting specifies the amount of time between the start of a job and the next start of the same job.

To view this information, complete the following steps:

1. Connect to the materialized view database as an administrative user.
2. Run the following query:

```
COLUMN RNAME HEADING 'Refresh|Group|Name' FORMAT A10
COLUMN ROWNER HEADING 'Refresh|Group|Owner' FORMAT A10
COLUMN BROKEN HEADING 'Broken?' FORMAT A7
COLUMN next_refresh HEADING 'Next Refresh'
COLUMN INTERVAL HEADING 'Interval' FORMAT A20

SELECT RNAME,
 ROWNER,
 BROKEN,
 TO_CHAR(NEXT_DATE, 'DD-MON-YYYY HH:MI:SS AM') next_refresh,
 INTERVAL
 FROM DBA_REFRESH
 ORDER BY 1;
```

Your output looks similar to the following:

| Refresh | Refresh    |         |                         |                |
|---------|------------|---------|-------------------------|----------------|
| Group   | Group      |         |                         |                |
| Name    | Owner      | Broken? | Next Refresh            | Interval       |
| HR_REFG | MVIEWADMIN | N       | 24-OCT-2003 07:18:44 AM | SYSDATE + 1/24 |

The `N` in the `Broken?` column means that the job is not broken. Therefore, the refresh job will run at the next start time. A `Y` in this column means that the job is broken.

## 61.7.3 Determining the Job ID for Each Refresh Job at a Materialized View Database

Query the `DBA_REFRESH` and `DBA_JOBS` views to determine the job identification number for each refresh job at a materialized view database.

You can run a query to list the following information about the refresh jobs at a materialized view database:

- The job identification number of each refresh job. Each job created by the DBMS\_JOB package is assigned a unique identification number.
- The privilege schema, which is the schema whose default privileges apply to the job.
- The schema that owns each refresh job.
- The name of the refresh group that the job refreshes.
- The status of the refresh job, either normal or broken.

To view this information, complete the following steps:

1. Connect to the materialized view database as an administrative user.
2. Run the following query:

```
COLUMN JOB HEADING 'Job ID' FORMAT 999999
COLUMN PRIV_USER HEADING 'Privilege|Schema' FORMAT A10
COLUMN RNAME HEADING 'Refresh|Group|Name' FORMAT A10
COLUMN ROWNER HEADING 'Refresh|Group|Owner' FORMAT A10
COLUMN BROKEN HEADING 'Broken?' FORMAT A7

SELECT J.JOB,
 J.PRIV_USER,
 R.ROWNER,
 R.RNAME,
 J.BROKEN
 FROM DBA_REFRESH R, DBA_JOBS J
 WHERE R.JOB = J.JOB
 ORDER BY 1;
```

Your output looks similar to the following:

| Job ID | Schema     | Refresh    | Refresh | Broken? |
|--------|------------|------------|---------|---------|
|        |            | Privilege  | Group   |         |
| 21     | MVIEWADMIN | MVIEWADMIN | HR_REFG | N       |

The N in the Broken? column means that the job is not broken. Therefore, the job will run at the next start time. A Y in this column means that the job is broken.

## 61.7.4 Determining Which Materialized Views Are Currently Refreshing

Query the V\$MVREFRESH view to determine which materialized views are currently refreshing.

Complete the following steps to show the materialized views that are currently refreshing:

1. Connect to the materialized view database as an administrative user.
2. Run the following query:

```
COLUMN SID HEADING 'Session|Identifier' FORMAT 9999
COLUMN SERIAL# HEADING 'Serial|Number' FORMAT 999999
COLUMN CURRMVOWNER HEADING 'Owner' FORMAT A15
COLUMN CURRMVNAME HEADING 'Materialized|View' FORMAT A25
```

```
SELECT * FROM V$MVREFRESH;
```

Your output looks similar to the following:

| Identifier | Session Number | Serial Number | Owner | Materialized View |
|------------|----------------|---------------|-------|-------------------|
|            | 19             | 233           | HR    | COUNTRIES_MV      |
|            | 5              | 647           | HR    | EMPLOYEES_MV      |

# Troubleshooting Problems with Read-Only Materialized Views

You can diagnose and solve problems with database links, materialized view creation, and materialized view refresh.

- [Diagnosing Problems with Database Links](#)  
If you think a database link is not functioning properly, then you can drop and re-create it using Oracle Enterprise Manager Cloud Control, SQL\*Plus, or another tool.
- [Problems Creating Materialized Views](#)  
There are items to check if you have problems creating a materialized view.
- [Refresh Problems](#)  
You can diagnose and solve common refresh problems.
- [Advanced Troubleshooting of Refresh Problems](#)  
There are several items you can check if you have problems with refreshing a materialized view.

## 62.1 Diagnosing Problems with Database Links

If you think a database link is not functioning properly, then you can drop and re-create it using Oracle Enterprise Manager Cloud Control, SQL\*Plus, or another tool.

- Ensure that the database link name is the same as the global name of the target database.
- Ensure that the scheduled interval is what you want.
- Ensure that the scheduled interval is not shorter than the required execution time.

If you used a connection qualifier in a database link to a given database, then the other databases that link to that database must have the same connection qualifier. For example, suppose you create a database link as follows:

```
CREATE DATABASE LINK dbs1.example.com@myethernet CONNECT TO myadmin
IDENTIFIED BY password USING 'connect_string_myethernet';
```

All the databases, whether master databases or materialized view databases, associated with `dbs1.example.com@myethernet` must include `myethernet` as the connection qualifier.

 **See Also:**

- "[Using Connection Qualifiers to Specify Service Names Within Link Names](#)" for more information database links and connection qualifiers
- "[Required Database Links for Materialized Views](#)"

## 62.2 Problems Creating Materialized Views

There are items to check if you have problems creating a materialized view.

If you unsuccessfully attempt to create a materialized view, then try the following:

- Ensure that you have the necessary privileges to create the materialized view. You need SELECT privilege on the master table and its materialized view log. See "[Required Privileges](#)" for more information.
- If you are trying to create a fast refresh primary key or subquery materialized view, then ensure that the materialized view log on the master table logs primary keys.
- If you are trying to create a fast refresh rowid materialized view, then ensure that the materialized view log on the master table logs rowids.
- Check if the materialized view log has the required columns added for subquery materialized views. See "[Logging Columns in a Materialized View Log](#)" for information.
- Check if the materialized view log exists for all tables that are involved in a fast refresh materialized view. If the materialized view contains a subquery, then each table referenced in the subquery should have a materialized view log.

## 62.3 Refresh Problems

You can diagnose and solve common refresh problems.

- [Common Refresh Problems](#)  
Several common factors can prevent the automatic refresh of a group of materialized views.
- [Automatic Refresh Retries](#)  
When Oracle Database fails to refresh a refresh group automatically, the refresh group remains due for its refresh to complete.
- [Fast Refresh Errors at New Materialized View Databases](#)  
In some cases, a materialized view log for a master table might be purged during the creation of a materialized view at a new materialized view database.
- [Materialized Views Continually Refreshing](#)  
If you encounter a situation where Oracle Database continually refreshes a group of materialized views, then check the group's refresh interval.
- [Materialized View Logs Growing Too Large](#)  
If a materialized view log at a master database is growing too large, then check to see whether a network or database failure has prevented the master database from becoming aware that a materialized view has been dropped.

### 62.3.1 Common Refresh Problems

Several common factors can prevent the automatic refresh of a group of materialized views.

These factors include the following:

- The lack of a job slave at the materialized view database
- An intervening network or server failure
- An intervening server shutdown

When a refresh group is experiencing problems, ensure that none of the preceding situations is preventing Oracle Database from completing group refreshes.

### 62.3.2 Automatic Refresh Retries

When Oracle Database fails to refresh a refresh group automatically, the refresh group remains due for its refresh to complete.

Oracle Database will retry an automatic refresh of a group with the following behavior:

- Oracle Database retries the refresh group refresh first one minute later, then two minutes later, four minutes later, and so on, with the retry interval doubling with each failed attempt to refresh the group.
- Oracle Database does not allow the retry interval to exceed the refresh interval itself.
- Oracle Database retries the automatic refresh up to sixteen times.

If after 16 attempts to refresh a refresh group Oracle Database continues to encounter errors, then Oracle Database considers the group broken. You can query the `BROKEN` column of the `USER_REFRESH` and `USER_REFRESH_CHILDREN` data dictionary views to see the current status of a refresh group.

The errors causing Oracle Database to consider a refresh group broken are recorded in a trace file. After you correct the problems preventing a refresh group from refreshing successfully, you must refresh the refresh group manually. Oracle Database then resets the broken flag so that automatic refreshes can happen again.

#### See Also:

The name of the materialized view trace file is of the form `jn`, where `n` is operating system specific. See the Oracle documentation for your operating system for the name on your system.

### 62.3.3 Fast Refresh Errors at New Materialized View Databases

In some cases, a materialized view log for a master table might be purged during the creation of a materialized view at a new materialized view database.

When this happens, you might encounter the following errors:

ORA-12004 REFRESH FAST cannot be used for materialized view *materialized\_view\_name*  
ORA-12034 materialized view log on *materialized\_view\_name* younger than last refresh

#### See Also:

"[Adding a New Materialized View Database](#)" for a complete description of how to avoid this problem.

### 62.3.4 Materialized Views Continually Refreshing

If you encounter a situation where Oracle Database continually refreshes a group of materialized views, then check the group's refresh interval.

Oracle Database evaluates a refresh group's automatic refresh interval before starting the refresh. If a refresh group's refresh interval is less than the amount of time it takes to refresh all materialized views in the group, then Oracle Database continually starts a refresh group refresh each time the job slave checks the queue of outstanding jobs.

### 62.3.5 Materialized View Logs Growing Too Large

If a materialized view log at a master database is growing too large, then check to see whether a network or database failure has prevented the master database from becoming aware that a materialized view has been dropped.

You might need to purge part of the materialized view log or unregister the unused materialized view database.

## 62.4 Advanced Troubleshooting of Refresh Problems

There are several items you can check if you have problems with refreshing a materialized view.

If you have a problem refreshing a materialized view, then try the following:

- Check the `NEXT_DATE` value in the `DBA_REFRESH_CHILDREN` view to determine if the refresh has been scheduled.
- If the refresh interval has passed, then check the `DBA_REFRESH` view for the associated job number for the materialized view refresh and then diagnose the problem with job queues.
- Check if there are job slaves running. Check the `JOB_QUEUE_PROCESSES` initialization parameter, query the `DBA_JOBS_RUNNING` view, and use your operating system to check if the job slaves are still running.
- You also might encounter an error if you attempt to define a master detail relationship between two materialized views. You should define master detail relationships only on the master tables by using declarative referential integrity constraints. The related materialized views should then be placed in the same refresh group to preserve this relationship. However, you can define deferred (or deferrable) constraints on materialized views.

- Materialized views in the same refresh groups have their rows updated in a single transaction. Such a transaction can be very large, requiring either a large rollback segment at the materialized view database, with the rollback segment specified to be used during refresh, or more frequent refreshes to reduce the transaction size.
- If Oracle error ORA-12004 occurs, then the master database might have run out of rollback segments when trying to maintain the materialized view log, or the materialized view log might be out of date. For example, the materialized view log might have been purged or re-created.
- Complete refreshes of a single materialized view internally use the TRUNCATE feature to increase speed and reduce rollback segment requirements. However, until the materialized view refresh is complete, users might temporarily see no data in the materialized view. Refreshes of multiple materialized views (for example, refresh groups) do not use the TRUNCATE feature.
- Reorganization of the master table (for example, to reclaim system resources) should TRUNCATE the master table to force rowid materialized views to do complete refreshes. Otherwise, the materialized views have incorrect references to master table rowids. You use the BEGIN\_TABLE\_REORGANIZATION and END\_TABLE\_REORGANIZATION procedures in the DBMS\_MVIEW package to reorganize a master table.
- If while refreshing you see an ORA-00942 (table or view does not exist), then check your database links and ensure that you still have the required privileges on the master table and the materialized view log.
- If a fast refresh was succeeding but then fails, then check whether:
  - The materialized view log was truncated, purged, or dropped.
  - You still have the required privileges on the materialized view log.
- If a force refresh takes an inordinately long time, then check if the materialized view log used by the refresh has been dropped.
- If the materialized view was created with BUILD DEFERRED, and its first fast refresh fails, then ensure that a previous complete refresh was done successfully before checking for other problems.

# Part IX

## Appendices

Appendices contain supplemental material for this document.

- [Support for DBMS\\_JOB](#)  
Oracle Scheduler replaces the `DBMS_JOB` package.

# A

## Support for DBMS\_JOB

Oracle Scheduler replaces the DBMS\_JOB package.

- [Oracle Scheduler Replaces DBMS\\_JOB](#)

In Oracle Database 11g Release 2 (11.2), Oracle Scheduler replaces DBMS\_JOB. Oracle Scheduler is more powerful and flexible than DBMS\_JOB, which is a package used to schedule jobs. Although DBMS\_JOB is still supported in Oracle Database 12c Release 2 (12.2) for backward compatibility, Oracle strongly recommends that you switch from DBMS\_JOB to Oracle Scheduler.

- [Moving from DBMS\\_JOB to Oracle Scheduler](#)

This section illustrates some examples of how you can take jobs created with the DBMS\_JOB package and rewrite them using Oracle Scheduler, which you configure and control with the DBMS\_SCHEDULER package.

### A.1 Oracle Scheduler Replaces DBMS\_JOB

In Oracle Database 11g Release 2 (11.2), Oracle Scheduler replaces DBMS\_JOB. Oracle Scheduler is more powerful and flexible than DBMS\_JOB, which is a package used to schedule jobs. Although DBMS\_JOB is still supported in Oracle Database 12c Release 2 (12.2) for backward compatibility, Oracle strongly recommends that you switch from DBMS\_JOB to Oracle Scheduler.

- [Configuring DBMS\\_JOB](#)

The JOB\_QUEUE\_PROCESSES initialization parameter specifies the maximum number of processes that can be created for the execution of jobs.

- [Using Both DBMS\\_JOB and Oracle Scheduler](#)

DBMS\_JOB and Oracle Scheduler (the Scheduler) use the same job coordinator to start job slaves.

#### A.1.1 Configuring DBMS\_JOB

The JOB\_QUEUE\_PROCESSES initialization parameter specifies the maximum number of processes that can be created for the execution of jobs.

Beginning with Oracle Database 12c Release 2, JOB\_QUEUE\_PROCESSES defaults to 4000. The job coordinator process starts only as many job queue processes as are required, based on the number of jobs to run and available resources. You can set JOB\_QUEUE\_PROCESSES to a lower number to limit the number of job queue processes.

Setting JOB\_QUEUE\_PROCESSES to 0 disables DBMS\_JOB jobs and DBMS\_SCHEDULER jobs.

 **See Also:**

*Oracle Database Reference* for more information about the `JOB_QUEUE_PROCESSES` initialization parameter

## A.1.2 Using Both DBMS\_JOB and Oracle Scheduler

`DBMS_JOB` and Oracle Scheduler (the Scheduler) use the same job coordinator to start job slaves.

You can use the `JOB_QUEUE_PROCESSES` initialization parameter to limit the number job slaves for both `DBMS_JOB` and the Scheduler.

If `JOB_QUEUE_PROCESSES` is 0, both `DBMS_JOB` and Oracle Scheduler jobs are disabled.

 **See Also:**

- [Scheduling Jobs with Oracle Scheduler](#)
- ["Setting Scheduler Preferences"](#)
- *Oracle Database Reference* for more information about the `JOB_QUEUE_PROCESSES` initialization parameter

## A.2 Moving from DBMS\_JOB to Oracle Scheduler

This section illustrates some examples of how you can take jobs created with the `DBMS_JOB` package and rewrite them using Oracle Scheduler, which you configure and control with the `DBMS_SCHEDULER` package.

- [Creating a Job](#)

An example illustrates creating a job using the `DBMS_JOB` package and the `DBMS_SCHEDULER` package.

- [Altering a Job](#)

An example illustrates altering a job using the `DBMS_JOB` package and the `DBMS_SCHEDULER` package.

- [Removing a Job from the Job Queue](#)

An example illustrates removing a job using the `DBMS_JOB` package and the `DBMS_SCHEDULER` package.

### A.2.1 Creating a Job

An example illustrates creating a job using the `DBMS_JOB` package and the `DBMS_SCHEDULER` package.

The following example creates a job using `DBMS_JOB`:

```
VARIABLE jobno NUMBER;
BEGIN
 DBMS_JOB.SUBMIT(:jobno, 'INSERT INTO employees VALUES (7935, ''SALLY'',
 ''DOGAN'', ''sally.dogan@examplecorp.com'', NULL, SYSDATE, ''AD_PRES'', NULL,
 NULL, NULL, NULL);', SYSDATE, 'SYSDATE+1');
 COMMIT;
END;
/
```

The following is an equivalent statement using DBMS\_SCHEDULER:

```
BEGIN
 DBMS_SCHEDULER.CREATE_JOB(
 job_name => 'job1',
 job_type => 'PLSQL_BLOCK',
 job_action => 'INSERT INTO employees VALUES (7935, ''SALLY'',
 ''DOGAN'', ''sally.dogan@examplecorp.com'', NULL, SYSDATE, ''AD_PRES'', NULL,
 NULL, NULL, NULL);',
 start_date => SYSDATE,
 repeat_interval => 'FREQ = DAILY; INTERVAL = 1');
END;
/
```

## A.2.2 Altering a Job

An example illustrates altering a job using the DBMS\_JOB package and the DBMS\_SCHEDULER package.

The following example alters a job using DBMS\_JOB:

```
BEGIN
 DBMS_JOB.WHAT(31, 'INSERT INTO employees VALUES (7935, ''TOM'', ''DOGAN'',
 ''tom.dogan@examplecorp.com'', NULL, SYSDATE, ''AD_PRES'', NULL,
 NULL, NULL, NULL);');
 COMMIT;
END;
/
```

This changes the action for JOB1 to insert a different value.

The following is an equivalent statement using DBMS\_SCHEDULER:

```
BEGIN
 DBMS_SCHEDULER.SET_ATTRIBUTE(
 name => 'JOB1',
 attribute => 'job_action',
 value => 'INSERT INTO employees VALUES (7935, ''TOM'', ''DOGAN'',
 ''tom.dogan@examplecorp.com'', NULL, SYSDATE, ''AD_PRES'', NULL,
 NULL, NULL, NULL);');
END;
/
```

## A.2.3 Removing a Job from the Job Queue

An example illustrates removing a job using the DBMS\_JOB package and the DBMS\_SCHEDULER package.

The following example removes a job using DBMS\_JOB, where 14144 is the number of the job being run:

```
BEGIN
 DBMS_JOB.REMOVE(14144);
COMMIT;
END;
/
```

Using DBMS\_SCHEDULER, you would issue the following statement instead:

```
BEGIN
 DBMS_SCHEDULER.DROP_JOB('myjob1');
END;
/
```

 **See Also:**

Sample Schemas  
  description, [2-67](#)

savepoints

- in-doubt transactions, [35-9, 35-11](#)

schagent utility, [30-10](#)

Scheduler

- administering, [30-1](#)

- architecture, [28-33](#)

- CDB, [48-1](#)

- closing a PDB, [48-3](#)

- configuring, [30-1](#)

- credentials for jobs, [28-10](#)

- data dictionary views reference, [30-29](#)

- e-mail notifications, [29-96](#)

- examples of using, [30-21](#)

- import and export, [30-17](#)

- invocations to CDB, [48-1](#)

- maintenance window, [26-3](#)

- monitoring and managing, [30-12](#)

- monitoring jobs, [29-88](#)

- objects, [28-3](#)

- overview, [28-1](#)

- security, [30-17](#)

- support for Oracle Data Guard, [28-38, 30-27](#)

- troubleshooting, [30-18](#)

- job does not run, [30-18](#)

- using in RAC, [28-37](#)

- using job coordinator in CDB, [48-2](#)

- using slave processes in CDB, [48-2](#)

Scheduler (*continued*)

- Views, new and changed, [48-3](#)

Scheduler agent, [30-5](#)

- configuration, [30-8](#)

- installation, [30-8](#)

- setup, [30-8](#)

Scheduler chain condition syntax, [29-58](#)

Scheduler job credentials

- specifying, [29-9](#)

Scheduler objects, naming, [29-2](#)

Scheduler privileges reference, [30-28](#)

SCHEDULER\_BATCH\_ERRORS view, [29-24](#)

schedules

- altering, [29-32](#)

- creating, [29-32](#)

- creating and managing, to define Scheduler jobs, [29-31](#)

- dropping, [29-32](#)

- overview, [28-5](#)

schema objects, [18-26](#)

- analyzing, [18-3](#)

- creating multiple objects, [18-2](#)

- data dictionary views reference, [18-34](#)

- defining using DBMS\_METADATA package, [18-33](#)

- dependencies between, [18-23](#)

- distributed database naming conventions for, [31-21](#)

- global names, [31-21](#)

- listing by type, [18-35](#)

- name resolution in distributed databases, [31-21, 31-38](#)

- name resolution in SQL statements, [18-26](#)

- privileges to rename, [18-22](#)

- referencing with synonyms, [32-27](#)

- renaming, [18-22](#)

- validating structure, [18-4](#)

- viewing information, [18-33, 19-37](#)

schema objects space usage

- data dictionary views reference, [19-38](#)

schemas

- creating for materialized views, [60-5](#)

SCN

- See system change number

SCOPE clause, [2-52](#)

script jobs, [28-30](#)

scripts, authenticating users in, [2-65](#)

security

- accessing a database, [7-1](#)

- administrator of, [7-1](#)

- centralized user management in distributed databases, [31-27](#)

- database security, [7-1](#)

- distributed databases, [31-24](#)

- establishing policies, [7-1](#)

security (*continued*)  
 privileges, 7-1  
 remote objects, 32-26  
 Scheduler, 30-17  
 using synonyms, 32-28

SEED FILE\_NAME\_CONVERT clause, 37-12

Segment Advisor, 19-18  
 configuring Scheduler job, 19-31  
 invoking with Oracle Enterprise Manager Cloud Control, 19-20  
 invoking with PL/SQL, 19-22  
 running manually, 19-20  
 using, 19-19  
 viewing results, 19-25  
 views, 19-32

SEGMENT\_FIX\_STATUS procedure  
 DBMS\_REPAIR, 25-2

segments  
 available space, 19-37  
 data dictionary views for, 19-38  
 deallocating unused space, 19-17  
 displaying information on, 19-39  
 dropping for empty tables, 19-36  
 shrinking, 19-33

SELECT statement  
 FOR UPDATE clause and location transparency, 32-30

SEQUENCE\_CACHE\_ENTRIES parameter, 24-22

sequences  
 accessing, 24-18  
 altering, 24-18  
 caching sequence numbers, 24-21  
 creating, 24-17, 24-22  
 CURRVAL, 24-20  
 data dictionary views reference, 24-25  
 dropping, 24-22  
 managing, 24-16  
 NEXTVAL, 24-19  
 Oracle Real Applications Clusters and, 24-18

SERVER parameter  
 net service name, 32-15

server parameter file  
 creating, 2-50  
 defined, 2-47  
 exporting, 2-54  
 migrating to, 2-48  
 recovering, 2-55  
 RMAN backup, 2-55  
 setting initialization parameter values, 2-51  
 SPFILE initialization parameter, 2-50  
 viewing parameter settings, 2-56

server processes, 5-2  
 archiver (ARCn), 5-26  
 background, 5-26

server processes (*continued*)  
 checkpoint (CKPT), 5-26  
 database writer (DBWn), 5-26  
 dedicated, 5-2  
 dispatcher (Dnnn), 5-26  
 dispatchers, 5-16  
 log writer (LGWR), 5-26  
 monitoring locks, 8-11  
 process monitor (PMON), 5-26  
 recoverer (RECO), 5-26  
 shared server, 5-3  
 system monitor (SMON), 5-26  
 trace files for, 8-2  
 server-generated alerts, 8-6  
 servers  
 role in two-phase commit, 34-5

service names  
 database links and, 32-12

SERVICE\_NAME\_CONVERT clause, 38-15

services  
 controlling automatic startup of, 3-7  
 create, 57-29  
 creating with SRVCTL and Oracle Restart, 4-23  
 PDBs, 43-18  
 role-based, 3-7

services management, 57-29

session trees for distributed transactions  
 clients, 34-5  
 commit point site, 34-6, 34-7  
 database servers, 34-5  
 definition, 34-4  
 global coordinators, 34-5  
 local coordinators, 34-5  
 tracing transactions, 35-5

sessions  
 active, 5-36  
 inactive, 5-37  
 setting advice for transactions, 35-9  
 terminating, 5-35

SET TIME\_ZONE clause  
 ALTER SESSION, 2-31  
 CREATE DATABASE, 2-31

SGA  
 See system global area

SGA\_MIN\_SIZE parameter, 46-14

SGA\_TARGET parameter, 46-14

shard  
 adding, 57-14, 57-15  
 deploy, 57-16  
 validate, 57-14

shard director  
 creating, 57-24  
 removing, 57-25  
 updating, 57-25

shard director management, [57-24](#)  
 shard management, [57-10](#)  
 sharded database (SDB), [49-1](#)  
 sharded database discovery, [57-7](#)  
 sharded tables, [49-1](#)  
 shardgroup  
     creating, [57-28](#)  
 shardgroup management, [57-28](#)  
 sharding  
     See Oracle Sharding  
 shards, [49-1](#)  
 shardspace  
     creating, [57-28](#)  
 shardspace management, [57-27](#)  
 shared database links  
     configuring, [32-15](#)  
     creating, [32-15](#)  
     dedicated servers, creating links to, [32-15](#)  
     determining whether to use, [32-14](#)  
     example, [31-19](#)  
     shared servers, creating links to, [32-16](#)  
 shared server, [5-3](#)  
     configuring dispatchers, [5-13](#)  
     data dictionary views reference, [5-19](#)  
     disabling, [5-11](#), [5-19](#)  
     initialization parameters, [5-8](#)  
     interpreting trace output, [8-6](#)  
     setting minimum number of servers, [5-11](#)  
     trace files for processes, [8-2](#)  
 shared SQL  
     for remote and distributed statements, [31-34](#)  
 shared temporary tablespaces, [13-15](#)  
 SHARED\_POOL\_SIZE parameter, [46-14](#)  
 shrinking segments online, [19-33](#)  
 shutdown  
     default mode, [3-17](#)  
 SHUTDOWN command  
     closing a PDB, [43-12](#)  
     IMMEDIATE clause, [3-18](#)  
     interrupting, [3-20](#)  
     NORMAL clause, [3-17](#)  
     PDBs, [43-14](#)  
 shutting down an instance  
     CDBs, [41-57](#)  
 simple materialized views, [58-9](#)  
 Simple Network Management Protocol (SNMP)  
     support  
         database management, [31-31](#)  
 single-file tablespaces  
     description, [13-9](#)  
 single-instance  
     defined, [2-9](#)  
 single-table hash clusters, [23-7](#)  
 site autonomy  
     distributed databases, [31-23](#)  
     SKIP\_CORRUPT\_BLOCKS procedure, [25-7](#)  
     DBMS\_REPAIR, [25-2](#)  
     example, [25-13](#)  
 skipping chain steps, [29-67](#)  
 SNAPSHOT COPY clause, [38-41](#)  
 SORT\_AREA\_SIZE initialization parameter  
     index creation and, [21-3](#)  
 SOURCE\_FILE\_DIRECTORY clause, [38-14](#)  
 SOURCE\_FILE\_NAME\_CONVERT clause, [38-13](#)  
 space  
     deallocating unused, [19-35](#)  
     reclaiming unused, [19-17](#)  
 space allocation  
     resumable, [19-6](#)  
 space management  
     data types, space requirements, [19-37](#)  
     deallocating unused space, [19-17](#)  
     Segment Advisor, [19-17](#)  
     shrink segment, [19-17](#)  
 space usage alerts for tablespaces, [19-3](#)  
 SPFILE initialization parameter, [2-50](#)  
 SQL  
     submitting, [1-9](#)  
 SQL failure  
     repairing with SQL Repair Advisor, [9-36](#)  
 SQL patch  
     disabling, [9-38](#)  
     removing, [9-38](#)  
     viewing, [9-38](#)  
 SQL Repair Advisor  
     about, [9-36](#)  
     repairing SQL failure with, [9-36](#)  
     running, [9-37](#)  
 SQL scripts  
     CDBs, [41-51](#)  
 SQL statements  
     distributed databases and, [31-33](#)  
 SQL test case builder, [9-3](#)  
 SQL\_TRACE initialization parameter  
     trace files and, [8-2](#)  
 SQL\*Loader  
     about, [1-46](#), [20-39](#)  
     application containers, [44-31](#)  
 SQL\*Plus, [1-9](#)  
     about, [1-10](#)  
     connecting with, [1-10](#)  
     starting, [3-7](#)  
     starting a database, [3-3](#)  
     starting an instance, [3-3](#)  
 SRVCTL  
     add asm command, [4-38](#)  
     add command, usage description, [4-37](#)  
     add database command, [4-39](#)  
     add listener command, [4-42](#)

**SRVCTL (*continued*)**

add ons command, [4-42](#)  
 adding a disk group with, [4-37](#)  
 case sensitivity, [4-35](#), [4-95](#)  
 case sensitivity of commands, [4-35](#), [4-96](#)  
 command reference, [4-34](#)  
 commands  
      downgrade database, [4-55](#)  
      upgrade database, [4-94](#), [4-95](#)  
 commands, case sensitivity, [4-35](#), [4-95](#)  
 component names, [4-35](#)  
 config asm command, [4-48](#)  
 config command, usage description, [4-47](#)  
 config database command, [4-48](#)  
 config listener command, [4-49](#)  
 config ons command, [4-50](#)  
 config service command, [4-50](#)  
 creating and deleting databases services  
     with, [4-23](#)  
 disable asm command, [4-52](#)  
 disable command, usage description, [4-51](#)  
 disable database command, [4-52](#)  
 disable diskgroup command, [4-52](#)  
 disable listener command, [4-53](#)  
 disable ons command, [4-53](#)  
 disable service command, [4-54](#)  
 enable asm command, [4-56](#)  
 enable command, usage description, [4-55](#)  
 enable database command, [4-56](#)  
 enable diskgroup command, [4-57](#)  
 enable listener command, [4-57](#)  
 enable ons command, [4-58](#)  
 enable service command, [4-58](#)  
 getenv asm command, [4-59](#)  
 getenv command, usage description, [4-59](#)  
 getenv database command, [4-60](#)  
 getenv listener command, [4-60](#)  
 help for, [4-15](#)  
 modify asm command, [4-61](#)  
 modify command, usage description, [4-61](#)  
 modify database command, [4-62](#)  
 modify listener command, [4-63](#)  
 modify ons command, [4-64](#)  
 modify service command, [4-64](#)  
 preparing to run, [4-14](#)  
 reference, [4-34](#)  
 remove asm command, [4-70](#)  
 remove command, usage description, [4-69](#)  
 remove database command, [4-70](#)  
 remove diskgroup command, [4-71](#)  
 remove listener command, [4-71](#)  
 remove ons command, [4-72](#)  
 remove service command, [4-72](#)  
 setenv asm command, [4-74](#)  
 setenv command, usage description, [4-73](#)

**SRVCTL (*continued*)**

setenv database command, [4-75](#)  
 setenv listener command, [4-76](#)  
 start asm command, [4-77](#)  
 start command, usage description, [4-76](#)  
 start database command, [4-77](#)  
 start diskgroup command, [4-78](#)  
 start home command, [4-78](#)  
 start listener command, [4-79](#)  
 start ons command, [4-80](#)  
 start service command, [4-80](#)  
 status asm command, [4-82](#)  
 status command, usage description, [4-81](#)  
 status database command, [4-82](#)  
 status diskgroup command, [4-83](#)  
 status home command, [4-83](#)  
 status listener command, [4-84](#)  
 status ons command, [4-84](#)  
 status service command, [4-85](#)  
 stop asm command, [4-86](#)  
 stop command, usage description, [4-85](#)  
 stop database command, [4-87](#)  
 stop diskgroup command, [4-88](#)  
 stop home command, [4-89](#)  
 stop listener command, [4-90](#)  
 stop ons command, [4-90](#)  
 stop service command, [4-90](#)  
 unsetenv asm command, [4-93](#)  
 unsetenv command, usage description, [4-92](#)  
 unsetenv database command, [4-93](#)  
 unsetenv listener command, [4-94](#)  
 SRVCTL stop option  
     default, [3-17](#)  
 STALE status  
     of redo log members, [11-18](#)  
 stalled chain (Scheduler), [29-68](#)  
 standby database  
     CDBs, [41-5](#)  
     standby transmission mode  
         definition of, [12-15](#)  
 STANDBYS clause, [38-19](#)  
 starting a database, [3-1](#)  
     forcing, [3-12](#)  
     Oracle Enterprise Manager Cloud Control,  
         [3-3](#)  
     recovery and, [3-13](#)  
     Recovery Manager, [3-3](#)  
     restricted mode, [3-11](#)  
     SQL\*Plus, [3-3](#)  
     when control files unavailable, [3-9](#)  
     when redo logs unavailable, [3-9](#)  
 starting an instance  
     automatically at system startup, [3-13](#)  
     database closed and mounted, [3-11](#)  
     forcing, [3-12](#)

starting an instance (*continued*)  
 mounting and opening the database, 3-10  
 normally, 3-10  
 Oracle Enterprise Manager Cloud Control, 3-3  
 recovery and, 3-13  
 Recovery Manager, 3-3  
 remote instance startup, 3-13  
 restricted mode, 3-11  
 SQL\*Plus, 3-3  
 when control files unavailable, 3-9  
 when redo logs unavailable, 3-9  
 without mounting a database, 3-10

startup  
 of database services, controlling, 3-7

STARTUP command  
 NOMOUNT clause, 2-16, 37-20  
 PDBs, 41-38, 43-13  
 RECOVER clause, 3-13  
 starting a database, 3-3, 3-8  
 starting a PDB, 43-12

statement transparency in distributed database managing, 32-30

statistics  
 automatically collecting for tables, 20-54

STATISTICS\_LEVEL initialization parameter  
 Database Resource Manager, 27-2

stderr  
 for local external jobs, 28-24, 28-25  
 retrieving, 28-24, 28-25

stdout  
 for local external jobs, 28-24, 28-25  
 retrieving, 28-24, 28-25, 29-18

steps, chain  
 dropping, 29-65

stopping  
 chain steps, 29-65  
 chains, 29-65  
 jobs, 29-21

STORAGE clause, 38-7

storage parameters  
 INITIAL, 20-57  
 INITTRANS, altering, 20-57  
 MAXTRANS, altering, 20-57  
 MINEXTENTS, 20-57  
 PCTINCREASE, 20-57

storage subsystems  
 mapping files to physical devices, 14-23, 14-33

stored procedures  
 managing privileges, 32-30  
 remote object security, 32-30

submitting SQL and commands to the database, 1-9

subqueries  
 in remote updates, 31-33  
 in unions  
   materialized views, 58-17  
 materialized views, 58-14, 58-20  
   AND condition, 58-20  
   column logging, 58-20  
   EXISTS condition, 58-20  
   joins, 58-20  
   many to many, 58-16  
   many to one, 58-14  
   one to many, 58-15  
   restrictions, 58-20

statement transparency in distributed databases, 32-30

subsetting  
 materialized views, 58-13  
 column objects, 58-26

SunSoft SunNet Manager, 31-31

Support Workbench, 9-10  
 for Oracle ASM instance, 9-24  
 viewing problems with, 9-23

SWITCH LOGFILE clause  
 ALTER SYSTEM statement, 11-19

synchronizing applications, 44-20

synonyms  
 creating, 24-23, 32-27  
 data dictionary views reference, 24-25  
 definition and creation, 32-27  
 displaying dependencies of, 18-35  
 dropping, 24-25  
 examples, 32-27

location transparency in distributed databases, 32-26

managing, 24-23, 24-25

managing privileges in remote database, 32-28

name resolution in distributed databases, 31-41

private, 24-23  
 public, 24-23
