- Specify `SID = 'sid'` if you want Oracle Database to change the value of the parameter only for the instance `sid`. This setting takes precedence over previous and subsequent `ALTER SYSTEM SET` statements that specify `SID = '*'`.

If you do not specify this clause, then:

- If the instance was started up with a pfile (traditional plain-text initialization parameter file), then Oracle Database assumes the SID of the current instance.
- If the instance was started up with an spfile (server parameter file), then Oracle Database assumes `SID = '*'`.

If you specify an instance other than the current instance, then Oracle Database sends a message to that instance to change the parameter value in the memory of that instance.

**USE_STORED_OUTLINES Clause**

**Note:**

Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. Refer to *Oracle Database SQL Tuning Guide* for more information about SQL plan management.

`USE_STORED_OUTLINES` is a system parameter, not an initialization parameter. You cannot set it in a pfile or spfile, but you can set it with an `ALTER SYSTEM` statement. This parameter determines whether the optimizer will use stored public outlines to generate execution plans.

- `TRUE` causes the optimizer to use outlines stored in the `DEFAULT` category when compiling requests.
- `FALSE` specifies that the optimizer should not use stored outlines. This is the default.
- `category_name` causes the optimizer to use outlines stored in the `category_name` category when compiling requests.

**GLOBAL_TOPIC_ENABLED**
GLOBAL_TOPIC_ENABLED is a system parameter, not an initialization parameter. You cannot set it in a pfile or spfile, but you can set it with an ALTER SYSTEM statement. If GLOBAL_TOPIC_ENABLED = TRUE when a queue table is created, altered, or dropped, then the corresponding Lightweight Directory Access Protocol (LDAP) entry is also created, altered or dropped.

The parameter works the same way for the Java Message Service (JMS). If a database has been configured to use LDAP and the GLOBAL_TOPIC_ENABLED parameter has been set to TRUE, then all JMS queues and topics are automatically registered with the LDAP server when they are created. The administrator can also create aliases to the queues and topics registered in LDAP. Queues and topics that are registered in LDAP can be looked up through JNDI using the name or alias of the queue or topic.

Shared Server Parameters

When you start your instance, Oracle Database creates shared server processes and dispatcher processes for the shared server architecture based on the values of the SHARED_SERVERS and DISPATCHERS initialization parameters. You can also set the SHARED_SERVERS and DISPATCHERS parameters with ALTER SYSTEM to perform one of the following operations while the instance is running:

- Create additional shared server processes by increasing the minimum number of shared server processes.
- Terminate existing shared server processes after their current calls finish processing.
- Create more dispatcher processes for a specific protocol, up to a maximum across all protocols specified by the initialization parameter MAX_DISPATCHERS.
- Terminate existing dispatcher processes for a specific protocol after their current user processes disconnect from the instance.

See Also:

- Oracle Real Application Clusters Administration and Deployment Guide for information on setting parameter values for an individual instance in an Oracle Real Application Clusters environment

alter_system_reset_clause

This clause lets you reset an initialization parameter.

The semantics of this clause are similar to the set_parameter_clause, except instead of changing the value of an initialization parameter, this clause removes the setting of an initialization parameter. Refer to the set_parameter_clause to learn about the parameters you can reset, and for the full semantics of the SCOPE and SID clauses.
RELOCATE CLIENT

This clause is valid only if you are using Oracle Flex ASM. You must issue this clause from within an Oracle ASM instance, not from a normal database instance.

Use this clause to relocate the specified client to the least loaded Oracle ASM instance. When you issue this clause, the connection to the client is terminated and the client fails over to the least loaded instance. If the client is currently connected to the least loaded instance, then the connection to the client is terminated and the client fails over to that same instance.

For client_id, specify a string of the following form enclosed in single quotation marks:

instance_name:db_name

where instance_name is the identifier for the client and db_name is the database name for the client. You can find these values by querying the INSTANCE_NAME and DB_NAME columns of the V$ASM_CLIENT dynamic performance view.

See Also:

• Oracle Automatic Storage Management Administrator's Guide for more information on managing Oracle Flex ASM
• Oracle Database Reference for more information on the V$ASM_CLIENT dynamic performance view

cancel_sql_clause

Use this clause to terminate an SQL operation that is consuming excessive resources, including parallel servers. You must provide the session id and the session serial number to identify the SQL statement that you want to cancel. If you do not provide these required arguments, the SQL statement will not run.

• session_id is required and stands for the session identifier.
• serial_number is required and stands for the serial number of the session.
• @instance_id is optional. If this argument is omitted, the instance id of the current session is used.
• sql_id is optional. If this argument is omitted, the SQL statement currently running in the specified session is terminated.

FLUSH PASSWORDFILE_METADATA_CACHE

If the location or the name of the password file changes, you must notify the database that a change has occurred. The command ALTER SYSTEM FLUSH PASSWORDFILE_METADATA_CACHE flushes the password file metadata cache stored in the SGA and informs the database that a change has occurred.

The command also flushes the cache from all the RAC instances if it is run in a cluster environment. Note the delay in propagating the change across all instances. Until the flush is fully propagated, some instances might continue to use the old password file.
Examples

Archiving Redo Logs Manually: Examples

The following statement manually archives the redo log file group containing the redo log entry with the SCN 9356083:

```
ALTER SYSTEM ARCHIVE LOG CHANGE 9356083;
```

The following statement manually archives the redo log file group containing a member named 'disk1:log6.log' to an archived redo log file in the location 'diska:

```
ALTER SYSTEM ARCHIVE LOG
    LOGFILE 'disk1:log6.log'
    TO 'diska:[arch$]';
```

Enabling Query Rewrite: Example

This statement enables query rewrite in all sessions for all materialized views for which query rewrite has not been explicitly disabled:

```
ALTER SYSTEM SET QUERY_REWRITE_ENABLED = TRUE;
```

Restricting Sessions: Example

You might want to restrict sessions if you are performing application maintenance and you want only application developers with RESTRICTED SESSION system privilege to log on. To restrict sessions, issue the following statement:

```
ALTER SYSTEM
    ENABLE RESTRICTED SESSION;
```

You can then terminate any existing sessions using the KILL SESSION clause of the ALTER SYSTEM statement.

After performing maintenance on your application, issue the following statement to allow any user with CREATE SESSION system privilege to log on:

```
ALTER SYSTEM
    DISABLE RESTRICTED SESSION;
```

Establishing a Wallet and Encryption Key: Examples

The following statements load information from the server wallet into memory and set the Transparent Data Encryption master key:

```
ALTER SYSTEM SET ENCRYPTION WALLET OPEN IDENTIFIED BY "password";
ALTER SYSTEM SET ENCRYPTION KEY IDENTIFIED BY "password";
```

These statements assume that you have initialized the security module and created a wallet with password.

Closing a Wallet: Examples

The following statement removes password-based wallet information from memory:

```
ALTER SYSTEM SET ENCRYPTION WALLET CLOSE IDENTIFIED BY "password";
```

The following statement removes password-based wallet information and auto-login information, if present, from memory:
ALTER SYSTEM SET ENCRYPTION WALLET CLOSE;

Clearing the Shared Pool: Example

You might want to clear the shared pool before beginning performance analysis. To clear the shared pool, issue the following statement:

ALTER SYSTEM FLUSH SHARED_POOL;

Forcing a Checkpoint: Example

The following statement forces a checkpoint:

ALTER SYSTEM CHECKPOINT;

Enabling Resource Limits: Example

This ALTER SYSTEM statement dynamically enables resource limits:

ALTER SYSTEM SET RESOURCE_LIMIT = TRUE;

Changing Shared Server Settings: Examples

The following statement changes the minimum number of shared server processes to 25:

ALTER SYSTEM SET SHARED_SERVERS = 25;

If there are currently fewer than 25 shared server processes, then Oracle Database creates more. If there are currently more than 25, then Oracle Database terminates some of them when they are finished processing their current calls if the load could be managed by the remaining 25.

The following statement dynamically changes the number of dispatcher processes for the TCP/IP protocol to 5 and the number of dispatcher processes for the ipc protocol to 10:

ALTER SYSTEM
SET DISPATCHERS =
    '(INDEX=0) (PROTOCOL=TCP) (DISPATCHERS=5)',
    '(INDEX=1) (PROTOCOL=ipc) (DISPATCHERS=10)';

If there are currently fewer than 5 dispatcher processes for TCP, then Oracle Database creates new ones. If there are currently more than 5, then Oracle Database terminates some of them after the connected users disconnect.

If there are currently fewer than 10 dispatcher processes for ipc, then Oracle Database creates new ones. If there are currently more than 10, then Oracle Database terminates some of them after the connected users disconnect.

If there are currently existing dispatchers for another protocol, then the preceding statement does not affect the number of dispatchers for that protocol.

Changing Licensing Parameters: Examples

The following statement dynamically changes the limit on sessions for your instance to 64 and the warning threshold for sessions on your instance to 54:

ALTER SYSTEM
SET LICENSE_MAX_SESSIONS = 64
LICENSE_SESSIONS_WARNING = 54;
If the number of sessions reaches 54, then Oracle Database writes a warning message to the ALERT file for each subsequent session. Also, users with RESTRICTED SESSION system privilege receive warning messages when they begin subsequent sessions.

If the number of sessions reaches 64, then only users with RESTRICTED SESSION system privilege can begin new sessions until the number of sessions falls below 64 again.

The following statement dynamically disables the limit for sessions on your instance. After you issue this statement, Oracle Database no longer limits the number of sessions on your instance.

```
ALTER SYSTEM SET LICENSE_MAX_SESSIONS = 0;
```

The following statement dynamically changes the limit on the number of users in the database to 200. After you issue the preceding statement, Oracle Database prevents the number of users in the database from exceeding 200.

```
ALTER SYSTEM SET LICENSE_MAX_USERS = 200;
```

**Forcing a Log Switch: Example**

You might want to force a log switch to drop or rename the current redo log file group or one of its members, because you cannot drop or rename a file while Oracle Database is writing to it. The forced log switch affects only the redo log thread of your instance. The following statement forces a log switch:

```
ALTER SYSTEM SWITCH LOGFILE;
```

**Enabling Distributed Recovery: Example**

The following statement enables distributed recovery:

```
ALTER SYSTEM ENABLE DISTRIBUTED RECOVERY;
```

You might want to disable distributed recovery for demonstration or testing purposes. You can disable distributed recovery in both single-process and multiprocess mode with the following statement:

```
ALTER SYSTEM DISABLE DISTRIBUTED RECOVERY;
```

When your demonstration or testing is complete, you can then enable distributed recovery again by issuing an ALTER SYSTEM statement with the ENABLE DISTRIBUTED RECOVERY clause.

**Terminating a Session: Example**

You might want to terminate the session of a user that is holding resources needed by other users. The user receives an error message indicating that the session has been terminated. That user can no longer make calls to the database without beginning a new session. Consider this data from the `V$SESSION` dynamic performance table, when the users `SYS` and `oe` both have open sessions:

```
SELECT sid, serial#, username
FROM V$SESSION;
```

```
SID SERIAL# USERNAME
---------- ---------- ------------------------------
29 85 SYS
```
The following statement terminates the session of the user `scott` using the SID and SERIAL# values from V$SESSION:

```
ALTER SYSTEM KILL SESSION '39, 23';
```

### Disconnecting a Session: Example

The following statement disconnects user `scott`'s session, using the SID and SERIAL# values from V$SESSION:

```
ALTER SYSTEM DISCONNECT SESSION '13, 8' POST_TRANSACTION;
```

## ALTER TABLE

### Purpose

Use the `ALTER TABLE` statement to alter the definition of a nonpartitioned table, a partitioned table, a table partition, or a table subpartition. For object tables or relational tables with object columns, use `ALTER TABLE` to convert the table to the latest definition of its referenced type after the type has been altered.

### Note:

Oracle recommends that you use the `ALTER MATERIALIZED VIEW LOG` statement, rather than `ALTER TABLE`, whenever possible for operations on materialized view log tables.

### See Also:

- [CREATE TABLE](#) for information on creating tables
- *Oracle Text Reference* for information on `ALTER TABLE` statements in conjunction with Oracle Text

### Prerequisites

The table must be in your own schema, or you must have `ALTER` object privilege on the table, or you must have `ALTER ANY TABLE` system privilege.

### Additional Prerequisites for Partitioning Operations

If you are not the owner of the table, then you need the `DROP ANY TABLE` privilege in order to use the `drop_table_partition` or `truncate_table_partition` clause.
You must also have space quota in the tablespace in which space is to be acquired in order to use the `add_table_partition`, `modify_table_partition`, `move_table_partition`, and `split_table_partition` clauses.

When a partitioning operation cascades to reference-partitioned child tables, privileges are not required on the reference-partitioned child tables.

When using the `exchange_partition_subpart` clause, if the table data being exchanged contains an identity column and you are not the owner of both tables involved in the exchange, then you must have the `ALTER ANY SEQUENCE` system privilege.

You cannot partition a non-partitioned table that has an object type.

**Additional Prerequisites for Constraints and Triggers**

To enable a unique or primary key constraint, you must have the privileges necessary to create an index on the table. You need these privileges because Oracle Database creates an index on the columns of the unique or primary key in the schema containing the table.

To enable or disable triggers, the triggers must be in your schema or you must have the `ALTER ANY TRIGGER` system privilege.

---

**See Also:**

`CREATE INDEX` for information on the privileges needed to create indexes

---

**Additional Prerequisites When Using Object Types**

To use an object type in a column definition when modifying a table, either that object must belong to the same schema as the table being altered, or you must have either the `EXECUTE ANY TYPE` system privilege or the `EXECUTE` object privilege for the object type.

**Additional Prerequisites for Flashback Data Archive Operations**

To use the `flashback_archive_clause` to enable historical tracking for the table, you must have the `FLASHBACK ARCHIVE` object privilege on the flashback data archive that will contain the historical data. To use the `flashback_archive_clause` to disable historical tracking for the table, you must have the `FLASHBACK ARCHIVE ADMINISTER` system privilege or you must be logged in as `SYSDBA`.

**Additional Prerequisite for Referring to Editioned Objects**

To specify an edition in the `evaluation_edition_clause` or the `unusable_editions_clause`, you must have the `USE` privilege on the edition.

Semantics  
Many clauses of the `ALTER TABLE` statement have the same functionality they have in a `CREATE TABLE` statement. For more information on such clauses, see `CREATE TABLE`.  

>Note:  
Operations performed by the `ALTER TABLE` statement can cause Oracle Database to invalidate procedures and stored functions that access the table. For information on how and when the database invalidates such objects, see `Oracle Database Development Guide`.  

schema  
Specify the schema containing the table. If you omit `schema`, then Oracle Database assumes the table is in your own schema.  

table  
Specify the name of the table to be altered.
Note:

If you alter a table that is a master table for one or more materialized views, then Oracle Database marks the materialized views INVALID. Invalid materialized views cannot be used by query rewrite and cannot be refreshed. For information on revalidating a materialized view, see ALTER MATERIALIZED VIEW.

See Also:

Oracle Database Data Warehousing Guide for more information on materialized views in general

Restrictions on Altering Temporary Tables

You can modify, drop columns from, or rename a temporary table. However, for a temporary table you cannot:

- Add columns of nested table type. You can add columns of other types.
- Specify referential integrity (foreign key) constraints for an added or modified column.
- Specify the following clauses of the LOB_storage_clause for an added or modified LOB column: TABLESPACE, storage_clause, logging_clause, allocate_extent_clause, or deallocate_unused_clause.
- Specify the physical_attributes_clause, nested_table_col_properties, parallel_clause, allocate_extent_clause, deallocate_unused_clause, or any of the index-organized table clauses.
- Exchange partitions between a partition and a temporary table.
- Specify the logging_clause.
- Specify MOVE.
- Add an INVISIBLE column or modify an existing column to be INVISIBLE.

Restrictions on Altering External Tables

You can add, drop, or modify the columns of an external table. However, for an external table you cannot:

- Add a LONG, LOB, or object type column or change the data type of an external table column to any of these data types.
- Modify the storage parameters of an external table.
- Specify the logging_clause.
- Specify MOVE.
- Add an INVISIBLE column or modify an existing column to be INVISIBLE.
**memoptimize_read_clause**

Use this clause to improve the performance of high-frequency data query operations. The MEMOPTIMIZE_POOL_SIZE initialization parameter controls the size of the memoptimize pool. Note that the feature uses additional memory from the SGA.

- You must specify this clause as a top-level attribute of the table, it cannot be specified at the partition or subpartition level.
- You must explicitly enable the table for MEMOPTIMIZE FOR READ before you can read data from the table.
- You must explicitly disable the table for NO MEMOPTIMIZE FOR READ when you no longer need it.

**memoptimize_write_clause**

Use this clause to enable fast ingest. Fast ingest optimizes the processing of high frequency single row data inserts from Internet of Things (IoT) applications by using a large buffering pool to store the inserts before writing them to disk.

**alter_table_properties**

Use the alter_table_clauses to modify a database table.

**physical_attributes_clause**

The physical_attributes_clause lets you change the value of the PCTFREE, PCTUSED, and INITRANS parameters and storage characteristics. Refer to physical_attributes_clause and storage_clause for a full description of these parameters and characteristics.

**Restrictions on Altering Table Physical Attributes**

Altering physical attributes is subject to the following restrictions:

- You cannot specify the PCTUSED parameter for the index segment of an index-organized table.

- If you attempt to alter the storage attributes of tables in locally managed tablespaces, then Oracle Database raises an error. However, if some segments of a partitioned table reside in a locally managed tablespace and other segments reside in a dictionary-managed tablespace, then the database alters the storage attributes of the segments in the dictionary-managed tablespace but does not alter the attributes of the segments in the locally managed tablespace, and does not raise an error.

- For segments with automatic segment-space management, the database ignores attempts to change the PCTUSED setting. If you alter the PCTFREE setting, then you must subsequently run the DBMS_REPAIR.SEGMENT_FIX_STATUS procedure to implement the new setting on blocks already allocated to the segment.

**Cautions on Altering Tables Physical Attributes**

The values you specify in this clause affect the table as follows:

- For a nonpartitioned table, the values you specify override any values specified for the table at create time.
• For a range-, list-, or hash-partitioned table, the values you specify are the default values for the table and the actual values for every existing partition, overriding any values already set for the partitions. To change default table attributes without overriding existing partition values, use the `modify_table_default_attrs` clause.

• For a composite-partitioned table, the values you specify are the default values for the table and all partitions of the table and the actual values for all subpartitions of the table, overriding any values already set for the subpartitions. To change default partition attributes without overriding existing subpartition values, use the `modify_table_default_attrs` clause with the FOR PARTITION clause.

`logging_clause`

Use the `logging_clause` to change the logging attribute of the table. The `logging_clause` specifies whether subsequent `ALTER TABLE ... MOVE` and `ALTER TABLE ... SPLIT` operations will be logged or not logged.

When used with the `modify_table_default_attrs` clause, this clause affects the logging attribute of a partitioned table.

See Also:

- `logging_clause` for a full description of this clause
- Oracle Database VLDB and Partitioning Guide for more information about the `logging_clause` and parallel DML

`table_compression`

The `table_compression` clause is valid only for heap-organized tables. Use this clause to instruct Oracle Database whether to compress data segments to reduce disk and memory use. Refer to the `CREATE TABLE` `table_compression` for the full semantics of this clause and for information on creating objects with table compression.

Note:

The first time a table is altered in such a way that compressed data will be added, all bitmap indexes and bitmap index partitions on that table must be marked UNUSABLE.

`inmemory_table_clause`

Use this clause to enable or disable a table or table column for the In-Memory Column Store (IM column store), or to change the In-Memory attributes for a table or table column.

- Specify `INMEMORY` to enable a table for the IM column store, or to change the `inmemory_attributes` for a table that is already enabled for the IM column store.
- Specify `NO INMEMORY` to disable a table for the IM column store.
- Specify the `inmemory_column_clause` to enable or disable a table column for the IM column store, or to change the `inmemory_memcompress` setting for a table.
column. If you specify this clause when the table or partition is disabled for the IM column store, then the column settings will take effect when the table or partition is subsequently enabled for the IM column store. Regardless of whether the table or partition is enabled or disabled for the IM column store, when you specify NO INMEMORY for a column, any previously specified inmemory_memcompress setting for the column is lost. Refer to the inmemory_column_clause of CREATE TABLE for the full semantics of this clause.

This inmemory_table_clause has the same semantics as the inmemory_table_clause of CREATE TABLE, with the following additions:

- When you specify the inmemory_memcompress clause to change the data compression method for a table that is already enabled for the IM column store, any columns that were previously assigned a specific data compression method will retain that data compression method. Refer to the inmemory_memcompress clause of CREATE TABLE for more information on this clause.

- When you specify the inmemory_distribute clause, if you omit one subclause, then its setting remains unchanged. That is, if you specify only the AUTO or BY clause, then the FOR SERVICE setting for the table remains unchanged, and if you specify only the FOR SERVICE clause, then the AUTO or BY setting for the table remains unchanged. If you omit both subclauses and specify only the DISTRIBUTE keyword, then the table is assigned the DISTRIBUTE AUTO setting and its FOR SERVICE setting remains unchanged. Refer to the inmemory_distribute clause of CREATE TABLE for more information on this clause.

- When you specify NO INMEMORY to disable a partitioned or nonpartitioned table for the IM column store, any column-level In-Memory settings are lost. If you subsequently enable the table for the IM column store, then all columns will use the In-Memory settings for the table, unless you specify otherwise when enabling the table.

- When you specify NO INMEMORY to disable a partition for the IM column store, the column-level In-Memory settings are retained, even if all partitions in the table are disabled. If you subsequently enable the table or a partition for the IM column store, then the column-level In-Memory settings will go into effect, unless you specify otherwise when enabling the table or partition.

- If a table is currently populated in the IM column store and you change any inmemory_attribute of the table other than PRIORITY, then the database evicts the table from the IM column store. The repopulation behavior depends on the PRIORITY setting.

**inmemory_clause**

Use this clause to enable or disable a table partition for the IM column store, or to change the In-Memory parameters for a table partition. This clause has the same semantics in CREATE TABLE and ALTER TABLE. Refer to the inmemory_clause in the documentation on CREATE TABLE for the full semantics of this clause.

You can specify INMEMORY on non-partitioned tables using the ORACLE_HIVE, ORACLE_HDFS, and ORACLE_BIGDATA driver types.

**Restriction**

If a segment on disk is 64 KB or less, then it is not populated in the IM column store. Therefore, some small database objects that were enabled for the IM column store might not be populated.
**ilm_clause**

Use this clause to add, delete, enable, or disable Automatic Data Optimization policies for the table.

**ADD POLICY**

Specify this clause to add a policy for the table.

Use `ilm_policy_clause` to specify the policy. Refer to the `ilm_policy_clause` for the full semantics of this clause

Oracle Database assigns a name to the policy of the form $P_n$ where $n$ is an integer value

**{ DELETE | ENABLE | DISABLE } POLICY**

Specify these clauses to delete a policy for the table, enable a policy for the table, or disable a policy for the table, respectively.

For `ilm_policy_name`, specify the name of the policy. You can view policy names by querying the `POLICY_NAME` column of the `DBA_ILMPOLICIES` view.

**{ DELETE_ALL, ENABLE_ALL, DISABLE_ALL }**

Specify these clauses to delete all policies for the table, enable all policies for the table, or disable all policies for the table, respectively.

---

**See Also:**

*Oracle Database VLDB and Partitioning Guide* for more information on managing policies for Automatic Data Optimization

---

**ilm_policy_clause**

This clause lets you specify an Automatic Data Optimization policy. You can use the `ilm_compression_policy` clause to specify a compression policy, the `ilm_tiering_policy` clause to specify a storage tiering policy, or the `ilm_inmemory_policy` clause to specify an In-Memory Column Store policy.

**ilm_compression_policy**

Use this clause to specify a compression policy. This type of policy instructs the database to compress data when a specified condition is met. Use the `SEGMENT`, `GROUP`, or `ROW` clause to specify a segment-level, group-level, or row-level compression policy.

**table_compression**

Use the `table_compression` clause to specify the compression type. This clause applies to segment-level and group-level compression policies.

You must specify a compression type that is higher than the current compression type. The order of compression types from lowest to highest is:

- NOCOMPRESS
- ROW STORE COMPRESS BASIC
ROW STORE COMPRESS ADVANCED
COLUMN STORE COMPRESS FOR QUERY LOW
COLUMN STORE COMPRESS FOR QUERY HIGH
COLUMN STORE COMPRESS FOR ARCHIVE LOW
COLUMN STORE COMPRESS FOR ARCHIVE HIGH

Refer to table_compression for the full semantics of this clause.

SEGMENT

Specify SEGMENT to create a segment-level compression policy. This type of policy instructs the database to compress table segments when the condition specified in the AFTER clause is met or when the PL/SQL function specified in the ON clause returns TRUE.

GROUP

Specify GROUP to create a group-level compression policy. This type of policy instructs the database to compress the table and its dependent objects, such as indexes and SecureFiles LOBs, when the condition specified in the AFTER clause is met or when the PL/SQL function specified in the ON clause returns TRUE.

ROW

Specify ROW to create a row-level compression policy. This type of policy instructs the database to compress database blocks in which all the rows have not been modified for a specified period of time. When creating a row-level policy, you must specify ROW STORE COMPRESS ADVANCED or COLUMN STORE COMPRESS FOR QUERY compression, and you must specify AFTER ilm_time_period OF NO MODIFICATION. Refer to table_compression for the full semantics of the ROW STORE COMPRESS ADVANCED and COLUMN STORE COMPRESS FOR QUERY clauses.

AFTER

Use this clause to describe the condition that must be met in order for the policy to take effect. The condition consists of a length of time, specified with the ilm_time_period clause, and one of the following condition types:

- **OF NO ACCESS**: The policy will take effect after table has not been accessed for the specified length of time.
- **OF NO MODIFICATION**: The policy will take effect after table has not been modified for the specified length of time.
- **OF CREATION**: The policy will take effect when the specified length of time has passed since table was created.

ilm_time_period

Specify a length of time in days, months, or years after which the condition must be met. For integer, specify a positive integer. The DAY and DAYS keywords can be used interchangeably and are provided for semantic clarity. This is also the case for the MONTH and MONTHS keywords, and the YEAR and YEARS keywords.

ON

Use this clause to specify a PL/SQL function that returns a boolean value. For function_name, specify the name of the function. The policy will take effect when the function returns TRUE.
**ilm_tiering_policy**

Use this clause to specify a storage tiering policy. This type of policy instructs the database to migrate data to a specified tablespace, either when a specified condition is met or when data usage reaches a specified limit. Use the `SEGMENT` or `GROUP` clause to specify a segment-level or group-level policy. You can migrate data to a read/write tablespace or a read-only tablespace.

**TIER TO tablespace**

Use this clause to migrate data to a read/write `tablespace`.

- If you specify the `ON function` clause, then data will be migrated when function returns `TRUE`. Refer to the `ON` clause for the full semantics of this clause.
- If you omit the `ON function` clause, then data will be migrated when data usage of the tablespace quota reaches the percentage defined by `TBS_PERCENT_USED`. The database will make a best effort to migrate enough data so that the amount of free space within the tablespace quota reaches the percentage defined by `TBS_PERCENT_FREE`. Refer to *Oracle Database PL/SQL Packages and Types Reference* for more information on `TBS_PERCENT_USED` and `TBS_PERCENT_FREE`, which are constants in the `DBMS_ILM_ADMIN` package.

**TIER TO tablespace READ ONLY**

Use this clause to migrate data to a read-only tablespace. When migrating data to the tablespace, the database temporarily places the tablespace in read/write mode, migrates the data, and then places the tablespace back in read-only mode.

- If you specify the `AFTER` clause, then data will be migrated when the specified condition is met. Refer to the `AFTER` clause for the full semantics of this clause.
- If you specify the `ON function` clause, then data will be migrated when function returns `TRUE`. Refer to the `ON` clause for the full semantics of this clause.

**SEGMENT | GROUP**

Specify `SEGMENT` to create a segment-level storage tiering policy. This type of policy instructs the database to migrate table segments to `tablespace`. Specify `GROUP` to create a group-level storage tiering policy. This type of policy instructs the database to migrate the table and its dependent objects, such as indexes and SecureFiles LOBs, to `tablespace`. The default is `SEGMENT`.

**Note:**

The `ON function_name` clause is not supported for tablespaces.
**ilm_inmemory_policy**

Use this clause to specify an In-Memory Column Store (IM column store) policy. This type of policy instructs the database to enable or disable the table for the IM column store, or to change the compression method for the table in the IM column store, when a specified condition is met.

**SET INMEMORY**

Use this clause to enable the table for the IM column store when the specified condition is met. You can optionally use the `inmemory_attributes` clause to specify how table data will be stored in the IM column store. Refer to `inmemory_attributes` for the full semantics of this clause.

**MODIFY INMEMORY**

Use this clause to change the compression method for table data stored in the IM column store when the specified condition is met. The table must be enabled for the IM column store.

You must specify a compression method that is higher than the current compression method. The order of compression methods from lowest to highest is:

- NO INMEMORY
- MEMCOMPRESS FOR DML
- MEMCOMPRESS FOR QUERY LOW
- MEMCOMPRESS FOR QUERY HIGH
- MEMCOMPRESS FOR CAPACITY LOW
- MEMCOMPRESS FOR CAPACITY HIGH

Refer to `inmemory_memcompress` for the full semantics of this clause.

**NO INMEMORY**

Use this clause to disable the table for the IM column store when the specified condition is met.

**SEGMENT**

The `SEGMENT` keyword is optional and is provided for semantic clarity. IM column store policies are always segment-level policies.

**AFTER | ON**

The `AFTER` and `ON` clauses enable you to specify the condition that must be met in order for the IM column store policy to take effect:

- If you specify the `AFTER` clause, then the policy will take effect when the specified condition is met. Refer to the `AFTER` clause for the full semantics of this clause.
- If you specify the `ON` function clause, then the policy will take effect when function returns `TRUE`. Refer to the `ON` clause for the full semantics of this clause.

**Note:**

The `ON function_name` clause is not supported for tablespaces.
See Also:

Oracle Database In-Memory Guide for more information on using Automatic Data Optimization policies with the IM column store

supplemental_table_logging

Use the supplemental_table_logging clause to add or drop a redo log group or one or more supplementally logged columns in a redo log group.

- In the ADD clause, use supplemental_log_grp_clause to create named supplemental log group. Use the supplemental_id_key_clause to create a system-generated log group.
- On the DROP clause, use GROUP log_group syntax to drop a named supplemental log group and use the supplemental_id_key_clause to drop a system-generated log group.

The supplemental_log_grp_clause and the supplemental_id_key_clause have the same semantics in CREATE TABLE and ALTER TABLE statements. For full information on these clauses, refer to supplemental_log_grp_clause and supplemental_id_key_clause in the documentation on CREATE TABLE.

allocate_extent_clause

Use the allocate_extent_clause to explicitly allocate a new extent for the table, the partition or subpartition, the overflow data segment, the LOB data segment, or the LOB index.

Restriction on Allocating Table Extents

You cannot allocate an extent for a temporary table or for a range- or composite-partitioned table.

dealocate_unused_clause

deallocate_unused_clause Use the deallocate_unused_clause to explicitly deallocate unused space at the end of the table, partition or subpartition, overflow data segment, LOB data segment, or LOB index and make the space available for other segments in the tablespace.
CACHE | NOCACHE

The CACHE and NOCACHE clauses have the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on these clauses, refer to "CACHE | NOCACHE | CACHE READS" in the documentation on CREATE TABLE. If you omit both of these clauses in an ALTER TABLE statement, then the existing value is unchanged.

RESULT_CACHE

The RESULT_CACHE clause has the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on this clause, refer to "RESULT_CACHE Clause" in the documentation on CREATE TABLE. If you omit this clause in an ALTER TABLE statement, then the existing setting is unchanged.

upgrade_table_clause

The upgrade_table_clause is relevant for object tables and for relational tables with object columns. It lets you instruct Oracle Database to convert the metadata of the target table to conform with the latest version of each referenced type. If table is already valid, then the table metadata remains unchanged.

Restriction on Upgrading Object Tables and Columns

Within this clause, you cannot specify object_type_col_properties as a clause of column_properties.

INCLUDING DATA

Specify INCLUDING DATA if you want Oracle Database to convert the data in the table to the latest type version format. You can define the storage for any new column while upgrading the table by using the column_properties and the LOB_partition_storage. This is the default.

You can convert data in the table at the time you upgrade the type by specifying CASCADE INCLUDING TABLE DATA in the dependent_handling_clause of the ALTER TYPE statement. See Oracle Database PL/SQL Language Reference for information on this clause. For information on whether a table contains data based on an older type version, refer to the DATA_UPGRADED column of the USER_TAB_COLUMNS data dictionary view.

NOT INCLUDING DATA

Specify NOT INCLUDING DATA if you want Oracle Database to leave column data unchanged.

Restriction on NOT INCLUDING DATA

You cannot specify NOT INCLUDING DATA if the table contains columns in Oracle8 release 8.0.x image format. To determine whether the table contains such columns, refer to the V80_FMT_IMAGE column of the USER_TAB_COLUMNS data dictionary view.
The `records_per_block_clause` lets you specify whether Oracle Database restricts the number of records that can be stored in a block. This clause ensures that any bitmap indexes subsequently created on the table will be as compressed as possible.

**Restrictions on Records in a Block**

The `record_per_block_clause` is subject to the following restrictions:

- You cannot specify either `MINIMIZE` or `NOMINIMIZE` if a bitmap index has already been defined on the table. You must first drop the bitmap index.
- You cannot specify this clause for an index-organized table or a nested table.

**MINIMIZE**

Specify `MINIMIZE` to instruct Oracle Database to calculate the largest number of records in any block in the table and to limit future inserts so that no block can contain more than that number of records.

Oracle recommends that a representative set of data already exist in the table before you specify `MINIMIZE`. If you are using table compression (see `table_compression`), then a representative set of compressed data should already exist in the table.

**Restriction on MINIMIZE**

You cannot specify `MINIMIZE` for an empty table.

**NOMINIMIZE**

Specify `NOMINIMIZE` to disable the `MINIMIZE` feature. This is the default.

**row_movement_clause**

You cannot disable row movement in a reference-partitioned table unless row movement is also disabled in the parent table. Otherwise, this clause has the same semantics in `CREATE TABLE` and `ALTER TABLE` statements. For complete information on these clauses, refer to `row_movement_clause` in the documentation on `CREATE TABLE`.

**flashback_archive_clause**

You must have the `FLASHBACK ARCHIVE` object privilege on the specified flashback data archive to specify this clause. Use this clause to enable or disable historical tracking for the table.

- Specify `FLASHBACK ARCHIVE` to enable tracking for the table. You can specify `flashback_archive` to designate a particular flashback data archive for this table. The flashback data archive you specify must already exist.
If you omit the archive name, then the database uses the default flashback data archive designated for the system. If no default flashback data archive has been designated for the system, then you must specify `flashback_archive`.

You cannot specify `FLASHBACK ARCHIVE` to change the flashback data archive for this table. Instead you must first issue an `ALTER TABLE` statement with the `NO FLASHBACK ARCHIVE` clause and then issue an `ALTER TABLE` statement with the `FLASHBACK ARCHIVE` clause.

- **Specify NO FLASHBACK ARCHIVE to disable tracking for the table.**

---

### See Also:

The `CREATE TABLE` `flashback_archive_clause` for information on creating a table with tracking enabled and `CREATE FLASHBACK ARCHIVE` for information on creating default flashback data archives.

### RENAME TO

Use the `RENAME` clause to rename `table` to `new_table_name`.

Using this clause invalidates any dependent materialized views. For more information on materialized views, see `CREATE MATERIALIZED VIEW` and *Oracle Database Data Warehousing Guide*.

If a domain index is defined on the table, then the database invokes the `ODCIIndexAlter()` method with the `RENAME` option. This operation establishes correspondence between the indextype metadata and the base table.

### Restriction on Renaming Tables

You cannot rename a sharded table or a duplicated table.

### `shrink_clause`

The shrink clause lets you manually shrink space in a table, index-organized table or its overflow segment, index, partition, subpartition, LOB segment, materialized view, or materialized view log. This clause is valid only for segments in tablespaces with automatic segment management. By default, Oracle Database compacts the segment, adjusts the high water mark, and releases the recuperated space immediately.

Compacting the segment requires row movement. Therefore, you must enable row movement for the object you want to shrink before specifying this clause. Further, if your application has any rowid-based triggers, you should disable them before issuing this clause.

---

### Note:

Do not attempt to enable row movement for an index-organized table before specifying the `shrink_clause`. The `ROWID` of an index-organized table is its primary key, which never changes. Therefore, row movement is neither relevant nor valid for such tables.
Restrictions:

The shrink_clause is not supported on IOT partition tables.

COMPACT

If you specify COMPACT, then Oracle Database only defragments the segment space and compacts the table rows for subsequent release. The database does not readjust the high water mark and does not release the space immediately. You must issue another ALTER TABLE ... SHRINK SPACE statement later to complete the operation. This clause is useful if you want to accomplish the shrink operation in two shorter steps rather than one longer step.

For an index or index-organized table, specifying ALTER [INDEX | TABLE] ... SHRINK SPACE COMPACT is equivalent to specifying ALTER [INDEX | TABLE] ... COALESCE. The shrink_clause can be cascaded (refer to the CASCADE clause, which follows) and compacts the segment more densely than does a coalesce operation, which can improve performance. However, if you do not want to release the unused space, then you can use the appropriate COALESCE clause.

CASCADE

If you specify CASCADE, then Oracle Database performs the same operations on all dependent objects of table, including secondary indexes on index-organized tables.

Restrictions on the shrink_clause

The shrink_clause is subject to the following restrictions:

- You cannot combine this clause with any other clauses in the same ALTER TABLE statement.
- Segment shrink is not supported for tables with function-based indexes, domain indexes, or bitmap join indexes.
- This clause does not shrink mapping tables of index-organized tables, even if you specify CASCADE.
- You can specify this clause for a table with Advanced Row Compression enabled (ROW STORE COMPRESS ADVANCED). You cannot specify this clause for a table with any other type of table compression enabled.
- You cannot shrink a table that is the master table of an ON COMMIT materialized view. Rowid materialized views must be rebuilt after the shrink operation.

READ ONLY | READ WRITE

Specify READ ONLY to put the table in read-only mode. When the table is in READ ONLY mode, you cannot issue any DML statements that affect the table or any SELECT ... FOR UPDATE statements. You can issue DDL statements as long as they do not modify any table data. Operations on indexes associated with the table are allowed when the table is in READ ONLY mode. See Oracle Database Administrator’s Guide for the complete list of operations that are allowed and disallowed on read-only tables.

Specify READ WRITE to return a read-only table to read/write mode.
REKEY encryption_spec

Use the REKEY clause to generate a new encryption key or to switch between different algorithms. This operation returns only after all encrypted columns in the table, including LOB columns, have been reencrypted.

DEFAULT COLLATION

This clause lets you change the default collation for the table. For collation_name, specify a valid named collation or pseudo-collation.

The new default collation for the table is assigned to columns of a character data type that are subsequently added to the table with an ALTER TABLE ADD statement or modified from a non-character data type with an ALTER TABLE MODIFY statement. The collations for existing columns in the table are not changed. Refer to the DEFAULT COLLATION clause of CREATE TABLE for the full semantics of this clause.

[NO] ROW ARCHIVAL

Specify this clause to enable or disable table for row archival.

- Specify ROW ARCHIVAL to enable table for row archival. A hidden column ORA_ARCHIVE_STATE is created in the table. If the table is already populated with data, then the value of ORA_ARCHIVE_STATE is set to 0 for each existing row in the table. You can subsequently use the UPDATE statement to set the value of ORA_ARCHIVE_STATE to 1 for rows you want to archive.
- Specify NO ROW ARCHIVAL to disable table for row archival. The hidden column ORA_ARCHIVE_STATE is dropped from the table.

Restrictions on [NO] ROW ARCHIVAL

The following restrictions apply to this clause:

- You cannot specify the ROW ARCHIVAL clause for a table that already contains a column named ORA_ARCHIVE_STATE.
- You cannot specify the NO ROW ARCHIVAL clause for tables owned by SYS.

See Also:

- The CREATE TABLE ROW ARCHIVAL clause for the full semantics of this clause
- Oracle Database VLDB and Partitioning Guide for more information on In-Database Archiving

attribute_clustering_clause

Use the ADD attribute_clustering_clause to enable the table for attribute clustering. The attribute_clustering_clause has the same semantics for ALTER TABLE and CREATE TABLE. Refer to the attribute_clustering_clause in the documentation on CREATE TABLE.
MODIFY CLUSTERING

Use this clause to allow or disallow attribute clustering for the table during direct-path insert operations or data movement operations. The table must be enabled for attribute clustering. The clustering_when clause and the zonemap_clause have the same semantics for ALTER TABLE and CREATE TABLE. Refer to the clustering_when clause and the zonemap_clause in the documentation on CREATE TABLE.

DROP CLUSTERING

Use this clause to disable the table for attribute clustering.

If a zone map on the table was created using the WITH MATERIALIZED ZONEMAP clause of CREATE TABLE or ALTER TABLE, then the zone map will be dropped. If a zone map on the table was created using the CREATE MATERIALIZED ZONEMAP statement, then the zone map will not be dropped.

alter_iot_clauses

index_org_table_clause

This clause lets you alter some of the characteristics of an existing index-organized table. Index-organized tables keep data sorted on the primary key and are therefore best suited for primary-key-based access and manipulation. See index_org_table_clause in the context of CREATE TABLE.

See Also:

"Modifying Index-Organized Tables: Examples"

prefix_compression

Use the prefix_compression clause to enable prefix compression for the table. Specify COMPRESS to instruct Oracle Database to combine the primary key index blocks of the index-organized table where possible to free blocks for reuse. You can specify this clause with the parallel_clause. Specify NOCOMPRESS to disable prefix compression for the table.

PCTTHRESHOLD integer

Refer to "PCTTHRESHOLD integer" in the documentation on CREATE TABLE.

INCLUDING column_name

Refer to "INCLUDING column_name" in the documentation on CREATE TABLE.

overflow_attributes

The overflow_attributes let you specify the overflow data segment physical storage and logging attributes to be modified for the index-organized table. Parameter values specified in this clause apply only to the overflow data segment.
add_overflow_clause

The `add_overflow_clause` lets you add an overflow data segment to the specified index-organized table. You can also use this clause to explicitly allocate an extent to or deallocate unused space from an existing overflow segment.

Use the `STORE IN tablespace` clause to specify tablespace storage for the entire overflow segment. Use the `PARTITION` clause to specify tablespace storage for the segment by partition.

For a partitioned index-organized table:

- If you do not specify `PARTITION`, then Oracle Database automatically allocates an overflow segment for each partition. The physical attributes of these segments are inherited from the table level.
- If you want to specify separate physical attributes for one or more partitions, then you must specify such attributes for every partition in the table. You need not specify the name of the partitions, but you must specify their attributes in the order in which they were created.

You can find the order of the partitions by querying the `PARTITION_NAME` and `PARTITION_POSITION` columns of the `USER_IND_PARTITIONS` view.

If you do not specify `TABLESPACE` for a particular partition, then the database uses the tablespace specified for the table. If you do not specify `TABLESPACE` at the table level, then the database uses the tablespace of the partition primary key index segment.

Restrictions on Overflow Attributes

Within the `segment_attributes_clause`:

- You cannot specify the `OPTIMAL` parameter of the `physical_attributes_clause`.
- You cannot specify tablespace storage for the overflow segment using this clause. For a nonpartitioned table, you can use `ALTER TABLE ... MOVE ... OVERFLOW` to move the segment to a different tablespace. For a partitioned table, use `ALTER TABLE ... MODIFY DEFAULT ATTRIBUTES ... OVERFLOW` to change the default tablespace of the overflow segment.

Additional restrictions apply if `table` is in a locally managed tablespace, because in such tablespaces several segment attributes are managed automatically by the database.

See Also:

- `allocate_extent_clause` and `deallocate_unused_clause` for full descriptions of these clauses of the `add_overflow_clause`
**alter_overflow_clause**

The *alter_overflow_clause* lets you change the definition of the overflow segment of an existing index-organized table.

The restrictions that apply to the *add_overflow_clause* also apply to the *alter_overflow_clause*.

---

**Note:**

When you add a column to an index-organized table, Oracle Database evaluates the maximum size of each column to estimate the largest possible row. If an overflow segment is needed but you have not specified `OVERFLOW`, then the database raises an error and does not execute the `ALTER TABLE` statement. This checking function guarantees that subsequent DML operations on the index-organized table will not fail because an overflow segment is lacking.

---

**alter_mapping_table_clauses**

The *alter_mapping_table_clauses* is valid only if *table* is index organized and has a mapping table.

**allocate_extent_clause**

Use the *allocate_extent_clause* to allocate a new extent at the end of the mapping table for the index-organized table. Refer to *allocate_extent_clause* for a full description of this clause.

**deallocate_unused_clause**

Specify the *deallocate_unused_clause* to deallocate unused space at the end of the mapping table of the index-organized table. Refer to *deallocate_unused_clause* for a full description of this clause.

Oracle Database automatically maintains all other attributes of the mapping table or its partitions.

**COALESCE Clause**

Specify *COALESCE* to instruct Oracle Database to merge the contents of index blocks of the index the database uses to maintain the index-organized table where possible to free blocks for reuse. Refer to the *shrink_clause* for information on the relationship between these two clauses.

**alter_XMLSchema_clause**

This clause is valid as part of *alter_table_properties* only if you are modifying an XMLType table with BINARY XML storage. Refer to *XMLSchema_spec* in the documentation on CREATE TABLE for more information on the *ALLOW* and *DISALLOW* clauses.
column clauses

Use these clauses to add, drop, or otherwise modify a column.

add_column_clause

The add_column_clause lets you add a column to a table.

See Also:

CREATE TABLE for a description of the keywords and parameters of this clause and “Adding a Table Column: Example”

column_definition

Unless otherwise noted in this section, the elements of column_definition have the same behavior when adding a column to an existing table as they do when creating a new table. Refer to the column_definition clause of CREATE TABLE for information.

Restriction on column_definition

The SORT parameter is valid only when creating a new table. You cannot specify SORT in the column_definition of an ALTER TABLE ... ADD statement.

When you add a column, the initial value of each row for the new column is null, unless you specify the DEFAULT clause.

You can add an overflow data segment to each partition of a partitioned index-organized table.

You can add LOB columns to nonpartitioned and partitioned tables. You can specify LOB storage at the table and at the partition or subpartition level.

If you previously created a view with a query that used the SELECT * syntax to select all columns from table, and you now add a column to table, then the database does not automatically add the new column to the view. To add the new column to the view, re-create the view using the CREATE VIEW statement with the OR REPLACE clause. Refer to CREATE VIEW for more information.

Restrictions on Adding Columns

The addition of columns is subject to the following restrictions:

• You cannot add a LOB column or an INVISIBLE column to a cluster table.

• If you add a LOB column to a hash-partitioned table, then the only attribute you can specify for the new partition is TABLESPACE.

• You cannot add a column with a NOT NULL constraint if table has any rows unless you also specify the DEFAULT clause.

• If you specify this clause for an index-organized table, then you cannot specify any other clauses in the same statement.

• You cannot add a column to a duplicated table.
DEFAULT

Use the DEFAULT clause to specify a default for a new column or a new default for an existing column. Oracle Database assigns this value to the column if a subsequent INSERT statement omits a value for the column.

The data type of the expression must match the data type specified for the column. The column must also be large enough to hold this expression.

The DEFAULT expression can include any SQL function as long as the function does not return a literal argument, a column reference, or a nested function invocation.

The DEFAULT expression can include the sequence pseudocolumns CURRVAL and NEXTVAL, as long as the sequence exists and you have the privileges necessary to access it. Users who perform subsequent inserts that use the DEFAULT expression must have the INSERT privilege on the table and the SELECT privilege on the sequence. If the sequence is later dropped, then subsequent insert statements where the DEFAULT expression is used will result in an error. If you are adding a new column to a table, then the order in which NEXTVAL is assigned to each existing row is nondeterministic. If you do not fully qualify the sequence by specifying the sequence owner, for example, SCOTT.SEQ1, then Oracle Database will default the sequence owner to be the user who issues the ALTER TABLE statement. For example, if user MARY adds a column to SCOTT.TABLE and refers to a sequence that is not fully qualified, such as SEQ2, then the column will use sequence MARY.SEQ2. Synonyms on sequences undergo a full name resolution and are stored as the fully qualified sequence in the data dictionary; this is true for public and private synonyms. For example, if user BETH adds a column referring to public or private synonym SYN1 and the synonym refers to PETER.SEQ7, then the column will store PETER.SEQ7 as the default.

If you specify the DEFAULT clause for a column, then the default value is stored as metadata but the column itself is not populated with data. However, subsequent queries that specify the new column are rewritten so that the default value is returned in the result set. This optimized behavior is subject to the following restrictions:

- The table cannot have any LOB columns. It cannot be index-organized, temporary, or part of a cluster. It also cannot be a queue table, an object table, or the container table of a materialized view.
- If the table has a Virtual Private Database (VPD) policy on it, then the optimized behavior will not take place unless the user who issues the ALTER TABLE ... ADD statement has the EXEMPT ACCESS POLICY system privilege.
- The column being added cannot be encrypted, and cannot be an object column, nested table column, or a LOB column.
- The DEFAULT expression cannot include the sequence pseudocolumns CURRVAL or NEXTVAL.

If the optimized behavior cannot take place due to the preceding restrictions, then Oracle Database updates each row in the newly created column with the default value. In this case, the database does not fire any UPDATE triggers that are defined on the table.

Restrictions on Default Column Values

Default column values are subject to the following restrictions:
• A DEFAULT expression cannot contain references to PL/SQL functions or to other columns, the pseudocolumns LEVEL, PRIOR, and ROWNUM, or date constants that are not fully specified.

• The expression can be of any form except a scalar subquery expression.

**ON NULL**

If you specify the **ON NULL** clause, then Oracle Database assigns the **DEFAULT** column value when a subsequent **INSERT** statement attempts to assign a value that evaluates to **NULL**.

When you specify **ON NULL**, the **NOT NULL** constraint and **NOT DEFERRABLE** constraint state are implicitly specified. If you specify an inline constraint that conflicts with **NOT NULL** and **NOT DEFERRABLE**, then an error is raised.

> See Also:

"Specifying a Default Column Value: Examples"

**identity_clause**

The **identity_clause** has the same semantics when you add an identity column that it has when you create an identity column. Refer to **CREATE TABLE identity_clause** for more information.

When you add a new identity column to a table, all existing rows are updated using the sequence generator. The order in which a value is assigned to each existing row is nondeterministic.

**identity_options**

Use the **identity_options** clause to configure the sequence generator. The **identity_options** clause has the same parameters as the **CREATE SEQUENCE** statement. Refer to **CREATE SEQUENCE** for a full description of these parameters and characteristics. The exception is **START WITH LIMIT VALUE**, which is specific to **identity_options** and can only be used with **ALTER TABLE MODIFY**. Refer to **identity_options** for more information.

**inline_constraint**

Use **inline_constraint** to add a constraint to the new column.

**inline_ref_constraint**

This clause lets you describe a new column of type REF. Refer to **constraint** for syntax and description of this type of constraint, including restrictions.

**virtual_column_definition**

The **virtual_column_definition** has the same semantics when you add a column that it has when you create a column.
Restriction on Adding a Virtual Column

You cannot add a virtual column when the SQL expression for the virtual column involves a column on which an Oracle Data Redaction policy is defined.

**column_properties**

The clauses of `column_properties` determine the storage characteristics of an object type, nested table, varray, or LOB column.

**object_type_col_properties**

This clause is valid only when you are adding a new object type column or attribute. To modify the properties of an existing object type column, use the `modify_column_clauses`. The semantics of this clause are the same as for `CREATE TABLE` unless otherwise noted.

Use the `object_type_col_properties` clause to specify storage characteristics for a new object column or attribute or an element of a collection column or attribute.

For complete information on this clause, refer to `object_type_col_properties` in the documentation on `CREATE TABLE`.

**nested_table_col_properties**

The `nested_table_col_properties` clause lets you specify separate storage characteristics for a nested table, which in turn lets you to define the nested table as an index-organized table. You must include this clause when creating a table with columns or column attributes whose type is a nested table. (Clauses within this clause that function the same way they function for parent object tables are not repeated here. See the `CREATE TABLE` clause `nested_table_col_properties` for more information about these clauses.)

- For `nested_item`, specify the name of a column (or a top-level attribute of the nested table object type) whose type is a nested table.
  
  If the nested table is a multilevel collection, and the inner nested table does not have a name, then specify `COLUMN_VALUE` in place of the `nested_item` name.

- For `storage_table`, specify the name of the table where the rows of `nested_item` reside. The storage table is created in the same schema and the same tablespace as the parent table.

Restrictions on Nested Table Column Properties

Nested table column properties are subject to the following restrictions:

- You cannot specify the `parallel_clause`.
- You cannot specify `CLUSTER` as part of the `physical_properties` clause.
varray_col_properties

The varray_col_properties clause lets you specify separate storage characteristics for the LOB in which a varray will be stored. If you specify this clause, then Oracle Database will always store the varray in a LOB, even if it is small enough to be stored inline. If varray_item is a multilevel collection, then the database stores all collection items nested within varray_item in the same LOB in which varray_item is stored.

Restriction on Varray Column Properties

You cannot specify TABLESPACE as part of LOB_parameters for a varray column. The LOB tablespace for a varray defaults to the tablespace of the containing table.

out_of_line_part_storage

This clause lets you specify storage attributes the newly added column for each partition or subpartition in a partitioned table. For any partition or subpartition you do not name in this clause, the storage attributes for the new column are the same as those specified in the nested_table_col_properties at the table level.

LOB_storage_clause

Use the LOB_storage_clause to specify the LOB storage characteristics for a newly added LOB column, LOB partition, or LOB subpartition, or when you are converting a LONG column into a LOB column. You cannot use this clause to modify an existing LOB. Instead, you must use the modify_LOB_storage_clause.

Unless otherwise noted in this section, all LOB parameters, in both the LOB_storage_clause and the modify_LOB_storage_clause, have the same semantics in an ALTER TABLE statement that they have in a CREATE TABLE statement. Refer to the CREATE TABLE LOB_storage_clause for complete information on this clause.

Restriction on LOB Parameters

The only parameter of LOB_parameters you can specify for a hash partition or hash subpartition is TABLESPACE.

CACHE READS Clause

When you add a new LOB column, you can specify the logging attribute with CACHE READS, as you can when defining a LOB column at create time. Refer to the CREATE TABLE clause CACHE READS for full information on this clause.

ENABLE | DISABLE STORAGE IN ROW

You cannot change STORAGE IN ROW once it is set. Therefore, you cannot specify this clause as part of the modify_col_properties clause. However, you can change this setting when adding a new column (add_column_clause) or when moving the table (move_table_clause). Refer to the CREATE TABLE clause ENABLE STORAGE IN ROW for complete information on this clause.
CHUNK integer

You use cannot use the modify_col_properties clause to change the value of CHUNK after it has been set. If you require a different CHUNK value for a column after it has been created, use ALTER TABLE ... MOVE. Refer to the CREATE TABLE clause CHUNK integer for more information.

RETENTION

For BasicFiles LOBs, if the database is in automatic undo mode, then you can specify RETENTION instead of PCTVERSION to instruct Oracle Database to retain old versions of this LOB. This clause overrides any prior setting of PCTVERSION. Refer to the CREATE TABLE clause LOB_retention_clause for a full description of this parameter.

FREEPOOLS integer

For BasicFiles LOBs, if the database is in automatic undo mode, then you can use this clause to specify the number of freelist groups for this LOB. This clause overrides any prior setting of FREELIST GROUPS. Refer to the CREATE TABLE clause FREEPOOLS integer for a full description of this parameter. The database ignores this parameter for SecureFiles LOBs.

LOB_partition_storage

You can specify only one list of LOB_partition_storage clauses in a single ALTER TABLE statement, and all LOB_storage_clauses and varray_col_properties clause must precede the list of LOB_partition_storage clauses. Refer to the CREATE TABLE clause LOB_partition_storage for full information on this clause, including restrictions.

XMLType_column_properties

Refer to the CREATE TABLE clause XMLType_column_properties for a full description of this clause.

See Also:

- **LOB_storage_clause** for information on the LOB_segnames and \nLOB_parameters clauses
- "XMLType Column Examples" for an example of XMLType columns in \nobject-relational tables and "Using XML in SQL Statements " for an \nexample of creating an XMLSchema
- Oracle XML DB Developer's Guide for more information on XMLType \ncolumns and tables and on creating an XMLSchema

modify_column_clauses

Use the modify_column_clauses to modify the properties of an existing column, the \nvisibility of an existing column, or the substitutability of an existing object type column.
modify_col_properties

Use this clause to modify the properties of the column. Any of the optional parts of the column definition (data type, default value, or constraint) that you omit from this clause remain unchanged.

datatype

You can change the data type of any column if all rows of the column contain nulls. However, if you change the data type of a column in a materialized view container table, then Oracle Database invalidates the corresponding materialized view.

You can omit the data type only if the statement also designates the column as part of the foreign key of a referential integrity constraint. The database automatically assigns the column the same data type as the corresponding column of the referenced key of the referential integrity constraint.

You can always increase the size of a character or raw column or the precision of a numeric column, whether or not all the rows contain nulls. You can reduce the size of a data type of a column as long as the change does not require data to be modified. The database scans existing data and returns an error if data exists that exceeds the new length limit.

When you increase the size of a VARCHAR2, NVARCHAR2, or RAW column to exceed 4000 bytes, Oracle Database performs an in-place length extension and does not migrate the inline storage to external LOB storage. This enables uninterrupted migration of large tables, especially after migration, to leverage extended data types. However, the inline storage of the column will not be preserved during table reorganization operations, such as CREATE TABLE ... AS SELECT, export, import, or online redefinition. To migrate to the new out-of-line storage of extended data type columns, you must recreate the table using one of the aforementioned methods. The inline storage of the column will be preserved during table or partition movement operations, such as ALTER TABLE MOVE [[SUB]PARTITION], and partition maintenance operations, such as ALTER TABLE SPLIT [SUB]PARTITION, ALTER TABLE MERGE [SUB]PARTITIONS, and ALTER TABLE COALESCE [SUB]PARTITIONS.

Note:

Oracle recommends against excessively increasing the size of a VARCHAR2, NVARCHAR2, or RAW column beyond 4000 bytes for the following reasons:

- Row chaining may occur.
- Data that is stored inline must be read in its entirety, whether a column is selected or not. Therefore, extended data type columns that are stored inline can have a negative impact on performance.
You can reduce the size of a data type of a column as long as the change does not require data to be modified. The database scans existing data and returns an error if data exists that exceeds the new length limit.

You can change a DATE column to a TIMESTAMP or TIMESTAMP WITH LOCAL TIME ZONE column, and you can change a TIMESTAMP or TIMESTAMP WITH LOCAL TIME ZONE column to a DATE column. The following rules apply:

- When you change a TIMESTAMP or TIMESTAMP WITH LOCAL TIME ZONE column to a DATE column, Oracle Database updates each column value that has nonzero fractional seconds by rounding the value to the nearest second. If, while updating such a value, Oracle Database encounters a minute field greater than or equal to 60 (which can occur in a boundary case when the daylight saving rule switches), then it updates the minute field by subtracting 60 from it.

- After you change a TIMESTAMP WITH LOCAL TIME ZONE column to a DATE column, the values in the column still represent the local time that they represented in the database time zone. However, the database time zone is no longer associated with the values. When queried in SQL*Plus, the values are no longer automatically adjusted to the session time zone. It is now the responsibility of applications processing the column values to interpret them in a particular time zone.

If the table is empty, then you can increase or decrease the leading field or the fractional second value of a datetime or interval column. If the table is not empty, then you can only increase the leading field or fractional second of a datetime or interval column.

You can use the TO_LOB function to change a LONG column to a CLOB or NCLOB column, and a LONG RAW column to a BLOB column. However, you cannot use the TO_LOB function from within a PL/SQL package. Instead use the TO_CLOB (character) or TO_BLOB (raw) functions.

- The modified LOB column inherits all constraints and triggers that were defined on the original LONG column. If you want to change any constraints, then you must do so in a subsequent ALTER TABLE statement.

- If any domain indexes are defined on the LONG column, then you must drop them before modifying the column to a LOB.

- After the modification, you will have to rebuild all other indexes on all columns of the table.

You can use the TO_CLOB (character) function to convert NCLOB columns to CLOB columns.

See Also:

- Oracle Database SecureFiles and Large Objects Developer's Guide for information on LONG to LOB migration
- ALTER INDEX for information on dropping and rebuilding indexes

For CHAR and VARCHAR2 columns, you can change the length semantics by specifying CHAR (to indicate character semantics for a column that was originally specified in bytes) or BYTE (to indicate byte semantics for a column that was originally specified in characters). To learn the length semantics of existing columns, query the CHAR_USED column of the ALL_, USER_, or DBA_TAB_COLUMNS data dictionary view.
You can specify a user-defined datatype as non-persistable when creating or altering the datatype. Instances of non-persistable types cannot persist on disk. See CREATE TYPE for more on user-defined datatypes declared as non-persistable types.

**COLLATE**

Use this clause to set or change the data-bound collation for a column. For `column_collation_name`, specify a valid named collation or pseudo-collation. Refer to the DEFAULT COLLATION clause of CREATE TABLE for more information on data-bound collations.

**Restrictions on Changing Column Collation**

The modification of the column collation is subject to the following restrictions:

- If the column belongs to an index key, then its collation can only be changed:
  - among collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, and USING_NLS_SORT_CS
  - between collations BINARY_CI and USING_NLS_SORT_CI
  - between collations BINARY_AI and USING_NLS_SORT_AI
- If the column belongs to a range- or list-partitioning key, is referenced by a bitmap join index, belongs to the primary key of an index-organized table, or to the key of a domain index, including an Oracle Text index, then its collation can only be changed among the collations BINARY, USING_NLS_COMP, USING_NLS_SORT, and USING_NLS_SORT_CS.
- If the column belongs to an attribute clustering key, then its collation can only be changed between the collations BINARY and USING_NLS_COMP.

**identity_clause**

Use `identity_clause` to modify the properties of an identity column. You cannot specify this clause on a column that is not an identity column. If you do not specify ALWAYS or BY DEFAULT, then the current generation type is retained. Refer to CREATE TABLE `identity_clause` for more information on ALWAYS and BY DEFAULT.

**identity_options**
Use the `identity_options` clause to configure the sequence generator. The `identity_options` clause has the same parameters as the `CREATE SEQUENCE` statement. Refer to `CREATE SEQUENCE` for a full description of these parameters and characteristics. The exceptions are:

- **START WITH LIMIT VALUE**, which is specific to `identity_options`, can only be used with `ALTER TABLE MODIFY`. If you specify `START WITH LIMIT VALUE`, then Oracle Database locks the table and finds the maximum identity column value in the table (for increasing sequences) or the minimum identity column value (for decreasing sequences) and assigns the value as the sequence generator’s high water mark. The next value returned by the sequence generator will be the high water mark + `INCREMENT BY integer` for increasing sequences, or the high water mark - `INCREMENT BY integer` for decreasing sequences.

- If you change the value of `START WITH`, then the default values will be used for all other parameters in this clause unless you specify otherwise.

**DROP IDENTITY**

Use this clause to remove the identity property from a column, including the sequence generator and **NOT NULL** and **NOT DEFERRABLE** constraints. Identity column values in existing rows are not affected.

**ENCRYPT `encryption_spec` | DECRYPT**

Use this clause to decrypt an encrypted column, to encrypt an unencrypted column, or to change the integrity algorithm or the `SALT` option of an encrypted column.

When encrypting an existing column, if you specify `encryption_spec`, it must match the encryption specification of any other encrypted columns in the same table. Refer to the `CREATE TABLE` clause `encryption_spec` for additional information and restrictions on the `encryption_spec`.

If a materialized view log is defined on the table, then Oracle Database encrypts or decrypts in the materialized view log any columns you encrypt or decrypt in this clause.

**Restrictions on ENCRYPT `encryption_spec` | DECRYPT**

This clause is subject to the following restrictions:

- If the new or existing column is a LOB column, then it must be stored as a SecureFiles LOB, and you cannot specify the `SALT` option.

- You cannot encrypt or decrypt a column on which a fine-grained audit policy for the `UPDATE` statement is enabled. However, you can disable the fine-grained audit policy, encrypt or decrypt the column, and then enable the fine-grained audit policy.

**inline_constraint**

This clause lets you add a constraint to a column you are modifying. To change the state of existing constraints on existing columns, use the `constraint_clauses`.

**See Also:**

"Data Encryption: Examples"
LOB_storage_clause

The LOB_storage_clause is permitted within modify_col_properties only if you are converting a LONG column to a LOB column. In this case only, you can specify LOB storage for the column using the LOB_storage_clause. However, you can specify only the single column as a LOB_item. Default LOB storage attributes are used for any attributes you omit in the LOB_storage_clause.

alter_XMLSchema_clause

This clause is valid within modify_col_properties only for XMLType tables with BINARY XML storage. Refer to XMLSchema_spec in the documentation on CREATE TABLE for more information on the ALLOW and DISALLOW clauses.

Restrictions on Modifying Column Properties

The modification of column properties is subject to the following restrictions:

- You cannot change the data type of a LOB column.
- You cannot modify a column of a table if a domain index is defined on the column. You must first drop the domain index and then modify the column.
- You cannot modify the data type or length of a column that is part of the partitioning or subpartitioning key of a table or index.
- You can change a CHAR column to VARCHAR2 (or VARCHAR) and a VARCHAR2 (or VARCHAR) column to CHAR only if the BLANK_TRIMMING initialization parameter is set to TRUE and the column size stays the same or increases. If the BLANK_TRIMMING initialization parameter is set to TRUE, then you can also reduce the column size to any size greater than or equal to the maximum trimmed data value.
- You cannot change a LONG or LONG RAW column to a LOB if the table is part of a cluster. If you do change a LONG or LONG RAW column to a LOB, then the only other clauses you can specify in this ALTER TABLE statement are the DEFAULT clause and the LOB_storage_clause.
- You can specify the LOB_storage_clause as part of modify_col_properties only when you are changing a LONG or LONG RAW column to a LOB.
- You cannot specify a column of data type ROWID for an index-organized table, but you can specify a column of type UROWID.
- You cannot change the data type of a column to REF.
- You cannot modify the properties of a column in a duplicated table.

See Also:

ALTER MATERIALIZED VIEW for information on revalidating a materialized view

modify_virtcol_properties

This clause lets you modify a virtual column in the following ways:

- Specify the COLLATE clause to set or change the data-bound collation for a virtual column. For column_collation_name, specify a valid named collation or pseudo-
collation. Refer to the DEFAULT COLLATION clause of CREATE TABLE for more information on data-bound collations.

- If the virtual column refers to an editioned PL/SQL function, then you can modify the evaluation edition or the unusable editions for a virtual column. The `evaluation_edition_clause` and the `unusable_editions_clause` have the same semantics when you modify a virtual column that they have when you create a virtual column. For complete information, refer to `evaluation_edition_clause` and `unusable_editions_clause` in the documentation on CREATE TABLE.

Restrictions on Modifying Virtual Columns

The following restrictions apply to modifying virtual columns:

- Specifying the `COLLATE` clause to set or change the data-bound collation for a virtual column is subject to the restrictions listed in Restrictions on Changing Column Collation.

- If an index is defined on a virtual column and you modify its evaluation edition or unusable editions, then the database will invalidate all indexes on the virtual column. If you attempt to modify any other properties of the virtual column, then an error occurs.

modify_col_visibility

Use this clause to change the visibility of `column`. For complete information, refer to "VISIBLE | INVISIBLE" in the documentation on CREATE TABLE.

Restriction on Modifying Column Visibility

You cannot change a `VISIBLE` column to `INVISIBLE` in a table owned by SYS.

modify_col_substitutable

Use this clause to set or change the substitutability of an existing object type column.

The `FORCE` keyword drops any hidden columns containing typeid information or data for subtype attributes. You must specify `FORCE` if the column or any attributes of its type are not `FINAL`.

Restrictions on Modifying Column Substitutability

The modification of column substitutability is subject to the following restrictions:

- You can specify this clause only once in any ALTER TABLE statement.

- You cannot modify the substitutability of a column in an object table if the substitutability of the table itself has been set.

- You cannot specify this clause if the column was created or added using the `IS OF TYPE` syntax, which limits the range of subtypes permitted in an object column or attribute to a particular subtype. Refer to `substitutable_column_clause` in the documentation on CREATE TABLE for information on the `IS OF TYPE` syntax.

- You cannot change a varray column to `NOT SUBSTITUTEABLE`, even by specifying `FORCE`, if any of its attributes are nested object types that are not `FINAL`.
**drop_column_clause**

The *drop_column_clause* lets you free space in the database by dropping columns you no longer need or by marking them to be dropped at a future time when the demand on system resources is less.

- If you drop a nested table column, then its storage table is removed.
- If you drop a LOB column, then the LOB data and its corresponding LOB index segment are removed.
- If you drop a BFILE column, then only the locators stored in that column are removed, not the files referenced by the locators.
- If you drop or mark unused a column defined as an *INCLUDING* column, then the column stored immediately before this column will become the new *INCLUDING* column.

**SET UNUSED Clause**

Specify *SET UNUSED* to mark one or more columns as unused. For an internal heap-organized table, specifying this clause does not actually remove the target columns from each row in the table. It does not restore the disk space used by these columns. Therefore, the response time is faster than when you execute the *DROP* clause.

When you specify this clause for a column in an external table, the clause is transparently converted to an *ALTER TABLE ... DROP COLUMN* statement. The reason for this is that any operation on an external table is a metadata-only operation, so there is no difference in the performance of the two commands.

You can view all tables with columns marked *UNUSED* in the data dictionary views `USER_UNUSED_COL_TABS`, `DBA_UNUSED_COL_TABS`, and `ALL_UNUSED_COL_TABS`.

> **See Also:**

*[Oracle Database Reference]* for information on the data dictionary views

Unused columns are treated as if they were dropped, even though their column data remains in the table rows. After a column has been marked *UNUSED*, you have no access to that column. A `SELECT *` query will not retrieve data from unused columns. In addition, the names and types of columns marked *UNUSED* will not be displayed during a `DESCRIBE`, and you can add to the table a new column with the same name as an unused column.
Note:

Until you actually drop these columns, they continue to count toward the absolute limit of 1000 columns in a single table. However, as with all DDL statements, you cannot roll back the results of this clause. You cannot issue SET USED counterpart to retrieve a column that you have SET UNUSED. Refer to CREATE TABLE for more information on the 1000-column limit.

Also, if you mark a LONG column as UNUSED, then you cannot add another LONG column to the table until you actually drop the unused LONG column.

ONLINE

Specify ONLINE to indicate that DML operations on the table will be allowed while marking the column or columns UNUSED.

Restrictions on Marking Columns Unused

The following restrictions apply to the SET UNUSED clause:

- You cannot specify the ONLINE clause when marking a column with a DEFERRABLE constraint as UNUSED.
- Columns in tables owned by SYS cannot be marked as UNUSED.

DROP Clause

Specify DROP to remove the column descriptor and the data associated with the target column from each row in the table. If you explicitly drop a particular column, then all columns currently marked UNUSED in the target table are dropped at the same time.

When the column data is dropped:

- All indexes defined on any of the target columns are also dropped.
- All constraints that reference a target column are removed.
- If any statistics types are associated with the target columns, then Oracle Database disassociates the statistics from the column with the FORCE option and drops any statistics collected using the statistics type.

Note:

If the target column is a parent key of a nontarget column, or if a check constraint references both the target and nontarget columns, then Oracle Database returns an error and does not drop the column unless you have specified the CASCADE CONSTRAINTS clause. If you have specified that clause, then the database removes all constraints that reference any of the target columns.
DROP UNUSED COLUMNS Clause

Specify `DROP UNUSED COLUMNS` to remove from the table all columns currently marked as unused. Use this statement when you want to reclaim the extra disk space from unused columns in the table. If the table contains no unused columns, then the statement returns with no errors.

`column`

Specify one or more columns to be set as unused or dropped. Use the `COLUMN` keyword only if you are specifying only one column. If you specify a column list, then it cannot contain duplicates.

CASCADE CONSTRAINTS

Specify `CASCADE CONSTRAINTS` if you want to drop all foreign key constraints that refer to the primary and unique keys defined on the dropped columns as well as all multicolumn constraints defined on the dropped columns. If any constraint is referenced by columns from other tables or remaining columns in the target table, then you must specify `CASCADE CONSTRAINTS`. Otherwise, the statement aborts and an error is returned.

INVALIDATE

The `INVALIDATE` keyword is optional. Oracle Database automatically invalidates all dependent objects, such as views, triggers, and stored program units. Object invalidation is a recursive process. Therefore, all directly dependent and indirectly dependent objects are invalidated. However, only local dependencies are invalidated, because the database manages remote dependencies differently from local dependencies.

An object invalidated by this statement is automatically revalidated when next referenced. You must then correct any errors that exist in that object before referencing it.

CHECKPOINT

Specify `CHECKPOINT` if you want Oracle Database to apply a checkpoint for the `DROP COLUMN` operation after processing `integer` rows; `integer` is optional and must be greater than zero. If `integer` is greater than the number of rows in the table, then the database applies a checkpoint after all the rows have been processed. If you do not specify `integer`, then the database sets the default of 512. Checkpointing cuts down the amount of undo logs accumulated during the `DROP COLUMN` operation to avoid running out of undo space. However, if this statement is interrupted after a checkpoint
has been applied, then the table remains in an unusable state. While the table is unusable, the only operations allowed on it are DROP TABLE, TRUNCATE TABLE, and ALTER TABLE DROP ... COLUMNS CONTINUE (described in sections that follow).

You cannot use this clause with SET UNUSED, because that clause does not remove column data.

**DROP COLUMNS CONTINUE Clause**

Specify DROP COLUMNS CONTINUE to continue the drop column operation from the point at which it was interrupted. Submitting this statement while the table is in an invalid state results in an error.

**Restrictions on Dropping Columns**

Dropping columns is subject to the following restrictions:

- Each of the parts of this clause can be specified only once in the statement and cannot be mixed with any other ALTER TABLE clauses. For example, the following statements are not allowed:

  ```sql
  ALTER TABLE t1 DROP COLUMN f1 DROP (f2);
  ALTER TABLE t1 DROP COLUMN f1 SET UNUSED (f2);
  ALTER TABLE t1 DROP (f1) ADD (f2 NUMBER);
  ALTER TABLE t1 SET UNUSED (f3)
    ADD (CONSTRAINT ck1 CHECK (f2 > 0));
  ```

- You can drop an object type column only as an entity. To drop an attribute from an object type column, use the ALTER TYPE ... DROP ATTRIBUTE statement with the CASCADE INCLUDING TABLE DATA clause. Be aware that dropping an attribute affects all dependent objects. See Oracle Database PL/SQL Language Reference for more information.

- You can drop a column from an index-organized table only if it is not a primary key column. The primary key constraint of an index-organized table can never be dropped, so you cannot drop a primary key column even if you have specified CASCADE CONSTRAINTS.

- You can export tables with dropped or unused columns. However, you can import a table only if all the columns specified in the export files are present in the table (none of those columns has been dropped or marked unused). Otherwise, Oracle Database returns an error.

- You can set unused a column from a table that uses COMPRESS BASIC, but you cannot drop the column. However, all clauses of the drop_column_clause are valid for tables that use ROW STORE COMPRESS ADVANCED. See the semantics for table_compression for more information.

- You cannot drop a column on which a domain index has been built.

- You cannot drop a SCOPE table constraint or a WITH ROWID constraint on a REF column.

- You cannot use this clause to drop:
  - A pseudocolumn, cluster column, or partitioning column. You can drop nonpartitioning columns from a partitioned table if all the tablespaces where the partitions were created are online and in read/write mode.
  - A column from a nested table, an object table, a duplicated table, or a table owned by SYS.
add_period_clause

Use the add_period_clause to add a valid time dimension to table.

The period_definition clause of ALTER TABLE has the same semantics as in CREATE TABLE, with the following exceptions and additions:

- valid_time_column must not already exist in table.
- If you specify start_time_column and end_time_column, then these columns must already exist in table or you must specify the add_column_clause for each of these columns.
- If you specify start_time_column and end_time_column and these columns already exist in table and are populated with data, then for all rows where both columns have non-NULL values, the value of start_time_column must be earlier than the value of end_time_column.

See Also:
CREATE TABLE period_definition for the full semantics of this clause

drop_period_clause

Use the drop_period_clause to drop a valid time dimension from table.

For valid_time_column, specify the name of the valid time dimension you want to drop.

This clause has the following effects:

- The valid_time_column will be dropped from table.
- If the start time column and end time column were automatically created by Oracle Database when the valid time dimension was created, either with CREATE TABLE ... period_definition or ALTER TABLE ... add_period_clause, then they will be dropped. Otherwise, these columns will remain in table and revert to regular table columns.

See Also:
CREATE TABLE period_definition for more information on the valid_time_column, start time column, and end time column
rename_column_clause

Use the `rename_column_clause` to rename a column of `table`. The new column name must not be the same as any other column name in `table`.

When you rename a column, Oracle Database handles dependent objects as follows:

- Function-based indexes and check constraints that depend on the renamed column remain valid.
- Dependent views, triggers, functions, procedures, and packages are invalidated. Oracle Database attempts to revalidate them when they are next accessed, but you may need to alter these objects with the new column name if revalidation fails.
- If a domain index is defined on the column being renamed, then the database invokes the ODCIIndexAlter method with the `RENAME` option. This operation establishes correspondence between the indextype metadata and the base table.

Restrictions on Renaming Columns

Renaming columns is subject to the following restrictions:

- You cannot combine this clause with any of the other `column_clauses` in the same statement.
- You cannot rename a column that is used to define a join index. Instead you must drop the index, rename the column, and re-create the index.
- You cannot rename a column in a duplicated table.

See Also:

"Renaming a Column: Example"

modify_collection_retrieval

Use the `modify_collection_retrieval` clause to change what Oracle Database returns when a collection item is retrieved from the database.

`collection_item`

Specify the name of a column-qualified attribute whose type is nested table or varray.

`RETURN AS`

Specify what Oracle Database should return as the result of a query:

- `LOCATOR` specifies that a unique locator for the nested table is returned.
- `VALUE` specifies that a copy of the nested table itself is returned.

See Also:

"Collection Retrieval: Example"
modify_LOB_storage_clause

The modify_LOB_storage_clause lets you change the physical attributes of LOB_item. You can specify only one LOB_item for each modify_LOB_storage_clause.

The sections that follow describe the semantics of parameters specific to modify_LOB_parameters. Unless otherwise documented in this section, the remaining LOB parameters have the same semantics when altering a table that they have when you are creating a table. Refer to the restrictions at the end of this section and to the CREATE TABLE clause LOB_storage_parameters for more information.

Note:

• You can modify LOB storage with an ALTER TABLE statement or with online redefinition by using the DBMS_REDEFINITION package. If you have not enabled LOB encryption, compression, or deduplication at create time, Oracle recommends that you use online redefinition to enable them after creation, as this process is more disk space efficient for changes to these three parameters. See Oracle Database PL/SQL Packages and Types Reference for more information on DBMS_REDEFINITION.

• You cannot convert a LOB from one type of storage to the other. Instead you must migrate to SecureFiles or BasicFiles by using online redefinition or partition exchange.

PCTVERSION integer

Refer to the CREATE TABLE clause PCTVERSION integer for information on this clause.

LOB_retention_clause

If the database is in automatic undo mode, then you can specify RETENTION instead of PCTVERSION to instruct Oracle Database to retain old versions of this LOB. This clause overrides any prior setting of PCTVERSION.

FREEPOOLS integer

For BasicFiles LOBs, if the database is in automatic undo mode, then you can use this clause to specify the number of freelist groups for this LOB. This clause overrides any prior setting of FREELIST GROUPS. Refer to the CREATE TABLE clause FREEPOOLS integer for a full description of this parameter. The database ignores this parameter for SecureFiles LOBs.

REBUILD FREEPOOLS

This clause applies only to BasicFiles LOBs, not to SecureFiles LOBs. The REBUILD FREEPOOLS clause removes all the old versions of data from the LOB column. This clause is useful for removing all retained old version space in a LOB segment, freeing that space to be used immediately by new LOB data.

LOB_deduplicate_clause

This clause is valid only for SecureFiles LOBs. KEEP_DUPLICATES disables LOB deduplication. DEDUPLICATE enables LOB deduplication. All lobs in the segment are read, and any matching LOBs are deduplicated before returning.
**LOB_compression_clause**

This clause is valid only for SecureFiles LOBs. **COMPRESS** compresses all LOBs in the segment and then returns. **NOCOMPRESS** uncompresses all LOBs in the segment and then returns.

**ENCRIPT | DECRYPT**

LOB encryption has the same semantics as column encryption in general. See "**ENCRIPT encryption_spec | DECRYPT**" for more information.

**CACHE, NOCACHE, CACHE READS**

When you modify a LOB column from **CACHE** or **NOCACHE** to **CACHE READS**, or from **CACHE READS** to **CACHE** or **NOCACHE**, you can change the logging attribute. If you do not specify **LOGGING** or **NOLOGGING**, then this attribute defaults to the current logging attribute of the LOB column. If you do not specify **CACHE**, **NOCACHE**, or **CACHE READS**, then Oracle Database retains the existing values of the LOB attributes.

**Restrictions on Modifying LOB Storage**

Modifying LOB storage is subject to the following restrictions:

- You cannot modify the value of the **INITIAL** parameter in the **storage_clause** when modifying the LOB storage attributes.
- You cannot specify both the **allocate_extent_clause** and the **deallocate_unused_clause** in the same statement.
- You cannot specify both the **PCTVERSION** and **RETENTION** parameters.
- You cannot specify the **shrink_clause** for SecureFiles LOBs.

**See Also:**

- **LOB_storage_clause** (in **CREATE TABLE**) for information on setting LOB parameters and **"LOB Columns: Examples"**

**alter_varray_col_properties**

The **alter_varray_col_properties** clause lets you change the storage characteristics of an existing LOB in which a varray is stored.

**Restriction on Altering Varray Column Properties**

You cannot specify the **TABLESPACE** clause of **LOB_parameters** as part of this clause. The LOB tablespace for a varray defaults to the tablespace of the containing table.

**REKEY encryption_spec**

The **REKEY** clause causes the database to generate a new encryption key. All encrypted columns in the table are reencrypted using the new key and, if you specify the **USING clause** of the **encryption_spec**, a new encryption algorithm. You cannot combine this clause with any other clauses in this **ALTER TABLE** statement.
**See Also:**

*Oracle Database Advanced Security Guide* for more information on transparent column encryption

**constraint_clauses**

Use the `constraint_clauses` to add a new constraint using out-of-line declaration, modify the state of an existing constraint, or drop a constraint. Refer to `constraint` for a description of all the keywords and parameters of out-of-line constraints and `constraint_state`.

**Adding a Constraint**

The `ADD` clause lets you add a new out-of-line constraint or out-of-line `REF` constraint to the table.

**Restrictions on Adding a Constraint**

Adding constraints is subject to the following restrictions:

- You cannot add a constraint to a duplicated table.
- You cannot add a foreign key constraint to a sharded table.

**See Also:**

"Disabling a CHECK Constraint: Example", "Specifying Object Identifiers: Example", and "REF Columns: Examples"

**Modifying a Constraint**

The `MODIFY CONSTRAINT` clause lets you change the state of an existing constraint.

The `CASCADE` keyword is valid only when you are disabling a unique or primary key constraint on which a foreign key constraint is defined. In this case, you must specify `CASCADE` so that the unique or primary key constraint and all of its dependent foreign key constraints are disabled.

**Restrictions on Modifying Constraints**

Modifying constraints is subject to the following restrictions:

- You cannot change the state of a `NOT DEFERRABLE` constraint to `INITIALLY DEFERRED`.
- If you specify this clause for an index-organized table, then you cannot specify any other clauses in the same statement.
- You cannot change the `NOT NULL` constraint on a foreign key column of a reference-partitioned table, and you cannot change the state of a partitioning referential constraint of a reference-partitioned table.
- You cannot modify a constraint on a duplicated table.
Renaming a Constraint

The `RENAME CONSTRAINT` clause lets you rename any existing constraint on `table`. The new constraint name cannot be the same as any existing constraint on any object in the same schema. All objects that are dependent on the constraint remain valid.

See Also:
"Renaming Constraints: Example"

`drop_constraint_clause`

The `drop_constraint_clause` lets you drop an integrity constraint from the database. Oracle Database stops enforcing the constraint and removes it from the data dictionary. You can specify only one constraint for each `drop_constraint_clause`, but you can specify multiple `drop_constraint_clause` in one statement.

**PRIMARY KEY**

Specify `PRIMARY KEY` to drop the primary key constraint of `table`.

**UNIQUE**

Specify `UNIQUE` to drop the unique constraint on the specified columns.

If you drop the primary key or unique constraint from a column on which a bitmap join index is defined, then Oracle Database invalidates the index. See `CREATE INDEX` for information on bitmap join indexes.

**CONSTRAINT**

Specify `CONSTRAINT constraint_name` to drop an integrity constraint other than a primary key or unique constraint.

**CASCADE**

Specify `CASCADE` if you want all other integrity constraints that depend on the dropped integrity constraint to be dropped as well.

**KEEP INDEX | DROP INDEX**

Specify `KEEP INDEX` or `DROP INDEX` to indicate whether Oracle Database should preserve or drop the index it has been using to enforce the `PRIMARY KEY` or `UNIQUE` constraint.

**ONLINE**

Specify `ONLINE` to indicate that DML operations on the table will be allowed while dropping the constraint.

Restrictions on Dropping Constraints
Dropping constraints is subject to the following restrictions:

- You cannot drop a primary key or unique key constraint that is part of a referential integrity constraint without also dropping the foreign key. To drop the referenced key and the foreign key together, use the CASCADE clause. If you omit CASCADE, then Oracle Database does not drop the primary key or unique constraint if any foreign key references it.
- You cannot drop a primary key constraint (even with the CASCADE clause) on a table that uses the primary key as its object identifier (OID).
- If you drop a referential integrity constraint on a REF column, then the REF column remains scoped to the referenced table.
- You cannot drop the scope of a REF column.
- You cannot drop the NOT NULL constraint on a foreign key column of a reference-partitioned table, and you cannot drop a partitioning referential constraint of a reference-partitioned table.
- You cannot drop the NOT NULL constraint on a column that is defined with a default column value using the ON NULL clause.
- You cannot specify the ONLINE clause when dropping a DEFERRABLE constraint.

See Also:

"Dropping Constraints: Examples"

**alter_external_table**

Use the `alter_external_table` clauses to change the characteristics of an external table. This clause has no affect on the external data itself. The syntax and semantics of the parallel_clause, enable_disable_clause, external_table_data_props, and REJECT LIMIT clause are the same as described for CREATE TABLE. See the external_table_clause (in CREATE TABLE).

**PROJECT COLUMN Clause**

This clause lets you determine how the access driver validates the rows of an external table in subsequent queries. The default is `PROJECT COLUMN ALL`, which means that the access driver processes all column values, regardless of which columns are selected, and validates only those rows with fully valid column entries. If any column value would raise an error, such as a data type conversion error, then the row is rejected even if that column was not referenced in the select list. If you specify `PROJECT COLUMN REFERENCED`, then the access driver processes only those columns in the select list.

The `ALL` setting guarantees consistent result sets. The `REFERENCED` setting can result in different numbers of rows returned, depending on the columns referenced in subsequent queries, but is faster than the `ALL` setting. If a subsequent query selects all columns of the external table, then the settings behave identically.

**Restrictions on Altering External Tables**

Altering external tables is subject to the following restrictions:

- You cannot modify an external table using any clause outside of this clause.
• You cannot add a LONG, varray, or object type column to an external table, nor can you change the data type of an external table column to any of these data types.

• You cannot modify the storage parameters of an external table.

**alter_table_partitioning**

The clauses in this section apply only to partitioned tables. You cannot combine partition operations with other partition operations or with operations on the base table in the same **ALTER TABLE** statement.

**Notes on Changing Table Partitioning**

The following notes apply when changing table partitioning:

• If you drop, exchange, truncate, move, modify, or split a partition on a table that is a master table for one or more materialized views, then existing bulk load information about the table will be deleted. Therefore, be sure to refresh all dependent materialized views before performing any of these operations.

• If a bitmap join index is defined on table, then any operation that alters a partition of table causes Oracle Database to mark the index **UNUSABLE**.

• The only **alter_table_partitioning** clauses you can specify for a reference-partitioned table are **modify_table_default_attrs**, **move_table_[sub]partition**, **truncate_partition_subpart**, and **exchange_partition_subpart**. None of these operations cascade to any child table of the reference-partitioned table. No other partition maintenance operations are valid on a reference-partitioned table, but you can specify the other partition maintenance operations on the parent table of a reference-partitioned table, and the operation will cascade to the child reference-partitioned table.

• When adding partitions and subpartitions, bear in mind that you can specify up to a total of 1024K-1 partitions and subpartitions for each table.

• When you add a table partition or subpartition and you omit the partition name, the database generates a name using the rules described in "Notes on Partitioning in General".

• When you move, add (hash only), coalesce, drop, split, merge, rename, or truncate a table partition or subpartition, the procedures, functions, packages, package bodies, views, type bodies, and triggers that reference the table remain valid. All other dependent objects are invalidated.

• Deferred segment creation is not supported for partition maintenance operations that create new segments on tables with LOB columns; segments will always be created for the involved (sub)partitions.

• For sharded tables, the only clauses you can specify for modifying table partitions and subpartitions are **UNUSABLE LOCAL INDEXES** and **REBUILD UNUSABLE LOCAL INDEXES**. You cannot perform any other modifications for individual partitions and subpartitions on a system sharded table.

• For user-defined sharded tables the following operations on partitions and subpartitions are supported:
  – add partition, add subpartition
  – drop partition, drop subpartition
  – split partition
  – modify partition to add or drop values to a list partition
• For sharded tables, the only supported partition maintenance operations are truncating partitions and subpartitions. You cannot perform any other partition maintenance operations on a sharded table.

For additional information on partition operations on tables with an associated CONTEXT domain index, refer to Oracle Text Reference.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for a discussion of these restrictions.

modify_table_default_attrs

The modify_table_default_attrs clause lets you specify new default values for the attributes of table. Only attributes named in the statement are affected. Partitions and LOB partitions you create subsequently will inherit these values unless you override them explicitly when creating the partition or LOB partition. Existing partitions and LOB partitions are not affected by this clause.

Only attributes named in the statement are affected, and the default values specified are overridden by any attributes specified at the individual partition or LOB partition level.

• FOR partition_extended_name applies only to composite-partitioned tables. This clause specifies new default values for the attributes of the partition identified in partition_extended_name. Subpartitions and LOB subpartitions of that partition that you create subsequently will inherit these values unless you override them explicitly when creating the subpartition or LOB subpartition. Existing subpartitions are not affected by this clause.

If you are modifying the default directory, you can save its location using DEFAULT DIRECTORY directory.

• PCTTHRESHOLD, prefix_compression, and the alter_overflow_clause are valid only for partitioned index-organized tables.

• You can specify the prefix_compression clause only if prefix compression is already specified at the table level. Further, you cannot specify an integer after the COMPRESS keyword. Prefix length can be specified only when you create the table.

• You cannot specify the PCTUSED parameter in segment_attributes for the index segment of an index-organized table.

• The read_only_clause lets you modify the default read-only or read/write mode for the table. The new default mode will be assigned to partitions or subpartitions that are subsequently added to the table, unless you override this behavior by specifying the mode for the new partition or subpartition. When you modify the default read-only or read/write mode of a table, you do not change the mode of the existing partitions and subpartitions in the table. Refer to the read_only_clause of CREATE TABLE for the full semantics of this clause.

• The indexing_clause lets you modify the default indexing property for the table. The new default indexing property will be assigned to partitions or subpartitions that are subsequently added to the table, unless you override this behavior by specifying the indexing property for the new partition or subpartition. When you modify the default indexing property of a table, you do not change the indexing property of the existing partitions and subpartitions in the table. Refer to the indexing_clause of CREATE TABLE for the full semantics of this clause.
**alter_automatic_partitioning**

This clause allows you to manage automatic list-partitioned tables, as follows:

- Use the `SET PARTITIONING AUTOMATIC` clause to convert a regular list-partitioned table to an automatic list-partitioned table.
- Use the `SET PARTITIONING MANUAL` clause to convert an automatic list-partitioned table to a regular list-partitioned table.
- You can specify the `SET STORE IN` clause only for automatic list-partitioned tables. It lets you specify one or more tablespaces into which the database will store data for any subsequent automatically created list partitions. This clause overrides any tablespaces that might have been set for the table by a previously issued `SET STORE IN` clause.

To determine whether an existing table is an automatic list-partitioned table, you can query the `AUTOLIST` column of the `USER_., DBA_., ALL_PART_TABLES` data dictionary views.

**Restriction on alter_automatic_partitioning**

You cannot convert a regular list-partitioned table that contains a `DEFAULT` partition to an automatic list-partitioned table.

---

**See Also:**

The `AUTOMATIC` clause in the documentation on `CREATE TABLE` for more information on automatic list-partitioned tables

**alter_interval_partitioning**

Use this clause:

- To convert an existing range-partitioned table to interval partitioning. The database automatically creates partitions of the specified numeric range or datetime interval as needed for data beyond the highest value allowed for the last range partition. If the table has reference-partitioned child tables, then the child tables are converted to interval reference-partitioned child tables.
- To change the interval of an existing interval-partitioned table. The database first converts existing interval partitions to range partitions and determines the high value of the defined range partitions. The database then automatically creates partitions of the specified numeric range or datetime interval as needed for data that is beyond that high value.
- To change the tablespace storage for an existing interval-partitioned table. If the table has interval reference-partitioned child tables, then the new tablespace storage is inherited by any child table that does not have its own table-level default tablespace.
- To change an interval-partitioned table back to a range-partitioned table. Use `SET INTERVAL ()` to disable interval partitioning. The database converts existing interval partitions to range partitions, using the higher boundaries of created interval partitions as upper boundaries for the range partitions to be created. If the table
has interval reference-partitioned child tables, then the child tables are converted to ordinary reference-partitioned child tables.

For `expr`, specify a valid number or interval expression.

---

**See Also:**

The CREATE TABLE "INTERVAL Clause" and Oracle Database VLDB and Partitioning Guide for more information on interval partitioning

---

**set_subpartition_template**

Use the `set_subpartition_template` clause to create or replace existing default range, list, or hash subpartition definitions for each table partition. This clause is valid only for composite-partitioned tables. It replaces the existing subpartition template or creates a new template if you have not previously created one. Existing subpartitions are not affected, nor are existing local and global indexes. However, subsequent partitioning operations (such as add and merge operations) will use the new template.

You can drop an existing subpartition template by specifying `ALTER TABLE table SET SUBPARTITION TEMPLATE ()`.

The `set_subpartition_template` clause has the same semantics as the `subpartition_template` clause of CREATE TABLE. Refer to the `subpartition_template` clause of CREATE TABLE for more information.

**modify_table_partition**

The `modify_table_partition` clause lets you change the real physical attributes of a range, hash, list partition, or system partition. This clause optionally modifies the storage attributes of one or more LOB items for the partition. You can specify new values for physical attributes (with some restrictions, as noted in the sections that follow), logging, and storage parameters.

For all types of partitions, you can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses".

For partitioned index-organized tables, you can also update the mapping table in conjunction with partition changes. See the `alter_mapping_table_clauses`.

**read_only_clause**

Use the `read_only_clause` to put a table partition in read-only or read/write mode. Refer to the `read_only_clause` of CREATE TABLE for the full semantics of this clause.

**indexing_clause**

Use the `indexing_clause` to modify the indexing property of a table partition. The indexing property determines whether the partition is included in partial indexes on the table. You can specify the `indexing_clause` in the `modify_range_partition`, `modify_hash_partition`, and `modify_list_partition` clauses.

Specify INDEXING ON to change the indexing property for a table partition to ON. This operation has no effect on full indexes on the table. It has the following effects on partial indexes on the table:
• Local partial indexes: The table partition is included in the index. The corresponding index partition is rebuilt and marked USABLE.

• Global partial indexes: The table partition is included in the index. Index entries for the table partition are added to the index as part of routine index maintenance. Specify INDEXING OFF to change the indexing property for a table partition to OFF. This operation has no effect on full indexes on the table. It has the following effects on partial indexes on the table:

• Local partial indexes: The table partition is excluded from the index. The corresponding index partition is marked UNUSABLE.

• Global partial indexes: The table partition is excluded from the index. Index entries for the table partition are removed from the index. This is a metadata-only operation and the index entries will continue to be physically stored in the index. You can remove these orphaned index entries by specifying COALESCE CLEANUP in the ALTER INDEX statement or in the modify_index_partition clause.

Restriction on column of type object

You cannot partition a table that has an object type. The alter table modification to a partitioned state is only supported for non-partitioned heap tables with zero columns of type object.

Restriction on the indexing_clause

You can specify this clause only for partitions of a simple partitioned table. For composite-partitioned tables, you can specify the indexing_clause at the table subpartition level. Refer to modify_table_subpartition for more information.

Notes on Modifying Table Partitions

The following notes apply to operations on range, list, and hash table partitions:

• For all types of table partition, in the partition_attributes clause, the shrink_clause lets you compact an individual partition segment. Refer to shrink_clause for additional information on this clause.

• The syntax and semantics for modifying a system partition are the same as those for modifying a hash partition. Refer to modify_hash_partition.

• If table is composite partitioned, then:
  – If you specify the allocate_extent_clause, then Oracle Database allocates an extent for each subpartition of partition.
  – If you specify the deallocate_unused_clause, then Oracle Database deallocates unused storage from each subpartition of partition.
  – Any other attributes changed in this clause will be changed in subpartitions of partition as well, overriding existing values. To avoid changing the attributes of existing subpartitions, use the FOR PARTITION clause of modify_table_default_attrs.

• When you modify the partition_attributes of a table partition with equipartitioned nested tables, the changes do not apply to the nested table partitions corresponding to the table partition being modified. However, you can modify the storage table of the nested table partition directly with an ALTER TABLE statement.
Unless otherwise documented, the remaining clauses of `partition_attributes` have the same behavior they have when you are creating a partitioned table. Refer to the `CREATE TABLE table_partitioning_clauses` for more information.

**See Also:**
"Modifying Table Partitions: Examples"

modify_range_partition

Use this clause to modify the characteristics of a range partition.

add_range_subpartition

This clause is valid only for range-range composite partitions. It lets you add one or more range subpartitions to `partition`.

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to add a subpartition to composite-partitioned external table. In this case, you can specify the optional `external_part_subpart_data_props` clause of the `range_subpartition_desc` clause. Refer to `external_part_subpart_data_props` for the full semantics of this clause.

Restriction on Adding Range Subpartitions

If `table` is an index-organized table, then you can add only one range subpartition at a time.

add_hash_subpartition

This clause is valid only for range-hash composite partitions. The `add_hash_subpartition` clause lets you add a hash subpartition to `partition`. Oracle Database populates the new subpartition with rows rehashed from the other subpartition(s) of `partition` as determined by the hash function. For optimal load balancing, the total number of subpartitions should be a power of 2.

In the `partitioning_storage_clause`, the only clause you can specify for subpartitions is the `TABLESPACE` clause. If you do not specify `TABLESPACE`, then the new subpartition will reside in the default tablespace of `partition`.

Oracle Database adds local index partitions corresponding to the selected partition.

Oracle Database marks `UNUSABLE` the local index partitions corresponding to the added partitions. The database invalidates any indexes on heap-organized tables. You can update these indexes during this operation using the `update_index_clauses`.

add_list_subpartition

This clause is valid only for range-list and list-list composite partitions. It lets you add one or more list subpartitions to `partition`, and only if you have not already created a DEFAULT subpartition.

- The `list_values_clause` is required in this operation, and the values you specify in the `list_values_clause` cannot exist in any other subpartition of `partition`. However, these values can duplicate values found in subpartitions of other partitions.
In the \texttt{partitioning\_storage\_clause}, the only clauses you can specify for subpartitions are the \texttt{TABLESPACE} clause and table compression.

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to add a subpartition to composite-partitioned external table. In this case, you can specify the optional \texttt{external\_part\_subpart\_data\_props} clause of the \texttt{list\_subpartition\_desc} clause. Refer to \texttt{external\_part\_subpart\_data\_props} for the full semantics of this clause.

For each added subpartition, Oracle Database also adds a subpartition with the same value list to all local index partitions of the table. The status of existing local and global index partitions of \texttt{table} are not affected.

Restrictions on Adding List Subpartitions

The following restrictions apply to adding list subpartitions:

- You cannot specify this clause if you have already created a \texttt{DEFAULT} subpartition for this partition. Instead you must split the \texttt{DEFAULT} partition using the \texttt{split\_list\_subpartition} clause.
- If \texttt{table} is an index-organized table, then you can add only one list subpartition at a time.

\texttt{coalesce\_table\_subpartition}

\texttt{COALESCE SUBPARTITION} applies only to hash subpartitions. Use the \texttt{COALESCE SUBPARTITION} clause if you want Oracle Database to select the last hash subpartition, distribute its contents into one or more remaining subpartitions (determined by the hash function), and then drop the last subpartition.

- Oracle Database drops local index partitions corresponding to the selected partition.
- Oracle Database marks \texttt{UNUSABLE} the local index partitions corresponding to one or more absorbing partitions. The database invalidates any global indexes on heap-organized tables. You can update these indexes during this operation using the \texttt{update\_index\_clauses}.

\texttt{modify\_hash\_partition}

When modifying a hash partition, in the \texttt{partition\_attributes} clause, you can specify only the \texttt{allocate\_extent\_clause} and \texttt{deallocate\_unused\_clause}. All other attributes of the partition are inherited from the table-level defaults except \texttt{TABLESPACE}, which stays the same as it was at create time.

\texttt{modify\_list\_partition}

Clauses available to you when modifying a list partition have the same semantics as when you are modifying a range partition. When modifying a list partition, the following additional clauses are available:

\texttt{ADD | DROP VALUES} Clauses

These clauses are valid only when you are modifying composite partitions. Local and global indexes on the table are not affected by either of these clauses.

- Use the \texttt{ADD VALUES} clause to extend the \texttt{partition\_key\_value} list of \texttt{partition} to include additional values. The added partition values must comply with all rules and restrictions listed in the \texttt{CREATE TABLE} clause \texttt{list\_partitions}.
• Use the DROP VALUES clause to reduce the partition_key_value list of partition by eliminating one or more partition_key_value. When you specify this clause, Oracle Database checks to ensure that no rows with this value exist. If such rows do exist, then Oracle Database returns an error.

**Note:**

ADD VALUES and DROP VALUES operations on a table with a DEFAULT list partition are enhanced if you have defined a local prefixed index on the table.

Restrictions on Adding and Dropping List Values

Adding and dropping list values are subject to the following restrictions:

- You cannot add values to or drop values from a DEFAULT list partition.
- If the table contains a DEFAULT partition and you attempt to add values to a nondefault partition, then Oracle Database will check that the values being added do not already exist in the DEFAULT partition. If the values do exist in the DEFAULT partition, then Oracle Database returns an error.

modify_table_subpartition

This clause applies only to composite-partitioned tables. Its subclauses let you modify the characteristics of an individual range, list, or hash subpartition.

The shrink_clause lets you compact an individual subpartition segment. Refer to shrink_clause for additional information on this clause.

You can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses".

Use the read_only_clause to put a table subpartition in read-only or read/write mode. Refer to the read_only_clause of CREATE TABLE for the full semantics of this clause.

Use the indexing_clause to modify the indexing property of a table subpartition. The indexing property determines whether the subpartition is included in partial indexes on the table. Modifying the indexing property of table subpartitions has the same effect on index subpartitions as modifying the indexing property of table partitions has on index partitions. Refer to the indexing_clause of modify_table_partition for details.

Restriction on Modifying Hash Subpartitions

The only modify_LOB_parameters you can specify for subpartition are the allocate_extent_clause and deallocate_unused_clause.

**ADD | DROP VALUES Clauses**

These clauses are valid only when you are modifying list subpartitions. Local and global indexes on the table are not affected by either of these clauses.

• Use the ADD VALUES clause to extend the subpartition_key_value list of subpartition to include additional values. The added partition values must comply with all rules and restrictions listed in the CREATE TABLE clause list_partitions.
• Use the DROP VALUES clause to reduce the subpartition_key_value list of subpartition by eliminating one or more subpartition_key_value. When you specify this clause, Oracle Database checks to ensure that no rows with this value exist. If such rows do exist, then Oracle Database returns an error.

You can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses".

Restriction on Modifying List Subpartitions

The only modify_LOB_parameters you can specify for subpartition are the allocate_extent_clause and deallocate_unused_clause.

move_table_partition

Use the move_table_partition clause to move partition to another segment. You can move partition data to another tablespace, recluster data to reduce fragmentation, or change create-time physical attributes.

If the table contains LOB columns, then you can use the LOB_storage_clause to move the LOB data and LOB index segments associated with this partition. Only the LOBs named are affected. If you do not specify the LOB_storage_clause for a particular LOB column, then its LOB data and LOB index segments are not moved.

If the table contains nested table columns, then you can use the nested_table_col_properties clause of the table_partition_description to move the nested table segments associated with this partition. Only the nested table items named are affected. If you do not specify the nested_table_col_properties clause of the table_partition_description for a particular nested table column, then its segments are not moved.

Oracle Database moves local index partitions corresponding to the specified partition. If the moved partitions are not empty, then the database marks them UNUSABLE. The database invalidates global indexes on heap-organized tables. You can update these indexes during this operation using the update_index_clauses.

When you move a LOB data segment, Oracle Database drops the old data segment and corresponding index segment and creates new segments even if you do not specify a new tablespace.

The move operation obtains its parallel attribute from the parallel_clause, if specified. When it is not specified, the default parallel attributes of the table, if any, are used. If neither is specified, then Oracle Database performs the move serially.

Specifying the parallel_clause in MOVE PARTITION does not change the default parallel attributes of table.

Note:

For index-organized tables, Oracle Database uses the address of the primary key, as well as its value, to construct logical rowids. The logical rowids are stored in the secondary index of the table. If you move a partition of an index-organized table, then the address portion of the rowids will change, which can hamper performance. To ensure optimal performance, rebuild the secondary index(es) on the moved partition to update the rowids.
MAPPING TABLE

The MAPPING TABLE clause is relevant only for an index-organized table that already has a mapping table defined for it. Oracle Database moves the mapping table along with the moved index-organized table partition. The mapping table partition inherits the physical attributes of the moved index-organized table partition. This is the only way you can change the attributes of the mapping table partition. If you omit this clause, then the mapping table partition retains its original attributes.

Oracle Database marks UNUSABLE all corresponding bitmap index partitions.

Refer to the mapping_table_clauses (in CREATE TABLE) for more information on this clause.

ONLINE

Specify ONLINE to indicate that DML operations on the table partition will be allowed while moving the table partition.

Restrictions on the ONLINE Clause

The ONLINE clause is subject to the following restrictions when moving table partitions:

- You cannot specify the ONLINE clause for tables owned by SYS.
- You cannot specify the ONLINE clause for index-organized tables.
- You cannot specify the ONLINE clause for heap-organized tables that contain object types or on which bitmap join indexes or domain indexes are defined.
- Parallel DML and direct path INSERT operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online partition MOVE, due to conflicting locks.

Restrictions on Moving Table Partitions

Moving table partitions is subject to the following restrictions:

- If partition is a hash partition, then the only attribute you can specify in this clause is TABLESPACE.
- You cannot specify this clause for a partition containing subpartitions. However, you can move subpartitions using the move_table_subpartition clause.

move_table_subpartition

Use the move_table_subpartition clause to move the subpartition identified by subpartition_extended_name to another segment. If you do not specify TABLESPACE, then the subpartition remains in the same tablespace.

If the subpartition is not empty, then Oracle Database marks UNUSABLE all local index subpartitions corresponding to the subpartition being moved. You can update all indexes on heap-organized tables during this operation using the update_index_clauses.
If the table contains LOB columns, then you can use the `LOB_storage_clause` to move the LOB data and LOB index segments associated with this subpartition. Only the LOBs specified are affected. If you do not specify the `LOB_storage_clause` for a particular LOB column, then its LOB data and LOB index segments are not moved.

When you move a LOB data segment, Oracle Database drops the old data segment and corresponding index segment and creates new segments even if you do not specify a new tablespace.

**ONLINE**

Specify **ONLINE** to indicate that DML operations on the table subpartition will be allowed while moving the table subpartition.

**Restrictions on the ONLINE Clause**

The **ONLINE** clause for moving table subpartitions is subject to the same restrictions as the **ONLINE** clause for moving table partitions. Refer to "Restrictions on the ONLINE Clause."

**Restriction on Moving Table Subpartitions**

The only clauses of the `partitioning_storage_clause` you can specify are the `TABLESPACE` clause and `table_compression`.

**add_external_partition_attrs**

Use this clause to add external parameters to a partitioned table.

**add_table_partition**

Use the `add_table_partition` clause to add one or more range, list, or system partitions to `table`, or to add one hash partition to `table`.

For each partition added, Oracle Database adds to any local index defined on `table` a new partition with the same name as that of the base table partition. If the index already has a partition with such a name, then Oracle Database generates a partition name of the form `SYS_Pn`.

If `table` is index organized, then for each partition added Oracle Database adds a partition to any mapping table and overflow area defined on the table as well.

If `table` is the parent table of a reference-partitioned table, then you can use the `dependent_tables_clause` to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

The default indexing property of `table` is inherited by the new table partition(s). You can override this by setting the indexing property of a list, range, or system partition using the `indexing_clause` in the `table_partition_description` clause, or a hash partition using the `indexing_clause` in the `add_hash_partition_clause`.

For each partition added to a composite-partitioned table, Oracle Database adds a new index partition with the same subpartition descriptions to all local indexes defined on `table`. Global indexes defined on `table` are not affected. If you specify the indexing property for the new table partition, then the new subpartitions inherit the indexing property for the partition. Otherwise, the new subpartitions inherit the default indexing property for the table. You can override this by setting the indexing property of a subpartition using the `indexing_clause` in the `range_subpartition_desc`, `individual_hash_subparts`, and `list_subpartition_desc` clauses.
BEFORE Clause

You can specify the optional BEFORE clause only when adding system partitions to `table`. This clause lets you specify where the new partition(s) should be added in relation to existing partitions. You cannot split a system partition. Therefore, this clause is useful if you want to divide the contents of one existing partition among multiple new partitions. If you omit this clause, then the database adds the new partition(s) after the existing partitions.

Restriction on Adding Table Partitions

If `table` is an index-organized table, or if a local domain index is defined on `table`, then you can add only one partition at a time.

> See Also:

"Adding a Table Partition with a LOB and Nested Table Storage: Examples" and "Adding Multiple Partitions to a Table: Example"

`add_range_partition_clause`

The `add_range_partition_clause` lets you add a new range partition to the high end of a range-partitioned or composite range-partitioned table (after the last existing partition).

If a domain index is defined on `table`, then the index must not be marked IN_PROGRESS or FAILED.

Restrictions on Adding Range Partitions

Adding range partitions is subject to the following restrictions:

- If the upper partition bound of each partitioning key in the existing high partition is MAXVALUE, then you cannot add a partition to the table. Instead, use the `split_table_partition` clause to add a partition at the beginning or the middle of the table.
- The `prefix_compression` and OVERFLOW clauses, are valid only for a partitioned index-organized table. You can specify `prefix_compression` only if prefix compression is enabled at the table level. You can specify OVERFLOW only if the partitioned table already has an overflow segment.
- You cannot specify the PCTUSED parameter for the index segment of an index-organized table.

`range_values_clause`

Specify the upper bound for the new partition. The `value_list` is a comma-delimited, ordered list of literal values corresponding to the partitioning key columns. The `value_list` must collate greater than the partition bound for the highest existing partition in the table.

`table_partition_description`

Use this clause to specify any create-time physical attributes for the new partition. If the table contains LOB columns, then you can also specify partition-level attributes for one or more LOB items.
Starting with Oracle Database 12c Release 2 (12.2), Oracle supports partitioned and composite-partitioned external tables. When adding a partition to such a table, you can optionally use this clause to specify the DEFAULT DIRECTORY and LOCATION for the partition. Refer to DEFAULT DIRECTORY and LOCATION in the documentation on CREATE TABLE for the full semantics of these clauses.

Subpartition Descriptions

These clauses are valid only for composite-partitioned tables. Use the range_subpartition_desc, list_subpartition_desc, individual_hash_subparts, or hash_subparts_by_quantity clause as appropriate, if you want to specify subpartitions for the new partition. This clause overrides any subpartition descriptions defined in subpartition_template at the table level.

**add_hash_partition_clause**

The add_hash_partition_clause lets you add a new hash partition to the high end of a hash-partitioned table. Oracle Database populates the new partition with rows rehashed from other partitions of table as determined by the hash function. For optimal load balancing, the total number of partitions should be a power of 2.

You can specify a name for the partition, and optionally a tablespace where it should be stored. If you do not specify a name, then the database assigns a partition name of the form SYS_Pn. If you do not specify TABLESPACE, then the new partition is stored in the default tablespace of the table. Other attributes are always inherited from table-level defaults.

If this operation causes data to be rehashed among partitions, then the database marks UNUSABLE any corresponding local index partitions. You can update all indexes on heap-organized tables during this operation using the update_index_clauses.

Use the parallel_clause to specify whether to parallelize the creation of the new partition.

Use the read_only_clause to put a table partition in read-only or read/write mode. Refer to the read_only_clause of CREATE TABLE for the full semantics of this clause.

Use the indexing_clause to specify the indexing property for the partition. If you do not specify this clause, then the partition inherits the default indexing property of table.

**See Also:**

CREATE TABLE and Oracle Database VLDB and Partitioning Guide for more information on hash partitioning

**add_list_partition_clause**

The add_list_partition_clause lets you add a new partition to table using a new set of partition values. You can specify any create-time physical attributes for the new partition. If the table contains LOB columns, then you can also specify partition-level attributes for one or more LOB items.

**Restrictions on Adding List Partitions**
You cannot add a list partition if you have already defined a DEFAULT partition for the table. Instead, you must use the `split_table_partition` clause to split the DEFAULT partition.

See Also:

- `list_partitions` of `CREATE TABLE` for more information and restrictions on list partitions
- “Working with Default List Partitions: Example”

`add_system_partition_clause`

Use this clause to add a partition to a system-partitioned table. Oracle Database adds a corresponding index partition to all local indexes defined on the table.

The `table_partition_description` lets you specify partition-level attributes of the new partition. The values of any unspecified attributes are inherited from the table-level values.

Restriction on Adding System Partitions

You cannot specify the `OVERFLOW` clause when adding a system partition.

See Also:

The `CREATE TABLE` clause `system_partitioning` for more information on system partitions

`coalesce_table_partition`

`COALESCE` applies only to hash partitions. Use the `coalesce_table_partition` clause to indicate that Oracle Database should select the last hash partition, distribute its contents into one or more remaining partitions as determined by the hash function, and then drop the last partition.

Oracle Database drops local index partitions corresponding to the selected partition. The database marks UNUSABLE the local index partitions corresponding to one or more absorbing partitions. The database invalidates any indexes on heap-organized tables. You can update all indexes during this operation using the `update_index_clauses`.

Restriction on Coalescing Table Partitions

If you update global indexes using the `update_all_indexes_clause`, then you can specify only the keywords UPDATE INDEXES, not the subclause.

`drop_external_partition_attrs`

Use this clause to drop external parameters in a partitioned table.
The `drop_table_partition` clause removes partitions, and the data in those partitions, from a partitioned table. If you want to drop a partition but keep its data in the table, then you must merge the partition into one of the adjacent partitions.

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to drop a partition from a partitioned table or composite-partitioned external table.

Use the `partition_extended_names` clause to specify one or more partitions to be dropped. When specifying multiple partitions, you must specify all partitions by name, as shown in the upper branch of the syntax diagram, or all partitions using the `FOR` clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one drop operation.

- If `table` has LOB columns, then Oracle Database also drops the LOB data and LOB index partitions and any subpartitions corresponding to the table partition(s) being dropped.
- If `table` has equipartitioned nested table columns, then Oracle Database also drops the nested table partitions corresponding to the table partition(s) being dropped.
- If `table` is index organized and has a mapping table defined on it, then the database drops the corresponding mapping table partition(s) as well.
- Oracle Database drops local index partitions and subpartitions corresponding to the dropped partition(s), even if they are marked `UNUSABLE`.

You can update indexes on `table` during this operation using the `update_index_clauses`. Updates to global indexes are metadata-only and the index entries for records that are dropped by the drop operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the `ALTER INDEX` statement or in the `modify_index_partition` clause.

If you specify the `parallel_clause` with the `update_index_clauses`, then the database parallelizes the index update, not the drop operation.

If you drop a range partition and later insert a row that would have belonged to the dropped partition, then the database stores the row in the next higher partition. However, if that partition is the highest partition, then the insert will fail, because the range of values represented by the dropped partition is no longer valid for the table.

**Restrictions on Dropping Table Partitions**

Dropping table partitions is subject to the following restrictions:

- You cannot drop a partition of a hash-partitioned table. Instead, use the `coalesce_table_partition` clause.
- You cannot drop all of the partitions in a table. Instead, drop the table.
If you update global indexes using the `update_all_indexes_clause`, then you can specify only the `UPDATE INDEXES` keywords but not the subclause.

If `table` is an index-organized table, or if a local domain index is defined on `table`, then you can drop only one partition at a time.

You cannot drop a partition of a duplicated table.

Dropping a partition does not place the partition in the Oracle Database recycle bin, regardless of the setting of the recycle bin. Dropped partitions are immediately removed from the system.

### See Also:

"Dropping a Table Partition: Example"

**drop_table_subpartition**

Use this clause to drop range or list subpartitions from a range, list, or hash composite-partitioned table. Oracle Database deletes any rows in the dropped subpartition(s).

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to drop a subpartition from a composite-partitioned external table.

Use the `subpartition_extended_names` clause to specify one or more subpartitions to be dropped. When specifying multiple subpartitions, you must specify all subpartitions by name, as shown in the upper branch of the syntax diagram, or all subpartitions using the `FOR` clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one drop operation.

Oracle Database drops the corresponding subpartition(s) of any local index. Other index subpartitions are not affected. Any global indexes are marked `UNUSABLE` unless you specify the `update_global_index_clause` or `update_all_indexes_clause`. Updates to global indexes are metadata-only and the index entries for records that are dropped by the drop operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the `ALTER INDEX` statement or in the `modify_index_partition` clause.

### Restrictions on Dropping Table Subpartitions

Dropping table subpartitions is subject to the following restrictions:

- You cannot drop a hash subpartition. Instead use the `MODIFY PARTITION ... COALESCE SUBPARTITION` syntax.
- You cannot drop all of the subpartitions in a partition. Instead, use the `drop_table_partition` clause.
- If you update the global indexes, then you cannot specify the optional subclause of the `update_all_indexes_clause`.
- If `table` is an index-organized table, then you can drop only one subpartition at a time.
- When dropping multiple subpartitions, all of the subpartitions must be in the same partition.
You cannot drop a subpartition of a duplicated table.

rename_partition_subpart

Use the `rename_partition_subpart` clause to rename a table partition or subpartition to `new_name`. For both partitions and subpartitions, `new_name` must be different from all existing partitions and subpartitions of the same table.

If `table` is index organized, then Oracle Database assigns the same name to the corresponding primary key index partition as well as to any existing overflow partitions and mapping table partitions.

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to rename a partition or subpartition in a partitioned or composite-partitioned external table.

See Also:

"Renaming Table Partitions: Examples"

truncate_partition_subpart

Specify `TRUNCATE partition_extended_names` to remove all rows from the partition(s) identified by `partition_extended_names` or, if the table is composite partitioned, all rows from the subpartitions of those partitions. Specify `TRUNCATE subpartition_extended_names` to remove all rows from individual subpartitions. If `table` is index organized, then Oracle Database also truncates any corresponding mapping table partitions and overflow area partitions.

When specifying multiple partitions, you must specify all partitions by name, as shown in the upper branch of the `partition_extended_names` syntax diagram, or all partitions using the `FOR` clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one truncate operation. The same rule applies when specifying multiple subpartitions with the `subpartition_extended_names` clause.

For each specified partition or subpartition:

- If the partition or subpartition to be truncated contain data, then you must first disable any referential integrity constraints on the table. Alternatively, you can delete the rows and then truncate the partition.
- If `table` contains any LOB columns, then the LOB data and LOB index segments for the partition are also truncated. If `table` is composite partitioned, then the LOB data and LOB index segments for the subpartitions of the partition are truncated.
- If `table` contains any equipartitioned nested tables, then you cannot truncate the parent partition unless its corresponding nested table partition is empty.
- If a domain index is defined on `table`, then the index must not be marked `IN_PROGRESS` or `FAILED`, and the index partition corresponding to the table partition being truncated must not be marked `IN_PROGRESS`.

For each partition or subpartition truncated, Oracle Database also truncates corresponding local index partitions and subpartitions. If those index partitions or subpartitions are marked `UNUSABLE`, then the database truncates them and resets the `UNUSABLE` marker to `VALID`. 
You can update indexes on `table` during this operation using the `update_index_clauses`. Updates to global indexes are metadata-only and the index entries for records that are dropped by the truncate operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the `ALTER INDEX` statement or in the `modify_index_partition` clause.

If you specify the `parallel_clause` with the `update_index_clauses`, then the database parallelizes the index update, not the truncate operation.

**DROP STORAGE**

Specify `DROP STORAGE` to deallocate all space from the deleted rows, except the space allocated by the `MINEXTENTS` parameter. This space can subsequently be used by other objects in the table space.

**DROP ALL STORAGE**

Specify `DROP ALL STORAGE` to deallocate all space from the deleted rows, including the space allocated by the `MINEXTENTS` parameter. All segments for the partition(s) or subpartition(s), as well as all segments for their dependent objects, will be deallocated.

**Restrictions on DROP ALL STORAGE**

This clause is subject to the same restrictions as described in "Restrictions on Deferred Segment Creation".

**REUSE STORAGE**

Specify `REUSE STORAGE` to keep space from the deleted rows allocated to the partition(s) or subpartition(s). The space is subsequently available only for inserts and updates to the same partition(s) or subpartition(s).

**CASCADE**

Specify `CASCADE` to truncate the corresponding partition(s) or subpartition(s) in all reference-partitioned child tables of `table`.

**Restrictions on Truncating Table Partitions and Subpartitions**

Truncating table partitions and subpartitions is subject to the following restrictions:

- If you update global indexes using the `update_all_indexes_clause`, then you can specify only the `UPDATE INDEXES` keywords, not the subclause.
- If `table` is an index-organized table, or if a local domain index is defined on `table`, then you can truncate only one table partition or one table subpartition at a time.
- You cannot truncate partitions or subpartitions in a duplicated table.

**See Also:**

"Truncating Table Partitions: Example"

**split_table_partition**

The `split_table_partition` clause lets you create, from the partition identified by `partition_extended_name`, multiple new partitions, each with a new segment, new
physical attributes, and new initial extents. The segment associated with the current partition is discarded.

The new partitions inherit all unspecified physical attributes from the current partition.

Note:

Oracle Database can optimize and speed up `SPLIT PARTITION` and `SPLIT SUBPARTITION` operations if specific conditions are met. Refer to Oracle Database VLDB and Partitioning Guide for information on optimizing these operations.

- If you split a `DEFAULT` list partition, then the last resulting partition will have the `DEFAULT` value. All other resulting partitions will have the specified split values.
- If `table` is index organized, then Oracle Database splits any corresponding mapping table partition and places it in the same tablespace as the parent index-organized table partition. The database also splits any corresponding overflow area, and you can use the `OVERFLOW` clause to specify segment attributes for the new overflow areas.
- If `table` contains LOB columns, then you can use the `LOB_storage_clause` to specify separate LOB storage attributes for the LOB data segments resulting from the split. The database drops the LOB data and LOB index segments of the current partition and creates new segments for each LOB column, for each partition, even if you do not specify a new tablespace.
- If `table` contains nested table columns, then you can use the `split_nested_table_part` clause to specify the storage table names and segment attributes of the nested table segments resulting from the split. The database drops the nested table segments of the current partition and creates new segments for each nested table column, for each partition. This clause allows for multiple nested table columns in the parent table as well as multilevel nested table columns.

Oracle Database splits the corresponding local index partition, even if it is marked `UNUSABLE`. The database marks `UNUSABLE`, and you must rebuild the local index partitions corresponding to the split partitions. The new index partitions inherit their attributes from the partition being split. The database stores the new index partitions in the default tablespace of the index partition being split. If that index partition has no default tablespace, then the database uses the tablespace of the new underlying table partitions.

AT Clause

The `AT` clause applies only to range partitions and lets you split one range partition into two range partitions. Specify the new noninclusive upper bound for the first of the two new partitions. The value list must compare less than the original partition bound for the current partition and greater than the partition bound for the next lowest partition (if there is one).

VALUES Clause

The `VALUES` clause applies only to list partitions and allows you to split one list partition into two list partitions. If the table is partitioned on one key column, then use the upper branch of the `list_values` syntax to specify a list of values for that column.
You can specify NULL if you have not already specified NULL for another partition in the table. If the table is partitioned on multiple key columns, then use the lower branch of the list_values syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. Oracle Database creates the first new partition using the list_values you specify and creates the second new partition using the remaining partition values from the current partition. Therefore, the value list cannot contain all of the partition values of the current partition, nor can it contain any partition values that do not already exist for the current partition.

**INTO Clause**

The INTO clause lets you describe the new partitions resulting from the split.

- The AT ... INTO clause lets you describe the partitions resulting from splitting one range partition into two range partitions. In range_partition_desc, the keyword PARTITION is required even if you do not specify the optional names and physical attributes of the two partitions resulting from the split. If you do not specify new partition names, then Oracle Database assigns names of the form SYS_Pn. Any attributes you do not specify are inherited from the current partition.

- The VALUES ... INTO clause lets you describe the partitions resulting from splitting one list partition into two list partitions. In list_partition_desc, the keyword PARTITION is required even if you do not specify the optional names and physical attributes of the two partitions resulting from the split. If you do not specify new partition names, then Oracle Database assigns names of the form SYS_Pn. Any attributes you do not specify are inherited from the current partition.

- The INTO clause lets you split one range partition into two or more range partitions, or one list partition into two or more list partitions. If you do not specify new partition names, then Oracle Database assigns names of the form SYS_Pn. Any attributes you do not specify are inherited from the current partition.
  - You must specify range partitions in ascending order of their partition bounds. The partition bound of the first specified range partition must be greater than the partition bound for the next lowest partition in the table (if there is one). Do not specify a partition bound for the last range partition; it will inherit the partition bound of the current partition.
  - For list partitions, all specified partition values for the new partitions must exist in the current partition. Do not specify any partition values for the last partition. Oracle Database creates the last partition using the remaining partition values from the current partition.

For range-hash composite-partitioned tables, if you specify subpartitioning for the new partitions, then you can specify only TABLESPACE and table compression for the subpartitions. All other attributes are inherited from the current partition. If you do not specify subpartitioning for the new partitions, then their tablespace is also inherited from the current partition.

For range-list and list-list composite-partitioned tables, you cannot specify subpartitions for the new partitions at all. The list subpartitions of the split partition inherit the number of subpartitions and value lists from the current partition.

For all composite-partitioned tables for which you do not specify subpartition names for the newly created subpartitions, the newly created subpartitions inherit their names from the parent partition as follows:
• For those subpartitions in the parent partition with names of the form
  \textit{partition\_name underscore (subpartition\_name)} (for example, \textit{P1\_SUBP1}),
  Oracle Database generates corresponding names in the newly created
  subpartitions using the new partition names (for example \textit{P1A\_SUB1} and \textit{P1B\_SUB1}).
• For those subpartitions in the parent partition with names of any other form, Oracle
  Database generates subpartition names of the form \textit{SYS\_SUBPn}.

Oracle Database splits the corresponding partition(s) in each local index defined on
\textit{table}, even if the index is marked \textit{UNUSABLE}.

If \textit{table} is the parent table of a reference-partitioned table, then you can use the
\textit{dependent\_tables\_clause} to propagate the partition maintenance operation you are
specifying in this statement to all the reference-partitioned child tables.

Oracle Database invalidates any indexes on heap-organized tables. You can update
these indexes during this operation using the \textit{update\_index\_clauses}.

The \textit{parallel\_clause} lets you parallelize the split operation but does not change the
default parallel attributes of the table.

\textbf{ONLINE}

Specify \textbf{ONLINE} to indicate that DML operations on the table will be allowed while
splitting the table partition.

\textbf{Restrictions on the ONLINE Clause}

The \textbf{ONLINE} clause is subject to the following restrictions when splitting table partitions:

• You cannot specify the \textbf{ONLINE} clause for tables owned by \textit{SYS}.
• You cannot specify the \textbf{ONLINE} clause for index-organized tables.
• You cannot specify the \textbf{ONLINE} clause if a domain index is defined on the table.
• You cannot specify the \textbf{ONLINE} clause for heap-organized tables that contain object
types or on which bitmap join indexes are defined.
• Parallel DML and direct path \textbf{INSERT} operations require an exclusive lock on the
table. Therefore, these operations are not supported concurrently with an ongoing
online partition split, due to conflicting locks.

\textbf{Restrictions on Splitting Table Partitions}

Splitting table partitions is subject to the following restrictions:

• You cannot specify this clause for a hash partition.
• You cannot specify the \textbf{parallel\_clause} for index-organized tables.
• If \textit{table} is an index-organized table, or if a local domain index is defined on \textit{table},
  then you can split the partition into only two new partitions.

\textbf{See Also:}

"Splitting Table Partitions: Examples"
split_table_subpartition
Use this clause to split a subpartition into multiple new subpartitions with nonoverlapping value lists.

Note:
Oracle Database can optimize and speed up SPLIT PARTITION and SPLIT SUBPARTITION operations if specific conditions are met. Refer to Oracle Database VLDB and Partitioning Guide for information on optimizing these operations.

AT Clause
The AT clause is valid only for range subpartitions. Specify the new noninclusive upper bound for the first of the two new subpartitions. The value list must compare less than the original subpartition bound for the subpartition identified by subpartition_extended_name and greater than the partition bound for the next lowest subpartition (if there is one).

VALUES Clause
The VALUES clause is valid only for list subpartitions. If the table is subpartitioned on one key column, then use the upper branch of the list_values syntax to specify a list of values for that column. You can specify NULL if you have not already specified NULL for another subpartition in the same partition. If the table is subpartitioned on multiple key columns, then use the lower branch of the list_values syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. Oracle Database creates the first new subpartition using the subpartition value list you specify and creates the second new partition using the remaining partition values from the current subpartition. Therefore, the value list cannot contain all of the partition values of the current subpartition, nor can it contain any partition values that do not already exist for the current subpartition.

INTO Clause
The INTO clause lets you describe the new subpartitions resulting from the split.

- The AT ... INTO clause lets you describe the two subpartitions resulting from splitting one range partition into two range partitions. In range_subpartition_desc, the keyword SUBPARTITION is required even if you do not specify the optional names and attributes of the two new subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBPn Any attributes you do not specify are inherited from the current subpartition.

- The VALUES ... INTO clause lets you describe the two subpartitions resulting from splitting one list partition into two list partitions. In list_subpartition_desc, the keyword SUBPARTITION is required even if you do not specify the optional names and attributes of the two new subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBPn Any attributes you do not specify are inherited from the current subpartition.
The INTO clause lets you split one range subpartition into two or more range subpartitions, or one list subpartition into two or more list subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBPn. Any attributes you do not specify are inherited from the current subpartition.

- You must specify range subpartitions in ascending order of their subpartition bounds. The subpartition bound of the first specified range subpartition must be greater than the subpartition bound for the next lowest subpartition (if there is one). Do not specify a subpartition bound for the last range subpartition; it will inherit the partition bound of the current subpartition.
- For list subpartitions, all specified subpartition values for the new subpartitions must exist in the current subpartition. Do not specify any subpartition values for the last subpartition. Oracle Database creates the last subpartition using the remaining partition values from the current subpartition.

Oracle Database splits any corresponding local subpartition index, even if it is marked UNUSABLE. The new index subpartitions inherit the names of the new table subpartitions unless those names are already held by index subpartitions. In that case, the database assigns new index subpartition names of the form SYS_SUBPn. The new index subpartitions inherit physical attributes from the parent subpartition. However, if the parent subpartition does not have a default TABLESPACE attribute, then the new subpartitions inherit the tablespace of the corresponding new table subpartitions.

Oracle Database invalidates indexes on heap-organized tables. You can update these indexes by using the `update_index_clauses`.

**ONLINE**

Specify ONLINE to indicate that DML operations on the table will be allowed while splitting the table subpartition.

**Restrictions on the ONLINE Clause**

The ONLINE clause for splitting table subpartitions is subject to the same restrictions as the ONLINE clause for splitting table partitions. Refer to Restrictions on the ONLINE Clause.

**Restrictions on Splitting Table Subpartitions**

Splitting table subpartitions is subject to the following restrictions:

- You cannot specify this clause for a hash subpartition.
- In subpartition descriptions, the only clauses of `partitioning_storage_clause` you can specify are TABLESPACE and table compression.
- You cannot specify the parallel_clause for index-organized tables.
- If `table` is an index-organized table, then you can split the subpartition into only two new subpartitions.

**merge_table_partitions**

The merge_table_partitions clause lets you merge the contents of two or more range, list, or system partitions of `table` into one new partition and then drop the original partitions. This clause is not valid for hash partitions. Use the coalesce_table_partition clause instead.
Specify a comma-separated list of two or more range, list, or system partitions to be merged. You can use the TO clause to specify two or more adjacent range partitions to be merged.

For each partition, use partition to specify a partition name or the FOR clause to specify a partition without using its name. See "References to Partitioned Tables and Indexes" for more information on the FOR clause.

- The partitions to be merged must be adjacent and must be specified in ascending order of their partition bounds if they are range partitions. List partitions and system partitions need not be adjacent in order to be merged.
- When you merge range partitions, the new partition inherits the partition bound of the highest of the original partitions.
- When you merge list partitions, the resulting partition value list is the union of the set of the partition values lists of the partitions being merged. If you merge a DEFAULT list partition with other list partitions, then the resulting partition will be the DEFAULT partition and will have the DEFAULT value.
- When you merge composite range partitions or composite list partitions, range-list or list-list composite partitions, you cannot specify subpartition descriptions. Oracle Database obtains the subpartitioning information from the subpartition template. If you have not specified a subpartition template, then the database creates one MAXVALUE subpartition from range subpartitions or one DEFAULT subpartition from list subpartitions.

Any attributes you do not specify explicitly for the new partition are inherited from table-level defaults. However, if you reuse one of the partition names for the new partition, then the new partition inherits values from the partition whose name is being reused rather than from table-level default values.

Oracle Database drops local index partitions corresponding to the selected partitions and marks UNUSABLE the local index partition corresponding to merged partition. The database also marks UNUSABLE any global indexes on heap-organized tables. You can update all these indexes during this operation using the update_index_clauses.

If table is the parent table of a reference-partitioned table, then you can use the dependent_tables_clause to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

ONLINE

Specify ONLINE to allow DML operations on the table partitions during the merge partitions operation.

Restriction on Merging Table Partitions

If table is an index-organized table, or if a local domain index is defined on table, then you can merge only two partitions at a time.

See Also:

"Merging Two Table Partitions: Example", "Merging Four Adjacent Range Partitions: Example", and "Working with Default List Partitions: Example"
merge_table_subpartitions

The `merge_table_subpartitions` clause lets you merge the contents of two or more range or list subpartitions of `table` into one new subpartition and then drop the original subpartitions. This clause is not valid for hash subpartitions. Use the `coalesce_hash_subpartition` clause instead.

Specify a comma-separated list of two or more range or list subpartitions to be merged. You can use the `TO` clause to specify two or more adjacent range subpartitions to be merged.

For each subpartition, use `subpartition` to specify a subpartition name or the `FOR` clause to specify a subpartition without using its name. See “References to Partitioned Tables and Indexes” for more information on the `FOR` clause.

The subpartitions to be merged must belong to the same partition. If they are range subpartitions, then they must be adjacent. If they are list subpartitions, then they need not be adjacent. The data in the resulting subpartition consists of the combined data from the merged subpartitions.

If you specify the `INTO` clause, then in the `range_subpartition_desc` or `list_subpartition_desc` you cannot specify the `range_values_clause` or `list_values_clause`, respectively. Further, the only clauses you can specify in the `partitioning_storage_clause` are the `TABLESPACE` clause and `table_compression`.

Any attributes you do not specify explicitly for the new subpartition are inherited from partition-level values. However, if you reuse one of the subpartition names for the new subpartition, then the new subpartition inherits values from the subpartition whose name is being reused rather than from partition-level default values.

Oracle Database merges corresponding local index subpartitions and marks the resulting index subpartition `UNUSABLE`. The database also marks `UNUSABLE` both partitioned and nonpartitioned global indexes on heap-organized tables. You can update all indexes during this operation using the `update_index_clauses`.

ONLINE

Specify `ONLINE` to allow DML operations on the table subpartitions during the merge subpartitions operation.

Restriction on Merging Table Subpartitions

If `table` is an index-organized table, then you can merge only two subpartitions at a time.

exchange_partition_subpart

Use the `EXCHANGE PARTITION` or `EXCHANGE SUBPARTITION` clause to exchange the data and index segments of:

- One nonpartitioned table with:
  - one range, list, or hash partition
  - one range, list, or hash subpartition
- One range-partitioned table with the range subpartitions of a range-range or list-range composite-partitioned table partition
• One hash-partitioned table with the hash subpartitions of a range-hash or list-hash composite-partitioned table partition
• One list-partitioned table with the list subpartitions of a range-list or hash-list composite-partitioned table partition

In all cases, the structure of the table and the partition or subpartition being exchanged, including their partitioning keys, must be identical. In the case of list partitions and subpartitions, the corresponding value lists must also match.

This clause facilitates high-speed data loading when used with transportable tablespaces.

See Also:

Oracle Database Administrator's Guide for information on transportable tablespaces

If \textit{table} contains LOB columns, then for each LOB column Oracle Database exchanges LOB data and LOB index partition or subpartition segments with corresponding LOB data and LOB index segments of \textit{table}.

If \textit{table} has nested table columns, then for each such column Oracle Database exchanges nested table partition segments with corresponding nested table segments of the nonpartitioned table.

If \textit{table} contains an identity column, then so must the partition or subpartition being exchanged, and vice versa. The sequence generators must both be increasing or decreasing. The sequence generators are not exchanged, so \textit{table} and the partition or subpartition will continue to use the same sequence generators. The high water mark for both sequence generators will be adjusted so that new identity column values will not conflict with existing values.

All of the segment attributes of the two objects (including tablespace and logging) are also exchanged.

Existing statistics for the table being exchanged into the partitioned table will be exchanged. However, the global statistics for the partitioned table will not be altered. Use the \texttt{DBMS_STATS.GATHER_TABLE_STATS} procedure to re-create global statistics. You can set the \texttt{GRANULARITY} attribute equal to 'APPROXGLOBAL AND PARTITION' to speed up the process and aggregate new global statistics based on the existing partition statistics. See Oracle Database PL/SQL Packages and Types Reference for more information on this packaged procedure.

Oracle Database invalidates any global indexes on the objects being exchanged. You can update the global indexes on the table whose partition is being exchanged by using either the update\_global\_index\_clause or the update\_all\_indexes\_clause. For the update\_all\_indexes\_clause, you can specify only the keywords UPDATE INDEXES, not the subclause. Global indexes on the table being exchanged remain invalidated. The update\_global\_index\_clause and update\_all\_indexes\_clause do not update local indexes during an exchange operation. You can specify local index maintenance by using the INCLUDING | EXCLUDING INDEXES clause. If you specify the parallel\_clause with either of these clauses, then the database parallelizes the index update, not the exchange operation.
WITH TABLE

Specify the `table` with which the partition or subpartition will be exchanged. If you omit `schema`, then Oracle Database assumes that `table` is in your own schema.

INCLUDING | EXCLUDING INDEXES

Specify `INCLUDING INDEXES` if you want local index partitions or subpartitions to be exchanged with the corresponding table index (for a nonpartitioned table) or local indexes (for a hash-partitioned table). Specify `EXCLUDING INDEXES` if you want all index partitions or subpartitions corresponding to the partition and all the regular indexes and index partitions on the exchanged table to be marked `UNUSABLE`. If you omit this clause, then the default is `EXCLUDING INDEXES`.

WITH | WITHOUT VALIDATION

Specify `WITH VALIDATION` if you want Oracle Database to return an error if any rows in the exchanged table do not map into partitions or subpartitions being exchanged. Specify `WITHOUT VALIDATION` if you do not want Oracle Database to check the proper mapping of rows in the exchanged table. If you omit this clause, then the default is `WITH VALIDATION`.

exceptions_clause

See "Handling Constraint Exceptions " for information on this clause. In the context of exchanging partitions, this clause is valid only if the partitioned table has been defined with a `UNIQUE` constraint, and that constraint must be in `DISABLE VALIDATE` state. This clause is valid only for exchanging partition, not subpartitions.

CASCADE

Specify `CASCADE` to exchange the corresponding partition or subpartition in all reference-partitioned child tables of `table`. The reference-partitioned table hierarchies of the source and target must match.

Restrictions on CASCADE

The following restrictions apply to the `CASCADE` clause:

- You cannot specify `CASCADE` if a parent key in the reference-partitioned table hierarchy is referenced by multiple partitioning constraints.
- You cannot specify `CASCADE` if a domain index or an `XMLIndex` index is defined on any of the reference-partitioned child tables of `table`. 

See Also:

- The DBMS_IOT package in Oracle Database PL/SQL Packages and Types Reference for information on the SQL scripts
- Oracle Database Administrator's Guide for information on eliminating migrated and chained rows
- constraint for more information on constraint checking and "Creating an Exceptions Table for Index-Organized Tables: Example"

Notes on Exchanging Partitions and Subpartitions

The following notes apply when exchanging partitions and subpartitions:

- Both tables involved in the exchange must have the same primary key, and no validated foreign keys can be referencing either of the tables unless the referenced table is empty.
- When exchanging partitioned index-organized tables:
  - The source and target table or partition must have their primary key set on the same columns, in the same order.
  - If prefix compression is enabled, then it must be enabled for both the source and the target, and with the same prefix length.
  - Both the source and target must be index organized.
  - Both the source and target must have overflow segments, or neither can have a mapping table.
  - Both the source and target must have identical storage attributes for any LOB columns.

See Also:

"Exchanging Table Partitions: Example"

dependent_tables_clause

This clause is valid only when you are altering the parent table of a reference-partitioned table. The clause lets you specify attributes of partitions that are created by the operation for reference-partitioned child tables of the parent table.

- If the parent table is not composite partitioned, then specify one or more child tables, and for each child table specify one partition_spec for each partition created in the parent table.
- If the parent table is composite, then specify one or more child tables, and for each child table specify one partition_spec for each subpartition created in the parent table.
UNUSABLE LOCAL INDEXES Clauses

These two clauses modify the attributes of local index partitions and index subpartitions corresponding to partition, depending on whether you are modifying a partition or subpartition.

- **UNUSABLE LOCAL INDEXES** marks UNUSABLE the local index partition or index subpartition associated with partition.
- **REBUILD UNUSABLE LOCAL INDEXES** rebuilds the unusable local index partition or index subpartition associated with partition.

Restrictions on UNUSABLE LOCAL INDEXES

This clause is subject to the following restrictions:

- You cannot specify this clause with any other clauses of the modify_table_partition clause.
- You cannot specify this clause in the modify_table_partition clause for a partition that has subpartitions. However, you can specify this clause in the modify_table_subpartition clause.

**update_index_clauses**

Use the update_index_clauses to update the indexes on table as part of the table partitioning operation. When you perform DDL on a table partition, if an index is defined on table, then Oracle Database invalidates the entire index, not just the partitions undergoing DDL. This clause lets you update the index partition you are changing during the DDL operation, eliminating the need to rebuild the index after the DDL.

The update_index_clauses are not needed, and are not valid, for partitioned index-organized tables. Index-organized tables are primary key based, so Oracle can keep global indexes USABLE during operations that move data but do not change its value.

**update_global_index_clause**

Use this clause to update only global indexes on table. Oracle Database marks UNUSABLE all local indexes on table.

**UPDATE GLOBAL INDEXES**

Specify **UPDATE GLOBAL INDEXES** to update the global indexes defined on table.

Restriction on Updating Global Indexes

If the global index is a global domain index defined on a LOB column, then Oracle Database marks the domain index UNUSABLE instead of updating it.

**INVALIDATE GLOBAL INDEXES**
Specify **INVALIDATE GLOBAL INDEXES** to invalidate the global indexes defined on `table`.

If you specify neither, then Oracle Database invalidates the global indexes.

**Restrictions on Invalidating Global Indexes**

This clause is supported only for global indexes. It is not supported for index-organized tables. In addition, this clause updates only indexes that are **USABLE** and **VALID**. **UNUSABLE** indexes are left unusable, and **INVALID** global indexes are ignored.

**update_all_indexes_clause**

Use this clause to update all indexes on `table`.

**update_index_partition**

This clause is valid only for operations on table partitions and affects only local indexes.

- The `index_partition_description` lets you specify physical attributes, tablespace storage, and logging for each partition of each local index. If you specify only the **PARTITION** keyword, then Oracle Database updates the index partition as follows:
  - For operations on a single table partition (such as **MOVE PARTITION** and **SPLIT PARTITION**), the corresponding index partition inherits the attributes of the affected index table partition, Oracle Database does not generate names for new index partitions, so any new index partitions resulting from this operation inherit their names from the corresponding new table partition.
  - For **MERGE PARTITION** operations, the resulting local index partition inherits its name from the resulting table partition and inherits its attributes from the local index.

For a domain index, you can use the **PARAMETERS** clause to specify the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine. The **PARAMETERS** clause is valid only for domain indexes, and is the only part of the `index_partition_description` you can specify for a domain index.

**See Also:**

*Oracle Database Data Cartridge Developer's Guide* for more information on domain indexes

- For a composite-partitioned index, the `index_subpartition_clause` lets you specify tablespace storage for each subpartition. Refer to the `index_subpartition_clause` (in **CREATE INDEX**') for more information on this component of the `update_index_partition` clause.

For information on the **USABLE** and **UNUSABLE** keywords, refer to **ALTER INDEX ... USABLE** | **UNUSABLE**.

**update_index_subpartition**

This clause is valid only for operations on subpartitions of composite-partitioned tables and affects only local indexes on composite-partitioned tables. It lets you specify tablespace storage for one or more subpartitions.
Restrictions on Updating All Indexes

The following restrictions apply to the `update_all_indexes_clause`:

- You cannot specify this clause for index-organized tables.
- When you exchange a partition or subpartition with the `exchange_partition_subpart` clause, the `update_all_indexes_clause` is applicable only to global indexes. Therefore, you cannot specify the `update_index_partition` or `update_index_subpartition` clauses. You can, however, specify local index maintenance during an exchange operation by using the `INCLUDING | EXCLUDING INDEXES` clause.

See Also:
"Updating Global Indexes: Example" and "Updating Partitioned Indexes: Example"

parallel_clause

The `parallel_clause` lets you change the default degree of parallelism for queries and DML on the table.

For complete information on this clause, refer to `parallel_clause` in the documentation on CREATE TABLE.

Restrictions on Changing Table Parallelization

Changing parallelization is subject to the following restrictions:

- If `table` contains any columns of LOB or user-defined object type, then subsequent INSERT, UPDATE, and DELETE operations on `table` are executed serially without notification. Subsequent queries, however, are executed in parallel.
- If you specify the `parallel_clause` in conjunction with the `move_table_clause`, then the parallelism applies only to the move, not to subsequent DML and query operations on the table.

See Also:
"Specifying Parallel Processing: Example"

filter_condition

This clause lets you specify which rows to preserve during the following ALTER TABLE operations: moving, splitting, or merging table partitions or subpartitions; moving a table; or converting a nonpartitioned table to a partitioned table. The database preserves only the rows that satisfy the condition specified in the `where_clause`. Refer to the `where_clause` in the documentation on SELECT for the full semantics of this clause.

Restrictions on Filter Conditions

The following restrictions apply to the `filter_condition` clause:
• Filter conditions are supported only for heap-organized tables.
• Filter conditions can refer only to columns in the table being altered. Filter conditions cannot contain operations, such as joins or subqueries, that reference other database objects.
• Filter conditions are unsupported for tables with primary or unique keys that are referenced by enabled foreign keys.

Restrictions and Notes on Using Filter Conditions with Online Operations

The following restrictions and notes apply when you specify a filter condition for an online ALTER TABLE operation:

• You cannot specify both the filter_condition and ONLINE clauses if supplemental logging is enabled.
• When you specify both the filter_condition and ONLINE clauses, DML operations on the table are allowed during the ALTER TABLE operation. The filter condition does not have a direct effect on the concurrent DML operations. However, consider this combination carefully, because the filter operation and the DML operations could unintentionally conflict, as follows:
  – Inserts into a nonpartitioned table will succeed. Inserts into a partitioned table will succeed if they do not violate the partitioning key criteria.
  – Delete operations will apply only to rows that are preserved by the filter condition throughout the ALTER TABLE operation.
  – Update operations will apply only to rows that are preserved by the filter condition throughout the ALTER TABLE operation. These update operations will succeed, regardless of whether the update operation would have disqualified the rows for preservation by the filter condition.
  – Rows that do not qualify for preservation by the filter condition at the onset of the ALTER TABLE operation will not be preserved, regardless of whether an update operation would qualify the rows for preservation.

allow_disallow_clustering

This clause is valid for tables that use attribute clustering. It lets you allow or disallow attribute clustering for data movement that occurs during the move table operation specified by the move_table_clause, and the table partition and subpartition maintenance operations specified by the coalesce_table_[sub]partition, merge_table_[sub]partitions, move_table_[sub]partition, and split_table_[sub]partition clauses.

• Specify ALLOW CLUSTERING to allow attribute clustering for data movement. This clause overrides a NO ON DATA MOVEMENT setting in the DDL that created or altered the table.
• Specify DISALLOW CLUSTERING to disallow attribute clustering for data movement. This clause overrides a YES ON DATA MOVEMENT setting in the DDL that created or altered the table.

The allow_disallow_clustering clause has no effect if you specify it for a table that does not use attribute clustering.
\{ \text{DEFERRED} | \text{IMMEDIATE} \} \text{ INVALIDATION}

This clause lets you control when the database invalidates dependent cursors while performing table partition maintenance operations.

- If you specify \text{DEFERRED INVALIDATION}, then the database avoids or defers invalidating dependent cursors, when possible.
- If you specify \text{IMMEDIATE INVALIDATION}, then the database immediately invalidates dependent cursors, as it did in Oracle Database 12c Release 1 (12.1) and prior releases. This is the default.

If you omit this clause, then the value of the \text{CURSOR_INVALIDATION} initialization parameter determines when cursors are invalidated.

You can specify this clause only when performing table partition maintenance operations; it is not supported for any other \text{ALTER TABLE} operations.

\begin{itemize}
\item \text{Oracle Database SQL Tuning Guide} for more information on cursor invalidation
\item \text{Oracle Database Reference} for more information in the \text{CURSOR_INVALIDATION} initialization parameter
\end{itemize}

\textbf{move\_table\_clause}

The \text{move\_table\_clause} lets you relocate data of a nonpartitioned table or of a partition of a partitioned table into a new segment, optionally in a different tablespace, and optionally modify any of its storage attributes.

You can also move any LOB data segments associated with the table or partition using the \text{LOB\_storage\_clause} and \text{varray\_col\_properties} clause. LOB items not specified in this clause are not moved.

If you move the table to a different tablespace and the \text{COMPATIBLE} parameter is set to 10.0 or higher, then Oracle Database leaves the storage table of any nested table columns in the tablespace in which it was created. If \text{COMPATIBLE} is set to any value less than 10.0, then the database silently moves the storage table to the new tablespace along with the table.

\textbf{ONLINE Clause}

Specify \text{ONLINE} if you want DML operations on the table to be allowed while the table is being moved.

\textbf{Restrictions on Moving Tables Online}
Moving tables online is subject to the following restrictions:

- You cannot combine this clause with any other clause in the same statement.
- You cannot specify this clause for a partitioned index-organized table.
- You cannot specify this clause if a domain index is defined on the table.
- Parallel DML and direct path `INSERT` operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online table `MOVE`, due to conflicting locks.
- You cannot specify this clause for index-organized tables that contain any LOB, `VARRAY`, Oracle-supplied type, or user-defined object type columns.

**index_org_table_clause**

For an index-organized table, the `index_org_table_clause` of the `move_table_clause` lets you additionally specify overflow segment attributes. The `move_table_clause` rebuilds the primary key index of the index-organized table. The overflow data segment is not rebuilt unless the `OVERFLOW` keyword is explicitly stated, with two exceptions:

- If you alter the values of `PCTTHRESHOLD` or the `INCLUDING` column as part of this `ALTER TABLE` statement, then the overflow data segment is rebuilt.
- If you explicitly move any of out-of-line columns (LOBs, varrays, nested table columns) in the index-organized table, then the overflow data segment is also rebuilt.

The index and data segments of LOB columns are not rebuilt unless you specify the LOB columns explicitly as part of this `ALTER TABLE` statement.

**mapping_table_clause**

Specify `MAPPING TABLE` if you want Oracle Database to create a mapping table if one does not already exist. If it does exist, then the database moves the mapping table along with the index-organized table, and marks any bitmapped indexes `UNUSABLE`. The new mapping table is created in the same tablespace as the parent table.

Specify `NOMAPPING` to instruct the database to drop an existing mapping table.

Refer to mapping_table_clauses (in CREATE TABLE) for more information on this clause.

**Restriction on Mapping Tables**

You cannot specify `NOMAPPING` if any bitmapped indexes have been defined on `table`.

**prefix_compression**

Use the `prefix_compression` clause to enable or disable prefix compression in an index-organized table.

- `COMPRESS` enables prefix compression, which eliminates repeated occurrence 1 of primary key column values in index-organized tables. Use `integer` to specify the prefix length (number of prefix columns to compress).
  
The valid range of prefix length values is from 1 to the number of primary key columns minus 1. The default prefix length is the number of primary key columns minus 1.
- `NOCOMPRESS` disables prefix compression in index-organized tables. This is the default.
TABLESPACE `tablespace`
Specify the tablespace into which the rebuilt index-organized table is to be stored.

LOB_storage_clause
Use this clause to move a LOB segment to a different tablespace. You cannot use this clause to move a LOB segment if the table contains a LONG column. Instead, you must either convert the LONG column to a LOB, or you must export the table, re-create the table specifying the desired tablespace storage for the LOB column, and re-import the table data.

UPDATE INDEXES
This clause is valid only when performing online or offline moves of heap-organized tables. It allows you to update all global indexes on the table.

You can optionally change the tablespace for an index or index partition, as follows:

- Specify the segment_attributes_clause to change the tablespace of a nonpartitioned global index. Within this clause, you can specify only the TABLESPACE clause.
- Specify the update_index_partition clause to change the tablespace for a partition of a partitioned global index. Within this clause, you can specify only the TABLESPACE clause of the segment_attributes_clause.

Restrictions on Moving Tables
Moving tables is subject to the following restrictions:

- If you specify MOVE, then it must be the first clause in the ALTER TABLE statement, and the only clauses outside this clause that are allowed are the physical_attributes_clause, the parallel_clause, and the LOB_storage_clause.
- You cannot move a table containing a LONG or LONG RAW column.
- You cannot MOVE an entire partitioned table (either heap- or index-organized). You must move individual partitions or subpartitions.

Note:
For any LOB columns you specify in a move_table_clause:

- Oracle Database drops the old LOB data segment and corresponding index segment and creates new segments, even if you do not specify a new tablespace.
- If the LOB index in table resided in a different tablespace from the LOB data, then Oracle Database collocates the LOB index in the same tablespace with the LOB data after the move.

See Also:
move_table_partition and move_table_subpartition
modify_to_partitioned

Use this clause to partition a nonpartitioned or partitioned table, including indexes, online or offline.

You can change a nonpartitioned or partitioned table into any type of partitioned or composite partitioned table with the following characteristics:

- All data in the original table is preserved.
- The data in the newly created partitions or subpartitions of the modified table is stored in the same tablespace as the original table, unless you specify otherwise in the table_partitioning_clauses.
- Local index partitions or subpartitions and lob partitions or subpartitions of the modified table will be co-located with the table partitions or subpartitions unless you specify otherwise in the table_partitioning_clauses.
- All triggers, constraints, and VPD policies defined on the original table are preserved.
- If table compression is defined on the original nonpartitioned table, then the partitioned table will use the same type of table compression.
- In case of modifying a partitioned table, the compression setting of the newly created partitions or subpartitions is derived from the default compression setting of the partitioned table prior to the modification unless all partitions or subpartitions shared the same compression method.

Each range, list, or hash partitioning or subpartitioning key column with a character data type, specified in the modify_to_partitioned clause must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

table_partitioning_clauses

Use this clause to specify the partitioning attributes for the table.

Each range, list, or hash partitioning or subpartitioning key column with a character data type, specified in the modify_to_partitioned clause must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

This clause has the same semantics here as it has for the CREATE TABLE statement. Refer to the CREATE TABLE table_partitioning_clauses for the full semantics of this clause.

ONLINE

Specify ONLINE to indicate that DML operations on the table will be allowed while changing to a partitioned table.

UPDATE INDEXES

Use this clause to specify how existing indexes on the table are converted into global partitioned indexes or local partitioned indexes.

- For index, specify the name of an existing index on the table.
- Specify the local_partitioned_index clause to convert index into a local partitioned index. This clause has the same semantics here as it has for
the CREATE INDEX statement. Refer to the clause `local_partitioned_index` in the documentation on CREATE INDEX for the full semantics of this clause.

- Specify the `global_partitioned_index` clause to convert index into a global partitioned index. This clause has the same semantics here as it has for the CREATE INDEX statement. Refer to the clause `global_partitioned_index` in the documentation on CREATE INDEX for the full semantics of this clause.

- Specify the `GLOBAL` keyword to allow prefixed partitioned and nonpartitioned global indexes to retain their global shape. This clause prevents such indexes from being converted to local partitioned indexes; it has no effect on nonprefixed global indexes.

If you specify only the `UPDATE INDEXES` keywords, or omit the `UPDATE INDEXES` clause altogether, then existing indexes are converted as follows:

- Nonprefixed indexes retain their original shape: normal indexes are converted to nonpartitioned global indexes, nonpartitioned global indexes remain the same, and partitioned global indexes remain the same and retain their partitioning shape.

- Prefixed indexes are converted to local partitioned indexes. Prefixed indexes include partitioning keys in the index definition, but the index definition is not limited to including only the partitioning keys.

- Bitmap indexes are converted to local partitioned indexes, regardless of whether they are prefixed or not.

**Default Index Rules for Conversion from Partitioned to Partitioned Table**

The rule set for default index conversion for partitioned to partitioned table is identical to the one for nonpartitioned to partitioned table, with additional handling of existing local indexes on the partitioned table.

- If the index is already local, then the index stays as a local index if the index column is prefixed on both sides of the partitioning dimensions.

- If the partitioning columns are a subset of the key columns, (that is, they are prefixed), then the global index is converted to local. If the global index is not prefixed, then the shape of the global index is retained.

**Restrictions on Changing a Nonpartitioned Table to a Partitioned Table**

The following restrictions apply to the `modify_to_partitioned` clause:

- You cannot specify this clause for an index-organized table.
- You cannot specify this clause if a domain index is defined on the table.
- You cannot specify ONLINE when changing a nonpartitioned table to a reference-partitioned child table. This operation is supported only in offline mode.

---

**See Also:**

`Oracle Database VLDB and Partitioning Guide` for more information on converting a nonpartitioned table into a partitioned table.
**modify_opaque_type**

Use the `modify_opaque_type` clause to instruct the database to store the specified abstract data type or XMLType in an ANYDATA column using unpacked storage.

You can specify any abstract data type with this clause. However, it is primarily useful because it allows you to specify the following data types, which cannot be stored in an ANYDATA column using conventional storage:

- XMLType
- Abstract data types that contain one or more attributes of type XMLType, CLOB, BLOB, or NCLOB.

When you use **unpacked storage**, data types are stored in system-generated hidden columns that are associated with the ANYDATA column. You can insert and query these data types as you would data types that are stored in an ANYDATA column using conventional storage.

**anydata_column**

Specify the name of a column of type ANYDATA. If `type_name` is an abstract data type that does not contain an attribute of type XMLType, CLOB, BLOB, or NCLOB, then `anydata_column` must be empty.

**type_name**

Specify the name of one or more abstract data types or XMLType. The abstract data type can contain an attribute of type XMLType, CLOB, BLOB, or NCLOB. The type can be EDITIONABLE. When you subsequently insert these data types into `anydata_column`, they will use unpacked storage. If you previously specified this clause for the same `anydata_column`, then unpacked storage will continue to be used for the previously specified data types as well as the newly specified data types.

---

**See Also:**

*Oracle Database PL/SQL Packages and Types Reference* for information on the ANYDATA type and "Unpacked Storage in ANYDATA Columns: Example"

---

**enable_disable_clause**

The `enable_disable_clause` lets you specify whether and how Oracle Database should apply an integrity constraint. The DROP and KEEP clauses are valid only when you are disabling a unique or primary key constraint.

---

**See Also:**

- The `enable_disable_clause` (in CREATE TABLE) for a complete description of this clause, including notes and restrictions that relate to this statement
TABLE LOCK

Oracle Database permits DDL operations on a table only if the table can be locked during the operation. Such table locks are not required during DML operations.

Note:
Table locks are not acquired on temporary tables.

• Specify ENABLE TABLE LOCK to enable table locks, thereby allowing DDL operations on the table. All currently executing transactions must commit or roll back before Oracle Database enables the table lock.

Note:
Oracle Database waits until active DML transactions in the database have completed before locking the table. Sometimes the resulting delay is considerable.

• Specify DISABLE TABLE LOCK to disable table locks, thereby preventing DDL operations on the table.

Note:
Parallel DML operations are not performed when the table lock of the target table is disabled.

ALL TRIGGERS

Use the ALL TRIGGERS clause to enable or disable all triggers associated with the table.

• Specify ENABLE ALL TRIGGERS to enable all triggers associated with the table. Oracle Database fires the triggers whenever their triggering condition is satisfied.

To enable a single trigger, use the enable_clause of ALTER TRIGGER.

See Also:
CREATE TRIGGER, ALTER TRIGGER, and "Enabling Triggers: Example"

• Specify DISABLE ALL TRIGGERS to disable all triggers associated with the table. Oracle Database does not fire a disabled trigger even if the triggering condition is satisfied.
CONTAINER_MAP

Use the CONTAINER_MAP clause to enable or disable the table to be queried using a container map.

- Specify ENABLE CONTAINER_MAP to enable the table to be queried using a container map.
- Specify DISABLE CONTAINER_MAP to disable the table from being queried using a container map.

CONTAINERS_DEFAULT

Use the CONTAINERS_DEFAULT clause to enable or disable the table for the CONTAINERS clause.

- Specify ENABLE CONTAINERS_DEFAULT to enable the table for the CONTAINERS clause.
- Specify DISABLE CONTAINERS_DEFAULT to disable the table for the CONTAINERS clause.

Examples

Adding Constraints to Tables: Example

The following statements create a new table to manipulate data and display the information in the newly created table:

```
CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;
SELECT * FROM JOBS_Temp WHERE MIN_SALARY < 3000;
```

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>JOB_TITLE</th>
<th>MIN_SALARY</th>
<th>MAX_SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>PU_CLERK</td>
<td>Purchasing Clerk</td>
<td>2500</td>
<td>5500</td>
</tr>
<tr>
<td>ST_CLERK</td>
<td>Stock Clerk</td>
<td>2008</td>
<td>5000</td>
</tr>
<tr>
<td>SH_CLERK</td>
<td>Shipping Clerk</td>
<td>2500</td>
<td>5500</td>
</tr>
</tbody>
</table>

The following statement updates the column values to a higher value:

```
UPDATE JOBS_Temp SET MIN_SALARY = 2300 WHERE MIN_SALARY < 2010;
```

The following statement adds a constraint:

```
ALTER TABLE JOBS_Temp ADD CONSTRAINT chk_sal_min CHECK (MIN_SALARY >=2010);
```

The following statement displays the table information:

```
SELECT * FROM JOBS_Temp WHERE MIN_SALARY < 3000;
```

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>JOB_TITLE</th>
<th>MIN_SALARY</th>
<th>MAX_SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>PU_CLERK</td>
<td>Purchasing Clerk</td>
<td>2500</td>
<td>5500</td>
</tr>
<tr>
<td>ST_CLERK</td>
<td>Stock Clerk</td>
<td>2300</td>
<td>5000</td>
</tr>
<tr>
<td>SH_CLERK</td>
<td>Shipping Clerk</td>
<td>2500</td>
<td>5500</td>
</tr>
</tbody>
</table>

The following statement displays the constraint:

```
SELECT CONSTRAINT_NAME FROM USER_CONSTRAINTS WHERE TABLE_NAME='JOBS_TEMP';
```
Collection Retrieval: Example

The following statement modifies nested table column `ad_textdocs_ntab` in the sample table `sh.print_media` so that when queried it returns actual values instead of locators:

```
ALTER TABLE print_media MODIFY NESTED TABLE ad_textdocs_ntab RETURN AS VALUE;
```

Specifying Parallel Processing: Example

The following statement specifies parallel processing for queries to the sample table `oe.customers`:

```
ALTER TABLE customers PARALLEL;
```

Changing the State of a Constraint: Examples

The following statement places in `ENABLE VALIDATE` state an integrity constraint named `emp_manager_fk` in the `employees` table:

```
ALTER TABLE employees
    ENABLE VALIDATE CONSTRAINT emp_manager_fk
    EXCEPTIONS INTO exceptions;
```

Each row of the `employees` table must satisfy the constraint for Oracle Database to enable the constraint. If any row violates the constraint, then the constraint remains disabled. The database lists any exceptions in the table `exceptions`. You can also identify the exceptions in the `employees` table with the following statement:

```
SELECT e.*
FROM employees e, exceptions ex
WHERE e.rowid = ex.row_id
    AND ex.table_name = 'EMPLOYEES'
    AND ex.constraint = 'EMP_MANAGER_FK';
```

The following statement tries to place in `ENABLE NOVALIDATE` state two constraints on the `employees` table:

```
ALTER TABLE employees
    ENABLE NOVALIDATE PRIMARY KEY
    ENABLE NOVALIDATE CONSTRAINT emp_last_name_nn;
```

This statement has two `ENABLE` clauses:

- The first places a primary key constraint on the table in `ENABLE NOVALIDATE` state.
• The second places the constraint named `emp_last_name_nn` in `ENABLE NOVALIDATE` state.

In this case, Oracle Database enables the constraints only if both are satisfied by each row in the table. If any row violates either constraint, then the database returns an error and both constraints remain disabled.

Consider the foreign key constraint on the `location_id` column of the `departments` table, which references the primary key of the `locations` table. The following statement disables the primary key of the `locations` table:

```
ALTER TABLE locations
    MODIFY PRIMARY KEY DISABLE CASCADE;
```

The unique key in the `locations` table is referenced by the foreign key in the `departments` table, so you must specify `CASCADE` to disable the primary key. This clause disables the foreign key as well.

Creating an Exceptions Table for Index-Organized Tables: Example

The following example creates the `except_table` table to hold rows from the index-organized table `hr.countries` that violate the primary key constraint:

```
EXECUTE DBMS_IOT.BUILD_EXCEPTIONS_TABLE ('hr', 'countries', 'except_table');

ALTER TABLE countries
    ENABLE PRIMARY KEY
    EXCEPTIONS INTO except_table;
```

To specify an exception table, you must have the privileges necessary to insert rows into the table. To examine the identified exceptions, you must have the privileges necessary to query the exceptions table.

See Also:

- INSERT and SELECT for information on the privileges necessary to insert rows into tables

Disabling a CHECK Constraint: Example

The following statement defines and disables a `CHECK` constraint on the `employees` table:

```
ALTER TABLE employees ADD CONSTRAINT check_comp
    CHECK (salary + (commission_pct*salary) <= 5000)
    DISABLE;
```

The constraint `check_comp` ensures that no employee's total compensation exceeds $5000. The constraint is disabled, so you can increase an employee's compensation above this limit.

Enabling Triggers: Example

The following statement enables all triggers associated with the `employees` table:

```
ALTER TABLE employees
    ENABLE ALL TRIGGERS;
```
Deallocating Unused Space: Example

The following statement frees all unused space for reuse in table employees, where the high water mark is above MINEXTENTS:

```sql
ALTER TABLE employees
    DEALLOCATE UNUSED;
```

Modifying the Collation of a Column for Fine-Grained Case-Insensitivity: Example

This example shows how to modify a column to be case-insensitive. First, create and populate table students as follows:

```sql
CREATE TABLE students (last_name VARCHAR2(20), id NUMBER);
```

```sql
INSERT INTO students VALUES('Dodd', 364);
INSERT INTO students VALUES('de Niro', 132);
INSERT INTO students VALUES('Vogel', 837);
INSERT INTO students VALUES('van der Kamp', 549);
INSERT INTO students VALUES('van Der Meer', 624);
```

The following statement returns column last_name in alphabetical order. Notice that the results are case-sensitive; lowercase letters are ordered after uppercase letters.

```sql
SELECT last_name, id
FROM students
ORDER BY last_name;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dodd</td>
<td>364</td>
</tr>
<tr>
<td>Vogel</td>
<td>837</td>
</tr>
<tr>
<td>de Niro</td>
<td>132</td>
</tr>
<tr>
<td>van Der Meer</td>
<td>624</td>
</tr>
<tr>
<td>van der Kamp</td>
<td>549</td>
</tr>
</tbody>
</table>

The following statement changes the data-bound collation of column last_name to case-insensitive collation BINARY_CI:

```sql
ALTER TABLE students
    MODIFY (last_name COLLATE BINARY_CI);
```

The following statement again returns column last_name in alphabetical order. Notice that the results are now case-insensitive:

```sql
SELECT last_name, id
FROM students
ORDER BY last_name;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>de Niro</td>
<td>132</td>
</tr>
<tr>
<td>Dodd</td>
<td>364</td>
</tr>
<tr>
<td>van der Kamp</td>
<td>549</td>
</tr>
<tr>
<td>van Der Meer</td>
<td>624</td>
</tr>
<tr>
<td>Vogel</td>
<td>837</td>
</tr>
</tbody>
</table>

Renaming a Column: Example
The following example renames the `credit_limit` column of the sample table `oe.customers` to `credit_amount`:

```
ALTER TABLE customers
    RENAME COLUMN credit_limit TO credit_amount;
```

**Dropping a Column: Example**

This statement illustrates the `drop_column_clause` with `CASCADE CONSTRAINTS`. Assume table `t1` is created as follows:

```
CREATE TABLE t1 (
    pk NUMBER PRIMARY KEY,
    fk NUMBER,
    c1 NUMBER,
    c2 NUMBER,
    CONSTRAINT ri FOREIGN KEY (fk) REFERENCES t1,
    CONSTRAINT ck1 CHECK (pk > 0 and c1 > 0),
    CONSTRAINT ck2 CHECK (c2 > 0)
);
```

An error will be returned for the following statements:

/* The next two statements return errors: */
ALTER TABLE t1 DROP (pk);  -- pk is a parent key
ALTER TABLE t1 DROP (c1);  -- c1 is referenced by multicol
                        -- constraint ck1

Submitting the following statement drops column `pk`, the primary key constraint, the foreign key constraint, `ri`, and the check constraint, `ck1`:

```
ALTER TABLE t1 DROP (pk) CASCADE CONSTRAINTS;
```

If all columns referenced by the constraints defined on the dropped columns are also dropped, then `CASCADE CONSTRAINTS` is not required. For example, assuming that no other referential constraints from other tables refer to column `pk`, then it is valid to submit the following statement without the `CASCADE CONSTRAINTS` clause:

```
ALTER TABLE t1 DROP (pk, fk, c1);
```

**Dropping Unused Columns: Example**

The following statements create a new table to manipulate data and display the information in the newly created table:

```
CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;
```

```
SELECT * FROM JOBS_Temp WHERE MAX_SALARY > 20000;
```

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>JOB_TITLE</th>
<th>MIN_SALARY</th>
<th>MAX_SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AD_PRES</td>
<td>President</td>
<td>20080</td>
<td>40000</td>
</tr>
<tr>
<td>AD_VP</td>
<td>Administration Vice President</td>
<td>15000</td>
<td>30000</td>
</tr>
<tr>
<td>SA_MAN</td>
<td>Sales Manager</td>
<td>10000</td>
<td>20080</td>
</tr>
</tbody>
</table>

The following statement adds two new columns:

```
ALTER TABLE JOBS_Temp ADD (DUMMY1 NUMBER(2), DUMMY2 NUMBER(2));
```

The following statements inserts values into the newly added columns:
INSERT INTO JOBS_Temp(JOB_ID, JOB_TITLE, DUMMY1, DUMMY2) VALUES ('D', 'DUMMY', 10, 20);

The following statement sets the newly added columns to unused:
ALTER TABLE JOBS_TEMP SET UNUSED (DUMMY1, DUMMY2);

The following statement displays the count of unused columns:
SELECT * FROM USER_UNUSED_COL_TABS WHERE TABLE_NAME='JOBS_TEMP';

TABLE_NAME    COUNT
---------    ---------
JOBS_TEMP    2

The following statement drops the unused columns:
ALTER TABLE JOBS_TEMP DROP UNUSED COLUMNS;

The following statement displays the table information:
SELECT * FROM JOBS_TEMP;

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>JOB_TITLE</th>
<th>MIN_SALARY</th>
<th>MAX_SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>AD_PRES</td>
<td>President</td>
<td>20080</td>
<td>40000</td>
</tr>
<tr>
<td>AD_VP</td>
<td>Administration Vice President</td>
<td>15000</td>
<td>30000</td>
</tr>
<tr>
<td>AD_ASST</td>
<td>Administration Assistant</td>
<td>3000</td>
<td>6000</td>
</tr>
<tr>
<td>FI_MGR</td>
<td>Finance Manager</td>
<td>8200</td>
<td>16000</td>
</tr>
<tr>
<td>FI_ACCOUNT</td>
<td>Accountant</td>
<td>4200</td>
<td>9000</td>
</tr>
<tr>
<td>AC_MGR</td>
<td>Accounting Manager</td>
<td>8200</td>
<td>16000</td>
</tr>
<tr>
<td>AC_ACCOUNT</td>
<td>Public Accountant</td>
<td>4200</td>
<td>9000</td>
</tr>
<tr>
<td>SA_MAN</td>
<td>Sales Manager</td>
<td>10000</td>
<td>20080</td>
</tr>
<tr>
<td>SA_REP</td>
<td>Sales Representative</td>
<td>6000</td>
<td>12008</td>
</tr>
<tr>
<td>PU_MAN</td>
<td>Purchasing Manager</td>

<td>9000</td>
</tr>
<tr>
<td>PR_REP</td>
<td>Public Relations Representative</td>
<td>4500</td>
<td>10500</td>
</tr>
<tr>
<td>D</td>
<td>DUMMY</td>
<td></td>
<td></td>
</tr>
<tr>
<td>D</td>
<td>DUMMY</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Live SQL:
View and run a related example on Oracle Live SQL at Dropping Unused Columns

Modifying Index-Organized Tables: Examples
This statement modifies the INITRANS parameter for the index segment of index-organized table countries_demo, which is based on hr.countries:

```
ALTER TABLE countries_demo INITRANS 4;
```

The following statement adds an overflow data segment to index-organized table countries:

```
ALTER TABLE countries_demo ADD OVERFLOW;
```

This statement modifies the INITRANS parameter for the overflow data segment of index-organized table countries:

```
ALTER TABLE countries_demo OVERFLOW INITRANS 4;
```

### Splitting Table Partitions: Examples

The following statement splits the old partition sales_q4_2000 in the sample table sh.sales, creating two new partitions, naming one sales_q4_2000b and reusing the name of the old partition for the other:

```
ALTER TABLE sales SPLIT PARTITION SALES_Q4_2000
  AT (TO_DATE('15-NOV-2000','DD-MON-YYYY'))
  INTO (PARTITION SALES_Q4_2000, PARTITION SALES_Q4_2000b);
```

The following statement splits the old partition sales_q1_2002 into three new partitions sales_jan_2002, sales_feb_2002, and sales_mar_2002:

```
ALTER TABLE sales SPLIT PARTITION SALES_Q1_2002 INTO (PARTITION SALES_JAN_2002 VALUES LESS THAN (TO_DATE('01-FEB-2002','DD-MON-YYYY')), PARTITION SALES_FEB_2002 VALUES LESS THAN (TO_DATE('01-MAR-2002','DD-MON-YYYY')), PARTITION SALES_MAR_2002);
```

The following statements create a partitioned version of the pm.print_media table. The LONG column in the print_media table has been converted to LOB. The table is stored in tablespaces created in "Creating Oracle Managed Files: Examples". The object types underlying the ad_textdocs_ntab and ad_header columns are created in the script that creates the pm sample schema:

```
CREATE TABLE print_media_part (
  product_id NUMBER(6),
  ad_id NUMBER(6),
  ad_composite BLOB,
  ad_sourcetext CLOB,
  ad_finaltext CLOB,
  ad_fitextn NCLOB,
  ad_textdocs_ntab TEXTDOC_TAB,
  ad_photo BLOB,
  ad_graphic BFILE,
  ad_header ADHEADER_TYP)
NESTED TABLE ad_textdocs_ntab STORE AS textdoc_nt
PARTITION BY RANGE (product_id)
  (PARTITION p1 VALUES LESS THAN (100),
   PARTITION p2 VALUES LESS THAN (200));
```

The following statement splits partition p2 of that table into partitions p2a and p2b:

```
ALTER TABLE print_media_part
  SPLIT PARTITION p2 AT (150) INTO
```
In both partitions p2a and p2b, Oracle Database creates the LOB segments for columns ad_photo and ad_composite in tablespace omf_ts2. The LOB segments for the remaining columns in partition p2a are stored in tablespace omf_ts1. The LOB segments for the remaining columns in partition p2b remain in the tablespaces in which they resided prior to this ALTER statement. However, the database creates new segments for all the LOB data and LOB index segments, even if they are not moved to a new tablespace.

The database also creates new segments for nested table column ad_textdocs_ntab. The storage tables is those new segments are nt_p2a and nt_p2b.

**Merging Two Table Partitions: Example**

The following statement merges back into one partition the partitions created in "Splitting Table Partitions: Examples":

```sql
ALTER TABLE sales
MERGE PARTITIONS sales_q4_2000, sales_q4_2000b
INTO PARTITION sales_q4_2000;
```

The next statement reverses the example in "Splitting Table Partitions: Examples":

```sql
ALTER TABLE print_media_part
MERGE PARTITIONS p2a, p2b INTO PARTITION p2ab TABLESPACE example
NESTED TABLE ad_textdocs_ntab STORE AS nt_p2ab;
```

**Merging Four Adjacent Range Partitions: Example**

The following statement merges four adjacent range partitions, sales_q1_2000, sales_q2_2000, sales_q3_2000, and sales_q4_2000 into one partition sales_all_2000:

```sql
ALTER TABLE sales
MERGE PARTITIONS sales_q1_2000 TO sales_q4_2000
INTO PARTITION sales_all_2000;
```

**Adding a Table Partition with a LOB and Nested Table Storage: Examples**

The following statement adds a partition p3 to the print_media_part table (see preceding example) and specifies storage characteristics for the BLOB, CLOB, and nested table columns of that table:

```sql
ALTER TABLE print_media_part ADD PARTITION p3 VALUES LESS THAN (400)
LOB (ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts1)
LOB (ad_sourcetext, ad_finaltext) STORE AS (TABLESPACE omf_ts2)
NESTED TABLE ad_textdocs_ntab STORE AS nt_p3;
```

The LOB data and LOB index segments for columns ad_photo and ad_composite in partition p3 will reside in tablespace omf_ts1. The remaining attributes for these LOB columns will be inherited first from the table-level defaults, and then from the tablespace defaults.
The LOB data segments for columns `ad_source_text` and `ad_finaltext` will reside in the `omf_ts2` tablespace, and will inherit all other attributes first from the table-level defaults, and then from the tablespace defaults.

The partition for the storage table for nested table storage column `ad_textdocs_ntab` corresponding to partition `p3` of the base table is named `nt_p3` and inherits all other attributes first from the table-level defaults, and then from the tablespace defaults.

**Adding Multiple Partitions to a Table: Example**

The following statement adds three partitions to the table `print_media_part` created in "Splitting Table Partitions: Examples":

```sql
ALTER TABLE print_media_part ADD
  PARTITION p3 values less than (300),
  PARTITION p4 values less than (400),
  PARTITION p5 values less than (500);
```

**Working with Default List Partitions: Example**

The following statements use the list partitioned table created in "List Partitioning Example". The first statement splits the existing default partition into a new `south` partition and a default partition:

```sql
ALTER TABLE list_customers SPLIT PARTITION rest
  VALUES ('MEXICO', 'COLOMBIA')
  INTO (PARTITION south, PARTITION rest);
```

The next statement merges the resulting default partition with the `asia` partition:

```sql
ALTER TABLE list_customers
  MERGE PARTITIONS asia, rest INTO PARTITION rest;
```

The next statement re-creates the `asia` partition by splitting the default partition:

```sql
ALTER TABLE list_customers SPLIT PARTITION rest
  VALUES ('CHINA', 'THAILAND')
  INTO (PARTITION asia, PARTITION rest);
```

**Dropping a Table Partition: Example**

The following statement drops partition `p3` created in "Adding a Table Partition with a LOB and Nested Table Storage: Examples":

```sql
ALTER TABLE print_media_part DROP PARTITION p3;
```

**Exchanging Table Partitions: Example**

This example creates the table `exchange_table` with the same structure as the partitions of the `list_customers` table created in "List Partitioning Example". It then replaces partition `rest` of table `list_customers` with table `exchange_table` without exchanging local index partitions with corresponding indexes on `exchange_table` and without verifying that data in `exchange_table` falls within the bounds of partition `rest`:

```sql
CREATE TABLE exchange_table (
  customer_id     NUMBER(6),
  cust_first_name VARCHAR2(20),
  cust_last_name  VARCHAR2(20),
  cust_address    CUST_ADDRESS_TYP,
  nls_territory   VARCHAR2(30),
  cust_email      VARCHAR2(40));
```
ALTER TABLE list_customers
    EXCHANGE PARTITION rest WITH TABLE exchange_table
    WITHOUT VALIDATION;

Modifying Table Partitions: Examples

The following statement marks all the local index partitions corresponding to the asia partition of the list_customers table UNUSABLE:

ALTER TABLE list_customers MODIFY PARTITION asia UNUSABLE LOCAL INDEXES;

The following statement rebuilds all the local index partitions that were marked UNUSABLE:

ALTER TABLE list_customers MODIFY PARTITION asia REBUILD UNUSABLE LOCAL INDEXES;

Moving Table Partitions: Example

The following statement moves partition p2b (from "Splitting Table Partitions: Examples") to tablespace omf_ts1:

ALTER TABLE print_media_part
    MOVE PARTITION p2b TABLESPACE omf_ts1;

Renaming Table Partitions: Examples

The following statement renames a partition of the sh.sales table:

ALTER TABLE sales RENAME PARTITION sales_q4_2003 TO sales_currentq;

Truncating Table Partitions: Example

The following statement uses the print_media_demo table created in "Partitioned Table with LOB Columns Example". It deletes all the data in the p1 partition and deallocates the freed space:

ALTER TABLE print_media_demo
    TRUNCATE PARTITION p1 DROP STORAGE;

Updating Global Indexes: Example

The following statement splits partition sales_q1_2000 of the sample table sh.sales and updates any global indexes defined on it:

ALTER TABLE sales SPLIT PARTITION sales_q1_2000
    AT (TO_DATE('16-FEB-2000','DD-MON-YYYY'))
    INTO (PARTITION qa_2000, PARTITION qb_2000)
    UPDATE GLOBAL INDEXES;

Updating Partitioned Indexes: Example

The following statement splits partition costs_Q4_2003 of the sample table sh.costs and updates the local index defined on it. It uses the tablespaces created in "Creating Basic Tablespaces: Examples".

CREATE INDEX cost_ix ON costs(channel_id) LOCAL;

ALTER TABLE costs
    SPLIT PARTITION costs_q4_2003 at
Specifying Object Identifiers: Example

The following statements create an object type, a corresponding object table with a primary-key-based object identifier, and a table having a user-defined REF column:

```sql
CREATE TYPE emp_t AS OBJECT (empno NUMBER, address CHAR(30));
CREATE TABLE emp OF emp_t (
  empno PRIMARY KEY)
  OBJECT IDENTIFIER IS PRIMARY KEY;
CREATE TABLE dept (dno NUMBER, mgr_ref REF emp_t SCOPE is emp);
```

The next statements add a constraint and a user-defined REF column, both of which reference table `emp`:

```sql
ALTER TABLE dept ADD CONSTRAINT mgr_cons FOREIGN KEY (mgr_ref) REFERENCES emp;
ALTER TABLE dept ADD sr_mgr REF emp_t REFERENCES emp;
```

Adding a Table Column: Example

The following statement adds to the `countries` table a column named `duty_pct` of data type NUMBER and a column named `visa_needed` of data type VARCHAR2 with a size of 3 and a CHECK integrity constraint:

```sql
ALTER TABLE countries
  ADD (duty_pct     NUMBER(2,2)  CHECK (duty_pct < 10.5),
       visa_needed  VARCHAR2(3));
```

Adding a Virtual Table Column: Example

The following statement adds to a copy of the `hr.employees` table a column named `income`, which is a combination of salary plus commission. Both salary and commission are NUMBER columns, so the database creates the virtual column as a NUMBER column even though the data type is not specified in the statement:

```sql
CREATE TABLE emp2 AS SELECT * FROM employees;
ALTER TABLE emp2 ADD (income AS (salary + (salary*commission_pct)));
```

Modifying Table Columns: Examples

The following statement increases the size of the `duty_pct` column:

```sql
ALTER TABLE countries
  MODIFY (duty_pct NUMBER(3,2));
```

Because the MODIFY clause contains only one column definition, the parentheses around the definition are optional.

The following statement changes the values of the PCTFREE and PCTUSED parameters for the `employees` table to 30 and 60, respectively:
ALTER TABLE employees
  PCTFREE 30
  PCTUSED 60;

Modifying Storage Attributes for a Table

The following statement creates a table named JOBS_TEMP by using the existing JOBS table:

CREATE TABLE JOBS_TEMP AS SELECT * FROM HR.JOBS;

The following statement queries the USER_TABLES table for storage parameters:

```
SELECT initial_extent,
       next_extent,
       min_extents,
       max_extents,
       pct_increase,
       blocks,
       sample_size
FROM   user_tables
WHERE  table_name = 'JOBS_TEMP';
```

```
INITIAL_EXTENT NEXT_EXTENT MIN_EXTENTS MAX_EXTENTS PCT_INCREASE
-------------- ----------- ----------- ----------- ------------
65536        1048576           1
2147483645                       1          19
```

The following statement alters the JOBS_TEMP table with new storage parameters:

```
ALTER TABLE JOBS_TEMP MOVE
  STORAGE ( INITIAL 20K
            NEXT 40K
            MINEXTENTS 2
            MAXEXTENTS 20
            PCTINCREASE 0 )
  TABLESPACE USERS;
```

The following statement queries the USER_TABLES table for the new storage parameters:

```
SELECT initial_extent,
       next_extent,
       min_extents,
       max_extents,
       pct_increase,
       blocks,
       sample_size
FROM   user_tables
WHERE  table_name = 'JOBS_TEMP';
```
### Adding, Altering, Renaming and Dropping Table Columns: Example

The following statements create a new table to manipulate data and display the information in the newly created table:

```sql
CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;
SELECT * FROM JOBS_Temp WHERE MAX_SALARY > 30000;
```

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>JOB_TITLE</th>
<th>MIN_SALARY</th>
<th>MAX_SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>AD_PRES</td>
<td>President</td>
<td>20080</td>
<td>40000</td>
</tr>
</tbody>
</table>

The following statement modifies an existing column definition:

```sql
ALTER TABLE JOBS_Temp MODIFY(JOB_TITLE VARCHAR2(100));
```

The following statement adds two new columns to the table:

```sql
ALTER TABLE JOBS_Temp ADD (BONUS NUMBER (7,2), COMM NUMBER (5,2), DUMMY NUMBER(2));
```

The following statement displays the newly added columns:

```sql
SELECT JOB_ID, BONUS, COMM, DUMMY FROM JOBS_Temp WHERE MAX_SALARY > 20000;
```

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>BONUS</th>
<th>COMM</th>
<th>DUMMY</th>
</tr>
</thead>
<tbody>
<tr>
<td>AD_PRES</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AD_VP</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SA_MAN</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following statements rename an existing column and display the modified column:

```sql
ALTER TABLE JOBS_Temp RENAME COLUMN COMM TO COMMISSION;
SELECT JOB_ID, COMMISSION FROM JOBS_Temp WHERE MAX_SALARY > 20000;
```

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>COMMISSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>AD_PRES</td>
<td></td>
</tr>
<tr>
<td>AD_VP</td>
<td></td>
</tr>
<tr>
<td>SA_MAN</td>
<td></td>
</tr>
</tbody>
</table>

The following statement drops a single column from the table:
ALTER TABLE JOBS_Temp DROP COLUMN DUMMY;

The following statement drops multiple columns from the table:

ALTER TABLE JOBS_Temp DROP (BONUS, COMMISSION);

---

Live SQL:

View and run a related example on Oracle Live SQL at Modifying Table Columns

---

Data Encryption: Examples

The following statement encrypts the salary column of the hr.employees table using the encryption algorithm AES256. As described in "Semantics" above, you must first enable Transparent Data Encryption:

```
ALTER TABLE employees
  MODIFY (salary ENCRYPT USING 'AES256' 'NOMAC');
```

The following statement adds a new encrypted column online_acct_pw to the oe.customers table, using the default encryption algorithm AES192. Specifying NO SALT will allow a B-tree index to be created on the column, if desired.

```
ALTER TABLE customers
  ADD (online_acct_pw VARCHAR2(8) ENCRYPT 'NOMAC' NO SALT);
```

The following example decrypts the customer.online_acct_pw column:

```
ALTER TABLE customers
  MODIFY (online_acct_pw DECRYPT);
```

Allocating Extents: Example

The following statement allocates an extent of 5 kilobytes for the employees table and makes it available to instance 4:

```
ALTER TABLE employees
  ALLOCATE EXTENT (SIZE 5K INSTANCE 4);
```

Because this statement omits the DATAFILE parameter, Oracle Database allocates the extent in one of the data files belonging to the tablespace containing the table.

Specifying a Default Column Value: Examples

This statement modifies the min_price column of the product_information table so that it has a default value of 10:

```
ALTER TABLE product_information
  MODIFY (min_price DEFAULT 10);
```

If you subsequently add a new row to the product_information table and do not specify a value for the min_price column, then the value of the min_price column is automatically 10:

```
INSERT INTO product_information (product_id, product_name, list_price)
  VALUES (300, 'left-handed mouse', 40.50);
```
SELECT product_id, product_name, list_price, min_price
FROM product_information
WHERE product_id = 300;

PRODUCT_ID PRODUCT_NAME LIST_PRICE MIN_PRICE
---------- -------------------- ---------- ----------
300 left-handed mouse 40.5 10

To discontinue previously specified default values, so that they are no longer automatically inserted into newly added rows, replace the values with NULL, as shown in this statement:

ALTER TABLE product_information
MODIFY (min_price DEFAULT NULL);

The MODIFY clause need only specify the column name and the modified part of the definition, rather than the entire column definition. This statement has no effect on any existing values in existing rows.

The following example adds a column defined with DEFAULT ON NULL to a table. The DEFAULT column value includes the sequence pseudocolumn NEXTVAL.

Create sequence s1 and table t1 as follows:

CREATE SEQUENCE s1 START WITH 1;
CREATE TABLE t1 (name VARCHAR2(10));
INSERT INTO t1 VALUES('Kevin');
INSERT INTO t1 VALUES('Julia');
INSERT INTO t1 VALUES('Ryan');

Add column id, which defaults to s1.NEXTVAL. The default column value for id is assigned to each existing row in the table. The order in which s1.NEXTVAL is assigned to each row is nondeterministic.

ALTER TABLE t1 ADD (id NUMBER DEFAULT ON NULL s1.NEXTVAL NOT NULL);

SELECT id, name FROM t1 ORDER BY id;

ID NAME
-------- ----
1 Kevin   
2 Julia   
3 Ryan

If you subsequently add a new row to the table and specify a NULL value for the id column, then the DEFAULT ON NULL expression s1.NEXTVAL is inserted.

INSERT INTO t1(id, name) VALUES(NULL, 'Sean');

SELECT id, name FROM t1 ORDER BY id;

ID NAME
-------- ----
1 Kevin   
2 Julia   
3 Ryan   
4 Sean

Adding a Constraint to an XMLType Table: Example
The following example adds a primary key constraint to the `xwarehouses` table, created in "XMLType Examples":

```
ALTER TABLE xwarehouses
  ADD (PRIMARY KEY(XMLDATA."WarehouseID"));
```

Refer to XMLDATA Pseudocolumn for information about this pseudocolumn.

Renaming Constraints: Example

The following statement renames the `cust_fname_nn` constraint on the sample table `oe.customers` to `cust_firstname_nn`:

```
ALTER TABLE customers RENAME CONSTRAINT cust_fname_nn TO cust_firstname_nn;
```

Dropping Constraints: Examples

The following statement drops the primary key of the `departments` table:

```
ALTER TABLE departments
  DROP PRIMARY KEY CASCADE;
```

If you know that the name of the PRIMARY KEY constraint is `pk_dept`, then you could also drop it with the following statement:

```
ALTER TABLE departments
  DROP CONSTRAINT pk_dept CASCADE;
```

The CASCADE clause causes Oracle Database to drop any foreign keys that reference the primary key.

The following statement drops the unique key on the email column of the employees table:

```
ALTER TABLE employees
  DROP UNIQUE (email);
```

The DROP clause in this statement omits the CASCADE clause. Because of this omission, Oracle Database does not drop the unique key if any foreign key references it.

LOB Columns: Examples

The following statement adds CLOB column `resume` to the employee table and specifies LOB storage characteristics for the new column:

```
ALTER TABLE employees ADD (resume CLOB)
  LOB (resume) STORE AS resume_seg (TABLESPACE example);
```

To modify the LOB column `resume` to use caching, enter the following statement:

```
ALTER TABLE employees MODIFY LOB (resume) (CACHE);
```

The following statement adds a SecureFiles CLOB column `resume` to the employee table and specifies LOB storage characteristics for the new column. SecureFiles LOBs must be stored in tablespaces with automatic segment-space management. Therefore, the LOB data in this example is stored in the `auto_seg_ts` tablespace, which was created in "Specifying Segment Space Management for a Tablespace: Example":

```
ALTER TABLE employees ADD (resume CLOB)
  LOB (resume) STORE AS SECUREFILE resume_seg (TABLESPACE auto_seg_ts);
```
To modify the LOB column `resume` so that it does not use caching, enter the following statement:

```
ALTER TABLE employees MODIFY LOB (resume) (NOCACHE);
```

**Nested Tables: Examples**

The following statement adds the nested table column `skills` to the `employee` table:

```
ALTER TABLE employees ADD (skills skill_table_type)
    NESTED TABLE skills STORE AS nested_skill_table;
```

You can also modify nested table storage characteristics. Use the name of the storage table specified in the `nested_table_col_properties` to make the modification. You cannot query or perform DML statements on the storage table. Use the storage table only to modify the nested table column storage characteristics.

The following statement creates table `vet_service` with nested table column `client` and storage table `client_tab`. Nested table `client_tab` is modified to specify constraints:

```sql
CREATE TYPE pet_t AS OBJECT
    (pet_id NUMBER, pet_name VARCHAR2(10), pet_dob DATE);
/
CREATE TYPE pet AS TABLE OF pet_t;
/
CREATE TABLE vet_service (vet_name VARCHAR2(30),
    client pet)
    NESTED TABLE client STORE AS client_tab;
ALTER TABLE client_tab ADD UNIQUE (pet_id);
```

The following statement alters the storage table for a nested table of `REF` values to specify that the `REF` is scoped:

```sql
CREATE TYPE emp_t AS OBJECT (eno number, ename char(31));
CREATE TYPE emps_t AS TABLE OF REF emp_t;
CREATE TABLE emptab OF emp_t;
CREATE TABLE dept (dno NUMBER, employees emps_t)
    NESTED TABLE employees STORE AS deptemps;
ALTER TABLE deptemps ADD (SCOPE FOR (COLUMN_VALUE) IS emptab);
```

Similarly, to specify storing the `REF` with rowid:

```sql
ALTER TABLE deptemps ADD (REF(column_value) WITH ROWID);
```

In order to execute these `ALTER TABLE` statements successfully, the storage table `deptemps` must be empty. Also, because the nested table is defined as a table of scalar values (`REF` values), Oracle Database implicitly provides the column name `COLUMN_VALUE` for the storage table.
REF Columns: Examples

The following statement creates an object type `dept_t` and then creates table `staff`:

```
CREATE TYPE dept_t AS OBJECT
  (deptno NUMBER, dname VARCHAR2(20));
/
CREATE TABLE staff
  (name   VARCHAR2(100),
   salary NUMBER,
   dept   REF dept_t);
```

An object table `offices` is created as:

```
CREATE TABLE offices OF dept_t;
```

The `dept` column can store references to objects of `dept_t` stored in any table. If you would like to restrict the references to point only to objects stored in the `departments` table, then you could do so by adding a scope constraint on the `dept` column as follows:

```
ALTER TABLE staff
  ADD (SCOPE FOR (dept) IS offices);
```

The preceding `ALTER TABLE` statement will succeed only if the `staff` table is empty.

If you want the `REF` values in the `dept` column of `staff` to also store the rowids, then issue the following statement:

```
ALTER TABLE staff
  ADD (REF(dept) WITH ROWID);
```

Unpacked Storage in ANYDATA Columns: Example

This example creates a table with an `ANYDATA` column, stores opaque data types in the `ANYDATA` column using unpacked storage, and then queries the data types. This example assumes that you are connected to the database as user `hr`.

Create table `t1`, which contains a `NUMBER` column `n` and an `ANYDATA` column `x`:

```
CREATE TABLE t1 (n NUMBER, x ANYDATA);
```

Create an object type `clob_typ`, which contains a CLOB attribute:

```
CREATE OR REPLACE TYPE clob_typ AS OBJECT (c clob);
/
```

Enable unpacked storage of the opaque data types `XMLType` and `clob_typ` in `ANYDATA` column `x` of table `t1`:
ALTER TABLE t1 MODIFY OPAQUE TYPE x STORE (XMLType, clob_typ) UNPACKED;

Insert XMLType and clob_typ objects into table t1. These types will use unpacked storage:

INSERT INTO t1
VALUES(1, anydata.convertobject(XMLType('<Test>This is test XML</Test>')));

INSERT INTO t1
VALUES(2, anydata.convertobject(clob_typ(TO_CLOB('This is a test CLOB'))));

Query table t1 to view the names of the types stored in ANYDATA column x:

SELECT t1.*, anydata.getTypeName(t1.x) typename FROM t1;

<table>
<thead>
<tr>
<th>N</th>
<th>X()</th>
<th>TYPENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANYDATA()</td>
<td>SYS.XMLTYPE</td>
</tr>
<tr>
<td>2</td>
<td>ANYDATA()</td>
<td>HR.CLOB_TYP</td>
</tr>
</tbody>
</table>

Create functions that allow you to query the values stored in the XMLType and clob_typ data types:

CREATE FUNCTION get_xmltype (ad IN ANYDATA) RETURN VARCHAR2 AS
  rtn_val PLS_INTEGER;
  my_xmltype XMLType;
  string_val VARCHAR2(30);
  BEGIN
    rtn_val := ad.getObject(my_xmltype);
    string_val := my_xmltype.getstringval();
    RETURN (string_val);
  END;
/

CREATE FUNCTION get_clob_typ (ad IN ANYDATA) RETURN VARCHAR2 AS
  rtn_val PLS_INTEGER;
  my_clob_typ clob_typ;
  string_val VARCHAR2(30);
  BEGIN
    rtn_val := ad.getObject(my_clob_typ);
    string_val := (my_clob_typ.c);
    RETURN (string_val);
  END;
/

Query table t1 to view the values stored in each data type in ANYDATA column x:

SELECT t1.*, anydata.getTypeName(t1.x) typename, CASE
  WHEN anydata.gettypename(t1.x) = 'SYS.XMLTYPE' THEN get_xmltype(t1.x)
  WHEN anydata.gettypename(t1.x) = 'HR.CLOB_TYP' THEN get_clob_typ(t1.x)
END string_value FROM t1;

<table>
<thead>
<tr>
<th>N</th>
<th>X()</th>
<th>TYPENAME</th>
<th>STRING_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANYDATA()</td>
<td>SYS.XMLTYPE</td>
<td>&lt;Test&gt;This is test XML&lt;/Test&gt;</td>
</tr>
<tr>
<td>2</td>
<td>ANYDATA()</td>
<td>HR.CLOB_TYP</td>
<td>This is a test CLOB</td>
</tr>
</tbody>
</table>

Additional Examples
For examples of defining integrity constraints with the ALTER TABLE statement, see the constraint.

For examples of changing the storage parameters of a table, see the storage_clause.

**ALTER TABLESPACE**

**Purpose**

Use the ALTER TABLESPACE statement to alter an existing tablespace or one or more of its data files or temp files.

You cannot use this statement to convert a dictionary-managed tablespace to a locally managed tablespace. For that purpose, use the DBMS_SPACE_ADMIN package, which is documented in Oracle Database PL/SQL Packages and Types Reference.

**Prerequisites**

To alter the SYSAUX tablespace, you must have the SYSDBA system privilege.

If you have the ALTER TABLESPACE system privilege, then you can perform any ALTER TABLESPACE operation. If you have the MANAGE TABLESPACE system privilege, then you can only perform the following operations:

- Take a tablespace online or offline
- Begin or end a backup
- Make a tablespace read only or read write
- Change the state of a tablespace to **PERMANENT** or **TEMPORARY**
- Set the default logging mode of a tablespace to **LOGGING** or **NOLOGGING**
- Put a tablespace in force logging mode or take it out of force logging mode
- Rename a tablespace or a tablespace data file
- Specify **RETENTION GUARANTEE** or **RETENTION NOGUARANTEE** for an undo tablespace
- Resize a data file for a tablespace
- Enable or disable autoextension of a data file for a tablespace
- Shrink the amount of space a temporary tablespace or a temp file is taking

Before you can make a tablespace read only, the following conditions must be met:

- The tablespace must be online.
- The tablespace must not contain any active rollback segments. For this reason, the SYSTEM tablespace can never be made read only, because it contains the SYSTEM rollback segment. Additionally, because the rollback segments of a read-
only tablespace are not accessible, Oracle recommends that you drop the rollback
segments before you make a tablespace read only.

- The tablespace must not be involved in an open backup, because the end of a
backup updates the header file of all data files in the tablespace.

Performing this function in restricted mode may help you meet these restrictions,
because only users with RESTRICTED SESSION system privilege can be logged on.

Syntax

```
alter_tablespace::=
```

```
ALTER TABLESPACE tablespace alter_tablespace_attr;
```

```
(alter_tablespace_attr::=)

---

Chapter 12
ALTER TABLESPACE

12-182
Semantics

tablespace

Specify the name of the tablespace to be altered.

Restrictions on Altering Tablespaces

Altering tablespaces is subject to the following restrictions:

- If tablespace is an undo tablespace, then the only other clauses you can specify in this statement are ADD DATAFILE, RENAME DATAFILE, RENAME TO (renaming the tablespace), DATAFILE ... ONLINE, DATAFILE ... OFFLINE, BEGIN BACKUP, and END BACKUP.

- You cannot make the SYSTEM tablespace read only or temporary and you cannot take it offline.

- For locally managed temporary tablespaces, the only clause you can specify in this statement is the ADD clause.

See Also:
Oracle Database Administrator's Guide for information on automatic undo management and undo tablespaces

alter_tablespace_attrs

Use the alter_tablespace_attrs clauses to change the attributes of the tablespace.

default_tablespace_params

This clause lets you specify new default parameters for the tablespace. The new default parameters apply to objects subsequently created in the tablespace.

The clauses default_table_compression, default_index_compression, inmemory_clause, ilm_clause, and storage_clause have the same semantics in CREATE TABLESPACE and ALTER TABLESPACE. For complete information on these clauses, refer to the default_tablespace_params clause in the documentation on CREATE TABLESPACE.

MINIMUM EXTENT

This clause is valid only for permanent dictionary-managed tablespaces. The MINIMUM EXTENT clause lets you control free space fragmentation in the tablespace by ensuring that every used or free extent in a tablespace is at least as large as, and is a multiple of, the value specified in the size_clause.

Restriction on MINIMUM EXTENT

You cannot specify this clause for a locally managed tablespace or for a dictionary-managed temporary tablespace.
RESIZE Clause

This clause is valid only for bigfile tablespaces, including shadow tablespaces which store lost write protection tracking data. It lets you increase or decrease the size of the single data file to an absolute size. Use K, M, G, or T to specify the size in kilobytes, megabytes, gigabytes, or terabytes, respectively.

To change the size of a newly added data file or temp file in smallfile tablespaces, use the ALTER DATABASE ... autoextend_clause (see database_file_clauses).

COALESCE

For each data file in the tablespace, this clause combines all contiguous free extents into larger contiguous extents.

SHRINK SPACE Clause

This clause is valid only for temporary tablespaces. It lets you reduce the amount of space the tablespace is taking. In the optional KEEP clause, the size_clause defines the lower bound that a tablespace can be shrunk to. It is the opposite of MAXSIZE for an autoextensible tablespace. If you omit the KEEP clause, then the database will attempt to shrink the tablespace as much as possible as long as other tablespace storage attributes are satisfied.

RENAME Clause

Use this clause to rename tablespace. This clause is valid only if tablespace and all its data files are online and the COMPATIBLE parameter is set to 10.0.0 or greater. You can rename both permanent and temporary tablespaces.

If tablespace is read only, then Oracle Database does not update the data file headers to reflect the new name. The alert log will indicate that the data file headers have not been updated.
Note:

If you re-create the control file, and if the data files that Oracle Database uses for this purpose are restored backups whose headers reflect the old tablespace name, then the re-created control file will also reflect the old tablespace name. However, after the database is fully recovered, the control file will reflect the new name.

If *tablespace* has been designated as the undo tablespace for any instance in an Oracle Real Application Clusters (Oracle RAC) environment, and if a server parameter file was used to start up the database, then Oracle Database changes the value of the *UNDO_TABLESPACE* parameter for that instance in the server parameter file (*SPFILE*) to reflect the new tablespace name. If a single-instance database is using a parameter file (*pfile*) instead of an *spfile*, then the database puts a message in the alert log advising the database administrator to change the value manually in the *pfile*.

Note:

The `RENAME` clause does not change the value of the *UNDO_TABLESPACE* parameter in the running instance. Although this does not affect the functioning of the undo tablesapce, Oracle recommends that you issue the following statement to manually change the value of *UNDO_TABLESPACE* to the new tablespace name for the duration of the instance:

```
ALTER SYSTEM SET UNDO_TABLESPACE = new_tablespace_name SCOPE = MEMORY;
```

You only need to issue this statement once. If the *UNDO_TABLESPACE* parameter is set to the new tablespace name in the *pfile* or *spfile*, then the parameter will be set correctly when the instance is next restarted.

Restriction on Renaming Tablespaces

You cannot rename the *SYSTEM* or *SYSAUX* tablespaces.

BACKUP Clauses

Use these clauses to move all data files in a tablespace into or out of online (sometimes called hot) backup mode.

See Also:

- *Oracle Database Administrator's Guide* for information on restarting the database without media recovery
- `ALTER DATABASE "BACKUP Clauses"` for information on moving all data files in the database into and out of online backup mode
- `ALTER DATABASE alter_datafile_clause` for information on taking individual data files out of online backup mode
BEGIN BACKUP

Specify **BEGIN BACKUP** to indicate that an open backup is to be performed on the data files that make up this tablespace. This clause does not prevent users from accessing the tablespace. You must use this clause before beginning an open backup.

**Restrictions on Beginning Tablespace Backup**

Beginning tablespace backup is subject to the following restrictions:

- You cannot specify this clause for a read-only tablespace or for a temporary locally managed tablespace.
- While the backup is in progress, you cannot take the tablespace offline normally, shut down the instance, or begin another backup of the tablespace.

[See Also:](#) "Backing Up Tablespaces: Examples"

END BACKUP

Specify **END BACKUP** to indicate that an online backup of the tablespace is complete. Use this clause as soon as possible after completing an online backup. Otherwise, if an instance failure or **SHUTDOWN ABORT** occurs, then Oracle Database assumes that media recovery (possibly requiring archived redo log) is necessary at the next instance startup.

**Restriction on Ending Tablespace Backup**

You cannot use this clause on a read-only tablespace.

**datafile_tempfile_clauses**

The tablespace file clauses let you add or modify a data file or temp file.

**ADD Clause**

Specify **ADD** to add to the tablespace a data file or temp file specified by **file_specification**. Use the **datafile_tempfile_spec** form of **file_specification** (see [file_specification](#)) to list regular data files and temp files in an operating system file system or to list Oracle Automatic Storage Management disk group files.

For locally managed temporary tablespaces, this is the only clause you can specify at any time.

If you omit **file_specification**, then Oracle Database creates an Oracle Managed File of 100M with **AUTOEXTEND** enabled.

You can add a data file or temp file to a locally managed tablespace that is online or to a dictionary managed tablespace that is online or offline. Ensure the file is not in use by another database.

**Restriction on Adding Data Files and Temp Files**

You cannot specify this clause for a bigfile (single-file) tablespace, as such a tablespace has only one data file or temp file.
Note:

On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

See Also:

`file_specification`, "Adding and Dropping Data Files and Temp Files: Examples", and "Adding an Oracle-managed Data File: Example"

DROP Clause

Specify `DROP` to drop from the tablespace an empty data file or temp file specified by `filename` or `file_number`. This clause causes the data file or temp file to be removed from the data dictionary and deleted from the operating system. The database must be open at the time this clause is specified.

The `ALTER TABLESPACE ... DROP TEMPFILE` statement is equivalent to specifying the `ALTER DATABASE TEMPFILE ... DROP INCLUDING DATAFILES`.

Restrictions on Dropping Files

To drop a data file or temp file, the data file or temp file:

- Must be empty.
- Cannot be the first data file that was created in the tablespace. In such cases, drop the tablespace instead.
- Cannot be in a read-only tablespace that was migrated from dictionary managed to locally managed. Dropping a data file from all other read-only tablespaces is supported.
- Cannot be offline.

See Also:

- `ALTER DATABASE alter_tempfile_clause` for additional information on dropping temp files
- `Oracle Database Administrator's Guide` for information on data file numbers and for guidelines on managing data files
- "Adding and Dropping Data Files and Temp Files: Examples"
**SHRINK TEMPFILE Clause**

This clause is valid only when altering a temporary tablespace. It lets you reduce the amount of space the specified temp file is taking. In the optional `KEEP` clause, the `size_clause` defines the lower bound that the temp file can be shrunk to. It is the opposite of `MAXSIZE` for an autoextensible tablespace. If you omit the `KEEP` clause, then the database will attempt to shrink the temp file as much as possible as long as other storage attributes are satisfied.

**RENAME DATAFILE Clause**

Specify `RENAME DATAFILE` to rename one or more of the tablespace data files. The database must be open, and you must take the tablespace offline before renaming it. Each `filename` must fully specify a data file using the conventions for filenames on your operating system.

This clause merely associates the tablespace with the new file rather than the old one. This clause does not actually change the name of the operating system file. You must change the name of the file through your operating system.

---

**See Also:**

"Moving and Renaming Tablespaces: Example"

---

**ONLINE | OFFLINE Clauses**

Use these clauses to take all data files or temp files in the tablespace offline or put them online. These clauses have no effect on the `ONLINE` or `OFFLINE` status of the tablespace itself.

The database must be mounted. If `tablespace` is `SYSTEM`, or an undo tablespace, or the default temporary tablespace, then the database must not be open.

**`tablespace_logging_clauses`**

Use these clauses to set or change the logging characteristics of the tablespace.

**`logging_clause`**

Specify `LOGGING` if you want logging of all tables, indexes, and partitions within the tablespace. The tablespace-level logging attribute can be overridden by logging specifications at the table, index, and partition levels.

When an existing tablespace logging attribute is changed by an `ALTER TABLESPACE` statement, all tables, indexes, and partitions created `after` the statement will have the new default logging attribute (which you can still subsequently override). The logging attribute of existing objects is not changed.

If the tablespace is in `FORCE LOGGING` mode, then you can specify `Nologging` in this statement to set the default logging mode of the tablespace to `FORCE LOGGING`, but this will not take the tablespace out of `FORCE LOGGING` mode.

**[NO] FORCE LOGGING**
Use this clause to put the tablespace in force logging mode or take it out of force logging mode. The database must be open and in READ WRITE mode. Neither of these settings changes the default LOGGING or NOLOGGING mode of the tablespace.

**Restriction on Force Logging Mode**

You cannot specify FORCE LOGGING for an undo or a temporary tablespace.

> See Also:

*Oracle Database Administrator’s Guide* for information on when to use FORCE LOGGING mode and "Changing Tablespace Logging Attributes: Example"

**tablespace_group_clause**

This clause is valid only for locally managed temporary tablespaces. Use this clause to add *tablespace* to or remove it from the *tablespace_group_name* tablespace group.

- Specify a group name to indicate that *tablespace* is a member of this tablespace group. If *tablespace_group_name* does not already exist, then Oracle Database implicitly creates it when you alter tablespace to be a member of it.
- Specify an empty string (' ') to remove *tablespace* from the *tablespace_group_name* tablespace group.

**Restriction on Tablespace Groups**

You cannot specify a tablespace group for a permanent tablespace or for a dictionary-managed temporary tablespace.

> See Also:

*Oracle Database Administrator's Guide* for more information on tablespace groups and "Assigning a Tablespace Group: Example"

**tablespace_state_clauses**

Use these clauses to set or change the state of the tablespace.

**ONLINE | OFFLINE**

Specify ONLINE to bring the tablespace online. Specify OFFLINE to take the tablespace offline and prevent further access to its segments. When you take a tablespace offline, all of its data files are also offline.
Before taking a tablespace offline for a long time, consider changing the tablespace allocation of any users who have been assigned the tablespace as either a default or temporary tablespace. While the tablespace is offline, such users cannot allocate space for objects or sort areas in the tablespace. See ALTER USER for more information on allocating tablespace quota to users.

Restriction on Taking Tablespaces Offline

You cannot take a temporary tablespace offline.

OFFLINE NORMAL

Specify NORMAL to flush all blocks in all data files in the tablespace out of the system global area (SGA). You need not perform media recovery on this tablespace before bringing it back online. This is the default.

OFFLINE TEMPORARY

If you specify TEMPORARY, then Oracle Database performs a checkpoint for all online data files in the tablespace but does not ensure that all files can be written. Files that are offline when you issue this statement may require media recovery before you bring the tablespace back online.

OFFLINE IMMEDIATE

If you specify IMMEDIATE, then Oracle Database does not ensure that tablespace files are available and does not perform a checkpoint. You must perform media recovery on the tablespace before bringing it back online.

The FOR RECOVER setting for ALTER TABLESPACE ... OFFLINE has been deprecated. The syntax is supported for backward compatibility. However, Oracle recommends that you use the transportable tablespaces feature for tablespace recovery.

Specify READ ONLY to place the tablespace in transition read-only mode. In this state, existing transactions can complete (commit or roll back), but no further DML operations are allowed to the tablespace except for rollback of existing transactions.
that previously modified blocks in the tablespace. You cannot make the SYSAUX, SYSTEM, or temporary tablespaces READ ONLY.

When a tablespace is read only, you can copy its files to read-only media. You must then rename the data files in the control file to point to the new location by using the SQL statement ALTER DATABASE ... RENAME.

**See Also:**

- *Oracle Database Concepts* for more information on read-only tablespaces
- ALTER DATABASE

Specify READ WRITE to indicate that write operations are allowed on a previously read-only tablespace.

**PERMANENT | TEMPORARY**

Specify PERMANENT to indicate that the tablespace is to be converted from a temporary to a permanent tablespace. A permanent tablespace is one in which permanent database objects can be stored. This is the default when a tablespace is created.

Specify TEMPORARY to indicate that the tablespace is to be converted from a permanent to a temporary tablespace. A temporary tablespace is one in which no permanent database objects can be stored. Objects in a temporary tablespace persist only for the duration of the session.

**Restrictions on Temporary Tablespaces**

Temporary tablespaces are subject to the following restrictions:

- You cannot specify TEMPORARY for the SYSAUX tablespace.
- If tablespace was not created with a standard block size, then you cannot change it from permanent to temporary.
- You cannot specify TEMPORARY for a tablespace in FORCE LOGGING mode.

**autoextend_clause**

This clause is valid only for bigfile (single-file) tablespaces. Use this clause to enable or disable autoextension of the single data file in the tablespace. To enable or disable autoextension of a newly added data file or temp file in smallfile tablespaces, use the `autoextend_clause` of the `database_file_clauses` in the ALTER DATABASE statement.

**See Also:**

- *Oracle Database Administrator's Guide* for information about bigfile (single-file) tablespaces
- *file_specification* for more information about the `autoextend_clause`
**flashback_mode_clause**

Use this clause to specify whether this tablespace should participate in any subsequent `FLASHBACK DATABASE` operation.

- For you to turn `FLASHBACK` mode on, the database must be mounted and closed.
- For you to turn `FLASHBACK` mode off, the database must be mounted, either open `READ WRITE` or closed.

This clause is not valid for temporary tablespaces.

Refer to `CREATE TABLESPACE` for more complete information on this clause.

**See Also:**

`Oracle Database Backup and Recovery User's Guide` for more information about Flashback Database

**tablespace_retention_clause**

This clause has the same semantics in `CREATE TABLESPACE` and `ALTER TABLESPACE` statements. Refer to `tablespace_retention_clause` in the documentation on `CREATE TABLESPACE`.

**alter_tablespace_encryption**

These clauses let you encrypt, decrypt, or rekey the tablespace.

**OFFLINE**

This clause lets you encrypt or decrypt the tablespace with offline conversion. The tablespace must be offline or the database must be mounted, but not open. The offline conversion method does not use auxiliary disk space or files; it operates directly on the existing datafiles. Therefore, you should perform a full backup of the tablespace before converting it offline.

- Specify `ENCRYPT` to encrypt the tablespace. You can encrypt the tablespace using AES128, AES192, or AES256 algorithms. The tablespace must be unencrypted.
- Specify `DECRYPT` to decrypt the tablespace. The tablespace must have been previously encrypted with offline conversion (`OFFLINE ENCRYPT`).

If an offline conversion operation is interrupted, then you can reissue the offline conversion command to finish the operation.

**ONLINE**

This clause lets you encrypt, decrypt, or rekey the tablespace with online conversion. The tablespace must be online. The online conversion method creates a new datafile for each datafile in the tablespace. Therefore, before using this clause, ensure that the amount of free disk space is greater than or equal to the amount of disk space currently used by the tablespace.

- Specify `ENCRYPT` to encrypt the tablespace. The tablespace must be unencrypted.
• Specify `REKEY` to encrypt an encrypted the tablespace using a different encryption algorithm. The tablespace must have been encrypted when it was created or encrypted with online conversion (`ONLINE ENCRYPT`).

• Specify `DECRYPT` to decrypt the tablespace. The tablespace must have been encrypted when it was created or encrypted with online conversion (`ONLINE ENCRYPT`).

If an online conversion operation is interrupted, then you can issue the `FINISH` clause to finish the operation. Refer to the `FINISH` clause.

`tablespace_encryption_spec`

Use this clause to specify the encryption algorithm to use when encrypting or rekeying the tablespace. If you omit this clause, then the datafiles will be encrypted using the `AES128` algorithm. Refer to `tablespace_encryption_spec` in the documentation on `CREATE TABLESPACE` for the full semantics of this clause.

`ts_file_name_convert`

Use this clause to determine how the database generates the names of the new datafiles that are created during online conversion.

If `FILE_NAME_CONVERT` is omitted, Oracle will internally select a name for the auxiliary file, and later rename it back to the original name.

- For `filename_pattern`, specify a string found in an existing datafile name.
- For `replacement_filename_pattern`, specify a replacement string. Oracle Database will replace `filename_pattern` with `replacement_filename_pattern` when naming the new datafile.
- Specify `KEEP` to retain the original files after the tablespace conversion is finished. If you omit this clause, then the original files are deleted when the conversion is finished.

`FINISH`

This clause lets you finish a previously interrupted online conversion operation. The `ENCRYPT`, `DECRYPT`, `REKEY`, and `ts_file_name_convert` clauses have the same semantics here as they have for the `ONLINE` clause. Refer to the `ONLINE` clause for complete information.

Restriction on the `alter_tablespace_encryption` Clause

You cannot perform offline or online conversions on temporary tablespaces.

`lost_write_protection`

Specify this clause to enable, remove, or suspend lost write protection for a shadow tablespace, where lost write protection tracking data is stored.

Enable Lost Write Protection for a Shadow Tablespace: Example

```
ALTER TABLESPACE <shadow_tablespace_name>
   ENABLE
   LOST WRITE PROTECTION
```

Remove Lost Write Protection for a Shadow Tablespace: Example

```
ALTER TABLESPACE <shadow_tablespace_name>
   DISABLE LOST WRITE PROTECTION
```
ALTER TABLESPACE <shadow_tablespace_name>
  REMOVE
  LOST WRITE PROTECTION

SUSPEND Lost Write Protection for a Shadow Tablespace: Example

ALTER TABLESPACE <shadow_tablespace_name>
  SUSPEND
  LOST WRITE PROTECTION

Examples

Backing Up Tablespaces: Examples

The following statement signals to the database that a backup is about to begin:

ALTER TABLESPACE tbs_01
  BEGIN BACKUP;

The following statement signals to the database that the backup is finished:

ALTER TABLESPACE tbs_01
  END BACKUP;

Moving and Renaming Tablespaces: Example

This example moves and renames a data file associated with the tbs_02 tablespace, created in "Enabling Autoextend for a Tablespace: Example", from diskb:tbs_f5.dbf to diska:tbs_f5.dbf:

1. Take the tablespace offline using an ALTER TABLESPACE statement with the OFFLINE clause:

   ALTER TABLESPACE tbs_02 OFFLINE NORMAL;

2. Copy the file from diskb:tbs_f5.dbf to diska:tbs_f5.dbf using your operating system commands.

3. Rename the data file using an ALTER TABLESPACE statement with the RENAME DATAFILE clause:

   ALTER TABLESPACE tbs_02
     RENAME DATAFILE 'diskb:tbs_f5.dbf'
     TO 'diska:tbs_f5.dbf';

4. Bring the tablespace back online using an ALTER TABLESPACE statement with the ONLINE clause:

   ALTER TABLESPACE tbs_02 ONLINE;

Adding and Dropping Data Files and Temp Files: Examples

The following statement adds a data file to the tablespace. When more space is needed, new 10-kilobytes extents will be added up to a maximum of 100 kilobytes:

ALTER TABLESPACE tbs_03
  ADD DATAFILE 'tbs_f04.dbf'
  SIZE 100K
  AUTOEXTEND ON
  NEXT 10K
  MAXSIZE 100K;

The following statement drops the empty data file:
ALTER TABLESPACE tbs_03
   DROP DATAFILE 'tbs_f04.dbf';

The following statements add a temp file to the temporary tablespace created in
"Creating a Temporary Tablespace: Example" and then drops the temp file:
ALTER TABLESPACE temp_demo ADD TEMPFILE 'temp05.dbf' SIZE 5 AUTOEXTEND ON;
ALTER TABLESPACE temp_demo DROP TEMPFILE 'temp05.dbf';

**Managing Space in a Temporary Tablespace: Example**

The following statement manages the space in the temporary tablespace created in
"Creating a Temporary Tablespace: Example" using the SHRINK SPACE clause. The
KEEP clause is omitted, so the database will attempt to shrink the tablespace as much
as possible as long as other tablespace storage attributes are satisfied.
ALTER TABLESPACE temp_demo SHRINK SPACE;

**Adding an Oracle-managed Data File: Example**

The following example adds an Oracle-managed data file to the omf_ts1 tablespace
(see "Creating Oracle Managed Files: Examples" for the creation of this tablespace).
The new data file is 100M and is autoextensible with unlimited maximum size:
ALTER TABLESPACE omf_ts1 ADD DATAFILE;

**Changing Tablespace Logging Attributes: Example**

The following example changes the default logging attribute of a tablespace to
NOLOGGING:
ALTER TABLESPACE tbs_03 NOLOGGING;

Altering a tablespace logging attribute has no affect on the logging attributes of the
existing schema objects within the tablespace. The tablespace-level logging attribute
can be overridden by logging specifications at the table, index, and partition levels.

**Changing Undo Data Retention: Examples**

The following statement changes the undo data retention for tablespace undots1 to
normal undo data behavior:
ALTER TABLESPACE undots1
   RETENTION NOGUARANTEE;

The following statement changes the undo data retention for tablespace undots1 to
behavior that preserves unexpired undo data:
ALTER TABLESPACE undots1
   RETENTION GUARANTEE;
ALTER TABLESPACE SET

Note:

This SQL statement is valid only if you are using Oracle Sharding. For more information on Oracle Sharding, refer to Oracle Database Administrator's Guide.

Purpose

Use the ALTER TABLESPACE SET statement to change an attribute of an existing tablespace set. The attribute change is applied to all tablespaces in the tablespace set.

See Also:

CREATE TABLESPACE SET and DROP TABLESPACE SET

Prerequisites

You must be connected to a shard catalog database as an SDB user.

If you have the ALTER TABLESPACE system privilege, then you can perform any ALTER TABLESPACE SET operation. If you have the MANAGE TABLESPACE system privilege, then you can only perform the following operations:

• Take all tablespaces in a tablespace set online or offline
• Begin or end a backup
• Make all tablespaces in a tablespace set read only or read write
• Set the default logging mode of all tablespaces in a tablespace set to LOGGING or NOLOGGING
• Put all tablespaces in a tablespace set in force logging mode or take them out of force logging mode
• Resize all data files for a tablespace set
• Enable or disable autoextension of all data files for a tablespace set

Before you can make a tablespace set read only, the following conditions must be met:

• The tablespaces in the tablespace set must be online.
• The tablespace set must not contain any active rollback segments. Additionally, because the rollback segments of a read-only tablespace set are not accessible, Oracle recommends that you drop the rollback segments before you make a tablespace set read only.
• The tablespace set must not be involved in an open backup, because the end of a backup updates the header file of all data files in the tablespace set.
Syntax

```
alter_tablespace_set ::= 
```

(See the following clauses of ALTER TABLESPACE: default_tablespace_params ::=, size_clause ::=, datafile_tempfile_clauses ::=, tablespace_logging_clauses ::=, tablespace_state_clauses ::=, autoextend_clause ::=, alter_tablespace_encryption ::=)

Semantics

**tablespace_set**

Specify the name of the tablespace set to be altered.

**alter_tablespace_attrs**

Use this clause to change an attribute for all tablespaces in the tablespace set.
The subclauses of alter_tablespace_attrs have the same semantics here as for the ALTER TABLESPACE statement, with the following exceptions:

- You cannot specify the following subclauses for tablespace sets:
  - MINIMUM EXTENT size_clause
  - SHRINK SPACE [ KEEP size_clause ]
  - tablespace_group_clause
  - flashback_mode_clause
  - tablespace_retention_clause

- For the datafile_tempfile_clauses, only the following subclauses are supported for tablespace sets:
  - RENAME DATAFILE
  - DATAFILE { ONLINE | OFFLINE }

- For the tablespace_state_clauses, the PERMANENT and TEMPORARY subclauses are not supported for tablespace sets.

See Also:

alter_tablespace_attrs in the documentation on ALTER TABLESPACE for the full semantics of this clause

Examples

Altering a Tablespace Set: Example

The following statement puts all tablespaces in tablespace set ts1 in force logging mode:

```
ALTER TABLESPACE SET ts1
    FORCE LOGGING;
```

ALTER TRIGGER

Purpose

Triggers are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the ALTER TRIGGER statement to enable, disable, or compile a database trigger.

Note:

This statement does not change the declaration or definition of an existing trigger. To redeclare or redefine a trigger, use the CREATE TRIGGER statement with the OR REPLACE keywords.
Prerequisites

The trigger must be in your own schema or you must have ALTER ANY TRIGGER system privilege.

In addition, to alter a trigger on DATABASE, you must have the ADMINISTER DATABASE TRIGGER privilege.

Syntax

\[
alter\_trigger::=
\]

\[
\text{ALTER}\ \text{TRIGGER}\ \text{schema}\ .\ \text{trigger}\_name\ \text{trigger}\_compile\_clause\ \text{ENABLE}\ |\ \text{DISABLE}\ |\ \text{RENAME}\ TO\ new\_name\ |\ \text{EDITIONABLE}\ |\ \text{NONEDITIONABLE}\ ;
\]

(triggerCompileClause: See Oracle Database PL/SQL Language Reference for the syntax of this clause.)

Semantics

**schema**

Specify the schema containing the trigger. If you omit schema, then Oracle Database assumes the trigger is in your own schema.

**trigger_name**

Specify the name of the trigger to be altered.
trigger_compile_clause

See Oracle Database PL/SQL Language Reference for the syntax and semantics of this clause and for complete information on creating and compiling triggers.

ENABLE | DISABLE

Specify ENABLE to enable the trigger. You can also use the ENABLE ALL TRIGGERS clause of ALTER TABLE to enable all triggers associated with a table. See ALTER TABLE.

Specify DISABLE to disable the trigger. You can also use the DISABLE ALL TRIGGERS clause of ALTER TABLE to disable all triggers associated with a table.

RENAME Clause

Specify RENAME TO new_name to rename the trigger. Oracle Database renames the trigger and leaves it in the same state it was in before being renamed.

When you rename a trigger, the database rebuilds the remembered source of the trigger in the USER_SOURCE, ALL_SOURCE, and DBA_SOURCE data dictionary views. As a result, comments and formatting may change in the TEXT column of those views even though the trigger source did not change.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the trigger becomes an editioned or noneditioned object if editioning is later enabled for the schema object type TRIGGER in schema. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see Oracle Database Development Guide.

Restriction on NONEDITIONABLE

You cannot specify NONEDITIONABLE for a crossedition trigger.

ALTER TYPE

Purpose

Object types are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the ALTER TYPE statement to add or drop member attributes or methods. You can change the existing properties (FINAL or INSTANTIABLE) of an object type, and you can modify the scalar attributes of the type.

You can also use this statement to recompile the specification or body of the type or to change the specification of an object type by adding new object member subprogram specifications.

Prerequisites

The object type must be in your own schema and you must have CREATE TYPE or CREATE ANY TYPE system privilege, or you must have ALTER ANY TYPE system privileges.
Syntax

\[ alter_type ::= \]

\[ \text{ALTER \ TYPE} \ schema \ . \ type_name \ alter_type_clause \ EDITIONABLE \ NONEDITIONABLE \]

(alter_type_clause: See Oracle Database PL/SQL Language Reference for the syntax of this clause.)

Semantics

\textit{schema}

Specify the schema that contains the type. If you omit \textit{schema}, then Oracle Database assumes the type is in your current schema.

\textit{type_name}

Specify the name of an object type, a nested table type, or a varray type.

\textbf{Restriction on type_name}

You cannot evolve an editioned object type. The \texttt{ALTER TYPE} statement fails with ORA-22348 if either of the following is true:

- The type is an editioned object type and the \texttt{ALTER TYPE} statement has no \texttt{type_compile_clause}. You can use the \texttt{ALTER TYPE} statement to recompile an editioned object type, but not for any other purpose.
- The type has a dependent that is an editioned object type and the \texttt{ALTER TYPE} statement has a \texttt{CASCADE} clause.

Refer to Oracle Database PL/SQL Language Reference for more information on the \texttt{type_compile_clause} and the \texttt{CASCADE} clause.

\textit{alter_type_clause}

See Oracle Database PL/SQL Language Reference for the syntax and semantics of this clause and for complete information on creating and compiling object types.

\textbf{EDITIONABLE | NONEDITIONABLE}

Use these clauses to specify whether the type becomes an editioned or noneditioned object if editioning is later enabled for the \texttt{schema} object type \texttt{TYPE} in \texttt{schema}. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see Oracle Database Development Guide.

\textbf{ALTER USER}

\textbf{Purpose}

Use the \texttt{ALTER USER} statement:
• To change the authentication or database resource characteristics of a database user
• To permit a proxy server to connect as a client without authentication
• In an Oracle Automatic Storage Management (Oracle ASM) cluster, to change the password of a user in the password file that is local to the Oracle ASM instance of the current node

See Also:

*Oracle Database Security Guide* for detailed information about user authentication methods

Prerequisites

In general, you must have the *ALTER USER* system privilege. However, the current user can change his or her own password without this privilege.

To change the password of a *SYS* user, the password file must exist.

You must be authenticated *AS SYSASM* to change the password of a user other than yourself in an Oracle ASM instance password file.

To specify the *CONTAINER* clause, you must be connected to a multitenant container database (CDB). If the current container is the root, then you can specify CONTAINER = ALL or CONTAINER = CURRENT. If the current container is a pluggable database (PDB), then you can specify only CONTAINER = CURRENT.

To set and modify *CONTAINER_DATA* attributes using the *container_data_clause*, you must be connected to a CDB and the current container must be the root.
Syntax

`alter_user ::= `
Semantics

The keywords, parameters, and clauses described in this section are unique to "ALTER USER" or have different semantics than they have in "CREATE USER". Keywords, parameters, and clauses that do not appear here have the same meaning as in the "CREATE USER" statement.
IDENTIFIED Clause

BY password

Specify BY password to specify a new password for the user. Passwords are case sensitive. Any subsequent CONNECT string used to connect this user to the database must specify the password using the same case (upper, lower, or mixed) that is used in this ALTER USER statement. Passwords can contain single-byte, or multibyte characters, or both from your database character set.

Note:
Oracle Database expects a different timestamp for each resetting of a particular password. If you reset one password multiple times within one second (for example, by cycling through a set of passwords using a script), then the database may return an error message that the password cannot be reused. For this reason, Oracle recommends that you avoid using scripts to reset passwords.

You can omit the REPLACE clause if you are setting your own password or you have the ALTER USER system privilege and you are changing another user's password. However, unless you have the ALTER USER system privilege, you must always specify the REPLACE clause if a password complexity verification function has been enabled, either by running the UTLPWDMG.SQL script or by specifying such a function in the PASSWORD_VERIFY_FUNCTION parameter of a profile that has been assigned to the user.

In an Oracle ASM cluster, you can use this clause to change the password of a user in the password file that is local to an Oracle ASM instance of the current node. You must be authenticated AS SYSASM to specify IDENTIFIED BY password without the REPLACE old_password clause. If you are not authenticated AS SYSASM, then you can only change your own password by specifying REPLACE old_password.

Oracle Database does not check the old password, even if you provide it in the REPLACE clause, unless you are changing your own existing password.
GLOBALLY

Refer to CREATE USER for more information on this clause.

You can change a user’s access verification method from IDENTIFIED GLOBALLY to either IDENTIFIED BY password or IDENTIFIED EXTERNALLY. You can change a user’s access verification method to IDENTIFIED GLOBALLY from one of the other methods only if all external roles granted explicitly to the user are revoked.

EXTERNALLY

Refer to CREATE USER for more information on this clause.

NO AUTHENTICATION Clause

Use this clause to change an existing user account with authentication to a schema account without authentication to prevent logins to the account.

DEFAULT COLLATION Clause

Use this clause to change the default collation for the schema owned by the user. The new default collation is assigned to tables, views, and materialized views that are subsequently created in the schema. It does not influence default collations for existing tables views, and materialized views. Refer to the DEFAULT COLLATION Clause clause of CREATE USER for the full semantics of this clause.

DEFAULT TABLESPACE Clause

Use this clause to assign or reassign a tablespace for the user's permanent segments. This clause overrides any default tablespace that has been specified for the database.

Restriction on Default Tablespaces

You cannot specify a locally managed temporary tablespace, including an undo tablespace, or a dictionary-managed temporary tablespace, as a user's default tablespace.

[LOCAL] TEMPORARY TABLESPACE Clause

Use this clause to assign or reassign a temporary tablespace or tablespace group for the user's temporary segments.
• Specify `tablespace` to indicate the user's temporary tablespace. Specify `TEMPORARY TABLESPACE` to indicate a shared temporary tablespace. Specify `LOCAL TEMPORARY TABLESPACE` to indicate a local temporary tablespace. If you are connected to a CDB, then you can specify `CDB$DEFAULT` to use the CDB-wide default temporary tablespace.

• Specify `tablespace_group_name` to indicate that the user can save temporary segments in any tablespace in the tablespace group specified by `tablespace_group_name`. Local temporary tablespaces cannot be part of a tablespace group.

Restriction on User Temporary Tablespace

Any individual tablespace you assign or reassign as the user's temporary tablespace must be a temporary tablespace and must have a standard block size.

**See Also:**

"Assigning a Tablespace Group: Example"

**DEFAULT ROLE Clause**

Specify the roles enabled by default for the user at logon. This clause can contain only roles that have been granted directly to the user with a `GRANT` statement, or roles created by the user with the `CREATE ROLE` privilege. You cannot use the `DEFAULT ROLE` clause to specify:

• Roles not granted to the user
• Roles granted through other roles
• Roles managed by an external service (such as the operating system), or by the Oracle Internet Directory
• Roles that are enabled by the `SET ROLE` statement, such as password-authenticated roles and secure application roles

**See Also:**

`CREATE ROLE`

**Assigning Default Roles to Common Users in a CDB**

You can modify the default role assigned to a common user both in the current container and across all containers in a CDB.

While assigning a default role to a common user across all containers, `role` must be a common role that was commonly granted to the common user.

While assigning a default role to a common user in the current container, `role` must be one of the following:

• A local role that was granted to the common user in the current container
• A common role that was granted to the common user, either commonly or locally in the current container

ENABLE EDITIONS

This clause is not reversible. Specify ENABLE EDITIONS to allow the user to create multiple versions of editionable objects in this schema using editions. Editionable objects in non-editions-enabled schemas cannot be editioned.

Use the FOR clause to specify one or more object types for which the user can create editionable objects. For a list of valid values for object_type, query the V$EDITIONABLE_TYPES dynamic performance view. If you omit the FOR clause, then the user can create editionable objects for all editionable object types.

See Also:

Oracle Database Reference for more information about the V$EDITIONABLE_TYPES dynamic performance view

If the schema to be editions-enabled contains any objects that are not editionable and that depend on editionable type objects in the schema, then you must specify FORCE to enable editions for this schema. In this case, all the objects that are not editionable and that depend on the editionable type objects in the schema being editions-enabled become invalid.

[HTTP] DIGEST Clause

This clause lets you enable or disable HTTP Digest Access Authentication for the user.

• Specify ENABLE to enable HTTP Digest Access Authentication. After you specify this clause, the user’s password must be changed. This causes the database to generate an HTTP Digest verifier for the new password. Only then will HTTP Digest Access Authentication take effect. One way to ensure that the user’s password is changed after you issue this clause is to specify the PASSWORD EXPIRE clause in the same statement with the HTTP DIGEST ENABLE clause, as follows:

```
ALTER USER user PASSWORD EXPIRE HTTP DIGEST ENABLE;
```

This causes the database to prompt the user for a new password on his or her next attempt to log in to the database. After that, HTTP Digest Access Authentication will take effect for the user.

• Specify DISABLE to disable HTTP Digest Access Authentication for the user. You do not need to change the user’s password in order for this clause to take effect. Specifying the DISABLE clause removes the HTTP Digest from dictionary tables.

```
ALTER USER user PASSWORD EXPIRE HTTP DIGEST DISABLE;
```

Refer to [HTTP] DIGEST Clause in the documentation on CREATE USER for more information on this clause.
CONTAINER Clause

If the current container is a PDB, then you can specify CONTAINER = CURRENT to change the attributes of a local user, or the container-specific attributes (such as the default tablespace) of a common user, in the current container. If the current container is the root, then you can specify CONTAINER = ALL to change the attributes of a common user across the entire CDB. If you omit this clause and the current container is a PDB, then CONTAINER = CURRENT is the default. If you omit this clause and the current container is the root, then CONTAINER = ALL is the default.

Restriction on Modifying Common Users in a CDB

Certain attributes of a common user must be modified for all the containers in a CDB and not for only some containers. Therefore, when you use any of the following clauses to modify a common user, ensure that you modify all of the containers by connecting to the root and specifying CONTAINER=ALL:

- IDENTIFIED clause
- PASSWORD clause
- [HTTP] DIGEST clause

container_data_clause

The container_data_clause allows you the set and modify CONTAINER_DATA attributes for a common user. Use the FOR clause to indicate whether to set or modify the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute. These attributes determine the set of containers (which can never exclude the root) whose data will be visible via CONTAINER_DATA objects to the specified common user when the current session is the root.

To specify the container_data_clause, the current session must be the root and you must specify CONTAINER = CURRENT.

SET CONTAINER_DATA

Use this clause to set the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. When you specify this clause, you replace the existing value, if any, of the CONTAINER_DATA attribute.

Use container_name to specify one or more containers that will be accessible to the user.

Use ALL to specify that all current and future containers in the CDB will be accessible to the user.

Use DEFAULT to specify the default behavior, which is as follows:

- For a default CONTAINER_DATA attribute, the current container, that is, the root, and the CDB as a whole will be accessible to the user.
- For an object-specific CONTAINER_DATA attribute, the database will use the user's default CONTAINER_DATA attribute.
**Note:**

CONTAINER_DATA attributes that are set to DEFAULT are not visible in the DBA_CONTAINER_DATA view.

**ADD CONTAINER_DATA**

Use this clause to add containers to the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. Use container_name to specify one or more containers to add.

You cannot use this clause if the default CONTAINER_DATA attribute is set to ALL. If you use this clause when the default CONTAINER_DATA attribute is set to DEFAULT, then CDB$ROOT will automatically be added to the set of containers, unless the set already contains CDB$ROOT.

You cannot use this clause if the object-specific CONTAINER_DATA attribute is set to ALL or DEFAULT.

**REMOVE CONTAINER_DATA**

Use this clause to remove containers from the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. Use container_name to specify one or more containers to remove.

You cannot use this clause if the default CONTAINER_DATA attribute or object-specific CONTAINER_DATA attribute is set to ALL or DEFAULT.

**FOR container_data_object**

If you specify the FOR clause, then you can set and modify the object-specific CONTAINER_DATA attribute for container_data_object for a common user. container_data_object must be a CONTAINER_DATA table or view. If you omit schema, then Oracle Database assumes that container_data_object is in your own schema.

If you omit the FOR clause, then you can set and modify the default CONTAINER_DATA attribute for a common user.

**See Also:**

Oracle Database Security Guide for more information about enabling common users to view information about PDB objects

**proxy_clause**

The proxy_clause lets you control the ability of an enterprise user (a user outside the database) or a database proxy (another database user) to connect as the database user being altered.

**GRANT CONNECT THROUGH**

Specify GRANT CONNECT THROUGH to allow the connection.

**REVOKE CONNECT THROUGH**
Specify REVOKE CONNECT THROUGH to prohibit the connection.

ENTERPRISE USER

This clause lets you expose user to proxy use by enterprise users. The administrator working in Oracle Internet Directory must then grant privileges for appropriate enterprise users to act on behalf of user.

db_user_proxy

This clause lets you expose user to proxy use by database user db_user_proxy (the proxy).

- The proxy will have all privileges that were directly granted to user.
- The proxy will have all roles associated with user, unless you specify the WITH clauses of db_user_proxy_clauses to limit the proxy to some or none of the roles of user. For each role associated with the proxy, if the role is enabled by default for user at login, then that role will also be enabled by default for the proxy at login.

db_user_proxy_clauses

You can enable password-protected roles in a proxy session. Both secure application role and password-protected roles provide a secure method for enabling a role in a session. Oracle recommends using secure password roles instead of password protected roles in instances where the password has to be maintained and transmitted over insecure channels, or if more than one person needs to know the password. Password-protected roles in a proxy session are suitable for situations where automation is used to set the role.

Proxy users can access password-protected roles. Specify the WITH clauses to limit the proxy to some or none of the roles associated with user, and the AUTHENTICATION REQUIRED clause to specify whether authentication is required.

WITH ROLE

WITH ROLE role_name permits the proxy to connect as the specified user and to activate only the roles that are specified by role_name. This clause can contain only roles that are associated with user. Password protected roles and secure application roles also need to be listed in the WITH ROLE clause if the Proxy user will need to use these secure roles. These secure roles will be included with the WITH ROLE ALL clause (the default if WITH ROLE is not specified). If WITH ROLE doesn't specify the secure roles, then those cannot be enabled even with right password.

WITH ROLE ALL EXCEPT

WITH ROLE ALL EXCEPT role_name permits the proxy to connect as the specified user and to activate all roles associated with that user except those specified for role_name. This clause can contain only roles that are associated with user.

WITH NO ROLES

WITH NO ROLES permits the proxy to connect as the specified user, but prohibits the proxy from activating any of that user's roles after connecting, even the secure roles like password protected roles and secure application roles.

AUTHENTICATION REQUIRED

Oracle Database does not expect the proxy to authenticate the user unless you specify the AUTHENTICATION REQUIRED clause. This clause ensures that authentication
credentials for the user must be presented when the user is authenticated through the specified proxy. The credential is a password.

**AUTHENTICATED USING**

The **AUTHENTICATED USING** clauses, which appeared in the syntax of earlier releases, have been deprecated and are no longer needed. If you specify the **AUTHENTICATED USING PASSWORD** clause, then Oracle Database converts it to the **AUTHENTICATION REQUIRED** clause. Specifying the **AUTHENTICATED USING CERTIFICATE** clause or the **AUTHENTICATED USING DISTINGUISHED NAME** clause is equivalent to omitting the **AUTHENTICATION REQUIRED** clause.

---

**See Also:**

- *Oracle Security Overview* for an overview of database security and for information on middle-tier systems and proxy authentication
- *Oracle Database Security Guide* for more information on proxies and their use of the database and "Proxy Users: Examples"

---

**Examples**

**Changing User Identification: Example**

The following statement changes the password of the user sidney (created in "Creating a Database User: Example") second_2nd_pwd and default tablespace to the tablespace example:

```sql
ALTER USER sidney
    IDENTIFIED BY second_2nd_pwd
    DEFAULT TABLESPACE example;
```

The following statement assigns the new_profile profile (created in "Creating a Profile: Example") to the sample user sh:

```sql
ALTER USER sh
    PROFILE new_profile;
```

In subsequent sessions, sh is restricted by limits in the new_profile profile.

The following statement makes all roles granted directly to sh default roles, except the dw_manager role:

```sql
ALTER USER sh
    DEFAULT ROLE ALL EXCEPT dw_manager;
```

At the beginning of sh's next session, Oracle Database enables all roles granted directly to sh except the dw_manager role.

**Changing User Authentication: Examples**

The following statement changes the authentication mechanism of user app_user1 (created in "Creating a Database User: Example"):

```sql
ALTER USER app_user1 IDENTIFIED GLOBALLY AS 'CN=tom,O=oracle,C=US';
```

The following statement causes user sidney's password to expire:
ALTER USER sidney PASSWORD EXPIRE;

If you cause a database user's password to expire with PASSWORD EXPIRE, then the user (or the DBA) must change the password before attempting to log in to the database following the expiration. However, tools such as SQL*Plus allow the user to change the password on the first attempted login following the expiration.

**Assigning a Tablespace Group: Example**

The following statement assigns tbs_grp_01 (created in "Adding a Temporary Tablespace to a Tablespace Group: Example") as the tablespace group for user sh:

```
ALTER USER sh
  TEMPORARY TABLESPACE tbs_grp_01;
```

**Proxy Users: Examples**

The following statement alters the user app_user1. The example permits the app_user1 to connect through the proxy user sh. The example also allows app_user1 to enable its warehouse_user role (created in "Creating a Role: Example") when connected through the proxy sh:

```
ALTER USER app_user1
  GRANT CONNECT THROUGH sh
  WITH ROLE warehouse_user;
```

To show basic syntax, this example uses the sample database Sales History user (sh) as the proxy. Normally a proxy user would be an application server or middle-tier entity. For information on creating the interface between an application user and a database by way of an application server, refer to Oracle Call Interface Programmer's Guide.

**See Also:**

- “Creating External Database Users: Examples” to see how to create the app_user user
- “Creating a Role: Example” to see how to create the dw_user role

The following statement takes away the right of user app_user1 to connect through the proxy user sh:

```
ALTER USER app_user1 REVOKE CONNECT THROUGH sh;
```

The following hypothetical examples shows another method of proxy authentication:

```
ALTER USER sully GRANT CONNECT THROUGH OAS1
  AUTHENTICATED USING PASSWORD;
```

The following example exposes the user app_user1 to proxy use by enterprise users. The enterprise users cannot act on behalf of app_user1 until the Oracle Internet Directory administrator has granted them appropriate privileges:

```
ALTER USER app_user1
  GRANT CONNECT THROUGH ENTERPRISE USERS;
```
ALTER VIEW

Purpose

Use the ALTER VIEW statement to explicitly recompile a view that is invalid or to modify view constraints. Explicit recompilation lets you locate recompilation errors before run time. You may want to recompile a view explicitly after altering one of its base tables to ensure that the alteration does not affect the view or other objects that depend on it.

You can also use ALTER VIEW to define, modify, or drop view constraints.

You cannot use this statement to change the definition of an existing view. Further, if DDL changes to the view’s base tables invalidate the view, then you cannot use this statement to compile the invalid view. In these cases, you must redefine the view using CREATE VIEW with the OR REPLACE keywords.

When you issue an ALTER VIEW statement, Oracle Database recompiles the view regardless of whether it is valid or invalid. The database also invalidates any local objects that depend on the view.

If you alter a view that is referenced by one or more materialized views, then those materialized views are invalidated. Invalid materialized views cannot be used by query rewrite and cannot be refreshed.

See Also:

- CREATE VIEW for information on redefining a view and ALTER MATERIALIZED VIEW for information on revalidating an invalid materialized view
- Oracle Database Data Warehousing Guide for general information on data warehouses
- Oracle Database Concepts for more about dependencies among schema objects

Prerequisites

The view must be in your own schema or you must have ALTER ANY TABLE system privilege.
Syntax

\[ alter\_view::= \]

Semantics

**schema**

Specify the schema containing the view. If you omit `schema`, then Oracle Database assumes the view is in your own schema.

**view**

Specify the name of the view to be recompiled.

**MODIFY CONSTRAINT Clause**

Use the `MODIFY CONSTRAINT` clause to change the `RELY` or `NORELY` setting of an existing view constraint. Refer to "Notes on View Constraints" for general information on view constraints.

**Restriction on Modifying Constraints**

You cannot change the setting of a unique or primary key constraint if it is part of a referential integrity constraint without dropping the foreign key or changing its setting to match that of `view`.

**ADD Clause**

Use the `ADD` clause to add a constraint to `view`. Refer to `constraint` for information on view constraints and their restrictions.
DROP Clause

Use the DROP clause to drop an existing view constraint.

Restriction on Dropping Constraints

You cannot drop a unique or primary key constraint if it is part of a referential integrity constraint on a view.

COMPILE

The COMPILE keyword directs Oracle Database to recompile the view.

{ READ ONLY | READ WRITE }

These clauses are valid only for editioning views.

- Specify READ ONLY to indicate that the editioning view cannot be updated.
- Specify READ WRITE to return a read-only editioning view to read/write status.

When you specify these clauses, the database does not invalidate dependent objects, but it may invalidate cursors.

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the view becomes an editioned or noneditioned object if editioning is later enabled for the schema object type VIEW in schema. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see Oracle Database Development Guide.

See Also:

CREATE VIEW for information about editioning views

Examples

Altering a View: Example

To recompile the view customer_ro (created in "Creating a Read-Only View: Example"), issue the following statement:

```sql
ALTER VIEW customer_ro
    COMPILE;
```

If Oracle Database encounters no compilation errors while recompiling customer_ro, then customer_ro becomes valid. If recompiling results in compilation errors, then the database returns an error and customer_ro remains invalid.

Oracle Database also invalidates all dependent objects. These objects include any procedures, functions, package bodies, and views that reference customer_ro. If you subsequently reference one of these objects without first explicitly recompiling it, then the database recompiles it implicitly at run time.
ANALYZE

Purpose

Use the ANALYZE statement to collect statistics, for example, to:

- Collect or delete statistics about an index or index partition, table or table partition, index-organized table, cluster, or scalar object attribute.
- Validate the structure of an index or index partition, table or table partition, index-organized table, cluster, or object reference (REF).
- Identify migrated and chained rows of a table or cluster.

Note:

The use of ANALYZE for the collection of optimizer statistics is obsolete.

If you want to collect optimizer statistics, use the DBMS_STATS package, which lets you collect statistics in parallel, global statistics for partitioned objects, and helps you fine tune your statistics collection in other ways. See Oracle Database PL/SQL Packages and Types Reference for more information on the DBMS_STATS package.

Use the ANALYZE statement only for the following cases:

- To use the VALIDATE or LIST CHAINED ROWS clauses
- To collect information on freelist blocks

Prerequisites

The schema object to be analyzed must be local, and it must be in your own schema or you must have the ANALYZE ANY system privilege.

If you want to list chained rows of a table or cluster into a list table, then the list table must be in your own schema, or you must have INSERT privilege on the list table, or you must have INSERT ANY TABLE system privilege.

If you want to validate a partitioned table, then you must have the INSERT object privilege on the table into which you list analyzed rowids, or you must have the INSERT ANY TABLE system privilege.
Syntax

\[
\text{analyze} ::= \\
\text{ANALYZE TABLE schema . table \(\text{INDEX schema . index\).}} \\
\text{CLUSTER schema . cluster \(\text{partition_extension_clause\).}} \\
\text{validation_clauses \(\text{LIST CHAINED ROWS \(\text{DELETE SYSTEM STATISTICS\).}}\)
\]

\[
\text{partition_extension_clause} ::= \\
\text{PARTITION ( partition ) \(\text{FOR ( partition_key_value \(\text{SUBPARTITION ( subpartition ) \(\text{FOR ( subpartition_key_value\).}}\)
\]

\[
\text{validation_clauses} ::= \\
\text{VALIDATE REF UPDATE SET DANGLING TO NULL \(\text{VALIDATE STRUCTURE CASCADE FAST COMPLETE OFFLINE ONLINE into_clause\).}
\]

\[
\text{into_clause} ::= \\
\text{INTO schema . table}
\]
Semantics

schema

Specify the schema containing the table, index, or cluster. If you omit schema, then Oracle Database assumes the table, index, or cluster is in your own schema.

TABLE table

Specify a table to be analyzed. When you analyze a table, the database collects statistics about expressions occurring in any function-based indexes as well. Therefore, be sure to create function-based indexes on the table before analyzing the table. Refer to CREATE INDEX for more information about function-based indexes.

When analyzing a table, the database skips all domain indexes marked LOADING or FAILED.

For an index-organized table, the database also analyzes any mapping table and calculates its PCT_ACCESSS_DIRECT statistics. These statistics estimate the accuracy of guess data block addresses stored as part of the local rowids in the mapping table.

Oracle Database collects the following statistics for a table. Statistics marked with an asterisk are always computed exactly. Table statistics, including the status of domain indexes, appear in the data dictionary views USER_TABLES, ALL_TABLES, and DBA_TABLES in the columns shown in parentheses.

- Number of rows (NUM_ROWS)
- * Number of data blocks below the high water mark—the number of data blocks that have been formatted to receive data, regardless whether they currently contain data or are empty (BLOCKS)
- * Number of data blocks allocated to the table that have never been used (EMPTY_BLOCKS)
- Average available free space in each data block in bytes (AVG_SPACE)
- Number of chained rows (CHAIN_COUNT)
- Average row length, including the row overhead, in bytes (AVG_ROW_LEN)

Restrictions on Analyzing Tables

Analyzing tables is subject to the following restrictions:

- You cannot use ANALYZE to collect statistics on data dictionary tables.
- You cannot use ANALYZE to collect statistics on an external table. Instead, you must use the DBMS_STATS package.
- You cannot use ANALYZE to collect default statistics on a temporary table. However, if you have already created an association between one or more columns of a temporary table and a user-defined statistics type, then you can use ANALYZE to collect the user-defined statistics on the temporary table.
- You cannot compute or estimate statistics for the following column types: REF column types, varrays, nested tables, LOB column types (LOB column types are not analyzed, they are skipped), LONG column types, or object types. However, if a statistics type is associated with such a column, then Oracle Database collects user-defined statistics.
See Also:

• ASSOCIATE STATISTICS
• Oracle Database Reference for information on the data dictionary views

**partition_extension_clause**

Specify the partition or subpartition, or the partition or subpartition value, on which you want statistics to be gathered. You cannot use this clause when analyzing clusters.

If you specify **PARTITION** and **table** is composite-partitioned, then Oracle Database analyzes all the subpartitions within the specified partition.

**INDEX index**

Specify an index to be analyzed.

Oracle Database collects the following statistics for an index. Statistics marked with an asterisk are always computed exactly. For conventional indexes, when you compute or estimate statistics, the statistics appear in the data dictionary views **USER_INDEXES**, **ALL_INDEXES**, and **DBA_INDEXES** in the columns shown in parentheses.

- * Depth of the index from its root block to its leaf blocks (**BLEVEL**)
- Number of leaf blocks (**LEAF_BLOCKS**)
- Number of distinct index values (**DISTINCT_KEYS**)
- Average number of leaf blocks for each index value (**AVG_LEAF_BLOCKS_PER_KEY**)
- Average number of data blocks for each index value (for an index on a table) (**AVG_DATA_BLOCKS_PER_KEY**)
- Clustering factor (how well ordered the rows are about the indexed values) (**CLUSTERING_FACTOR**)

For domain indexes, this statement invokes the user-defined statistics collection function specified in the statistics type associated with the index (see **ASSOCIATE STATISTICS**). If no statistics type is associated with the domain index, then the statistics type associated with its indextype is used. If no statistics type exists for either the index or its indextype, then no user-defined statistics are collected. User-defined index statistics appear in the **STATISTICS** column of the data dictionary views **USER_USTATS**, **ALL_USTATS**, and **DBA_USTATS**.
Note:

- When you analyze an index from which a substantial number of rows has been deleted, Oracle Database sometimes executes a **COMPUTE** statistics operation (which can entail a full table scan) even if you request an **ESTIMATE** statistics operation. Such an operation can be quite time consuming.
- In some cases, analyzing an index with the **ANALYZE** statement takes an inordinate amount of time to complete. In these cases, you can use a SQL query to validate the index. If the query determines that there is an inconsistency between a table and the index, then you can use the **ANALYZE** statement for a thorough analysis of the index. Refer to *Oracle Database Administrator’s Guide* for more information.

Restriction on Analyzing Indexes

You cannot analyze a domain index that is marked **IN_PROGRESS** or **FAILED**.

See Also:

- **CREATE INDEX** for more information on domain indexes
- *Oracle Database Reference* for information on the data dictionary views
- "Analyzing an Index: Example"

**CLUSTER cluster**

Specify a cluster to be analyzed. When you collect statistics for a cluster, Oracle Database also automatically collects the statistics for all the tables in the cluster and all their indexes, including the cluster index.

For both indexed and hash clusters, the database collects the average number of data blocks taken up by a single cluster key (**AVG_BLOCKS_PER_KEY**). These statistics appear in the data dictionary views **ALL_CLUSTERS**, **USER_CLUSTERS**, and **DBA_CLUSTERS**.

See Also:

*Oracle Database Reference* for information on the data dictionary views and "Analyzing a Cluster: Example"

**validation_clauses**

The validation clauses let you validate **REF** values and the structure of the analyzed object.
VALIDATE REF UPDATE Clause

Specify `VALIDATE REF UPDATE` to validate the REF values in the specified table, check the rowid portion in each REF, compare it with the true rowid, and correct it, if necessary. You can use this clause only when analyzing a table.

If the owner of the table does not have the READ or SELECT object privilege on the referenced objects, then Oracle Database will consider them invalid and set them to null. Subsequently these REF values will not be available in a query, even if it is issued by a user with appropriate privileges on the objects.

SET DANGLING TO NULL

`SET DANGLING TO NULL` sets to null any REF values (whether or not scoped) in the specified table that are found to point to an invalid or nonexistent object.

VALIDATE STRUCTURE

Specify `VALIDATE STRUCTURE` to validate the structure of the analyzed object. The statistics collected by this clause are not used by the Oracle Database optimizer.

- For a table, Oracle Database verifies the integrity of each of the data blocks and rows. For an index-organized table, the database also generates compression statistics (optimal prefix compression count) for the primary key index on the table.
- For a cluster, Oracle Database automatically validates the structure of the cluster tables.
- For a partitioned table, Oracle Database also verifies that each row belongs to the correct partition. If a row does not collate correctly, then its rowid is inserted into the `INVALID_ROWS` table.
- For a temporary table, Oracle Database validates the structure of the table and its indexes during the current session.
- For an index, Oracle Database verifies the integrity of each data block in the index and checks for block corruption. This clause does not confirm that each row in the table has an index entry or that each index entry points to a row in the table. You can perform these operations by validating the structure of the table with the `CASCADE` clause.

Oracle Database also computes compression statistics (optimal prefix compression count) for all normal indexes.

Oracle Database stores statistics about the index in the data dictionary views `INDEX_STATS` and `INDEX_HISTOGRAM`. 
If Oracle Database encounters corruption in the structure of the object, then an error message is returned. In this case, drop and re-create the object.

**CASCADE**

Specify **CASCADE** if you want Oracle Database to validate the structure of the indexes associated with the table or cluster. If you use this clause when validating a table, then the database also validates the indexes defined on the table. If you use this clause when validating a cluster, then the database also validates all the cluster tables indexes, including the cluster index.

By default, **CASCADE** performs a **COMPLETE** validation, which can be resource intensive. Specify **FAST** if you want the database to check for the existence of corruptions without reporting details about the corruption. If the **FAST** check finds a corruption, you can then use the **CASCADE** option without the **FAST** clause to locate and learn details about it.

If you use this clause to validate an enabled (but previously disabled) function-based index, then validation errors may result. In this case, you must rebuild the index.

**ONLINE | OFFLINE**

Specify **ONLINE** to enable Oracle Database to run the validation while DML operations are ongoing within the object. The database reduces the amount of validation performed to allow for concurrency.

**Note:**

When you validate the structure of an object **ONLINE**, Oracle Database does not collect any statistics, as it does when you validate the structure of the object **OFFLINE**.

Specify **OFFLINE**, to maximize the amount of validation performed. This setting prevents **INSERT**, **UPDATE**, and **DELETE** statements from concurrently accessing the object during validation but allows queries. This is the default.

**Restriction on ONLINE**

You cannot specify **ONLINE** when analyzing a cluster.

**INTO**

The **INTO** clause of **VALIDATE STRUCTURE** is valid only for partitioned tables. Specify a table into which Oracle Database lists the rowids of the partitions whose rows do not collate correctly. If you omit **schema**, then the database assumes the list is in your own schema. If you omit this clause altogether, then the database assumes that the table is named **INVALID_ROWS**. The SQL script used to create this table is **UTLVALID.SQL**.
LIST CHAINED ROWS

**LIST CHAINED ROWS** lets you identify migrated and chained rows of the analyzed table or cluster. You cannot use this clause when analyzing an index.

In the **INTO** clause, specify a table into which Oracle Database lists the migrated and chained rows. If you omit **schema**, then the database assumes the chained-rows table is in your own schema. If you omit this clause altogether, then the database assumes that the table is named **CHAINED_ROWS**. The chained-rows table must be on your local database.

You can create the CHAINED_ROWS table using one of these scripts:

- **UTLCHAIN.SQL** uses physical rowids. Therefore it can accommodate rows from conventional tables but not from index-organized tables. (See the Note that follows.)
- **UTLCHN1.SQL** uses universal rowids, so it can accommodate rows from both conventional and index-organized tables.

If you create your own chained-rows table, then it must follow the format prescribed by one of these two scripts.

If you are analyzing index-organized tables based on primary keys (rather than universal rowids), then you must create a separate chained-rows table for each index-organized table to accommodate its primary-key storage. Use the SQL scripts **DBMSIOTC.SQL** and **PRVTIOTC.PLL** to define the **BUILD_CHAIN_ROWS_TABLE** procedure, and then execute this procedure to create an **IOT_CHAINED_ROWS** table for each such index-organized table.

See Also:

- The **DBMS_IOT** package in *Oracle Database PL/SQL Packages and Types Reference* for information on the packaged SQL scripts
- "Listing Chained Rows: Example"

DELETE STATISTICS

Specify **DELETE STATISTICS** to delete any statistics about the analyzed object that are currently stored in the data dictionary. Use this statement when you no longer want Oracle Database to use the statistics.

When you use this clause on a table, the database also automatically removes statistics for all the indexes defined on the table. When you use this clause on a cluster, the database also automatically removes statistics for all the cluster tables and all their indexes, including the cluster index.

Specify **SYSTEM** if you want Oracle Database to delete only system (not user-defined) statistics. If you omit **SYSTEM**, and if user-defined column or index statistics were collected for an object, then the database also removes the user-defined statistics by invoking the statistics deletion function specified in the statistics type that was used to collect the statistics.
Examples

Deleting Statistics: Example

The following statement deletes statistics about the sample table `oe.orders` and all its indexes from the data dictionary:

```
ANALYZE TABLE orders DELETE STATISTICS;
```

Analyzing an Index: Example

The following statement validates the structure of the sample index `oe.inv_product_ix`:

```
ANALYZE INDEX inv_product_ix VALIDATE STRUCTURE;
```

Validating a Table: Example

The following statement analyzes the sample table `hr.employees` and all of its indexes:

```
ANALYZE TABLE employees VALIDATE STRUCTURE CASCADE;
```

For a table, the `VALIDATE REF UPDATE` clause verifies the `REF` values in the specified table, checks the rowid portion of each `REF`, and then compares it with the true rowid. If the result is an incorrect rowid, then the `REF` is updated so that the rowid portion is correct.

The following statement validates the `REF` values in the sample table `oe.customers`:

```
ANALYZE TABLE customers VALIDATE REF UPDATE;
```

The following statement validates the structure of the sample table `oe.customers` while allowing simultaneous DML:

```
ANALYZE TABLE customers VALIDATE STRUCTURE ONLINE;
```

Analyzing a Cluster: Example

The following statement analyzes the `personnel` cluster (created in "Creating a Cluster: Example"), all of its tables, and all of their indexes, including the cluster index:

```
ANALYZE CLUSTER personnel
  VALIDATE STRUCTURE CASCADE;
```

Listing Chained Rows: Example

The following statement collects information about all the chained rows in the table `orders`:

```
ANALYZE TABLE orders
  LIST CHAINED ROWS INTO chained_rows;
```
ASSOCIATE STATISTICS

Purpose

Use the ASSOCIATE STATISTICS statement to associate a statistics type (or default statistics) containing functions relevant to statistics collection, selectivity, or cost with one or more columns, standalone functions, packages, types, domain indexes, or indextypes.

For a listing of all current statistics type associations, query the USER_ASSOCIATIONS data dictionary view. If you analyze the object with which you are associating statistics, then you can also query the associations in the USER_USTATS view.

Prerequisites

To issue this statement, you must have the appropriate privileges to alter the base object (table, function, package, type, domain index, or indextype). In addition, unless you are associating only default statistics, you must have execute privilege on the statistics type. The statistics type must already have been defined.

Syntax

```
associate_statistics ::= ASSOCIATE STATISTICS WITH column_association function_association storage_table_clause;
```
**default_selectivity_clause::=**

```
DEFAULT SELECTIVITY (default_selectivity)
```

**storage_table_clause::=**

```
WITH (SYSTEM USER MANAGED STORAGE TABLES)
```

**Semantics**

**column_association**

Specify one or more table columns. If you do not specify `schema`, then Oracle Database assumes the table is in your own schema.

**function_association**

Specify one or more standalone functions, packages, user-defined data types, domain indexes, or indextypes. If you do not specify `schema`, then Oracle Database assumes the object is in your own schema.

- **FUNCTIONS** refers only to standalone functions, not to method types or to built-in functions.
- **TYPES** refers only to user-defined types, not to built-in SQL data types.

**Restriction on function_association**

You cannot specify an object for which you have already defined an association. You must first disassociate the statistics from this object.

**See Also:**

DISASSOCIATE STATISTICS "Associating Statistics: Example"

**using_statistics_type**

Specify the statistics type (or a synonym for the type) being associated with column, function, package, type, domain index, or indextype. The `statistics_type` must already have been created.

The **NULL** keyword is valid only when you are associating statistics with a column or an index. When you associate a statistics type with an object type, columns of that object type inherit the statistics type. Likewise, when you associate a statistics type with an indextype, index instances of the indextype inherit the statistics type. You can override this inheritance by associating a different statistics type for the column or
index. Alternatively, if you do not want to associate any statistics type for the column or index, then you can specify NULL in the using_statistics_type clause.

**Restriction on Specifying Statistics Type**

You cannot specify NULL for functions, packages, types, or index types.

---

**See Also:**

*Oracle Database Data Cartridge Developer’s Guide* for information on creating statistics collection functions

---

**default_cost_clause**

Specify default costs for standalone functions, packages, types, domain indexes, or index types. If you specify this clause, then you must include one number each for CPU cost, I/O cost, and network cost, in that order. Each cost is for a single execution of the function or method or for a single domain index access. Accepted values are integers of zero or greater.

**default_selectivity_clause**

Specify as a percent the default selectivity for predicates with standalone functions, types, packages, or user-defined operators. The default_selectivity_clause must be a number between 0 and 100. Values outside this range are ignored.

**Restriction on the default_selectivity_clause**

You cannot specify DEFAULT SELECTIVITY for domain indexes or index types.

---

**See Also:**

"Specifying Default Cost: Example"

---

**storage_table_clause**

This clause is relevant only for statistics on INDEXTYPE.

- Specify WITH SYSTEM MANAGED STORAGE TABLES to indicate that the storage of statistics data is to be managed by the system. The type you specify in statistics_type should be storing the statistics related information in tables that are maintained by the system. Also, the indextype you specify must already have been created or altered to support the WITH SYSTEM MANAGED STORAGE TABLES clause.

- Specify WITH USER MANAGED STORAGE TABLES to indicate that the tables that store the user-defined statistics will be managed by the user. This is the default behavior.

**Examples**

**Associating Statistics: Example**
This statement creates an association for the standalone package `emp_mgmt`. See *Oracle Database PL/SQL Language Reference* for the example that creates this package.

```
ASSOCIATE STATISTICS WITH PACKAGES emp_mgmt DEFAULT SELECTIVITY 10;
```

### Specifying Default Cost: Example

This statement specifies that using the domain index `salary_index`, created in "Using Extensible Indexing", to implement a given predicate always has a CPU cost of 100, I/O cost of 5, and network cost of 0.

```
ASSOCIATE STATISTICS WITH INDEXES salary_index DEFAULT COST (100,5,0);
```

The optimizer will use these default costs instead of calling a cost function.

# AUDIT (Traditional Auditing)

This section describes the `AUDIT` statement for *traditional auditing*, which is the same auditing functionality used in releases earlier than Oracle Database 12c.

Beginning with Oracle Database 12c, Oracle introduces *unified auditing*, which provides a full set of enhanced auditing features. For backward compatibility, traditional auditing is still supported. However, Oracle recommends that you plan the migration of your existing audit settings to the new unified audit policy syntax. For new audit requirements, Oracle recommends that you use the new unified auditing. Traditional auditing may be desupported in a future major release.

### See Also:

- [AUDIT (Unified Auditing)](Oracle Database PL/SQL Packages and Types Reference) for a description of the `AUDIT` statement for unified auditing

### Purpose

Use the `AUDIT` statement to:

- Track the issuance of SQL statements in subsequent user sessions. You can track the issuance of a specific SQL statement or of all SQL statements authorized by a particular system privilege. Auditing operations on SQL statements apply only to subsequent sessions, not to current sessions.
- Track operations on a specific schema object. Auditing operations on schema objects apply to current sessions as well as to subsequent sessions.

### See Also:

- [Oracle Database PL/SQL Packages and Types Reference](Oracle Database PL/SQL Packages and Types Reference) for information on the `DBMS_FGA` package, which lets you create and administer value-based auditing policies
- [NOAUDIT (Traditional Auditing)](Oracle Database PL/SQL Packages and Types Reference)
Prerequisites

To audit issuances of a SQL statement, you must have the AUDIT SYSTEM system privilege. However, the AUDIT SYSTEM system privilege is not required when you use the IN SESSION CURRENT clause.

To collect auditing results, you must enable auditing by setting the initialization parameter AUDIT_TRAIL to a value other than the default setting of NONE. You can specify auditing options regardless of whether auditing is enabled. However, Oracle Database does not generate audit records until you enable auditing.

To audit operations on a schema object, the object you choose for auditing must be in your own schema or you must have AUDIT ANY system privilege. In addition, if the object you choose for auditing is a directory object, even if you created it, then you must have AUDIT ANY system privilege.

When you are connected to a multitenant container database (CDB), you must have the privileges described in this section, either granted locally in the current container or granted commonly.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB). To specify CONTAINER = ALL, the current container must be the root.

Notes on Using the AUDIT Statement in a CDB

When you issue the AUDIT statement in a CDB, the database performs auditing as follows:

- If you issue the AUDIT statement when the current container is a PDB, then the database performs auditing in that PDB. If you specify the auditing_by_clause, then user must be a local user in the PDB or a common user. If you specify the audit_schema_object_clause, then the object must be a local object in the PDB.

- If you issue the AUDIT statement when the current container is the root, then the database performs auditing across the entire CDB, that is, in the root and all PDBs. If you specify the auditing_by_clause, then user must be a common user. If you omit the auditing_by_clause, then all common users are audited. If you specify the audit_schema_object_clause, then the object must be a local object in the root or a common object.

**Note:**

The AUDIT ANY system privileges allows the grantee to audit any object in any schema except the SYS schema.

**See Also:**

Oracle Database Reference for information on the AUDIT_TRAIL parameter

\[ \text{auditing_on_clause} \]

Chapter 12
AUDIT (Traditional Auditing)
**Semantics**

**audit_operation_clause**

Use the audit_operation_clause to audit specified operations, regardless of the schema objects affected by the operations.

**sql_statementShortcut**

Specify a shortcut to audit the use of specific SQL statements. Table 12-1 and Table 12-2 list the shortcuts and the SQL statements they audit.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not confuse SQL statement shortcuts with system privileges. For example:</td>
</tr>
</tbody>
</table>

- An AUDIT USER statement specifies the USER shortcut for auditing of all CREATE USER, ALTER USER, and DROP USER SQL statements. Auditing in this case includes an operation in which a user changes his or her own password with an ALTER USER statement.

- An AUDIT ALTER USER statement specifies the ALTER USER system privilege for auditing of all operations that make use of that system privilege. Auditing in this case does not include an operation in which a user changes his or her own password, because that operation does not require the ALTER USER system privilege.

For each audited operation, Oracle Database produces an audit record containing this information:

- The user performing the operation
- The type of operation
- The object involved in the operation
The date and time of the operation

Oracle Database writes audit records to the audit trail, which is a database table containing audit records. You can review database activity by examining the audit trail through data dictionary views.

**See Also:**

- Oracle Database Security Guide 11g Release 2 (11.2) for a listing of the audit trail data dictionary views. Refer to Oracle Database Upgrade Guide for instructions on how to locate the Oracle Database 11g Release 2 (11.2) documentation.
- Oracle Database Reference for detailed descriptions of the data dictionary views
- "Auditing SQL Statements Relating to Roles: Example"

**system_privilege**

Specify a system privilege to audit SQL statements and other operations that are authorized by the specified system privilege.

**Note:**

Auditing the use of a system privilege containing the `ANY` keyword is more restrictive than auditing the use of the same privilege without the `ANY` keyword. For example:

- `AUDIT CREATE PROCEDURE` audits the statements issued using either the `CREATE PROCEDURE` or `CREATE ANY PROCEDURE` privilege.
- `AUDIT CREATE ANY PROCEDURE` audits only those statements issued using the `CREATE ANY PROCEDURE` privilege.

Rather than specifying many individual system privileges, you can specify the roles `CONNECT`, `RESOURCE`, and `DBA`. Doing so is equivalent to auditing all of the system privileges granted to those roles.

Oracle Database also provides three shortcuts for specifying groups of system privileges and statement options at once:

**ALL**

Specify `ALL` to audit all statements options shown in Table 12-1 but not the additional statement options shown in Table 12-2.

**ALL STATEMENTS**

Specify `ALL STATEMENTS` to audit all top-level SQL statements executed. Top-level SQL statements are issued directly by a user. SQL statements run from within a PL/SQL procedure or function are not considered top-level statements. Therefore, this clause does not audit the statements executed within PL/SQL procedures or functions. However, the execution of the PL/SQL procedure or function itself is audited. This
clause is useful if you want to audit all the statements in a specific environment, regardless of other auditing configurations that are system wide or user specific.

**ALL PRIVILEGES**

Specify **ALL PRIVILEGES** to audit system privileges.

> Note:

Oracle recommends that you specify individual system privileges and statement options for auditing rather than roles or shortcuts. The specific system privileges and statement options encompassed by roles and shortcuts change from one release to the next and may not be supported in future versions of Oracle Database.

**See Also:**

- Table 18-1 for a list of all system privileges and the operations that they authorize
- *Oracle Database Security Guide* for more information on the CONNECT, RESOURCE, and DBA roles

**auditing_by_clause**

Specify the **auditing_by_clause** to restrict auditing to only SQL statements issued by the specified users. If you omit this clause, then Oracle Database audits all users' statements.

**IN SESSION CURRENT**

Use this clause to limit auditing to the current session. Auditing will persist until the end of the session and cannot be stopped using the NOAUDIT statement.

**audit_schema_object_clause**

Use the **audit_schema_object_clause** to audit operations on specific schema objects.

**Restriction on the audit_schema_object_clause**

When connected to a CDB, you can specify the **audit_schema_object_clause**, but you cannot also specify the CONTAINER clause. This restriction does not limit functionality because the only allowed values for the CONTAINER clause are the default values. Refer to **CONTAINER Clause** for more information.

**sql_operation**

Specify the SQL operation to be audited. Table 12-3 shows the types of objects that can be audited, and for each object the SQL statements that can be audited. For
example, if you choose to audit a table with the `ALTER` operation, then Oracle Database audits all `ALTER TABLE` statements issued against the table. If you choose to audit a sequence with the `SELECT` operation, then the database audits all statements that use any values of the sequence.

**ALL**

Specify `ALL` as a shortcut equivalent to specifying all SQL operations applicable for the type of object.

**auditing_on_clause**

The `auditing_on_clause` lets you specify the particular schema object to be audited.

```sql
-- Example of auditing on a table
AUDIT table1
  ON DEFAULT
    schema SCHEMA1
    object TABLE1

-- Example of auditing on a sequence
AUDIT seq1
  ON DIRECTORY
    schema SCHEMA2
    object SEQUENCE1
```

**See Also:**

- "Auditing Queries on a Table: Example",
- "Auditing Inserts and Updates on a Table: Example",
- "Auditing Operations on a Sequence: Example"

**schema**

Specify the schema containing the object chosen for auditing. If you omit `schema`, then Oracle Database assumes the object is in your own schema.

**object**

Specify the name of the object to be audited. The object must be a table, view, sequence, stored procedure, function, package, materialized view, mining model, or library.

You can also specify a synonym for a table, view, sequence, procedure, stored function, package, materialized view, or user-defined type.

**ON DEFAULT**

Specify `ON DEFAULT` to establish the specified object options as default object options for subsequently created objects. After you have established these default auditing options, any subsequently created object is automatically audited with those options. The default auditing options for a view are always the union of the auditing options for the base tables of the view. You can see the current default auditing options by querying the `ALL_DEF_AUDIT_OPTS` data dictionary view.

When you change the default auditing options, the auditing options for previously created objects remain the same. You can change the auditing options for an existing object only by specifying the object in the `ON` clause of the `AUDIT` statement.

**See Also:**

- "Setting Default Auditing Options: Example"

**ON DIRECTORY**

The `ON DIRECTORY` clause lets you specify the name of a directory chosen for auditing.
ON MINING MODEL

The ON MINING MODEL clause lets you specify the name of a mining model to be audited.

ON SQL TRANSLATION PROFILE

The ON SQL TRANSLATION PROFILE clause lets you specify the name of a SQL translation profile to be audited.

NETWORK

Use this clause to detect internal failures in the network layer.

See Also:

Oracle Database Security Guide 11g Release 2 (11.2) for information on network auditing. Refer to Oracle Database Upgrade Guide for instructions on how to locate the Oracle Database 11g Release 2 (11.2) documentation.

DIRECT_PATH LOAD

Use this clause to audit SQL*Loader direct path loads.

BY SESSION

In earlier releases, BY SESSION caused the database to write a single record for all SQL statements or operations of the same type executed on the same schema objects in the same session. Beginning with this release of Oracle Database, both BY SESSION and BY ACCESS cause Oracle Database to write one audit record for each audited statement and operation. BY SESSION continues to populate different values to the audit trail compared with BY ACCESS. Oracle recommends that you include the BY ACCESS clause for all AUDIT statements, which results in a more detailed audit record. If you specify neither clause, then BY ACCESS is the default.

Note:

This change applies only to schema object audit options, statement options and system privileges that audit SQL statements other than data definition language (DDL) statements. The database has always audited BY ACCESS all SQL statements and system privileges that audit a DDL statement.

BY ACCESS

Specify BY ACCESS if you want Oracle Database to write one record for each audited statement and operation.
Note:

If you specify either a SQL statement shortcut or a system privilege that audits a data definition language (DDL) statement, then the database always audits by access. In all other cases, the database honors the BY SESSION or BY ACCESS specification.

For statement options and system privileges that audit SQL statements other than DDL, you can specify either BY SESSION or BY ACCESS. BY ACCESS is the default.

WHenever [NOT] SUCCESSFUL

Specify WHENEVER SUCCESSFUL to audit only SQL statements and operations that succeed.

Specify WHENEVER NOT SUCCESSFUL to audit only SQL statements and operations that fail or result in errors.

If you omit this clause, then Oracle Database performs the audit regardless of success or failure.

CONTAINER Clause

The CONTAINER clause applies only when you are connected to a CDB. You can use this clause to specify the scope of the AUDIT statement. However, it is not necessary to specify the CONTAINER clause because its default values are the only allowed values.

- If you issue the AUDIT statement when the current container is a PDB, then you can optionally specify CONTAINER = CURRENT, which is the default.
- If you issue the AUDIT statement when the current container is the root, then you can optionally specify CONTAINER = ALL, which is the default.

<tr>
<td>Object Type</td>
<td>ALTER, AUDIT, GRANT</td>
</tr>
</tbody>
</table>

Note 1: The **FLASHBACK** audit object option applies only to flashback queries.

Note 2: Java schema objects (sources, classes, and resources) are considered the same as procedures, functions, and packages for purposes of auditing options.

Note 3: When you audit the **EXECUTE** operation on a PL/SQL stored procedure or stored function, the database considers only its ability to find the procedure or function and authorize its execution when determining the success or failure of the operation for the purposes of auditing. Therefore, if you specify the **WHENEVER NOT SUCCESSFUL** clause, then only invalid object errors, non-existent object errors, and authorization failures are audited; errors encountered during the execution of the procedure or function are not audited. If you specify the **WHENEVER SUCCESSFUL** clause, then all executions that are not blocked by invalid object errors, non-existent object errors, or authorization failures are audited, regardless of whether errors are encountered during execution.

Note 4: To audit the failure of a recursive SQL operation inside a PL/SQL stored procedure or stored function, configure auditing for the SQL operation.
Note 5: You can audit INSERT, UPDATE, and DELETE operations only on updatable materialized views.

Examples

Auditing SQL Statements Relating to Roles: Example

To choose auditing for every SQL statement that creates, alters, drops, or sets a role, regardless of whether the statement completes successfully, issue the following statement:

AUDIT ROLE;

To choose auditing for every statement that successfully creates, alters, drops, or sets a role, issue the following statement:

AUDIT ROLE
WHENEVER SUCCESSFUL;

To choose auditing for every CREATE ROLE, ALTER ROLE, DROP ROLE, or SET ROLE statement that results in an Oracle Database error, issue the following statement:

AUDIT ROLE
WHENEVER NOT SUCCESSFUL;

Auditing Query and Update SQL Statements: Example

To choose auditing for any statement that queries or updates any table, issue the following statement:

AUDIT SELECT TABLE, UPDATE TABLE;

To choose auditing for statements issued by the users hr and oe that query or update a table or view, issue the following statement

AUDIT SELECT TABLE, UPDATE TABLE
BY hr, oe;

Auditing Deletions: Example

To choose auditing for statements issued using the DELETE ANY TABLE system privilege, issue the following statement:

AUDIT DELETE ANY TABLE;

Auditing Statements Relating to Directories: Examples

To choose auditing for statements issued using the CREATE ANY DIRECTORY system privilege, issue the following statement:

AUDIT CREATE ANY DIRECTORY;

To choose auditing for CREATE DIRECTORY (and DROP DIRECTORY) statements that do not use the CREATE ANY DIRECTORY system privilege, issue the following statement:

AUDIT DIRECTORY;

To choose auditing for every statement that reads files from the bfile_dir directory, issue the following statement:

AUDIT READ ON DIRECTORY bfile_dir;
To choose auditing for every statement that reads files from any directory, issue the following statement:

AUDIT READ DIRECTORY;

**Auditing Queries on a Table: Example**

To choose auditing for every SQL statement that queries the *employees* table in the schema *hr*, issue the following statement:

AUDIT SELECT
    ON hr.employees;

To choose auditing for every statement that successfully queries the *employees* table in the schema *hr*, issue the following statement:

AUDIT SELECT
    ON hr.employees
    WHENEVER SUCCESSFUL;

To choose auditing for every statement that queries the *employees* table in the schema *hr* and results in an Oracle Database error, issue the following statement:

AUDIT SELECT
    ON hr.employees
    WHENEVER NOT SUCCESSFUL;

**Auditing Inserts and Updates on a Table: Example**

To choose auditing for every statement that inserts or updates a row in the *customers* table in the schema *oe*, issue the following statement:

AUDIT INSERT, UPDATE
    ON oe.customers;

**Auditing Operations on a Sequence: Example**

To choose auditing for every statement that performs any operation on the *employees_seq* sequence in the schema *hr*, issue the following statement:

AUDIT ALL
    ON hr.employees_seq;

The preceding statement uses the **ALL** shortcut to choose auditing for the following statements that operate on the sequence:

- ALTER SEQUENCE
- AUDIT
- GRANT
- any statement that accesses the values of the sequence using the pseudocolumns CURRVAL or NEXTVAL

**Setting Default Auditing Options: Example**

The following statement specifies default auditing options for objects created in the future:

AUDIT ALTER, GRANT, INSERT, UPDATE, DELETE
    ON DEFAULT;
Any objects created later are automatically configured for audit with the specified options that apply to them.

- If you create a table, then Oracle Database automatically configures audit options `ALTER`, `GRANT`, `INSERT`, `UPDATE`, or `DELETE` issued against the table.
- If you create a view, then Oracle Database automatically configures audit options `GRANT`, `INSERT`, `UPDATE`, or `DELETE` against the view.
- If you create a sequence, then Oracle Database automatically configures audit options `ALTER` or `GRANT` against the sequence.
- If you create a procedure, package, or function, then Oracle Database automatically configures audit options `ALTER` or `GRANT` against it.

**AUDIT (Unified Auditing)**

This section describes the `AUDIT` statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

**Purpose**

Use the `AUDIT` statement to:

- Enable a unified audit policy for all users or for specified users
- Specify whether an audit record is created if the audited event fails, succeeds, or both
- Specify application context attributes, whose values will be recorded in audit records

Operations performed with this statement take effect in subsequent user sessions, not in the current session.

**See Also:**

- `NOAUDIT` (Unified Auditing)
- `CREATE AUDIT POLICY` (Unified Auditing)
- `ALTER AUDIT POLICY` (Unified Auditing)
- `DROP AUDIT POLICY` (Unified Auditing)

**Prerequisites**

You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

If you are connected to a multitenant container database (CDB), then to enable a common unified audit policy, the current container must be the root and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To enable a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted `AUDIT SYSTEM` privilege.
privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the container.

To specify the AUDIT CONTEXT ... statement when connected to a CDB, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the current session's container.

**Syntax**

```sql
unified_audit ::= 
```

```sql
by_users_with_roles ::= 
```

**Semantics**

**policy**

Specify the name of the unified audit policy to be enabled. The policy must have been created using the CREATE AUDIT POLICY statement.

You can find descriptions of all unified audit policies by querying the AUDIT_UNIFIED_POLICIES view and descriptions of all enabled unified audit policies by querying the AUDIT_UNIFIED_ENABLED_POLICIES view.

When you enable a unified audit policy, all SQL statements and operations that satisfy either a system privilege or action or role audit option specified in the enabled policy will be audited—that is, a unified audit record will be created in the UNIFIED_AUDIT_TRAIL view. If a single SQL statement or operation satisfies multiple enabled policies, then only one unified audit record will be created and all satisfied audit policy names will appear in a comma-separated list in the UNIFIED_AUDIT_POLICIES column of the UNIFIED_AUDIT_TRAIL view.
BY | EXCEPT

Specify the **BY** clause to enable *policy* for only the specified users.

Specify the **EXCEPT** clause to enable *policy* for all users except the specified users.

If you omit the **BY** and **EXCEPT** clauses and the **by_users_with_roles** clause, then Oracle Database enables *policy* for all users.

If *policy* is a common unified audit policy, then *user* must be a common user. If *policy* is a local unified audit policy, then *user* must be a common user or a local user in the container to which you are connected.

**Notes on the BY and EXCEPT Clauses**

The following notes apply to the **BY** and **EXCEPT** clauses:

- If multiple **AUDIT ... BY ...** statements are specified for the same unified audit policy, then the policy is enabled for the union of the users specified in each statement.

- If multiple **AUDIT ... EXCEPT ...** statements are specified for the same unified audit policy, then only the most recently specified statement takes effect. That is, the policy is enabled for all users except the users specified in the most recent **AUDIT ... EXCEPT ...** statement.

- If a policy is enabled using the **BY** clause and you would like to instead enable it using the **EXCEPT** clause, then you must first use the **NOAUDIT ... BY ...** statement to disable the policy for all users for whom the policy is currently enabled, and then enable the policy with the **AUDIT ... EXCEPT ...** statement.

- If a policy is enabled using the **EXCEPT** clause and you would like to instead enable it using the **BY** clause, then you must first use the **NOAUDIT** statement to disable the audit policy. Note that you cannot specify the **EXCEPT** clause with the **NOAUDIT** statement. You can then enable the policy with the **AUDIT ... BY ...** statement.

**Restriction on the BY and EXCEPT Clauses**

You cannot specify an **AUDIT ... BY ...** statement and an **AUDIT ... EXCEPT ...** statement for the same unified audit policy. If you attempt to do so, then an error occurs.

**by_users_with_roles**

Specify this clause to enable *policy* for users who have been directly or indirectly granted the specified roles. If you subsequently grant one of the roles to an additional user or to a role which is directly or indirectly granted to a user, then the policy automatically applies to that user. If you subsequently revoke one of the roles from a user or from a role which was directly or indirectly granted to a role or a user, then the policy no longer applies to that user.
When you are connected to a CDB, if `policy` is a common unified audit policy, then `role` must be a common role. If `policy` is a local unified audit policy, then `role` must be a common role or a local role in the container to which you are connected.

**Enabling a Local Audit Policy on Roles**

Local audit policy can be enabled on local roles as well as on common roles. When a local audit policy is enabled on a common role, it generates audit records when a common role is granted to user locally or commonly in the container.

**Enabling a Common Audit Policy on Roles**

Common audit policy can only be enabled on common roles. When a common audit policy is enabled on a common role, it generates audit records when a common role is granted to an user commonly or locally in the ROOT container.

**WHENEVER [NOT] SUCCESSFUL**

Specify `WHENEVER SUCCESSFUL` to audit only SQL statements and operations that succeed.

Specify `WHENEVER NOT SUCCESSFUL` to audit only SQL statements and operations that fail or result in errors.

If you omit this clause, then Oracle Database performs the audit regardless of success or failure.

**CONTEXT Clause**

Specify the `CONTEXT` clause to include the values of context attributes in audit records.

- For `namespace`, specify the context namespace.
- For `attribute`, specify one or more context attributes whose values you want to include in audit records.
- Use the optional `BY user` clause to include the values of the context attributes only in audit records for events executed by the specified users. If you omit the `BY` clause, then the values of the context attributes are included in all audit records.

If you specify the `CONTEXT` clause when the current container is the root of a CDB, then the values of context attributes will be included in audit records only for events executed in the root. If you specify the optional `BY` clause, then `user` must be a common user.

If you specify the `CONTEXT` clause when the current container is a pluggable database (PDB), then the values of context attributes will be included in audit records only for events executed in that PDB. If you specify the optional `BY` clause, then `user` must be a common user or a local user in that PDB.

You can find the application context attributes that are configured to be captured in the audit trail by querying the `AUDIT_UNIFIED_CONTEXTS` view.

**See Also:**

*Oracle Database Reference* for more information on the `AUDIT_UNIFIED_CONTEXTS` view.
Examples

The following examples enable unified audit policies that were created in the CREATE AUDIT POLICY "Examples".

Enabling a Unified Audit Policy for All Users: Example

The following statement enables unified audit policy table_pol for all users:

```
AUDIT POLICY table_pol;
```

The following statement verifies that table_pol is enabled for all users:

```
SELECT policy_name, enabled_option, entity_name
    FROM audit_unified_enabled_policies
    WHERE policy_name = 'TABLE_POL';
```

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPTION</th>
<th>ENTITY_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_POL</td>
<td>BY</td>
<td>ALL USERS</td>
</tr>
</tbody>
</table>

Enabling a Unified Audit Policy for Specific Users: Examples

The following statement enables unified audit policy dml_pol for only users hr and sh:

```
AUDIT POLICY dml_pol BY hr, sh;
```

The following statement verifies that dml_pol is enabled for only users hr and sh:

```
SELECT policy_name, enabled_option, entity_name
    FROM audit_unified_enabled_policies
    WHERE policy_name = 'DML_POL'
    ORDER BY user_name;
```

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPTION</th>
<th>ENTITY_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>HR</td>
</tr>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>SH</td>
</tr>
</tbody>
</table>

The following statement enables unified audit policy read_dir_pol for all users except hr:

```
AUDIT POLICY read_dir_pol EXCEPT hr;
```

The following statement verifies that read_dir_pol is enabled for all users except hr:

```
SELECT policy_name, enabled_option, entity_name
    FROM audit_unified_enabled_policies
    WHERE policy_name = 'READ_DIR_POL';
```

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPTION</th>
<th>ENTITY_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ_DIR_POL</td>
<td>EXCEPT</td>
<td>HR</td>
</tr>
</tbody>
</table>

The following statement enables unified audit policy security_pol for user hr and audits only the SQL statements and operations that fail:

```
AUDIT POLICY security_pol BY hr WHENEVER NOT SUCCESSFUL;
```

The following statement verifies that security_pol is enabled for only user hr and that only the SQL statements and operations that fail will be audited:
SELECT policy_name, enabled_option, entity_name, success, failure
FROM audit_unified_enabled_policies
WHERE policy_name = 'SECURITY_POL';

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPTION</th>
<th>ENTITY_NAME</th>
<th>SUCCESS</th>
<th>FAILURE</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECURITY_POL</td>
<td>BY</td>
<td>HR</td>
<td>NO</td>
<td>YES</td>
</tr>
</tbody>
</table>

Including Values of Context Attributes in Audit Records: Example

The following statement instructs the database to include the values of namespace USERENV attributes CURRENT_USER and DB_NAME in all audit records for user hr:

AUDIT CONTEXT NAMESPACE userenv
  ATTRIBUTES current_user, db_name
  BY hr;

CALL

Purpose

Use the CALL statement to execute a routine (a standalone procedure or function, or a procedure or function defined within a type or package) from within SQL.

`Note:`

The restrictions on user-defined function expressions specified in “Function Expressions” apply to the CALL statement as well.

`See Also:`

Oracle Database PL/SQL Language Reference for information on creating such routine

Prerequisites

You must have EXECUTE privilege on the standalone routine or on the type or package in which the routine is defined.

Syntax

`call::=`
You can execute a routine in two ways. You can issue a call to the routine itself by name, by using the `routine_clause`, or you can invoke a routine inside the type of an expression, by using an `object_access_expression`.

**routine_clause**
Specify the name of the function or procedure being called, or a synonym that resolves to a function or procedure.

When you call a member function or procedure of a type, if the first argument (`SELF`) is a null `IN OUT` argument, then Oracle Database returns an error. If `SELF` is a null `IN` argument, then the database returns null. In both cases, the function or procedure is not invoked.

**Restriction on Functions**
If the routine is a function, then the `INTO` clause is required.

**schema**
Specify the schema in which the standalone routine, or the package or type containing the routine, resides. If you do not specify `schema`, then Oracle Database assumes the routine is in your own schema.

**type or package**
Specify the type or package in which the routine is defined.

@dblink

In a distributed database system, specify the name of the database containing the standalone routine, or the package or function containing the routine. If you omit dblink, then Oracle Database looks in your local database.

See Also:

"Calling a Procedure: Example" for an example of calling a routine directly

object_access_expression

If you have an expression of an object type, such as a type constructor or a bind variable, then you can use this form of expression to call a routine defined within the type. In this context, the object_access_expression is limited to method invocations.

See Also:

"Object Access Expressions" for syntax and semantics of this form of expression, and "Calling a Procedure Using an Expression of an Object Type: Example" for an example of calling a routine using an expression of an object type

argument

Specify one or more arguments to the routine, if the routine takes arguments. You can use positional, named, or mixed notation for argument. For example, all of the following notations are correct:

CALL my_procedure(arg1 => 3, arg2 => 4)

CALL my_procedure(3, 4)

CALL my_procedure(3, arg2 => 4)

Restrictions on Applying Arguments to Routines

The argument is subject to the following restrictions:

• The data types of the parameters passed by the CALL statement must be SQL data types. They cannot be PL/SQL-only data types such as BOOLEAN.

• An argument cannot be a pseudocolumn or either of the object reference functions VALUE or REF.

• Any argument that is an IN OUT or OUT argument of the routine must correspond to a host variable expression.

• The number of arguments, including any return argument, is limited to 1000.

• You cannot bind arguments of character and raw data types (CHAR, VARCHAR2, NCHAR, NVARCHAR2, RAW, LONG RAW) that are larger than 4K.
The INTO clause applies only to calls to functions. Specify which host variable will store the return value of the function.

Specify the value or condition of the host variable.

---

See Also:

Pro*C/C++ Programmer's Guide for more information on host variables and indicator variables

Examples

Calling a Procedure: Example

The following statement removes the Entertainment department (created in "Inserting Sequence Values: Example") using uses the remove_dept procedure. See Oracle Database PL/SQL Language Reference for the example that creates this procedure.

CALL emp_mgmt.remove_dept(162);

Calling a Procedure Using an Expression of an Object Type: Example

The following examples show how call a procedure by using an expression of an object type in the CALL statement. The example uses the warehouse_typ object type in the order entry sample schema OE:

```
ALTER TYPE warehouse_typ
   ADD MEMBER FUNCTION ret_name
   RETURN VARCHAR2
   CASCADE;
CREATE OR REPLACE TYPE BODY warehouse_typ
   AS MEMBER FUNCTION ret_name
   RETURN VARCHAR2
   IS
   BEGIN
      RETURN self.warehouse_name;
   END;
END;
/
VARIABLE x VARCHAR2(25);

CALL warehouse_typ(456, 'Warehouse 456', 2236).ret_name()
   INTO :x;

PRINT x;
X
--------------------------------
Warehouse 456
```

The next example shows how to use an external function to achieve the same thing:
CREATE OR REPLACE FUNCTION ret_warehouse_typ(x warehouse_typ)
RETURN warehouse_typ
IS
BEGIN
RETURN x;
END;
/
CALL ret_warehouse_typ(warehouse_typ(234, 'Warehouse 234',
2235)).ret_name()
INTO :x;
PRINT x;
X
--------------------------------
Warehouse 234

COMMENT

Purpose
Use the COMMENT statement to add to the data dictionary a comment about a table or table column, unified audit policy, edition, indextype, materialized view, mining model, operator, or view.

To drop a comment from the database, set it to the empty string ''.

See Also:

- "Comments " for more information on associating comments with SQL statements and schema objects
- Oracle Database Reference for information on the data dictionary views that display comments

Prerequisites
The object about which you are adding a comment must be in your own schema or:

- To add a comment to a table, view, or materialized view, you must have COMMENT ANY TABLE system privilege.
- To add a comment to a unified audit policy, you must have the AUDIT SYSTEM system privilege or the AUDIT_ADMIN role.
- To add a comment to an edition, you must have the CREATE ANY EDITION system privilege, granted either directly or through a role.
- To add a comment to an indextype, you must have the CREATE ANY INDEXTYPE system privilege.
- To add a comment to a mining model, you must have the COMMENT ANY MINING MODEL system privilege.
- To add a comment to an operator, you must have the CREATE ANY OPERATOR system privilege.
Syntax

\[
\textit{comment} ::= \\
\]
TABLE Clause
Specify the schema and name of the table or materialized view to be commented. If you omit `schema`, then Oracle Database assumes the table or materialized view is in your own schema.

**Note:**
In earlier releases, you could use this clause to create a comment on a materialized view. You should now use the `COMMENT ON MATERIALIZED VIEW` clause for materialized views.

INDEXTYPE Clause
Specify the name of the indextype to be commented. If you omit `schema`, then Oracle Database assumes the indextype is in your own schema.

You can view the comments on a particular indextype by querying the data dictionary views `USER_INDEXTYPE_COMMENTS`, `DBA_INDEXTYPE_COMMENTS`, or `ALL_INDEXTYPE_COMMENTS`.

MATERIALIZED VIEW Clause
Specify the name of the materialized view to be commented. If you omit `schema`, then Oracle Database assumes the materialized view is in your own schema.

You can view the comments on a particular materialized view by querying the data dictionary views `USER_MVIEW_COMMENTS`, `DBA_MVIEW_COMMENTS`, or `ALL_MVIEW_COMMENTS`.

MINING MODEL
Specify the name of the mining model to be commented.

You can view the comments on a particular mining model by querying the `COMMENTS` column of the data dictionary views `USER_MINING_MODELS`, `DBA_MINING_MODELS`, or `ALL_MINING_MODELS`.

OPERATOR Clause
Specify the name of the operator to be commented. If you omit `schema`, then Oracle Database assumes the operator is in your own schema.

You can view the comments on a particular operator by querying the data dictionary views `USER_OPERATOR_COMMENTS`, `DBA_OPERATOR_COMMENTS`, or `ALL_OPERATOR_COMMENTS`.

IS 'string'
Specify the text of the comment. Refer to "Text Literals" for a syntax description of 'string'.

Examples
Creating Comments: Example
To insert an explanatory remark on the `job_id` column of the `employees` table, you might issue the following statement:

```sql
COMMENT ON COLUMN employees.job_id
  IS 'abbreviated job title';
```

To drop this comment from the database, issue the following statement:

```sql
COMMENT ON COLUMN employees.job_id IS '';
```
This chapter contains the following SQL statements:

- COMMIT
- CREATE ANALYTIC VIEW
- CREATE ATTRIBUTE DIMENSION
- CREATE AUDIT POLICY (Unified Auditing)
- CREATE CLUSTER
- CREATE CONTEXT
- CREATE CONTROLFILE
- CREATE DATABASE
- CREATE DATABASE LINK
- CREATE DIMENSION
- CREATE DIRECTORY
- CREATE DISKGROUP
- CREATE EDITION
- CREATE FLASHBACK ARCHIVE
- CREATE FUNCTION
- CREATE HIERARCHY
- CREATE INDEX
- CREATE INDEXTYPE
- CREATE INMEMORY JOIN GROUP
- CREATE JAVA

**COMMIT**

**Purpose**

Use the **COMMIT** statement to end your current transaction and make permanent all changes performed in the transaction. A transaction is a sequence of SQL statements that Oracle Database treats as a single unit. This statement also erases all savepoints in the transaction and releases transaction locks.

Until you commit a transaction:

- You can see any changes you have made during the transaction by querying the modified tables, but other users cannot see the changes. After you commit the
transaction, the changes are visible to other users’ statements that execute after the commit.

- You can roll back (undo) any changes made during the transaction with the ROLLBACK statement (see ROLLBACK).

Oracle Database issues an implicit COMMIT under the following circumstances:

- Before any syntactically valid data definition language (DDL) statement, even if the statement results in an error
- After any data definition language (DDL) statement that completes without an error

You can also use this statement to:

- Commit an in-doubt distributed transaction manually
- Terminate a read-only transaction begun by a SET TRANSACTION statement

Oracle recommends that you explicitly end every transaction in your application programs with a COMMIT or ROLLBACK statement, including the last transaction, before disconnecting from Oracle Database. If you do not explicitly commit the transaction and the program terminates abnormally, then the last uncommitted transaction is automatically rolled back.

A normal exit from most Oracle utilities and tools causes the current transaction to be committed. A normal exit from an Oracle precompiler program does not commit the transaction and relies on Oracle Database to roll back the current transaction.

See Also:

- Oracle Database Concepts for more information on transactions
- SET TRANSACTION for more information on specifying characteristics of a transaction

Prerequisites

You need no privileges to commit your current transaction.

To manually commit a distributed in-doubt transaction that you originally committed, you must have FORCE TRANSACTION system privilege. To manually commit a distributed in-doubt transaction that was originally committed by another user, you must have FORCE ANY TRANSACTION system privilege.
Syntax

commit ::= 

Semantics

COMMIT

All clauses after the COMMIT keyword are optional. If you specify only COMMIT, then the default is COMMIT WORK WRITE WAIT IMMEDIATE.

WORK

The WORK keyword is supported for compliance with standard SQL. The statements COMMIT and COMMIT WORK are equivalent.

COMMENT Clause

This clause is supported for backward compatibility. Oracle recommends that you use named transactions instead of commit comments.

Specify a comment to be associated with the current transaction. The 'text' is a quoted literal of up to 255 bytes that Oracle Database stores in the data dictionary view DBA_2PC_PENDING along with the transaction ID if a distributed transaction becomes in doubt. This comment can help you diagnose the failure of a distributed transaction.

See Also:

- COMMENT for more information on adding comments to SQL statements

- SET TRANSACTION and Oracle Database Concepts for more information on named transactions
WRITE Clause

Use this clause to specify the priority with which the redo information generated by the commit operation is written to the redo log. This clause can improve performance by reducing latency, thus eliminating the wait for an I/O to the redo log. Use this clause to improve response time in environments with stringent response time requirements where the following conditions apply:

- The volume of update transactions is large, requiring that the redo log be written to disk frequently.
- The application can tolerate the loss of an asynchronously committed transaction.
- The latency contributed by waiting for the redo log write to occur contributes significantly to overall response time.

You can specify the `WAIT` | `NOWAIT` and `IMMEDIATE` | `BATCH` clauses in any order.

**Note:**
If you omit this clause, then the behavior of the commit operation is controlled by the `COMMIT_LOGGING` and `COMMIT_WAIT` initialization parameters, if they have been set.

WAIT | NOWAIT

Use these clauses to specify when control returns to the user.

- The `WAIT` parameter ensures that the commit will return only after the corresponding redo is persistent in the online redo log. Whether in `BATCH` or `IMMEDIATE` mode, when the client receives a successful return from this `COMMIT` statement, the transaction has been committed to durable media. A crash occurring after a successful write to the log can prevent the success message from returning to the client. In this case the client cannot tell whether or not the transaction committed.
- The `NOWAIT` parameter causes the commit to return to the client whether or not the write to the redo log has completed. This behavior can increase transaction throughput. With the `WAIT` parameter, if the commit message is received, then you can be sure that no data has been lost.

**Note:**
With `NOWAIT`, a crash occurring after the commit message is received, but before the redo log record(s) are written, can falsely indicate to a transaction that its changes are persistent.

If you omit this clause, then the transaction commits with the `WAIT` behavior.

IMMEDIATE | BATCH

Use these clauses to specify when the redo is written to the log.
• The **IMMEDIATE** parameter causes the log writer process (LGWR) to write the transaction's redo information to the log. This operation option forces a disk I/O, so it can reduce transaction throughput.

• The **BATCH** parameter causes the redo to be buffered to the redo log, along with other concurrently executing transactions. When sufficient redo information is collected, a disk write of the redo log is initiated. This behavior is called "group commit", as redo for multiple transactions is written to the log in a single I/O operation.

If you omit this clause, then the transaction commits with the **IMMEDIATE** behavior.

---

**See Also:**

*Oracle Database Concepts* for more information on asynchronous commit

---

**FORCE Clause**

In a distributed database system, the **FORCE string [, integer]** clause lets you manually commit an in-doubt distributed transaction. The transaction is identified by the 'string' containing its local or global transaction ID. To find the IDs of such transactions, query the data dictionary view `DBA_2PC_PENDING`. You can use `integer` to specifically assign the transaction a system change number (SCN). If you omit `integer`, then the transaction is committed using the current SCN.

---

**Note:**

A **COMMIT** statement with a **FORCE** clause commits only the specified transactions. Such a statement does not affect your current transaction.

---

**See Also:**

*Oracle Database Administrator’s Guide* for more information on these topics

---

**Examples**

**Committing an Insert: Example**

This statement inserts a row into the `hr.regions` table and commits this change:

```sql
INSERT INTO regions VALUES (5, 'Antarctica');
COMMIT WORK;
```

To commit the same insert operation and instruct the database to buffer the change to the redo log, without initiating disk I/O, use the following **COMMIT** statement:

```sql
COMMIT WRITE BATCH;
```
Commenting on COMMIT: Example

The following statement commits the current transaction and associates a comment with it:

```sql
COMMIT
    COMMENT 'In-doubt transaction Code 36, Call (415) 555-2637';
```

If a network or machine failure prevents this distributed transaction from committing properly, then Oracle Database stores the comment in the data dictionary along with the transaction ID. The comment indicates the part of the application in which the failure occurred and provides information for contacting the administrator of the database where the transaction was committed.

Forcing an In-Doubt Transaction: Example

The following statement manually commits a hypothetical in-doubt distributed transaction. Query the `V$CORRUPT_XID_LIST` data dictionary view to find the transaction IDs of corrupt transactions. You must have DBA privileges to view the `V$CORRUPT_XID_LIST` and to issue this statement.

```sql
COMMIT FORCE '22.57.53';
```

CREATE ANALYTIC VIEW

Purpose

Use the `CREATE ANALYTIC VIEW` statement to create an analytic view. An analytic view specifies the source of its fact data and defines measures that describe calculations or other analytic operations to perform on the data. An analytic view also specifies the attribute dimensions and hierarchies that define the rows of the analytic view.

Tip:

You can view and run SQL scripts that create analytic views at the Oracle Live SQL website at https://livesql.oracle.com/apex/livesql/file/index.html. The website has scripts and tutorials that demonstrate the creation and use of analytic views.

Prerequisites

To create an analytic view in your own schema, you must have the `CREATE ANALYTIC VIEW` system privilege. To create an analytic view in another user's schema, you must have the `CREATE ANY ANALYTIC VIEW` system privilege.
Syntax

create_analytic_view ::= create_analytic_view::=

cache_specification::=  
  MEASURE GROUP ALL (measure_name, levels_clause) MATERIALIZED  

levels_clause::=  
  LEVELS (level_specification)  

level_specification::=  
  (dim_name.hier_name.level_name)  

Semantics  

OR REPLACE  
 Specify OR REPLACE to replace an existing definition of an analytic view with a different definition.  

FORCE and NOFORCE  
 Specify FORCE to force the creation of the analytic view even if it does not successfully compile. If you specify NOFORCE, then the analytic view must compile successfully, otherwise an error occurs. The default is NOFORCE.  

schema  
 Specify the schema in which to create the analytic view. If you do not specify a schema, then Oracle Database creates the analytic view in your own schema.  

analytic_view  
 Specify a name for the analytic view.  

sharing_clause  
 Specify whether to create the analytic view as an application common object. Specifying METADATA shares the analytic view’s metadata, but its data is unique to each container. Specifying DATA shares the analytic view object; its data is the same for all containers in the application container and the data is stored only in the application root. Specifying NONE excludes the analytic view from being shared.
```
**classification clause**

Use the classification clause to specify values for the `CAPTION` or `DESCRIPTION` classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the `CAPTION` and `DESCRIPTION` classifications, you may use the DDL shortcuts `CAPTION 'caption'` and `DESCRIPTION 'description'` or the full classification syntax.

You may vary the classification values by language. To specify a language for the `CAPTION` or `DESCRIPTION` classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is `NULL`. The language value must either be `NULL` or a valid `NLS_LANGUAGE` value.

**using clause**

Specify a fact table or view. External and remote tables are permitted. You may specify a table or view in another schema. You can specify an alias for the table or view.

**dim_by clause**

Specify the attribute dimensions of the analytic view.

**dim_key**

Specify an attribute dimension, columns of the fact table, columns of the attribute dimension, and hierarchies that are related in the analytic view.

With the `KEY` keyword, specify one or more columns in the fact table.

With the `REFERENCES` keyword, specify attributes of the attribute dimensions that the analytic view is dimensioned by. Each attribute must be a level key. The `DISTINCT` keyword supports the use of denormalized fact tables, in which the attribute dimension and fact data are in the same table. Use `REFERENCES DISTINCT` when an attribute dimension is defined using the fact table.

With the `HIERARCHIES` keyword, specify the hierarchies in the analytic view that use the attribute dimension.

**dim_ref**

Specify an attribute dimension. You can specify an alias for an attribute dimension, which is required if you use the same dimension more than once or if you use multiple dimensions with the same name from different schemas.

**hier_ref**

Specify a hierarchy. You can specify an alias for a hierarchy. You can specify one of the hierarchies in the list as the default. If you do not specify a default, the first hierarchy in the list is the default.

**measures clause**

Specify the measures for the analytic view.
**av_measure**
Define a measure using either a single fact column or an expression over measures in this analytic view. A measure can be either a base measure or a calculated measure.

**base_measure_clause**
Define a base measure by optionally specifying a fact column or a meas_aggregate_clause, or both. If you do not specify a fact column, then the analytic view uses the column of the fact table that has the same name as the measure. If a column by the same name does not exist, an error is raised.

**calc_measure_clause**
Define a calculated measure by specifying an analytic view expression. The expression may reference other measures in the analytic view, but may not reference fact columns. Calculated measures do not have an aggregate clause because they're computed over the aggregated base measures.

For the syntax and descriptions of analytic view expressions, see Analytic View Expressions.

**default_measure_clause**
Specify a measure to use as the default measure for the analytic view. If you do not specify a measure, the first measure defined is the default.

**meas_aggregate_clause**
Specify a default aggregation operator for a base measure. If you do not specify an aggregation operator, then the operator specified by the default_aggregate_clause is used.

**default_aggregate_clause**
Specify a default aggregation for all base measures in the analytic view. If you do not specify a default aggregation, then the default value is SUM.

**cache_clause**
Specify a cache clause to improve query response time when an appropriate materialized view is available. You can specify one or more cache specifications.

**cache_specification**
Specify one or more measure groups for a cache clause. To include all measure groups, specify ALL. Each measure group can contain one or more measures and one or more level groupings. A level grouping can contain one or more level specifications.

**level_specification**
Specify one or more levels for a level grouping of a measure group for a cache specification. Specify only one level per hierarchy. A materialized view must exist that contains the aggregated values for the hierarchy level.
**Examples**

The following is a description of the SALES_FACT table:

```
desc SALES_FACT
Name              Null? Type
----------------- ----- -------------
MONTH_ID                VARCHAR2(10)
CATEGORY_ID             NUMBER(6)
STATE_PROVINCE_ID       VARCHAR2(120)
UNITS                   NUMBER(6)
SALES                   NUMBER(12,2)
```

The following example creates the SALES_AV analytic view using the SALES_FACT table:

```
CREATE OR REPLACE ANALYTIC VIEW sales_av
USING sales_fact
DIMENSION BY
  (time_attr_dim -- An attribute dimension of
time data
    KEY month_id REFERENCES month_id
    HIERARCHIES (time_hier DEFAULT),
  product_attr_dim -- An attribute dimension of
  product data
    KEY category_id REFERENCES category_id
    HIERARCHIES (product_hier DEFAULT),
  geography_attr_dim -- An attribute dimension of
  store data
    KEY state_province_id
    REFERENCES state_province_id HIERARCHIES (geography_hier DEFAULT)
)
MEASURES
  (sales FACT sales, -- A base measure
  units FACT units, -- A base measure
  sales_prior_period AS -- Calculated measures
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1)),
  sales_year_ago AS
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1
    ACROSS ANCESTOR AT LEVEL year)),
  chg_sales_year_ago AS
    (LAG_DIFF(sales) OVER (HIERARCHY time_hier OFFSET 1
    ACROSS ANCESTOR AT LEVEL year)),
  pct_chg_sales_year_ago AS
    (LAG_DIFF_PERCENT(sales) OVER (HIERARCHY time_hier OFFSET 1
    ACROSS ANCESTOR AT LEVEL year)),
  sales_qtr_ago AS
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1
    ACROSS ANCESTOR AT LEVEL quarter)),
  chg_sales_qtr_ago AS
    (LAG_DIFF(sales) OVER (HIERARCHY time_hier OFFSET 1
    ACROSS ANCESTOR AT LEVEL quarter))
```
CREATE ATTRIBUTE DIMENSION

Purpose

Use the CREATE ATTRIBUTE DIMENSION statement to create an attribute dimension. An attribute dimension specifies dimension members for one or more analytic view hierarchies. It specifies the data source it is using and the members it includes. It specifies levels for its members and determines attribute relationships between levels.

Tip:

You can view and run SQL scripts that create attribute dimensions at the Oracle Live SQL website at https://livesql.oracle.com/apex/livesql/file/index.html. The website has scripts and tutorials that demonstrate the creation and use of analytic views.

Prerequisites

To create an attribute dimension in your own schema, you must have the CREATE ATTRIBUTE DIMENSION system privilege. To create an attribute dimension in another user's schema, you must have the CREATE ANY ATTRIBUTE DIMENSION system privilege.

Syntax

```
create_attribute_dimension ::= CREATE | OR REPLACE | NOFORCE | FORCE | ATTRIBUTE DIMENSION |
                         | schema . attr_dimension |
                         | sharing_clause |
                         | classification_clause |
                         | DIMENSION TYPE STANDARD |
                         | attr_dim_using_clause |
                         | attributes_clause |

```

**Semantics**

**OR REPLACE**

Specify `OR REPLACE` to replace an existing definition of an attribute dimension with a different definition.

**FORCE and NOFORCE**

Specify `FORCE` to force the creation of the attribute dimension even if it does not successfully compile. If you specify `NOFORCE`, then the attribute dimension must compile successfully, otherwise an error occurs. The default is `NOFORCE`. 
**schema**

Specify the schema in which to create the attribute dimension. If you do not specify a schema, then Oracle Database creates the attribute dimension in your own schema.

**attr_dimension**

Specify a name for the attribute dimension.

**sharing_clause**

Specify whether to create the attribute dimension as an application common object. Specifying **METADATA** shares the attribute dimension’s metadata, but its data is unique to each container. Specifying **DATA** shares the attribute dimension object; its data is the same for all containers in the application container and the data is stored only in the application root. Specifying **NONE** excludes the attribute dimension from being shared.

**classification_clause**

Use the classification clause to specify values for the **CAPTION** or **DESCRIPTION** classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the **CAPTION** and **DESCRIPTION** classifications, you may use the DDL shortcuts **CAPTION 'caption'** and **DESCRIPTION 'description'** or the full classification syntax.

You may vary the classification values by language. To specify a language for the **CAPTION** or **DESCRIPTION** classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is **NULL**. The language value must either be **NULL** or a valid **NLS_LANGUAGE** value.

**DIMENSION TYPE**

An attribute dimension may be either a **STANDARD** or a **TIME** type. A **STANDARD** type attribute dimension has **STANDARD** type levels. Each level of a **TIME** type attribute dimension is one of the time types. The default **DIMENSION TYPE** is **STANDARD**.

**attr_dim_using_clause**

With the **USING** keyword, specify a table or view. You may specify an alias for the table or view by using the **AS** keyword. Optionally, you may specify a join path. Use join paths to specify joins when the attribute dimension uses tables organized in a snowflake schema.

**join_path_clause**

The join path clause specifies a join condition between columns in different tables. The name for the join path specified by the **join_path_name** argument must be unique for each join path included in the **USING** clause.
**join_condition**

A join condition consists of one or more join condition elements; each additional join condition element is included by an **AND** operation.

**join_condition_element**

In a join condition element, the column references on the left-hand-side must come from a different table than the column references on the right-hand-side.

**attributes_clause**

Specify one or more `attr_dim_attribute_clause` clauses.

**attr_dim_attribute_clause**

Specify a column from the `attr_dim_using_clause` source. The attribute has the name of the column unless you specify an alias using the AS keyword. You may specify classifications for each attribute.

**attr_dim_level_clause**

Specify a level in the attribute dimension. A level specifies key and optional alternate key attributes that provide the members of the level.

If the key attribute has no null values, then you may specify **NOT NULL**, which is the default. If it does have one or more null values, then specify **SKIP WHEN NULL**.

**LEVEL TYPE**

A **STANDARD** type attribute dimension has **STANDARD** type levels. You do not need to specify a **LEVEL TYPE** for a **STANDARD** type attribute dimension.

In a **TIME** type attribute dimension, you must specify a level type. The type of the level may be one of the time types. You must specify a time type even if the values of the level members are not of that type. For example, you may have a **SEASON** level with values that are the names of seasons. In defining the level, you must specify any one of the time level types, such as **QUARTERS**. An application may use the level type designations for whatever purpose it chooses.

**DETERMINES**

With the **DETERMINES** keyword, you may specify other attributes of the attribute dimension that this level determines. If an attribute has only one value for each value of another attribute, then the value of the first attribute determines the value of the other attribute. For example, the **QUARTER_ID** attribute has only one value for each value of the **MONTH_ID** attribute, so you can include the the **QUARTER_ID** attribute in the **DETERMINES** phrase of the **MONTHS** level.

**key_clause**

Specify one or more attributes as the key for the level.

**alternate_key_clause**

Specify one or more attributes as the alternate key for the level.
**dim_order_clause**
Specify the ordering of the members of the level.

**all_clause**
Optionally specify MEMBER NAME, MEMBER CAPTION, and MEMBER DESCRIPTION values for the implicit ALL level. By default, the MEMBER NAME value is ALL.

**Examples**
The following example describes the TIME_DIM table:

```sql
desc TIME_DIM
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MONTH_ID</td>
<td></td>
<td>VARCHAR2(10)</td>
</tr>
<tr>
<td>CATEGORY_ID</td>
<td></td>
<td>NUMBER(6)</td>
</tr>
<tr>
<td>STATE_PROVINCE_ID</td>
<td></td>
<td>VARCHAR2(120)</td>
</tr>
<tr>
<td>UNITS</td>
<td></td>
<td>NUMBER(6)</td>
</tr>
<tr>
<td>SALES</td>
<td></td>
<td>NUMBER(12,2)</td>
</tr>
<tr>
<td>YEAR_ID</td>
<td>NOT NULL</td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>YEAR_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(40)</td>
</tr>
<tr>
<td>YEAR_END_DATE</td>
<td></td>
<td>DATE</td>
</tr>
<tr>
<td>QUARTER_ID</td>
<td>NOT NULL</td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>QUARTER_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(40)</td>
</tr>
<tr>
<td>QUARTER_END_DATE</td>
<td></td>
<td>DATE</td>
</tr>
<tr>
<td>QUARTER_OF_YEAR</td>
<td></td>
<td>NUMBER</td>
</tr>
<tr>
<td>MONTH_ID</td>
<td>NOT NULL</td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>MONTH_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(40)</td>
</tr>
<tr>
<td>MONTH_END_DATE</td>
<td></td>
<td>DATE</td>
</tr>
<tr>
<td>MONTH_OF_YEAR</td>
<td></td>
<td>NUMBER</td>
</tr>
<tr>
<td>MONTH_LONG_NAME</td>
<td></td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>SEASON</td>
<td></td>
<td>VARCHAR2(10)</td>
</tr>
<tr>
<td>SEASON_ORDER</td>
<td></td>
<td>NUMBER(38)</td>
</tr>
<tr>
<td>MONTH_OF_QUARTER</td>
<td></td>
<td>NUMBER(38)</td>
</tr>
</tbody>
</table>

The following example creates a TIME type attribute dimension, using columns from the TIME_DIM table:

```sql
CREATE OR REPLACE ATTRIBUTE DIMENSION time_attr_dim
DIMENSION TYPE TIME
USING time_dim
ATTRIBUTES
(year_id
  CLASSIFICATION caption VALUE 'YEAR_ID'
  CLASSIFICATION description VALUE 'YEAR ID',
year_name
  CLASSIFICATION caption VALUE 'YEAR_NAME'
  CLASSIFICATION description VALUE 'Year',
year_end_date
  CLASSIFICATION caption VALUE 'YEAR_END_DATE'
  CLASSIFICATION description VALUE 'Year End Date',
```
CREATE ATTRIBUTE DIMENSION

quarter_id
CLASSIFICATION caption VALUE 'QUARTER_ID'
CLASSIFICATION description VALUE 'QUARTER ID',

quarter_name
CLASSIFICATION caption VALUE 'QUARTER_NAME'
CLASSIFICATION description VALUE 'Quarter',

quarter_end_date
CLASSIFICATION caption VALUE 'QUARTER_END_DATE'
CLASSIFICATION description VALUE 'Quarter End Date',

quarter_of_year
CLASSIFICATION caption VALUE 'QUARTER_OF_YEAR'
CLASSIFICATION description VALUE 'Quarter of Year',

month_id
CLASSIFICATION caption VALUE 'MONTH_ID'
CLASSIFICATION description VALUE 'MONTH ID',

month_name
CLASSIFICATION caption VALUE 'MONTH_NAME'
CLASSIFICATION description VALUE 'Month',

month_long_name
CLASSIFICATION caption VALUE 'MONTH_LONG_NAME'
CLASSIFICATION description VALUE 'Month Long Name',

month_end_date
CLASSIFICATION caption VALUE 'MONTH_END_DATE'
CLASSIFICATION description VALUE 'Month End Date',

month_of_quarter
CLASSIFICATION caption VALUE 'MONTH_OF_QUARTER'
CLASSIFICATION description VALUE 'Month of Quarter',

month_of_year
CLASSIFICATION caption VALUE 'MONTH_OF_YEAR'
CLASSIFICATION description VALUE 'Month of Year',

season
CLASSIFICATION caption VALUE 'SEASON'
CLASSIFICATION description VALUE 'Season',

season_order
CLASSIFICATION caption VALUE 'SEASON_ORDER'
CLASSIFICATION description VALUE 'Season Order'

LEVEL month
LEVEL TYPE MONTHS
CLASSIFICATION caption VALUE 'MONTH'
CLASSIFICATION description VALUE 'Month'
KEY month_id
MEMBER NAME month_name
MEMBER CAPTION month_name
MEMBER DESCRIPTION month_long_name
ORDER BY month_end_date
DETERMINES (month_end_date,
quarter_id,
season,
season_order,
month_of_year,
month_of_quarter)

LEVEL quarter
LEVEL TYPE QUARTERS
CLASSIFICATION caption VALUE 'QUARTER'
CLASSIFICATION description VALUE 'Quarter'
The following example describes the PRODUCT_DIM table:

desc PRODUCT_DIM

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEPARTMENT_ID</td>
<td>NOT NULL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>DEPARTMENT_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(100)</td>
</tr>
<tr>
<td>CATEGORY_ID</td>
<td>NOT NULL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>CATEGORY_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(100)</td>
</tr>
</tbody>
</table>

The following example creates a STANDARD type attribute dimension, using columns from the PRODUCT_DIM table:

CREATE OR REPLACE ATTRIBUTE DIMENSION product_attr_dim USING product_dim
ATTRIBUTES
(department_id,
   department_name,
   category_id,
   category_name)
LEVEL DEPARTMENT
The following example describes the GEOGRAPHY_DIM table:

desc GEOGRAPHY_DIM

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEPARTMENT_ID</td>
<td>NOT NULL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>DEPARTMENT_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(100)</td>
</tr>
<tr>
<td>CATEGORY_ID</td>
<td>NOT NULL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>CATEGORY_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(100)</td>
</tr>
<tr>
<td>REGION_ID</td>
<td>NOT NULL</td>
<td>VARCHAR2(120)</td>
</tr>
<tr>
<td>REGION_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(100)</td>
</tr>
<tr>
<td>COUNTRY_ID</td>
<td>NOT NULL</td>
<td>VARCHAR2(2)</td>
</tr>
<tr>
<td>COUNTRY_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(120)</td>
</tr>
<tr>
<td>STATE_PROVINCE_ID</td>
<td>NOT NULL</td>
<td>VARCHAR2(120)</td>
</tr>
<tr>
<td>STATE_PROVINCE_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(400)</td>
</tr>
</tbody>
</table>

The following example creates an STANDARD type attribute dimension, using columns from the GEOGRAPHY_DIM table:

CREATE OR REPLACE ATTRIBUTE DIMENSION geography_attr_dim USING geography_dim
ATTRIBUTES
(region_id,
 region_name,
 country_id,
 country_name,
 state_province_id,
 state_province_name)
LEVEL REGION
 KEY region_id
 ALTERNATE KEY region_name
 MEMBER NAME region_name
 MEMBER CAPTION region_name
 ORDER BY region_name
LEVEL COUNTRY
 KEY country_id
 ALTERNATE KEY country_name
 MEMBER NAME country_name
 MEMBER CAPTION country_name
CREATE AUDIT POLICY (Unified Auditing)

This section describes the CREATE AUDIT POLICY statement for unified auditing. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to Oracle Database Security Guide for more information on unified auditing.

Purpose

Use the CREATE AUDIT POLICY statement to create a unified audit policy.

### See Also:

- ALTER AUDIT POLICY (Unified Auditing)
- DROP AUDIT POLICY (Unified Auditing)
- AUDIT (Unified Auditing)
- NOAUDIT (Unified Auditing)

### Prerequisites

You must have the AUDIT SYSTEM system privilege or the AUDIT_ADMIN role.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To create a common unified audit policy, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role. To create a local unified audit policy, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the container to which you are connected.
Syntax

\[
\text{create_audit_policy ::= CREATE AUDIT POLICY policy privilege_audit_clause action_audit_clause role_audit_clause WHEN 'audit_condition' EVALUATE PER STATEMENT SESSION INSTANCE ONLY TOPLEVEL CONTAINER = ALL CURRENT ;}
\]

Note:
You must specify at least one of the clauses `privilege_audit_clause`, `action_audit_clause`, or `role_audit_clause`.

\[(\text{privilege_audit_clause ::=, action_audit_clause ::=, role_audit_clause ::=})\]

\[
\text{privilege_audit_clause ::= PRIVILEGES system_privilege}
\]

\[
\text{action_audit_clause ::= standard_actions component_actions}
\]

Note:
You can specify only the `standard_actions` clause, only the `component_actions` clause, or both clauses in either order, but you can specify each clause at most once.
**standard_actions ::=**

**component_actions ::=**

**role_audit_clause ::=**

**Semantics**

**policy**

Specify the name of the unified audit policy to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

You can find the names of all unified audit policies by querying the AUDIT_UNIFIED_POLICIES view.

**See Also:**

Oracle Database Reference for more information on the AUDIT_UNIFIED_POLICIES view
**privilege_audit_clause**

Use this clause to audit one or more system privileges. SQL statements that require the system privilege(s) in order to succeed are audited. For `system_privilege`, specify a valid system privilege. To view all valid system privileges, query the NAME column of the `SYSTEM_PRIVILEGE_MAP` view.

**Restriction on Auditing System Privileges**

You cannot audit the following system privileges: INHERIT ANY PRIVILEGES, SYSASM, SYSBACKUP, SYSDBA, SYSDG, SYSKM, SYSRAC, and SYSOPER.

**action_audit_clause**

Use this clause to specify one or more actions to be audited. Use the `standard_actions` clause to audit actions on standard RDBMS objects and to audit standard RDBMS system actions for the database. Use the `component_actions` clause to audit actions for components.

**standard_actions**

Use this clause to audit actions on standard RDBMS objects and to audit standard RDBMS system actions for the database.

**object_action ON**

Use this clause to audit an action on the specified object. For `object_action`, specify the action to be audited. Table 13-1 lists the actions that can be audited on each type of object.

**ALL ON**

Use this clause to audit all actions on the specified object. All of the actions listed in Table 13-1 for the type of object that you specify in the `ON` clause will be audited.

**ON Clause**

Use the `ON` clause to specify the object to be audited. Directories and data mining models are identified separately because they reside in separate namespaces. To audit actions on a directory, specify `ON DIRECTORY directory_name`. To audit actions on a data mining model, specify `ON MINING MODEL object_name`. To audit actions on the other types of objects listed in Table 13-1, specify `ON object_name`. If you do not qualify `object_name` with `schema`, then the database assumes the object is in your own schema.

**Table 13-1   Unified Auditing Objects and Actions**

<table>
<thead>
<tr>
<th>Type of Object</th>
<th>Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directory</td>
<td>AUDIT, GRANT, READ</td>
</tr>
<tr>
<td>Function</td>
<td>AUDIT, EXECUTE (Notes 1 and 2), GRANT</td>
</tr>
<tr>
<td>Java Schema Objects (Source, Class, Resource)</td>
<td>AUDIT, EXECUTE, GRANT</td>
</tr>
<tr>
<td>Library</td>
<td>EXECUTE, GRANT</td>
</tr>
<tr>
<td>Materialized Views</td>
<td>ALTER, AUDIT, COMMENT, DELETE, INDEX, INSERT, LOCK, SELECT, UPDATE</td>
</tr>
</tbody>
</table>
### Table 13-1 (Cont.) Unified Auditing Objects and Actions

<table>
<thead>
<tr>
<th>Type of Object</th>
<th>Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mining Model</td>
<td>AUDIT, COMMENT, GRANT, RENAME, SELECT</td>
</tr>
<tr>
<td>Object Type</td>
<td>ALTER, AUDIT, GRANT</td>
</tr>
<tr>
<td>Package</td>
<td>AUDIT, EXECUTE, GRANT</td>
</tr>
<tr>
<td>Procedure</td>
<td>AUDIT, EXECUTE (Notes 1 and 2), GRANT</td>
</tr>
<tr>
<td>Sequence</td>
<td>ALTER, AUDIT, GRANT, SELECT</td>
</tr>
<tr>
<td>Table</td>
<td>ALTER, AUDIT, COMMENT, DELETE, FLASHBACK, GRANT, INDEX, INSERT, LOCK, RENAME, SELECT, UPDATE</td>
</tr>
<tr>
<td>View</td>
<td>AUDIT, DELETE, FLASHBACK, GRANT, INSERT, LOCK, RENAME, SELECT, UPDATE</td>
</tr>
</tbody>
</table>

**Note 1:** When you audit the `EXECUTE` operation on a PL/SQL stored procedure or a stored function, the database considers only its ability to find the procedure or function and authorize its execution when determining the success or failure of the operation for the purposes of auditing. Therefore, if you specify the `WHENEVER NOT SUCCESSFUL` clause, then only invalid object errors, non-existent object errors, and authorization failures are audited; errors encountered during the execution of the procedure or function are not audited. If you specify the `WHENEVER SUCCESSFUL` clause, then all executions that are not blocked by invalid object errors, non-existent object errors, or authorization failures are audited, regardless of whether errors are encountered during execution.

**Note 2:** To audit the failure of a recursive SQL operation inside a PL/SQL stored procedure or stored function, configure auditing for the SQL operation.

**Note 3:** The auditing of `EXECUTE` on a PL/SQL stored procedure, function, or package in the database happens during the instantiation phase of the procedure, function, or package.

**system_action**

Use this clause to audit a system action for the database. To view the valid values for `system_action`, query the `NAME` column of the `AUDITABLE_SYSTEM_ACTIONS` view where `COMPONENT` is 'Standard'.

**ALL**

Use this clause to audit all system actions for the database.

**component_actions**

Use this clause to audit actions for the following components: Oracle Data Pump, Oracle SQL*Loader Direct Path Load, Oracle Label Security, Oracle Database Real Application Security, and Oracle Database Vault.

**DATAPUMP**

Use this clause to audit actions for Oracle Data Pump. For `component_action`, specify the action to be audited. To view the valid actions for Oracle Data Pump, query the `NAME` column of the `AUDITABLE_SYSTEM_ACTIONS` view where `COMPONENT` is `Datapump`. For example:
SELECT name FROM auditable_system_actions WHERE component = 'Datapump';

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Data Pump.

**DIRECT_LOAD**

Use this clause to audit actions for Oracle SQL*Loader Direct Path Load. For *component_action*, specify the action to be audited. To view the valid actions for Oracle SQL*Loader Direct Path Load, query the `NAME` column of the `AUDITABLE_SYSTEM_ACTIONS` view where `COMPONENT` is `Direct path API`. For example:

SELECT name FROM auditable_system_actions WHERE component = 'Direct path API';

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle SQL*Loader Direct Path Load.

**OLS**

Use this clause to audit actions for Oracle Label Security. For *component_action*, specify the action to be audited. To view the valid actions for Oracle Label Security, query the `NAME` column of the `AUDITABLE_SYSTEM_ACTIONS` view where `COMPONENT` is `Label Security`. For example:

SELECT name FROM auditable_system_actions WHERE component = 'Label Security';

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Label Security.

**XS**

Use this clause to audit actions for Oracle Database Real Application Security. For *component_action*, specify the action to be audited. To view the valid actions for Oracle Database Real Application Security, query the `NAME` column of the `AUDITABLE_SYSTEM_ACTIONS` view where `COMPONENT` is `XS`. For example:

SELECT name FROM auditable_system_actions WHERE component = 'XS';

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Database Real Application Security.

**DV**

Use this clause to audit actions for Oracle Database Vault. For *component_action*, specify the action to be audited. To view the valid actions for Oracle Database Vault, query the `NAME` column of the `AUDITABLE_SYSTEM_ACTIONS` view where `COMPONENT` is `Database Vault`. For example:

SELECT name FROM auditable_system_actions WHERE component = 'Database Vault';

For *object_name*, specify the name of the Database Vault object to be audited.

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Database Vault.

**role_audit_clause**

Use this clause to specify one or more roles to be audited. When you audit a role, Oracle Database audits all system privileges that are granted directly to the role. SQL statements that require the system privileges in order to succeed are audited. For
role, specify either a user-defined (local or external) or predefined role. For a list of predefined roles, refer to Oracle Database Security Guide.

WHEN Clause

Use this clause to control when the unified audit policy is enforced.

**audit_condition**

Specify a condition that determines if the unified audit policy is enforced. If **audit_condition** evaluates to **TRUE**, then the policy is enforced. If **FALSE**, then the policy is not enforced.

The **audit_condition** can have a maximum length of 4000 characters. It can contain expressions, as well as the following functions and conditions:

- **Numeric functions**: BITAND, CEIL, FLOOR, POWER
- **Character functions returning character values**: CONCAT, LOWER, UPPER
- **Character functions returning number values**: INSTR, LENGTH
- **Environment and identifier functions**: SYS_CONTEXT, UID
- **Comparison conditions**: =, !=, <>, <, >, <=, >=
- **Logical conditions**: AND, OR
- **Null conditions**: IS [NOT] NULL
- **[NOT] BETWEEN condition**
- **[NOT] IN condition**

The **audit_condition** must be enclosed in single quotation marks. If the **audit_condition** contains a single quotation mark, then specify two single quotation marks instead. For example, to specify the following condition:

SYS_CONTEXT('USERENV', 'CLIENT_IDENTIFIER') = 'myclient'

Specify the following for **'audit_condition'**:

'SYS_CONTEXT(''USERENV'', ''CLIENT_IDENTIFIER'') = ''myclient'''

The **EVALUATE PER** clauses evaluate the audit condition per instance per container. For example, if a condition is evaluated in one container, it will be evaluated again in any other container even if the instance is same.

**EVALUATE PER STATEMENT**

Specify this clause to evaluate the **audit_condition** for each auditable statement. If the **audit_condition** evaluates to **TRUE**, then the unified audit policy is enforced for the statement. If **FALSE**, then the unified audit policy is not enforced for the statement.

**EVALUATE PER SESSION**

Specify this clause to evaluate the **audit_condition** once during the session. The **audit_condition** is evaluated for the first auditable statement that is executed during the session. If the **audit_condition** evaluates to **TRUE**, then the unified audit policy is enforced for all applicable statements for the rest of the session. If **FALSE**, then the unified audit policy is not enforced for all applicable statements for the rest of the session.
EVALUATE PER INSTANCE

Specify this clause to evaluate the \textit{audit\textunderscore condition} once during the lifetime of the instance. The \textit{audit\textunderscore condition} is evaluated for the first auditable statement that is executed during the instance lifetime. If the \textit{audit\textunderscore condition} evaluates to \textit{TRUE}, then the unified audit policy is enforced for all applicable statements for the rest of the lifetime of the instance. If \textit{FALSE}, then the unified audit policy is not enforced for all applicable statements for the rest of the lifetime of the instance.

ONLY TOLEVEL

Specify the \textit{ONLY TOLEVEL} clause when you want to audit the SQL statements issued directly by a user.

SQL statements that are run from within a PL/SQL procedure are not considered top-level statements. You can audit top-level statements from all users, including user \textit{SYS}.

For more see \textit{Database Security Guide}.

CONTAINER Clause

Use the \textit{CONTAINER} clause to specify the scope of the unified audit policy.

- Specify \texttt{CONTAINER = ALL} to create a \textit{common unified audit policy}. This type of policy is available to all pluggable databases (PDBs) in the CDB. The current container must be the root. If you specify the \texttt{ACTIONS object\textunderscore action ON} or \texttt{ACTIONS ALL ON} clause, then you must specify a common object or an application common object.
- Specify \texttt{CONTAINER = CURRENT} to create a \textit{local unified audit policy} in the current container. The current container can be the root or a PDB.

If you omit this clause, then \texttt{CONTAINER = CURRENT} is the default.

\begin{itemize}
  \item \textbf{Note:}
  \begin{quote}
  You cannot alter the scope of a unified audit policy after it has been created.
  \end{quote}
\end{itemize}

Examples

Auditing System Privileges: Example

The following statement creates unified audit policy \texttt{table\_pol}, which audits the system privileges \texttt{CREATE ANY TABLE} and \texttt{DROP ANY TABLE}:

\begin{verbatim}
CREATE AUDIT POLICY table\_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE;
\end{verbatim}

The following statement verifies that \texttt{table\_pol} now appears in the \texttt{AUDIT\_UNIFIED\_POLICIES} view:

\begin{verbatim}
SELECT *
  FROM audit\_unified\_policies
WHERE policy\_name = 'TABLE\_POL';
\end{verbatim}

Auditing Actions on Objects: Examples
The following statement creates unified audit policy `dml_pol`, which audits `DELETE`, `INSERT`, and `UPDATE` actions on table `hr.employees`, and all auditable actions on table `hr.departments`:

```sql
CREATE AUDIT POLICY dml_pol
    ACTIONS DELETE on hr.employees,
             INSERT on hr.employees,
             UPDATE on hr.employees,
             ALL on hr.departments;
```

The following statement creates unified audit policy `read_dir_pol`, which audits `READ` actions on directory `bfile_dir` (created in "Creating a Directory: Examples"):

```sql
CREATE AUDIT POLICY read_dir_pol
    ACTIONS READ ON DIRECTORY bfile_dir;
```

Auditing System Actions: Examples

The following query displays the standard RDBMS system actions that can be audited for the database:

```sql
SELECT name FROM auditable_system_actions
    WHERE component = 'Standard'
    ORDER BY name;
```

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADMINISTER KEY MANAGEMENT</td>
</tr>
<tr>
<td>ALL</td>
</tr>
<tr>
<td>ALTER ASSEMBLY</td>
</tr>
<tr>
<td>ALTER AUDIT POLICY</td>
</tr>
<tr>
<td>ALTER CLUSTER</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

The following statement creates unified audit policy `security_pol`, which audits the system action `ADMINISTER KEY MANAGEMENT`:

```sql
CREATE AUDIT POLICY security_pol
    ACTIONS ADMINISTER KEY MANAGEMENT;
```

The following statement creates unified audit policy `dir_pol`, which audits all read, write, and execute operations on any directory:

```sql
CREATE AUDIT POLICY dir_pol
    ACTIONS READ DIRECTORY, WRITE DIRECTORY, EXECUTE DIRECTORY;
```

The following statement creates unified audit policy `all_actions_pol`, which audits all standard RDBMS system actions for the database:

```sql
CREATE AUDIT POLICY all_actions_pol
    ACTIONS ALL;
```

Auditing Component Actions: Example

The following query displays the actions that can be audited for Oracle Data Pump:

```sql
SELECT name FROM auditable_system_actions
    WHERE component = 'Datapump';
```

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
</tr>
</tbody>
</table>
The following statement creates unified audit policy `dp_actions_pol`, which audits IMPORT actions for Oracle Data Pump:

```
CREATE AUDIT POLICY dp_actions_pol
  ACTIONS COMPONENT = datapump IMPORT;
```

**Auditing Roles: Example**

The following statement creates unified audit policy `java_pol`, which audits the predefined roles `java_admin` and `java_deploy`:

```
CREATE AUDIT POLICY java_pol
  ROLES java_admin, java_deploy;
```

**Auditing System Privileges, Actions, and Roles: Example**

The following statement creates unified audit policy `hr_admin_pol`, which audits multiple system privileges, actions, and roles:

```
CREATE AUDIT POLICY hr_admin_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
  ACTIONS DELETE on hr.employees,
      INSERT on hr.employees,
      UPDATE on hr.employees,
      ALL on hr.departments,
      LOCK TABLE
  ROLES audit_admin, audit_viewer;
```

**Controlling When a Unified Audit Policy is Enforced: Examples**

The following statement creates unified audit policy `order_updates_pol`, which audits UPDATE actions on table `oe.orders`. This policy is enforced only when the auditable statement is issued by an external user. The audit condition is checked once per session.

```
CREATE AUDIT POLICY order_updates_pol
  ACTIONS UPDATE ON oe.orders
  WHEN 'SYS_CONTEXT(''USERENV'', ''IDENTIFICATION_TYPE'') = ''EXTERNAL'''
  EVALUATE PER SESSION;
```

The following statement creates unified audit policy `emp_updates_pol`, which audits DELETE, INSERT, and UPDATE actions on table `hr.employees`. This policy is enforced only when the auditable statement is issued by a user who does not have a UID of 100, 105, or 107. The audit condition is checked for each auditable statement.

```
CREATE AUDIT POLICY emp_updates_pol
  ACTIONS DELETE on hr.employees,
      INSERT on hr.employees,
      UPDATE on hr.employees
  WHEN 'UID NOT IN (100, 105, 107)'
  EVALUATE PER STATEMENT;
```

**Creating a Local Unified Audit Policy: Example**

The following statement creates local unified audit policy `local_table_pol`, which audits the system privileges `CREATE ANY TABLE` and `DROP ANY TABLE` in the current container:

```
CREATE AUDIT POLICY (Unified Auditing)
CREATE AUDIT POLICY local_table_pol
   PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
   CONTAINER = CURRENT;

Creating a Common Unified Audit Policy: Example

The following statement creates common unified audit policy common_role1_pol, which audits the common role c##role1 (created in CREATE ROLE "Examples") across the entire CDB:

CREATE AUDIT POLICY common_role1_pol
   ROLES c##role1
   CONTAINER = ALL;

CREATE CLUSTER

Purpose

Use the CREATE CLUSTER statement to create a cluster. A cluster is a schema object that contains data from one or more tables.

- An indexed cluster must contain more than one table, and all of the tables in the cluster have one or more columns in common. Oracle Database stores together all the rows from all the tables that share the same cluster key.
- In a hash cluster, which can contain one or more tables, Oracle Database stores together rows that have the same hash key value.

For information on existing clusters, query the USER_CLUSTERS, ALL_CLUSTERS, and DBA_CLUSTERS data dictionary views.

See Also:

- Oracle Database Concepts for general information on clusters
- Oracle Database SQL Tuning Guide for suggestions on when to use clusters
- Oracle Database Reference for information on the data dictionary views

Prerequisites

To create a cluster in your own schema, you must have CREATE CLUSTER system privilege. To create a cluster in another user's schema, you must have CREATE ANY CLUSTER system privilege. Also, the owner of the schema to contain the cluster must have either space quota on the tablespace containing the cluster or the UNLIMITED TABLESPACE system privilege.

Oracle Database does not automatically create an index for a cluster when the cluster is initially created. Data manipulation language (DML) statements cannot be issued against cluster tables in an indexed cluster until you create a cluster index with a CREATE INDEX statement.
Syntax

create_cluster ::= 

\[
\text{CREATE CLUSTER} \quad \text{schema} \quad \text{cluster} \\
\text{column} \quad \text{datatype} \quad \text{COLLATE} \quad \text{column_collation_name} \quad \text{SORT} \\
\text{physical_attributes_clause} \quad \text{SIZE} \quad \text{size_clause} \quad \text{TABLESPACE} \quad \text{tablespace} \\
\text{INDEX} \quad \text{SINGLE} \quad \text{TABLE} \quad \text{HASHKEYS} \quad \text{integer} \quad \text{HASH} \quad \text{IS} \quad \text{expr} \\
\text{parallel_clause} \quad \text{NOPARALLEL} \quad \text{PARALLEL} \quad \text{integer} \\
\text{cluster_range_partitions} \\
\]

(\text{physical_attributesClause ::=, size_clause ::=, cluster_range_partitions ::=})

\[
\text{physical_attributes_clause ::=} \\
\text{PCTFREE} \quad \text{integer} \\
\text{PCTUSED} \quad \text{integer} \\
\text{INITTRANS} \quad \text{integer} \\
\text{storage_clause} \\
\]

(storage_clause ::=)

\[
\text{parallel_clause ::=} \\
\text{NOPARALLEL} \\
\text{PARALLEL} \quad \text{integer} \\
\]

Chapter 13
CREATE CLUSTER

13-35
**cluster_range_partitions::=**

- PARTITION BY RANGE (column)
- (PARTITION partition range_values_clause table_partition_description,)

**(range_values_clause::=, table_partition_description::=)**

**Semantics**

**schema**

Specify the schema to contain the cluster. If you omit `schema`, then Oracle Database creates the cluster in your current schema.

**cluster**

Specify is the name of the cluster to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

After you create a cluster, you add tables to it. A cluster can contain a maximum of 32 tables. Object tables and tables containing LOB columns or columns of the Any* Oracle-supplied types cannot be part of a cluster. After you create a cluster and add tables to it, the cluster is transparent. You can access clustered tables with SQL statements just as you can access nonclustered tables.

**See Also:**

- `CREATE TABLE` for information on adding tables to a cluster, "Creating a Cluster: Example", and "Adding Tables to a Cluster: Example"

**column**

Specify one or more names of columns in the cluster key. You can specify up to 16 cluster key columns. These columns must correspond in both data type and size to columns in each of the clustered tables, although they need not correspond in name.

You cannot specify integrity constraints as part of the definition of a cluster key column. Instead, you can associate integrity constraints with the tables that belong to the cluster.

**See Also:**

- "Cluster Keys: Example"
**datatype**

Specify the data type of each cluster key column.

**Restrictions on Cluster Data Types**

Cluster data types are subject to the following restrictions:

- You cannot specify a cluster key column of data type `LONG`, `LONG RAW`, `REF`, `nested table`, `varray`, `BLOB`, `CLOB`, `BFILE`, the Any* Oracle-supplied types, or user-defined object type.
- You can specify a column of type `ROWID`, but Oracle Database does not guarantee that the values in such columns are valid rowids.

> See Also:

"Data Types " for information on data types

**COLLATE**

Use this clause to specify the data-bound collation for character data type columns in the cluster key.

For `column_collation_name`, specify the collation as follows:

- When creating an indexed cluster or a sorted hash cluster, you can specify one of the following collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.
- When creating a hash cluster that is not sorted, you can specify any valid named collation or pseudo-collation.

If you omit this clause, then columns in the cluster key inherit the effective schema default collation of the schema containing the cluster. Refer to the `DEFAULT_COLLATION` clause of `ALTER SESSION` for more information on the effective schema default collation.

The collations of cluster key columns must match the collations of the corresponding columns in the tables created in the cluster.

You can specify the `COLLATE` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

To change the collation of a cluster key column, you must recreate the cluster.

**SORT**

The `SORT` keyword is valid only if you are creating a hash cluster. This clause instructs Oracle Database to sort the rows of the cluster on this column after applying the hash function when performing a DML operation. Doing so may improve response time during subsequent queries on the clustered data.

**Restriction on Sorted Hash Clusters**

Row dependency is not supported for sorted hash clusters.
physical_attributes_clause

The `physical_attributes_clause` lets you specify the storage characteristics of the cluster. Each table in the cluster uses these storage characteristics as well. If you do not specify values for these parameters, then Oracle Database uses the following defaults:

- **PCTFREE**: 10
- **PCTUSED**: 40
- **INITRANS**: 2 or the default value of the tablespace to contain the cluster, whichever is greater

SIZE

Specify the amount of space in bytes reserved to store all rows with the same cluster key value or the same hash value. This space determines the maximum number of cluster or hash values stored in a data block. If `SIZE` is not a divisor of the data block size, then Oracle Database uses the next largest divisor. If `SIZE` is larger than the data block size, then the database uses the operating system block size, reserving at least one data block for each cluster or hash value.

The database also considers the length of the cluster key when determining how much space to reserve for the rows having a cluster key value. Larger cluster keys require larger sizes. To see the actual size, query the `KEY_SIZE` column of the `USER_CLUSTERS` data dictionary view. (This value does not apply to hash clusters, because hash values are not actually stored in the cluster.)

If you omit this parameter, then the database reserves one data block for each cluster key value or hash value.

TABLESPACE

Specify the tablespace in which the cluster is to be created.

INDEX Clause

Specify `INDEX` to create an indexed cluster. In an indexed cluster, Oracle Database stores together rows having the same cluster key value. Each distinct cluster key value is stored only once in each data block, regardless of the number of tables and rows in which it occurs. If you specify neither `INDEX` nor `HASHKEYS`, then Oracle Database creates an indexed cluster by default.
After you create an indexed cluster, you must create an index on the cluster key before you can issue any data manipulation language (DML) statements against a table in the cluster. This index is called the **cluster index**.

You cannot create a cluster index for a hash cluster, and you need not create an index on a hash cluster key.

### HASHKEYS Clause

Specify the `HASHKEYS` clause to create a **hash cluster** and specify the number of hash values for the hash cluster. In a hash cluster, Oracle Database stores together rows that have the same hash key value. The hash value for a row is the value returned by the hash function of the cluster.

Oracle Database rounds up the `HASHKEYS` value to the nearest prime number to obtain the actual number of hash values. The minimum value for this parameter is 2. If you omit both the `INDEX` clause and the `HASHKEYS` parameter, then the database creates an indexed cluster by default.

When you create a hash cluster, the database immediately allocates space for the cluster based on the values of the `SIZE` and `HASHKEYS` parameters.

### SINGLE TABLE

**SINGLE TABLE** indicates that the cluster is a type of hash cluster containing only one table. This clause can provide faster access to rows in the table.

**Restriction on Single-table Clusters**

Only one table can be present in the cluster at a time. However, you can drop the table and create a different table in the same cluster.

### HASH IS expr

Specify an expression to be used as the hash function for the hash cluster. The expression:
• Must evaluate to a positive value
• Must contain at least one column, with referenced columns of any data type as long as the entire expression evaluates to a number of scale 0. For example:
  \( \text{number\_column} \times \text{LENGTH(varchar2\_column)} \)
• Cannot reference user-defined PL/SQL functions
• Cannot reference the pseudocolumns \text{LEVEL} or \text{ROWNUM}
• Cannot reference the user-related functions \text{USERENV}, \text{UID}, or \text{USER} or the datetime functions \text{CURRENT\_DATE}, \text{CURRENT\_TIMESTAMP}, \text{DBTIMEZONE}, \text{EXTRACT (datetime)}, \text{FROM\_TZ}, \text{LOCALTIMESTAMP}, \text{NUMTODSINTERVAL}, \text{NUMTOYMINTERVAL}, \text{SESSIONTIMEZONE}, \text{SYSDATE}, \text{SYSTIMESTAMP}, \text{TO\_DSINTERVAL}, \text{TO\_TIMESTAMP}, \text{TO\_DATE}, \text{TO\_TIMESTAMP\_T2}, \text{TO\_YMINTERVAL}, \text{and} \text{TZ\_OFFSET}.
• Cannot evaluate to a constant
• Cannot be a scalar subquery expression
• Cannot contain columns qualified with a schema or object name (other than the cluster name)

If you omit the \text{HASH IS} clause, then Oracle Database uses an internal hash function for the hash cluster.

For information on existing hash functions, query the \text{USER\_}, \text{ALL\_}, and \text{DBA\_CLUSTER\_HASH\_EXPRESSIONS} data dictionary tables.

The cluster key of a hash column can have one or more columns of any data type. Hash clusters with composite cluster keys or cluster keys made up of noninteger columns must use the internal hash function.

### See Also:

\text{Oracle Database Reference} for information on the data dictionary views

**parallel\_clause**

The \text{parallel\_clause} lets you parallelize the creation of the cluster.

For complete information on this clause, refer to \text{parallel\_clause} in the documentation on \text{CREATE TABLE}.

**NOROWDEPENDENCIES | ROWDEPENDENCIES**

This clause has the same behavior for a cluster that it has for a table. Refer to "\text{NOROWDEPENDENCIES | ROWDEPENDENCIES}" in \text{CREATE TABLE} for information.

**CACHE | NOCACHE**

**CACHE**

Specify \text{CACHE} if you want the blocks retrieved for this cluster to be placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This clause is useful for small lookup tables.

**NOCACHE**
Specify **NOCACHE** if you want the blocks retrieved for this cluster to be placed at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. This is the default behavior.

**NOCACHE** has no effect on clusters for which you specify **KEEP** in the **storage_clause**.

**cluster_range_partitions**

Specify the **cluster_range_partitions** clause to create a range-partitioned hash cluster. If you specify this clause, then you must also specify the **HASHKEYS** clause.

Use the **cluster_range_partitions** clause to partition the cluster on ranges of values from the column list. When you add a table to a range-partitioned hash cluster, it is automatically partitioned on the same columns, with the same number of partitions, and on the same partition bounds as the cluster. Oracle Database assigns system-generated names to the table partitions.

Each partitioning key column with a character data type must have one of the following declared collations: **BINARY**, **USING_NLS_COMP**, **USING_NLS_SORT**, or **USING_NLS_SORT_CS**.

The **cluster_range_partitions** clause has the same semantics as the **range_partitions** clause of **CREATE TABLE**, except that here you cannot specify the **INTERVAL** clause. For complete information, refer to **range_partitions** in the documentation on **CREATE TABLE**.

**See Also:**

"Range-Partitioned Hash Clusters: Example"

**Examples**

**Creating a Cluster: Example**

The following statement creates a cluster named **personnel** with the cluster key column **department**, a cluster size of 512 bytes, and storage parameter values:

```sql
CREATE CLUSTER personnel
   (department NUMBER(4))
SIZE 512
STORAGE (initial 100K next 50K);
```

**Cluster Keys: Example**

The following statement creates the cluster index on the cluster key of **personnel**:

```sql
CREATE INDEX idx_personnel ON CLUSTER personnel;
```

After creating the cluster index, you can add tables to the index and perform DML operations on those tables.

**Adding Tables to a Cluster: Example**

The following statements create some departmental tables from the sample **hr.employees** table and add them to the personnel cluster created in the earlier example:
CREATE TABLE dept_10
    CLUSTER personnel (department_id)
    AS SELECT * FROM employees WHERE department_id = 10;

CREATE TABLE dept_20
    CLUSTER personnel (department_id)
    AS SELECT * FROM employees WHERE department_id = 20;

Hash Clusters: Examples

The following statement creates a hash cluster named language with the cluster key column cust_language, a maximum of 10 hash key values, each of which is allocated 512 bytes, and storage parameter values:

```sql
CREATE CLUSTER language (cust_language VARCHAR2(3))
    SIZE 512 HASHKEYS 10
    STORAGE (INITIAL 100k next 50k);
```

Because the preceding statement omits the HASH IS clause, Oracle Database uses the internal hash function for the cluster.

The following statement creates a hash cluster named address with the cluster key made up of the columns postal_code and country_id, and uses a SQL expression containing these columns for the hash function:

```sql
CREATE CLUSTER address
    (postal_code NUMBER, country_id CHAR(2))
    HASHKEYS 20
    HASH IS MOD(postal_code + country_id, 101);
```

Single-Table Hash Clusters: Example

The following statement creates a single-table hash cluster named cust_orders with the cluster key customer_id and a maximum of 100 hash key values, each of which is allocated 512 bytes:

```sql
CREATE CLUSTER cust_orders (customer_id NUMBER(6))
    SIZE 512 SINGLE TABLE HASHKEYS 100;
```

Range-Partitioned Hash Clusters: Example

The following statement creates a range-partitioned hash cluster named sales with five range partitions based on the amount sold. The cluster key is made up of the columns amount_sold and prod_id. The cluster uses the hash function \((\text{amount}_\text{sold} \times 10 + \text{prod}_\text{id})\) and has a maximum of 100000 hash key values, each of which is allocated 300 bytes.

```sql
CREATE CLUSTER sales (amount_sold NUMBER, prod_id NUMBER)
    HASHKEYS 100000
    HASH IS (amount_sold * 10 + prod_id)
    SIZE 300
    TABLESPACE example
    PARTITION BY RANGE (amount_sold)
        (PARTITION p1 VALUES LESS THAN (2001),
        PARTITION p2 VALUES LESS THAN (4001),
        PARTITION p3 VALUES LESS THAN (6001),
        PARTITION p4 VALUES LESS THAN (8001),
        PARTITION p5 VALUES LESS THAN (MAXVALUE));
```

Create Cluster Tables: Example
The following statement creates a cluster named `emp_dept` with the default key size (600):

```sql
CREATE CLUSTER emp_dept (deptno NUMBER(3))
SIZE 600
TABLESPACE USERS
STORAGE (INITIAL 200K
NEXT 300K
MINEXTENTS 2
PCTINCREASE 33);
```

The following statement creates a cluster table named `dept` under `emp_dept` cluster:

```sql
CREATE TABLE dept (
    deptno NUMBER(3) PRIMARY KEY
) CLUSTER emp_dept (deptno);
```

The following statement creates another cluster table named `empl` under `emp_dept` cluster:

```sql
CREATE TABLE empl (
    emplno NUMBER(5) PRIMARY KEY,
    emplname VARCHAR2(15) NOT NULL,
    deptno NUMBER(3) REFERENCES dept
) CLUSTER emp_dept (deptno);
```

The following statement creates an index for the `emp_dept` cluster:

```sql
CREATE INDEX emp_dept_index
ON CLUSTER emp_dept
TABLESPACE USERS
STORAGE (INITIAL 50K
NEXT 50K
MINEXTENTS 2
MAXEXTENTS 10
PCTINCREASE 33);
```

The following statement queries `USER_CLUSTERS` to display the cluster metadata:

```sql
SELECT CLUSTER_NAME, TABLESPACE_NAME, CLUSTER_TYPE, PCT_INCREASE, MIN_EXTENTS, MAX_EXTENTS FROM USER_CLUSTERS;
```

```
CLUSTER_NAME    TABLESPACE    CLUST PCT_INCREASE MIN_EXTENTS MAX_EXTENTS
--------------- ---------- ----- ------------ ----------- -----------
EMP_DEPT        USERS       INDEX            1  2147483645
```

The following statement queries `USER_CLU_COLUMNS` to display the cluster metadata:

```sql
SELECT * FROM USER_CLU_COLUMNS;
```

```
CLUSTER_NAME    CLU_COLUMN_NAME      TABLE_NAME TAB_COLUMN_NAME
--------------- ---------------------- ---------- ---------------
```
The following statement queries USER_INDEXES to display the index attributes of the emp_dept cluster:

```
SELECT INDEX_NAME, INDEX_TYPE, PCT_INCREASE, MIN_EXTENTS, MAX_EXTENTS
FROM USER_INDEXES WHERE TABLE_NAME='EMP_DEPT';
```

<table>
<thead>
<tr>
<th>INDEX_NAME</th>
<th>INDEX_TYPE</th>
<th>PCT_INCREASE</th>
<th>MIN_EXTENTS</th>
<th>MAX_EXTENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>EMP_DEPT_INDEX</td>
<td>CLUSTER</td>
<td>1</td>
<td>2147483645</td>
<td></td>
</tr>
</tbody>
</table>

**Live SQL:**

View and run a related example on Oracle Live SQL at [Create Cluster Tables](#).

## CREATE CONTEXT

### Purpose

Use the `CREATE CONTEXT` statement to:

- Create a namespace for a context (a set of application-defined attributes that validates and secures an application)
- Associate the namespace with the externally created package that sets the context

You can use the `DBMS_SESSION.SET_CONTEXT` procedure in your designated package to set or reset the attributes of the context.

### See Also:

- *Oracle Database Security Guide* for a discussion of contexts
- *Oracle Database PL/SQL Packages and Types Reference* for information on the `DBMS_SESSION.SET_CONTEXT` procedure

### Prerequisites

To create a context namespace, you must have `CREATE ANY CONTEXT` system privilege.

Note that you cannot use a synonym for a package name in the `CREATE CONTEXT` command.
Syntax

```
create_context ::= CREATE OR REPLACE CONTEXT namespace USING schema .
```

Semantics

**OR REPLACE**

Specify `OR REPLACE` to redefine an existing context namespace using a different package.

**namespace**

Specify the name of the context namespace to create or modify. The name must satisfy the requirements listed in "Database Object Naming Rules". Context namespaces are always stored in the schema `SYS`.

**See Also:**

"Database Object Naming Rules" for guidelines on naming a context namespace

**schema**

Specify the schema owning `package`. If you omit `schema`, then Oracle Database uses the current schema.

**package**

Specify the PL/SQL package that sets or resets the context attributes under the namespace for a user session.

To provide some design flexibility, Oracle Database does not verify the existence of the schema or the validity of the package at the time you create the context.

**INITIALIZED Clause**

The `INITIALIZED` clause lets you specify an entity other than Oracle Database that can initialize the context namespace.

**EXTERNALLY**
EXTERNALLY indicates that the namespace can be initialized using an OCI interface when establishing a session.

See Also:
Oracle Call Interface Programmer’s Guide for information on using OCI to establish a session

GLOBALLY indicates that the namespace can be initialized by the LDAP directory when a global user connects to the database.

After the session is established, only the designated PL/SQL package can issue commands to write to any attributes inside the namespace.

See Also:
Oracle Database Security Guide for information on establishing globally initialized contexts

ACCESS GLOBALLY
This clause indicates that any application context set in namespace is accessible throughout the entire instance. This setting lets multiple sessions share application attributes.

Examples
Creating an Application Context: Example
This example uses a PL/SQL package emp_mgmt, which validates and secures a human resources application. See Oracle Database PL/SQL Language Reference for the example that creates that package. The following statement creates the context namespace hr_context and associates it with the package emp_mgmt:

```
CREATE CONTEXT hr_context USING emp_mgmt;
```

You can control data access based on this context using the SYS_CONTEXT function. For example, the emp_mgmt package has defined an attribute department_id as a particular department identifier. You can secure the base table employees by creating a view that restricts access based on the value of department_id, as follows:

```
CREATE VIEW hr_org_secure_view AS
    SELECT * FROM employees
    WHERE department_id = SYS_CONTEXT('hr_context', 'department_id');
```
CREATE CONTROLFILE

Note:
Oracle recommends that you perform a full backup of all files in the database before using this statement. For more information, see Oracle Database Backup and Recovery User's Guide.

Purpose
The CREATE CONTROLFILE statement should be used in only a few cases. Use this statement to re-create a control file if all control files being used by the database are lost and no backup control file exists. You can also use this statement to change the maximum number of redo log file groups, redo log file members, archived redo log files, data files, or instances that can concurrently have the database mounted and open.

To change the name of the database, Oracle recommends that you use the DBNEWID utility rather than the CREATE CONTROLFILE statement. DBNEWID is preferable because no OPEN RESETLOGS operation is required after changing the database name.

See Also:
• Oracle Database Utilities for more information about the DBNEWID utility
• ALTER DATABASE "BACKUP CONTROLFILE Clause" for information creating a script based on an existing database control file

Prerequisites
To create a control file, you must have the SYSDBA or SYSBACKUP system privilege.

The database must not be mounted by any instance. After successfully creating the control file, Oracle mounts the database in the mode specified by the CLUSTER_DATABASE parameter. The DBA must then perform media recovery before opening the database. If you are using the database with Oracle Real Application Clusters (Oracle RAC), then you must then shut down and remount the database in SHARED mode (by setting the value of the CLUSTER_DATABASE initialization parameter to TRUE) before other instances can start up.
Syntax

```
create_controlfile::=
  CREATE CONTROLFILE REUSE SET DATABASE database logfile_clause RESETLOGS NORESETLOGS DATAFILE file_specification,

logfile_clause::=
  LOGFILE GROUP integer file_specification,

file_specification::=
  CHARACTER_SET character_set

character_set_clause::=
  CHARACTER SET character_set

(storage_clause::=)

logfile_clause::=

(character_set_clause::=)
```

Semantics

When you issue a CREATE CONTROLFILE statement, Oracle Database creates a new control file based on the information you specify in the statement. The control file
resides in the location specified in the `CONTROL_FILES` initialization parameter. If that parameter does not have a value, then the database creates an Oracle-managed control file in the default control file destination, which is one of the following (in order of precedence):

1. One or more control files as specified in the `DB_CREATE_ONLINE_LOG_DEST_n` initialization parameter. The file in the first directory is the primary control file. When `DB_CREATE_ONLINE_LOG_DEST_n` is specified, the database does not create a control file in `DB_CREATE_FILE_DEST` or in `DB_RECOVERY_FILE_DEST` (the fast recovery area).

2. If no value is specified for `DB_CREATE_ONLINE_LOG_DEST_n`, but values are set for both the `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST`, then the database creates one control file in each location. The location specified in `DB_CREATE_FILE_DEST` is the primary control file.

3. If a value is specified only for `DB_CREATE_FILE_DEST`, then the database creates one control file in that location.

4. If a value is specified only for `DB_RECOVERY_FILE_DEST`, then the database creates one control file in that location.

If no values are set for any of these parameters, then the database creates a control file in the default location for the operating system on which the database is running. This control file is not an Oracle Managed File.

If you omit any clauses, then Oracle Database uses the default values rather than the values for the previous control file. After successfully creating the control file, Oracle Database mounts the database in the mode specified by the initialization parameter `CLUSTER_DATABASE`. If that parameter is not set, then the default value is `FALSE`, and the database is mounted in `EXCLUSIVE` mode. Oracle recommends that you then shut down the instance and take a full backup of all files in the database.

---

**See Also:**

*Oracle Database Backup and Recovery User's Guide*

---

**REUSE**

Specify `REUSE` to indicate that existing control files identified by the initialization parameter `CONTROL_FILES` can be reused, overwriting any information they may currently contain. If you omit this clause and any of these control files already exists, then Oracle Database returns an error.

**DATABASE Clause**

Specify the name of the database. The value of this parameter must be the existing database name established by the previous `CREATE DATABASE` statement or `CREATE CONTROLFILE` statement.

**SET DATABASE Clause**

Use `SET DATABASE` to change the name of the database. The name of a database can be as long as eight bytes.
When you specify this clause, you must also specify **RESETLOGS**. If you want to rename the database and retain your existing log files, then after issuing this **CREATE CONTROLFILE** statement you must complete a full database recovery using an **ALTER DATABASE RECOVER USING BACKUP CONTROLFILE** statement.

**logfile_clause**

Use the **logfile_clause** to specify the redo log files for your database. You must list all members of all redo log file groups.

Use the **redo_log_file_spec** form of **file_specification** (see **file_specification**) to list regular redo log files in an operating system file system or to list Oracle ASM disk group redo log files. When using a form of **ASM_filename**, you cannot specify the **autoextend_clause** of the **redo_log_file_spec**.

If you specify **RESETLOGS** in this clause, then you must use one of the file creation forms of **ASM_filename**. If you specify **NORESETLOGS**, then you must specify one of the reference forms of **ASM_filename**.

### See Also:

**ASM_filename** for information on the different forms of syntax and **Oracle Automatic Storage Management Administrator's Guide** for general information about using Oracle ASM

**GROUP integer**

Specify the logfile group number. If you specify **GROUP** values, then Oracle Database verifies these values with the **GROUP** values when the database was last open.

If you omit this clause, then the database creates logfiles using system default values. In addition, if either the **DB_CREATE_ONLINE_LOG_DEST_n** or **DB_CREATE_FILE_DEST** initialization parameter has been set, and if you have specified **RESETLOGS**, then the database creates two logs in the default logfile destination specified in the **DB_CREATE_ONLINE_LOG_DEST_n** parameter, and if it is not set, then in the **DB_CREATE_FILE_DEST** parameter.

### See Also:

**file_specification** for a full description of this clause

**RESETLOGS**

Specify **RESETLOGS** if you want Oracle Database to ignore the contents of the files listed in the **LOGFILE** clause. These files do not have to exist. You must specify this clause if you have specified the **SET DATABASE** clause.

Each **redo_log_file_spec** in the **LOGFILE** clause must specify the **SIZE** parameter. The database assigns all online redo log file groups to thread 1 and enables this thread for public use by any instance. After using this clause, you must open the database using the **RESETLOGS** clause of the **ALTER DATABASE** statement.
NORESETLOGS

Specify `NORESETLOGS` if you want Oracle Database to use all files in the `LOGFILE` clause as they were when the database was last open. These files must exist and must be the current online redo log files rather than restored backups. The database reassigns the redo log file groups to the threads to which they were previously assigned and reenables the threads as they were previously enabled.

You cannot specify `NORESETLOGS` if you have specified the `SET DATABASE` clause to change the name of the database. Refer to “SET DATABASE Clause” for more information.

DATAFILE Clause

Specify the data files of the database. You must list all data files. These files must all exist, although they may be restored backups that require media recovery.

Do not include in the `DATAFILE` clause any data files in read-only tablespaces. You can add these types of files to the database later. Also, do not include in this clause any temporary data files (temp files).

Use the `datafile_tempfile_spec` form of `file_specification` (see `file_specification`) to list regular data files and temp files in an operating system file system or to list Oracle ASM disk group files. When using a form of `ASM_filename`, you must use one of the reference forms of `ASM_filename`. Refer to `ASM_filename` for information on the different forms of syntax.

> See Also:

*Oracle Automatic Storage Management Administrator’s Guide* for general information about using Oracle ASM

Restriction on DATAFILE

You cannot specify the `autoextend_clause` of `file_specification` in this `DATAFILE` clause.

MAXLOGFILES Clause

Specify the maximum number of online redo log file groups that can ever be created for the database. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The default and maximum values depend on your operating system. The value that you specify should not be less than the greatest `GROUP` value for any redo log file group.

MAXLOGMEMBERS Clause

Specify the maximum number of members, or identical copies, for a redo log file group. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The minimum value is 1. The maximum and default values depend on your operating system.
MAXLOGHISTORY Clause

This parameter is useful only if you are using Oracle Database in ARCHIVELOG mode. Specify your current estimate of the maximum number of archived redo log file groups needed for automatic media recovery of the database. The database uses this value to determine how much space to allocate in the control file for the names of archived redo log files.

The minimum value is 0. The default value is a multiple of the MAXINSTANCES value and depends on your operating system. The maximum value is limited only by the maximum size of the control file. The database will continue to add additional space to the appropriate section of the control file as needed, so that you do not need to re-create the control file if your original configuration is no longer adequate. As a result, the actual value of this parameter can eventually exceed the value you specify.

MAXDATAFILES Clause

Specify the initial sizing of the data files section of the control file at CREATE DATABASE or CREATE CONTROLFILE time. An attempt to add a file whose number is greater than MAXDATAFILES, but less than or equal to DB_FILES, causes the control file to expand automatically so that the data files section can accommodate more files.

The number of data files accessible to your instance is also limited by the initialization parameter DB_FILES.

MAXINSTANCES Clause

Specify the maximum number of instances that can simultaneously have the database mounted and open. This value takes precedence over the value of the initialization parameter INSTANCES. The minimum value is 1. The maximum and default values depend on your operating system.

ARCHIVELOG | NOARCHIVELOG

Specify ARCHIVELOG to archive the contents of redo log files before reusing them. This clause prepares for the possibility of media recovery as well as instance or system failure recovery.

If you omit both the ARCHIVELOG clause and NOARCHIVELOG clause, then Oracle Database chooses NOARCHIVELOG mode by default. After creating the control file, you can change between ARCHIVELOG mode and NOARCHIVELOG mode with the ALTER DATABASE statement.

FORCE LOGGING

Use this clause to put the database into FORCE LOGGING mode after control file creation. When the database is in this mode, Oracle Database logs all changes in the database except changes to temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any NOLOGGING or FORCE LOGGING settings you specify for individual tablespaces and any NOLOGGING settings you specify for individual database objects. If you omit this clause, then the database will not be in FORCE LOGGING mode after the control file is created.
**SET STANDBY NOLOGGING FOR DATA AVAILABILITY | LOAD PERFORMANCE**

**SET STANDBY NOLOGGING**

The `SET STANDBY NOLOGGING` disables logging on the standby. You can specify it in two modes:

- **SET STANDBY NOLOGGING FOR DATA AVAILABILITY** guarantees full data replication to the standby database. The primary and standby databases are synchronized during the load. In cases of network congestion the primary database will throttle its load.

- **SET STANDBY NOLOGGING FOR LOAD PERFORMANCE** to maintain speed of primary database load and synchronize with the standby later.

**Restrictions On SET STANDBY NOLOGGING**

The `SET STANDBY NOLOGGING` clause cannot be used at the same time as `FORCE LOGGING`.

**character_set_clause**

If you specify a character set, then Oracle Database reconstructs character set information in the control file. If media recovery of the database is subsequently required, then this information will be available before the database is open, so that tablespace names can be correctly interpreted during recovery. This clause is required only if you are using a character set other than the default, which depends on your operating system. Oracle Database prints the current database character set to the alert log in `$ORACLE_HOME/log` during startup.

If you are re-creating your control file and you are using Recovery Manager for tablespace recovery, and if you specify a different character set from the one stored in the data dictionary, then tablespace recovery will not succeed. However, at database open, the control file character set will be updated with the correct character set from the data dictionary.

You cannot modify the character set of the database with this clause.

`Oracle Database Backup and Recovery User's Guide` for more information on tablespace recovery

**Examples**

**Creating a Controlfile: Example**

This statement re-creates a control file. In this statement, database `demo` was created with the WE8DEC character set. The example uses the word `path` where you
would normally insert the path on your system to the appropriate Oracle Database directories.

STARTUP NOMOUNT

CREATE CONTROLFILE REUSE DATABASE "demo" NORESETLOGS NOARCHIVELOG
MAXLOGFILES 32
MAXLOGMEMBERS 2
MAXDATAFILES 32
MAXINSTANCES 1
MAXLOGHISTORY 449
LOGFILE
  GROUP 1 '/path/oracle/dbs/t_log1.f' SIZE 500K,
  GROUP 2 '/path/oracle/dbs/t_log2.f' SIZE 500K
# STANDBY LOGFILE
DATAFILE
  '/path/oracle/dbs/t_db1.f',
  '/path/oracle/dbs/dbu19i.dbf',
  '/path/oracle/dbs/tbs_11.f',
  '/path/oracle/dbs/smundo.dbf',
  '/path/oracle/dbs/demo.dbf'
CHARACTER SET WE8DEC;

Note:
This statement prepares a database for initial use and erases any data currently in the specified files. Use this statement only when you understand its ramifications.

Note:
In this release of Oracle Database and in subsequent releases, several enhancements are being made to ensure the security of default database user accounts. You can find a security checklist for this release in Oracle Database Security Guide. Oracle recommends that you read this checklist and configure your database accordingly.

Purpose
Use the CREATE DATABASE statement to create a database, making it available for general use.

This statement erases all data in any specified data files that already exist in order to prepare them for initial database use. If you use the statement on an existing database, then all data in the data files is lost.

After creating the database, this statement mounts it in either exclusive or parallel mode, depending on the value of the CLUSTER_DATABASE initialization parameter and
opens it, making it available for normal use. You can then create tablespaces for the database.

See Also:

- **ALTER DATABASE** for information on modifying a database

- **CREATE TABLESPACE** for information on creating tablespaces

Prerequisites

To create a database, you must have the **SYSDBA** system privilege. An initialization parameter file with the name of the database to be created must be available, and you must be in **STARTUP NOMOUNT** mode.

Semantics

database

Specify the name of the database to be created. The name must match the value of the DB_NAME initialization parameter. The name can be up to 8 bytes long and can contain only ASCII characters. The following characters are valid in a database name: alphanumeric characters, underscore (_), number sign (#), and dollar sign ($). No other characters are valid. The database name must start with an alphabetic character. Oracle Database writes this name into the control file. If you subsequently issue
an ALTER DATABASE statement that explicitly specifies a database name, then Oracle Database verifies that name with the name in the control file.

The database name is case insensitive and is stored in uppercase ASCII characters. If you specify the database name as a quoted identifier, then the quotation marks are silently ignored.

Note:

You cannot use special characters from European or Asian character sets in a database name. For example, characters with umlauts are not allowed.

If you omit the database name from a CREATE DATABASE statement, then Oracle Database uses the name specified by the initialization parameter DB_NAME. The DB_NAME initialization parameter must be set in the database initialization parameter file, and if you specify a different name from the value of that parameter, then the database returns an error. Refer to "Database Object Naming Rules" for additional rules to which database names should adhere.

USER SYS ..., USER SYSTEM ...

Use these clauses to establish passwords for the SYS and SYSTEM users. These clauses are not mandatory in this release. However, if you specify either clause, then you must specify both clauses.

If you do not specify these clauses, then Oracle Database creates the default password change_on_install for user SYS. You can change this password later with the statement ALTER USER.

See Also:

ALTER USER

CONTROLFILE REUSE Clause

Specify CONTROLFILE REUSE to reuse existing control files identified by the initialization parameter CONTROL_FILES, overwriting any information they currently contain. Normally you use this clause only when you are re-creating a database, rather than creating one for the first time. When you create a database for the first time, Oracle Database creates a control file in the default destination, which is dependent on the value or several initialization parameters. See CREATE CONTROLFILE, "Semantics".

You cannot use this clause if you also specify a parameter value that requires that the control file be larger than the existing files. These parameters are MAXLOGFILES, MAXLOGMEMBERS, MAXLOGHISTORY, MAXDATAFILES, and MAXINSTANCES.

If you omit this clause and any of the files specified by CONTROL_FILES already exist, then the database returns an error.
MAXDATAFILES Clause
Specify the initial sizing of the data files section of the control file at \texttt{CREATE DATABASE} or \texttt{CREATE CONTROLFILE} time. An attempt to add a file whose number is greater than \texttt{MAXDATAFILES}, but less than or equal to \texttt{DB_FILES}, causes the Oracle Database control file to expand automatically so that the data files section can accommodate more files.

The number of data files accessible to your instance is also limited by the initialization parameter \texttt{DB_FILES}.

MAXINSTANCES Clause
Specify the maximum number of instances that can simultaneously have this database mounted and open. This value takes precedence over the value of initialization parameter \texttt{INSTANCES}. The minimum value is 1. The maximum value is 1055. The default depends on your operating system.

CHARACTER SET Clause
Specify the character set the database uses to store data. The supported character sets and default value of this parameter depend on your operating system.

Restriction on CHARACTER SET
You cannot specify the \texttt{AL16UTF16} character set as the database character set.

\textbf{See Also:}
\textit{Oracle Database Globalization Support Guide} for more information about choosing a character set

NATIONAL CHARACTER SET Clause
Specify the national character set used to store data in columns specifically defined as \texttt{NCHAR}, \texttt{NCLOB}, or \texttt{NVARCHAR2}. Valid values are \texttt{AL16UTF16} and \texttt{UTF8}. The default is \texttt{AL16UTF16}.

\textbf{See Also:}
\textit{Oracle Database Globalization Support Guide} for information on Unicode data type support

SET DEFAULT TABLESPACE Clause
Use this clause to determine the default type of subsequently created tablespaces and of the \texttt{SYSTEM} and \texttt{SYSAUX} tablespaces. Specify either \texttt{BIGFILE} or \texttt{SMALLFILE} to set the default type of subsequently created tablespaces as a bigfile or smallfile tablespace, respectively.

- A \textbf{bigfile tablespace} contains only one data file or temp file, which can contain up to approximately 4 billion ($2^{32}$) blocks. The maximum size of the single data file or
temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.

- A **smallfile tablespace** is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million \(2^{22}\) blocks.

If you omit this clause, then Oracle Database creates smallfile tablespaces by default.

---

**See Also:**

- *Oracle Database Administrator's Guide* for more information about bigfile tablespaces
- “Setting the Default Type of Tablespaces: Example” for an example using this syntax

---

**database_logging_clauses**

Use the **database_logging_clauses** to determine how Oracle Database will handle redo log files for this database.

**LOGFILE Clause**

Specify one or more files to be used as redo log files. Use the *redo_log_file_spec* form of *file_specification* to create regular redo log files in an operating system file system or to create Oracle ASM disk group redo log files. When using a form of *ASM_filename*, you cannot specify the *autoextend_clause* of *redo_log_file_spec*.

The *redo_log_file_spec* clause specifies a redo log file group containing one or more redo log file members (copies). All redo log files specified in a CREATE DATABASE statement are added to redo log thread number 1.

---

**See Also:**

*file_specification* for a full description of this clause

---

If you omit the **LOGFILE clause**, then Oracle Database creates an Oracle-managed log file member in the default destination, which is one of the following locations (in order of precedence):

- If *DB_CREATE_ONLINE_LOG_DEST_n* is set, then the database creates a log file member in each directory specified, up to the value of the *MAXLOGMEMBERS* initialization parameter.
- If the *DB_CREATE_ONLINE_LOG_DEST_n* parameter is not set, but both the *DB_CREATE_FILE_DEST* and *DB_RECOVERY_FILE_DEST* initialization parameters are set, then the database creates one Oracle-managed log file member in each of those locations. The log file in the *DB_CREATE_FILE_DEST* destination is the first member.
- If only the *DB_CREATE_FILE_DEST* initialization parameter is specified, then Oracle Database creates a log file member in that location.
• If only the `DB_RECOVERY_FILE_DEST` initialization parameter is specified, then Oracle Database creates a log file member in that location.

In all these cases, the parameter settings must correctly specify operating system filenames or creation form Oracle ASM filenames, as appropriate.

If no values are set for any of these parameters, then the database creates a log file in the default location for the operating system on which the database is running. This log file is not an Oracle Managed File.

**GROUP integer**

Specify the number that identifies the redo log file group. The value of `integer` can range from 1 to the value of the `MAXLOGFILES` parameter. A database must have at least two redo log file groups. You cannot specify multiple redo log file groups having the same `GROUP` value. If you omit this parameter, then Oracle Database generates its value automatically. You can examine the `GROUP` value for a redo log file group through the dynamic performance view `V$LOG`.

**MAXLOGFILES Clause**

Specify the maximum number of redo log file groups that can ever be created for the database. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The default, minimum, and maximum values depend on your operating system.

**MAXLOGMEMBERS Clause**

Specify the maximum number of members, or copies, for a redo log file group. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The minimum value is 1. The maximum and default values depend on your operating system.

**MAXLOGHISTORY Clause**

This parameter is useful only if you are using Oracle Database in `ARCHIVELOG` mode with Oracle Real Application Clusters (Oracle RAC). Specify the maximum number of archived redo log files for automatic media recovery of Oracle RAC. The database uses this value to determine how much space to allocate in the control file for the names of archived redo log files. The minimum value is 0. The default value is a multiple of the `MAXINSTANCES` value and depends on your operating system. The maximum value is limited only by the maximum size of the control file.

**ARCHIVELOG**

Specify `ARCHIVELOG` if you want the contents of a redo log file group to be archived before the group can be reused. This clause prepares for the possibility of media recovery.

**NOARCHIVELOG**

Specify `NOARCHIVELOG` if the contents of a redo log file group need not be archived before the group can be reused. This clause does not allow for the possibility of media recovery.

The default is `NOARCHIVELOG` mode. After creating the database, you can change between `ARCHIVELOG` mode and `NOARCHIVELOG` mode with the `ALTER DATABASE` statement.

**FORCE LOGGING**
Use this clause to put the database into **FORCE LOGGING** mode. Oracle Database will log all changes in the database except for changes in temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any **NOLOGGING** or **FORCE LOGGING** settings you specify for individual tablespaces and any **NOLOGGING** settings you specify for individual database objects.

**FORCE LOGGING** mode is persistent across instances of the database. If you shut down and restart the database, then the database is still in **FORCE LOGGING** mode. However, if you re-create the control file, then Oracle Database will take the database out of **FORCE LOGGING** mode unless you specify **FORCE LOGGING** in the **CREATE CONTROLFILE** statement.

---

**Note:**

**FORCE LOGGING** mode can have performance effects. Refer to *Oracle Database Administrator's Guide* for information on when to use this setting.

---

**See Also:**

**CREATE CONTROLFILE**

---

**SET STANDBY NOLOGGING FOR DATA AVAILABILITY | LOAD PERFORMANCE**

The **SET STANDBY NOLOGGING** disables logging on the standby. You can specify it in two modes:

- **SET STANDBY NOLOGGING FOR DATA AVAILABILITY** guarantees full data replication to the standby database. The primary and standby databases are synchronized during the load. In cases of network congestion the primary database will throttle its load.

- **SET STANDBY NOLOGGING FOR LOAD PERFORMANCE** to maintain speed of primary database load and synchronize with the standby later.

**Restrictions SET STANDBY NOLOGGING**

The **SET STANDBY NOLOGGING** clause cannot be used at the same time as **FORCE LOGGING**.

**tablespace_clauses**

Use the tablespace clauses to configure the **SYSTEM** and **SYSAUX** tablespaces and to specify a default temporary tablespace and an undo tablespace.

**extent_management_clause**

Use this clause to create a locally managed **SYSTEM** tablespace. If you omit this clause, then the **SYSTEM** tablespace will be dictionary managed.
When you create a locally managed SYSTEM tablespace, you cannot change it to be dictionary managed, nor can you create any other dictionary-managed tablespaces in this database.

If you specify this clause, then the database must have a default temporary tablespace, because a locally managed SYSTEM tablespace cannot store temporary segments.

- If you specify EXTENT MANAGEMENT LOCAL but you do not specify the DATAFILE clause, then you can omit the default_temp_tablespace clause. Oracle Database will create a default temporary tablespace called TEMP with one data file of size 10M with autoextend disabled.
- If you specify both EXTENT MANAGEMENT LOCAL and the DATAFILE clause, then you must also specify the default_temp_tablespace clause and explicitly specify a temp file for that temporary tablespace.

If you have opened the instance in automatic undo mode, similar requirements exist for the database undo tablespace:

- If you specify EXTENT MANAGEMENT LOCAL but you do not specify the DATAFILE clause, then you can omit the undo_tablespace clause. Oracle Database will create an undo tablespace named SYS_UNDOTBS.
- If you specify both EXTENT MANAGEMENT LOCAL and the DATAFILE clause, then you must also specify the undo_tablespace clause and explicitly specify a data file for that tablespace.

See Also:

Oracle Database Administrator's Guide for more information on locally managed and dictionary-managed tablespaces

DATAFILE Clause

Specify one or more files to be used as data files. All these files become part of the SYSTEM tablespace. Use the data file_tempfile_spec form of file_specification to create regular data files and temp files in an operating system file system or to create Oracle ASM disk group files.

This clause is optional, as is the DATAFILE clause of the undo_tablespace clause. Therefore, to avoid ambiguity, if your intention is to specify a data file for the SYSTEM tablespace with this clause, then do not specify it immediately after an undo_tablespace clause that does not include the optional DATAFILE clause. If you do so, then Oracle Database will interpret the DATAFILE clause to be part of the undo_tablespace clause.
The syntax for specifying data files for the **SYSTEM** tablespace is the same as that for specifying data files during tablespace creation using the **CREATE TABLESPACE** statement, whether you are storing files using Oracle ASM or in a file system.

**See Also:**

**CREATE TABLESPACE** for information on specifying data files

If you are running the database in automatic undo mode and you specify a data file name for the **SYSTEM** tablespace, then Oracle Database expects to generate data files for all tablespaces. Oracle Database does this automatically if you are using Oracle Managed Files—you have set a value for the **DB_CREATE_FILE_DEST** initialization parameter. However, if you are not using Oracle Managed Files and you specify this clause, then you must also specify the **undo_tablespace** clause and the **default_temp_tablespace** clause.

If you omit this clause, then:

- If the **DB_CREATE_FILE_DEST** initialization parameter is set, then Oracle Database creates a 100 MB Oracle-managed data file with a system-generated name in the default file destination specified in the parameter.

- If the **DB_CREATE_FILE_DEST** initialization parameter is not set, then Oracle Database creates one data file whose name and size depend on your operating system.

**See Also:**

**file_specification** for syntax

**SYSAUX Clause**

Oracle Database creates both the **SYSTEM** and **SYSAUX** tablespaces as part of every database. Use this clause if you are not using Oracle Managed Files and you want to specify one or more data files for the **SYSAUX** tablespace.

You must specify this clause if you have specified one or more data files for the **SYSTEM** tablespace using the **DATAFILE** clause. If you are using Oracle Managed Files and you omit this clause, then the database creates the **SYSAUX** data files in the default location set up for Oracle Managed Files.

If you have enabled Oracle Managed Files and you omit the **SYSAUX** clause, then the database creates the **SYSAUX** tablespace as an online, permanent, locally managed tablespace with one data file of 100 MB, with logging enabled and automatic segment-space management.

The syntax for specifying data files for the **SYSAUX** tablespace is the same as that for specifying data files during tablespace creation using the **CREATE TABLESPACE** statement, whether you are storing files using Oracle ASM or in a file system.
See Also:

- **CREATE TABLESPACE** for information on creating the **SYSAUX** tablespace during database upgrade and for information on specifying data files in a tablespace
- *Oracle Database Administrator's Guide* for more information on creating the **SYSAUX** tablespace

### default_tablespace

Specify this clause to create a default permanent tablespace for the database. Oracle Database creates a smallfile tablespace and subsequently will assign to this tablespace any non-**SYSTEM** users for whom you do not specify a different permanent tablespace. If you do not specify this clause, then the **SYSTEM** tablespace is the default permanent tablespace for non-**SYSTEM** users.

The **DATAFILE** clause and **extent_management_clause** have the same semantics they have in a **CREATE TABLESPACE** statement. Refer to "**DATAFILE | TEMPFILE Clause**" and **extent_management_clause** for information on these clauses.

### default_temp_tablespace

Use this clause to create a default shared temporary tablespace or a default local temporary tablespace. Oracle Database will assign to these temporary tablespaces any users for whom you do not specify different temporary tablespaces.

- Specify **DEFAULT TEMPORARY TABLESPACE** to create a default shared temporary tablespace for the database. Shared temporary tablespaces were available in prior releases of Oracle Database and were called "temporary tablespaces." Elsewhere in this guide, the term "temporary tablespace" refers to a shared temporary tablespace unless specified otherwise. If you do not specify this clause, and if the database does not create a default shared temporary tablespace automatically in the process of creating a locally managed **SYSTEM** tablespace, then the **SYSTEM** tablespace is the default shared temporary tablespace.

- Starting with Oracle Database 12c Release 2 (12.2), you can specify **DEFAULT LOCAL TEMPORARY TABLESPACE** to create a default local temporary tablespace. Local temporary tablespaces are useful for Oracle Real Application Clusters and Oracle Flex Clusters. They store a separate, nonshared temp file for each database instance, which can improve I/O performance. A local temporary tablespace must be a **BIGFILE** tablespace.
  - Specify **FOR ALL** to instruct the database to create separate, nonshared temp files for all HUB and LEAF nodes.
  - Specify **FOR LEAF** to instruct the database to create separate nonshared temp files for only LEAF nodes. If you specify this clause, then HUB nodes will use the default shared temporary tablespace. For SQL operations that span both HUB and LEAF nodes, HUB nodes will use the default shared temporary tablespace and LEAF nodes will use the default local temporary tablespace.

If you do not create a local temporary tablespace, then HUB and LEAF nodes will use the default shared temporary tablespace.
Specify **BIGFILE** or **SMALLFILE** to determine whether the default temporary tablespace is a bigfile or smallfile tablespace. These clauses have the same semantics as in the "**SET DEFAULT TABLESPACE Clause** ".

The **TEMPFILE** clause part of this clause is optional if you have enabled Oracle Managed Files by setting the **DB_CREATE_FILE_DEST** initialization parameter. If you have not specified a value for this parameter, then the **TEMPFILE** clause is required. If you have specified **BIGFILE**, then you can specify only one temp file in this clause.

The syntax for specifying temp files for the default temporary tablespace is the same as that for specifying temp files during temporary tablespace creation using the CREATE TABLESPACE statement, whether you are storing files using Oracle ASM or in a file system.

The **extent_management_clause** clause has the same semantics in CREATE DATABASE and CREATE TABLESPACE statements. For complete information, refer to the CREATE TABLESPACE ...

**See Also:**

CREATE TABLESPACE for information on specifying temp files

**Note:**

On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

**Restrictions on Default Temporary Tablespaces**

Default temporary tablespaces are subject to the following restrictions:

- You cannot specify the **SYSTEM** tablespace in this clause.
- The default temporary tablespace must have a standard block size.

**undo_tablespace**

If you have opened the instance in automatic undo mode (the **UNDO_MANAGEMENT** initialization parameter is set to **AUTO**, which is the default), then you can specify the **undo_tablespace** to create a tablespace to be used for undo data. Oracle strongly recommends that you use automatic undo mode. However, if you want undo space management to be handled by way of rollback segments, then you must omit this clause. You can also omit this clause if you have set a value for the **UNDO_TABLESPACE** initialization parameter. If that parameter has been set, and if you specify this clause, then **tablespace** must be the same as that parameter value.
• Specify `BIGFILE` if you want the undo tablespace to be a bigfile tablespace. A bigfile tablespace contains only one data file, which can be up to 8 exabytes (8 million terabytes) in size.

• Specify `SMALLFILE` if you want the undo tablespace to be a smallfile tablespace. A smallfile tablespace is a traditional Oracle Database tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million \(2^{22}\) blocks.

• The `DATAFILE` clause part of this clause is optional if you have enabled Oracle Managed Files by setting the `DB_CREATE_FILE_DEST` initialization parameter. If you have not specified a value for this parameter, then the `DATAFILE` clause is required. If you have specified `BIGFILE`, then you can specify only one data file in this clause.

The syntax for specifying data files for the undo tablespace is the same as that for specifying data files during tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

**See Also:**

- `CREATE TABLESPACE` for information on specifying data files

If you specify this clause, then Oracle Database creates an undo tablespace named `tablespace`, creates the specified data file(s) as part of the undo tablespace, and assigns this tablespace as the undo tablespace of the instance. Oracle Database will manage undo data using this undo tablespace. The `DATAFILE` clause of this clause has the same behavior as described in "DATAFILE Clause".

If you have specified a value for the `UNDO_TABLESPACE` initialization parameter in your initialization parameter file before mounting the database, then you must specify the same name in this clause. If these names differ, then Oracle Database will return an error when you open the database.

If you omit this clause, then Oracle Database creates a default database with a default smallfile undo tablespace named `SYS_UNDOTBS` and assigns this default tablespace as the undo tablespace of the instance. This undo tablespace allocates disk space from the default files used by the `CREATE DATABASE` statement, and it has an initial extent of 10M. Oracle Database handles the system-generated data file as described in "DATAFILE Clause". If Oracle Database is unable to create the undo tablespace, then the entire `CREATE DATABASE` operation fails.

**See Also:**

- *Oracle Database Administrator's Guide* for information on automatic undo management and undo tablespaces
- `CREATE TABLESPACE` for information on creating an undo tablespace after database creation
**set_time_zone_clause**

Use the `SET TIME_ZONE` clause to set the time zone of the database. You can specify the time zone in two ways:

- By specifying a displacement from UTC (Coordinated Universal Time—formerly Greenwich Mean Time). The valid range of `hh:mi` is -12:00 to +14:00.
- By specifying a time zone region. To see a listing of valid time zone region names, query the `TZNAME` column of the `V$TIMEZONE_NAMES` dynamic performance view.

**Note:**

Oracle recommends that you set the database time zone to UTC (0:00). Doing so can improve performance, especially across databases, as no conversion of time zones will be required.

**See Also:**

*Oracle Database Reference* for information on the dynamic performance views

Oracle Database normalizes all `TIMESTAMP WITH LOCAL TIME ZONE` data to the time zone of the database when the data is stored on disk. If you do not specify the `SET TIME_ZONE` clause, then the database uses the operating system time zone of the server. If the operating system time zone is not a valid Oracle Database time zone, then the database time zone defaults to UTC.

**USER_DATA TABLESPACE Clause**

This clause lets you create a tablespace that is used for storing user data and database options such as Oracle XML DB.

- If you specify this clause when creating a multitenant container database (CDB), then the tablespace is created as part of the seed. Pluggable databases (PDBs) subsequently created using the seed will include this tablespace and its data file. The tablespace and data file specified in this clause are not used by the root.
- If you specify this clause when creating a non-CDB, then the tablespace is created as part of the non-CDB.

Specify `BIGFILE` or `SMALLFILE` to determine whether the tablespace is a bigfile or smallfile tablespace. If you omit these clauses, then Oracle Database creates a tablespace of the type that you specify with the `SET DEFAULT TABLESPACE` clause. If you do not specify the `SET DEFAULT TABLESPACE` clause, then Oracle Database creates a smallfile tablespace. These clauses have the same semantics as in the "SET DEFAULT TABLESPACE Clause".

Use the `datafile_tempfile_spec` clause to specify one or more data files for the tablespace. Refer to `datafile_tempfile_spec` for the full semantics of this clause.
**enable_pluggable_database**

Specify this clause to create a CDB. Before issuing the `CREATE DATABASE` statement, you must set the `ENABLE_PLUGGABLE_DATABASE` initialization parameter to `TRUE`. The `CREATE DATABASE` statement will create a CDB that contains a root and a seed container. You can then create PDBs in the CDB by using the `CREATE PLUGGABLE DATABASE` statement. If you omit the `enable_pluggable_database` clause, then a non-CDB is created and it can never contain any containers.

See Also:
- Oracle Database Administrator's Guide for the complete steps for creating a CDB
- CREATE PLUGGABLE DATABASE
- "Creating a CDB: Example"

**file_name_convert**

Use the `file_name_convert` clause to determine how the database generates the names of files (such as data files and wallet files) associated with the seed by using the names of files associated with the root.

- For `filename_pattern`, specify a string found in file names associated with the root.
- For `replacement_filename_pattern`, specify a replacement string.

Oracle Database will replace `filename_pattern` with `replacement_filename_pattern` when generating the names of files associated with the seed.

File name patterns cannot match files or directories managed by Oracle Managed Files.

You can specify `FILE_NAME_CONVERT = NONE`, which is the same as omitting this clause. If you omit this clause, then the database first attempts to use Oracle Managed Files to generate seed file names. If you are not using Oracle Managed Files, then the database uses the `PDB_FILE_NAME_CONVERT` initialization parameter to generate file names. If this parameter is not set, then an error occurs.

**tablespace_datafile_clauses**

Use these clauses to specify attributes for all data files comprising the `SYSTEM` and `SYSAUX` tablespaces in the seed PDB. If you do not specify `SIZE size_clause`, then the data file size for a given tablespace will be set to a predetermined fraction of the size of the corresponding root data file. If you do not specify the `autoextend_clause`, then those values are inherited from the root.

Refer to `size_clause` and `autoextend_clause` for the full semantics of these clauses.

**undo_mode_clause**

This clause lets you specify local undo mode or shared undo mode for the CDB.
• Use LOCAL UNDO ON to specify local undo mode for the CDB. In this mode, every container in the CDB uses local undo.

• Use LOCAL UNDO OFF to specify shared undo mode for the CDB. In this mode, there is one active undo tablespace for a single-instance CDB, or for an Oracle RAC CDB, there is one active undo tablespace for each instance.

If you omit this clause, then the default is LOCAL UNDO OFF.

**USING MIRROR COPY**

Use this clause to create a database with new_database_name using the prepared files of the mirror copy, identified by mirror_name.

**Examples**

**Creating a Database: Example**

The following statement creates a database and fully specifies each argument:

```sql
CREATE DATABASE sample
  CONTROLFILE REUSE
  LOGFILE
    GROUP 1 ('diskx:log1.log', 'disky:log1.log') SIZE 50K,
    GROUP 2 ('diskx:log2.log', 'disky:log2.log') SIZE 50K
  MAXLOGFILES 5
  MAXLOGHISTORY 100
  MAXDATAFILES 10
  MAXINSTANCES 2
  ARCHIVELOG
  CHARACTER SET AL32UTF8
  NATIONAL CHARACTER SET AL16UTF16
  DATAFILE
    'disk1:df1.dbf' AUTOEXTEND ON,
    'disk2:df2.dbf' AUTOEXTEND ON NEXT 10M MAXSIZE UNLIMITED
  DEFAULT TEMPORARY TABLESPACE temp_ts
  UNDO TABLESPACE undo_ts
  SET TIME_ZONE = '+02:00';
```

This example assumes that you have enabled Oracle Managed Files by specifying a value for the DB_CREATE_FILE_DEST parameter in your initialization parameter file. Therefore no file specification is needed for the DEFAULT TEMPORARY TABLESPACE and UNDO TABLESPACE clauses.

**Creating a CDB: Example**

The following statement creates a CDB newcdb. The ENABLE PLUGGABLE DATABASE clause indicates that a CDB is being created. The CDB will contain a root (CDB$ROOT) and a seed (PDB$SEED). The FILE_NAME_CONVERT clause specifies that names of files for the seed will be generated by replacing /u01/app/oracle/oradata/newcdb in the names of files associated with the root with /u01/app/oracle/oradata/pdbseed.

```sql
CREATE DATABASE newcdb
  USER SYS IDENTIFIED BY sys_password
  USER SYSTEM IDENTIFIED BY system_password
  LOGFILE GROUP 1 ('/u01/logs/my/reedo01a.log', '/u02/logs/my/reedo01b.log') SIZE 100M BLOCKSIZE 512,
    GROUP 2 ('/u01/logs/my/reedo02a.log', '/u02/logs/my/reedo02b.log') SIZE 100M BLOCKSIZE 512,
    GROUP 3 ('/u01/logs/my/reedo03a.log', '/u02/logs/my/reedo03b.log') SIZE 100M BLOCKSIZE 512
```
CREATE DATABASE LINK

Purpose

Use the CREATE DATABASE LINK statement to create a database link. A database link is a schema object in one database that enables you to access objects on another database. The other database need not be an Oracle Database system. However, to access non-Oracle systems you must use Oracle Heterogeneous Services.

After you have created a database link, you can use it in SQL statements to refer to tables, views, and PL/SQL objects in the other database by appending @dblink to the table, view, or PL/SQL object name. You can query a table or view in the other database with the SELECT statement. You can also access remote tables and views using any INSERT, UPDATE, DELETE, or LOCK TABLE statement.
See Also:

- *Oracle Database Development Guide* for information about accessing remote tables or views with PL/SQL functions, procedures, packages, and data types
- *Oracle Database Administrator's Guide* for information on distributed database systems
- *Oracle Database Reference* for descriptions of existing database links in the `ALL_DB_LINKS`, `DBA_DB_LINKS`, and `USER_DB_LINKS` data dictionary views and for information on monitoring the performance of existing links through the `V$DBLINK` dynamic performance view
- *ALTER DATABASE LINK* for information on altering a database link when the password of a connection or authentication user changes.
- *DROP DATABASE LINK* for information on dropping existing database links
- *INSERT*, *UPDATE*, *DELETE*, and *LOCK TABLE* for using links in DML operations

Prerequisites

To create a private database link, you must have the `CREATE DATABASE LINK` system privilege. To create a public database link, you must have the `CREATE PUBLIC DATABASE LINK` system privilege. Also, you must have the `CREATE SESSION` system privilege on the remote Oracle Database.

Oracle Net must be installed on both the local and remote Oracle Databases.

Syntax

```sql
create_database_link::=  
CREATE (SHARED PUBLIC DATABASE LINK dblink)  
CONNECT TO CURRENT_USER user IDENTIFIED BY password dblink_authentication USING connect_string
```

(dblink::=)
**dblink_authentication**:=

```
AUTHENTICATED BY user IDENTIFIED BY password
```

### Semantics

**SHARED**

Specify **SHARED** to create a database link that can be shared by multiple sessions using a single network connection from the source database to the target database. In a shared server configuration, shared database links can keep the number of connections into the remote database from becoming too large. Shared links are typically also public database links. However, a shared private database link can be useful when many clients access the same local schema, and therefore use the same private database link.

In a shared database link, multiple sessions in the source database share the same connection to the target database. Once a session is established on the target database, that session is disassociated from the connection, to make the connection available to another session on the source database. To prevent an unauthorized session from attempting to connect through the database link, when you specify **SHARED** you must also specify the `dblink_authentication` clause for the users authorized to use the database link.

**PUBLIC**

Specify **PUBLIC** to create a public database link visible to all users. If you omit this clause, then the database link is private and is available only to you.

The data accessible on the remote database depends on the identity the database link uses when connecting to the remote database:

- If you specify `CONNECT TO user IDENTIFIED BY password`, then the database link connects with the specified user and password.
- If you specify `CONNECT TO CURRENT_USER`, then the database link connects with the user in effect based on the scope in which the link is used.
- If you omit both of those clauses, then the database link connects to the remote database as the locally connected user.

**See Also:**

*Oracle Database Administrator's Guide* for more information about shared database links

"Defining a Public Database Link: Example"
Specify the complete or partial name of the database link. If you specify only the database name, then Oracle Database implicitly appends the database domain of the local database.

Use only ASCII characters for `dblink`. Multibyte characters are not supported. The database link name is case insensitive and is stored in uppercase ASCII characters. If you specify the database name as a quoted identifier, then the quotation marks are silently ignored.

If the value of the `GLOBAL_NAMES` initialization parameter is `TRUE`, then the database link must have the same name as the database to which it connects. If the value of `GLOBAL_NAMES` is `FALSE`, and if you have changed the global name of the database, then you can specify the global name.

The maximum number of database links that can be open in one session or one instance of an Oracle RAC configuration depends on the value of the `OPEN_LINKS` and `OPEN_LINKS_PER_INSTANCE` initialization parameters.

**Restriction on Creating Database Links**

You cannot create a database link in another user's schema, and you cannot qualify `dblink` with the name of a schema. Periods are permitted in names of database links, so Oracle Database interprets the entire name, such as `ralph.linktosales`, as the name of a database link in your schema rather than as a database link named `linktosales` in the schema `ralph`.

**See Also:**

- “References to Objects in Remote Databases” for guidelines for naming database links
- *Oracle Database Reference* for information on the `GLOBAL_NAMES`, `OPEN_LINKS`, and `OPEN_LINKS_PER_INSTANCE` initialization parameters
- “RENAME GLOBAL_NAME Clause” (an `ALTER DATABASE` clause) for information on changing the database global name

**CONNECT TO Clause**

The `CONNECT TO` clause lets you specify the user and credentials, if any, to be used to connect to the remote database.

**CURRENT_USER Clause**

Specify `CURRENT_USER` to create a **current user database link**. The current user must be a global user with a valid account on the remote database.

If the database link is used directly rather than from within a stored object, then the current user is the same as the connected user.

When executing a stored object (such as a procedure, view, or trigger) that initiates a database link, `CURRENT_USER` is the name of the user that owns the stored object, and not the name of the user that called the object. For example, if the database link
appears inside procedure scott.p (created by scott), and user jane calls procedure scott.p, then the current user is scott.

However, if the stored object is an invoker-rights function, procedure, or package, then the invoker's authorization ID is used to connect as a remote user. For example, if the privileged database link appears inside procedure scott.p (an invoker-rights procedure created by scott), and user Jane calls procedure scott.p, then CURRENT_USER is jane and the procedure executes with Jane's privileges.

See Also:

• CREATE FUNCTION for more information on invoker-rights functions
• "Defining a CURRENT_USER Database Link: Example"

user IDENTIFIED BY password

Specify the user name and password used to connect to the remote database using a fixed user database link. If you omit this clause, then the database link uses the user name and password of each user who is connected to the database. This is called a connected user database link.

See Also:

"Defining a Fixed-User Database Link: Example"

dblink_authentication

You can specify this clause only if you are creating a shared database link—that is, you have specified the SHARED clause. Specify the username and password on the target instance. This clause authenticates the user to the remote server and is required for security. The specified username and password must be a valid username and password on the remote instance. The username and password are used only for authentication. No other operations are performed on behalf of this user.

USING 'connect string'

Specify the service name of a remote database. If you specify only the database name, then Oracle Database implicitly appends the database domain to the connect string to create a complete service name. Therefore, if the database domain of the remote database is different from that of the current database, then you must specify the complete service name.

See Also:

Oracle Database Administrator's Guide for information on specifying remote databases
Examples

The examples that follow assume two databases, one with the database name local and the other with the database name remote. The examples use the Oracle Database domain. Your database domain will be different.

Defining a Public Database Link: Example

The following statement defines a shared public database link named remote that refers to the database specified by the service name remote:

```sql
CREATE PUBLIC DATABASE LINK remote
  USING 'remote';
```

This database link allows user hr on the local database to update a table on the remote database (assuming hr has appropriate privileges):

```sql
UPDATE employees@remote
  SET salary=salary*1.1
  WHERE last_name = 'Baer';
```

Defining a Fixed-User Database Link: Example

In the following statement, user hr on the remote database defines a fixed-user database link named local to the hr schema on the local database:

```sql
CREATE DATABASE LINK local
  CONNECT TO hr IDENTIFIED BY password
  USING 'local';
```

After this database link is created, hr can query tables in the schema hr on the local database in this manner:

```sql
SELECT * FROM employees@local;
```

User hr can also use DML statements to modify data on the local database:

```sql
INSERT INTO employees@local
  (employee_id, last_name, email, hire_date, job_id)
VALUES (999, 'Claus', 'sclaus@example.com', SYSDATE, 'SH_CLERK');

UPDATE jobs@local SET min_salary = 3000
  WHERE job_id = 'SH_CLERK';

DELETE FROM employees@local
  WHERE employee_id = 999;
```

Using this fixed database link, user hr on the remote database can also access tables owned by other users on the same database. This statement assumes that user hr has the READ or SELECT privilege on the oe.customers table. The statement connects to the user hr on the local database and then queries the oe.customers table:

```sql
SELECT * FROM oe.customers@local;
```

Defining a CURRENT_USER Database Link: Example

The following statement defines a current-user database link to the remote database, using the entire service name as the link name:

```sql
CREATE DATABASE LINK 13-77
  USING 'remote';
```
CREATE DATABASE LINK remote.us.example.com
  CONNECT TO CURRENT_USER
  USING 'remote';

The user who issues this statement must be a global user registered with the LDAP directory service.

You can create a synonym to hide the fact that a particular table is on the remote database. The following statement causes all future references to emp_table to access the employees table owned by hr on the remote database:

CREATE SYNONYM emp_table
  FOR oe.employees@remote.us.example.com;

CREATE DIMENSION

Purpose

Use the CREATE DIMENSION statement to create a dimension. A dimension defines a parent-child relationship between pairs of column sets, where all the columns of a column set must come from the same table. However, columns in one column set (called a level) can come from a different table than columns in another set. The optimizer uses these relationships with materialized views to perform query rewrite. The SQL Access Advisor uses these relationships to recommend creation of specific materialized views.

Note:

Oracle Database does not automatically validate the relationships you declare when creating a dimension. To validate the relationships specified in the hierarchy_clause and the dimension_join_clause of CREATE DIMENSION, you must run the DBMS_OLAP.VALIDATE_DIMENSION procedure.

See Also:

- CREATE MATERIALIZED VIEW for more information on materialized views
- Oracle Database SQL Tuning Guide for more information on query rewrite, the optimizer and the SQL Access Advisor

Prerequisites

To create a dimension in your own schema, you must have the CREATE DIMENSION system privilege. To create a dimension in another user's schema, you must have the CREATE ANY DIMENSION system privilege. In either case, you must have the READ or SELECT object privilege on any objects referenced in the dimension.
Syntax

create_dimension ::= 

level_clause ::= 

hierarchy_clause ::= 

dimension_join_clause ::= 

attribute_clause ::=
extended_attribute_clause ::= 

ATTRIBUTE attribute LEVEL level DETERMINES dependent_column

Semantics

schema
Specify the schema in which the dimension will be created. If you do not specify schema, then Oracle Database creates the dimension in your own schema.

dimension
Specify the name of the dimension. The name must satisfy the requirements listed in "Database Object Naming Rules".

level_clause
The level_clause defines a level in the dimension. A level defines dimension hierarchies and attributes.

level
Specify the name of the level.

level_table . level_column
Specify the columns in the level. You can specify up to 32 columns. The tables you specify in this clause must already exist.

SKIP WHEN NULL
Specify this clause to indicate that if the specified level is NULL, then the level is to be skipped. This clause lets you preserve the hierarchical chain of parent-child relationship by an alternative path that skips over the specified level. See hierarchy_clause.

Restrictions on Dimension Level Columns
Dimension level columns are subject to the following restrictions:

- All of the columns in a level must come from the same table.
- If columns in different levels come from different tables, then you must specify the dimension_join_clause.
- The set of columns you specify must be unique to this level.
- The columns you specify cannot be specified in any other dimension.
- Each level_column must be non-null unless the level is specified with SKIP WHEN NULL. The non-null columns need not have NOT NULL constraints. The column for which you specify SKIP WHEN NULL cannot have a NOT NULL constraint.)
hierarchy_clause

The hierarchy_clause defines a linear hierarchy of levels in the dimension. Each hierarchy forms a chain of parent-child relationships among the levels in the dimension. Hierarchies in a dimension are independent of each other. They may, but need not, have columns in common.

Each level in the dimension should be specified at most once in this clause, and each level must already have been named in the level_clause.

hierarchy

Specify the name of the hierarchy. This name must be unique in the dimension.

child_level

Specify the name of a level that has an n:1 relationship with a parent level. The level_columns of child_level cannot be null, and each child_level value uniquely determines the value of the next named parent_level.

If the child level_table is different from the parent level_table, then you must specify a join relationship between them in the dimension_join_clause.

parent_level

Specify the name of a level.

dimension_join_clause

The dimension_join_clause lets you specify an inner equijoin relationship for a dimension whose columns are contained in multiple tables. This clause is required and permitted only when the columns specified in the hierarchy are not all in the same table.

child_key_column

Specify one or more columns that are join-compatible with columns in the parent level.

If you do not specify the schema and table of each child_column, then the schema and table are inferred from the CHILD OF relationship in the hierarchy_clause. If you do specify the schema and column of a child_key_column, then the schema and table must match the schema and table of columns in the child of parent_level in the hierarchy_clause.

parent_level

Specify the name of a level.

Restrictions on Join Dimensions

Join dimensions are subject to the following restrictions:

• You can specify only one dimension_join_clause for a given pair of levels in the same hierarchy.

• The child_key_columns must be non-null, and the parent key must be unique and non-null. You need not define constraints to enforce these conditions, but queries may return incorrect results if these conditions are not true.

• Each child key must join with a key in the parent_level table.
• Self-joins are not permitted. The child_key_columns cannot be in the same table as parent_level.

• All of the child key columns must come from the same table.

• The number of child key columns must match the number of columns in parent_level, and the columns must be joinable.

• You cannot specify multiple child key columns unless the parent level consists of multiple columns.

attribute_clause

The attribute_clause lets you specify the columns that are uniquely determined by a hierarchy level. The columns in level must all come from the same table as the dependent_columns. The dependent_columns need not have been specified in the level_clause.

For example, if the hierarchy levels are city, state, and country, then city might determine mayor, state might determine governor, and country might determine president.

extended_attribute_clause

This clause lets you specify an attribute name for one or more level-to-column relations. The type of attribute you create with this clause is not different from the type of attribute created using the attribute_clause. The only difference is that this clause lets you assign a name to the attribute that is different from the level name.

Examples

Creating a Dimension: Examples

This statement was used to create the customers_dim dimension in the sample schema sh:

```
CREATE DIMENSION customers_dim
  LEVEL customer IS (customers.cust_id)
  LEVEL city IS (customers.cust_city)
  LEVEL state IS (customers.cust_state_province)
  LEVEL country IS (countries.country_id)
  LEVEL subregion IS (countries.country_subregion)
  LEVEL region IS (countries.country_region)
HIERARCHY geog_rollup ( 
   customer CHILD OF 
   city CHILD OF 
   state CHILD OF 
   country CHILD OF 
   subregion CHILD OF 
   region 
  JOIN KEY (customers.country_id) REFERENCES country)
ATTIBUTE customer DETERMINES 
 (cust_first_name, cust_last_name, cust_gender, 
  cust_marital_status, cust_year_of_birth, 
  cust_income_level, cust_credit_limit)
ATTIBUTE country DETERMINES (countries.country_name)
```

Creating a Dimension with Extended Attributes: Example
Alternatively, the extended_attribute_clause could have been used instead of the attribute_clause, as shown in the following example:

```
CREATE DIMENSION customers_dim
   LEVEL customer IS (customers.cust_id)
   LEVEL city IS (customers.cust_city)
   LEVEL state IS (customers.cust_state_province)
   LEVEL country IS (countries.country_id)
   LEVEL subregion IS (countries.country_subregion)
   LEVEL region IS (countries.country_region)
HIERARCHY geog_rollup (
   customer CHILD OF
   city CHILD OF
   state CHILD OF
   country CHILD OF
   subregion CHILD OF
   region
JOIN KEY (customers.country_id) REFERENCES country
)
ATTRIBUTE customer_info LEVEL customer DETERMINES
   cust_first_name, cust_last_name, cust_gender,
   cust_marital_status, cust_year_of_birth,
   cust_income_level, cust_credit_limit
ATTRIBUTE country DETERMINES (countries.country_name);
```

Creating a Dimension with NULL Column Values: Example

The following example shows how to create the dimension if one of the level columns is null and you want to preserve the hierarchical chain. The example uses the cust_marital_status column for simplicity because it is not a NOT NULL column. If it had such a constraint, then you would have to disable the constraint before using the SKIP WHEN NULL clause.

```
CREATE DIMENSION customers_dim
   LEVEL customer IS (customers.cust_id)
   LEVEL status IS (customers.cust_marital_status) SKIP WHEN NULL
   LEVEL city IS (customers.cust_city)
   LEVEL state IS (customers.cust_state_province)
   LEVEL country IS (countries.country_id)
   LEVEL subregion IS (countries.country_subregion) SKIP WHEN NULL
   LEVEL region IS (countries.country_region)
HIERARCHY geog_rollup (
   customer CHILD OF
   city CHILD OF
   state CHILD OF
   country CHILD OF
   subregion CHILD OF
   region
JOIN KEY (customers.country_id) REFERENCES country
)
ATTRIBUTE customer DETERMINES
   cust_first_name, cust_last_name, cust_gender,
   cust_marital_status, cust_year_of_birth,
   cust_income_level, cust_credit_limit
ATTRIBUTE country DETERMINES (countries.country_name);
```
CREATE DIRECTORY

Purpose

Use the create directory statement to create a directory object. A directory object specifies an alias for a directory on the server file system where external binary file LOBs (BFILES) and external table data are located. You can use directory names when referring to BFILES in your PL/SQL code and OCI calls, rather than hard coding the operating system path name, for management flexibility.

All directories are created in a single namespace and are not owned by an individual schema. You can secure access to the BFILES stored within the directory structure by granting object privileges on the directories to specific users.

See Also:

- "Large Object (LOB) Data Types " for more information on BFILE objects
- GRANT for more information on granting object privileges
- external_table_clause::= of CREATE TABLE

Prerequisites

You must have the CREATE ANY DIRECTORY system privilege to create directories.

When you create a directory, you are automatically granted the READ, WRITE, and EXECUTE object privileges on the directory, and you can grant these privileges to other users and roles. The DBA can also grant these privileges to other users and roles.

WRITE privileges on a directory are useful in connection with external tables. They let the grantee determine whether the external table agent can write a log file or a bad file to the directory.

For file storage, you must also create a corresponding operating system directory, an Oracle Automatic Storage Management (Oracle ASM) disk group, or a directory within an Oracle ASM disk group. Your system or database administrator must ensure that the operating system directory has the correct read and write permissions for Oracle Database processes.

Privileges granted for the directory are created independently of the permissions defined for the operating system directory, and the two may or may not correspond exactly. For example, an error occurs if sample user hr is granted READ privilege on the directory object but the corresponding operating system directory does not have READ permission defined for Oracle Database processes.

Restrictions

Symbolic links are not allowed in the directory object paths or filenames when opening BFILE objects. The entire directory path and filename is checked and the following error is returned if any symbolic link is found:

ORA-22288: file or LOB operation FILEOPEN failed soft link in path
**Workaround**

If the database directory object or filename you are trying to open contains symbolic links, change it to provide the real path and filename.

**Syntax**

```
create_directory ::=  
```

```
CREATE
OR REPLACE
DIRECTORY directory
SHARING =
METADATA
NONE
AS 'path_name';
```

**Semantics**

**OR REPLACE**

Specify `OR REPLACE` to re-create the directory database object if it already exists. You can use this clause to change the definition of an existing directory without dropping, re-creating, and regranting database object privileges previously granted on the directory.

Users who had previously been granted privileges on a redefined directory can still access the directory without being regranted the privileges.

**See Also:**

`DROP DIRECTORY` for information on removing a directory from the database

**SHARING**

This clause applies only when creating a directory in an application root. This type of directory is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the directory is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the directory’s metadata, but its data is unique to each container. This type of directory is referred to as a metadata-linked application common object.
- **NONE** - The directory is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the directory. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

You cannot change the sharing attribute of a directory after it is created.
directory

Specify the name of the directory object to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ".

Oracle Database does not verify that the directory you specify actually exists. Therefore, take care that you specify a valid directory in your operating system. In addition, if your operating system uses case-sensitive path names, then be sure you specify the directory in the correct format. You need not include a trailing slash at the end of the path name.

Do not refer to a parent directory in the directory name. For example, the following syntax is valid:

create directory mydir as '/scratch/data/file_data';

However, the following syntax is not valid:

create directory mydir as '/scratch/../../file_data';

path_name

Specify the full path name of the operating system directory of the server where the files are located. The single quotation marks are required, with the result that the path name is case sensitive.

Examples

Creating a Directory: Examples

The following statement creates a directory database object that points to a directory on the server:

create directory admin as '/disk1/oracle/admin';

The following statement redefines directory database object bfile_dir to enable access to BFILES stored in the operating system directory /usr/bin/bfile_dir:

create or replace directory bfile_dir as '/usr/bin/bfile_dir';
CREATE DISKGROUP

Note:
This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to Oracle Automatic Storage Management Administrator's Guide.

Purpose
Use the CREATE DISKGROUP clause to name a group of disks and specify that Oracle Database should manage the group for you. Oracle Database manages a disk group as a logical unit and evenly spreads each file across the disks to balance I/O. Oracle Database also automatically distributes database files across all available disks in disk groups and rebalances storage automatically whenever the storage configuration changes.

This statement creates a disk group, assigns one or more disks to the disk group, and mounts the disk group for the first time. Note that CREATE DISKGROUP only mounts a disk group on the local node. If you want Oracle ASM to mount the disk group automatically in subsequent instances, then you must add the disk group name to the value of the ASM_DISKGROUPS initialization parameter in the initialization parameter file. If you use an SPFILE, then the disk group is added to the initialization parameter automatically.

See Also:
- ALTER DISKGROUP for information on modifying disk groups
- Oracle Automatic Storage Management Administrator's Guide for information on Oracle ASM and using disk groups to simplify database administration
- ASM_DISKGROUPS for more information about adding disk group names to the initialization parameter file
- V$ASM_OPERATION for information on monitoring Oracle ASM operations
- DROP DISKGROUP for information on dropping a disk group

Prerequisites
You must have the SYSASM system privilege to issue this statement.

Before issuing this statement, you must format the disks using an operating system format utility. Also ensure that the Oracle Database user has read/write permission and the disks can be discovered using the ASM_DISKSTRING.
When you store your database files in Oracle ASM disk groups, rather than in a file system, before the database instance can access your files in the disk groups, you must configure and start up an Oracle ASM instance to manage the disk groups.

Each database instance communicates with a single Oracle ASM instance on the same node as the database. Multiple database instances on the same node can communicate with a single Oracle ASM instance.

Syntax

`create_diskgroup ::=`

```
CREATE DISKGROUP diskgroup_name
HIGH
NORMAL
FLEX
EXTENDED
SITE site_name
EXTERNAL
REDUNDANCY
QUORUM
REGULAR FAILGROUP failgroup_name
DISK qualified_disk_clause
,
ATTRIBUTE 'attribute_name' = 'attribute_value'
,
;
```

`qualified_disk_clause ::=`

```
NAME disk_name SIZE size_clause
FORCE
NOFORCE
```

(`size_clause ::=`)  

`diskgroup_name`

Specify the name of the disk group. The name must satisfy the requirements listed in "Database Object Naming Rules". However, disk groups are not schema objects.
Note:

Oracle does not recommend using quoted identifiers for disk group names. These quoted identifiers are accepted when issuing the `CREATE DISKGROUP` statement in SQL*Plus, but they may not be valid when using other tools that manage disk groups.

REDUNDANCY Clause

The `REDUNDANCY` clause lets you specify the redundancy level of the disk group.

- **NORMAL REDUNDANCY** requires the existence of at least two failure groups (see the `FAILGROUP` clause that follows). Oracle ASM provides redundancy for all files in the disk group according to the attributes specified in the disk group templates. NORMAL REDUNDANCY disk groups can tolerate the loss of one group. Refer to `ALTER DISKGROUP` ... `diskgroup_template_clauses` for more information on disk group templates.

  NORMAL REDUNDANCY is the default if you omit the `REDUNDANCY` clause. Therefore, if you omit this clause, you must create at least two failure groups, or the create operation will fail.

- **HIGH REDUNDANCY** requires the existence of at least three failure groups. Oracle ASM fixes mirroring at 3-way mirroring, with each extent getting two mirrored copies. HIGH REDUNDANCY disk groups can tolerate the loss of two failure groups.

- **FLEX REDUNDANCY** is a type of disk group that allows a database to specify its own redundancy after the disk group is created. A file's redundancy can also be changed after its creation. This type of disk group supports Oracle ASM file groups and quota groups. A flex disk group requires the existence of at least three failure groups. If a flex disk group has fewer than five failure groups, then it can tolerate the loss of one; otherwise, it can tolerate the loss of two failure groups. To create a flex disk group, the `COMPATIBLE.ASM` and `COMPATIBLE.RDBMS` disk group attributes must be set to 12.2 or greater.

- **EXTENDED REDUNDANCY** is a disk group that has all the features of a flex disk group in addition to being highly available in an extended cluster environment. The cluster contains nodes that span multiple physically separated sites. For more see About Oracle ASM Extended Disk Groups.

  You can use the `SITE` keyword to specify the redundancy of files and file groups in an extended disk group for each site, rather than for each disk group.

- **EXTERNAL REDUNDANCY** indicates that Oracle ASM does not provide any redundancy for the disk group. The disks within the disk group must provide redundancy (for example, using a storage array), or you must be willing to tolerate loss of the disk group if a disk fails (for example, in a test environment). You cannot specify the `FAILGROUP` clause if you specify EXTERNAL REDUNDANCY.

You cannot change the redundancy level after the disk group has been created, with the following exception: You can convert a normal or high redundancy disk group to a flex disk group. For more information, see the `convert_redundancy_clause` of `ALTER DISKGROUP`.
QUORUM | REGULAR

Use these keywords to qualify either failure group or disk specifications.

- **REGULAR** disks, or disks in non-quorum failure groups, can contain any files.
- **QUORUM** disks, or disks in quorum failure groups, cannot contain any database files, the Oracle Cluster Registry (OCR), or dynamic volumes. However, **QUORUM** disks can contain the voting file for Cluster Synchronization Services (CSS). Oracle ASM uses quorum disks or disks in quorum failure groups for voting files whenever possible.

A quorum failure group is not considered when determining redundancy requirements with respect to storing user data.

If you specify neither keyword, then **REGULAR** is the default.

Specify either **QUORUM** or **REGULAR** before the keyword **FAILGROUP** if you are explicitly specifying the failure group. If you are creating a disk group with implicitly created failure groups, then specify these keywords before the keyword **DISK**.

See Also:

*Oracle Automatic Storage Management Administrator's Guide* for more information about quorum and regular disks and failure groups

FAILGROUP Clause

Use this clause to specify a name for one or more failure groups. If you omit this clause, and you have specified **NORMAL** or **HIGH REDUNDANCY**, then Oracle Database automatically adds each disk in the disk group to its own failure group. The implicit name of the failure group is the same as the operating system independent disk name (see "NAME Clause").

You cannot specify this clause if you are creating an **EXTERNAL REDUNDANCY** disk group.

**qualified_disk_clause**

Specify **DISK** **qualified_disk_clause** to add a disk to a disk group.

**search_string**

For each disk you are adding to the disk group, specify the operating system dependent search string that Oracle ASM will use to find the disk. The **search_string** must point to a subset of the disks returned by discovery using the strings in the **ASM_DISKSTRING** initialization parameter. If **search_string** does not point to any disks the Oracle Database user has read/write access to, then Oracle ASM returns an error. If it points to one or more disks that have already been assigned to a different disk group, then Oracle Database returns an error unless you also specify **FORCE**.

For each valid candidate disk, Oracle ASM formats the disk header to indicate that it is a member of the new disk group.
NAME Clause

The NAME clause is valid only if the search_string points to a single disk. This clause lets you specify an operating system independent name for the disk. The name can be up to 30 characters long and can contain only alphanumeric characters. The first character must be alphabetic. If you omit this clause and you assigned a label to a disk through ASMLIB, then that label is used as the disk name. If you omit this clause and you did not assign a label through ASMLIB, then Oracle ASM creates a default name of the form diskgroupname_####, where #### is the disk number. You use this name to refer to the disk in subsequent Oracle ASM operations.

SIZE Clause

Use this clause to specify in bytes the size of the disk. If you specify a size greater than the capacity of the disk, then Oracle ASM returns an error. If you specify a size less than the capacity of the disk, then you limit the disk space Oracle ASM will use. The size value must be identical for all disks in a disk group. If you omit this clause, then Oracle ASM attempts programmatically to determine the size of the disk.

FORCE

Specify FORCE if you want Oracle ASM to add the disk to the disk group even if the disk is already a member of a different disk group.

Note:

Using FORCE in this way may destroy existing disk groups.

For this clause to be valid, the disk must already be a member of a disk group and the disk cannot be part of a mounted disk group.

NOFORCE

Specify NOFORCE if you want Oracle ASM to return an error if the disk is already a member of a different disk group. NOFORCE is the default.

ATTRIBUTE Clause

Use this clause to set attribute values for the disk group. You can view the current attribute values by querying the V$ASM_ATTRIBUTE view. Table 13-2 lists the attributes you can set with this clause. All attribute values are strings.
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS_CONTROL.ENABLED</td>
<td>true or false</td>
<td>Specifies whether Oracle ASM File Access Control is enabled for a disk group. If set to true, accessing Oracle ASM files is subject to access control. If false, any user can access every file in the disk group. All other operations behave independently of this attribute. The default value is false. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.2, you can set this attribute in an ALTER DISKGROUP ... SET ATTRIBUTE statement. You cannot set this attribute when creating a disk group. When you set up file access control on an existing disk group, the files previously created remain accessible by everyone, unless you run the ALTER DISKGROUP SET PERMISSION statement to restrict the permissions. <strong>Note:</strong> This attribute is used in conjunction with ACCESS_CONTROL.UMASK to manage Oracle ASM File Access Control. After setting the ACCESS_CONTROL.ENABLED disk attribute, you must set permissions with the ACCESS_CONTROL.UMASK attribute.</td>
</tr>
<tr>
<td>ACCESS_CONTROL.UMASK</td>
<td>A three-digit number where each digit is 0, 2, or 6.</td>
<td>Determines which permissions are masked out on the creation of an Oracle ASM file for the user that owns the file (first digit), users in the same user group (second digit), and others not in the user group (third digit). This attribute applies to all files on a disk group. Setting to 0 masks out nothing. Setting to 2 masks out write permission. Setting to 6 masks out both read and write permissions. The default value is 066. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.2, you can set this attribute in an ALTER DISKGROUP ... SET ATTRIBUTE statement. You cannot set this attribute when creating a disk group. When you set up file access control on an existing disk group, the files previously created remain accessible by everyone, unless you run the ALTER DISKGROUP SET PERMISSION statement to restrict the permissions. <strong>Note:</strong> This attribute is used in conjunction with ACCESS_CONTROL.ENABLED to manage Oracle ASM File Access Control. Before setting ACCESS_CONTROL.UMASK, you must set ACCESS_CONTROL.ENABLED to true.</td>
</tr>
<tr>
<td>AU_SIZE</td>
<td>Size in bytes. Valid values are powers of 2 from 1M to 64M. Examples ‘4M’, ‘4194304’.</td>
<td>Specifies the allocation unit size. This attribute can be set only during disk group creation; it cannot be modified with an ALTER DISKGROUP statement.</td>
</tr>
<tr>
<td>COMPATIBLE.ADVM</td>
<td>Valid Oracle Database version number</td>
<td>Determines whether the disk group can contain Oracle ADVM volumes. The value must be set to 11.2 or higher. Before setting this attribute, the COMPATIBLE.ASM value must be 11.2 or higher. Also, the Oracle ADVM volume drivers must be loaded. By default, the value of the COMPATIBLE.ADVM attribute is empty until set.</td>
</tr>
</tbody>
</table>
### Table 13-2  (Cont.) Disk Group Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPATIBLE.ASM</td>
<td>Valid Oracle Database version number</td>
<td>Determines the minimum software version for an Oracle ASM instance that can use the disk group. This setting also affects the format of the data structures for the Oracle ASM metadata on the disk. For Oracle ASM in Oracle Database 11g, 10.1 is the default setting for the COMPATIBLE.ASM attribute when using the SQL CREATE DISKGROUP statement, the ASMCMD mkdg command, and Oracle Enterprise Manager Create Disk Group page. When creating a disk group with ASMCA, the default setting is 11.2.</td>
</tr>
<tr>
<td>COMPATIBLE.RDBMS</td>
<td>Valid Oracle Database version number</td>
<td>Determines the minimum COMPATIBLE database initialization parameter setting for any database instance that is allowed to use the disk group. Before advancing the COMPATIBLE.RDBMS attribute, ensure that the values for the COMPATIBLE initialization parameter for all of the databases that access the disk group are set to at least the value of the new setting for COMPATIBLE.RDBMS. For example, if the COMPATIBLE initialization parameters of the databases are set to either 11.1 or 11.2, then COMPATIBLE.RDBMS can be set to any value between 10.1 and 11.1 inclusively. For Oracle ASM in Oracle Database 11g, 10.1 is the default setting for the COMPATIBLE.RDBMS attribute when using the SQL CREATE DISKGROUP statement, the ASMCMD mkdg command, ASMCA Create Disk Group page, and Oracle Enterprise Manager Create Disk Group page.</td>
</tr>
</tbody>
</table>
| CONTENT.CHECK   | true or false                                     | Enables (true) or disables (false) content checking when performing data copy operations for rebalancing a disk group. You cannot set this attribute when creating a disk group. The default value is dependent on the COMPATIBLE.ASM attribute and follows this rule:  
  - If COMPATIBLE.ASM \( \geq 19.0.0.0.0 \), then CONTENT.CHECK defaults to true.  
  - If COMPATIBLE.ASM \( < 19.0.0.0.0 \), then CONTENT.CHECK defaults to false.  
  
  **Note:** This rule is ONLY true for the creation of new diskgroups. If the COMPATIBLE.ASM attribute of an existing diskgroup is updated to 19.0.0.0.0 or above, the CONTENT.CHECK attribute remains at its current value. |
### Table 13-2 (Cont.) Disk Group Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISK_REPAIR_TIME</td>
<td>0 to 136 years</td>
<td>When disks are taken offline, Oracle ASM drops them after a default period of time. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.1, you can set the <code>disk_repair_time</code> attribute in an <code>ALTER DISKGROUP ... SET ATTRIBUTE</code> statement to change that default period of time so that the disk can be repaired and brought back online. You cannot set this attribute when creating a disk group. The time can be specified in units of minute (M) or hour (H). The specified time elapses only when the disk group is mounted. If you omit the unit, then the default is H. If you omit this attribute, and both compatible.rdbms and compatible.asm are set to at least 11.1, then the default is 12 H. Otherwise the disk is dropped immediately. You can override this attribute with an <code>ALTER DISKGROUP ... OFFLINE DISK</code> statement and the <code>DROP AFTER</code> clause. <strong>Note:</strong> If a disk is taken offline using the current value of <code>disk_repair_time</code>, and the value of this attribute is subsequently changed, then the changed value is used by Oracle ASM in the disk offline logic. <strong>See Also:</strong> The ALTER DISKGROUP ... <code>disk_offline_clause</code> and Oracle Automatic Storage Management Administrator’s Guide for more information.</td>
</tr>
<tr>
<td>FAILGROUP_REPAIR_TIME</td>
<td>&lt;number&gt;m (number of minutes) or &lt;number&gt;h (number of hours)</td>
<td>Specifies a default repair time for the failure groups in the disk group. The failure group repair time is used if Oracle ASM determines that an entire failure group has failed. The default value is 24 hours (24h). If there is a repair time specified for a disk, such as with the <code>DROP AFTER</code> clause of the ALTER DISKGROUP OFFLINE DISK statement, then that disk repair time overrides the failure group repair time. This attribute can only be set when altering a disk group and is only applicable to normal and high redundancy disk groups.</td>
</tr>
<tr>
<td>LOGICAL_SECTOR_SIZE</td>
<td>512, 4096, or 4K</td>
<td>Sets the logical sector size of a disk group. This value specifies the smallest possible I/O that the disk group can accept. The default value is estimated from the disks that join the disk group. To set this disk group attribute during the creation of a disk group or to alter it after a disk group has been created, the COMPATIBLE.ASM disk group attribute must be set to 12.2 or higher.</td>
</tr>
<tr>
<td>PHYS_META_REPLICATED</td>
<td>true or false</td>
<td>Tracks the replication status of a disk group. When the Oracle ASM compatibility of a disk group is advanced to 12.0 or higher, the physical metadata of each disk, including its disk header, free space table blocks and allocation table blocks, is replicated. The replication is performed online asynchronously. <code>PHYS_META_REPLICATED</code> is set to true by Oracle ASM if the physical metadata of every disk in the disk group has been replicated. This disk group attribute is only defined in a disk group with the Oracle ASM disk group compatibility (COMPATIBLE.ASM) set to 12.0 and higher. This attribute is read-only and is intended for information only. You cannot set or change its value.</td>
</tr>
</tbody>
</table>
Table 13-2    (Cont.) Disk Group Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREFERRED_READ.ENABLED</td>
<td>true or false</td>
<td>In an Oracle extended cluster, which contains nodes that span multiple physically separated sites, the PREFERRED_READ.ENABLED disk group attribute controls whether preferred read functionality is enabled for a disk group. If preferred read functionality is enabled, then this functionality enables an instance to determine and read from disks at the same site as itself, which can improve performance. For extended clusters, the default value is true. For clusters that are not extended (only one physical site), preferred read is disabled (false). Preferred read status applies to extended, normal, high, and flex redundancy disk groups. This disk group attribute is only defined in a disk group with the Oracle ASM disk group compatibility (COMPATIBLE.ASM) set to 12.2 and higher.</td>
</tr>
<tr>
<td>SECTOR_SIZE</td>
<td>512, 4096, or 4K</td>
<td>Sets the physical sector size of a disk group. All disks in the disk group must have this physical sector size. The default value is obtained from the disks that join the disk group. To set this disk group attribute during the creation of a disk group, the COMPATIBLE.ASM and COMPATIBLE.RDBMS disk group attributes must be set to 11.2 or higher. To alter this disk group attribute after a disk group has been created, the COMPATIBLE.ASM disk group attribute must be set to 12.2 or higher.</td>
</tr>
<tr>
<td>THIN_PROVISIONED</td>
<td>true or false</td>
<td>Enables (true) or disables (false) the functionality to discard unused storage space after a disk group rebalance is completed. The default value is false.</td>
</tr>
<tr>
<td>CONTENT_HARDCHECK</td>
<td>true or false</td>
<td>CONTENT_HARDCHECK enables or disables Hardware Assisted Resilient Data (HARD) checking when performing data copy operations for rebalancing a disk group. This attribute can only be set when altering a disk group.</td>
</tr>
</tbody>
</table>

1 Specify at least the first two digits of a valid Oracle Database release number. Refer to Oracle Database Administrator's Guide for information on specifying valid version numbers. For example, you can specify compatibility as '11.2' or '12.1'.

See Also: Oracle Automatic Storage Management Administrator's Guide for more information on managing these attribute settings.

Examples

The following example assumes that the ASM_DISKSTRING parameter is a superset of /devices/disks/c*, /devices/disks/c* points to at least one device to be used as an Oracle ASM disk, and the Oracle Database user has read/write permission to the disks.
Creating a Diskgroup: Example

The following statement creates an Oracle ASM disk group `dgroup_01` where no redundancy for the disk group is provided by Oracle ASM and includes all disks that match the `search_string`:

```
CREATE DISKGROUP dgroup_01
    EXTERNAL REDUNDANCY
    DISK '/devices/disks/c*';
```

**CREATE EDITION**

**Purpose**

This statement creates a new edition as a child of an existing edition. An edition makes it possible to have two or more versions of the same editionable objects in the database. When you create an edition, it immediately inherits all of the editionable objects of its parent edition. The following object types are editionable:

- Synonym
- View
- Function
- Procedure
- Package (specification and body)
- Type (specification and body)
- Library
- Trigger

An editionable object is an object of one of the above editionable object types in an editions-enabled schema. The ability to have multiple versions of these objects in the database greatly facilitates online application upgrades.

**Note:**

All database object types not listed above are not editionable. Changes to object types that are not editionable are immediately visible across all editions in the database.

Every newly created or upgraded Oracle Database has one default edition named `ORASBASE`, which serves as the parent of the first edition created with a `CREATE EDITION` statement. You can subsequently designate a user-defined edition as the database default edition using an `ALTER DATABASE DEFAULT EDITION` statement.
Prerequisites

To create an edition, you must have the `CREATE ANY EDITION` system privilege, granted either directly or through a role. To create an edition as a child of another edition, you must have the `USE` object privilege on the parent edition.

Syntax

```
create_edition ::= CREATE EDITION edition AS CHILD OF parent_edition;
```

Semantics

`edition`

Specify the name of the edition to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

To view the editions that have been created for the database, query the `EDITION_NAME` column of the `DBA_OBJECTS` or `ALL_OBJECTS` data dictionary view.

When you create an edition, the system automatically grants you the `USE` object privilege `WITH GRANT OPTION` on the edition you create.

**Note:**

Oracle strongly recommends that you do not name editions with the prefixes `ORA`, `ORACLE`, `SYS`, `DBA`, and `DBMS`, as these prefixes are reserved for internal use.

**AS CHILD OF Clause**

If you use this clause, then the new edition is created as a child of `parent_edition`. If you omit this clause, then the new edition is created as a child of the leaf edition. At the time of its creation, the new edition inherits all editioned objects from its parent edition.

**Restriction on Editions**
An edition can have only one child edition. If you specify for `parent_edition` an edition that already has a child edition, then an error is returned.

Examples

The following very simple examples are intended to show the syntax for creating and working with an edition. For realistic examples of using editions refer to Oracle Database Development Guide.

In the following statements, the user HR is given the privileges needed to create and use an edition:

```
GRANT CREATE ANY EDITION, DROP ANY EDITION to HR;
Grant succeeded.

ALTER USER hr ENABLE EDITIONS;
User altered.

HR creates a new edition TEST_ED for testing purposes:

CREATE EDITION test_ed;

HR then creates an editioning view `ed_view` in the default edition ORA$BASE for testing purposes, first verifying that the current edition is the default edition:

```
SELECT SYS_CONTEXT('userenv', 'current_edition_name') FROM DUAL;
SYS_CONTEXT('USERENV','CURRENT_EDITION_NAME')
--------------------------------------------------------------------------------
ORA$BASE
1 row selected.
```

CREATE EDITIONING VIEW e_view AS
  SELECT last_name, first_name, email FROM employees;
View created.

```
DESCRIBE e_view
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
LAST_NAME                                 NOT NULL VARCHAR2(25)
FIRST_NAME                                         VARCHAR2(20)
EMAIL                                     NOT NULL VARCHAR2(25)
```

The view is then actualized in the TEST_ED edition when HR uses the TEST_ED edition and re-creates the view in a different form:

```
ALTER SESSION SET EDITION = TEST_ED;
Session altered.

CREATE OR REPLACE EDITIONING VIEW e_view AS
  SELECT last_name, first_name, email, salary FROM employees;
View created.
```

The view in the TEST_ED edition has an additional column:

```
DESCRIBE e_view
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
LAST_NAME                                 NOT NULL VARCHAR2(25)
FIRST_NAME                                         VARCHAR2(20)
```
CREATE FLASHBACK ARCHIVE

Purpose

Use the CREATE FLASHBACK ARCHIVE statement to create a flashback data archive, which provides the ability to automatically track and archive transactional data changes to specified database objects. A flashback data archive consists of multiple tablespaces and stores historic data from all transactions against tracked tables. The data is stored in internal history tables.

Flashback data archives retain historical data for the time duration specified using the RETENTION parameter. Historical data can be queried using the Flashback Query AS OF clause. Archived historic data that has aged beyond the specified retention period is automatically purged.

Flashback data archives retain historical data across data definition language (DDL) changes to tables enabled for flashback data archive. Flashback data archives supports many common DDL statements, including some DDL statements that alter table definitions or incur data movement. DDL statements that are not supported result in error ORA-55610.
**Prerequisites**

You must have the `FLASHBACK ARCHIVE ADMINISTER` system privilege to create a flashback data archive. In addition, you must have the `CREATE TABLESPACE` system privilege to create a flashback data archive, as well as sufficient quota on the tablespace in which the historical information will reside. To designate a flashback data archive as the system default flashback data archive, you must be logged in as SYSDBA.

**Syntax**

```sql
create_flashback_archive ::= 
CREATE FLASHBACK ARCHIVE DEFAULT 
flashback_archive TABLESPACE tablespace 
flashback_archive_quota NO OPTIMIZE DATA 
flashback_archive_retention ;
```

- `flashback_archive_quota ::= QUOTA integer M G T P E`
- `flashback_archive_retention ::= RETENTION integer YEAR MONTH DAY`
Semantics

**DEFAULT**

You must be logged in as **SYSDBA** to specify **DEFAULT**. Use this clause to designate this flashback data archive as the default flashback data archive for the database. When a **CREATE TABLE** or **ALTER TABLE** statement specifies the **flashback_archive_clause** without specifying a flashback data archive name, the database uses the default flashback data archive to store data from that table.

You cannot specify this clause if a default flashback data archive already exists. However, you can replace an existing default flashback data archive using the **ALTER FLASHBACK ARCHIVE ... SET DEFAULT** clause.

---

**See Also:**

The **CREATE TABLE flashback_archive_clause** for more information

---

**flashback_archive**

Specify the name of the flashback data archive. The name must satisfy the requirements specified in "Database Object Naming Rules".

**TABLESPACE Clause**

Specify the tablespace where the archived data for this flashback data archive is to be stored. You can specify only one tablespace with this clause. However, you can subsequently add tablespaces to the flashback data archive with an **ALTER FLASHBACK ARCHIVE** statement.

**flashback_archive_quota**

Specify the amount of space in the initial tablespace to be reserved for the archived data. If the space for archiving in a flashback data archive becomes full, then DML operations on tracked tables that use this flashback data archive will fail. The database issues an out-of-space alert when the content of the flashback data archive is 90% of the specified quota, to allow time to purge old data or add additional quota. If you omit this clause, then the flashback data archive has unlimited quota on the specified tablespace.

**[NO] OPTIMIZE DATA**

Specify **OPTIMIZE DATA** to enable optimization for flashback data archive history tables. This instructs the database to optimize the storage of data in history tables using any of the following features: Advanced Row Compression, Advanced LOB Compression, Advanced LOB Deduplication, segment-level compression tiering, and row-level compression tiering. To specify this clause, you must have a license for the Advanced Compression option.

Specify **NO OPTIMIZE DATA** to instruct the database not to optimize the storage of data in history tables. This is the default.
**flashback_archive_retention**

Specify the length of time in months, days, or years that the archived data should be retained in the flashback data archive. If the length of time causes the flashback data archive to become full, then the database responds as described in *flashback_archive_quota*.

**Examples**

The following statement creates two flashback data archives for testing purposes. The first is designated as the default for the database. For both of them, the space quota is 1 megabyte, and the archive retention is one day.

```sql
CREATE FLASHBACK ARCHIVE DEFAULT test_archive1
    TABLESPACE example
    QUOTA 1 M
    RETENTION 1 DAY;

CREATE FLASHBACK ARCHIVE test_archive2
    TABLESPACE example
    QUOTA 1 M
    RETENTION 1 DAY;
```

The next statement alters the default flashback data archive to extend the retention period to 1 month:

```sql
ALTER FLASHBACK ARCHIVE test_archive1
    MODIFY RETENTION 1 MONTH;
```

The next statement specifies tracking for the `oe.customers` table. The flashback data archive is not specified, so data will be archived in the default flashback data archive, `test_archive1`:

```sql
ALTER TABLE oe.customers
    FLASHBACK ARCHIVE;
```

The next statement specifies tracking for the `oe.orders` table. In this case, data will be archived in the specified flashback data archive, `test_archive2`:

```sql
ALTER TABLE oe.orders
    FLASHBACK ARCHIVE test_archive2;
```

The next statement drops `test_archive2` flashback data archive:

```sql
DROP FLASHBACK ARCHIVE test_archive2;
```

**CREATE FUNCTION**

**Purpose**

Functions are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE FUNCTION` statement to create a standalone stored function or a call specification.
A stored function (also called a user function or user-defined function) is a set of PL/SQL statements you can call by name. Stored functions are very similar to procedures, except that a function returns a value to the environment in which it is called. User functions can be used as part of a SQL expression.

A call specification declares a Java method or a third-generation language (3GL) routine so that it can be called from PL/SQL. You can also use the CALL SQL statement to call such a method or routine. The call specification tells Oracle Database which Java method, or which named function in which shared library, to invoke when a call is made. It also tells the database what type conversions to make for the arguments and return value.

Note:
You can also create a function as part of a package using the CREATE PACKAGE statement.

See Also:
- CREATE PROCEDURE for a general discussion of procedures and functions, CREATE PACKAGE for information on creating packages, ALTER FUNCTION and DROP FUNCTION for information on modifying and dropping a function
- CREATE LIBRARY for information on shared libraries
- Oracle Database Development Guide for more information about registering external functions

Prerequisites
To create or replace a function in your own schema, you must have the CREATE PROCEDURE system privilege. To create or replace a function in another user’s schema, you must have the CREATE ANY PROCEDURE system privilege.

Syntax
Functions are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

create_function::=  

(PL/SQL function source: See Oracle Database PL/SQL Language Reference.)
Semantics

OR REPLACE

Specify OR REPLACE to re-create the function if it already exists. Use this clause to change the definition of an existing function without dropping, re-creating, and regranting object privileges previously granted on the function. If you redefine a function, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined function can still access the function without being regranted the privileges.

If any function-based indexes depend on the function, then Oracle Database marks the indexes DISABLED.

See Also:

ALTER FUNCTION for information on recompiling functions using SQL

[ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the function is an editioned or noneditioned object if editioning is enabled for the schema object type FUNCTION in schema. The default is EDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

plsql_function_source

See Oracle Database PL/SQL Language Reference for the syntax and semantics of the plsql_function_source, including examples.

CREATE HIERARCHY

Purpose

Use the CREATE HIERARCHY statement to create a hierarchy. A hierarchy specifies the hierarchical relationships among the levels of an attribute dimension.

Tip:

You can view and run SQL scripts that create hierarchies at the Oracle Live SQL website at https://livesql.oracle.com/apex/livesql/file/index.html. The website has scripts and tutorials that demonstrate the creation and use of analytic views.

Prerequisites

To create a hierarchy in your own schema, you must have the CREATE HIERARCHY system privilege. To create a hierarchy in another user's schema, you must have the CREATE ANY HIERARCHY system privilege.
Syntax

create_hierarchy ::= 

CREATE OR REPLACE NOFORCE FORCE HIERARCHY schema . hierarchy sharing_clause classification_clause hier_using_clause level_hier_clause hier_attrs_clause ;

sharing_clause ::= 

SHARING = METADATA DATA NONE

classification_clause ::= 

CAPTION caption DESCRIPTION description
CLASSIFICATION classification_name VALUE classification_value LANGUAGE language

hier_using_clause ::= 

USING schema . attribute_dimension level_hier_clause

level_hier_clause ::= 

1 level CHILD OF 1
**hier_attrs_clause::=**

```
HIERARCHICAL
```

```
ATributes

```

```
hier_attr_clause
```

**hier_attr_clause::=**

```
hier_attr_name
```

```
<table>
<thead>
<tr>
<th>classification_clause</th>
</tr>
</thead>
</table>
```

**hier_attr_name::=**

```
MEMBER_NAME
```

```
MEMBER_UNIQUE_NAME
```

```
MEMBER_CAPTION
```

```
MEMBER_DESCRIPTION
```

```
LEVEL_NAME
```

```
HIER_ORDER
```

```

```

```
IS_LEAF
```

```
PARENT_LEVEL_NAME
```

```
PARENT_UNIQUE_NAME
```

**Semantics**

**OR REPLACE**

Specify **OR REPLACE** to replace an existing definition of a hierarchy with a different definition.

**FORCE and NOFORCE**

Specify **FORCE** to force the creation of the hierarchy even if it does not successfully compile. If you specify **NOFORCE**, then the hierarchy must compile successfully, otherwise an error occurs. The default is **NOFORCE**.

**schema**

Specify the schema in which to create the hierarchy. If you do not specify a schema, then Oracle Database creates the hierarchy in your own schema.
**hierarchy**

Specify a name for the hierarchy.

**sharing clause**

Specify whether to create the hierarchy as an application common object. Specifying `METADATA` shares the hierarchy's metadata, but its data is unique to each container. Specifying `DATA` shares the hierarchy object; its data is the same for all containers in the application container and the data is stored only in the application root. Specifying `NONE` excludes the hierarchy from being shared.

**classification clause**

Use the classification clause to specify values for the `CAPTION` or `DESCRIPTION` classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the `CAPTION` and `DESCRIPTION` classifications, you may use the DDL shortcuts `CAPTION 'caption'` and `DESCRIPTION 'description'` or the full classification syntax.

You may vary the classification values by language. To specify a language for the `CAPTION` or `DESCRIPTION` classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is `NULL`. The language value must either be `NULL` or a valid `NLS_LANGUAGE` value.

**hier_using clause**

Specify the attribute dimension that has the members of the hierarchy.

**level_hier clause**

Specify the organization of the hierarchy levels.

**hierAttrs clause**

Specify classifications that contain descriptive metadata for the hierarchical attributes. A `hier_attr_clause` for a given `hier_attr_name` may appear only once in the list.

All hierarchies always contain all of the hierarchical attributes, but a hierarchical attribute does not have descriptive metadata associated with it unless you specify it with this clause.

**hier_attr clause**

Specify a hierarchical attribute and provide one or more classifications for it.

**hier_attr_name**

Specify a hierarchical attribute.
Examples

The following example creates the TIME_HIER hierarchy:

```
CREATE OR REPLACE HIERARCHY time_hier  -- Hierarchy name
USING time_attr_dim               -- Refers to TIME_ATTR_DIM attribute
dimension
(month CHILD OF                  -- Months in the attribute dimension
quarter CHILD OF
year);
```

The following example creates the PRODUCT_HIER hierarchy:

```
CREATE OR REPLACE HIERARCHY product_hier
USING product_attr_dim
(category
  CHILD OF department);
```

The following example creates the GEOGRAPHY_HIER hierarchy:

```
CREATE OR REPLACE HIERARCHY geography_hier
USING geography_attr_dim
(state_province
  CHILD OF country
  CHILD OF region);
```

CREATE INDEX

Purpose

Use the CREATE INDEX statement to create an index on:

- One or more columns of a table, a partitioned table, an index-organized table, or a cluster
- One or more scalar typed object attributes of a table or a cluster
- A nested table storage table for indexing a nested table column

An index is a schema object that contains an entry for each value that appears in the indexed column(s) of the table or cluster and provides direct, fast access to rows. The maximum size of a single index entry is dependent on the block size of the database.

Oracle Database supports several types of index:

- **Normal indexes.** (By default, Oracle Database creates B-tree indexes.)
- **Bitmap indexes**, which store rowids associated with a key value as a bitmap.
- **Partitioned indexes**, which consist of partitions containing an entry for each value that appears in the indexed column(s) of the table.
- **Function-based indexes**, which are based on expressions. They enable you to construct queries that evaluate the value returned by an expression, which in turn may include built-in or user-defined functions.
• **Domain indexes**, which are instances of an application-specific index of type `indextype`.

**Note:**
- *Oracle Database Concepts* for a discussion of indexes
- *Oracle Database Reference* for more information about the limits related to index size
- `ALTER INDEX` and `DROP INDEX`

**Prerequisites**

To create an index in your own schema, one of the following conditions must be true:

- The table or cluster to be indexed must be in your own schema.
- You must have the `INDEX` object privilege on the table to be indexed.
- You must have the `CREATE ANY INDEX` system privilege.

To create an index in another schema, you must have the `CREATE ANY INDEX` system privilege. Also, the owner of the schema to contain the index must have either the `UNLIMITED TABLESPACE` system privilege or space quota on the tablespaces to contain the index or index partitions.

To create a function-based index, in addition to the prerequisites for creating a conventional index, if the index is based on user-defined functions, then those functions must be marked `DETERMINISTIC`. A function-based index is executed with the credentials of the index owner, so the index owner must have the `EXECUTE` object privilege on the function.

To create a domain index in your own schema, in addition to the prerequisites for creating a conventional index, you must also have the `EXECUTE` object privilege on the `indextype`. If you are creating a domain index in another user's schema, then the index owner also must have the `EXECUTE` object privilege on the `indextype` and its underlying implementation type. Before creating a domain index, you should first define the `indextype`.

**Semantics**

**UNIQUE**

Specify **UNIQUE** to indicate that the value of the column (or columns) upon which the index is based must be unique.

**Restrictions on Unique Indexes**

Unique indexes are subject to the following restrictions:

- You cannot specify both **UNIQUE** and **BITMAP**.
- You cannot specify **UNIQUE** for a domain index.

**BITMAP**

Specify **BITMAP** to indicate that the index is to be created with a bitmap for each distinct key, rather than indexing each row separately. Bitmap indexes store the rowids associated with a key value as a bitmap. Each bit in the bitmap corresponds to a possible rowid. If the bit is set, then it means that the row with the corresponding rowid contains the key value. The internal representation of bitmaps is best suited for applications with low levels of concurrent transactions, such as data warehousing.

**Note:**

Oracle does not index table rows in which all key columns are null except in the case of bitmap indexes. Therefore, if you want an index on all rows of a table, then you must either specify **NOT NULL** constraints for the index key columns or create a bitmap index.

**See Also:**

"Unique Constraints" for information on the conditions that satisfy a unique constraint.
Restrictions on Bitmap Indexes

Bitmap indexes are subject to the following restrictions:

- You cannot specify `BITMAP` when creating a global partitioned index.
- You cannot create a bitmap secondary index on an index-organized table unless the index-organized table has a mapping table associated with it.
- You cannot specify both `UNIQUE` and `BITMAP`.
- You cannot specify `BITMAP` for a domain index.
- A bitmap index can have a maximum of 30 columns.

See Also:

- Oracle Database Concepts and Oracle Database SQL Tuning Guide for more information about using bitmap indexes
- CREATE TABLE for information on mapping tables
- "Bitmap Index Examples"

schema

Specify the schema to contain the index. If you omit `schema`, then Oracle Database creates the index in your own schema.

index

Specify the name of the index to be created. The name must satisfy the requirements listed in Database Object Naming Rules.

See Also:

Creating an Index: Example and Creating an Index on an XMLType Table: Example

cluster_index_clause

Use the `cluster_index_clause` to identify the cluster for which a cluster index is to be created. If you do not qualify `cluster` with `schema`, then Oracle Database assumes the cluster is in your current schema. You cannot create a cluster index for a hash cluster.

See Also:

CREATE CLUSTER and "Creating a Cluster Index: Example"
**table_index Clause**

Specify the table on which you are defining the index. If you do not qualify `table` with `schema`, then Oracle Database assumes the table is contained in your own schema.

You create an index on a nested table column by creating the index on the nested table storage table. Include the `NESTED_TABLE_ID` pseudocolumn of the storage table to create a `UNIQUE` index, which effectively ensures that the rows of a nested table value are distinct.

*See Also:*

"Indexes on Nested Tables: Example"

You can perform DDL operations (such as `ALTER TABLE`, `DROP TABLE`, `CREATE INDEX`) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an `INSERT` operation on the table. A session becomes unbound to the temporary table by issuing a `TRUNCATE` statement or at session termination, or, for a transaction-specific temporary table, by issuing a `COMMIT` or `ROLLBACK` statement.

**Restrictions on the table_index Clause**

This clause is subject to the following restrictions:

- If `index` is locally partitioned, then `table` must be partitioned.
- If `table` is index-organized, then this statement creates a secondary index. The index contains the index key and the logical rowid of the index-organized table. The logical rowid excludes columns that are also part of the index key. You cannot specify `REVERSE` for this secondary index, and the combined size of the index key and the logical rowid should be less than the block size.
- If `table` is a temporary table, then `index` will also be temporary with the same scope (session or transaction) as `table`. The following restrictions apply to indexes on temporary tables:
  - The only part of `index_properties` you can specify is `index_attributes`.
  - Within `index_attributes`, you cannot specify the `physical_attributes_clause`, `the parallel_clause`, `the logging_clause`, or `TABLESPACE`.
  - You cannot create a domain index or a partitioned index on a temporary table.
- You cannot create an index on an external table.

*See Also:*

`CREATE TABLE` and *Oracle Database Concepts* for more information on temporary tables
Specify a correlation name (alias) for the table upon which you are building the index.

Note:
This alias is required if the \textit{index\_expr} references any object type attributes or object type methods. See "Creating a Function-based Index on a Type Method: Example" and "Indexing on Substitutable Columns: Examples".

For \textit{index\_expr}, specify the column or column expression upon which the index is based.

You can create multiple indexes on the same set of columns, column expressions, or both if the following conditions are met:

- The indexes are of different types, use different partitioning, or have different uniqueness properties.
- Only one of the indexes is \texttt{VISIBLE} at any given time.

See Also:
\textit{Oracle Database Administrator's Guide} for more information on creating multiple indexes

Specify the name of one or more columns in the table. A bitmap index can have a maximum of 30 columns. Other indexes can have as many as 32 columns. These columns define the \textit{index key}.

If a unique index is local nonprefixed (see \textit{local\_partitioned\_index}), then the index key must contain the partitioning key.

See Also:
\textit{Oracle Database VLDB and Partitioning Guide} for information on prefixed and nonprefixed indexes

You can create an index on a scalar object attribute column or on the system-defined \texttt{NESTED\_TABLE\_ID} column of the nested table storage table. If you specify an object attribute column, then the column name must be qualified with the table name. If you specify a nested table column attribute, then it must be qualified with the outermost table name, the containing column name, and all intermediate attribute names leading to the nested table column attribute.
When you create an index on a column or expression with a declared or derived named collation other than BINARY, or a declared or derived pseudo-collation USING_NLS_SORT_CI or USING_NLS_SORT_AI, the database creates a functional index on the function NLSSORT. See Oracle Database Globalization Support Guide for more information.

Creating an Index on an Extended Data Type Column

If column is an extended data type column, then you may receive a "maximum key length exceeded" error when attempting to create the index. The maximum key length for an index varies depending on the database block size and some additional index metadata stored in a block. For example, for databases that use the Oracle standard 8K block size, the maximum key length is approximately 6400 bytes.

To work around this situation, you must shorten the length of the values you want to index, using one of the following methods:

- Create a function-based index to shorten the values stored in the extended data type column as part of the expression used for the index definition.
- Create a virtual column to shorten the values stored in the extended data type column as part of the expression used for the virtual column definition and build a normal index on the virtual column. Using a virtual column also enables you to leverage functionality for regular columns, such as collecting statistics and using constraint and triggers.

For both methods you can use either the SUBSTR or STANDARD_HASH function to shorten the values of the extended data type column to build an index. These methods have the following advantages and disadvantages:

- Use the SUBSTR function to return a substring, or prefix, of column that is an acceptable length for the index key. This type of index can be used for equality, IN-list, and range predicates on the original column without the need to specify the SUBSTR column as part of the predicate. Refer to SUBSTR for more information.
- Using the STANDARD_HASH function is likely to create an index that is more compact than the substring-based index and may result in fewer unnecessary index accesses. This type of index can be used for equality and IN-list predicates on the original column without the need to specify the SUBSTR column as part of the predicate. Refer to STANDARD_HASH for more information.

The following example shows how to create a function-based index on an extended data type column:

```
CREATE INDEX index ON table (SUBSTR(column, 0, n));
```

For n, specify a prefix length that is large enough to differentiate between values in column.

The following example shows how to create a virtual column for an extended data type column, and then create an index on the virtual column:

```
ALTER TABLE table ADD (new_hash_column AS (STANDARD_HASH(column)));
CREATE INDEX index ON table (new_hash_column);
```
Restrictions on Index Columns

The following restrictions apply to index columns:

- You cannot create an index on columns or attributes whose type is user-defined, `LONG`, `LONG RAW`, `LOB`, or `REF`, except that Oracle Database supports an index on `REF` type columns or attributes that have been defined with a `SCOPE` clause.
- Only normal (B-tree) indexes can be created on encrypted columns, and they can only be used for equality searches.

`column_expression`

Specify an expression built from columns of `table`, constants, SQL functions, and user-defined functions. When you specify `column_expression`, you create a function-based index.

Name resolution of the function is based on the schema of the index creator. User-defined functions used in `column_expression` are fully name resolved during the `CREATE INDEX` operation.

After creating a function-based index, collect statistics on both the index and its base table using the `DBMS_STATS` package. Such statistics will enable Oracle Database to correctly decide when to use the index.

Function-based unique indexes can be useful in defining a conditional unique constraint on a column or combination of columns. Refer to "Using a Function-based Index to Define Conditional Uniqueness: Example" for an example.

Notes on Function-based Indexes

The following notes apply to function-based indexes:

- When you subsequently query a table that uses a function-based index, Oracle Database will not use the index unless the query filters out nulls. However, Oracle Database will use a function-based index in a query even if the columns...
specified in the WHERE clause are in a different order than their order in the column_expression that defined the function-based index.

**See Also:**

“Function-Based Index Examples”

- If the function on which the index is based becomes invalid or is dropped, then Oracle Database marks the index DISABLED. Queries on a DISABLED index fail if the optimizer chooses to use the index. DML operations on a DISABLED index fail unless the index is also marked UNUSABLE and the parameter SKIP_UNUSABLE_INDEXES is set to true. Refer to ALTER SESSION for more information on this parameter.

- If a public synonym for a function, package, or type is used in column_expression, and later an actual object with the same name is created in the table owner’s schema, then Oracle Database disables the function-based index. When you subsequently enable the function-based index using ALTER INDEX ... ENABLE or ALTER INDEX ... REBUILD, the function, package, or type used in the column_expression continues to resolve to the function, package, or type to which the public synonym originally pointed. It will not resolve to the new function, package, or type.

- If the definition of a function-based index generates internal conversion to character data, then use caution when changing NLS parameter settings. Function-based indexes use the current database settings for NLS parameters. If you reset these parameters at the session level, then queries using the function-based index may return incorrect results. Two exceptions are the collation parameters (NLS_SORT and NLS_COMP). Oracle Database handles the conversions correctly even if these have been reset at the session level.

- Oracle Database cannot convert data in all cases, even when conversion is explicitly requested. For example, an attempt to convert the string '105 lbs' from VARCHAR2 to NUMBER using the TO_NUMBER function fails with an error. Therefore, if column_expression contains a data conversion function such as TO_NUMBER or TO_DATE, and if a subsequent INSERT or UPDATE statement includes data that the conversion function cannot convert, then the index will cause the INSERT or UPDATE statement to fail.

- If column_expression contains a datetime format model, then the function-based index expression defining the column may contain format elements that are different from those specified. For example, define a function-based index using the yyyy datetime format element:

```sql
CREATE INDEX cust_eff_ix ON customers
  (NVL(cust_eff_to, TO_DATE('9000-01-01 00:00:00', 'yyyy-mm-dd hh24:mi:ss')));
```

Query the ALL_IND_EXPRESSIONS view to see that the function-based index expression defining the column uses the syyyy datetime format element:

```sql
SELECT column_expression
  FROM all_ind_expressions
  WHERE index_name='CUST_EFF_IX';
```

COLUMN_EXPRESSION
Restrictions on Function-based Indexes

Function-based indexes are subject to the following restrictions:

- The value returned by the function referenced in column_expression is subject to the same restrictions as are the index columns of a B-tree index. Refer to "Restrictions on Index Columns".
- Any user-defined function referenced in column_expression must be declared as DETERMINISTIC.
- For a function-based globally partitioned index, the column_expression cannot be the partitioning key.
- The column_expression can be any of the forms of expression described in Column Expressions.
- All functions must be specified with parentheses, even if they have no parameters. Otherwise Oracle Database interprets them as column names.
- Any function you specify in column_expression must return a repeatable value. For example, you cannot specify the SYSDATE or USER function or the ROWNUM pseudocolumn.

See Also:
CREATE FUNCTION and Oracle Database PL/SQL Language Reference

ASC | DESC

Use ASC or DESC to indicate whether the index should be created in ascending or descending order. Indexes on character data are created in ascending or descending order of the character values in the database character set.

Oracle Database treats descending indexes as if they were function-based indexes. As with other function-based indexes, the database does not use descending indexes until you first analyze the index and the table on which the index is defined. See the column_expression clause of this statement.

Ascending unique indexes allow multiple NULL values. However, in descending unique indexes, multiple NULL values are treated as duplicate values and therefore are not permitted.

Restriction on Ascending and Descending Indexes

You cannot specify either of these clauses for a domain index. You cannot specify DESC for a reverse index. Oracle Database ignores DESC if index is bitmapped or if the COMPATIBLE initialization parameter is set to a value less than 8.1.0.

index_attributes

Specify the optional index attributes.
**physical_attributes_clause**

Use the **physical_attributes_clause** to establish values for physical and storage characteristics for the index.

If you omit this clause, then Oracle Database sets **PCTFREE** to 10 and **INITRANS** to 2.

**Restriction on Index Physical Attributes**

You cannot specify the **PCTUSED** parameter for an index.

---

**See Also:**

- **physical_attributes_clause** and **storage_clause** for a complete description of these clauses

---

**TABLESPACE**

For **tablespace**, specify the name of the tablespace to hold the index, index partition, or index subpartition. If you omit this clause, then Oracle Database creates the index in the default tablespace of the owner of the schema containing the index.

For a local index, you can specify the keyword **DEFAULT** in place of **tablespace**. New partitions or subpartitions added to the local index will be created in the same tablespace(s) as the corresponding partitions or subpartitions of the underlying table.

**index_compression**

The **index_compression** clauses let you enable or disable index compression for the index. Specify the **COMPRESS** clause of **prefix_compression** to enable prefix compression for the index, specify the **COMPRESS ADVANCED** clause of **advanced_index_compression** to enable advanced index compression for the index, or specify the **NOCOMPRESS** clause of either **prefix_compression** or **advanced_index_compression** to disable compression for the index. The default is **NOCOMPRESS**.

If you want to use compression for a partitioned index, then you must create the index with compression enabled at the index level. You can subsequently enable and disable the compression setting for individual partitions of such a partitioned index. You can also enable and disable compression when rebuilding individual partitions. You can modify an existing nonpartitioned index to enable or disable compression only when rebuilding the index.

**prefix_compression**

Specify **COMPRESS** to enable **prefix compression**, also known as key compression, which eliminates repeated occurrence of key column values. Use **integer** to specify the prefix length (number of prefix columns to compress). You can specify prefix compression for indexes that are nonunique or unique indexes of at least two columns.

- For unique indexes, the range of valid prefix length values is from 1 to the number of key columns minus 1. The default prefix length is the number of key columns minus 1.
• For nonunique indexes, the range of valid prefix length values is from 1 to the number of key columns. The default prefix length is the number of key columns.

**advanced_index_compression**

Specify this clause to enable **advanced index compression**. Advanced index compression improves compression ratios significantly while still providing efficient access to indexes. Therefore, advanced index compression works well on all supported indexes, including those indexes that are not good candidates for prefix compression.

• **COMPRESS ADVANCED LOW** - This level compresses the index less than the **HIGH** level, but provides faster access to the index. You can specify this clause for indexes that are nonunique or unique indexes of at least two columns. Before enabling COMPRESS ADVANCED LOW, the database must be at 12.1.0 or higher compatibility level.

• **COMPRESS ADVANCED HIGH** - This level compresses the index more than the **LOW** level, but provides slower access to the index. You can specify this clause for indexes that are nonunique or unique indexes of one or more columns. Before enabling COMPRESS ADVANCED HIGH, the database must be at 12.2.0 or higher compatibility level.

If you omit the **LOW** and **HIGH** keywords, then the default is **HIGH**.

**Restrictions on Index Compression**

The following restrictions apply to index compression:

• You cannot specify prefix compression or advanced index compression for a bitmap index.

• You cannot specify advanced index compression for index-organized tables.

---

**See Also:**

• *Oracle Database Administrator's Guide* for more information on prefix compression and advanced index compression

• “Compressing an Index: Example”

**partial_index_clause**

You can specify this clause only when creating an index on a partitioned table. Specify **INDEXING FULL** to create a **full index**. Specify **INDEXING PARTIAL** to create a **partial index**. The default is **INDEXING FULL**.

A full index includes all partitions in the underlying table, regardless of their indexing properties. A partial index includes only partitions in the underlying table with an indexing property of **ON**.

If a partial index is a local partitioned index, then index partitions that correspond with table partitions with an indexing property of **ON** are marked **USABLE**. Index partitions that correspond with table partitions with an indexing property of **OFF** are marked **UNUSABLE**.
If the underlying table is a composite-partitioned table, then the preceding conditions for index partitions and table partitions apply instead to index subpartitions and table subpartitions.

Restrictions on Partial Indexes

Partial indexes are subject to the following restrictions:

- The underlying table of a partial index cannot be a nonpartitioned table.
- Unique indexes cannot be partial indexes. This applies to indexes created with the `CREATE UNIQUE INDEX` statement and indexes that are implicitly created when you specify a unique constraint on one or more columns.

See Also:

`CREATE TABLE indexing_clause` for information on the indexing property

SORT | NOSORT

By default, Oracle Database sorts indexes in ascending order when it creates the index. You can specify `NOSORT` to indicate to the database that the rows are already stored in the database in ascending order, so that Oracle Database does not have to sort the rows when creating the index. If the rows of the indexed column or columns are not stored in ascending order, then the database returns an error. For greatest savings of sort time and space, use this clause immediately after the initial load of rows into a table. If you specify neither of these keywords, then `SORT` is the default.

Restrictions on NOSORT

This parameter is subject to the following restrictions:

- You cannot specify `REVERSE` with this clause.
- You cannot use this clause to create a cluster index partitioned or bitmap index.
- You cannot specify this clause for a secondary index on an index-organized table.

REVERSE

Specify `REVERSE` to store the bytes of the index block in reverse order, excluding the rowid.

Restrictions on Reverse Indexes

Reverse indexes are subject to the following restrictions:

- You cannot specify `NOSORT` with this clause.
- You cannot reverse a bitmap index or an index on an index-organized table.

VISIBLE | INVISIBLE

Use this clause to specify whether the index is visible or invisible to the optimizer. An invisible index is maintained by DML operations, but it is not be used by the optimizer during queries unless you explicitly set the parameter `OPTIMIZER_USE_INVISIBLE_INDEXES` to `TRUE` at the session or system level.
To determine whether an existing index is visible or invisible to the optimizer, you can query the VISIBILITY column of the USER_, DBA_, ALL_INDEXES data dictionary views.

**logging clause**

Specify whether the creation of the index will be logged (LOGGING) or not logged (NOLOGGING) in the redo log file. This setting also determines whether subsequent Direct Loader (SQL*Loader) and direct-path INSERT operations against the index are logged or not logged. LOGGING is the default.

If index is nonpartitioned, then this clause specifies the logging attribute of the index.

If index is partitioned, then this clause determines:

- The default value of all partitions specified in the CREATE statement, unless you specify the logging_clause in the PARTITION description clause
- The default value for the segments associated with the index partitions
- The default value for local index partitions or subpartitions added implicitly during subsequent ALTER TABLE ... ADD PARTITION operations

The logging attribute of the index is independent of that of its base table.

If you omit this clause, then the logging attribute is that of the tablespace in which it resides.

**ONLINE**

Specify ONLINE to indicate that DML operations on the table will be allowed during creation of the index.

**Restrictions on Online Index Building**

Online index building is subject to the following restrictions:

- Parallel DML is not supported during online index building. If you specify ONLINE and then issue parallel DML statements, then Oracle Database returns an error.
- You can specify ONLINE for a bitmap index or a cluster index as long as you set COMPATIBLE to 10 or higher.
• You cannot specify ONLINE for a conventional index on a UROWID column.

• For a nonunique secondary index on an index-organized table, the number of index key columns plus the number of primary key columns that are included in the logical rowid in the index-organized table cannot exceed 32. The logical rowid excludes columns that are part of the index key.

See Also:
Oracle Database Concepts for a description of online index building and rebuilding

parallel_clause

Specify the parallel_clause if you want creation of the index to be parallelized.

For complete information on this clause, refer to parallel_clause in the documentation on CREATE TABLE.

Index Partitioning Clauses

Use the global_partitioned_index clause and the local_partitioned_index clauses to partition index.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for a discussion of these restrictions.

See Also:
"Partitioned Index Examples"

global_partitioned_index

The global_partitioned_index clause lets you specify that the partitioning of the index is user defined and is not equipartitioned with the underlying table. By default, nonpartitioned indexes are global indexes.

You can partition a global index by range or by hash. In both cases, you can specify up to 32 columns as partitioning key columns. The partitioning column list must specify a left prefix of the index column list. If the index is defined on columns a, b, and c, then for the columns you can specify (a, b, c), or (a, b), or (a, c), but you cannot specify (b, c) or (c) or (b, a). If you specify a partition name, then it must conform to the rules for naming schema objects and their parts as described in "Database Object Naming Rules". If you omit the partition names, then Oracle Database assigns names of the form SYS_Pn.

GLOBAL PARTITION BY RANGE

Use this clause to create a range-partitioned global index. Oracle Database will partition the global index on the ranges of values from the table columns you specify in the column list.
GLOBAL PARTITION BY HASH

Use this clause to create a hash-partitioned global index. Oracle Database assigns rows to the partitions using a hash function on values in the partitioning key columns.

See Also:
The CREATE TABLE clause hash_partitions for information on the two methods of hash partitioning and "Creating a Hash-Partitioned Global Index: Example"

Restrictions on Global Partitioned Indexes

Global partitioned indexes are subject to the following restrictions:

- The partitioning key column list cannot contain the ROWID pseudocolumn or a column of type ROWID.
- The only property you can specify for hash partitions is tablespace storage. Therefore, you cannot specify LOB or varray storage clauses in the partitioning_storage_clause of individual_hash_partitions.
- You cannot specify the OVERFLOW clause of hash_partitions_by_quantity, as that clause is valid only for index-organized table partitions.
- In the partitioning_storage_clause, you cannot specify table_compression or the inmemory_clause, but you can specify index_compression.

Note:

If your enterprise has or will have databases using different character sets, then use caution when partitioning on character columns. The sort sequence of characters is not identical in all character sets.

See Also:
Oracle Database Globalization Support Guide for more information on character set support

index_partitioning_clause

Use this clause to describe the individual index partitions. The number of repetitions of this clause determines the number of partitions. If you omit partition, then Oracle Database generates a name with the form SYS_Pn.
For VALUES LESS THAN (value_list), specify the noninclusive upper bound for the current partition in a global index. The value list is a comma-delimited, ordered list of literal values corresponding to the column list in the global_partitioned_index clause. Always specify MAXVALUE as the value of the last partition.

**Note:**

If the index is partitioned on a DATE column, and if the date format does not specify the first two digits of the year, then you must use the TO_DATE function with a 4-character format mask for the year. The date format is determined implicitly by NLS_TERRITORY or explicitly by NLS_DATE_FORMAT. Refer to Oracle Database Globalization Support Guide for more information on these initialization parameters.

**See Also:**

"Range Partitioning Example"

`local_partitioned_index`

The `local_partitioned_index` clauses let you specify that the index is partitioned on the same columns, with the same number of partitions and the same partition bounds as `table`. For composite-partitioned tables, this clause lets you specify that the index is subpartitioned on the same columns, with the same number of subpartitions and the same subpartition bounds as `table`. Oracle Database automatically maintains local index partitioning as the underlying table is repartitioned.

If you specify only the keyword LOCAL and do not specify a subclause, then Oracle Database creates each index partition in the same tablespace as its corresponding table partition and assigns it the same name as its corresponding table partition. If `table` is a composite-partitioned table, then Oracle Database creates each index subpartition in the same tablespace as its corresponding table subpartition and assigns it the same name as its corresponding table subpartition.

If you specify a partition name, then it must conform to the rules for naming schema objects and their parts as described in "Database Object Naming Rules". If you omit a partition name, then Oracle Database generates a name that is consistent with the corresponding table partition. If the name conflicts with an existing index partition name, then the database uses the form SYS_Pn.

`on_range_partitioned_table`

This clause lets you specify the names and attributes of index partitions on a range-partitioned table. If you specify this clause, then the number of PARTITION clauses must be equal to the number of table partitions, and in the same order.

You cannot specify prefix compression for an index partition unless you have specified prefix compression for the index.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE.
on_list_partitioned_table

The on_list_partitioned_table clause is identical to on_range_partitioned_table.

on_hash_partitioned_table

This clause lets you specify names and tablespace storage for index partitions on a hash-partitioned table.

If you specify any PARTITION clauses, then the number of these clauses must be equal to the number of table partitions. You can optionally specify tablespace storage for one or more individual partitions. If you do not specify tablespace storage either here or in the STORE IN clause, then the database stores each index partition in the same tablespace as the corresponding table partition.

The STORE IN clause lets you specify one or more tablespaces across which Oracle Database will distribute all the index hash partitions. The number of tablespaces need not equal the number of index partitions. If the number of index partitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE.

on_comp_partitioned_table

This clause lets you specify the name and attributes of index partitions on a composite-partitioned table.

The STORE IN clause is valid only for range-hash or list-hash composite-partitioned tables. It lets you specify one or more default tablespaces across which Oracle Database will distribute all index hash subpartitions for all partitions. You can override this storage by specifying different default tablespace storage for the subpartitions of an individual partition in the second STORE IN clause in the index_subpartition_clause.

For range-range, range-list, and list-list composite-partitioned tables, you can specify default attributes for the range or list subpartitions in the PARTITION clause. You can override this storage by specifying different attributes for the range or list subpartitions of an individual partition in the SUBPARTITION clause of the index_subpartition_clause.

You cannot specify prefix compression for an index partition unless you have specified prefix compression for the index.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE.

index_subpartition_clause

This clause lets you specify names and tablespace storage for index subpartitions in a composite-partitioned table.

The STORE IN clause is valid only for hash subpartitions of a range-hash and list-hash composite-partitioned table. It lets you specify one or more tablespaces across which Oracle Database will distribute all the index hash subpartitions. The SUBPARTITION clause is valid for all subpartition types.

If you specify any SUBPARTITION clauses, then the number of those clauses must be equal to the number of table subpartitions. If you specify a subpartition name, then
it must conform to the rules for naming schema objects and their parts as described in "Database Object Naming Rules". If you omit subpartition, then the database generates a name that is consistent with the corresponding table subpartition. If the name conflicts with an existing index subpartition name, then the database uses the form SYS_SUBPn.

The number of tablespaces need not equal the number of index subpartitions. If the number of index subpartitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

If you do not specify tablespace storage for subpartitions either in the on_comp_partitioned_table clause or in the index_subpartition_clause, then Oracle Database uses the tablespace specified for index. If you also do not specify tablespace storage for index, then the database stores the subpartition in the same tablespace as the corresponding table subpartition.

For more information on the USABLE and UNUSABLE clauses, refer to CREATE INDEX ... USABLE | UNUSABLE.

domain_index_clause

Use the domain_index_clause to indicate that index is a domain index, which is an instance of an application-specific index of type indextype.

Creating a domain index requires a number of preceding operations. You must first create an implementation type for an indextype. You must also create a functional implementation and then create an operator that uses the function. Next you create an indextype, which associates the implementation type with the operator. Finally, you create the domain index using this clause. Refer to Extended Examples, which contains an example of creating a simple domain index, including all of these operations.

index_expr

In the index_expr (in table_index_clause), specify the table columns or object attributes on which the index is defined. You can define multiple domain indexes on a single column only if the underlying indextypes are different and the indextypes support a disjoint set of user-defined operators.

Restrictions on Domain Indexes

Domain indexes are subject to the following restrictions:

- The index_expr (in table_index_clause) can specify only a single column, and the column cannot be of data type REF, varray, nested table, LONG, or LONG RAW.
- You cannot create a bitmap or unique domain index.
- You cannot create a domain index on a temporary table.
- You can create local domain indexes on only range-, list-, hash-, and interval-partitioned tables, with one exception: You cannot create a local domain index on an automatic list-partitioned table.
- Domain indexes can be created only on table columns declared with collation BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS. See Oracle Database Globalization Support Guide for more information.

indextype
For `indextype`, specify the name of the indextype. This name should be a valid schema object that has already been created.

If you have installed Oracle Text, then you can use various built-in indextypes to create Oracle Text domain indexes. For more information on Oracle Text and the indexes it uses, refer to *Oracle Text Reference*.

**See Also:**
CREATE INDEXTYPE

**local_domain_index_clause**

Use this clause to specify that the index is a local index on a partitioned table.

- The `PARTITIONS` clause lets you specify names for the index partitions. The number of partitions you specify must match the number of partitions in the base table. If you omit this clause, then the database creates the partitions with system-generated names of the form `SYS_Pn`.

- The `PARAMETERS` clause lets you specify the parameter string specific to an individual partition. If you omit this clause, then the parameter string associated with the index is also associated with the partition.

**parallel_clause**

Use the `parallel_clause` to parallelize creation of the domain index. For a nonpartitioned domain index, Oracle Database passes the explicit or default degree of parallelism to the `ODCIIndexCreate` cartridge routine, which in turn establishes parallelism for the index. For local domain indexes, this clause causes the index partitions to be created in parallel.

**See Also:**
*Oracle Database Data Cartridge Developer's Guide* for complete information on the Oracle Data Cartridge Interface (ODCI) routines

**PARAMETERS**

In the `PARAMETERS` clause, specify the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine. The maximum length of the parameter string is 1000 characters.

When you specify this clause at the top level of the syntax, the parameters become the default parameters for the index partitions. If you specify this clause as part of the `local_domain_index_clause`, then you override any default parameters with parameters for the individual partition.

After the domain index is created, Oracle Database invokes the appropriate ODCI routine. If the routine does not return successfully, then the domain index is marked `FAILED`. The only operations supported on an failed domain index are `DROP INDEX` and (for non-local indexes) `REBUILD INDEX`.
XMLIndex_clause

The XMLIndex_clause lets you define an XMLIndex index, typically on a column contain XML data. An XMLIndex index is a type of domain index designed specifically for the domain of XML data.

XMLIndex_parameters_clause

This clause lets you specify information about the path table and about the secondary indexes corresponding to the components of XMLIndex. This clause also lets you specify information about the structured component of the index. The maximum length of the parameter string is 1000 characters.

When you specify this clause at the top level of the syntax, the parameters become the parameters of the index and the default parameters for the index partitions. If you specify this clause as part of the local_xmlindex_clause clause, then you override any default parameters with parameters for the individual partition.

bitmap_join_index_clause

Use the bitmap_join_index_clause to define a bitmap join index. A bitmap join index is defined on a single table. For an index key made up of dimension table columns, it stores the fact table rowids corresponding to that key. In a data warehousing environment, the table on which the index is defined is commonly referred to as a fact table, and the tables with which this table is joined are commonly referred to as dimension tables. However, a star schema is not a requirement for creating a join index.

ON

In the ON clause, first specify the fact table, and then inside the parentheses specify the columns of the dimension tables on which the index is defined.

FROM

In the FROM clause, specify the joined tables.

WHERE

In the WHERE clause, specify the join condition.

If the underlying fact table is partitioned, then you must also specify one of the local_partitioned_index clauses (see local_partitioned_index).
Restrictions on Bitmap Join Indexes

In addition to the restrictions on bitmap indexes in general (see BITMAP), the following restrictions apply to bitmap join indexes:

- You cannot create a bitmap join index on a temporary table.
- No table may appear twice in the FROM clause.
- You cannot create a function-based join index.
- The dimension table columns must be either primary key columns or have unique constraints.
- If a dimension table has a composite primary key, then each column in the primary key must be part of the join.
- You cannot specify the local_partitioned_index clause unless the fact table is partitioned.
- A bitmap join index definition can only reference columns with collation BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS. For any of these collations, index keys are collated and the join condition is evaluated using the BINARY collation. See Oracle Database Globalization Support Guide for more information.

Note:

Oracle Database Data Warehousing Guide for information on fact and dimension tables and on using bitmap indexes in a data warehousing environment

USABLE | UNUSABLE

You can specify the USABLE and UNUSABLE keywords:

- For an index, in the CREATE INDEX statement
- For an index partition, in the on_range_partitioned_table, on_list_partitioned_table, on_hash_partitioned_table, and on_comp_partitioned_table clauses
- For an index subpartition, in the index_subpartition_clause

For nonpartitioned indexes, specify UNUSABLE to create an index in an unusable state. An unusable index must be rebuilt, or dropped and re-created, before it can be used. Specify USABLE to create an index in a usable state. USABLE is the default.

For partitioned indexes, specify USABLE or UNUSABLE as follows:

- If you specify UNUSABLE for the index, then all index partitions are marked UNUSABLE.
- If you specify USABLE for the index, then all index partitions are marked USABLE.
- If you do not specify USABLE or UNUSABLE for the index, then all index partitions are marked USABLE. The exception is a local partial index. If you specify the LOCAL and INDEXING PARTIAL clauses, and do not specify USABLE or UNUSABLE, then each index partition is marked USABLE if the indexing property of its corresponding table
partition is ON, or UNUSABLE if the indexing property of its corresponding table partition is OFF.

You can override the preceding conditions by specifying USABLE or UNUSABLE for a specific index partition.

If the underlying table is a composite-partitioned table, then the preceding conditions for index partitions and table partitions apply instead to index subpartitions and table subpartitions.

After you create a partitioned index, you can choose to rebuild specific index partitions or subpartitions to make them USABLE. Doing so can be useful if you want to maintain indexes only on some index partitions or subpartitions—for example, if you want to enable index access for new partitions but not for old partitions.

When an index, or some partitions or subpartitions of an index, are created UNUSABLE, no segment is allocated for the unusable object. The unusable index or index partition consumes no space in the database.

If an index, or some partitions or subpartitions of the index, are marked UNUSABLE, then the index will be considered as an access path by the optimizer only under the following circumstances: the optimizer must know at compile time which partitions are to be accessed, and all of those partitions to be accessed must be marked USABLE. Therefore, the query cannot contain any bind variables.

**Restrictions on USABLE | UNUSABLE**

The following restrictions apply when marking an index USABLE or UNUSABLE:

- You cannot specify this clause for an index on a temporary table.
- Unusable indexes or index partitions will still have a segment under the following conditions:
  - The index (or index partition) is owned by SYS, SYSTEM, PUBLIC, OUTLN, or XDB
  - The index (or index partition) is stored in dictionary-managed tablespaces
  - The global partitioned or nonpartitioned index on a partitioned table becomes unusable due to a partition maintenance operation

**{ DEFERRED | IMMEDIATE } INVALIDATION**

This clause lets you control when the database invalidates dependent cursors while creating the index. It has the same semantics here as for the ALTER INDEX statement. Refer to { DEFERRED | IMMEDIATE } INVALIDATION in the documentation on ALTER INDEX for the full semantics of this clause.

**Examples**

**General Index Examples**

**Creating an Index: Example**

The following statement shows how the sample index ord_customer_ix on the customer_id column of the sample table oe.orders was created:

```sql
CREATE INDEX ord_customer_ix
  ON orders (customer_id);
```

**Compressing an Index: Example**
To create the `ord_customer_ix_demo` index with the `COMPRESS` clause, you might issue the following statement:

```sql
CREATE INDEX ord_customer_ix_demo
ON orders (customer_id, sales_rep_id)
COMPRESS 1;
```

The index will compress repeated occurrences of `customer_id` column values.

Creating an Index in `NOLOGGING` Mode: Example

If the sample table `orders` had been created using a fast parallel load (so all rows were already sorted), then you could issue the following statement to quickly create an index.

```sql
/* Unless you first sort the table oe.orders, this example fails
   because you cannot specify NOSORT unless the base table is
   already sorted.
*/
CREATE INDEX ord_customer_ix_demo
ON orders (order_mode)
NOSORT
NOLOGGING;
```

Creating a Cluster Index: Example

To create an index for the `personnel` cluster, which was created in "Creating a Cluster: Example", issue the following statement:

```sql
CREATE INDEX idx_personnel ON CLUSTER personnel;
```

No index columns are specified, because cluster indexes are automatically built on all the columns of the cluster key. For cluster indexes, all rows are indexed.

Creating an Index on an XMLType Table: Example

The following example creates an index on the area element of the `xwarehouses` table (created in "XMLType Table Examples"):

```sql
CREATE INDEX area_index ON xwarehouses e
 (EXTRACTVALUE(VALUE(e),'/Warehouse/Area'));
```

Such an index would greatly improve the performance of queries that select from the table based on, for example, the square footage of a warehouse, as shown in this statement:

```sql
SELECT e.getClobVal() AS warehouse
FROM xwarehouses e
WHERE EXISTSNODE(VALUE(e),'/Warehouse/Area>50000') = 1;
```

See Also:

- `EXISTSNODE` and `VALUE`

Function-Based Index Examples

The following examples show how to create and use function-based indexes.
Creating a Function-Based Index: Example

The following statement creates a function-based index on the `employees` table based on an uppercase evaluation of the `last_name` column:

```
CREATE INDEX upper_ix ON employees (UPPER(last_name));
```

See the "Prerequisites" for the privileges and parameter settings required when creating function-based indexes.

To increase the likelihood that Oracle Database will use the index rather than performing a full table scan, be sure that the value returned by the function is not null in subsequent queries. For example, this statement will use the index, unless some other condition exists that prevents the optimizer from doing so:

```
SELECT first_name, last_name
FROM employees WHERE UPPER(last_name) IS NOT NULL
ORDER BY UPPER(last_name);
```

Without the `WHERE` clause, Oracle Database may perform a full table scan.

In the next statements showing index creation and subsequent query, Oracle Database will use index `income_ix` even though the columns are in reverse order in the query:

```
CREATE INDEX income_ix
ON employees(salary + (salary*commission_pct));
```

```
SELECT first_name||' '||last_name "Name"
FROM employees
WHERE (salary*commission_pct) + salary > 15000
ORDER BY employee_id;
```

Creating a Function-Based Index on a LOB Column: Example

The following statement uses the `text_length` function to create a function-based index on a LOB column in the sample `pm` schema. See Oracle Database PL/SQL Language Reference for the example that creates this function. The example selects rows from the sample table `print_media` where that CLOB column has fewer than 1000 characters.

```
CREATE INDEX src_idx ON print_media(text_length(ad_sourcetext));
```

```
SELECT product_id FROM print_media
WHERE text_length(ad_sourcetext) < 1000
ORDER BY product_id;
```

PRODUCT_ID
----------
2056
2268
3060
3106

Creating a Function-based Index on a Type Method: Example

This example entails an object type `rectangle` containing two number attributes: `length` and `width`. The `area()` method computes the area of the rectangle.

```
CREATE TYPE rectangle AS OBJECT
( length NUMBER,
  width NUMBER,
  area() NUMBER
);
```

```
SELECT product_id FROM print_media
WHERE text_length(ad_sourcetext) < 1000
ORDER BY product_id;
```
width NUMBER,
    MEMBER FUNCTION area RETURN NUMBER DETERMINISTIC
);  

CREATE OR REPLACE TYPE BODY rectangle AS
    MEMBER FUNCTION area RETURN NUMBER IS
    BEGIN
        RETURN (length*width);
    END;
END;

Now, if you create a table rect_tab of type rectangle, you can create a function-based index on the area() method as follows:

CREATE TABLE rect_tab OF rectangle;
CREATE INDEX area_idx ON rect_tab x (x.area());

You can use this index efficiently to evaluate a query of the form:

SELECT * FROM rect_tab x WHERE x.area() > 100;

**Using a Function-based Index to Define Conditional Uniqueness: Example**

The following statement creates a unique function-based index on the oe.orders table that prevents a customer from taking advantage of promotion ID 2 ("blowout sale") more than once:

CREATE UNIQUE INDEX promo_ix ON orders
    (CASE WHEN promotion_id = 2 THEN customer_id ELSE NULL END,
    CASE WHEN promotion_id = 2 THEN promotion_id ELSE NULL END);

INSERT INTO orders (order_id, order_date, customer_id, order_total, promotion_id)
    VALUES (2459, systimestamp, 106, 251, 2);
1 row created.

INSERT INTO orders (order_id, order_date, customer_id, order_total, promotion_id)
    VALUES (2460, systimestamp+1, 106, 110, 2);
insert into orders (order_id, order_date, customer_id, order_total, promotion_id) *
ERROR at line 1:
ORA-00001: unique constraint (OE.PROMO_IX) violated

The objective is to remove from the index any rows where the promotion_id is not equal to 2. Oracle Database does not store in the index any rows where all the keys are NULL. Therefore, in this example, both customer_id and promotion_id are mapped to NULL unless promotion_id is equal to 2. The result is that the index constraint is violated only if promotion_id is equal to 2 for two rows with the same customer_id value.

**Partitioned Index Examples**

**Creating a Range-Partitioned Global Index: Example**

The following statement creates a global prefixed index cost_ix on the sample table sh.sales with three partitions that divide the range of costs into three groups:

CREATE INDEX cost_ix ON sales (amount_sold)
    GLOBAL PARTITION BY RANGE (amount_sold)
        (PARTITION p1 VALUES LESS THAN (1000),
        PARTITION p2 VALUES LESS THAN (2500),
        PARTITION p3 VALUES LESS THAN (MAXVALUE));
Creating a Hash-Partitioned Global Index: Example

The following statement creates a hash-partitioned global index `cust_last_name_ix` on the sample table `sh.customers` with four partitions:

```
CREATE INDEX cust_last_name_ix ON customers (cust_last_name)
    GLOBAL PARTITION BY HASH (cust_last_name)
    PARTITIONS 4;
```

Creating an Index on a Hash-Partitioned Table: Example

The following statement creates a local index on the `category_id` column of the `hash_products` partitioned table (which was created in "Hash Partitioning Example"). The `STORE IN` clause immediately following `LOCAL` indicates that `hash_products` is hash partitioned. Oracle Database will distribute the hash partitions between the `tbs1` and `tbs2` tablespaces:

```
CREATE INDEX prod_idx ON hash_products(category_id) LOCAL
    STORE IN (tbs_01, tbs_02);
```

The creator of the index must have quota on the tablespaces specified. See `CREATE TABLESPACE` for examples that create tablespaces `tbs_01` and `tbs_02`.

Creating an Index on a Composite-Partitioned Table: Example

The following statement creates a local index on the `composite_sales` table, which was created in "Composite-Partitioned Table Examples". The `STORAGE` clause specifies default storage attributes for the index. However, this default is overridden for the five subpartitions of partitions `q3_2000` and `q4_2000`, because separate `TABLESPACE` storage is specified.

The creator of the index must have quota on the tablespaces specified. See `CREATE TABLESPACE` for examples that create tablespaces `tbs_02` and `tbs_03`.

```
CREATE INDEX sales_ix ON composite_sales(time_id, prod_id)
    STORAGE (INITIAL 1M)
    LOCAL
        (PARTITION q1_1998,
         PARTITION q2_1998,
         PARTITION q3_1998,
         PARTITION q4_1998,
         PARTITION q1_1999,
         PARTITION q2_1999,
         PARTITION q3_1999,
         PARTITION q4_1999,
         PARTITION q1_2000,
         PARTITION q2_2000
             (SUBPARTITION pq2001, SUBPARTITION pq2002,
              SUBPARTITION pq2003, SUBPARTITION pq2004,
              SUBPARTITION pq2005, SUBPARTITION pq2006,
              SUBPARTITION pq2007, SUBPARTITION pq2008),
         PARTITION q3_2000
             (SUBPARTITION c1 TABLESPACE tbs_02,
              SUBPARTITION c2 TABLESPACE tbs_02,
              SUBPARTITION c3 TABLESPACE tbs_02,
              SUBPARTITION c4 TABLESPACE tbs_02,
              SUBPARTITION c5 TABLESPACE tbs_02),
         PARTITION q4_2000
             (SUBPARTITION pq4001 TABLESPACE tbs_03,
              SUBPARTITION pq4002 TABLESPACE tbs_03,
              SUBPARTITION pq4003 TABLESPACE tbs_03,
```
SUBPARTITION pq4004 TABLESPACE tbs_03)
);

**Bitmap Index Examples**

The following creates a bitmap index on the table `oe.hash_products`, which was created in "Hash Partitioning Example":

```
CREATE BITMAP INDEX product_bm_ix
ON hash_products(list_price)
    LOCAL(PARTITION ix_p1 TABLESPACE tbs_01,
    PARTITION ix_p2,
    PARTITION ix_p3 TABLESPACE tbs_02,
    PARTITION ix_p4 TABLESPACE tbs_03)
TABLESPACE tbs_04;
```

Because `hash_products` is a partitioned table, the bitmap join index must be locally partitioned. In this example, the user must have quota on tablespaces specified. See **CREATE TABLESPACE** for examples that create tablespaces `tbs_01`, `tbs_02`, `tbs_03`, and `tbs_04`.

The next series of statements shows how one might create a bitmap join index on a fact table using a join with a dimension table.

```
CREATE TABLE hash_products
    ( product_id          NUMBER(6)
    , product_name        VARCHAR2(50)
    , product_description VARCHAR2(2000)
    , category_id         NUMBER(2)
    , weight_class        NUMBER(1)
    , warranty_period     INTERVAL YEAR TO MONTH
    , supplier_id         NUMBER(6)
    , product_status      VARCHAR2(20)
    , list_price          NUMBER(8,2)
    , min_price           NUMBER(8,2)
    , catalog_url         VARCHAR2(50)
    CONSTRAINT pk_product_id PRIMARY KEY (product_id)
    , CONSTRAINT product_status_lov_demo
      CHECK (product_status in ('orderable'
                                   ,'planned'
                                   ,'under development'
                                   ,'obsolete'))
    )
PARTITION BY HASH (product_id)
PARTITIONS 5
STORE IN (example);
```

```
CREATE TABLE sales_quota
    ( product_id          NUMBER(6)
    , customer_name       VARCHAR2(50)
    , order_qty           NUMBER(6)
    CONSTRAINT u_product_id UNIQUE(product_id)
    )
);

CREATE BITMAP INDEX product_bm_ix
ON hash_products(list_price)
FROM hash_products h, sales_quota s
WHERE h.product_id = s.product_id
    LOCAL(PARTITION ix_p1 TABLESPACE example,
       PARTITION ix_p2,
       PARTITION ix_p3 TABLESPACE example,
```
Indexes on Nested Tables: Example

The sample table `pm.print_media` contains a nested table column `ad_textdocs_ntab`, which is stored in storage table `textdocs_nestedtab`. The following example creates a unique index on storage table `textdocs_nestedtab`:

```
CREATE UNIQUE INDEX nested_tab_ix
  ON textdocs_nestedtab(NESTED_TABLE_ID, document_typ);
```

Including pseudocolumn `NESTED_TABLE_ID` ensures distinct rows in nested table column `ad_textdocs_ntab`.

Indexing on Substitutable Columns: Examples

You can build an index on attributes of the declared type of a substitutable column. In addition, you can reference the subtype attributes by using the appropriate `TREAT` function. The following example uses the table `books`, which is created in "Substitutable Table and Column Examples". The statement creates an index on the salary attribute of all employee authors in the `books` table:

```
CREATE INDEX salary_i
  ON books (TREAT(author AS employee_t).salary);
```

The target type in the argument of the `TREAT` function must be the type that added the attribute being referenced. In the example, the target of `TREAT` is `employee_t`, which is the type that added the `salary` attribute.

If this condition is not satisfied, then Oracle Database interprets the `TREAT` function as any functional expression and creates the index as a function-based index. For example, the following statement creates a function-based index on the `salary` attribute of part-time employees, assigning nulls to instances of all other types in the type hierarchy.

```
CREATE INDEX salary_func_i ON persons p
  (TREAT(VALUE(p) AS part_time_emp_t).salary);
```

You can also build an index on the type-discriminant column underlying a substitutable column by using the `SYS_TYPEID` function.

**Note:**

Oracle Database uses the type-discriminant column to evaluate queries that involve the `IS OF type` condition. The cardinality of the typeid column is normally low, so Oracle recommends that you build a bitmap index in this situation.

The following statement creates a bitmap index on the typeid of the author column of the `books` table:

```
CREATE BITMAP INDEX typeid_i ON books (SYS_TYPEID(author));
```
CREATE INDEXTYPE

Purpose
Use the CREATE INDEXTYPE statement to create an indextype, which is an object that specifies the routines that manage a domain (application-specific) index. Indextypes reside in the same namespace as tables, views, and other schema objects. This statement binds the indextype name to an implementation type, which in turn specifies and refers to user-defined index functions and procedures that implement the indextype.

Prerequisites
To create an indextype in your own schema, you must have the CREATE INDEXTYPE system privilege. To create an indextype in another schema, you must have the CREATE ANY INDEXTYPE system privilege. In either case, you must have the EXECUTE object privilege on the implementation type and the supported operators.

An indextype supports one or more operators, so before creating an indextype, you must first design the operator or operators to be supported and provide functional implementation for those operators.
Syntax

\textit{create\_indextype}::=

\begin{verbatim}
CREATE OR REPLACE INDEXTYPE \textit{schema}.\textit{indextype}
FOR \textit{schema}.\textit{operator}(\textit{parameter_type}),
using_type_clause
WITH LOCAL RANGE PARTITION storage_table_clause
;
\end{verbatim}

\textit{using\_type\_clause}::=

\begin{verbatim}
USING \textit{schema}.\textit{implementation\_type}
array\_DML\_clause
\end{verbatim}

\textit{array\_DML\_clause}::=

\begin{verbatim}
WITH \textit{WITH}\textit{OUT}\textit{WITH ARRAY DML}
(\textit{schema}.\textit{type}, \textit{schema}.\textit{varray\_type})
\end{verbatim}

\textit{storage\_table\_clause}::=

\begin{verbatim}
WITH SYSTEM USER MANAGED STORAGE TABLES
\end{verbatim}
Semantics

schema
Specify the name of the schema in which the indextype resides. If you omit schema, then Oracle Database creates the indextype in your own schema.

indextype
Specify the name of the indextype to be created. The name must satisfy the requirements listed in “Database Object Naming Rules ”.

FOR Clause
Use the FOR clause to specify the list of operators supported by the indextype.

• For schema, specify the schema containing the operator. If you omit schema, then Oracle assumes the operator is in your own schema.
• For operator, specify the name of the operator supported by the indextype.
  All the operators listed in this clause must be valid operators.
• For parameter_type, list the types of parameters to the operator.

using_type_clause
The USING clause lets you specify the type that provides the implementation for the new indextype.

For implementation_type, specify the name of the type that implements the appropriate Oracle Data Cartridge Interface (ODCI).

• You must specify a valid type that implements the routines in the ODCI.
• The implementation type must reside in the same schema as the indextype.

See Also:
Oracle Database Data Cartridge Developer's Guide for additional information on this interface

WITH LOCAL PARTITION
Use this clause to indicate that the indextype can be used to create local domain indexes on range-, list-, hash-, and interval-partitioned tables. You use this clause in combination with the storage_table_clause in several ways (see storage_table_clause).

• The recommended method is to specify WITH LOCAL PARTITION WITH SYSTEM MANAGED STORAGE TABLES. This combination uses system-managed storage tables, which are the preferred storage management, and lets you create local domain indexes on range-, list-, hash-, and interval-partitioned tables. In this case the RANGE keyword is optional and ignored, because it is no longer needed if you specify WITH LOCAL PARTITION WITH SYSTEM MANAGED STORAGE TABLES.
You can specify WITH LOCAL RANGE PARTITION (including the RANGE keyword) and omit the storage_table clause. Local domain indexes on range-partitioned tables are supported with user-managed storage tables for backward compatibility. Oracle does not recommend this combination because it uses the less efficient user-managed storage tables.

If you omit this clause entirely, then you cannot subsequently use this indextype to create a local domain index on a range, list-, hash-, or interval-partitioned table.

storage_table_clause

Use this clause to specify how storage tables and partition maintenance operations for indexes built on this indextype are managed:

- Specify WITH SYSTEM MANAGED STORAGE TABLES to indicate that the storage of statistics data is to be managed by the system. The type you specify in statistics_type should be storing the statistics related information in tables that are maintained by the system. Also, the indextype you specify must already have been created or altered to support the WITH SYSTEM MANAGED STORAGE TABLES clause.

- Specify WITH USER MANAGED STORAGE TABLES to indicate that the tables that store the user-defined statistics will be managed by the user. This is the default behavior.

See Also:

Oracle Database Data Cartridge Developer's Guide for more information about storage tables for domain indexes

array_DML_clause

Use this clause to let the indextype support the array interface for the ODCIIndexInsert method.

type and varray_type

If the data type of the column to be indexed is a user-defined object type, then you must specify this clause to identify the varray varray_type that Oracle should use to hold column values of type. If the indextype supports a list of types, then you can specify a corresponding list of varray types. If you omit schema for either type or varray_type, then Oracle assumes the type is in your own schema.

If the data type of the column to be indexed is a built-in system type, then any varray type specified for the indextype takes precedence over the ODCI types defined by the system.

See Also:

Oracle Database Data Cartridge Developer's Guide for more information on the ODCI array interface
Examples

Creating an Indextype: Example

The following statement creates an indextype named `position_indextype` and specifies the `position_between` operator that is supported by the indextype and the `position_im` type that implements the index interface. Refer to "Using Extensible Indexing" for an extensible indexing scenario that uses this indextype:

```sql
CREATE INDEXTYPE position_indextype
    FOR position_between(NUMBER, NUMBER, NUMBER)
    USING position_im;
```

CREATE INMEMORY JOIN GROUP

Purpose

Use the CREATE INMEMORY JOIN GROUP statement to create a join group, which is an object that specifies frequently joined columns from the same table or different tables. Such columns typically contain values of compatible data types that fall in similar ranges. When you create a join group, Oracle Database stores special metadata for the columns in the global dictionary, which enables the database to optimize join queries for the columns. In order to achieve this optimization, the table columns must be populated in the In-Memory Column Store (IM column store).

Creating a join group for tables causes the current In-Memory contents of these tables to be invalidated. Subsequent repopulation causes the In-Memory Compression Units (IMCUs) of the tables to be re-encoded with the global dictionary. Thus, Oracle recommends that you first create the join group, and then populate the tables.

See Also:

- ALTER INMEMORY JOIN GROUP and DROP INMEMORY JOIN GROUP
- Oracle Database In-Memory Guide for more information on join groups

Prerequisites

To create a join group in another user's schema, or to include in the join group a column in a table in another user's schema, you must have the CREATE ANY TABLE system privilege.
Syntax

create_inmemory_join_group ::= 

```sql
CREATE INMEMORY JOIN GROUP
schema .
join_group
(
schema .
table ( column ) ,
schema .
table ( column )
,
) ;
```

Semantics

**schema**

Specify the schema to contain the join group. If you omit `schema`, then the database creates the join group in your own schema.

**join_group**

Specify the name of the join group to be created. The name must satisfy the requirements listed in “Database Object Naming Rules ”.

**schema**

Specify the schema of the table that contains a column to be included in the join group. If you omit `schema`, then Oracle Database assumes the table is in your own schema.

**table**

Specify the name of the table that contains a column to be included in the join group.

**column**

Specify the name of a column to be included in the join group. A join group can contain columns in the same table or different tables.

**Restrictions on Join Groups**

The following restrictions apply to join groups:

- A join group must contain at least 1 column.
- A join group can contain at most 255 columns.
- A table column can be a member of at most one join group.
- Oracle Active Data Guard does not support join groups.
Examples

The following statement creates a join group named `prod_id1` in the `oe` schema. Both tables involved in this join group reside in the `oe` schema.

```sql
CREATE INMEMORY JOIN GROUP prod_id1
    (inventories(product_id), order_items(product_id));
```

The following statement creates a join group named `prod_id2` in the `oe` schema. The table `inventories` resides in the `oe` schema and the table `online_media` resides in the `pm` schema.

```sql
CREATE INMEMORY JOIN GROUP prod_id2
    (inventories(product_id), pm.online_media(product_id));
```

CREATE JAVA

Purpose

Use the `CREATE JAVA` statement to create a schema object containing a Java source, class, or resource.

See Also:

- *Oracle Database Java Developer’s Guide* for Java concepts and information about Java stored procedures
- *Oracle Database JDBC Developer’s Guide* for information on JDBC

Prerequisites

To create or replace a schema object containing a Java source, class, or resource in your own schema, you must have `CREATE PROCEDURE` system privilege. To create or replace such a schema object in another user’s schema, you must have `CREATE ANY PROCEDURE` system privilege.
Syntax

create_java ::=  

invoker_rights_clause ::=  

Semantics

OR REPLACE

Specify OR REPLACE to re-create the schema object containing the Java class, source, or resource if it already exists. Use this clause to change the definition of an existing object without dropping, re-creating, and regranting object privileges previously granted.

If you redefine a Java schema object and specify RESOLVE or COMPILE, then Oracle Database recompiles or resolves the object. Whether or not the resolution or
compilation is successful, the database invalidates classes that reference the Java schema object.

Users who had previously been granted privileges on a redefined function can still access the function without being regranted the privileges.

### See Also:

ALTER JAVA for additional information

---

**RESOLVE | COMPILE**

**RESOLVE** and **COMPILE** are synonymous keywords. They specify that Oracle Database should attempt to resolve the Java schema object that is created if this statement succeeds.

- When applied to a class, resolution of referenced names to other class schema objects occurs.
- When applied to a source, source compilation occurs.

**Restriction on RESOLVE and COMPILE**

You cannot specify these keywords for a Java resource.

**NOFORCE**

Specify **NOFORCE** to roll back the results of this **CREATE** command if you have specified either **RESOLVE** or **COMPILE** and the resolution or compilation fails. If you do not specify this option, then Oracle Database takes no action if the resolution or compilation fails, and the created schema object remains.

**JAVA SOURCE Clause**

Specify **JAVA SOURCE** to load a Java source file.

**JAVA CLASS Clause**

Specify **JAVA CLASS** to load a Java class file.

**JAVA RESOURCE Clause**

Specify **JAVA RESOURCE** to load a Java resource file.

**NAMED Clause**

The **NAMED** clause is required for a Java source or resource. The **primary_name** must be enclosed in double quotation marks and its length must not exceed 4000 bytes in the database character set.

- For a Java source, this clause specifies the name of the schema object in which the source code is held. A successful **CREATE JAVA SOURCE** statement will also create additional schema objects to hold each of the Java classes defined by the source.
- For a Java resource, this clause specifies the name of the schema object to hold the Java resource.
Use double quotation marks to preserve a lower- or mixed-case `primary_name`.

If you do not specify `schema`, then Oracle Database creates the object in your own schema.

Restrictions on NAMED Java Classes

The `NAMED` clause is subject to the following restrictions:

- You cannot specify `NAMED` for a Java class.
- The `primary_name` cannot contain a database link.

SCHEMA Clause

The `SCHEMA` clause applies only to a Java class. This optional clause specifies the schema in which the object containing the Java file will reside. If you do not specify this clause, then Oracle Database creates the object in your own schema.

SHARING

This clause applies only when creating a Java schema object in an application root. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the Java schema object is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the Java schema object's metadata, but its data is unique to each container. This type of Java schema object is referred to as a metadata-linked application common object.
- **NONE** - The Java schema object is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the Java schema object. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

You cannot change the sharing attribute of a Java schema object after it is created.

See Also:

- *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
- *Oracle Database Administrator’s Guide* for complete information on creating application common objects

`invoker_rights_clause`

Use the `invoker_rights_clause` to indicate whether the methods of the class execute with the privileges and in the schema of the user who owns the class or with the privileges and in the schema of `CURRENT_USER`.

This clause also determines how Oracle Database resolves external names in queries, DML operations, and dynamic SQL statements in the member functions and procedures of the type.
AUTHID CURRENT_USER

CURRENT_USER indicates that the methods of the class execute with the privileges of CURRENT_USER. This clause is the default and creates an invoker-rights class.

This clause also specifies that external names in queries, DML operations, and dynamic SQL statements resolve in the schema of CURRENT_USER. External names in all other statements resolve in the schema in which the methods reside.

AUTHID DEFINER

DEFINER indicates that the methods of the class execute with the privileges of the owner of the schema in which the class resides, and that external names resolve in the schema where the class resides. This clause creates a definer-rights class.

See Also:

- Oracle Database Java Developer’s Guide
- Oracle Database PL/SQL Language Reference for information on how CURRENT_USER is determined

RESOLVER Clause

The RESOLVER clause lets you specify a mapping of the fully qualified Java name to a Java schema object, where:

- match_string is either a fully qualified Java name, a wildcard that can match such a Java name, or a wildcard that can match any name.
- schema_name designates a schema to be searched for the corresponding Java schema object.
- A dash (-) as an alternative to schema_name indicates that if match_string matches a valid Java name, Oracle Database can leave the name unresolved. The resolution succeeds, but the name cannot be used at run time by the class.

This mapping is stored with the definition of the schema objects created in this command for use in later resolutions (either implicit or in explicit ALTER JAVA ... RESOLVE statements).

USING Clause

The USING clause determines a sequence of character data (CLOB or BFILE) or binary data (BLOB or BFILE) for the Java class or resource. Oracle Database uses the sequence of characters to define one file for a Java class or resource, or one source file and one or more derived classes for a Java source.

BFILE Clause

Specify the directory and filename of a previously created file on the operating system (directory_object_name) and server file (server_file_name) containing the sequence. BFILE is usually interpreted as a character sequence by CREATE JAVA SOURCE and as a binary sequence by CREATE JAVA CLASS or CREATE JAVA RESOURCE.

CLOB | BLOB | BFILE subquery
Specify a subquery that selects a single row and column of the type specified (CLOB, BLOB, or BFILE). The value of the column makes up the sequence of characters.

---

**Note:**

In earlier releases, the USING clause implicitly supplied the keyword SELECT. This is no longer the case. However, the subquery without the keyword SELECT is still supported for backward compatibility.

---

**key_for_BLOB**

The `key_for_BLOB` clause supplies the following implicit query:

```sql
SELECT LOB FROM CREATE$JAVA$LOB$TABLE
WHERE NAME = 'key_for_BLOB';
```

**Restriction on the key_for_BLOB Clause**

For you to use this case, the table `CREATE$JAVA$LOB$TABLE` must exist in the current schema and must have a column `LOB` of type `BLOB` and a column `NAME` of type `VARCHAR2`.

**AS source_char**

Specify a sequence of characters for a Java source.

**Examples**

**Creating a Java Class Object: Example**

The following statement creates a schema object containing a Java class using the name found in a Java binary file:

```sql
CREATE JAVA CLASS USING BFILE (java_dir, 'Agent.class')
```

This example assumes the directory object `java_dir`, which points to the operating system directory containing the Java class `Agent.class`, already exists. In this example, the name of the class determines the name of the Java class schema object.

**Creating a Java Source Object: Example**

The following statement creates a Java source schema object:

```sql
CREATE JAVA SOURCE NAMED "Welcome" AS
public class Welcome {
    public static String welcome() {
        return "Welcome World";
    }
}
```

**Creating a Java Resource Object: Example**

The following statement creates a Java resource schema object named `apptext` from a `bfile`:

```sql
CREATE JAVA RESOURCE NAMED "appText"
USING BFILE (java_dir, 'textBundle.dat')
```
SQL Statements: CREATE LIBRARY to CREATE SCHEMA

This chapter contains the following SQL statements:

- CREATE LIBRARY
- CREATE LOCKDOWN PROFILE
- CREATE MATERIALIZED VIEW
- CREATE MATERIALIZED VIEW LOG
- CREATE MATERIALIZED ZONEMAP
- CREATE OPERATOR
- CREATE OUTLINE
- CREATE PACKAGE
- CREATE PACKAGE BODY
- CREATE PFILE
- CREATE PLUGGABLE DATABASE
- CREATE PROCEDURE
- CREATE PROFILE
- CREATE RESTORE POINT
- CREATE ROLE
- CREATE ROLLBACK SEGMENT
- CREATE SCHEMA

CREATE LIBRARY

Purpose

Use the CREATE LIBRARY statement to create a schema object associated with an operating-system shared library. The name of this schema object can then be used in the call_spec of CREATE FUNCTION or CREATE PROCEDURE statements, or when declaring a function or procedure in a package or type, so that SQL and PL/SQL can call to third-generation-language (3GL) functions and procedures.

See Also:

CREATE FUNCTION and Oracle Database PL/SQL Language Reference for more information on functions and procedures
Prerequisites

The CREATE LIBRARY statement is valid only on platforms that support shared libraries and dynamic linking.

To create a library in your own schema, you must have the CREATE LIBRARY system privilege. To create a library in another user's schema, you must have the CREATE ANY LIBRARY system privilege.

To use the library in the call_spec of a CREATE FUNCTION statement, or when declaring a function in a package or type, you must have the EXECUTE object privilege on the library and the CREATE FUNCTION system privilege. Refer to Oracle Database PL/SQL Language Reference for information on the call_spec of a CREATE FUNCTION statement.

To use the library in the call_spec of a CREATE PROCEDURE statement, or when declaring a procedure in a package or type, you must have the EXECUTE object privilege on the library and the CREATE PROCEDURE system privilege. Refer to Oracle Database PL/SQL Language Reference for information on the call_spec of a CREATE PROCEDURE statement.

To execute a procedure or function defined with the call_spec (including a procedure or function defined within a package or type), you must have the EXECUTE object privilege on the procedure or function (but you do not need the EXECUTE object privilege on the library).

Syntax

Libraries are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

create_library::=

\[
\text{CREATE OR REPLACE} \quad \text{EDITIONABLE} \quad \text{NONEDITIONABLE} \quad \text{LIBRARY} \quad \text{plsql_library_source} \\
\]

(plsql_library_source: See Oracle Database PL/SQL Language Reference.)

Semantics

OR REPLACE

Specify OR REPLACE to re-create the library if it already exists. Use this clause to change the definition of an existing library without dropping, re-creating, and regranting object privileges granted on it.

Users who had previously been granted privileges on a redefined library can still access the library without being regranted the privileges.

[ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the library is an editioned or noneditioned object if editioning is enabled for the schema object type LIBRARY in schema. The default is
CREATE LOCKDOWN PROFILE

Purpose

Use the `CREATE LOCKDOWN PROFILE` statement to create a PDB lockdown profile. You can use PDB lockdown profiles in a multitenant container database (CDB) to restrict user operations in PDBs.

After you create a PDB lockdown profile, you can add restrictions to the profile with the `ALTER LOCKDOWN PROFILE` statement. You can restrict user operations associated with certain database features, options, and SQL statements.

When a lockdown profile is assigned to a PDB, users in that PDB cannot perform the operations that are disabled for the profile. To assign a lockdown profile, set its name for the value of the `PDB_LOCKDOWN` initialization parameter. You can assign a lockdown profile to individual PDBs, or to all PDBs in a CDB or application container, as follows:

- If you set `PDB_LOCKDOWN` while connected to a CDB root, then the lockdown profile applies to all PDBs in the CDB. It does not apply to the CDB root.
- If you set `PDB_LOCKDOWN` while connected to an application root, then the lockdown profile applies to the application root and all PDBs in the application container.
- If you set `PDB_LOCKDOWN` while connected to a particular PDB, then the lockdown profile applies to that PDB and overrides the lockdown profile for the CDB or application container, if one exists.

See Also:

- `ALTER LOCKDOWN PROFILE` and `DROP LOCKDOWN PROFILE`
- `Oracle Database Security Guide` for more information on PDB lockdown profiles

Prerequisites

- The `CREATE LOCKDOWN PROFILE` statement must be issued from the CDB or the Application Root.
- You must have the `CREATE LOCKDOWN PROFILE` system privilege in the container in which the statement is issued.
- The PDB lockdown profile name must be unique in the container in which the statement is issued.
Syntax

create_lockdown_profile ::= 

CREATE LOCKDOWN PROFILE profile_name
static_base_profile
dynamic_base_profile
;

static_base_profile ::= 

FROM base_profile

dynamic_base_profile ::= 

INCLUDING base_profile

Semantics

profile_name

You can create a new PDB lockdown profile with a name that you specify. The name must satisfy the requirements listed in “Database Object Naming Rules”. The lockdown profile can be derived from a static, or dynamic base profile.

static_base_profile

Use this option to create a new lockdown profile with a base profile. The rules of the base profile in effect at profile creation time will be copied to the new lockdown profile. Changes to the base profile after the lockdown profile is created will not apply to the lockdown profile.

dynamic_base_profile

Use this option to create a new lockdown profile that will change with changes to the base profile. The new lockdown profile will inherit DISABLE rules of the base profile as well and subsequent changes to the base profile. The rules of the base profile have precedence in any conflict with rules that may be explicitly added to the lockdown profile. For example, the OPTION_VALUE clause of the base profile takes precedence over the OPTION_VALUE clause of the dynamic base profile.

Example

The following statement creates PDB lockdown profile hr_prof with a dynamic base profile PRIVATE_DBAAS:

CREATE LOCKDOWN PROFILE hr_prof INCLUDING PRIVATE_DBAAS;
CREATE MATERIALIZED VIEW

Purpose

Use the CREATE MATERIALIZED VIEW statement to create a materialized view. A materialized view is a database object that contains the results of a query. The FROM clause of the query can name tables, views, and other materialized views. Collectively these objects are called master tables (a replication term) or detail tables (a data warehousing term). This reference uses “master tables” for consistency. The databases containing the master tables are called the master databases.

Note:

The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

For replication purposes, materialized views allow you to maintain read-only copies of remote data on your local node. You can select data from a materialized view as you would from a table or view. In replication environments, the materialized views commonly created are primary key, rowid, object, and subquery materialized views.

See Also:

Oracle Database Administrator’s Guide for information on the types of materialized views used to support replication

For data warehousing purposes, the materialized views commonly created are materialized aggregate views, single-table materialized aggregate views, and materialized join views. All three types of materialized views can be used by query rewrite, an optimization technique that transforms a user request written in terms of master tables into a semantically equivalent request that includes one or more materialized views.

See Also:

- ALTER MATERIALIZED VIEW
- Oracle Database Data Warehousing Guide for information on the types of materialized views used to support data warehousing

Prerequisites

The privileges required to create a materialized view should be granted directly rather than through a role.

To create a materialized view in your own schema:
• You must have been granted the `CREATE MATERIALIZED VIEW` system privilege and either the `CREATE TABLE` or `CREATE ANY TABLE` system privilege.

• You must also have access to any master tables of the materialized view that you do not own, either through a `READ` or `SELECT` object privilege on each of the tables or through the `READ ANY TABLE` or `SELECT ANY TABLE` system privilege.

To create a materialized view in another user's schema:

• You must have the `CREATE ANY MATERIALIZED VIEW` system privilege.

• The owner of the materialized view must have the `CREATE TABLE` system privilege. The owner must also have access to any master tables of the materialized view that the schema owner does not own (for example, if the master tables are on a remote database) and to any materialized view logs defined on those master tables, either through a `READ` or `SELECT` object privilege on each of the tables or through the `READ ANY TABLE` or `SELECT ANY TABLE` system privilege.

To create a refresh-on-commit materialized view (`REFRESH ON COMMIT` clause), in addition to the preceding privileges, you must have the `ON COMMIT REFRESH` object privilege on any master tables that you do not own or you must have the `ON COMMIT REFRESH` system privilege.

To create the materialized view with query rewrite enabled, in addition to the preceding privileges:

• If the schema owner does not own the master tables, then the schema owner must have the `GLOBAL QUERY REWRITE` privilege or the `QUERY REWRITE` object privilege on each table outside the schema.

• If you are defining the materialized view on a prebuilt container (`ON PREBUILT TABLE` clause), then you must have the `READ` or `SELECT` privilege with grant option on the container table.

The user whose schema contains the materialized view must have sufficient quota in the target tablespace to store the master table and index of the materialized view or must have the `UNLIMITED TABLESPACE` system privilege.

When you create a materialized view, Oracle Database creates one internal table and at least one index, and may create one view, all in the schema of the materialized view. Oracle Database uses these objects to maintain the materialized view data. You must have the privileges necessary to create these objects.

You can create the following types of local materialized views (including both `ON COMMIT` and `ON DEMAND`) on master tables with commit SCN-based materialized view logs:

• Materialized aggregate views, including materialized aggregate views on a single table

• Materialized join views

• Primary-key-based and rowid-based single table materialized views

• `UNION ALL` materialized views, where each `UNION ALL` branch is one of the above materialized view types

You cannot create remote materialized views on master tables with commit SCN-based materialized view logs.

Creating a materialized view on master tables with different types of materialized view logs (that is, a master table with timestamp-based materialized view logs and a master
table with commit SCN-based materialized view logs) is not supported and causes ORA-32414.

To specify an edition in the `evaluation_edition_clause` or the `unusable_editions_clause`, you must have the `USE` privilege on the edition.

Semantics

**schema**

Specify the schema to contain the materialized view. If you omit `schema`, then Oracle Database creates the materialized view in your schema.

**materialized_view**

Specify the name of the materialized view to be created. The name must satisfy the requirements listed in "Database Object Naming Rules". Oracle Database generates names for the table and indexes used to maintain the materialized view by adding a prefix or suffix to the materialized view name.
column_alias

You can specify a column alias for each column of the materialized view. The column alias list explicitly resolves any column name conflict, eliminating the need to specify aliases in the SELECT clause of the materialized view. If you specify any column alias in this clause, then you must specify an alias for each data source referenced in the SELECT clause.

encrypt clause

Use this clause to encrypt this column of the materialized view. Refer to the CREATE TABLE clause encryption_spec for more information on column encryption.

of object_type

The OF object_type clause lets you explicitly create an object materialized view of type object_type.

See Also:

See CREATE TABLE ... object_table for more information on the OF type_name clause

scoped_table_ref_constraint

Use the SCOPE FOR clause to restrict the scope of references to a single object table. You can refer either to the table name with scope_table_name or to a column alias. The values in the REF column or attribute point to objects in scope_table_name or c_alias, in which object instances of the same type as the REF column are stored. If you specify aliases, then they must have a one-to-one correspondence with the columns in the SELECT list of the defining query of the materialized view.

See Also:

"SCOPE REF Constraints" for more information

default collation

Use this clause to specify the default collation for the materialized view. The default collation is used as the derived collation for all the character literals included in the defining query of the materialized view. The default collation is not used by the materialized view columns; the collations for the materialized view columns are derived from the materialized view's defining subquery. The CREATE MATERIALIZED VIEW statement fails with an error, or the materialized view is created in an invalid state, if any of its character columns is based on an expression in the defining subquery that has no derived collation.

For collation_name, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the materialized view is set to the effective schema default collation of the schema containing the materialized view.
Refer to the DEFAULT_COLLATION clause of ALTER SESSION for more information on the effective schema default collation.

You can specify the DEFAULT_COLLATION clause only if the COMPATIBLE initialization parameter is set to 12.2 or greater, and the MAX_STRING_SIZE initialization parameter is set to EXTENDED.

To change the default collation for a materialized view, you must recreate the materialized view.

Restrictions on the Default Collation for Materialized Views

The following restrictions apply when specifying the default collation for a materialized view:

- If the defining query of the materialized view contains the WITH plsql_declarations clause, then the default collation of the materialized view must be USING_NLS_COMP.
- If the materialized view is created on a prebuilt table, then the declared collations of the table columns must be the same as the corresponding collations of the materialized view columns, as derived from the defining query.

ON PREBUILT TABLE Clause

The ON PREBUILT TABLE clause lets you register an existing table as a preinitialized materialized view. This clause is particularly useful for registering large materialized views in a data warehousing environment. The table must have the same name and be in the same schema as the resulting materialized view.

If the materialized view is dropped, then the preexisting table reverts to its identity as a table.

Note:

This clause assumes that the table object reflects the materialization of a subquery. Oracle strongly recommends that you ensure that this assumption is true in order to ensure that the materialized view correctly reflects the data in its master tables.

The ON PREBUILT TABLE clause could be useful in the following scenarios:

- You have a table representing the result of a query. Creating the table was an expensive operation that possibly took a long time. You want to create a materialized view on the query. You can use the ON PREBUILT TABLE clause to avoid the expense of executing the query and populating the container for the materialized view.
- You temporarily discontinue having a materialized view, but keep its container table, using the DROP MATERIALIZED VIEW ... PRESERVE TABLE statement. You then decide to recreate the materialized view and you know that the master tables of the view have not changed. You can create the materialized view using the ON PREBUILT TABLE clause. This avoids the expense and time of creating and populating the container table for the materialized view.
If you specify `ON PREBUILT TABLE`, then Oracle database does not create the `I_SNAP$` index. This index improves fast refresh performance. If you want the benefits of this index, then you can create it manually. Refer to *Oracle Database Data Warehousing Guide* for more information.

**WITH REDUCED PRECISION**

Specify `WITH REDUCED PRECISION` to authorize the loss of precision that will result if the precision of the table or materialized view columns do not exactly match the precision returned by `subquery`.

**WITHOUT REDUCED PRECISION**

Specify `WITHOUT REDUCED PRECISION` to require that the precision of the table or materialized view columns match exactly the precision returned by `subquery`, or the create operation will fail. This is the default.

**Restrictions on Using Prebuilt Tables**

Prebuilt tables are subject to the following restrictions:

- Each column alias in `subquery` must correspond to a column in the prebuilt table, and corresponding columns must have matching data types.
- If you specify this clause, then you cannot specify a `NOT NULL` constraint for any column that is not referenced in `subquery` unless you also specify a default value for that column.
- You cannot specify the `ON PREBUILT TABLE` clause when creating a rowid materialized view.

---

**See Also:**

"Creating Prebuilt Materialized Views: Example"

---

*physical_properties_clause*

The components of the `physical_properties_clause` have the same semantics for materialized views that they have for tables, with exceptions and additions described in the sections that follow.

**Restriction on the `physical_properties_clause`**

You cannot specify `ORGANIZATION EXTERNAL` for a materialized view.

*deferred_segment_creation*

Use this clause to determine when the segment for this materialized view should be created. See the `CREATE TABLE` clause `deferred_segment_creation` for more information.

*segment_attributes_clause*

Use the `segment_attributes_clause` to establish values for the `PCTFREE`, `PCTUSED`, and `INITrans` parameters, the storage characteristics for the materialized view, to assign a tablespace, and to specify whether logging is to occur. In the `USING INDEX` clause, you cannot specify `PCTFREE` or `PCTUSED`. 
TABLESPACE Clause
Specify the tablespace in which the materialized view is to be created. If you omit this clause, then Oracle Database creates the materialized view in the default tablespace of the schema containing the materialized view.

See Also:
- physical_attributes_clause and storage_clause for a complete description of these clauses, including default values

logging_clause
Specify LOGGING or NOLOGGING to establish the logging characteristics for the materialized view. The logging characteristic affects the creation of the materialized view and any nonatomic refresh that is initiated by way of the DBMS_REFRESH package. The default is the logging characteristic of the tablespace in which the materialized view resides.

See Also:
- logging_clause for a full description of this clause and Oracle Database PL/SQL Packages and Types Reference for more information on atomic and nonatomic refresh

table_compression
Use the table_compression clause to instruct the database whether to compress data segments to reduce disk and memory use. This clause has the same semantics in CREATE MATERIALIZED VIEW and CREATE TABLE. Refer to the table_compression clause in the documentation on CREATE TABLE for the full semantics of this clause.

inmemory_table_clause
Use the inmemory_table_clause to enable or disable the materialized view for the In-Memory Column Store (IM column store). This clause has the same semantics as the inmemory_table_clause in the CREATE TABLE documentation.

inmemory_column_clause
Use the inmemory_column_clause to disable specific materialized view columns for the IM column store, and to specify the data compression method for specific columns. This clause has the same semantics here as it has for the inmemory_column_clause in the CREATE TABLE documentation, with the following addition: If you specify the inmemory_column_clause, then you must also specify a column_alias for each column in the materialized view.

index_org_table_clause
The ORGANIZATION INDEX clause lets you create an index-organized materialized view. In such a materialized view, data rows are stored in an index defined on the primary
key of the materialized view. You can specify index organization for the following types of materialized views:

- Read-only and updatable object materialized views. You must ensure that the master table has a primary key.
- Read-only and updatable primary key materialized views.
- Read-only rowid materialized views.

The keywords and parameters of the `index_org_table_clause` have the same semantics as described in `CREATE TABLE`, with the restrictions that follow.

### See Also:
The `index_org_table_clause` of `CREATE TABLE`.

#### Restrictions on Index-Organized Materialized Views
Index-organized materialized views are subject to the following restrictions:

- You cannot specify the following `CREATE MATERIALIZED VIEW` clauses: `CACHE` or `NOCACHE`, `CLUSTER`, or `ON PREBUILT TABLE`.
- In the `index_org_table_clause`:
  - You cannot specify the `mapping_table_clause`.
  - You can specify `COMPRESS` only for a materialized view based on a composite primary key. You can specify `NOCOMPRESS` for a materialized view based on either a simple or composite primary key.

#### CLUSTER Clause
The `CLUSTER` clause lets you create the materialized view as part of the specified cluster. A cluster materialized view uses the space allocation of the cluster. Therefore, you do not specify physical attributes or the `TABLESPACE` clause with the `CLUSTER` clause.

#### Restriction on Cluster Materialized Views
If you specify `CLUSTER`, then you cannot specify the `table_partitioning_clauses` in `materialized_view_props`.

#### materialized_view_props
Use these property clauses to describe a materialized view that is not based on an existing table. To create a materialized view that is based on an existing table, use the `ON PREBUILT TABLE` clause.

#### column_properties
The `column_properties` clause lets you specify the storage characteristics of a LOB, nested table, varray, or XMLType column. The `object_type_col_properties` are not relevant for a materialized view.
See Also:
CREATE TABLE for detailed information about specifying the parameters of this clause

table_partitioning_clauses

The table_partitioning_clauses let you specify that the materialized view is partitioned on specified ranges of values or on a hash function. Partitioning of materialized views is the same as partitioning of tables.

See Also:

| table_partitioning_clauses | in the CREATE TABLE documentation |

CACHE | NOCACHE

For data that will be accessed frequently, CACHE specifies that the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. NOCACHE specifies that the blocks are placed at the least recently used end of the LRU list.

Note:

NOCACHE has no effect on materialized views for which you specify KEEP in the storage_clause.

See Also:

| CREATE TABLE | for information about specifying CACHE or NOCACHE |

parallel_clause

The parallel_clause lets you indicate whether parallel operations will be supported for the materialized view and sets the default degree of parallelism for queries and DML on the materialized view after creation.

For complete information on this clause, refer to parallel_clause in the documentation on CREATE TABLE.

build_clause

The build_clause lets you specify when to populate the materialized view.

IMMEDIATE
Specify **IMMEDIATE** to indicate that the materialized view is to be populated immediately. This is the default.

**DEFERRED**

Specify **DEFERRED** to indicate that the materialized view is to be populated by the next **REFRESH** operation. The first (deferred) refresh must always be a complete refresh. Until then, the materialized view has a staleness value of **UNUSABLE**, so it cannot be used for query rewrite.

**USING INDEX Clause**

The **USING INDEX** clause lets you establish the value of the **INTRANS** and **STORAGE** parameters for the default index Oracle Database uses to maintain the materialized view data. If **USING INDEX** is not specified, then default values are used for the index. Oracle Database uses the default index to speed up incremental (**FAST**) refresh of the materialized view.

**Restriction on USING INDEX clause**

You cannot specify the **PCTUSED** parameter in this clause.

**USING NO INDEX Clause**

Specify **USING NO INDEX** to suppress the creation of the default index. You can create an alternative index explicitly by using the **CREATE INDEX** statement. You should create such an index if you specify **USING NO INDEX** and you are creating the materialized view with the fast refresh method (**REFRESH FAST**).

**create_mv_refresh**

Use the **create_mv_refresh** clause to specify the default methods, modes, and times for the database to refresh the materialized view. If the master tables of a materialized view are modified, then the data in the materialized view must be updated to make the materialized view accurately reflect the data currently in its master tables. This clause lets you schedule the times and specify the method and mode for the database to refresh the materialized view.

**Restriction on Synchronous Refresh**

If you are using the synchronous refresh method, then you must specify **ON DEMAND** and **USING TRUSTED CONSTRAINTS**.

**Note:**

This clause only sets the default refresh options. For instructions on actually implementing the refresh, refer to *Oracle Database Administrator’s Guide* and *Oracle Database Data Warehousing Guide*. 
FAST Clause

Specify FAST to indicate the fast refresh method, which performs the refresh according to the changes that have occurred to the master tables. The changes for conventional DML changes are stored in the materialized view log associated with the master table. The changes for direct-path INSERT operations are stored in the direct loader log.

If you specify REFRESH FAST, then the CREATE statement will fail unless materialized view logs already exist for the materialized view master tables. Oracle Database creates the direct loader log automatically when a direct-path INSERT takes place. No user intervention is needed.

For both conventional DML changes and for direct-path INSERT operations, other conditions may restrict the eligibility of a materialized view for fast refresh.

Restrictions on FAST Refresh

FAST refresh is subject to the following restrictions:

• When you specify FAST refresh at create time, Oracle Database verifies that the materialized view you are creating is eligible for fast refresh. When you change the refresh method to FAST in an ALTER MATERIALIZED VIEW statement, Oracle Database does not perform this verification. If the materialized view is not eligible for fast refresh, then Oracle Database returns an error when you attempt to refresh this view.

• Materialized views are not eligible for fast refresh if the defining query contains an analytic function or the XMLTable function.

• Materialized views are not eligible for fast refresh if the defining query references a table on which an XMLIndex index is defined.

• You cannot fast refresh a materialized view if any of its columns is encrypted.
See Also:

- Oracle Database Administrator's Guide for restrictions on fast refresh in replication environments
- Oracle Database Data Warehousing Guide for restrictions on fast refresh in data warehousing environments
- The EXPLAIN_MVIEW procedure of the DBMS_MVIEW package for help diagnosing problems with fast refresh and the TUNE_MVIEW procedure of the DBMS_MVIEW package for correction of query rewrite problems
- "Analytic Functions"
- "Creating a Fast Refreshable Materialized View: Example"

COMPLETE Clause

Specify COMPLETE to indicate the complete refresh method, which is implemented by executing the defining query of the materialized view. If you request a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

FORCE Clause

Specify FORCE to indicate that when a refresh occurs, Oracle Database will perform a fast refresh if one is possible or a complete refresh if fast refresh is not possible. If you do not specify a refresh method (FAST, COMPLETE, or FORCE), then FORCE is the default.

ON COMMIT Clause

Specify ON COMMIT to indicate that a refresh is to occur whenever the database commits a transaction that operates on a master table of the materialized view. This clause may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.

You can specify only one of the ON COMMIT, ON DEMAND, and ON STATEMENT clauses. If you specify ON COMMIT, then you cannot also specify START WITH or NEXT.

Restrictions on Refreshing ON COMMIT

The following restrictions apply to the ON COMMIT clause:

- This clause is not supported for materialized views containing object types or Oracle-supplied types.
- This clause is not supported for materialized views with remote tables.
- If you specify this clause, then you cannot subsequently execute a distributed transaction on any master table of this materialized view. For example, you cannot insert into the master by selecting from a remote table. The ON DEMAND clause does not impose this restriction on subsequent distributed transactions on master tables.

ON DEMAND Clause

Specify ON DEMAND to indicate that database will not refresh the materialized view unless the user manually launches a refresh through one of the three DBMS_MVIEW refresh procedures.
You can specify only one of the ON COMMIT, ON DEMAND, and ON STATEMENT clauses. If you omit all three of these clauses, then ON DEMAND is the default. You can override this default setting by specifying the START WITH or NEXT clauses, either in the same CREATE MATERIALIZED VIEW statement or a subsequent ALTER MATERIALIZED VIEW statement.

START WITH and NEXT take precedence over ON DEMAND. Therefore, in most circumstances it is not meaningful to specify ON DEMAND when you have specified START WITH or NEXT.

See Also:

- Oracle Database PL/SQL Packages and Types Reference for information on these procedures
- Oracle Database Data Warehousing Guide on the types of materialized views you can create by specifying REFRESH ON DEMAND

ON STATEMENT Clause

Specify ON STATEMENT to indicate that an automatic refresh is to occur every time a DML operation is performed on any of the materialized view's base tables.

You can specify only one of the ON COMMIT, ON DEMAND, and ON STATEMENT clauses. You can specify ON STATEMENT only when creating a materialized view. You cannot subsequently alter the materialized view to use ON STATEMENT refresh.

Restrictions on Refreshing ON STATEMENT

The following restrictions apply to the ON STATEMENT clause:

- This clause can be used only with materialized views that are fast refreshable. The ON STATEMENT clause must be specified with the REFRESH FAST clause.
- The base tables referenced in the materialized view's defining query must be connected in a join graph that uses the star schema or snowflake schema model. The query must contain exactly one centralized fact table and one or more dimension tables, with all pairs of joined tables being related using primary key-foreign key constraints.
  - There is no restriction on the depth of the snowflake model.
  - The constraints can be in RELY mode. However, you must include the USING TRUSTED CONSTRAINT clause while creating the materialized view to use the RELY constraint.
- The materialized view's defining query must include the ROWID column of the fact table.
- The materialized view's defining query cannot include any of the following: invisible columns, ANSI join syntax, complex query, inline view as base table, composite primary key, LONG columns, and LOB columns.
- You cannot alter the definition of an existing materialized view that uses the ON STATEMENT refresh mode.
- You cannot alter an existing materialized view and enable ON STATEMENT refresh for it.
• The following operations cause a materialized view with `ON STATEMENT` refresh to become unusable:
  – `UPDATE` operations on one or more dimension tables on which the materialized view is based
  – Partition maintenance operations and `TRUNCATE` operations on any base table

However, a materialized view with the `ON STATEMENT` refresh mode can be partitioned.

• All the restrictions that apply to the `ON COMMIT` clause apply to `ON STATEMENT`.

### START WITH Clause

Specify a datetime expression for the first automatic refresh time.

### NEXT Clause

Specify a datetime expression for calculating the interval between automatic refreshes.

Both the `START WITH` and `NEXT` values must evaluate to a time in the future. If you omit the `START WITH` value, then the database determines the first automatic refresh time by evaluating the `NEXT` expression with respect to the creation time of the materialized view. If you specify a `START WITH` value but omit the `NEXT` value, then the database refreshes the materialized view only once. If you omit both the `START WITH` and `NEXT` values, or if you omit the `create_mv_refresh` entirely, then the database does not automatically refresh the materialized view.

### WITH PRIMARY KEY Clause

Specify `WITH PRIMARY` to create a primary key materialized view. This is the default and should be used in all cases except those described for `WITH ROWID`. Primary key materialized views allow materialized view master tables to be reorganized without affecting the eligibility of the materialized view for fast refresh. The master table must contain an enabled primary key constraint, and the defining query of the materialized view must specify all of the primary key columns directly. In the defining query, the primary key columns cannot be specified as the argument to a function such as `UPPER`.

### Restriction on Primary Key Materialized Views

You cannot specify this clause for an object materialized view. Oracle Database implicitly refreshes objects materialized `WITH OBJECT ID`.

---

**See Also:**

*Oracle Database Administrator’s Guide* for detailed information about primary key materialized views and "Creating Primary Key Materialized Views: Example"

---

### WITH ROWID Clause

Specify `WITH ROWID` to create a rowid materialized view. Rowid materialized views are useful if the materialized view does not include all primary key columns of the master tables. Rowid materialized views must be based on a single table and cannot contain any of the following:

• Distinct or aggregate functions
The WITH ROWID clause has no effect if there are multiple master tables in the defining query.

Rowid materialized views are not eligible for fast refresh after a master table reorganization until a complete refresh has been performed.

**Restriction on Rowid Materialized Views**

You cannot specify this clause for an object materialized view. Oracle Database implicitly refreshes objects materialized WITH OBJECT ID.

**USING ROLLBACK SEGMENT Clause**

This clause is not valid if your database is in automatic undo mode, because in that mode Oracle Database uses undo tablespaces instead of rollback segments. Oracle strongly recommends that you use automatic undo mode. This clause is supported for backward compatibility with replication environments containing older versions of Oracle Database that still use rollback segments.

For `rollback_segment`, specify the remote rollback segment to be used during materialized view refresh.

**DEFAULT**

`DEFAULT` specifies that Oracle Database will choose automatically which rollback segment to use. If you specify `DEFAULT`, then you cannot specify `rollback_segment`. `DEFAULT` is most useful when modifying, rather than creating, a materialized view.

**MASTER**

`MASTER` specifies the remote rollback segment to be used at the remote master site for the individual materialized view.

**LOCAL**

`LOCAL` specifies the remote rollback segment to be used for the local refresh group that contains the materialized view. This is the default.
See Also:

*Oracle Database PL/SQL Packages and Types Reference* for information on specifying the local materialized view rollback segment using the `DBMS_REFRESH` package

If you omit `rollback_segment`, then the database automatically chooses the rollback segment to be used. One master rollback segment is stored for each materialized view and is validated during materialized view creation and refresh. If the materialized view is complex, then the database ignores any master rollback segment you specify.

**USING ... CONSTRAINTS Clause**

The `USING ... CONSTRAINTS` clause lets Oracle Database choose more rewrite options during the refresh operation, resulting in more efficient refresh execution. The clause lets Oracle Database use unenforced constraints, such as dimension relationships or constraints in the `RELY` state, rather than relying only on enforced constraints during the refresh operation.

The `USING TRUSTED CONSTRAINTS` clause enables you to create a materialized view on top of a table that has a non-NULL Virtual Private Database (VPD) policy on it. In this case, you must ensure that the materialized view behaves correctly. Materialized view results are computed based on the rows and columns filtered by VPD policy. Therefore, you must coordinate the materialized view definition with the VPD policy to ensure the correct results. Without the `USING TRUSTED CONSTRAINTS` clause, any VPD policy on a master table will prevent a materialized view from being created.

**Note:**

The `USING TRUSTED CONSTRAINTS` clause lets Oracle Database use dimension and constraint information that has been declared trustworthy by the database administrator but that has not been validated by the database. If the dimension and constraint information is valid, then performance may improve. However, if this information is invalid, then the refresh procedure may corrupt the materialized view even though it returns a success status.

If you omit this clause, then the default is `USING ENFORCED CONSTRAINTS`.

**NEVER REFRESH Clause**

Specify `NEVER REFRESH` to prevent the materialized view from being refreshed with any Oracle Database refresh mechanism or packaged procedure. Oracle Database will ignore any `REFRESH` statement on the materialized view issued from such a procedure. If you specify this clause, then you can perform DML operations on the materialized view. To reverse this clause, you must issue an `ALTER MATERIALIZED VIEW ... REFRESH` statement.

**evaluation_edition_clause**

You must specify this clause if `subquery` references an editioned object. Use this clause to specify the edition that is searched during name resolution of the editioned object—the evaluation edition.
• Specify CURRENT EDITION to search the edition in which this DDL statement is executed.
• Specify EDITION edition to search edition.
• Specifying NULL EDITION is equivalent to omitting the evaluation_edition_clause.

If you omit the evaluation_edition_clause, then editioned objects are invisible during name resolution and an error will result. Dropping the evaluation edition invalidates the materialized view.

See Also:
Oracle Database Development Guide for more information on specifying the evaluation edition for a materialized view

{ ENABLE | DISABLE } ON QUERY COMPUTATION

This clause lets you create a real-time materialized view or a regular view. A real-time materialized view provides fresh data to user queries even when the materialized view is not in sync with its base tables due to data changes. Instead of modifying the materialized view, the optimizer writes a query that combines the existing rows in the materialized view with changes recorded in log files (either materialized view logs or the direct loader logs). This is called on-query computation.

• Specify ENABLE ON QUERY COMPUTATION to create a real-time materialized view by enabling on-query computation. This allows you to directly query up-to-date data from the materialized view by specifying the FRESH_MV hint in the SELECT statement. If the materialized view is also enabled for query rewrite, then on-query computation occurs automatically during query rewrite.

• Specify DISABLE ON QUERY COMPUTATION to create a regular materialized view by disabling on-query computation. This is the default.

Restrictions on Real-Time Materialized Views

Real-time materialized views are subject to the following restrictions:

• Real-time materialized views cannot be used when one or more materialized view logs created on the base tables are either unusable or nonexistent.

• A real-time materialized view must be refreshable using out-of-place refresh, log-based refresh, or partition change tracking (PCT) refresh.

• A refresh-on-commit materialized view cannot be a real-time materialized view.

• If a real-time materialized view is a nested materialized view that is defined on top of one or more base materialized views, then query rewrite occurs only if all the base materialized views are fresh. If one or more base materialized views are stale, then query rewrite is not performed using this real-time materialized view.

• The cursors of queries that directly access real-time materialized views are not shared.
query_rewrite_clause

The query_rewrite_clause lets you specify whether the materialized view is eligible to be used for query rewrite.

ENABLE Clause

Specify ENABLE to enable the materialized view for query rewrite. If you also specify the unusableEditions_clause, then the materialized view is not enabled for query rewrite in the unusable editions.

Restrictions on Enabling Query Rewrite

Enabling of query rewrite is subject to the following restrictions:

- You can enable query rewrite only if all user-defined functions in the materialized view are DETERMINISTIC.
- You can enable query rewrite only if expressions in the statement are repeatable. For example, you cannot include CURRENT_TIME or USER, sequence values (such as the CURRVAL or NEXTVAL pseudocolumns), or the SAMPLE clause (which may sample different rows as the contents of the materialized view change).

Note:

- Query rewrite is disabled by default, so you must specify this clause to make materialized views eligible for query rewrite.
- After you create the materialized view, you must collect statistics on it using the DBMS_STATS package. Oracle Database needs the statistics generated by this package to optimize query rewrite.
See Also:

- Oracle Database Data Warehousing Guide for more information on query rewrite
- Oracle Database Data Warehousing Guide to learn how to use refresh statistics to monitor the performance of materialized view refresh operations
- Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_STATS package
- The EXPLAIN_MVIEW procedure of the DBMS_MVIEW package for help diagnosing problems with query rewrite and the TUNE_MVIEW procedure of the DBMS_MVIEW package for correction of query rewrite problems
- CREATE FUNCTION

DISABLE Clause

Specify DISABLE to indicate that the materialized view is not eligible for use by query rewrite. A disabled materialized view can be refreshed.

**unusableEditionsClause**

This clause lets you specify that the materialized view is not eligible for query rewrite in one or more editions. You can specify this clause regardless of whether you specify the ENABLE or DISABLE clause. If you specify the DISABLE clause, then this clause will take effect if the materialized view is subsequently enabled for query rewrite using the ALTER MATERIALIZED VIEW ... ENABLE QUERY REWRITE statement.

UNUSABLE BEFORE Clause

This clause lets you specify that the materialized view is not eligible for query rewrite in the ancestors of an edition.

- If you specify CURRENT EDITION, then the materialized view is not eligible for query rewrite in the ancestors of the current edition.
- If you specify EDITION edition, then the materialized view is not eligible for query rewrite in the ancestors of the specified edition.

UNUSABLE BEGINNING WITH Clause

This clause lets you specify that the materialized view is not eligible for query rewrite in an edition and its descendants.

- If you specify CURRENT EDITION, then the materialized view is not eligible for query rewrite in the current edition and its descendants.
- If you specify EDITION edition, then the materialized view is not eligible for query rewrite in the specified edition and its descendants.
- Specifying NULL EDITION is equivalent to omitting the UNUSABLE BEGINNING WITH clause.

The materialized view has a dependency on each edition in which it is not eligible for query rewrite. If such an edition is subsequently dropped, then the dependency is removed. However, the materialized view is not invalidated.
**AS subquery**

Specify the defining query of the materialized view. When you create the materialized view, Oracle Database executes this subquery and places the results in the materialized view. This subquery is any valid SQL subquery. However, not all subqueries are fast refreshable, nor are all subqueries eligible for query rewrite.

**Notes on the Defining Query of a Materialized View**

The following notes apply to materialized views:

- Oracle Database does not execute the defining query immediately if you specify **BUILD DEFERRED**.
- Oracle recommends that you qualify each table and view in the **FROM clause** of the defining query of the materialized view with the schema containing it.
- In order to create a materialized view whose defining query selects from a master table that has a Virtual Private Database (VPD) policy, you must specify the **REFRESH USING TRUSTED CONSTRAINTS clause**.

**Restrictions on the Defining Query of a Materialized View**

The materialized view query is subject to the following restrictions:

- The defining query of a materialized view can select from tables, views, or materialized views owned by the user **SYS**, but you cannot enable **QUERY REWRITE** on such a materialized view.
- The defining query of a materialized view cannot select from a **V$** view or a **GV$** view.
- You cannot define a materialized view with a subquery in the select list of the defining query. You can, however, include subqueries elsewhere in the defining query, such as in the **WHERE clause**.
- You cannot use the **AS OF clause** of the **flashback_query_clause** in the defining query of a materialized view.
- Materialized join views and materialized aggregate views with a **GROUP BY clause** cannot select from an index-organized table.
- Materialized views cannot contain columns of data type **LONG** or **LONG RAW**.
- Materialized views cannot contain virtual columns.
- You cannot create a materialized view log on a temporary table. Therefore, if the defining query references a temporary table, then this materialized view will not be eligible for **FAST refresh**, nor can you specify the **QUERY REWRITE clause** in this statement.
- If the **FROM clause** of the defining query references another materialized view, then you must always refresh the materialized view referenced in the defining query before refreshing the materialized view you are creating in this statement.
- Materialized views with join expressions in the defining query cannot have XML data type columns. The XML data types include **XMLType** and URI data type columns.

If you are creating a materialized view enabled for query rewrite, then:
• The defining query cannot contain, either directly or through a view, references to ROWNUM, USER, SYSDATE, remote tables, sequences, or PL/SQL functions that write or read database or package state.

• Neither the materialized view nor the master tables of the materialized view can be remote.

If you want the materialized view to be eligible for fast refresh using a materialized view log, or synchronous refresh using a staging log, then some additional restrictions apply.

See Also:

• Oracle Database Data Warehousing Guide for restrictions relating to using fast refresh and synchronous refresh

• Oracle Database Administrator's Guide for more information on restrictions relating to replication

• "Creating Materialized Join Views: Example", "Creating Subquery Materialized Views: Example", and "Creating a Nested Materialized View: Example"

Examples

The following examples require the materialized logs that are created in the "Examples" section of CREATE MATERIALIZED VIEW LOG.

Creating a Simple Materialized View: Example

The following statement creates a very simple materialized view based on the employees and table in the hr schema:

```
CREATE MATERIALIZED VIEW mv1 AS SELECT * FROM hr.employees;
```

By default, Oracle Database creates a primary key materialized view with refresh on demand only. If a materialized view log exists on employees, then mv1 can be altered to be capable of fast refresh. If no such log exists, then only full refresh of mv1 is possible. Oracle Database uses default storage properties for mv1. The only privileges required for this operation are the CREATE MATERIALIZED VIEW system privilege, and the READ or SELECT object privilege on hr.employees.

Creating Subquery Materialized Views: Example

The following statement creates a subquery materialized view based on the customers and countries tables in the sh schema at the remote database:

```
CREATE MATERIALIZED VIEW foreign_customers
  AS SELECT * FROM sh.customers@remote cu
  WHERE EXISTS
    (SELECT * FROM sh.countries@remote co
     WHERE co.country_id = cu.country_id);
```

Creating Materialized Aggregate Views: Example

The following statement creates and populates a materialized aggregate view on the sample sh.sales table and specifies the default refresh method, mode, and time. It
uses the materialized view log created in "Creating a Materialized View Log for Fast Refresh: Examples", as well as the two additional logs shown here:

CREATE MATERIALIZED VIEW LOG ON times
  WITH ROWID, SEQUENCE (time_id, calendar_year)
  INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW LOG ON products
  WITH ROWID, SEQUENCE (prod_id)
  INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW sales_mv
  BUILD IMMEDIATE
  REFRESH FAST ON COMMIT
  AS SELECT t.calendar_year, p.prod_id,
          SUM(s.amount_sold) AS sum_sales
  FROM times t, products p, sales s
  WHERE t.time_id = s.time_id AND p.prod_id = s.prod_id
  GROUP BY t.calendar_year, p.prod_id;

Creating Materialized Join Views: Example

The following statement creates and populates the materialized aggregate view sales_by_month_by_state using tables in the sample sh schema. The materialized view will be populated with data as soon as the statement executes successfully. By default, subsequent refreshes will be accomplished by reexecuting the defining query of the materialized view:

CREATE MATERIALIZED VIEW sales_by_month_by_state
  TABLESPACE example
  PARALLEL 4
  BUILD IMMEDIATE
  REFRESH COMPLETE
  ENABLE QUERY REWRITE
  AS SELECT t.calendar_month_desc, c.cust_state_province,
          SUM(s.amount_sold) AS sum_sales
  FROM times t, sales s, customers c
  WHERE s.time_id = t.time_id AND s.cust_id = c.cust_id
  GROUP BY t.calendar_month_desc, c.cust_state_province;

Creating Prebuilt Materialized Views: Example

The following statement creates a materialized aggregate view for the preexisting summary table, sales_sum_table:

CREATE TABLE sales_sum_table
  (month VARCHAR2(8), state VARCHAR2(40), sales NUMBER(10,2));

CREATE MATERIALIZED VIEW sales_sum_table
  ON PREBUILT TABLE WITH REDUCED PRECISION
  ENABLE QUERY REWRITE
  AS SELECT t.calendar_month_desc AS month,
          c.cust_state_province AS state,
          SUM(s.amount_sold) AS sales
  FROM times t, customers c, sales s
  WHERE s.time_id = t.time_id AND s.cust_id = c.cust_id
  GROUP BY t.calendar_month_desc, c.cust_state_province;

In the preceding example, the materialized view has the same name and also has the same number of columns with the same data types as the prebuilt table. The
WITH REDUCED PRECISION clause allows for differences between the precision of the materialized view columns and the precision of the values returned by the subquery.

Creating Primary Key Materialized Views: Example

The following statement creates the primary key materialized view `catalog` on the sample table `oe.product_information`:

```
CREATE MATERIALIZED VIEW catalog
  REFRESH FAST START WITH SYSDATE NEXT SYSDATE + 1/4096
  WITH PRIMARY KEY
  AS SELECT * FROM product_information;
```

Creating Rowid Materialized Views: Example

The following statement creates a rowid materialized view on the sample table `oe.orders`:

```
CREATE MATERIALIZED VIEW order_data REFRESH WITH ROWID
  AS SELECT * FROM orders;
```

Periodic Refresh of Materialized Views: Example

The following statement creates the primary key materialized view `emp_data` and populates it with data from the sample table `hr.employees`:

```
CREATE MATERIALIZED VIEW LOG ON employees
  WITH PRIMARY KEY
  INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW emp_data
  PCTFREE 5 PCTUSED 60
  TABLESPACE example
  STORAGE (INITIAL 50K)
  REFRESH FAST NEXT sysdate + 7
  AS SELECT * FROM employees;
```

The preceding statement does not include a START WITH parameter, so Oracle Database determines the first automatic refresh time by evaluating the NEXT value using the current SYSDATE. A materialized view log was created for the employee table, so Oracle Database performs a fast refresh of the materialized view every 7 days, beginning 7 days after the materialized view is created.

Because the materialized view conforms to the conditions for fast refresh, the database will perform a fast refresh. The preceding statement also establishes storage characteristics that the database uses to maintain the materialized view.

Automatic Refresh Times for Materialized Views: Example

The following statement creates the complex materialized view `all_customers` that queries the employee tables on the remote and local databases:

```
CREATE MATERIALIZED VIEW all_customers
  PCTFREE 5 PCTUSED 60
  TABLESPACE example
  STORAGE (INITIAL 50K)
  USING INDEX STORAGE (INITIAL 25K)
  REFRESH START WITH ROUND(SYSDATE + 1) + 11/24
  NEXT NEXT_DAY(TRUNC(SYSDATE), 'MONDAY') + 15/24
  AS SELECT * FROM sh.customers@remote
```
Oracle Database automatically refreshes this materialized view tomorrow at 11:00 a.m. and subsequently every Monday at 3:00 p.m. The default refresh method is **FORCE**. The defining query contains a **UNION** operator, which is not supported for fast refresh, so the database will automatically perform a complete refresh.

The preceding statement also establishes storage characteristics for both the materialized view and the index that the database uses to maintain it:

- The first **STORAGE** clause establishes the sizes of the first and second extents of the materialized view as 50 kilobytes each.
- The second **STORAGE** clause, appearing with the **USING INDEX** clause, establishes the sizes of the first and second extents of the index as 25 kilobytes each.

### Creating a Fast Refreshable Materialized View: Example

The following statement creates a fast-refreshable materialized view that selects columns from the `order_items` table in the sample `oe` schema, using the **UNION** set operator to restrict the rows returned from the `product_information` and `inventories` tables using **WHERE** conditions. The materialized view logs for `order_items` and `product_information` were created in the "Examples " section of **CREATE MATERIALIZED VIEW LOG**. This example also requires a materialized view log on `oe.inventories`.

```
CREATE MATERIALIZED VIEW LOG ON inventories
    WITH (quantity_on_hand);

CREATE MATERIALIZED VIEW warranty_orders REFRESH FAST AS
    SELECT order_id, line_item_id, product_id FROM order_items o
    WHERE EXISTS
        (SELECT * FROM inventories i WHERE o.product_id = i.product_id
         AND i.quantity_on_hand IS NOT NULL)
    UNION
    SELECT order_id, line_item_id, product_id FROM order_items
    WHERE quantity > 5;
```

The materialized view `warranty_orders` requires that materialized view logs be defined on `order_items` (with `product_id` as a join column) and on `inventories` (with `quantity_on_hand` as a filter column). See "**Specifying Filter Columns for Materialized View Logs: Example**" and "**Specifying Join Columns for Materialized View Logs: Example**".

### Creating a Nested Materialized View: Example

The following example uses the materialized view from the preceding example as a master table to create a materialized view tailored for a particular sales representative in the sample `oe` schema:

```
CREATE MATERIALIZED VIEW my_warranty_orders
    AS SELECT w.order_id, w.line_item_id, o.order_date
    FROM warranty_orders w, orders o
    WHERE o.order_id = w.order_id
    AND o.sales_rep_id = 165;
```
CREATE MATERIALIZED VIEW LOG

Purpose

Use the CREATE MATERIALIZED VIEW LOG statement to create a materialized view log, which is a table associated with the master table of a materialized view.

Note:

The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

Materialized view logs are used for two types of materialized view refreshes: fast refresh and synchronous refresh.

Fast refresh uses a conventional materialized view log. During a fast refresh (also called an incremental refresh), when DML changes are made to master table data, Oracle Database stores rows describing those changes in the materialized view log and then uses the materialized view log to refresh materialized views based on the master table.

Synchronous refresh uses a special type of materialized view log called a staging log. During a synchronous refresh, DML changes are first described in the staging log and then applied to the master tables and the materialized views simultaneously. This guarantees that the master table data and materialized view data are in sync throughout the refresh process. This refresh method is useful in data warehousing environments.

Without a materialized view log, Oracle Database must reexecute the materialized view query to refresh the materialized view. This process is called a complete refresh. Usually, a complete refresh takes more time to complete than a fast refresh or a synchronous refresh.

A materialized view log is located in the master database in the same schema as the master table. A master table can have only one materialized view log defined on it.

To fast refresh or synchronous refresh a materialized join view, you must create a materialized view log for each of the tables referenced by the materialized view.

Fast refresh supports two types of materialized view logs: timestamp-based materialized view logs and commit SCN-based materialized view logs. Timestamp-based materialized view logs use timestamps and require some setup operations when preparing to refresh the materialized view. Commit SCN-based materialized view logs use commit SCN data rather than timestamps, which removes the need for the setup operations and thus can improve the speed of the materialized view refresh. If you specify the COMMIT SCN clause, then a commit SCN-based materialized view log is created. Otherwise, a time-stamp based materialized view log is created. Note that only new materialized view logs can take advantage of COMMIT SCN. Existing materialized view logs cannot be altered to add COMMIT SCN unless they are dropped and recreated. Refer to Oracle Database Data Warehousing Guide for more information.

Synchronous refresh supports only timestamp-based staging logs.
See Also:

- CREATE MATERIALIZED VIEW, ALTER MATERIALIZED VIEW, Oracle Database Concepts, Oracle Database Data Warehousing Guide, and Oracle Database Administrator’s Guide for information on materialized views in general
- ALTER MATERIALIZED VIEW LOG for information on modifying a materialized view log
- DROP MATERIALIZED VIEW LOG for information on dropping a materialized view log
- Oracle Database Utilities for information on using direct loader logs

Prerequisites

The privileges required to create a materialized view log directly relate to the privileges necessary to create the underlying objects associated with a materialized view log.

- If you own the master table, then you can create an associated materialized view log if you have the CREATE TABLE privilege.
- If you are creating a materialized view log for a table in another user’s schema, then you must have the CREATE ANY TABLE and COMMENT ANY TABLE system privileges, as well as either the READ or SELECT object privilege on the master table or the READ ANY TABLE or SELECT ANY TABLE system privilege.

In either case, the owner of the materialized view log must have sufficient quota in the tablespace intended to hold the materialized view log or must have the UNLIMITED TABLESPACE system privilege.

See Also:

Oracle Database Data Warehousing Guide for more information about the prerequisites for creating a materialized view log

Restrictions

The statement CREATE MATERIALIZED VIEW LOG does not support the following columns in the Master Table:

- Hidden columns
- Identity columns
- BFILE columns
- Temporal validity columns

for_refresh_clause::=

Chapter 14
CREATE MATERIALIZED VIEW LOG
Semantics

schema
Specify the schema containing the materialized view log master table. If you omit schema, then Oracle Database assumes the master table is contained in your own schema. Oracle Database creates the materialized view log in the schema of its master table. You cannot create a materialized view log for a table in the schema of the user SYS.

table
Specify the name of the master table for which the materialized view log is to be created. Oracle Database encrypts any columns in the materialized view log that are encrypted in the master table, using the same encryption algorithm.

Restrictions on Master Tables of Materialized View Logs
The following restrictions apply to master tables of materialized view logs:

- You cannot create a materialized view log for a temporary table or for a view.
- You cannot create a materialized view log for a master table with a virtual column.

See Also:
"Creating a Materialized View Log for Fast Refresh: Examples"

physical_attributes_clause
Use the physical_attributes_clause to define physical and storage characteristics for the materialized view log.

See Also:
physical_attributes_clause and storage_clause for a complete description of these clauses, including default values

TABLESPACE Clause
Specify the tablespace in which the materialized view log is to be created. If you omit this clause, then the database creates the materialized view log in the default tablespace of the schema of the materialized view log.

logging_clause
Specify either LOGGING or NOLOGGING to establish the logging characteristics for the materialized view log. The default is the logging characteristic of the tablespace in which the materialized view log resides.
CACHE | NOCACHE

For data that will be accessed frequently, CACHE specifies that the blocks retrieved for this log are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables.

NOCACHE specifies that the blocks are placed at the least recently used end of the LRU list. The default is NOCACHE.

Note:

NOCACHE has no effect on materialized view logs for which you specify KEEP in the storage_clause.

parallel_clause

The parallel_clause lets you indicate whether parallel operations will be supported for the materialized view log.

For complete information on this clause, refer to parallel_clause in the documentation on CREATE TABLE.

table_partitioning_clauses

Use the table_partitioning_clauses to indicate that the materialized view log is partitioned on specified ranges of values or on a hash function. Partitioning of materialized view logs is the same as partitioning of tables.

WITH Clause

Use the WITH clause to indicate whether the materialized view log should record the primary key, rowid, object ID, or a combination of these row identifiers when rows
in the master are changed. You can also use this clause to add a sequence to the
materialized view log to provide additional ordering information for its records.

This clause also specifies whether the materialized view log records additional
columns that might be referenced as filter columns, which are non-primary-key
columns referenced by subquery materialized views, or join columns, which are
non-primary-key columns that define a join in the subquery WHERE clause.

If you omit this clause, or if you specify the clause without PRIMARY KEY, ROWID, or
OBJECT ID, then the database stores primary key values by default. However, the
database does not store primary key values implicitly if you specify only OBJECT ID or
ROWID at create time. A primary key log, created either explicitly or by default, performs
additional checking on the primary key constraint.

**OBJECT ID**

Specify OBJECT ID to indicate that the system-generated or user-defined object
identifier of every modified row should be recorded in the materialized view log.

**Restriction on OBJECT ID**

You can specify OBJECT ID only when creating a log on an object table, and you cannot
specify it for storage tables.

**PRIMARY KEY**

Specify PRIMARY KEY to indicate that the primary key of all rows changed should be
recorded in the materialized view log.

**ROWID**

Specify ROWID to indicate that the rowid of all rows changed should be recorded in the
materialized view log.

**SEQUENCE**

Specify SEQUENCE to indicate that a sequence value providing additional ordering
information should be recorded in the materialized view log. Sequence numbers are
necessary to support fast refresh after some update scenarios.

> See Also:

*Oracle Database Data Warehousing Guide* for more information on the use
of sequence numbers in materialized view logs and for examples that use
this clause

**COMMIT SCN**

Without the COMMIT SCN clause, the materialized view log is based on timestamps
and requires some setup operations when preparing to refresh the materialized view.
Specify COMMIT SCN to instruct the database to use commit SCN data rather than
timestamps. This setting removes the need for the setup operations and thus can
improve the speed of the materialized view refresh.

You can create the following types of local materialized views (including both ON
COMMIT and ON DEMAND) on master tables with commit SCN-based materialized view
logs:
• Materialized aggregate views, including materialized aggregate views on a single table
• Materialized join views
• Primary-key-based and rowid-based single table materialized views
• \texttt{UNION ALL} materialized views, where each \texttt{UNION ALL} branch is one of the above materialized view types

You cannot create remote materialized views on master tables with commit SCN-based materialized view logs.

Restrictions on COMMIT SCN

The following restrictions apply to COMMIT SCN:

• Use of COMMIT SCN on a table with one or more LOB columns is not supported and causes ORA-32421.
• Creating a materialized view on master tables with different types of materialized view logs (that is, a master table with timestamp-based materialized view logs and a master table with commit SCN-based materialized view logs) is not supported and causes ORA-32414.
• If you specify COMMIT SCN, then you cannot specify \texttt{FOR SYNCHRONOUS REFRESH}.

\textit{column}

Specify the columns whose values you want to be recorded in the materialized view log for all rows that are changed. Typically these columns are filter columns and join columns.

Restrictions on the WITH Clause

This clause is subject to the following restrictions:

• You can specify only one \texttt{PRIMARY KEY}, one \texttt{ROWID}, one \texttt{OBJECT ID}, one \texttt{SEQUENCE}, and one column list for each materialized view log.
• Primary key columns are implicitly recorded in the materialized view log. Therefore, you cannot specify any of the following combinations if \textit{column} contains one of the primary key columns:

\begin{verbatim}
WITH ... PRIMARY KEY ... (column)
WITH ... (column) ... PRIMARY KEY
WITH (column)
\end{verbatim}

\textbf{See Also:}

• \texttt{CREATE MATERIALIZED VIEW} for information on explicit and implicit inclusion of materialized view log values
• \textit{Oracle Database Administrator's Guide} for more information about filter columns and join columns
• "Specifying Filter Columns for Materialized View Logs: Example" and "Specifying Join Columns for Materialized View Logs: Example"
NEW VALUES Clause
The new values clause lets you determine whether Oracle Database saves both old and new values for update DML operations in the materialized view log.

See Also:
"Including New Values in Materialized View Logs: Example"

INCLUDING
Specify including to save both new and old values in the log. If this log is for a table on which you have a single-table materialized aggregate view, and if you want the materialized view to be eligible for fast refresh, then you must specify including.

EXCLUDING
Specify excluding to disable the recording of new values in the log. This is the default. You can use this clause to avoid the overhead of recording new values. Do not use this clause if you have a fast-refreshable single-table materialized aggregate view defined on the master table.

mv_log_purge_clause
Use this clause to specify the purge time for the materialized view log.
- immediate synchronous: the materialized view log is purged immediately after refresh. This is the default.
- immediate asynchronous: the materialized view log is purged in a separate Oracle Scheduler job after the refresh operation.
- start with, next, and repeat interval set up a scheduled purge that is independent of the materialized view refresh and is initiated during create or alter materialized view log statement. This is very similar to scheduled refresh syntax in a create or alter materialized view statement:
  - The start with datetime expression specifies when the purge starts.
  - The next datetime expression computes the next run time for the purge.

If you specify repeat interval, then the next run time will be: sysdate + interval_expr.

A create materialized view log statement with a scheduled purge creates an Oracle Scheduler job to perform log purge. The job calls the DBMS_SNAPSHOT.PURGE_LOG procedure to purge the materialized view logs. This process allows you to amortize the purging costs over several materialized view refreshes.

Restriction on mv_log_purge_clause
This clause is not valid for materialized view logs on temporary tables.
for_refresh_clause

Use this clause to specify the refresh method for which the materialized view log will be used. You can specify only one refresh method for any given master table.

FOR SYNCHRONOUS REFRESH

Specify this clause to create a staging log that can be used for synchronous refresh. Use staging_log_name to specify the name of the staging log to be created. The staging log will be created in the schema in which the master table resides.

After you create the staging log, you cannot perform DML operations directly on the master table. You must use the procedures in the DBMS_SYNC_REFRESH package to prepare and execute change data operations.

Restrictions on Synchronous Refresh

The following restrictions apply to synchronous refresh:

- If you specify FOR SYNCHRONOUS REFRESH, then you cannot specify COMMIT SCN.
- To be eligible for synchronous refresh, the master table must satisfy the following criteria:
  - If the master table is a fact table, then it must be partitioned.
  - The master table must have a key. If the master table is a dimension table, then it must have a primary key defined on it. If the master table is a fact table, then the set of columns that are the foreign keys of the dimension tables joined to the fact table are deemed to be the key.
  - The master table cannot have a non-NULL Virtual Private Database (VPD) policy or a trigger defined on it.

Oracle Database may allow you to create a staging log on a master table even if all of the preceding criteria are not met. However, the master table will not be eligible for synchronous refresh.

- Any existing materialized views on the master table must be refresh-on-demand materialized views. If an existing materialized view is a refresh-on-commit materialized view, then you must change it to a refresh-on-demand materialized view with the alter_mv_refresh clause of ALTER MATERIALIZED VIEW before you create the staging log.
FOR FAST REFRESH

Specify this clause to create a materialized view log that can be used for fast refresh. The materialized view log will be created in the same schema in which the master table resides. This is the default.

Examples

Creating a Materialized View Log for Fast Refresh: Examples

The following statement creates a materialized view log on the `oe.customers` table that specifies physical and storage characteristics:

```sql
CREATE MATERIALIZED VIEW LOG ON customers
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K);
```

The materialized view log on `customers` supports fast refresh for primary key materialized views only.

The following statement creates another version of the materialized view log with the `ROWID` clause, which enables fast refresh for more types of materialized views:

```sql
CREATE MATERIALIZED VIEW LOG ON customers WITH PRIMARY KEY, ROWID;
```

This materialized view log on `customers` makes fast refresh possible for rowid materialized views and for materialized join views. To provide for fast refresh of materialized aggregate views, you must also specify the `SEQUENCE` and `INCLUDING NEW VALUES` clauses, as shown in the example that follows.

Specify a Purge Repeat Interval for a Materialized View Log: Example

The following statement creates a materialized view log on the `oe.orders` table. The contents of the log will be purged once every five days, beginning five days after the creation date of the materialized view log:

```sql
CREATE MATERIALIZED VIEW LOG ON orders
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K)
  PURGE REPEAT INTERVAL '5' DAY;
```

Specifying Filter Columns for Materialized View Logs: Example

The following statement creates a materialized view log on the `sh.sales` table and is used in "Creating Materialized Aggregate Views: Example". It specifies as filter columns all of the columns of the table referenced in that materialized view.
CREATE MATERIALIZED VIEW LOG ON sales
    WITH ROWID, SEQUENCE(amount_sold, time_id, prod_id)
    INCLUDING NEW VALUES;

Specifying Join Columns for Materialized View Logs: Example

The following statement creates a materialized view log on the order_items table of the sample oe schema. The log records primary keys and product_id, which is used as a join column in "Creating a Fast Refreshable Materialized View: Example".

CREATE MATERIALIZED VIEW LOG ON order_items WITH (product_id);

Including New Values in Materialized View Logs: Example

The following example creates a materialized view log on the oe.product_information table that specifies INCLUDING NEW VALUES:

CREATE MATERIALIZED VIEW LOG ON product_information
    WITH ROWID, SEQUENCE (list_price, min_price, category_id), PRIMARY KEY
    INCLUDING NEW VALUES;

You could create the following materialized aggregate view to use the product_information log:

CREATE MATERIALIZED VIEW products_mv
    REFRESH FAST ON COMMIT
    AS SELECT SUM(list_price - min_price), category_id
    FROM product_information
    GROUP BY category_id;

This materialized view is eligible for fast refresh because the log defined on its master table includes both old and new values.

Creating a Staging Log for Synchronous Refresh: Example

The following statement creates a staging log on the sh.sales fact table. The staging log is named mystage_log and is stored in the sh schema. It can be used for synchronous refresh.

CREATE MATERIALIZED VIEW LOG ON sales
    PCTFREE 5
    TABLESPACE example
    STORAGE (INITIAL 10K)
    FOR SYNCHRONOUS REFRESH USING mystage_log;

CREATE MATERIALIZED ZONEMAP

Purpose

Use the CREATE MATERIALIZED ZONEMAP statement to create a zone map.

A zone map is a special type of materialized view that stores information about zones. A zone is a set of contiguous data blocks on disk that stores the values of one or more table columns. Multiple zones are usually required to store all of the values of the table columns. A zone map tracks the minimum and maximum table column values stored in each zone.

Zone maps enable you to reduce the I/O and CPU costs of table scans. When a SQL statement contains predicates on columns in a zone map, the database compares the
predicate values to the minimum and maximum table column values stored in each zone to determine which zones to read during SQL execution.

Oracle Database supports the following types of zone maps:

- **A basic zone map** is defined on a single table and maintains zone information for specified columns in that table.
  
  You can create a basic zone map either by specifying the `create_zonemap_on_table` clause, or by specifying the `create_zonemap_as_subquery` clause where the FROM clause of the defining subquery specifies a single table.

- **A join zone map** is defined on two or more joined tables and maintains zone information for specified columns in any of the joined tables.
  
  You can create a join zone map by specifying the `create_zonemap_as_subquery` clause. The FROM clause of the defining subquery must specify a table that is left outer joined with one or more other tables.

Zone maps are commonly used with star schemas in data warehousing environments. However, a star schema is not a requirement for creating a zone map. In either case, this reference uses star schema terminology to refer to the tables in a zone map. In a join zone map, the outer table of the join(s) is referred to as the **fact table**, and the tables with which this table is joined are referred to as **dimension tables**. Collectively these tables are called the **base tables** of the zone map. In a basic zone map, the single table on which the zone map is defined is referred to as both the fact table and the base table of the zone map.

A base table of a zone map can be a partitioned or composite-partitioned table. In this case, the zone map maintains minimum and maximum column values for each partition (and subpartition) as well as for each zone.

You can create zone maps for use with or without attribute clustering:

- To create a zone map for use with attribute clustering, use either of the following methods:
  - Use the `CREATE MATERIALIZED ZONEMAP` statement and include attribute clustered columns in the zone map. Refer to the `attribute_clustering_clause` of `CREATE TABLE` and the `attribute_clustering_clause` clause of `ALTER TABLE` for more information.
  - Specify the `WITH MATERIALIZED ZONEMAP` clause while creating or modifying an attribute clustered table. Refer to the `zonemap_clause` of `CREATE TABLE` and the `MODIFY CLUSTERING` clause of `ALTER TABLE` for more information.

- To create a zone map for use without attribute clustering, use the `CREATE MATERIALIZED ZONEMAP` statement and include columns that are not attribute clustered in the zone map.

**See Also:**

*Oracle Database Data Warehousing Guide* for more information on zone maps.
Prerequisites

To create a zone map in your own schema:

- You must have the CREATE MATERIALIZED VIEW system privilege and either the CREATE TABLE or CREATE ANY TABLE system privilege.
- You must have access to any base tables of the zone map that you do not own, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a zone map in another user's schema:

- You must have the CREATE ANY MATERIALIZED VIEW system privilege.
- The owner of the zone map must have the CREATE TABLE system privilege. The owner must also have access to any base tables of the zone map that the schema owner does not own, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a refresh-on-commit zone map (REFRESH ON COMMIT clause), in addition to the preceding privileges, you must have the ON COMMIT REFRESH object privilege on any base tables that you do not own or you must have the ON COMMIT REFRESH system privilege. Unlike materialized views, you can create a refresh-on-commit zone map even if there are no materialized view logs on the base tables.

When you create a zone map, Oracle Database creates one internal table and at least one index, all in the schema of the zone map. Oracle Database uses these objects to maintain the zone map data. You must have the privileges necessary to create these objects, and you must have sufficient quota in the target tablespace to store these objects or you must have the UNLIMITED TABLESPACE system privilege.

Syntax

\[ \text{create\_materialized\_zonemap::=} \]

\[ \text{create\_zonemap\_on\_table::=} \]

CREATE MATERIALIZED ZONEMAP schema . zonemap_name [zonemap_attributes [zonemap_refresh_clause [ENABLE | DISABLE] PRUNING]]

ON schema . table [materialized_view (column)]
**create_zonemap_as_subquery::=**

```
CREATE MATERIALIZED ZONEMAP
  schema
  zonemap_name
  zonemap_attributes
  zonemap_refresh_clause
    ENABLE
    DISABLE
    PRUNING
    AS
    query_block
```

**zonemap_attributes::=**

```
TABLESPACE
  tablespace
  SCALE
  integer
  CACHE
  NOCACHE
```

**zonemap_refresh_clause::=**

```
REFRESH
  FAST
  COMPLETE
  FORCE
  ON
  LOAD
  DATA
  MOVEMENT
  COMMIT
  LOAD
  DATA
  MOVEMENT
```

**Note:**

When specifying the `zonemap_refresh_clause`, you must specify at least one clause after the `REFRESH` keyword.

**Semantics**

**create_zonemap_on_table**

Use this clause to create a basic zone map.

**ON Clause**
In the `ON` clause, first specify the fact table for the zone map, and then inside the parentheses specify one or more columns of the fact table to be included in the zone map.

For each specified fact table column, Oracle creates two columns in the zone map. These two columns contain the minimum and maximum values of the fact table column in each zone. Oracle generates names for the zone map columns of the form `MIN_1_column` and `MAX_1_column` for the first specified fact table column, `MIN_2_column` and `MAX_2_column` for the second specified fact table column, and so on.

If you omit `schema`, then Oracle assumes the fact table is in your own schema. The fact table can be a table or a materialized view.

**create_zonemap_as_subquery**

Use this clause to create a basic zone map or a join zone map. To create a basic zone map, specify a single base table in the `FROM` clause of the defining subquery. To create a join zone map, specify a table that is left outer joined to one or more other tables in the `FROM` clause of the defining subquery.

**column_alias**

You can specify a column alias for each table column to be included in the zone map. The column alias list explicitly resolves any column name conflict, eliminating the need to specify aliases in the `SELECT` list of the defining subquery. If you specify any column alias in this clause, then you must specify an alias for each column in the `SELECT` list of the defining subquery. The first column alias you specify must be `ZONE_ID$`, which corresponds to the first column in the `SELECT` list, the `SYS_OP_ZONE_ID` function expression.

**AS query_block**

Specify the defining subquery of the zone map. The subquery must consist of a single `query_block`. You can specify only the `SELECT`, `FROM`, `WHERE`, and `GROUP BY` clauses of `query_block`, and those clauses must satisfy the following requirements:

- The first column in the `SELECT` list must be the `SYS_OP_ZONE_ID` function expression. Refer to `SYS_OP_ZONE_ID` for more information.
- The remaining columns in the `SELECT` list must be function expressions that return minimum and maximum values for the columns you want to include in the zone map. For each column, specify a pair of function expressions of the following form:

  ```sql
  MIN([table.]column), MAX([table.]column)
  ```

  For `table`, specify the name or table alias for the table that contains the column. The table can be a fact table or dimension table. For `column`, specify the name or column alias for the column.

  - The `FROM` clause can specify a fact table alone, or a fact table and one or more dimension tables with each dimension table left outer joined to the fact table. You can specify `LEFT [OUTER] JOIN` syntax in the `FROM` clause, or apply the outer join operator (+) to dimension table columns in the join condition in the `WHERE` clause. You can optionally specify a table alias for any of the tables in the `FROM` clause. Fact tables and dimension tables can be tables or materialized views.
  - In the `WHERE` clause, you can specify only left outer join conditions using the outer join operator (+).
• You must specify a `GROUP BY` clause with the same `SYS_OP_ZONE_ID` function expression that you specified for the first column of the `SELECT` list.

**schema**

Specify the schema to contain the zone map. If you omit `schema`, then Oracle Database creates the zone map in your schema.

**zonemap_name**

Specify the name of the zone map to be created. The name must satisfy the requirements listed in “Database Object Naming Rules”.

**zonemap_attributes**

Use this clause to specify the following attributes for the zone map: `TABLESPACE`, `SCALE`, `PCTFREE`, `PCTUSED`, and `CACHE` or `NOCACHE`.

**TABLESPACE**

Specify the `tablespace` in which the zone map is to be created. If you omit this clause, then Oracle Database creates the zone map in the default tablespace of the schema containing the zone map.

**SCALE**

This clause lets you specify the zone map scale, which determines the number of contiguous disk blocks that form a zone. The scale is an integer value that represents a power of 2. For example, a scale of 10 means up to $2^{10}$, or 1024, contiguous disk blocks will form a zone. For `integer`, specify a value between 4 and 16, inclusive. The recommended value is 10; this is the default.

**PCTFREE**

Specify an `integer` representing the percentage of space in each data block of the zone map reserved for future updates to rows of the zone map. The integer value must be between 0 and 99, inclusive. The default value is 10. Refer to `physical_attributes_clause` for more information on the `PCTFREE` parameter.

**PCTUSED**

Specify an `integer` representing the minimum percentage of used space that Oracle maintains for each data block of the zone map. The integer value must be between 0 and 99, inclusive. The default value is 40. Refer to `physical_attributes_clause` for more information on the `PCTUSED` parameter.

**CACHE | NOCACHE**

For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this zone map are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed.

`NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list. The default is `NOCACHE`.

**zonemap_refresh_clause**

Use this clause to specify the default refresh method and mode for the zone map. If you do not specify a refresh method (`FAST`, `COMPLETE`, or `FORCE`), then `FORCE` is the
default method. If you do not specify a refresh mode (ON clauses), then ON LOAD DATA MOVEMENT is the default mode.

FAST
Specify FAST to indicate the fast refresh method, which performs the refresh according to the changes that have occurred to the base tables. While zone maps are internally implemented as a type of materialized view, materialized view logs on base tables are not needed to perform a fast refresh of a zone map

COMPLETE
Specify COMPLETE to indicate the complete refresh method, which is implemented by executing the defining query of the zone map. If you request a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

FORCE
Specify FORCE to indicate that when a refresh occurs, Oracle Database will perform a fast refresh if one is possible or a complete refresh if fast refresh is not possible. This is the default.

ON DEMAND
Specify ON DEMAND to indicate that database will not refresh the zone map unless you manually issue an ALTER MATERIALIZED ZONEMAP ... REBUILD statement. If you specify this clause, then the zone map is referred to as a refresh-on-demand zone map. Refer to REBUILD in the documentation on ALTER MATERIALIZED ZONEMAP for more information on rebuilding a zone map.

ON COMMIT
Specify ON COMMIT to indicate that a refresh is to occur whenever the database commits a transaction that operates on a base table of the zone map. If you specify this clause, then the zone map is referred to as a refresh-on-commit zone map. This clause may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.

ON LOAD
Specify ON LOAD to indicate that a refresh is to occur at the end of a direct-path insert (serial or parallel) resulting either from an INSERT or a MERGE operation.

ON DATA MOVEMENT
Specify ON DATA MOVEMENT to indicate that a refresh is to occur at the end of the following data movement operations:

- Data redefinition using the DBMS_REDEFINITION package
- Table partition maintenance operations that are specified by the following clauses of ALTER TABLE: coalesce_table, merge_table_partitions, move_table_partition, and split_table_partition

ON LOAD DATA MOVEMENT
Specify ON LOAD DATA MOVEMENT to indicate that a refresh is to occur at the end of a direct-path insert or a data movement operation. This is the default.
ENABLE | DISABLE PRUNING

This clause lets you control the use of the zone map for pruning.

- Specify **ENABLE PRUNING** to enable use of the zone map for pruning. This is the default.
- Specify **DISABLE PRUNING** to disable use of the zone map for pruning. The optimizer will not use the zone map for pruning, but the database will continue to maintain the zone map.

If the setting is **ENABLE PRUNING**, then the optimizer will consider using the zone map for pruning during SQL operations that include any of the following conditions:

- **Comparison conditions**: =, <=, <, >=, >

  The condition must be a simple comparison condition that has a column name on one side and a literal or bind variable on the other side. For example:

  WHERE country_name = 'United States of America'
  WHERE country_name = :country1
  WHERE 10000 >= salary

- **IN condition**

  The **IN** condition must have a column name on the left side and an expression list of literals or bind variables on the right side. For example:

  WHERE country_name IN ('Germany', 'India', 'United Kingdom')
  WHERE country_name IN (:country1, :country2, :country3)
  WHERE prod_id IN (20, 48, 132, 143)

- **LIKE condition**

  The **LIKE** condition must have a column name on the left side and a text literal on the right side. The text literal is the pattern for the **LIKE** condition and it must contain at least one pattern matching character. Valid pattern matching characters are the underscore (_), which matches exactly one character, and the percent sign (%), which matches zero or more characters. The first character of the pattern cannot be a pattern matching character. For example:

  WHERE prod_name LIKE 'DVD%
  WHERE prod_name LIKE 'Model%Cordless%Battery'
  WHERE prod_name LIKE 'CD%Pack of _'

**See Also:**

- **Conditions** for more information on conditions

Restrictions on Zone Maps

Zone maps are subject to the following restrictions:

- A table can be a fact table for at most one zone map. A table can be a dimension table for multiple zone maps. A table can be a fact table for one zone map and a dimension table for other zone maps.
- A base table of a zone map cannot be an external table, an index-organized table, a remote table, a temporary table, or a view.
A base table of a zone map cannot be in the schema of the user SYS.

A zone map cannot be partitioned.

You can define a zone map on a column of any scalar data type other than BFILE, BLOB, CLOB, LONG, LONG RAW, or NCLOB.

All joins specified in the defining subquery of a zone map must be left outer equijoins with the fact table on the left side.

If the FROM clause of the defining subquery for a zone map references a materialized view, then you must refresh that materialized view before refreshing the zone map.

You cannot perform DML operations directly on a zone map.

Each column of the zone map must have one of the following declared collations: BINARY or USING_NLS_COMP.

Examples

The following statement creates a basic zone map called sales_zmap. The zone map tracks columns cust_id and prod_id in the table sales.

```sql
CREATE MATERIALIZED ZONEMAP sales_zmap
ON sales(cust_id, prod_id);
```

The following statement creates a basic zone map called sales_zmap that is similar to the zone map created in the previous example. However, this statement uses a defining subquery to create the zone map.

```sql
CREATE MATERIALIZED ZONEMAP sales_zmap
AS SELECT SYS_OP_ZONE_ID(rowid),
         MIN(cust_id), MAX(cust_id),
         MIN(prod_id), MAX(prod_id)
FROM sales
GROUP BY SYS_OP_ZONE_ID(rowid);
```

The following statement creates a join zone map called sales_zmap. The fact table for the zone map is sales and the zone map has one dimension table: customers. The zone map tracks two columns in the dimension table: cust_state_province and cust_city.

```sql
CREATE MATERIALIZED ZONEMAP sales_zmap
AS SELECT SYS_OP_ZONE_ID(s.rowid),
         MIN(cust_state_province), MAX(cust_state_province),
         MIN(cust_city), MAX(cust_city)
FROM sales s
LEFT OUTER JOIN customers c ON s.cust_id = c.cust_id
GROUP BY SYS_OP_ZONE_ID(s.rowid);
```

The following statement creates a join zone map called sales_zmap. The fact table for the zone map is sales and the zone map has two dimension tables: products and customers. The zone map tracks five columns in the dimension tables: prod_category and prod_subcategory in the products table, and country_id, cust_state_province, and cust_city in the customers table.

```sql
CREATE MATERIALIZED ZONEMAP sales_zmap
AS SELECT SYS_OP_ZONE_ID(s.rowid),
         MIN(prod_category), MAX(prod_category),
         MIN(prod_subcategory), MAX(prod_subcategory),
```
The following statement creates a join zone map that is identical to the zone map created in the previous example. The only difference is that the previous example uses the LEFT OUTER JOIN syntax in the FROM clause and the following example uses the outer join operator (+) in the WHERE clause.

```sql
CREATE MATERIALIZED ZONEMAP sales_zmap
AS SELECT SYS_OP_ZONE_ID(s.rowid),
        MIN(prod_category), MAX(prod_category),
        MIN(prod_subcategory), MAX(prod_subcategory),
        MIN(country_id), MAX(country_id),
        MIN(cust_state_province), MAX(cust_state_province),
        MIN(cust_city), MAX(cust_city)
FROM sales s,
     products p, customers c
WHERE s.prod_id = p.prod_id(+)
  AND s.cust_id = c.cust_id(+)
GROUP BY sys_op_zone_id(s.rowid);
```

### CREATE OPERATOR

**Purpose**

Use the `CREATE OPERATOR` statement to create a new operator and define its bindings.

Operators can be referenced by index types and by SQL queries and DML statements. The operators, in turn, reference functions, packages, types, and other user-defined objects.

**See Also:**

Oracle Database Data Cartridge Developer’s Guide and Oracle Database Concepts for a discussion of these dependencies and of operators in general

**Prerequisites**

To create an operator in your own schema, you must have the `CREATE OPERATOR` system privilege. To create an operator in another schema, you must have the `CREATE ANY OPERATOR` system privilege. In either case, you must also have the `EXECUTE object privilege` on the functions and operators referenced.

**Syntax**

```
create_operator ::= CREATE OR REPLACE OPERATOR schema . operator binding_clause;
```
binding_clause ::= 

```
BINDING ( parameter_type
, RETURN return_type
implementation_clause
using_function_clause
, implementation_clause
```

implementation_clause ::= 

```
ANCILLARY TO primary_operator ( parameter_type
, context_clause
```

context_clause ::= 

```
WITH INDEX CONTEXT , SCAN CONTEXT implementation_type
COMPUTE ANCILLARY DATA
WITH COLUMN CONTEXT
```

using_function_clause ::= 

```
USING schema . package . type . function_name
```

**Semantics**

**OR REPLACE**

Specify OR REPLACE to replace the definition of the operator schema object.

**Restriction on Replacing an Operator**

You can replace the definition only if the operator has no dependent objects, such as indextypes supporting the operator.
schema
Specify the schema containing the operator. If you omit schema, then the database creates the operator in your own schema.

operator
Specify the name of the operator to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

binding_clause
Use the binding_clause to specify one or more parameter data types (parameter_type) for binding the operator to a function. The signature of each binding—the sequence of the data types of the arguments to the corresponding function—must be unique according to the rules of overloading.

The parameter_type can itself be an object type. If it is, then you can optionally qualify it with its schema.

Restriction on Binding Operators
You cannot specify a parameter_type of REF, LONG, or LONG RAW.

See Also:
Oracle Database PL/SQL Language Reference for more information about overloading

RETURN Clause
Specify the return data type for the binding.

The return_type can itself be an object type. If so, then you can optionally qualify it with its schema.

Restriction on Binding Return Data Type
You cannot specify a return_type of REF, LONG, or LONG RAW.

implementation_clause
Use this clause to describe the implementation of the binding.

ANCILLARY TO Clause
Use the ANCILLARY TO clause to indicate that the operator binding is ancillary to the specified primary operator binding (primary_operator). If you specify this clause, then do not specify a previous binding with just one number parameter.

context_clause
Use the context_clause to describe the functional implementation of a binding that is not ancillary to a primary operator binding.

WITH INDEX CONTEXT, SCAN CONTEXT
Use this clause to indicate that the functional evaluation of the operator uses the index and a scan context that is specified by the implementation type.

**COMPUTE ANCILLARY DATA**

Specify **COMPUTE ANCILLARY DATA** to indicate that the operator binding computes ancillary data.

**WITH COLUMN CONTEXT**

Specify **WITH COLUMN CONTEXT** to indicate that Oracle Database should pass the column information to the functional implementation for the operator.

If you specify this clause, then the signature of the function implemented must include one extra **ODCIFuncCallInfo** structure.

---

**See Also:**

*Oracle Database Data Cartridge Developer's Guide* for instructions on using the **ODCIFuncCallInfo** routine

---

**using_function_clause**

The **using_function_clause** lets you specify the function that provides the implementation for the binding. The **function_name** can be a standalone function, packaged function, type method, or a synonym for any of these.

If the function is subsequently dropped, then the database marks all dependent objects **INVALID**, including the operator. However, if you then subsequently issue an **ALTER OPERATOR ... DROP BINDING** statement to drop the binding, then subsequent queries and DML will revalidate the dependent objects.

**Examples**

**Creating User-Defined Operators: Example**

This example creates a very simple functional implementation of equality and then creates an operator that uses the function. For a more complete set of examples, see *Oracle Database Data Cartridge Developer's Guide*.

```sql
CREATE FUNCTION eq_f(a VARCHAR2, b VARCHAR2) RETURN NUMBER AS
BEGIN
    IF a = b THEN RETURN 1;
    ELSE RETURN 0;
END;
/

CREATE OPERATOR eq_op
    BINDING (VARCHAR2, VARCHAR2)
    RETURN NUMBER
    USING eq_f;
```
CREATE OUTLINE

Purpose

Note:

Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.

You can migrate existing stored outlines to SQL plan baselines by using the MIGRATE_STORED_OUTLINE function of the DBMS_SPM package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the DROP_MIGRATED_STORED_OUTLINE function of the DBMS_SPM package.

See Also: Oracle Database SQL Tuning Guide for more information about SQL plan management and Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_SPM package.

Use the CREATE OUTLINE statement to create a stored outline, which is a set of attributes used by the optimizer to generate an execution plan. You can then instruct the optimizer to use a set of outlines to influence the generation of execution plans whenever a particular SQL statement is issued, regardless of changes in factors that can affect optimization. You can also modify an outline so that it takes into account changes in these factors.

Note:

The SQL statement you want to affect must be an exact string match of the statement specified when creating the outline.

See Also:

- Oracle Database SQL Tuning Guide for information on execution plans
- ALTER OUTLINE for information on modifying an outline
- ALTER SESSION and ALTER SYSTEM for information on the USE_STORED_OUTLINES and USE_PRIVATE_OUTLINES parameters
Prerequisites

To create a public or private outline, you must have the `CREATE ANY OUTLINE` system privilege.

If you are creating a clone outline from a source outline, then you must also have the `SELECT_CATALOG_ROLE` role.

You can enable or disable the use of stored outlines dynamically for an individual session or for the system:

- Enable the `USE_STORED_OUTLINES` parameter to use public outlines.
- Enable the `USE_PRIVATE_OUTLINES` parameter to use private stored outlines.

Syntax

```
create_outline ::= CREATE
                  OR REPLACE
                  PUBLIC
                  PRIVATE
                  OUTLINE
                  outline
                  FROM
                  PUBLIC
                  PRIVATE
                  source_outline
                  FOR CATEGORY category ON statement
;
```

**Note:**

None of the clauses after `outline` are required. However, you must specify at least one clause after `outline`, and it must be either the `FROM` clause or the `ON` clause.

Semantics

**OR REPLACE**

Specify `OR REPLACE` to replace an existing outline with a new outline of the same name.

**PUBLIC | PRIVATE**

Specify `PUBLIC` if you are creating an outline for use by `PUBLIC`. This is the default.

Specify `PRIVATE` to create an outline for private use by the current session only. The data of this outline is stored in the current schema.
outline

Specify the unique name to be assigned to the stored outline. The name must satisfy the requirements listed in "Database Object Naming Rules". If you do not specify outline, then the database generates an outline name.

See Also:
"Creating an Outline: Example"

FROM source_outline Clause

Use the FROM clause to create a new outline by copying an existing one. By default, Oracle Database looks for source_category in the public area. If you specify PRIVATE, then the database looks for the outline in the current schema.

Restriction on Copying an Outline

If you specify the FROM clause, then you cannot specify the ON clause.

See Also:
"Creating a Private Clone Outline: Example" and "Publicizing a Private Outline to the Public Area: Example"

FOR CATEGORY Clause

Specify an optional name used to group stored outlines. For example, you could specify a category of outlines for end-of-week use and another for end-of-quarter use. If you do not specify category, then the outline is stored in the DEFAULT category.

ON Clause

Specify the SQL statement for which the database will create an outline when the statement is compiled. This clause is optional only if you are creating a copy of an existing outline using the FROM clause.

You can specify any one of the following statements: SELECT, DELETE, UPDATE, INSERT ... SELECT, CREATE TABLE ... AS SELECT.

Restrictions on the ON Clause

This clause is subject to the following restrictions:

- If you specify the ON clause, then you cannot specify the FROM clause.
- You cannot create an outline on a multitable INSERT statement.
- The SQL statement in the ON clause cannot include any DML operation on a remote object.
In subsequent statements, you can specify additional outlines for the same SQL statement, but each outline for the same statement must specify a different category in the CATEGORY clause.

Examples

Creating an Outline: Example

The following statement creates a stored outline by compiling the ON statement. The outline is called salaries and is stored in the category special.

CREATE OUTLINE salaries FOR CATEGORY special
  ON SELECT last_name, salary FROM employees;

When this same SELECT statement is subsequently compiled, if the USE_STORED_OUTLINES parameter is set to special, the database generates the same execution plan as was generated when the outline salaries was created.

Creating a Private Clone Outline: Example

The following statement creates a stored private outline my_salaries based on the public category salaries created in the preceding example.

CREATE OR REPLACE PRIVATE OUTLINE my_salaries
  FROM salaries;

Publicizing a Private Outline to the Public Area: Example

The following statement copies back (publicizes) a private outline to the public area after private editing:

CREATE OR REPLACE OUTLINE public_salaries
  FROM PRIVATE my_salaries;

CREATE PACKAGE

Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE PACKAGE statement to create the specification for a stored package, which is an encapsulated collection of related procedures, functions, and other program objects stored together in the database. The package specification declares these objects. The package body, specified subsequently, defines these objects.
Prerequisites

To create or replace a package in your own schema, you must have the `CREATE PROCEDURE` system privilege. To create or replace a package in another user’s schema, you must have the `CREATE ANY PROCEDURE` system privilege.

To embed a `CREATE PACKAGE` statement inside an Oracle Database precompiler program, you must terminate the statement with the keyword `END-EXEC` followed by the embedded SQL statement terminator for the specific language.

See Also:

Oracle Database PL/SQL Language Reference for more information

Syntax

Packages are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

\[
\text{create\_package::=} 
\]

\[
\text{CREATE OR REPLACE EDITIONABLE NONEDITIONABLE PACKAGE \text{plsql\_package\_source}} 
\]

\[
\text{(plsql\_package\_source: See Oracle Database PL/SQL Language Reference.)} 
\]

Semantics

**OR REPLACE**

Specify `OR REPLACE` to re-create the package specification if it already exists. Use this clause to change the specification of an existing package without dropping, re-
creating, and regranting object privileges previously granted on the package. If you change a package specification, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined package can still access the package without being regranted the privileges.

If any function-based indexes depend on the package, then the database marks the indexes **DISABLED**.

### See Also:

**ALTER PACKAGE** for information on recompiling package specifications

### [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the package is an editioned or noneditioned object if editioning is enabled for the schema object type `PACKAGE` in `schema`. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

`pksql_package_source`

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `pksql_package_source`, including examples.

# CREATE PACKAGE BODY

### Purpose

Package bodies are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE PACKAGE BODY` statement to create the body of a stored `package`, which is an encapsulated collection of related procedures, stored functions, and other program objects stored together in the database. The `package body` defines these objects. The `package specification`, defined in an earlier `CREATE PACKAGE` statement, declares these objects.

Packages are an alternative to creating procedures and functions as standalone schema objects.
Prerequisites

To create or replace a package in your own schema, you must have the CREATE PROCEDURE system privilege. To create or replace a package in another user's schema, you must have the CREATE ANY PROCEDURE system privilege. In both cases, the package body must be created in the same schema as the package.

To embed a CREATE PACKAGE BODY statement inside an Oracle Database precompiler program, you must terminate the statement with the keyword END-EXEC followed by the embedded SQL statement terminator for the specific language.

See Also:

Oracle Database PL/SQL Language Reference

Syntax

Package bodies are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

```
create_package_body ::= CREATE OR REPLACE EDITIONABLE NONEDITIONABLE PACKAGE BODY plsql_package_body_source
```

(plsql_package_body_source: See Oracle Database PL/SQL Language Reference.)

Semantics

OR REPLACE

Specify OR REPLACE to re-create the package body if it already exists. Use this clause to change the body of an existing package without dropping, re-creating, and regranting object privileges previously granted on it. If you change a package body, then Oracle Database recompiles it.
Users who had previously been granted privileges on a redefined package can still access the package without being regranted the privileges.

See Also:

ALTER PACKAGE for information on recompiling package bodies

[ EDITIONABLE | NONEDITIONABLE ]

If you do not specify this clause, then the package body inherits EDITIONABLE or NONEDITIONABLE from the package specification. If you do specify this clause, then it must match that of the package specification.

plsql_package_body_source

See Oracle Database PL/SQL Language Reference for the syntax and semantics of the plsql_package_body_source.

CREATE PFILE

Purpose

Use the CREATE PFILE statement to export either a binary server parameter file or the current In-Memory parameter settings into a text initialization parameter file. Creating a text parameter file is a convenient way to get a listing of the current parameter settings being used by the database, and it lets you edit the file easily in a text editor and then convert it back into a server parameter file using the CREATE SPFILE statement.

Upon successful execution of this statement, Oracle Database creates a text parameter file on the server. In an Oracle Real Application Clusters environment, it will contain all parameter settings of all instances. It will also contain any comments that appeared on the same line with a parameter setting in the server parameter file.

Note on Creating Text Parameter Files in a CDB

When you create a text parameter file in a multitenant container database (CDB), the current container can be the root or a PDB.

- If the current container is the root, then the database creates a text file that contains the parameter settings for the root.
- If the current container is a PDB, then the database creates a text file that contains the parameter settings for the PDB. In this case you must specify a pfile_name.
Prerequisites

You must have one of the following system privileges to execute this statement:

- SYSDBA
- SYSDG
- SYSOPER
- SYSSBACKUP
- SYSASM
- SYSRAC

You can execute this statement either before or after instance startup.

Restrictions

You cannot overwrite OS files as a SYSDG, SYSOPER, or SYSRAC user.

Syntax

create_pfile::=

Semantics

pfile_name

Specify the name of the text parameter file you want to create. If you do not specify pfile_name, then Oracle Database uses the platform-specific default initialization parameter file name. pfile_name can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.

spfile_name

Specify the name of the binary server parameter from which you want to create a text file.
If you specify `spfile_name`, then the file must exist on the server. If the file does not reside in the default directory for server parameter files on your operating system, then you must specify the full path.

If you do not specify `spfile_name`, then the database uses the spfile that is currently associated with the instance, usually the one that was used a startup. If no spfile is associated with the instance, then the database looks for the platform-specific default server parameter file name. If that file does not exist, then the database returns an error.

**See Also:**
the appropriate operating-system-specific documentation for default parameter file names

### MEMORY
Specify `MEMORY` to create a pfile using the current system-wide parameter settings. In an Oracle RAC environment, the created file will contain the parameter settings from each instance.

**Examples**

#### Creating a Parameter File: Example

The following example creates a text parameter file `my_init.ora` from a binary server parameter file `s_params.ora`:

```sql
CREATE PFILE = 'my_init.ora' FROM SPFILE = 's_params.ora';
```

**Note:**

Typically you will need to specify the full path and filename for parameter files on your operating system. Refer to your Oracle operating system documentation for path information.

### CREATE PLUGGABLE DATABASE

**Purpose**

Use the `CREATE PLUGGABLE DATABASE` statement to create a pluggable database (PDB).

This statement enables you to perform the following tasks:

- Create a PDB by using the seed as a template
  
  Use the `create_pdb_from_seed` clause to create a PDB by using the seed in the multitenant container database (CDB) as a template. The files associated with the seed are copied to a new location and the copied files are then associated with the new PDB.

- Create a PDB by cloning an existing PDB or non-CDB
Use the `create_pdb_clone` clause to create a PDB by copying an existing PDB or non-CDB and then plugging the copy into the CDB. The files associated with the existing PDB or non-CDB are copied to a new location and the copied files are associated with the new PDB.

- Create a PDB by plugging an unplugged PDB or a non-CDB into a CDB
  Use the `create_pdb_from_xml` clause to plug an unplugged PDB or a non-CDB into a CDB, using an XML metadata file.

- Create a proxy PDB by referencing another PDB. A proxy PDB provides fully functional access to the referenced PDB.
  Use the `create_pdb_clone` clause and specify `AS PROXY FROM` to create a proxy PDB.

- Create an application container, application seed, or application PDB
  Use the `create_pdb_from_seed`, `create_pdb_clone`, or `create_pdb_from_xml` clause. To create an application container, you must specify the `AS APPLICATION CONTAINER` clause. To create an application seed, you must specify the `AS SEED` clause.

**Note:**

When a new PDB is established in a CDB, it is possible that the name of a service offered by the new PDB will collide with an existing service name. The namespace in which a collision can occur is that of the listener that gives access to the CDB. Within that namespace, collisions are possible among the names of non-CDB's default services, CDB's default services, PDB's default services, and user-defined services. For example, if two or more CDBs on the same computer system use the same listener, and the newly established PDB has the same service name as another PDB in these CDBs, then a collision occurs.

When you create a PDB, you can specify new names for any potential colliding service names. See the clause `service_name_convert`. If you discover a service name collision after a PDB is created, you must not attempt to operate the PDB that causes a collision with an existing service name. If the colliding name is that of the PDB's default service, then you must rename the PDB. If the colliding name is that of a user-created service within the PDB, then you must drop that service and create one in its place, with a non-colliding name, that has the same purpose and properties.

**See Also:**

- *Oracle Multitenant Administrator’s Guide* for more information on multi-tenant architecture and concepts.
- *ALTER PLUGGABLE DATABASE* and *DROP PLUGGABLE DATABASE* for information on modifying and dropping PDBs
Prerequisites

You must be connected to a CDB. The CDB must be open and in `READ WRITE` mode.

To create a PDB or an application container, the current container must be the root and you must have the `CREATE PLUGGABLE DATABASE` system privilege, granted commonly.

To create an application seed or an application PDB, the current container must be an application root, the application container must be open and in `READ WRITE` mode, and you must have the `CREATE PLUGGABLE DATABASE` system privilege, either granted commonly or granted locally in that application container.

To specify the `create_pdb_clone` clause:

- If `src_pdb_name` refers to a PDB in the same CDB, then you must have the `CREATE PLUGGABLE DATABASE` system privilege in the root of the CDB in which the new PDB will be created and in the PDB being cloned.
- If `src_pdb_name` refers to a PDB in a remote database or a non-CDB, then you must have the `CREATE PLUGGABLE DATABASE` system privilege in the root of the CDB in which the new PDB will be created and the remote user must have the `CREATE PLUGGABLE DATABASE` system privilege in the PDB or non-CDB to which `src_pdb_name` refers.

See *Oracle Multitenant Administrator's Guide* for more information on the prerequisites to PDB creation.

Chapter 14
CREATE PLUGGABLE DATABASE
Semantics

 pdb_name

Specify the name of the PDB to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ". The first character of a PDB name must be an alphabet character. The remaining characters can be alphanumeric or the underscore character (_).

The PDB name must be unique in the CDB, and it must be unique within the scope of all the CDBs whose instances are reached through a specific listener.

AS APPLICATION CONTAINER

Specify this clause to create an application container.

See Also:
Oracle Database Administrator's Guide for the complete steps for creating an application container

using_snapshot_clause

Specify this clause to create a PDB from an existing PDB snapshot that can be identified by its name, SCN, or timestamp.

If you additionally specify SNAPSHOT COPY, then the new PDB will depend on the existence of the specified PDB snapshot. This will affect your ability to drop or purge the new PDB.

AS SEED

Specify this clause to create an application seed. The database assigns the seed a name of the form application_container_name$SEED.

An application container can have at most one application seed. The application seed is optional, but, if it exists, you can use it to create application PDBs quickly that match the requirements of the application container. An application seed enables instant provisioning of application PDBs that are created from it.

See Also:
Oracle Database Administrator's Guide for the complete steps for creating an application seed

create_pdb_from_seed

This clause enables you to create a PDB by using the seed in the CDB as a template.
ADMIN USER

Use this clause to create an administrative user who can be granted the privileges required to perform administrative tasks on the PDB. For admin_user_name, specify name of the user to be created. Use the IDENTIFIED BY clause to specify the password for admin_user_name. Oracle Database creates a local user in the PDB and grants the PDB_DBA local role to that user.

pdb_dba_roles

This clause lets you grant one or more roles to the PDB_DBA role. Use this clause to grant roles that have the privileges required by the administrative user of the PDB. For role, specify a predefined role. For a list of predefined roles, refer to Oracle Database Security Guide.

You can also use the GRANT statement to grant roles to the PDB_DBA role after the PDB has been created. Until you have granted the appropriate privileges to the PDB_DBA role, the SYS and SYSTEM users can perform administrative tasks on a PDB.

parallel_pdb_creation_clause

This clause instructs the CDB to use parallel execution servers to copy the new PDB’s data files to a new location. This may result in faster creation of the PDB.

PARALLEL

If you specify PARALLEL, then the CDB automatically chooses the number of parallel execution servers to use. This is the default if the COMPATIBLE initialization parameter is set to 12.2 or higher.

PARALLEL integer

Use integer to specify the number of parallel execution servers to use. The CDB can ignore this setting, depending on the current database load and the number of available parallel execution servers. If you specify a value of 0 or 1, then the CDB does not parallelize the creation of the PDB. This can result in a longer PDB creation time.

default_tablespace

If you specify this clause, then Oracle Database creates a smallfile tablespace and sets it as the default permanent tablespace for the PDB. Oracle Database will assign the default tablespace to any non-SYSTEM user for whom a different permanent tablespace is not specified. The default_tablespace clause has the same semantics that it has for the CREATE DATABASE statement. For full information, refer to default_tablespace in the documentation on CREATE DATABASE.

pdb_storage_clause

Use this clause to specify storage limits for the PDB.
• Use MAXSIZE to limit the amount of storage that can be used by all tablespaces in the PDB to the value specified with size_clause. This limit includes the size of data files and temporary files for tablespaces belonging to the PDB. Specify MAXSIZE UNLIMITED to enforce no limit.

• Use MAX_AUDIT_SIZE to limit the amount of storage that can be used by unified audit OS spillover (.bin format) files in the PDB to the value specified with size_clause. Specify MAX_AUDIT_SIZE UNLIMITED to enforce no limit.

• Use MAX_DIAG_SIZE to limit the amount of storage for diagnostics (trace files and incident dumps) in the Automatic Diagnostic Repository (ADR) that can be used by the PDB to the value specified with size_clause. Specify MAX_DIAG_SIZE UNLIMITED to enforce no limit.

If you omit this clause, or specify STORAGE UNLIMITED, then there are no storage limits for the PDB. This is equivalent to specifying STORAGE (MAXSIZE UNLIMITED MAX_AUDIT_SIZE UNLIMITED MAX_DIAG_SIZE UNLIMITED).

file_name_convert

Use this clause to determine how the database generates the names of files (such as data files and wallet files) for the PDB.

• For filename_pattern, specify a string found in names of files associated with the seed (when creating a PDB by using the seed), associated with the source PDB (when cloning a PDB), or listed in the XML file (when plugging a PDB into a CDB).

• For replacement_filename_pattern, specify a replacement string.

Oracle Database will replace filename_pattern with replacement_filename_pattern when generating the names of files associated with the new PDB.

File name patterns cannot match files or directories managed by Oracle Managed Files.

You can specify FILE_NAME_CONVERT = NONE, which is the same as omitting this clause. If you omit this clause, then the database first attempts to use Oracle Managed Files to generate file names. If you are not using Oracle Managed Files, then the database uses the PDB_FILE_NAME_CONVERT initialization parameter to generate file names. If this parameter is not set, then an error occurs.

service_name_convert

Use this clause to rename the user-defined services of the new PDB based on the service names of the source PDB. When the service name of a new PDB conflicts with an existing service name in the CDB, plug-in violations can result. This clause enables you to avoid these violations.

• For service_name, specify the name of a service found in the PDB seed (when creating a PDB in an application container by using the application seed) or in the source PDB (when cloning a PDB or plugging a PDB into a CDB).

• For replacement_service_name, specify the replacement name for the service.

Oracle Database will use the replacement service name for the service in the PDB being created.

You can specify SERVICE_NAME_CONVERT = NONE, which is the same as omitting this clause.

Restrictions on service_name_convert
The service_name_convert clause is subject to the following restrictions:

- You cannot change the name of the default service for a PDB. The default service has the same name as the PDB.
- You cannot specify this clause when you use the create_pdb_from_seed clause to create a PDB from the CDB seed, because the CDB seed does not have user-defined services. You can, however, specify this clause when you use the create_pdb_from_seed clause to create an application PDB from the application seed.

**path_prefix_clause**

Use this clause to ensure that file paths for directory objects associated with the PDB are restricted to the specified directory or its subdirectories. This clause also ensures that the following files associated with the PDB are restricted to the specified directory: the Oracle XML repository for the PDB, files created with a CREATE PFILE statement, and the export directory for Oracle wallets. You cannot modify the setting of this clause after you create the PDB. This clause does not affect files created by Oracle Managed Files.

- For path_name, specify the absolute path name of an operating system directory. The single quotation marks are required, with the result that the path name is case sensitive. Oracle Database uses path_name as a prefix for all file paths associated with the PDB.

  Be sure to specify path_name so that the resulting path name will be properly formed when relative paths are appended to it. For example, on UNIX systems, be sure to end path_name with a forward slash (/), such as:

  ```
  PATH_PREFIX = '/disk1/oracle/dba/salespdb/
  ```

- For directory_object_name, specify the name of a directory object that exists in the CDB root (CDB$ROOT). The directory object points to the absolute path to be used for PATH_PREFIX.

- If you specify PATH_PREFIX = NONE, then the relative paths for directory objects associated with the PDB are treated as absolute paths and are not restricted to a particular directory.

Omitting the path_prefix_clause is equivalent to specifying PATH_PREFIX = NONE.

After the path_prefix_clause is specified for a PDB, existing directory objects might not work as expected, since the PATH_PREFIX string is always added as a prefix to all local directory objects in the PDB. The path_prefix_clause only applies to user-created directory objects. It does not apply to Oracle-supplied directory objects.

**tempfile_reuse_clause**

When you create a PDB, Oracle Database associates temp files with the new PDB. Depending on how you create the PDB, the temp files may already exist and may have been previously used.

Specify TEMPFILE REUSE to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. If you specify this clause and a temp file does not exist, then the database creates the temp file.

If you do not specify TEMPFILE REUSE and a temp file to be associated with the new PDB already exists, then the database returns an error and does not create the PDB.
user_tablespaces_clause

This clause lets you specify the tablespaces to be made available in the new PDB. The **SYSTEM**, **SYSAUX**, and **TEMP** tablespaces are available in all PDBs and cannot be specified in this clause.

You can use this clause to separate the data for multiple schemas into different PDBs. For example, when you move a non-CDB to a PDB, and the non-CDB had a number of schemas that each supported a different application, you can use this clause to separate the data belonging to each schema into a separate PDB, assuming that each schema used a separate tablespace in the non-CDB.

- Specify `tablespace` to make the tablespace available in the new PDB. You can specify more than one tablespace in a comma-separated list.
- Specify `ALL` to make all tablespaces available in the new PDB. This is the default.
- Specify `ALL EXCEPT` to make all tablespaces available in the new PDB, except the specified tablespaces.
- Specify `NONE` to make only the **SYSTEM**, **SYSAUX**, and **TEMP** tablespaces available in the new PDB.

When the compatibility level of the CDB is **12.2** or higher, the tablespaces that are excluded by this clause are created offline in the new PDB, and they have no data files associated with them. When the compatibility level of the CDB is lower than **12.2**, the tablespaces that are excluded by this clause are offline in the new PDB, and all data files that belong to these tablespaces are unnamed and offline.

{ SNAPSHOT COPY | NO DATA }

These clauses apply only when cloning a PDB with the `create_pdb_clone` clause. They do not apply when cloning a non-CDB. By default, the database creates each tablespace to be made available in the new PDB according to the settings specified for cloning the PDB. These clauses allow you to override those settings as follows:

- **SNAPSHOT COPY** - Clone the tablespace using storage snapshots.
- **NO DATA** - Clone the data model definition of the tablespace, but not the tablespace's data.

{ COPY | MOVE | NOCOPY }

These clauses apply when you plug in a PDB with the `create_pdb_from_xml` clause. By default, the database creates each tablespace to be made available in the new PDB according to the settings specified for plugging in the PDB. These clauses allow you to override those settings as follows:

- **COPY** - Copy the tablespace files to the new location.
- **MOVE** - Move the tablespace files to the new location.
- **NOCOPY** - Do not copy or move the tablespace files to the new location.

standbys_clause

Use this clause to specify whether the new PDB is included in one or more standby CDBs. If you include a PDB in a standby CDB, then during standby recovery the standby CDB will search for the data files for the PDB. If the data files are not found,
then standby recovery will stop and you must copy the data files to the correct location before you can restart recovery.

- Specify `cdb_name` to include the new PDB in the specified standby CDB. You can specify more than one standby CDB name in a comma-separated list.
- Specify `ALL` to include the new PDB in all standby CDBs. This is the default.
- Specify `ALL EXCEPT` to include the new PDB in all standby CDBs, except the specified standby CDBs.
- Specify `NONE` to exclude the new PDB from all standby CDBs. When a PDB is excluded from all standby CDBs, the PDB's data files are unnamed and marked offline on all of the standby CDBs. Standby recovery will not stop if the data files for the PDB are not found on the standby. If you instantiate a new standby CDB after the PDB is created, then you must explicitly disable the PDB for recovery on the new standby CDB.

You can enable a PDB on a standby CDB after it was excluded on that standby CDB by copying the data files to the correct location, bringing the PDB online, and marking it as enabled for recovery.

**logging_clause**

Use this clause to specify the default logging attribute for tablespaces created within the PDB. The logging attribute controls whether certain DML operations are logged in the redo log file (`LOGGING`) or not (`NOLOGGING`). The default is `LOGGING`.

When creating a tablespace, you can override the default logging attribute by specifying the `logging_clause` of the `CREATE TABLESPACE` statement.

Refer to `logging_clause` for a full description of this clause.

**create_file_dest_clause**

By default, a newly created PDB inherits its Oracle Managed Files settings from the root. If the root uses Oracle Managed Files, then the PDB also uses Oracle Managed Files. The PDB shares the same base file system directory for Oracle Managed Files with the root and has its own subdirectory named with the GUID of the PDB. If the root does not use Oracle Managed Files, then the PDB also does not use Oracle Managed Files.

This clause lets you override the default behavior. You can enable or disable Oracle Managed Files for the PDB and you specify a different base file system directory or Oracle ASM disk group for the PDB's files.

- Specify `NONE` to disable Oracle Managed Files for the PDB.
- Specify either `directory_path_name` or `diskgroup_name` to enable Oracle Managed Files for the PDB.

Specify `directory_path_name` to designate the base file system directory for the PDB's files. Specify the full path name of the operating system directory. The directory must exist and Oracle processes must have appropriate permissions on the directory. The single quotation marks are required, with the result that the path name is case sensitive.

Specify `diskgroup_name` to designate the default Oracle ASM disk group for the PDB's files.
If you specify a value other than NONE, then the database implicitly sets the `DB_CREATE_FILE_DEST` initialization parameter with `SCOPE=SPFILE` in the PDB.

**HOST and PORT**

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB.

When creating a referenced PDB:

- If the name of the listener is different from the host name of the PDB, then you must specify the `HOST` clause. For `hostname`, specify the fully qualified domain name of the listener. Enclose `hostname` in single quotation marks. For example: 'myhost.example.com'.

  In an Oracle Real Application Clusters (Oracle RAC) environment, you can specify for `hostname` any of the hosts for the PDB.

- If the port number of the listener is not 1521, then you must specify the `PORT` clause. For `number`, specify the port number for the listener.

A proxy PDB uses a database link to establish communication with its referenced PDB. After communication is established, the proxy PDB communicates directly with the referenced PDB without using a database link. The host name and port number of the listener for the referenced PDB must be correct for the proxy PDB to function properly.

**See Also:**

The clause `AS PROXY FROM` of `create_pdb_clone` for information on creating a proxy PDB

`create_pdb_clone`

This clause enables you to create a new PDB by cloning a source to a target PDB. The source can be a PDB in the local CDB, a PDB in a remote CDB, or a non-CDB. The target PDB is the clone of the source.

If the source is a PDB in the local CDB, then the source PDB can be plugged in or unplugged. If the source is a PDB in a remote CDB, then the source PDB must be plugged in.

If the source is a non-CDB or a PDB in a remote CDB, then the source and the CDB that contains the target PDB must meet the following requirements:

- They must have the same endian format.
- They must have compatible character sets and national character sets, which means:
  - Every character in the source character set is available in the local CDB character set.
  - Every character in the source character set has the same code point value in the local CDB character set.
- They must have the same set of database options installed.
Users in the PDB who used the default temporary tablespace of the source non-CDB or PDB use the default temporary tablespace of the new PDB. Users who used non-default temporary tablespaces in the non-CDB or PDB continue to use the same local temporary tablespaces in the new PDB.

You can clone a united PDB or an isolated PDB with the same command. The only difference is that the keystore password you must provide are for different keystores.

**Hot Clone a PDB: Example**

```
CREATE PLUGGABLE DATABASE CDB1_PDB2_CLONE FROM CDB1_PDB2
  KEYSTORE IDENTIFIED BY keystore_password
```

For a **united** PDB:

- `keystore_password` is the **ROOT** keystore password.
- The wallet must be open in **ROOT**.

For an **isolated** PDB:

- `keystore_password` is the **new** keystore password for the PDB CDB1_PDB2_CLONE.
- The wallet must be open in CDB1_PDB2_CLONE.

**Clone a PDB: Example**

**United PDB**

```
CREATE PLUGGABLE DATABASE CDB1_PDB1_C AS CLONE USING '/tmp/cdb1_pdb3.pdb'
  KEYSTORE IDENTIFIED BY keystore_password DECRYPT USING transport_secret
```

- The wallet must be open in **ROOT**, if TDE is in use.
- If there are TDE keys in the .pdb file, you must specify `KEYSTORE IDENTIFIED BY` and provide `transport_secret`.
- `keystore_password` is the **ROOT** keystore password.

**Isolated PDB**

```
CREATE PLUGGABLE DATABASE CDB1_PDB2_C AS CLONE USING '/tmp/cdb1_pdb2.pdb'
```

- You need not specify `KEYSTORE IDENTIFIED BY` or `transport_secret`. If specified, they are ignored.
- The wallet need **not** be open in **ROOT**.

**See Also:**

*Oracle Database Administrator’s Guide* for the complete steps for creating a PDB by cloning an existing PDB

**FROM**

Use this clause to specify the source PDB or non-CDB. The files associated with the source are copied to a new location and these copied files are then associated with the new PDB.

The source PDB or non-CDB cannot be closed. It can be open as follows:
• If the CDB that contains the source PDB (the source CDB) or the source non-CDB is in ARCHIVELOG mode and local undo mode, then the source PDB or the source non-CDB can be open in READ WRITE mode and fully functional during the cloning operation. This is called hot PDB cloning.

• If the source CDB or source non-CDB is not in ARCHIVELOG mode, then the source PDB or non-CDB must be open READ ONLY.

Specify the source PDB or non-CDB as follows:

• If the source is a PDB in the local CDB, then use src_pdb_name to specify the name of the source PDB. You cannot specify PDB$SEED for src_pdb_name. Instead, use the create_pdb_from_seed clause to create a PDB by using the seed as a template.

• If the source is a PDB in a remote CDB, then use src_pdb_name to specify the name of the source PDB and dblink to specify the name of the database link to use to connect to the remote CDB.

• If the source is a non-CDB, then specify NON$CDB@dblink, where dblink is the name of the database link to use to connect to the non-CDB.

AS PROXY FROM

Use this clause to create a proxy PDB by referencing a different PDB, which is referred to as the referenced PDB. The referenced PDB can be in the same CDB as the proxy PDB or in a different CDB. A local proxy PDB is in the same CDB as its referenced PDB, and a remote proxy PDB is in a different CDB than its referenced PDB.

For src_pdb_name@dblink, specify the referenced PDB.

See Also:

Oracle Database Administrator’s Guide for the complete steps for creating a proxy PDB

default_tablespace

Use this clause to specify a permanent default tablespace for the PDB. Oracle Database will assign the default tablespace to any non-SYSTEM user for whom a different permanent tablespace is not specified. The tablespace must already exist in the source PDB or non-CDB. Because the tablespace already exists, you cannot specify the DATAFILE clause or the extent_management_clause when creating a PDB with the create_pdb_clone clause.

pdb_storage_clause

Use this clause to specify storage limits for the new PDB. Refer to pdb_storage_clause for the full semantics of this clause.

file_name_convert

Use this clause to determine how the database generates the names of files for the new PDB. Refer to file_name_convert for the full semantics of this clause.
**service_name_convert**

Use this clause to determine how the database renames services for the new PDB. Refer to `service_name_convert::=` for the full semantics of this clause.

**path_prefix_clause**

Use this clause to ensure that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. Refer to `path_prefix_clause` for the full semantics of this clause.

**tempfile_reuse_clause**

Specify `TEMPFILE_REUSE` to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. Refer to `tempfile_reuse_clause` for the full semantics of this clause.

**SNAPSHOT COPY**

You can specify `SNAPSHOT COPY` only when cloning a PDB. This clause is not supported when cloning a non-CDB. The source PDB can be in the local CDB or a remote CDB. The `SNAPSHOT COPY` clause instructs the database to clone the source PDB using storage snapshots. This reduces the time required to create the clone because the database does not need to make a complete copy of the source data files.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB and the `CLONEDB` initialization parameter is set to `FALSE`, the underlying file system for the source PDB’s files must support storage snapshots. Such file systems include Oracle Automatic Storage Management Cluster File System (Oracle ACFS) and Direct NFS Client storage.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB and the `CLONEDB` initialization parameter is set to `TRUE`, the underlying file system for the source PDB’s files can be any local file system, network file system (NFS), or clustered file system that has Direct NFS enabled. However, the source PDB must remain in open read-only mode as long as any clones exist.

Direct NFS Client enables an Oracle database to access network attached storage (NAS) devices directly, rather than using the operating system kernel NFS client. If the PDB files are stored on Direct NFS Client storage, then the following additional requirements must be met:

- The source PDB files must be located on an NFS volume.
- Storage credentials must be stored in a Transparent Data Encryption keystore.
- The storage user must have the privileges required to create and destroy snapshots on the volume that hosts the source PDB files.
- Credentials must be stored in the keystore using an `ADMINISTER KEY MANAGEMENT ADD SECRET` SQL statement.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB, the following restrictions apply to the source PDB as long as any clones exist:

- It cannot be unplugged.
- It cannot be dropped.
PDB clones created using the \texttt{SNAPSHOT COPY} clause cannot be unplugged. They can only be dropped. Attempting to unplug a clone created using the \texttt{SNAPSHOT COPY} clause results in an error.

For a PDB created using the \texttt{SNAPSHOT COPY} clause in an Oracle Real Application Clusters (Oracle RAC) environment, each node that must access the PDB's files must be mounted. For Oracle RAC databases running on Linux or UNIX platforms, the underlying NFS volumes must be mounted. If the Oracle RAC database is running on a Windows platform and using Direct NFS for shared storage, then you must update the `oranfstab` file on all nodes with the created volume export and mount entries.

Storage clones are named and tagged using the new PDB GUID. You can query the `CLONETAG` column of `DBA_PDB_HISTORY` view to view clone tags for storage clones.

\textbf{keystore\_clause}

Specify this clause if the source database has encrypted data or a keystore set. For \texttt{keystore\_password}, specify the password for the keystore. You must provide this password even if the source database is using an auto-login software keystore. You can find if the source database has encrypted data by querying the `DBA_ENCRYPTED_COLUMNS` data dictionary view or the `V\_$ENCRYPTED_TABLESPACES` dynamic performance view.

\textbf{pdb\_refresh\_mode\_clause}

The \texttt{REFRESH MODE} clause applies only when cloning a PDB. The source PDB must be in a remote CDB, that is, you must specify the source PDB using the \texttt{FROM src\_pdb\_name@dblink} clause.

This clause lets you specify the refresh mode of the PDB. You can use this clause to create a \textbf{refreshable PDB}. Changes in the source PDB can be propagated to the refreshable PDB, either manually or automatically. This operation is called a refresh. You can specify the following refresh modes:

- **MANUAL** - This mode allows you to refresh the refreshable PDB manually at any time by issuing an \texttt{ALTER PLUGGABLE DATABASE REFRESH} statement.

- **EVERY \texttt{refresh\_interval} MINUTES or HOURS** – This mode instructs the database to refresh the refreshable PDB every \texttt{refresh\_interval} of selected time units, minutes or hours. If you select MINUTES, the \texttt{refresh\_interval} must be less than 3000. If you select HOURS, the \texttt{refresh\_interval} must be less than 2000. This mode also allows you to refresh the PDB manually at any time by issuing an \texttt{ALTER PLUGGABLE DATABASE REFRESH} statement.

- **NONE** - If you specify this mode, then the clone PDB is not a refreshable PDB. The database cannot refresh the PDB automatically and you cannot refresh the PDB manually. If you specify this mode, then you cannot later change the PDB into a refreshable PDB. This is the default.

A refreshable PDB can be opened only in \texttt{READ ONLY} mode. A refreshable PDB must be closed in order for a refresh to occur. If it is not closed when you attempt to perform a manual refresh, then an error will occur. If it is not closed when the database attempts an automatic refresh, then the refresh will be deferred until the next scheduled refresh.
RELOCATE

Use this clause to relocate a PDB from one CDB to another. The database first clones the source PDB to the target PDB, and then removes the source PDB. The database also moves the files associated with the PDB to a new location. This operation is the fastest way to relocate a PDB with minimal down time. The down time for the PDB is approximately the time required to copy the PDB's files from their old location to their new location. The source PDB can be open in READ WRITE mode and fully functional during the relocation operation.

You can specify the availability level with the AVAILABILITY keyword. The default availability is NORMAL. If you specify AVAILABILITY MAX, then additional operations are performed to ensure a smooth migration of the workload in a persistent connection between source and target.

In the create_pdb_clone clause, you must use the FROM src_pdb_name@dblink syntax to identify the location of the source PDB. For src_pdb_name, specify the name of the source PDB. For dblink, specify a database link that indicates the location of the source PDB. The database link must have been created in the CDB to which the PDB will be relocated. It can connect either to the root of the remote CDB or to the remote PDB.

See Also:

Oracle Database Administrator’s Guide for the complete steps for relocating a PDB

NO DATA

The NO DATA clause applies only when cloning a PDB. This clause specifies that the source PDB’s data model definition is cloned, but not the PDB’s data. The dictionary data in the source PDB is cloned, but all user-created table and index data from the source PDB is discarded.

Restrictions on the NO DATA Clause

The following restrictions apply to the NO DATA clause:

• The source PDB should be open in read only mode when you use the NO DATA clause to clone a PDB.
• You cannot specify NO DATA when cloning a non-CDB.

See Also:

• ALTER PLUGGABLE DATABASE REFRESH for information on refreshing a PDB manually
• ALTER PLUGGABLE DATABASE pdb_refresh_mode_clause for information on changing the refresh mode of a PDB
• Oracle Database Administrator’s Guide for more information on refreshable PDBs
• You cannot specify NO DATA if the source PDB contains clustered tables, Advanced Queuing (AQ) tables, index-organized tables, or tables that contain abstract data type columns.

HOST and PORT

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB. Refer to HOST and PORT for the full semantics of these clauses.

create_pdb_from_xml

This clause enables you to create a PDB by plugging an unplugged PDB or a non-CDB (the source database) into a CDB (the target CDB). If the source database is an unplugged PDB, then it may have been unplugged from the target CDB or a different CDB.

The source database and the target CDB must meet the following requirements:

• They must have the same endian format.
• They must have compatible character sets and national character sets, which means:
  – Every character in the source database character set is available in the target CDB character set.
  – Every character in the source database character set has the same code point value in the target CDB character set.
• They must have the same set of database options installed.

See Also:

• Oracle Database Administrator's Guide for the complete steps for creating a PDB by plugging an unplugged PDB into a CDB and creating a PDB using a non-CDB
• Oracle Database PL/SQL Packages and Types Reference for more information on the DBMS_PDB package

AS CLONE

Specify this clause only if the target CDB already contains a PDB that was created using the same set of data files. The source files remain as an unplugged PDB and can be used again. Specifying AS CLONE also ensures that Oracle Database generates new identifiers, such as DBID and GUID, for the new PDB.

USING

This clause lets you specify a file that contains information about the source database that you are plugging in. For filename, specify the full path name of the file. You can obtain this file in one of the following ways:

• If the source database is an unplugged PDB, then the file was created by the pdb_unplug_clause of ALTER PLUGGABLE DATABASE as follows:
If the filename ends with the extension .xml, then it is an XML file containing metadata about the PDB. In this case, you must ensure that the XML metadata file, as well as the PDB's data files, are in a location that is accessible to the CDB.

If the filename ends with the extension .pdb, then it is a PDB archive file. This is a compressed file that includes an XML file containing metadata about the PDB, as well as the PDB's data files. The PDB archive file must exist in a location that is accessible to the CDB. When you use a .pdb archive file, this file is extracted when you plug in the PDB, and the PDB's files are placed in the same directory as the .pdb archive file. Therefore, the source_file_directory clause is not required.

If the source database is a non-CDB, then you must create the XML metadata file using the DBMS_PDB package, and ensure that the XML metadata file, as well as the source non-CDB's data files, are in a location that is accessible to the CDB.

See Also:
- pdb_unplug_clause of ALTER PLUGGABLE DATABASE
- Oracle Database PL/SQL Packages and Types Reference for more information on the DBMS_PDB package

source_file_name_convert
Specify this clause only if the contents of the XML file do not accurately describe the locations of the source files. If the files that must be used to plug in the source database are no longer in the location specified in the XML file, then use this clause to map the specified file names to the actual file names.

- For filename_pattern, specify the string for the location of the files as specified in the XML file.
- For replacement_filename_pattern, specify the string for the actual location that contains the files that must be used to create the PDB.

Oracle Database will replace filename_pattern with replacement_filename_pattern when searching for the source database files.

File name patterns cannot match files or directories managed by Oracle Managed Files.

If the files that must be used to create the PDB exist in the location specified in the XML file, you can either omit this clause or specify SOURCE_FILE_NAME_CONVERT=NONE.

source_file_directory
Specify this clause only if the contents of the XML file do not accurately describe the locations of the source files and the source files are all present in a single directory. This clause is convenient when you have a large number of data files and specifying a replacement file name pattern for each file using the source_file_name_convert clause is not feasible.
For directory_path_name, specify the absolute path of the directory that contains the source files. The directory is scanned to find the appropriate files based on the unplugged PDB's XML file.

You can specify this clause for configurations that use Oracle Managed Files and for configurations that do not use Oracle Managed Files.

If the files that must be used to create the PDB exist in the location specified in the XML file, you can either omit this clause or specify SOURCE_FILE_DIRECTORY=NONE.

**COPY**

Specify COPY if you want the files listed in the XML file to be copied to the new location and used for the new PDB. This is the default. You can use the optional file_name_convert clause to use pattern replacement in the new file names. Refer to file_name_convert for the full semantics of this clause.

**MOVE**

Specify MOVE if you want the files listed in the XML file to be moved, rather than copied, to the new location and used for the new PDB. You can use the optional file_name_convert clause to use pattern replacement in the new file names. Refer to file_name_convert for the full semantics of this clause.

**NOCOPY**

Specify NOCOPY if you want the files for the PDB to remain in their current locations. Use this clause if there is no need to copy or move the files required to plug in the PDB.

**service_name_convert**

Use this clause to determine how the database renames services for the new PDB. Refer to service_name_convert for the full semantics of this clause.

**default_tablespace**

Use this clause to specify a permanent default tablespace for the PDB. Oracle Database will assign the default tablespace to any non-SYSTEM user for whom a different permanent tablespace is not specified. The tablespace must already exist in the source database. Because the tablespace already exists, you cannot specify the DATAFILE clause or the extent_management_clause when creating a PDB with the create_pdb_from_xml clause.

**pdb_storage_clause**

Use this clause to specify storage limits for the new PDB. Refer to pdb_storage_clause for the full semantics of this clause.

**path_prefix_clause**

Use this clause to ensure that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. Refer to path_prefix_clause for the full semantics of this clause.
**tempfile_reuse_clause**

Specify **TEMPFILE REUSE** to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. Refer to **tempfile_reuse_clause** for the full semantics of this clause.

**HOST and PORT**

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB. Refer to **HOST and PORT** for the full semantics of these clauses.

**create_pdb_from_mirror_copy**

Specify this clause to create a pluggable database **new_pdb_name** using the prepared files of the mirror copy **mirror_name**. The new PDB will be split from the source database using the prepared files created by the **prepare_clause**.

- You must execute this clause from the root container.
- The meaning of the other optional parameters remains unchanged by this clause.
- You can only split one database from a prepared mirror copy. If you want to create additional splits, you must prepare a new mirror copy.

**using_snapshot_clause**

Specify this clause to create a PDB using an existing PDB snapshot that can be identified by its name, SCN, or timestamp.

If you create a PDB specifying **SNAPSHOT COPY**, then the new PDB will depend on the existence of the PDB snapshot. This will affect your ability to drop or purge the PDB.

**container_map_clause**

Specify this clause in CDB Root, Application Root or both to dynamically update changes as they happen to the new PDB.

You must note the following points with container maps:

- The **container_map_clause** is **optional**.
- The **add_partition_clause** will add a new partition to the container map defined in the Root (CDB Root and/or Application Root) of the new PDB.
- The **split_partition_clause** will split an existing partition of the container map defined in the Root (CDB Root and/or Application Root) of the new PDB.
- In the absence of **add_partition_clause** and **split_partition_clause**, container map defined in the Root of the new PDB is not updated.
- For PDB relocate, container map defined in the Root (CDB Root and/or Application Root) of the source PDB are automatically updated to reflect the "drop" of the source PDB.
- Dynamic maintenance of container map defined using hash partitioning is not supported

**Add a New Partition to a Range-Partitioned Container Map: Example**
CREATE PLUGGABLE DATABASE cdb1_pdb3
  ADMIN USER IDENTIFIED BY manager
  FILE_NAME_CONVERT=('cdb1_pdb0, cdb1_pdb3')
  CONTAINER_MAP UPDATE (ADD PARTITION cdb1_pdb3 VALUES LESS THAN (100));
ALTER PLUGGABLE DATABASE cdb1_pdb3 OPEN

Split an Existing Partition of a Range-Partitioned Container Map to Create a New
Partition: Example

CREATE PLUGGABLE DATABASE cdb1_pdb4
  ADMIN USER IDENTIFIED BY manager
  FILE_NAME_CONVERT=('cdb1_pdb0, cdb1_pdb4')
  CONTAINER_MAP UPDATE (SPLIT PARTITION cdb1_pdb3
                      AT (50)
                      INTO
                      (PARTITION cdb1_pdb3, PARTITION cdb1_pdb3))
ALTER PLUGGABLE DATABASE cdb1_pdb4 OPEN

Verify Updated in Range-Partitioned Container Map: Example

SELECT partition_name, high_value
FROM dba_tab_partitions
WHERE table_name='MAP' AND table_owner='SYS'

pdb_snapshot_clause

Specify this clause if you want to be able to create PDB snapshots.

• NONE is the default. It means that no snapshots of the PDB can be created.
• MANUAL means that the PDB snapshot can only be created manually.
• If snapshot interval is specified, PDB snapshots will be created automatically at
  specified interval. In addition, a user will also be able to create PDB snapshots
  manually
  • If expressed in minutes, snapshot_interval must be less than 3000.
  • If expressed in hours, snapshot_interval must be less than 2000.

create_pdb_decrypt_from_xml

You must have the SYSKM privilege to execute this command.

For PDBs in united mode, the following restrictions apply:

• You must specify the clause if you are using a TDE protected database. Otherwise
  it is optional.
• You need not specify the clause for an isolated PDB.
• The wallet must be open in ROOT.
• The wallet file is copied in all cases: NOCOPY, COPY, and MOVE.

Plugging a PDB from an XML Metadata File: Example

CREATE PLUGGABLE DATABASE CDB1_PDB2 USING '/tmp/cdb1_pdb2.xml' NOCOPY
  KEYSTORE IDENTIFIED BY keystore_password DECRYPT USING transport_secret

Plugging a PDB from an Archive File: Example

CREATE PLUGGABLE DATABASE CDB1_PDB1_1_C USING '/tmp/cdb1_pdb3.pdb' DECRYPT USING
  transport_secret
For PDBs in **isolated** mode, you need not specify `DECRYPT USING transport_secret`. This is not required because the wallet file is copied during the creation of an unplugged PDB from an XML file. If you are creating a PDB from an archive file with the `.pdb` extension, the wallet file of the PDB is available in the zipped archive.

If the `ewallet.p12` file already exists at the destination, a backup is automatically initiated. The backup file has the following format: `ewallet_PLGDB_2017090517455564.p12`.

**Examples**

**Creating a PDB by Using the Seed: Example**

The following statement creates a PDB `salespdb` by using the seed in the CDB as a template. The administrative user `salesadm` is created and granted the `dba` role. The default tablespace assigned to any non-SYSTEM users for whom no permanent tablespace is assigned is `sales`. File names for the new PDB will be constructed by replacing `/disk1/oracle/dbs/pdbseed/` in the file names in the seed with `/disk1/oracle/dbs/salespdb/`. All tablespaces that belong to `sales` must not exceed 2G. The location of all directory object paths associated with `salespdb` are restricted to the directory `/disk1/oracle/dbs/salespdb/`.

```sql
CREATE PLUGGABLE DATABASE salespdb
  ADMIN USER salesadm IDENTIFIED BY password
  ROLES = (dba)
  DEFAULT TABLESPACE sales
    DATAFILE '/disk1/oracle/dbs/salespdb/sales01.dbf' SIZE 250M AUTOEXTEND ON
    FILE_NAME_CONVERT = ('/disk1/oracle/dbs/pdbseed/', '/disk1/oracle/dbs/salespdb/')
    STORAGE (MAXSIZE 2G)
    PATH_PREFIX = '/disk1/oracle/dbs/salespdb/';
```

**Cloning a PDB From an Existing PDB: Example**

The following statement creates a PDB `newpdb` by cloning PDB `salespdb`. PDBs `newpdb` and `salespdb` are in the same CDB. Because no storage limits are explicitly specified, there is no limit on the amount of storage for `newpdb`. The files are copied from `/disk1/oracle/dbs/salespdb/` to `/disk1/oracle/dbs/newpdb/`. The location of all directory object paths associated with `newpdb` are restricted to the directory `/disk1/oracle/dbs/newpdb/`.

```sql
CREATE PLUGGABLE DATABASE newpdb FROM salespdb
  FILE_NAME_CONVERT = ('/disk1/oracle/dbs/salespdb/', '/disk1/oracle/dbs/newpdb/')
  PATH_PREFIX = '/disk1/oracle/dbs/newpdb/';
```

**Plugging a PDB into a CDB: Example**

The following statement plugs the PDB `salespdb`, which was previously unplugged, into the CDB. The details about the metadata describing `salespdb` are stored in the XML file `/disk1/usr/salespdb.xml`. The XML file does not accurately describe the current locations of the files. Therefore, the `SOURCE_FILE_NAME_CONVERT` clause is used to indicate that the files are in `/disk2/oracle/dbs/salespdb/`, not `/disk1/oracle/dbs/salespdb/`. The `NOCOPY` clause indicates that the files are already in the correct location. All tablespaces that belong to `sales` must not exceed 2G. A file with the same name as the temp file specified in the XML file exists in the target location. Therefore, the `TEMPFILE REUSE` clause is required.

```sql
CREATE PLUGGABLE DATABASE salespdb
  SOURCE_FILE_NAME_CONVERT = ('/disk1/oracle/dbs/salespdb/', '/disk2/oracle/dbs/salespdb/')
  NOCOPY
  TEMPFILE REUSE
```

**Chapter 14**

**CREATE PLUGGABLE DATABASE**

14-97
CREATE PLUGGABLE DATABASE salespdb
  USING '/disk1/usr/salespdb.xml'
  SOURCE_FILE_NAME_CONVERT =
    ('/disk1/oracle/dbs/salespdb/', '/disk2/oracle/dbs/salespdb/')
  NOCOPY
  STORAGE (MAXSIZE 2G)
  TEMPFILE REUSE;

CREATE PROCEDURE

Purpose

Procedures are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE PROCEDURE statement to create a standalone stored procedure or a call specification.

A procedure is a group of PL/SQL statements that you can call by name. A call specification (sometimes called call spec) declares a Java method or a third-generation language (3GL) routine so that it can be called from SQL and PL/SQL. The call spec tells Oracle Database which Java method to invoke when a call is made. It also tells the database what type conversions to make for the arguments and return value.

Stored procedures offer advantages in the areas of development, integrity, security, performance, and memory allocation.

See Also:

- Oracle Database Development Guide for more information on stored procedures, including how to call stored procedures and for information about registering external procedures.
- CREATE FUNCTION for information specific to functions, which are similar to procedures in many ways.
- CREATE PACKAGE for information on creating packages. The CREATE PROCEDURE statement creates a procedure as a standalone schema object. You can also create a procedure as part of a package.
- ALTER PROCEDURE and DROP PROCEDURE for information on modifying and dropping a standalone procedure.
- CREATE LIBRARY for more information about shared libraries.

Prerequisites

To create or replace a procedure in your own schema, you must have the CREATE PROCEDURE system privilege. To create or replace a procedure in another user's schema, you must have the CREATE ANY PROCEDURE system privilege.

To invoke a call spec, you may need additional privileges, for example, the EXECUTE object privilege on the C library for a C call spec.
To embed a `CREATE PROCEDURE` statement inside an Oracle precompiler program, you must terminate the statement with the keyword `END-EXEC` followed by the embedded SQL statement terminator for the specific language.

### See Also:

- *Oracle Database PL/SQL Language Reference* or *Oracle Database Java Developer's Guide* for more information

### Syntax

Procedures are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

```sql
create_procedure ::= CREATE
                   OR REPLACE
                   [ EDITIONABLE | NONEDITIONABLE ]
                   PROCEDURE
                   plsql_procedure_source
                   (plsql_procedure_source: See Oracle Database PL/SQL Language Reference.)
```

### Semantics

**OR REPLACE**

Specify `OR REPLACE` to re-create the procedure if it already exists. Use this clause to change the definition of an existing procedure without dropping, re-creating, and regranting object privileges previously granted on it. If you redefine a procedure, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined procedure can still access the procedure without being regranted the privileges.

If any function-based indexes depend on the procedure, then Oracle Database marks the indexes `DISABLED`.

### See Also:

- `ALTER PROCEDURE` for information on recompiling procedures

### [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the procedure is an editioned or noneditioned object if editioning is enabled for the schema object type `PROCEDURE` in `schema`. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*. 
CREATE PROFILE

Note:

Oracle recommends that you use the Database Resource Manager rather than this SQL statement to establish resource limits. The Database Resource Manager offers a more flexible means of managing and tracking resource use. For more information on the Database Resource Manager, refer to Oracle Database Administrator’s Guide.

Purpose

Use the CREATE PROFILE statement to create a profile, which is a set of limits on database resources. If you assign the profile to a user, then that user cannot exceed these limits.

To specify resource limits for a user, you must:

• Enable resource limits dynamically with the ALTER SYSTEM statement or with the initialization parameter RESOURCE_LIMIT. This parameter does not apply to password resources. Password resources are always enabled.
• Create a profile that defines the limits using the CREATE PROFILE statement
• Assign the profile to the user using the CREATE USER or ALTER USER statement

In a multitenant environment, different profiles can be assigned to a common user in the root and in a PDB. When the common user logs in to the PDB, a profile whose setting applies to the session depends on whether the settings are password-related or resource-related.

• Password-related profile settings are fetched from the profile that is assigned to the common user in the root. For example, suppose you assign a common profile c##prof (in which FAILED_LOGIN_ATTEMPTS is set to 1) to common user c##admin in the root. In a PDB that user is assigned a local profile local_prof (in which FAILED_LOGIN_ATTEMPTS is set to 6.) Common user c##admin is allowed only one failed login attempt when he or she tries to log in to the PDB where loc_prof is assigned to him.

• Resource-related profile settings specified in the profile assigned to a user in a PDB get used without consulting resource-related settings in a profile assigned to the common user in the root. For example, if the profile local_prof that is assigned to user c##admin in a PDB has SESSIONS_PER_USER set to 2, then c##admin is only allowed only 2 concurrent sessions when he or she logs in to the PDB loc_prof is assigned to him, regardless of value of this setting in a profile assigned to him in the root.

plsql_procedure_source

See Oracle Database PL/SQL Language Reference for the syntax and semantics of the plsql_procedure_source.
Prerequisites

To create a profile, you must have the `CREATE PROFILE` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

Syntax

```
create_profile ::= CREATE PROFILE profile LIMIT resource_parameters password_parameters CONTAINER = CURRENT ALL;
```

```
resource_parameters ::= ...
```

See Also:

- `ALTER SYSTEM` for information on enabling resource limits dynamically
- `Oracle Database Reference` for information on the `RESOURCE_LIMIT` parameter
- `CREATE USER` and `ALTER USER` for information on profiles
(size_clause::=)

password_parameters::=

Semantics

profile

Specify the name of the profile to be created. The name must satisfy the requirements listed in "Database Object Naming Rules". Use profiles to limit the database resources available to a user for a single call or a single session.

In a non-CDB, a profile name cannot begin with C## or c##.

In a CDB, the requirements for a profile name are as follows:
• The name of a **common profile** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is `C##`.

• The name of a **local profile** must not begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local profile can never begin with `C##` or `c##`.

**Note:**

If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local profile names with one exception: the name of a local profile can never begin with `C##` or `c##`. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common profiles when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

Oracle Database enforces resource limits in the following ways:

• If a user exceeds the `CONNECT_TIME` or `IDLE_TIME` session resource limit, then the database rolls back the current transaction and ends the session. When the user process next issues a call, the database returns an error.

• If a user attempts to perform an operation that exceeds the limit for other session resources, then the database aborts the operation, rolls back the current statement, and immediately returns an error. The user can then commit or roll back the current transaction, and must then end the session.

• If a user attempts to perform an operation that exceeds the limit for a single call, then the database aborts the operation, rolls back the current statement, and returns an error, leaving the current transaction intact.

**Note:**

• You can use fractions of days for all parameters that limit time, with days as units. For example, 1 hour is 1/24 and 1 minute is 1/1440.

• You can specify resource limits for users regardless of whether the resource limits are enabled. However, Oracle Database does not enforce the limits until you enable them.

**See Also:**

“Creating a Profile: Example”
UNLIMITED

When specified with a resource parameter, UNLIMITED indicates that a user assigned this profile can use an unlimited amount of this resource. When specified with a password parameter, UNLIMITED indicates that no limit has been set for the parameter.

DEFAULT

Specify DEFAULT if you want to omit a limit for this resource in this profile. A user assigned this profile is subject to the limit for this resource specified in the DEFAULT profile. The DEFAULT profile initially defines unlimited resources. You can change those limits with the ALTER PROFILE statement.

Any user who is not explicitly assigned a profile is subject to the limits defined in the DEFAULT profile. Also, if the profile that is explicitly assigned to a user omits limits for some resources or specifies DEFAULT for some limits, then the user is subject to the limits on those resources defined by the DEFAULT profile.

resource_parameters

SESSIONS_PER_USER

Specify the number of concurrent sessions to which you want to limit the user.

CPU_PER_SESSION

Specify the CPU time limit for a session, expressed in hundredth of seconds.

CPU_PER_CALL

Specify the CPU time limit for a call (a parse, execute, or fetch), expressed in hundredths of seconds.

CONNECT_TIME

Specify the total elapsed time limit for a session, expressed in minutes.

IDLE_TIME

Specify the permitted periods of continuous inactive time during a session, expressed in minutes. Long-running queries and other operations are not subject to this limit.

When you set an idle timeout of X minutes, note that the session will take a couple of additional minutes to be terminated.

On the client application side, the error message shows up only the next time, when the idle client attempts to issue a new command.

LOGICAL_READS_PER_SESSION

Specify the permitted number of data blocks read in a session, including blocks read from memory and disk.

LOGICAL_READS_PER_CALL

Specify the permitted number of data blocks read for a call to process a SQL statement (a parse, execute, or fetch).

PRIVATE_SGA
Specify the amount of private space a session can allocate in the shared pool of the system global area (SGA). Refer to `size_clause` for information on that clause.

**Note:**

This limit applies only if you are using shared server architecture. The private space for a session in the SGA includes private SQL and PL/SQL areas, but not shared SQL and PL/SQL areas.

**COMPOSITE_LIMIT**

Specify the total resource cost for a session, expressed in service units. Oracle Database calculates the total service units as a weighted sum of `CPU_PER_SESSION`, `CONNECT_TIME`, `LOGICAL_READS_PER_SESSION`, and `PRIVATE_SGA`.

**See Also:**

- `ALTER RESOURCE COST` for information on how to specify the weight for each session resource
- “Setting Profile Resource Limits: Example”

**password_parameters**

Use the following clauses to set password parameters. Parameters that set lengths of time—that is, all the password parameters except `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_REUSE_MAX`—are interpreted in number of days. For testing purposes you can specify minutes (\(n/1440\)) or even seconds (\(n/86400\)) for these parameters. You can also use a decimal value for this purpose (for example .0833 for approximately one hour). The minimum value is 1 second. The maximum value is 24855 days. For `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_REUSE_MAX`, you must specify an integer.

**FAILED_LOGIN_ATTEMPTS**

Specify the number of consecutive failed attempts to log in to the user account before the account is locked. If you omit this clause, then the default is 10 times.

**PASSWORD_LIFE_TIME**

Specify the number of days the same password can be used for authentication. If you also set a value for `PASSWORD_GRACE_TIME`, then the password expires if it is not changed within the grace period, and further connections are rejected. If you omit this clause, then the default is 180 days.

**See Also:**

`Oracle Database Security Guide` for information on setting `PASSWORD_LIFE_TIME` to a low value.
PASSWORD_REUSE_TIME and PASSWORD_REUSE_MAX

These two parameters must be set in conjunction with each other. PASSWORD_REUSE_TIME specifies the number of days before which a password cannot be reused. PASSWORD_REUSE_MAX specifies the number of password changes required before the current password can be reused. For these parameter to have any effect, you must specify a value for both of them.

- If you specify a value for both of these parameters, then the user cannot reuse a password until the password has been changed the number of times specified for PASSWORD_REUSE_MAX during the number of days specified for PASSWORD_REUSE_TIME.

  For example, if you specify PASSWORD_REUSE_TIME to 30 and PASSWORD_REUSE_MAX to 10, then the user can reuse the password after 30 days if the password has already been changed 10 times.

- If you specify a value for either of these parameters and specify UNLIMITED for the other, then the user can never reuse a password.

- If you specify DEFAULT for either parameter, then Oracle Database uses the value defined in the DEFAULT profile. By default, all parameters are set to UNLIMITED in the DEFAULT profile. If you have not changed the default setting of UNLIMITED in the DEFAULT profile, then the database treats the value for that parameter as UNLIMITED.

- If you set both of these parameters to UNLIMITED, then the database ignores both of them. This is the default if you omit both parameters.

PASSWORD_LOCK_TIME

Specify the number of days an account will be locked after the specified number of consecutive failed login attempts. If you omit this clause, then the default is 1 day.

PASSWORD_GRACE_TIME

Specify the number of days after the grace period begins during which a warning is issued and login is allowed. If you omit this clause, then the default is 7 days.

INACTIVE_ACCOUNT_TIME

Specify the permitted number of consecutive days of no logins to the user account, after which the account will be locked. The minimum value is 15 days. There is no maximum value. If you omit this clause, then the default is UNLIMITED.

PASSWORD_VERIFY_FUNCTION

The PASSWORD_VERIFY_FUNCTION clause lets a PL/SQL password complexity verification script be passed as an argument to the CREATE PROFILE statement. Oracle Database provides a default script, but you can create your own routine or use third-party software instead.

- For function, specify the name of the password complexity verification routine. The function must exist in the SYS schema and you must have EXECUTE privilege on the function.

- Specify NULL to indicate that no password verification is performed.

If you specify expr for any of the password parameters, then the expression can be of any form except scalar subquery expression.
When you assign a profile to an external user or a global user, the password parameters do not take effect for that user.

See Also:

"Setting Profile Password Limits: Example"

CONTAINER Clause

The CONTAINER clause applies when you are connected to a CDB. However, it is not necessary to specify the CONTAINER clause because its default values are the only allowed values.

- To create a common profile, you must be connected to the root. You can optionally specify CONTAINER = ALL, which is the default when you are connected to the root.
- To create a local profile, you must be connected to a PDB. You can optionally specify CONTAINER = CURRENT, which is the default when you are connected to a PDB.

Examples

Creating a Profile: Example

The following statement creates the profile new_profile:

```
CREATE PROFILE new_profile
  LIMIT PASSWORD_REUSE_MAX 10
  PASSWORD_REUSE_TIME 30;
```

Setting Profile Resource Limits: Example

The following statement creates the profile app_user:

```
CREATE PROFILE app_user
  LIMIT
    SESSIONS_PER_USER      UNLIMITED
    CPU_PER_SESSION        UNLIMITED
    CPU_PER_CALL           3000
    CONNECT_TIME           45
    LOGICAL_READS_PER_SESSION  DEFAULT
    LOGICAL_READS_PER_CALL  1000
    PRIVATE_SGA            15K
    COMPOSITE_LIMIT        5000000;
```

If you assign the app_user profile to a user, then the user is subject to the following limits in subsequent sessions:

- The user can have any number of concurrent sessions.
- In a single session, the user can consume an unlimited amount of CPU time.
- A single call made by the user cannot consume more than 30 seconds of CPU time.
- A single session cannot last for more than 45 minutes.
- In a single session, the number of data blocks read from memory and disk is subject to the limit specified in the DEFAULT profile.
• A single call made by the user cannot read more than 1000 data blocks from memory and disk.
• A single session cannot allocate more than 15 kilobytes of memory in the SGA.
• In a single session, the total resource cost cannot exceed 5 million service units. The formula for calculating the total resource cost is specified by the ALTER RESOURCE COST statement.
• Since the app_user profile omits a limit for IDLE_TIME and for password limits, the user is subject to the limits on these resources specified in the DEFAULT profile.

Setting Profile Password Limits: Example

The following statement creates the app_user2 profile with password limits values set:

```sql
CREATE PROFILE app_user2 LIMIT
   FAILED_LOGIN_ATTEMPTS 5
   PASSWORD_LIFE_TIME 60
   PASSWORD_REUSE_TIME 60
   PASSWORD_REUSE_MAX 5
   PASSWORD_VERIFY_FUNCTION ora12c_verify_function
   PASSWORD_LOCK_TIME 1/24
   PASSWORD_GRACE_TIME 10
   INACTIVE_ACCOUNT_TIME 30;
```

This example uses the default Oracle Database password verification function, ora12c_verify_function. Refer to Oracle Database Security Guide for information on using this verification function provided or designing your own verification function.

CREATE RESTORE POINT

Purpose

Use the CREATE RESTORE POINT statement to create a restore point, which is a name associated with a timestamp or an SCN of the database. A restore point can be used to flash back a table or the database to the time specified by the restore point without the need to determine the SCN or timestamp. Restore points are also useful in various RMAN operations, including backups and database duplication. You can use RMAN to create restore points in the process of implementing an archival backup.

See Also:

- Oracle Database Backup and Recovery User's Guide for more information on creating and using restore points and guaranteed restore points, for information on database duplication, and for information on archival backups
- FLASHBACK DATABASE, FLASHBACK TABLE, and DROP RESTORE POINT for information on using and dropping restore points

Prerequisites

To create a normal restore point, you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege.
To create a guaranteed restore point, you must fulfill one of the following conditions:

- You must connect as SYSDBA, or as SYSBACKUP, or as SYSDG.
- You must have been granted the SYSDBA privilege and be using a multitenant database.
- You must be running as user SYS, and be using a multitenant database.

To view or use a restore point, you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege or the SELECT_CATALOG_ROLE role.

You can create a restore point on a primary or standby database. The database can be open, or mounted but not open. If the database is mounted, then it must have been shut down consistently before being mounted unless it is a physical standby database.

You must have created a fast recovery area before creating a guaranteed restore point. You need not enable flashback database before you create the guaranteed restore point. The database must be in ARCHIVELOG mode if you are creating a guaranteed restore point.

You need not enable flashback database before you create a normal restore point, because normal restore points have other applications besides FLASHBACK DATABASE. However, you would need to have enabled flashback database before you create a normal restore point, if you intend to perform a FLASHBACK DATABASE to that normal restore point.

You can create, use, or view a restore point when connected to a multitenant container database (CDB) as follows:

- To create a normal CDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To create a guaranteed CDB restore point, the current container must be the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To view a CDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege or the SELECT_CATALOG_ROLE role, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly, or the current container must be a PDB and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.
- To use a CDB restore point, you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege or the SELECT_CATALOG_ROLE role, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To create a normal PDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly, or the current container must be the PDB for which you want to create the restore point and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.
• To create a guaranteed PDB restore point, the current container must be the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly, or the current container must be the PDB for which you want to create the restore point and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

• To view a PDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege or the SELECT_CATALOG_ROLE role, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly, or the current container must be the PDB for the restore point and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

• To use a PDB restore point, the current container must be the PDB for the restore point and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

Syntax

```
create_restore_point ::= CREATE CLEAN RESTORE POINT restore_point FOR PLUGGABLE DATABASE pdb_name AS OF TIMESTAMP SCN expr PRESERVE GUARANTEE FLASHBACK DATABASE ;
```

Semantics

**CLEAN**

You can specify CLEAN only when creating a PDB restore point. The PDB must use shared undo and must be closed with no outstanding transactions. Flashing back a PDB using shared undo to a clean PDB restore point does not require restoring backups or creating a clone instance. Therefore, it is faster than flashing back a PDB using shared undo to an SCN or other type of restore point.

**restore_point**

Specify the name of the restore point. The name must satisfy the requirements listed in "Database Object Naming Rules".

In a multitenant environment, the CDB and PDBs have their own namespaces for restore points. Therefore, the CDB and each PDB can have a restore point with the same name. When you specify a restore point name in a PDB or for a PDB operation, the name is first interpreted as a PDB restore point for the concerned PDB. If a PDB restore point with the specified name is not found, then it is interpreted as a CDB restore point.

The database can retain at least 2048 normal restore points. In a Multitenant environment, a CDB can retain at least 2048 normal restore points across the entire
CDB, including PDB restore points. Normal restore points are retained in the database for at least the number of days specified for the `CONTROL_FILE_RECORD_KEEP_TIME` initialization parameter. The default value of that parameter is 7 days. Guaranteed restore points are retained in the database until explicitly dropped by the user.

If you specify neither `PRESERVE` nor `GUARANTEE FLASHBACK DATABASE`, then the resulting restore point enables you to flash the database back to a restore point within the time period determined by the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter. The database automatically manages such restore points. When the maximum number of restore points is reached, according to the rules described in `restore_point` above, the database automatically drops the oldest restore point.

Under some circumstances the restore points will be retained in the RMAN recovery catalog for use in restoring long-term backups. You can explicitly drop a restore point using the `DROP RESTORE POINT` statement.

**FOR PLUGGABLE DATABASE**

This clause enables you to create a PDB restore point when you are connected to the root. For `pdb_name`, specify the name of the PDB.

If you are connected to the PDB for which you want to create the restore point, then it is not necessary to specify this clause. However, if you specify this clause, then you must specify the name of the PDB to which you are connected.

**AS OF Clause**

Use this clause to create a restore point at a specified datetime or SCN in the past. If you specify `TIMESTAMP`, then `expr` must be a valid datetime expression resolving to a time in the past. If you specify `SCN`, then `expr` must be a valid SCN in the database in the past. In either case, `expr` must refer to a datetime or SCN in the current incarnation of the database.

**PRESERVE**

Specify `PRESERVE` to indicate that the restore point must be explicitly deleted. Such restore points are useful for preserving a flashback database.

**GUARANTEE FLASHBACK DATABASE**

A guaranteed restore point enables you to flash the database back deterministically to the restore point regardless of the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter setting. The guaranteed ability to flash back depends on sufficient space being available in the fast recovery area.

Guaranteed restore points guarantee only that the database will maintain enough flashback logs to flashback the database to the guaranteed restore point. It does not guarantee that the database will have enough undo to flashback any table to the same restore point.

Guaranteed restore points are always preserved. They must be dropped explicitly by the user using the `DROP RESTORE POINT` statement. They do not age out. Guaranteed restore points can use considerable space in the fast recovery area. Therefore, Oracle recommends that you create guaranteed restore points only after careful consideration.

**Examples**

**Creating and Using a Restore Point: Example**
The following example creates a normal restore point, updates a table, and then flashes back the altered table to the restore point. The example assumes the user hr has the appropriate system privileges to use each of the statements.

```sql
CREATE RESTORE POINT good_data;
SELECT salary FROM employees WHERE employee_id = 108;

SALARY
--------
  12000

UPDATE employees SET salary = salary*10
WHERE employee_id = 108;

SELECT salary FROM employees
WHERE employee_id = 108;

SALARY
--------
  120000

COMMIT;

FLASHBACK TABLE employees TO RESTORE POINT good_data;

SELECT salary FROM employees
WHERE employee_id = 108;

SALARY
--------
  12000

CREATE ROLE
```

**Purpose**

Use the `CREATE ROLE` statement to create a role, which is a set of privileges that can be granted to users or to other roles. You can use roles to administer database privileges. You can add privileges to a role and then grant the role to a user. The user can then enable the role and exercise the privileges granted by the role.

A role contains all privileges granted to the role and all privileges of other roles granted to it. A new role is initially empty. You add privileges to a role with the `GRANT` statement.

If you create a role that is NOT IDENTIFIED or is IDENTIFIED EXTERNALLY or BY password, then Oracle Database grants you the role with ADMIN OPTION. However, if you create a role IDENTIFIED GLOBALLY, then the database does not grant you the role. A global role cannot be granted to a user or role directly. Global roles can be granted only through enterprise roles.
Prerequisites

You must have the `CREATE ROLE` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

Syntax

```
create_role::=  
```

Semantics

`role`

Specify the name of the role to be created. The name must satisfy the requirements listed in "Database Object Naming Rules". Oracle recommends that the role contain at least one single-byte character regardless of whether the database character set also contains multibyte characters. The maximum length of the role name is 30 bytes. The
The maximum number of user-defined roles that can be enabled for a single user at one time is 148.

In a non-CDB, a role name cannot begin with C## or c##.

In a CDB, the requirements for a role name are as follows:

- The name of a common role must begin with characters that are a case-insensitive match to the prefix specified by the COMMON_USER_PREFIX initialization parameter. By default, the prefix is C##.

- The name of a local role must not begin with characters that are a case-insensitive match to the prefix specified by the COMMON_USER_PREFIX initialization parameter. Regardless of the value of COMMON_USER_PREFIX, the name of a local role can never begin with C## or c##.

**Note:**

If the value of COMMON_USER_PREFIX is an empty string, then there are no requirements for common or local role names with one exception: the name of a local role can never begin with C## or c##. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common roles when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

Some roles are defined by SQL scripts provided on your distribution media.

**See Also:**

- GRANT for a list of these predefined roles and SET ROLE for information on enabling and disabling roles for a user

**NOT IDENTIFIED Clause**

Specify NOT IDENTIFIED to indicate that this role is authorized by the database and that no password is required to enable the role.

**IDENTIFIED Clause**

Use the IDENTIFIED clause to indicate that a user must be authorized by the specified method before the role is enabled with the SET ROLE statement.

**BY password**

You can create a local role with a password with the BY password clause. This means that you must specify the password to the database at the time you enable the role.

The password can contain any characters from the database character set except the NULL character (CHR(0)) and the double-quote. The password is syntactically an identifier, and may need to be enclosed in double-quotes as required by the "Database Object Naming Rules". You must ensure that your database, and the clients that
need to enable the role are configured to support all the characters comprising the password.

You can enable password-protected roles in a proxy session. Both secure application role and password-protected roles provide a secure method for enabling a role in a session. Oracle recommends using secure password roles instead of password protected roles in instances where the password has to be maintained and transmitted over insecure channels, or if more than one person needs to know the password. Password-protected roles in a proxy session are suitable for situations where automation is used to set the role.

**USING package**

The **USING package** clause lets you create a **secure application role**, which is a role that can be enabled only by applications using an authorized package. If you do not specify **schema**, then the database assumes the package is in your own schema.

**EXTERNALLY**

Specify **EXTERNALLY** to create an **external role**. An external user must be authorized by an external service, such as an operating system or third-party service, before enabling the role.

Depending on the operating system, the user may have to specify a password to the operating system before the role is enabled.

**GLOBALLY**

Specify **GLOBALLY** to create a **global role**. A global user must be authorized to use the role by the enterprise directory service before the role is enabled at login.

Specify **GLOBALLY** with **AS** to map a directory group to a global role when using centrally managed users. The directory group is identified by its domain name.

**Example: Map a Directory User to a Global User**

```sql
CREATE USER scott_global IDENTIFIED GLOBALLY AS 'cn=scott taylor,ou=sales,dc=abccorp,dc=com';
```

This effectively maps a directory user named ‘scott taylor’ in the ‘sales’ organization unit of the abccorp.com domain to a database global user ‘scott_global’.

**CONTAINER Clause**

The **CONTAINER** clause applies when you are connected to a CDB. However, it is not necessary to specify the **CONTAINER** clause because its default values are the only allowed values.

- To create a common role, you must be connected to the root. You can optionally specify **CONTAINER = ALL**, which is the default when you are connected to the root.
To create a local role, you must be connected to a PDB. You can optionally specify
CONTAINER = CURRENT, which is the default when you are connected to a PDB.

Examples

Creating a Role: Example

The following statement creates the role **dw_manager**:

```sql
CREATE ROLE dw_manager;
```

Users who are subsequently granted the **dw_manager** role will inherit all of the
privileges that have been granted to this role.

You can add a layer of security to roles by specifying a password, as in the following
example:

```sql
CREATE ROLE dw_manager
    IDENTIFIED BY warehouse;
```

Users who are subsequently granted the **dw_manager** role must specify the password
**warehouse** to enable the role with the SET ROLE statement.

The following statement creates global role **warehouse_user**:

```sql
CREATE ROLE warehouse_user IDENTIFIED GLOBALLY;
```

The following statement creates the same role as an external role:

```sql
CREATE ROLE warehouse_user IDENTIFIED EXTERNALLY;
```

The following statement creates local role **role1** in the current PDB. The current
container must be a PDB when you issue this statement:

```sql
CREATE ROLE role1 CONTAINER = CURRENT;
```

The following statement creates common role **c##role1**. The current container must
be the root when you issue this statement:

```sql
CREATE ROLE c##role1 CONTAINER = ALL;
```

---

**Note:**

Oracle strongly recommends that you run your database in automatic undo
management mode instead of using rollback segments. Do not use rollback
segments unless you must do so for compatibility with earlier versions
of Oracle Database. Refer to *Oracle Database Administrator’s Guide* for
information on automatic undo management.

**Purpose**

Use the `CREATE ROLLBACK SEGMENT` statement to create a **rollback segment**, which
is an object that Oracle Database uses to store data necessary to reverse, or undo,
changes made by transactions.
The information in this section assumes that your database is not running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `MANUAL` or not set at all). If your database is running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `AUTO`, which is the default), then rollback segments are not permitted. However, errors generated in rollback segment operations are suppressed.

Further, if your database has a locally managed `SYSTEM` tablespace, then you cannot create rollback segments in any dictionary-managed tablespace. Instead, you must either use the automatic undo management feature or create locally managed tablespaces to hold the rollback segments.

### Note:

A tablespace can have multiple rollback segments. Generally, multiple rollback segments improve performance.

- The tablespace must be online for you to add a rollback segment to it.
- When you create a rollback segment, it is initially offline. To make it available for transactions by your Oracle Database instance, bring it online using the `ALTER ROLLBACK SEGMENT` statement. To bring it online automatically whenever you start up the database, add the segment name to the value of the `ROLLBACK_SEGMENT` initialization parameter.

To use objects in a tablespace other than the `SYSTEM` tablespace:

- If you are using rollback segments for undo, then at least one rollback segment (other than the `SYSTEM` rollback segment) must be online.
- If you are running the database in automatic undo mode, then at least one `UNDO` tablespace must be online.

### See Also:

- `ALTER ROLLBACK SEGMENT` for information on altering a rollback segment
- `DROP ROLLBACK SEGMENT` for information on removing a rollback segment
- `Oracle Database Reference` for information on the `UNDO_MANAGEMENT` parameter
- `Oracle Database Administrator's Guide` for information on automatic undo mode

### Prerequisites

To create a rollback segment, you must have the `CREATE ROLLBACK SEGMENT` system privilege.
Syntax

\[
create\_rollback\_segment::= \\
\]

PUBLIC
ROLLBACK
SEGMENT
rollback_segment
TABLESPACE tablespace
storage_clause

(\textit{storage}\_\textit{clause} )

Semantics

PUBLIC

Specify PUBLIC to indicate that the rollback segment is public and is available to any instance. If you omit this clause, then the rollback segment is private and is available only to the instance naming it in its initialization parameter ROLLBACK\_SEGMENTS.

rollback_segment

Specify the name of the rollback segment to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

TABLESPACE

Use the TABLESPACE clause to identify the tablespace in which the rollback segment is created. If you omit this clause, then the database creates the rollback segment in the SYSTEM tablespace.

\section{Note:}

Oracle Database must access rollback segments frequently. Therefore, Oracle strongly recommends that you do not create rollback segments in the SYSTEM tablespace, either explicitly or implicitly by omitting this clause. In addition, to avoid high contention for the tablespace containing the rollback segment, it should not contain other objects such as tables and indexes, and it should require minimal extent allocation and deallocation.

To achieve these goals, create rollback segments in locally managed tablespaces with autoallocation disabled—in tablespaces created with the EXTENT MANAGEMENT LOCAL clause with the UNIFORM setting. The AUTOALLOCATE setting is not supported.

\section{See Also:}

CREATE TABLESPACE
**storage_clause**

The `storage_clause` lets you specify storage characteristics for the rollback segment.

- The `OPTIMAL` parameter of the `storage_clause` is of particular interest, because it applies only to rollback segments.
- You cannot specify the `PCTINCREASE` parameter of the `storage_clause` with `CREATE ROLLBACK SEGMENT`.

---

**Examples**

**Creating a Rollback Segment: Example**

The following statement creates a rollback segment with default storage values in an appropriately configured tablespace:

```sql
CREATE TABLESPACE rbs_ts
  DATAFILE 'rbs01.dbf' SIZE 10M
  EXTENT MANAGEMENT LOCAL UNIFORM SIZE 100K;
/* This example and the next will fail if your database is in automatic undo mode. */
CREATE ROLLBACK SEGMENT rbs_one
  TABLESPACE rbs_ts;
```

The preceding statement is equivalent to the following:

```sql
CREATE ROLLBACK SEGMENT rbs_one
  TABLESPACE rbs_ts
  STORAGE
  ( INITIAL 10K );
```

---

**CREATE SCHEMA**

**Purpose**

Use the `CREATE SCHEMA` statement to create multiple tables and views and perform multiple grants in your own schema in a single transaction.

To execute a `CREATE SCHEMA` statement, Oracle Database executes each included statement. If all statements execute successfully, then the database commits the transaction. If any statement results in an error, then the database rolls back all the statements.
Note:

This statement does not actually create a schema. Oracle Database automatically creates a schema when you create a user (see CREATE USER). This statement lets you populate your schema with tables and views and grant privileges on those objects without having to issue multiple SQL statements in multiple transactions.

Prerequisites

The CREATE SCHEMA statement can include CREATE TABLE, CREATE VIEW, and GRANT statements. To issue a CREATE SCHEMA statement, you must have the privileges necessary to issue the included statements.

Syntax

```
create_schema ::= CREATE SCHEMA AUTHORIZATION schema
create_table_statement
create_view_statement
grant_statement
;
```

Semantics

**schema**

Specify the name of the schema. The schema name must be the same as your Oracle Database username.

**create_table_statement**

Specify a CREATE TABLE statement to be issued as part of this CREATE SCHEMA statement. Do not end this statement with a semicolon (or other terminator character).

See Also:

CREATE TABLE

**create_view_statement**

Specify a CREATE VIEW statement to be issued as part of this CREATE SCHEMA statement. Do not end this statement with a semicolon (or other terminator character).

See Also:

CREATE VIEW
grant_statement

Specify a GRANT statement to be issued as part of this CREATE SCHEMA statement. Do not end this statement with a semicolon (or other terminator character). You can use this clause to grant object privileges on objects you own to other users. You can also grant system privileges to other users if you were granted those privileges WITH ADMIN OPTION.

See Also:

- GRANT

The CREATE SCHEMA statement supports the syntax of these statements only as defined by standard SQL, rather than the complete syntax supported by Oracle Database.

The order in which you list the CREATE TABLE, CREATE VIEW, and GRANT statements is unimportant. The statements within a CREATE SCHEMA statement can reference existing objects or objects you create in other statements within the same CREATE SCHEMA statement.

Restriction on Granting Privileges to a Schema

The syntax of the parallel_clause is allowed for a CREATE TABLE statement in CREATE SCHEMA, but parallelism is not used when creating the objects.

See Also:

- The parallel_clause in the CREATE TABLE documentation

Examples

Creating a Schema: Example

The following statement creates a schema named oe for the sample order entry user oe, creates the table new_product, creates the view new_product_view, and grants the SELECT object privilege on new_product_view to the sample human resources user hr.

```sql
CREATE SCHEMA AUTHORIZATION oe
CREATE TABLE new_product
    (color VARCHAR2(10) PRIMARY KEY, quantity NUMBER)
CREATE VIEW new_product_view
AS SELECT color, quantity FROM new_product WHERE color = 'RED'
GRANT select ON new_product_view TO hr;
```
15

SQL Statements: CREATE SEQUENCE to DROP CLUSTER

This chapter contains the following SQL statements:

• CREATE SEQUENCE
• CREATE SPFILE
• CREATE SYNONYM
• CREATE TABLE
• CREATE TABLESPACE
• CREATE TABLESPACE SET
• CREATE TRIGGER
• CREATE TYPE
• CREATE TYPE BODY
• CREATE USER
• CREATE VIEW
• DELETE
• DISASSOCIATE STATISTICS
• DROP ANALYTIC VIEW
• DROP ATTRIBUTE DIMENSION
• DROP AUDIT POLICY (Unified Auditing)
• DROP CLUSTER

CREATE SEQUENCE

Purpose

Use the CREATE SEQUENCE statement to create a sequence, which is a database object from which multiple users may generate unique integers. You can use sequences to automatically generate primary key values.

When a sequence number is generated, the sequence is incremented, independent of the transaction committing or rolling back. If two users concurrently increment the same sequence, then the sequence numbers each user acquires may have gaps, because sequence numbers are being generated by the other user. One user can never acquire the sequence number generated by another user. After a sequence value is generated by one user, that user can continue to access that value regardless of whether the sequence is incremented by another user.

Sequence numbers are generated independently of tables, so the same sequence can be used for one or for multiple tables. It is possible that individual sequence numbers
will appear to be skipped, because they were generated and used in a transaction that ultimately rolled back. Additionally, a single user may not realize that other users are drawing from the same sequence.

After a sequence is created, you can access its values in SQL statements with the CURRVAL pseudocolumn, which returns the current value of the sequence, or the NEXTVAL pseudocolumn, which increments the sequence and returns the new value.

### See Also:
- [Pseudocolumns](#) for more information on using the CURRVAL and NEXTVAL pseudocolumns
- "How to Use Sequence Values " for information on using sequences
- ALTER SEQUENCE or DROP SEQUENCE for information on modifying or dropping a sequence

### Prerequisites

To create a sequence in your own schema, you must have the [CREATE SEQUENCE](#) system privilege.

To create a sequence in another user's schema, you must have the [CREATE ANY SEQUENCE](#) system privilege.
Syntax

\[ create\_sequence::= \]

Semantics

**schema**

Specify the schema to contain the sequence. If you omit `schema`, then Oracle Database creates the sequence in your own schema.
**sequence**

Specify the name of the sequence to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

If you specify none of the clauses INCREMENT BY through GLOBAL, then you create an ascending sequence that starts with 1 and increases by 1 with no upper limit. Specifying only INCREMENT BY -1 creates a descending sequence that starts with -1 and decreases with no lower limit.

- To create a sequence that increments without bound, for ascending sequences, omit the MAXVALUE parameter or specify NOMAXVALUE. For descending sequences, omit the MINVALUE parameter or specify the NOMINVALUE.
- To create a sequence that stops at a predefined limit, for an ascending sequence, specify a value for the MAXVALUE parameter. For a descending sequence, specify a value for the MINVALUE parameter. Also specify NOCYCLE. Any attempt to generate a sequence number once the sequence has reached its limit results in an error.
- To create a sequence that restarts after reaching a predefined limit, specify values for both the MAXVALUE and MINVALUE parameters. Also specify CYCLE.

**SHARING**

This clause applies only when creating a sequence in an application root. This type of sequence is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the sequence is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the sequence’s metadata, but its data is unique to each container. This type of sequence is referred to as a metadata-linked application common object.
- **DATA** - A data link shares the sequence, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of sequence is referred to as a data-linked application common object.
- **NONE** - The sequence is not shared.

If you omit this clause, then the database uses the value of the DEFAULT_SHARING initialization parameter to determine the sharing attribute of the sequence. If the DEFAULT_SHARING initialization parameter does not have a value, then the default is METADATA.

You cannot change the sharing attribute of a sequence after it is created.

---

**See Also:**

- Oracle Database Reference for more information on the DEFAULT_SHARING initialization parameter
- Oracle Database Administrator’s Guide for complete information on creating application common objects
INCREMENT BY

Specify the interval between sequence numbers. This integer value can be any positive or negative integer, but it cannot be 0. This value can have 28 or fewer digits for an ascending sequence and 27 or fewer digits for a descending sequence. The absolute of this value must be less than the difference of MAXVALUE and MINVALUE. If this value is negative, then the sequence descends. If the value is positive, then the sequence ascends. If you omit this clause, then the interval defaults to 1.

START WITH

Specify the first sequence number to be generated. Use this clause to start an ascending sequence at a value greater than its minimum or to start a descending sequence at a value less than its maximum. For ascending sequences, the default value is the minimum value of the sequence. For descending sequences, the default value is the maximum value of the sequence. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values.

Note:
This value is not necessarily the value to which an ascending or descending cycling sequence cycles after reaching its maximum or minimum value, respectively.

MAXVALUE

Specify the maximum value the sequence can generate. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values. MAXVALUE must be equal to or greater than START WITH and must be greater than MINVALUE.

NOMAXVALUE

Specify NOMAXVALUE to indicate a maximum value of \(10^{28} - 1\) for an ascending sequence or -1 for a descending sequence. This is the default.

MINVALUE

Specify the minimum value of the sequence. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values. MINVALUE must be less than or equal to START WITH and must be less than MAXVALUE.

NOMINVALUEN

Specify NOMINVALUE to indicate a minimum value of 1 for an ascending sequence or -(\(10^{27}\) -1) for a descending sequence. This is the default.

CYCLE

Specify CYCLE to indicate that the sequence continues to generate values after reaching either its maximum or minimum value. After an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum, it generates its maximum value.
NOCYCLE

Specify NOCYCLE to indicate that the sequence cannot generate more values after reaching its maximum or minimum value. This is the default.

CACHE

Specify how many values of the sequence the database preallocates and keeps in memory for faster access. This integer value can have 28 or fewer digits. The minimum value for this parameter is 2. For sequences that cycle, this value must be less than the number of values in the cycle. You cannot cache more values than will fit in a given cycle of sequence numbers. Therefore, the maximum value allowed for CACHE must be less than the value determined by the following formula:

$$\text{CEIL} \left( \frac{\text{MAXVALUE} - \text{MINVALUE}}{\text{ABS(INCREMENT)}} \right)$$

If a system failure occurs, then all cached sequence values that have not been used in committed DML statements are lost. The potential number of lost values is equal to the value of the CACHE parameter.

Note:
Oracle recommends using the CACHE setting to enhance performance if you are using sequences in an Oracle Real Application Clusters environment.

NOCACHE

Specify NOCACHE to indicate that values of the sequence are not preallocated. If you omit both CACHE and NOCACHE, then the database caches 20 sequence numbers by default.

ORDER

Specify ORDER to guarantee that sequence numbers are generated in order of request. This clause is useful if you are using the sequence numbers as timestamps. Guaranteeing order is usually not important for sequences used to generate primary keys.

NOORDER

Specify NOORDER if you do not want to guarantee sequence numbers are generated in order of request. This is the default.

KEEP

Specify KEEP if you want NEXTVAL to retain its original value during replay for Application Continuity. This behavior will occur only if the user running the application is the owner of the schema containing the sequence. This clause is useful for providing bind variable consistency at replay after recoverable errors. Refer to Oracle Database Development Guide for more information on Application Continuity.
NOKEEP

Specify NOKEEP if you do not want NEXTVAL to retain its original value during replay for Application Continuity. This is the default.

Note:

The KEEP and NOKEEP clauses apply only to the owner of the schema containing the sequence. You can control whether NEXTVAL retains its original value for other users during replay for Application Continuity by granting or revoking the KEEP SEQUENCE object privilege on the sequence. Refer to Table 18-2 for more information on the KEEP SEQUENCE object privilege.

SCALE

Use SCALE to enable sequence scalability. When SCALE is specified, a numeric offset is affixed to the beginning of the sequence which removes all duplicates in generated values.

EXTEND

If you specify EXTEND with SCALE the generated sequence values are all of length \((x+y)\), where \(x\) is the length of the scalable offset (default value is 6), and \(y\) is the maximum number of digits in the sequence \((\text{maxvalue/minvalue})\).

When you use SCALE it is highly recommended that you not use ORDER simultaneously on the sequence.

NOEXTEND

NOEXTEND is the default setting for the SCALE clause. With the NOEXTEND setting, the generated sequence values are at most as wide as the maximum number of digits in the sequence \((\text{maxvalue/minvalue})\). This setting is useful for integration with existing applications where sequences are used to populate fixed width columns.

NOSCALE

Use NOSCALE to disable sequence scalability.

SHARD

For complete semantics on the SHARD clause please refer to the SHARD clause of the ALTER SEQUENCE statement.

SESSION

Specify SESSION to create a session sequence, which is a special type of sequence that is specifically designed to be used with global temporary tables that have session visibility. Unlike the existing regular sequences (referred to as "global" sequences for the sake of comparison), a session sequence returns a unique range of sequence numbers only within a session, but not across sessions. Another difference is that session sequences are not persistent. If a session goes away, so does the state of the session sequences that were accessed during the session.
Session sequences must be created by a read-write database but can be accessed on any read-write or read-only databases (either a regular database temporarily open read-only or a standby database).

The `CACHE`, `NOCACHE`, `ORDER`, or `NOORDER` clauses are ignored when specified with the `SESSION` clause.

---

**See Also:**

*Oracle Data Guard Concepts and Administration* for more information on session sequences

---

GLOBAL

Specify `GLOBAL` to create a global, or regular, sequence. This is the default.

**Examples**

**Creating a Sequence: Example**

The following statement creates the sequence `customers_seq` in the sample schema `oe`. This sequence could be used to provide customer ID numbers when rows are added to the `customers` table.

```
CREATE SEQUENCE customers_seq
    START WITH 1000
    INCREMENT BY 1
    NOCACHE
    NOCYCLE;
```

The first reference to `customers_seq.nextval` returns 1000. The second returns 1001. Each subsequent reference will return a value 1 greater than the previous reference.

---

**CREATE SPFILE**

**Purpose**

Use the `CREATE SPFILE` statement to create a server parameter file either from a traditional plain-text initialization parameter file or from the current system-wide settings. Server parameter files are binary files that exist only on the server and are called from client locations to start up the database.

Server parameter files let you make persistent changes to individual parameters. When you use a server parameter file, you can specify in an `ALTER SYSTEM SET parameter` statement that the new parameter value should be persistent. This means that the new value applies not only in the current instance, but also to any instances that are started up subsequently. Traditional plain-text parameter files do not let you make persistent changes to parameter values.

Server parameter files are located on the server, so they allow for automatic database tuning by Oracle Database and for backup by Recovery Manager (RMAN).

To use a server parameter file when starting up the database, you must create it using the `CREATE SPFILE` statement.
All instances in an Oracle Real Application Clusters environment must use the same server parameter file. However, when otherwise permitted, individual instances can have different settings of the same parameter within this one file. Instance-specific parameter definitions are specified as $SID$.parameter = value, where $SID$ is the instance identifier.

The method of starting up the database with a server parameter file depends on whether you create a default or nondefault server parameter file. Refer to "Creating a Server Parameter File: Examples" for examples of how to use server parameter files.

Note on Creating Server Parameter Files in a CDB

When you create a server parameter file in a multitenant container database (CDB), the current container can be the root or a PDB.

- If the current container is the root, then the values that you set for initialization parameters in the root are used as default values for all other containers.
- If the current container is a PDB, then the database stores the PDB's initialization parameter values internally, rather than in a file. Therefore, you cannot specify an `spfile_name`. The values that you set for initialization parameters in the PDB are persistent and override any values set for those parameters in the root.

You can subsequently use the `ALTER SYSTEM` statement to modify initialization parameter values for the root or a PDB.

**See Also:**

- CREATE PFILE for information on creating a regular text parameter file from a binary server parameter file
- Oracle Database Administrator’s Guide for information on traditional plain-text initialization parameter files and server parameter files
- Oracle Real Application Clusters Administration and Deployment Guide for information on using server parameter files in an Oracle Real Application Clusters environment

**Prerequisites**

You must have the `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSCOLER` system privilege to execute this statement. You can execute this statement before or after instance startup. However, if you have already started an instance using `spfile_name`, you cannot specify the same `spfile_name` in this statement.

To create a server parameter file in a CDB, the current container must be the root and you must have the commonly granted `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSCOLER` system privilege.
Syntax

create_spfile::=

```
CREATE SPFILE = 'spfile_name'
FROM PFILE = 'pfile_name'
AS COPY MEMORY
```

Semantics

**spfile_name**

This clause lets you specify a name for the server parameter file you are creating. If you specify `spfile_name`, then Oracle Database creates a nondefault server parameter file.

- For `spfile_name`, you can specify a traditional filename, a file in an Oracle ACFS file system, or an Oracle Storage Management (Oracle ASM) filename.
- If you specify a traditional filename or a file in an Oracle ACFS file system, then `spfile_name` can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.
- If you specify the Oracle ASM filename syntax, then the database creates the spfile in an Oracle ASM disk group.
- When using a nondefault server parameter file, you must specify the server parameter filename in the `STARTUP` command when you start up the database. The exception to this rule is as follows:
  - If the database is defined as a resource in Oracle Clusterware, the instance from which the command is issued is running, and you specify the `spfile_name`, specify the `FROM PFILE` clause, and omit the `AS COPY` clause, then this statement automatically updates the SPFILE in the database resource. In this case, you can start up the database without referring to the server parameter file by name. If the instance from which the command is issued is not running, then the SPFILE in the database resource must be updated manually using `srvctl modify database -d dbname -spfile spfile_path`.

If you omit `spfile_name`, then Oracle Database uses the platform-specific default server parameter filename. If such a file already exists on the server, then this statement overwrites it. When using a default server parameter file, you can start up the database without referring to the file by name.

**Restriction on spfile_name**

You cannot specify `spfile_name` when creating a server parameter file while connected to a PDB.
See Also:

- "Creating a Server Parameter File: Examples" for information on starting up the database with default and nondefault server parameter files
- `file_specification` for the syntax of traditional and Oracle ASM filenames and `ALTER DISKGROUP` for information on modifying the characteristics of an Oracle ASM file
- The appropriate operating-system-specific documentation for default parameter file names

`pfile_name`

Specify the traditional plain-text initialization parameter file from which you want to create a server parameter file. The traditional parameter file must reside on the server.

- If you specify `pfile_name` and the traditional parameter file does not reside in the default directory for parameter files on your operating system, then you must specify the full path.
- If you do not specify `pfile_name`, then Oracle Database looks in the default directory for parameter files on your operating system for the default parameter filename and uses that file. If that file does not exist in the expected directory, then the database returns an error.

**Note:**

In an Oracle Real Application Clusters environment, you must first combine all instance parameter files into one file before specifying that filename in this statement to create a server parameter file. For information on accomplishing this step, see *Oracle Real Application Clusters Administration and Deployment Guide*.

**AS COPY**

This clause applies only if the database is defined as a resource in Oracle Clusterware. By default, if you specify both the `spfile_name` and the `FROM PFILE` clause, then the `CREATE SPFILE` statement automatically updates the SPFILE in the database resource. You can specify `AS COPY` to prevent the database from updating the SPFILE in the database resource.

**MEMORY**

Specify `MEMORY` to create an spfile using the current system-wide parameter settings. In an Oracle RAC environment, the created file will contain the parameter settings from each instance.

**Examples**

*Creating a Server Parameter File: Examples*
The following example creates a default server parameter file from a traditional plain-text parameter file named \texttt{t\_init1.ora}:

\begin{verbatim}
CREATE SPFILE
   FROM PFILE = '$ORACLE_HOME/work/t_init1.ora';
\end{verbatim}

\noindent\textbf{Note:}

\begin{quote}
Typically you will need to specify the full path and filename for parameter files on your operating system.
\end{quote}

When you create a default server parameter file, you subsequently start up the database using that server parameter file by using the SQL\*Plus command \texttt{STARTUP} without the \texttt{PFILE} parameter, as follows:

\begin{verbatim}
STARTUP
\end{verbatim}

The following example creates a nondefault server parameter file \texttt{s\_params.ora} from a traditional plain-text parameter file named \texttt{t\_init1.ora}:

\begin{verbatim}
CREATE SPFILE = 's_params.ora'
   FROM PFILE = '$ORACLE_HOME/work/t_init1.ora';
\end{verbatim}

When you create a nondefault server parameter file, you subsequently start up the database by first creating a traditional parameter file containing the following single line:

\begin{verbatim}
spfile = 's_params.ora'
\end{verbatim}

The name of this parameter file must comply with the naming conventions of your operating system. You then use the single-line parameter file in the \texttt{STARTUP} command. The following example shows how to start up the database, assuming that the single-line parameter file is named \texttt{new\_param.ora}:

\begin{verbatim}
STARTUP PFILE=new_param.ora
\end{verbatim}

\section*{CREATE SYNONYM}

\subsection*{Purpose}

Use the \texttt{CREATE SYNONYM} statement to create a \texttt{synonym}, which is an alternative name for a table, view, sequence, operator, procedure, stored function, package, materialized view, Java class schema object, user-defined object type, or another synonym. A synonym places a dependency on its target object and becomes invalid if the target object is changed or dropped.

Synonyms provide both data independence and location transparency. Synonyms permit applications to function without modification regardless of which user owns the table or view and regardless of which database holds the table or view. However, synonyms are not a substitute for privileges on database objects. Appropriate privileges must be granted to a user before the user can use the synonym.

You can refer to synonyms in the following DML statements: \texttt{SELECT}, \texttt{INSERT}, \texttt{UPDATE}, \texttt{DELETE}, \texttt{FLASHBACK TABLE}, \texttt{EXPLAIN PLAN}, \texttt{LOCK TABLE}, \texttt{MERGE}, and \texttt{CALL}.
You can refer to synonyms in the following DDL statements: AUDIT, NOAUDIT, GRANT, REVOKE, and COMMENT.

See Also:

Oracle Database Concepts for general information on synonyms

Prerequisites

To create a private synonym in your own schema, you must have the CREATE SYNONYM system privilege.

To create a private synonym in another user’s schema, you must have the CREATE ANY SYNONYM system privilege.

To create a PUBLIC synonym, you must have the CREATE PUBLIC SYNONYM system privilege.

Syntax

\[
create	extunderscore synonym ::= \\
\text{CREATE OR REPLACE EDITIONABLE NONEDITIONABLE PUBLIC SYNONYM schema . synonym SHARING = METADATA NONE FOR schema . object @ dblink ;}
\]

Semantics

OR REPLACE

Specify OR REPLACE to re-create the synonym if it already exists. Use this clause to change the definition of an existing synonym without first dropping it.

Restriction on Replacing a Synonym

You cannot use the OR REPLACE clause for a type synonym that has any dependent tables or dependent valid user-defined object types.

[ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the synonym is an editioned or noneditioned object if editioning is enabled for the schema object type SYNONYM in schema. For private synonyms, the default is EDITIONABLE. For public synonyms, the default is NONEDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.
PUBLIC

Specify PUBLIC to create a public synonym. Public synonyms are accessible to all users. However each user must have appropriate privileges on the underlying object in order to use the synonym.

When resolving references to an object, Oracle Database uses a public synonym only if the object is not prefaced by a schema and is not followed by a database link.

If you omit this clause, then the synonym is private. A private synonym name must be unique in its schema. A private synonym is accessible to users other than the owner only if those users have appropriate privileges on the underlying database object and specify the schema along with the synonym name.

Notes on Public Synonyms

The following notes apply to public synonyms:

- If you create a public synonym and it subsequently has dependent tables or dependent valid user-defined object types, then you cannot create another database object of the same name as the synonym in the same schema as the dependent objects.
- Take care not to create a public synonym with the same name as an existing schema. If you do so, then all PL/SQL units that use that name will be invalidated.

schema

Specify the schema to contain the synonym. If you omit schema, then Oracle Database creates the synonym in your own schema. You cannot specify a schema for the synonym if you have specified PUBLIC.

database object name

Specify the name of the synonym to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

Note:

The maximum length of a synonym name is subject to the following rules:

- If the COMPATIBLE initialization parameter is set to a value of 12.2 or higher, then the maximum length of a synonym name is 128 bytes. The database will allow you to create and drop synonyms of length 129 to 4000 bytes. However, unless these longer synonym names represent a Java name they will not work in any other SQL command.
- If the COMPATIBLE initialization parameter is set to a value lower than 12.2, then the maximum length of a synonym name is 30 bytes. The database will allow you to create and drop synonyms of length 31 to 128 bytes. However, unless these longer synonym names represent a Java name they will not work in any other SQL command.

The longer synonym names are transformed into obscure shorter strings for storage in the data dictionary.
SHARING

This clause applies only when creating a synonym in an application root. This type of synonym is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the synonym is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the synonym's metadata, but its data is unique to each container. This type of synonym is referred to as a metadata-linked application common object.
- **NONE** - The synonym is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the synonym. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

You cannot change the sharing attribute of a synonym after it is created.

FOR Clause

Specify the object for which the synonym is created. The schema object for which you are creating the synonym can be of the following types:

- Table or object table
- View or object view
- Sequence
- Stored procedure, function, or package
- Materialized view
- Java class schema object
- User-defined object type
- Synonym

The schema object need not currently exist and you need not have privileges to access the object.
Restriction on the FOR Clause

The schema object cannot be contained in a package.

**schema**

Specify the schema in which the object resides. If you do not qualify object with `schema`, then the database assumes that the schema object is in your own schema.

If you are creating a synonym for a procedure or function on a remote database, then you must specify `schema` in this `CREATE` statement. Alternatively, you can create a local public synonym on the database where the object resides. However, the database link must then be included in all subsequent calls to the procedure or function.

**dblink**

You can specify a complete or partial database link to create a synonym for a schema object on a remote database where the object is located. If you specify `dblink` and omit `schema`, then the synonym refers to an object in the schema specified by the database link. Oracle recommends that you specify the schema containing the object in the remote database.

If you omit `dblink`, then Oracle Database assumes the object is located on the local database.

Restriction on Database Links

You cannot specify `dblink` for a Java class synonym.

See Also:

- "References to Objects in Remote Databases" for more information on referring to database links
- `CREATE DATABASE LINK` for more information on creating database links

Examples

**CREATE SYNONYM: Examples**

To define the synonym `offices` for the table `locations` in the schema `hr`, issue the following statement:

```sql
CREATE SYNONYM offices FOR hr.locations;
```

To create a `PUBLIC` synonym for the `employees` table in the schema `hr` on the remote database, you could issue the following statement:

```sql
CREATE PUBLIC SYNONYM emp_table FOR hr.employees@remote.us.example.com;
```

A synonym may have the same name as the underlying object, provided the underlying object is contained in another schema.

**Oracle Database Resolution of Synonyms: Example**
Oracle Database attempts to resolve references to objects at the schema level before resolving them at the PUBLIC synonym level. For example, the schemas oe and sh both contain tables named customers. In the next example, user SYSTEM creates a PUBLIC synonym named customers for oe.customers:

```
CREATE PUBLIC SYNONYM customers FOR oe.customers;
```

If the user sh then issues the following statement, then the database returns the count of rows from sh.customers:

```
SELECT COUNT(*) FROM customers;
```

To retrieve the count of rows from oe.customers, the user sh must preface customers with the schema name. (The user sh must have select permission on oe.customers as well.)

```
SELECT COUNT(*) FROM oe.customers;
```

If the user hr's schema does not contain an object named customers, and if hr has select permission on oe.customers, then hr can access the customers table in oe's schema by using the public synonym customers:

```
SELECT COUNT(*) FROM customers;
```

## CREATE TABLE

### Purpose

Use the CREATE TABLE statement to create one of the following types of tables:

- A **relational table**, which is the basic structure to hold user data.
- An **object table**, which is a table that uses an object type for a column definition. An object table is explicitly defined to hold object instances of a particular type.

You can also create an object type and then use it in a column when creating a relational table.

Tables are created with no data unless a subquery is specified. You can add rows to a table with the INSERT statement. After creating a table, you can define additional columns, partitions, and integrity constraints with the ADD clause of the ALTER TABLE statement. You can change the definition of an existing column or partition with the MODIFY clause of the ALTER TABLE statement.

### See Also:

- *Oracle Database Administrator's Guide* and CREATE TYPE for more information about creating objects
- ALTER TABLE and DROP TABLE for information on modifying and dropping tables
Prerequisites

To create a **relational table** in your own schema, you must have the `CREATE TABLE` system privilege. To create a table in another user’s schema, you must have the `CREATE ANY TABLE` system privilege. Also, the owner of the schema to contain the table must have either space quota on the tablespace to contain the table or the `UNLIMITED TABLESPACE` system privilege.

In addition to these table privileges, to create an object table or a relational table with an object type column, the owner of the table must have the `EXECUTE` object privilege in order to access all types referenced by the table, or you must have the `EXECUTE ANY TYPE` system privilege. These privileges must be granted explicitly and not acquired through a role.

Additionally, if the table owner intends to grant access to the table to other users, then the owner must have been granted the `EXECUTE` object privilege on the referenced types **WITH** **GRANT OPTION**, or have the `EXECUTE ANY TYPE` system privilege **WITH ADMIN OPTION**. Without these privileges, the table owner has insufficient privileges to grant access to the table to other users.

To enable a unique or primary key constraint, you must have the privileges necessary to create an index on the table. You need these privileges because Oracle Database creates an index on the columns of the unique or primary key in the schema containing the table.

**To specify an edition in the** `evaluation_edition_clause` **or the** `unusable_editions_clause`, **you must have the** `USE` **privilege on the edition.**

**To specify the** `zonemap_clause`, **you must have the permissions necessary to create a zone map.** Refer to the “Prerequisites” section in the documentation on `CREATE MATERIALIZED ZONEMAP`.

To create an **external table**, you must have the required read and write operating system privileges on the appropriate operating system directories. You must have the `READ` object privilege on the database directory object corresponding to the operating system directory in which the external data resides. You must also have the `WRITE` object privilege on the database directory in which the files will reside if you specify a log file or bad file in the `opaque_format_spec` or if you unload data into an external table from a database table by specifying the `AS subquery` clause.

To create an **XMLType table** in a different database schema from your own, you must have not only privilege `CREATE ANY TABLE` but also privilege `CREATE ANY INDEX`. This is because a unique index is created on column `OBJECT_ID` when you create the table. Column `OBJECT_ID` stores a system-generated object identifier.

**Semantics**

**GLOBAL TEMPORARY**

Specify `GLOBAL TEMPORARY` to create a temporary table, whose definition is visible to all sessions with appropriate privileges. The data in a temporary table is visible only to the session that inserts the data into the table.

When you first create a temporary table, its metadata is stored in the data dictionary, but no space is allocated for table data. Space is allocated for the table segment at the time of the first DML operation on the table. The temporary table definition persists in the same way as the definitions of regular tables, but the table segment and any data the table contains are either session-specific or transaction-specific data. You specify whether the table segment and data are session- or transaction-specific with the `ON COMMIT` clause.

You can perform DDL operations (such as `ALTER TABLE`, `DROP TABLE`, `CREATE INDEX`) on a temporary table only when no session is bound to it. A session becomes bound to
a temporary table with an INSERT operation on the table. A session becomes unbound to a temporary table with a TRUNCATE statement or at session termination, or, for a transaction-specific temporary table, by issuing a COMMIT or ROLLBACK statement.

PRIVATE TEMPORARY

Specify PRIVATE TEMPORARY to create a private temporary table.

A private temporary table differs from a temporary table in that its definition and data are visible only within the session that created it. Use the ON COMMIT clause to define the scope of a private temporary table: either transaction or session. The ON COMMIT clause used with the keywords DROP DEFINITION creates a transaction-specific table whose data and definition are dropped when the transaction commits. This is the default behavior. The ON COMMIT clause used with keywords PRESERVE DEFINITION creates a session-specific table whose definition is preserved when the transaction commits. See here for usage details of the ON COMMIT clause.

Three DDL statements are supported for private temporary tables: CREATE, DROP, and TRUNCATE.

Restrictions

You must be a user other than SYS to create private temporary tables.

See Also:

Oracle Database Concepts for information on temporary tables and "Creating a Table: Temporary Table Example"

Restrictions on Temporary Tables

Temporary tables are subject to the following restrictions:

- Temporary tables cannot be partitioned, clustered, or index organized.
- You cannot specify any foreign key constraints on temporary tables.
- Temporary tables cannot contain columns of nested table.
- You cannot specify the following clauses of the LOB storage clause: TABLESPACE, storage clause, or logging clause.
- Parallel UPDATE, DELETE and MERGE are not supported for temporary tables.
- The only part of the segment_attributes clause you can specify for a temporary table is TABLESPACE, which allows you to specify a single temporary table space.
- Distributed transactions are not supported for temporary tables.
- A temporary table cannot contain INVISIBLE columns.

Restrictions on Private Temporary Tables

In addition to the general limitations of temporary tables, private temporary tables are subject to the following restrictions:

- The name of private temporary tables must always be prefixed with whatever is defined with the init.ora parameter PRIVATE_TEMP_TABLE_PREFIX. The default is ORA$PTT_.
• You cannot create indexes, materialized views, or zone maps on private temporary tables.
• You cannot define column with default values.
• You cannot reference private temporary tables in any permanent object, e.g. views or triggers.
• Private temporary tables are not visible through database links.

**SHARDED**

Specify SHARDED to create a sharded table.

This clause is valid only if you are using Oracle Sharding, which is a data tier architecture in which data is horizontally partitioned across independent databases. Each database in such configuration is called a shard. All of the shards together make up a single logical database, which is referred to as a sharded database (SDB). Horizontal partitioning involves splitting a table across shards so that each shard contains the table with the same columns but a different subset of rows. A table split up in this manner is called a sharded table.

When you create a sharded table, you must specify a tablespace set in which to create the table. There is no default tablespace set for sharded tables. See CREATE TABLESPACE SET for more information.

Oracle Sharding is based on the Oracle Partitioning feature. Therefore, a sharded table must be a partitioned or composite-partitioned table. When creating a sharded table, you must specify one of the `table_partitioning_clauses`. See `table_partitioning_clauses` for the full semantics of these clauses.

**Restrictions on Sharded Tables**

The following restrictions apply to sharded tables:

• In system-managed sharding you can create multiple root tables (and therefore table families) without throwing ORA-02530, when the CREATE SHARDED TABLE statement does not contain a PARTITION BY REFERENCE or PARENT clause and there is already a root table in existence.
• Even though you can create more than one table family with system sharding, only one table family is supported for user-defined and composite sharding.
• A sharded table cannot be a temporary table or an index-organized table.
• A sharded table cannot contain a nested table column or an identity column.
• You cannot specify a tablespace for a sharded system or composite sharded table with the TABLESPACE clause, because user-defined sharded tables require sharded tablespaces and not tablespace sets.
• You cannot create tablespace sets in a user-defined sharding environment.
• A sharded tablespace is required for sharded tables. Normal tablespaces are not supported.
• You cannot specify the same tablespace for multiple partitions of the sharded table. This rule applies to subpartitions also. The same tablespace cannot be specified for subpartitions belonging to different partitions of a sharded table.
• You must specify a tablespace per partition of non-reference partitioned sharded tables.
• For user defined sharding the partition method must be range or list. Autolist and Interval partitioning is not supported.
• The list partition method can only have one partitioning column.
• Default partitions are not supported in list partitioned tables.
• NULL partitions are not supported in list partitioned tables.
• A primary key constraint defined on a sharded table must contain the sharding columns. A foreign key constraint on a column of a sharded table referencing a duplicated table column is not supported.
• System partitioning and interval-range partitioning are not supported for sharded tables.
• You cannot specify a virtual column in a sharded table in the PARTITION BY or PARTITIONSET BY clauses.

See Also:
Oracle Database Administrator’s Guide for more on sharded tables.

DUPLICATED
This clause is valid only if you are using Oracle Sharding. Specify DUPLICATED to create a duplicated table, which is duplicated on all shards. It can be a nonpartitioned table or partitioned table.

Duplicated tables are not tied to any table family.

Restrictions on Duplicated Tables
The following restrictions apply to duplicated tables:
• A duplicated table cannot contain a LONG column.
• The maximum number of non-primary key columns in a duplicated table is 999.
• An XMLType column in a duplicated table can be used only in an Automatic Segment Space Management (ASSM) tablespace.
• A duplicated table cannot be a temporary table.
• A duplicated table cannot be a reference-partitioned table or a system-partitioned table.
• You cannot specify NOLOGGING or PARALLEL for a duplicated table.
• You cannot enable a duplicated table for the In-Memory Column Store.

schema
Specify the schema to contain the table. If you omit schema, then the database creates the table in your own schema.

table
Specify the name of the table or object table to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".
**SHARING**

This clause applies only when creating a table in an application root. This type of table is called an application common object and its data can be shared with the application PDBs that belong to the application root. To determine how the table data is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the table's metadata, but its data is unique to each container. This type of table is referred to as a metadata-linked application common object.

- **DATA** - A data link shares the table, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of table is referred to as a data-linked application common object.

- **EXTENDED DATA** - An extended data link shares the table, and its data in the application root is the same for all containers in the application container. However, each application PDB in the application container can store data that is unique to the application PDB. For this type of table, data is stored in the application root and, optionally, in each application PDB. This type of table is referred to as an extended data-linked application common object.

- **NONE** - The table is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the table. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

When creating a relational table, you can specify `METADATA`, `DATA`, `EXTENDED DATA`, or `NONE`.

When creating an object table or an `XMLTYPE` table, you can specify only `METADATA` or `NONE`.

You cannot change the sharing attribute of a table after it is created.

---

**See Also:**

- [Oracle Database Reference](oracle-database-reference.html) for more information on the `DEFAULT_SHARING` initialization parameter
- [Oracle Database Administrator’s Guide](oracle-database-administrator-guide.html) for complete information on creating application common objects

---

**relational_table**

This clause lets you create a relational table.
relational_properties
The relational properties describe the components of a relational table.

column_definition
The column_definition lets you define the characteristics of the column.

Specifying column_definition with AS subquery
If you specify the AS subquery clause, and each column returned by subquery has a column name or is an expression with a specified column alias, then you can omit the column_definition clause. In this case, the names of the columns of table are the same as the names of the columns returned by subquery. The exception is creating an index-organized table, for which you must specify the column_definition clause, because you must designate a primary key column. Regardless of the table type, if you specify the column_definition clause and the AS subquery clause, then you must omit datatype from the column_definition clause.

column
Specify the name of a column of the table. The name must satisfy the requirements listed in “Database Object Naming Rules”.
If you also specify AS subquery, then you can omit column and datatype unless you are creating an index-organized table. If you specify AS subquery when creating an index-organized table, then you must specify column, and you must omit datatype.

The absolute maximum number of columns in a table is 1000. When you create an object table or a relational table with columns of object, nested table, varray, or REF type, Oracle Database maps the columns of the user-defined types to relational columns, in effect creating hidden columns that count toward the 1000-column limit. A relational column that stores a user-defined type attribute inherits the collation property of the attribute. In Oracle Database 12c Release 2 (12.2), user-defined types are created using the pseudo-collation property USING_NLS_COMP and their corresponding relational columns inherit this property.

datatype
Specify the data type of a column.
In general, you must specify datatype. However, the following exceptions apply:

• You must omit datatype if you specify the AS subquery clause.
• You can also omit datatype if the statement designates the column as part of a foreign key in a referential integrity constraint. Oracle Database automatically assigns to the column the data type of the corresponding column of the referenced key of the referential integrity constraint.

Restrictions on Table Column Data Types

• Do not create a table with LONG columns. Use LOB columns (CLOB, NCLOB, BLOB) instead. LONG columns are supported only for backward compatibility.

• You can specify a column of type ROWID, but Oracle Database does not guarantee that the values in such columns are valid rowids.
You can specify a user-defined datatype as non-persistable when creating or altering the datatype. Instances of non-persistable types cannot persist on disk. See CREATE TYPE for more on user-defined datatypes declared as non-persistable types.

### COLLATE

The COLLATE clause lets you specify a data-bound collation for the column.

For column_collation_name, specify a valid named collation or pseudo-collation. For columns of data type CLOB or NCLOB, the only allowed value for column_collation_name is the pseudo-collation USING_NLS_COMP.

If you omit this clause, then the column is assigned:

- the pseudo-collation USING_NLS_COMP, if the column has the data type CLOB or NCLOB, or
- the collation of the corresponding parent key column, if the column belongs to a foreign key, or
- the default collation for the table as it stands at the time the column is created.

Refer to the DEFAULT COLLATION clause for more information on the default collation for a table.

You can specify the COLLATE clause only if the COMPATIBLE initialization parameter is set to 12.2 or greater, and the MAX_STRING_SIZE initialization parameter is set to EXTENDED.

### SORT

The SORT keyword is valid only if you are creating this table as part of a hash cluster and only for columns that are also cluster columns.

This clause instructs the database to sort the rows of the cluster on this column after applying the hash function when performing a DML operation. Doing so may improve response time during subsequent operations on the clustered data.

### VISIBLE | INVISIBLE

Use this clause to specify whether column is VISIBLE or INVISIBLE. The default is VISIBLE.

INVISIBLE columns are user-specified hidden columns. To display or assign a value to an INVISIBLE column, you must specify its name explicitly. For example:
• The SELECT * syntax will not display an INVISIBLE column. However, if you include an INVISIBLE column in the select list of a SELECT statement, then the column will be displayed.

• You cannot implicitly specify a value for an INVISIBLE column in the VALUES clause of an INSERT statement. You must specify the INVISIBLE column in the column list.

• You must explicitly specify an INVISIBLE column in Oracle Call Interface (OCI) describes.

• You can configure SQL*Plus to allow INVISIBLE column information to be viewed with the DESCRIBE command. Refer to SQL*Plus User’s Guide and Reference for more information.

Notes on VISIBLE and INVISIBLE Columns

The following notes apply to VISIBLE and INVISIBLE columns:

• An INVISIBLE column can be used as a partitioning key when specified as part of CREATE TABLE.

• You can specify INVISIBLE columns in a column_expression.

• A virtual column can be an INVISIBLE column.

• PL/SQL %ROWTYPE attributes do not show INVISIBLE columns.

• The COLUMN_ID column of the ALL_, DBA_, and USER_TAB_COLUMNS data dictionary views determines the order in which a SELECT * query returns columns for a table, view, or materialized view. The value of COLUMN_ID is NULL for INVISIBLE columns. When you make an invisible column visible, it will be assigned the next highest available COLUMN_ID value. When you make a visible column invisible, its COLUMN_ID value is set to NULL and COLUMN_ID is decremented by 1 for any columns with a higher COLUMN_ID.

Restrictions on VISIBLE and INVISIBLE Columns

The following restrictions apply to VISIBLE and INVISIBLE columns:

• INVISIBLE columns are not supported in external tables, cluster tables, or temporary tables.

• You cannot make a system-generated hidden column visible.

Note:

To determine whether a column is a system-generated hidden column, query the HIDDEN_COLUMN and USER_GENERATED columns of the ALL_, DBA_, and USER_TAB_COLS data dictionary views. Refer to Oracle Database Reference for more information.

DEFAULT

The DEFAULT clause lets you specify a value to be assigned to the column if a subsequent INSERT statement omits a value for the column. The data type of the expression must match the data type specified for the column. The column must also be large enough to hold this expression.
The **DEFAULT** expression can include any SQL function as long as the function does not return a literal argument, a column reference, or a nested function invocation.

The **DEFAULT** expression can include the sequence pseudocolumns **CURRVAL** and **NEXTVAL**, as long as the sequence exists and you have the privileges necessary to access it. Users who perform subsequent inserts that use the **DEFAULT** expression must have the **INSERT** privilege on the table and the **SELECT** privilege on the sequence. If the sequence is later dropped, then subsequent **INSERT** statements where the **DEFAULT** expression is used will result in an error. If you do not fully qualify the sequence by specifying the sequence owner, for example, **SCOTT SEQ1**, then Oracle Database will default the sequence owner to be the user who issues the **CREATE TABLE** statement. For example, if user **MARY** creates **SCOTT TABLE** and refers to a sequence that is not fully qualified, such as **SEQ2**, then the column will use sequence **MARY SEQ2**. Synonyms on sequences undergo a full name resolution and are stored as the fully qualified sequence in the data dictionary; this is true for public and private synonyms. For example, if user **BETH** adds a column referring to public or private synonym **SYN1** and the synonym refers to **PETER SEQ7**, then the column will store **PETER SEQ7** as the default.

**Restrictions on Default Column Values**

Default column values are subject to the following restrictions:

- A **DEFAULT** expression cannot contain references to PL/SQL functions or to other columns, the pseudocolumns **LEVEL**, **PRIOR**, and **ROWNUM**, or date constants that are not fully specified.
- The expression can be of any form except a scalar subquery expression.

**See Also:**

"About SQL Expressions" for the syntax of `expr`

**ON NULL**

If you specify the **ON NULL** clause, then Oracle Database assigns the **DEFAULT** column value when a subsequent **INSERT** statement attempts to assign a value that evaluates to **NULL**.

When you specify **ON NULL**, the **NOT NULL** constraint and **NOT DEFERRABLE** constraint state are implicitly specified. If you specify an inline constraint that conflicts with **NOT NULL** and **NOT DEFERRABLE**, then an error is raised.

**Restriction on the ON NULL Clause**

You cannot specify this clause for an object type column or a **REF** column.

**See Also:**

"Creating a Table with a DEFAULT ON NULL Column Value: Example"
identity_clause

Use this clause to specify an identity column. The identity column will be assigned an increasing or decreasing integer value from a sequence generator for each subsequent `INSERT` statement. You can use the `identity_options` clause to configure the sequence generator.

ALWAYS

If you specify `ALWAYS`, then Oracle Database always uses the sequence generator to assign a value to the column. If you attempt to explicitly assign a value to the column using `INSERT` or `UPDATE`, then an error will be returned. This is the default.

BY DEFAULT

If you specify `BY DEFAULT`, then Oracle Database uses the sequence generator to assign a value to the column by default, but you can also explicitly assign a specified value to the column. If you specify `ON NULL`, then Oracle Database uses the sequence generator to assign a value to the column when a subsequent `INSERT` statement attempts to assign a value that evaluates to NULL.

identity_options

Use the `identity_options` clause to configure the sequence generator. The `identity_options` clause has the same parameters as the `CREATE SEQUENCE` statement. Refer to `CREATE SEQUENCE` for a full description of these parameters and characteristics. The exception is `START WITH LIMIT VALUE`, which is specific to `identity_options` and can only be used with `ALTER TABLE MODIFY`. Refer to `identity_options` for more information.

Note:

When you create an identity column, Oracle recommends that you specify the `CACHE` clause with a value higher than the default of 20 to enhance performance.

Restrictions on Identity Columns

Identity columns are subject to the following restrictions:

- You can specify only one identity column per table.
- If you specify `identity_clause`, then you must specify a numeric data type for `datatype` in the `column_definition` clause. You cannot specify a user-defined data type.
- If you specify `identity_clause`, then you cannot specify the `DEFAULT` clause in the `column_definition` clause.
- When you specify `identity_clause`, the NOT NULL constraint and NOT DEFERRABLE constraint state are implicitly specified. If you specify an inline constraint that conflicts with NOT NULL and NOT DEFERRABLE, then an error is raised.
- If an identity column is encrypted, then the encryption algorithm may be inferred. Oracle recommends that you use a strong encryption algorithm on identity columns.
CREATE TABLE AS SELECT will not inherit the identity property on a column.

See Also:

"Creating a Table with an Identity Column: Examples"

encryption_spec

The ENCRYPT clause lets you use the Transparent Data Encryption (TDE) feature to encrypt the column you are defining. You can encrypt columns of type CHAR, NCHAR, VARCHAR2, NVARCHAR2, NUMBER, DATE, LOB, and RAW. The data does not appear in its encrypted form to authorized users, such as the user who encrypts the column.

Note:

Column encryption requires that a system administrator with appropriate privileges has initialized the security module, opened a keystore, and set an encryption key. Refer to Oracle Database Advanced Security Guide for general information about column encryption and to security_clauses for related ALTER SYSTEM statements.

USING 'encrypt_algorithm'

Use this clause to specify the name of the algorithm to be used. Valid algorithms are AES256, AES192, AES128 and 3DES168. If the COMPATIBLE initialization parameter is set to 12.2 or higher, then the following algorithms are also valid: ARIA128, ARIA192, ARIA256, GOST256, and SEED128. If you omit this clause, then the database uses AES192. If you encrypt more than one column in the same table, and if you specify the USING clause for one of the columns, then you must specify the same encryption algorithm for all the encrypted columns.

IDENTIFIED BY password

If you specify this clause, then the database derives the column key from the specified password.

'integrity_algorithm'

Use this clause to specify the integrity algorithm to be used. Valid integrity algorithms are SHA-1 and NOMAC.

• If you specify SHA-1, then TDE uses the Secure Hash Algorithm (SHA-1) and adds a 20-byte Message Authentication Code (MAC) to each encrypted value for integrity checking. This is the default.

• If you specify NOMAC, then TDE does not add a MAC and does not perform the integrity check. This saves 20 bytes of disk space per encrypted value. Refer to Oracle Database Advanced Security Guide for more information on using NOMAC to save disk space and improve performance.

All encrypted columns in a table must use the same integrity algorithm. If you already have a table column using the SHA-1 algorithm, then you cannot use the NOMAC parameter to encrypt another column in the same table. Refer to the REKEY
encryption_spec clause of ALTER TABLE to learn how to change the integrity algorithm used by all encrypted columns in a table.

SALT | NO SALT

Specify SALT to instruct the database to append a random string, called "salt," to the clear text of the column before encrypting it. This is the default.

Specify NO SALT to prevent the database from appending salt to the clear text of the column before encrypting it.

The following considerations apply when specifying SALT or NO SALT for encrypted columns:

- If you want to use the column as an index key, then you must specify NO SALT. Refer to Oracle Database Advanced Security Guide for a description of "salt" in this context.
- If you specify table compression for the table, then the database does not compress the data in encrypted columns with SALT.

You cannot specify SALT or NO SALT for LOB encryption.

Restrictions on encryption_spec

The following restrictions apply to column encryption:

- Transparent Data Encryption is not supported by the traditional import and export utilities or by transportable-tablespace-based export. Use the Data Pump import and export utilities with encrypted columns instead.
- To encrypt a column in an external table, the table must use ORACLE_DATAPUMP as its access type.
- You cannot encrypt a column in tables owned by SYS.
- You cannot encrypt a foreign key column.

See Also:
Oracle Database Advanced Security Guide for more information about Transparent Data Encryption

virtual_column_definition

The virtual_column_definition clause lets you create a virtual column. A virtual column is not stored on disk. Rather, the database derives the values in a virtual column on demand by computing a set of expressions or functions. Virtual columns can be used in queries, DML, and DDL statements. They can be indexed, and you can collect statistics on them. Thus, they can be treated much as other columns. Exceptions and restrictions are listed below in "Notes on Virtual Columns" and "Restrictions on Virtual Columns".

column

For column, specify the name of the virtual column.

datatype
You can optionally specify the data type of the virtual column. If you omit `datatype`, then the database determines the data type of the column based on the data type of the underlying expressions. All Oracle scalar data types and `XMLType` are supported.

**COLLATE**

The `COLLATE` clause lets you specify a data-bound collation for the virtual column. For `column_collation_name`, specify a valid named collation or pseudo-collation. If you omit this clause, then the column is assigned the default collation for the table as it stands at the time the column is created, unless the column belongs to a foreign key, in which case it inherits the collation from the corresponding column of the parent key. Refer to the `DEFAULT COLLATION` clause for more information on the default collation for a table.

You can specify the `COLLATE` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

**VISIBLE | INVISIBLE**

Use this clause to specify whether virtual column is `VISIBLE` or `INVISIBLE`. The default is `VISIBLE`. For complete information, refer to "VISIBLE | INVISIBLE".

**GENERATED ALWAYS**

The optional keywords `GENERATED ALWAYS` are provided for semantic clarity. They indicate that the column is not stored on disk, but is evaluated on demand.

**column_expression**

The `AS` `column_expression` clause determines the content of the column. Refer to "Column Expressions" for more information on `column_expression`.

**VIRTUAL**

The optional keyword `VIRTUAL` is provided for semantic clarity.

**evaluation_edition_clause**

You must specify this clause if `column_expression` refers to an editioned PL/SQL function. Use this clause to specify the edition that is searched during name resolution of the editioned PL/SQL function—the evaluation edition.

- Specify `CURRENT EDITION` to search the edition in which this DDL statement is executed.
- Specifying `NULL EDITION` is equivalent to omitting the `evaluation_edition_clause`.

If you omit the `evaluation_edition_clause`, then editioned objects are invisible during name resolution and an error will result. If the evaluation edition is dropped, then a subsequent query on the virtual column will result in an error.

The database does not maintain dependencies on the functions referenced by a virtual column. Therefore, if a virtual column refers to a noneditioned function, and the function becomes editioned, then the following operations may raise an error:

- Querying the virtual column
- Updating a row that includes the virtual column
• Firing a trigger that accesses the virtual column

See Also:

Oracle Database Development Guide for more information on specifying the evaluation edition for a virtual column

unusable_editions_clause

This clause lets you specify that the virtual column expression is unusable for evaluating queries in one or more editions. The remaining editions form a range of editions in which it is safe for the optimizer to use the virtual column expression to evaluate queries.

For example, suppose you define a function-based index on the virtual column. The optimizer can use the function-based index to evaluate queries that contain the virtual column expression in their `WHERE` clause. If a query is compiled in an edition that is in the usable range of editions for the virtual column, then the optimizer will consider using the index to evaluate the query. If a query is compiled in an edition outside the usable range of editions for the virtual column, then the optimizer will not consider using the index.

See Also:

Oracle Database Concepts for more information on optimization with function-based indexes

UNUSABLE BEFORE Clause

This clause lets you specify that the virtual column expression is unusable for evaluating queries in the ancestors of an edition.

• If you specify `CURRENT EDITION`, then the virtual column expression is unusable in the ancestors of the edition in which this DDL statement is executed.
• If you specify `EDITION edition`, then the virtual column expression is unusable in the ancestors of the specified `edition`.

UNUSABLE BEGINNING WITH Clause

This clause lets you specify that the virtual column expression is unusable for evaluating queries in an edition and its descendants.

• If you specify `CURRENT EDITION`, then the virtual column expression is unusable in the edition in which this DDL statement is executed and its descendants.
• If you specify `EDITION edition`, then the virtual column expression is unusable in the specified `edition` and its descendants.
• Specifying `NULL EDITION` is equivalent to omitting the UNUSABLE BEGINNING WITH clause.

If an edition specified in this clause is subsequently dropped, there is no effect on the virtual column.
Notes on Virtual Columns

- If `column_expression` refers to a column on which column-level security is implemented, then the virtual column does not inherit the security rules of the base column. In such a case, you must ensure that data in the virtual column is protected, either by duplicating a column-level security policy on the virtual column or by applying a function that implicitly masks the data. For example, it is common for credit card numbers to be protected by a column-level security policy, while still allowing call center employees to view the last four digits of the credit card number for validation purposes. In such a case, you could define the virtual column to take a substring of the last four digits of the credit card number.

- A table index defined on a virtual column is equivalent to a function-based index on the table.

- You cannot directly update a virtual column. Thus, you cannot specify a virtual column in the `SET` clause of an `UPDATE` statement. However, you can specify a virtual column in the `WHERE` clause of an `UPDATE` statement. Likewise, you can specify a virtual column in the `WHERE` clause of a `DELETE` statement to delete rows from a table based on the derived value of the virtual column.

- A query that specifies in its `FROM` clause a table containing a virtual column is eligible for result caching. Refer to "RESULT_CACHE Hint " for more information on result caching.

- The `column_expression` can refer to a PL/SQL function if the function is explicitly designated `DETERMINISTIC` during its creation. However, if the function is subsequently replaced, definitions dependent on the virtual column are not invalidated. In such a case, if the table contains data, queries that reference the virtual column may return incorrect results if the virtual column is used in the definition of constraints, indexes, or materialized views or for result caching. Therefore, in order to replace the deterministic PL/SQL function for a virtual column.
  - Disable and re-enable any constraints on the virtual column.
  - Rebuild any indexes on the virtual column.
  - Fully refresh materialized views accessing the virtual column.
  - Flush the result cache if cached queries have accessed the virtual column.
  - Regather statistics on the table.

- A virtual column can be an `INVISIBLE` column. The `column_expression` can contain `INVISIBLE` columns.

Restrictions on Virtual Columns

- You can create virtual columns only in relational heap tables. Virtual columns are not supported for index-organized, external, object, cluster, or temporary tables.

- The `column_expression` in the `AS` clause has the following restrictions:
  - It cannot refer to another virtual column by name.
  - Any columns referenced in `column_expression` must be defined on the same table.
  - It can refer to a deterministic user-defined function, but if it does, then you cannot use the virtual column as a partitioning key column.
  - The output of `column_expression` must be a scalar value.
The virtual column cannot be an Oracle supplied data type, a user-defined type, or LOB or LONG RAW.

You cannot specify a call to a PL/SQL function in the defining expression for a virtual column that you want to use as a partitioning column.

See Also:

"Column Expressions " for additional information and restrictions on column_expression

See Also:

"Adding a Virtual Table Column: Example" and Oracle Database Administrator's Guide for examples of creating tables with virtual columns

**period_definition**

Use the period_definition clause to create a valid time dimension for table. This clause implements Temporal Validity support for table. If you specify this clause, then one column in table, the start time column, contains a start date or timestamp, and another column in table, the end time column, contains an end date or timestamp. These two columns define a valid time dimension for table—that is, a period of time for which each row is considered valid. You can use Oracle Flashback Query to retrieve rows from table based on whether they are considered valid as of a specified time, before a specified time, or during a specified time period.

You can specify at most one valid time dimension when you create a table. You can subsequently add additional valid time dimensions to a table with the add_period_clause of ALTER TABLE.

**valid_time_column**

Specify the name of the valid time dimension. The name must satisfy the requirements listed in "Database Object Naming Rules ". Oracle Database creates an INVISIBLE virtual column with this name of data type NUMBER in table.

**start_time_column and end_time_column**

You can optionally specify these clauses as follows:

- Use start_time_column to specify the name of the start time column, which contains the start date or timestamp.
- Use end_time_column to specify the name of the end time column, which contains the end date or timestamp.

The names you specify for start_time_column and end_time_column must satisfy the requirements listed in "Database Object Naming Rules ". If you specify these clauses, then you must define start_time_column and end_time_column in the column_definition clause of CREATE TABLE. Each column must be of a datetime data type (DATE, TIMESTAMP, TIMESTAMP WITH TIME Zone, or TIMESTAMP WITH LOCAL TIME Zone) and can be VISIBLE or INVISIBLE.
If you do not specify these clauses, then Oracle Database creates a start
time column named `valid_time_column_START`, and an end time column named
`valid_time_column_END`. These columns are of data type `TIMESTAMP WITH TIME ZONE`
and are `INVISIBLE`.

You can insert and update values in the start time column and end time column as you
would any column, with the following considerations:

- If the value of the start time column is NULL, then the row is considered valid
  for all time values that occur before, but not including, the value of the end time
  column.
- If the value of the end time column is NULL, then the row is considered valid for all
  time values that occur on or after the value of the start time column.
- If the value of neither column is NULL, then the value of the start time column
  must be earlier than the value of the end time column. The row is considered valid
  for all time values that occur on or after the value of the start time column, and up
  to, but not including, the value of the end time column.
- If the value of both columns is NULL, then the row is considered valid for all time
  values.

Restrictions on Valid Time Dimension Columns

The following restrictions apply to valid time dimension columns:

- The `valid_time_column` is for internal use only. You cannot perform DDL or
  DML operations on it with one exception: You can drop the column by using the
  `drop_period_clause` of `ALTER TABLE`.
- You can drop the start time column and end time column only by using the
  `drop_period_clause` of `ALTER TABLE`.
- If the start time column and end time column are automatically created by Oracle
  Database, then they are `INVISIBLE` and you cannot subsequently make them
  `VISIBLE`.

See Also:

- `Oracle Database Development Guide` for more information on Temporal
  Validity
- `SELECT flashback_query_clause` for more information on Oracle
  Flashback Query
- `ALTER TABLE add_period_clause` and `drop_period_clause` for information
  how to add and drop a valid time dimension

Constraint Clauses

Use these clauses to create constraints on the table columns. You must specify a
`PRIMARY KEY` constraint for an index-organized table, and it cannot be `DEFERRABLE`.
Refer to `constraint` for syntax and description of these constraints as well as examples.

`inline_ref_constraint` and `out_of_line_ref_constraint`
These clauses let you describe a column of type REF. The only difference between these clauses is that you specify `out_of_line_ref_constraint` from the table level, so you must identify the REF column or attribute you are defining. Specify `inline_ref_constraint` as part of the definition of the REF column or attribute.

**See Also:**

"REF Constraint Examples"

**inline_constraint**

Use the `inline_constraint` to define an integrity constraint as part of the column definition.

You can create UNIQUE, PRIMARY KEY, and REFERENCES constraints on scalar attributes of object type columns. You can also create NOT NULL constraints on object type columns and CHECK constraints that reference object type columns or any attribute of an object type column.

**out_of_line_constraint**

Use the `out_of_line_constraint` syntax to define an integrity constraint as part of the table definition.

**supplemental_logging_props**

The `supplemental_logging_props` clause lets you instruct the database to put additional data into the log stream to support log-based tools.

**supplemental_log.grp_clause**

Use this clause to create a named log group.

- The `NO LOG` clause lets you omit from the redo log one or more columns that would otherwise be included in the redo for the named log group. You must specify at least one fixed-length column without `NO LOG` in the named log group.
- If you specify `ALWAYS`, then during an update, the database includes in the redo all columns in the log group. This is called an **unconditional log group** (sometimes called an "always log group"), because Oracle Database supplementally logs all the columns in the log group when the associated row is modified. If you omit `ALWAYS`, then the database supplementally logs all the columns in the log group only if any column in the log group is modified. This is called a **conditional log group**.

You can query the appropriate `USER_`, `ALL_`, or `DBA_LOG_GROUP_COLUMNS` data dictionary view to determine whether any supplemental logging has already been specified.

**supplemental_id_key_clause**

Use this clause to specify that all or a combination of the primary key, unique key, and foreign key columns should be supplementally logged. Oracle Database will generate either an **unconditional log group** or a **conditional log group**. With an unconditional log group, the database supplementally logs all the columns in the log group when the associated row is modified. With a conditional log group, the database supplementally logs all the columns in the log group only if any column in the log group is modified.
• If you specify ALL COLUMNS, then the database includes in the redo log all the fixed-length maximum size columns of that row. Such a redo log is a system-generated unconditional log group.

• If you specify PRIMARY KEY COLUMNS, then for all tables with a primary key, the database places into the redo log all columns of the primary key whenever an update is performed. Oracle Database evaluates which columns to supplementally log as follows:
  – First the database chooses columns of the primary key constraint, if the constraint is validated or marked RELY and is not marked as DISABLED or INITIALLY DEFERRED.
  – If no primary key columns exist, then the database looks for the smallest UNIQUE index with at least one NOT NULL column and uses the columns in that index.
  – If no such index exists, then the database supplementally logs all scalar columns of the table.

• If you specify UNIQUE COLUMNS, then for all tables with a unique key or a bitmap index, if any of the unique key or bitmap index columns are modified, the database places into the redo log all other columns belonging to the unique key or bitmap index. Such a log group is a system-generated conditional log group.

• If you specify FOREIGN KEY COLUMNS, then for all tables with a foreign key, if any foreign key columns are modified, the database places into the redo log all other columns belonging to the foreign key. Such a redo log is a system-generated conditional log group.

If you specify this clause multiple times, then the database creates a separate log group for each specification. You can query the appropriate USER_, ALL_, or DBA_LOG_GROUPS data dictionary view to determine whether any supplemental logging data has already been specified.

DEFAULT COLLATION

This clause lets you specify the default collation for the table. The default collation is assigned to columns of the table that are of a character data type and are created with this statement or subsequently added to the table with an ALTER TABLE statement. For collation_name, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the table is set to the effective schema default collation of the schema containing the table. Refer to the DEFAULT_COLLATION clause of ALTER SESSION for more information on the effective schema default collation.

You can override the table’s default collation and assign a data-bound collation to a particular column by specifying the COLLATE clause in the column_definition or virtual_column_definition clause of CREATE TABLE or ALTER TABLE, or the modify_col_properties or modify_virtcol_properties clause of ALTER TABLE.

You can specify the DEFAULT_COLLATION clause only if the COMPATIBLE initialization parameter is set to 12.2 or greater, and the MAX_STRING_SIZE initialization parameter is set to EXTENDED.

Restriction on Collation for CLOB and NCLOB Columns
If a column has the data type of `CLOB` or `NCLOB`, then its specified collation must be `USING_NLS_COMP`. The collation of `CLOB` and `NCLOB` columns is always `USING_NLS_COMP` and is not affected by the default collation for the table.

**See Also:**

*Oracle Database Globalization Support Guide* for full information on default collations and data-bound collations

**ON COMMIT**

The *ON COMMIT* clause is relevant only if you are creating a global temporary table. This clause specifies whether the data in the temporary table persists for the duration of a transaction or a session.

**DELETE ROWS**

Specify `DELETE ROWS` for a transaction-specific temporary table. This is the default. Oracle Database will truncate the table (delete all its rows) after each commit.

**PRESERVE ROWS**

Specify `PRESERVE ROWS` for a session-specific temporary table. Oracle Database will truncate the table (delete all its rows) when you terminate the session.

The scope of a private temporary table is also defined using the *ON COMMIT* clause but with the keywords `DROP DEFINITION` and `PRESERVE DEFINITION` to define a transaction-specific or session-specific table respectively.

**DROP DEFINITION**

Specify `DROP DEFINITION` to create a private temporary table whose content and definition are dropped when the transaction commits. The scope of this private temporary table is limited to the transaction. This is the default.

**PRESERVE DEFINITION**

Specify `PRESERVE DEFINITION` to create a private temporary table whose definition is preserved when the transaction commits. The scope of this private temporary table is extended to the session.

**physical_properties**

The physical properties relate to the treatment of extents and segments and to the storage characteristics of the table.

**INTERNAL | EXTERNAL**

Use the keyword `INTERNAL` to indicate an internal partition. This is the default. Use the keyword `EXTERNAL` to indicate an external partition.

**deferred_segment_creation**

Use this clause to determine when the database should create the segment(s) for this table:

- **SEGMENT CREATION DEFERRED**: This clause defers creation of the table segment — as well as segments for any LOB columns of the table, any indexes created
implicitly as part of table creation, and any indexes subsequently explicitly created
on the table — until the first row of data is inserted into the table. At that time,
the segments for the table, LOB columns and indexes, and explicitly created
indexes are all materialized and inherit any storage properties specified in this
CREATE TABLE statement or, in the case of explicitly created indexes, the CREATE
INDEX statement. These segments are created regardless whether the initial insert
operation is uncommitted or rolled back. This is the default value.

**Caution:**
When creating many tables with deferred segment creation, ensure that
you allocate enough space for your database so that when the first rows
are inserted, there is enough space for all the new segments.

- **SEGMENT CREATION IMMEDIATE:** The table segment is created as part of this CREATE
  TABLE statement.

Immediate segment creation is useful, for example, if your application depends upon
the object appearing in the DBA_, USER_, and ALL_SEGMENTS data dictionary views,
because the object will not appear in those views until the segment is created.
This clause overrides the setting of the DEFERRED_SEGMENT_CREATION initialization
parameter.

To determine whether a segment has been created for an existing table or its
LOB columns or indexes, query the SEGMENT_CREATED column of USER_TABLES,
USER_INDEXES, or USER_LOBS.

**Notes on Tables Without Segments**

The following rules apply to a table whose segment has not yet been materialized:

- If you create this table with CREATE TABLE ... AS subquery, then if the source table
  has no rows, segment creation of the new table is deferred. If the source table has
  rows, then segment creation of the new table is not deferred.

- If you specify ALTER TABLE ... ALLOCATE EXTENT before the segment is materialized,
  then the segment is materialized and then an extent is allocated. However the
  ALLOCATE EXTENT clause in a DDL statement on any indexes of the table will return
  an error.

- In a DDL statement on the table or its LOB columns or indexes, any specification
  of DEALLOCATE UNUSED is silently ignored.

- ONLINE operations on indexes of a table or table partition without a segment will
  silently be disabled; that is, they will proceed OFFLINE.

- If any of the following DDL statements are executed on a table with one or more
  LOB columns, then the resulting partition(s) or subpartition(s) will be materialized:
  - ALTER TABLE SPLIT [SUB]PARTITION
  - ALTER TABLE MERGE [SUB]PARTITIONS
  - ALTER TABLE ADD [SUB]PARTITION (hash partitions only)
  - ALTER TABLE COALESCE [SUB]PARTITION (hash partitions only)

**Restrictions on Deferred Segment Creation**
This clause is subject to the following restrictions:

- You cannot defer segment creation for the following types of tables: clustered tables, global temporary tables, session-specific temporary tables, internal tables, external tables, and tables owned by SYS, SYSTEM, PUBLIC, OUTLN, or XDB.
- Deferred segment creation is not supported in dictionary-managed tablespaces.
- Deferred segment creation is not supported in the SYSTEM tablespace.
- Serializable transactions do not work with deferred segment creation. Trying to insert data into an empty table with no segment created causes an error.

### See Also:

- Oracle Database Concepts for general information on segment allocation
- Oracle Database Reference for more information about the DEFERRED_SEGMENT_CREATION initialization parameter

#### segment_attributes_clause

The `segment_attributes_clause` lets you specify physical attributes and tablespace storage for the table.

#### physical_attributes_clause

The `physical_attributes_clause` lets you specify the value of the PCTFREE, PCTUSED, and INITRANS parameters and the storage characteristics of the table.

- For a nonpartitioned table, each parameter and storage characteristic you specify determines the actual physical attribute of the segment associated with the table.
- For partitioned tables, the value you specify for the parameter or storage characteristic is the default physical attribute of the segments associated with all partitions specified in this CREATE statement (and in subsequent ALTER TABLE ... ADD PARTITION statements), unless you explicitly override that value in the PARTITION clause of the statement that creates the partition.

If you omit this clause, then Oracle Database sets PCTFREE to 10, PCTUSED to 40, and INITRANS to 1.

### See Also:

- `physical_attributes_clause` and `storage_clause` for a description of these clauses
- “Creating a Table: Storage Example”

#### TABLESPACE

Specify the tablespace in which Oracle Database creates the table, object table OIDINDEX, partition, LOB data segment, LOB index segment, or index-organized table overflow data segment. If you omit `TABLESPACE`, then the database creates that item in the default tablespace of the owner of the schema containing the table.
For a heap-organized table with one or more LOB columns, if you omit the `TABLESPACE` clause for LOB storage, then the database creates the LOB data and index segments in the tablespace where the table is created.

For an index-organized table with one or more LOB columns, if you omit `TABLESPACE`, then the LOB data and index segments are created in the tablespace in which the primary key index segment of the index-organized table is created.

For nonpartitioned tables, the value specified for `TABLESPACE` is the actual physical attribute of the segment associated with the table. For partitioned tables, the value specified for `TABLESPACE` is the default physical attribute of the segments associated with all partitions specified in the `CREATE` statement and on subsequent `ALTER TABLE ... ADD PARTITION` statements, unless you specify `TABLESPACE` in the `PARTITION` description.

---

**See Also:**

`CREATE TABLESPACE` for more information on tablespaces

---

**TABLESPACE SET**

This clause is valid only when creating a sharded table by specifying the `SHARED` keyword of `CREATE TABLE`. Use this clause to specify the tablespace set in which Oracle Database creates the table.

You can only associate a tablespace set with one table family when you use the `CREATE SHARDED TABLE` statement. If you try to use a tablespace set with more than one table family, an error will be thrown.

**logging_clause**

Specify whether the creation of the table and of any indexes required because of constraints, partition, or LOB storage characteristics will be logged in the redo log file (`LOGGING`) or not (`NOLOGGING`). The logging attribute of the table is independent of that of its indexes.

This attribute also specifies whether subsequent direct loader (SQL*Loader) and direct-path `INSERT` operations against the table, partition, or LOB storage are logged (`LOGGING`) or not logged (`NOLOGGING`).

Refer to `logging_clause` for a full description of this clause.

**table_compression**

The `table_compression` clause is valid only for heap-organized tables. Use this clause to instruct the database whether to compress data segments to reduce disk use. The `COMPRESS` clauses enable table compression. The `NOCOMPRESS` clause disables table compression. The default is `NOCOMPRESS`.

**COMPRESS**

Specifying only the keyword `COMPRESS` is equivalent to specifying `ROW STORE COMPRESS BASIC` and enables basic table compression.

**ROW STORE COMPRESS BASIC**
When you enable table compression by specifying either `ROW STORE COMPRESS` or `ROW STORE COMPRESS BASIC`, you enable basic table compression. Oracle Database attempts to compress data during direct-path `INSERT` operations when it is productive to do so. The original import utility (`imp`) does not support direct-path `INSERT`, and therefore cannot import data in a compressed format.

Tables with basic table compression use a `PCTFREE` value of 0 to maximize compression, unless you explicitly set a value for `PCTFREE` in the `physical_attributes_clause`.

In earlier releases, basic table compression was enabled using `COMPRESS BASIC`. This syntax is still supported for backward compatibility.

---

**See Also:**

"Conventional and Direct-Path INSERT" for information on direct-path `INSERT` operations, including restrictions

---

**ROW STORE COMPRESS ADVANCED**

When you enable table compression by specifying `ROW STORE COMPRESS ADVANCED`, you enable Advanced Row Compression. Oracle Database compresses data during all DML operations on the table. This form of compression is recommended for OLTP environments.

Tables with `ROW STORE COMPRESS ADVANCED` or `NOCOMPRESS` use the `PCTFREE` default value of 10, to maximize compress while still allowing for some future DML changes to the data, unless you override this default explicitly.

In earlier releases, Advanced Row Compression was called OLTP table compression and was enabled using `COMPRESS FOR OLTP`. This syntax is still supported for backward compatibility.

**COLUMN STORE COMPRESS FOR { QUERY | ARCHIVE }**

When you specify `COLUMN STORE COMPRESS FOR QUERY` or `COLUMN STORE COMPRESS FOR ARCHIVE`, you enable Hybrid Columnar Compression. With Hybrid Columnar Compression, data can be compressed during direct-path inserts, conventional inserts, and array inserts. During the load process, data is transformed into a column-oriented format and then compressed. Oracle Database uses a compression algorithm appropriate for the level you specify. In general, the higher the level, the greater the compression ratio. Hybrid Columnar Compression can result in higher compression ratios, at a greater CPU cost. Therefore, this form of compression is recommended for data that is not frequently updated.

`COLUMN STORE COMPRESS FOR QUERY` is useful in data warehousing environments. Valid values are `LOW` and `HIGH`, with `HIGH` providing a higher compression ratio. The default is `HIGH`.

`COLUMN STORE COMPRESS FOR ARCHIVE` uses higher compression ratios than `COLUMN STORE COMPRESS FOR QUERY`, and is useful for compressing data that will be stored for long periods of time. Valid values are `LOW` and `HIGH`, with `HIGH` providing the highest possible compression ratio. The default is `LOW`.
Specifying `COLUMN STORE COMPRESS` is equivalent to specifying `COLUMN STORE COMPRESS FOR QUERY HIGH`.

Tables with `COLUMN STORE COMPRESS FOR QUERY` or `COLUMN STORE COMPRESS FOR ARCHIVE` use a PCTFREE value of 0 to maximize compression, unless you explicitly set a value for PCTFREE in the `physical_attributes_clause`. For these tables, PCTFREE has no effect for blocks loaded using direct-path INSERT. PCTFREE is honored for blocks loaded using conventional INSERT, and for blocks created as a result of DML operations on blocks originally loaded using direct-path INSERT.

**[NO] ROW LEVEL LOCKING**

If you specify `ROW LEVEL LOCKING`, then Oracle Database uses row-level locking during DML operations. This improves the performance of these operations when accessing Hybrid Columnar Compressed data. If you specify `NO ROW LEVEL LOCKING`, then row-level locking is not used. The default is `NO ROW LEVEL LOCKING`.

In earlier releases, Hybrid Columnar Compression was enabled using `COMPRESS FOR QUERY` and `COMPRESS FOR ARCHIVE`. This syntax is still supported for backward compatibility.

### See Also:

*Oracle Database Concepts* for more information on Hybrid Columnar Compression, which is a feature of certain Oracle storage systems

### Notes on Table Compression

You can specify table compression for the following portions of a heap-organized table:

- For an entire table, in the `physical_properties` clause of `relational_table` or `object_table`
- For a range partition, in the `table_partition_description` of the `range_partitions` clause
- For a composite range partition, in the `table_partition_description` of the `range_partition_desc` clause
- For a composite list partition, in the `table_partition_description` of the `list_partition_desc` clause
- For a list partition, in the `table_partition_description` of the `list_partitions` clause
- For a system or reference partition, in the `table_partition_description` of the `reference_partition_desc` clause
- For the storage table of a nested table, in the `nested_table_col_properties` clause
Restrictions on Table Compression

Table compression is subject to the following restrictions:

- Data segments of BasicFiles LOBs are not compressed. For information on compression of SecureFiles LOBs, see `LOB_compression_clause`.
- You cannot drop a column from a table that uses `COMPRESS BASIC`, although you can set such a column as unused. All of the operations of the `ALTER TABLE ... drop_column_clause` are valid for tables that use `ROW STORE COMPRESS ADVANCED`, `COLUMN STORE COMPRESS FOR QUERY`, and `COLUMN STORE COMPRESS FOR ARCHIVE`.
- You cannot specify any type of table compression for an index-organized table, any overflow segment or partition of an overflow segment, or any mapping table segment of an index-organized table.
- You cannot specify any type of table compression for external tables or for tables that are part of a cluster.
- You cannot specify any type of table compression for tables with `LONG` or `LONG RAW` columns, tables that are owned by the `SYS` schema and reside in the `SYSTEM` tablespace, or tables with `ROWDEPENDENCIES` enabled.
- You cannot specify Hybrid Columnar Compression on tables that are enabled for flashback archiving.
- You cannot specify Hybrid Columnar Compression on the following object-relational features: object tables, `XMLType` tables, columns with abstract data types, collections stored as tables, or `OPAQUE` types, including `XMLType` columns stored as objects.
- When you update a row in a table compressed with Hybrid Columnar Compression, the `ROWID` of the row may change.
- In tables compressed with Hybrid Columnar Compression, updates to a single row may result in locks on multiple rows. Concurrency for write transactions may therefore be affected.
- If a table compressed with Hybrid Columnar Compression has a foreign key constraint, and you insert data using `INSERT with the APPEND hint`, then the data will be compressed to a lesser level than is typical with Hybrid Columnar Compression. To compress the data with Hybrid Columnar Compression, disable the foreign key constraint, insert the data using `INSERT with the APPEND hint`, and then reenable the foreign key constraint.

`inmemory_table_clause`

Use this clause to enable or disable the table for the In-Memory Column Store (IM column store). The IM column store is an optional, static SGA pool that stores copies of tables and partitions in a special columnar format optimized for rapid scans. The IM
column store does not replace the buffer cache, but acts as a supplement so that both memory areas can store the same data in different formats.

- Specify **INMEMORY** to enable the table for the IM column store.
  
  You can optionally use the `inmemory_attributes` clause to specify how table data is stored in the IM column store. This clause enables you to specify the data compression method and the data population priority. In an Oracle RAC environment, it also enables you to specify how the data is distributed and duplicated across Oracle RAC instances. Refer to the `inmemory_attributes` clause for more information.

- Specify **NO INMEMORY** to disable the table for the IM column store.

- Specify the `inmemory_column_clause` to enable or disable specific table columns for the IM column store, and to specify the data compression method for specific columns. Refer to the `inmemory_column_clause` for more information.

If you omit this clause, then the table is assigned the default IM column store settings for the tablespace in which it is created. Refer to the `inmemory_clause` of `CREATE TABLESPACE` for more information on specifying the default IM column store settings for a tablespace.

In an Oracle Active Data Guard environment, if you specify this clause for a table on the primary database, then the table is enabled or disabled for the IM column store in the Oracle Active Data Guard instance.

**Note:**

The `INMEMORY_CLAUSE_DEFAULT` initialization parameter enables you to specify a default IM column store clause for new tables and materialized views. Refer to `Oracle Database Reference` for more information on the `INMEMORY_CLAUSE_DEFAULT` initialization parameter.

**Restrictions on the In-Memory Column Store**

The following restrictions apply to the In-Memory Column Store:

- You cannot specify the **INMEMORY** clause for index-organized tables.

- You cannot specify the **INMEMORY** clause for tables that are owned by the **SYS** schema and reside in the **SYSTEM** or **SYSAUX** tablespace.

- Starting with Oracle Database 18c, you can specify the **INMEMORY** clause for external tables. You must set the `QUERY_REWRITE_INTEGRITY` initialization parameter to `stale_tolerated` for the DDL to parse correctly. The policy may not be changed via `ALTER` to anything other than `stale_tolerated` if `INMEMORY` is specified.

- The IM column store does not support **LONG** or **LONG RAW** columns, out-of-line columns (LOBs, varrays, nested table columns), or extended data type columns. If you enable a table for the IM column store and it contains any of these types of columns, then the columns will not be populated in the IM column store.

- If you enable a table for the IM column store and it contains a virtual column, then the column will be populated in the IM column store only if the value of the `INMEMORY_VIRTUAL_COLUMNS` initialization parameter is `ENABLED` and the SQL
expression for the virtual column refers only to columns that are enabled for the IM column store.

See Also:
Oracle Database In-Memory Guide for an overview of the IM column store

inmemory_attributes

Use the inmemory_memcompress, inmemory_priority, inmemory_distribute, and inmemory_duplicate clauses to specify how table data is stored in the IM column store.

inmemory_memcompress

Use this clause to specify the compression method for table data stored in the IM column store. This data is called In-Memory data. To instruct the database to not compress In-Memory data, specify NO MEMCOMPRESS. To instruct the database to compress In-Memory data, specify MEMCOMPRESS FOR followed by one of the following methods:

- **DML** - This method is optimized for DML operations and performs little or no data compression.
- **QUERY** - Specifying QUERY is equivalent to specifying QUERY LOW.
- **QUERY LOW** - This method compresses In-Memory data the least (except for DML) and results in the best query performance. This is the default.
- **QUERY HIGH** - This method compresses In-Memory data more than QUERY LOW, but less than CAPACITY LOW.
- **CAPACITY** - Specifying CAPACITY is equivalent to specifying CAPACITY LOW.
- **CAPACITY LOW** - This method compresses In-Memory data more than QUERY HIGH, but less than CAPACITY HIGH, and results in excellent query performance.
- **CAPACITY HIGH** - This method compresses In-Memory data the most and results in good query performance.

inmemory_priority

Use the PRIORITY clause to specify the data population priority for table data in the IM column store. This clause controls the priority of population, but not the speed of population.

- Specify NONE for on-demand population. In this case, the database populates table data in the IM column store when the table it is accessed through a full table scan. If the table is never accessed, or if it is accessed only through an index scan or fetch by rowid, then population never occurs. This is the default.
- Specify one of the following priority levels for priority-based population: LOW, MEDIUM, HIGH, or CRITICAL. In this case, the database automatically populates table data in the IM column store using an internally managed priority queue; a full scan is not a necessary condition for population. The database queues population of the table data based on the specified priority level. For example, a table with the setting INMEMORY PRIORITY CRITICAL takes precedence over a table with the
setting INMEMORY PRIORITY HIGH, which in turn takes precedence over a table with the setting INMEMORY PRIORITY LOW, and so on. If the IM column store has insufficient space, then the database does not populate additional table data until space is available.

\textit{inmemory\_distribute}

The \textit{DISTRIBUTE} clause is applicable only if you are using Oracle Real Application Clusters (Oracle RAC) or Oracle Active Data Guard. It lets you specify how table data in the IM column store is distributed across Oracle RAC instances, and lets you specify the database instances in which the data is eligible to be populated.

\textbf{AUTO and BY}

Use the \texttt{AUTO} and \texttt{BY} clauses to specify how table data in the IM column store is distributed across Oracle RAC instances. You can specify the following options:

- \texttt{AUTO} - Oracle Database controls how data is distributed across Oracle RAC instances. Large tables are distributed across Oracle RAC instances depending on their access patterns. Smaller tables may be distributed between instances. This is the default.
- \texttt{BY ROWID RANGE} - Data in certain ranges of rowids is distributed to different Oracle RAC instances.
- \texttt{BY PARTITION} - Data in partitions is distributed to different Oracle RAC instances.
- \texttt{BY SUBPARTITION} - Data in subpartitions is distributed to different Oracle RAC instances.

You can only use \texttt{AUTO} and \texttt{BY} to distribute the In-Memory Compression Units (IMCUs) for an object between instances in a single Oracle RAC database, not between a primary instance and standby instance in Active Data Guard.

\textbf{FOR SERVICE}

Use the \texttt{FOR SERVICE} clause to specify the Oracle RAC or Oracle Active Data Guard instances in which the object is eligible to be populated. You can specify the following options:

- \texttt{DEFAULT} - The object is eligible for population on all instances specified with the \texttt{PARALLEL\_INSTANCE\_GROUP} initialization parameter. If this parameter is not set, then the object is populated on all instances. This is the default.
- \texttt{ALL} - The object is eligible for population on all instances, regardless of the value of the \texttt{PARALLEL\_INSTANCE\_GROUP} initialization parameter.
- \texttt{service\_name} - The object is eligible for population only on instances belonging to the specified service and only when the service is active and not blocked on an instance.
- \texttt{NONE} - The object is not eligible for population on any instances. This option lets you disable IM column store population while preserving the other In-Memory attributes for the table. These attributes take effect if you subsequently enable IM column store population for the table by specifying \texttt{FOR SERVICE DEFAULT, FOR SERVICE ALL, or FOR SERVICE service\_name in the \textit{inmemory\_distribute} clause of an \texttt{ALTER TABLE} statement.}

In Oracle RAC, the \texttt{FOR SERVICE} clause specifies the instances within the Oracle RAC database. In Active Data Guard, the primary and standby databases may use a single-instance or Oracle RAC configuration. In Active Data Guard, the \texttt{FOR SERVICE}
The DUPLICATE clause is applicable only if you are using Oracle Real Application Clusters (Oracle RAC) on an engineered system. It controls how table data in the IM column store is duplicated across Oracle RAC instances. You can specify the following options:

- **DUPLICATE** - Data is duplicated on one Oracle RAC instance, resulting in the data existing on a total of two Oracle RAC instances.
- **DUPLICATE ALL** - Data is duplicated across all Oracle RAC instances. If you specify DUPLICATE ALL, then the database uses the DISTRIBUTE AUTO setting, regardless of whether or how you specify the `inmemory_distribute` clause.
- **NO DUPLICATE** - Data is not duplicated across Oracle RAC instances. This is the default.

**inmemory_column_clause**

Use this clause to enable or disable specific table columns for the IM column store, and to specify the data compression method for specific columns. If you specify this clause when creating a NO INMEMORY table, then the column settings will take effect when the table or partition is subsequently enabled for the IM column store.

- **Specify INMEMORY** to enable the specified table columns for the IM column store. You can optionally use the `inmemory_memcompress` clause to specify the data compression method for specific columns. See `inmemory_memcompress`. If you omit the `inmemory_memcompress` clause, then the table column uses the data compression method for the table. You cannot specify the PRIORITY, DISTRIBUTE, or DUPLICATE settings for a specific table column. These settings are the same for all table columns as they are for the table.
- **Specify NO INMEMORY** to disable the specified table columns for the IM column store.

If you omit the `inmemory_column_clause`, then all table columns use the IM column store settings for the table.

**Restrictions on inmemory_column_clause**

- You cannot specify this clause for a LONG or LONG RAW column, an out-of-line column (LOB, varray, nested table column), or an extended data type column.
- To selectively enable a virtual column for the IM column store, the value of the INMEMORY_VIRTUAL_COLUMNS initialization parameter must be ENABLED or MANUAL, and the SQL expression for the virtual column must refer only to columns that are enabled for the IM column store.

**inmemory_clause**

Use this clause to enable or disable a table partition for the IM column store. In order to specify this clause, the table must be enabled for the IM column store. If you omit this clause, then the table partition uses the IM column store settings for the table.

The `inmemory_attributes` clause has the same semantics for table partitions as for tables. Refer to the `inmemory_attributes` clause for full information.
You can specify `INMEMORY` on non-partitioned tables using the `ORACLE_HIVE`, `ORACLE_HDFS`, and `ORACLE_BIGDATA` driver types.

**ilm clause**

Use this clause to add an Automatic Data Optimization policy to `table`.

This clause has the same semantics in `CREATE TABLE` and `ALTER TABLE`, with the following additional restriction: You can specify only the `ADD POLICY` clause for `CREATE TABLE`. Refer to the `ilm_clause` for the full semantics of this clause.

**See Also:**

Oracle Database VLDB and Partitioning Guide for more information on managing policies for Automatic Data Optimization

**Restrictions on Automatic Data Optimization**

Automatic Data Optimization is subject to the following restrictions:

- Automatic Data Optimization is not supported for tables that contain object types, index-organized tables, clustered tables, or materialized views.
- Row-level policies are not supported for tables that support Temporal Validity or tables that are enabled for row archiving for In-Database Archiving.

**ilm_policy_clause**

Use this clause to describe the Automatic Data Optimization policy.

This clause has the same semantics in `CREATE TABLE` and `ALTER TABLE`. Refer to `ilm_policy_clause` for the full semantics of this clause.

**RECOVERABLE | UNRECOVERABLE**

These keywords are deprecated and have been replaced with `LOGGING` and `NOLOGGING`, respectively. Although `RECOVERABLE` and `UNRECOVERABLE` are supported for backward compatibility, Oracle strongly recommends that you use the `LOGGING` and `NOLOGGING` keywords.

**Restrictions on [UN]RECOVERABLE**

This clause is subject to the following restrictions:

- You cannot specify `RECOVERABLE` for partitioned tables or LOB storage characteristics.
- You cannot specify `UNRECOVERABLE` for partitioned or index-organized tables.
- You can specify `UNRECOVERABLE` only with `AS subquery`.

**ORGANIZATION**

The `ORGANIZATION` clause lets you specify the order in which the data rows of the table are stored.

**HEAP**
**HEAP** indicates that the data rows of table are stored in no particular order. This is the default.

**INDEX**

INDEX indicates that table is created as an index-organized table. In an index-organized table, the data rows are held in an index defined on the primary key for the table.

**EXTERNAL**

EXTERNAL indicates that table is a read-only table located outside the database.

---

**index_org_table_clause**

Use the index_org_table_clause to create an index-organized table. Oracle Database maintains the table rows, both primary key column values and nonkey column values, in an index built on the primary key. Index-organized tables are therefore best suited for primary key-based access and manipulation. An index-organized table is an alternative to:

- A noncluster table indexed on the primary key by using the CREATE INDEX statement
- A cluster table stored in an indexed cluster that has been created using the CREATE CLUSTER statement that maps the primary key for the table to the cluster key

You must specify a primary key for an index-organized table, because the primary key uniquely identifies a row. The primary key cannot be DEFERRABLE. Use the primary key instead of the rowid for directly accessing index-organized rows.

If an index-organized table is partitioned and contains LOB columns, then you should specify the index_org_table_clause first, then the LOB_storage_clause, and then the appropriate table_partitioning_clauses.

You cannot use the TO_LOB function to convert a LONG column to a LOB column in the subquery of a CREATE TABLE ... AS SELECT statement if you are creating an index-organized table. Instead, create the index-organized table without the LONG column, and then use the TO_LOB function in an INSERT ... AS SELECT statement.

The ROWID pseudocolumn of an index-organized table returns logical rowids instead of physical rowids. A column that you create with the data type ROWID cannot store the logical rowids of the IOT. The only data you can store in a column of type ROWID is rowids from heap-organized tables. If you want to store the logical rowids of an IOT, then create a column of type UROWID instead. A column of type UROWID can store both physical and logical rowids.
Restrictions on Index-Organized Tables

Index-organized tables are subject to the following restrictions:

- You cannot define a virtual column for an index-organized table.
- You cannot specify the `composite_range_partitions`, `composite_list_partitions`, or `composite_hash_partitions` clauses for an index-organized table.
- If the index-organized table is a nested table or varray, then you cannot specify `table_partitioning_clauses`.
- The collations of character data type columns belonging to the primary key of an index-organized table must be `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

**PCTTHRESHOLD integer**

Specify the percentage of space reserved in the index block for an index-organized table row. `PCTTHRESHOLD` must be large enough to hold the primary key. All trailing columns of a row, starting with the column that causes the specified threshold to be exceeded, are stored in the overflow segment. `PCTTHRESHOLD` must be a value from 1 to 50. If you do not specify `PCTTHRESHOLD`, then the default is 50.

**Restriction on PCTTHRESHOLD**

You cannot specify `PCTTHRESHOLD` for individual partitions of an index-organized table.

**mapping_table_clauses**

Specify `MAPPING TABLE` to instruct the database to create a mapping of local to physical `ROWIDs` and store them in a heap-organized table. This mapping is needed in order to create a bitmap index on the index-organized table. If the index-organized table is partitioned, then the mapping table is also partitioned and its partitions have the same name and physical attributes as the base table partitions.

Oracle Database creates the mapping table or mapping table partition in the same tablespace as its parent index-organized table or partition. You cannot query, perform DML operations on, or modify the storage characteristics of the mapping table or its partitions.

**prefix_compression**

The `prefix_compression` clauses let you enable or disable prefix compression for index-organized tables.

- Specify `COMPRESS` to enable `prefix compression`, also known as key compression, for an index-organized table, which eliminates repeated occurrence of primary key column values in index-organized tables. Use `integer` to specify the prefix length, which is the number of prefix columns to compress.
The valid range of prefix length values is from 1 to the number of primary key columns minus 1. The default prefix length is the number of primary key columns minus 1.

- Specify NOCOMPRESS to disable prefix compression in index-organized tables. This is the default.

**Restriction on Prefix Compression of Index-organized Tables**

At the partition level, you can specify COMPRESS, but you cannot specify the prefix length with integer.

`index_org_overflow_clause`

The `index_org_overflow_clause` lets you instruct the database that index-organized table data rows exceeding the specified threshold are placed in the data segment specified in this clause.

- When you create an index-organized table, Oracle Database evaluates the maximum size of each column to estimate the largest possible row. If an overflow segment is needed but you have not specified OVERFLOW, then the database raises an error and does not execute the CREATE TABLE statement. This checking function guarantees that subsequent DML operations on the index-organized table will not fail because an overflow segment is lacking.

- All physical attributes and storage characteristics you specify in this clause after the OVERFLOW keyword apply only to the overflow segment of the table. Physical attributes and storage characteristics for the index-organized table itself, default values for all its partitions, and values for individual partitions must be specified before this keyword.

- If the index-organized table contains one or more LOB columns, then the LOBs will be stored out-of-line unless you specify OVERFLOW, even if they would otherwise be small enough be to stored inline.

- If `table` is partitioned, then the database equipartitions the overflow data segments with the primary key index segments.

**INCLUDING `column_name`**

Specify a column at which to divide an index-organized table row into index and overflow portions. The primary key columns are always stored in the index. `column_name` can be either the last primary key column or any non primary key column. All non primary key columns that follow `column_name` are stored in the overflow data segment.

If an attempt to divide a row at `column_name` causes the size of the index portion of the row to exceed the specified or default PCTTHRESHOLD value, then the database breaks up the row based on the PCTTHRESHOLD value.

**Restriction on the INCLUDING Clause**

You cannot specify this clause for individual partitions of an index-organized table.

**EXTERNAL PARTITION ATTRIBUTES**

Use the EXTERNAL PARTITION ATTRIBUTES clause to specify table level external parameters in a hybrid partitioned table.
**external_table_clause**

Use the `external_table_clause` to create an external table, which allows you to process data that is stored outside the database from within the database without loading any of the data into the database.

Defining an external table only creates metadata in the data dictionary, pointing to data outside the database and providing seamless read only access to such data.

Because external tables have no data in the database, you define them with a small subset of the clauses normally available when creating tables.

In addition to supporting external data residing in operating file systems and Big Data sources and formats such as HDFS and Hive, Oracle supports external data residing in objects via the `DBMS_CLOUD` package.

You can work with data in object stores using the `DBMS_CLOUD` package or by manually defining external tables. Oracle strongly recommends using `DBMS_CLOUD` for the additional functionality that is fully compatible with Oracle autonomous database.

### See Also:

- `DBMS_CLOUD`
- Managing External Tables

Because external tables have no data in the database, you define them with a small subset of the clauses normally available when creating tables.

- Within the `relational_properties` clause, you can specify only `column`, `datatype`, `ENCRYPT`, `inline_constraint`, and `out_of_line_constraint`. You can specify the `ENCRYPT` clause only when you specify the `ORACLE_DATAPUMP` access driver and the `AS subquery` clause to load data into the external table. Within the `inline_constraint` and `out_of_line_constraint` clauses, you can specify all subclauses except `CHECK`.

- Within the `physical_properties` clause, you can specify only the organization of the table (`ORGANIZATION EXTERNAL external_table_clause`).

- Within the `table_properties` clause, you can specify the `parallel_clause`. The `parallel_clause` lets you parallelize subsequent queries on the external data and subsequent operations that populate the external table.

Starting with Oracle Database 12c Release 2 (12.2), you can create a partitioned external table. To do this, within the `table_properties` clause, you can specify the following subclauses of the `table_partitioning_clauses`:

- `range_partitions` - specify this clause to create a range-partitioned or interval-partitioned external table

- `list_partitions` - specify this clause to create a list-partitioned external table. Within this clause, you cannot specify the `AUTOMATIC` clause; an automatic list-partitioned table cannot be an external table.

- `composite_range_partitions` - specify this clause to create a range-range, range-list, interval-range, or interval-list composite-partitioned external table
– composite_list_partitions - specify this clause to create a list-range or list-list composite-partitioned external table. Within this clause, you cannot specify the AUTOMATIC clause; an automatic composite-partitioned table cannot be an external table.

• You can populate the external table at create time by using the AS subquery clause.

No other clauses are permitted in the same CREATE TABLE statement.

See Also:
• “External Table Example”
• ALTER TABLE ... "PROJECT COLUMN Clause" for information on the effect of changing the default property of the column projection
• Oracle Database Data Warehousing Guide, Oracle Database Administrator’s Guide, and Oracle Database Utilities for information on the uses for external tables

Restrictions on External Tables

External tables are subject to the following restrictions:

• An external table cannot be a temporary table.

• You can specify only the following types of constraints on an external table: NOT NULL constraints, unique constraints, primary key constraints, and foreign key constraints. When you specify unique constraints, primary key constraints, or foreign key constraints, you must also specify RELY DISABLE. These constraints are declarative and are not enforced. They can increase query performance and reduce resource consumption because more optimizer transformations can be taken into account. In order for the optimizer to utilize these RELY DISABLE constraints, the QUERY_REWRITE_INTEGRITY initialization parameter must be set to either trusted or stale_tolerated.

• You cannot create an index on an external table.

• An external table cannot contain INVISIBLE columns.

• An external table cannot have object type, varray, or LONG columns. However, you can populate LOB columns of an external table with varray or LONG data from an internal database table.

• Only ORACLE_LOADER and ORACLE_DATAPUMP access types are permitted for external tables that can be populated into the inmemory column store.

TYPE

TYPE access_driver_type indicates the access driver of the external table. The access driver is the API that interprets the external data for the database. Oracle Database provides the following access drivers: ORACLE_LOADER, ORACLE_DATAPUMP, ORACLE_HDFS, and ORACLE_HIVE. If you do not specify TYPE, then the database uses ORACLE_LOADER as the default access driver. You must specify the ORACLE_DATAPUMP access driver if you specify the AS subquery clause to unload data from one Oracle Database and reload it into the same or a different Oracle Database.
DEFAULT DIRECTORY

DEFAULT DIRECTORY lets you specify a default directory object corresponding to a
directory on the file system where the external data sources may reside. The default
directory can also be used by the access driver to store auxiliary files such as error
logs.

ACCESS PARAMETERS

The optional ACCESS PARAMETERS clause lets you assign values to the parameters of
the specific access driver for this external table.

- The opaque_format_spec specifies all access parameters for the ORACLE_LOADER,
  ORACLE_DATAPUMP, ORACLE_HDFS, and ORACLE_HIVE access drivers. See Oracle
  Database Utilities for descriptions of the ORACLE_LOADER, ORACLE_DATAPUMP,
  ORACLE_HDFS, and ORACLE_HIVE access parameters.

  Field names specified in the opaque_format_spec must match columns in the table
definition. Oracle Database ignores any field in the opaque_format_spec that is not
matched by a column in the table definition.

- USING CLOB subquery lets you derive the parameters and their values through a
  subquery. The subquery cannot contain any set operators or an ORDER BY clause. It
  must return one row containing a single item of data type CLOB.

Whether you specify the parameters in an opaque_format_spec or derive them using a
subquery, the database does not interpret anything in this clause. It is up to the access
driver to interpret this information in the context of the external data.

For inline external tables and external modify query statements you must use
opaque_format_spec within single quotes. For DDL statements you must use
opaque_format_spec without single quotes.

LOCATION

The LOCATION clause lets you specify one or more external data sources. Usually the
locationSpecifier is a file, but it need not be. Oracle Database does not interpret
this clause. It is up to the access driver to interpret this information in the context of the
external data.

You must specify the LOCATION clause as follows:

- When creating a nonpartitioned external table, you must specify the LOCATION
  clause at the table level in the external_table_data_props clause.

- When creating a partitioned external table, you must specify the LOCATION clause
  at the partition level in the external_part_subpart_data_props clause.

- When creating a composite-partitioned external table, you must
  specify the LOCATION clause at the subpartition level in the
  external_part_subpart_data_props clause.

REJECT LIMIT
The **REJECT LIMIT** clause lets you specify how many conversion errors can occur during a query of the external data before an Oracle Database error is returned and the query is aborted. The default value is 0.

**CLUSTER Clause**

The **CLUSTER** clause indicates that the table is to be part of *cluster*. The columns listed in this clause are the table columns that correspond to the cluster columns. Generally, the cluster columns of a table are the column or columns that make up its primary key or a portion of its primary key. Refer to **CREATE CLUSTER** for more information.

Specify one column from the table for each column in the cluster key. The columns are matched by position, not by name.

A cluster table uses the space allocation of the cluster. Therefore, do not use the **PCTFREE**, **PCTUSED**, or **INITRANS** parameters, the **TABLESPACE** clause, or the **storage_clause** with the **CLUSTER** clause.

**Restrictions on Cluster Tables**

Cluster tables are subject to the following restrictions:

- Object tables and tables containing LOB columns or columns of the Any* Oracle-supplied types cannot be part of a cluster.
- You cannot specify the **parallel_clause** or **CACHE** or **NOCACHE** for a table that is part of a cluster.
- You cannot specify **CLUSTER** with either **ROWDEPENDENCIES** or **NOROWDEPENDENCIES** unless the cluster has been created with the same **ROWDEPENDENCIES** or **NOROWDEPENDENCIES** setting.
- A cluster table cannot contain **INVISIBLE** columns.

**table_properties**

The **table_properties** further define the characteristics of the table.

**column_properties**

Use the **column_properties** clauses to specify the storage attributes of a column.

**object_type_col_properties**

The **object_type_col_properties** determine storage characteristics of an object column or attribute or of an element of a collection column or attribute.

**column**

For **column**, specify an object column or attribute.

**substitutable_column_clause**

The **substitutable_column_clause** indicates whether object columns or attributes in the same hierarchy are substitutable for each other. You can specify that a column is of a particular type, or whether it can contain instances of its subtypes, or both.

- If you specify **ELEMENT**, then you constrain the element type of a collection column or attribute to a subtype of its declared type.
• The IS OF [TYPE] (ONLY type) clause constrains the type of the object column to a subtype of its declared type.

• NOT SUBSTITUTABLE AT ALL LEVELS indicates that the object column cannot hold instances corresponding to any of its subtypes. Also, substitution is disabled for any embedded object attributes and elements of embedded nested tables and varrays. The default is SUBSTITUTABLE AT ALL LEVELS.

Restrictions on the substitutable_column_clause

This clause is subject to the following restrictions:

• You cannot specify this clause for an attribute of an object column. However, you can specify this clause for a object type column of a relational table and for an object column of an object table if the substitutability of the object table itself has not been set.

• For a collection type column, the only part of this clause you can specify is [NOT] SUBSTITUTABLE AT ALL LEVELS.

LOB_storage_clause

The LOB_storage_clause lets you specify the storage attributes of LOB data segments. You must specify at least one clause after the STORE AS keywords. If you specify more than one clause, then you must specify them in the order shown in the syntax diagram, from top to bottom.

For a nonpartitioned table, this clause specifies the storage attributes of LOB data segments of the table.

For a partitioned table, Oracle Database implements this clause depending on where it is specified:

• For a partitioned table specified at the table level—when specified in the physical_properties clause along with one of the partitioning clauses—this clause specifies the default storage attributes for LOB data segments associated with each partition or subpartition. These storage attributes apply to all partitions or subpartitions unless overridden by a LOB_storage_clause at the partition or subpartition level.

• For an individual partition of a partitioned table—when specified as part of a table_partition_description—this clause specifies the storage attributes of the data segments of the partition or the default storage attributes of any subpartitions of the partition. A partition-level LOB_storage_clause overrides a table-level LOB_storage_clause.

• For an individual subpartition of a partitioned table—when specified as part of subpartition_by_hash or subpartition_by_list—this clause specifies the storage attributes of the data segments of the subpartition. A subpartition-level LOB_storage_clause overrides both partition-level and table-level LOB_storage_clauses.

Restriction on the LOB_storage_clause:

Only the TABLESPACE clause is allowed when specifying the LOB_storage_clause in a subpartition.
LOB_item

Specify the LOB column name or LOB object attribute for which you are explicitly defining tablespace and storage characteristics that are different from those of the table. Oracle Database automatically creates a system-managed index for each LOB_item you create.

SECUREFILE | BASICFILE

Use this clause to specify the type of LOB storage, either high-performance LOB (SecureFiles), or the traditional LOB (BasicFiles).

Note:

You cannot convert a LOB from one type of storage to the other. Instead you must migrate to SecureFiles or BasicFiles by using online redefinition or partition exchange.

LOB_segname

Specify the name of the LOB data segment. You cannot use LOB_segname if you specify more than one LOB_item.

LOB_storage_parameters

The LOB_storage_parameters clause lets you specify various elements of LOB storage.

TABLESPACE Clause

Use this clause to specify the tablespace in which LOB data is to be stored.

TABLESPACE SET Clause

This clause is valid only when creating a sharded table by specifying the SHARDED keyword of CREATE TABLE. Use this clause to specify the tablespace set in which LOB data is to be stored.
**storage_clause**

Use the *storage_clause* to specify various aspects of LOB segment storage. Of particular interest in the context of LOB storage is the MAXSIZE clause of the *storage_clause*, which can be used in combination with the LOB_retention_clause of LOB_parameters. Refer to *storage_clause* for more information.

**LOB_parameters**

Several of the LOB_parameters are no longer needed if you are using SecureFiles for LOB storage. The PCTVERSION and FREEPOOLS parameters are valid and useful only if you are using BasicFiles LOB storage.

**ENABLE STORAGE IN ROW**

If you enable storage in row, then the LOB value is stored in the row (inline) if its length is less than approximately 4000 bytes minus system control information. This is the default.

**Restriction on Enabling Storage in Row**

For an index-organized table, you cannot specify this parameter unless you have specified an OVERFLOW segment in the index_org_table_clause.

**DISABLE STORAGE IN ROW**

If you disable storage in row, then the LOB value is stored outside of the row out of line regardless of the length of the LOB value.

The LOB locator is always stored inline regardless of where the LOB value is stored. You cannot change the value of STORAGE IN ROW once it is set except by moving the table. See the move_table_clause in the ALTER TABLE documentation for more information.

**CHUNK integer**

Specify the number of bytes to be allocated for LOB manipulation. If integer is not a multiple of the database block size, then the database rounds up in bytes to the next multiple. For example, if the database block size is 2048 and integer is 2050, then the database allocates 4096 bytes (2 blocks). The maximum value is 32768 (32K), which is the largest Oracle Database block size allowed. The default CHUNK size is one Oracle Database block.

The value of CHUNK must be less than or equal to the value of NEXT, either the default value or that specified in the storage_clause. If CHUNK exceeds the value of NEXT, then the database returns an error. You cannot change the value of CHUNK once it is set.

**PCTVERSION integer**

Specify the maximum percentage of overall LOB storage space used for maintaining old versions of the LOB. If the database is running in manual undo mode, then the default value is 10, meaning that older versions of the LOB data are not overwritten until they consume 10% of the overall LOB storage space.

You can specify the PCTVERSION parameter whether the database is running in manual or automatic undo mode. PCTVERSION is the default in manual undo mode. RETENTION is the default in automatic undo mode. You cannot specify both PCTVERSION and RETENTION.
This clause is not valid if you have specified SECUREFILE. If you specify both SECUREFILE and PCTVERSION, then the database silently ignores the PCTVERSION parameter.

**LOB_retention_clause**

Use this clause to specify whether you want the LOB segment retained for flashback purposes, consistent-read purposes, both, or neither.

You can specify the RETENTION parameter only if the database is running in automatic undo mode. Oracle Database uses the value of the UNDO_RETENTION initialization parameter to determine the amount of committed undo data to retain in the database. In automatic undo mode, RETENTION is the default value unless you specify PCTVERSION. You cannot specify both PCTVERSION and RETENTION.

You can specify the optional settings after RETENTION only if you are using SecureFiles. The SECUREFILE parameter of the LOB_storage_clause indicates that the database will use SecureFiles to manage storage dynamically, taking into account factors such as the undo mode of the database.

- Specify `MAX` to signify that the undo should be retained until the LOB segment has reached MAXSIZE. If you specify `MAX`, then you must also specify the MAXSIZE clause in the storage_clause.
- Specify `MIN` if the database is in flashback mode to limit the undo retention duration for the specific LOB segment to n seconds.
- Specify `AUTO` if you want to retain undo sufficient for consistent read purposes only.
- Specify `NONE` if no undo is required for either consistent read or flashback purposes.

If you do not specify the RETENTION parameter, or you specify RETENTION with no optional settings, then RETENTION is set to DEFAULT, which is functionally equivalent to AUTO.

---

**See Also:**

- CREATE TABLE clause [LOB_storage_parameters](#) for more information on simplified LOB storage using SecureFiles
- Oracle Database SecureFiles and Large Objects Developer's Guide for more information on using SecureFiles
- [flashback_mode_clause](#) of ALTER DATABASE for information on putting a database in flashback mode
- “Creating an Undo Tablespace: Example”

**FREEPOOLS integer**

Specify the number of groups of free lists for the LOB segment. Normally `integer` will be the number of instances in an Oracle Real Application Clusters environment or 1 for a single-instance database.

You can specify this parameter only if the database is running in automatic undo mode. In this mode, FREEPOOLS is the default unless you specify the FREELIST GROUPS
parameter of the storage_clause. If you specify neither FREEPOOLS nor FREELIST GROUPS, then the database uses a default of FREEPOOLS 1 if the database is in automatic undo management mode and a default of FREELIST GROUPS 1 if the database is in manual undo management mode.

This clause is not valid if you have specified SECUREFILE. If you specify both SECUREFILE and FREEPOOLS, then the database silently ignores the FREEPOOLS parameter.

Restriction on FREEPOOLS

You cannot specify both FREEPOOLS and the FREELIST GROUPS parameter of the storage_clause.

LOB_deduplicate_clause

This clause is valid only for SecureFiles LOBs. Use the LOB_deduplicate_clause to enable or disable LOB deduplication, which is the elimination of duplicate LOB data.

The DEDUPLICATE keyword instructs the database to eliminate duplicate copies of LOBs. Using a secure hash index to detect duplication, the database coalesces LOBs with identical content into a single copy, reducing storage consumption and simplifying storage management.

If you omit this clause, then LOB deduplication is disabled by default.

This clause implements LOB deduplication for the entire LOB segment. To enable or disable deduplication for an individual LOB, use the DBMS_LOB.SETOPTIONS procedure.

See Also:

Oracle Database SecureFiles and Large Objects Developer's Guide for more information about LOB deduplication and Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_LOB package

LOB_compression_clause

This clause is valid only for SecureFiles LOBs, not for BasicFiles LOBs. Use the LOB_compression_clause to instruct the database to enable or disable server-side LOB compression. Random read/write access is possible on server-side compressed LOB segments. LOB compression is independent from table compression or index compression. If you omit this clause, then the default is NOCOMPRESS.

You can specify HIGH, MEDIUM, or LOW to vary the degree of compression. The HIGH degree of compression incurs higher latency than MEDIUM but provides better compression. The LOW degree results in significantly higher decompression and compression speeds, at the cost of slightly lower compression ratio than either HIGH or MEDIUM. If you omit this optional parameter, then the default is MEDIUM.

This clause implements server-side LOB compression for the entire LOB segment. To enable or disable compression on an individual LOB, use the DBMS_LOB.SETOPTIONS procedure.
See Also:

Oracle Database SecureFiles and Large Objects Developer's Guide for more information on server-side LOB storage and Oracle Database PL/SQL Packages and Types Reference for information about client-side LOB compression using the UTL_COMPRESS supplied package and for information about the DBMS_LOB package.

**encrypt | decrypt**

These clauses are valid only for LOBs that are using SecureFiles for LOB storage. Specify `encrypt` to encrypt all LOBs in the column. Specify `decrypt` to keep the LOB in cleartext. If you omit this clause, then `decrypt` is the default.

Refer to `encryption_spec` for general information on that clause. When applied to a LOB column, `encryption_spec` is specific to the individual LOB column, so the encryption algorithm can differ from that of other LOB columns and other non-LOB columns. Use the `encryption_spec` as part of the `column_definition` to encrypt the entire LOB column. Use the `encryption_spec` as part of the `LOB_storage_clause` in the `table_partition_description` to encrypt a LOB partition.

**Restriction on encryption_spec for LOBs**

You cannot specify the `SALT` or `NO SALT` clauses of `encryption_spec` for LOB encryption.

See Also:

Oracle Database SecureFiles and Large Objects Developer's Guide for more information on LOB encryption and Oracle Database PL/SQL Packages and Types Reference for information the DBMS_LOB package.

**cache | nocache | cache reads**

Refer to `cache | nocache | cache reads` for information on these clauses.

**LOB_partition_storage**

The `LOB_partition_storage` clause lets you specify a separate `LOB_storage_clause` or `varray_col_properties` clause for each partition. You must specify the partitions in the order of partition position. You can find the order of the partitions by querying the `PARTITION_NAME` and `PARTITION_POSITION` columns of the `USER_IND_PARTITIONS` view.

If you do not specify a `LOB_storage_clause` or `varray_col_properties` clause for a particular partition, then the storage characteristics are those specified for the LOB item at the table level. If you also did not specify any storage characteristics for the LOB item at the table level, then Oracle Database stores the LOB data partition in the same tablespace as the table partition to which it corresponds.

**Restrictions on LOB_partition_storage**

`LOB_partition_storage` is subject to the following restrictions:
In the `LOB_parameters` of the `LOB_storage_clause`, you cannot specify `encryption_spec`, because it is invalid to specify an encryption algorithm for partitions and subpartitions.

You can only specify the `TABLESPACE` clause for hash partitions and all types of subpartitions.

`varray_col_properties`

The `varray_col_properties` let you specify separate storage characteristics for the LOB in which a varray will be stored. If `varray_item` is a multilevel collection, then the database stores all collection items nested within `varray_item` in the same LOB in which `varray_item` is stored.

- For a nonpartitioned table—when specified in the `physical_properties` clause without any of the partitioning clauses—this clause specifies the storage attributes of the LOB data segments of the varray.
- For a partitioned table specified at the table level—when specified in the `physical_properties` clause along with one of the partitioning clauses—this clause specifies the default storage attributes for the varray LOB data segments associated with each partition (or its subpartitions, if any).
- For an individual partition of a partitioned table—when specified as part of a `table_partition_description`—this clause specifies the storage attributes of the varray LOB data segments of that partition or the default storage attributes of the varray LOB data segments of any subpartitions of this partition. A partition-level `varray_col_properties` overrides a table-level `varray_col_properties`.
- For an individual subpartition of a partitioned table—when specified as part of `subpartition_by_hash` or `subpartition_by_list`—this clause specifies the storage attributes of the varray data segments of this subpartition. A subpartition-level `varray_col_properties` overrides both partition-level and table-level `varray_col_properties`.

`STORE AS [SECUREFILE | BASICFILE] LOB` Clause

If you specify `STORE AS LOB`, then:

- If the maximum varray size is less than approximately 4000 bytes, then the database stores the varray as an inline LOB unless you have disabled storage in row.
- If the maximum varray size is greater than approximately 4000 bytes or if you have disabled storage in row, then the database stores the varray as an out-of-line LOB.

If you do not specify `STORE AS LOB`, then storage is based on the maximum possible size of the varray rather than on the actual size of a varray column. The maximum size of the varray is the number of elements times the element size, plus a small amount for system control information. If you omit this clause, then:

- If the maximum size of the varray is less than approximately 4000 bytes, then the database does not store the varray as a LOB, but as inline data.
- If the maximum size is greater than approximately 4000 bytes, then the database always stores the varray as a LOB.
  - If the actual size is less than approximately 4000 bytes, then it is stored as an inline LOB.
– If the actual size is greater than approximately 4000 bytes, then it is stored as an out-of-line LOB, as is true for other LOB columns.

**substitutable_column_clause**

The **substitutable_column_clause** has the same behavior as described for **object_type_col_properties**.

---

> **See Also:**
>  
> "Substitutable Table and Column Examples"

---

**Restriction on Varray Column Properties**

You cannot specify this clause on an interval partitioned table.

**nested_table_col_properties**

The **nested_table_col_properties** let you specify separate storage characteristics for a nested table, which in turn enables you to define the nested table as an index-organized table. Unless you explicitly specify otherwise in this clause:

- For a nonpartitioned table, the storage table is created in the same schema and the same tablespace as the parent table.
- For a partitioned table, the storage table is created in the default tablespace of the schema. By default, nested tables are equipartitioned with the partitioned base table.
- In either case, the storage table uses default storage characteristics, and stores the nested table values of the column for which it was created.

You must include this clause when creating a table with columns or column attributes whose type is a nested table. Clauses within **nested_table_col_properties** that function the same way they function for the parent table are not repeated here.

**nested_item**

Specify the name of a column, or of a top-level attribute of the object type of the tables, whose type is a nested table.

**COLUMN_VALUE**

If the nested table is a multilevel collection, then the inner nested table or varray may not have a name. In this case, specify **COLUMN_VALUE** in place of the **nested_item** name.

---

> **See Also:**
>  
> "Creating a Table: Multilevel Collection Example" for examples using **nested_item** and **COLUMN_VALUE**

---

**LOCAL | GLOBAL**
Specify `LOCAL` to equipartition the nested table with the base table. This is the default. Oracle Database automatically creates a local partitioned index for the partitioned nested table.

Specify `GLOBAL` to indicate that the nested table is a nonpartitioned nested table of a partitioned base table.

**storage_table**

Specify the name of the table where the rows of `nested_item` reside.

You cannot query or perform DML statements on `storage_table` directly, but you can modify its storage characteristics by specifying its name in an `ALTER TABLE` statement.

---

**See Also:**

- `ALTER TABLE` for information about modifying nested table column storage characteristics

---

**RETURN [AS]**

Specify what Oracle Database returns as the result of a query.

- `VALUE` returns a copy of the nested table itself.
- `LOCATOR` returns a collection locator to the copy of the nested table.

  The locator is scoped to the session and cannot be used across sessions. Unlike a LOB locator, the collection locator cannot be used to modify the collection instance.

If you do not specify the `segment_attributes_clause` or the `LOB_storage_clause`, then the nested table is heap organized and is created with default storage characteristics.

**Restrictions on Nested Table Column Properties**

Nested table column properties are subject to the following restrictions:

- You cannot specify this clause for a temporary table.
- You cannot specify this clause on an interval partitioned table.
- You cannot specify the `oid_clause`.
- At create time, you cannot use `object_properties` to specify an `out_of_line_ref_constraint`, `inline_ref_constraint`, or foreign key constraint for the attributes of a nested table.

---

**See Also:**

- `ALTER TABLE` for information about modifying nested table column storage characteristics
- "Nested Table Example" and "Creating a Table: Multilevel Collection Example"
**XMLType_column_properties**

The XMLType_column_properties let you specify storage attributes for an XMLTYPE column.

**XMLType_storage**

XMLType data can be stored in binary XML, CLOB, or object-relational columns.

- Specify BINARY XML to store the XML data in compact binary XML format. Any LOB parameters you specify are applied to the underlying BLOB column created for storing the binary XML encoded value.

In earlier releases, binary XML data is stored by default in a BasicFiles LOB. Beginning with Oracle Database 11g Release 2 (11.2.0.2), if the COMPATIBLE initialization parameter is 11.2 or higher and you do not specify BASICFILE or SECUREFILE, then binary XML data is stored in a SecureFiles LOB whenever possible. If SecureFiles LOB storage is not possible then the binary XML data is stored in a BasicFiles LOB. This can occur if either of the following is true:
  - The tablespace for the XMLType table does not use automatic segment space management.
  - A setting in file init.ora prevents SecureFiles LOB storage. For example, see parameter DB_SECURITYFILE in Oracle Database Reference.

- Specify CLOB if you want the database to store the XMLType data in a CLOB column. Storing data in a CLOB column preserves the original content and enhances retrieval time.

  If you specify LOB storage, then you can specify either LOB parameters or the XMLSchema_spec clause, but not both. Specify the XMLSchema_spec clause if you want to restrict the table or column to particular schema-based XML instances.

  If you do not specify BASICFILE or SECUREFILE with this clause, then the CLOB column is stored in a BasicFiles LOB.

- Specify OBJECT RELATIONAL if you want the database to store the XMLType data in object-relational columns. Storing data objects relationally lets you define indexes on the relational columns and enhances query performance.

  If you specify object-relational storage, then you must also specify the XMLSchema_spec clause.

Use the ALL VARRAYS AS clause if you want the database to store all varrays in an XMLType column.

In earlier releases, XMLType data is stored in a CLOB column in a BasicFiles LOB by default. Beginning with Oracle Database 11g Release 2 (11.2.0.2), if the COMPATIBLE initialization parameter is 11.2 or higher and you do not specify the XMLType_storage

Note:

Oracle recommends against storing XMLType data in a CLOB column. CLOB storage of XMLType is deprecated. Use binary XML storage of XMLType instead.
clause, then XMLType data is stored in a binary XML column in a SecureFiles LOB. If SecureFiles LOB storage is not possible, then it is stored in a binary XML column in a BasicFiles LOB.

See Also:

Oracle Database SecureFiles and Large Objects Developer’s Guide for more information on SecureFiles LOBs

XMLSchema_spec

Refer to the XMLSchema_spec for the full semantics of this clause.

See Also:

• LOB_storage_clause for information on the LOB_segname and LOB_parameters clauses
• "XMLType Column Examples" for examples of XMLType columns in object-relational tables and "Using XML in SQL Statements " for an example of creating an XMLSchema
• Oracle XML DB Developer’s Guide for more information on XMLType columns and tables and on creating XMLSchemas
• Oracle Database PL/SQL Packages and Types Reference for information on the DBMS_XMLSCHEMA package

XMLType_virtual_columns

This clause is valid only for XMLType tables with binary XML storage, which you designate in the XMLType_storage clause. Specify the VIRTUAL_COLUMNS clause to define virtual columns, which can be used as in a function-based index or in the definition of a constraint. You cannot define a constraint on such a virtual column during creation of the table, but you can use a subsequent ALTER TABLE statement to add a constraint to the column.

See Also:

Oracle XML DB Developer’s Guide for examples of how to use this clause in an XML environment

read_only_clause

This clause lets you specify whether to create a table, partition, or subpartition in read-only or read/write mode.

• Use READ ONLY to specify read-only mode. When an object is in read-only mode, you cannot issue any DML statements that affect the object or any SELECT ... FOR
UPDATE ... statements on the object. You can issue DDL statements as long as they
do not modify any table data. See Oracle Database Administrator’s Guide for the
complete list of operations that are allowed and disallowed on read-only objects.

- Use READ WRITE to specify read/write mode. This is the default.

When you specify this clause for a partitioned table, you specify the default read-only
or read/write mode for the table. This mode is assigned to all partitions in the table
at creation time, as well as any partitions that are subsequently added to the table,
unless you override this behavior by specifying the mode at the partition level.

When you specify this clause for a composite-partitioned table, you specify the default
read-only or read/write mode for all partitions in the table. You can override this
behavior by specifying this clause for a particular partition. The default mode of a
partition is assigned to all subpartitions in the partition at creation time, as well as
any subpartitions that are subsequently added to the partition, unless you override this
behavior by specifying the mode at the subpartition level.

**indexing_clause**

The *indexing_clause* is valid only for partitioned tables. Use this clause to set the
*indexing property* for a table, table partition, or table subpartition.

- Specify INDEXING ON to set the indexing property to ON. This is the default.
- Specify INDEXING OFF to set the indexing property to OFF.

The indexing property determines whether table partitions and subpartitions are
included in partial indexes on the table.

- For simple partitioned tables, partitions with an indexing property of ON are
  included in partial indexes on the table. Partitions with an indexing property of
  OFF are excluded.
- For composite-partitioned tables, subpartitions with an indexing property of ON are
  included in partial indexes on the table. Subpartitions with an indexing property of
  OFF are excluded.

You can specify the *indexing_clause* at the table, partition, or subpartition level.
When you specify the *indexing_clause* at the table level, in the *table_properties*
clause, you set the default indexing property for the table. Interval partitions, which
are automatically created by the database, always inherit the default indexing property
for the table. Other types of partitions and subpartitions inherit the default indexing
property as follows:

- For simple partitioned tables, partitions inherit the default indexing property for the
table. You can override this behavior by specifying the *indexing_clause* for an
  individual partition:
  - For a range partition, in the *table_partition_description* of the
    *range_partitions* clause
  - For a hash partition, in the *individual_hash_partitions* clause of the
    *hash_partitions* clause
  - For a list partition, in the *table_partition_description* of the
    *list_partitions* clause
  - For a reference partition, in the *table_partition_description* of the
    *reference_partition_desc* clause of the *reference_partitioning* clause
For a system partition, in the `table_partition_description` of the `reference_partition_desc` clause of the `system_partitioning` clause

For composite-partitioned tables, subpartitions inherit the default indexing property for the table. You can override this behavior by specifying the `indexing_clause` for an individual partition or subpartition.

If you specify the `indexing_clause` for a partition, then its subpartitions inherit the indexing property of the partition:

- For composite range partitions, in the `table_partition_description` of the `composite_range_partitions` clause
- For composite list partitions, in the `table_partition_description` of the `composite_list_partitions` clause
- For composite hash partitions, in the `individual_hash_partitions` clause of the `composite_hash_partitions` clause

You can set the indexing property of a subpartition by specifying the `indexing_clause` for the subpartition:

- For range subpartitions, in the `range_subpartition_desc` clause of the `composite_range_partitions` clause
- For list subpartitions, in the `list_subpartition_desc` clause of the `composite_list_partitions` clause
- For hash subpartitions, in the `individual_hash_subparts` clause of the `composite_hash_partitions` clause

**See Also:**

*Oracle Database Reference* for information on viewing the indexing property of a table, table partition, or table subpartition.

- To view the default indexing property of a table, query the `DEF_INDEXING` column of the `*_PART_TABLES` views.
- To view the indexing property of a table partition, query the `INDEXING` column of the `*_TAB_PARTITIONS` views.
- To view the indexing property of a table subpartition, query the `INDEXING` column of the `*_TAB_SUBPARTITIONS` views.

**Restrictions on the `indexing_clause`**

The `indexing_clause` is subject to the following restrictions:

- You cannot specify the `indexingClause` for nonpartitioned tables.
- You cannot specify the `indexingClause` for index-organized tables.
See Also:

The partial_index_clause of CREATE INDEX for more information on partial indexes

**table_partitioning_clauses**

Use the table_partitioning_clauses to create a partitioned table.

**Notes on Partitioning in General**

The following notes pertain to all types of partitioning:

- You can specify up to a total of 1024K-1 partitions and subpartitions.
- You can create a partitioned table with just one partition. A table with one partition is different from a nonpartitioned table. For example, you cannot add a partition to a nonpartitioned table.
- You can specify a name for every table and LOB partition and for every table and LOB subpartition, but you need not do so. If you specify a name, then it must conform to the rules for naming schema objects and their parts as described in Database Object Naming Rules. If you omit the name, then the database generates names as follows:
  - If you omit a partition name, then the database generates a name of the form SYS_Pn. System-generated names for LOB data and LOB index partitions take the form SYS_LOB_Pn and SYS_IL_Pn, respectively.
  - If you specify a subpartition name in subpartition_template, then for each subpartition created with that template, the database generates a name by concatenating the partition name with the template subpartition name. For LOB subpartitions, the generated LOB subpartition name is a concatenation of the partition name and the template LOB segment name. If the COMPATIBLE initialization parameter is set to 12.2 or higher, then the maximum length of the concatenation is 128 bytes; otherwise, the maximum length is 30 bytes. If the concatenation exceeds the maximum length, then the database returns an error and the statement fails.
  - If you omit a subpartition name when specifying an individual subpartition, and you have not specified subpartition_template, then the database generates a name of the form SYS_SUBPn. The corresponding system-generated names for LOB data and index subpartitions are SYS_LOB_SUBPn and SYS_IL_SUBPn, respectively.
- Tablespace storage can be specified at various levels in the CREATE TABLE statement for both table segments and LOB segments. The number of tablespaces does not have to equal the number of partitions or subpartitions. If the number of partitions or subpartitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

The database evaluates tablespace storage in the following order of descending priority:

- Tablespace storage specified at the individual table subpartition or LOB subpartition level has the highest priority, followed by storage specified for the partition or LOB in the subpartition_template.
Tables are grouped or 'partitioned' in a tablespace and stored in separate pieces called 'subpartitions'.

- Tablespace storage specified at the individual table partition or LOB partition level. Storage parameters specified here take precedence over the subpartition_template.
- Tablespace storage specified for the table
- Default tablespace storage specified for the user

**Restrictions on Partitioning in General**

All partitioning is subject to the following restrictions:

- You cannot partition a table that is part of a cluster.
- You cannot partition a nested table or varray that is defined as an index-organized table.
- You cannot partition a table containing any LONG or LONG RAW columns.

**Restrictions on Hybrid Partitioned Tables**

Hybrid partitioned tables are subject to the following restrictions:

- Restrictions that apply to external tables also apply to hybrid partitioned tables unless explicitly noted.
- No support for REFERENCE and SYSTEM partitioning methods.
- Only single level LIST and RANGE partitioning are supported.
- No unique indexes or global unique indexes. Only partial indexes are allowed and unique indexes cannot be partial.
- Only single level list partitioning is supported for Hive.
- Attribute clustering (CLUSTERING clause) is not allowed.
- DML operations only on internal partitions of a hybrid partitioned table (external partitions are treated as read-only partitions).
- In-memory defined on the table level only has an effect on internal partitions of the hybrid partitioned table.
- No column default value is allowed.
- Invisible columns are not allowed.
- The CELLMEMORY clause is not allowed.
- SPLIT, MERGE, and MOVE maintenance operations are not allowed on external partitions.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for a discussion of these restrictions.

**See Also:**

"Partitioning Examples"
range_partitions

Use the `range_partitions` clause to partition the table on ranges of values from the column list. For an index-organized table, the column list must be a subset of the primary key columns of the table.

Restrictions on Range Partitioning

Range partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- Partitioning key columns must be of type `CHAR`, `NCHAR`, `VARCHAR2`, `VARCHAR`, `NUMBER`, `FLOAT`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH LOCAL TIMEZONE`, or `RAW`.
- Each range partitioning key column with a character data type that belongs to an `XMLType` table or a table with an `XMLType` column, or that is used as a sharding key column must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`. For all these collations, partition bounds are checked using the collation `BINARY`.
- You cannot specify NULL in the `VALUES` clause.

column

Specify an ordered list of columns used to determine into which partition a row belongs. These columns are the partitioning key. You can specify virtual columns and `INVISIBLE` columns as partitioning key columns.

INTERVAL Clause

Use this clause to establish interval partitioning for the table. Interval partitions are partitions based on a numeric range or datetime interval. They extend range partitioning by instructing the database to create partitions of the specified range or interval automatically when data inserted into the table exceeds all of the range partitions. For each automatically created partition, the database generates a name of the form `SYS_Pn`. The database guarantees that automatically generated partition names are unique and do not violate namespace rules.

- For `expr`, specify a valid number or interval expression.
- The optional `STORE IN` clause lets you specify one or more tablespaces into which the database will store interval partition data.
- You must also specify at least one range partition using the `PARTITION` clause of `range_partitions`. The range partition key value determines the high value of the range partitions, which is called the transition point, and the database creates interval partitions for data beyond that transition point.

Restrictions on Interval Partitioning

The `INTERVAL` clause is subject to the restrictions listed in "Restrictions on Partitioning in General" and "Restrictions on Range Partitioning". The following additional restrictions apply:

- You can specify only one partitioning key column, and it must be of type `NUMBER`, `DATE`, `FLOAT`, or `TIMESTAMP`.
- This clause is not supported for index-organized tables.
- This clause is not supported for tables containing varray columns.
- You cannot create an interval-partitioned table with equipartitioned nested tables. If you create an interval-partitioned table using nested tables or XML object-relational data types, then the nested tables will be created as nonpartitioned tables.
- This clause is supported for tables containing XMLType columns only if the XML data is stored as binary XML.
- Interval partitioning is not supported at the subpartition level.
- Serializable transactions do not work with interval partitioning. Trying to insert data into a partition of an interval partitioned table that does not yet have a segment causes an error.
- In the VALUES clause:
  - You cannot specify MAXVALUE (an infinite upper bound), because doing so would defeat the purpose of the automatic addition of partitions as needed.
  - You cannot specify NULL values for the partitioning key column.

See Also:

Oracle Database VLDB and Partitioning Guide for more information on interval partitioning

PARTITION partition

If you specify a partition name, then the name partition must conform to the rules for naming schema objects and their part as described in "Database Object Naming Rules". If you omit partition, then the database generates a name as described in "Notes on Partitioning in General".

range_values_clause

Specify the noninclusive upper bound for the current partition. The value list is an ordered list of literal values corresponding to the column list in the range_partitions clause. You can substitute the keyword MAXVALUE for any literal in the value list. MAXVALUE specifies a maximum value that will always sort higher than any other value, including null.

Specifying a value other than MAXVALUE for the highest partition bound imposes an implicit integrity constraint on the table.
table_partition_description

Use the table_partition_description to define the physical and storage characteristics of the table.

The clauses deferred_segment_creation, segment_attributes_clause, table_compression, inmemory_clause, and iim_clause have the same function as described for the physical_properties of the table as a whole.

Use the indexing_clause to set the indexing property for a range, list, system, or reference table partition. Refer to the indexing_clause for more information.

The prefix_compression clause and OVERFLOW clause, have the same function as described for the index_org_table_clause.

LOB_storage_clause

The LOB_storage_clause lets you specify LOB storage characteristics for one or more LOB items in this partition or in any range or list subpartitions of this partition. If you do not specify the LOB_storage_clause for a LOB item, then the database generates a name for each LOB data partition as described in "Notes on Partitioning in General".

varray_col_properties

The varray_col_properties let you specify storage characteristics for one or more varray items in this partition or in any range or list subpartitions of this partition.

nested_table_col_properties

The nested_table_col_properties let you specify storage characteristics for one or more nested table storage table items in this partition or in any range or list subpartitions of this partition. Storage characteristics specified in this clause override any storage attributes specified at the table level.

partitioning_storage_clause

Use the partitioning_storage_clause to specify storage characteristics for hash partitions and for range, hash, and list subpartitions.
Restrictions on partitioning_storage_clause

This clause is subject to the following restrictions:

- The TABLESPACE SET clause is valid only when creating a sharded table by specifying the SHARDED keyword of CREATE TABLE. Use this clause to specify the tablespace set in which table partition data is to be stored.
- The OVERFLOW clause is relevant only for index-organized partitioned tables and is valid only within the individual_hash_partitions clause. It is not valid for range or hash partitions or for subpartitions of any type.
- You cannot specify the advanced_index_compression clause of the index_compression clause.
- You can specify the prefix_compression clause of the indexing_clause only for partitions of index-organized tables and you can specify COMPRESS or NOCOMPRESS, but you cannot specify the prefix length with integer.

list_partitions

Use the list_partitions clause to partition the table on a list of literal values for each column in the column list. List partitioning is useful for controlling how individual rows map to specific partitions.

Restrictions on List Partitioning

List partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- You cannot specify more than one partitioning key column when partitioning an index-organized table.
- The partitioning key columns must be of type CHAR, NCHAR, VARCHAR2, NVARCHAR2, VARCHAR, NUMBER, FLOAT, DATE, TIMESTAMP, TIMESTAMP WITH LOCAL TIMEZONE, or RAW.
- Each list partitioning key column with a character data type that belongs to an XMLType table or a table with an XMLType column, or that is used as a sharding key column must have one of the BINARY following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS. For all these collations, partitions are matched using the collation BINARY.

AUTOMATIC

Specify AUTOMATIC to create an automatic list-partitioned table. This type of table enables the database to create additional partitions on demand.

When you create an automatic list-partitioned table, you specify partitions and partitioning key values just as you would when creating a regular list-partitioned table. However, you do not specify a DEFAULT partition. As data is loaded into the table, the database automatically creates a new partition when the loaded partitioning key values do not correspond to any of the existing partitions. If list partitioning is defined with a single partitioning key value, then the database creates a new partition for each new partitioning key value. If list partitioning is defined with multiple partitioning key columns, then the database creates a new partition for each new and unique set of partitioning key values. For each automatically created partition, the database generates a name of the form SYS_Pn. The database guarantees that automatically generated partition names are unique and do not violate namespace rules.
You can specify the AUTOMATIC keyword for list-partitioned tables, and list-range, list-list, list-hash, and list-interval composite-partitioned tables. For composite-partitioned tables, each automatically created list partition will have one subpartition, unless a subpartition template is defined for the table.

If a local partitioned index is defined on an automatic list-partitioned table, then local index partitions will be created when the corresponding table partitions are created.

**Restrictions on Automatic List Partitioning**

Automatic list partitioning is subject to the restrictions listed in "Restrictions on List Partitioning". The following additional restrictions apply:

- An automatic list-partitioned table must have at least one partition when created. Because new partitions are automatically created for new, and unknown, partitioning key values, an automatic list-partitioned table cannot have a DEFAULT partition.
- Automatic list partitioning is not supported for index-organized tables or external tables.
- Automatic list partitioning is not supported for tables containing varray columns.
- You cannot create a local domain index on an automatic list-partitioned table. You can create a global domain index on an automatic list-partitioned table.
- An automatic list-partitioned table cannot be a child table or a parent table for reference partitioning.
- Automatic list partitioning is not supported at the subpartition level.

**STORE IN**

The optional `STORE IN` clause lets you specify one or more tablespaces into which the database will store data for the automatically created list partitions.

**Note:**

You can change an automatic list-partitioned table to a regular list-partitioned table, and vice versa. You can also change the tablespaces into which the database will store data for automatically created list partitions. See the clause `alter_automatic_partitioning` of `ALTER TABLE` for more information.

**list_values_clause**

The `list_values_clause` of each partition must have at least one value. If the table is partitioned on one key column, then use the upper branch of the `list_values` syntax to specify a list of values for that column. In this case, no value, including NULL, can appear in more than one partition. If the table is partitioned on multiple key columns, then use the lower branch of the `list_values` syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. In this case, individual key column values can appear in more than one partition; however, no complete value list can appear in more than one partition. List partitions are not ordered.
If you specify the literal `NULL` for a partition value in the `VALUES` clause, then to access data in that partition in subsequent queries, you must use an `IS NULL` condition in the `WHERE` clause, rather than a comparison condition.

The `DEFAULT` keyword creates a partition into which the database will insert any row that does not map to another partition. Therefore, you can specify `DEFAULT` for only one partition, and you cannot specify any other values for that partition. Further, the default partition must be the last partition you define. The use of `DEFAULT` is similar to the use of `MAXVALUE` for range partitions.

The string comprising the list of values for each partition can be up to 4K bytes. The total number of values for all partitions cannot exceed 64K-1.

The partitioning key column for a list partition can be an extended data type column, which has a maximum size of 32767 bytes. In this case, the list of values that you want to specify for a partition may exceed the 4K byte limit. You can work around this limitation by using one of the following methods:

- Use the `DEFAULT` partition for values that exceed the 4K byte limit.
- Use a hash function, such as `STANDARD_HASH`, in the partition key column to create unique identifiers of lengths less than 4K bytes. See `STANDARD_HASH` for more information.

**Restriction on the `list_values_clause`**

You cannot specify a `DEFAULT` partition for an automatic list-partitioned table.

---

**See Also:**

"Extended Data Types" for more information on extended data types

---

**table_partition_description**

The subclauses of the `table_partition_description` have the same behavior as described for range partitions in `table_partition_description`.

**hash_partitions**

Use the `hash_partitions` clause to specify that the table is to be partitioned using the hash method. Oracle Database assigns rows to partitions using a hash function on values found in columns designated as the partitioning key. You can specify individual hash partitions, or you can specify how many hash partitions the database should create.

**Restrictions on Hash Partitioning**

Hash partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- Partitioning key columns must be of type `CHAR`, `NCHAR`, `VARCHAR2`, `NVARCHAR2`, `VARCHAR`, `NUMBER`, `FLOAT`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH LOCAL TIMEZONE`, or `RAW`.
- Each hash partitioning key column with a character data type that belongs to an `XMLType` table or a table with an `XMLType` column, or that is used as a
sharding key column must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

column
Specify an ordered list of columns used to determine into which partition a row belongs (the partitioning key).

individual_hash_partitions
Use this clause to specify individual partitions by name.

Use the indexing_clause to set the indexing property for a hash partition. Refer to the indexing_clause for more information.

Restriction on Specifying Individual Hash Partitions
The only clauses you can specify in the partitioning_storage_clause are the TABLESPACE clause and table compression.

Note:
If your enterprise has or will have databases using different character sets, then use caution when partitioning on character columns. The sort sequence of characters is not identical in all character sets. Refer to Oracle Database Globalization Support Guide for more information on character set support.

hash_partitions_by_quantity
An alternative to defining individual partitions is to specify the number of hash partitions. In this case, the database assigns partition names of the form SYS_Pn. The STORE IN clause lets you specify one or more tablespaces where the hash partition data is to be stored. The number of tablespaces need not equal the number of partitions. If the number of partitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

For both methods of hash partitioning, for optimal load balancing you should specify a number of partitions that is a power of 2. When you specify individual hash partitions, you can specify both TABLESPACE and table compression in the partitioning_storage_clause. When you specify hash partitions by quantity, you can specify only TABLESPACE. Hash partitions inherit all other attributes from table-level defaults.

The table_compression clause has the same function as described for the table_properties of the table as a whole.

The prefix_compression clause and the OVERFLOW clause have the same function as described for the index_org_table_clause.

Tablespace storage specified at the table level is overridden by tablespace storage specified at the partition level, which in turn is overridden by tablespace storage specified at the subpartition level.

In the individual_hash_partitions clause, the TABLESPACE clause of the partitioning_storage_clause determines tablespace storage only for the individual partition being created. In the hash_partitions_by_quantity clause, the STORE IN
clause determines placement of partitions as the table is being created and the default storage location for subsequently added partitions.

**Restriction on Specifying Hash Partitions by Quantity**

You cannot specify the `advanced_index_compression` clause of the `index_compression` clause.

---

**See Also:**

*Oracle Database VLDB and Partitioning Guide* for more information on hash partitioning

---

**composite_range_partitions**

Use the `composite_range_partitions` clause to first partition table by range, and then partition the partitions further into range, hash, or list subpartitions.

The `INTERVAL` clause has the same semantics for composite range partitioning that it has for range partitioning. Refer to "INTERVAL Clause" for more information.

Specify `subpartition_by_range`, `subpartition_by_hash` or `subpartition_by_list` to indicate the type of subpartitioning you want for each composite range partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement or subsequently created subpartitions.

After establishing the type of subpartitioning you want for the table, and optionally a subpartition template, you must define at least one range partition.

- You must specify the `range_values_clause`, which has the same requirements as for noncomposite range partitions.
- Use the `table_partition_description` to define the physical and storage characteristics of the each partition.
- In the `range_partition_desc`, use `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity` to specify characteristics for the individual subpartitions of the partition. The values you specify in these clauses supersede for these subpartitions any values you have specified in the `subpartition_template`.
- The only characteristics you can specify for a hash or list subpartition or any LOB subpartition are `TABLESPACE` and `table_compression`.

**Restrictions on Composite Range Partitioning**

Regardless of the type of subpartitioning, composite range partitioning is subject to the following restrictions:

- The only physical attributes you can specify at the subpartition level are `TABLESPACE` and table compression.
- You cannot specify composite partitioning for an index-organized table. Therefore, the `OVERFLOW` clause of the `table_partition_description` is not valid for composite-partitioned tables.
You cannot specify composite partitioning for tables containing XMLType columns.

Each range, list, or hash subpartitioning key column with a character data type that belongs to an XMLType table or a table with an XMLType column must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

See Also:
"Composite-Partitioned Table Examples" for examples of composite range partitioning and Oracle Database VLDB and Partitioning Guide for examples of composite list partitioning

composite_list_partitions

Use the composite_list_partitions clause to first partition table by list, and then partition the partitions further into range, hash, or list subpartitions.

Specify subpartition_by_range, subpartition_by_hash or subpartition_by_list to indicate the type of subpartitioning you want for each composite list partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement and for subsequently created subpartitions.

After establishing the type of subpartitioning you want for each composite partition, and optionally defining a subpartition template, you must define at least one list partition.

• In the list_partition_desc, you must specify the list_values_clause, which has the same requirements as for noncomposite list partitions.

• Use the table_partition_description to define the physical and storage characteristics of the each partition.

• In the list_partition_desc, use range_subpartition_desc, list_subpartition_desc, individual_hash_subparts, or hash_subparts_by_quantity to specify characteristics for the individual subpartitions of the partition. The values you specify in these clauses supersede the for these subpartitions any values you have specified in the subpartition_template.

Specify AUTOMATIC to create an automatic list-range, list-list, list-hash, or list-interval composite-partitioned table. This type of table enables the database to create additional partitions on demand. The optional STORE IN clause lets you specify one or more tablespaces into which the database will store data for the automatically created partitions. The AUTOMATIC and STORE IN clauses have the same semantics here as they have for noncomposite list partitions. Refer to AUTOMATIC and STORE IN in the documentation on list_partitions for the full semantics of these clauses. Automatic composite-partitioned tables are subject to the restrictions listed in Restrictions on Composite List Partitioning and Restrictions on Automatic List Partitioning.

Restrictions on Composite List Partitioning

Composite list partitioning is subject to the same restrictions as described in "Restrictions on Composite Range Partitioning".
**composite_hash_partitions**

Use the `composite_hash_partitions` clause to first partition table using the hash method, and then partition the partitions further into range, hash, or list subpartitions.

Specify `subpartition_by_range`, `subpartition_by_hash` or `subpartition_by_list` to indicate the type of subpartitioning you want for each composite range partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement or subsequently created subpartitions.

After establishing the type of subpartitioning you want for the table, you must specify `individual_hash_partitions` or `hash_partitions_by_quantity`.

**Restrictions on Composite Hash Partitioning**

Composite hash partitioning is subject to the same restrictions as described in "Restrictions on Composite Range Partitioning".

**subpartition_template**

The `subpartition_template` is an optional element of range, list, and hash subpartitioning. The template lets you define default subpartitions for each table partition. Oracle Database will create these default subpartition characteristics in any partition for which you do not explicitly define subpartitions. This clause is useful for creating symmetric partitions. You can override this clause by explicitly defining subpartitions at the partition level, in the `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity clause`.

When defining subpartitions with a template, you can explicitly define range, list, or hash subpartitions, or you can define a quantity of hash subpartitions.

- To explicitly define subpartitions, use `range_subpartition_desc`, `list_subpartition_desc`, or `individual_hash_subparts`. You must specify a name for each subpartition. If you specify the `LOB_partitioning_clause` of the `partitioning_storage_clause`, then you must specify `LOB_segname`.

- To define a quantity of hash subpartitions, specify a positive integer for `hash_subpartition_quantity`. The database creates that number of subpartitions in each partition and assigns subpartition names of the form `SYS_SUBPn`.

**Note:**

When you specify tablespace storage for the subpartition template, it does not override any tablespace storage you have specified explicitly for the partitions of `table`. To specify tablespace storage for subpartitions, do one of these things:

- Omit tablespace storage at the partition level and specify tablespace storage in the subpartition template.
- Define individual subpartitions with specific tablespace storage.

**Restrictions on Subpartition Templates**
Subpartition templates are subject to the following restrictions:

- If you specify `TABLESPACE` for one LOB subpartition, then you must specify `TABLESPACE` for all of the LOB subpartitions of that LOB column. You can specify the same tablespace for more than one LOB subpartition.
- If you specify separate LOB storage for list subpartitions using the `partitioning_storage_clause`, either in the `subpartition_template` or when defining individual subpartitions, then you must specify `LOB_segname` for both LOB and varray columns.

**subpartition_by_range**

Use the `subpartition_by_range` clause to indicate that the database should subpartition by range each partition in `table`. The subpartitioning column list is unrelated to the partitioning key but is subject to the same restrictions (see `column`).

You can use the `subpartition_template` to specify default subpartition characteristic values. See `subpartition_template`. The database uses these values for any subpartition in this partition for which you do not explicitly specify the characteristic.

You can also define range subpartitions individually for each partition using the `range_subpartition_desc` of `range_partition_desc` or `list_partition_desc`. If you omit both `subpartition_template` and the `range_subpartition_desc`, then the database creates a single `MAXVALUE` subpartition.

**subpartition_by_list**

Use the `subpartition_by_list` clause to indicate that the database should subpartition each partition in the table on lists of literal values from the `column` list. You can specify a maximum of 16 list subpartitioning key columns.

You can use the `subpartition_template` to specify default subpartition characteristic values. See `subpartition_template`. The database uses these values for any subpartition in this partition for which you do not explicitly specify the characteristic.

You can also define list subpartitions individually for each partition using the `list_subpartition_desc` of `range_partition_desc` or `list_partition_desc`. If you omit both `subpartition_template` and the `list_subpartition_desc`, then the database creates a single `DEFAULT` subpartition.

**Restrictions on List Subpartitioning**

List subpartitioning is subject to the same restrictions as described in Restrictions on Composite Range Partitioning.

**subpartition_by_hash**

Use the `subpartition_by_hash` clause to indicate that the database should subpartition by hash each partition in `table`. The subpartitioning column list is unrelated to the partitioning key but is subject to the same restrictions (see `column`).

You can define the subpartitions using the `subpartition_template` or the `SUBPARTITIONS integer` clause. See `subpartition_template`. In either case, for optimal load balancing you should specify a number of partitions that is a power of 2.

If you specify `SUBPARTITIONS integer`, then you determine the default number of subpartitions in each partition of `table`, and optionally one or more tablespaces in which they are to be stored. The default value is 1. If you omit both this clause and
subpartition_template, then the database will create each partition with one hash subpartition.

**Notes on Composite Partitions**

The following notes apply to composite partitions:

- For all subpartitions, you can use the `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity` to specify individual subpartitions by name, and optionally some other characteristics.

- Alternatively, for hash and list subpartitions:
  - You can specify the number of subpartitions and optionally one or more tablespaces where they are to be stored. In this case, Oracle Database assigns subpartition names of the form `SYS_SUBPn`.
  - If you omit the subpartition description and if you have created a subpartition template, then the database uses the template to create subpartitions. If you have not created a subpartition template, then the database creates one hash subpartition or one `DEFAULT` list subpartition.

- For all types of subpartitions, if you omit the subpartitions description entirely, then the database assigns subpartition names as follows:
  - If you have specified a subpartition template and you have specified partition names, then the database generates subpartition names of the form `partition_name underscore (_) subpartition_name` (for example, `P1_SUB1`).
  - If you have not specified a subpartition template or if you have specified a subpartition template but did not specify partition names, then the database generates subpartition names of the form `SYS_SUBPn`.

**reference_partitioning**

Use this clause to partition the table by reference. Partitioning by reference is a method of equipartitioning the table being created (the *child table*) by a referential constraint to an existing partitioned table (the *parent table*). When you partition a table by reference, partition maintenance operations subsequently performed on the parent table automatically cascade to the child table. Therefore, you cannot perform partition maintenance operations on a reference-partitioned table directly.

If the parent table is an interval-partitioned table, then partitions in the reference-partitioned child table that correspond to interval partitions in the parent table will be created during inserts into the child table. When an interval partition in a child table is created, the partition name is inherited from the associated parent table partition. If the child table has a table-level default tablespace, then it will be used as the tablespace for the new interval partition. Otherwise, the tablespace will be inherited from the parent table partition. Refer to *Oracle Database VLDB and Partitioning Guide* for more information on referencing an interval-partitioned table.

**constraint**

The partitioning referential constraint must meet the following conditions:

- You must specify a referential integrity constraint defined on the table being created, which must refer to a primary key or unique constraint on the parent table. The constraint must be in `ENABLE VALIDATE NOT DEFERRABLE` state, which is the default when you specify a referential integrity constraint during table creation.
• All foreign key columns referenced in the constraint must be NOT NULL.
• When you specify the constraint, you cannot specify the ON DELETE SET NULL clause of the `references_clause`.
• The parent table referenced in the constraint must be an existing partitioned table. It can be partitioned by any method.
• The foreign and parent keys cannot contain any virtual columns that reference PL/SQL functions or LOB columns.

`reference_partition_desc`

Use this optional clause to specify partition names and to define the physical and storage characteristics of the partition. The subclauses of the `table_partition_description` have the same behavior as described for range partitions in `table_partition_description`.

If you specify this clause when creating a reference-partitioned child table whose parent is an interval-partitioned table, then the partition descriptors are used for the child table's non-interval partitions. Partition descriptors cannot be specified for interval partitions.

Restrictions on Reference Partitioning

Reference partitioning is subject to the restrictions listed in Restrictions on Partitioning in General. The following additional restrictions apply:

• Restrictions for reference partitioning are derived from the partitioning strategy of the parent table.
• Neither the parent table nor the child table can be an automatic list-partitioned table.
• You cannot specify this clause for an index-organized table, an external table, or a domain index storage table.
• The parent table can be partitioned by reference, but `constraint` cannot be self-referential. The table being created cannot be partitioned based on a reference to itself.
• If `ROW MOVEMENT` is enabled for the parent table, it must also be enabled for the child table.

See Also:

Oracle Database VLDB and Partitioning Guide for more information on partitioning by reference and “Reference Partitioning Example”

`system_partitioning`

Use this clause to create system partitions. System partitioning does not entail any partitioning key columns, nor do system partitions have any range or list bounds or hash algorithms. Rather, they provide a way to equipartition dependent tables such as nested table or domain index storage tables with partitioned base tables.

• If you specify only `PARTITION BY SYSTEM`, then the database creates one partition with a system-generated name of the form `SYS_Pn`.
If you specify PARTITION BY SYSTEM PARTITIONS integer, then the database creates as many partitions as you specify in integer, which can range from 1 to 1024K-1.

The description of the partition takes the same syntax as reference partitions, so they share the reference_partition_desc. You can specify additional partition attributes with the reference_partition_desc syntax. However, within the table_partition_description, you cannot specify the OVERFLOW clause.

Restrictions on System Partitioning

System partitioning is subject to the following restrictions:

- You cannot system partition an index-organized table or a table that is part of a cluster.
- Composite partitioning is not supported with system partitioning.
- You cannot split a system partition.
- You cannot specify system partitioning in a CREATE TABLE ... AS SELECT statement.
- To insert data into a system-partitioned table using an INSERT INTO ... AS subquery statement, you must use partition-extended syntax to specify the partition into which the values returned by the subquery will be inserted.

See Also:

Refer to Oracle Database Data Cartridge Developer’s Guide for information on the uses for system partitioning and "References to Partitioned Tables and Indexes "

consistent_hash_partitions

This clause is valid only for sharded tables. Use this clause to create consistent hash partitions.

Each sharding key column with a character data type must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

consistent_hash_with_subpartitions

This clause is valid only for sharded tables. Use this clause to create consistent hash with subpartitions.

Each sharding key column with a character data type must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

range_partitionset_clause

Use this clause to create a range partition set.

In the SUBPARTITION BY clause, within the subpartition_template clause, you cannot specify a tablespace for a subpartition. That is, for range, list, and individual hash subpartitions, you cannot specify the TABLESPACE clause of the partitioning_storage_clause, and in the hash_subpartitions_by_quantity clause, you cannot specify the STORE IN (tablespace) clause.
In the `PARTITIONS AUTO` clause, within the `subpartition_template` clause of the `range_partitionset_desc` clause, you can specify a tablespace for a subpartition.

Each super sharding or sharding key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

**list_partitionset_clause**

Use this clause to create a list partition set.

In the `SUBPARTITION` clause, within the `subpartition_template` clause, you cannot specify a tablespace for a subpartition. That is, for range, list, and individual hash subpartitions, you cannot specify the `TABLESPACE` clause of the `partitioning_storage_clause`, and in the `hash_subpartitions_by_quantity` clause, you cannot specify the `STORE IN (tablespace)` clause.

In the `PARTITIONS AUTO` clause, within the `subpartition_template` clause of the `list_partitionset_desc` clause, you can specify a tablespace for a subpartition.

Each super sharding or sharding key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

**attribute_clustering Clause**

Use this clause to enable the table for attribute clustering. Attribute clustering lets you cluster data in close physical proximity based on the content of specified columns.

Attribute clustering can be based only on columns in `table` or on joined values from other tables. The latter is called join attribute clustering.

<table>
<thead>
<tr>
<th>See Also:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database Data Warehousing Guide for more information on attribute clustering</td>
</tr>
</tbody>
</table>

**clustering join**

Use this clause to specify join attribute clustering. Use the `JOIN` clause to specify the joined values from other tables on which to base the attribute clustering. You can specify a maximum of four `JOIN` clauses.

**cluster_clause**

Use this clause to specify the type of ordering to use for the table: linear ordering or interleaved ordering. If you do not specify the `LINEAR` or `INTERLEAVED` keyword, then the default is `LINEAR`.

**BY LINEAR ORDER**

Use this clause to specify linear ordering. This type of ordering stores data according to the order of the specified columns. If you specify this clause, then you can specify only one clustering column group, which can contain at most 10 columns.

**BY INTERLEAVED ORDER**
Use this clause to specify interleaved ordering. This type of ordering uses a special multidimensional clustering technique, similar to z-ordering, that permits multicolumn clustering. If you specify this clause, then you can specify at most four clustering column groups, with a maximum of 40 columns across all groups.

**clustering_columns**

Use this clause to specify one or more clustering column groups.

**clustering_column_group**

Use this clause to specify one or more columns to be included in the clustering column group.

**Restriction on Attribute Clustering Columns**

Each character column in the clustering column group must have one of the following declared collations: `BINARY` or `USING_NLS_COMP`.

**clustering_when**

Use these clauses to allow or disallow attribute clustering during direct-path insert operations and data movement operations.

**ON LOAD**

Specify `YES ON LOAD` to allow, or `NO ON LOAD` to disallow, attribute clustering during direct-path inserts (serial or parallel) resulting either from an `INSERT` or a `MERGE` operation.

The default is `YES ON LOAD`.

**ON DATA MOVEMENT**

Specify `YES ON DATA MOVEMENT` to allow, or `NO ON DATA MOVEMENT` to disallow, attribute clustering for data movement that occurs during the following operations:

- Data redefinition using the `DBMS_REDEFINITION` package
- Table partition maintenance operations that are specified by the following clauses of `ALTER TABLE`: `coalesce_table, merge_table_partitions, move_table_partition, and split_table_partition`

The default is `YES ON DATA MOVEMENT`.

**zonemap_clause**

Use this clause to create a zone map on the table. The zone map tracks the columns specified in the `clustering_columns` clause.

- Specify `WITH MATERIALIZED ZONEMAP` to create a zone map. For `zonemap_name`, specify the name of the zone map to be created. If you omit `zonemap_name`, then the name of the zone map is `ZMAP$_table`.
- Specify `WITHOUT MATERIALIZED ZONEMAP` to not create a zone map. This is the default.

If you subsequently drop the table or use the `ALTER TABLE` statement to drop clustering or modify clustering ... `WITHOUT MATERIALIZED ZONEMAP`, then the zone map will be dropped.
See Also:

CREATE MATERIALIZED ZONEMAP for more information on zone maps

Restrictions on Attribute Clustering

The following restrictions apply to attribute clustering:

- Attribute clustering is not supported for temporary tables or external tables.
- The table being created must be a heap-organized table. However, tables specified in the `clustering_join` clause can be heap-organized or index-organized tables.
- Clustering columns must be of a scalar data type and cannot be encrypted.
- If you specify `BY LINEAR ORDER`, then you can specify only one clustering column group, which can contain at most 10 columns.
- If you specify `BY INTERLEAVED ORDER`, then you can specify at most four clustering column groups, with a maximum of 40 columns across all groups.
- For join attribute clustering:
  - The number of dimension tables cannot exceed four.
  - The join to the table or tables providing the attribute clustering columns must be on a unique key or primary key column to avoid row duplication.
- Attribute clustering will not order rows that are inserted using `MERGE` statements or multitable insert operations.

**CACHE | NOCACHE | CACHE READS**

Use these clauses to indicate how Oracle Database should store blocks in the buffer cache. For LOB storage, you can specify `CACHE`, `NOCACHE`, or `CACHE READS`. For other types of storage, you can specify only `CACHE` or `NOCACHE`.

If you omit these clauses, then:

- In a `CREATE TABLE` statement, `NOCACHE` is the default.
- In an `ALTER TABLE` statement, the existing value is not changed.

The behavior of `CACHE` and `NOCACHE` described in this section does not apply when Oracle Database chooses to use direct reads or to perform table scans using parallel query.

**CACHE**

For data that is accessed frequently, this clause indicates that the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables.
See Also:

Oracle Database Concepts for more information on how the database maintains the least recently used (LRU) list

As a parameter in the LOB_storage_clause, CACHE specifies that the database places LOB data values in the buffer cache for faster access. The database evaluates this parameter in conjunction with the logging_clause. If you omit this clause, then the default value for both BasicFiles and SecureFiles LOBs is NOCACHE LOGGING.

Restriction on CACHE

You cannot specify CACHE for an index-organized table. However, index-organized tables implicitly provide CACHE behavior.

NOCACHE

For data that is not accessed frequently, this clause indicates that the blocks retrieved for this table are placed at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. NOCACHE is the default for LOB storage.

As a parameter in the LOB_storage_clause, NOCACHE specifies that the LOB values are not brought into the buffer cache. NOCACHE is the default for LOB storage.

Restriction on NOCACHE

You cannot specify NOCACHE for an index-organized table.

CACHE READS

CACHE READS applies only to LOB storage. It specifies that LOB values are brought into the buffer cache only during read operations but not during write operations.

logging_clause

Use this clause to indicate whether the storage of data blocks should be logged or not.

See Also:

logging_clause for a description of the logging_clause when specified as part of LOB_parameters

RESULT_CACHE Clause

Use this clause to determine whether the results of statements or query blocks that name this table are considered for storage in the result cache. Two modes of result caching are available:

• DEFAULT: Result caching is not determined at the table level. The query is considered for result caching if the RESULT_CACHE_MODE initialization parameter is set to FORCE, or if that parameter is set to MANUAL and the RESULT_CACHE hint is specified in the query. This is the default if you omit this clause.
• **FORCE**: If all tables names in the query have this setting, then the query is always considered for caching unless the `NO_RESULT_CACHE` hint is specified for the query. If one or more tables named in the query are set to `DEFAULT`, then the effective table annotation for that query is considered to be `DEFAULT`, with the semantics described above.

You can query the `RESULT_CACHE` column of the `DBA_`, `ALL_`, and `USER_TABLES` data dictionary views to learn the result cache mode of the table.

The `RESULT_CACHE` and `NO_RESULT_CACHE` SQL hints take precedence over these result cache table annotations and the `RESULT_CACHE_MODE` initialization parameter. The `RESULT_CACHE_MODE` setting of `FORCE` in turn takes precedence over this table annotation clause.

**Note:**

The `RESULT_CACHE_MODE` setting of `FORCE` is not recommended, as it can cause significant performance and latching overhead, as database and clients will try to cache all queries.

**See Also:**

- *Oracle Call Interface Programmer's Guide* and *Oracle Database Concepts* for general information about result caching
- *Oracle Database Performance Tuning Guide* for information about using this clause
- *Oracle Database Reference* for information about the `RESULT_CACHE_MODE` initialization parameter and the `*_TABLES` data dictionary views
- "RESULT_CACHE Hint" and "NO_RESULT_CACHE Hint" for information about the hints

**parallel_clause**

The `parallel_clause` lets you parallelize creation of the table and set the default degree of parallelism for queries and the DML `INSERT`, `UPDATE`, `DELETE`, and `MERGE` after table creation.

**Note:**

The syntax of the `parallel_clause` supersedes syntax appearing in earlier releases of Oracle. The superseded syntax is still supported for backward compatibility, but may result in slightly different behavior from that documented.

`NOPARALLEL`
Specify `NOPARALLEL` for serial execution. This is the default.

**PARALLEL**

Specify `PARALLEL` if you want Oracle to select a degree of parallelism equal to the number of CPUs available on all participating instances times the value of the `PARALLEL_THREADS_PER_CPU` initialization parameter.

**PARALLEL integer**

Specification of `integer` indicates the **degree of parallelism**, which is the number of parallel threads used in the parallel operation. Each parallel thread may use one or two parallel execution servers. Normally Oracle calculates the optimum degree of parallelism, so it is not necessary for you to specify `integer`.

> **See Also:**
> `parallel_clause` for more information on this clause

**NOROWDEPENDENCIES | ROWDEPENDENCIES**

This clause lets you specify whether `table` will use **row-level dependency tracking**. With this feature, each row in the table has a system change number (SCN) that represents a time greater than or equal to the commit time of the last transaction that modified the row. You cannot change this setting after `table` is created.

**ROWDEPENDENCIES**

Specify `ROWDEPENDENCIES` if you want to enable row-level dependency tracking. This setting is useful primarily to allow for parallel propagation in replication environments. It increases the size of each row by 6 bytes.

**Restriction on the ROWDEPENDENCIES Clause**

Oracle does not support table compression for tables that use row-level dependency tracking. If you specify both the `ROWDEPENDENCIES` clause and the `table_compression` clause, then the `table_compression` clause is ignored. To remove the `ROWDEPENDENCIES` attribute, you must redefine the table using the `DBMS_REDEFINITION` package or recreate the table.

**NOROWDEPENDENCIES**

Specify `NOROWDEPENDENCIES` if you do not want `table` to use the row-level dependency tracking feature. This is the default.

**enable_disable_clause**

The `enable_disable_clause` lets you specify whether Oracle Database should apply a constraint. By default, constraints are created in **ENABLE VALIDATE** state.

**Restrictions on Enabling and Disabling Constraints**

Enabling and disabling constraints are subject to the following restrictions:

- To enable or disable any integrity constraint, you must have defined the constraint in this or a previous statement.
• You cannot enable a foreign key constraint unless the referenced unique or primary key constraint is already enabled.
• In the index_properties clause of the using_index_clause, the INDEXTYPE IS ... clause is not valid in the definition of a constraint.

See Also:
constraint for more information on constraints and "Creating a Table: ENABLE/DISABLE Examples"

ENABLE Clause
Use this clause if you want the constraint to be applied to the data in the table. This clause is described fully in "ENABLE Clause" in the documentation on constraints.

DISABLE Clause
Use this clause if you want to disable the integrity constraint. This clause is described fully in "DISABLE Clause" in the documentation on constraints.

UNIQUE
The UNIQUE clause lets you enable or disable the unique constraint defined on the specified column or combination of columns.

PRIMARY KEY
The PRIMARY KEY clause lets you enable or disable the primary key constraint defined on the table.

CONSTRAINT
The CONSTRAINT clause lets you enable or disable the integrity constraint named constraint_name.

KEEP | DROP INDEX
This clause lets you either preserve or drop the index Oracle Database has been using to enforce a unique or primary key constraint.

Restriction on Preserving and Dropping Indexes
You can specify this clause only when disabling a unique or primary key constraint.

using_index_clause
The using_index_clause lets you specify an index for Oracle Database to use to enforce a unique or primary key constraint, or lets you instruct the database to create the index used to enforce the constraint.
See Also:

- CREATE INDEX for a description of \textit{index\_attributes}, the \textit{global\_partitioned\_index} and \textit{local\_partitioned\_index} clauses, NOSORT, and the \textit{logging\_clause} in relation to indexes
- \textit{constraint} for information on the \textit{using\_index\_clause} and on PRIMARY KEY and UNIQUE constraints
- “Explicit Index Control Example” for an example of using an index to enforce a constraint

\section*{CASCADE}

Specify \texttt{CASCADE} to disable any integrity constraints that depend on the specified integrity constraint. To disable a primary or unique key that is part of a referential integrity constraint, you must specify this clause.

\subsection*{Restriction on CASCADE}

You can specify \texttt{CASCADE} only if you have specified \texttt{DISABLE}.

\section*{row\_movement\_clause}

The \texttt{row\_movement\_clause} lets you specify whether the database can move a table row. It is possible for a row to move, for example, during table compression or an update operation on partitioned data.

\subsection*{Note:}

If you need static rowids for data access, then do not enable row movement. For a normal (heap-organized) table, moving a row changes the rowid of the row. For a moved row in an index-organized table, the logical rowid remains valid, although the physical guess component of the logical rowid becomes inaccurate.

- Specify \texttt{ENABLE} to allow the database to move a row, thus changing the rowid.
- Specify \texttt{DISABLE} if you want to prevent the database from moving a row, thus preventing a change of rowid.

If you omit this clause, then the database disables row movement.

\subsection*{Restriction on Row Movement}

You cannot specify this clause for a nonpartitioned index-organized table.

\section*{flashback\_archive\_clause}

You must have the \texttt{FLASHBACK ARCHIVE} object privilege on the specified flashback data archive to specify this clause. Use this clause to enable or disable historical tracking for the table.
• Specify `FLASHBACK ARCHIVE` to enable tracking for the table. You can specify `flashback_archive` to designate a particular flashback data archive for this table. The flashback data archive you specify must already exist.

If you omit `flashback_archive`, then the database uses the default flashback data archive designated for the system. If no default flashback data archive has been designated for the system, then you must specify `flashback_archive`.

• Specify `NO FLASHBACK ARCHIVE` to disable tracking for the table. This is the default.

**Restrictions on `flashback_archive_clause`**

Flashback data archives are subject to the following restrictions:

• You cannot specify this clause for a nested table, clustered table, temporary table, remote table, or external table.

• You cannot specify this clause for a table compressed with Hybrid Columnar Compression.

• The table for which you are specifying this clause cannot contain any `LONG` or nested table columns.

• If you specify this clause and subsequently copy the table to a different database —using the export and import utilities or the transportable tablespace feature— then the copied table will not be enabled for tracking and the archived data for the original table will not be available for the copied table.

**See Also:**

• *Oracle Database Development Guide* for general information on using flashback data archives

• *ALTER FLASHBACK ARCHIVE* for information on changing the quota and retention attributes of the flashback data archive, as well as adding or changing tablespace storage for the flashback data archive

**ROW ARCHIVAL**

Specify this clause to enable table for row archival. This clause lets you implement In-Database Archiving, which allows you to designate table rows as active or archived. You can then perform queries on only the active rows within the table.

When you specify this clause, a hidden column `ORA_ARCHIVE_STATE` is created in the table. The column is of data type `VARCHAR2`. You can specify a value of 0 or 1 for this column to indicate whether a row is active (0) or archived (1). If you do not specify a value for `ORA_ARCHIVE_STATE` when inserting data into the table, then the value is set to 0.

• If `ROW_ARCHIVE_VISIBILITY = ACTIVE` for the session, then the database will consider only active rows when performing queries on the table.

• If `ROW_ARCHIVE_VISIBILITY = ALL` for the session, then the database will consider all rows when performing queries on the table.
FOR EXCHANGE WITH TABLE

This clause lets you create a table that matches the structure of an existing partitioned table. The two tables are then eligible for exchanging partitions and subpartitions. For **table**, specify an existing partitioned table. For **schema**, specify the schema that contains the existing partitioned table. If you omit **schema**, then the database assumes the table is in your own schema.

This operation creates a metadata clone, without data, of the partitioned table. The clone has the same column ordering and column properties of the original table. Column properties copied to the clone during this operation include unusable columns, invisible columns, virtual expression columns, functional index expression columns, and other internal settings and attributes. Indexes on the existing partitioned table are not created on the clone table.

You can subsequently use the **exchange_partition_subpart** clause of **ALTER TABLE** to exchange partitions or subpartitions between the two tables. Refer to **exchange_partition_subpart** in the documentation on **ALTER TABLE** for more information.

Restrictions on FOR EXCHANGE WITH TABLE

Each super sharding or sharding key column with a character data type must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.

The following restrictions apply to the **FOR EXCHANGE WITH TABLE** clause:

- If you specify this clause, then you cannot specify the **relational_properties** clause.
- If you specify this clause, then within the **table_properties** clause, you can specify only the **table_partitioning_clause**.
- Within the **table_partitioning_clause** each key column with a character data type must have one of the following declared collations: BINARY, USING_NLS_COMP, USING_NLS_SORT, or USING_NLS_SORT_CS.
- When you create a clone for a partition of a composite-partitioned table, you must explicitly specifying the appropriate **table_partitioning_clause** that matches exactly the subpartitioning of the partition you want to exchange.
- You cannot create a clone of a partitioned index-organized table.
- Oracle does not clone the statistics setup of the partitioned table. For example, if you plan to perform an exchange with a partitioned table for which incremental statistics are enabled, you must manually enable the creation of a table synopsis.
on the clone table. See Oracle Database SQL Tuning Guide for more information on maintaining incremental statistics on partitioned tables.

**AS subquery**

Specify a subquery to determine the contents of the table. The rows returned by the subquery are inserted into the table upon its creation.

For object tables, subquery can contain either one expression corresponding to the table type, or the number of top-level attributes of the table type. Refer to SELECT for more information.

If subquery returns the equivalent of part or all of an existing materialized view, then the database may rewrite the query to use the materialized view in place of one or more tables specified in subquery.

---

**See Also:**

Oracle Database Data Warehousing Guide for more information on materialized views and query rewrite

Oracle Database derives data types and lengths from the subquery. Oracle Database follows the following rules for integrity constraints and other column and table attributes:

- Oracle Database automatically defines on columns in the new table any **NOT NULL** constraints that have a state of **NOT DEFERRABLE** and **VALIDATE**, and were explicitly created on the corresponding columns of the selected table if the subquery selects the column rather than an expression containing the column. If any rows violate the constraint, then the database does not create the table and returns an error.

- **NOT NULL** constraints that were implicitly created by Oracle Database on columns of the selected table (for example, for primary keys) are not carried over to the new table.

- In addition, primary keys, unique keys, foreign keys, check constraints, partitioning criteria, indexes, and column default values are not carried over to the new table.

- If the selected table is partitioned, then you can choose whether the new table will be partitioned the same way, partitioned differently, or not partitioned. Partitioning is not carried over to the new table. Specify any desired partitioning as part of the CREATE TABLE statement before the AS subquery clause.

- A column that is encrypted using Transparent Data Encryption in the selected table will not be encrypted in the new table unless you define the column in the new table as encrypted at create time.

---

**Note:**

Oracle recommends that you encrypt sensitive columns before populating them with data. This will avoid creating clear text copies of sensitive data.
If each column returned by subquery has a column name or is an expression with a specified column alias, then you can omit the columns from the table definition entirely. In this case, the names of the columns of table are the same as the columns in subquery. The exception is creating an index-organized table, for which you must specify the columns in the table definition because you must specify a primary key column.

You can use subquery in combination with the TO_LOB function to convert the values in a LONG column in another table to LOB values in a column of the table you are creating.

**See Also:**
- Oracle Database SecureFiles and Large Objects Developer's Guide for a discussion of why and when to copy LONG data to a LOB
- "Conversion Functions " for a description of how to use the TO_LOB function
- SELECT for more information on the order_by_clause
- Oracle Database SQL Tuning Guide for information on statistics gathering when using the AS subquery clause

**parallel_clause**

If you specify the parallel_clause in this statement, then the database will ignore any value you specify for the INITIAL storage parameter and will instead use the value of the NEXT parameter.

**See Also:**
- storage_clause for information on these parameters

**ORDER BY**

The ORDER BY clause lets you order rows returned by the subquery.

When specified with CREATE TABLE, this clause does not necessarily order data across the entire table. For example, it does not order across partitions. Specify this clause if you intend to create an index on the same key as the ORDER BY key column. Oracle Database will cluster data on the ORDER BY key so that it corresponds to the index key.

**Restrictions on the Defining Query of a Table**

The table query is subject to the following restrictions:

- The number of columns in the table must equal the number of expressions in the subquery.
- The column definitions can specify only column names, default values, and integrity constraints, not data types.
• You cannot define a foreign key constraint in a `CREATE TABLE` statement that contains `AS subquery` unless the table is reference partitioned and the constraint is the table's partitioning referential constraint. In all other cases, you must create the table without the constraint and then add it later with an `ALTER TABLE` statement.

`object_table`

The `OF` clause lets you explicitly create an `object table` of type `object_type`. The columns of an object table correspond to the top-level attributes of type `object_type`. Each row will contain an object instance, and each instance will be assigned a unique, system-generated object identifier when a row is inserted. If you omit `schema`, then the database creates the object table in your own schema.

Object tables, as well as `XMLType` tables, object views, and `XMLType` views, do not have any column names specified for them. Therefore, Oracle defines a system-generated pseudocolumn `OBJECT_ID`. You can use this column name in queries and to create object views with the `WITH OBJECT IDENTIFIER` clause.

---

**See Also:**

"Object Column and Table Examples"

---

`object_table_substitution`

Use the `object_table_substitution` clause to specify whether row objects corresponding to subtypes can be inserted into this object table.

**NOT SUBSTITUTABLE AT ALL LEVELS**

`NOT SUBSTITUTABLE AT ALL LEVELS` indicates that the object table being created is not substitutable. In addition, substitution is disabled for all embedded object attributes and elements of embedded nested tables and arrays. The default is `SUBSTITUTABLE AT ALL LEVELS`.

---

**See Also:**

- `CREATE TYPE` for more information about creating object types

---

`object_properties`

The properties of object tables are essentially the same as those of relational tables. However, instead of specifying columns, you specify attributes of the object.

For `attribute`, specify the qualified column name of an item in an object.

`oid_clause`
The `oid_clause` lets you specify whether the object identifier of the object table should be system generated or should be based on the primary key of the table. The default is `SYSTEM GENERATED`.

**Restrictions on the `oid_clause`**

This clause is subject to the following restrictions:

- You cannot specify `OBJECT IDENTIFIER IS PRIMARY KEY` unless you have already specified a `PRIMARY KEY` constraint for the table.
- You cannot specify this clause for a nested table.

**Note:**

A primary key object identifier is locally unique but not necessarily globally unique. If you require a globally unique identifier, then you must ensure that the primary key is globally unique.

**`oid_index_clause`**

This clause is relevant only if you have specified the `oid_clause` as `SYSTEM GENERATED`. It specifies an index, and optionally its storage characteristics, on the hidden object identifier column.

For `index`, specify the name of the index on the hidden system-generated object identifier column. If you omit `index`, then the database generates a name.

**`physical_properties` and `table_properties`**

The semantics of these clauses are documented in the corresponding sections under relational tables. See `physical_properties` and `table_properties`.

**`XMLType_table`**

Use the `XMLType_table` syntax to create a table of data type `XMLType`. Most of the clauses used to create an `XMLType` table have the same semantics that exist for object tables. The clauses specific to `XMLType` tables are described in this section.

Object tables, as well as `XMLType` tables, object views, and `XMLType` views, do not have any column names specified for them. Therefore, Oracle defines a system-generated pseudocolumn `OBJECT_ID`. You can use this column name in queries and to create object views with the `WITH OBJECT IDENTIFIER` clause.

**`XMLSchema_spec`**

This clause lets you specify the URL of a registered XMLSchema, either in the `XMLSCHEMA` clause or as part of the `ELEMENT` clause, and an XML element name.

You must specify an element, although the XMLSchema URL is optional. If you do specify an XMLSchema URL, then you must already have registered the XMLSchema using the `DBMS_XMLSCHEMA` package.

The optional `STORE ALL VARRAYS AS` clause lets you specify how all varrays in the `XMLType` table or column are to be stored.

- `STORE ALL VARRAYS AS LOBS` indicates that all varrays are to be stored as LOBs.
• **STORE ALL VARRAYS AS TABLES** indicates that all varrays are to be stored as tables.

  The optional **ALLOW | DISALLOW** clauses are valid only if you have specified **BINARY XML** storage.

  • **ALLOW NONSCHEMA** indicates that non-schema-based documents can be stored in the **XMLType** column.

  • **DISALLOW NONSCHEMA** indicates that non-schema-based documents cannot be stored in the **XMLType** column. This is the default.

  • **ALLOW ANYSCHEMA** indicates that any schema-based document can be stored in the **XMLType** column.

  • **DISALLOW ANYSCHEMA** indicates that any schema-based document cannot be stored in the **XMLType** column. This is the default.

---

---

**MEMOPTIMIZE FOR READ**

Use this clause to enable fast lookup. Fast lookup improves the performance high frequency data query operations. The **MEMOPTIMIZE_POOL_SIZE** initialization parameter controls the size of the memoptimize pool. Note that the feature uses additional memory from the SGA.

• You must specify this clause as a top-level attribute of the table, it cannot be specified at the partition or subpartition level.

• You must explicitly enable the table for **MEMOPTIMIZE FOR READ** before you can read data from the table.

**MEMOPTIMIZE FOR WRITE**

Use this clause to enable fast ingest. Fast ingest optimizes memory processing of high frequency single row data inserts from Internet of Things (IoT) applications.

• **MEMOPTIMIZE FOR WRITE** is a top-level attribute and cannot be used at the partition or subpartition level.

• A table must be enabled for **MEMOPTIMIZE FOR WRITE** before data for that table can be written to the IGA.

**PARENT**

You can use this clause to create a child table in a sharded table family.

A sharded table family is a set of tables that are sharded in the same way. Corresponding partitions of all tables in a table family are stored in the same shard.
This enables you to minimize the number of multishard joins when querying data in the table family.

There are two methods for creating a sharded table family. The recommended method involves using reference partitioning. However, if it is impossible or undesirable to create the primary and foreign key constraints that are required for reference partitioning, then you can use the `PARENT` clause to create a sharded table family.

The rules for creating a sharded table family differ depending on which method you use. When you create a sharded table family by using the `PARENT` clause, the following rules apply:

- The sharded table family can contain only two levels of tables: a parent table, and one or more child tables.
- All tables in the family must be explicitly partitioned using the same partitioning scheme. Each table can use a different subpartitioning scheme, or none at all.
- You must first create the parent table, and it must be a sharded table.
- You can then use the `CREATE SHARDED TABLE ... PARENT ...` statement to create each child table. For `table`, specify the name of the parent table. For `schema`, specify the schema that contains the parent table. If you omit `schema`, then the database assumes the parent table is in your own schema.

You can create multiple sharded table families with system sharding but at most one with composite or user-defined sharding.

**See Also:**

`Oracle Database Administrator's Guide` for more information on creating sharded table families using reference partitioning or the `PARENT` clause

**Examples**

**Creating Tables: General Examples**

This statement shows how the `employees` table owned by the sample human resources (hr) schema was created. A hypothetical name is given to the table and constraints so that you can duplicate this example in your test database:

```sql
CREATE TABLE employees_demo
  ( employee_id NUMBER(6),
    first_name VARCHAR2(20),
    last_name VARCHAR2(25),
    CONSTRAINT emp_last_name_nn_demo NOT NULL,
    email VARCHAR2(25),
    CONSTRAINT emp_email_nn_demo NOT NULL,
    phone_number VARCHAR2(20),
    hire_date DATE DEFAULT SYSDATE,
    CONSTRAINT emp_hire_date_nn_demo NOT NULL,
    job_id VARCHAR2(10),
    CONSTRAINT emp_job_nn_demo NOT NULL,
    salary NUMBER(8,2),
    CONSTRAINT emp_salary_nn_demo NOT NULL,
    commission_pct NUMBER(2,2),
    manager_id NUMBER(6),
    department_id NUMBER(4)
  );
```
This table contains twelve columns. The employee_id column is of data type NUMBER. The hire_date column is of data type DATE and has a default value of SYSDATE. The last_name column is of type VARCHAR2 and has a NOT NULL constraint, and so on.

Creating a Table: Storage Example

To define the same employees_demo table in the example tablespace with a small storage capacity, issue the following statement:

```sql
CREATE TABLE employees_demo
(
    employee_id    NUMBER(6),
    first_name     VARCHAR2(20),
    last_name      VARCHAR2(25) CONSTRAINT emp_last_name_nn_demo NOT NULL,
    email          VARCHAR2(25) CONSTRAINT emp_email_nn_demo     NOT NULL,
    phone_number   VARCHAR2(20),
    hire_date      DATE  DEFAULT SYSDATE CONSTRAINT emp_hire_date_nn_demo  NOT NULL,
    job_id         VARCHAR2(10) CONSTRAINT emp_job_nn_demo  NOT NULL,
    salary         NUMBER(8,2) CONSTRAINT emp_salary_nn_demo  NOT NULL,
    commission_pct NUMBER(2,2),
    manager_id     NUMBER(6),
    department_id  NUMBER(4),
    dn             VARCHAR2(300),
    CONSTRAINT emp_salary_min_demo CHECK (salary > 0),
    CONSTRAINT emp_email_uk_demo UNIQUE (email)
) TABLESPACE example
STORAGE (INITIAL 8M);
```

Creating a Table with a DEFAULT ON NULL Column Value: Example

The following statement creates a table myemp, which can be used to store employee data. The department_id column is defined with a DEFAULT ON NULL column value of 50. Therefore, if a subsequent INSERT statement attempts to assign a NULL value to department_id, then the value of 50 will be assigned instead.

```sql
CREATE TABLE myemp (employee_id number, last_name varchar2(25), department_id NUMBER DEFAULT ON NULL 50 NOT NULL);
```

In the employees table, employee_id 178 has a NULL value for department_id:

```sql
SELECT employee_id, last_name, department_id
FROM employees
WHERE department_id IS NULL;
```
Populate the `myemp` table with the `employee_id`, `last_name`, and `department_id` column data from the `employees` table:

```sql
INSERT INTO myemp (employee_id, last_name, department_id)
(SELECT employee_id, last_name, department_id from employees);
```

In the `myemp` table, `employee_id` 178 has a value of 50 for `department_id`:

```sql
SELECT employee_id, last_name, department_id
FROM myemp
WHERE employee_id = 178;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>DEPARTMENT_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>178</td>
<td>Grant</td>
<td>50</td>
</tr>
</tbody>
</table>

Creating a Table with an Identity Column: Examples

The following statement creates a table `t1` with an identity column `id`. The sequence generator will always assign increasing integer values to `id`, starting with 1.

```sql
CREATE TABLE t1 (id NUMBER GENERATED AS IDENTITY);
```

The following statement creates a table `t2` with an identity column `id`. The sequence generator will, by default, assign increasing integer values to `id` in increments of 10 starting with 100.

```sql
CREATE TABLE t2 (id NUMBER GENERATED BY DEFAULT AS IDENTITY (START WITH 100 INCREMENT BY 10));
```

Creating a Table: Temporary Table Example

The following statement creates a temporary table `today_sales` for use by sales representatives in the sample database. Each sales representative session can store its own sales data for the day in the table. The temporary data is deleted at the end of the session.

```sql
CREATE GLOBAL TEMPORARY TABLE today_sales
ON COMMIT PRESERVE ROWS
AS SELECT * FROM orders WHERE order_date = SYSDATE;
```

Creating a Table with Deferred Segment Creation: Example

The following statement creates a table with deferred segment creation. Oracle Database will not create a segment for the data of this table until data is inserted into the table:

```sql
CREATE TABLE later (col1 NUMBER, col2 VARCHAR2(20)) SEGMENT CREATION DEFERRED;
```

Substitutable Table and Column Examples

The following statements create a type hierarchy, which can be used to create a substitutable table. Type `employee_t` inherits the `name` and `ssn` attributes from type `person_t` and in addition has `department_id` and `salary` attributes. Type `part_time_emp_t` inherits all of the attributes from `employee_t` and, through `employee_t`, those of `person_t` and in addition has a `num_hrs` attribute. Type `part_time_emp_t` is final by default, so no further subtypes can be created under it.

```sql
CREATE TYPE person_t AS OBJECT (name VARCHAR2(100), ssn NUMBER) NOT FINAL;
/
CREATE TYPE employee_t UNDER person_t  
  (department_id NUMBER, salary NUMBER) NOT FINAL;
/

CREATE TYPE part_time_emp_t UNDER employee_t (num_hrs NUMBER);
/

The following statement creates a substitutable table from the person_t type:

CREATE TABLE persons OF person_t;

The following statement creates a table with a substitutable column of type person_t:

CREATE TABLE books (title VARCHAR2(100), author person_t);

When you insert into persons or books, you can specify values for the attributes of person_t or any of its subtypes. Examples of insert statements appear in "Inserting into a Substitutable Tables and Columns: Examples".

You can extract data from such tables using built-in functions and conditions. For examples, see the functions TREAT and SYS_TYPEID, and the "IS OF type Condition" condition.

Creating a Table: Parallelism Examples

The following statement creates a table using an optimum number of parallel execution servers to scan employees and to populate dept_80:

CREATE TABLE dept_80 
  PARALLEL 
  AS SELECT * FROM employees 
  WHERE department_id = 80;

Using parallelism speeds up the creation of the table, because the database uses parallel execution servers to create the table. After the table is created, querying the table is also faster, because the same degree of parallelism is used to access the table.

The following statement creates the same table serially. Subsequent DML and queries on the table will also be serially executed.

CREATE TABLE dept_80 
  AS SELECT * FROM employees 
  WHERE department_id = 80;

Creating a Table: ENABLE/DISABLE Examples

The following statement shows how the sample table departments was created. The example defines a NOT NULL constraint, and places it in ENABLE VALIDATE state. A hypothetical name is given to the table so that you can duplicate this example in your test database:

CREATE TABLE departments_demo 
  ( department_id NUMBER(4) 
  , department_name VARCHAR2(30) 
    CONSTRAINT dept_name_nn NOT NULL 
  , manager_id NUMBER(6) 
  , location_id NUMBER(4) 
  , dn VARCHAR2(300) 
  ) ;
The following statement creates the same `departments_demo` table but also defines a disabled primary key constraint:

```sql
CREATE TABLE departments_demo
    ( department_id    NUMBER(4)   PRIMARY KEY DISABLE
    , department_name  VARCHAR2(30)
        CONSTRAINT dept_name_nn  NOT NULL
    , manager_id       NUMBER(6)
    , location_id      NUMBER(4)
    , dn               VARCHAR2(300)
    ) ;
```

**Nested Table Example**

The following statement shows how the sample table `pm.print_media` was created with a nested table column `ad_textdocs_ntab`:

```sql
CREATE TABLE print_media
    ( product_id        NUMBER(6)
    , ad_id             NUMBER(6)
    , ad_composite      BLOB
    , ad_sourcetext     CLOB
    , ad_finaltext      CLOB
    , ad_fltextn        NCLOB
    , ad_textdocs_ntab  textdoc_tab
    , ad_photo          BLOB
    , ad_graphic        BFILE
    , ad_header         adheader_typ
    ) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab;
```

**Creating a Table: Multilevel Collection Example**

The following example shows how an account manager might create a table of customers using two levels of nested tables:

```sql
CREATE TYPE phone AS OBJECT (telephone NUMBER);
/
CREATE TYPE phone_list AS TABLE OF phone;
/
CREATE TYPE my_customers AS OBJECT (
    cust_name VARCHAR2(25),
    phones phone_list);
/
CREATE TYPE customer_list AS TABLE OF my_customers;
/
CREATE TABLE business_contacts (
    company_name VARCHAR2(25),
    company_reps customer_list
    NESTED TABLE company_reps STORE AS outer_ntab
    (NESTED TABLE phones STORE AS inner_ntab);
```

The following variation of this example shows how to use the `COLUMN_VALUE` keyword if the inner nested table has no column or attribute name:

```sql
CREATE TYPE phone AS TABLE OF NUMBER;
/
CREATE TYPE phone_list AS TABLE OF phone;
/
CREATE TABLE my_customers (
    name VARCHAR2(25),
    phone_numbers phone_list)
```
NESTED TABLE phone_numbers STORE AS outer_ntab
(NESTED TABLE COLUMN_VALUE STORE AS inner_ntab);

Creating a Table: LOB Column Example

The following statement is a variation of the statement that created the pm.print_media table with some added LOB storage characteristics:

```
CREATE TABLE print_media_new
  ( product_id        NUMBER(6)
  , ad_id             NUMBER(6)
  , ad_composite      BLOB
  , ad_sourcetext     CLOB
  , ad_finaltext      CLOB
  , ad_fltextn        NCLOB
  , ad_textdocs_ntab  textdoc_tab
  , ad_photo          BLOB
  , ad_graphic        BFILE
  , ad_header         adheader_typ
  ) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab_new
LOB (ad_sourcetext, ad_finaltext) STORE AS
  (TABLESPACE example
   STORAGE (INITIAL 6144)
   CHUNK 4000
   NOCACHE LOGGING);
```

In the example, the database rounds the value of `CHUNK` up to 4096 (the nearest multiple of the block size of 2048).

Index-Organized Table Example

The following statement is a variation of the sample table `hr.countries`, which is index organized:

```
CREATE TABLE countries_demo
  ( country_id      CHAR(2)
    CONSTRAINT country_id_nn_demo NOT NULL
  , country_name    VARCHAR2(40)
  , currency_name   VARCHAR2(25)
  , currency_symbol VARCHAR2(3)
  , region          VARCHAR2(15)
  , CONSTRAINT    country_c_id_pk_demo
    PRIMARY KEY (country_id ) 
  )
ORGANIZATION INDEX
INCLUDING country_name
PCTTHRESHOLD 2
STORAGE
  { INITIAL 4K }
OVERFLOW
STORAGE
  { INITIAL 4K };
```

External Table Example

The following statement creates an external table that represents a subset of the sample table `hr.departments`. The `TYPE` clause specifies that the access driver type for the table is `ORACLE_LOADER`. The `ACCESS PARAMETERS()` clause specifies parameter values for the `ORACLE_LOADER` access driver. These parameters are shown in italics and form the `opaque_format_spec`. The syntax for `opaque_format_spec` depends on the access driver type and is outside the scope of this document. Refer to
Oracle Database Utilities for details on the ORACLE_LOADER access driver and the opaque_format_spec syntax.

```sql
CREATE TABLE dept_external (
  deptno   NUMBER(6),
  dname    VARCHAR2(20),
  loc      VARCHAR2(25)
)
ORGANIZATION EXTERNAL
  (TYPE oracle_loader
   DEFAULT DIRECTORY admin
   ACCESS PARAMETERS
   {
     RECORDS DELIMITED BY newline
     BADFILE 'ulcasel.bad'
     DISCARDFILE 'ulcasel.dis'
     LOGFILE 'ulcasel.log'
     SKIP 20
     FIELDS TERMINATED BY "","" OPTIONALLY ENCLOSED BY '"'
     {
       deptno   INTEGER EXTERNAL(6),
       dname    CHAR(20),
       loc      CHAR(25)
     }
   }
)
LOCATION ('ulcasel.ctl')
)
REJECT LIMIT UNLIMITED;
```

See Also:

"Creating a Directory: Examples" to see how the admin directory was created

**XMLType Examples**

This section contains brief examples of creating an XMLType table or XMLType column. For a more expanded version of these examples, refer to "Using XML in SQL Statements".

**XMLType Table Examples**

The following example creates a very simple XMLType table with one implicit binary XML column:

```sql
CREATE TABLE xwarehouses OF XMLTYPE;
```

The following example creates an XMLSchema-based table. The XMLSchema must already have been created (see "Using XML in SQL Statements" for more information):

```sql
CREATE TABLE xwarehouses OF XMLTYPE
  XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
  ELEMENT "Warehouse";
```

You can define constraints on an XMLSchema-based table, and you can also create indexes on XMLSchema-based tables, which greatly enhance subsequent queries.
You can create object-relational views on XMLType tables, and you can create XMLType views on object-relational tables.

See Also:

- "Using XML in SQL Statements" for an example of adding a constraint
- "Creating an Index on an XMLType Table: Example" for an example of creating an index
- "Creating an XMLType View: Example" for an example of creating an XMLType view

XMLType Column Examples

The following example creates a table with an XMLType column stored as a CLOB. This table does not require an XMLSchema, so the content structure is not predetermined:

```
CREATE TABLE xwarehouses (
    warehouse_id   NUMBER,
    warehouse_spec XMLTYPE)
XMLTYPE warehouse_spec STORE AS CLOB
(TABLESPACE example
 STORAGE (INITIAL 6144)
 CHUNK 4000
 NOCACHE LOGGING);
```

The following example creates a similar table, but stores XMLType data in an object relational XMLType column whose structure is determined by the specified schema:

```
CREATE TABLE xwarehouses (
    warehouse_id   NUMBER,
    warehouse_spec XMLTYPE)
XMLTYPE warehouse_spec STORE AS OBJECT RELATIONAL
XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
ELEMENT "Warehouse";
```

The following example creates another similar table with an XMLType column stored as a SecureFiles CLOB. This table does not require an XMLSchema, so the content structure is not predetermined. SecureFiles LOBs require a tablespace with automatic segment-space management, so the example uses the tablespace created in "Specifying Segment Space Management for a Tablespace: Example".

```
CREATE TABLE xwarehouses (
    warehouse_id   NUMBER,
    warehouse_spec XMLTYPE)
XMLTYPE warehouse_spec STORE AS SECUREFILE CLOB
(TABLESPACE auto_seg_ts
 STORAGE (INITIAL 6144)
 CACHE);
```

Partitioning Examples

Range Partitioning Example
The `sales` table in the sample schema `sh` is partitioned by range. The following example shows an abbreviated variation of the `sales` table. Constraints and storage elements have been omitted from the example.

```sql
CREATE TABLE range_sales
(
    prod_id        NUMBER(6),
    cust_id        NUMBER,
    time_id        DATE,
    channel_id     CHAR(1),
    promo_id       NUMBER(6),
    quantity_sold  NUMBER(3),
    amount_sold    NUMBER(10,2)
)
PARTITION BY RANGE (time_id)

(PARTITION SALES_Q1_1998 VALUES LESS THAN (TO_DATE('01-APR-1998','DD-MON-YYYY'))),
PARTITION SALES_Q2_1998 VALUES LESS THAN (TO_DATE('01-JUL-1998','DD-MON-YYYY'))),
PARTITION SALES_Q3_1998 VALUES LESS THAN (TO_DATE('01-OCT-1998','DD-MON-YYYY'))),
PARTITION SALES_Q4_1998 VALUES LESS THAN (TO_DATE('01-JAN-1999','DD-MON-YYYY'))),
PARTITION SALES_Q1_1999 VALUES LESS THAN (TO_DATE('01-APR-1999','DD-MON-YYYY'))),
PARTITION SALES_Q2_1999 VALUES LESS THAN (TO_DATE('01-JUL-1999','DD-MON-YYYY'))),
PARTITION SALES_Q3_1999 VALUES LESS THAN (TO_DATE('01-OCT-1999','DD-MON-YYYY'))),
PARTITION SALES_Q4_1999 VALUES LESS THAN (TO_DATE('01-JAN-2000','DD-MON-YYYY'))),
PARTITION SALES_Q1_2000 VALUES LESS THAN (TO_DATE('01-APR-2000','DD-MON-YYYY'))),
PARTITION SALES_Q2_2000 VALUES LESS THAN (TO_DATE('01-JUL-2000','DD-MON-YYYY'))),
PARTITION SALES_Q3_2000 VALUES LESS THAN (TO_DATE('01-OCT-2000','DD-MON-YYYY'))),
PARTITION SALES_Q4_2000 VALUES LESS THAN (MAXVALUE));
```

For information about partitioned table maintenance operations, see Oracle Database VLDB and Partitioning Guide.

**Range Partitioning Live SQL Example**

The following statement creates a table partitioned by range:

```sql
CREATE TABLE empl_h
(
    employee_id  NUMBER(6) PRIMARY KEY,
    first_name   VARCHAR2(20),
    last_name    VARCHAR2(25),
    email        VARCHAR2(25),
    phone_number VARCHAR2(20),
    hire_date    DATE DEFAULT SYSDATE,
    job_id       VARCHAR2(10),
    salary       NUMBER(8,2),
    part_name    VARCHAR2(25)
)
PARTITION BY RANGE (hire_date)

(PARTITION hire_q1 VALUES less than(to_date('01-APR-2014', 'DD-MON-YYYY'))),
PARTITION hire_q2 VALUES less than(to_date('01-JUL-2014', 'DD-MON-YYYY'))),
PARTITION hire_q3 VALUES less than(to_date('01-OCT-2014', 'DD-MON-YYYY')));
```

The following statements insert rows into the partitions:

```sql
INSERT INTO empl_h (employee_id, first_name, last_name, email, phone_number, hire_date, job_id, salary, Part_name)
VALUES (1, 'Jane', 'Doe', 'example.com', '415.555.0100', '10-Feb-2014', '1001', 5001,'HIRE_Q1');

INSERT INTO empl_h (employee_id, first_name, last_name, email, phone_number, hire_date, job_id, salary, Part_name)
```
VALUES (2, 'John', 'Doe', 'example.net', '415.555.0101', '10-Apr-2014', '1002', 7001,'HIRE_Q2');

INSERT INTO empl_h (employee_id, first_name, last_name, email, phone_number, hire_date, job_id, salary, Part_name) VALUES (3, 'Isabelle', 'Owl', 'example.org', '415.555.0102', '10-Sep-2014', '1003', 10001,'HIRE_Q3');

INSERT INTO empl_h (employee_id, first_name, last_name, email, phone_number, hire_date, job_id, salary, Part_name) VALUES (4, 'Smith', 'Jones', 'example.in', '415.555.0103', '10-Dec-2014', '1004', 12001,'HIRE_Q4');

The following statements display the partition names using data dictionary tables:

SELECT PARTITION_NAME FROM USER_TAB_PARTITIONS WHERE TABLE_NAME = 'EMPL_H';

PARTITION_NAME
---------------
HIRE_Q1
HIRE_Q2
HIRE_Q3
HIRE_Q4

SELECT TABLE_NAME, PARTITIONING_TYPE, STATUS FROM USER_PART_TABLES WHERE TABLE_NAME = 'EMPL_H';

TABLE_NAME    PARTITIONING_TYPE    STATUS
----------    -----------------    ------
EMPL_H        RANGE            VALID

The following statement creates a table named parts by selecting a particular column from the data dictionary table user_tab_partitions:

CREATE TABLE parts (p_name) AS SELECT PARTITION_NAME FROM USER_TAB_PARTITIONS WHERE TABLE_NAME = 'EMPL_H';

The following statement displays the table data:

select * from parts;

P_NAME
------
HIRE_Q1
HIRE_Q2
HIRE_Q3
HIRE_Q4

The following statement compares the columns from the two tables and displays the information based on the comparison:

select E.HIRE_DATE,E.JOB_ID,P.p_name from empl_h E, parts P where E.Part_name = P.p_name;

<table>
<thead>
<tr>
<th>HIRE_DATE</th>
<th>JOB_ID</th>
<th>P_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>10-FEB-14</td>
<td>1001</td>
<td>HIRE_Q1</td>
</tr>
<tr>
<td>10-APR-14</td>
<td>1002</td>
<td>HIRE_Q2</td>
</tr>
<tr>
<td>10-SEP-14</td>
<td>1003</td>
<td>HIRE_Q3</td>
</tr>
<tr>
<td>10-DEC-14</td>
<td>1004</td>
<td>HIRE_Q4</td>
</tr>
</tbody>
</table>
Interval Partitioning Example

The following example creates a variation of the oe.customers table that is partitioned by interval on the credit_limit column. One range partition is created to establish the transition point. All of the original data in the table is within the bounds of the range partition. Then data is added that exceeds the range partition, and the database creates a new interval partition.

```sql
CREATE TABLE customers_demo (
    customer_id number(6),
    cust_first_name varchar2(20),
    cust_last_name varchar2(20),
    credit_limit number(9,2))
PARTITION BY RANGE (credit_limit)
INTERVAL (1000)
(PARTITION p1 VALUES LESS THAN (5001));
```

```sql
INSERT INTO customers_demo
    (customer_id, cust_first_name, cust_last_name, credit_limit)
    (select customer_id, cust_first_name, cust_last_name, credit_limit
    from customers);
```

Query the USER_TAB_PARTITIONS data dictionary view before the database creates the interval partition:

```sql
SELECT partition_name, high_value FROM user_tab_partitions WHERE table_name = 'CUSTOMERS_DEMO';
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>HIGH_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>5001</td>
</tr>
</tbody>
</table>

Insert data into the table that exceeds the high value of the range partition:

```sql
INSERT INTO customers_demo
    VALUES (699, 'Fred', 'Flintstone', 5500);
```

Query the USER_TAB_PARTITIONS view again after the insert to learn the system-generated name of the interval partition created to accommodate the inserted data. (The system-generated name will vary for each session.)

```sql
SELECT partition_name, high_value FROM user_tab_partitions
    WHERE table_name = 'CUSTOMERS_DEMO'
    ORDER BY partition_name;
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>HIGH_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>5001</td>
</tr>
<tr>
<td>SYS_P44</td>
<td>6001</td>
</tr>
</tbody>
</table>

List Partitioning Example

The following statement shows how the sample table oe.customers might have been created as a list-partitioned table. Some columns and all constraints of the sample table have been omitted in this example.

```sql
CREATE TABLE list_customers (
    customer_id             NUMBER(6),
    cust_first_name         VARCHAR2(20),
    cust_last_name          VARCHAR2(20),
    credit_limit number(9,2))
```

```sql
PARTITION BY LIST (credit_limit)
(PARTITION p1 list VALUES LESS THAN (5000));
```

```sql
INSERT INTO list_customers
    (customer_id, cust_first_name, cust_last_name, credit_limit)
    (select customer_id, cust_first_name, cust_last_name, credit_limit
    from customers);
```

Query the USER_TAB_PARTITIONS view before the database creates the list partition:

```sql
SELECT partition_name, high_value FROM user_tab_partitions WHERE table_name = 'CUSTOMERS_DEMO';
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>HIGH_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>5001</td>
</tr>
</tbody>
</table>

Insert data into the table that exceeds the high value of the list partition:

```sql
INSERT INTO list_customers
    VALUES (699, 'Fred', 'Flintstone', 6000);
```

Query the USER_TAB_PARTITIONS view again after the insert to learn the system-generated name of the list partition created to accommodate the inserted data. (The system-generated name will vary for each session.)

```sql
SELECT partition_name, high_value FROM user_tab_partitions
    WHERE table_name = 'CUSTOMERS_DEMO'
    ORDER BY partition_name;
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>HIGH_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>5001</td>
</tr>
<tr>
<td>SYS_P44</td>
<td>6001</td>
</tr>
</tbody>
</table>
Partitioned Table with LOB Columns Example

This statement creates a partitioned table print_media_demo with two partitions p1 and p2, and a number of LOB columns. The statement uses the sample table pm.print_media.

CREATE TABLE print_media_demo
(
    product_id NUMBER(6),
    ad_id NUMBER(6),
    ad_composite BLOB,
    ad_sourcetext CLOB,
    ad_finaltext CLOB,
    ad_fltextn NCLOB,
    ad_textdocs_ntab textdoc_tab,
    ad_photo BLOB,
    ad_graphic BFILE,
    ad_header adheader_typ
) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab_demo
LOB (ad_composite, ad_photo, ad_finaltext)
STORE AS(STORAGE (INITIAL 20M))
PARTITION BY RANGE (product_id)
(PARTITION p1 VALUES LESS THAN (3000) TABLESPACE tbs_01
LOB (ad_composite, ad_photo)
STORE AS (TABLESPACE tbs_02 STORAGE (INITIAL 10M))
NESTED TABLE ad_textdocs_ntab STORE AS nt_p1 (TABLESPACE example),
PARTITION P2 VALUES LESS THAN (MAXVALUE)
LOB (ad_composite, ad_finaltext)
STORE AS SECUREFILE (TABLESPACE auto_seg_ts)
NESTED TABLE ad_textdocs_ntab STORE AS nt_p2
)
TABLESPACE tbs_03;

Partition p1 will be in tablespace tbs_01. The LOB data partitions for ad_composite and ad_photo will be in tablespace tbs_02. The LOB data partition for the remaining LOB columns will be in tablespace tbs_01. The storage attribute INITIAL is specified for LOB columns ad_composite and ad_photo. Other attributes will be inherited from the default table-level specification. The default LOB storage attributes not specified at the table level will be inherited from the tablespace tbs_02 for columns ad_composite and ad_photo and from tablespace tbs_01 for the remaining LOB columns. LOB index partitions will be in the same tablespaces as the corresponding LOB data partitions. Other storage attributes will be based on values of the corresponding attributes of the LOB data partitions and default attributes of the tablespace where the index partitions reside. The nested table partition for ad_textdocs_ntab will be stored as nt_p1 in tablespace example.

Partition p2 will be in the default tablespace tbs_03. The LOB data for ad_composite and ad_finaltext will be in tablespace auto_seg_ts as SecureFiles LOBs. The LOB data for the remaining LOB columns will be in tablespace tbs_03. The LOB index for columns ad_composite and ad_finaltext will be in tablespace auto_seg_ts.
LOB index for the remaining LOB columns will be in tablespace tbs_03. The nested table partition for ad_textdocs_ntab will be stored as nt_p2 in the default tablespace tbs_03.

Hash Partitioning Example

The sample table oe.product_information is not partitioned. However, you might want to partition such a large table by hash for performance reasons, as shown in this example. The tablespace names are hypothetical in this example.

```sql
CREATE TABLE hash_products
( product_id          NUMBER(6)   PRIMARY KEY
, product_name        VARCHAR2(50)
, product_description VARCHAR2(2000)
, category_id         NUMBER(2)
, weight_class        NUMBER(1)
, warranty_period     INTERVAL YEAR TO MONTH
, supplier_id         NUMBER(6)
, product_status      VARCHAR2(20)
, list_price          NUMBER(8,2)
, min_price           NUMBER(8,2)
, catalog_url         VARCHAR2(50)
, CONSTRAINT product_status_lov_demo
    CHECK (product_status in ('orderable'
                               , 'planned'
                               , 'under development'
                               , 'obsolete'))
)
PARTITION BY HASH (product_id)
PARTITIONS 4
STORE IN (tbs_01, tbs_02, tbs_03, tbs_04);
```

Reference Partitioning Example

The next statement uses the hash_products partitioned table created in the preceding example. It creates a variation of the oe.order_items table that is partitioned by reference to the hash partitioning on the product id of hash_products. The resulting child table will be created with five partitions. For each row of the child table part_order_items, the database evaluates the foreign key value (product_id) to determine the partition number of the parent table hash_products to which the referenced key belongs. The part_order_items row is placed in its corresponding partition.

```sql
CREATE TABLE part_order_items
( order_id        NUMBER(12) PRIMARY KEY,
  line_item_id    NUMBER(3),
  product_id      NUMBER(6) NOT NULL,
  unit_price      NUMBER(8,2),
  quantity        NUMBER(8),
  CONSTRAINT product_id_fk
    FOREIGN KEY (product_id) REFERENCES hash_products(product_id)
)
PARTITION BY REFERENCE (product_id_fk);
```

Composite-Partitioned Table Examples

The table created in the "Range Partitioning Example" divides data by time of sale. If you plan to access recent data according to distribution channel as well as time, then composite partitioning might be more appropriate. The following example creates a copy of that range_sales table but specifies range-hash composite partitioning. The partitions with the most recent data are subpartitioned with both system-generated and
CREATE TABLE composite_sales
(
prod_id NUMBER(6),
cust_id NUMBER,
time_id DATE,
channel_id CHAR(1),
promo_id NUMBER(6),
quantity_sold NUMBER(3),
amount_sold NUMBER(10,2)
)
PARTITION BY RANGE (time_id)
SUBPARTITION BY HASH (channel_id)
(PARTITION SALES_Q1_1998 VALUES LESS THAN (TO_DATE('01-APR-1998','DD-MON-YYYY')),
PARTITION SALES_Q2_1998 VALUES LESS THAN (TO_DATE('01-JUL-1998','DD-MON-YYYY')),
PARTITION SALES_Q3_1998 VALUES LESS THAN (TO_DATE('01-OCT-1998','DD-MON-YYYY')),
PARTITION SALES_Q4_1998 VALUES LESS THAN (TO_DATE('01-JAN-1999','DD-MON-YYYY')),
PARTITION SALES_Q1_1999 VALUES LESS THAN (TO_DATE('01-APR-1999','DD-MON-YYYY')),
PARTITION SALES_Q2_1999 VALUES LESS THAN (TO_DATE('01-JUL-1999','DD-MON-YYYY')),
PARTITION SALES_Q3_1999 VALUES LESS THAN (TO_DATE('01-OCT-1999','DD-MON-YYYY')),
PARTITION SALES_Q4_1999 VALUES LESS THAN (TO_DATE('01-JAN-2000','DD-MON-YYYY')),
PARTITION SALES_Q1_2000 VALUES LESS THAN (TO_DATE('01-APR-2000','DD-MON-YYYY')),
PARTITION SALES_Q2_2000 VALUES LESS THAN (TO_DATE('01-JUL-2000','DD-MON-YYYY'))
SUBPARTITIONS 8,
PARTITION SALES_Q3_2000 VALUES LESS THAN (TO_DATE('01-OCT-2000','DD-MON-YYYY'))
(SUBPARTITION ch_c,
SUBPARTITION ch_i,
SUBPARTITION ch_p,
SUBPARTITION ch_s,
SUBPARTITION ch_t),
PARTITION SALES_Q4_2000 VALUES LESS THAN (MAXVALUE)
SUBPARTITIONS 4)
;

The following examples creates a partitioned table of customers based on the sample table oe.customers. In this example, the table is partitioned on the credit_limit column and list subpartitioned on the nls_territory column. The subpartition template determines the subpartitioning of any subsequently added partitions, unless you override the template by defining individual subpartitions. This composite partitioning makes it possible to query the table based on a credit limit range within a specified region:

CREATE TABLE customers_part
(
customer_id       NUMBER(6),
cust_first_name   VARCHAR2(20),
cust_last_name    VARCHAR2(20),
nls_territory     VARCHAR2(30),
credit_limit      NUMBER(9,2))
PARTITION BY RANGE (credit_limit)
SUBPARTITION BY LIST (nls_territory)
SUBPARTITION TEMPLATE
(SUBPARTITION east VALUES
  ('CHINA', 'JAPAN', 'INDIA', 'THAILAND'),
SUBPARTITION west VALUES
  ('AMERICA', 'GERMANY', 'ITALY', 'SWITZERLAND'),
SUBPARTITION other VALUES (DEFAULT))
(PARTITION p1 VALUES LESS THAN (1000),
PARTITION p2 VALUES LESS THAN (2500),
PARTITION p3 VALUES LESS THAN (MAXVALUE));
Object Column and Table Examples

Creating Object Tables: Examples

Consider object type `department_typ`:

```sql
CREATE TYPE department_typ AS OBJECT
  ( d_name   VARCHAR2(100),
    d_address VARCHAR2(200) );
/
```

Object table `departments_obj_t` holds department objects of type `department_typ`:

```sql
CREATE TABLE departments_obj_t OF department_typ;
```

The following statement creates object table `salesreps` with a user-defined object type, `salesrep_typ`:

```sql
CREATE OR REPLACE TYPE salesrep_typ AS OBJECT
  ( repId NUMBER,
    repName VARCHAR2(64));
CREATE TABLE salesreps OF salesrep_typ;
```

Creating a Table with a User-Defined Object Identifier: Example

This example creates an object type and a corresponding object table whose object identifier is primary key based:

```sql
CREATE TYPE employees_typ AS OBJECT
  (e_no NUMBER, e_address CHAR(30));
/
CREATE TABLE employees_obj_t OF employees_typ (e_no PRIMARY KEY)
  OBJECT IDENTIFIER IS PRIMARY KEY;
```

You can subsequently reference the `employees_obj_t` object table using either `inline_ref_constraint` or `out_of_line_ref_constraint` syntax:

```sql
CREATE TABLE departments_t
  (d_no    NUMBER,
   mgr_ref REF employees_typ SCOPE IS employees_obj_t);
CREATE TABLE departments_t
  (d_no NUMBER,
   mgr_ref REF employees_typ
     CONSTRAINT mgr_in_emp REFERENCES employees_obj_t);
```

Specifying Constraints on Type Columns: Example

The following example shows how to define constraints on attributes of an object type column:

```sql
CREATE TYPE address_t AS OBJECT
  ( hno    NUMBER,
    street VARCHAR2(40),
    city   VARCHAR2(20),
    zip    VARCHAR2(5),
    phone  VARCHAR2(10) );
/
```
CREATE TYPE person AS OBJECT
  ( name VARCHAR2(40),
    dateofbirth DATE,
    homeaddress address_t,
    manager REF person );
/

CREATE TABLE persons OF person
  ( homeaddress NOT NULL,
    UNIQUE (homeaddress.phone),
    CHECK (homeaddress.zip IS NOT NULL),
    CHECK (homeaddress.city <> 'San Francisco') );

CREATE TABLESPACE Purpose
Use the CREATE TABLESPACE statement to create a tablespace, which is an allocation of space in the database that can contain schema objects.

• A permanent tablespace contains persistent schema objects. Objects in permanent tablespaces are stored in data files.
• An undo tablespace is a type of permanent tablespace used by Oracle Database to manage undo data if you are running your database in automatic undo management mode. Oracle strongly recommends that you use automatic undo management mode rather than using rollback segments for undo.
• A temporary tablespace contains schema objects only for the duration of a session. Objects in temporary tablespaces are stored in temp files.

When you create a tablespace, it is initially a read/write tablespace. You can subsequently use the ALTER TABLESPACE statement to take the tablespace offline or online, add data files or temp files to it, or make it a read-only tablespace.

You can also drop a tablespace from the database with the DROP TABLESPACE statement.

See Also:

• Oracle Database Concepts for information on tablespaces
• ALTER TABLESPACE and DROP TABLESPACE for information on modifying and dropping tablespaces

Prerequisites
You must have the CREATE TABLESPACE system privilege. To create the SYSAUX tablespace, you must have the SYSDBA system privilege.

Before you can create a tablespace, you must create a database to contain it, and the database must be open.
To use objects in a tablespace other than the `SYSTEM` tablespace:

- If you are running the database in automatic undo management mode, then at least one `UNDO` tablespace must be online.
- If you are running the database in manual undo management mode, then at least one rollback segment other than the `SYSTEM` rollback segment must be online.

**Note:**
Oracle strongly recommends that you run your database in automatic undo management mode. For more information, refer to *Oracle Database Administrator's Guide*.

**Syntax**

```
create_tablespace ::= CREATE TABLESPACE tablespace DATAFILE file_specification,
    permanent_tablespace_attrs, IN SHARDSPACE shardspace,
    temporary_tablespace_clause, undo_tablespace_clause ;
```

```
(permanent_tablespace_clause ::=, temporary_tablespace_clause ::=, undo_tablespace_clause ::=)
```

```
permanent_tablespace_clause ::= TABLESPACE tablespace DATAFILE file_specification,
    permanent_tablespace_attrs,
    IN SHARDSPACE shardspace
```

```
(file_specification ::=, permanent_tablespace_attrs ::=)
```
permanent_tablespace_attrs ::= 

MINIMUM EXTENT size_clause
BLOCKSIZE integer

tablespace_encryption_clause::=)

**tablespace_group_clause::=**

```
TABLESPACE GROUP tablespace_group_name
```

**lost_write_protection ::=**

```
ENABLE
DISABLE
REMOVE
SUSPEND
LOST WRITE PROTECTION
```

**Semantics**

**BIGFILE | SMALLFILE**

Use this clause to determine whether the tablespace is a bigfile or smallfile tablespace. This clause overrides any default tablespace type setting for the database.

- A **bigfile tablespace** contains only one data file or temp file, which can contain up to approximately 4 billion \(2^{32}\) blocks. The minimum size of the single data file or temp file is 12 megabytes (MB) for a tablespace with 32K blocks and 7MB for a tablespace with 8K blocks. The maximum size of the single data file or temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.
A smallfile tablespace is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million \((2^{22})\) blocks.

If you omit this clause, then Oracle Database uses the current default tablespace type of permanent or temporary tablespace that is set for the database. If you specify BIGFILE for a permanent tablespace, then the database by default creates a locally managed tablespace with automatic segment-space management.

Restriction on Bigfile Tablespaces

You can specify only one data file in the DATAFILE clause or one temp file in the TEMPFILE clause.

See Also:

- *Oracle Database Administrator's Guide* for more information on using bigfile tablespaces
- "Creating a Bigfile Tablespace: Example"

**permanent_tablespace_clause**

Use the following clauses to create a permanent tablespace. (Some of these clauses are also used to create a temporary or undo tablespace.)

**tablespace**

Specify the name of the tablespace to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

**Note on the SYSAUX Tablespace**

SYSAUX is a required auxiliary system tablespace. You must use the CREATE TABLESPACE statement to create the SYSAUX tablespace if you are upgrading from a release earlier than Oracle Database 11g. You must have the SYSDBA system privilege to specify this clause, and you must have opened the database in UPGRADE mode.

You must specify EXTENT MANAGEMENT LOCAL and SEGMENT SPACE MANAGEMENT AUTO for the SYSAUX tablespace. The DATAFILE clause is optional only if you have enabled Oracle Managed Files. See "DATAFILE | TEMPFILE Clause" for the behavior of the DATAFILE clause.

Take care to allocate sufficient space for the SYSAUX tablespace. For guidelines on creating this tablespace, refer to *Oracle Database Upgrade Guide*.

**Restrictions on the SYSAUX Tablespace**

You cannot specify OFFLINE or TEMPORARY for the SYSAUX tablespace.

**DATAFILE | TEMPFILE Clause**

Specify the data files to make up the permanent tablespace or the temp files to make up the temporary tablespace. Use the `datafile_tempfile_spec` form of `file_specification` to create regular data files and temp files in an operating system.
file system or to create Oracle Automatic Storage Management (Oracle ASM) disk group files.

You must specify the `DATAFILE` or `TEMPFILE` clause unless you have enabled Oracle Managed Files by setting a value for the `DB_CREATE_FILE_DEST` initialization parameter. For Oracle ASM disk group files, the parameter must be set to a multiple file creation form of Oracle ASM filenames. If this parameter is set, then the database creates a system-named 100 MB file in the default file destination specified in the parameter. The file has `AUTOEXTEND` enabled and an unlimited maximum size.

**Note:**

Media recovery does not recognize temp files.

**See Also:**

- *Oracle Automatic Storage Management Administrator’s Guide* for more information on using Oracle ASM
- *file_specification* for a full description, including the `AUTOEXTEND` parameter and the multiple file creation form of Oracle ASM filenames

**Notes on Specifying Data Files and Temp Files**

- You can create a tablespace within an Oracle ASM disk group by providing only the disk group name in the `datafile_tempfile_spec`. In this case, Oracle ASM creates a data file in the specified disk group with a system-generated filename. The data file is auto-extensible with an unlimited maximum size and a default size of 100 MB. You can use the `autoextend_clause` to override the default size.
- If you use one of the reference forms of the `ASM_filename`, which refers to an existing file, then you must also specify `REUSE`.

**Note:**

On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.
permanent_tablespace_attrs

Use the `permanent_tablespace_attrs` clauses to set the attributes of the tablespace.

MINIMUM EXTENT Clause

This clause is valid only for a dictionary-managed tablespace. Specify the minimum size of an extent in the tablespace. This clause lets you control free space fragmentation in the tablespace by ensuring that the size of every used or free extent in a tablespace is at least as large as, and is a multiple of, the value specified in the `size_clause`.

See Also:

- `size_clause` for information on that clause and *Oracle Database VLDB and Partitioning Guide* for more information about using `MINIMUM EXTENT` to control fragmentation

BLOCKSIZE Clause

Use the `BLOCKSIZE` clause to specify a nonstandard block size for the tablespace. In order to specify this clause, the `DB_CACHE_SIZE` and at least one `DB_nK_CACHE_SIZE` parameter must be set, and the integer you specify in this clause must correspond with the setting of one `DB_nK_CACHE_SIZE` parameter setting.

Restriction on BLOCKSIZE

You cannot specify nonstandard block sizes for a temporary tablespace or if you intend to assign this tablespace as the temporary tablespace for any users.

Note:

Oracle recommend that you do not store tablespaces with a 2K block size on 4K sector size disks, because performance degradation can result.
See Also:

Oracle Database Reference for information on the $DB_nK_CACHE_SIZE$ parameter and Oracle Database Concepts for information on multiple block sizes.

logging_clause

Specify the default logging attributes of all tables, indexes, materialized views, materialized view logs, and partitions within the tablespace. This clause is not valid for a temporary or undo tablespace.

If you omit this clause, then the default is LOGGING. The exception is creating a tablespace in a PDB. In this case, if you omit this clause, then the tablespace uses the logging attribute of the PDB. Refer to the logging_clause of CREATE PLUGGABLE DATABASE for more information.

The tablespace-level logging attribute can be overridden by logging specifications at the table, index, materialized view, materialized view log, and partition levels.

See Also:

logging_clause for a full description of this clause

FORCE LOGGING

Use this clause to put the tablespace into FORCE LOGGING mode. Oracle Database will log all changes to all objects in the tablespace except changes to temporary segments, overriding any NOLOGGING setting for individual objects. The database must be open and in READ WRITE mode.

This setting does not exclude the NOLOGGING attribute. You can specify both FORCE LOGGING and NOLOGGING. In this case, NOLOGGING is the default logging mode for objects subsequently created in the tablespace, but the database ignores this default as long as the tablespace or the database is in FORCE LOGGING mode. If you subsequently take the tablespace out of FORCE LOGGING mode, then the NOLOGGING default is once again enforced.

Note:

FORCE LOGGING mode can have performance effects. Refer to Oracle Database Administrator's Guide for information on when to use this setting.

Restriction on Forced Logging

You cannot specify FORCE LOGGING for an undo or temporary tablespace.
**tablespace_encryption_clause**

Use this clause to specify whether to create an encrypted or unencrypted tablespace. If you create an encrypted tablespace, then Transparent Data Encryption (TDE) is applied to all data files of the tablespace.

**ENCRYPT | DECRYPT**

Specify **ENCRYPT** to create an encrypted tablespace. Specify **DECRYPT** to create an unencrypted tablespace.

If you omit this clause, then the value of the **ENCRYPT_NEW_TABLESPACES** initialization parameter determines whether the tablespace is encrypted upon creation. Refer to *Oracle Database Reference* for more information on the **ENCRYPT_NEW_TABLESPACES** initialization parameter.

Before issuing this clause, you must already have loaded the TDE master key into database memory or established a connection to the HSM. For more information, see the **open_keystore** clause of **ADMINISTER KEY MANAGEMENT** or "SET ENCRYPTION WALLET Clause" of **ALTER SYSTEM**.

**tablespace_encryption_spec**

Specify **USING 'encrypt_algorithm'** to indicate the name of the encryption algorithm to be used. Valid algorithms are **AES256**, **AES192**, **AES128** and **3DES168**. If the **COMPATIBLE** initialization parameter is set to 12.2 or higher, then the following algorithms are also valid: **ARIA128**, **ARIA192**, **ARIA256**, **GOST256**, and **SEED128**. If you omit this clause, then the database uses **AES128**.

---

**See Also:**

"Creating an Encrypted Tablespace: Example"

---

**default_tablespace_params**

The **DEFAULT** clause lets you specify default parameters for the tablespace.

**default_table_compression**

Use this clause to specify default compression of data for all tables created in the tablespace. This clause is not valid for a temporary tablespace. The subclauses of this clause have the same semantics as they have for the **table_compression** clause of the **CREATE TABLE** statement, with one exception: The **COMPRESS FOR OLTP** clause here is equivalent to the **ROW STORE COMPRESS ADVANCED** clause of **CREATE TABLE**. Refer to the **table_compression** clauses of **CREATE TABLE** for the full semantics of these subclauses.

**default_index_compression**

Use this clause to specify default compression of data for all indexes created in the tablespace. This clause is not valid for a temporary tablespace. The subclauses of this clause have the same semantics as they have for the **advanced_index_compression** clause of the **CREATE INDEX** statement. Refer to the **advanced_index_compression** clause of **CREATE INDEX** for the full semantics of these subclauses.
**inmemory_clause**

Use the `inmemory_clause` to specify the default In-Memory Column Store (IM column store) settings for all tables and materialized views created in the tablespace. This clause is not valid for a temporary tablespace.

- Specify `INMEMORY` to enable all tables and materialized views for the IM column store.

  You can optionally use the `inmemory_attributes` clause to specify how the table or materialized view data is stored in the IM column store. The `inmemory_attributes` clause has the same semantics in `CREATE TABLE` and `CREATE TABLESPACE`. Refer to the `inmemory_attributes` clause of `CREATE TABLE` for the full semantics of this clause.

- Specify `NO INMEMORY` to disable all tables and materialized views for the IM column store. This is the default.

**ilm_clause**

Use the `ilm_clause` to specify default Automatic Data Optimization settings for all tables created in the tablespace. This clause is not valid for a temporary tablespace. Refer to the `ilm_clause` of `CREATE TABLE` for the full semantics of this clause.

**storage_clause**

Use the `storage_clause` to specify storage parameters for all objects created in the tablespace. This clause is not valid for a temporary tablespace or a locally managed tablespace. For a dictionary-managed tablespace, you can specify the following storage parameters with this clause: `ENCRYPT`, `INITIAL`, `NEXT`, `MINEXTENTS`, `MAXEXTENTS`, `MAXSIZE`, and `PCTINCREASE`. Refer to `storage_clause` for more information.

**Note:**

The `ENCRYPT` clause of the `storage_clause` is supported for backward compatibility. However, beginning with Oracle Database 12c Release 2 (12.2), you can instead specify `ENCRYPT` in the `tablespace_encryption_clause`. Refer to `tablespace_encryption_clause` for more information.

**See Also:**

"Creating Basic Tablespaces: Examples"

**ONLINE | OFFLINE Clauses**

Use these clauses to determine whether the tablespace is online or offline. This clause is not valid for a temporary tablespace.

**ONLINE**
Specify **ONLINE** to make the tablespace available immediately after creation to users who have been granted access to the tablespace. This is the default.

**OFFLINE**

Specify **OFFLINE** to make the tablespace unavailable immediately after creation.

The data dictionary view **DBA_TABLESPACES** indicates whether each tablespace is online or offline.

**extent_management_clause**

The **extent_management_clause** lets you specify how the extents of the tablespace will be managed.

- **AUTOALLOCATE** specifies that the tablespace is system managed. Users cannot specify an extent size. You cannot specify **AUTOALLOCATE** for a temporary tablespace.

- **UNIFORM** specifies that the tablespace is managed with uniform extents of **SIZE** bytes. The default **SIZE** is 1 megabyte. All extents of temporary tablespaces are of uniform size, so this keyword is optional for a temporary tablespace. However, you must specify **UNIFORM** in order to specify **SIZE**. You cannot specify **UNIFORM** for an undo tablespace.

If you do not specify **AUTOALLOCATE** or **UNIFORM**, then the default is **UNIFORM** for temporary tablespaces and **AUTOALLOCATE** for all other types of tablespaces.

If you do not specify the **extent_management_clause**, then Oracle Database interprets the **MINIMUM EXTENT clause** and the **DEFAULT storage_clause** to determine extent management.

**Note:**

After you have specified extent management with this clause, you can change extent management only by migrating the tablespace.

**Note:**

The **DICTIONARY** keyword is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you create locally managed tablespaces. Locally managed tablespaces are much more efficiently managed than dictionary-managed tablespaces. The creation of new dictionary-managed tablespaces is scheduled for desupport.

**See Also:**

*Oracle Database Concepts* for a discussion of locally managed tablespaces.
Restrictions on Extent Management

Extent management is subject to the following restrictions:

- A permanent locally managed tablespace can contain only permanent objects. If you need a locally managed tablespace to store temporary objects, for example, if you will assign it as a user's temporary tablespace, then use the `temporary_tablespace_clause`.

- If you specify this clause, then you cannot specify `DEFAULT storage_clause`, `MINIMUM EXTENT`, or the `temporary_tablespace_clause`.

See Also:

*Oracle Database Administrator's Guide* for information on changing extent management by migrating tablespaces and "Creating a Locally Managed Tablespace: Example"

**segment_management_clause**

The `segment_management_clause` is relevant only for permanent, locally managed tablespaces. It lets you specify whether Oracle Database should track the used and free space in the segments in the tablespace using free lists or bitmaps. This clause is not valid for a temporary tablespace.

**AUTO**

Specify **AUTO** if you want the database to manage the free space of segments in the tablespace using a bitmap. If you specify **AUTO**, then the database ignores any specification for `PCTUSED`, `FREELIST`, and `FREELIST GROUPS` in subsequent storage specifications for objects in this tablespace. This setting is called **automatic segment-space management** and is the default.

**MANUAL**

Specify **MANUAL** if you want the database to manage the free space of segments in the tablespace using free lists. Oracle strongly recommends that you do not use this setting and that you create tablespaces with automatic segment-space management.

To determine the segment management of an existing tablespace, query the `SEGMENT_SPACE_MANAGEMENT` column of the `DBA_TABLESPACES` or `USER_TABLESPACES` data dictionary view.

**Note:**

If you specify **AUTO** segment management, then:

- If you set extent management to **LOCAL UNIFORM**, then you must ensure that each extent contains at least 5 database blocks.

- If you set extent management to **LOCAL AUTOALLOCATE**, and if the database block size is 16K or greater, then Oracle manages segment space by creating extents with a minimum size of 5 blocks rounded up to 64K.
Restrictions on Automatic Segment-Space Management

This clause is subject to the following restrictions:

- You can specify this clause only for a permanent, locally managed tablespace.
- You cannot specify this clause for the SYSTEM tablespace.

See Also:

- Oracle Automatic Storage Management Administrator’s Guide for information on automatic segment-space management and when to use it
- Oracle Database Reference for information on the data dictionary views
- “Specifying Segment Space Management for a Tablespace: Example”

flashback_mode_clause

Use this clause in conjunction with the ALTER DATABASE FLASHBACK clause to specify whether the tablespace can participate in FLASHBACK DATABASE operations. This clause is useful if you have the database in FLASHBACK mode but you do not want Oracle Database to maintain Flashback log data for this tablespace.

This clause is not valid for temporary or undo tablespaces.

FLASHBACK ON

Specify FLASHBACK ON to put the tablespace in FLASHBACK mode. Oracle Database will save Flashback log data for this tablespace and the tablespace can participate in a FLASHBACK DATABASE operation. If you omit the flashback_mode_clause, then FLASHBACK ON is the default.

FLASHBACK OFF

Specify FLASHBACK OFF to take the tablespace out of FLASHBACK mode. Oracle Database will not save any Flashback log data for this tablespace. You must take the data files in this tablespace offline or drop them prior to any subsequent FLASHBACK DATABASE operation. Alternatively, you can take the entire tablespace offline. In either case, the database does not drop existing Flashback logs.

Note:

The FLASHBACK mode of a tablespace is independent of the FLASHBACK mode of an individual table.
**See Also:**

- *Oracle Database Backup and Recovery User's Guide* for information on Oracle Flashback Database
- `ALTER DATABASE` and `FLASHBACK DATABASE` for information on setting the `FLASHBACK` mode of the entire database and reverting the database to an earlier version
- `FLASHBACK TABLE` and `flashback_query_clause`

**lost_write_protection**

Specify the `lost_write_protection` clause to create a storage area for lost write records. This storage area or shadow tablespace must be created, before you can enable lost write protection on datafiles and databases.

You may create as many shadow tablespaces as you need, and name them as you would any other tablespace.

**Create a Shadow Tablespace: Example**

```sql
CREATE BIGFILE TABLESPACE <shadow_tablespace_name>
  DATAFILE <datafile_name>
  SIZE 100000000 BLOCKSIZE 8K
  LOST WRITE PROTECTION
```

This command creates the shadow tablespace. To enable lost write protection on datafiles and databases, you must specify the `lost_write_protection` clause with the `ALTER TABLESPACE`, `ALTER DATABASE`, and `ALTER PLUGGABLE DATABASE` statements.

**undo_tablespace_clause**

Specify `UNDO` to create an undo tablespace. When you run the database in automatic undo management mode, Oracle Database manages undo space using the undo tablespace instead of rollback segments. This clause is useful if you are now running in automatic undo management mode but your database was not created in automatic undo management mode.

Oracle Database always assigns an undo tablespace when you start up the database in automatic undo management mode. If no undo tablespace has been assigned to this instance, then the database uses the `SYSTEM` rollback segment. You can avoid this by creating an undo tablespace, which the database will implicitly assign to the instance if no other undo tablespace is currently assigned.

The `DATAFILE` clause is described in "DATAFILE | TEMPFILE Clause".

**extent_management_clause**

It is unnecessary to specify the `extent_management_clause` when creating an undo tablespace, because undo tablespaces must be locally managed tablespaces that use `AUTOALLOCATE` extent management. If you do specify this clause, then you must specify `EXTENT MANAGEMENT LOCAL` or `EXTENT MANAGEMENT LOCAL AUTOALLOCATE`, both of which are the same as omitting this clause. Refer to `extent_management_clause` for the full semantics of this clause.

**tablespace_retention_clause**
This clause is valid only for undo tablespaces.

- **RETENTION GUARANTEE** specifies that Oracle Database should preserve unexpired undo data in all undo segments of *tablespace* even if doing so forces the failure of ongoing operations that need undo space in those segments. This setting is useful if you need to issue an Oracle Flashback Query or an Oracle Flashback Transaction Query to diagnose and correct a problem with the data.

- **RETENTION NOGUARANTEE** returns the undo behavior to normal. Space occupied by unexpired undo data in undo segments can be consumed if necessary by ongoing transactions. This is the default.

*tablespace_encryption_clause*

This clause has the same semantics for undo tablespaces as for permanent tablespaces. Refer to *tablespace_encryption_clause* in the documentation on permanent tablespaces for full information.

**Restrictions on Undo Tablespaces**

Undo tablespaces are subject to the following restrictions:

- You cannot create database objects in this tablespace. It is reserved for system-managed undo data.

- The only clauses you can specify for an undo tablespace are the **DATAFILE** clause, the **tablespace_retention_clause**, the **tablespace_encryption_clause**, and the **extent_management_clause** to specify **local AUTOALLOCATE** extent management. You cannot specify **local UNIFORM** extent management or **dictionary extent management** using the **extent_management_clause**. All undo tablespaces are created permanent, read/write, and in logging mode. Values for **MINIMUM EXTENT** and **DEFAULT STORAGE** are system generated.

**See Also:**

- *Oracle Database Administrator's Guide* for information on automatic undo management and undo tablespaces and *Oracle Database Reference* for information on the **UNDO_MANAGEMENT** parameter

- **CREATE DATABASE** for information on creating an undo tablespace during database creation, and **ALTER TABLESPACE** and **DROP TABLESPACE**

- "Creating an Undo Tablespace: Example"

*temporary_tablespace_clause*

Use this clause to create a temporary tablespace, which is an allocation of space in the database that can contain transient data that persists only for the duration of a session. This transient data cannot be recovered after process or instance failure.

The transient data can be user-generated schema objects such as temporary tables or system-generated data such as temp space used by hash joins and sort operations. When a temporary tablespace, or a tablespace group of which this tablespace is a member, is assigned to a particular user, then Oracle Database uses the tablespace for sorting operations in transactions initiated by that user.
You can create two types of temporary tablespaces:

- You can create a shared temporary tablespace by specifying the `TEMPORARY TABLESPACE` clause. A shared temporary tablespace stores temp files on shared disk, so that the temporary space is accessible to all database instances. Shared temporary tablespaces were available in prior releases of Oracle Database and were called "temporary tablespaces." Elsewhere in this guide, the term "temporary tablespace" refers to a shared temporary tablespace unless specified otherwise.

- Starting with Oracle Database 12c Release 2 (12.2), you can create a local temporary tablespace by specifying the `LOCAL temporary TABLESPACE` clause. Local temporary tablespaces are useful in an Oracle Clusterware environment. They store a separate, nonshared temp files for each database instance, which can improve I/O performance. A local temporary tablespace must be a `BIGFILE` tablespace.
  
  - Specify `FOR ALL` to instruct the database to create separate, nonshared temp files for all HUB and LEAF nodes.
  - Specify `FOR LEAF` to instruct the database to create separate nonshared temp files for only LEAF nodes.

**TEMPFILE**

The `TEMPFILE` clause is described in "DATAFILE | TEMPFILE Clause".

**tablespace_group_clause**

This clause is relevant only for temporary tablespaces. Use this clause to determine whether `tablespace` is a member of a tablespace group. A tablespace group lets you assign multiple temporary tablespaces to a single user and increases the addressability of temporary tablespaces.

- Specify a group name to indicate that `tablespace` is a member of this tablespace group. The group name cannot be the same as `tablespace` or any other existing tablespace. If the tablespace group already exists, then Oracle Database adds the new tablespace to that group. If the tablespace group does not exist, then the database creates the group and adds the new tablespace to that group.

- Specify an empty string (""") to indicate that `tablespace` is not a member of any tablespace group.

**Restriction on Tablespace Groups**

Tablespace groups support only shared temporary tablespaces. You cannot add a local temporary tablespace to a tablespace group.

**extent_management_clause**

The `extent_management_clause` is described in `extent_management_clause`.

**tablespace_encryption_clause**

This clause has the same semantics for temporary tablespaces as for permanent tablespaces. Refer to `tablespace_encryption_clause` in the documentation on permanent tablespaces for full information.
Restrictions on Temporary Tablespaces

The data stored in temporary tablespaces persists only for the duration of a session. Therefore, only a subset of the `CREATE TABLESPACE` clauses are relevant for temporary tablespaces. The only clauses you can specify for a temporary tablespace are the `TEMPFILE` clause, the `tablespace_group_clause`, the `extent_management_clause`, and the `tablespace_encryption_clause`.

Examples

These examples assume that your database is using 8K blocks.

Creating a Bigfile Tablespace: Example

The following example creates a bigfile tablespace `bigtbs_01` with a data file `bigtbs_f1.dbf` of 20 MB:

```
CREATE BIGFILE TABLESPACE bigtbs_01
  DATAFILE 'bigtbs_f1.dbf'
  SIZE 20M AUTOEXTEND ON;
```

Creating an Undo Tablespace: Example

The following example creates a 10 MB undo tablespace `undots1`:

```
CREATE UNDO TABLESPACE undots1
  DATAFILE 'undotbs_1a.dbf'
  SIZE 10M AUTOEXTEND ON
  RETENTION GUARANTEE;
```

Creating a Temporary Tablespace: Example

This statement shows how the temporary tablespace that serves as the default temporary tablespace for database users in the sample database was created:

```
CREATE TEMPORARY TABLESPACE temp_demo
  TEMPFILE 'temp01.dbf' SIZE 5M AUTOEXTEND ON;
```

Assuming that the default database block size is 2K, and that each bit in the map represents one extent, then each bit maps 2,500 blocks.

The following example sets the default location for data file creation and then creates a tablespace with an Oracle-managed temp file in the default location. The temp file is 100 M and is autoextensible with unlimited maximum size. These are the default values for Oracle Managed Files:
ALTER SYSTEM SET DB_CREATE_FILE_DEST = '$ORACLE_HOME/rdbms/dbs';

CREATE TEMPORARY TABLESPACE tbs_05;

Adding a Temporary Tablespace to a Tablespace Group: Example

The following statement creates the tbs_temp_02 temporary tablespace as a member of the tbs_grp_01 tablespace group. If the tablespace group does not already exist, then Oracle Database creates it during execution of this statement:

CREATE TEMPORARY TABLESPACE tbs_temp_02
  TEMPFILE 'temp02.dbf' SIZE 5M AUTOEXTEND ON
  TABLESPACE GROUP tbs_grp_01;

Creating Basic Tablespaces: Examples

This statement creates a tablespace named tbs_01 with one data file:

CREATE TABLESPACE tbs_01
  DATAFILE 'tbs_f2.dbf' SIZE 40M
  ONLINE;

This statement creates tablespace tbs_03 with one data file and allocates every extent as a multiple of 500K:

CREATE TABLESPACE tbs_03
  DATAFILE 'tbs_f03.dbf' SIZE 20M
  LOGGING;

Enabling Autoextend for a Tablespace: Example

This statement creates a tablespace named tbs_02 with one data file. When more space is required, 500 kilobyte extents will be added up to a maximum size of 100 megabytes:

CREATE TABLESPACE tbs_02
  DATAFILE 'diskb:tbs_f5.dbf' SIZE 500K REUSE
  AUTOEXTEND ON NEXT 500K MAXSIZE 100M;

Creating a Locally Managed Tablespace: Example

The following statement assumes that the database block size is 2K.

CREATE TABLESPACE tbs_04 DATAFILE 'file_1.dbf' SIZE 10M
  EXTENT MANAGEMENT LOCAL UNIFORM SIZE 128K;

This statement creates a locally managed tablespace in which every extent is 128K and each bit in the bit map describes 64 blocks.

The following statement creates a locally managed tablespace with uniform extents and shows an example of a table stored in that tablespace:

CREATE TABLESPACE lmt1 DATAFILE 'lmt_file2.dbf' SIZE 100m REUSE
  EXTENT MANAGEMENT LOCAL UNIFORM SIZE 1M;

CREATE TABLE lmt_table1 (col1 NUMBER, col2 VARCHAR2(20))
  TABLESPACE lmt1 STORAGE (INITIAL 2m);

The initial segment size of the table is 2M.

The following example creates a locally managed tablespace without uniform extents:
CREATE TABLESPACE lmt2 DATAFILE 'lmt_file3.dbf' SIZE 100m REUSE
   EXTENT MANAGEMENT LOCAL;

CREATE TABLE lmt_table2 (col1 NUMBER, col2 VARCHAR2(20))
   TABLESPACE lmt2 STORAGE (INITIAL 2m MAXSIZE 100m);

The initial segment size of the table is 2M. Oracle Database determines the size of
each extent and the total number of extents allocated to satisfy the initial segment
size. The segment's maximum size is limited to 100M.

Creating an Encrypted Tablespace: Example

In the following example, the first statement enables encryption for the database by
opening the wallet. The second statement creates an encrypted tablespace.

ALTER SYSTEM SET ENCRYPTION WALLET OPEN IDENTIFIED BY "wallet_password";

CREATE TABLESPACE encrypt_ts
   DATAFILE '$ORACLE_HOME/dbs/encrypt_df.dbf' SIZE 1M
   ENCRYPTION USING 'AES256' ENCRYPT;

Specifying Segment Space Management for a Tablespace: Example

The following example creates a tablespace with automatic segment-space
management:

CREATE TABLESPACE auto_seg_ts DATAFILE 'file_2.dbf' SIZE 1M
   EXTENT MANAGEMENT LOCAL
   SEGMENT SPACE MANAGEMENT AUTO;

Creating Oracle Managed Files: Examples

The following example sets the default location for data file creation and creates
a tablespace with a data file in the default location. The data file is 100M and is
autoextensible with an unlimited maximum size:

ALTER SYSTEM SET DB_CREATE_FILE_DEST = '$ORACLE_HOME/rdbms/dbs';

CREATE TABLESPACE omf_ts1;

The following example creates a tablespace with an Oracle-managed data file of 100M
that is not autoextensible:

CREATE TABLESPACE omf_ts2 DATAFILE AUTOEXTEND OFF;

CREATE TABLESPACE SET

Note:

This SQL statement is valid only if you are using Oracle Sharding. For more
information on Oracle Sharding, refer to Oracle Database Administrator's
Guide.
Purpose

Use the `CREATE TABLESPACE SET` statement to create a tablespace set. A tablespace set can be used in a sharded database as a logical storage unit for one or more sharded tables and indexes.

A tablespace set consists of multiple tablespaces distributed across shards in a shardspace. The database automatically creates the tablespaces in a tablespace set. The number of tablespaces is determined automatically and is equal to the number of chunks in the corresponding shardspace.

All tablespaces in a tablespace set are permanent bigfile tablespaces; a tablespace set does not contain `SYSTEM`, undo, or temporary tablespaces. The database automatically creates one data file for each tablespace. All tablespaces in a tablespace set share the same attributes. You can modify attributes for all tablespaces in a tablespace set with the `ALTER TABLESPACE SET` statement.

See Also:

`ALTER TABLESPACE SET` and `DROP TABLESPACE SET`

Prerequisites

You must be connected to a shard catalog database as an SDB user.

You must have the `CREATE TABLESPACE` system privilege.

Syntax

`create_tablespace_set::=`
**permanent_tablespace_attrs::=**

(See the following clauses of CREATE TABLESPACE:
logging_clause::=, tablespace_encryption_clause::=, default_tablespace_params::=, extent_management_clause::=, segment_management_clause::=, flashback_mode_clause::=)

**Semantics**

**tablespace_set**

Specify the name of the tablespace set to be created. The name must satisfy the requirements listed in Database Object Naming Rules.

**IN SHARDSPACE**

Specify this clause if you are using composite sharding. For shardspace_name, specify the name of the shardspace in which the tablespace set is to be created.

Omit this clause if you are using system-managed sharding. In this case, the tablespace set is created in the default shardspace for the sharded database.

**USING TEMPLATE**

The USING TEMPLATE clause allows you to specify attributes for the tablespaces in the tablespace set.

The DATAFILE and permanent_tablespace_attrs clauses have the same semantics here as for the CREATE TABLESPACE statement, with the following exceptions:

- For the DATAFILE file_specification clause, you can specify only the SIZE clause and the autoextend_clause.
• You cannot specify the MINIMUM EXTENT size_clause.

• For the segment_management_clause, you can specify only SEGMENT SPACE MANAGEMENT AUTO. The MANUAL setting is not supported.

See Also:
file_specification and permanent_tablespace_attrs in the documentation on CREATE TABLESPACE for the full semantics of these clauses

Examples
Creating a Tablespace Set: Example

The following statement creates tablespace set tsl:

```
CREATE TABLESPACE SET tsl
    IN SHARDSPACE sgr1
    USING TEMPLATE
    ( DATAFILE SIZE 100m
      EXTENT MANAGEMENT LOCAL
      SEGMENT SPACE MANAGEMENT AUTO
    );
```

CREATE TRIGGER

Purpose

Triggers are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE TRIGGER statement to create a database trigger, which is:

• A stored PL/SQL block associated with a table, a schema, or the database or

• An anonymous PL/SQL block or a call to a procedure implemented in PL/SQL or Java

Oracle Database automatically executes a trigger when specified conditions occur.

See Also:
ALTER TRIGGER and DROP TRIGGER

Prerequisites

To create a trigger in your own schema on a table in your own schema or on your own schema (SCHEMA), you must have the CREATE TRIGGER system privilege.

To create a trigger in any schema on a table in any schema, or on another user’s schema (schema.SCHEMA), you must have the CREATE ANY TRIGGER system privilege.
In addition to the preceding privileges, to create a trigger on `DATABASE`, you must have the `ADMINISTER DATABASE TRIGGER` system privilege.

To create a trigger on a pluggable database (PDB), the current container must be that PDB and you must have the `ADMINISTER DATABASE TRIGGER` system privilege. For information about PDBs, see *Oracle Database Administrator’s Guide*.

In addition to the preceding privileges, to create a crossedition trigger, you must be enabled for editions. For information about enabling editions for a user, see *Oracle Database Development Guide*.

If the trigger issues SQL statements or calls procedures or functions, then the owner of the trigger must have the privileges necessary to perform these operations. These privileges must be granted directly to the owner rather than acquired through roles.

**Syntax**

Triggers are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

```
CREATE OR REPLACE EDITIONABLE NONEDITIONABLE TRIGGER plsql_trigger_source
```

**(plsql_trigger_source)**: See *Oracle Database PL/SQL Language Reference.**

**Semantics**

**OR REPLACE**

Specify `OR REPLACE` to re-create the trigger if it already exists. Use this clause to change the definition of an existing trigger without first dropping it.

**[ EDITIONABLE | NONEDITIONABLE ]**

Use these clauses to specify whether the trigger is an editioned or noneditioned object if editioning is enabled for the schema object type `TRIGGER` in `schema`. The default is EDITIONABLE. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

**Restriction on NONEDITIONABLE**

You cannot specify `NONEDITIONABLE` for a crossedition trigger.

**plsql_trigger_source**

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_trigger_source`.  

```
CREATE TRIGGER
```
CREATE TYPE

Purpose

Object types are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE TYPE statement to create the specification of an object type, a SQLJ object type, a named varying array (varray), a nested table type, or an incomplete object type. You create object types with the CREATE TYPE and the CREATE TYPE BODY statements. The CREATE TYPE statement specifies the name of the object type, its attributes, methods, and other properties. The CREATE TYPE BODY statement contains the code for the methods that implement the type.

Note:

• If you create an object type for which the type specification declares only attributes but no methods, then you need not specify a type body.
• If you create a SQLJ object type, then you cannot specify a type body. The implementation of the type is specified as a Java class.

An incomplete type is a type created by a forward type definition. It is called “incomplete” because it has a name but no attributes or methods. It can be referenced by other types, and so can be used to define types that refer to each other. However, you must fully specify the type before you can use it to create a table or an object column or a column of a nested table type.

See Also:

• CREATE TYPE BODY for information on creating the member methods of a type
• Oracle Database Object-Relational Developer's Guide for more information about objects, incomplete types, varrays, and nested tables

Prerequisites

To create a type in your own schema, you must have the CREATE TYPE system privilege. To create a type in another user's schema, you must have the CREATE ANY TYPE system privilege. You can acquire these privileges explicitly or be granted them through a role.

To create a subtype, you must have the UNDER ANY TYPE system privilege or the UNDER object privilege on the supertype.

The owner of the type must be explicitly granted the EXECUTE object privilege in order to access all other types referenced within the definition of the type, or the type owner.
must be granted the **EXECUTE ANY TYPE** system privilege. The owner cannot obtain these privileges through roles.

If the type owner intends to grant other users access to the type, then the owner must be granted the **EXECUTE** object privilege on the referenced types with the **GRANT OPTION** or the **EXECUTE ANY TYPE** system privilege with the **ADMIN OPTION**. Otherwise, the type owner has insufficient privileges to grant access on the type to other users.

**User-Defined Datatypes Declared as Non-Persistable Datatypes**

You can specify a user-defined datatype as non-persistable when creating the datatype. Instances of non-persistable types cannot persist on disk. Perisistable data types include the following:

- ANSI-supported data types, for example **NUMERIC**, **DECIMAL**, **REAL**.
- Oracle built-in data types, for example **NUMBER**, **VARCHAR2**, **TIMESTAMP**.
- Oracle-supplied data types, for example **ANYDATA**, **XML Type**, **ORDImage**.

**Rules For SQL User-Defined Data Types**

- A persistable type cannot have attributes or elements of non-persistable types.
- A non-persistable type can have attributes or elements of both persistable and non-persistable types.
- A sub-type must inherit the persistence property from its super type.
- A **REF** type is persistable and can hold references only to objects of persistable types.
- You cannot persist instances of non-persistable types on disk. If you create a table with a type that has been declared as non-persistable, the **CREATE TABLE** statement will fail. The following operations will likewise fail:
  - Create or alter a relational table with columns of non-persistable types.
  - Create an object table with columns of non-persistable types.
  - Store instances of non-persistable types in an **ANYDATA** instance which is persisted on disk.

**Syntax**

Types are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

```
create_type ::= CREATE OR REPLACE EDITIONABLE NONEDITIONABLE TYPE plsql_type_source
```

*(plsql_type_source: See Oracle Database PL/SQL Language Reference.)*
Semantics

OR REPLACE

Specify OR REPLACE to re-create the type if it already exists. Use this clause to change the definition of an existing type without first dropping it.

Users previously granted privileges on the re-created object type can use and reference the object type without being granted privileges again.

If any function-based indexes depend on the type, then Oracle Database marks the indexes DISABLED.

[ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the type is an editioned or noneditioned object if editioning is enabled for the schema object type TYPE in schema. The default is EDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

plsql_type_source

See Oracle Database PL/SQL Language Reference for the syntax and semantics of the plsql_type_source.

CREATE TYPE BODY

Purpose

Type bodies are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE TYPE BODY to define or implement the member methods defined in the object type specification. You create object types with the CREATE TYPE and the CREATE TYPE BODY statements. The CREATE TYPE statement specifies the name of the object type, its attributes, methods, and other properties. The CREATE TYPE BODY statement contains the code for the methods that implement the type.

For each method specified in an object type specification for which you did not specify the call_spec, you must specify a corresponding method body in the object type body.

Note:

If you create a SQLJ object type, then specify it as a Java class.
See Also:

- CREATE TYPE for information on creating a type specification
- ALTER TYPE for information on modifying a type specification

Prerequisites

Every member declaration in the CREATE TYPE specification for object types must have a corresponding construct in the CREATE TYPE or CREATE TYPE BODY statement.

To create or replace a type body in your own schema, you must have the CREATE TYPE or the CREATE ANY TYPE system privilege. To create an object type in another user’s schema, you must have the CREATE ANY TYPE system privilege. To replace an object type in another user’s schema, you must have the DROP ANY TYPE system privilege.

Syntax

Type bodies are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

\[
\text{create_type_body ::= CREATE OR REPLACE EDITIONABLE NONEDITIONABLE TYPE BODY plsql_type_body_source (plsql_type_body_source: See Oracle Database PL/SQL Language Reference.)}
\]

Semantics

OR REPLACE

Specify OR REPLACE to re-create the type body if it already exists. Use this clause to change the definition of an existing type body without first dropping it.

Users previously granted privileges on the re-created object type body can use and reference the object type body without being granted privileges again.

You can use this clause to add new member subprogram definitions to specifications added with the ALTER TYPE ... REPLACE statement.

[ EDITIONABLE | NONEDITIONABLE ]

If you do not specify this clause, then the type body inherits EDITIONABLE or NONEDITIONABLE from the type specification. If you do specify this clause, then it must match that of the type specification.

plsql_type_body_source

See Oracle Database PL/SQL Language Reference for the syntax and semantics of the plsql_type_body_source.
CREATE USER

Purpose

Use the CREATE USER statement to create and configure a database user, which is an account through which you can log in to the database, and to establish the means by which Oracle Database permits access by the user.

You can issue this statement in an Oracle Automatic Storage Management (Oracle ASM) cluster to add a user and password combination to the password file that is local to the Oracle ASM instance of the current node. Each node’s Oracle ASM instance can use this statement to update its own password file. The password file itself must have been created by the ORAPWD utility.

You can enable a user to connect to the database through a proxy application or application server. For syntax and discussion, refer to ALTER USER.

Prerequisites

You must have the CREATE USER system privilege. When you create a user with the CREATE USER statement, the user’s privilege domain is empty. To log on to Oracle Database, a user must have the CREATE SESSION system privilege. Therefore, after creating a user, you should grant the user at least the CREATE SESSION system privilege. Refer to GRANT for more information.

Only a user authenticated AS SYSASM can issue this command to modify the Oracle ASM instance password file.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB).
Syntax

\[
\text{create\_user::=}
\]

(Semantics)

\(\text{user}\)

Specify the name of the user to be created. This name can contain only characters from your database character set and must follow the rules described in the section "Database Object Naming Rules". Oracle recommends that the user name contain at least one single-byte character regardless of whether the database character set also contains multibyte characters.
In a non-CDB, a user name cannot begin with C## or c##.

In a CDB, the requirements for a user name are as follows:

- The name of a common user must begin with characters that are a case-insensitive match to the prefix specified by the COMMON_USER_PREFIX initialization parameter. By default, the prefix is C##.

- The name of a local user must not begin with characters that are a case-insensitive match to the prefix specified by the COMMON_USER_PREFIX initialization parameter. Regardless of the value of COMMON_USER_PREFIX, the name of a local user can never begin with C## or c##.

**Note:**

If the value of COMMON_USER_PREFIX is an empty string, then there are no requirements for common or local user names with one exception: the name of a local user can never begin with C## or c##. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common users when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

**Note:**

Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

**See Also:**

"Creating a Database User: Example"

**IDENTIFIED Clause**

The IDENTIFIED clause lets you indicate how Oracle Database authenticates the user.

**BY password**

The BY password clause lets you creates a local user and indicates that the user must specify password to log on to the database. Passwords are case sensitive. Any subsequent CONNECT string used to connect this user to the database must specify the password using the same case (upper, lower, or mixed) that is used in this CREATE USER statement or a subsequent ALTER USER statement. Passwords can contain any single-byte, multibyte, or special characters, or any combination of these, from your database character set, with the exception of the double quotation mark ("), the return character. If a password starts with a non-alphabetic character, or contains a character other than an alphanumeric character, the underscore (_), dollar sign ($), or pound sign (#), then it must be enclosed in double quotation marks. Otherwise, enclosing a password in double quotation marks is optional.
Passwords must follow the rules described in the section "Database Object Naming Rules", unless you are using one of the three Oracle Database password complexity verification routines. These routines require a more complex combination of characters than the normal naming rules permit. You implement these routines with the UTLPWDMG.SQL script, which is further described in Oracle Database Security Guide.

**Note:**

Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

**See Also:**

Oracle Database Security Guide for more information about case-sensitive passwords, password complexity, and other password guidelines.

[HTTP] DIGEST Clause

This clause lets you ENABLE or DISABLE HTTP Digest Access Authentication for the user. The default is DISABLE.

The HTTP keyword is optional and is provided for semantic clarity.

**Restriction on the [HTTP] DIGEST Clause**

You cannot specify this clause for external or global users.

**EXTERNALLY Clause**

Specify EXTERNALLY to create an external user. Such a user must be authenticated by an external service, such as an operating system or a third-party service. In this case, Oracle Database relies on authentication by the operating system or third-party service to ensure that a specific external user has access to a specific database user.

**AS 'certificate_DN'**

This clause is required for and used for SSL-authenticated external users only. The certificate_DN is the distinguished name in the user's PKI certificate in the user's wallet. The maximum length of certificate_DN is 1024 characters.

**AS 'kerberos_principal_name'**

This clause is required for and used for Kerberos-authenticated external users only. The maximum length of kerberos_principal_name is 1024 characters.
Note:

Oracle strongly recommends that you do not use IDENTIFIED EXTERNALLY with operating systems that have inherently weak login security.

Restriction on Creating External Users

Oracle ASM does not support the creation of external users.

See Also:

- Oracle Database Enterprise User Security Administrator's Guide for more information on externally identified users
- "Creating External Database Users: Examples"

GLOBALLY Clause

The GLOBALLY clause lets you create a **global user**. Such a user must be authorized by the enterprise directory service (Oracle Internet Directory).

The directory_DN string can take one of two forms:

- The X.509 name at the enterprise directory service that identifies this user. It should be of the form `CN=username,other_attributes`, where `other_attributes` is the rest of the user's distinguished name (DN) in the directory. This form uses the LDAP Data Interchange Format (LDIF) and creates a **private global schema**.
- A null string (""") indicating that the enterprise directory service will map authenticated global users to this database schema with the appropriate roles. This form is the same as specifying the GLOBALLY keyword alone and creates a **shared global schema**.

The maximum length of `directory_DN` is 1024 characters.

You can control the ability of an application server to connect as the specified user and to activate that user's roles using the `ALTER USER` statement.

Restriction on Creating Global Users

Oracle ASM does not support the creation of global users.

See Also:

- Oracle Database Security Guide for more information on global users
- ALTER USER
- "Creating a Global Database User: Example"
NO AUTHENTICATION Clause

Use the `NO AUTHENTICATION` clause to create a schema that does not have a password and cannot be logged into. This is intended for schema only accounts and reduces maintenance by removing default passwords and any requirement to rotate the password.

DEFAULT COLLATION Clause

This clause lets you specify the default collation for the schema owned by the user. The default collation is assigned to tables, views, and materialized views that are subsequently created in the schema.

For `collation_name`, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the schema owned by the user is set to the `USING_NLS_COMP` pseudo-collation.

You can override this clause and assign a different default collation to a particular table, materialized view, or view by specifying the `DEFAULT COLLATION` clause of the `CREATE` or `ALTER` statement for the table, materialized view, or view. You can also override the default collations of all schemas for the duration of a database session by setting the default collation for the session. See the `DEFAULT_COLLATION` clause of `ALTER SESSION` for more details.

You can specify the `DEFAULT COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to `12.2` or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

DEFAULT TABLESPACE Clause

Specify the default tablespace for objects that are created in the user's schema. If you omit this clause, then the user's objects are stored in the database default tablespace. If no default tablespace has been specified for the database, then the user's objects are stored in the `SYSTEM` tablespace.

Restriction on Default Tablespaces

You cannot specify a locally managed temporary tablespace, including an undo tablespace, or a dictionary-managed temporary tablespace, as a user's default tablespace.

See Also:

- `CREATE TABLESPACE` for more information on tablespaces in general and undo tablespaces in particular
- `Oracle Database Security Guide` for more information on assigning default tablespaces to users

[LOCAL] TEMPORARY TABLESPACE Clause

Specify the tablespace or tablespace group for the user's temporary segments. If you omit this clause, then the user's temporary segments are stored in the database default temporary tablespace or, if none has been specified, in the `SYSTEM` tablespace.
• Specify `tablespace` to indicate the user's temporary tablespace. Specify `TEMPORARY TABLESPACE` to indicate a shared temporary tablespace. Specify `LOCAL TEMPORARY TABLESPACE` to indicate a local temporary tablespace. If you are connected to a CDB, then you can specify `CDB$DEFAULT` to use the CDB-wide default temporary tablespace.

• Specify `tablespace_group_name` to indicate that the user can save temporary segments in any tablespace in the tablespace group specified by `tablespace_group_name`. Local temporary tablespaces cannot be part of a tablespace group.

Restrictions on Temporary Tablespace

This clause is subject to the following restrictions:

• The tablespace must be a temporary tablespace and must have a standard block size.

• The tablespace cannot be an undo tablespace or a tablespace with automatic segment-space management.

See Also:

• `Oracle Database Administrator's Guide` for information about tablespace groups and `Oracle Database Security Guide` for information on assigning temporary tablespaces to users

• `CREATE TABLESPACE` for more information on undo tablespaces and segment management

• "Assigning a Tablespace Group: Example"

QUOTA Clause

Use the `QUOTA` clause to specify the maximum amount of space the user can allocate in the tablespace.

A `CREATE USER` statement can have multiple `QUOTA` clauses for multiple tablespaces.

`UNLIMITED` lets the user allocate space in the tablespace without bound.

The maximum amount of space that you can specify is 2 terabytes (TB). If you need more space, then specify `UNLIMITED`.

Restriction on the QUOTA Clause

You cannot specify this clause for a temporary tablespace.

See Also:

• `size_clause` for information on that clause and `Oracle Database Security Guide` for more information on assigning tablespace quotas
PROFILE Clause

Specify the profile you want to assign to the user. The profile limits the amount of
database resources the user can use. If you omit this clause, then Oracle Database
assigns the DEFAULT profile to the user.

Note:

Oracle recommends that you use the Database Resource Manager rather
SQL profiles to establish database resource limits. The Database Resource
Manager offers a more flexible means of managing and tracking resource
use. For more information on the Database Resource Manager, refer to
Oracle Database Administrator's Guide.

See Also:

GRANT and CREATE PROFILE

PASSWORD EXPIRE Clause

Specify PASSWORD EXPIRE if you want the user's password to expire. This setting
forces the user or the DBA to change the password before the user can log in to
the database.

ACCOUNT Clause

Specify ACCOUNT LOCK to lock the user's account and disable access. Specify ACCOUNT
UNLOCK to unlock the user's account and enable access to the account. The default is
ACCOUNT UNLOCK.

ENABLE EDITIONS

This clause is not reversible. Specify ENABLE EDITIONS to allow the user to create
multiple versions of editionable objects in this schema using editions. Editionable
objects in schemas that are not editions-enabled cannot be editioned.

Restriction on Enabling Editions

You cannot enable editions for any schemas supplied by Oracle except for the sample
schemas in the seed database.

CONTAINER Clause

The CONTAINER clause applies when you are connected to a CDB. However, it is not
necessary to specify the CONTAINER clause because its default values are the only
allowed values.

• To create a common user, you must be connected to the root. You can optionally
specify CONTAINER = ALL, which is the default when you are connected to the root.
• To create a local user, you must be connected to a PDB. You can optionally specify CONTAINER = CURRENT, which is the default when you are connected to a PDB.

While creating a common user, any default tablespace, temporary tablespace, or profile specified using the following clauses must exist in all the containers belonging to the CDB:

- DEFAULT TABLESPACE
- TEMPORARY TABLESPACE
- QUOTA
- PROFILE

If these objects do not exist in all the containers, the CREATE USER statement fails.

Examples

All of the following examples use the example tablespace, which exists in the seed database and is accessible to the sample schemas.

Creating a Database User: Example

If you create a new user with PASSWORD EXPIRE, then the user's password must be changed before the user attempts to log in to the database. You can create the user sidney by issuing the following statement:

```
CREATE USER sidney
  IDENTIFIED BY out_standing1
  DEFAULT TABLESPACE example
  QUOTA 10M ON example
  TEMPORARY TABLESPACE temp
  QUOTA 5M ON system
  PROFILE app_user
  PASSWORD EXPIRE;
```

The user sidney has the following characteristics:

- The password out_standing1
- Default tablespace example, with a quota of 10 megabytes
- Temporary tablespace temp
- Access to the tablespace SYSTEM, with a quota of 5 megabytes
- Limits on database resources defined by the profile app_user (which was created in “Creating a Profile: Example”)
- An expired password, which must be changed before sidney can log in to the database

Creating External Database Users: Examples

The following example creates an external user, who must be identified by an external source before accessing the database:

```
CREATE USER app_user1
  IDENTIFIED EXTERNALLY
  DEFAULT TABLESPACE example
  QUOTA 5M ON example
  PROFILE app_user;
```
The user `app_user1` has the following additional characteristics:

- Default tablespace `example`
- Default temporary tablespace `example`
- 5M of space on the tablespace `example` and unlimited quota on the temporary tablespace of the database
- Limits on database resources defined by the `app_user` profile

To create another user accessible only by an operating system account, prefix the user name with the value of the initialization parameter `OS_AUTHENT_PREFIX`. For example, if this value is "ops$", then you can create the externally identified user `external_user` with the following statement:

```
CREATE USER ops$external_user
   IDENTIFIED EXTERNALLY
   DEFAULT TABLESPACE example
   QUOTA 5M ON example
   PROFILE app_user;
```

Creating a Global Database User: Example

The following example creates a global user. When you create a global user, you can specify the X.509 name that identifies this user at the enterprise directory server:

```
CREATE USER global_user
   IDENTIFIED GLOBALLY AS 'CN=analyst, OU=division1, O=oracle, C=US'
   DEFAULT TABLESPACE example
   QUOTA 5M ON example;
```

Creating a Common User in a CDB

The following example creates a common user called `c##comm_user` in a CDB. Before you run this `CREATE USER` statement, ensure that the tablespaces `example` and `temp_tbs` exist in all of the containers in the CDB.

```
CREATE USER c##comm_user
   IDENTIFIED BY comm_pwd
   DEFAULT TABLESPACE example
   QUOTA 20M ON example
   TEMPORARY TABLESPACE temp_tbs;
```

The user `comm_user` has the following additional characteristics:

- The password `comm_pwd`
- Default tablespace `example`, with a quota of 20 megabytes
- Temporary tablespace `temp_tbs`

**CREATE VIEW**

**Purpose**

Use the `CREATE VIEW` statement to define a view, which is a logical table based on one or more tables or views. A view contains no data itself. The tables upon which a view is based are called base tables.
You can also create an **object view** or a relational view that supports LOBs, object types, REF data types, nested table, or varray types on top of the existing view mechanism. An object view is a view of a user-defined type, where each row contains objects, each object with a unique object identifier.

You can also create **XMLType views**, which are similar to object views but display data from XMLSchema-based tables of **XMLType**.

**See Also:**
- Oracle Database Concepts, Oracle Database Development Guide, and Oracle Database Administrator’s Guide for information on various types of views and their uses
- Oracle XML DB Developer’s Guide for information on XMLType views
- ALTER VIEW and DROP VIEW for information on modifying a view and removing a view from the database

**Prerequisites**

To create a view in your own schema, you must have the **CREATE VIEW** system privilege. To create a view in another user’s schema, you must have the **CREATE ANY VIEW** system privilege.

To create a subview, you must have the **UNDER ANY VIEW** system privilege or the **UNDER** object privilege on the superview.

The owner of the schema containing the view must have the privileges necessary to either select (READ or SELECT privilege), insert, update, or delete rows from all the tables or views on which the view is based. The owner must be granted these privileges directly, rather than through a role.

To use the basic constructor method of an object type when creating an object view, one of the following must be true:

- The object type must belong to the same schema as the view to be created.
- You must have the **EXECUTE ANY TYPE** system privileges.
- You must have the **EXECUTE** object privilege on that object type.

**See Also:**
- SELECT, INSERT, UPDATE, and DELETE for information on the privileges required by the owner of a view on the base tables or views of the view being created
Syntax

```plaintext

```
WITH READ ONLY CHECK OPTION CONSTRAINT constraint
```

Chapter 15
CREATE VIEW

15-189
Semantics

OR REPLACE

Specify OR REPLACE to re-create the view if it already exists. You can use this clause to change the definition of an existing view without dropping, re-creating, and regranting object privileges previously granted on it.

INSTEAD OF triggers defined on a conventional view are dropped when the view is re-created. DML triggers defined on an editioning view are retained when an editioning view is re-created. However, such triggers can be rendered permanently invalid if the editioning view has changed so that it can no longer be compiled—for example if an editioning view column referenced in the trigger definition has been dropped.

If any materialized views are dependent on view, then those materialized views will be marked UNUSABLE and will require a full refresh to restore them to a usable state. Invalid materialized views cannot be used by query rewrite and cannot be refreshed until they are recompiled.

You cannot replace a conventional view with an editioning view or an editioning view with a conventional view. See Oracle Database Development Guide for more information on editioning views.

See Also:

- ALTER MATERIALIZED VIEW for information on refreshing invalid materialized views
- Oracle Database Concepts for information on materialized views in general
- CREATE TRIGGER for more information about the INSTEAD OF clause

FORCE

Specify FORCE if you want to create the view regardless of whether the base tables of the view or the referenced object types exist or the owner of the schema containing the view has privileges on them. These conditions must be true before any SELECT, INSERT, UPDATE, or DELETE statements can be issued against the view.

If the view definition contains any constraints, CREATE VIEW ... FORCE fails if the base table does not exist or the referenced object type does not exist. CREATE VIEW ... FORCE also fails if the view definition names a constraint that does not exist.

NO FORCE

Specify NOFORCE if you want to create the view only if the base tables exist and the owner of the schema containing the view has privileges on them. This is the default.

EDITIONING

Use this clause to create an editioning view. An editioning view is a single-table view that selects all rows from the base table and displays a subset of the base table columns. You can use an editioning view to isolate an application from DDL changes...
to the base table during administrative operations such as upgrades. You can obtain information about the relationship of existing editioning view to their base tables by querying the USER_, ALL_, and DBA_EDITIONING_VIEW data dictionary views.

The owner of an editioning view must be editions-enabled. Refer to ENABLE EDITIONS for more information.

**Notes on Editioning Views**

Editioning views differ from conventional views in several important ways:

- Editioning views are intended only to select and provide aliases for a subset of columns in a table. Therefore, the syntax for creating an editioning view is more limited than the syntax for creating a conventional view. Any violation of the restrictions that follow causes the creation of the view to fail, even if you specify FORCE.

- You can create DML triggers on editioning views. In this case, the database considers the editioning view to be the base object of the trigger. Such triggers fire when a DML operation target the editioning view itself. They do not fire if the DML operation targets the base table.

- You cannot create INSTEAD OF triggers on editioning views.

**Restrictions on Editioning Views**

Editioning views are subject to the following restrictions:

- Within any edition, you can create only one editioning view for any single table.

- You cannot specify the object_view_clause, XMLType_view_clause, or BEQUEATH clause.

- You cannot define a constraint WITH CHECK OPTION on an editioning view.

- In the select list of the defining subquery, you can specify only simple references to the columns of the base table, and you can specify each column of the base table only once in the select list. The asterisk wildcard symbol * and t_alias.* are supported to designate all columns of a base table.

- The FROM clause of the defining subquery of the view can reference only a single existing database table. Joins are not permitted. The base table must be in the same schema as the view being created. You cannot use a synonym to identify the table, but you can specify a table alias.

- The following clauses of the defining subquery are not valid for editioning views: subquery_factoring_clause, DISTINCT or UNIQUE, where_clause, hierarchical_query_clause, group_by_clause, HAVING condition, model_clause, or the set operators (UNION, INTERSECT, or MINUS)

---

**See Also:**

- Oracle Database Development Guide for detailed information about editioning views
- CREATE EDITION for information about editions, including an example of an editioning view
EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the view becomes an editioned or noneditioned object if editioning is enabled for the schema object type VIEW in schema. The default is EDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

schema

Specify the schema to contain the view. If you omit schema, then Oracle Database creates the view in your own schema.

view

Specify the name of the view or the object view. The name must satisfy the requirements listed in "Database Object Naming Rules ".

Restriction on Views

If a view has INSTEAD OF triggers, then any views created on it must have INSTEAD OF triggers, even if the views are inherently updatable.

See Also:
"Creating a View: Example"

SHARING

This clause applies only when creating a view in an application root. This type of view is called an application common object and its data can be shared with the application PDBs that belong to the application root. To determine how the view data is shared, specify one of the following sharing attributes:

- METADATA - A metadata link shares the view's metadata, but its data is unique to each container. This type of view is referred to as a metadata-linked application common object.
- DATA - A data link shares the view, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of view is referred to as a data-linked application common object.
- EXTENDED DATA - An extended data link shares the view, and its data in the application root is the same for all containers in the application container. However, each application PDB in the application container can store data that is unique to the application PDB. For this type of view, data is stored in the application root and, optionally, in each application PDB. This type of view is referred to as an extended data-linked application common object.
- NONE - The view is not shared.

If you omit this clause, then the database uses the value of the DEFAULT_SHARING initialization parameter to determine the sharing attribute of the view. If the DEFAULT_SHARING initialization parameter does not have a value, then the default is METADATA.
When creating a conventional view, you can specify METADATA, DATA, EXTENDED DATA, or NONE.

When creating an object view or an XMLTYPE view, you can specify only METADATA or NONE.

You cannot change the sharing attribute of a view after it is created.

**See Also:**

- *Oracle Database Reference* for more information on the DEFAULT_SHARING initialization parameter
- *Oracle Database Administrator’s Guide* for complete information on creating application common objects

**alias**

Specify names for the expressions selected by the defining query of the view. The number of aliases must match the number of expressions selected by the view. Aliases must follow the rules for naming Oracle Database schema objects. Aliases must be unique within the view.

If you omit the aliases, then the database derives them from the columns or column aliases in the query. For this reason, you must use aliases if the query contains expressions rather than only column names. Also, you must specify aliases if the view definition includes constraints.

**Restriction on View Aliases**

You cannot specify an alias when creating an object view.

**See Also:**

"Syntax for Schema Objects and Parts in SQL Statements"

**VISIBLE | INVISIBLE**

Use this clause to specify whether a view column is VISIBLE or INVISIBLE. By default, view columns are VISIBLE regardless of their visibility in the base tables, unless you specify INVISIBLE. This applies to conventional views and editioning views. For complete information on these clauses, refer to "VISIBLE | INVISIBLE" in the documentation on CREATE TABLE.

**inline_constraint and out_of_line_constraint**

You can specify constraints on views and object views. You define the constraint at the view level using the out_of_line_constraint clause. You define the constraint as part of column or attribute specification using the inline_constraint clause after the appropriate alias.

Oracle Database does not enforce view constraints. For a full discussion of view constraints, including restrictions, refer to "View Constraints ". 
object_view_clause

The object_view_clause lets you define a view on an object type.

See Also:
"Creating a View with Constraints: Example"

OF type_name Clause

Use this clause to explicitly create an object view of type type_name. The columns of an object view correspond to the top-level attributes of type type_name. Each row will contain an object instance and each instance will be associated with an object identifier as specified in the WITH OBJECT IDENTIFIER clause. If you omit schema, then the database creates the object view in your own schema.

Object tables, as well as XMLType tables, object views, and XMLType views, do not have any column names specified for them. Therefore, Oracle Database defines a system-generated pseudocolumn OBJECT_ID. You can use this column name in queries and to create object views with the WITH OBJECT IDENTIFIER clause.

WITH OBJECT IDENTIFIER Clause

Use the WITH OBJECT IDENTIFIER clause to specify a top-level (root) object view. This clause lets you specify the attributes of the object type that will be used as a key to identify each row in the object view. In most cases these attributes correspond to the primary key columns of the base table. You must ensure that the attribute list is unique and identifies exactly one row in the view. The WITH OBJECT IDENTIFIER and WITH OBJECT ID clauses can be used interchangeably and are provided for semantic clarity.

Restrictions on Object Views

Object views are subject to the following restrictions:

- If you try to dereference or pin a primary key REF that resolves to more than one instance in the object view, then the database returns an error.
- You cannot specify this clause if you are creating a subview, because subviews inherit object identifiers from superviews.

If the object view is defined on an object table or an object view, then you can omit this clause or specify DEFAULT.

DEFAULT

Specify DEFAULT if you want the database to use the intrinsic object identifier of the underlying object table or object view to uniquely identify each row.

attribute
For attribute, specify an attribute of the object type from which the database should create the object identifier for the object view.

**UNDER Clause**

Use the `UNDER` clause to specify a subview based on an object superview.

**Restrictions on Subviews**

Subviews are subject to the following restrictions:

- You must create a subview in the same schema as the superview.
- The object type `type_name` must be the immediate subtype of `superview`.
- You can create only one subview of a particular type under the same superview.

**See Also:**

- `CREATE TYPE` for information about creating objects
- *Oracle Database Reference* for information on data dictionary views

**XMLType_view_clause**

Use this clause to create an XMLType view, which displays data from an XMLSchema-based table of type XMLType. The `XMLSchema_spec` indicates the XMLSchema to be used to map the XML data to its object-relational equivalents. The XMLSchema must already have been created before you can create an XMLType view.

The `WITH OBJECT IDENTIFIER` and `WITH OBJECT ID` clauses can be used interchangeably and are provided for semantic clarity.

Object tables, as well as XMLType tables, object views, and XMLType views, do not have any column names specified for them. Therefore, Oracle Database defines a system-generated pseudocolumn `OBJECT_ID`. You can use this column name in queries and to create object views with the `WITH OBJECT IDENTIFIER` clause.

**See Also:**

- *Oracle XML DB Developer's Guide* for information on XMLType views and XMLSchemas
- "Creating an XMLType View: Example" and "Creating a View on an XMLType Table: Example"

**DEFAULT COLLATION**

Use this clause to specify the default collation for the view. The default collation is used as the derived collation for all the character literals included in the defining query of the view. The default collation is not used by the view columns; the collations for the view columns are derived from the view's defining subquery. The `CREATE VIEW` statement fails with an error if any of its character columns is based on an expression in the defining subquery that has no derived collation.
For `collation_name`, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the view is set to the effective schema default collation of the schema containing the view. Refer to the `DEFAULT_COLLATION` clause of `ALTER SESSION` for more information on the effective schema default collation.

You can specify the `DEFAULT_COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

To change the default collation for a view, you must recreate the view.

**Restriction on the Default Collation for Views**

If the defining query of the view contains the `WITH plsql_declarations` clause, then the default collation of the view must be `USING_NLS_COMP`.

**BEQUEATH**

Use the `BEQUEATH` clause to specify whether functions referenced in the view are executed using the view invoker's rights or the view definer's rights.

**CURRENT_USER**

If you specify `BEQUEATH CURRENT_USER`, then functions referenced by the view are executed using the view invoker's rights as long as one of the following conditions is met:

- The view owner has the `INHERIT PRIVILEGES` object privilege on the invoking user.
- The view owner has the `INHERIT ANY PRIVILEGES` system privilege.

If a query of the view invokes an identity- or privilege-sensitive SQL function, or an invoker's rights PL/SQL or Java function, then the current schema, current user, and currently enabled roles within the operation's execution are inherited from the querying user's environment, rather than from the owner of the view.

This clause does not turn the view itself into an invoker's rights object. Name resolution within the view is still handled using the view owner's schema, and privilege checking for the view is done using the view owner's privileges.

**DEFINER**

If you specify `BEQUEATH DEFINER`, then functions referenced by the view are executed using the view definer's rights. If a query on the view invokes an identity- or privilege-sensitive SQL function, or an invoker's rights PL/SQL or Java function, then the current schema, current user, and currently enabled roles within the operation's execution are inherited from the owner of the view.

Name resolution within the view is handled using the view owner's schema, and privilege checking for the view is done using the view owner's privileges.

This is the default.

**Restriction on the BEQUEATH Clause**

You cannot specify this clause with the `EDITIONING` clause.
AS subquery

Specify a subquery that identifies columns and rows of the table(s) that the view is based on. The select list of the subquery can contain up to 1000 expressions.

If you create views that refer to remote tables and views, then the database links you specify must have been created using the `CONNECT TO` clause of the `CREATE DATABASE LINK` statement, and you must qualify them with a schema name in the view subquery.

If you create a view with the `flashback_query_clause` in the defining query, then the database does not interpret the `AS OF` expression at create time but rather each time a user subsequently queries the view.

Restrictions on the Defining Query of a View

The view query is subject to the following restrictions:

- The subquery cannot select the CURRVAL or NEXTVAL pseudocolumns.
- If the subquery selects the ROWID, ROWNUM, or LEVEL pseudocolumns, then those columns must have aliases in the view subquery.
- If the subquery uses an asterisk (\*) to select all columns of a table, and you later add new columns to the table, then the view will not contain those columns until you re-create the view by issuing a `CREATE OR REPLACE VIEW` statement.
- For object views, the number of elements in the subquery select list must be the same as the number of top-level attributes for the object type. The data type of each of the selecting elements must be the same as the corresponding top-level attribute.
- You cannot specify the SAMPLE clause.

The preceding restrictions apply to materialized views as well.

Notes on Updatable Views

The following notes apply to updatable views:

An updatable view is one you can use to insert, update, or delete base table rows. You can create a view to be inherently updatable, or you can create an INSTEAD OF trigger on any view to make it updatable.

To learn whether and in what ways the columns of an inherently updatable view can be modified, query the `USER_UPDATABLE_COLUMNS` data dictionary view. The information
displayed by this view is meaningful only for inherently updatable views. For a view to be inherently updatable, the following conditions must be met:

- Each column in the view must map to a column of a single table. For example, if a view column maps to the output of a `TABLE` clause (an unnested collection), then the view is not inherently updatable.
- The view must not contain any of the following constructs:
  - A set operator
  - A `DISTINCT` operator
  - An aggregate or analytic function
  - `GROUP BY`, `ORDER BY`, `MODEL`, `CONNECT BY`, or `START WITH` clause
  - A collection expression in a `SELECT` list
  - A subquery in a `SELECT` list
  - A subquery designated with `READ ONLY`
  - Joins, with some exceptions, as documented in Oracle Database Administrator's Guide
- In addition, if an inherently updatable view contains pseudocolumns or expressions, then you cannot update base table rows with an `UPDATE` statement that refers to any of these pseudocolumns or expressions.
- If you want a join view to be updatable, then all of the following conditions must be true:
  - The DML statement must affect only one table underlying the join.
  - For an `INSERT` statement, the view must not be created with `CHECK OPTION`, and all columns into which values are inserted must come from a key-preserved table. A key-preserved table is one for which every primary key or unique key value in the base table is also unique in the join view.
  - For an `UPDATE` statement, the view must not be created with `CHECK OPTION`, and all columns updated must be extracted from a key-preserved table.
  - For a `DELETE` statement, if the join results in more than one key-preserved table, then Oracle Database deletes from the first table named in the `FROM` clause, whether or not the view was created with `CHECK OPTION`.

See Also:

- Oracle Database Administrator's Guide for more information on updatable views
- "Creating an Updatable View: Example", "Creating a Join View: Example" for an example of updatable join views and key-preserved tables, and Oracle Database PL/SQL Language Reference for an example of an INSTEAD OF trigger on a view that is not inherently updatable

**subquery_restriction_clause**

Use the `subquery_restriction_clause` to restrict the defining query of the view in one of the following ways:
WITH READ ONLY

Specify WITH READ ONLY to indicate that the table or view cannot be updated.

WITH CHECK OPTION

Specify WITH CHECK OPTION to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the FROM clause but not in subquery in the WHERE clause.

CONSTRAINT constraint

Specify the name of the READ ONLY or CHECK OPTION constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form SYS_Cn, where $n$ is an integer that makes the constraint name unique within the database.

Note:

For tables, WITH CHECK OPTION guarantees that inserts and updates result in tables that the defining table subquery can select. For views, WITH CHECK OPTION cannot make this guarantee if:

- There is a subquery within the defining query of this view or any view on which this view is based or
- INSERT, UPDATE, or DELETE operations are performed using INSTEAD OF triggers.

Restriction on the subquery_restriction_clause

You cannot specify this clause if you specify an ORDER BY clause.

See Also:

"Creating a Read-Only View: Example"

CONTAINER_MAP

Specify the CONTAINER_MAP clause to enable the view to be queried using a container map.

CONTAINERS_DEFAULT

Specify the CONTAINERS_DEFAULT clause to enable the view for the CONTAINERS clause.

Examples

Creating a View: Example

The following statement creates a view of the sample table employees named emp_view. The view shows the employees in department 20 and their annual salary:
CREATE VIEW emp_view AS
    SELECT last_name, salary*12 annual_salary
    FROM employees
    WHERE department_id = 20;

The view declaration need not define a name for the column based on the expression salary*12, because the subquery uses a column alias (annual_salary) for this expression.

Creating an Editioning View: Example

The following statement creates an editioning view of the orders table:

CREATE EDITIONING VIEW ed_orders_view (o_id, o_date, o_status)
    AS SELECT order_id, order_date, order_status FROM orders
    WITH READ ONLY;

You can use this view to isolate an application from DDL changes to the orders table during an administrative operation such as an upgrade. You can create a DML trigger on this view, so that the trigger fires when a DML operation targets the view itself, but does not fire if the DML operation targets the orders table.

Creating a View with Constraints: Example

The following statement creates a restricted view of the sample table hr.employees and defines a unique constraint on the email view column and a primary key constraint for the view on the emp_id view column:

CREATE VIEW emp_sal (emp_id, last_name,
    email UNIQUE RELY DISABLE NOVALIDATE,
    CONSTRAINT id_pk PRIMARY KEY (emp_id) RELY DISABLE NOVALIDATE)
    AS SELECT employee_id, last_name, email FROM employees;

Creating an Updatable View: Example

The following statement creates an updatable view named clerk of all clerks in the employees table. Only the employees' IDs, last names, department numbers, and jobs are visible in this view, and these columns can be updated only in rows where the employee is a kind of clerk:

CREATE VIEW clerk AS
    SELECT employee_id, last_name, department_id, job_id
    FROM employees
    WHERE job_id = 'PU_CLERK'
    OR job_id = 'SH_CLERK'
    OR job_id = 'ST_CLERK';

This view lets you change the job_id of a purchasing clerk to purchasing manager (PU_MAN):

UPDATE clerk SET job_id = 'PU_MAN' WHERE employee_id = 118;

The next example creates the same view WITH CHECK OPTION. You cannot subsequently insert a new row into clerk if the new employee is not a clerk. You can update an employee's job_id from one type of clerk to another type of clerk, but the update in the preceding statement would fail, because the view cannot access employees with non-clerk job_id.

CREATE VIEW clerk AS
    SELECT employee_id, last_name, department_id, job_id
FROM employees
WHERE job_id = 'PU_CLERK'
  or job_id = 'SH_CLERK'
  or job_id = 'ST_CLERK'
WITH CHECK OPTION;

Creating a Join View: Example

A join view is one whose view subquery contains a join. If at least one column in the
join has a unique index, then it may be possible to modify one base table in a join
view. You can query USER_UPDATABLE_COLUMNS to see whether the columns in a join
view are updatable. For example:

CREATE VIEW locations_view AS
    SELECT d.department_id, d.department_name, l.location_id, l.city
    FROM departments d, locations l
    WHERE d.location_id = l.location_id;

SELECT column_name, updatable
    FROM user_updatable_columns
    WHERE table_name = 'LOCATIONS_VIEW'
    ORDER BY column_name, updatable;

<table>
<thead>
<tr>
<th>COLUMN_NAME</th>
<th>UPD</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEPARTMENT_ID</td>
<td>YES</td>
</tr>
<tr>
<td>DEPARTMENT_NAME</td>
<td>YES</td>
</tr>
<tr>
<td>LOCATION_ID</td>
<td>NO</td>
</tr>
<tr>
<td>CITY</td>
<td>NO</td>
</tr>
</tbody>
</table>

In the preceding example, the primary key index on the location_id column of the
locations table is not unique in the locations_view view. Therefore, locations is not
a key-preserved table and columns from that base table are not updatable.

INSERT INTO locations_view VALUES
    (999, 'Entertainment', 87, 'Roma');

ERROR at line 1:
ORA-01776: cannot modify more than one base table through a join view

You can insert, update, or delete a row from the departments base table, because all
the columns in the view mapping to the departments table are marked as updatable
and because the primary key of departments is retained in the view.

INSERT INTO locations_view (department_id, department_name)
    VALUES (999, 'Entertainment');

1 row created.

Note:

For you to insert into the table using the view, the view must contain all NOT NULL
columns of all tables in the join, unless you have specified DEFAULT values for the NOT NULL columns.
Creating a Read-Only View: Example

The following statement creates a read-only view named `customer_ro` of the `oe.customers` table. Only the customers' last names, language, and credit limit are visible in this view:

```sql
CREATE VIEW customer_ro (name, language, credit) AS
    SELECT cust_last_name, nls_language, credit_limit
    FROM customers
    WITH READ ONLY;
```

Creating an Object View: Example

The following example shows the creation of the type `inventory_typ` in the `oc` schema, and the `oc_inventories` view that is based on that type:

```sql
CREATE TYPE inventory_typ
    OID '82A4AF6A4CD4656DE034080020E0EE3D'
    AS OBJECT
    ( product_id    NUMBER(6),
    , warehouse     warehouse_typ
    , quantity_on_hand    NUMBER(8) )
/
CREATE OR REPLACE VIEW oc_inventories OF inventory_typ
    WITH OBJECT OID (product_id)
    AS
    SELECT i.product_id,
            warehouse_typ(w.warehouse_id, w.warehouse_name, w.location_id),
    i.quantity_on_hand
    FROM inventories i, warehouses w
    WHERE i.warehouse_id=w.warehouse_id;
```

Creating a View on an XMLType Table: Example

The following example builds a regular view on the XMLType table `xwarehouses`, which was created in “Examples”:

```sql
CREATE VIEW warehouse_view AS
    SELECT VALUE(p) AS warehouse_xml
    FROM xwarehouses p;
```

You select from such a view as follows:

```sql
SELECT e.warehouse_xml.getclobval()
    FROM warehouse_view e
    WHERE EXISTSNODE(warehouse_xml, '//Docks') =1;
```

Creating an XMLType View: Example

In some cases you may have an object-relational table upon which you would like to build an XMLType view. The following example creates an object-relational table resembling the XMLType column `warehouse_spec` in the sample table `oe.warehouses`, and then creates an XMLType view of that table:
CREATE TABLE warehouse_table
(
    WarehouseID       NUMBER,
    Area              NUMBER,
    Docks             NUMBER,
    DockType          VARCHAR2(100),
    WaterAccess       VARCHAR2(10),
    RailAccess        VARCHAR2(10),
    Parking           VARCHAR2(20),
    VClearance        NUMBER
);

INSERT INTO warehouse_table
VALUES(5, 103000,3,'Side Load','false','true','Lot',15);

CREATE VIEW warehouse_view OF XMLTYPE
XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
ELEMENT "Warehouse"
WITH OBJECT ID
(extract(OBJECT_VALUE, '/Warehouse/Area/text()').getnumberval())
AS SELECT XMLELEMENT("Warehouse",
    XMLFOREST(WarehouseID as "Building",
        area as "Area",
        docks as "Docks",
        docktype as "DockType",
        wateraccess as "WaterAccess",
        railaccess as "RailAccess",
        parking as "Parking",
        VClearance as "VClearance")
) FROM warehouse_table;

You query this view as follows:

SELECT VALUE(e) FROM warehouse_view e;

DELETE

Purpose

Use the DELETE statement to remove rows from:

• An unpartitioned or partitioned table
• The unpartitioned or partitioned base table of a view
• The unpartitioned or partitioned container table of a writable materialized view
• The unpartitioned or partitioned master table of an updatable materialized view

Prerequisites

For you to delete rows from a table, the table must be in your own schema or you must have the DELETE object privilege on the table.

For you to delete rows from an updatable materialized view, the materialized view must be in your own schema or you must have the DELETE object privilege on the materialized view.

For you to delete rows from the base table of a view, the owner of the schema containing the view must have the DELETE object privilege on the base table. Also, if
the view is in a schema other than your own, then you must have the DELETE object privilege on the view.

The DELETE ANY TABLE system privilege also allows you to delete rows from any table or table partition or from the base table of any view.

To delete rows from an object on a remote database, you must also have the READ or SELECT object privilege on the object.

If the SQL92_SECURITY initialization parameter is set to TRUE and the DELETE operation references table columns, such as the columns in a where_clause, then you must also have the SELECT object privilege on the object from which you want to delete rows.

You cannot delete rows from a table if a function-based index on the table has become invalid. You must first validate the function-based index.

Syntax

\[

integer
UNLIMITED
```
Semantics

**hint**

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

**See Also:**

"Hints " for the syntax and description of hints

**from_clause**

Use the FROM clause to specify the database objects from which you are deleting rows.

The **ONLY** syntax is relevant only for views. Use the **ONLY** clause if the view in the FROM clause belongs to a view hierarchy and you do not want to delete rows from any of its subviews.

**DML_table_expression_clause**

Use this clause to specify the objects from which data is being deleted.

**schema**

Specify the schema containing the table or view. If you omit schema, then Oracle Database assumes the table or view is in your own schema.

**table | view | materialized view | subquery**

Specify the name of a table, view, materialized view, or the column or columns resulting from a subquery, from which the rows are to be deleted.

When you delete rows from an updatable view, Oracle Database deletes rows from the base table.

You cannot delete rows from a read-only materialized view. If you delete rows from a writable materialized view, then the database removes the rows from the underlying container table. However, the deletions are overwritten at the next refresh operation. If you delete rows from an updatable materialized view that is part of a materialized view group, then the database also removes the corresponding rows from the master table.

If table or the base table of view or the master table of materialized_view contains one or more domain index columns, then this statement executes the appropriate indextype delete routine.

**See Also:**

*Oracle Database Data Cartridge Developer's Guide* for more information on these routines
Issuing a **DELETE** statement against a table fires any **DELETE** triggers defined on the table.

All table or index space released by the deleted rows is retained by the table and index.

**partition_extension_clause**

Specify the name or partition key value of the partition or subpartition targeted for deletes within the object.

You need not specify the partition name when deleting values from a partitioned object. However, in some cases, specifying the partition name is more efficient than a complicated **where_clause**.

**See Also:**

"References to Partitioned Tables and Indexes " and “Deleting Rows from a Partition: Example”

**dblink**

Specify the complete or partial name of a database link to a remote database where the object is located. You can delete rows from a remote object only if you are using Oracle Database distributed functionality.

**Note:**

Starting with Oracle Database 12c Release 2 (12.2), the **DELETE** statement accepts remote LOB locators as bind variables. Refer to the “Distributed LOBs” chapter in Oracle Database SecureFiles and Large Objects Developer’s Guide for more information.

**See Also:**

"References to Objects in Remote Databases " for information on referring to database links and "Deleting Rows from a Remote Database: Example"

If you omit **dblink**, then the database assumes that the object is located on the local database.

**subquery_restriction_clause**

The **subquery_restriction_clause** lets you restrict the subquery in one of the following ways:

**WITH READ ONLY**

Specify **WITH READ ONLY** to indicate that the table or view cannot be updated.
WITH CHECK OPTION

Specify `WITH CHECK OPTION` to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

CONSTRAINT `constraint`

Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where `n` is an integer that makes the constraint name unique within the database.

`See Also:`

"Using the WITH CHECK OPTION Clause: Example"

`table_collection_expression`

The `table_collection_expression` lets you inform Oracle that the value of `collection_expression` should be treated as a table for purposes of query and DML operations. The `collection_expression` can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called `collection unnesting`.

The optional plus (+) is relevant if you are joining the `TABLE` collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

`Note:`

In earlier releases of Oracle, when `collection_expression` was a subquery, `table_collection_expression` was expressed as `THE subquery`. That usage is now deprecated.

You can use a `table_collection_expression` in a correlated subquery to delete rows with values that also exist in another table.

`See Also:`

"Table Collections: Examples"

`collection_expression`

Specify a subquery that selects a nested table column from the object from which you are deleting.

Restrictions on the `dml_table_expression_clause` Clause
This clause is subject to the following restrictions:

- You cannot execute this statement if table or the base or master table of view or materialized_view contains any domain indexes marked IN_PROGRESS or FAILED.

- You cannot insert into a partition if any affected index partitions are marked UNUSABLE.

- You cannot specify the ORDER BY clause in the subquery of the DML_table_expression_clause.

- You cannot delete from a view except through INSTEAD OF triggers if the defining query of the view contains one of the following constructs:
  - A set operator
  - A DISTINCT operator
  - An aggregate or analytic function
  - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
  - A collection expression in a SELECT list
  - A subquery in a SELECT list
  - A subquery designated WITH READ ONLY
  - Joins, with some exceptions, as documented in Oracle Database Administrator's Guide

If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the DELETE statement will fail unless the SKIP_UNUSABLE_INDEXES initialization parameter has been set to true.

See Also:
ALTER SESSION

t_alias
Provide a correlation name for the table, view, materialized view, subquery, or collection value to be referenced elsewhere in the statement. This alias is required if the DML_table_expressionClause references any object type attributes or object type methods. Table aliases are generally used in DELETE statements with correlated queries.

where_clause
Use the where_clause to delete only rows that satisfy the condition. The condition can reference the object from which you are deleting and can contain a subquery. You can delete rows from a remote object only if you are using Oracle Database distributed functionality. Refer to Conditions for the syntax of condition.

If this clause contains a subquery that refers to remote objects, then the DELETE operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the subquery in the DML_table_expressionClause refers to any remote objects, then the DELETE operation will run serially without notification. Refer to the parallel_clause in the CREATE TABLE documentation for additional information.
If you omit `dblink`, then the database assumes that the table or view is located on the local database.

If you omit the `where_clause`, then the database deletes all rows of the object.

**returning_clause**

This clause lets you return values from deleted columns, and thereby eliminate the need to issue a `SELECT` statement following the `DELETE` statement.

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table. When operating on a single row, a DML statement with a `returning_clause` can retrieve column expressions using the affected row, rowid, and `REFs` to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the `returning_clause` stores values from expressions, rowids, and `REFs` involving the affected rows in bind arrays.

**expr**

Each item in the `expr` list must be a valid expression syntax.

**INTO**

The `INTO` clause indicates that the values of the changed rows are to be stored in the variable(s) specified in `data_item` list.

**data_item**

Each `data_item` is a host variable or PL/SQL variable that stores the retrieved `expr` value.

For each expression in the `RETURNING` list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the `INTO` list.

**Restrictions on the RETURNING Clause**

The following restrictions apply to the `RETURNING` clause:

- The `expr` is restricted as follows:
  - For `UPDATE` and `DELETE` statements each `expr` must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same `returning_clause`. For `INSERT` statements, each `expr` must be a simple expression. Aggregate functions are not supported in an `INSERT` statement `RETURNING` clause.
  - Single-set aggregate function expressions cannot include the `DISTINCT` keyword.
- If the `expr` list contains a primary key column or other `NOT NULL` column, then the update statement fails if the table has a `BEFORE UPDATE` trigger defined on it.
- You cannot specify the `returning_clause` for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve `LONG` types with this clause.
• You cannot specify this clause for a view on which an INSTEAD OF trigger has been defined.

See Also:

- Oracle Database PL/SQL Language Reference for information on using the BULK COLLECT clause to return multiple values to collection variables
- "Using the RETURNING Clause: Example"

error_logging_clause

The error_logging_clause has the same behavior in DELETE statement as it does in an INSERT statement. Refer to the INSERT statement error_logging_clause for more information.

See Also:

"Inserting Into a Table with Error Logging: Example"

Examples

Deleting Rows: Examples

The following statement deletes all rows from the sample table oe.product_descriptions where the value of the language_id column is AR:

```
DELETE FROM product_descriptions
  WHERE language_id = 'AR';
```

The following statement deletes from the sample table hr.employees purchasing clerks whose commission rate is less than 10%:

```
DELETE FROM employees
  WHERE job_id = 'SA_REP'
  AND commission_pct < .2;
```

The following statement has the same effect as the preceding example, but uses a subquery:

```
DELETE FROM (SELECT * FROM employees)
  WHERE job_id = 'SA_REP'
  AND commission_pct < .2;
```

Deleting Rows from a Remote Database: Example

The following statement deletes specified rows from the locations table owned by the user hr on a database accessible by the database link remote:

```
DELETE FROM hr.locations@remote
  WHERE location_id > 3000;
```

Deleting Nested Table Rows: Example
For an example that deletes nested table rows, refer to "Table Collections: Examples".

Deleting Rows from a Partition: Example

The following example removes rows from partition sales_q1_1998 of the sh.sales table:

```sql
DELETE FROM sales PARTITION (sales_q1_1998)
  WHERE amount_sold > 1000;
```

Using the RETURNING Clause: Example

The following example returns column salary from the deleted rows and stores the result in bind variable :bnd1. The bind variable must already have been declared.

```sql
DELETE FROM employees
  WHERE job_id = 'SA_REP'
  AND hire_date + TO_YMINTERVAL('01-00') < SYSDATE
RETURNING salary INTO :bnd1;
```

Deleting Data from a Table: Example

The following statements create a table named product_price_history and insert data into it:

```sql
CREATE TABLE product_price_history (  
  product_id          INTEGER NOT NULL,  
  price               INTEGER NOT NULL,  
  currency_code       VARCHAR2(3 CHAR) NOT NULL,  
  effective_from_date DATE NOT NULL,  
  effective_to_date   DATE,  
  CONSTRAINT product_price_history_pk  
    PRIMARY KEY (product_id, currency_code, effective_from_date)  
) PARTITION BY RANGE (effective_from_date) (  
  PARTITION p0 VALUES less than (DATE'2015-01-02'),  
  PARTITION p1 VALUES less than (DATE'2015-01-03'),  
  PARTITION p2 VALUES less than (DATE'2015-01-04')  
);

INSERT INTO product_price_history
WITH prices AS (  
  SELECT 1, 100, 'USD', DATE'2015-01-01', DATE'2015-01-02'
  FROM dual UNION ALL
  SELECT 1, 60, 'GBP', DATE'2015-01-01', DATE'2015-01-02'
  FROM dual UNION ALL
  SELECT 1, 110, 'EUR', DATE'2015-01-01', DATE'2015-01-02'
  FROM dual UNION ALL
  SELECT 1, 101, 'USD', DATE'2015-01-02', DATE'2015-01-03'
  FROM dual UNION ALL
  SELECT 1, 62, 'GBP', DATE'2015-01-02', DATE'2015-01-03'
  FROM dual UNION ALL
  SELECT 1, 109, 'EUR', DATE'2015-01-02', DATE'2015-01-03'
  FROM dual UNION ALL
  SELECT 1, 105, 'USD', DATE'2015-01-03', NULL
  FROM dual UNION ALL
  SELECT 1, 61, 'GBP', DATE'2015-01-03', NULL
  FROM dual UNION ALL
  SELECT 1, 107, 'EUR', DATE'2015-01-03', NULL
  FROM dual UNION ALL
  SELECT 2, 30, 'USD', DATE'2015-01-01', DATE'2015-01-03'
  FROM dual UNION ALL
)  
```
SELECT 2, 33, 'USD', DATE'2015-01-03', NULL
FROM   dual UNION ALL
SELECT 3, 100, 'GBP', DATE'2015-01-03', NULL
FROM   dual
);
SELECT *
FROM   prices;

The following statement deletes the rows from the table product_price_history where product_id is 3:
DELETE FROM product_price_history WHERE product_id = 3;

The following procedure deletes the rows from the product_price_history where product_id is 2 and effective_to_date is NULL:
DECLARE
    currency product_price_history.currency_code%TYPE;
BEGIN
    DELETE product_price_history
    WHERE  product_id = 2
    AND    effective_to_date IS NULL
    returning currency_code INTO currency;
    dbms_output.Put_line(currency);
END;

USD

The following statement deletes the rows from the table product_price_history where currency_code is 'EUR':
DELETE (SELECT * FROM product_price_history) WHERE  currency_code = 'EUR';

The following statement uses a subquery to delete rows from product_price_history:
DELETE product_price_history pp
WHERE  (product_id, currency_code, effective_from_date)
    IN (SELECT product_id, currency_code, Max(effective_from_date)
        FROM   product_price_history
        GROUP BY product_id, currency_code);

The following statement uses partitions to delete rows from product_price_history:
DELETE product_price_history partition (p1);

The following statement displays the table information:
SELECT * FROM product_price_history;

<table>
<thead>
<tr>
<th>PRODUCT_ID</th>
<th>PRICE</th>
<th>CUR</th>
<th>EFFECTIVE</th>
<th>EFFECTIVE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>100</td>
<td>USD</td>
<td>01-JAN-15</td>
<td>02-JAN-15</td>
</tr>
<tr>
<td>1</td>
<td>60</td>
<td>GBP</td>
<td>01-JAN-15</td>
<td>02-JAN-15</td>
</tr>
</tbody>
</table>

The following statement deletes all rows from product_price_history:
DELETE product_price_history;
DISASSOCIATE STATISTICS

Purpose

Use the DISASSOCIATE STATISTICS statement to disassociate default statistics or a statistics type from columns, standalone functions, packages, types, domain indexes, or indextypes.

See Also:

ASSOCIATE STATISTICS for more information on statistics type associations

Prerequisites

To issue this statement, you must have the appropriate privileges to alter the underlying table, function, package, type, domain index, or indextype.
Syntax

dissociate_statistics ::= 

Semantics

FROM COLUMNS | FUNCTIONS | PACKAGES | TYPES | INDEXES | INDEXTYPES

Specify one or more columns, standalone functions, packages, types, domain indexes, or indextypes from which you are disassociating statistics.

If you do not specify schema, then Oracle Database assumes the object is in your own schema.

If you have collected user-defined statistics on the object, then the statement fails unless you specify FORCE.

FORCE

Specify FORCE to remove the association regardless of whether any statistics exist for the object using the statistics type. If statistics do exist, then the statistics are deleted before the association is deleted.
When you drop an object with which a statistics type has been associated, Oracle Database automatically disassociates the statistics type with the FORCE option and drops all statistics that have been collected with the statistics type.

Examples

Disassociating Statistics: Example

This statement disassociates statistics from the `emp_mgmt` package. See Oracle Database PL/SQL Language Reference for the example that creates this package in the `hr` schema.

```
DISASSOCIATE STATISTICS FROM PACKAGES hr.emp_mgmt;
```

DROP ANALYTIC VIEW

Purpose

Use the DROP ANALYTIC VIEW statement to drop an analytic view. An ANALYTIC VIEW object is a component of analytic views.

Prerequisites

To drop an analytic view in your own schema, you must have the DROP ANALYTIC VIEW system privilege. To drop an analytic view in another user’s schema, you must have the DROP ANY ANALYTIC VIEW system privilege.

Syntax

```
drop_analytic_view ::= DROP ANALYTIC VIEW schema . analytic_view_name ;
```

Semantics

`schema`

Specify the schema in which the analytic view exists. If you do not specify a schema, then Oracle Database looks for the analytic view in your own schema.

`analytic_view_name`

Specify the name of the analytic view to drop.
Example

The following statement drops the specified analytic view object:

DROP ANALYTIC VIEW sales_av;

DROP ATTRIBUTE DIMENSION

Purpose

Use the DROP ATTRIBUTE DIMENSION statement to drop an attribute dimension. An ATTRIBUTE DIMENSION object is a component of analytic views.

Prerequisites

To drop an attribute dimension in your own schema, you must have the DROP ATTRIBUTE DIMENSION system privilege. To drop an analytic view in another user’s schema, you must have the DROP ANY ATTRIBUTE DIMENSION system privilege.

Syntax

\[ \text{drop_attribute_dimension}::= \]

\[
\text{DROP ATTRIBUTE DIMENSION schema . attr_dimension_name ;}
\]

Semantics

\text{schema}

Specify the schema in which the attribute dimension exists. If you do not specify a schema, then Oracle Database looks for the attribute dimension in your own schema.

\text{attr_dimension_name}

Specify the name of the attribute dimension to drop.

Example

The following statement drops the specified attribute dimension object:

DROP ATTRIBUTE DIMENSION product_attr_dim;

DROP AUDIT POLICY (Unified Auditing)

This section describes the DROP AUDIT POLICY statement for unified auditing. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to Oracle Database Security Guide for more information on unified auditing.
Purpose

Use the `DROP AUDIT POLICY` statement to remove a unified audit policy from the database.

See Also:

- `CREATE AUDIT POLICY` (Unified Auditing)
- `ALTER AUDIT POLICY` (Unified Auditing)
- `AUDIT` (Unified Auditing)
- `NOAUDIT` (Unified Auditing)

Prerequisites

You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

To drop a common unified audit policy, the current container must be the root and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To drop a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the container.

Syntax

\[
\text{drop_audit_policy} ::= \begin{array}{c}
\text{DROP AUDIT POLICY} \ \text{policy} ;
\end{array}
\]

Semantics

\textit{policy}

Specify the name of the unified audit policy you want to drop. The policy must have been created using the `CREATE AUDIT POLICY` statement.

You can find the names of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view and the names of all \textit{enabled} unified audit policies by querying the `AUDIT_UNIFIED_ENABLED_POLICIES` view

Restriction on Dropping Unified Audit Policies

You cannot drop an enabled unified audit policy. You must first disable the policy using the `NOAUDIT` statement.
Examples

Dropping a Unified Audit Policy: Example

The following statement drops unified audit policy `table_pol`:

```
DROP AUDIT POLICY table_pol;
```

**DROP CLUSTER**

**Purpose**

Use the **DROP CLUSTER** clause to remove a cluster from the database.

**Note:**

When you drop a cluster, any tables in the recycle bin that were once part of that cluster are purged from the recycle bin and can no longer be recovered with a **FLASHBACK TABLE** operation.

You cannot uncluster an individual table. Instead you must perform these steps:

1. Create a new table with the same structure and contents as the old one, but with no **CLUSTER** clause.
2. Drop the old table.
3. Use the **RENAME** statement to give the new table the name of the old one.

**See Also:**

`CREATE TABLE, DROP TABLE, RENAME, GRANT` for information on these steps

**Prerequisites**

The cluster must be in your own schema or you must have the **DROP ANY CLUSTER** system privilege.

---

**See Also:**

- **CREATE AUDIT POLICY** (Unified Auditing)
- *Oracle Database Reference* for more information on the `AUDIT_UNIFIED_POLICIES` and `AUDIT_UNIFIED_ENABLED_POLICIES` views
Syntax

\textit{drop\_cluster}\::=  \\
\hspace{1cm} \textit{DROP CLUSTER} \textit{schema} \textit{cluster} \textit{INCLUDING TABLES} \textit{CASCADE CONSTRAINTS};

Semantics

\textit{schema}

Specify the schema containing the cluster. If you omit \textit{schema}, then the database assumes the cluster is in your own schema.

\textit{cluster}

Specify the name of the cluster to be dropped. Dropping a cluster also drops the cluster index and returns all cluster space, including data blocks for the index, to the appropriate tablespace(s).

\textbf{INCLUDING TABLES}

Specify \textit{INCLUDING TABLES} to drop all tables that belong to the cluster.

\textbf{CASCADE CONSTRAINTS}

Specify \textit{CASCADE CONSTRAINTS} to drop all referential integrity constraints from tables outside the cluster that refer to primary and unique keys in tables of the cluster. If you omit this clause and such referential integrity constraints exist, then the database returns an error and does not drop the cluster.

Examples

\textbf{Dropping a Cluster: Examples}

The following examples drop the clusters created in the "Examples" section of \texttt{CREATE CLUSTER}.

The following statements drops the \textit{language} cluster:

\begin{verbatim}
DROP CLUSTER language;
\end{verbatim}

The following statement drops the \textit{personnel} cluster as well as tables \texttt{dept\_10} and \texttt{dept\_20} and any referential integrity constraints that refer to primary or unique keys in those tables:

\begin{verbatim}
DROP CLUSTER personnel
    INCLUDING TABLES
    CASCADE CONSTRAINTS;
\end{verbatim}
SQL Statements: DROP CONTEXT to DROP JAVA

This chapter contains the following SQL statements:

• DROP CONTEXT
• DROP DATABASE
• DROP DATABASE LINK
• DROP DIMENSION
• DROP DIRECTORY
• DROP DISKGROUP
• DROP EDITION
• DROP FLASHBACK ARCHIVE
• DROP FUNCTION
• DROP HIERARCHY
• DROP INDEX
• DROP INDEXTYPE
• DROP INMEMORY JOIN GROUP
• DROP JAVA

DROP CONTEXT

Purpose

Use the DROP CONTEXT statement to remove a context namespace from the database.

Removing a context namespace does not invalidate any context under that namespace that has been set for a user session. However, the context will be invalid when the user next attempts to set that context.

See Also:

CREATE CONTEXT and Oracle Database Security Guide for more information on contexts

Prerequisites

You must have the DROP ANY CONTEXT system privilege.
Syntax

\textit{\texttt{drop\_context}}::= \texttt{DROP CONTEXT namespace ;}

Semantics

\textit{\texttt{namespace}}

Specify the name of the context namespace to drop. You cannot drop the built-in namespace \texttt{USERENV}.

\textbf{See Also:}

\texttt{SYS_CONTEXT} for information on the \texttt{USERENV} namespace

Examples

\textbf{Dropping an Application Context: Example}

The following statement drops the context created in \texttt{CREATE CONTEXT}:

\begin{verbatim}
DROP CONTEXT hr_context;
\end{verbatim}

\textbf{DROP DATABASE}

Purpose

\textbf{Note:}

You cannot roll back a \texttt{DROP DATABASE} statement.

Use the \texttt{DROP DATABASE} statement to drop the database. This statement is useful when you want to drop a test database or drop an old database after successful migration to a new host.

\textbf{See Also:}

\textit{Oracle Database Backup and Recovery User's Guide} for more information on dropping the database
Prerequisites

You must have the SYSDBA system privilege to issue this statement. The database must be mounted in exclusive and restricted mode, and it must be closed.

Syntax

\[ \text{drop\_database::=} \]

Semantics

When you issue this statement, Oracle Database drops the database and deletes all control files and data files listed in the control file. If the database used a server parameter file (spfile), then the spfile is also deleted.

 Archived logs and backups are not removed, but you can use Recovery Manager (RMAN) to remove them. If the database is on raw disks, then this statement does not delete the actual raw disk special files.

### DROP DATABASE LINK

#### Purpose

Use the DROP DATABASE LINK statement to remove a database link from the database.

See Also:

CREATE DATABASE LINK for information on creating database links

#### Prerequisites

A private database link must be in your own schema. To drop a PUBLIC database link, you must have the DROP PUBLIC DATABASE LINK system privilege.

#### Syntax

\[ \text{drop\_database\_link::=} \]

#### Semantics

PUBLIC

You must specify PUBLIC to drop a PUBLIC database link.
**dblink**

Specify the name of the database link to be dropped.

**Restriction on Dropping Database Links**

You cannot drop a database link in another user's schema, and you cannot qualify `dblink` with the name of a schema, because periods are permitted in names of database links. Therefore, Oracle Database interprets the entire name, such as `ralph.linktosales`, as the name of a database link in your schema rather than as a database link named `linktosales` in the schema `ralph`.

**Examples**

**Dropping a Database Link: Example**

The following statement drops the public database link named `remote`, which was created in "Defining a Public Database Link: Example":

```
DROP PUBLIC DATABASE LINK remote;
```

---

**DROP DIMENSION**

**Purpose**

Use the `DROP DIMENSION` statement to remove the named dimension.

This statement does not invalidate materialized views that use relationships specified in dimensions. However, requests that have been rewritten by query rewrite may be invalidated, and subsequent operations on such views may execute more slowly.

**See Also:**

- `CREATE DIMENSION` and `ALTER DIMENSION` for information on creating and modifying a dimension
- `Oracle Database Concepts` for general information about dimensions

**Prerequisites**

The dimension must be in your own schema or you must have the `DROP ANY DIMENSION` system privilege to use this statement.

**Syntax**

```
drop_dimension::=  
```

```
DROP DIMENSION schema . dimension ;
```
Semantics

**schema**

Specify the name of the schema in which the dimension is located. If you omit `schema`, then Oracle Database assumes the dimension is in your own schema.

**dimension**

Specify the name of the dimension you want to drop. The dimension must already exist.

Examples

**Dropping a Dimension: Example**

This example drops the `sh.customers_dim` dimension:

```
DROP DIMENSION customers_dim;
```

See Also:

"Creating a Dimension: Examples" and "Modifying a Dimension: Examples" for examples of creating and modifying this dimension

---

**DROP DIRECTORY**

**Purpose**

Use the `DROP DIRECTORY` statement to remove a directory object from the database.

See Also:

`CREATE DIRECTORY` for information on creating a directory

**Prerequisites**

To drop a directory, you must have the `DROP ANY DIRECTORY` system privilege.

Note:

Do not drop a directory when files in the associated file system are being accessed by PL/SQL or OCI programs.
Syntax

\textit{drop\_directory}::= \texttt{DROP \_DIRECTORY} \texttt{directory\_name};

Semantics

\textit{directory\_name}

Specify the name of the directory database object to be dropped.

Oracle Database removes the directory object but does not delete the associated operating system directory on the server file system.

Examples

\textbf{Dropping a Directory: Example}

The following statement drops the directory object \texttt{bfile\_dir}:

\texttt{DROP \_DIRECTORY bfile\_dir;}

\textbf{See Also:}

"Creating a Directory: Examples"

\textbf{DROP DISKGROUP}

\begin{quote}
\textbf{Note:}

This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to \textit{Oracle Automatic Storage Management Administrator's Guide}.
\end{quote}

\textbf{Purpose}

The \texttt{DROP \_DISKGROUP} statement lets you drop an Oracle ASM disk group along with all the files in the disk group. Oracle ASM first ensures that no files in the disk group are open. It then drops the disk group and all its member disks and clears the disk header.
Prerequisites
You must have the SYSASM system privilege and you must have an Oracle ASM instance started, from which you issue this statement. The disk group to be dropped must be mounted.

Syntax
\[
\text{drop_diskgroup} ::= \\
\text{DROP DISKGROUP} \text{diskgroup_name}
\]

Semantics
\text{diskgroup_name}
Specify the name of the disk group you want to drop.

**INCLUDING CONTENTS**
Specify \text{INCLUDING CONTENTS} to confirm that Oracle ASM should drop all the files in the disk group. You must specify this clause if the disk group contains any files.

**FORCE**
This clause clears the headers on the disk belonging to a disk group that cannot be mounted by the Oracle ASM instance. The disk group cannot be mounted by any instance of the database.

The Oracle ASM instance first determines whether the disk group is being used by any other Oracle ASM instance using the same storage subsystem. If it is being used, and if the disk group is in the same cluster, or on the same node, then the statement fails. If the disk group is in a different cluster, then the system further checks to determine whether the disk group is mounted by any instance in the other cluster. If it is mounted elsewhere, then the statement fails. However, this latter check is not as definitive as the checks for disk groups in the same cluster. Therefore, use this clause with caution.
EXCLUDING CONTENTS

Specify `EXCLUDING CONTENTS` to ensure that Oracle ASM drops the disk group only when the disk group is empty. This is the default. If the disk group is not empty, then an error will be returned.

Examples

Dropping a Diskgroup: Example

The following statement drops the Oracle ASM disk group `dgroup_01`, which was created in “Creating a Diskgroup: Example”, and all of the files in the disk group:

```
DROP DISKGROUP dgroup_01 INCLUDING CONTENTS;
```

DROP EDITION

Purpose

Use the `DROP EDITION` statement to drop an edition, along with all actual editionable objects it contains. An actual editionable object is an editionable object that has been created or modified in an edition.

See Also:

- `CREATE EDITION` for a listing of editionable object types

Prerequisites

You must have the `DROP ANY EDITION` system privilege, granted either directly or through a role.

Syntax

```
drop_edition ::= DROP EDITION edition CASCADE ;
```

Semantics

Objects that are not editionable, or that are editionable but have not been actualized in the current edition, are not dropped.

You must specify `CASCADE` if the specified edition contains any actual editionable objects.

This statement is subject to the following conditions and restrictions:

- The specified edition cannot have both a parent edition and a child edition.
- `DROP EDITION` will fail if you attempt to drop the default edition.
DROP EDITION will fail if you attempt to drop the root edition and the recycle bin contains at least one object that used to be in that edition before it was dropped. Under these circumstances, even DROP EDITION CASCADE will fail. In this case, you can purge all objects from the recycle bin with the PURGE DBA_RECYCLEBIN statement and then drop the edition. Refer to PURGE for more information.

DROP EDITION will also fail if you attempt to drop the leaf edition and the recycle bin contains at least one object that used to be in that edition before it was dropped. However, under these circumstances, DROP EDITION CASCADE will succeed.

The only type of editioned object that might be in the recycle bin is a trigger.

See Also:
- Oracle Database Development Guide
- Oracle Database PL/SQL Packages and Types Reference

Examples
For examples that use this statement, refer to CREATE EDITION.

DROP FLASHBACK ARCHIVE

Purpose
Use the DROP FLASHBACK ARCHIVE clause to remove a flashback data archive from the system. This statement removes the flashback data archive and all the historical data in it, but does not drop the tablespaces that were used by the flashback data archive.

Prerequisites
You must have the FLASHBACK ARCHIVE ADMINISTER system privilege to drop a flashback data archive.

Syntax

\[
\text{drop\_flashback\_archive ::=}
\]

Semantics

\text{flashback\_archive}

Specify the name of the flashback data archive you want to drop.
DROP FUNCTION

Purpose

Functions are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping functions.

Use the DROP FUNCTION statement to remove a standalone stored function from the database.

Note:

Do not use this statement to remove a function that is part of a package. Instead, either drop the entire package using the DROP PACKAGE statement or redefine the package without the function using the CREATE PACKAGE statement with the OR REPLACE clause.

Prerequisites

The function must be in your own schema or you must have the DROP ANY PROCEDURE system privilege.

Syntax

\[ \text{drop\_function ::= \{DROP FUNCTION } \text{ schema } \text{.function\_name} ; \]

Semantics

\textit{schema}

Specify the schema containing the function. If you omit \textit{schema}, then Oracle Database assumes the function is in your own schema.

\textit{function\_name}

Specify the name of the function to be dropped.

Oracle Database invalidates any local objects that depend on, or call, the dropped function. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error if you have not re-created the dropped function.
If any statistics types are associated with the function, then the database disassociates the statistics types with the `FORCE` option and drops any user-defined statistics collected with the statistics type.

---

**See Also:**

- *Oracle Database Concepts* for more information on how Oracle Database maintains dependencies among schema objects, including remote objects
- `ASSOCIATE STATISTICS` and `DISASSOCIATE STATISTICS` for more information on statistics type associations

---

**Examples**

**Dropping a Function: Example**

The following statement drops the function `SecondMax` in the sample schema `oe` and invalidates all objects that depend upon `SecondMax`:

```
DROP FUNCTION oe.SecondMax;
```

---

**DROP HIERARCHY**

**Purpose**

Use the `DROP HIERARCHY` statement to drop a hierarchy. A `HIERARCHY` object is a component of analytic views.

**Prerequisites**

To drop a hierarchy in your own schema, you must have the `DROP HIERARCHY` system privilege. To drop a hierarchy in another user's schema, you must have the `DROP ANY HIERARCHY` system privilege.

**Syntax**

```
drop_hierarchy ::= DROP HIERARCHY schema . hierarchy_name ;
```
Semantics

schema

Specify the schema in which the hierarchy exists. If you do not specify a schema, then Oracle Database looks for the hierarchy in your own schema.

hierarchy_name

Specify the name of the hierarchy to drop.

Example

The following statement drops the specified hierarchy object:

DROP HIERARCHY product_hier;

DROP INDEX

Purpose

Use the DROP INDEX statement to remove an index or domain index from the database.

When you drop a global partitioned index, a range-partitioned index, or a hash-partitioned index, all the index partitions are also dropped. If you drop a composite-partitioned index, then all the index partitions and subpartitions are also dropped.

In addition, when you drop a domain index:

• Oracle Database invokes the appropriate routine.
• If any statistics are associated with the domain index, then Oracle Database disassociates the statistics types with the FORCE clause and removes the user-defined statistics collected with the statistics type.

See Also:

– Oracle Database Data Cartridge Developer's Guide for information on the routines
– CREATE INDEX and ALTER INDEX for information on creating and modifying an index
– The domain_index_clause of CREATE INDEX for more information on domain indexes
– ASSOCIATE STATISTICS and DISASSOCIATE STATISTICS for more information on statistics type associations

Prerequisites

The index must be in your own schema or you must have the DROP ANY INDEX system privilege.
Syntax

\[
\text{drop\_index::=} \quad \text{DROP INDEX} \quad \text{schema} \quad \text{index} \quad \text{ONLINE} \quad \text{FORCE} \quad \text{DEFERRED} \quad \text{IMMEDIATE} \quad \text{INVALIDATION} ;
\]

Semantics

schema

Specify the schema containing the index. If you omit `schema`, then Oracle Database assumes the index is in your own schema.

index

Specify the name of the index to be dropped. When the index is dropped, all data blocks allocated to the index are returned to the tablespace that contained the index.

ONLINE

Specify `ONLINE` to indicate that DML operations on the table or partition will be allowed while dropping the index.

FORCE

`FORCE` applies only to domain indexes. This clause drops the domain index even if the indextype routine invocation returns an error or the index is marked `IN_PROGRESS`. Without `FORCE`, you cannot drop a domain index if its indextype routine invocation returns an error or the index is marked `IN_PROGRESS`.

\{ DEFERRED | IMMEDIATE \} INVALIDATION

This clause lets you control when the database invalidates dependent cursors while dropping the index. It has the same semantics here as for the `ALTER INDEX` statement, with the following addition: When you drop an index with `DEFERRED INVALIDATION`, Oracle database will immediately invalidate any DML statement or query that references the dropped index in its plan.

See \{ DEFERRED | IMMEDIATE \} INVALIDATION in the documentation on `ALTER INDEX` for the full semantics of this clause.

Restrictions on Dropping Indexes

The following restrictions apply to dropping indexes:

- You cannot drop a domain index if the index or any of its index partitions is marked `IN_PROGRESS`.
- You cannot specify the `ONLINE` clause when dropping a domain index, a cluster index, or an index on a queue table.
Examples

Dropping an Index: Example

This statement drops an index named `ord_customer_ix_demo`, which was created in "Compressing an Index: Example":

```
DROP INDEX ord_customer_ix_demo;
```

DROP INDEXTYPE

Purpose

Use the `DROP INDEXTYPE` statement to drop an indextype as well as any association with a statistics type.

See Also:

`CREATE INDEXTYPE` for more information on indextypes

Prerequisites

The indextype must be in your own schema or you must have the `DROP ANY INDEXTYPE` system privilege.

Syntax

```
drop_indextype::=
```

Semantics

`schema`

Specify the schema containing the indextype. If you omit `schema`, then Oracle Database assumes the indextype is in your own schema.

`indextype`

Specify the name of the indextype to be dropped.

If any statistics types have been associated with indextype, then the database disassociates the statistics type from the indextype and drops any statistics that have been collected using the statistics type.
See Also:

ASSOCIATE STATISTICS and DISASSOCIATE STATISTICS for more information on statistics associations

FORCE

Specify FORCE to drop the indextype even if the indextype is currently being referenced by one or more domain indexes. Oracle Database marks those domain indexes INVALID. Without FORCE, you cannot drop an indextype if any domain indexes reference the indextype.

Examples

Dropping an Indextype: Example

The following statement drops the indextype position_indextype, created in "Using Extensible Indexing", and marks INVALID any domain indexes defined on this indextype:

DROP INDEXTYPE position_indextype FORCE;

DROP INMEMORY JOIN GROUP

Purpose

Use the DROP INMEMORY JOIN GROUP statement to remove a join group from the database.

See Also:

- CREATE INMEMORY JOIN GROUP and ALTER INMEMORY JOIN GROUP
- Oracle Database In-Memory Guide for more information on join groups

Prerequisites

If the join group is in another user's schema, then you must have the DROP ANY TABLE system privilege.

Syntax

\[
\text{drop_inmemory_join_group::=}
\]

\[
\text{DROP INMEMORY JOIN GROUP \text{schema} . \text{join_group} ;}
\]
Semantics

**schema**

Specify the schema containing the join group. If you omit `schema`, then the database assumes the join group is in your own schema.

**join_group**

Specify the name of the join group to be dropped.

You can view existing join groups by querying the `DBA_JOINGROUPS` or `USER_JOINGROUPS` data dictionary view. Refer to Oracle Database Reference for more information on these views.

Examples

The following statement drops the join group `prod_id1`:

```
DROP INMEMORY JOIN GROUP prod_id1;
```

**DROP JAVA**

Purpose

Use the DROP JAVA statement to drop a Java source, class, or resource schema object.

See Also:

- CREATE JAVA for information on creating Java objects
- Oracle Database Java Developer's Guide for more information on resolving Java sources, classes, and resources

Prerequisites

The Java source, class, or resource must be in your own schema or you must have the DROP ANY PROCEDURE system privilege. You also must have the EXECUTE object privilege on Java classes to use this command.

Syntax

```
drop_java::=
```

```sql
DROP JAVA
SOURCE
CLASS
RESOURCE
schema
object_name;
```
Semantics

JAVA SOURCE
Specify SOURCE to drop a Java source schema object and all Java class schema objects derived from it.

JAVA CLASS
Specify CLASS to drop a Java class schema object.

JAVA RESOURCE
Specify RESOURCE to drop a Java resource schema object.

object_name
Specify the name of an existing Java class, source, or resource schema object. Enclose the object_name in double quotation marks to preserve lower- or mixed-case names.

Examples

Dropping a Java Class Object: Example
The following statement drops the Java class Agent, created in "Creating a Java Class Object: Example":

DROP JAVA CLASS "Agent";
This chapter contains the following SQL statements:

- DROP LIBRARY
- DROP LOCKDOWN PROFILE
- DROP MATERIALIZED VIEW
- DROP MATERIALIZED VIEW LOG
- DROP MATERIALIZED ZONEMAP
- DROP OPERATOR
- DROP OUTLINE
- DROP PACKAGE
- DROP PLUGGABLE DATABASE
- DROP PROCEDURE
- DROP PROFILE
- DROP RESTORE POINT
- DROP ROLE
- DROP ROLLBACK SEGMENT
- DROP SEQUENCE
- DROP SYNONYM

DROP LIBRARY

Purpose

Use the DROP LIBRARY statement to remove an external procedure library from the database.

See Also:

CREATE LIBRARY for information on creating a library

Prerequisites

You must have the DROP ANY LIBRARY system privilege.
Syntax

\[ \text{drop_library ::= } \]

\[
\text{DROP LIBRARY library_name ;}
\]

Semantics

library_name

Specify the name of the external procedure library being dropped.

Examples

Dropping a Library: Example

The following statement drops the ext_lib library:

\[
\text{DROP LIBRARY ext_lib ;}
\]

DROP LOCKDOWN PROFILE

Purpose

Use the DROP LOCKDOWN PROFILE statement to remove a PDB lockdown profile from the database. A PDB that was assigned the dropped profile will continue to be assigned the profile, but will not be subject to the restrictions imposed by the dropped profile.

If the PDB_LOCKDOWN initialization parameter for a CDB, an application root, or a PDB has the value of the dropped lockdown profile, then the restrictions imposed by the dropped profile will be disabled when you drop it. However, the value of the PDB_LOCKDOWN initialization parameter will remain until you explicitly unset it.

See Also:

- CREATE LOCKDOWN PROFILE and ALTER LOCKDOWN PROFILE
- Oracle Database Security Guide for more information on PDB lockdown profiles

Prerequisites

- You must issue this statement from the CDB Root or the Application Root.
- You must have the DROP LOCKDOWN PROFILE system privilege in the container where you mean to issue the statement.
Syntax

\[ \text{drop_lockdown_profile} ::= \]

\[
\text{DROP LOCKDOWN PROFILE } \text{profile_name} ;
\]

Semantics

\textit{profile_name}

Specify the name of the PDB lockdown profile to be dropped.

You can find the names of existing PDB lockdown profiles by querying the \texttt{DBA_LOCKDOWN_PROFILES} data dictionary view.

\begin{itemize}
  \item \textbf{See Also:} \textit{Oracle Database Reference} for more information on the \texttt{DBA_LOCKDOWN_PROFILES} data dictionary view and the \texttt{PDB_LOCKDOWN} initialization parameter
\end{itemize}

Example

The following statement drops PDB lockdown profile \texttt{hr_prof}:

\[
\text{DROP LOCKDOWN PROFILE } \texttt{hr_prof} ;
\]

\section*{DROP MATERIALIZED VIEW}

Purpose

Use the \texttt{DROP MATERIALIZED VIEW} statement to remove an existing materialized view from the database.

When you drop a materialized view, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the materialized view.

\begin{itemize}
  \item \textbf{Note:} The keyword \texttt{SNAPSHOT} is supported in place of \texttt{MATERIALIZED VIEW} for backward compatibility.
\end{itemize}
Prerequisites

The materialized view must be in your own schema or you must have the `DROP ANY MATERIALIZED VIEW` system privilege. You must also have the privileges to drop the internal table, views, and index that the database uses to maintain the materialized view data.

Syntax

```
drop_materialized_view::=
```

Semantics

**schema**

Specify the schema containing the materialized view. If you omit `schema`, then Oracle Database assumes the materialized view is in your own schema.

**materialized_view**

Specify the name of the existing materialized view to be dropped.

- If you drop a simple materialized view that is the least recently refreshed materialized view of a master table, then the database automatically purges from the master table materialized view log only the rows needed to refresh the dropped materialized view.
• If you drop a materialized view that was created on a prebuilt table, then the database drops the materialized view, and the prebuilt table reverts to its identity as a table.

• When you drop a master table, the database does not automatically drop materialized views based on the table. However, the database returns an error when it tries to refresh a materialized view based on a master table that has been dropped.

• If you drop a materialized view, then any compiled requests that were rewritten to use the materialized view will be invalidated and recompiled automatically. If the materialized view was prebuilt on a table, then the table is not dropped, but it can no longer be maintained by the materialized view refresh mechanism.

**PRESERVE TABLE Clause**

This clause lets you retain the materialized view container table and its contents after the materialized view object is dropped. The resulting table has the same name as the dropped materialized view.

Oracle Database removes all metadata associated with the materialized view. However, indexes created on the container table automatically during creation of the materialized view are preserved, with one exception: the index created during the creation of a rowid materialized view is dropped. Also, if the materialized view has any nested table columns, then the storage tables for those columns are preserved, along with their metadata.

**Restriction on the PRESERVE TABLE Clause**

This clause is not valid for materialized views that have been imported from releases earlier than Oracle9i, when these objects were called "snapshots".

**Examples**

**Dropping a Materialized View: Examples**

The following statement drops the materialized view `emp_data` in the sample schema `hr`:

```
DROP MATERIALIZED VIEW emp_data;
```

The following statement drops the `sales_by_month_by_state` materialized view and the underlying table of the materialized view, unless the underlying table was registered in the `CREATE MATERIALIZED VIEW` statement with the `ON PREBUILT TABLE` clause:

```
DROP MATERIALIZED VIEW sales_by_month_by_state;
```

**DROP MATERIALIZED VIEW LOG**

**Purpose**

Use the `DROP MATERIALIZED VIEW LOG` statement to remove a materialized view log from the database.
Note:
The keyword **SNAPSHOT** is supported in place of **MATERIALIZED VIEW** for backward compatibility.

See Also:
- **CREATE MATERIALIZED VIEW** and **ALTER MATERIALIZED VIEW** for more information on materialized views
- **CREATE MATERIALIZED VIEW LOG** for information on materialized view logs
- *Oracle Database Administrator’s Guide* for information on materialized views in a replication environment
- *Oracle Database Data Warehousing Guide* for information on materialized views in a data warehousing environment

Prerequisites
To drop a materialized view log, you must have the privileges needed to drop a table.

See Also:
**DROP TABLE**

Syntax

```sql
drop_materialized_view_log ::= 
```

Semantics

**schema**
Specify the schema containing the materialized view log and its master table. If you omit **schema**, then Oracle Database assumes the materialized view log and master table are in your own schema.

**table**
Specify the name of the master table associated with the materialized view log to be dropped.
After you drop a materialized view log that was created for Fast Refresh, some materialized views based on the materialized view log master table can no longer be fast refreshed. These materialized views include rowid materialized views, primary key materialized views, and subquery materialized views.

See Also:

Oracle Database Data Warehousing Guide for a description of these types of materialized views

After you drop a materialized view log that was created for Synchronous Refresh (a staging log), the materialized views based on the staging log master table can no longer be synchronous refreshed.

Examples

Dropping a Materialized View Log: Example

The following statement drops the materialized view log on the oe.customers master table:

```
DROP MATERIALIZED VIEW LOG ON customers;
```

DROP MATERIALIZED ZONEMAP

Purpose

Use the DROP MATERIALIZED ZONEMAP statement to remove an existing zone map from the database.

Prerequisites

The zone map must be in your own schema or you must have the DROP ANY MATERIALIZED VIEW system privilege. You must also have the privileges to drop the internal table and indexes that the database uses to maintain the zone map data.

See Also:

DROP TABLE and DROP INDEX for information on privileges required to drop objects that the database uses to maintain the zone map

Syntax

```
drop_materialized_zonemap::=
```

![Diagram of DROP MATERIALIZED ZONEMAP syntax]
Semantics

schema
Specify the schema containing the zone map. If you omit schema, then Oracle Database assumes the zone map is in your own schema.

zonemap_name
Specify the name of the existing zone map to be dropped.

Example

Dropping a Zone Map: Examples

The following statement drops the zone map sales_zmap:

```
DROP MATERIALIZED ZONEMAP sales_zmap;
```

DROP OPERATOR

Purpose

Use the DROP OPERATOR statement to drop a user-defined operator.

See Also:

- CREATE OPERATOR and ALTER OPERATOR for information on creating and modifying operators
- "User-Defined Operators" and Oracle Database Data Cartridge Developer's Guide for more information on operators in general
- ALTER INDEXTYPE for information on dropping an operator of a user-defined indextype

Prerequisites

The operator must be in your schema or you must have the DROP ANY OPERATOR system privilege.

Syntax

```
drop_operator::=
```

```
DROP OPERATOR
```

```
operator
```

```
FORCE
```

```
```

```
```

```
```

```
```

```
```

```
```

```
```

```
```

```

```
```

```
```

```
```

```
```

```
```

```
```

```
```

```
```

```
```

```
```

```
Semantics

**schema**
Specify the schema containing the operator. If you omit `schema`, then Oracle Database assumes the operator is in your own schema.

**operator**
Specify the name of the operator to be dropped.

**FORCE**
Specify `FORCE` to drop the operator even if it is currently being referenced by one or more schema objects, such as indextypes, packages, functions, procedures, and so on. The database marks any such dependent objects `INVALID`. Without `FORCE`, you cannot drop an operator if any schema objects reference it.

**Examples**

**Dropping a User-Defined Operator: Example**
The following statement drops the operator `eq_op`:

```
DROP OPERATOR eq_op;
```

Because the `FORCE` clause is not specified, this operation will fail if any of the bindings of this operator are referenced by an indextype.

## DROP OUTLINE

### Purpose

> **Note:**

- Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.

- You can migrate existing stored outlines to SQL plan baselines by using the `MIGRATE_STORED_OUTLINE` function of the `DBMS_SPM` package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the `DROP_MIGRATED_STORED_OUTLINE` function of the `DBMS_SPM` package.

- **See Also:** *Oracle Database SQL Tuning Guide* for more information about SQL plan management and *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_SPM` package

Use the `DROP OUTLINE` statement to drop a stored outline.
Prerequisites
To drop an outline, you must have the DROP ANY OUTLINE system privilege.

Syntax
\[
\text{drop\_outline} ::= \text{DROP OUTLINE}\ outline\;
\]

Semantics
\[
\text{outline}
\]
Specify the name of the outline to be dropped.

After the outline is dropped, if the SQL statement for which the stored outline was created is compiled, then the optimizer generates a new execution plan without the influence of the outline.

Examples
Dropping an Outline: Example
The following statement drops the stored outline called \text{salaries}.
\[
\text{DROP OUTLINE salaries;}
\]

DROP PACKAGE

Purpose
Packages are defined using PL/SQL. Refer to \textit{Oracle Database PL/SQL Language Reference} for complete information on creating, altering, and dropping packages.

Use the DROP PACKAGE statement to remove a stored package from the database. This statement drops the body and specification of a package.

\textbf{Note:}
Do not use this statement to remove a single object from a package. Instead, re-create the package without the object using the CREATE PACKAGE and CREATE PACKAGE BODY statements with the OR REPLACE clause.
Prerequisites

The package must be in your own schema or you must have the DROP ANY PROCEDURE system privilege.

Syntax

\textit{drop\_package}::=

\begin{verbatim}
DROP PACKAGE
\end{verbatim}

Semantics

\textbf{BODY}

Specify \textit{BODY} to drop only the body of the package. If you omit this clause, then Oracle Database drops both the body and specification of the package.

When you drop only the body of a package but not its specification, the database does not invalidate dependent objects. However, you cannot call one of the procedures or stored functions declared in the package specification until you re-create the package body.

\textit{schema}

Specify the schema containing the package. If you omit \textit{schema}, then the database assumes the package is in your own schema.

\textit{package}

Specify the name of the package to be dropped.

Oracle Database invalidates any local objects that depend on the package specification. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error if you have not re-created the dropped package.

If any statistics types are associated with the package, then the database disassociates the statistics types with the \textit{FORCE} clause and drops any user-defined statistics collected with the statistics types.

\textbf{See Also:}

\begin{itemize}
  \item [\textbf{ASSOCIATE STATISTICS} and \textbf{DISASSOCIATE STATISTICS}]
\end{itemize}

Examples

\textbf{Dropping a Package: Example}

The following statement drops the specification and body of the \texttt{emp\_mgmt\_package}, invalidating all objects that depend on the specification. See \textit{Oracle Database PL/SQL Language Reference} for the example that creates this package.
Purpose

Use the `DROP PLUGGABLE DATABASE` statement to drop a pluggable database (PDB). The PDB can be a traditional PDB, an application container, an application seed, or an application PDB.

When you drop a PDB, the control file of the multitenant container database (CDB) is modified to remove all references to the dropped PDB and its data files. Archived logs and backups associated with the dropped PDB are not deleted. You can delete them using Oracle Recovery Manager (RMAN), or you can retain them in case you subsequently want to perform point-in-time recovery of the PDB.

⚠️ **Caution:**

You cannot roll back a `DROP PLUGGABLE DATABASE` statement.

Prerequisites

You must be connected to a CDB.

To drop a traditional PDB or an application container, the current container must be the root, you must be authenticated as `SYSDBA` or `SYSOPER`, and the `SYSDBA` or `SYSOPER` privilege must be either granted to you commonly, or granted to you locally in the root and locally in traditional PDB or application container you want to drop. The application container must be empty, that is, it must not contain an application seed or any application PDBs.

To drop an application seed, the current container must be the root or the application root, you must be authenticated as `SYSDBA` or `SYSOPER`, and the `SYSDBA` or `SYSOPER` privilege must be either granted to you commonly, or granted to you locally in the root or application root.

To drop an application PDB, the current container must be the root or the application root, you must be authenticated as `SYSDBA` or `SYSOPER`, and the `SYSDBA` or `SYSOPER` privilege must be either granted to you commonly, or granted to you locally in the root or application root, and locally in the application PDB you want to drop.

To specify `KEEP DATAFILES` (the default), the PDB you want to drop must be unplugged.

To specify `INCLUDING DATAFILES`, the PDB you want to drop must be in mounted mode or it must be unplugged.

Syntax

```
drop_pluggable_database::=  
```

```sql
DROP PLUGGABLE DATABASE pdb_name 
KEEP | INCLUDING DATAFILES;
```
Semantics

\textit{pdb\_name}

Specify the name of the PDB you want to drop. You cannot drop the seed (PDB$SEED). However, you can drop an application seed.

**KEEP DATAFILES**

Specify \textit{KEEP DATAFILES} to retain the data files associated with the PDB after the PDB is dropped. The temp file for the PDB is deleted because it is no longer needed. This is the default.

Keeping data files may be useful in scenarios where a PDB that is unplugged from one CDB is plugged into another CDB, with both CDBs sharing storage devices.

**INCLUDING DATAFILES**

Specify \textit{INCLUDING DATAFILES} to delete the data files associated with the PDB being dropped. The temp file for the PDB is also deleted.

Restriction on Dropping SNAPSHOT COPY PDBs

If a PDB was created with the \textit{SNAPSHOT COPY} clause, then you must specify \textit{INCLUDING DATAFILES} when you drop the PDB.

Examples

**Dropping a PDB: Example**

The following statement drops the PDB \texttt{pdb1} and its associated data files:

\begin{verbatim}
DROP PLUGGABLE DATABASE pdb1
  INCLUDING DATAFILES;
\end{verbatim}

\section*{DROP PROCEDURE}

**Purpose**

Procedures are defined using PL/SQL. Refer to \textit{Oracle Database PL/SQL Language Reference} for complete information on creating, altering, and dropping procedures.

Use the \texttt{DROP PROCEDURE} statement to remove a standalone stored procedure from the database. Do not use this statement to remove a procedure that is part of a package. Instead, either drop the entire package using the \texttt{DROP PACKAGE} statement, or redefine the package without the procedure using the \texttt{CREATE PACKAGE} statement with the \texttt{OR REPLACE} clause.

**Prerequisites**

The procedure must be in your own schema or you must have the \texttt{DROP ANY PROCEDURE} system privilege.
Syntax

\[ \text{drop\_procedure} ::= \]

Semantics

\textit{schema}

Specify the schema containing the procedure. If you omit \textit{schema}, then Oracle Database assumes the procedure is in your own schema.

\textit{procedure}

Specify the name of the procedure to be dropped.

When you drop a procedure, Oracle Database invalidates any local objects that depend upon the dropped procedure. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error message if you have not re-created the dropped procedure.

Examples

\textbf{Dropping a Procedure: Example}

The following statement drops the procedure \texttt{remove\_emp} owned by the user \texttt{hr} and invalidates all objects that depend upon \texttt{remove\_emp}:

\begin{verbatim}
DROP PROCEDURE hr.remove_emp;
\end{verbatim}

\section*{DROP PROFILE}

\textbf{Purpose}

Use the \texttt{DROP PROFILE} statement to remove a profile from the database. You can drop any profile except the \texttt{DEFAULT} profile.

\textbf{See Also:}

\begin{itemize}
  \item \texttt{CREATE PROFILE} and \texttt{ALTER PROFILE} on creating and modifying a profile
\end{itemize}

\textbf{Prerequisites}

You must have the \texttt{DROP PROFILE} system privilege.
Syntax

\[
\text{drop\_profile} ::= \text{DROP PROFILE profile \text{CASCADE};}
\]

Semantics

\textit{profile}

Specify the name of the profile to be dropped.

\textit{CASCADE}

Specify \textit{CASCADE} to deassign the profile from any users to whom it is assigned. Oracle Database automatically assigns the \texttt{DEFAULT} profile to such users. You must specify this clause to drop a profile that is currently assigned to users.

Examples

Dropping a Profile: Example

The following statement drops the profile \texttt{app\_user}, which was created in “Creating a Profile: Example”. Oracle Database drops the profile \texttt{app\_user} and assigns the \texttt{DEFAULT} profile to any users currently assigned the \texttt{app\_user} profile:

\[
\text{DROP PROFILE app\_user \text{CASCADE};}
\]

DROP RESTORE POINT

Purpose

Use the \texttt{DROP RESTORE POINT} statement to remove a normal restore point or a guaranteed restore point from the database.

- You need not drop normal restore points. The database automatically drops the oldest restore points when necessary, as described in the semantics for \texttt{restore\_point}. However, you can drop a normal restore point if you want to reuse the name.
- Guaranteed restore points are not dropped automatically. Therefore, if you want to remove a guaranteed restore point from the database, then you must do so explicitly using this statement.

See Also:

\texttt{CREATE RESTORE POINT}, \texttt{FLASHBACK DATABASE}, and \texttt{FLASHBACK TABLE} for information on creating and using restore points.
Prerequisites

To drop a normal restore point, you must have the `SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSBACKUP, or SYSDG system privilege`.

To drop a guaranteed restore point, you must fulfill one of the following conditions:

- You must connect `AS SYSDBA, or AS SYSBACKUP, or AS SYSDG`.
- You must have been granted the `SYSDBA` privilege, and be using a multitenant database.
- You must be running as user `SYS`, and be using a a multitenant database.

You can drop a restore point when connected to a multitenant container database (CDB) as follows:

- To drop a normal CDB restore point, the current container must be the root and you must have the `SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege`, either granted commonly or granted locally in the root, or the `SYSDBA, SYSBACKUP, or SYSDG system privilege` granted commonly.
- To drop a guaranteed CDB restore point, the current container must be the root and you must have the `SYSDBA, SYSBACKUP, or SYSDG system privilege` granted commonly.
- To drop a normal PDB restore point, the current container must be the root and you must have the `SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege`, granted commonly, or the current container must be the PDB in which you want to create the restore point and you must have the `SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege`, granted commonly or granted locally in that PDB.
- To drop a guaranteed PDB restore point, the current container must be the root and you must have the `SYSDBA, SYSBACKUP, or SYSDG system privilege`, granted commonly, or the current container must be the PDB in which you want to create the restore point and you must have the `SYSDBA, SYSBACKUP, or SYSDG system privilege`, granted commonly or granted locally in that PDB.

Syntax

```
drop_restore_point::=

DROP RESTORE POINT restore_point FOR PLUGGABLE DATABASE pdb_name
;
```

Semantics

`restore_point`

Specify the name of the restore point you want to drop.

`FOR PLUGGABLE DATABASE`

This clause enables you to drop a PDB restore point when you are connected to the root. For `pdb_name`, specify the name of the PDB that contains the restore point you want to drop.
If you are connected to the PDB from which you want to drop the restore point, then it is not necessary to specify this clause. However, if you specify this clause, then you must specify the name of the PDB to which you are connected.

Examples

Dropping a Restore Point: Example

The following example drops the good_data restore point, which was created in "Creating and Using a Restore Point: Example":

```
DROP RESTORE POINT good_data;
```

DROPROLE

Purpose

Use the DROPROLE statement to remove a role from the database. When you drop a role, Oracle Database revokes it from all users and roles to whom it has been granted and removes it from the database. User sessions in which the role is already enabled are not affected. However, no new user session can enable the role after it is dropped.

See Also:

- `CREATE ROLE` and `ALTER ROLE` for information on creating roles and changing the authorization needed to enable a role
- `SET ROLE` for information on disabling roles for the current session

Prerequisites

You must have been granted the role with the ADMIN OPTION or you must have the DROP ANY ROLE system privilege.

Syntax

```
drop_role::=
```

Semantics

```
role
```

Specify the name of the role to be dropped.

Examples

Dropping a Role: Example

To drop the role dw_manager, which was created in "Creating a Role: Example", issue the following statement:
Purpose

Use the `DROP ROLLBACK SEGMENT` to remove a rollback segment from the database. When you drop a rollback segment, all space allocated to the rollback segment returns to the tablespace.

**Note:**

If your database is running in automatic undo mode, then this is the only valid operation on rollback segments. In that mode, you cannot create or alter a rollback segment.

Prerequisites

You must have the `DROP ROLLBACK SEGMENT` system privilege, and the rollback segment must be offline.

Syntax

```
drop_rollback_segment ::= DROP ROLLBACK SEGMENT rollback_segment;
```

Semantics

`rollback_segment`

Specify the name the rollback segment to be dropped.

Restrictions on Dropping Rollback Segments

This statement is subject to the following restrictions:

- You can drop a rollback segment only if it is offline. To determine whether a rollback segment is offline, query the data dictionary view `DBA_ROLLBACK_SEGS`. Offline rollback segments have the value `AVAILABLE` in the `STATUS` column. You can take a rollback segment offline with the `OFFLINE` clause of the `ALTER ROLLBACK SEGMENT` statement.

- You cannot drop the `SYSTEM` rollback segment.

Examples

**Dropping a Rollback Segment: Example**

The following syntax drops the rollback segment created in "Creating a Rollback Segment: Example":

```
DROP ROLLBACK SEGMENT rbs_one;
```
DROP SEQUENCE

Purpose

Use the DROP SEQUENCE statement to remove a sequence from the database.

You can also use this statement to restart a sequence by dropping and then re-creating it. For example, if you have a sequence with a current value of 150 and you would like to restart the sequence with a value of 27, then you can drop the sequence and then re-create it with the same name and a START WITH value of 27.

See Also:

CREATE SEQUENCE and ALTER SEQUENCE for more information on creating and modifying a sequence

Prerequisites

The sequence must be in your own schema or you must have the DROP ANY SEQUENCE system privilege.

Syntax

\[ \text{drop_sequence ::= } \]

Semantics

\textit{schema}

Specify the schema containing the sequence. If you omit \textit{schema}, then Oracle Database assumes the sequence is in your own schema.

\textit{sequence_name}

Specify the name of the sequence to be dropped.

Examples

Dropping a Sequence: Example

The following statement drops the sequence \texttt{customers_seq} owned by the user \texttt{oe}, which was created in "Creating a Sequence: Example". To issue this statement, you must either be connected as user \texttt{oe} or have the DROP ANY SEQUENCE system privilege:

\[
\text{DROP SEQUENCE oe.customers_seq;}
\]
DROP SYNONYM

Purpose
Use the DROP SYNONYM statement to remove a synonym from the database or to change the definition of a synonym by dropping and re-creating it.

See Also:
CREATE SYNONYM for more information on synonyms

Prerequisites
To drop a private synonym, either the synonym must be in your own schema or you must have the DROP ANY SYNONYM system privilege.

To drop a PUBLIC synonym, you must have the DROP PUBLIC SYNONYM system privilege.

Syntax

\[
drop\_synonym::= \\
drop\_synonym::= \text{DROP PUBLIC SYNONYM schema . synonym FORCE};
\]

Semantics

PUBLIC
You must specify PUBLIC to drop a public synonym. You cannot specify schema if you have specified PUBLIC.

\[
schema
\]
Specify the schema containing the synonym. If you omit schema, then Oracle Database assumes the synonym is in your own schema.

\[
synonym
\]
Specify the name of the synonym to be dropped.

If you drop a synonym for the master table of a materialized view, and if the defining query of the materialized view specified the synonym rather than the actual table name, then Oracle Database marks the materialized view unusable.

If an object type synonym has any dependent tables or user-defined types, then you cannot drop the synonym unless you also specify FORCE.
FORCE

Specify FORCE to drop the synonym even if it has dependent tables or user-defined types.

Note:

Oracle does not recommend that you specify FORCE to drop object type synonyms with dependencies. This operation can result in invalidation of other user-defined types or marking UNUSED the table columns that depend on the synonym. For information about type dependencies, see Oracle Database Object-Relational Developer's Guide.

Examples

Dropping a Synonym: Example

To drop the public synonym named customers, which was created in "Oracle Database Resolution of Synonyms: Example", issue the following statement:

```
DROP PUBLIC SYNONYM customers;
```
This chapter contains the following SQL statements:

- DROP TABLE
- DROP TABLESPACE
- DROP TABLESPACE SET
- DROP TRIGGER
- DROP TYPE
- DROP TYPE BODY
- DROP USER
- DROP VIEW
- EXPLAIN PLAN
- FLASHBACK DATABASE
- FLASHBACK TABLE
- GRANT
- INSERT
- LOCK TABLE

## DROP TABLE

### Purpose

Use the `DROP TABLE` statement to move a table or object table to the recycle bin or to remove the table and all its data from the database entirely.

### Note:

Unless you specify the `PURGE` clause, the `DROP TABLE` statement does not result in space being released back to the tablespace for use by other objects, and the space continues to count toward the user's space quota.

For an external table, this statement removes only the table metadata in the database. It has no affect on the actual data, which resides outside of the database.

When you drop a table that is part of a cluster, the table is moved to the recycle bin. However, if you subsequently drop the cluster, then the table is purged from the recycle bin and can no longer be recovered with a `FLASHBACK TABLE` operation.
Dropping a table invalidates dependent objects and removes object privileges on the table. If you want to re-create the table, then you must regrant object privileges on the table, re-create the indexes, integrity constraints, and triggers for the table, and respecify its storage parameters. Truncating has none of these effects. Therefore, removing rows with the TRUNCATE statement can be more efficient than dropping and re-creating a table.

See Also:

- CREATE TABLE and ALTER TABLE for information on creating and modifying tables
- TRUNCATE TABLE and DELETE for information on removing data from a table
- FLASHBACK TABLE for information on retrieving a dropped table from the recycle bin

Prerequisites

The table must be in your own schema or you must have the DROP ANY TABLE system privilege.

You can perform DDL operations (such as ALTER TABLE, DROP TABLE, CREATE INDEX) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an INSERT operation on the table. A session becomes unbound to the temporary table by issuing a TRUNCATE statement or at session termination, or, for a transaction-specific temporary table, by issuing a COMMIT or ROLLBACK statement.

You can drop a private temporary table using the existing DROP TABLE command. Dropping a private temporary table will not commit an existing transaction. This applies to both transaction-specific and session-specific private temporary tables. Note that a dropped private temporary table will not go into the RECYCLEBIN.

Syntax

\[
\text{drop\_table::=} \\
\text{DROP TABLE schema . table CASCADE CONSTRAINTS PURGE} \\
\]

Semantics

schema

Specify the schema containing the table. If you omit schema, then Oracle Database assumes the table is in your own schema.

table

Specify the name of the table to be dropped. Oracle Database automatically performs the following operations:
• All rows from the table are dropped.

• All table indexes and domain indexes are dropped, as well as any triggers defined on the table, regardless of who created them or whose schema contains them. If table is partitioned, then any corresponding local index partitions are also dropped.

• All the storage tables of nested tables and LOBs of table are dropped.

• When you drop a range-, hash-, or list-partitioned table, then the database drops all the table partitions. If you drop a composite-partitioned table, then all the partitions and subpartitions are also dropped.

• When you drop a partitioned table with the PURGE keyword, the statement executes as a series of subtransactions, each of which drops a subset of partitions or subpartitions and their metadata. This division of the drop operation into subtransactions optimizes the processing of internal system resource consumption (for example, the library cache), especially for the dropping of very large partitioned tables. As soon as the first subtransaction commits, the table is marked UNUSABLE. If any of the subtransactions fails, then the only operation allowed on the table is another DROP TABLE ... PURGE statement. Such a statement will resume work from where the previous DROP TABLE statement failed, assuming that you have corrected any errors that the previous operation encountered.

You can list the tables marked UNUSABLE by such a drop operation by querying the status column of the *_TABLES, *_PART_TABLES, *_ALL_TABLES, or *_OBJECT_TABLES data dictionary views, as appropriate.

See Also:
Oracle Database VLDB and Partitioning Guide for more information on dropping partitioned tables.

• For an index-organized table, any mapping tables defined on the index-organized table are dropped.

• For a domain index, the appropriate drop routines are invoked. Refer to Oracle Database Data Cartridge Developer's Guide for more information on these routines.

• If any statistics types are associated with the table, then the database disassociates the statistics types with the FORCE clause and removes any user-defined statistics collected with the statistics type.

See Also:
ASSOCIATE STATISTICS and DISASSOCIATE STATISTICS for more information on statistics type associations

• If the table is not part of a cluster, then the database returns all data blocks allocated to the table and its indexes to the tablespaces containing the table and its indexes.
To drop a cluster and all its the tables, use the DROP CLUSTER statement with the INCLUDING TABLES clause to avoid dropping each table individually. See DROP CLUSTER.

• If the table is a base table for a view, a container or master table of a materialized view, or if it is referenced in a stored procedure, function, or package, then the database invalidates these dependent objects but does not drop them. You cannot use these objects unless you re-create the table or drop and re-create the objects so that they no longer depend on the table.

If you choose to re-create the table, then it must contain all the columns selected by the subqueries originally used to define the materialized views and all the columns referenced in the stored procedures, functions, or packages. Any users previously granted object privileges on the views, stored procedures, functions, or packages need not be regranted these privileges.

If the table is a master table for a materialized view, then the materialized view can still be queried, but it cannot be refreshed unless the table is re-created so that it contains all the columns selected by the defining query of the materialized view.

If the table has a materialized view log, then the database drops this log and any other direct-path INSERT refresh information associated with the table.

Restrictions on Dropping Tables

• You cannot directly drop the storage table of a nested table. Instead, you must drop the nested table column using the ALTER TABLE ... DROP COLUMN clause.

• You cannot drop the parent table of a reference-partitioned table. You must first drop all reference-partitioned child tables.

• You cannot drop a table that uses a flashback data archive for historical tracking. You must first disable the table’s use of the flashback data archive.

CASCADE CONSTRAINTS

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints that refer to primary and unique keys in the dropped table. If you omit this clause, and such referential integrity constraints exist, then the database returns an error and does not drop the table.

PURGE

Specify PURGE if you want to drop the table and release the space associated with it in a single step. If you specify PURGE, then the database does not place the table and its dependent objects into the recycle bin.

Note:

You cannot roll back a DROP TABLE statement with the PURGE clause, nor can you recover the table if you have dropped it with the PURGE clause.

Using this clause is equivalent to first dropping the table and then purging it from the recycle bin. This clause lets you save one step in the process. It also provides enhanced security if you want to prevent sensitive material from appearing in the recycle bin.
See Also:

*Oracle Database Administrator's Guide* for information on the recycle bin and naming conventions for objects in the recycle bin

Examples

**Dropping a Table: Example**

The following statement drops the `oe.list_customers` table created in "List Partitioning Example".

```sql
DROP TABLE list_customers PURGE;
```

---

**DROP TABLESPACE**

**Purpose**

Use the `DROP TABLESPACE` statement to remove a tablespace from the database.

When you drop a tablespace, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the tablespace.

---

See Also:

*CREATE TABLESPACE* and *ALTER TABLESPACE* for information on creating and modifying a tablespace

**Prerequisites**

You must have the `DROP TABLESPACE` system privilege. You cannot drop a tablespace if it contains any rollback segments holding active transactions.

**Syntax**

```sql
drop_tablespace ::= 
```

---

![Diagram of DROP TABLESPACE syntax]
**Semantics**

*tablespace*

Specify the name of the tablespace to be dropped, including those of shadow tablespaces, that store lost write protection updates.

You can drop a tablespace regardless of whether it is online or offline. Oracle recommends that you take the tablespace offline before dropping it to ensure that no SQL statements in currently running transactions access any of the objects in the tablespace.

You cannot drop the `SYSTEM` tablespace. You can drop the `SYSAUX` tablespace only if you have the `SYSDBA` system privilege and you have started the database in `UPGRADE` mode.

You may want to alert any users who have been assigned the tablespace as either a default or temporary tablespace. After the tablespace has been dropped, these users cannot allocate space for objects or sort areas in the tablespace. You can reassign users new default and temporary tablespaces with the `ALTER USER` statement.

Any objects that were previously dropped from the tablespace and moved to the recycle bin are purged from the recycle bin. Oracle Database removes from the data dictionary all metadata about the tablespace and all data files and temp files in the tablespace. The database also automatically drops from the operating system any Oracle-managed data files and temp files in the tablespace. Other data files and temp files are not removed from the operating system unless you specify `INCLUDING CONTENTS AND DATAFILES`.

You cannot use this statement to drop a tablespace group. However, if `tablespace` is the only tablespace in a tablespace group, then Oracle Database removes the tablespace group from the data dictionary as well.

**Restrictions on Dropping Tablespaces**

Dropping tablespaces is subject to the following restrictions:

- You cannot drop a tablespace that contains a domain index or any objects created by a domain index.
- You cannot drop an undo tablespace if it is being used by any instance or if it contains any undo data needed to roll back uncommitted transactions.
- You cannot drop a tablespace that has been designated as the default tablespace for the database. You must first reassign another tablespace as the default tablespace and then drop the old default tablespace.
- You cannot drop a temporary tablespace if it is part of the database default temporary tablespace group. You must first remove the tablespace from the database default temporary tablespace group and then drop it.
- You cannot drop a temporary tablespace if it contains segments that are in use by existing sessions. In this case, no error is raised. The database waits until there are no segments in use by existing sessions and then drops the tablespace.
- You cannot drop a tablespace, even with the `INCLUDING CONTENTS` and `CASCADE CONSTRAINTS` clauses, if doing so would disable a primary key or unique constraint in another tablespace. For example, if the tablespace being dropped contains a primary key index, but the primary key column itself is in a different tablespace,
then you cannot drop the tablespace until you have manually disabled the primary key constraint in the other tablespace.

See Also:
Oracle Database Data Cartridge Developer's Guide and Oracle Database Concepts for more information on domain indexes

{ DROP | KEEP } QUOTA

Specify DROP QUOTA to drop all user quotas for the tablespace. Specify KEEP QUOTA to retain all user quotas for the tablespace. The default is KEEP QUOTA.

You can view all user quotas for a tablespace by querying the DBA_TS_QUOTAS data dictionary view.

INCLUDING CONTENTS

Specify INCLUDING CONTENTS to drop all the contents of the tablespace, including those of shadow tablespaces that store lost write protection updates. You must specify this clause to drop a tablespace that contains any database objects. If you omit this clause, and the tablespace is not empty, then the database returns an error and does not drop the tablespace.

DROP TABLESPACE fails, even if you specify INCLUDING CONTENTS, if the tablespace contains some, but not all, of the partitions or subpartitions of a single table. If all the partitions or subpartitions of a partitioned table reside in tablespace, then DROP TABLESPACE ... INCLUDING CONTENTS drops tablespace, as well as any associated index segments, LOB data and index segments, and nested table data and index segments of table in other tablespace(s).

For a partitioned index-organized table, if all the primary key index segments are in this tablespace, then this clause will also drop any overflow segments that exist in other tablespaces, as well as any associated mapping table in other tablespaces. If some of the primary key index segments are not in this tablespace, then the statement will fail. In that case, before you can drop the tablespace, you must use ALTER TABLE ... MOVE PARTITION to move those primary key index segments into this tablespace, drop the partitions whose overflow data segments are not in this tablespace, and drop the partitioned index-organized table.

If the tablespace contains a master table of a materialized view, then the database invalidates the materialized view.

If the tablespace contains a materialized view log, then the database drops the log and any other direct-path INSERT refresh information associated with the table.

AND DATAFILES

When you specify INCLUDING CONTENTS, the AND DATAFILES clause lets you instruct the database to delete the associated operating system files as well. Oracle Database writes a message to the alert log for each operating system file deleted. This clause is not needed for Oracle Managed Files, because they are removed from the system even if you do not specify AND DATAFILES.

KEEP DATAFILES
When you specify INCLUDING CONTENTS, the KEEP DATAFILES clause lets you instruct the database to leave untouched the associated operating system files, including Oracle Managed Files. You must specify this clause if you are using Oracle Managed Files and you do not want the associated operating system files removed by the INCLUDING CONTENTS clause.

**CASCADE CONSTRAINTS**

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints from tables outside `tablespace` that refer to primary and unique keys of tables inside `tablespace`. If you omit this clause and such referential integrity constraints exist, then Oracle Database returns an error and does not drop the tablespace.

**Examples**

**Dropping a Tablespace: Example**

The following statement drops the `tbs_01` tablespace and drops all referential integrity constraints that refer to primary and unique keys inside `tbs_01`:

```
DROP TABLESPACE tbs_01
  INCLUDING CONTENTS
  CASCADE CONSTRAINTS;
```

**Dropping a Shadow Tablespace: Example**

The following statement tries to move the tracked data in the shadow tablespace to another shadow tablespace. This only works if there are shadow tablespaces in the PDB with enough free space.

```
DROP TABLESPACE <shadow_tablespace_name>
```

The following statement drops the shadow tablespace and all its contents. All the tracking data is lost.

**Dropping Shadow Tablespace Including Contents: Example**

```
DROP TABLESPACE <shadow_tablespace_name>
  INCLUDING CONTENTS
```

**Deleting Operating System Files: Example**

The following example drops the `tbs_02` tablespace and deletes all associated operating system data files:

```
DROP TABLESPACE tbs_02
  INCLUDING CONTENTS AND DATAFILES;
```

**Note:**

This SQL statement is valid only if you are using Oracle Sharding. For more information on Oracle Sharding, refer to *Oracle Database Administrator’s Guide*. 

---
Purpose

Use the `DROP TABLESPACE SET` statement to drop a tablespace set from a shardgroup.

When you drop a tablespace set, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the tablespace set.

See Also:

CREATE TABLESPACE SET and ALTER TABLESPACE SET

Prerequisites

You must be connected to a shard catalog database as an SDB user.

You must have the `DROP TABLESPACE` system privilege. You cannot drop a tablespace set if its tablespaces contain any rollback segments holding active transactions.

Syntax

```
drop_tablespace_set::=  
  DROP TABLESPACE SET tablespace_set
  INCLUDING CONTENTS
  AND
  KEEP
  DATAFILES
  CASCADE
  CONSTRAINTS
```

Semantics

`tablespace_set`

Specify the name of the tablespace set to be dropped.

INCLUDING CONTENTS

This clause lets you specify how the database manages objects and datafiles associated with the tablespaces in the tablespace set during the drop operation. The `INCLUDING CONTENTS` clause has the same semantics here as for the `DROP TABLESPACE` statement. See INCLUDING CONTENTS for the full semantics of this clause.

Examples

**Dropping a Tablespace Set: Example**

The following statement drops the tablespace set `ts1`:

```
DROP TABLESPACE SET ts1;
```
DROP TRIGGER

Purpose
Triggers are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping triggers.

Use the DROP TRIGGER statement to remove a database trigger from the database.

See Also:
CREATE TRIGGER and ALTER TRIGGER

Prerequisites
The trigger must be in your own schema or you must have the DROP ANY TRIGGER system privilege. To drop a trigger on DATABASE in another user's schema, you must also have the ADMINISTER DATABASE TRIGGER system privilege.

Syntax

\[
drop\_trigger::=\,
\]

Semantics

\textit{schema}

Specify the schema containing the trigger. If you omit \textit{schema}, then Oracle Database assumes the trigger is in your own schema.

\textit{trigger}

Specify the name of the trigger to be dropped. Oracle Database removes it from the database and does not fire it again.

Examples

Dropping a Trigger: Example
The following statement drops the \texttt{salary\_check} trigger in the schema \texttt{hr}:

\begin{verbatim}
DROP TRIGGER hr.salary_check;
\end{verbatim}
DROP TYPE

Purpose
Object types are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping object types.

Use the DROP TYPE statement to drop the specification and body of an object type, a varray, or a nested table type.

Prerequisites
The object type, varray, or nested table type must be in your own schema or you must have the DROP ANY TYPE system privilege.

Syntax

drop_type ::= 

DROP TYPE

Semantics

schema
Specify the schema containing the type. If you omit schema, then Oracle Database assumes the type is in your own schema.

type_name
Specify the name of the object, varray, or nested table type to be dropped. You can drop only types with no type or table dependencies.

If type_name is a supertype, then this statement will fail unless you also specify FORCE.
If you specify FORCE, then the database invalidates all subtypes depending on this supertype.

If type_name is a statistics type, then this statement will fail unless you also specify FORCE. If you specify FORCE, then the database first disassociates all objects that are associated with type_name and then drops type_name.

See Also:
ASSOCIATE STATISTICS and DISASSOCIATE STATISTICS for more information on statistics types

If type_name is an object type that has been associated with a statistics type, then the database first attempts to disassociate type_name from the statistics type and then
drops type_name. However, if statistics have been collected using the statistics type, then the database will be unable to disassociate type_name from the statistics type, and this statement will fail.

If type_name is an implementation type for an indextype, then the indextype will be marked INVALID.

If type_name has a public synonym defined on it, then the database will also drop the synonym.

Unless you specify FORCE, you can drop only object types, nested tables, or varray types that are standalone schema objects with no dependencies. This is the default behavior.

### See Also:

CREATE INDEXTYPE

### FORCE

Specify FORCE to drop the type even if it has dependent database objects. Oracle Database marks UNUSED all columns dependent on the type to be dropped, and those columns become inaccessible.

### Note:

Oracle does not recommend that you specify FORCE to drop object types with dependencies. This operation is not recoverable and could cause the data in the dependent tables or columns to become inaccessible.

### VALIDATE

If you specify VALIDATE when dropping a type, then Oracle Database checks for stored instances of this type within substitutable columns of any of its supertypes. If no such instances are found, then the database completes the drop operation.

This clause is meaningful only for subtypes. Oracle recommends the use of this option to safely drop subtypes that do not have any explicit type or table dependencies.

### Examples

**Dropping an Object Type: Example**

The following statement removes object type person_t. See Oracle Database PL/SQL Language Reference for the example that creates this object type. Any columns that are dependent on person_t are marked UNUSED and become inaccessible.

```
DROP TYPE person_t FORCE;
```
DROP TYPE BODY

Purpose

Object types are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping object types.

Use the DROP TYPE BODY statement to drop the body of an object type, varray, or nested table type. When you drop a type body, the object type specification still exists, and you can re-create the type body. Prior to re-creating the body, you can still use the object type, although you cannot call the member functions.

Prerequisites

The object type body must be in your own schema or you must have the DROP ANY TYPE system privilege.

Syntax

\[
drop\_type\_body::=\ \\
\text{DROP TYPE BODY} \text{schema} . \text{type}\_name ;
\]

Semantics

\text{schema}

Specify the schema containing the object type. If you omit \text{schema}, then Oracle Database assumes the object type is in your own schema.

\text{type}\_name

Specify the name of the object type body to be dropped.

Restriction on Dropping Type Bodies

You can drop a type body only if it has no type or table dependencies.

Examples

Dropping an Object Type Body: Example

The following statement removes object type body \text{data}\_typ1. See Oracle Database PL/SQL Language Reference for the example that creates this object type.

\[\text{DROP TYPE BODY data}\_typ1;\]

DROP USER

Purpose

Use the DROP USER statement to remove a database user and optionally remove the user's objects.
In an Oracle Automatic Storage Management (Oracle ASM) cluster, a user authenticated as SYSASM can use this clause to remove a user from the password file that is local to the Oracle ASM instance of the current node.

When you drop a user, Oracle Database also purges all of that user's schema objects from the recycle bin.

**Note:**

Do not attempt to drop the users SYS or SYSTEM. Doing so will corrupt your database.

**See Also:**

CREATE USER and ALTER USER for information on creating and modifying a user

**Prerequisites**

You must have the DROP USER system privilege. In an Oracle ASM cluster, you must be authenticated as SYSASM.

**Syntax**

```
drop_user::=  
```

**Semantics**

*user*

Specify the user to be dropped. Oracle Database does not drop users whose schemas contain objects unless you specify **CASCADE** or unless you first explicitly drop the user's objects.

**Restriction on Dropping Users**

You cannot drop a user whose schema contains a table that uses a flashback data archive for historical tracking. You must first disable the table's use of the flashback data archive.

**CASCADE**

Specify CASCADE to drop all objects in the user's schema before dropping the user. You must specify this clause to drop a user whose schema contains any objects.
• If the user's schema contains tables, then Oracle Database drops the tables and automatically drops any referential integrity constraints on tables in other schemas that refer to primary and unique keys on these tables.

• If this clause results in tables being dropped, then the database also drops all domain indexes created on columns of those tables and invokes appropriate drop routines.

See Also:

Oracle Database Data Cartridge Developer's Guide for more information on these routines

• Oracle Database invalidates, but does not drop, the following objects in other schemas:
  – Views or synonyms for objects in the dropped user's schema
  – Stored procedures, functions, or packages that query objects in the dropped user's schema

• Oracle Database does not drop materialized views in other schemas that are based on tables in the dropped user's schema. However, because the base tables no longer exist, the materialized views in the other schemas can no longer be refreshed.

• Oracle Database drops all triggers in the user's schema.

• Oracle Database does not drop roles created by the user.

Note:

Oracle Database also drops with FORCE all types owned by the user. See the FORCE keyword of DROP TYPE.

Examples

Dropping a Database User: Example

If user Sidney's schema contains no objects, then you can drop sidney by issuing the statement:

```
DROP USER sidney;
```

If Sidney's schema contains objects, then you must use the CASCADE clause to drop sidney and the objects:

```
DROP USER sidney CASCADE;
```
DROP VIEW

Purpose

Use the DROP VIEW statement to remove a view or an object view from the database. You can change the definition of a view by dropping and re-creating it.

See Also:

CREATE VIEW and ALTER VIEW for information on creating and modifying a view

Prerequisites

The view must be in your own schema or you must have the DROP ANY VIEW system privilege.

Syntax

drop_view::= DROP VIEW schema . view CASCADE CONSTRAINTS ;

Semantics

schema

Specify the schema containing the view. If you omit schema, then Oracle Database assumes the view is in your own schema.

view

Specify the name of the view to be dropped.

Oracle Database does not drop views, materialized views, and synonyms that are dependent on the view but marks them INVALID. You can drop them or redefine views and synonyms, or you can define other views in such a way that the invalid views and synonyms become valid again.

If any subviews have been defined on view, then the database invalidates the subviews as well. To determine whether the view has any subviews, query the SUPERVIEW_NAME column of the USER_VIEWS, ALL_VIEWS, or DBA_VIEWS data dictionary views.
CASCADe CONSTRAINTS

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints that refer to primary and unique keys in the view to be dropped. If you omit this clause, and such constraints exist, then the DROP statement fails.

Examples

Dropping a View: Example

The following statement drops the emp_view view, which was created in "Creating a View: Example":

```
DROP VIEW emp_view;
```

EXPLAIN PLAN

Purpose

Use the EXPLAIN PLAN statement to determine the execution plan Oracle Database follows to execute a specified SQL statement. This statement inserts a row describing each step of the execution plan into a specified table. You can also issue the EXPLAIN PLAN statement as part of the SQL trace facility.

This statement also determines the cost of executing the statement. If any domain indexes are defined on the table, then user-defined CPU and I/O costs will also be inserted.

The definition of a sample output table PLAN_TABLE is available in a SQL script on your distribution media. Your output table must have the same column names and data types as this table. The common name of this script is UTLXPLAN.SQL. The exact name and location depend on your operating system.

Oracle Database provides information on cached cursors through several dynamic performance views:

- For information on the work areas used by SQL cursors, query V$SQL_WORKAREA.
- For information on the execution plan for a cached cursor, query V$SQL_PLAN.
- For execution statistics at each step or operation of an execution plan of cached cursors (for example, number of produced rows, number of blocks read), query V$SQL_PLAN_STATISTICS.
- For a selective precomputed join of the preceding three views, query V$SQL_PLAN_STATISTICS_ALL.
Execution statistics at each step or operation of an execution plan of cached cursors are displayed in \texttt{V$SQL\_PLAN\_MONITOR} if the statement execution is monitored. You can force monitoring using the \texttt{MONITOR} hint.

\textbf{See Also:}

- \textit{Oracle Database SQL Tuning Guide} for information on the output of \texttt{EXPLAIN PLAN}, how to use the SQL trace facility, and how to generate and interpret execution plans
- \textit{Oracle Database Reference} for information on dynamic performance views

\textbf{Prerequisites}

To issue an \texttt{EXPLAIN PLAN} statement, you must have the privileges necessary to insert rows into an existing output table that you specify to hold the execution plan.

You must also have the privileges necessary to execute the SQL statement for which you are determining the execution plan. If the SQL statement accesses a view, then you must have privileges to access any tables and views on which the view is based. If the view is based on another view that is based on a table, then you must have privileges to access both the other view and its underlying table.

To examine the execution plan produced by an \texttt{EXPLAIN PLAN} statement, you must have the privileges necessary to query the output table.

The \texttt{EXPLAIN PLAN} statement is a data manipulation language (DML) statement, rather than a data definition language (DDL) statement. Therefore, Oracle Database does not implicitly commit the changes made by an \texttt{EXPLAIN PLAN} statement. If you want to keep the rows generated by an \texttt{EXPLAIN PLAN} statement in the output table, then you must commit the transaction containing the statement.

\textbf{See Also:}

\texttt{INSERT} and \texttt{SELECT} for information on the privileges you need to populate and query the plan table

\textbf{Syntax}

\begin{verbatim}
explain_plan::=
\end{verbatim}

\begin{verbatim}
EXPLAIN PLAN SET STATEMENT_ID = string INTO schema . table @ dblink FOR statement ;
\end{verbatim}
Semantics

SET STATEMENT_ID Clause

Specify a value for the STATEMENT_ID column for the rows of the execution plan in the output table. You can then use this value to identify these rows among others in the output table. Be sure to specify a STATEMENT_ID value if your output table contains rows from many execution plans. If you omit this clause, then the STATEMENT_ID value defaults to null.

INTO table Clause

Specify the name of the output table, and optionally its schema and database. This table must exist before you use the EXPLAIN PLAN statement.

If you omit schema, then the database assumes the table is in your own schema.

The dblink can be a complete or partial name of a database link to a remote Oracle Database where the output table is located. You can specify a remote output table only if you are using Oracle Database distributed functionality. If you omit dblink, then the database assumes the table is on your local database. See "References to Objects in Remote Databases " for information on referring to database links.

If you omit INTO altogether, then the database assumes an output table named PLAN_TABLE in your own schema on your local database.

FOR statement Clause

Specify a SELECT, INSERT, UPDATE, DELETE, MERGE, CREATE TABLE, CREATE INDEX, or ALTER INDEX ... REBUILD statement for which the execution plan is generated.

Notes on EXPLAIN PLAN

The following notes apply to EXPLAIN PLAN:

- If statement includes the parallel_clause, then the resulting execution plan will indicate parallel execution. However, EXPLAIN PLAN actually inserts the statement into the plan table, so that the parallel DML statement you submit is no longer the first DML statement in the transaction. This violates the Oracle Database restriction of one parallel DML statement in a single transaction, and the statement will be executed serially. To maintain parallel execution of the statements, you must commit or roll back the EXPLAIN PLAN statement, and then submit the parallel DML statement.

- To determine the execution plan for an operation on a temporary table, EXPLAIN PLAN must be run from the same session, because the data in temporary tables is session specific.

Examples

EXPLAIN PLAN Examples

The following statement determines the execution plan and cost for an UPDATE statement and inserts rows describing the execution plan into the specified plan_table table with the STATEMENT_ID value of 'Raise in Tokyo':

EXPLAIN PLAN
  SET STATEMENT_ID = 'Raise in Tokyo'
INTO plan_table
FOR UPDATE employees
    SET salary = salary * 1.10
    WHERE department_id =
        (SELECT department_id FROM departments
            WHERE location_id = 1700);

The following SELECT statement queries the plan_table table and returns the execution plan and the cost:

SELECT id, LPAD(' ',2*(LEVEL-1))||operation operation, options, object_name, object_alias, position
FROM plan_table
START WITH id = 0 AND statement_id = 'Raise in Tokyo'
CONNECT BY PRIOR id = parent_id AND statement_id = 'Raise in Tokyo'
ORDER BY id;

The query returns this execution plan:

<table>
<thead>
<tr>
<th>ID</th>
<th>OPERATION</th>
<th>OPTIONS</th>
<th>OBJECT_NAME</th>
<th>OBJECT_ALIAS</th>
<th>POSITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>UPDATE STATEMENT</td>
<td></td>
<td></td>
<td></td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>UPDATE</td>
<td></td>
<td>EMPLOYEES</td>
<td>EMPLOYEES@UPD$1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>INDEX</td>
<td>RANGE SCAN</td>
<td>EMP_DEPARTMENT_IX</td>
<td>EMPLOYEES@SEL$1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>TABLE ACCESS</td>
<td>BY INDEX ROWID</td>
<td>DEPARTMENTS</td>
<td>DEPARTMENTS@SEL$1</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>INDEX</td>
<td>RANGE SCAN</td>
<td>DEPT_LOCATION_IX</td>
<td>DEPARTMENTS@SEL$1</td>
<td>1</td>
</tr>
</tbody>
</table>

The value in the POSITION column of the first row shows that the statement has a cost of 4.

EXPLAIN PLAN: Partitioned Example

The sample table sh.sales is partitioned on the time_id column. Partition sales_q3_2000 contains time values less than Oct. 1, 2000, and there is a local index sales_time_bix on the time_id column.

Consider the query:

EXPLAIN PLAN FOR
    SELECT * FROM sales
    WHERE time_id BETWEEN :h AND '01-OCT-2000';

where :h represents an already declared bind variable. EXPLAIN PLAN executes this query with PLAN_TABLE as the output table. The basic execution plan, including partitioning information, is obtained with the following query:

SELECT operation, options, partition_start, partition_stop, partition_id
FROM plan_table;

FLASHBACK DATABASE

Purpose

Use the FLASHBACK DATABASE statement to return the database to a past time or system change number (SCN). This statement provides a fast alternative to performing incomplete database recovery.

Following a FLASHBACK DATABASE operation, in order to have write access to the flashed back database, you must reopen it with an ALTER DATABASE OPEN RESETLOGS statement.
Prerequisites

You must have the SYSDBA, SYSBACKUP, or SYSDG system privilege.

If you are connected to a multitenant container database (CDB):

- To flash back a CDB, you must be connected to the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To flash back a PDB you must be connected to the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly, or you must be connected to the PDB you want to flash back and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

A fast recovery area must have been prepared for the database. The database must have been put in FLASHBACK mode with an ALTER DATABASE FLASHBACK ON statement unless you are flashing the database back to a guaranteed restore point. The database must be mounted but not open.

In addition:

- The database must run in ARCHIVELOG mode.
- The database must be mounted, but not open, with a current control file. The control file cannot be a backup or re-created. When the database control file is restored from backup or re-created, all existing flashback log information is discarded.
- The database must contain no online tablespaces for which flashback functionality was disabled with the SQL statement ALTER TABLESPACE...FLASHBACK OFF.

See Also:

- Oracle Database Backup and Recovery User’s Guide for more information on FLASHBACK DATABASE
- CREATE RESTORE POINT for information on restore points and guaranteed restore points
Syntax

flashback_database::=

Semantics

When you issue a FLASHBACK DATABASE statement, Oracle Database first verifies that all required archived and online redo logs are available. If they are available, then it reverts all currently online data files in the database to the SCN or time specified in this statement.

• The amount of Flashback data retained in the database is controlled by the DB_FLASHBACK_RETENTION_TARGET initialization parameter and the size of the fast recovery area. You can determine how far back you can flash back the database by querying the \$FLASHBACK_DATABASE_LOG view.

• If insufficient data remains in the database to perform the flashback, then you can use standard recovery procedures to recover the database to a past point in time.

• If insufficient data remains for a set of data files, then the database returns an error. In this case, you can take those data files offline and reissue the statement to revert the remainder of the database. You can then attempt to recover the offline data files using standard recovery procedures.

See Also:
Oracle Database Backup and Recovery User's Guide for more information on recovering data files

STANDBY

Specify STANDBY to revert the standby database to an earlier SCN or time. If the database is not a standby database, then the database returns an error. If you omit this clause, then database can be either a primary or a standby database.
PLUGGABLE

Specify PLUGGABLE to flash back a PDB. You must specify this clause whether the current container is the root or the PDB you want to flash back.

Restrictions on Flashing Back a PDB

• You cannot flash back a proxy PDB.
• If the CDB is in shared undo mode, then you can only flash back a PDB to a clean PDB restore point. Refer to the CLEAN clause of CREATE RESTORE POINT for more information.

database

If you are flashing back a non-CDB or a CDB, then you can optionally specify the name of the database to be flashed back. If you omit database, then Oracle Database flashes back the database identified by the value of the initialization parameter DB_NAME.

If you are flashing back a PDB and the current container is the root, then use database to specify the name of the PDB to be flashed back. If you are flashing back a PDB and the current container is that PDB, then you can optionally use database to specify the PDB name.

TO SCN Clause

Specify a system change number (SCN):

• TO SCN reverts the database back to its state at the specified SCN.
• TO BEFORE SCN reverts the database back to its state at the system change number just preceding the specified SCN.

You can determine the current SCN by querying the CURRENT_SCN column of the V$DATABASE view. This in turn lets you save the SCN to a spool file, for example, before running a high-risk batch job.

TO TIMESTAMP Clause

Specify a valid datetime expression.

• TO TIMESTAMP reverts the database back to its state at the specified timestamp.
• TO BEFORE TIMESTAMP reverts the database back to its state one second before the specified timestamp.

You can represent the timestamp as an offset from a determinate value, such as SYSDATE, or as an absolute system timestamp.
TO RESTORE POINT Clause

Specify this clause to flash back the database to the specified restore point. If you have not enabled flashback database, then this is the only clause you can specify in this `FLASHBACK DATABASE` statement. If the database is not in `FLASHBACK` mode, as described in the “Prerequisites” section above, then this is the only clause you can specify for this statement.

RESETLOGS

Specify `TO BEFORE RESETLOGS` to flash the database back to just before the last `resetlogs` operation (`ALTER DATABASE OPEN RESETLOGS`).

See Also:

`Oracle Database Backup and Recovery User's Guide` for more information about this clause

Examples

Assuming that you have prepared a fast recovery area for the database and enabled media recovery, enable database `FLASHBACK` mode and open the database with the following statements:

```
STARTUP MOUNT
ALTER DATABASE FLASHBACK ON;
ALTER DATABASE OPEN;
```

With your database open for at least a day, you can flash back the database one day with the following statements:

```
SHUTDOWN DATABASE
STARTUP MOUNT
FLASHBACK DATABASE TO TIMESTAMP SYSDATE-1;
```

FLASHBACK TABLE

Purpose

Use the `FLASHBACK TABLE` statement to restore an earlier state of a table in the event of human or application error. The time in the past to which the table can be flashed back is dependent on the amount of undo data in the system. Also, Oracle Database cannot restore a table to an earlier state across any DDL operations that change the structure of the table.
Note:

Oracle strongly recommends that you run your database in automatic undo mode by leaving the `UNDO_MANAGEMENT` initialization parameter set to `AUTO`, which is the default. In addition, set the `UNDO_RETENTION` initialization parameter to an interval large enough to include the oldest data you anticipate needing. For more information refer to the documentation on the `UNDO_MANAGEMENT` and `UNDO_RETENTION` initialization parameters.

You cannot roll back a `FLASHBACK TABLE` statement. However, you can issue another `FLASHBACK TABLE` statement and specify a time just prior to the current time. Therefore, it is advisable to record the current SCN before issuing a `FLASHBACK TABLE` clause.

See Also:

- `FLASHBACK DATABASE` for information on reverting the entire database to an earlier version
- the `flashback_query_clause` of `SELECT` for information on retrieving past data from a table
- `Oracle Database Backup and Recovery User's Guide` for additional information on using the `FLASHBACK TABLE` statement

Prerequisites

To flash back a table to an earlier SCN or timestamp, you must have either the `FLASHBACK` object privilege on the table or the `FLASHBACK ANY TABLE` system privilege. In addition, you must have the `READ` or `SELECT` object privilege on the table, and you must have the `INSERT`, `DELETE`, and `ALTER` object privileges on the table.

Row movement must be enabled for all tables in the Flashback list unless you are flashing back the table to `BEFORE DROP`. That operation is called a `flashback drop` operation, and it uses dropped data in the recycle bin rather than undo data. Refer to `row_movement_clause` for information on enabling row movement.

To flash back a table to a restore point, you must have the `SELECT ANY DICTIONARY` or `FLASHBACK ANY TABLE` system privilege or the `SELECT_CATALOG_ROLE` role.

To flash back a table to before a `DROP TABLE` operation, you need only the privileges necessary to drop the table.
Syntax

\[
\textit{flashback\_table} ::= \\
\text{FLASHBACK} \text{ TABLE} \text{ schema \textit{table}} \text{ TO} \text{ SCN TIMESTAMP expr RESTORE POINT \textit{restore\_point}} \text{ ENABLE | DISABLE TRIGGERS BEFORE DROP RENAME \textit{table}} ;
\]

Semantics

During an Oracle Flashback Table operation, Oracle Database acquires exclusive DML locks on all the tables specified in the Flashback list. These locks prevent any operations on the tables while they are reverting to their earlier state.

The Flashback Table operation is executed in a single transaction, regardless of the number of tables specified in the Flashback list. Either all of the tables revert to the earlier state or none of them do. If the Flashback Table operation fails on any table, then the entire statement fails.

At the completion of the Flashback Table operation, the data in \textit{table} is consistent with \textit{table} at the earlier time. However, \textit{FLASHBACK TABLE TO SCN or TIMESTAMP} does not preserve rowids, and \textit{FLASHBACK TABLE TO BEFORE DROP} does not recover referential constraints.

Oracle Database does not revert statistics associated with \textit{table} to their earlier form. Indexes on \textit{table} that exist currently are reverted and reflect the state of the table at the Flashback point. If the index exists now but did not yet exist at the Flashback point, then the database updates the index to reflect the state of the table at the Flashback point. However, indexes that were dropped during the interval between the Flashback point and the current time are not restored.

\textit{schema}

Specify the schema containing the table. If you omit \textit{schema}, then the database assumes the table is in your own schema.

\textit{table}

Specify the name of one or more tables containing data you want to revert to an earlier version.

Restrictions on Flashing Back Tables

This statement is subject to the following restrictions:
• Flashback Table operations are not valid for the following type objects: tables that are part of a cluster, materialized views, Advanced Queuing (AQ) tables, static data dictionary tables, system tables, remote tables, object tables, nested tables, or individual table partitions or subpartitions.

• The following DDL operations change the structure of a table, so that you cannot subsequently use the TO SCN or TO TIMESTAMP clause to flash the table back to a time preceding the operation: upgrading, moving, or truncating a table; adding a constraint to a table, adding a table to a cluster; modifying or dropping a column; changing a column encryption key; adding, dropping, merging, splitting, coalescing, or truncating a partition or subpartition (with the exception of adding a range partition).

TO SCN Clause

Specify the system change number (SCN) corresponding to the point in time to which you want to return the table. The expr must evaluate to a number representing a valid SCN.

TO TIMESTAMP Clause

Specify a timestamp value corresponding to the point in time to which you want to return the table. The expr must evaluate to a valid timestamp in the past. The table will be flashed back to a time within approximately 3 seconds of the specified timestamp.

TO RESTORE POINT Clause

Specify a restore point to which you want to flash back the table. The restore point must already have been created.

See Also:

CREATE RESTORE POINT for information on creating restore points

ENABLE | DISABLE TRIGGERS

By default, Oracle Database disables all enabled triggers defined on table during the Flashback Table operation and then reenables them after the Flashback Table operation is complete. Specify ENABLE TRIGGERS if you want to override this default behavior and keep the triggers enabled during the Flashback process.

This clause affects only those database triggers defined on table that are already enabled. To enable currently disabled triggers selectively, use the ALTER TABLE ... enable_disable_clause before you issue the FLASHBACK TABLE statement with the ENABLE TRIGGERS clause.

TO BEFORE DROP Clause

Use this clause to retrieve from the recycle bin a table that has been dropped, along with all possible dependent objects. The table must have resided in a locally managed tablespace other than the SYSTEM tablespace.
You can specify either the original user-specified name of the table or the system-generated name Oracle Database assigned to the object when it was dropped.

- System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, then the database retrieves that specified object.

To see the contents of your recycle bin, query the `USER_RECYCLEBIN` data dictionary view. You can use the `RECYCLEBIN` synonym instead. The following two statements return the same rows:

```sql
SELECT * FROM RECYCLEBIN;
SELECT * FROM USER_RECYCLEBIN;
```

- If you specify the user-specified name, and if the recycle bin contains more than one object of that name, then the database retrieves the object that was moved to the recycle bin most recently. If you want to retrieve an older version of the table, then do one of these things:
  - Specify the system-generated recycle bin name of the table you want to retrieve.
  - Issue additional `FLASHBACK TABLE ... TO BEFORE DROP` statements until you retrieve the table you want.

Oracle Database attempts to preserve the original table name. If a new table of the same name has been created in the same schema since the original table was dropped, then the database returns an error unless you also specify the `RENAME TO` clause.

**RENAME TO Clause**

Use this clause to specify a new name for the table being retrieved from the recycle bin.

**Notes on Flashing Back Dropped Tables**

The following notes apply to flashing back dropped tables:

- Oracle Database retrieves all indexes defined on the table retrieved from the recycle bin except for bitmap join indexes and domain indexes. (Bitmap join indexes and domain indexes are not put in the recycle bin during a `DROP TABLE` operation, so cannot be retrieved.)

- The database also retrieves all triggers and constraints defined on the table except for referential integrity constraints that reference other tables.

The retrieved indexes, triggers, and constraints have recycle bin names. Therefore it is advisable to query the `USER_RECYCLEBIN` view before issuing a `FLASHBACK TABLE ... TO BEFORE DROP` statement so that you can rename the retrieved triggers and constraints to more usable names.
• When you drop a table, all materialized view logs defined on the table are also dropped but are not placed in the recycle bin. Therefore, the materialized view logs cannot be flashed back along with the table.

• When you drop a table, any indexes on the table are dropped and put into the recycle bin along with the table. If subsequent space pressures arise, then the database reclaims space from the recycle bin by first purging indexes. In this case, when you flash back the table, you may not get back all of the indexes that were defined on the table.

• You cannot flash back a table if it has been purged, either by a user or by Oracle Database as a result of some space reclamation operation.

Examples

Restoring a Table to an Earlier State: Examples

The examples below create a new table, employees_test, with row movement enabled, update values within the new table, and issue the FLASHBACK TABLE statement.

Create table employees_test, with row movement enabled, from table employees of the sample hr schema:

```
CREATE TABLE employees_test
  AS SELECT * FROM employees;
```

As a benchmark, list those salaries less than 2500:

```
SELECT salary
  FROM employees_test
  WHERE salary < 2500;
```

<table>
<thead>
<tr>
<th>SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>2400</td>
</tr>
<tr>
<td>2200</td>
</tr>
<tr>
<td>2100</td>
</tr>
<tr>
<td>2400</td>
</tr>
<tr>
<td>2200</td>
</tr>
</tbody>
</table>

Note:

To allow time for the SCN to propagate to the mapping table used by the FLASHBACK TABLE statement, wait a minimum of 5 minutes prior to issuing the following statement. This wait would not be necessary if a previously existing table were being used in this example.

Enable row movement for the table:

```
ALTER TABLE employees_test
  ENABLE ROW MOVEMENT;
```

Issue a 10% salary increase to those employees earning less than 2500:

```
UPDATE employees_test
  SET salary = salary * 1.1
  WHERE salary < 2500;
```
As a second benchmark, list those salaries that remain less than 2500 following the 10% increase:

```
SELECT salary
FROM employees_test
WHERE salary < 2500;
```

```
SALARY
----------
2420
2310
2420
```

Restore the table employees_test to its state prior to the current system time. The unrealistic duration of 1 minute is used so that you can test this series of examples quickly. Under normal circumstances a much greater interval would have elapsed.

```
FLASHBACK TABLE employees_test
TO TIMESTAMP (SYSTIMESTAMP - INTERVAL '1' minute);
```

List those salaries less than 2500. After the FLASHBACK TABLE statement issued above, this list should match the list in the first benchmark.

```
SELECT salary
FROM employees_test
WHERE salary < 2500;
```

```
SALARY
----------
2400
2200
2100
2400
2200
```

**Retrieving a Dropped Table: Example**

If you accidentally drop the pm.print_media table and want to retrieve it, then issue the following statement:

```
FLASHBACK TABLE print_media TO BEFORE DROP;
```

If another print_media table has been created in the pm schema, then use the RENAME TO clause to rename the retrieved table:

```
FLASHBACK TABLE print_media TO BEFORE DROP RENAME TO print_media_old;
```

If you know that the employees table has been dropped multiple times, and you want to retrieve the oldest version, then query the USER_RECYCLEBIN table to determine the system-generated name, and then use that name in the FLASHBACK TABLE statement. (System-generated names in your database will differ from those shown here.)

```
SELECT object_name, droptime FROM user_recyclebin
WHERE original_name = 'PRINT_MEDIA';
```

```
OBJECT_NAME   DROPTIME
-------------
```
GRANT

Purpose

Use the GRANT statement to grant:

- System privileges to users and roles. Table 18-1 lists the system privileges (organized by the database object operated upon).

- Roles to users, roles, and program units. The granted roles can be either user-defined (local or external) or predefined. For a list of predefined roles, refer to Oracle Database Security Guide.

- Object privileges for a particular object to users and roles. Table 18-2 lists the object privileges (organized by the database object operated upon).

Note:

Global roles (created with IDENTIFIED GLOBALLY) are granted through enterprise roles and cannot be granted using the GRANT statement.

Notes on Authorizing Database Users

You can authorize database users through means other than the database and the GRANT statement.

- Many Oracle Database privileges are granted through supplied PL/SQL and Java packages. For information on those privileges, refer to the documentation for the appropriate package.

- Some operating systems have facilities that let you grant roles to Oracle Database users with the initialization parameter OS_ROLES. If you choose to grant roles to users through operating system facilities, then you cannot also grant roles to users with the GRANT statement, although you can use the GRANT statement to grant system privileges to users and system privileges and roles to other roles.

Note on Oracle Automatic Storage Management

A user authenticated AS SYSASM can use this statement to grant the system privileges SYSASM, SYSOPER, and SYSDBA to a user in the Oracle ASM password file of the current node.

Note on Editionable Objects

A GRANT operation to grant object privileges on an editionable object actualizes the object in the current edition. See Oracle Database Development Guide for more information about editions and editionable objects.
Prerequisites

To grant a **system privilege**, one of the following conditions must be met:

- You must have been granted the `GRANT ANY PRIVILEGE` system privilege. In this case, if you grant the system privilege to a role, then a user to whom the role has been granted does not have the privilege unless the role is enabled in user's session.

- You must have been granted the system privilege with the `ADMIN OPTION`. In this case, if you grant the system privilege to a role, then a user to whom the role has been granted has the privilege regardless whether the role is enabled in the user's session.

To grant a **role to a user or another role**, you must have been directly granted the role with the `ADMIN OPTION`, or you must have been granted the `GRANT ANY ROLE` system privilege, or you must have created the role.

To grant a **role to a program unit in your own schema**, you must have been directly granted the role with either the `ADMIN OPTION` or the `DELEGATE OPTION`, or you must have been granted the `GRANT ANY ROLE` system privilege, or you must have created the role.

To grant a **role to a program unit in another user's schema**, you must be the user `SYS` and the role must have been created by the schema owner or directly granted to the schema owner.

To grant an **object privilege on a user**, by specifying the `ON USER` clause of the `on_object_clause`, you must be the user on whom the privilege is granted, or you must have been granted the object privilege on that user with the `WITH GRANT OPTION`, or you must have been granted the `GRANT ANY OBJECT PRIVILEGE` system privilege. If you can grant an object privilege on a user only because you have the `GRANT ANY OBJECT PRIVILEGE`, then the `GRANTOR` column of the `*_TAB_PRIVS` views displays the user on whom the privilege is granted rather than the user who issued the `GRANT` statement.

To grant an **object privilege on all other types of objects**, you must own the object, or the owner of the object must have granted you the object privileges with the `WITH GRANT OPTION`, or you must have been granted the `GRANT ANY OBJECT PRIVILEGE` system privilege. If you have the `GRANT ANY OBJECT PRIVILEGE`, then you can grant the object privilege only if the object owner could have granted the same object privilege. In this case, the `GRANTOR` column of the `*_TAB_PRIVS` views displays the object owner rather than the user who issued the `GRANT` statement.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root.

Semantics

grant_system_privileges

Use these clauses to grant system privileges.

system_privilege

Specify the system privilege you want to grant. Table 18-1 lists the system privileges, organized by the database object operated upon.

- If you grant a privilege to a user, then the database adds the privilege to the user's privilege domain. The user can immediately exercise the privilege. Oracle recommends that you only grant the ANY privileges to trusted users.
- If you grant a privilege to a role, then the database adds the privilege to the privilege domain of the role. Users who have been granted and have enabled the role can immediately exercise the privilege. Other users who have been granted the role can enable the role and exercise the privilege.

See Also:

Granting a System Privilege to a User: Example and "Granting System Privileges to a Role: Example"

- If you grant a privilege to PUBLIC, then the database adds the privilege to the privilege domains of each user. All users can immediately perform operations authorized by the privilege. Oracle recommends against granting system privileges to PUBLIC.

role

Specify the role you want to grant. You can grant an Oracle Database predefined role or a user-defined role.

- If you grant a role to a user, then the database makes the role available to the user. The user can immediately enable the role and exercise the privileges in the privilege domain of the role.

In the case of a secure application role, you need not grant such a role directly to the user. You can let the associated PL/SQL package do this, assuming the user passes appropriate security policies. For more information, see the CREATE ROLE semantics for USING package and Oracle Database Security Guide

- If you grant a role to another role, then the database adds the privilege domain of the granted role to the privilege domain of the grantee role. Users who have been granted the grante role can enable it and exercise the privileges in the granted role's privilege domain.

- If you grant a role to PUBLIC, then the database makes the role available to all users. All users can immediately enable the role and exercise the privileges in the privilege domain of the role.

ALL PRIVILEGES
Specify **ALL PRIVILEGES** to grant all of the system privileges listed in [Table 18-1](#), except the **SELECT ANY DICTIONARY**, **ALTER DATABASE LINK**, and **ALTER PUBLIC DATABASE LINK** privileges.

However, granting and revoking **ALL PRIVILEGES** does not apply to **ADMINISTER KEY MANAGEMENT**. Granting **ALL PRIVILEGES** does not grant **ADMINISTER KEY MANAGEMENT**. Similarly, revoking **ALL PRIVILEGES** does not revoke **ADMINISTER KEY MANAGEMENT**.

### See Also:

- *Oracle Database Security Guide* for information on the Oracle predefined roles
- "Granting a Role to a Role: Example"
- CREATE ROLE for information on creating a user-defined role

### grantee_clause

Use the **grantee_clause** to specify the users or roles to which the system privilege, role, or object privilege is granted.

**PUBLIC**

Specify **PUBLIC** to grant the privileges to all users. Oracle recommends against granting system privileges to **PUBLIC**.

#### Restriction on Grantees

A user, role, or **PUBLIC** cannot appear more than once in the **grantee_clause**.

**grantee_identified_by**

The **grantee_identified_by** clause lets you assign passwords to users when granting them system privileges and roles. You must specify an equal number of users and passwords. The first password is assigned to the first user, the second password is assigned to the second user, and so on. If a specified user exists, then the database resets the user’s password. If a specified user does not exist, then the database creates the user with the password.

### See Also:

- CREATE USER for restrictions on usernames and passwords and "Assigning User Passwords When Granting a System Privilege: Example"

### WITH ADMIN OPTION

Specify **WITH ADMIN OPTION** to enable the grantee to:

- Grant the privilege or role to another user or role, unless the role is a **GLOBAL** role
- Revoke the privilege or role from another user or role
- Alter the privilege or role to change the authorization needed to access it
• Drop the privilege or role
• Grant the role to a program unit in the grantee’s schema.
• Revoke the role from a program unit in the grantee’s schema.

If you grant a system privilege or role to a user without specifying WITH ADMIN OPTION, and then subsequently grant the privilege or role to the user WITH ADMIN OPTION, then the user has the ADMIN OPTION on the privilege or role.

To revoke the ADMIN OPTION on a system privilege or role from a user, you must revoke the privilege or role from the user altogether and then grant the privilege or role to the user without the ADMIN OPTION.

See Also:
"Granting a Role with the ADMIN OPTION: Example"

WITH DELEGATE OPTION

You can specify this clause only when granting a role to a user.

Specify WITH DELEGATE OPTION to enable the grantee to:
• Grant the role to a program unit in the grantee’s schema
• Revoke the role from a program unit in the grantee’s schema

If you grant a role to a user without specifying WITH DELEGATE OPTION, and then subsequently grant the role to the user WITH DELEGATE OPTION, then the user has the DELEGATE OPTION on the role.

To revoke the DELEGATE OPTION on a role from a user, you must revoke the role from the user altogether and then grant the role to the user without the DELEGATE OPTION.

See Also:
• "Granting a Role with the DELEGATE OPTION: Example"
• The grant_roles_to_programs clause for more information on granting roles to program units

Restrictions on Granting System Privileges and Roles

Privileges and roles are subject to the following restrictions:
• A privilege or role cannot appear more than once in the list of privileges and roles to be granted.
• You cannot grant a role to itself.
• You cannot grant a role IDENTIFIED GLOBALLY to anything.
• You cannot grant a role IDENTIFIED EXTERNALLY to a global user or global role.
You cannot grant roles circularly. For example, if you grant the role banker to the role teller, then you cannot subsequently grant teller to banker.

You cannot grant an IDENTIFIED BY role, IDENTIFIED USING role, or IDENTIFIED EXTERNALLY role to another role.

grant_object_privileges

Use these clauses to grant object privileges.

object_privilege

Specify the object privilege you want to grant. Table 18-2 lists the object privileges, organized by the type of object on which they can be granted. When you grant an object privilege on a editionable object, either to a user or to a role, the object is actualized in the edition in which the grant is made. Refer to CREATE EDITION for information on editionable object types and editions.

Note:

To grant SELECT on a view to another user, either you must own all of the objects underlying the view or you must have been granted the SELECT object privilege WITH GRANT OPTION on all of those underlying objects. This is true even if the grantee already has SELECT privileges on those underlying objects.

To grant READ on a view to another user, either you must own all of the objects underlying the view or you must have been granted the READ or SELECT object privilege WITH GRANT OPTION on all of those underlying objects. This is true even if the grantee already has the READ or SELECT privilege on those underlying objects.

Restriction on Object Privileges

A privilege cannot appear more than once in the list of privileges to be granted.

ALL [PRIVILEGES]

Specify ALL to grant all the privileges for the object that you have been granted with the GRANT OPTION. The user who owns the schema containing an object automatically has all privileges on the object with the GRANT OPTION. The keyword PRIVILEGES is provided for semantic clarity and is optional.

column

Specify the table or view column on which privileges are to be granted. You can specify columns only when granting the INSERT, REFERENCES, or UPDATE privilege. If you do not list columns, then the grantee has the specified privilege on all columns in the table or view.

For information on existing column object grants, query the USER_, ALL_, or DBA_COL_PRIVS data dictionary view.
See Also:

Oracle Database Reference for information on the data dictionary views and “Granting Multiple Object Privileges on Individual Columns: Example”

**on_object_clause**

The on_object_clause identifies the object on which the privileges are granted. Users, directory objects, editions, data mining models, Java source and resource schema objects, and SQL translation profiles are identified separately because they reside in separate namespaces.

See Also:

"Granting Object Privileges to a Role: Example"

**object**

Specify the schema object on which the privileges are to be granted. If you do not qualify object with schema, then the database assumes the object is in your own schema. The object can be one of the following types:

- Table, view, or materialized view
- Sequence
- Procedure, function, or package
- User-defined type
- Synonym for any of the preceding items
- Directory, library, operator, or indextype
- Java source, class, or resource

You cannot grant privileges directly to a single partition of a partitioned table.

See Also:

"Granting Object Privileges on a Table to a User: Example", "Granting Object Privileges on a View: Example", and "Granting Object Privileges to a Sequence in Another Schema: Example"

**ON USER**

Specify one or more database users on whom privileges are to be granted.

Restriction on Granting Privileges on Users

You cannot grant privileges on user PUBLIC.
ON DIRECTORY
Specify the name of the directory object on which privileges are to be granted. You cannot qualify directory_name with a schema name.

See Also:
"Granting an Object Privilege on a User: Example"

ON EDITION
Specify the name of the edition on which the USE object privilege is to be granted. You cannot qualify edition_name with a schema name.

ON MINING MODEL
Specify the name of the mining model on which privileges are to be granted. If you do not qualify mining_model_name with schema, then the database assumes that the mining model is in your own schema.

ON JAVA SOURCE | RESOURCE
Specify the name of the Java source or resource schema object on which privileges are to be granted. If you do not qualify object with schema, then the database assumes that the object is in your own schema.

See Also:
CREATE JAVA

ON SQL TRANSLATION PROFILE
Specify the name of the SQL translation profile on which privileges are to be granted. If you do not qualify profile with schema, then the database assumes that the profile is in your own schema.

WITH HIERARCHY OPTION
Specify WITH HIERARCHY OPTION to grant the specified object privilege on all subobjects of object, such as subviews created under a view, including subobjects created subsequent to this statement.

This clause is meaningful only in combination with the READ or SELECT object privilege.

WITH GRANT OPTION
Specify `WITH GRANT OPTION` to enable the grantee to grant the object privileges to other users and roles.

If you grant an object privilege to a user without specifying `WITH GRANT OPTION`, and then subsequently grant the privilege to the user `WITH GRANT OPTION`, then the user has the `GRANT OPTION` on the privilege.

To revoke the `GRANT OPTION` on an object privilege from a user, you must revoke the privilege from the user altogether and then grant the privilege to the user without the `GRANT OPTION`.

**Restriction on Granting WITH GRANT OPTION**

You can specify `WITH GRANT OPTION` only when granting to a user or to `PUBLIC`, not when granting to a role.

`grant_roles_to_programs`

Use this clause to grant roles to program units. Such roles are called code based access control (CBAC) roles.

`role`

Specify the role you want to grant. You can grant an Oracle Database predefined role or a user-defined role. The role must have been created by or directly granted to the schema owner of the program unit.

`program_unit`

Specify the program unit to which the role is to be granted. You can specify a PL/SQL function, procedure, or package. If you do not specify `schema`, then Oracle Database assumes the function, procedure, or package is in your own schema.

---

### CONTAINER Clause

If the current container is a pluggable database (PDB):

- Specify `CONTAINER = CURRENT` to locally grant a system privilege, object privilege, or role to a user or role. The privilege or role is granted to the user or role only in the current PDB.

If the current container is the root:

- Specify `CONTAINER = CURRENT` to locally grant a system privilege, object privilege, or role to a common user or common role. The privilege or role is granted to the user or role only in the root.
- Specify `CONTAINER = ALL` to commonly grant a system privilege, object privilege on a common object, or role, to a common user or common role.

If you omit this clause, then `CONTAINER = CURRENT` is the default.
Note:
If you specify the CONTAINER clause when granting a privilege or role, then the current container must be the same container and you must specify the same CONTAINER clause when you revoke the privilege or role. Refer to the CONTAINER Clause of the REVOKE statement for more information.

Listings of System and Object Privileges

Table 18-1 System Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>System Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advisor Framework Privileges: All of the advisor framework privileges are part of the DBA role.</td>

</table>

**OLAP CUBES:**

The following privileges are valid when you are using Oracle Database with the OLAP option.

| CREATE CUBE          | Create OLAP cubes in the grantee’s schema.                                                                                                               |
| CREATE ANY CUBE      | Create OLAP cubes in any schema except SYS, AUDSYS.                                                                                                      |
| ALTER ANY CUBE       | Alter OLAP cubes in any schema except SYS, AUDSYS.                                                                                                       |
| DROP ANY CUBE        | Drop OLAP cubes in any schema except SYS, AUDSYS.                                                                                                       |
| SELECT ANY CUBE      | Query or view OLAP cubes in any schema except SYS, AUDSYS.                                                                                               |
| UPDATE ANY CUBE      | Update OLAP cubes in any schema except SYS, AUDSYS.                                                                                                      |

**OLAP CUBE MEASURE FOLDERS:**

The following privileges are valid when you are using Oracle Database with the OLAP option.

| CREATE MEASURE FOLDER | Create OLAP measure folders in the grantee’s schema.                                                                                                   |
| CREATE ANY MEASURE FOLDER | Create OLAP measure folders in any schema except SYS, AUDSYS.                                                                                     |
| DELETE ANY MEASURE FOLDER | Delete a measure from an OLAP measure folder in any schema except SYS, AUDSYS.                                                                        |
| DROP ANY MEASURE FOLDER | Drop OLAP measure folders in any schema except SYS, AUDSYS.                                                                                         |
| INSERT ANY MEASURE FOLDER | Insert a measure into an OLAP measure folder in any schema except SYS, AUDSYS.                                                                       |

**OLAP CUBE DIMENSIONS:**

The following privileges are valid when you are using Oracle Database with the OLAP option.

<p>| CREATE CUBE DIMENSION    | Create OLAP cube dimension in the grantee’s schema.                                                                                                    |
| CREATE ANY CUBE DIMENSION | Create OLAP cube dimensions in any schema except SYS, AUDSYS.                                                                                         |
| ALTER ANY CUBE DIMENSION | Alter OLAP cube dimensions in any schema except SYS, AUDSYS.                                                                                           |
| DELETE ANY CUBE DIMENSION | Delete from OLAP cube dimensions in any schema except SYS, AUDSYS.                                                                                   |</p>

### Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>System Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXECUTE ANY TYPE</td>
<td>Use and reference object types and collection types in any schema except SYS, AUDSYS, and invoke methods of an object type in any schema, except SYS, AUDSYS, if you make the grant to a specific user. If you grant EXECUTE ANY TYPE to a role, then users holding the enabled role will not be able to invoke methods of an object type in any schema.</td>
</tr>
<tr>
<td>UNDER ANY TYPE</td>
<td>Create subtypes under any nonfinal object types.</td>
</tr>
<tr>
<td>USERS:</td>
<td></td>
</tr>
<tr>
<td>CREATE USER</td>
<td>Create users. This privilege also allows the creator to:</td>
</tr>
<tr>
<td></td>
<td>• Assign quotas on any tablespace.</td>
</tr>
<tr>
<td></td>
<td>• Set default and temporary tablespaces.</td>
</tr>
<tr>
<td></td>
<td>• Assign a profile as part of a CREATE USER statement.</td>
</tr>
<tr>
<td>ALTER USER</td>
<td>Alter any user except SYS. This privilege authorizes the grantee to:</td>
</tr>
<tr>
<td></td>
<td>• Change another user’s password or authentication method.</td>
</tr>
<tr>
<td></td>
<td>• Assign quotas on any tablespace.</td>
</tr>
<tr>
<td></td>
<td>• Set default and temporary tablespaces.</td>
</tr>
<tr>
<td></td>
<td>• Assign a profile and default roles.</td>

<tr>
<td>VIEWS:</td>
<td></td>
</tr>
<tr>
<td>CREATE VIEW</td>
<td>Create views in the grantee’s schema.</td>
</tr>
<tr>
<td>CREATE ANY VIEW</td>
<td>Create views in any schema except SYS, AUDSYS.</td>
</tr>
<tr>
<td>DROP ANY VIEW</td>
<td>Drop views in any schema except SYS, AUDSYS.</td>
</tr>
<tr>
<td>UNDER ANY VIEW</td>
<td>Create subviews under any object views.</td>
</tr>
<tr>
<td>FLASHBACK ANY TABLE</td>
<td>Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.</td>
</tr>
<tr>
<td>MERGE ANY VIEW</td>
<td>If a user has been granted the MERGE ANY VIEW privilege, then for any query issued by that user, the optimizer can use view merging to improve query performance without performing the checks that would otherwise be performed to ensure that view merging does not violate any security intentions of the view creator. See also Oracle Database Reference for information on the OPTIMIZER_SECURE_VIEW_MERGING parameter and Oracle Database SQL Tuning Guide for information on view merging.</td>
</tr>
<tr>
<td>MISCELLANEOUS:</td>
<td></td>
</tr>
<tr>
<td>ANALYZE ANY</td>
<td>Analyze a table, cluster, or index in any schema except SYS.</td>
</tr>
<tr>
<td>AUDIT ANY</td>
<td>Audit an object in any schema, except SYS, AUDSYS, using AUDIT schema_objects statements.</td>
</tr>
<tr>
<td>System Privilege Name</td>
<td>Operations Authorized</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>BECOME USER</td>
<td>Allow users of the Data Pump Import utility (impdp) and the original Import utility (imp) to assume the identity of another user in order to perform operations that cannot be directly performed by a third party (for example, loading objects such as object privilege grants). Allow Streams administrators to create or alter capture users and apply users in a Streams environment. By default this privilege is part of the DBA role. Database Vault removes this privileges from the DBA role. Therefore, this privilege is needed by Streams only in an environment where Database Vault is installed.</td>
</tr>
<tr>
<td>CHANGE NOTIFICATION</td>
<td>Create a registration on queries and receive database change notifications in response to DML or DDL changes to the objects associated with the registered queries. Refer to Oracle Database Development Guide for more information on database change notification.</td>
</tr>
<tr>
<td>COMMENT ANY TABLE</td>
<td>Comment on a table, view, or column in any schema except SYS, AUDSYS.</td>
</tr>
<tr>
<td>EXEMPT ACCESS POLICY</td>
<td>Bypass fine-grained access control. <strong>Caution:</strong> This is a very powerful system privilege, as it lets the grantee bypass application-driven security policies. Database administrators should use caution when granting this privilege.</td>
</tr>
<tr>
<td>FORCE ANY TRANSACTION</td>
<td>Force the commit or rollback of any in-doubt distributed transaction in the local database. Induce the failure of a distributed transaction.</td>
</tr>
<tr>
<td>FORCE TRANSACTION</td>
<td>Force the commit or rollback of the grantee's in-doubt distributed transactions in the local database.</td>
</tr>
<tr>
<td>GRANT ANY OBJECT PRIVILEGE</td>
<td>Grant any object privilege that the object owner is permitted to grant. Revoke any object privilege that was granted by the object owner or by some other user with the GRANT ANY OBJECT PRIVILEGE privilege.</td>
</tr>
<tr>
<td>GRANT ANY PRIVILEGE</td>
<td>Grant any system privilege.</td>
</tr>
<tr>
<td>INHERIT ANY PRIVILEGES</td>
<td>Execute invoker's rights procedures owned by the grantee with the privileges of the invoker.</td>
</tr>
<tr>
<td>KEEP DATE TIME</td>
<td>The SYSDATE and SYSTIMESTAMP functions return their original values during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency after recoverable errors. <strong>Note:</strong> If this privilege is granted or revoked between runtime and failover of a request, then the original values are not returned during replay for Application Continuity for that request.</td>
</tr>
<tr>
<td>KEEP SYSGUID</td>
<td>The SYSGUID function returns its original value during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency after recoverable errors. <strong>Note:</strong> If this privilege is granted or revoked between runtime and failover of a request, then the original value is not returned during replay for Application Continuity for that request.</td>

<tr>
<td></td>
<td>Includes the ALTER DATABASE, ALTER SESSION, ALTER SYSTEM, CREATE SESSION, and SELECT ANY DICTIONARY privileges.</td>
</tr>
</tbody>
</table>
Table 18-1  (Cont.) System Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>System Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
</table>
| SYSKM                 | Perform the following encryption key management operations:  
                        Connect to the database even if the database is not open.  
                        SELECT on the following views when the database  
                        is open: V$CLIENT_SECRETS, V$ENCRYPTED_TABLESPACES,  
                        V$ENCRYPTION_KEYS, V$ENCRYPTION_WALLET and V$WALLET.  
                        Includes the ADMINISTER KEY MANAGEMENT and CREATE SESSION  
                        privileges. |
| SYSOPER               | STARTUP and SHUTDOWN operations.  
                        ALTER DATABASE: open, mount, or back up.  
                        ARCHIVELOG and RECOVERY.  
                        CREATE SPFILE.  
                        Includes the RESTRICTED SESSION privilege. |

Table 18-2  Object Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>Object Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANALYTIC VIEW PRIVILEGES</td>
<td>The following analytic view privileges authorize operations on analytic views.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Rename the analytic view.</td>
</tr>
<tr>
<td>READ</td>
<td>Query the object with the SELECT statement.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Query the object with the SELECT statement.</td>
</tr>
<tr>
<td>ATTRIBUTE DIMENSION PRIVILEGES</td>
<td>The following attribute dimension privileges authorize operations on attribute dimensions.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Rename the attribute dimension.</td>
</tr>
<tr>
<td>DIRECTORY PRIVILEGES</td>
<td>The following directory privileges provide secured access to the files stored in the operating system directory to which the directory object serves as a pointer. The directory object contains the full path name of the operating system directory where the files reside. Because the files are actually stored outside the database, Oracle Database server processes also need to have appropriate file permissions on the file system server. Granting object privileges on the directory database object to individual database users, rather than on the operating system, allows the database to enforce security during file operations.</td>
</tr>
<tr>
<td>READ</td>
<td>Read files in the directory.</td>
</tr>
</tbody>
</table>
| WRITE                        | Write files in the directory. This privilege is useful only in connection with external tables. It allows the grantee to determine whether the external table agent can write a log file or a bad file to the directory.  
Restriction: This privilege does not allow the grantee to write to a BFILE. |
<p>| EXECUTE                      | Execute a preprocessor program that resides in the directory. A preprocessor program converts data to a supported format when loading data records from an external table with the ORACLE_LOADER access driver. Refer to Oracle Database Utilities for more information. This privilege does not implicitly allow READ access on the external table data. |
| EDITION PRIVILEGE            | The following edition privilege authorizes the use of an edition. |
| USE                          | Use an edition. |</p>
<table>

Table 18-2  (Cont.) Object Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>Object Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>OLAP PRIVILEGES</strong></td>
<td>The following object privileges are valid if you are using Oracle Database with the OLAP option.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Insert members into the OLAP cube dimension or measures into the measures folder.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Change the definition of the OLAP cube dimension or cube.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Delete members from the OLAP cube dimension or measures from the measures folder.</td>
</tr>
<tr>
<td>SELECT</td>
<td>View or query the OLAP cube or cube dimension.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Update measure values of the OLAP cube or attribute values of the cube dimension.</td>
</tr>
<tr>
<td><strong>OPERATOR PRIVILEGE</strong></td>
<td>The following <strong>operator privilege</strong> authorizes operations on user-defined operators.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Reference an operator.</td>
</tr>
<tr>
<td><strong>PROCEDURE, FUNCTION, PACKAGE PRIVILEGES</strong></td>
<td>The following <strong>procedure, function, and package privileges</strong> authorize operations on procedures, functions, and packages. These privileges also apply to <strong>Java sources, classes, and resources</strong>, which Oracle Database treats as though they were procedures for purposes of granting object privileges.</td>
</tr>
<tr>
<td>DEBUG</td>
<td>Access, through a debugger, all public and nonpublic variables, methods, and types defined on the object. Place a breakpoint or stop at a line or instruction boundary within the procedure, function, or package. This privilege grants access to the declarations in the method or package specification and body.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Execute the procedure or function directly, or access any program object declared in the specification of a package, or compile the object implicitly during a call to a currently invalid or uncompiled function or procedure. This privilege does not allow the grantee to explicitly compile using <strong>ALTER PROCEDURE</strong> or <strong>ALTER FUNCTION</strong>. For explicit compilation you need the appropriate <strong>ALTER system privilege</strong>. Access, through a debugger, public variables, types, and methods defined on the procedure, function, or package. This privilege grants access to the declarations in the method or package specification only. Job scheduler objects are created using the <strong>DBMS_SCHEDULER</strong> package. After these objects are created, you can grant the <strong>EXECUTE</strong> object privilege on job scheduler classes and programs. You can also grant <strong>ALTER</strong> privilege on job scheduler jobs, programs, and schedules. <strong>Note:</strong> Users do not need this privilege to execute a procedure, function, or package indirectly.</td>
</tr>
<tr>
<td><strong>SCHEDULER PRIVILEGES</strong></td>
<td>Job scheduler objects are created using the <strong>DBMS_SCHEDULER</strong> package. After these objects are created, you can grant the following privileges.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Operations on job classes, programs, chains, and credentials.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Modifications to jobs, programs, chains, credentials, and schedules.</td>
</tr>
<tr>
<td>USE</td>
<td>Associate the specified scheduler resource object with programs and jobs.</td>
</tr>
<tr>
<td><strong>SEQUENCE PRIVILEGES</strong></td>
<td>The following <strong>sequence privileges</strong> authorize operations on a sequence.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Change the sequence definition with the <strong>ALTER SEQUENCE</strong> statement.</td>
</tr>
</tbody>
</table>
### Table 18-2  (Cont.) Object Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>Object Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEEP SEQUENCE</td>
<td>The sequence pseudocolumn NEXTVAL retains its original value during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency when replaying after recoverable errors. If this privilege is granted or revoked between runtime and failover of a request, then the original value of NEXTVAL is not retained during replay for Application Continuity for that request. <strong>Note:</strong> This privilege is not granted by the GRANT ALL PRIVILEGES ON sequence statement. You must explicitly grant this privilege. <strong>Note:</strong> This privilege is part of the DBA role.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Examine and increment values of the sequence with the CURRVAL and NEXTVAL pseudocolumns.</td>
</tr>
<tr>
<td>SQL TRANSLATION PROFILE</td>
<td>The following <strong>SQL translation profile privileges</strong> authorize operations on a SQL translation profile.</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td></td>

<tr>
<td>ALTER</td>
<td>Alter the translator, custom SQL statement translations, or custom error translations of a SQL translation profile.</td>
</tr>
<tr>
<td>USE</td>
<td>Use a SQL translation profile.</td>
</tr>
<tr>
<td>SYNONYM PRIVILEGES</td>
<td>Synonym privileges are the same as the privileges for the target object. Granting a privilege on a synonym is equivalent to granting the privilege on the base object. Similarly, granting a privilege on a base object is equivalent to granting the privilege on all synonyms for the object. If you grant to a user a privilege on a synonym, then the user can use either the synonym name or the base object name in the SQL statement that exercises the privilege.</td>
</tr>
<tr>
<td>TABLE PRIVILEGES</td>
<td>The following <strong>table privileges</strong> authorize operations on a table. Any one of the following object privileges, except the READ privilege, allows the grantee to lock the table in any lock mode with the LOCK TABLE statement. <strong>Note:</strong> For external tables, the only valid object privileges are ALTER, READ, and SELECT.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Change the table definition with the ALTER TABLE statement.</td>
</tr>
<tr>
<td>DEBUG</td>
<td>Access, through a debugger:</td>
</tr>
<tr>
<td></td>
<td>• PL/SQL code in the body of any triggers defined on the table</td>
</tr>
<tr>
<td></td>
<td>• Information on SQL statements that reference the table directly</td>
</tr>
<tr>
<td>DELETE</td>
<td>Remove rows from the table with the DELETE statement.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> You must grant the SELECT privilege on the table along with the DELETE privilege if the table is on a remote database.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Create an index on the table with the CREATE INDEX statement.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Add new rows to the table with the INSERT statement.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> You must grant the SELECT privilege on the table along with the INSERT privilege if the table is on a remote database.</td>
</tr>
<tr>
<td>READ</td>
<td>Query the table with the SELECT statement. Does not allow SELECT ... FOR UPDATE.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>Create a constraint that refers to the table. You cannot grant this privilege to a role.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Query the table with the SELECT statement, including SELECT ... FOR UPDATE.</td>
</tr>
</tbody>
</table>
### Table 18-2  (Cont.) Object Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>Object Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPDATE</td>
<td>Change data in the table with the <code>UPDATE</code> statement.</td>
</tr>
<tr>
<td><strong>Note:</strong> You must grant the <code>SELECT</code> privilege on the table along with the <code>UPDATE</code> privilege if the table is on a remote database.</td>
<td></td>
</tr>
<tr>
<td>USER PRIVILEGES</td>
<td>The following privileges authorize operations on a user.</td>
</tr>
<tr>
<td>INHERIT PRIVILEGES</td>
<td>Execute invoker’s rights procedures or functions owned by the grantee with the privileges of the invoker when the invoker is the user on whom this privilege is granted.</td>
</tr>
<tr>
<td>INHERIT REMOTE PRIVILEGES</td>
<td>Allow the user on whom this privilege is granted to execute definer's rights procedures or functions that contain current user database links and are owned by the grantee.</td>
</tr>
<tr>
<td>TRANSLATE SQL</td>
<td>Translate SQL through the grantee’s SQL translation profile for the user on whom this privilege is granted.</td>
</tr>
<tr>
<td>VIEW PRIVILEGES</td>
<td>The following <strong>view privileges</strong> authorize operations on a view. Any one of the following object privileges, except the <code>READ</code> privilege, allows the grantee to lock the view in any lock mode with the <code>LOCK TABLE</code> statement. To grant a privilege on a view, you must have that privilege with the <code>GRANT OPTION</code> on all of the base tables of the view.</td>
</tr>
<tr>
<td>DEBUG</td>
<td>Access, through a debugger:</td>
</tr>
<tr>
<td></td>
<td>• PL/SQL code in the body of any triggers defined on the view</td>
</tr>
<tr>
<td></td>
<td>• Information on SQL statements that reference the view directly</td>
</tr>
<tr>
<td>DELETE</td>
<td>Remove rows from the view with the <code>DELETE</code> statement.</td>

<td>INSERT</td>
<td>Add new rows to the view with the <code>INSERT</code> statement.</td>
</tr>
<tr>
<td>MERGE VIEW</td>
<td>This object privilege has the same behavior as the system privilege <code>MERGE ANY VIEW</code>, except that the privilege is limited to the views specified in the <code>ON</code> clause. For any query issued by the grantee on the specified views, the optimizer can use view merging to improve query performance without performing the checks that would otherwise be performed to ensure that view merging does not violate any security intentions of the view creator.</td>
</tr>
<tr>
<td>READ</td>
<td>Query the view with the <code>SELECT</code> statement. Does not allow <code>SELECT ... FOR UPDATE</code>.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>Define foreign key constraints on the view.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Query the view with the <code>SELECT</code> statement, including <code>SELECT ... FOR UPDATE</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>See Also:</strong> <a href="#">object_privilege</a> for additional information on granting this object privilege on a view</td>
</tr>
<tr>
<td>UNDER</td>
<td>Create a subview under this view. You can grant this object privilege only if you have the <code>UNDER ANY VIEW</code> privilege with <code>GRANT OPTION</code> on the immediate superview of this view.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Change data in the view with the <code>UPDATE</code> statement.</td>
</tr>
</tbody>
</table>

**Examples**

**Granting a System Privilege to a User: Example**

To grant the `CREATE SESSION` system privilege to the sample user `hr`, allowing `hr` to log on to Oracle Database, issue the following statement:
GRANT CREATE SESSION
    TO hr;

Assigning User Passwords When Granting a System Privilege: Example

Assume that user hr exists and user newuser does not exist. The following statement resets the user hr password to password1, creates user newuser with password2, and grants both users the CREATE SESSION system privilege:

GRANT CREATE SESSION
    TO hr, newuser IDENTIFIED BY password1, password2;

Granting System Privileges to a Role: Example

The following statement grants appropriate system privileges to a data warehouse manager role, which was created in the "Creating a Role: Example":

GRANT
    CREATE ANY MATERIALIZED VIEW,
    ALTER ANY MATERIALIZED VIEW,
    DROP ANY MATERIALIZED VIEW,
    QUERY REWRITE,
    GLOBAL QUERY REWRITE
    TO dw_manager
    WITH ADMIN OPTION;

The dw_manager privilege domain now contains the system privileges related to materialized views.

Granting a Role with the ADMIN OPTION: Example

To grant the dw_manager role with the ADMIN OPTION to the sample user sh, issue the following statement:

GRANT dw_manager
    TO sh
    WITH ADMIN OPTION;

User sh can now perform the following operations with the dw_manager role:

- Enable the role and exercise any privileges in the privilege domain of the role, including the CREATE MATERIALIZED VIEW system privilege
- Grant and revoke the role to and from other users
- Drop the role
- Grant and revoke the dw_manager role to and from program units in the sh schema

Granting a Role with the DELEGATE OPTION: Example

To grant the dw_manager role with the DELEGATE OPTION to the sample user sh, issue the following statement:

GRANT dw_manager
    TO sh
    WITH DELEGATE OPTION;

User sh can now grant and revoke the dw_manager role to and from program units in the sh schema.

Granting Object Privileges to a Role: Example
The following example grants the SELECT object privileges to a data warehouse user role, which was created in the "Creating a Role: Example":

GRANT SELECT ON sh.sales TO warehouse_user;

**Granting a Role to a Role: Example**

The following statement grants the warehouse_user role to the dw_manager role. Both roles were created in the "Creating a Role: Example":

GRANT warehouse_user TO dw_manager;

The dw_manager role now contains all of the privileges in the domain of the warehouse_user role.

**Granting an Object Privilege on a User: Example**

To grant the INHERIT PRIVILEGES object privilege on user sh to user hr, issue the following statement:

GRANT INHERIT PRIVILEGES ON USER sh TO hr;

**Granting an Object Privilege on a Directory: Example**

To grant READ on directory bfile_dir to user hr, with the GRANT OPTION, issue the following statement:

GRANT READ ON DIRECTORY bfile_dir TO hr
   WITH GRANT OPTION;

**Granting Object Privileges on a Table to a User: Example**

To grant all privileges on the table oe.bonuses, which was created in "Merging into a Table: Example", to the user hr with the GRANT OPTION, issue the following statement:

GRANT ALL ON bonuses TO hr
   WITH GRANT OPTION;

The user hr can subsequently perform the following operations:

- Exercise any privilege on the bonuses table
- Grant any privilege on the bonuses table to another user or role

**Granting Object Privileges on a View: Example**

To grant SELECT and UPDATE privileges on the view emp_view, which was created in "Creating a View: Example", to all users, issue the following statement:

GRANT SELECT, UPDATE
   ON emp_view TO PUBLIC;

All users can subsequently query and update the view of employee details.

**Granting Object Privileges to a Sequence in Another Schema: Example**

To grant SELECT privilege on the customers_seq sequence in the schema oe to the user hr, issue the following statement:

GRANT SELECT
   ON oe.customers_seq TO hr;
The user `hr` can subsequently generate the next value of the sequence with the following statement:

```sql
SELECT oe.customers_seq.NEXTVAL
FROM DUAL;
```

### Granting Multiple Object Privileges on Individual Columns: Example

To grant to user `oe` the `REFERENCES` privilege on the `employee_id` column and the `UPDATE` privilege on the `employee_id`, `salary`, and `commission_pct` columns of the `employees` table in the schema `hr`, issue the following statement:

```sql
GRANT REFERENCES (employee_id),
   UPDATE (employee_id, salary, commission_pct)
ON hr.employees
TO oe;
```

The user `oe` can subsequently update values of the `employee_id`, `salary`, and `commission_pct` columns. User `oe` can also define referential integrity constraints that refer to the `employee_id` column. However, because the `GRANT` statement lists only these columns, `oe` cannot perform operations on any of the other columns of the `employees` table.

For example, `oe` can create a table with a constraint:

```sql
CREATE TABLE dependent
  (dependno   NUMBER,
   dependname VARCHAR2(10),
   employee   NUMBER
  CONSTRAINT in_emp REFERENCES hr.employees(employee_id) );
```

The constraint `in_emp` ensures that all dependents in the `dependent` table correspond to an employee in the `employees` table in the schema `hr`.

### INSERT

#### Purpose

Use the `INSERT` statement to add rows to a table, the base table of a view, a partition of a partitioned table or a subpartition of a composite-partitioned table, or an object table or the base table of an object view.

#### Prerequisites

For you to insert rows into a table, the table must be in your own schema or you must have the `INSERT` object privilege on the table.

For you to insert rows into the base table of a view, the owner of the schema containing the view must have the `INSERT` object privilege on the base table. Also, if the view is in a schema other than your own, then you must have the `INSERT` object privilege on the view.

If you have the `INSERT ANY TABLE` system privilege, then you can also insert rows into any table or the base table of any view.

You must also have the `READ` or `SELECT` object privilege on the table into which you want to insert rows if the table is on a remote database.
Conventional and Direct-Path INSERT

You can use the INSERT statement to insert data into a table, partition, or view in two ways: conventional INSERT and direct-path INSERT. When you issue a conventional INSERT statement, Oracle Database reuses free space in the table into which you are inserting and maintains referential integrity constraints. With direct-path INSERT, the database appends the inserted data after existing data in the table. Data is written directly into data files, bypassing the buffer cache. Free space in the existing data is not reused. This alternative enhances performance during insert operations and is similar to the functionality of the Oracle direct-path loader utility, SQL*Loader. When you insert into a table that has been created in parallel mode, direct-path INSERT is the default.

The manner in which the database generates redo and undo data depends in part on whether you are using conventional or direct-path INSERT:

- **Conventional** INSERT always generates maximal redo and undo for changes to both data and metadata, regardless of the logging setting of the table and the archivelog and force logging settings of the database.

- **Direct-path** INSERT generates both redo and undo for metadata changes, because these are needed for operation recovery. For data changes, undo and redo are generated as follows:
  
  - Direct-path INSERT always bypasses undo generation for data changes.
  
  - If the database is not in ARCHIVELOG or FORCE LOGGING mode, then no redo is generated for data changes, regardless of the logging setting of the table.

  - If the database is in ARCHIVELOG mode (but not in FORCE LOGGING mode), then direct-path INSERT generates data redo for LOGGING tables but not for NOLOGGING tables.

  - If the database is in ARCHIVELOG and FORCE LOGGING mode, then direct-path SQL generate data redo for both LOGGING and NOLOGGING tables.

Direct-path INSERT is subject to a number of restrictions. If any of these restrictions is violated, then Oracle Database executes conventional INSERT serially without returning any message, unless otherwise noted:

- You can have multiple direct-path INSERT statements in a single transaction, with or without other DML statements. However, after one DML statement alters a particular table, partition, or index, no other DML statement in the transaction can access that table, partition, or index.

- Queries that access the same table, partition, or index are allowed before the direct-path INSERT statement, but not after it.

- If any serial or parallel statement attempts to access a table that has already been modified by a direct-path INSERT in the same transaction, then the database returns an error and rejects the statement.

- The target table cannot be of a cluster.

- The target table cannot contain object type columns.

- Direct-path INSERT is not supported for an index-organized table (IOT) if it has a mapping table, or if it is reference by a materialized view.

- Direct-path INSERT into a single partition of an index-organized table (IOT), into a partitioned IOT with only one partition, or into an IOT that is not partitioned, will be done serially, even if the IOT was created in parallel mode or you specify...
the APPEND or APPEND_VALUES hint. However, direct-path INSERT operations into a partitioned IOT will honor parallel mode as long as the partition-extended name is not used and the IOT has more than one partition.

- The target table cannot have any triggers or referential integrity constraints defined on it.
- The target table cannot be replicated.
- A transaction containing a direct-path INSERT statement cannot be or become distributed.

You cannot query or modify direct-path inserted data immediately after the insert is complete. If you attempt to do so, an ORA-12838 error is generated. You must first issue a COMMIT statement before attempting to read or modify the newly-inserted data.

Semantics

hint

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

For a multitable insert, if you specify the PARALLEL hint for any target table, then the entire multitable insert statement is parallelized even if the target tables have not been created or altered with PARALLEL specified. If you do not specify the PARALLEL hint, then the insert operation will not be parallelized unless all target tables were created or altered with PARALLEL specified.

See Also:
- "Hints " for the syntax and description of hints
- "Restrictions on Multitable Inserts"

single_table_insert

In a single-table insert, you insert values into one row of a table, view, or materialized view by specifying values explicitly or by retrieving the values through a subquery.

You can use the flashback_query_clause in subquery to insert past data into table. Refer to the flashback_query_clause of SELECT for more information on this clause.

Restriction on Single-table Inserts

If you retrieve values through a subquery, then the select list of the subquery must have the same number of columns as the column list of the INSERT statement. If you omit the column list, then the subquery must provide values for every column in the table.

See Also:
- "Inserting Values into Tables: Examples"
insert_into_clause

Use the **INSERT INTO** clause to specify the target object or objects into which the database is to insert data.

DML_table_expression_clause

Use the **INTO DML_table_expression_clause** to specify the objects into which data is being inserted.

schema

Specify the schema containing the table, view, or materialized view. If you omit **schema**, then the database assumes the object is in your own schema.

table | view | materialized_view | subquery

Specify the name of the table or object table, view or object view, materialized view, or the column or columns returned by a subquery, into which rows are to be inserted. If you specify a view or object view, then the database inserts rows into the base table of the view.

You cannot insert rows into a read-only materialized view. If you insert rows into a writable materialized view, then the database inserts the rows into the underlying container table. However, the insertions are overwritten at the next refresh operation. If you insert rows into an updatable materialized view that is part of a materialized view group, then the database also inserts the corresponding rows into the master table.

If any value to be inserted is a **REF** to an object table, and if the object table has a primary key object identifier, then the column into which you insert the **REF** must be a **REF** column with a referential integrity or **SCOPE** constraint to the object table.

If **table**, or the base table of **view**, contains one or more domain index columns, then this statement executes the appropriate indextype insert routine.

Issuing an **INSERT** statement against a table fires any **INSERT** triggers defined on the table.

See Also:

*Oracle Database Data Cartridge Developer's Guide* for more information on these routines

Restrictions on the DML_table_expression_clause

This clause is subject to the following restrictions:

- You cannot execute this statement if **table** or the base table of **view** contains any domain indexes marked **IN_PROGRESS** or **FAILED**.
- You cannot insert into a partition if any affected index partitions are marked **UNUSABLE**.
- With regard to the **ORDER BY** clause of the **subquery** in the **DML_table_expression_clause**, ordering is guaranteed only for the rows being
inserted, and only within each extent of the table. Ordering of new rows with respect to existing rows is not guaranteed.

- If a view was created using the WITH CHECK OPTION, then you can insert into the view only rows that satisfy the defining query of the view.
- If a view was created using a single base table, then you can insert rows into the view and then retrieve those values using the returning_clause.
- You cannot insert rows into a view except with INSTEAD OF triggers if the defining query of the view contains one of the following constructs:
  - A set operator
  - A DISTINCT operator
  - An aggregate or analytic function
  - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
  - A collection expression in a SELECT list
  - A subquery in a SELECT list
  - A subquery designated WITH READ ONLY
  - Joins, with some exceptions, as documented in Oracle Database Administrator’s Guide

- If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the INSERT statement will fail unless the SKIP_UNUSABLE_INDEXES session parameter has been set to TRUE. Refer to ALTER SESSION for information on the SKIP_UNUSABLE_INDEXES session parameter.

**partition_extension_clause**

Specify the name or partition key value of the partition or subpartition within table, or the base table of view, targeted for inserts.

If a row to be inserted does not map into a specified partition or subpartition, then the database returns an error.

**Restriction on Target Partitions and Subpartitions**

This clause is not valid for object tables or object views.

**See Also:**

"References to Partitioned Tables and Indexes"

**dblink**

Specify a complete or partial name of a database link to a remote database where the table or view is located. You can insert rows into a remote table or view only if you are using Oracle Database distributed functionality.

If you omit dblink, then Oracle Database assumes that the table or view is on the local database.
**Note:**

Starting with Oracle Database 12c Release 2 (12.2), the `INSERT` statement accepts remote LOB locators as bind variables. Refer to the “Distributed LOBs” chapter in *Oracle Database SecureFiles and Large Objects Developer’s Guide* for more information.

**See Also:**

- “Syntax for Schema Objects and Parts in SQL Statements” and “References to Objects in Remote Databases” for information on referring to database links
- “Inserting into a Remote Database: Example”

### `subquery_restriction_clause`

Use the `subquery_restriction_clause` to restrict the subquery in one of the following ways:

**WITH READ ONLY**

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

**WITH CHECK OPTION**

Specify `WITH CHECK OPTION` to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

**CONSTRAINT `constraint`**

Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where `n` is an integer that makes the constraint name unique within the database.

**See Also:**

"Using the WITH CHECK OPTION Clause: Example"

### `table_collection_expression`

The `table_collection_expression` lets you inform Oracle that the value of `collection_expression` should be treated as a table for purposes of query and DML operations. The `collection_expression` can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called `collection unnesting`. 
The optional plus (+) is relevant if you are joining the `TABLE` collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

**Note:**

In earlier releases of Oracle, when `collection_expression` was a subquery, `table_collection_expression` was expressed as `THE subquery`. That usage is now deprecated.

**See Also:**

"Table Collections: Examples"

t_alias
Specify a correlation name, which is an alias for the table, view, materialized view, or subquery to be referenced elsewhere in the statement.

**Restriction on Table Aliases**

You cannot specify `t_alias` during a multitable insert.

column
Specify a column of the table, view, or materialized view. In the inserted row, each column in this list is assigned a value from the `values_clause` or the subquery. If you want to assign a value to an INVISIBLE column, then you must include the column in this list.

If you omit one or more of the table’s columns from this list, then the column value of that column for the inserted row is the column default value as specified when the table was created or last altered. If any omitted column has a NOT NULL constraint and no default value, then the database returns an error indicating that the constraint has been violated and rolls back the `INSERT` statement. Refer to `CREATE TABLE` for more information on default column values.

If you omit the column list altogether, then the `values_clause` or query must specify values for all columns in the table.

values_clause
For a single-table insert operation, specify a row of values to be inserted into the table or view. You must specify a value in the `values_clause` for each column in the column list. If you omit the column list, then the `values_clause` must provide values for every column in the table.

For a multitable insert operation, each expression in the `values_clause` must refer to columns returned by the select list of the subquery. If you omit the `values_clause`, then the select list of the subquery determines the values to be inserted, so it must have the same number of columns as the column list of the corresponding
insert_into_clause. If you do not specify a column list in the insert_into_clause, then the computed row must provide values for all columns in the target table.

For both types of insert operations, if you specify a column list in the insert_into_clause, then the database assigns to each column in the list a corresponding value from the values clause or the subquery. You can specify DEFAULT for any value in the values_clause. If you have specified a default value for the corresponding column of the table or view, then that value is inserted. If no default value for the corresponding column has been specified, then the database inserts null. Refer to “About SQL Expressions” and SELECT for syntax of valid expressions.

Restrictions on Inserted Values

The value are subject to the following restrictions:

- You cannot insert a BFILE value until you have initialized the BFILE locator to null or to a directory name and filename.

  See Also:

  - BFILENAME for information on initializing BFILE values and for an example of inserting into a BFILE
  - Oracle Database SecureFiles and Large Objects Developer's Guide for information on initializing BFILE locators

- When inserting into a list-partitioned table, you cannot insert a value into the partitioning key column that does not already exist in the partition_key_value list of one of the partitions.

- You cannot specify DEFAULT when inserting into a view.

- If you insert string literals into a RAW column, then during subsequent queries Oracle Database will perform a full table scan rather than using any index that might exist on the RAW column.

  See Also:

  - "Using XML in SQL Statements" for information on inserting values into an XMLType table
  - "Inserting into a Substitutable Tables and Columns: Examples", "Inserting Using the TO_LOB Function: Example", "Inserting Sequence Values: Example", and "Inserting Using Bind Variables: Example"

returning_clause

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.
When operating on a single row, a DML statement with a `returning_clause` can retrieve column expressions using the affected row, rowid, and `REFs` to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the `returning_clause` stores values from expressions, rowids, and `REFs` involving the affected rows in bind arrays.

`expr`

Each item in the `expr` list must be a valid expression syntax.

`INTO`

The `INTO` clause indicates that the values of the changed rows are to be stored in the variable(s) specified in `data_item` list.

`data_item`

Each `data_item` is a host variable or PL/SQL variable that stores the retrieved `expr` value.

For each expression in the `RETURNING` list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the `INTO` list.

**Restrictions**

The following restrictions apply to the `RETURNING` clause:

- The `expr` is restricted as follows:
  - For UPDATE and DELETE statements each `expr` must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same `returning_clause`. For INSERT statements, each `expr` must be a simple expression. Aggregate functions are not supported in an INSERT statement `RETURNING` clause.
  - Single-set aggregate function expressions cannot include the `DISTINCT` keyword.
- If the `expr` list contains a primary key column or other `NOT NULL` column, then the update statement fails if the table has a BEFORE UPDATE trigger defined on it.
- You cannot specify the `returning_clause` for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve `LONG` types with this clause.
- You cannot specify this clause for a view on which an `INSTEAD OF` trigger has been defined.

**See Also:**

Oracle Database PL/SQL Language Reference for information on using the `BULK COLLECT` clause to return multiple values to collection variables.
**multi_table_insert**

In a **multitable insert**, you insert computed rows derived from the rows returned from the evaluation of a subquery into one or more tables.

Table aliases are not defined by the select list of the subquery. Therefore, they are not visible in the clauses dependent on the select list. For example, this can happen when trying to refer to an object column in an expression. To use an expression with a table alias, you must put the expression into the select list with a column alias, and then refer to the column alias in the **VALUES** clause or **WHEN** condition of the multitable insert.

**ALL into_clause**

Specify **ALL** followed by multiple **insert_into_clauses** to perform an **unconditional multitable insert**. Oracle Database executes each **insert_into_clause** once for each row returned by the subquery.

**conditional_insert_clause**

Specify the **conditional_insert_clause** to perform a **conditional multitable insert**. Oracle Database filters each **insert_into_clause** through the corresponding **WHEN** condition, which determines whether that **insert_into_clause** is executed. Each expression in the **WHEN** condition must refer to columns returned by the select list of the subquery. A single multitable insert statement can contain up to 127 **WHEN** clauses.

**ALL**

If you specify **ALL**, the default value, then the database evaluates each **WHEN** clause regardless of the results of the evaluation of any other **WHEN** clause. For each **WHEN** clause whose condition evaluates to true, the database executes the corresponding **INTO** clause list.

**FIRST**

If you specify **FIRST**, then the database evaluates each **WHEN** clause in the order in which it appears in the statement. For the first **WHEN** clause that evaluates to true, the database executes the corresponding **INTO** clause and skips subsequent **WHEN** clauses for the given row.

**ELSE clause**

For a given row, if no **WHEN** clause evaluates to true, then:

- If you have specified an **ELSE** clause, then the database executes the **INTO** clause list associated with the **ELSE** clause.
- If you did not specify an else clause, then the database takes no action for that row.

---

**See Also:**

"Multitable Inserts: Examples"

**Restrictions on Multitable Inserts**

Multitable inserts are subject to the following restrictions:
• You can perform multitable inserts only on tables, not on views or materialized views.
• You cannot perform a multitable insert into a remote table.
• You cannot specify a TABLE collection expression when performing a multitable insert.
• Multitable inserts are not parallelized if any target table is index organized or if any target table has a bitmap index defined on it.
• Plan stability is not supported for multitable insert statements.
• You cannot specify a sequence in any part of a multitable insert statement. A multitable insert is considered a single SQL statement. Therefore, the first reference to NEXTVAL generates the next number, and all subsequent references in the statement return the same number.

subquery

Specify a subquery that returns rows that are inserted into the table. The subquery can refer to any table, view, or materialized view, including the target tables of the INSERT statement. If the subquery selects no rows, then the database inserts no rows into the table.

You can use subquery in combination with the TO_LOB function to convert the values in a LONG column to LOB values in another column in the same or another table.

• To migrate LONG values to LOB values in another column in a view, you must perform the migration on the base table and then add the LOB column to the view.
• To migrate LONG values on a remote table to LOB values in a local table, you must perform the migration on the remote table using the TO_LOB function, and then perform an INSERT ... subquery operation to copy the LOB values from the remote table into the local table.

Notes on Inserting with a Subquery

The following notes apply when inserting with a subquery:

• If subquery returns the partial or total equivalent of a materialized view, then the database may use the materialized view for query rewrite in place of one or more tables specified in subquery.

> See Also:

Oracle Database Data Warehousing Guide for more information on materialized views and query rewrite

• If subquery refers to remote objects, then the INSERT operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the subquery in the DML_table_expression_clause refers to any remote objects, then the INSERT operation will run serially without notification. See parallel_clause for more information.
• If subquery includes an ORDER BY clause, then it will override row ordering specified using attribute clustering table properties.

- `BFILENAME` for an example of inserting into a `BFILE`
- Oracle Database SecureFiles and Large Objects Developer’s Guide for information on initializing `BFILES`
- "About SQL Expressions " and SELECT for syntax of valid expressions

**error_logging_clause**

The `error_logging_clause` lets you capture DML errors and the log column values of the affected rows and save them in an error logging table.

**INTO table**

Specify the name of the error logging table. If you omit this clause, then the database assigns the default name generated by the `DBMS_ERRLOG` package. The default error log table name is `ERR$_` followed by the first 25 characters of the name of the table upon which the DML operation is being executed.

**simple_expression**

Specify the value to be used as a statement tag, so that you can identify the errors from this statement in the error logging table. The expression can be either a text literal, a number literal, or a general SQL expression such as a bind variable. You can also use a function expression if you convert it to a text literal — for example, `TO_CHAR(SYSDATE)`.

**REJECT LIMIT**

This clause lets you specify an integer as an upper limit for the number of errors to be logged before the statement terminates and rolls back any changes made by the statement. The default rejection limit is zero. For parallel DML operations, the reject limit is applied to each parallel server.

**Restrictions on DML Error Logging**

- The following conditions cause the statement to fail and roll back without invoking the error logging capability:
  - Violated deferred constraints.
  - Any direct-path `INSERT` or `MERGE` operation that raises a unique constraint or index violation.
  - Any update operation `UPDATE` or `MERGE` that raises a unique constraint or index violation.
- You cannot track errors in the error logging table for `LONG`, `LOB`, or object type columns. However, the table that is the target of the DML operation can contain these types of columns.
  - If you create or modify the corresponding error logging table so that it contains a column of an unsupported type, and if the name of that column corresponds to an unsupported column in the target DML table, then the DML statement fails at parse time.
If the error logging table does not contain any unsupported column types, then all DML errors are logged until the reject limit of errors is reached. For rows on which errors occur, column values with corresponding columns in the error logging table are logged along with the control information.

See Also:

Oracle Database PL/SQL Packages and Types Reference for information on using the create_error_log procedure of the DBMS_ERRLOG package and Oracle Database Administrator's Guide for general information on DML error logging.

"Inserting Into a Table with Error Logging: Example"

Examples

Inserting Values into Tables: Examples

The following statement inserts a row into the sample table departments:

```sql
INSERT INTO departments
  VALUES (280, 'Recreation', 121, 1700);
```

If the departments table had been created with a default value of 121 for the manager_id column, then you could issue the same statement as follows:

```sql
INSERT INTO departments
  VALUES (280, 'Recreation', DEFAULT, 1700);
```

The following statement inserts a row with six columns into the employees table. One of these columns is assigned NULL and another is assigned a number in scientific notation:

```sql
INSERT INTO employees (employee_id, last_name, email, hire_date, job_id, salary, commission_pct)
  VALUES (207, 'Gregory', 'pgregory@example.com', sysdate, 'PU_CLERK', 1.2E3, NULL);
```

The following statement has the same effect as the preceding example, but uses a subquery in the DML_table_expression_clause:

```sql
INSERT INTO
  (SELECT employee_id, last_name, email, hire_date, job_id, salary, commission_pct FROM employees)
  VALUES (207, 'Gregory', 'pgregory@example.com', sysdate, 'PU_CLERK', 1.2E3, NULL);
```

Inserting Values with a Subquery: Example

The following statement copies employees whose commission exceeds 25% of their salary into the bonuses table, which was created in "Merging into a Table: Example":

```sql
INSERT INTO bonuses
  SELECT employee_id, salary*1.1
  FROM employees
  WHERE commission_pct > 0.25;
```
Inserting Into a Table with Error Logging: Example

The following statements create a raises table in the sample schema hr, create an error logging table using the DBMS_ERRLOG package, and populate the raises table with data from the employees table. One of the inserts violates the check constraint on raises, and that row can be seen in errlog. If more than ten errors had occurred, then the statement would have aborted, rolling back any insertions made:

```sql
CREATE TABLE raises (emp_id NUMBER, sal NUMBER
CONSTRAINT check_sal CHECK(sal > 8000));
EXECUTE DBMS_ERRLOG.CREATE_ERROR_LOG('raises', 'errlog');
INSERT INTO raises
SELECT employee_id, salary*1.1 FROM employees
WHERE commission_pct > .2
    LOG ERRORS INTO errlog ('my_bad') REJECT LIMIT 10;
SELECT ORA_ERR_MESG$, ORA_ERR_TAG$, emp_id, sal FROM errlog;
ORA_ERR_MESG$  ORA_ERR_TAG$  EMP_ID  SAL
--------------------------- -------------------- ------ -------
ORA-02290: check constraint my_bad               161    7700
(HR.SYS_C004266) violated
```

Inserting into a Remote Database: Example

The following statement inserts a row into the employees table owned by the user hr on the database accessible by the database link remote:

```sql
INSERT INTO employees@remote
VALUES (8002, 'Juan', 'Fernandez', 'juanf@example.com', NULL,
TO_DATE('04-OCT-1992', 'DD-MON-YYYY'), 'SH_CLERK', 3000,
NULL, 121, 20);
```

Inserting Sequence Values: Example

The following statement inserts a new row containing the next value of the departments_seq sequence into the departments table:

```sql
INSERT INTO departments
VALUES (departments_seq.nextval, 'Entertainment', 162, 1400);
```

Inserting Using Bind Variables: Example

The following example returns the values of the inserted rows into output bind variables :bnd1 and :bnd2. The bind variables must first be declared.

```sql
INSERT INTO employees
(employee_id, last_name, email, hire_date, job_id, salary)
VALUES
(employees_seq.nextval, 'Doe', 'john.doe@example.com',
SYSDATE, 'SH_CLERK', 2400)
RETURNING salary*12, job_id INTO :bnd1, :bnd2;
```

Inserting into a Substitutable Tables and Columns: Examples

The following example inserts into the persons table, which is created in "Substitutable Table and Column Examples". The first statement uses the root type person_t. The second insert uses the employee_t subtype of person_t, and the third insert uses the part_time_emp_t subtype of employee_t:
INSERT INTO persons VALUES (person_t('Bob', 1234));
INSERT INTO persons VALUES (employee_t('Joe', 32456, 12, 100000));
INSERT INTO persons VALUES (part_time_emp_t('Tim', 5678, 13, 1000, 20));

The following example inserts into the books table, which was created in “Substitutable Table and Column Examples”. Notice that specification of the attribute values is identical to that for the substitutable table example:

INSERT INTO books VALUES (    'An Autobiography', person_t('Bob', 1234));
INSERT INTO books VALUES (    'Business Rules', employee_t('Joe', 3456, 12, 10000));
INSERT INTO books VALUES (    'Mixing School and Work',    part_time_emp_t('Tim', 5678, 13, 1000, 20));

You can extract data from substitutable tables and columns using built-in functions and conditions. For examples, see the functions TREAT and SYS_TYPEID , and “IS OF type Condition”.

Inserting Using the TO_LOB Function: Example

The following example copies LONG data to a LOB column in the following long_tab table:

CREATE TABLE long_tab (pic_id NUMBER, long_pics LONG RAW);

First you must create a table with a LOB.

CREATE TABLE lob_tab (pic_id NUMBER, lob_pics BLOB);

Next, use an INSERT ... SELECT statement to copy the data in all rows for the LONG column into the newly created LOB column:

INSERT INTO lob_tab
    SELECT pic_id, TO_LOB(long_pics) FROM long_tab;

When you are confident that the migration has been successful, you can drop the long_pics table. Alternatively, if the table contains other columns, then you can simply drop the LONG column from the table as follows:

ALTER TABLE long_tab DROP COLUMN long_pics;

Multitable Inserts: Examples

The following example uses the multitable insert syntax to insert into the sample table sh.sales some data from an input table with a different structure.

Note:

A number of NOT NULL constraints on the sales table have been disabled for purposes of this example, because the example ignores a number of table columns for the sake of brevity.

The input table looks like this:
The multitable insert statement looks like this:

```sql
INSERT ALL
INTO sales (prod_id, cust_id, time_id, amount)
VALUES (product_id, customer_id, weekly_start_date, sales_sun)
INTO sales (prod_id, cust_id, time_id, amount)
VALUES (product_id, customer_id, weekly_start_date+1, sales_mon)
INTO sales (prod_id, cust_id, time_id, amount)
VALUES (product_id, customer_id, weekly_start_date+2, sales_tue)
INTO sales (prod_id, cust_id, time_id, amount)
VALUES (product_id, customer_id, weekly_start_date+3, sales_wed)
INTO sales (prod_id, cust_id, time_id, amount)
VALUES (product_id, customer_id, weekly_start_date+4, sales_thu)
INTO sales (prod_id, cust_id, time_id, amount)
VALUES (product_id, customer_id, weekly_start_date+5, sales_fri)
INTO sales (prod_id, cust_id, time_id, amount)
VALUES (product_id, customer_id, weekly_start_date+6, sales_sat)
SELECT product_id, customer_id, weekly_start_date, sales_sun,
sales_mon, sales_tue, sales_wed, sales_thu, sales_fri, sales_sat
FROM sales_input_table;
```

Assuming these are the only rows in the `sales` table, the contents now look like this:

```sql
SELECT * FROM sales
ORDER BY prod_id, cust_id, time_id;
```

The next examples insert into multiple tables. Suppose you want to provide to sales representatives some information on orders of various sizes. The following example
creates tables for small, medium, large, and special orders and populates those tables with data from the sample table oe.orders:

```
CREATE TABLE small_orders
(order_id NUMBER(12) NOT NULL,
customer_id NUMBER(6) NOT NULL,
order_total NUMBER(8,2),
sales_rep_id NUMBER(6)
);

CREATE TABLE medium_orders AS SELECT * FROM small_orders;

CREATE TABLE large_orders AS SELECT * FROM small_orders;

CREATE TABLE special_orders
(order_id NUMBER(12) NOT NULL,
customer_id NUMBER(6) NOT NULL,
order_total NUMBER(8,2),
sales_rep_id NUMBER(6),
credit_limit NUMBER(9,2),
cust_email VARCHAR2(40)
);
```

The first multitable insert populates only the tables for small, medium, and large orders:

```
INSERT ALL
WHEN order_total <= 100000 THEN
   INTO small_orders
WHEN order_total > 100000 AND order_total <= 200000 THEN
   INTO medium_orders
WHEN order_total > 200000 THEN
   INTO large_orders
SELECT order_id, order_total, sales_rep_id, customer_id
FROM orders;
```

You can accomplish the same thing using the ELSE clause in place of the insert into the large_orders table:

```
INSERT ALL
WHEN order_total <= 100000 THEN
   INTO small_orders
WHEN order_total > 100000 AND order_total <= 200000 THEN
   INTO medium_orders
ELSE
   INTO large_orders
SELECT order_id, order_total, sales_rep_id, customer_id
FROM orders;
```

The next example inserts into the small, medium, and large tables, as in the preceding example, and also puts orders greater than 290,000 into the special_orders table. This table also shows how to use column aliases to simplify the statement:

```
INSERT ALL
WHEN ottl <= 100000 THEN
   INTO small_orders
WHEN ottl > 100000 AND ottl <= 200000 THEN
   INTO medium_orders
ELSE
   INTO large_orders
SELECT order_id, order_total, sales_rep_id, customer_id
FROM orders;
```
Finally, the next example uses the FIRST clause to put orders greater than 290,000 into the `special_orders` table and exclude those orders from the `large_orders` table:

```
INSERT FIRST
  WHEN ottl <= 100000 THEN
    INTO small_orders
    VALUES(oid, ottl, sid, cid)
  WHEN ottl > 100000 and ottl <= 200000 THEN
    INTO medium_orders
    VALUES(oid, ottl, sid, cid)
  WHEN ottl > 290000 THEN
    INTO special_orders
  WHEN ottl > 200000 THEN
    INTO large_orders
    VALUES(oid, ottl, sid, cid)
SELECT o.order_id oid, o.customer_id cid, o.order_total ottl,
    o.sales_rep_id sid, c.credit_limit cl, c.cust_email cem
FROM orders o, customers c
WHERE o.customer_id = c.customer_id;
```

### Inserting Multiple Rows Using a Single Statement: Example

The following statements create three tables named people, patients, and staff:

```sql
CREATE TABLE people (  
    person_id INTEGER NOT NULL PRIMARY KEY,
    given_name VARCHAR2(100) NOT NULL,
    family_name VARCHAR2(100) NOT NULL,
    title VARCHAR2(20),
    birth_date DATE
);

CREATE TABLE patients (  
    patient_id INTEGER NOT NULL PRIMARY KEY REFERENCES people (person_id),
    last_admission_date DATE
);

CREATE TABLE staff (  
    staff_id INTEGER NOT NULL PRIMARY KEY REFERENCES people (person_id),
    hired_date DATE
);
```

The following statement inserts a row into the `people` table:

```
INSERT INTO people
VALUES (1, 'Dave', 'Badger', 'Mr', date'1960-05-01');
```

The following statement returns an error as there is no value provided for the `birth_date` column:

```
INSERT INTO people
VALUES (2, 'Simon', 'Fox', 'Mr');
```
The following statement inserts a row into the people table:

```sql
INSERT INTO people (person_id, given_name, family_name, title)
VALUES (2, 'Simon', 'Fox', 'Mr');
```

The following statement inserts a row into the people table and the value for the title column is populated by selecting a static value from the dual table:

```sql
INSERT INTO people (person_id, given_name, family_name, title)
VALUES (3, 'Dave', 'Frog', (SELECT 'Mr' FROM dual));
```

The following statement inserts multiple rows into the people table using ‘SELECT’ statement:

```sql
WITH names AS (
  SELECT 4, 'Ruth', 'Fox', 'Mrs' FROM dual UNION ALL
  SELECT 5, 'Isabelle', 'Squirrel', 'Miss' FROM dual UNION ALL
  SELECT 6, 'Justin', 'Frog', 'Master' FROM dual UNION ALL
  SELECT 7, 'Lisa', 'Owl', 'Dr' FROM dual
)
SELECT * FROM names;
```

The following statement rolls back all the previous DML operations:

```sql
ROLLBACK;
```

The following statement inserts multiple rows into the people table using ‘SELECT’ statement with a ‘WHERE’ condition:

```sql
WITH names AS (
  SELECT 4, 'Ruth', 'Fox', 'Mrs' FROM dual UNION ALL
  SELECT 5, 'Isabelle', 'Squirrel', 'Miss' FROM dual UNION ALL
  SELECT 6, 'Justin', 'Frog', 'Master' FROM dual UNION ALL
  SELECT 7, 'Lisa', 'Owl', 'Dr' FROM dual
)
SELECT * FROM names
WHERE family_name LIKE 'F%';
```

The following statement rolls back all the previous DML operations:

```sql
ROLLBACK;
```

The following statement inserts multiple rows into people, patients and staff table using ‘INSERT ALL’ statement:

```sql
INSERT ALL
/* Every one is a person */
INTO people (person_id, given_name, family_name, title)
VALUES (id, given_name, family_name, title)
INTO patients (patient_id, last_admission_date)
VALUES (id, admission_date)
INTO staff (staff_id, hired_date)
VALUES (id, hired_date)
WITH names AS (  
  SELECT 4 id, 'Ruth', 'Fox', 'Mrs' FROM dual UNION ALL
  SELECT 5 id, 'Isabelle', 'Squirrel', 'Miss' FROM dual UNION ALL
  SELECT 5 id, 'Isabelle', 'Squirrel', 'Miss' FROM dual UNION ALL
  SELECT 7 id, 'Lisa', 'Owl', 'Dr' FROM dual
)
SELECT * FROM names
WHERE family_name LIKE 'F%';
```
The following statement inserts multiple rows into people, patients and staff table using 'INSERT ALL' statement with various conditions:

```
INSERT ALL
/* Everyone is a person, so insert all rows into people */
WHEN 1=1 THEN
  INTO people (person_id, given_name, family_name, title)
  VALUES (id, given_name, family_name, title)
/* Only people with an admission date are patients */
WHEN admission_date IS NOT NULL THEN
  INTO patients (patient_id, last_admission_date)
  VALUES (id, admission_date)
/* Only people with a hired date are staff */
WHEN hired_date IS NOT NULL THEN
  INTO staff (staff_id, hired_date)
  VALUES (id, hired_date)
WITH names AS (}
  SELECT 4 id, 'Ruth' given_name, 'Fox' family_name, 'Mrs' title,
  NULL hired_date, DATE'2009-12-31' admission_date
  FROM dual UNION ALL
  SELECT 5 id, 'Isabelle' given_name, 'Squirrel' family_name, 'Miss' title,
  NULL hired_date, DATE'2014-01-01' admission_date
  FROM dual UNION ALL
  SELECT 6 id, 'Justin' given_name, 'Frog' family_name, 'Master' title,
  NULL hired_date, DATE'2015-04-22' admission_date
  FROM dual UNION ALL
  SELECT 7 id, 'Lisa' given_name, 'Owl' family_name, 'Dr' title,
  DATE'2015-01-01' hired_date, NULL admission_date
  FROM dual
}
SELECT * FROM names;
```

### LOCK TABLE

**Purpose**

Use the `LOCK TABLE` statement to lock one or more tables, table partitions, or table subpartitions in a specified mode. This lock manually overrides automatic locking and
permits or denies access to a table or view by other users for the duration of your operation.

Some forms of locks can be placed on the same table at the same time. Other locks allow only one lock for a table.

A locked table remains locked until you either commit your transaction or roll it back, either entirely or to a savepoint before you locked the table.

A lock never prevents other users from querying the table. A query never places a lock on a table. Readers never block writers and writers never block readers.

See Also:

- Oracle Database Concepts for a complete description of the interaction of lock modes
- COMMIT
- ROLLBACK
- SAVEPOINT

Prerequisites

The table or view must be in your own schema, or you must have the LOCK ANY TABLE system privilege, or you must have any object privilege (except the READ object privilege) on the table or view.

Syntax

lock_table::=
partition_extension_clause ::= 

Semantics

schema

Specify the schema containing the table or view. If you omit schema, then Oracle Database assumes the table or view is in your own schema.

table | view

Specify the name of the table or view to be locked.

If you specify view, then Oracle Database locks the base tables of the view.

If you specify the partition_extension_clause, then Oracle Database first acquires an implicit lock on the table. The table lock is the same as the lock you specify for the partition or subpartition, with two exceptions:

- If you specify a SHARE lock for the subpartition, then the database acquires an implicit ROW SHARE lock on the table.
- If you specify an EXCLUSIVE lock for the subpartition, then the database acquires an implicit ROW EXCLUSIVE lock on the table.

If you specify PARTITION and table is composite-partitioned, then the database acquires locks on all the subpartitions of the partition.

Restrictions on Locking Tables

The following restrictions apply to locking tables:

- If view is part of a hierarchy, then it must be the root of the hierarchy.
- You can acquire locks on only the existing partitions in an automatic list-partitioned table. That is, when you specify the following statement, the partition key value must correspond to a partition that already exists in the table; it cannot correspond to a partition that might be created on-demand at a later time:

  ![Diagram](image)

  `LOCK TABLE ... PARTITION FOR (partition_key_value) ...`

  **dblink**

  Specify a database link to a remote Oracle Database where the table or view is located. You can lock tables and views on a remote database only if you are using
Oracle distributed functionality. All tables locked by a `LOCK TABLE` statement must be on the same database.

If you omit `dblink`, then Oracle Database assumes the table or view is on the local database.

---

See Also:

"References to Objects in Remote Databases" for information on specifying database links

---

**lockmode Clause**

Specify one of the following modes:

**ROW SHARE**

`ROW SHARE` permits concurrent access to the locked table but prohibits users from locking the entire table for exclusive access. `ROW SHARE` is synonymous with `SHARE UPDATE`, which is included for compatibility with earlier versions of Oracle Database.

**ROW EXCLUSIVE**

`ROW EXCLUSIVE` is the same as `ROW SHARE`, but it also prohibits locking in `SHARE` mode. `ROW EXCLUSIVE` locks are automatically obtained when updating, inserting, or deleting.

**SHARE UPDATE**

See `ROW SHARE`.

**SHARE**

`SHARE` permits concurrent queries but prohibits updates to the locked table.

**SHARE ROW EXCLUSIVE**

`SHARE ROW EXCLUSIVE` is used to look at a whole table and to allow others to look at rows in the table but to prohibit others from locking the table in `SHARE` mode or from updating rows.

**EXCLUSIVE**

`EXCLUSIVE` permits queries on the locked table but prohibits any other activity on it.

**NOWAIT**

Specify `NOWAIT` if you want the database to return control to you immediately if the specified table, partition, or table subpartition is already locked by another user. In this case, the database returns a message indicating that the table, partition, or subpartition is already locked by another user.

**WAIT**

Use the `WAIT` clause to indicate that the `LOCK TABLE` statement should wait up to the specified number of seconds to acquire a DML lock. There is no limit on the value of `integer`. 
If you specify neither **NOWAIT** nor **WAIT**, then the database waits indefinitely until the table is available, locks it, and returns control to you. When the database is executing DDL statements concurrently with DML statements, a timeout or deadlock can sometimes result. The database detects such timeouts and deadlocks and returns an error.

### See Also:

*Oracle Database Administrator’s Guide* for more information about locking tables

### Examples

#### Locking a Table: Example

The following statement locks the `employees` table in exclusive mode but does not wait if another user already has locked the table:

```sql
LOCK TABLE employees
    IN EXCLUSIVE MODE
    NOWAIT;
```

The following statement locks the remote `employees` table that is accessible through the database link `remote`:

```sql
LOCK TABLE employees@remote
    IN SHARE MODE;
```
This chapter contains the following SQL statements:

- **MERGE**
- **NOAUDIT** (Traditional Auditing)
- **NOAUDIT** (Unified Auditing)
- **PURGE**
- **RENAME**
- **REVOKE**
- **ROLLBACK**
- **SAVEPOINT**
- **SELECT**
- **SET CONSTRAINT[S]**
- **SET ROLE**
- **SET TRANSACTION**
- **TRUNCATE CLUSTER**
- **TRUNCATE TABLE**
- **UPDATE**

## MERGE

### Purpose

Use the `MERGE` statement to select rows from one or more sources for update or insertion into a table or view. You can specify conditions to determine whether to update or insert into the target table or view.

This statement is a convenient way to combine multiple operations. It lets you avoid multiple `INSERT`, `UPDATE`, and `DELETE` DML statements.

`MERGE` is a deterministic statement. You cannot update the same row of the target table multiple times in the same `MERGE` statement.
**Note:**

In previous releases of Oracle Database, when you created an Oracle Virtual Private Database policy on an application that included the `MERGE INTO` statement, the `MERGE INTO` statement would be prevented with an ORA-28132: `Merge into syntax does not support security policies` error, due to the presence of the Virtual Private Database policy. Beginning with Oracle Database 11g Release 2 (11.2.0.2), you can create policies on applications that include `MERGE INTO` operations. To do so, in the `DBMS_RLS.ADD_POLICY` `statement_types` parameter, include the `INSERT`, `UPDATE`, and `DELETE` statements, or just omit the `statement_types` parameter altogether. Refer to *Oracle Database Security Guide* for more information on enforcing policies on specific SQL statement types.

**Prerequisites**

You must have the `INSERT` and `UPDATE` object privileges on the target table and the `READ` or `SELECT` object privilege on the source table. To specify the `DELETE` clause of the `merge_update_clause`, you must also have the `DELETE` object privilege on the target table.

**Syntax**

```
merge ::= 
```

```
MERGE hint INTO schema . table view t_alias 
USING schema . table view subquery 
ON ( condition )
merge_update_clause merge_insert_clause error_logging_clause 
;
```

*Note:* You must specify at least one of the clauses `merge_update_clause` or `merge_insert_clause`.

```
(merge_update_clause ::= , merge_insert_clause ::= , error_logging_clause ::= 
merge_update_clause ::= 
```
### merge_insert_clause::=

```
WHEN NOT MATCHED THEN INSERT ( column ) VALUES ( expr DEFAULT, )
WHERE condition
```

### where_clause::=

```
WHERE condition
```

### error_logging_clause::=

```
LOG ERRORS INTO schema . table ( simple_expression ) REJECT LIMIT integer UNLIMITED
```

### Semantics

**INTO Clause**

Use the INTO clause to specify the target table or view you are updating or inserting into. In order to merge data into a view, the view must be updatable. Refer to "Notes on Updatable Views" for more information.

**Restriction on Target Views**
You cannot specify a target view on which an INSTEAD OF trigger has been defined.

**USING Clause**

Use the **USING** clause to specify the source table or view you are updating or inserting from.

**Restriction on USING Clause**

You cannot use a subquery within the **SELECT** list of the **USING** clause.

**ON Clause**

Use the **ON** clause to specify the condition upon which the **MERGE** operation either updates or inserts. For each row in the target table for which the search condition is true, Oracle Database updates the row with corresponding data from the source table. If the condition is not true for any rows, then the database inserts into the target table based on the corresponding source table row.

**Restrictions on the ON Clause**

In previous releases of Oracle Database, when you created an Oracle Virtual Private Database policy on an application that included the **MERGE INTO** statement, the **MERGE INTO** statement would be prevented with an ORA-28132: Merge into syntax does not support security policies error, due to the presence of the Virtual Private Database policy. Beginning with Oracle Database 11g Release 2 (11.2.0.2), you can create policies on applications that include **MERGE INTO** operations. To do so, in the DBMS_RLS.ADD_POLICY **statement_types** parameter, include the INSERT, UPDATE, and DELETE statements, or just omit the **statement_types** parameter altogether. Refer to *Oracle Database Security Guide* for more information on enforcing policies on specific SQL statement types.

**merge_update_clause**

The **merge_update_clause** specifies the new column values of the target table. Oracle performs this update if the condition of the **ON** clause is true. If the update clause is executed, then all update triggers defined on the target table are activated.

Specify the **where_clause** if you want the database to execute the update operation only if the specified condition is true. The condition can refer to either the data source or the target table. If the condition is not true, then the database skips the update operation when merging the row into the table.

Specify the **DELETE where_clause** to clean up data in a table while populating or updating it. The only rows affected by this clause are those rows in the destination table that are updated by the merge operation. The **DELETE WHERE** condition evaluates the updated value, not the original value that was evaluated by the **UPDATE SET ... WHERE** condition. If a row of the destination table meets the **DELETE** condition but is not included in the join defined by the **ON** clause, then it is not deleted. Any delete triggers defined on the target table will be activated for each row deletion.

You can specify this clause by itself or with the **merge_insert_clause**. If you specify both, then they can be in either order.

**Restrictions on the merge_update_clause**

This clause is subject to the following restrictions:

- You cannot update a column that is referenced in the **ON condition** clause.
• You cannot specify `DEFAULT` when updating a view.

**merge_insert_clause**

The `merge_insert_clause` specifies values to insert into the column of the target table if the condition of the `ON` clause is false. If the insert clause is executed, then all insert triggers defined on the target table are activated. If you omit the column list after the `INSERT` keyword, then the number of columns in the target table must match the number of values in the `VALUES` clause.

To insert all of the source rows into the table, you can use a **constant filter predicate** in the `ON` clause condition. An example of a constant filter predicate is `ON (0=1)`. Oracle Database recognizes such a predicate and makes an unconditional insert of all source rows into the table. This approach is different from omitting the `merge_update_clause`. In that case, the database still must perform a join. With constant filter predicate, no join is performed.

Specify the `where_clause` if you want Oracle Database to execute the insert operation only if the specified condition is true. The condition can refer only to the data source table. Oracle Database skips the insert operation for all rows for which the condition is not true.

You can specify this clause by itself or with the `merge_update_clause`. If you specify both, then they can be in either order.

**Restriction on the merge_insert_clause**

You cannot specify `DEFAULT` when inserting into a view.

**error_logging_clause**

The `error_logging_clause` has the same behavior in a `MERGE` statement as in an `INSERT` statement. Refer to the `INSERT` statement `error_logging_clause` for more information.

"Inserting Into a Table with Error Logging: Example"

---

**Examples**

**Merging into a Table: Example**

The following example uses the `bonuses` table in the sample schema `oe` with a default bonus of 100. It then inserts into the `bonuses` table all employees who made sales, based on the `sales_rep_id` column of the `oe.orders` table. Finally, the human resources manager decides that employees with a salary of $8000 or less should receive a bonus. Those who have not made sales get a bonus of 1% of their salary. Those who already made sales get an increase in their bonus equal to 1% of their salary. The `MERGE` statement implements these changes in one step:

```sql
CREATE TABLE bonuses (employee_id NUMBER, bonus NUMBER DEFAULT 100);

INSERT INTO bonuses(employee_id)
(SELECT e.employee_id FROM employees e, orders o
 WHERE e.employee_id = o.sales_rep_id
GROUP BY e.employee_id);
```
SELECT * FROM bonuses ORDER BY employee_id;

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>BONUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>153</td>
<td>100</td>
</tr>
<tr>
<td>154</td>
<td>100</td>
</tr>
<tr>
<td>155</td>
<td>100</td>
</tr>
<tr>
<td>156</td>
<td>100</td>
</tr>
<tr>
<td>158</td>
<td>100</td>
</tr>
<tr>
<td>159</td>
<td>100</td>
</tr>
<tr>
<td>160</td>
<td>100</td>
</tr>
<tr>
<td>161</td>
<td>100</td>
</tr>
<tr>
<td>163</td>
<td>100</td>
</tr>
</tbody>
</table>

MERGE INTO bonuses D
USING (SELECT employee_id, salary, department_id FROM employees
WHERE department_id = 80) S
ON (D.employee_id = S.employee_id)
WHEN MATCHED THEN UPDATE SET D.bonus = D.bonus + S.salary*.01
  DELETE WHERE (S.salary > 8000)
WHEN NOT MATCHED THEN INSERT (D.employee_id, D.bonus)
  VALUES (S.employee_id, S.salary*.01)
  WHERE (S.salary <= 8000);

SELECT * FROM bonuses ORDER BY employee_id;

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>BONUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>153</td>
<td>180</td>
</tr>
<tr>
<td>154</td>
<td>175</td>
</tr>
<tr>
<td>155</td>
<td>170</td>
</tr>
<tr>
<td>159</td>
<td>180</td>
</tr>
<tr>
<td>160</td>
<td>175</td>
</tr>
<tr>
<td>161</td>
<td>170</td>
</tr>
<tr>
<td>164</td>
<td>72</td>
</tr>
<tr>
<td>165</td>
<td>68</td>
</tr>
<tr>
<td>166</td>
<td>64</td>
</tr>
<tr>
<td>167</td>
<td>62</td>
</tr>
<tr>
<td>171</td>
<td>74</td>
</tr>
<tr>
<td>172</td>
<td>73</td>
</tr>
<tr>
<td>173</td>
<td>61</td>
</tr>
<tr>
<td>179</td>
<td>62</td>
</tr>
</tbody>
</table>

**Conditional Insert and Update: Example**

The following example conditionally inserts and updates table data by using the `MERGE` statement.

The following statements create two tables named `people_source` and `people_target` and populate them with names:

```sql
CREATE TABLE people_source (  
  person_id  INTEGER NOT NULL PRIMARY KEY,  
  first_name VARCHAR2(20) NOT NULL,  
  last_name  VARCHAR2(20) NOT NULL,  
  title      VARCHAR2(10) NOT NULL
);

CREATE TABLE people_target (  
```

```sql```
### Merge Examples

#### Merge into People Target Table

```sql
person_id INTEGER NOT NULL PRIMARY KEY,
first_name VARCHAR2(20) NOT NULL,
last_name  VARCHAR2(20) NOT NULL,
title      VARCHAR2(10) NOT NULL
);

INSERT INTO people_target VALUES (1, 'John', 'Smith', 'Mr');
INSERT INTO people_target VALUES (2, 'alice', 'jones', 'Mrs');
INSERT INTO people_source VALUES (2, 'Alice', 'Jones', 'Mrs.');
INSERT INTO people_source VALUES (3, 'Jane', 'Doe', 'Miss');
INSERT INTO people_source VALUES (4, 'Dave', 'Brown', 'Mr');

COMMIT;
```

The following statement compares the contents of `people_target` and `people_source` by using the `person_id` column. The values in the `people_target` table are updated when there is a match in the `people_source` table:

```sql
MERGE INTO people_target pt
USING people_source ps
ON (pt.person_id = ps.person_id)
WHEN matched THEN UPDATE
  SET pt.first_name = ps.first_name,
      pt.last_name = ps.last_name,
      pt.title = ps.title;
```

The following statements display the contents of the `people_target` table and perform a rollback:

```sql
SELECT * FROM people_target;

PERSON_ID FIRST_NAME        LAST_NAME         TITLE
---------- -------------------- -------------------- ----------
    1 John         Smith             Mr
    2 Alice        Jones             Mrs.

ROLLBACK;
```

This statement compares the contents of the `people_target` and `people_source` tables by using the `person_id` column. The values in the `people_target` table are updated only when there is no match in the `people_source` table:

```sql
MERGE INTO people_target pt
USING people_source ps
ON (pt.person_id = ps.person_id)
WHEN NOT matched THEN INSERT
  (pt.person_id, pt.first_name, pt.last_name, pt.title)
VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title);
```
The following statements display the contents of the `people_target` table and perform a rollback:

SELECT * FROM people_target;

<table>
<thead>
<tr>
<th>PERSON_ID</th>
<th>FIRST_NAME</th>
<th>LAST_NAME</th>
<th>TITLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>John</td>
<td>Smith</td>
<td>Mr</td>
</tr>
<tr>
<td>2</td>
<td>Alice</td>
<td>Jones</td>
<td>Mrs.</td>
</tr>
<tr>
<td>3</td>
<td>Jane</td>
<td>Doe</td>
<td>Miss</td>
</tr>
<tr>
<td>4</td>
<td>Dave</td>
<td>Brown</td>
<td>Mr</td>
</tr>
</tbody>
</table>

ROLLBACK;

The following statement compares the contents of the `people_target` and `people_source` tables by using the `person_id` column and conditionally inserts and updates data in the `people_target` table. For each matching row in the `people_source` table, the values in the `people_target` table are updated by using the values from the `people_source` table. Any unmatched rows from the `people_source` table are added to the `people_target` table:

MERGE INTO people_target pt
USING people_source ps
ON    (pt.person_id = ps.person_id)
WHEN matched THEN UPDATE
    SET pt.first_name = ps.first_name,
        pt.last_name = ps.last_name,
        pt.title = ps.title
WHEN NOT matched THEN INSERT
    (pt.person_id, pt.first_name, pt.last_name, pt.title)
VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title);

The following statements display the contents of the `people_target` table and perform a rollback:

SELECT * FROM people_target;

<table>
<thead>
<tr>
<th>PERSON_ID</th>
<th>FIRST_NAME</th>
<th>LAST_NAME</th>
<th>TITLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>John</td>
<td>Smith</td>
<td>Mr</td>
</tr>
<tr>
<td>2</td>
<td>Alice</td>
<td>Jones</td>
<td>Mrs.</td>
</tr>
<tr>
<td>3</td>
<td>Jane</td>
<td>Doe</td>
<td>Miss</td>
</tr>
<tr>
<td>4</td>
<td>Dave</td>
<td>Brown</td>
<td>Mr</td>
</tr>
</tbody>
</table>

ROLLBACK;

The following statement compares the `people_target` and `people_source` tables by using the `person_id` column. When the `person_id` matches, the corresponding rows in the `people_target` table are updated by using values from the `people_source` table. The `DELETE` clause removes all the values in `people_target` where `title` is ‘Mrs.’. When the `person_id` does not match, the rows from the `people_source` table are
added to the `people_target` table. The `WHERE` clause ensures that only values that have `title` as 'Mr' are added to the `people_target` table:

```sql
MERGE INTO people_target pt
USING people_source ps
ON    (pt.person_id = ps.person_id)
WHEN matched THEN UPDATE
    SET pt.first_name = ps.first_name,
        pt.last_name = ps.last_name,
        pt.title = ps.title
    DELETE where pt.title  = 'Mrs.'
WHEN NOT matched THEN INSERT
    (pt.person_id, pt.first_name, pt.last_name, pt.title)
VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title)
WHERE ps.title = 'Mr';
```

The following statements display the contents of the `people_target` table and perform a rollback:

```sql
SELECT * FROM people_target;

<table>
<thead>
<tr>
<th>PERSON_ID</th>
<th>FIRST_NAME</th>
<th>LAST_NAME</th>
<th>TITLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>John</td>
<td>Smith</td>
<td>Mr</td>
</tr>
<tr>
<td>4</td>
<td>Dave</td>
<td>Brown</td>
<td>Mr</td>
</tr>
</tbody>
</table>

ROLLBACK;

**NOAUDIT (Traditional Auditing)**

This section describes the `NOAUDIT` statement for **traditional auditing**, which is the same auditing functionality used in releases earlier than Oracle Database 12c.

Beginning with Oracle Database 12c, Oracle introduces **unified auditing**, which provides a full set of enhanced auditing features. For backward compatibility, traditional auditing is still supported. However, Oracle recommends that you plan the migration of your existing audit settings to the new unified audit policy syntax. For new audit requirements, Oracle recommends that you use the new unified auditing. Traditional auditing may be desupported in a future major release.

**See Also:**

[NOAUDIT (Unified Auditing)] for a description of the `NOAUDIT` statement for unified auditing

**Purpose**

Use the `NOAUDIT` statement to stop auditing operations previously enabled by the `AUDIT` statement.
The **NOAUDIT** statement must have the same syntax as the previous **AUDIT** statement. Further, it reverses the effects only of that particular statement. For example, suppose one **AUDIT** statement A enables auditing for a specific user. A second statement B enables auditing for all users. A **NOAUDIT** statement C to disable auditing for all users reverses statement B. However, statement C leaves statement A in effect and continues to audit the user that statement A specified.

**See Also:**

AUDIT (Traditional Auditing)

**Prerequisites**

To stop auditing of SQL statements, you must have the **AUDIT SYSTEM** system privilege.

To stop auditing of schema objects, you must be the owner of the object on which you stop auditing or you must have the **AUDIT ANY** system privilege. In addition, if the object you chose for auditing is a directory, then even if you created it, you must have the **AUDIT ANY** system privilege.

To specify the **CONTAINER** clause, you must be connected to a multitenant container database (CDB). To specify **CONTAINER = ALL**, the current container must be the root and you must have the commonly granted **AUDIT SYSTEM** privilege in order to stop auditing for the issuances of a SQL statement, or the commonly granted **AUDIT ANY** privilege in order to stop auditing for the operations on a schema object. To specify **CONTAINER = CURRENT**, the current container must be a pluggable database (PDB) and you must have the locally granted **AUDIT SYSTEM** privilege in order to stop auditing the issuances of a SQL statement, or the locally granted **AUDIT ANY** privilege in order to stop auditing operations on a schema object.

**Syntax**

```sql
noaudit ::=  
```

```sql
NOAUDIT  
```

```sql
WHENEVER NOT SUCCESSFUL  
CONTAINER = CURRENT ALL  
```
audit_operation_clause::=

-- Diagram

auditing_by_clause::=

-- Diagram

audit_schema_object_clause::=

-- Diagram

auditing_on_clause::=

-- Diagram

Semantics

audit_operation_clause

Use the audit_operation_clause to stop auditing of a particular SQL statement.
statement_option

For sql_statementShortcut, specify the shortcut for the SQL statements for which auditing is to be stopped. Refer to Table 12-1 and Table 12-2 for a list of the SQL statement shortcuts and the SQL statements they audit.

ALL

Specify ALL to stop auditing of all statement options currently being audited because of an earlier AUDIT ALL . . . statement. You cannot use this clause to reverse an earlier AUDIT ALL STATEMENTS . . . statement.

ALL STATEMENTS

Specify ALL STATEMENTS to reverse an earlier AUDIT ALL STATEMENTS . . . statement. You cannot use this clause to reverse an earlier AUDIT ALL . . . statement.

system_privilege

For system_privilege, specify the system privilege for which auditing is to be stopped. Refer to Table 18-1 for a list of the system privileges and the statements they authorize.

ALL PRIVILEGES

Specify ALL PRIVILEGES to stop auditing of all system privileges currently being audited.

auditing_by_clause

Use the auditing_by_clause to stop auditing only for SQL statements issued by the specified users in their subsequent sessions. If you omit this clause, then Oracle Database stops auditing for all users’ statements, except for the situation described for WHENEVER SUCCESSFUL.

audit_schema_object_clause

Use the audit_schema_object_clause to stop auditing of a particular database object.

sql_operation

For sql_operation, specify the type of operation for which auditing is to be stopped on the object specified in the ON clause. Refer to Table 12-3 for a list of these options.

ALL

Specify ALL as a shortcut equivalent to specifying all SQL operations applicable for the type of object.

auditing_on_clause

The auditing_on_clause lets you specify the particular schema object for which auditing is to be stopped.

- For object, specify the object name of a table, view, sequence, stored procedure, function, or package, materialized view, or library. If you do not qualify object with schema, then Oracle Database assumes the object is in your own schema. Refer to AUDIT (Traditional Auditing) for information on auditing specific schema objects.
- The DIRECTORY Clause lets you specify the name of the directory on which auditing is to be stopped.
• The **SQL TRANSLATION PROFILE** clause lets you specify the SQL translation profile on which auditing is to be stopped.

• Specify **DEFAULT** to remove the specified object options as default object options for subsequently created objects.

**NETWORK**

Use this clause to discontinue auditing of database link usage and logins.

**DIRECT_PATH LOAD**

Use this clause to discontinue auditing of SQL*Loader direct path loads.

**WHENEVER [NOT] SUCCESSFUL**

Specify **WHENEVER SUCCESSFUL** to stop auditing only for SQL statements and operations on schema objects that complete successfully.

Specify **WHENEVER NOT SUCCESSFUL** to stop auditing only for SQL statements and operations that result in Oracle Database errors.

If you omit this clause, then the database stops auditing for all statements or operations, regardless of success or failure.

**CONTAINER Clause**

Use the **CONTAINER clause** to specify the scope of the **NOAUDIT** command.

• Specify **CONTAINER = CURRENT** to stop auditing in the PDB to which you are connected. If you specify the **auditing_by_clause**, then **user** must be a common user or local user in the current PDB. If you specify the **auditing_on_clause**, then the objects must be local objects in the current PDB.

• Specify **CONTAINER = ALL** to stop auditing across the entire CDB. If you specify the **auditing_by_clause**, then **user** must be a common user. If you do not specify the **auditing_on_clause**, then auditing is stopped for all common users and all local users in each PDB. If you specify the **auditing_on_clause**, then the objects must be common objects.

If you omit this clause, then **CONTAINER = CURRENT** is the default.

**Examples**

**Stop Auditing of SQL Statements Related to Roles: Example**

If you have chosen auditing for every SQL statement that creates or drops a role, then you can stop auditing of such statements by issuing the following statement:

```sql
NOAUDIT ROLE;
```

**Stop Auditing of Updates or Queries on Objects Owned by a Particular User: Example**

If you have chosen auditing for any statement that queries or updates any table issued by the users **hr** and **oe**, then you can stop auditing for queries by **hr** by issuing the following statement:

```sql
NOAUDIT SELECT TABLE BY hr;
```

The preceding statement stops auditing only queries by **hr**, so the database continues to audit queries and updates by **oe** as well as updates by **hr**.
Stop Auditing of Statements Authorized by a Particular Object Privilege: Example

To stop auditing on all statements that are authorized by DELETE ANY TABLE system privilege, issue the following statement:

```sql
NOAUDIT DELETE ANY TABLE;
```

Stop Auditing of Queries on a Particular Object: Example

If you have chosen auditing for every SQL statement that queries the `employees` table in the schema `hr`, then you can stop auditing for such queries by issuing the following statement:

```sql
NOAUDIT SELECT
   ON hr.employees;
```

Stop Auditing of Queries that Complete Successfully: Example

You can stop auditing for queries that complete successfully by issuing the following statement:

```sql
NOAUDIT SELECT
   ON hr.employees
   WHENEVER SUCCESSFUL;
```

This statement stops auditing only for successful queries. Oracle Database continues to audit queries resulting in Oracle Database errors.

**NOAUDIT (Unified Auditing)**

This section describes the `NOAUDIT` statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

### Purpose

Use the `NOAUDIT` statement to:

- Disable a unified audit policy for all users or for specified users
- Exclude the values of context attributes from audit records

Operations performed with this statement take effect in subsequent user sessions, not in the current session.

**See Also:**

- `AUDIT (Unified Auditing)`
- `CREATE AUDIT POLICY (Unified Auditing)`
- `ALTER AUDIT POLICY (Unified Auditing)`
- `DROP AUDIT POLICY (Unified Auditing)`
Prerequisites

You must have the **AUDIT SYSTEM** system privilege or the **AUDIT_ADMIN** role.

If you are connected to a multitenant container database (CDB), then to disable a common unified audit policy, the current container must be the root and you must have the commonly granted **AUDIT SYSTEM** privilege or the **AUDIT_ADMIN** common role. To disable a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted **AUDIT SYSTEM** privilege or the **AUDIT_ADMIN** common role, or you must have the locally granted **AUDIT SYSTEM** privilege or the **AUDIT_ADMIN** local role in the container.

To specify the **NOAUDIT CONTEXT ... statement** when connected to a CDB, you must have the commonly granted **AUDIT SYSTEM** privilege or the **AUDIT_ADMIN** common role, or you must have the locally granted **AUDIT SYSTEM** privilege or the **AUDIT_ADMIN** local role in the current session's container.

Syntax

\[
\text{unified_noaudit ::= NOAUDIT POLICY policy BY user, by_users_with_roles WHENEVER NOT SUCCESSFUL CONTEXT NAMESPACE namespace ATTRIBUTES attribute, BY user, by_users_with_roles }
\]

Semantics

\[
\text{policy}
\]

Specify the name of the unified audit policy you want to disable.

You can find descriptions of all unified audit policies by querying the **AUDIT_UNIFIED_POLICIES** view and descriptions of all enabled unified audit policies by querying the **AUDIT_UNIFIED_ENABLED_POLICIES** view.
CONTEXT Clause

Specify the CONTEXT clause to exclude the values of context attributes in audit records.

- For namespace, specify the context namespace.
- For attribute, specify one or more context attributes whose values you want to exclude from audit records.

If you specify the CONTEXT clause when the current container is the root of a CDB, then the values of context attributes will be included in audit records only for events executed in the root. If you specify the optional BY clause, then user must be a common user.

If you specify the CONTEXT clause when the current container is a pluggable database (PDB), then the values of context attributes will be included in audit records only for events executed in that PDB. If you specify the optional BY clause, then user must be a common user or a local user in that PDB.

You can find the application context attributes that are configured to be captured in the audit trail by querying the AUDIT_UNIFIED_CONTEXTS view.

BY

You can specify the BY clause for the NOAUDIT POLICY and NOAUDIT CONTEXT statements.

NOAUDIT POLICY ... BY

The behavior of the BY clause depends on whether policy is enabled for all users or specific users.

- If policy is enabled for all users, then you can disable policy for all users by omitting the BY clause. If you specify the BY clause, then the NOAUDIT POLICY statement will have no effect.
- If policy is enabled for one or more users (using the AUDIT POLICY ... BY ... statement), then you can:
  - Disable policy for one or more of those users by specifying the BY clause followed by the users for whom you want policy disabled
  - Completely disable policy by specifying the BY clause followed by all of the users for whom policy is enabled
If you do not specify the `BY` clause, then the **NOAUDIT POLICY** statement will have no effect.

- If `policy` is enabled for all users except specific users (using the **AUDIT POLICY ... EXCEPT ...** statement), then you can disable `policy` for all users by omitting the `BY` clause. If you specify the `BY` clause, then the **NOAUDIT POLICY** statement will have no effect.

If `policy` is a common unified audit policy, then `user` must be a common user. If `policy` is a local unified audit policy, then `user` must be a common user or a local user in the container to which you are connected.

**NOAUDIT CONTEXT ... BY**

The behavior of the `BY` clause depends on whether `attribute` is configured to be included in audit records for all users or specific users.

- If `attribute` is configured to be included in audit records for all users, then you can exclude `attribute` from audit records for all users by omitting the `BY` clause. If you specify the `BY` clause, then the **NOAUDIT CONTEXT** statement will have no effect.

- If `attribute` is configured to be included in audit records for specific users, then you can exclude `attribute` for one or more of those users by specifying the `BY` clause followed by the users for whom you want `attribute` excluded. If you do not specify the `BY` clause, then the **NOAUDIT CONTEXT** statement will have no effect.

**by_users_with_roles**

Specify this clause to disable `policy` only for users who have been directly granted the specified roles. If you subsequently grant one of the roles to an additional user, then the policy is automatically disabled for that user.

When you are connected to a CDB, if `policy` is a common unified audit policy, then `role` must be a common role. If `policy` is a local unified audit policy, then role must be a common role or a local role in the container to which you are connected.

**Examples**

The following examples disable unified audit policies that were created in the **CREATE AUDIT POLICY "Examples"** and enabled in the **AUDIT "Examples"**.

**Disabling a Unified Audit Policy for All Users: Example**

Assume that unified audit policy `table_pol` is enabled for all users. The following statement disables `table_pol` for all users:

```
NOAUDIT POLICY table_pol;
```

The following statement returns no rows, which verifies that `table_pol` is disabled for all users:

```
SELECT *
FROM audit_unified_enabled_policies
WHERE policy_name = 'TABLE_POL';
```

**Disabling a Unified Audit Policy for Specific Users: Example**

Assume that unified audit policy `dml_pol` is enabled for users `hr` and `sh`, as shown by the following query:
SELECT policy_name, enabled_option, entity_name
FROM audit_unified_enabled_policies
WHERE policy_name = 'DML_POL'
ORDER BY entity_name;

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPTION</th>
<th>ENTITY_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>HR</td>
</tr>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>SH</td>
</tr>
</tbody>
</table>

The following statement disables dml_pol for user hr:

NOAUDIT POLICY dml_pol BY hr;

The following statement verifies that dml_pol is now enabled for only user sh:

SELECT policy_name, enabled_option, entity_name
FROM audit_unified_enabled_policies
WHERE policy_name = 'DML_POL';

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPTION</th>
<th>ENTITY_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>SH</td>
</tr>
</tbody>
</table>

The following statement disables dml_pol for user sh:

NOAUDIT POLICY dml_pol BY sh;

The following statement returns no rows, which verifies that dml_pol is disabled for all users:

SELECT *
FROM audit_unified_enabled_policies
WHERE policy_name = 'DML_POL';

Excluding Values of Context Attributes in Audit Records: Example

The following statement instructs the database to exclude the values of namespace USERENV attributes CURRENT_USER and DB_NAME from all audit records for user hr:

NOAUDIT CONTEXT NAMESPACE userenv
ATTRIBUTES current_user, db_name
BY hr;

PURGE

Purpose

Use the PURGE statement to:

• Remove a table or index from your recycle bin and release all of the space associated with the object
• Remove part or all of a dropped tablespace or tablespace set from the recycle bin
• Remove the entire recycle bin
Note:

You cannot roll back a PURGE statement, nor can you recover an object after it is purged.

To see the contents of your recycle bin, query the USER_RECYCLEBIN data dictionary view. You can use the RECYCLEBIN synonym instead. The following two statements return the same rows:

```
SELECT * FROM RECYCLEBIN;
SELECT * FROM USER_RECYCLEBIN;
```

See Also:

- *Oracle Database Administrator's Guide* for information on the recycle bin and naming conventions for objects in the recycle bin
- *FLASHBACK TABLE* for information on retrieving dropped tables from the recycle bin
- *Oracle Database Reference* for information on using the RECYCLEBIN initialization parameter to control whether dropped tables go into the recycle bin

Prerequisites

To purge a table, the table must reside in your own schema or you must have the DROP ANY TABLE system privilege, or you must have the SYSDBA system privilege.

To purge an index, the index must reside in your own schema or you must have the DROP ANY INDEX system privilege, or you must have the SYSDBA system privilege.

To purge a tablespace or tablespace set, you must have the DROP TABLESPACE system privilege, or you must have the SYSDBA system privilege.

To purge a tablespace set, you must also be connected to a shard catalog database as an SDB user.

To perform the PURGE DBA_RECYCLEBIN operation, you must have the SYSDBA or PURGE DBA_RECYCLEBIN system privilege.
Syntax

```sql
purge ::= 
```

Semantics

**TABLE or INDEX**

Specify the name of the table or index in the recycle bin that you want to purge. You can specify either the original user-specified name or the system-generated name Oracle Database assigned to the object when it was dropped.

- If you specify the user-specified name, and if the recycle bin contains more than one object of that name, then the database purges the object that has been in the recycle bin the longest.
- System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, then the database purges that specified object.

When the database purges a table, all table partitions, LOBs and LOB partitions, indexes, and other dependent objects of that table are also purged.

**TABLESPACE or TABLESPACE SET**

Use this clause to purge all the objects residing in the specified tablespace or tablespace set from the recycle bin.

**USER user**

Use this clause to reclaim space in a tablespace or tablespace set for a specified user. This operation is useful when a particular user is running low on disk quota for the specified tablespace or tablespace set.

**RECYCLEBIN**

Use this clause to purge the current user's recycle bin. Oracle Database will remove all objects from the user's recycle bin and release all space associated with objects in the recycle bin.

**DBA_RECYCLEBIN**

This clause is valid only if you have the `SYSDBA` or `PURGE DBA_RECYCLEBIN` system privilege. It lets you remove all objects from the system-wide recycle bin, and is
equivalent to purging the recycle bin of every user. This operation is useful, for example, before backward migration.

Examples

**Remove a File From Your Recycle Bin: Example**

The following statement removes the table `test` from the recycle bin. If more than one version of `test` resides in the recycle bin, then Oracle Database removes the version that has been there the longest:

```
PURGE TABLE test;
```

To determine system-generated name of the table you want removed from your recycle bin, issue a `SELECT` statement on your recycle bin. Using that object name, you can remove the table by issuing a statement similar to the following statement. (The system-generated name will differ from the one shown in the example.)

```
PURGE TABLE RB$33750$TABLE$0;
```

**Remove the Contents of Your Recycle Bin: Example**

To remove the entire contents of your recycle bin, issue the following statement:

```
PURGE RECYCLEBIN;
```

### RENAME

#### Purpose

Use the `RENAME` statement to rename a table, view, sequence, or private synonym.

- Oracle Database automatically transfers integrity constraints, indexes, and grants on the old object to the new object.
- Oracle Database invalidates all objects that depend on the renamed object, such as views, synonyms, and stored procedures and functions that refer to a renamed table.

#### See Also:

- `CREATE SYNONYM` and `DROP SYNONYM`

#### Prerequisites

The object must be in your own schema.

#### Note:

You cannot roll back a `RENAME` statement.
Syntax

rename ::= 

```
RENAME old_name TO new_name ;
```

Semantics

old_name

Specify the name of an existing table, view, sequence, or private synonym.

new_name

Specify the new name to be given to the existing object. The new name must not already be used by another schema object in the same namespace and must follow the rules for naming schema objects.

Restrictions on Renaming Objects

Renaming objects is subject to the following restrictions:

- You cannot rename a public synonym. Instead, drop the public synonym and then re-create the public synonym with the new name.
- You cannot rename a type synonym that has any dependent tables or dependent valid user-defined object types.

See Also:

"Database Object Naming Rules"

Examples

Renaming a Database Object: Example

The following example uses a copy of the sample table hr.departments. To change the name of table departments_new to emp_departments, issue the following statement:

```sql
RENAME departments_new TO emp_departments;
```

You cannot use this statement directly to rename columns. However, you can rename a column using the ALTER TABLE ...

See Also:

rename_column_clause
Another way to rename a column is to use the RENAME statement together with the CREATE TABLE statement with AS subquery. This method is useful if you are changing the structure of a table rather than only renaming a column. The following statements re-create the sample table hr.job_history, renaming a column from department_id to dept_id:

```
CREATE TABLE temporary
  (employee_id, start_date, end_date, job_id, dept_id)
AS SELECT
  employee_id, start_date, end_date, job_id, department_id
FROM job_history;

DROP TABLE job_history;

RENAME temporary TO job_history;
```

Any integrity constraints defined on table job_history will be lost in the preceding example. You will have to redefine them on the new job_history table using an ALTER TABLE statement.

---

### REVOKE

#### Purpose

Use the REVOKE statement to:

- Revoke system privileges from users and roles
- Revoke roles from users, roles, and program units.
- Revoke object privileges for a particular object from users and roles

#### Note on Oracle Automatic Storage Management

A user authenticated AS SYSASM can use this statement to revoke the system privileges SYSASM, SYSOPER, and SYSDBA from a user in the Oracle ASM password file of the current node.

#### Note on Editionable Objects

A REVOKE operation to revoke object privileges on an editionable object actualizes the object in the current edition. See Oracle Database Development Guide for more information about editions and editionable objects.

#### See Also:

- **GRANT** for information on granting system privileges and roles
- **Table 18-2** for a listing of the object privileges for each type of object

#### Prerequisites

To revoke a **system privilege**, you must have been granted the privilege with the **ADMIN OPTION**. You can revoke any privilege if you have the **GRANT ANY PRIVILEGE** system privilege.
To revoke a role from a user or another role, you must have been directly granted the role with the ADMIN OPTION or you must have created the role. You can revoke any role if you have the GRANT ANY ROLE system privilege.

To revoke a role from a program unit, you must be the user SYS or you must be the schema owner of the program unit.

To revoke an object privilege, one of the following conditions must be met:

- You must previously have granted the object privilege to the user or role.
- You must have the GRANT ANY OBJECT PRIVILEGE system privilege. In this case, you can revoke any object privilege that was granted by the object owner or on behalf of the owner by a user with the GRANT ANY OBJECT PRIVILEGE. However, you cannot revoke an object privilege that was granted by way of a WITH GRANT OPTION grant.

See Also:
"Revoke Operations that Use GRANT ANY OBJECT PRIVILEGE: Example"

The REVOKE statement can revoke only privileges and roles that were previously granted directly with a GRANT statement. You cannot use this statement to revoke:

- Privileges or roles not granted to the revokee
- Roles or object privileges granted through the operating system
- Privileges or roles granted to the revokee through roles

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root.

Syntax

```
REVOKE
  revoke_system_privileges,
  revoke_object_privileges,
  revoke_roles_from_programs;
```

```
(revoke_system_privileges::=, revoke_object_privileges::=, 
  revoke_roles_from_programs::=)

revoke_system_privileges::=
```

```
  system_privilege
    role
      ALL PRIVILEGES
    FROM revokee_clause
```

(see diagram for visual representation)

Chapter 19
REVOKE
19-25
revoke_roles_from_programs ::= 

role \quad \text{FROM} \quad program_unit
,

role \quad \text{ALL} \quad \text{FROM} \quad program_unit
,

program_unit ::= 

FUNCTION \quad \text{schema} . \quad \text{function_name}

PROCEDURE \quad \text{schema} . \quad \text{procedure_name}

PACKAGE \quad \text{schema} . \quad \text{package_name}

Semantics

revoke_system_privileges

Use these clauses to revoke system privileges.

system_privilege

Specify the system privilege to be revoked. Refer to Table 18-1 for a list of the system privileges.

If you revoke a system privilege from a user, then the database removes the privilege from the user’s privilege domain. Effective immediately, the user cannot exercise the privilege.

If you revoke a system privilege from a role, then the database removes the privilege from the privilege domain of the role. Effective immediately, users with the role enabled cannot exercise the privilege. Also, other users who have been granted the role and subsequently enable the role cannot exercise the privilege.

If you revoke a system privilege from PUBLIC, then the database removes the privilege from the privilege domain of each user who has been granted the privilege through PUBLIC. Effective immediately, such users can no longer exercise the privilege. However, the privilege is not revoked from users who have been granted the privilege directly or through roles.

See Also:

"Revoking a System Privilege from a User: Example" and "Revoking a System Privilege from a Role: Example"
Oracle Database provides a shortcut for specifying all system privileges at once: Specify `ALL PRIVILEGES` to revoke all the system privileges listed in Table 18-1.

**Restriction on Revoking System Privileges**

A system privilege cannot appear more than once in the list of privileges to be revoked.

`role`

Specify the role to be revoked.

If you revoke a role from a `user`, then the database makes the role unavailable to the user. If the role is currently enabled for the user, then the user can continue to exercise the privileges in the role's privilege domain as long as it remains enabled. However, the user cannot subsequently enable the role.

If you revoke a role from another `role`, then the database removes the privilege domain of the revoked role from the privilege domain of the revokee role. Users who have been granted and have enabled the revokee role can continue to exercise the privileges in the privilege domain of the revoked role as long as the revokee role remains enabled. However, other users who have been granted the revokee role and subsequently enable it cannot exercise the privileges in the privilege domain of the revoked role.

---

**See Also:**

"Revoking a Role from a User: Example" and "Revoking a Role from a Role: Example"

If you revoke a role from `PUBLIC`, then the database makes the role unavailable to all users who have been granted the role through `PUBLIC`. Any user who has enabled the role can continue to exercise the privileges in its privilege domain as long as it remains enabled. However, users cannot subsequently enable the role. The role is not revoked from users who have been granted the role directly or through other roles.

**Restriction on Revoking System Roles**

A system role cannot appear more than once in the list of roles to be revoked. For information on the predefined roles, refer to *Oracle Database Security Guide*.

`revokee_clause`

Use the `revokee_clause` to specify the users or roles from which the system privilege, role, or object privilege is to be revoked.

`PUBLIC`

Specify `PUBLIC` to revoke the privileges or roles from all users.

`revoke_object_privileges`

Use these clauses to revoke object privileges.

`object_privilege`
Specify the object privilege to be revoked. The object privileges, categorized by the type of object to which they apply, are described in Table 18-2.

**Note:**

Each privilege authorizes some operation. By revoking a privilege, you prevent the revokee from performing that operation. However, multiple users may grant the same privilege to the same user, role, or PUBLIC. To remove the privilege from the grantee’s privilege domain, all grantors must revoke the privilege. If even one grantor does not revoke the privilege, then the grantee can still exercise the privilege by virtue of that grant.

If you revoke an object privilege from a **user**, then the database removes the privilege from the user’s privilege domain. Effective immediately, the user cannot exercise the privilege.

- If that user has granted that privilege to other users or roles, then the database also revokes the privilege from those other users or roles.
- If that user’s schema contains a procedure, function, or package that contains SQL statements that exercise the privilege, then the procedure, function, or package can no longer be executed.
- If that user’s schema contains a view on that object, then the database invalidates the view.
- If you revoke the REFERENCES object privilege from a user who has exercised the privilege to define referential integrity constraints, then you must specify the CASCADE CONSTRAINTS clause.

If you revoke an object privilege from a **role**, then the database removes the privilege from the privilege domain of the role. Effective immediately, users with the role enabled cannot exercise the privilege. Other users who have been granted the role cannot exercise the privilege after enabling the role.

If you revoke an object privilege from PUBLIC, then the database removes the privilege from the privilege domain of each user who has been granted the privilege through PUBLIC. Effective immediately, all such users are restricted from exercising the privilege. However, the privilege is not revoked from users who have been granted the privilege directly or through roles.

**ALL [PRIVILEGES]**

Specify **ALL** to revoke all object privileges that you have granted to the revokee. (The keyword **PRIVILEGES** is provided for semantic clarity and is optional.)

If no privileges have been granted on the object, then the database takes no action and does not return an error.

**Restriction on Revoking Object Privileges**

A privilege cannot appear more than once in the list of privileges to be revoked. A user, a role, or PUBLIC cannot appear more than once in the **FROM** clause.
CASCADE CONSTRAINTS

This clause is relevant only if you revoke the REFERENCES privilege or ALL [PRIVILEGES]. It drops any referential integrity constraints that the revokee has defined using the REFERENCES privilege, which might have been granted either explicitly or implicitly through a grant of ALL [PRIVILEGES].

See Also:

"Revoking an Object Privilege with CASCADE CONSTRAINTS: Example"

FORCE

Specify FORCE to revoke the EXECUTE object privilege on user-defined type objects with table or type dependencies. You must use FORCE to revoke the EXECUTE object privilege on user-defined type objects with table dependencies.

If you specify FORCE, then all privileges are revoked, all dependent objects are marked INVALID, data in dependent tables becomes inaccessible, and all dependent function-based indexes are marked UNUSABLE. Regranted the necessary type privilege will revalidate the table.

See Also:

Oracle Database Concepts for detailed information about type dependencies and user-defined object privileges

on_object_clause

The on_object_clause identifies the objects on which privileges are to be revoked.

object

Specify the object on which the object privileges are to be revoked. This object can be:

- A table, view, sequence, procedure, stored function, package, or materialized view
- A synonym for a table, view, sequence, procedure, stored function, package, materialized view, or user-defined type
- A library, indextype, or user-defined operator

If you do not qualify object with schema, then the database assumes the object is in your own schema.
If you revoke the `READ` or `SELECT` object privilege on the containing table or materialized view of a materialized view, whether the privilege was granted with or without the `GRANT OPTION`, then the database invalidates the materialized view.

If you revoke the `READ` or `SELECT` object privilege on any of the master tables of a materialized view, whether the privilege was granted with or without the `GRANT OPTION`, then the database invalidates both the materialized view and its containing table or materialized view.

**ON USER**

Specify one or more database users on whom privileges are to be revoked.

**See Also:**

"Revoking an Object Privilege on a User from a User: Example"

**ON DIRECTORY**

Specify the name of the directory object on which privileges are to be revoked. You cannot qualify `directory_name` with a schema name.

**See Also:**

CREATE DIRECTORY and “Revoking an Object Privilege on a Directory from a User: Example"

**ON EDITION**

Specify the name of the edition on which the `USE` object privilege is to be revoked. You cannot qualify `edition_name` with a schema name.

**ON MINING MODEL**

Specify the name of the mining model on which privileges are to be revoked. If you do not qualify `mining_model_name` with `schema`, then the database assumes that the mining model is in your own schema.

**ON JAVA SOURCE | RESOURCE**

Specify the name of the Java source or resource schema object on which privileges are to be revoked. If you do not qualify `object` with `schema`, then the database assumes that the object is in your own schema.

**ON SQL TRANSLATION PROFILE**
Specify the name of the SQL translation profile on which privileges are to be revoked. If you do not qualify profile with schema, then the database assumes the profile is in your own schema.

**revoke_roles_from_programs**

Use this clause to revoke code based access control (CBAC) roles from program units.

**role**

Specify the role you want to revoke.

**ALL**

Specify **ALL** to revoke all roles that are granted to the program unit.

**program_unit**

Specify the program unit from which the role is to be revoked. You can specify a PL/SQL function, procedure, or package. If you do not specify schema, then Oracle Database assumes the function, procedure, or package is in your own schema.

---

See Also:

*Oracle Database Security Guide* for more information on revoking CBAC roles from program units

---

**CONTAINER Clause**

If the current container is a pluggable database (PDB):

- Specify **CONTAINER = CURRENT** to revoke a locally granted system privilege, object privilege, or role from a local user, common user, local role, or common role. The privilege or role is revoked from the user or role only in the current PDB. This clause does not revoke privileges granted with **CONTAINER = ALL**.

If the current container is the root:

- Specify **CONTAINER = CURRENT** to revoke a locally granted system privilege, object privilege, or role from a common user or common role. The privilege or role is revoked from the user or role only in the root. This clause does not revoke privileges granted with **CONTAINER = ALL**.

- Specify **CONTAINER = ALL** to revoke a commonly granted system privilege, object privilege on a common object, or role from a common user or common role. The privilege or role is revoked from the user or role across the entire CDB. This clause can revoke only a privilege or role granted with **CONTAINER = ALL** from the specified common user or common role. This clause does not revoke privileges granted locally with **CONTAINER = CURRENT**. However, any locally granted privileges that depend on the commonly granted privilege being revoked are also revoked.

If you omit this clause, then **CONTAINER = CURRENT** is the default.

**Examples**

Revoking a System Privilege from a User: Example
The following statement revokes the DROP ANY TABLE system privilege from the users hr and oe:

REVOKE DROP ANY TABLE
  FROM hr, oe;

The users hr and oe can no longer drop tables in schemas other than their own.

**Revoking a Role from a User: Example**

The following statement revokes the role dw_manager from the user sh:

REVOKE dw_manager
  FROM sh;

The user sh can no longer enable the dw_manager role.

**Revoking a System Privilege from a Role: Example**

The following statement revokes the CREATE TABLESPACE system privilege from the dw_manager role:

REVOKE CREATE TABLESPACE
  FROM dw_manager;

Enabling the dw_manager role no longer allows users to create tablespaces.

**Revoking a Role from a Role: Example**

To revoke the role dw_user from the role dw_manager, issue the following statement:

REVOKE dw_user
  FROM dw_manager;

The dw_user role privileges are no longer granted to dw_manager.

**Revoking an Object Privilege from a User: Example**

You can grant DELETE, INSERT, READ, SELECT, and UPDATE privileges on the table orders to the user hr with the following statement:

GRANT ALL
  ON orders TO hr;

To revoke the DELETE privilege on orders from hr, issue the following statement:

REVOKE DELETE
  ON orders FROM hr;

**Revoking All Object Privileges from a User: Example**

To revoke the remaining privileges on orders that you granted to hr, issue the following statement:

REVOKE ALL
  ON orders FROM hr;

**Revoking Object Privileges from PUBLIC: Example**

You can grant SELECT and UPDATE privileges on the view emp_details_view to all users by granting the privileges to the role PUBLIC:
GRANT SELECT, UPDATE
ON emp_details_view TO public;

The following statement revokes UPDATE privilege on emp_details_view from all users:

REVOKE UPDATE
ON emp_details_view FROM public;

Users can no longer update the emp_details_view view, although users can still query it. However, if you have also granted the UPDATE privilege on emp_details_view to any users, either directly or through roles, then these users retain the privilege.

Revoking an Object Privilege on a User from a User: Example

You can grant the user hr the INHERIT PRIVILEGES privilege on user sh with the following statement:

GRANT INHERIT PRIVILEGES ON USER sh TO hr;

To revoke the INHERIT PRIVILEGES privilege on user sh from user hr, issue the following statement:

REVOKE INHERIT PRIVILEGES ON USER sh FROM hr;

Revoking an Object Privilege on a Sequence from a User: Example

You can grant the user oe the SELECT privilege on the departments_seq sequence in the schema hr with the following statement:

GRANT SELECT
ON hr.departments_seq TO oe;

To revoke the SELECT privilege on departments_seq from oe, issue the following statement:

REVOKE SELECT
ON hr.departments_seq FROM oe;

However, if the user hr has also granted SELECT privilege on departments to sh, then sh can still use departments by virtue of hr's grant.

Revoking an Object Privilege with CASCADE CONSTRAINTS: Example

You can grant to oe the privileges REFERENCES and UPDATE on the employees table in the schema hr with the following statement:

GRANT REFERENCES, UPDATE
ON hr.employees TO oe;

The user oe can exercise the REFERENCES privilege to define a constraint in his or her own dependent table that refers to the employees table in the schema hr:

CREATE TABLE dependent
(dependno NUMBER,
dependname VARCHAR2(10),
employee NUMBER
CONSTRAINT in_emp REFERENCES hr.employees(employee_id) );

You can revoke the REFERENCES privilege on hr.employees from oe by issuing the following statement that contains the CASCADE CONSTRAINTS clause:
REVOKE REFERENCES
  ON hr.employees
  FROM oe
  CASCADE CONSTRAINTS;

Revoking oe's REFERENCES privilege on hr.employees causes Oracle Database to drop the in_emp constraint, because oe required the privilege to define the constraint.

However, if oe has also been granted the REFERENCES privilege on hr.employees by a user other than you, then the database does not drop the constraint. oe still has the privilege necessary for the constraint by virtue of the other user's grant.

Revoking an Object Privilege on a Directory from a User: Example

You can revoke the READ object privilege on directory bfile_dir from hr by issuing the following statement:

REVOKE READ ON DIRECTORY bfile_dir FROM hr;

Revoke Operations that Use GRANT ANY OBJECT PRIVILEGE: Example

Suppose that the database administrator has granted GRANT ANY OBJECT PRIVILEGE to user sh. Now suppose that user hr grants the update privilege on the employees table to oe:

CONNECT hr
GRANT UPDATE ON employees TO oe WITH GRANT OPTION;

This grant gives user oe the right to pass the object privilege along to another user:

CONNECT oe
GRANT UPDATE ON hr.employees TO pm;

User sh, who has the GRANT ANY OBJECT PRIVILEGE, can now act on behalf of user hr and revoke the update privilege from user oe, because oe was granted the privilege by hr:

CONNECT sh
REVOKE UPDATE ON hr.employees FROM oe;

User sh cannot revoke the update privilege from user pm explicitly, because pm received the grant neither from the object owner (hr), nor from sh, nor from another user with GRANT ANY OBJECT PRIVILEGE, but from user oe. However, the preceding statement cascades, removing all privileges that depend on the one revoked. Therefore the object privilege is implicitly revoked from pm as well.

ROLLBACK

Purpose

Use the ROLLBACK statement to undo work done in the current transaction or to manually undo the work done by an in-doubt distributed transaction.
Oracle recommends that you explicitly end transactions in application programs using either a COMMIT or ROLLBACK statement. If you do not explicitly commit the transaction and the program terminates abnormally, then Oracle Database rolls back the last uncommitted transaction.

See Also:
- *Oracle Database Concepts* for information on transactions
- *Oracle Database Heterogeneous Connectivity User's Guide* for information on distributed transactions
- SET TRANSACTION for information on setting characteristics of the current transaction
- COMMIT and SAVEPOINT

Prerequisites
To roll back your current transaction, no privileges are necessary.

To manually roll back an in-doubt distributed transaction that you originally committed, you must have the FORCE TRANSACTION system privilege. To manually roll back an in-doubt distributed transaction originally committed by another user, you must have the FORCE ANY TRANSACTION system privilege.

Syntax

```sql
rollback ::= ROLLBACK WORK TO SAVEPOINT savepoint FORCE string ;
```

Semantics

**WORK**
The keyword WORK is optional and is provided for SQL standard compatibility.

**TO SAVEPOINT Clause**
Specify the savepoint to which you want to roll back the current transaction. If you omit this clause, then the ROLLBACK statement rolls back the entire transaction.

Using ROLLBACK without the TO SAVEPOINT clause performs the following operations:
• Ends the transaction
• Undoes all changes in the current transaction
• Erases all savepoints in the transaction
• Releases any transaction locks

See Also:
SAVEPOINT

Using ROLLBACK with the TO SAVEPOINT clause performs the following operations:
• Rolls back just the portion of the transaction after the savepoint. It does not end the transaction.
• Erases all savepoints created after that savepoint. The named savepoint is retained, so you can roll back to the same savepoint multiple times. Prior savepoints are also retained.
• Releases all table and row locks acquired since the savepoint. Other transactions that have requested access to rows locked after the savepoint must continue to wait until the transaction is committed or rolled back. Other transactions that have not already requested the rows can request and access the rows immediately.

Restriction on In-doubt Transactions
You cannot manually roll back an in-doubt transaction to a savepoint.

FORCE Clause
Specify FORCE to manually roll back an in-doubt distributed transaction. The transaction is identified by the string containing its local or global transaction ID. To find the IDs of such transactions, query the data dictionary view DBA_2PC_PENDING.

A ROLLBACK statement with a FORCE clause rolls back only the specified transaction. Such a statement does not affect your current transaction.

See Also:
Oracle Database Administrator’s Guide for more information on distributed transactions and rolling back in-doubt transactions

Examples
Rolling Back Transactions: Examples
The following statement rolls back your entire current transaction:

ROLLBACK;

The following statement rolls back your current transaction to savepoint banda_sal:

ROLLBACK TO SAVEPOINT banda_sal;
See "Creating Savepoints: Example" for a full version of the preceding example.

The following statement manually rolls back an in-doubt distributed transaction:

```
ROLLBACK WORK
FORCE '25.32.87';
```

**SAVEPOINT**

**Purpose**

Use the `SAVEPOINT` statement to create a name for a system change number (SCN), to which you can later roll back.

**See Also:**

- *Oracle Database Concepts* for information on savepoints.
- `ROLLBACK` for information on rolling back transactions
- `SET TRANSACTION` for information on setting characteristics of the current transaction

**Prerequisites**

None.

**Syntax**

```
savepoint ::= 
```

**Semantics**

`savepoint`

Specify the name of the savepoint to be created.

Savepoint names must be distinct within a given transaction. If you create a second savepoint with the same identifier as an earlier savepoint, then the earlier savepoint is erased. After a savepoint has been created, you can either continue processing, commit your work, roll back the entire transaction, or roll back to the savepoint.

**Examples**

**Creating Savepoints: Example**

To update the salary for Banda and Greene in the sample table `hr.employees`, check that the total department salary does not exceed 314,000, then reenter the salary for Greene:
UPDATE employees
    SET salary = 7000
    WHERE last_name = 'Banda';
SAVEPOINT banda_sal;

UPDATE employees
    SET salary = 12000
    WHERE last_name = 'Greene';
SAVEPOINT greene_sal;

SELECT SUM(salary) FROM employees;

ROLLBACK TO SAVEPOINT banda_sal;

UPDATE employees
    SET salary = 11000
    WHERE last_name = 'Greene';

COMMIT;

**SELECT**

**Purpose**

Use a **SELECT** statement or subquery to retrieve data from one or more tables, object tables, views, object views, materialized views, analytic views, or hierarchies.

If part or all of the result of a **SELECT** statement is equivalent to an existing materialized view, then Oracle Database may use the materialized view in place of one or more tables specified in the **SELECT** statement. This substitution is called **query rewrite**. It takes place only if cost optimization is enabled and the **QUERY_REWRITE_ENABLED** parameter is set to **TRUE**. To determine whether query rewrite has occurred, use the **EXPLAIN PLAN** statement.

**See Also:**

- **SQL Queries and Subqueries** for general information on queries and subqueries
- **Oracle Database Data Warehousing Guide** for more information on materialized views, query rewrite, and analytic views and hierarchies
- If you are querying JSON data see **Query JSON Data**
- If you are querying XML data see **Querying XML Content Stored in Oracle XML DB**
- **EXPLAIN PLAN**

**Prerequisites**

For you to select data from a table, materialized view, analytic view, or hierarchy, the object must be in your own schema or you must have the **READ** or **SELECT** privilege on the table, materialized view, analytic view, or hierarchy.

For you to select rows from the base tables of a view:
The object must be in your own schema or you must have the READ or SELECT privilege on it, and

- Whoever owns the schema containing the object must have the READ or SELECT privilege on the base tables.

The READ ANY TABLE or SELECT ANY TABLE system privilege also allows you to select data from any table, materialized view, analytic view, or hierarchy, or the base table of any materialized view, analytic view, or hierarchy.

To specify the FOR UPDATE clause, the preceding prerequisites apply with the following exception: The READ and READ ANY TABLE privileges, where mentioned, do not allow you to specify the FOR UPDATE clause.

To issue an Oracle Flashback Query using the flashback_query_clause, you must have the READ or SELECT privilege on the objects in the select list. In addition, either you must have FLASHBACK object privilege on the objects in the select list, or you must have FLASHBACK ANY TABLE system privilege.

Semantics

with_clause

Use the with_clause to define the following:

- PL/SQL procedures and functions (using the plsql_declarations clause)
- Subquery blocks (using subquery_factoring_clause or subav_factoring_clause, or both)

plsql_declarations

The plsql_declarations clause lets you declare and define PL/SQL functions and procedures. You can then reference the PL/SQL functions in the query in which you specify this clause, as well as its subqueries, if any. For the purposes of name resolution, these function names have precedence over schema-level stored functions.

If the query in which you specify this clause is not a top-level SELECT statement, then the following rules apply to the top-level SQL statement that contains the query:

- If the top-level statement is a SELECT statement, then it must have either a WITH plsql_declarations clause or the WITH_PLSQL hint.
- If the top-level statement is a DELETE, MERGE, INSERT, or UPDATE statement, then it must have the WITH_PLSQL hint.

The WITH_PLSQL hint only enables you to specify the WITH plsql_declarations clause within the statement. It is not an optimizer hint.

See Also:

- Oracle Database PL/SQL Language Reference for syntax and restrictions for function_declaration and procedure_declaration.
- “Using a PL/SQL Function in the WITH Clause: Examples”

subquery_factoring_clause

The subquery_factoring_clause lets you assign a name (query_name) to a subquery block. You can then reference the subquery block multiple places in the query by specifying query_name. Oracle Database optimizes the query by treating the query_name as either an inline view or as a temporary table. The query_name is subject to the same naming conventions and restrictions as database schema objects. Refer to “Database Object Naming Rules ” for information on database object names.
The column aliases following the `query_name` and the set operators separating multiple subqueries in the `AS` clause are valid and required for recursive subquery factoring. The `search_clause` and `cycle_clause` are valid only for recursive subquery factoring but are not required. See "Recursive Subquery Factoring".

You can specify this clause in any top-level `SELECT` statement and in most types of subqueries. The query name is visible to the main query and to all subsequent subqueries. For recursive subquery factoring, the query name is even visible to the subquery that defines the query name itself.

**Recursive Subquery Factoring**

If a `subquery_factoring_clause` refers to its own `query_name` in the subquery that defines it, then the `subquery_factoring_clause` is said to be **recursive**. A recursive `subquery_factoring_clause` must contain two query blocks: the first is the **anchor member** and the second is the **recursive member**. The anchor member must appear before the recursive member, and it cannot reference `query_name`. The anchor member can be composed of one or more query blocks combined by the set operators: `UNION ALL`, `UNION`, `INTERSECT` or `MINUS`. The recursive member must follow the anchor member and must reference `query_name` exactly once. You must combine the recursive member with the anchor member using the `UNION ALL` set operator.

The number of column aliases following `WITH query_name` and the number of columns in the `SELECT` lists of the anchor and recursive query blocks must be the same.

The recursive member cannot contain any of the following elements:

- The `DISTINCT` keyword or a `GROUP BY` clause
- The `model_clause`
- An aggregate function. However, analytic functions are permitted in the select list.
- Subqueries that refer to `query_name`.
- Outer joins that refer to `query_name` as the right table.

In previous releases of Oracle Database, the recursive member of a recursive `WITH` clause ran serially regardless of the parallelism of the entire query (also known as the top-level `SELECT` statement). Beginning with Oracle Database 12c Release 2 (12.2), the recursive member runs in parallel if the optimizer determines that the top-level `SELECT` statement can be executed in parallel.

**search_clause**

Use the `SEARCH` clause to specify an ordering for the rows.

- Specify `BREADTH FIRST BY` if you want sibling rows returned before any child rows are returned.
- Specify `DEPTH FIRST BY` if you want child rows returned before any siblings rows are returned.
- Sibling rows are ordered by the columns listed after the `BY` keyword.
- The `c_alias` list following the `SEARCH` keyword must contain column names from the column alias list for `query_name`.
- The `ordering_column` is automatically added to the column list for the query name. The query that selects from `query_name` can include an `ORDER BY` on
ordering_column to return the rows in the order that was specified by the SEARCH clause.

cycle_clause

Use the CYCLE clause to mark cycles in the recursion.

- The c_alias list following the CYCLE keyword must contain column names from the column alias list for query_name. Oracle Database uses these columns to detect a cycle.
- cycle_value and no_cycle_value should be character strings of length 1.
- If a cycle is detected, then the cycle mark column specified by cycle_mark_c_alias for the row causing the cycle is set to the value specified for cycle_value. The recursion will then stop for this row. That is, it will not look for child rows for the offending row, but it will continue for other noncyclic rows.
- If no cycles are found, then the cycle mark column is set to the default value specified for no_cycle_value.
- The cycle mark column is automatically added to the column list for the query_name.
- A row is considered to form a cycle if one of its ancestor rows has the same values for the cycle columns.

If you omit the CYCLE clause, then the recursive WITH clause returns an error if cycles are discovered. In this case, a row forms a cycle if one of its ancestor rows has the same values for all the columns in the column alias list for query_name that are referenced in the WHERE clause of the recursive member.

Restrictions on Subquery Factoring

This clause is subject to the following restrictions:

- You can specify only one subquery_factoring_clause in a single SQL statement. Any query_name defined in the subquery_factoring_clause can be used in any subsequent named query block in the subquery_factoring_clause.
- In a compound query with set operators, you cannot use the query_name for any of the component queries, but you can use the query_name in the FROM clause of any of the component queries.
- You cannot specify duplicate names in the column alias list for query_name.
- The name used for the ordering_column has to be different from the name used for cycle_mark_c_alias.
- The ordering_column and cycle mark column names cannot already be in the column alias list for query_name.

See Also:

- Oracle Database Concepts for information about inline views
- "Subquery Factoring: Example"
- "Recursive Subquery Factoring: Examples"
**subav_factoring_clause**

With the `subav_factoring_clause`, you can define a transitory analytic view that filters fact data prior to aggregation or adds calculated measures to a query of an analytic view. The `subav_name` argument assigns a name to the transitory analytic view. You can then reference the transitory analytic view multiple places in the query by specifying `subav_name`. The `subav_name` is subject to the same naming conventions and restrictions as database schema objects. Refer to "Database Object Naming Rules" for information on database object names.

You can specify this clause in any top-level `SELECT` statement and in most types of subqueries. The query name is visible to the main query and to all subsequent subqueries.

The `subav_clause` argument defines a transitory analytic view.

**subav_clause**

With the `USING` keyword, specify the name of an analytic view, which may be a transitory analytic view previously defined in the `WITH` clause or it may be a persistent analytic view. A persistent analytic view is defined in a `CREATE ANALYTIC VIEW` statement. If the analytic view is a persistent one, then the current user must have select access on it.

> See Also:

Analytic Views: Examples

**hierarchies_clause**

The `hierarchies_clause` specifies the hierarchies of the base analytic view that the results of the transitory analytic view are dimensioned by. With the `HIERARCHIES` keyword, specify the alias of one or more hierarchies of the base analytic view.

If you do not specify a `HIERARCHIES` clause, then the default hierarchies of the base analytic view are used.

**filter_clauses**

You may specify a given `hier_alias` in at most one `filter_clause`.

**filter_clause**

The filter clause applies the specified predicate condition to the fact table, which reduces the number of rows returned from the table before aggregation of the measure values. The predicate may contain any SQL row function or operation. The predicate may refer to any attribute of the specified hierarchy or it may refer to a measure of the analytic view if you specify the `MEASURES` keyword.

For example, the following clause restricts the aggregation of measure values to those for the first and second quarters of every year of a time hierarchy.

```
FILTER FACT (time_hier TO quarter_of_year IN (1,2))
```
If you then select from the transitory analytic view the sales for the years 2000 and 2001, the values returned are the aggregated values of the first and second quarters only.

An example of specifying a predicate for a measure in the filter clause is the following.

FILTER FACT (MEASURES TO sales BETWEEN 100 AND 200)

attr_dim_alias

The alias of an attribute dimension in the base analytic view. The USER_ANALYTIC_VIEW_DIMENSIONS view contains the aliases of the attribute dimensions in an analytic view.

hier_alias

The alias of a hierarchy in the base analytic view. The USER_ANALYTIC_VIEW_HIERS view contains the aliases of the hierarchies in an analytic view.

add_calcs_clause

With the ADD MEASURES keywords, you may add calculated measures to the transitory analytic view.

calc_meas_clause

Specify a name for the calculated measure and an analytic view expression that specifies values for the calculated measure. The analytic view expression can be any valid calc_meas_expression as described in Analytic View Expressions. For example, the following adds a calculated measure named "share_sales."

ADD MEASURES (share_sales AS (SHARE_OF(sales HIERARCHY time_hier PARENT)))

hint

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

See Also:

"Hints " for the syntax and description of hints

DISTINCT | UNIQUE

Specify DISTINCT or UNIQUE if you want the database to return only one copy of each set of duplicate rows selected. These two keywords are synonymous. Duplicate rows are those with matching values for each expression in the select list.

Restrictions on DISTINCT and UNIQUE Queries

These types of queries are subject to the following restrictions:
• When you specify DISTINCT or UNIQUE, the total number of bytes in all select list expressions is limited to the size of a data block minus some overhead. This size is specified by the initialization parameter DB_BLOCK_SIZE.

• You cannot specify DISTINCT if the select_list contains LOB columns.

ALL

Specify ALL if you want the database to return all rows selected, including all copies of duplicates. The default is ALL.

select_list

The select_list lets you specify the columns you want to retrieve from the database.

* (all-column wildcard)

Specify the all-column wildcard (asterisk) to select all columns, excluding pseudocolumns and INVISIBLE columns, from all tables, views, or materialized views listed in the FROM clause. The columns are returned in the order indicated by the COLUMN_ID column of the *_TAB_COLUMNS data dictionary view for the table, view, or materialized view.

If you are selecting from a table rather than from a view or a materialized view, then columns that have been marked as UNUSED by the ALTER TABLE SET UNUSED statement are not selected.

See Also:
ALTER TABLE, "Simple Query Examples", and "Selecting from the DUAL Table: Example"

query_name.*

Specify query_name followed by a period and the asterisk to select all columns from the specified subquery block. For query_name, specify a subquery block name already specified in the subquery_factoring_clause. You must have specified the subquery_factoring_clause in order to specify query_name in the select_list. If you specify query_name in the select_list, then you also must specify query_name in the query_table_expression (FROM clause).

table.* | view.* | materialized view.*

Specify the object name followed by a period and the asterisk to select all columns from the specified table, view, or materialized view. Oracle Database returns a set of columns in the order in which the columns were specified when the object was created. A query that selects rows from two or more tables, views, or materialized views is a join.

You can use the schema qualifier to select from a table, view, or materialized view in a schema other than your own. If you omit schema, then the database assumes the table, view, or materialized view is in your own schema.

### See Also:

"Joins"

#### t_alias .*

Specify a correlation name (alias) followed by a period and the asterisk to select all columns from the object with that correlation name specified in the FROM clause of the same subquery. The object can be a table, view, materialized view, or subquery. Oracle Database returns a set of columns in the order in which the columns were specified when the object was created. A query that selects rows from two or more objects is a join.

#### expr

Specify an expression representing the information you want to select. A column name in this list can be qualified with schema only if the table, view, or materialized view containing the column is qualified with schema in the FROM clause. If you specify a member method of an object type, then you must follow the method name with parentheses even if the method takes no arguments.

The expression can also hold a scalar value that can be return values of PL/SQL functions, subqueries that return a single value per row, and SQL macros.

#### c_alias

Specify an alias for the column expression. Oracle Database will use this alias in the column heading of the result set. The AS keyword is optional. The alias effectively renames the select list item for the duration of the query. The alias can be used in the order_by_clause but not other clauses in the query.

---

### See Also:

- Oracle Database Data Warehousing Guide for information on using the `expr AS c_alias` syntax with the `UNION ALL` operator in queries of multiple materialized views
- “About SQL Expressions” for the syntax of `expr`

---

### Restrictions on the Select List

The select list is subject to the following restrictions:

- If you also specify a `group_by_clause` in this statement, then this select list can contain only the following types of expressions:
  - Constants
  - Aggregate functions and the functions `USER`, `UID`, and `SYSDATE`
  - Expressions identical to those in the `group_by_clause`. If the `group_by_clause` is in a subquery, then all columns in the select list of the subquery must match the `GROUP BY` columns in the subquery. If the select list and `GROUP BY` columns
of a top-level query or of a subquery do not match, then the statement results in ORA-00979.

- Expressions involving the preceding expressions that evaluate to the same value for all rows in a group

- You can select a rowid from a join view only if the join has one and only one key-preserved table. The rowid of that table becomes the rowid of the view.

See Also:

Oracle Database Administrator's Guide for information on key-preserved tables

- If two or more tables have some column names in common, and if you are specifying a join in the FROM clause, then you must qualify column names with names of tables or table aliases.

FROM Clause

The FROM clause lets you specify the objects from which data is selected.

You can invoke a polymorphic table function (PTF) in the query block of the FROM clause like other existing table functions. A PTF is a table function whose operands can have more than one type.

Starting with Oracle Database Release 19c, version 19.7, you can write table valued macros and use them inside the FROM clause, where it would be legal to call a PL/SQL function. SQL table macros are expressions, typically used in a FROM clause, to act like a kind of polymorphic (parameterized) views. You must define these macro functions in PL/SQL and call them from SQL for them to function as macros.

See Also:

- PL/SQL Optimaztion and Tuning
- SQL Macro Clause

ONLY

The ONLY clause applies only to views. Specify ONLY if the view in the FROM clause is a view belonging to a hierarchy and you do not want to include rows from any of its subviews.

query_table_expression

Use the query_table_expression clause to identify a subquery block, table, view, materialized view, analytic view, hierarchy, partition, or subpartition, or to specify a subquery that identifies the objects. In order to specify a subquery block, you must have specified the subquery block name (query_name in the subquery_factoring_clause or subav_name in the subav_factoring_clause).
The analytic view in the expression may be a transitory analytic view defined in the `with_clause` or a persistent analytic view.

---

**See Also:**

"Using Subqueries: Examples"

---

**LATERAL**

Specify LATERAL to designate `subquery` as a lateral inline view. Within a lateral inline view, you can specify tables that appear to the left of the lateral inline view in the `FROM` clause of a query. You can specify this left correlation anywhere within `subquery` (such as the `SELECT`, `FROM`, and `WHERE` clauses) and at any nesting level.

**Restrictions on LATERAL**

Lateral inline views are subject to the following restrictions:

- If you specify LATERAL, then you cannot specify the `pivot_clause`, the `unpivot_clause`, or a pattern in the `table_reference` clause.
- If a lateral inline view contains the `query_partition_clause`, and it is the right side of a join clause, then it cannot contain a left correlation to the left table in the join clause. However, it can contain a left correlation to a table to its left in the `FROM` clause that is not the left table.
- A lateral inline view cannot contain a left correlation to the first table in a right outer join or full outer join.

---

**See Also:**

"Using Lateral Inline Views: Example"

---

**inline_external_table**

Specify this clause to inline an external table in a query. You must specify the table columns and properties for the external table that will be inlined in the query.

**inline_external_table_properties**

This clause extends the `external_table_data_props` with the `REJECT LIMIT` and `access_driver_type` options. Use this clause to specify the properties of the external table.

In addition to supporting external data residing in operating file systems and Big Data sources and formats such as HDFS and Hive, Oracle supports external data residing in objects.

**modified_external_table**

You can use this clause to override some external table properties specified by the `CREATE TABLE` or `ALTER TABLE` statements from within a query.
You can override external table parameters at runtime.

**Restrictions**

- You must specify the key words `EXTERNAL MODIFY` in the query. If you do not specify the keywords, you will see a Missing or invalid option error.

- You must reference an external table in the query. If you do not, you will see an error.

- You must specify at least one property in the query. One of `DEFAULT DIRECTORY`, `LOCATION`, `ACCESS PARAMETERS`, or `REJECT LIMIT`.

- If you specify more than one external table properties, they must be listed in order. First the `DEFAULT DIRECTORY` must be specified, followed by the `ACCESS PARAMETERS`, `LOCATION` and `REJECT LIMIT`. Otherwise an error will be raised.

- In the `DEFAULT DIRECTORY` clause, you must specify only one proper default directory. Otherwise a Missing DEFAULT keyword error will occur.

- You must enclose a filename in the `LOCATION` clause within quotes. Otherwise a Missing keyword error will occur. Note that the access driver will decide whether or not to allow a `LOCATION` clause in the query. If the clause is disallowed for a particular access driver, an error will be raised.

- For `ORACLE_LOADER` and `ORACLE_DATAPUMP` access drivers, the external file location in the `LOCATION` clause must be specified in the following format: directory: location, i.e, the directory and location must be separated by a colon. Multiple locations in the clause must be separated by a comma. Otherwise, a Missing keyword error will occur.

- Note that `LOCATION` will be made optional in `CREATE TABLE`, and must be specified either when creating or querying the external table. Otherwise an error will be raised in the access driver.

- When populating external data using `ORACLE_DATAPUMP` via CTS, the external file location must be specified. This will be the only case where `LOCATION` clause is mandatory in `CREATE TABLE`.

- When overriding access parameters, a proper access parameter list must be provided in the `ACCESS PARAMETERS` clause, with enclosing parentheses.

  Note that the syntax and allowable values for the access parameters in the `modified_external_table` clause are the same as for the external table DDL for each access driver. For more see Oracle Database Utilities for additional details regarding syntax and permissible values.

- If you specify the `REJECT LIMIT`, then it must either be `UNLIMITED` or some valid value that is within range. Otherwise a Reject limit out of range error will be raised.

**modify_external_table_properties**

You can specify the external table properties that you want to modify at run time using this clause. The parameters that you can modify are `DEFAULT DIRECTORY`, `LOCATION`, `ACCESS PARAMETERS` (BADFILE, LOGFILE, DISCARDFILE) and `REJECT LIMIT`.

**Example: Overriding External Table Parameters in a Query**

```sql
SELECT * FROM
sales_external EXTERNAL MODIFY (LOCATION 'sales_9.csv' REJECT LIMIT UNLIMITED);
```
**flashback_query_clause**

Use the `flashback_query_clause` to retrieve data from a table, view, or materialized view based on time dimensions associated with the data.

This clause implements SQL-driven Flashback, which lets you specify the following:

- A different system change number or timestamp for each object in the select list, using the clauses `VERSIONS BETWEEN { SCN | TIMESTAMP }` or `VERSIONS AS OF { SCN | TIMESTAMP }`. You can also implement session-level Flashback using the `DBMS_FLASHBACK` package.
- A valid time period for each object in the select list, using the clauses `VERSIONS PERIOD FOR` or `AS OF PERIOD FOR`. You can also implement valid-time session-level Flashback using the `DBMS_FLASHBACK_ARCHIVE` package.

A Flashback Query lets you retrieve a history of changes made to a row. You can retrieve the corresponding identifier of the transaction that made the change using the `VERSIONS_XID` pseudocolumn. You can also retrieve information about the transaction that resulted in a particular row version by issuing an Oracle Flashback Transaction Query. You do this by querying the `FLASHBACK_TRANSACTION_QUERY` data dictionary view for a particular transaction ID.

**VERSIONS BETWEEN { SCN | TIMESTAMP }**

Specify `VERSIONS BETWEEN` to retrieve multiple versions of the rows returned by the query. Oracle Database returns all committed versions of the rows that existed between two SCNs or between two timestamp values. The first specified SCN or timestamp must be earlier than the second specified SCN or timestamp. The rows returned include deleted and subsequently reinserted versions of the rows.

- Specify `VERSIONS BETWEEN SCN ...` to retrieve the versions of the row that existed between two SCNs. Both expressions must evaluate to a number and cannot evaluate to NULL. `MINVALUE` and `MAXVALUE` resolve to the SCN of the oldest and most recent data available, respectively.
- Specify `VERSIONS BETWEEN TIMESTAMP ...` to retrieve the versions of the row that existed between two timestamps. Both expressions must evaluate to a timestamp value and cannot evaluate to NULL. `MINVALUE` and `MAXVALUE` resolve to the timestamp of the oldest and most recent data available, respectively.

**AS OF { SCN | TIMESTAMP }**

Specify `AS OF` to retrieve the single version of the rows returned by the query at a particular change number (SCN) or timestamp. If you specify `SCN`, then `expr` must evaluate to a number. If you specify `TIMESTAMP`, then `expr` must evaluate to a timestamp value. In either case, `expr` cannot evaluate to NULL. Oracle Database returns rows as they existed at the specified system change number or time.

Oracle Database provides a group of version query pseudocolumns that let you retrieve additional information about the various row versions. Refer to "Version Query Pseudocolumns" for more information.

When both clauses are used together, the `AS OF` clause determines the SCN or moment in time from which the database issues the query. The `VERSIONS` clause determines the versions of the rows as seen from the `AS OF` point. The database returns null for a row version if the transaction started before the first `BETWEEN` value or ended after the `AS OF` point.
VERSIONS PERIOD FOR

Specify VERSIONS PERIOD FOR to retrieve rows from table based on whether they are considered valid during the specified time period. In order to use this clause, table must support Temporal Validity.

- For valid_time_column, specify the name of the valid time dimension column for table.
- Use the BETWEEN clause to specify the time period during which rows are considered valid. Both expressions must evaluate to a timestamp value and cannot evaluate to NULL. MINVALUE resolves to the earliest date or timestamp in the start time column of table. MAXVALUE resolves to latest date or timestamp in the end time column of table.

AS OF PERIOD FOR

Specify AS OF PERIOD FOR to retrieve rows from table based on whether they are considered valid as of the specified time. In order to use this clause, table must support Temporal Validity.

- For valid_time_column, specify the name of the valid time dimension column for table.
- Use expr to specify the time as of which rows are considered valid. The expression must evaluate to a timestamp value and cannot evaluate to NULL.

See Also:

- Oracle Database Development Guide for more information on Temporal Validity
- CREATE TABLE period_definition to learn how to configure a table to support Temporal Validity and for information about the valid_time_column, start time column, and end time column

Note on Flashback Queries

When performing a flashback query, Oracle Database might not use query optimizations that it would use for other types of queries, which could have a negative impact on performance. In particular, this occurs when you specify multiple flashback queries in a hierarchical query.

Restrictions on Flashback Queries

These queries are subject to the following restrictions:

- You cannot specify a column expression or a subquery in the expression of the AS OF clause.
- You cannot specify the AS OF clause if you have specified the for_update_clause.
- You cannot use the AS OF clause in the defining query of a materialized view.
- You cannot use the VERSIONS clause in flashback queries to temporary or external tables, or tables that are part of a cluster.
• You cannot use the VERSIONS clause in flashback queries to views. However, you can use the VERSIONS syntax in the defining query of a view.

• You cannot specify the flashback_query_clause if you have specified query_name in the query_table_expression.

See Also:

• *Oracle Database Development Guide* for more information on Oracle Flashback Query

• "Using Flashback Queries: Example"

• *Oracle Database Development Guide* and *Oracle Database PL/SQL Packages and Types Reference* for information about session-level Flashback using the DBMS_FLASHBACK package

• *Oracle Database Administrator’s Guide* and to the description of FLASHBACK_TRANSACTION_QUERY in the *Oracle Database Reference* for more information about transaction history

partition_extension_clause

For PARTITION or SUBPARTITION, specify the name or key value of the partition or subpartition within table from which you want to retrieve data.

For range- and list-partitioned data, as an alternative to this clause, you can specify a condition in the WHERE clause that restricts the retrieval to one or more partitions of table. Oracle Database will interpret the condition and fetch data from only those partitions. It is not possible to formulate such a WHERE condition for hash-partitioned data.

See Also:

"References to Partitioned Tables and Indexes " and “Selecting from a Partition: Example”

dblink

For dblink, specify the complete or partial name for a database link to a remote database where the table, view, or materialized view is located. This database need not be an Oracle Database.

See Also:

• "References to Objects in Remote Databases " for more information on referring to database links

• "Distributed Queries " for more information about distributed queries and "Using Distributed Queries: Example"
If you omit `dblink`, then the database assumes that the table, view, or materialized view is on the local database.

**Restrictions on Database Links**

Database links are subject to the following restrictions:

- You cannot query a user-defined type or an object `REF` on a remote table.
- You cannot query columns of type `ANYTYPE`, `ANYDATA`, or `ANYDATASET` from remote tables.

**table | view | materialized_view | analytic_view | hierarchy**

Specify the name of a table, view, materialized view, analytic view, or hierarchy from which data is selected.

**analytic_view**

A persistent analytic view defined with the `CREATE ANALYTIC VIEW` statement or a transitory analytic view defined in a `WITH` clause.

- [See Also: Analytic Views: Examples]

**hierarchy**

A hierarchy defined with the `CREATE HIERARCHY` statement.

**sample_clause**

The `sample_clause` lets you instruct the database to select from a random sample of data from the table, rather than from the entire table.

- [See Also: "Selecting a Sample: Examples"]

**BLOCK**

`BLOCK` instructs the database to attempt to perform random block sampling instead of random row sampling.

Block sampling is possible only during full table scans or index fast full scans. If a more efficient execution path exists, then Oracle Database does not perform block sampling. If you want to guarantee block sampling for a particular table or index, then use the `FULL` or `INDEX_FFS` hint.

Beginning with Oracle Database 12c Release 2 (12.2.), you can specify block sampling for external tables. In earlier releases, specifying block sampling for external tables had no effect; row sampling was performed.

**sample_percent**
For \textit{sample\_percent}, specify the percentage of the total row or block count to be included in the sample. The value must be in the range .000001 to, but not including, 100. This percentage indicates the probability of each row, or each cluster of rows in the case of block sampling, being selected as part of the sample. It does not mean that the database will retrieve exactly \textit{sample\_percent} of the rows of \textit{table}.

\begin{quote}
\textbf{WARNING:}

The use of statistically incorrect assumptions when using this feature can lead to incorrect or undesirable results.
\end{quote}

\textbf{SEED} \textit{seed\_value}

Specify this clause to instruct the database to attempt to return the same sample from one execution to the next. The \textit{seed\_value} must be an integer between 0 and 4294967295. If you omit this clause, then the resulting sample will change from one execution to the next.

\textbf{Restrictions on sample\_clause}

The following restrictions apply to the \textit{SAMPLE clause}:

- You cannot specify the \textit{SAMPLE clause} in a subquery in a DML statement.
- You can specify the \textit{SAMPLE clause} in a query on a base table, a container table of a materialized view, or a view that is key preserving. You cannot specify this clause on a view that is not key preserving.

\textit{subquery\_restriction\_clause}

The \textit{subquery\_restriction\_clause} lets you restrict the subquery in one of the following ways:

\textbf{WITH READ ONLY}

Specify \textbf{WITH READ ONLY} to indicate that the table or view cannot be updated.

\textbf{WITH CHECK OPTION}

Specify \textbf{WITH CHECK OPTION} to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the \textit{FROM clause} but not in subquery in the \textit{WHERE clause}.

\textbf{CONSTRAINT} \textit{constraint}

Specify the name of the \textit{CHECK OPTION} constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form \textit{SYS\_Cn}, where \textit{n} is an integer that makes the constraint name unique within the database.

\begin{quote}
\textbf{See Also:}

"Using the WITH CHECK OPTION Clause: Example"
\end{quote}
The table_collection_expression lets you inform Oracle that the value of collection_expression should be treated as a table for purposes of query and DML operations. The collection_expression can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called collection unnesting.

The optional plus (+) is relevant if you are joining the table_collection_expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

---

**Note:**

In earlier releases of Oracle, when collection_expression was a subquery, table_collection_expression was expressed as THE subquery. That usage is now deprecated.

---

The collection_expression can reference columns of tables defined to its left in the FROM clause. This is called left correlation. Left correlation can occur only in table_collection_expression. Other subqueries cannot contain references to columns defined outside the subquery.

The optional (+) lets you specify that table_collection_expression should return a row with all fields set to null if the collection is null or empty. The (+) is valid only if collection_expression uses left correlation. The result is similar to that of an outer join.

When you use the (+) syntax in the WHERE clause of a subquery in an UPDATE or DELETE operation, you must specify two tables in the FROM clause of the subquery. Oracle Database ignores the outer join syntax unless there is a join in the subquery itself.

---

See Also:

- "Outer Joins"
- "Table Collections: Examples" and "Collection Unnesting: Examples"

---

**t_alias**

Specify a correlation name, which is an alias for the table, view, materialized view, or subquery for evaluating the query. This alias is required if the select list references any object type attributes or object type methods. Correlation names are most often used in a correlated query. Other references to the table, view, or materialized view throughout the query must refer to this alias.
pivot_clause

The pivot_clause lets you write cross-tabulation queries that rotate rows into columns, aggregating data in the process of the rotation. The output of a pivot operation typically includes more columns and fewer rows than the starting data set. The pivot_clause performs the following steps:

1. The pivot_clause computes the aggregation functions specified at the beginning of the clause. Aggregation functions must specify a GROUP BY clause to return multiple values, yet the pivot_clause does not contain an explicit GROUP BY clause. Instead, the pivot_clause performs an implicit GROUP BY. The implicit grouping is based on all the columns not referred to in the pivot_clause, along with the set of values specified in the pivot_in_clause. If you specify more than one aggregation function, then you must provide aliases for at least all but one of the aggregation functions.

2. The grouping columns and aggregated values calculated in Step 1 are configured to produce the following cross-tabular output:
   a. All the implicit grouping columns not referred to in the pivot_clause, followed by
   b. New columns corresponding to values in the pivot_in_clause. Each aggregated value is transposed to the appropriate new column in the cross-tabulation. If you specify the XML keyword, then the result is a single new column that expresses the data as an XML string. The database generates a name for each new column. If you do not provide an alias for an aggregation function, then the database uses each pivot column value as the name for each new column to which that aggregated value is transposed. If you provide an alias for an aggregation function, then the database generates a name for each new column to which that aggregated value is transposed by concatenating the pivot column name, the underscore character (_), and the aggregation function alias. If a generated column name exceeds the maximum length of a column name, then an ORA-00918 error is returned. To avoid this issue, specify a shorter alias for the pivot column heading, the aggregation function, or both.

The subclauses of the pivot_clause have the following semantics:

XML

The optional XML keyword generates XML output for the query. The XML keyword permits the pivot_in_clause to contain either a subquery or the wildcard keyword ANY. Subqueries and ANY wildcards are useful when the pivot_in_clause values are not known in advance. With XML output, the values of the pivot column are evaluated at execution time. You cannot specify XML when you specify explicit pivot values using expressions in the pivot_in_clause.

When XML output is generated, the aggregate function is applied to each distinct pivot value, and the database returns a column of XMLType containing an XML string for all value and measure pairs.
expr

For expr, specify an expression that evaluates to a constant value of a pivot column. You can optionally provide an alias for each pivot column value. If there is no alias, the column heading becomes a quoted identifier.

subquery

A subquery is used only in conjunction with the XML keyword. When you specify a subquery, all values found by the subquery are used for pivoting. The output is not the same cross-tabular format returned by non-XML pivot queries. Instead of multiple columns specified in the pivot_in_clause, the subquery produces a single XML string column. The XML string for each row holds aggregated data corresponding to the implicit GROUP BY value of that row. The XML string for each output row includes all pivot values found by the subquery, even if there are no corresponding rows in the input data.

The subquery must return a list of unique values at the execution time of the pivot query. If the subquery does not return a unique value, then Oracle Database raises a run-time error. Use the DISTINCT keyword in the subquery if you are not sure the query will return unique values.

ANY

The ANY keyword is used only in conjunction with the XML keyword. The ANY keyword acts as a wildcard and is similar in effect to subquery. The output is not the same cross-tabular format returned by non-XML pivot queries. Instead of multiple columns specified in the pivot_in_clause, the ANY keyword produces a single XML string column. The XML string for each row holds aggregated data corresponding to the implicit GROUP BY value of that row. However, in contrast to the behavior when you specify subquery, the ANY wildcard produces an XML string for each output row that includes only the pivot values found in the input data corresponding to that row.

Oracle Database Data Warehousing Guide for more information about PIVOT and UNPIVOT and "Using PIVOT and UNPIVOT: Examples"

unpivot_clause

The unpivot_clause rotates columns into rows.

• The INCLUDE | EXCLUDE NULLS clause gives you the option of including or excluding null-valued rows. INCLUDE NULLS causes the unpivot operation to include null-valued rows; EXCLUDE NULLS eliminates null-values rows from the return set. If you omit this clause, then the unpivot operation excludes nulls.

• For column, specify a name for each output column that will hold measure values, such as sales_quantity.

• In the pivot_for_clause, specify a name for each output column that will hold descriptor values, such as quarter or product.

• In the unpivot_in_clause, specify the input data columns whose names will become values in the output columns of the pivot_for_clause. These input data columns have names specifying a category value, such as Q1, Q2, Q3, Q4. The
optional `AS` clause lets you map the input data column names to the specified literal values in the output columns.

The unpivot operation turns a set of value columns into one column. Therefore, the data types of all the value columns must be in the same data type group, such as numeric or character.

- If all the value columns are `CHAR`, then the unpivoted column is `CHAR`. If any value column is `VARCHAR2`, then the unpivoted column is `VARCHAR2`.
- If all the value columns are `NUMBER`, then the unpivoted column is `NUMBER`. If any value column is `BINARY_DOUBLE`, then the unpivoted column is `BINARY_DOUBLE`. If no value column is `BINARY_DOUBLE` but any value column is `BINARY_FLOAT`, then the unpivoted column is `BINARY_FLOAT`.

**containers_clause**

The `CONTAINERS` clause is useful in a multitenant container database (CDB). This clause lets you query data in the specified table or view across all containers in a CDB.

- To query data in a CDB, you must be a common user connected to the CDB root, and the table or view must exist in the root and all PDBs. The query returns all rows from the table or view in the CDB root and in all open PDBs.
- To query data in an application container, you must be a common user connected to the application root, and the table or view must exist in the application root and all PDBs in the application container. The query returns all rows from the table or view in the application root and in all open PDBs in the application container.

The table or view must be in your own schema. It is not necessary to specify `schema`, but if you do then you must specify your own schema.

The query returns all rows from the table or view in the root and in all open PDBs, except PDBs that are open in `RESTRICTED` mode. If the queried table or view does not already contain a `CON_ID` column, then the query adds a `CON_ID` column to the query result, which identifies the container whose data a given row represents.

**shards_clause**

Use the `shards_clause` to query Oracle supplied objects such as `V$`, `DBA/USER/ALL` views, and dictionary tables across shards. You can execute a query with the `shards_clause` only on the shard catalog database.

This feature enables easier centralized management by providing the ability to execute queries across all shards from a central shard catalog.
**join_clause**

Use the appropriate `join_clause` syntax to identify tables that are part of a join from which to select data. The `inner_cross_join_clause` lets you specify an inner or cross join. The `outer_join_clause` lets you specify an outer join. The `cross_outer_apply_clause` lets you specify a variation of an ANSI `CROSS JOIN` or an ANSI `LEFT OUTER JOIN` with left correlation support.

When you join more than two row sources, you can use parentheses to override default precedence. For example, the following syntax:

```
SELECT ... FROM a JOIN (b JOIN c) ...
```

results in a join of `b` and `c`, and then a join of that result set with `a`.

**See Also:**

**inner_cross_joinClause**

Inner joins return only those rows that satisfy the join condition.

**INNER**

Specify `INNER` to explicitly specify an inner join.

**JOIN**

The `JOIN` keyword explicitly states that a join is being performed. You can use this syntax to replace the comma-delimited table expressions used in `WHERE` clause joins with `FROM` clause join syntax.

**ON condition**

Use the `ON` clause to specify a join condition. Doing so lets you specify join conditions separate from any search or filter conditions in the `WHERE` clause.

**USING (column)**

When you are specifying an equijoin of columns that have the same name in both tables, the `USING column` clause indicates the columns to be used. You can use this clause only if the join columns in both tables have the same name. Within this clause, do not qualify the column name with a table name or table alias.

**CROSS**

The `CROSS` keyword indicates that a cross join is being performed. A cross join produces the cross-product of two relations and is essentially the same as the comma-delimited Oracle Database notation.

**NATURAL**

The `NATURAL` keyword indicates that a natural join is being performed. Refer to `NATURAL` for the full semantics of this clause.
**outer_join_clause**

Outer joins return all rows that satisfy the join condition and also return some or all of those rows from one table for which no rows from the other satisfy the join condition. You can specify two types of outer joins: a conventional outer join using the `table_reference` syntax on both sides of the join, or a partitioned outer join using the `query_partition_clause` on one side or the other. A partitioned outer join is similar to a conventional outer join except that the join takes place between the outer table and each partition of the inner table. This type of join lets you selectively make sparse data more dense along the dimensions of interest. This process is called **data densification**.

**query_partition_clause**

The `query_partition_clause` lets you define a **partitioned outer join**. Such a join extends the conventional outer join syntax by applying the outer join to partitions returned by the query. Oracle Database creates a partition of rows for each expression you specify in the `PARTITION BY` clause. The rows in each query partition have same value for the `PARTITION BY` expression.

The `query_partition_clause` can be on either side of the outer join. The result of a partitioned outer join is a **UNION** of the outer joins of each of the partitions in the partitioned result set and the table on the other side of the join. This type of result is useful for filling gaps in sparse data, which simplifies analytic calculations.

If you omit this clause, then the database treats the entire table expression —everything specified in `table_reference`—as a single partition, resulting in a conventional outer join.

To use the `query_partition_clause` in an analytic function, use the upper branch of the syntax (without parentheses). To use this clause in a model query (in the `model_column_clauses`) or a partitioned outer join (in the `outer_join_clause`), use the lower branch of the syntax (with parentheses).

**Restrictions on Partitioned Outer Joins**

Partitioned outer joins are subject to the following restrictions:

- You can specify the `query_partition_clause` on either the right or left side of the join, but not both.
- You cannot specify a **FULL** partitioned outer join.
- If you specify the `query_partition_clause` in an outer join with an `ON` clause, then you cannot specify a subquery in the `ON` condition.

> See Also:

"Using Partitioned Outer Joins: Examples"

**NATURAL**

The **NATURAL** keyword indicates that a natural join is being performed. A natural join is based on all columns in the two tables that have the same name. It selects rows from the two tables that have equal values in the relevant columns. If two columns
with the same name do not have compatible data types, then an error is raised. When specifying columns that are involved in the natural join, do not qualify the column name with a table name or table alias.

On occasion, the table pairings in natural or cross joins may be ambiguous. For example, consider the following join syntax:

\[ a \text{ NATURAL LEFT JOIN } b \text{ LEFT JOIN } c \text{ ON } b.c1 = c.c1 \]

This example can be interpreted in either of the following ways:

\[ a \text{ NATURAL LEFT JOIN } (b \text{ LEFT JOIN } c \text{ ON } b.c1 = c.c1) \]
\[ (a \text{ NATURAL LEFT JOIN } b) \text{ LEFT JOIN } c \text{ ON } b.c1 = c.c1 \]

To avoid this ambiguity, you can use parentheses to specify the pairings of joined tables. In the absence of such parentheses, the database uses left associativity, pairing the tables from left to right.

**Restriction on Natural Joins**

You cannot specify a LOB column, columns of `ANYTYPE`, `ANYDATA`, or `ANYDATASET`, or a collection column as part of a natural join.

**outer_join_type**

The `outer_join_type` indicates the kind of outer join being performed:

- Specify `RIGHT` to indicate a right outer join.
- Specify `LEFT` to indicate a left outer join.
- Specify `FULL` to indicate a full or two-sided outer join. In addition to the inner join, rows from both tables that have not been returned in the result of the inner join will be preserved and extended with nulls.
- You can specify the optional `OUTER` keyword following `RIGHT`, `LEFT`, or `FULL` to explicitly clarify that an outer join is being performed.

**ON condition**

Use the `ON` clause to specify a join condition. Doing so lets you specify join conditions separate from any search or filter conditions in the `WHERE` clause.

**Restriction on the ON condition Clause**

You cannot specify this clause with a `NATURAL` outer join.

**USING column**

In an outer join with the `USING` clause, the query returns a single column that coalesces the two matching columns in the join. The coalesce function is as follows:

\[ \text{COALESCE} (a, b) = a \text{ if } a \text{ NOT NULL, else } b. \]

Therefore:

- A left outer join returns all the common column values from the left table in the `FROM` clause.
- A right outer join returns all the common column values from the right table in the `FROM` clause.
- A full outer join returns all the common column values from both joined tables.
Restriction on the USING *column* Clause

The USING *column* clause is subject to the following restrictions:

- Within this clause, do not qualify the column name with a table name or table alias.
- You cannot specify a LOB column or a collection column in the USING *column* clause.
- You cannot specify this clause with a NATURAL outer join.

See Also:
- "Outer Joins" for additional rules and restrictions pertaining to outer joins
- Oracle Database Data Warehousing Guide for a complete discussion of partitioned outer joins and data densification
- "Using Outer Joins: Examples"

**cross_outer_apply_clause**

This clause allows you to perform a variation of an ANSI CROSS JOIN or an ANSI LEFT OUTER JOIN with left correlation support. You can specify a *table_reference* or *collection_expression* to the right of the APPLY keyword. The *table_reference* can be a table, inline view, or TABLE collection expression. The *collection_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. The *table_reference* or *collection_expression* can reference columns of tables defined in the FROM clause to the left of the APPLY keyword. This is called left correlation.

- Specify CROSS APPLY to perform a variation of an ANSI CROSS JOIN. Only rows from the table on the left side of the join that produce a result set from *table_reference* or *collection_expression* are returned.
- Specify OUTER APPLY to perform a variation of an ANSI LEFT OUTER JOIN. All rows from the table on the left side of the join are returned. Rows that do not produce a result set from *table_reference* or *collection_expression* have the NULL value in the corresponding column(s).

Restriction on the **cross_outer_apply_clause**

The *table_reference* cannot be a lateral inline view.

See Also:
- Using CROSS APPLY and OUTER APPLY Joins: Examples

**inline_analytic_view**

An inline analytic view is a transitory analytic view that is specified in the FROM clause. To create an inline analytic view, use the ANALYTIC VIEW keyword and specify a *subav_clause* that defines the analytic view. Optionally, you may specify
an inline_av_alias, which is an alias for the inline analytic view. The rules for the inline_av_alias are the same as the rules for an inline view alias.

See Also:
Analytic Views: Examples

where_clause

The WHERE condition lets you restrict the rows selected to those that satisfy one or more conditions. For condition, specify any valid SQL condition.

If you omit this clause, then the database returns all rows from the tables, views, or materialized views in the FROM clause.

Note:
If this clause refers to a DATE column of a partitioned table or index, then the database performs partition pruning only if:

- You created the table or index partitions by fully specifying the year using the TO_DATE function with a 4-digit format mask, and
- You specify the date in the where_clause of the query using the TO_DATE function and either a 2- or 4-digit format mask.

See Also:
- Conditions for the syntax description of condition
- "Selecting from a Partition: Example"

hierarchical_query_clause

The hierarchical_query_clause lets you select rows in a hierarchical order.

SELECT statements that contain hierarchical queries can contain the LEVEL pseudocolumn in the select list. LEVEL returns the value 1 for a root node, 2 for a child node of a root node, 3 for a grandchild, and so on. The number of levels returned by a hierarchical query may be limited by available user memory.

Oracle processes hierarchical queries as follows:

- A join, if present, is evaluated first, whether the join is specified in the FROM clause or with WHERE clause predicates.
- The CONNECT BY condition is evaluated.
- Any remaining WHERE clause predicates are evaluated.
If you specify this clause, then do not specify either ORDER BY or GROUP BY, because they will destroy the hierarchical order of the CONNECT BY results. If you want to order rows of siblings of the same parent, then use the ORDER SIBLINGS BY clause.

See Also:

"Hierarchical Queries " for a discussion of hierarchical queries and "Using the LEVEL Pseudocolumn: Examples"

START WITH Clause

Specify a condition that identifies the row(s) to be used as the root(s) of a hierarchical query. The condition can be any condition as described in Conditions. Oracle Database uses as root(s) all rows that satisfy this condition. If you omit this clause, then the database uses all rows in the table as root rows.

CONNECT BY Clause

Specify a condition that identifies the relationship between parent rows and child rows of the hierarchy. The condition can be any condition as described in Conditions. However, it must use the PRIOR operator to refer to the parent row.

See Also:

• Pseudocolumns for more information on LEVEL
• “Hierarchical Queries " for general information on hierarchical queries
• “Hierarchical Query Examples"

group_by_clause

Specify the GROUP BY clause if you want the database to group the selected rows based on the value of expr(s) for each row and return a single row of summary information for each group. If this clause contains CUBE or ROLLUP extensions, then the database produces superaggregate groupings in addition to the regular groupings.

Expressions in the GROUP BY clause can contain any columns of the tables, views, or materialized views in the FROM clause, regardless of whether the columns appear in the select list.

The GROUP BY clause groups rows but does not guarantee the order of the result set. To order the groupings, use the ORDER BY clause.
ROLLUP

The ROLLUP operation in the simple_grouping_clause groups the selected rows based on the values of the first n, n-1, n-2, ... 0 expressions in the GROUP BY specification, and returns a single row of summary for each group. You can use the ROLLUP operation to produce subtotal values by using it with the SUM function. When used with SUM, ROLLUP generates subtotals from the most detailed level to the grand total. Aggregate functions such as COUNT can be used to produce other kinds of superaggregates.

For example, given three expressions (n=3) in the ROLLUP clause of the simple_grouping_clause, the operation results in n+1 = 3+1 = 4 groupings.

Rows grouped on the values of the first n expressions are called regular rows, and the others are called superaggregate rows.

See Also:
Oracle Database Data Warehousing Guide for information on using ROLLUP with materialized views

CUBE

The CUBE operation in the simple_grouping_clause groups the selected rows based on the values of all possible combinations of expressions in the specification. It returns a single row of summary information for each group. You can use the CUBE operation to produce cross-tabulation values.

For example, given three expressions (n=3) in the CUBE clause of the simple_grouping Clause, the operation results in $2^n = 2^3 = 8$ groupings. Rows grouped on the values of n expressions are called regular rows, and the others are called superaggregate rows.
GROUPING SETS

GROUPING SETS are a further extension of the GROUP BY clause that let you specify multiple groupings of data. Doing so facilitates efficient aggregation by pruning the aggregates you do not need. You specify just the desired groups, and the database does not need to perform the full set of aggregations generated by CUBE or ROLLUP. Oracle Database computes all groupings specified in the GROUPING SETS clause and combines the results of individual groupings with a UNION ALL operation. The UNION ALL means that the result set can include duplicate rows.

Within the GROUP BY clause, you can combine expressions in various ways:

- To specify composite columns, group columns within parentheses so that the database treats them as a unit while computing ROLLUP or CUBE operations.
- To specify concatenated grouping sets, separate multiple grouping sets, ROLLUP, and CUBE operations with commas so that the database combines them into a single GROUP BY clause. The result is a cross-product of groupings from each grouping set.

HAVING Clause

Use the HAVING clause to restrict the groups of returned rows to those groups for which the specified condition is TRUE. If you omit this clause, then the database returns summary rows for all groups.

Specify GROUP BY and HAVING after the WHERE clause and HIERARCHICAL_QUERY_CLAUSE. If you specify both GROUP BY and HAVING, then they can appear in either order.

Restrictions on the GROUP BY Clause

This clause is subject to the following restrictions:

- You cannot specify LOB columns, nested tables, or varrays as part of expr.
• The expressions can be of any form except scalar subquery expressions.
• If the \textit{group\_by\_clause} references any object type columns, then the query will not be parallelized.

\textit{model\_clause}

The \textit{model\_clause} lets you view selected rows as a multidimensional array and randomly access cells within that array. Using the \textit{model\_clause}, you can specify a series of cell assignments, referred to as \textit{rules}, that invoke calculations on individual cells and ranges of cells. These rules operate on the results of a query and do not update any database tables.

When using the \textit{model\_clause} in a query, the \textit{SELECT} and \textit{ORDER BY} clauses must refer only to those columns defined in the \textit{model\_column\_clauses}.

\begin{mybluebox}
\textbf{See Also:}

• The syntax description of \textit{expr} in "About SQL Expressions " and the syntax description of \textit{condition} in Conditions
• Oracle Database Data Warehousing Guide for an expanded discussion and examples
• "The MODEL clause: Examples"
\end{mybluebox}

\textit{main\_model}

The \textit{main\_model} clause defines how the selected rows will be viewed in a multidimensional array and what rules will operate on which cells in that array.

\textit{model\_column\_clauses}

The \textit{model\_column\_clauses} define and classify the columns of a query into three groups: partition columns, dimension columns, and measure columns. For \textit{expr}, you can specify a column, constant, host variable, single-row function, aggregate function, or any expression involving them. If \textit{expr} is a column, then the column alias (\textit{c\_alias}) is optional. If \textit{expr} is not a column, then the column alias is required. If you specify a column alias, then you must use the alias to refer to the column in the \textit{model\_rules\_clause}, \textit{SELECT} list, and the query \textit{ORDER BY} clauses.

\textbf{PARTITION BY}

The \textit{PARTITION BY} clause specifies the columns that will be used to divide the selected rows into partitions based on the values of the specified columns.

\textbf{DIMENSION BY}

The \textit{DIMENSION BY} clause specifies the columns that will identify a row within a partition. The values of the dimension columns, along with those of the partition columns, serve as array indexes to the measure columns within a row.

\textbf{MEASURES}

The \textit{MEASURES} clause identifies the columns on which the calculations can be performed. Measure columns in individual rows are treated like cells that you can
reference, by specifying the values for the partition and dimension columns, and update.

**cell_reference_options**

Use the *cell_reference_options* clause to specify how null and absent values are treated in rules and how column uniqueness is constrained.

**IGNORE NAV**

When you specify `IGNORE NAV`, the database returns the following values for the null and absent values of the data type specified:

- Zero for numeric data types
- 01-JAN-2000 for datetime data types
- An empty string for character data types
- Null for all other data types

**KEEP NAV**

When you specify `KEEP NAV`, the database returns null for both null and absent cell values. `KEEP NAV` is the default.

**UNIQUE SINGLE REFERENCE**

When you specify `UNIQUE SINGLE REFERENCE`, the database checks only single-cell references on the right-hand side of the rule for uniqueness, not the entire query result set.

**UNIQUE DIMENSION**

When you specify `UNIQUE DIMENSION`, the database checks that the `PARTITION BY` and `DIMENSION BY` columns form a unique key to the query. `UNIQUE DIMENSION` is the default.

**model_rules_clause**

Use the *model_rules_clause* to specify the cells to be updated, the rules for updating those cells, and optionally, how the rules are to be applied and processed.

Each rule represents an assignment and consists of a left-hand side and right-hand side. The left-hand side of the rule identifies the cells to be updated by the right-hand side of the rule. The right-hand side of the rule evaluates to the values to be assigned to the cells specified on the left-hand side of the rule.

**UPSERT ALL**

`UPSERT ALL` allows `UPSERT` behavior for a rule with both positional and symbolic references on the left-hand side of the rule. When evaluating an `UPSERT ALL` rule, Oracle performs the following steps to create a list of cell references to be upserted:

1. Find the existing cells that satisfy all the symbolic predicates of the cell reference.
2. Using just the dimensions that have symbolic references, find the distinct dimension value combinations of these cells.
3. Perform a cross product of these value combinations with the dimension values specified by way of positional references.
Refer to *Oracle Database Data Warehousing Guide* for more information on the semantics of **UPSERT** ALL.

**UPSERT**

When you specify **UPSERT**, the database applies the rules to those cells referenced on the left-hand side of the rule that exist in the multidimensional array, and inserts new rows for those that do not exist. **UPSERT** behavior applies only when positional referencing is used on the left-hand side and a single cell is referenced. **UPSERT** is the default. Refer to *cell_assignment* for more information on positional referencing and single-cell references.

**UPDATE** and **UPSERT** can be specified for individual rules as well. When either **UPDATE** or **UPSERT** is specified for a specific rule, it takes precedence over the option specified in the **RULES** clause.

---

**Note:**

If an **UPSERT** ALL, **UPSERT**, or **UPDATE** rule does not contain the appropriate predicates, then the database may implicitly convert it to a different type of rule:

- If an **UPSERT** rule contains an existential predicate, then the rule is treated as an **UPDATE** rule.
- An **UPSERT** ALL rule must have at least one existential predicate and one qualified predicate on its left side. If it has no existential predicate, then it is treated as an **UPSERT** rule. If it has no qualified predicate, then it is treated as an **UPDATE** rule.

**UPDATE**

When you specify **UPDATE**, the database applies the rules to those cells referenced on the left-hand side of the rule that exist in the multidimensional array. If the cells do not exist, then the assignment is ignored.

**AUTOMATIC ORDER**

When you specify **AUTOMATIC ORDER**, the database evaluates the rules based on their dependency order. In this case, a cell can be assigned a value once only.

**SEQUENTIAL ORDER**

When you specify **SEQUENTIAL ORDER**, the database evaluates the rules in the order they appear. In this case, a cell can be assigned a value more than once. **SEQUENTIAL ORDER** is the default.

**ITERATE ... [UNTIL]**

Use **ITERATE ... [UNTIL]** to specify the number of times to cycle through the rules and, optionally, an early termination condition. The parentheses around the **UNTIL** condition are optional.

When you specify **ITERATE ... [UNTIL]**, rules are evaluated in the order in which they appear. Oracle Database returns an error if both **AUTOMATIC ORDER** and **ITERATE ... [UNTIL]** are specified in the **model_rules_clause**.
**cell_assignment**

The *cell_assignment* clause, which is the left-hand side of the rule, specifies one or more cells to be updated. When a *cell_assignment* references a single cell, it is called a **single-cell reference**. When more than one cell is referenced, it is called a **multiple-cell reference**.

All dimension columns defined in the *model_clause* must be qualified in the *cell_assignment* clause. A dimension can be qualified using either symbolic or positional referencing.

A **symbolic reference** qualifies a single dimension column using a Boolean condition like `dimension_column=constant`. A **positional reference** is one where the dimension column is implied by its position in the `DIMENSION BY` clause. The only difference between symbolic references and positional references is in the treatment of nulls.

Using a single-cell symbolic reference such as `a[x=null,y=2000]`, no cells qualify because `x=null` evaluates to `FALSE`. However, using a single-cell positional reference such as `a[null,2000]`, a cell where `x` is null and `y` is 2000 qualifies because null = null evaluates to `TRUE`. With single-cell positional referencing, you can reference, update, and insert cells where dimension columns are null.

You can specify a condition or an expression representing a dimension column value using either symbolic or positional referencing. The *condition* cannot contain aggregate functions or the `CV` function, and *condition* must reference a single dimension column. The *expr* cannot contain a subquery. Refer to “Model Expressions” for information on model expressions.

**single_column_for_loop**

The *single_column_for_loop* clause lets you specify a range of cells to be updated within a single dimension column.

The *IN* clause lets you specify the values of the dimension column as either a list of values or as a subquery. When using *subquery*, it cannot:

- Be a correlated query
- Return more than 10,000 rows
- Be a query defined in the *WITH* clause

The *FROM* clause lets you specify a range of values for a dimension column with discrete increments within the range. The *FROM* clause can only be used for those columns with a data type for which addition and subtraction is supported. The *INCREMENT* and *DECREMENT* values must be positive.

Optionally, you can specify the *LIKE* clause within the *FROM* clause. In the *LIKE* clause, *pattern* is a character string containing a single pattern-matching character `%`. This character is replaced during execution with the current incremented or decremented value in the *FROM* clause.

If all dimensions other than those used by a *FOR* loop involve a single-cell reference, then the expressions can insert new rows. The number of dimension value combinations generated by *FOR* loops is counted as part of the 10,000 row limit of the *MODEL* clause.

**multi_column_for_loop**
The `multi_column_for_loop` clause lets you specify a range of cells to be updated across multiple dimension columns. The `IN` clause lets you specify the values of the dimension columns as either multiple lists of values or as a subquery. When using `subquery`, it cannot:

- Be a correlated query
- Return more than 10,000 rows
- Be a query defined in the `WITH` clause

If all dimensions other than those used by a `FOR` loop involve a single-cell reference, then the expressions can insert new rows. The number of dimension value combinations generated by `FOR` loops is counted as part of the 10,000 row limit of the `MODEL` clause.

**See Also:**

*Oracle Database Data Warehousing Guide* for more information about using `FOR` loops in the `MODEL` clause.

### order_by_clause

Use the `ORDER BY` clause to specify the order in which cells on the left-hand side of the rule are to be evaluated. The `expr` must resolve to a dimension or measure column. If the `ORDER BY` clause is not specified, then the order defaults to the order of the columns as specified in the `DIMENSION BY` clause. See `order_by_clause` for more information.

#### Restrictions on the order_by_clause

Use of the `ORDER BY` clause in the model rule is subject to the following restrictions:

- You cannot specify `SIBLINGS`, `position`, or `c_alias` in the `order_by_clause` of the `model_clause`
- You cannot specify this clause on the left-hand side of the model rule and also specify a `FOR` loop on the right-hand side of the rule

#### expr

Specify an expression representing the value or values of the cell or cells specified on the right-hand side of the rule. `expr` cannot contain a subquery. Refer to "Model Expressions" for information on model expressions.

### return_rows_clause

The `return_rows_clause` lets you specify whether to return all rows selected or only those rows updated by the model rules. `ALL` is the default.

### reference_model

Use the `reference_model` clause when you need to access multiple arrays from inside the `model_clause`. This clause defines a read-only multidimensional array based on the results of a query.

The subclauses of the `reference_model` clause have the same semantics as for the `main_model` clause. Refer to `model_column_clauses` and `cell_reference_options`.

---

19-88
Restrictions on the reference_model Clause

This clause is subject to the following restrictions:

- **PARTITION BY** columns cannot be specified for reference models.
- The subquery of the reference model cannot refer to columns in an outer subquery.

Set Operators: UNION, UNION ALL, INTERSECT, MINUS

The set operators combine the rows returned by two SELECT statements into a single result. The number and data types of the columns selected by each component query must be the same, but the column lengths can be different. The names of the columns in the result set are the names of the expressions in the select list preceding the set operator.

If you combine more than two queries with set operators, then the database evaluates adjacent queries from left to right. The parentheses around the subquery are optional. You can use them to specify a different order of evaluation.

Refer to "The UNION [ALL], INTERSECT, MINUS Operators" for information on these operators, including restrictions on their use.

**order_by_clause**

Use the **ORDER BY** clause to order rows returned by the statement. Without an **order_by_clause**, no guarantee exists that the same query executed more than once will retrieve rows in the same order.

**SIBLINGS**

The **SIBLINGS** keyword is valid only if you also specify the **hierarchical_query_clause** (**CONNECT BY**). ORDER SIBLINGS BY preserves any ordering specified in the hierarchical query clause and then applies the **order_by_clause** to the siblings of the hierarchy.

**expr**

**expr** orders rows based on their value for **expr**. The expression is based on columns in the select list or columns in the tables, views, or materialized views in the FROM clause.

**position**

Specify **position** to order rows based on their value for the expression in this position of the select list. The **position** value must be an integer.

You can specify multiple expressions in the **order_by_clause**. Oracle Database first sorts rows based on their values for the first expression. Rows with the same value for the first expression are then sorted based on their values for the second expression, and so on. The database sorts nulls following all others in ascending order and preceding all others in descending order. Refer to "Sorting Query Results " for a discussion of ordering query results.

**ASC | DESC**

Specify whether the ordering sequence is ascending or descending. **ASC** is the default.

**NULLS FIRST | NULLS LAST**
Specify whether returned rows containing null values should appear first or last in the ordering sequence.

NULLS LAST is the default for ascending order, and NULLS FIRST is the default for descending order.

Restrictions on the ORDER BY Clause

The following restrictions apply to the ORDER BY clause:

- If you have specified the DISTINCT operator in this statement, then this clause cannot refer to columns unless they appear in the select list.
- An order_by_clause can contain no more than 255 expressions.
- You cannot order by a LOB, LONG, or LONG RAW column, nested table, or varray.
- If you specify a group_by_clause in the same statement, then this order_by_clause is restricted to the following expressions:
  - Constants
  - Aggregate functions
  - Analytic functions
  - The functions USER, UID, and SYSDATE
  - Expressions identical to those in the group_by_clause
  - Expressions comprising the preceding expressions that evaluate to the same value for all rows in a group

See Also:

- "Using the ORDER BY Clause: Examples"
- Restrictions for Linguistic Collations for information on implications of how ORDER BY character values are compared linguistically
- Appendix C in Oracle Database Globalization Support Guide for the collation determination rules for the expressions in the ORDER BY clause

row_limiting_clause

The row_limiting_clause allows you to limit the rows returned by the query. You can specify an offset, and the number of rows or percentage of rows to return. You can use this clause to implement top-N reporting. For consistent results, specify the order_by_clause to ensure a deterministic sort order.

OFFSET

Use this clause to specify the number of rows to skip before row limiting begins. offset must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then offset is treated as 0. If you specify NULL, or a number greater than or equal to the number of rows returned by the query, then 0 rows are returned. If offset includes a fraction, then the fractional portion is truncated. If you do not specify this clause, then offset is 0 and row limiting begins with the first row.
ROW | ROWS

These keywords can be used interchangeably and are provided for semantic clarity.

FETCH

Use this clause to specify the number of rows or percentage of rows to return. If you do not specify this clause, then all rows are returned, beginning at row offset + 1.

FIRST | NEXT

These keywords can be used interchangeably and are provided for semantic clarity.

rowcount | percent PERCENT

Use rowcount to specify the number of rows to return. rowcount must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then rowcount is treated as 0. If rowcount is greater than the number of rows available beginning at row offset + 1, then all available rows are returned. If rowcount includes a fraction, then the fractional portion is truncated. If rowcount is NULL, then 0 rows are returned.

Use percent PERCENT to specify the percentage of the total number of selected rows to return. percent must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then percent is treated as 0. If percent is NULL, then 0 rows are returned.

If you do not specify rowcount or percent PERCENT, then 1 row is returned.

ROW | ROWS

These keywords can be used interchangeably and are provided for semantic clarity.

ONLY | WITH TIES

Specify ONLY to return exactly the specified number of rows or percentage of rows.

Specify WITH TIES to return additional rows with the same sort key as the last row fetched. If you specify WITH TIES, then you must specify the order_by_clause. If you do not specify the order_by_clause, then no additional rows will be returned.

Restrictions on the row_limiting_clause

This clause is subject to the following restrictions:

- You cannot specify this clause with the for_update_clause.
- If you specify this clause, then the select list cannot contain the sequence pseudocolumns CURRVAL or NEXTVAL.
- Materialized views are not eligible for an incremental refresh if the defining query contains the row_limiting_clause.
- If the select list contains columns with identical names and you specify the row_limiting_clause, then an ORA-00918 error occurs. This error occurs whether the identically named columns are in the same table or in different tables. You can work around this issue by specifying unique column aliases for the identically named columns.
The `FOR UPDATE` clause lets you lock the selected rows so that other users cannot lock or update the rows until you end your transaction. You can specify this clause only in a top-level `SELECT` statement, not in subqueries.

Prior to updating a LOB value, you must lock the row containing the LOB. One way to lock the row is with an embedded `SELECT ... FOR UPDATE` statement. You can do this using one of the programmatic languages or `DBMS_LOB` package. For more information on lock rows before writing to a LOB, see Oracle Database SecureFiles and Large Objects Developer's Guide.

Nested table rows are not locked as a result of locking the parent table rows. If you want the nested table rows to be locked, then you must lock them explicitly.

**Restrictions on the FOR UPDATE Clause**

This clause is subject to the following restrictions:

- You cannot specify this clause with the following other constructs: the `DISTINCT` operator, `CURSOR` expression, set operators, `GROUP BY` clause, or aggregate functions.
- The tables locked by this clause must all be located on the same database and on the same database as any `LONG` columns and sequences referenced in the same statement.

In general, this clause is not supported on views. However, in some cases, a `SELECT ... FOR UPDATE` query on a view can succeed without any errors. This occurs when the view has been merged to its containing query block internally by the query optimizer, and `SELECT ... FOR UPDATE` succeeds on the internally transformed query. The examples in this section illustrate when using the `FOR UPDATE` clause on a view can succeed or fail.

- Using the `FOR UPDATE` clause on merged views
An error can occur when you use the `FOR UPDATE` clause on a merged view if both of the following conditions apply:

- The underlying column of the view is an expression
- The `FOR UPDATE` clause applies to a column list

The following statement succeeds because the underlying column of the view is not an expression:

```
SELECT employee_id FROM (SELECT * FROM employees) 
  FOR UPDATE OF employee_id;
```

The following statement succeeds because, while the underlying column of the view is an expression, the `FOR UPDATE` clause does not apply to a column list:

```
SELECT employee_id FROM (SELECT employee_id+1 AS employee_id FROM employees) 
  FOR UPDATE;
```

The following statement fails because the underlying column of the view is an expression and the `FOR UPDATE` clause applies to a column list:

```
SELECT employee_id FROM (SELECT employee_id+1 AS employee_id FROM employees) 
  FOR UPDATE OF employee_id;
```

```
* Error at line 2:
ORA-01733: virtual column not allowed here
```

• Using the `FOR UPDATE` clause on non-merged views

Since the `FOR UPDATE` clause is not supported on views, anything that prevents view merging, such as the `NO_MERGE` hint, parameters that disallow view merging, or something in the query structure that prevents view merging, will result in an ORA-02014 error.

In the following example, the GROUP BY statement prevents view merging, which causes an error:

```
SELECT avgsal
FROM (SELECT AVG(salary) AS avgsal FROM employees GROUP BY job_id) 
  FOR UPDATE;
FROM (SELECT AVG(salary) AS avgsal FROM employees GROUP BY job_id) 
  *;
```

```
* ERROR at line 2:
ORA-02014: cannot select FOR UPDATE from view with DISTINCT, GROUP BY, etc.
```

**Note:**

Due to the complexity of the view merging mechanism, Oracle recommends against using the `FOR UPDATE` clause on views.

**OF ... column**

Use the `OF ... column` clause to lock the select rows only for a particular table or view in a join. The columns in the `OF` clause only indicate which table or view rows are locked. The specific columns that you specify are not significant. However, you must specify an actual column name, not a column alias. If you omit this clause, then the database locks the selected rows from all the tables in the query.
NOWAIT | WAIT

The NOWAIT and WAIT clauses let you tell the database how to proceed if the SELECT statement attempts to lock a row that is locked by another user.

- Specify NOWAIT to return control to you immediately if a lock exists.
- Specify WAIT to instruct the database to wait integer seconds for the row to become available and then return control to you.

If you specify neither WAIT nor NOWAIT, then the database waits until the row is available and then returns the results of the SELECT statement.

SKIP LOCKED

SKIP LOCKED is an alternative way to handle a contending transaction that is locking some rows of interest. Specify SKIP LOCKED to instruct the database to attempt to lock the rows specified by the WHERE clause and to skip any rows that are found to be already locked by another transaction. This feature is designed for use in multiconsumer queue environments. It enables queue consumers to skip rows that are locked by other consumers and obtain unlocked rows without waiting for the other consumers to finish. Refer to Oracle Database Advanced Queuing User's Guide for more information.

Note on the WAIT and SKIP LOCKED Clauses

If you specify WAIT or SKIP LOCKED and the table is locked in exclusive mode, then the database will not return the results of the SELECT statement until the lock on the table is released. In the case of WAIT, the SELECT FOR UPDATE clause is blocked regardless of the wait time specified.

row_pattern_clause

The MATCH_RECOGNIZE clause lets you perform pattern matching. Use this clause to recognize patterns in a sequence of rows in table, which is called the row pattern input table. The result of a query that uses the MATCH_RECOGNIZE clause is called the row pattern output table.

The MATCH_RECOGNIZE enables you to do the following tasks:

- Logically partition and order the data with the PARTITION BY and ORDER BY clauses.
- Define measures, which are expressions usable in other parts of the SQL query, in the MEASURES clause.
- Define patterns of rows to seek using the PATTERN clause. These patterns use regular expression syntax, a powerful and expressive feature, applied to the pattern variables you define.
- Specify the logical conditions required to map a row to a row pattern variable in the DEFINE clause.

See Also:

- Oracle Database Data Warehousing Guide for more information on pattern matching
- "Row Pattern Matching: Example"
**row_pattern_partition_by**

Specify `PARTITION BY` to divide the rows in the row pattern input table into logical groups called row pattern partitions. Use `column` to specify one or more partitioning columns. Each partition consists of the set of rows in the row pattern input table that have the same value(s) on the partitioning column(s).

If you specify this clause, then matches are found within partitions and do not cross partition boundaries. If you do not specify this clause, then all rows of the row input table constitute a single row pattern partition.

**row_pattern_order_by**

Specify `ORDER BY` to order rows within each row pattern partition. Use `column` to specify one or more ordering columns. If you specify multiple columns, then Oracle Database first sorts rows based on their values for the first column. Rows with the same value for the first column are then sorted based on their values for the second column, and so on. Oracle Database sorts nulls following all others in ascending order.

If you do not specify this clause, then the result of the `row_pattern_clause` is nondeterministic and you may get inconsistent results each time you run the query.

**row_pattern_measures**

Use the `MEASURES` clause to define one or more row pattern measure columns. These columns are included in the row pattern output table and contain values that are useful for analyzing data.

When you define a row pattern measure column, using the `row_pattern_measure_column` clause, you specify its pattern measure expression. The values in the column are calculated by evaluating the pattern measure expression whenever a match is found.

**row_pattern_measure_column**

Use this clause to define a row pattern measure column.

- For `expr`, specify the pattern measure expression. A pattern measure expression is an expression as described in Expressions that can contain only the following elements:
  - Constants: Text literals and numeric literals
  - References to any column of the row pattern input table
  - The `CLASSIFIER` function, which returns the name of the primary row pattern variable to which the row is mapped. Refer to `row_pattern_classifier_func` for more information.
  - The `MATCH_NUMBER` function, which returns the sequential number of a row pattern match within the row pattern partition. Refer to `row_pattern_match_num_func` for more information.
  - Row pattern navigation functions: `PREV`, `NEXT`, `FIRST`, and `LAST`. Refer to `row_pattern_navigation_func` for more information.
  - Row pattern aggregate functions: `AVG`, `COUNT`, `MAX`, `MIN`, or `SUM`. Refer to `row_pattern_aggregate_func` for more information.
- For `c_alias`, specify the alias for the pattern measure expression. Oracle Database uses this alias in the column heading of the row pattern output table. The `AS` keyword is optional. The alias can be used in other parts of the query, such as the `SELECT ... ORDER BY` clause.

`row_pattern_rows_per_match`

This clause lets you specify whether the row pattern output table includes summary or detailed data about each match.

- If you specify `ONE ROW PER MATCH`, then each match produces one summary row. This is the default.
- If you specify `ALL ROWS PER MATCH`, then each match that spans multiple rows will produce one output row for each row in the match.

`row_pattern_skip_to`

This clause lets you specify the point to resume row pattern matching after a non-empty match is found.

- Specify `AFTER MATCH SKIP TO NEXT ROW` to resume pattern matching at the row after the first row of the current match.
- Specify `AFTER MATCH SKIP PAST LAST ROW` to resume pattern matching at the next row after the last row of the current match. This is the default.
- Specify `AFTER MATCH SKIP TO FIRST variable_name` to resume pattern matching at the first row that is mapped to pattern variable `variable_name`. The `variable_name` must be defined in the `DEFINE` clause.
- Specify `AFTER MATCH SKIP TO LAST variable_name` to resume pattern matching at the last row that is mapped to pattern variable `variable_name`. The `variable_name` must be defined in the `DEFINE` clause.
- `AFTER MATCH SKIP TO variable_name` has the same behavior as `AFTER MATCH SKIP TO LAST variable_name`.

See Also:

`Oracle Database Data Warehousing Guide` for more information on the `AFTER MATCH SKIP` clauses.

**PATTERN**

Use the `PATTERN` clause to define which pattern variables must be matched, the sequence in which they must be matched, and the quantity of rows that must be matched for each pattern variable.

A row pattern match consists of a set of contiguous rows in a row pattern partition. Each row of the match is mapped to a pattern variable. The mapping of rows to pattern variables must conform to the regular expression specified in the `row_pattern` clause, and all conditions in the `DEFINE` clause must be true.
Note:

It is outside the scope of this document to explain regular expression concepts and details. If you are not familiar with regular expressions, then you are encouraged to familiarize yourself with the topic using other sources.

The precedence of the elements that you specify in the regular expression of the PATTERNS clause, in decreasing order, is as follows:

- Row pattern elements (specified in the row_pattern_primary clause)
- Row pattern quantifiers (specified in the row_pattern_quantifier clause)
- Concatenation (specified in the row_pattern_term clause)
- Alternation (specified in the row_pattern clause)

See Also:

Oracle Database Data Warehousing Guide for more information on the PATTERNS clause

Row pattern

Use this clause to specify the row pattern. A row pattern is a regular expression that can take one of the following forms:

- A single row pattern term
  For example: PATTERN(A)
- A row pattern, a vertical bar, and a row pattern term
  For example: PATTERN(A | B)
- A recursively built row pattern, a vertical bar, and a row pattern term
  For example: PATTERN(A | B | C)

The vertical bar in this clause represents alternation. Alternation matches a single regular expression from a list of several possible regular expressions. Alternatives are preferred in the order they are specified. For example, if you specify PATTERN(A | B | C), then Oracle Database attempts to match A first. If A is not matched, then it attempts to match B. If B is not matched, then it attempts to match C.

Row pattern term

This clause lets you specify a row pattern term. A row pattern term can take one of the following forms:

- A single row pattern factor
  For example: PATTERN(A)
- A row pattern term followed by a row pattern factor.
  For example: PATTERN(A B)
A recursively built row pattern term followed by a row pattern factor

For example: `PATTERN(A B C)`

The syntax used in the second and third examples represents **concatenation**. Concatenation is used to list two or more items in a pattern to be matched and the order in which they are to be matched. For example, if you specify `PATTERN(A B C)`, then Oracle Database first matches `A`, then uses the resulting matched rows to match `B`, then uses the resulting matched rows to match `C`. Only rows that match `A`, `B`, and `C`, are included in the row pattern match.

**row_pattern_factor**

This clause lets you specify a row pattern factor. A row pattern factor consists of a row pattern element, specified using the `row_pattern_primary` clause, and an optional row pattern quantifier, specified using the `row_pattern_quantifier` clause.

**row_pattern_primary**

Use this clause to specify the row pattern element. Table 19-1 lists the valid row pattern elements and their descriptions.

**Table 19-1  Row Pattern Elements**

<table>
<thead>
<tr>
<th>Row Pattern Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>variable_name</code></td>
<td>Specify a primary pattern variable name that is defined in the <code>row_pattern_definition</code> clause. You cannot specify a union pattern variable that is defined in the <code>row_pattern_subset_item</code> clause.</td>
</tr>
<tr>
<td>$</td>
<td>$ matches the position after the last row in the partition. This element is an anchor. Anchors work in terms of positions rather than rows.</td>
</tr>
<tr>
<td>^</td>
<td>^ matches the position before the first row in the partition. This element is an anchor. Anchors work in terms of positions rather than rows</td>
</tr>
<tr>
<td><code>(row_pattern)</code></td>
<td>Use <code>row_pattern</code> to specify the row pattern to be matched. An empty pattern () matches an empty set of rows.</td>
</tr>
<tr>
<td><code>(- row_pattern -)</code></td>
<td>Exclusion syntax. Use <code>row_pattern</code> to specify parts of the pattern to be excluded from the output of ALL ROWS PER MATCH.</td>
</tr>
<tr>
<td><code>row_pattern_permute</code></td>
<td>Use <code>row_pattern_permute</code> to specify a pattern that is a permutation of row pattern elements. Refer to <code>row_pattern_permute</code> for the full semantics of this clause.</td>
</tr>
</tbody>
</table>

**row_pattern_permute**

Use the `PERMUTE` clause to express a pattern that is a permutation of the specified row pattern elements. For example, `PATTERN (PERMUTE (A, B, C))` is equivalent to an alternation of all permutations of the three row pattern elements `A`, `B`, and `C`, similar to the following:

`PATTERN (A B C | A C B | B A C | B C A | C A B | C B A)`

Note that the row pattern elements are expanded lexicographically and that each element to permute must be separated by a comma from the other elements.
row_pattern_quantifier

Use this clause to specify the row pattern quantifier, which is a postfix operator that defines the number of iterations accepted for a match.

Row pattern quantifiers are referred to as greedy; they will attempt to match as many instances of the regular expression on which they are applied as possible. The exception is row pattern quantifiers that have a question mark (?) as a suffix, which are referred to as reluctant. They will attempt to match as few instances as possible of the regular expression on which they are applied.

Table 19-2 lists the valid row pattern quantifiers and the number of iterations they accept for a match. In this table, \( n \) and \( m \) represent unsigned integers.

Table 19-2 Row Pattern Quantifiers

<table>
<thead>
<tr>
<th>Row Pattern Quantifier</th>
<th>Number of Iterations Accepted for a Match</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>0 or more iterations (greedy)</td>
</tr>
<tr>
<td>*?</td>
<td>0 or more iterations (reluctant)</td>
</tr>
<tr>
<td>+</td>
<td>1 or more iterations (greedy)</td>
</tr>
<tr>
<td>+?</td>
<td>1 or more iterations (reluctant)</td>
</tr>
<tr>
<td>?</td>
<td>0 or 1 iterations (greedy)</td>
</tr>
<tr>
<td>??</td>
<td>0 or 1 iterations (reluctant)</td>
</tr>
<tr>
<td>( {n,} )</td>
<td>( n ) or more iterations, ( n \geq 0 ) (greedy)</td>
</tr>
<tr>
<td>( {n,} ? )</td>
<td>( n ) or more iterations, ( n \geq 0 ) (reluctant)</td>
</tr>
<tr>
<td>( n, m )</td>
<td>Between ( n ) and ( m ) iterations, inclusive, ( 0 \leq n \leq m, 0 &lt; m ) (greedy)</td>
</tr>
<tr>
<td>( n, m ? )</td>
<td>Between ( n ) and ( m ) iterations, inclusive, ( 0 \leq n \leq m, 0 &lt; m ) (reluctant)</td>
</tr>
<tr>
<td>( , m )</td>
<td>Between 0 and ( m ) iterations, inclusive ( m &gt; 0 ) (greedy)</td>
</tr>
<tr>
<td>( , m ? )</td>
<td>Between 0 and ( m ) iterations, inclusive ( m &gt; 0 ) (reluctant)</td>
</tr>
<tr>
<td>( n ? )</td>
<td>( n ) iterations, ( n &gt; 0 )</td>
</tr>
</tbody>
</table>

See Also:

Oracle Database Data Warehousing Guide for more information on row pattern quantifiers
row_pattern_subset_clause

The SUBSET clause lets you specify one or more union row pattern variables. Use the row_pattern_subset_item clause to declare each union row pattern variable.

You can specify union row pattern variables in the following clauses:

- **MEASURES** clause: In the expression for a row pattern measure column. That is, in expression expr of the row_pattern_measure_column clause.
- **DEFINE** clause: In the condition that defines a primary pattern variable. That is, in condition of the row_pattern_definition clause

row_pattern_subset_item

This clause lets you create a grouping of multiple pattern variables that can be referred to with a variable name of its own. The variable name that refers to this grouping is called a union row pattern variable.

- For variable_name on the left side of the equal sign, specify the name of the union row pattern variable.
- On the right side of the equal sign, specify a comma-separated list of distinct primary row pattern variables within parentheses. This list cannot include any union row pattern variables.

See Also:

*Oracle Database Data Warehousing Guide* for more information on defining union row pattern variables

DEFINE

Use the DEFINE clause to specify one or more row pattern definitions. A row pattern definition specifies the conditions that a row must meet in order to be mapped to a specific pattern variable.

The DEFINE clause only supports running semantics.

See Also:

- *Oracle Database Data Warehousing Guide* for more information on the DEFINE clause
- *Oracle Database Data Warehousing Guide* for more information on running and final semantics

row_pattern_definition_list

This clause lets you specify one or more row pattern definitions.

row_pattern_definition
This clause lets you specify a row pattern definition, which contains the conditions that a row must meet in order to be mapped to the specified pattern variable.

- For variable_name, specify the name of the pattern variable.
- For condition, specify a condition as described in Conditions, with the following extension: condition can contain any of the functions described by row_pattern_navigation_func::= and row_pattern_aggregate_func::=.

row_pattern_rec_func

This clause comprises the following clauses, which let you specify row pattern recognition functions:

- row_pattern_classifier_func: Use this clause to specify the CLASSIFIER function, which returns a character string whose value is the name of the variable to which the row is mapped.
- row_pattern_match_num_func: Use this clause to specify the MATCH_NUMBER function, which returns a numeric value with scale 0 (zero) whose value is the sequential number of the match within the row pattern partition.
- row_pattern_navigation_func: Use this clause to specify functions that perform row pattern navigation operations.
- row_pattern_aggregate_func: Use this clause to specify an aggregate function in the expression for a row pattern measure column or in the condition that defines a primary pattern variable.

You can specify row pattern recognition functions in the following clauses:

- MEASURES clause: In the expression for a row pattern measure column. That is, in expression expr of the row_pattern_measure_column clause.
- DEFINE clause: In the condition that defines a primary pattern variable. That is, in condition of the row_pattern_definition clause.

A row pattern recognition function may behave differently depending whether you specify it in the MEASURES or DEFINE clause. These details are explained in the semantics for each clause.

row_pattern_classifier_func

The CLASSIFIER function returns a character string whose value is the name of the variable to which the row is mapped.

- In the MEASURES clause:
  - If you specify ONE ROW PER MATCH, then the query uses the last row of the match when processing the MEASURES clause, so the CLASSIFIER function returns the name of the pattern variable to which the last row of the match is mapped.
  - If you specify ALL ROWS PER MATCH, then for each row of the match found, the CLASSIFIER function returns the name of the pattern variable to which the row is mapped.

For empty matches—that is, matches that contain no rows, the CLASSIFIER function returns NULL.

- In the DEFINE clause, the CLASSIFIER function returns the name of the primary pattern variable to which the current row is mapped.

row_pattern_match_num_func
The MATCH_NUMBER function returns a numeric value with scale 0 (zero) whose value is the sequential number of the match within the row pattern partition.

Matches within a row pattern partition are numbered sequentially starting with 1 in the order in which they are found. If multiple rows satisfy a match, then they are all assigned the same match number. Note that match numbering starts over again at 1 in each row pattern partition, because there is no inherent ordering between row pattern partitions.

- In the MEASURES clause: You can use MATCH_NUMBER to obtain the sequential number of the match within the row pattern.
- In the DEFINE clause: You can use MATCH_NUMBER to define conditions that depend upon the match number.

**row_pattern_navigation_func**

This clause lets you perform the following row pattern navigation operations:

- Navigate among the group of rows mapped to a pattern variable using the FIRST and LAST functions of the row_pattern_nav_logical clause.
- Navigate among all rows in a row pattern partition using the PREV and NEXT functions of the row_pattern_nav_physical clause
- Nest the FIRST or LAST function within the PREV or NEXT function using the row_pattern_nav_compound clause.

**row_pattern_nav_logical**

This clause lets you use the FIRST and LAST functions to navigate among the group of rows mapped to a pattern variable using an optional logical offset.

- The FIRST function returns the value of expression expr when evaluated in the first row of the group of rows mapped to the pattern variable that is specified in expr. If no rows are mapped to the pattern variable, then the FIRST function returns NULL.
- The LAST function returns the value of expression expr when evaluated in the last row of the group of rows mapped to the pattern variable that is specified in expr. If no rows are mapped to the pattern variable, then the LAST function returns NULL.
- Use expr to specify the expression to be evaluated. It must contain at least one row pattern column reference. If it contains more than one row pattern column reference, then all must refer to the same pattern variable.
- Use the optional offset to specify the logical offset within the set of rows mapped to the pattern variable. When specified with the FIRST function, the offset is the number of rows from the first row, in ascending order. When specified with the LAST function, the offset is the number of rows from the last row in descending order. The default offset is 0.

For offset, specify a non-negative integer. It must be a runtime constant (literal, bind variable, or expressions involving them), but not a column or subquery.

If you specify an offset that is greater than or equal to the number of rows mapped to the pattern variable minus 1, then the function returns NULL.

You can specify running or final semantics for the FIRST and LAST functions as follows:

- The MEASURES clause supports running and final semantics. Specify RUNNING for running semantics. Specify FINAL for final semantics. The default is RUNNING.
The `DEFINE` clause supports only running semantics. Therefore, running semantics will be used whether you specify or omit `RUNNING`. You cannot specify `FINAL`.

**See Also:**
- *Oracle Database Data Warehousing Guide* for more information on the `FIRST` and `LAST` functions
- *Oracle Database Data Warehousing Guide* for more information on running and final semantics

### `row_pattern_nav_physical`

This clause lets you use the `PREV` and `NEXT` functions to navigate all rows in a row pattern partition using an optional physical offset.

- The `PREV` function returns the value of expression `expr` when evaluated in the previous row in the partition. If there is no previous row in the partition, then the `PREV` function returns `NULL`.
- The `NEXT` function returns the value of expression `expr` when evaluated in the next row in the partition. If there is no next row in the partition, then the `NEXT` function returns `NULL`.
- Use `expr` to specify the expression to be evaluated. It must contain at least one row pattern column reference. If it contains more than one row pattern column reference, then all must refer to the same pattern variable.
- Use the optional `offset` to specify the physical offset within the partition. When specified with the `PREV` function, it is the number of rows before the current row. When specified with the `NEXT` function, it is the number of rows after the current row. The default is 1. If you specify an offset of 0, then the current row is evaluated.

For `offset`, specify a non-negative integer. It must be a runtime constant (literal, bind variable, or expressions involving them), but not a column or subquery.

The `PREV` and `NEXT` functions always use running semantics. Therefore, you cannot specify the `RUNNING` or `FINAL` keywords with this clause.

**See Also:**
- *Oracle Database Data Warehousing Guide* for more information on the `PREV` and `NEXT` functions
- *Oracle Database Data Warehousing Guide* for more information on running and final semantics

### `row_pattern_nav_compound`

This clause lets you nest the `row_pattern_nav_logical` clause within the `row_pattern_nav_physical` clause. That is, it lets you nest the `FIRST` or `LAST` function within the `PREV` or `NEXT` function. The `row_pattern_nav_logical` clause is evaluated first and then the result is supplied to the `row_pattern_nav_physical` clause.
Refer to row_pattern_nav_logical and row_pattern_nav_physical for the full semantics of these clauses.

See Also:
Oracle Database Data Warehousing Guide for more information on nesting the FIRST and LAST functions within the PREV and NEXT functions

row_pattern_aggregate_func

This clause lets you use an aggregate function in the expression for a row pattern measure column or in the condition that defines a primary pattern variable.

For aggregate_function, specify any one of the AVG, COUNT, MAX, MIN, or SUM functions. The DISTINCT keyword is not supported.

You can specify running or final semantics for aggregate functions as follows:

- The MEASURES clause supports running and final semantics. Specify RUNNING for running semantics. Specify FINAL for final semantics. The default is RUNNING.
- The DEFINE clause supports only running semantics. Therefore, running semantics will be used whether you specify or omit RUNNING. You cannot specify FINAL.

See Also:
- Oracle Database Data Warehousing Guide for more information on aggregate functions
- Oracle Database Data Warehousing Guide for more information on running and final semantics

Examples

SQL Macros - Table Valued Macros: Examples

The macro function budget computes the amount of each department's budget for a given job. It returns the number of employees in each department with the specified job title.

create or replace function budget(job varchar2) return varchar2 SQL_MACRO is
begin
  return q'{
    select deptno, sum(sal) budget
    from emp
    where job = budget.job
    group by deptno
  }';
end;
/

SELECT * FROM budget ('MANAGER');
DEPTNO BUDGET
Using a PL/SQL Function in the WITH Clause: Examples

The following example declares and defines a PL/SQL function `get_domain` in the WITH clause. The `get_domain` function returns the domain name from a URL string, assuming that the URL string has the "www" prefix immediately preceding the domain name, and the domain name is separated by dots on the left and right. The `SELECT` statement uses `get_domain` to find distinct catalog domain names from the `orders` table in the oe schema.

```sql
WITH FUNCTION get_domain(url VARCHAR2) RETURN VARCHAR2 IS
    pos BINARY_INTEGER;
    len BINARY_INTEGER;
BEGIN
    pos := INSTR(url, 'www.');
    len := INSTR(SUBSTR(url, pos + 4), '.') - 1;
    RETURN SUBSTR(url, pos + 4, len);
END;
SELECT DISTINCT get_domain(catalog_url)
FROM product_information;
```

Subquery Factoring: Example

The following statement creates the query names `dept_costs` and `avg_cost` for the initial query block containing a join, and then uses the query names in the body of the main query.

```sql
WITH dept_costs AS (
    SELECT department_name, SUM(salary) dept_total
    FROM employees e, departments d
    WHERE e.department_id = d.department_id
    GROUP BY department_name),
avg_cost AS (
    SELECT SUM(dept_total)/COUNT(*) avg
    FROM dept_costs)
SELECT * FROM dept_costs
WHERE dept_total >
    (SELECT avg FROM avg_cost)
ORDER BY department_name;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_NAME</th>
<th>DEPT_TOTAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sales</td>
<td>304500</td>
</tr>
<tr>
<td>Shipping</td>
<td>156400</td>
</tr>
</tbody>
</table>

Recursive Subquery Factoring: Examples

The following statement shows the employees who directly or indirectly report to employee 101 and their reporting level.

```sql
WITH reports_to_101 (eid, emp_last, mgr_id, reportLevel) AS
    (SELECT employee_id, last_name, manager_id, 0 reportLevel
    WHERE
    
```
FROM employees
WHERE employee_id = 101
UNION ALL
SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1
FROM reports_to_101 r, employees e
WHERE r.eid = e.manager_id
)
SELECT eid, emp_last, mgr_id, reportLevel
FROM reports_to_101
ORDER BY reportLevel, eid;

The following statement shows employees who directly or indirectly report to employee 101, their reporting level, and their management chain.

WITH
reports_to_101 (eid, emp_last, mgr_id, reportLevel, mgr_list) AS
(
    SELECT employee_id, last_name, manager_id, 0 reportLevel,
    CAST(manager_id AS VARCHAR2(2000))
    FROM employees
    WHERE employee_id = 101
    UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1,
    CAST(mgr_list || ',' || manager_id AS VARCHAR2(2000))
    FROM reports_to_101 r, employees e
    WHERE r.eid = e.manager_id
)
SELECT eid, emp_last, mgr_id, reportLevel, mgr_list
FROM reports_to_101
ORDER BY reportLevel, eid;

EID  EMP_LAST  MGR_ID  REPORTLEVEL
------------  --------  -------  -----------
101 Kochhar     100      0
108 Greenberg   101      1
200 Whalen      101      1
203 Mavris      101      1
204 Baer        101      1

Analytic Views: Examples

The following statement uses the persistent analytic view sales_av. The query selects the member_name hierarchical attribute of time_hier, which is the alias of a hierarchy of the same name, and values from the sales and units measures of the analytic view that are dimensioned by the time attribute dimension used by the time_hier hierarchy. The results of the selection are filtered to those for the YEAR level of the hierarchy. The results are returned in hierarchical order.

SELECT time_hier.member_name as TIME,
       sales,
       units
FROM sales_av HIERARCHIES(time_hier)
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;

The results of the query are the following:

<table>
<thead>
<tr>
<th>TIME</th>
<th>SALES</th>
<th>UNITS</th>
</tr>
</thead>
<tbody>
<tr>
<td>CY2011</td>
<td>6755115980.73</td>
<td>24462444</td>
</tr>
<tr>
<td>CY2012</td>
<td>6901682398.95</td>
<td>24400619</td>
</tr>
<tr>
<td>CY2013</td>
<td>7240938717.57</td>
<td>24407259</td>
</tr>
<tr>
<td>CY2014</td>
<td>7579746352.89</td>
<td>24402666</td>
</tr>
<tr>
<td>CY2015</td>
<td>7941102885.15</td>
<td>24475206</td>
</tr>
</tbody>
</table>

Transitory Analytic View Examples

The following statement defines the transitory analytic view my_av in the WITH clause. The transitory analytic view is based on the persistent analytic view sales_av. The lag_sales calculated measure is a LAG calculation that is used at query time.

WITH
  my_av ANALYTIC VIEW AS (  
    USING sales_av HIERARCHIES (time_hier)
    ADD MEASURES (}
lag_sales AS (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1))
)
)

SELECT time_hier.member_name time, sales, lag_sales
FROM my_av HIERARCHIES (time_hier)
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;

The results of the query are the following:

<table>
<thead>
<tr>
<th>TIME</th>
<th>SALES</th>
<th>LAG_SALES</th>
</tr>
</thead>
<tbody>
<tr>
<td>CY2011</td>
<td>6755115981</td>
<td>(null)</td>
</tr>
<tr>
<td>CY2012</td>
<td>6901682399</td>
<td>6755115981</td>
</tr>
<tr>
<td>CY2013</td>
<td>7240938718</td>
<td>6901682399</td>
</tr>
<tr>
<td>CY2014</td>
<td>7579746353</td>
<td>7240938718</td>
</tr>
<tr>
<td>CY2015</td>
<td>7941102885</td>
<td>7579746353</td>
</tr>
</tbody>
</table>

The following statement defines a transitory analytic view that uses a filter clause.

WITH
my_av ANALYTIC VIEW AS (
    USING sales_av HIERARCHIES (time_hier)
    FILTER FACT {
        time_hier TO quarter_of_year IN (1, 2)
        AND year_name IN ('CY2011', 'CY2012')
    }
)

SELECT time_hier.member_name time, sales
FROM my_av HIERARCHIES (time_hier)
WHERE time_hier.level_name IN ('YEAR', 'QUARTER')
ORDER BY time_hier.hier_order;

The results of the query are the following:

<table>
<thead>
<tr>
<th>TIME</th>
<th>SALES</th>
</tr>
</thead>
<tbody>
<tr>
<td>CY2011</td>
<td>3340459835</td>
</tr>
<tr>
<td>Q1CY2011</td>
<td>1625299627</td>
</tr>
<tr>
<td>Q2CY2011</td>
<td>1715160208</td>
</tr>
<tr>
<td>CY2012</td>
<td>3397271965</td>
</tr>
<tr>
<td>Q1CY2012</td>
<td>1644857783</td>
</tr>
<tr>
<td>Q2CY2012</td>
<td>1752414182</td>
</tr>
</tbody>
</table>

Inline Analytic View Example

The following statement defines an inline analytic view in the FROM clause. The transitory analytic view is based on the persistent analytic view sales_av. The lag_sales calculated measure is a LAG calculation that is used at query time.

SELECT time_hier.member_name time, sales, lag_sales
FROM
    ANALYTIC VIEW (
USING sales_av HIERARCHIES (time_hier)
ADD MEASURES (
  lag_sales AS (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1))
)
)
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;

The results of the query are the following:

<table>
<thead>
<tr>
<th>TIME</th>
<th>SALES</th>
<th>LAG_SALES</th>
</tr>
</thead>
<tbody>
<tr>
<td>CY2011</td>
<td>6755115981</td>
<td>(null)</td>
</tr>
<tr>
<td>CY2012</td>
<td>6901682399</td>
<td>6755115981</td>
</tr>
<tr>
<td>CY2013</td>
<td>7240938718</td>
<td>6901682399</td>
</tr>
<tr>
<td>CY2014</td>
<td>7579746353</td>
<td>7240938718</td>
</tr>
<tr>
<td>CY2015</td>
<td>7941102885</td>
<td>7579746353</td>
</tr>
</tbody>
</table>

Simple Query Examples

The following statement selects rows from the employees table with the department number of 30:

```
SELECT *
FROM employees
WHERE department_id = 30
ORDER BY last_name;
```

The following statement selects the name, job, salary and department number of all employees except purchasing clerks from department number 30:

```
SELECT last_name, job_id, salary, department_id
FROM employees
WHERE NOT (job_id = 'PU_CLERK' AND department_id = 30)
ORDER BY last_name;
```

The following statement selects from subqueries in the FROM clause and for each department returns the total employees and salaries as a decimal value of all the departments:

```
SELECT a.department_id "Department",
       a.num_emp/b.total_count "%_Employees",
       a.sal_sum/b.total_sal "%_Salary"
FROM
  (SELECT department_id, COUNT(*) num_emp, SUM(salary) sal_sum
   FROM employees
   GROUP BY department_id) a,
  (SELECT COUNT(*) total_count, SUM(salary) total_sal
   FROM employees) b
ORDER BY a.department_id;
```

Selecting from a Partition: Example

You can select rows from a single partition of a partitioned table by specifying the keyword PARTITION in the FROM clause. This SQL statement assigns an alias for and retrieves rows from the sales_q2_2000 partition of the sample table sh.sales:
SELECT * FROM sales PARTITION (sales_q2_2000) s
    WHERE s.amount_sold > 1500
    ORDER BY cust_id, time_id, channel_id;

The following example selects rows from the oe.orders table for orders earlier than a specified date:

SELECT * FROM orders
    WHERE order_date < TO_DATE('2006-06-15', 'YYYY-MM-DD');

Selecting a Sample: Examples

The following query estimates the number of orders in the oe.orders table:

SELECT COUNT(*) * 10 FROM orders SAMPLE (10);

<table>
<thead>
<tr>
<th>COUNT(*)*10</th>
</tr>
</thead>
<tbody>
<tr>
<td>70</td>
</tr>
</tbody>
</table>

Because the query returns an estimate, the actual return value may differ from one query to the next.

SELECT COUNT(*) * 10 FROM orders SAMPLE (10);

<table>
<thead>
<tr>
<th>COUNT(*)*10</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
</tr>
</tbody>
</table>

The following query adds a seed value to the preceding query. Oracle Database always returns the same estimate given the same seed value:

SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED (1);

<table>
<thead>
<tr>
<th>COUNT(*)*10</th>
</tr>
</thead>
<tbody>
<tr>
<td>130</td>
</tr>
</tbody>
</table>

SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED(4);

<table>
<thead>
<tr>
<th>COUNT(*)*10</th>
</tr>
</thead>
<tbody>
<tr>
<td>120</td>
</tr>
</tbody>
</table>

SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED (1);

<table>
<thead>
<tr>
<th>COUNT(*)*10</th>
</tr>
</thead>
<tbody>
<tr>
<td>130</td>
</tr>
</tbody>
</table>

Using Flashback Queries: Example

The following statements show a current value from the sample table hr.employees and then change the value. The intervals used in these examples are very short for demonstration purposes. Time intervals in your own environment are likely to be larger.

SELECT salary FROM employees
    WHERE last_name = 'Chung';

 | SALARY |
UPDATE employees SET salary = 4000
    WHERE last_name = 'Chung';

SELECT salary FROM employees
    WHERE last_name = 'Chung';

SALARY
---------
4000

To learn what the value was before the update, you can use the following Flashback Query:

SELECT salary FROM employees
    AS OF TIMESTAMP (SYSTIMESTAMP - INTERVAL '1' MINUTE)
    WHERE last_name = 'Chung';

SALARY
---------
3800

To learn what the values were during a particular time period, you can use a version Flashback Query:

SELECT salary FROM employees
    VERSIONS BETWEEN TIMESTAMP SYSTIMESTAMP - INTERVAL '10' MINUTE AND
    SYSTIMESTAMP - INTERVAL '1' MINUTE
    WHERE last_name = 'Chung';

To revert to the earlier value, use the Flashback Query as the subquery of another UPDATE statement:

UPDATE employees SET salary =
    (SELECT salary FROM employees
     AS OF TIMESTAMP (SYSTIMESTAMP - INTERVAL '2' MINUTE)
     WHERE last_name = 'Chung')
    WHERE last_name = 'Chung';

SELECT salary FROM employees
    WHERE last_name = 'Chung';

SALARY
---------
3800

Using the GROUP BY Clause: Examples

To return the minimum and maximum salaries for each department in the employees table, issue the following statement:

SELECT department_id, MIN(salary), MAX(salary)
    FROM employees
    GROUP BY department_id
    ORDER BY department_id;
To return the minimum and maximum salaries for the clerks in each department, issue the following statement:

```sql
SELECT department_id, MIN(salary), MAX(salary)
FROM employees
WHERE job_id = 'PU_CLERK'
GROUP BY department_id
ORDER BY department_id;
```

**Using the GROUP BY CUBE Clause: Example**

To return the number of employees and their average yearly salary across all possible combinations of department and job category, issue the following query on the sample tables hr.employees and hr.departments:

```sql
SELECT DECODE(GROUPING(department_name), 1, 'All Departments',
              department_name) AS department_name,
       DECODE(GROUPING(job_id), 1, 'All Jobs', job_id) AS job_id,
       COUNT(*) "Total Empl", AVG(salary) * 12 "Average Sal"
FROM employees e, departments d
WHERE d.department_id = e.department_id
GROUP BY CUBE (department_name, job_id)
ORDER BY department_name, job_id;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_NAME</th>
<th>JOB_ID</th>
<th>Total Empl</th>
<th>Average Sal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accounting</td>
<td>AC_ACCOUNT</td>
<td>1</td>
<td>99600</td>
</tr>
<tr>
<td>Accounting</td>
<td>AC_MGR</td>
<td>1</td>
<td>144000</td>
</tr>
<tr>
<td>Accounting</td>
<td>All Jobs</td>
<td>2</td>
<td>121800</td>
</tr>
<tr>
<td>Administration</td>
<td>AD_ASST</td>
<td>1</td>
<td>52800</td>
</tr>
<tr>
<td>. . .</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Shipping</td>
<td>ST_CLERK</td>
<td>20</td>
<td>33420</td>
</tr>
<tr>
<td>Shipping</td>
<td>ST_MAN</td>
<td>5</td>
<td>87360</td>
</tr>
</tbody>
</table>

**Using the GROUPING SETS Clause: Example**

The following example finds the sum of sales aggregated for three precisely specified groups:

- (channel_desc, calendar_month_desc, country_id)
- (channel_desc, country_id)
- (calendar_month_desc, country_id)

Without the GROUPING SETS syntax, you would have to write less efficient queries with more complicated SQL. For example, you could run three separate queries and UNION them, or run a query with a CUBE(channel_desc, calendar_month_desc, country_id) operation and filter out five of the eight groups it would generate.

```sql
SELECT channel_desc, calendar_month_desc, co.country_id,
       TO_CHAR(sum(amount_sold) , '9,999,999,999') 'SALES$
FROM sales, customers, times, channels, countries co
WHERE sales.time_id=times.time_id
  AND sales.cust_id=customers.cust_id
  AND sales.channel_id=channels.channel_id
  AND customers.country_id = co.country_id
  AND channels.channel_desc IN ('Direct Sales', 'Internet')
  AND times.calendar_month_desc IN ('2000-09', '2000-10')
  AND co.country_iso_code IN ('UK', 'US')
GROUP BY GROUPING SETS((channel_desc, calendar_month_desc, co.country_id),
```
(channel_desc, co.country_id),
(calendar_month_desc, co.country_id) );

<table>
<thead>
<tr>
<th>CHANNEL_DESC</th>
<th>CALENDAR</th>
<th>COUNTRY_ID</th>
<th>SALES$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet</td>
<td>2000-09</td>
<td>52790</td>
<td>124,224</td>
</tr>
<tr>
<td>Direct Sales</td>
<td>2000-09</td>
<td>52790</td>
<td>638,201</td>
</tr>
<tr>
<td>Internet</td>
<td>2000-10</td>
<td>52790</td>
<td>137,054</td>
</tr>
<tr>
<td>Direct Sales</td>
<td>2000-10</td>
<td>52790</td>
<td>682,297</td>
</tr>
<tr>
<td></td>
<td>2000-09</td>
<td>52790</td>
<td>762,425</td>
</tr>
<tr>
<td></td>
<td>2000-10</td>
<td>52790</td>
<td>819,351</td>
</tr>
<tr>
<td>Internet</td>
<td></td>
<td>52790</td>
<td>261,278</td>
</tr>
<tr>
<td>Direct Sales</td>
<td></td>
<td>52790</td>
<td>1,320,497</td>
</tr>
</tbody>
</table>

The functions GROUP_ID, GROUPING, and GROUPING_ID for more information on those functions

Hierarchical Query Examples

The following query with a CONNECT BY clause defines a hierarchical relationship in which the employee_id value of the parent row is equal to the manager_id value of the child row:

```sql
SELECT last_name, employee_id, manager_id FROM employees
    CONNECT BY employee_id = manager_id
    ORDER BY last_name;
```

In the following CONNECT BY clause, the PRIOR operator applies only to the employee_id value. To evaluate this condition, the database evaluates employee_id values for the parent row and manager_id, salary, and commission_pct values for the child row:

```sql
SELECT last_name, employee_id, manager_id FROM employees
    CONNECT BY PRIOR employee_id = manager_id
    AND salary > commission_pct
    ORDER BY last_name;
```

To qualify as a child row, a row must have a manager_id value equal to the employee_id value of the parent row and it must have a salary value greater than its commission_pct value.

Using the HAVING Condition: Example

To return the minimum and maximum salaries for the employees in each department whose lowest salary is less than $5,000, issue the next statement:

```sql
SELECT department_id, MIN(salary), MAX(salary)
    FROM employees
    GROUP BY department_id
    HAVING MIN(salary) < 5000
    ORDER BY department_id;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_ID</th>
<th>MIN(SALARY)</th>
<th>MAX(SALARY)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>4400</td>
<td>4400</td>
</tr>
<tr>
<td>30</td>
<td>2500</td>
<td>11000</td>
</tr>
</tbody>
</table>
The following example uses a correlated subquery in a `HAVING` clause that eliminates from the result set any departments without managers and managers without departments:

```
SELECT department_id, manager_id
FROM employees
GROUP BY department_id, manager_id HAVING (department_id, manager_id) IN
(SELECT department_id, manager_id FROM employees x
WHERE x.department_id = employees.department_id)
ORDER BY department_id;
```

### Using the ORDER BY Clause: Examples

To select all purchasing clerk records from `employees` and order the results by salary in descending order, issue the following statement:

```
SELECT *
FROM employees
WHERE job_id = 'PU_CLERK'
ORDER BY salary DESC;
```

To select information from `employees` ordered first by ascending department number and then by descending salary, issue the following statement:

```
SELECT last_name, department_id, salary
FROM employees
ORDER BY department_id ASC, salary DESC, last_name;
```

To select the same information as the previous `SELECT` and use the positional `ORDER BY` notation, issue the following statement, which orders by ascending `department_id`, then descending `salary`, and finally alphabetically by `last_name`:

```
SELECT last_name, department_id, salary
FROM employees
ORDER BY 2 ASC, 3 DESC, 1;
```

### The MODEL clause: Examples

The view created below is based on the sample `sh` schema and is used by the example that follows.

```
CREATE OR REPLACE VIEW sales_view_ref AS
SELECT country_name country,
    prod_name prod,
    calendar_year year,
    SUM(amount_sold) sale,
    COUNT(amount_sold) cnt
FROM sales,times,customers,countries,products
WHERE sales.time_id = times.time_id
AND sales.prod_id = products.prod_id
AND sales.cust_id = customers.cust_id
AND customers.country_id = countries.country_id
AND (customers.country_id = 52779
    OR customers.country_id = 52776 )
AND (prod_name = 'Standard Mouse'
    OR prod_name = 'Mouse Pad' )
GROUP BY country_name,prod_name,calendar_year;
```
The next example creates a multidimensional array from `sales_view_ref` with columns containing country, product, year, and sales. It also:

- Assigns the sum of the sales of the Mouse Pad for years 1999 and 2000 to the sales of the Mouse Pad for year 2001, if a row containing sales of the Mouse Pad for year 2001 exists.

- Assigns the value of sales of the Standard Mouse for year 2001 to sales of the Standard Mouse for year 2002, creating a new row if a row containing sales of the Standard Mouse for year 2002 does not exist.

```sql
SELECT country, prod, year, s
FROM sales_view_ref
MODEL
PARTITION BY (country)
DIMENSION BY (prod, year)
MEASURES (sale s)
IGNORE NAV
UNIQUE DIMENSION
RULES UPSERT SEQUENTIAL ORDER
{
    s[prod='Mouse Pad', year=2001] =
    s['Mouse Pad', 1999] + s['Mouse Pad', 2000],
    s['Standard Mouse', 2002] = s['Standard Mouse', 2001]
}
ORDER BY country, prod, year;
```
The first rule uses **UPDATE** behavior because symbolic referencing is used on the left-hand side of the rule. The rows represented by the left-hand side of the rule exist, so the measure columns are updated. If the rows did not exist, then no action would have been taken.

The second rule uses **UPSERT** behavior because positional referencing is used on the left-hand side and a single cell is referenced. The rows do not exist, so new rows are inserted and the related measure columns are updated. If the rows did exist, then the measure columns would have been updated.

Oracle Database Data Warehousing Guide for an expanded discussion and examples

The next example uses the same `sales_view_ref` view and the analytic function `SUM` to calculate a cumulative sum (`csum`) of sales per country and per year.

```sql
SELECT country, year, sale, csum
FROM
  (SELECT country, year, SUM(sale) sale
   FROM sales_view_ref
   GROUP BY country, year
  )
MODEL DIMENSION BY (country, year)
  MEASURES (sale, 0 csum)
  RULES (csum[any, any]=
    SUM(sale) OVER (PARTITION BY country
                  ORDER BY year
                  ROWS UNBOUNDED PRECEDING)
  )
ORDER BY country, year;
```

<table>
<thead>
<tr>
<th>COUNTRY</th>
<th>YEAR</th>
<th>SALE</th>
<th>CSUM</th>
</tr>

</tbody>
</table>
Row Limiting: Examples

The following statement returns the 5 employees with the lowest `employee_id` values:

```sql
SELECT employee_id, last_name
FROM employees
ORDER BY employee_id
FETCH FIRST 5 ROWS ONLY;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>King</td>
</tr>
<tr>
<td>101</td>
<td>Kochhar</td>
</tr>
<tr>
<td>102</td>
<td>De Haan</td>
</tr>
<tr>
<td>103</td>
<td>Hunold</td>
</tr>
<tr>
<td>104</td>
<td>Ernst</td>
</tr>
</tbody>
</table>

The following statement returns the next 5 employees with the lowest `employee_id` values:

```sql
SELECT employee_id, last_name
FROM employees
ORDER BY employee_id
OFFSET 5 ROWS FETCH NEXT 5 ROWS ONLY;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>105</td>
<td>Austin</td>
</tr>
<tr>
<td>106</td>
<td>Pataballa</td>
</tr>
<tr>
<td>107</td>
<td>Lorentz</td>
</tr>
<tr>
<td>108</td>
<td>Greenberg</td>
</tr>
<tr>
<td>109</td>
<td>Faviet</td>
</tr>
</tbody>
</table>

The following statement returns the 5 percent of employees with the lowest salaries:

```sql
SELECT employee_id, last_name, salary
FROM employees
ORDER BY salary
FETCH FIRST 5 PERCENT ROWS ONLY;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>132</td>
<td>Olson</td>
<td>2100</td>
</tr>
<tr>
<td>128</td>
<td>Markle</td>
<td>2200</td>
</tr>
<tr>
<td>136</td>
<td>Philtanker</td>
<td>2200</td>
</tr>
<tr>
<td>127</td>
<td>Landry</td>
<td>2400</td>
</tr>
<tr>
<td>135</td>
<td>Gee</td>
<td>2400</td>
</tr>
<tr>
<td>119</td>
<td>Colmenares</td>
<td>2500</td>
</tr>
</tbody>
</table>

Because `WITH TIES` is specified, the following statement returns the 5 percent of employees with the lowest salaries, plus all additional employees with the same salary as the last row fetched in the previous example:

```sql
SELECT employee_id, last_name, salary
FROM employees
ORDER BY salary
FETCH FIRST 5 PERCENT ROWS WITH TIES;
```
<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>132</td>
<td>Olson</td>
<td>2100</td>
</tr>
<tr>
<td>128</td>
<td>Markle</td>
<td>2200</td>
</tr>
<tr>
<td>136</td>
<td>Philtanker</td>
<td>2200</td>
</tr>
<tr>
<td>127</td>
<td>Landry</td>
<td>2400</td>
</tr>
<tr>
<td>135</td>
<td>Gee</td>
<td>2400</td>
</tr>
<tr>
<td>119</td>
<td>Colmenares</td>
<td>2500</td>
</tr>
<tr>
<td>131</td>
<td>Marlow</td>
<td>2500</td>
</tr>
<tr>
<td>140</td>
<td>Patel</td>
<td>2500</td>
</tr>
<tr>
<td>144</td>
<td>Vargas</td>
<td>2500</td>
</tr>
<tr>
<td>182</td>
<td>Sullivan</td>
<td>2500</td>
</tr>
<tr>
<td>191</td>
<td>Perkins</td>
<td>2500</td>
</tr>
</tbody>
</table>

Using the FOR UPDATE Clause: Examples

The following statement locks rows in the `employees` table with purchasing clerks located in Oxford, which has `location_id` 2500, and locks rows in the `departments` table with departments in Oxford that have purchasing clerks:

```sql
SELECT e.employee_id, e.salary, e.commission_pct
FROM employees e, departments d
WHERE job_id = 'SA_REP'
AND e.department_id = d.department_id
AND location_id = 2500
ORDER BY e.employee_id
FOR UPDATE;
```

The following statement locks only those rows in the `employees` table with purchasing clerks located in Oxford. No rows are locked in the `departments` table:

```sql
SELECT e.employee_id, e.salary, e.commission_pct
FROM employees e JOIN departments d
USING (department_id)
WHERE job_id = 'SA_REP'
AND location_id = 2500
ORDER BY e.employee_id
FOR UPDATE OF e.salary;
```

Using the WITH CHECK OPTION Clause: Example

The following statement is legal even though the third value inserted violates the condition of the subquery `where_clause`:

```sql
INSERT INTO (SELECT department_id, department_name, location_id
FROM departments WHERE location_id < 2000)
VALUES (9999, 'Entertainment', 2500);
```

However, the following statement is illegal because it contains the `WITH CHECK OPTION` clause:

```sql
INSERT INTO (SELECT department_id, department_name, location_id
FROM departments WHERE location_id < 2000 WITH CHECK OPTION)
VALUES (9999, 'Entertainment', 2500);
```

ERROR at line 2:
ORA-01402: view WITH CHECK OPTION where-clause violation

Using PIVOT and UNPIVOT: Examples
The oe.orders table contains information about when an order was placed (order_date), how it was place (order_mode), and the total amount of the order (order_total), as well as other information. The following example shows how to use the PIVOT clause to pivot order_mode values into columns, aggregating order_total data in the process, to get yearly totals by order mode:

```sql
CREATE TABLE pivot_table AS
SELECT * FROM
(SELECT EXTRACT(YEAR FROM order_date) year, order_mode, order_total FROM orders)
PIVOT
(SUM(order_total) FOR order_mode IN ('direct' AS Store, 'online' AS Internet));
```

```
<table>
<thead>
<tr>
<th>YEAR</th>
<th>STORE</th>
<th>INTERNET</th>
</tr>
</thead>
<tbody>
<tr>
<td>2004</td>
<td>5546.6</td>
<td></td>
</tr>
<tr>
<td>2006</td>
<td>371895.5</td>
<td>100056.6</td>
</tr>
<tr>
<td>2007</td>
<td>1274078.8</td>
<td>1271019.5</td>
</tr>
<tr>
<td>2008</td>
<td>252108.3</td>
<td>393349.4</td>
</tr>
</tbody>
</table>
```

The UNPIVOT clause lets you rotate specified columns so that the input column headings are output as values of one or more descriptor columns, and the input column values are output as values of one or more measures columns. The first query that follows shows that nulls are excluded by default. The second query shows that you can include nulls using the INCLUDE NULLS clause.

```sql
SELECT * FROM pivot_table
UNPIVOT (yearly_total FOR order_mode IN (store AS 'direct', internet AS 'online'))
ORDER BY year, order_mode;
```

```
<table>
<thead>
<tr>
<th>YEAR</th>
<th>ORDER_ YEARLY_TOTAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>2004</td>
<td>direct 5546.6</td>
</tr>
<tr>
<td>2006</td>
<td>direct 371895.5</td>
</tr>
<tr>
<td>2006</td>
<td>online 100056.6</td>
</tr>
<tr>
<td>2007</td>
<td>direct 1274078.8</td>
</tr>
<tr>
<td>2007</td>
<td>online 1271019.5</td>
</tr>
<tr>
<td>2008</td>
<td>direct 252108.3</td>
</tr>
<tr>
<td>2008</td>
<td>online 393349.4</td>
</tr>
</tbody>
</table>
```

7 rows selected.

```sql
SELECT * FROM pivot_table
UNPIVOT INCLUDE NULLS
(yearly_total FOR order_mode IN (store AS 'direct', internet AS 'online'))
ORDER BY year, order_mode;
```

```
<table>
<thead>
<tr>
<th>YEAR</th>
<th>ORDER_ YEARLY_TOTAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>2004</td>
<td>direct 5546.6</td>
</tr>
<tr>
<td>2004</td>
<td>online</td>
</tr>
<tr>
<td>2006</td>
<td>direct 371895.5</td>
</tr>
<tr>
<td>2006</td>
<td>online 100056.6</td>
</tr>
<tr>
<td>2007</td>
<td>direct 1274078.8</td>
</tr>
<tr>
<td>2007</td>
<td>online 1271019.5</td>
</tr>
<tr>
<td>2008</td>
<td>direct 252108.3</td>
</tr>
<tr>
<td>2008</td>
<td>online 393349.4</td>
</tr>
</tbody>
</table>
```

7 rows selected.
Using Join Queries: Examples

The following examples show various ways of joining tables in a query. In the first example, an equijoin returns the name and job of each employee and the number and name of the department in which the employee works:

```
SELECT last_name, job_id, departments.department_id, department_name
FROM employees, departments
WHERE employees.department_id = departments.department_id
ORDER BY last_name, job_id;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>JOB_ID</th>
<th>DEPARTMENT_ID</th>
<th>DEPARTMENT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abel</td>
<td>SA_REP</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Ande</td>
<td>SA_REP</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Atkinson</td>
<td>ST_CLERK</td>
<td>50</td>
<td>Shipping</td>
</tr>
<tr>
<td>Austin</td>
<td>IT_PROG</td>
<td>60</td>
<td>IT</td>
</tr>
</tbody>
</table>

You must use a join to return this data because employee names and jobs are stored in a different table than department names. Oracle Database combines rows of the two tables according to this join condition:

```
employees.department_id = departments.department_id
```

The following equijoin returns the name, job, department number, and department name of all sales managers:

```
SELECT last_name, job_id, departments.department_id, department_name
FROM employees, departments
WHERE employees.department_id = departments.department_id
AND job_id = 'SA_MAN'
ORDER BY last_name;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>JOB_ID</th>
<th>DEPARTMENT_ID</th>
<th>DEPARTMENT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cambrault</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Errazuriz</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Partners</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Russell</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Zlotkey</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
</tbody>
</table>

This query is identical to the preceding example, except that it uses an additional `where_clause` condition to return only rows with a `job` value of ‘SA_MAN’.

Using Subqueries: Examples

To determine who works in the same department as employee 'Lorentz', issue the following statement:

```
SELECT last_name, department_id FROM employees
WHERE department_id =
  (SELECT department_id FROM employees
   WHERE last_name = 'Lorentz')
ORDER BY last_name, department_id;
```

To give all employees in the `employees` table a 10% raise if they have changed jobs—if they appear in the `job_history` table—issue the following statement:
UPDATE employees
    SET salary = salary * 1.1
    WHERE employee_id IN (SELECT employee_id FROM job_history);

To create a second version of the departments table new_departments, with only three of the columns of the original table, issue the following statement:

CREATE TABLE new_departments
    (department_id, department_name, location_id)
AS SELECT department_id, department_name, location_id
    FROM departments;

Using Self Joins: Example

The following query uses a self join to return the name of each employee along with the name of the employee’s manager. A WHERE clause is added to shorten the output.

```
SELECT e1.last_name||' works for '||e2.last_name
    "Employees and Their Managers"
FROM employees e1, employees e2
WHERE e1.manager_id = e2.employee_id
    AND e1.last_name LIKE 'R%'
ORDER BY e1.last_name;
```

Employees and Their Managers
-------------------------------
Rajs works for Mourgos
Raphaely works for King
Rogers works for Kaufling
Russell works for King

The join condition for this query uses the aliases e1 and e2 for the sample table employees:

e1.manager_id = e2.employee_id

Using Outer Joins: Examples

The following example shows how a partitioned outer join fills data gaps in rows to facilitate analytic function specification and reliable report formatting. The example first creates a small data table to be used in the join:

```
SELECT d.department_id, e.last_name
    FROM departments d LEFT OUTER JOIN employees e
    ON d.department_id = e.department_id
ORDER BY d.department_id, e.last_name;
```

Users familiar with the traditional Oracle Database outer joins syntax will recognize the same query in this form:

```
SELECT d.department_id, e.last_name
    FROM departments d, employees e
WHERE d.department_id = e.department_id(+)
ORDER BY d.department_id, e.last_name;
```

Oracle strongly recommends that you use the more flexible FROM clause join syntax shown in the former example.

The left outer join returns all departments, including those without any employees. The same statement with a right outer join returns all employees, including those not yet assigned to a department:
The employee Zeuss was added to the employees table for these examples, and is not part of the sample data.

```
SELECT d.department_id, e.last_name
FROM departments d RIGHT OUTER JOIN employees e
ON d.department_id = e.department_id
ORDER BY d.department_id, e.last_name;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>110</td>
<td>Gietz</td>
</tr>
<tr>
<td>110</td>
<td>Higgins</td>
</tr>
<tr>
<td>110</td>
<td>Grant</td>
</tr>
<tr>
<td>110</td>
<td>Zeuss</td>
</tr>
</tbody>
</table>

It is not clear from this result whether employees Grant and Zeuss have department_id NULL, or whether their department_id is not in the departments table.

To determine this requires a full outer join:

```
SELECT d.department_id as d_dept_id, e.department_id as e_dept_id, e.last_name
FROM departments d FULL OUTER JOIN employees e
ON d.department_id = e.department_id
ORDER BY d.department_id, e.last_name;
```

<table>
<thead>
<tr>
<th>D_DEPT_ID</th>
<th>E_DEPT_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>110</td>
<td>110</td>
<td>Gietz</td>
</tr>
<tr>
<td>110</td>
<td>110</td>
<td>Higgins</td>
</tr>
<tr>
<td>110</td>
<td>110</td>
<td>Grant</td>
</tr>
<tr>
<td>110</td>
<td>110</td>
<td>Zeuss</td>
</tr>
<tr>
<td>260</td>
<td>110</td>
<td>Higgins</td>
</tr>
<tr>
<td>260</td>
<td>110</td>
<td>Gietz</td>
</tr>
<tr>
<td>260</td>
<td>110</td>
<td>Grant</td>
</tr>
<tr>
<td>260</td>
<td>270</td>
<td></td>
</tr>
<tr>
<td>270</td>
<td>999</td>
<td>Zeuss</td>
</tr>
</tbody>
</table>

Because the column names in this example are the same in both tables in the join, you can also use the common column feature by specifying the USING clause of the join syntax. The output is the same as for the preceding example except that the USING clause coalesces the two matching columns department_id into a single column output:

```
SELECT department_id AS d_e_dept_id, e.last_name
FROM departments d FULL OUTER JOIN employees e
USING (department_id)
ORDER BY department_id, e.last_name;
```

<table>
<thead>
<tr>
<th>D_E_DEPT_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>110</td>
<td>Higgins</td>
</tr>
<tr>
<td>110</td>
<td>Gietz</td>
</tr>
<tr>
<td>110</td>
<td>Grant</td>
</tr>
<tr>
<td>110</td>
<td>Zeuss</td>
</tr>
<tr>
<td>260</td>
<td></td>
</tr>
<tr>
<td>260</td>
<td>270</td>
</tr>
</tbody>
</table>
Using Partitioned Outer Joins: Examples

The following example shows how a partitioned outer join fills in gaps in rows to facilitate analytic calculation specification and reliable report formatting. The example first creates and populates a simple table to be used in the join:

```sql
CREATE TABLE inventory (time_id DATE,
                        product VARCHAR2(10),
                        quantity NUMBER);

INSERT INTO inventory VALUES (TO_DATE('01/04/01', 'DD/MM/YY'), 'bottle', 10);
INSERT INTO inventory VALUES (TO_DATE('06/04/01', 'DD/MM/YY'), 'bottle', 10);
INSERT INTO inventory VALUES (TO_DATE('01/04/01', 'DD/MM/YY'), 'can', 10);
INSERT INTO inventory VALUES (TO_DATE('04/04/01', 'DD/MM/YY'), 'can', 10);

SELECT times.time_id, product, quantity FROM inventory
PARTITION BY  (product)
RIGHT OUTER JOIN times ON (times.time_id = inventory.time_id)
WHERE times.time_id BETWEEN TO_DATE('01/04/01', 'DD/MM/YY')
    AND TO_DATE('06/04/01', 'DD/MM/YY')
ORDER BY  2,1;
```

<table>
<thead>
<tr>
<th>TIME_ID</th>
<th>PRODUCT</th>
<th>QUANTITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>01-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>02-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>03-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>04-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>05-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>06-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
<tr>
<td>01-APR-01</td>
<td>can</td>
<td>10</td>
</tr>
<tr>
<td>02-APR-01</td>
<td>can</td>
<td></td>
</tr>
<tr>
<td>03-APR-01</td>
<td>can</td>
<td></td>
</tr>
<tr>
<td>04-APR-01</td>
<td>can</td>
<td>10</td>
</tr>
<tr>
<td>05-APR-01</td>
<td>can</td>
<td></td>
</tr>
<tr>
<td>06-APR-01</td>
<td>can</td>
<td></td>
</tr>
</tbody>
</table>

12 rows selected.

The data is now more dense along the time dimension for each partition of the product dimension. However, each of the newly added rows within each partition is null in the quantity column. It is more useful to see the nulls replaced by the preceding non-NULL value in time order. You can achieve this by applying the analytic function \texttt{LAST\_VALUE} on top of the query result:

```sql
SELECT time_id, product, LAST_VALUE(quantity IGNORE NULLS)
OVER (PARTITION BY product ORDER BY time_id) quantity
FROM ( SELECT times.time_id, product, quantity
        FROM inventory PARTITION BY  (product)
        RIGHT OUTER JOIN times ON (times.time_id = inventory.time_id)
        WHERE times.time_id BETWEEN TO_DATE('01/04/01', 'DD/MM/YY')
            AND TO_DATE('06/04/01', 'DD/MM/YY')
        ORDER BY  2,1;)
```

<table>
<thead>
<tr>
<th>TIME_ID</th>
<th>PRODUCT</th>
<th>QUANTITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>01-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
</tbody>
</table>

Chapter 19
SELECT
<table>
<thead>
<tr>
<th>Date</th>
<th>Type</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>02-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
<tr>
<td>03-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
<tr>
<td>04-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
<tr>
<td>05-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
<tr>
<td>06-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
<tr>
<td>01-APR-01</td>
<td>can</td>
<td>10</td>
</tr>
<tr>

<td>10</td>
</tr>
<tr>
<td>05-APR-01</td>
<td>can</td>
<td>10</td>
</tr>
<tr>
<td>06-APR-01</td>
<td>can</td>
<td>10</td>
</tr>
</tbody>
</table>

12 rows selected.

**See Also:**

*Oracle Database Data Warehousing Guide* for an expanded discussion on filling gaps in time series calculations and examples of usage.

### Using Antijoins: Example

The following example selects a list of employees who are not in a particular set of departments:

```sql
SELECT * FROM employees
WHERE department_id NOT IN
(SELECT department_id FROM departments
 WHERE location_id = 1700)
ORDER BY last_name;
```

### Using Semijoins: Example

In the following example, only one row needs to be returned from the `departments` table, even though many rows in the `employees` table might match the subquery. If no index has been defined on the `salary` column in `employees`, then a semijoin can be used to improve query performance.

```sql
SELECT * FROM departments
WHERE EXISTS
(SELECT * FROM employees
 WHERE departments.department_id = employees.department_id
 AND employees.salary > 2500)
ORDER BY department_name;
```

### Using CROSS APPLY and OUTER APPLY Joins: Examples

The following statement uses the `CROSS APPLY` clause of the `cross_outer_apply_clause`. The join returns only rows from the table on the left side of the join (`departments`) that produce a result from the inline view on the right side of the join. That is, the join returns only the departments that have at least one employee. The `WHERE` clause restricts the result set to include only the Marketing, Operations, and Public Relations departments. However, the Operations department is not included in the result set because it has no employees.

```sql
SELECT d.department_name, v.employee_id, v.last_name
FROM departments d CROSS APPLY (SELECT * FROM employees e
 WHERE e.department_id = d.department_id) v
```
WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
ORDER BY d.department_name, v.employee_id;

<table>
<thead>
<tr>
<th>DEPARTMENT_NAME</th>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marketing</td>
<td>201</td>
<td>Hartstein</td>
</tr>
<tr>
<td>Marketing</td>
<td>202</td>
<td>Fay</td>
</tr>
<tr>
<td>Public Relations</td>
<td>204</td>
<td>Baer</td>
</tr>
</tbody>
</table>

The following statement uses the `OUTER APPLY` clause of the `cross_outer_apply_clause`. The join returns all rows from the table on the left side of the join (`departments`) regardless of whether they produce a result from the inline view on the right side of the join. That is, the join returns all departments regardless of whether the departments have any employees. The `WHERE` clause restricts the result set to include only the Marketing, Operations, and Public Relations departments. The Operations department is included in the result set even though it has no employees.

```sql
SELECT d.department_name, v.employee_id, v.last_name
FROM departments d OUTER APPLY (SELECT * FROM employees e
WHERE e.department_id = d.department_id) v
WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
ORDER BY d.department_name, v.employee_id;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_NAME</th>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marketing</td>
<td>201</td>
<td>Hartstein</td>
</tr>
<tr>
<td>Marketing</td>
<td>202</td>
<td>Fay</td>
</tr>
<tr>
<td>Operations</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Public Relations</td>
<td>204</td>
<td>Baer</td>
</tr>
</tbody>
</table>

Using Lateral Inline Views: Example

The following example shows a join with two operands. The second operand is an inline view that specifies the first operand, table `e`, in the `WHERE` clause. This results in an error.

```sql
SELECT * FROM employees e, (SELECT * FROM departments d
WHERE e.department_id = d.department_id) v
WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
ORDER BY d.department_name, v.employee_id;
```

The following example shows a join with two operands. The second operand is a lateral inline view that specifies the first operand, table `e`, in the `WHERE` clause and succeeds without an error.

```sql
SELECT * FROM employees e, LATERAL(SELECT * FROM departments d
WHERE e.department_id = d.department_id);
```

### Table Collections: Examples

You can perform DML operations on nested tables only if they are defined as columns of a table. Therefore, when the `query_table_expr_clause` of an `INSERT`, `DELETE`, or `UPDATE` statement is a `table_collection_expression`, the collection expression must be a subquery that uses the `TABLE` collection expression to select the nested table column of the table. The examples that follow are based on the following scenario:

Suppose the database contains a table `hr_info` with columns `department_id`, `location_id`, and `manager_id`, and a column of `nested table type` `people` which has `last_name`, `department_id`, and `salary` columns for all the employees of each respective manager:
CREATE TYPE people_typ AS OBJECT (
    last_name VARCHAR2(25),
    department_id NUMBER(4),
    salary NUMBER(8,2));
/
CREATE TYPE people_tab_typ AS TABLE OF people_typ;
/
CREATE TABLE hr_info (
    department_id   NUMBER(4),
    location_id     NUMBER(4),
    manager_id      NUMBER(6),
    people          people_tab_typ)
    NESTED TABLE people STORE AS people_stor_tab;

INSERT INTO hr_info VALUES (280, 1800, 999, people_tab_typ());

The following example inserts into the people nested table column of the hr_info table for department 280:

INSERT INTO TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280)
VALUES ('Smith', 280, 1750);

The next example updates the department 280 people nested table:

UPDATE TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280) p
SET p.salary = p.salary + 100;

The next example deletes from the department 280 people nested table:

DELETE TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280) p
WHERE p.salary > 1700;

Collection Unnesting: Examples

To select data from a nested table column, use the TABLE collection expression to treat the nested table as columns of a table. This process is called collection unnesting.

You could get all the rows from hr_info, which was created in the preceding example, and all the rows from the people nested table column of hr_info using the following statement:

```
SELECT t1.department_id, t2.* FROM hr_info t1, TABLE(t1.people) t2
    WHERE t2.department_id = t1.department_id;
```

Now suppose that people is not a nested table column of hr_info, but is instead a separate table with columns last_name, department_id, address, hiredate, and salary. You can extract the same rows as in the preceding example with this statement:

```
SELECT t1.department_id, t2.*
    FROM hr_info t1, TABLE(CAST(MULTISET(?
    SELECT t3.last_name, t3.department_id, t3.salary
    FROM people t3
    WHERE t3.department_id = t1.department_id)
AS people_tab_typ)) t2;
```

Finally, suppose that people is neither a nested table column of table hr_info nor a table itself. Instead, you have created a function people_func that extracts from
various sources the name, department, and salary of all employees. You can get the same information as in the preceding examples with the following query:

```sql
SELECT t1.department_id, t2.* FROM hr_info t1, TABLE(CAST (people_func( ... ) AS people_tab_typ)) t2;
```

**See Also:**

*Oracle Database Object-Relational Developer's Guide* for more examples of collection unnesting.

### Using the LEVEL Pseudocolumn: Examples

The following statement returns all employees in hierarchical order. The root row is defined to be the employee whose job is `AD_VP`. The child rows of a parent row are defined to be those who have the employee number of the parent row as their manager number.

```sql
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart, employee_id, manager_id, job_id
FROM employees
START WITH job_id = 'AD_VP'
CONNECT BY PRIOR employee_id = manager_id;
```

<table>
<thead>
<tr>
<th>ORG_CHART</th>
<th>EMPLOYEE_ID</th>
<th>MANAGER_ID</th>
<th>JOB_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kochhar</td>
<td>101</td>
<td>100</td>
<td>AD_VP</td>
</tr>
<tr>
<td>Greenberg</td>
<td>108</td>
<td>101</td>
<td>FI_MGR</td>
</tr>
<tr>
<td>Faviet</td>
<td>109</td>
<td>108</td>
<td>FI_ACCOUNT</td>
</tr>
<tr>
<td>Chen</td>
<td>110</td>
<td>108</td>
<td>FI_ACCOUNT</td>
</tr>
<tr>
<td>Sciarra</td>
<td>111</td>
<td>108</td>
<td>FI_ACCOUNT</td>
</tr>
<tr>
<td>Urman</td>
<td>112</td>
<td>108</td>
<td>FI_ACCOUNT</td>
</tr>
<tr>
<td>Popp</td>
<td>113</td>
<td>108</td>
<td>FI_ACCOUNT</td>
</tr>
<tr>
<td>Whalen</td>
<td>200</td>
<td>101</td>
<td>AD_ASST</td>
</tr>
<tr>
<td>Mavris</td>
<td>203</td>
<td>101</td>
<td>HR_REP</td>
</tr>
<tr>
<td>Baer</td>
<td>204</td>
<td>101</td>
<td>PR_REP</td>
</tr>
<tr>
<td>Higgins</td>
<td>205</td>
<td>101</td>
<td>AC_MGR</td>
</tr>
<tr>
<td>Gietz</td>
<td>206</td>
<td>205</td>
<td>AC_ACCOUNT</td>
</tr>
<tr>
<td>De Haan</td>
<td>102</td>
<td>100</td>
<td>AD_VP</td>
</tr>
<tr>
<td>Hunold</td>
<td>103</td>
<td>102</td>
<td>IT_PROG</td>
</tr>
<tr>
<td>Ernst</td>
<td>104</td>
<td>103</td>
<td>IT_PROG</td>
</tr>
<tr>
<td>Austin</td>
<td>105</td>
<td>103</td>
<td>IT_PROG</td>
</tr>
<tr>
<td>Pataballa</td>
<td>106</td>
<td>103</td>
<td>IT_PROG</td>
</tr>
<tr>
<td>Lorentz</td>
<td>107</td>
<td>103</td>
<td>IT_PROG</td>
</tr>
</tbody>
</table>

The following statement is similar to the previous one, except that it does not select employees with the job `FI_MGR`.

```sql
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart, employee_id, manager_id, job_id
FROM employees
WHERE job_id != 'FI_MGR'
START WITH job_id = 'AD_VP'
CONNECT BY PRIOR employee_id = manager_id;
```

<table>
<thead>
<tr>
<th>ORG_CHART</th>
<th>EMPLOYEE_ID</th>
<th>MANAGER_ID</th>
<th>JOB_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kochhar</td>
<td>101</td>
<td>100</td>
<td>AD_VP</td>
</tr>
</tbody>
</table>
Oracle Database does not return the manager Greenberg, although it does return employees who are managed by Greenberg.

The following statement is similar to the first one, except that it uses the LEVEL pseudocolumn to select only the first two levels of the management hierarchy:

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
       employee_id, manager_id, job_id
FROM employees
  START WITH job_id = 'AD_PRES'
  CONNECT BY PRIOR employee_id = manager_id AND LEVEL <= 2;
```

```
ORG_CHART          EMPLOYEE_ID MANAGER_ID JOB_ID
------------------ ----------- ---------- ----------
King                       100            AD_PRES
Kochhar                  101        100 AD_VP
De Haan                  102        100 AD_VP
Raphaely                 114        100 PU_MAN
Weiss                    120        100 ST_MAN
Fripp                    121        100 ST_MAN
Kaufling                 122        100 ST_MAN
Vollman                  123        100 ST_MAN
Mourgos                  124        100 ST_MAN
Russell                  145        100 SA_MAN
Partners                 146        100 SA_MAN
Errazuriz                147        100 SA_MAN
Cambrault                148        100 SA_MAN
Zlotkey                  149        100 SA_MAN
Hartstein                201        100 MK_MAN
```

Using Distributed Queries: Example

This example shows a query that joins the departments table on the local database with the employees table on the remote database:

```
SELECT last_name, department_name
FROM employees@remote, departments
WHERE employees.department_id = departments.department_id;
```

Using Correlated Subqueries: Examples

The following examples show the general syntax of a correlated subquery:
SELECT select_list
    FROM table1 t_alias1
    WHERE expr operator
          (SELECT column_list
           FROM table2 t_alias2
           WHERE t_alias1.column operator t_alias2.column);

UPDATE table1 t_alias1
SET column =
    (SELECT expr
     FROM table2 t_alias2
     WHERE t_alias1.column = t_alias2.column);

DELETE FROM table1 t_alias1
WHERE column operator
    (SELECT expr
     FROM table2 t_alias2
     WHERE t_alias1.column = t_alias2.column);

The following statement returns data about employees whose salaries exceed their department average. The following statement assigns an alias to employees, the table containing the salary information, and then uses the alias in a correlated subquery:

SELECT department_id, last_name, salary
    FROM employees x
    WHERE salary > (SELECT AVG(salary)
                    FROM employees
                    WHERE x.department_id = department_id)
    ORDER BY department_id;

For each row of the employees table, the parent query uses the correlated subquery to compute the average salary for members of the same department. The correlated subquery performs the following steps for each row of the employees table:

1. The department_id of the row is determined.
2. The department_id is then used to evaluate the parent query.
3. If the salary in that row is greater than the average salary of the departments of that row, then the row is returned.

The subquery is evaluated once for each row of the employees table.

Selecting from the DUAL Table: Example

The following statement returns the current date:

SELECT SYSDATE FROM DUAL;

You could select SYSDATE from the employees table, but the database would return 14 rows of the same SYSDATE, one for every row of the employees table. Selecting from DUAL is more convenient.

Selecting Sequence Values: Examples

The following statement increments the employees_seq sequence and returns the new value:

SELECT employees_seq.nextval
    FROM DUAL;
The following statement selects the current value of employees_seq:

```
SELECT employees_seq.currval
FROM DUAL;
```

**Row Pattern Matching: Example**

This example uses row pattern matching to query stock price data. The following statements create table Ticker and inserts stock price data into the table:

```
CREATE TABLE Ticker (SYMBOL VARCHAR2(10), tstamp DATE, price NUMBER);

INSERT INTO Ticker VALUES('ACME', '01-Apr-11', 12);
INSERT INTO Ticker VALUES('ACME', '02-Apr-11', 17);
INSERT INTO Ticker VALUES('ACME', '03-Apr-11', 19);
INSERT INTO Ticker VALUES('ACME', '04-Apr-11', 21);
INSERT INTO Ticker VALUES('ACME', '05-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '06-Apr-11', 12);
INSERT INTO Ticker VALUES('ACME', '07-Apr-11', 15);
INSERT INTO Ticker VALUES('ACME', '08-Apr-11', 20);
INSERT INTO Ticker VALUES('ACME', '09-Apr-11', 24);
INSERT INTO Ticker VALUES('ACME', '10-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '11-Apr-11', 19);
INSERT INTO Ticker VALUES('ACME', '12-Apr-11', 15);
INSERT INTO Ticker VALUES('ACME', '13-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '14-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '15-Apr-11', 14);
INSERT INTO Ticker VALUES('ACME', '16-Apr-11', 12);
INSERT INTO Ticker VALUES('ACME', '17-Apr-11', 14);
INSERT INTO Ticker VALUES('ACME', '18-Apr-11', 24);
INSERT INTO Ticker VALUES('ACME', '19-Apr-11', 23);
INSERT INTO Ticker VALUES('ACME', '20-Apr-11', 22);
```

The following query uses row pattern matching to find all cases where stock prices dipped to a bottom price and then rose. This is generally called a V-shape. The resulting output contains only three rows because the query specifies **ONE ROW PER MATCH**, and three matches were found.

```
SELECT *
FROM Ticker MATCH_RECOGNIZE (
  PARTITION BY symbol
  ORDER BY tstamp
  MEASURES STRT.tstamp AS start_tstamp,
  LAST(DOWN.tstamp) AS bottom_tstamp,
  LAST(UP.tstamp) AS end_tstamp
  ONE ROW PER MATCH
  AFTER MATCH SKIP TO LAST UP
  PATTERN (STRT DOWN+ UP+)
  DEFINE
    DOWN AS DOWN.price < PREV(DOWN.price),
    UP AS UP.price > PREV(UP.price)
  ) MR
ORDER BY MR.symbol, MR.start_tstamp;
```

<table>
<thead>
<tr>
<th>SYMBOL</th>
<th>START_TST</th>
<th>BOTTOM_TS</th>
<th>END_TSTAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACME</td>
<td>05-APR-11</td>
<td>06-APR-11</td>
<td>10-APR-11</td>
</tr>
<tr>
<td>ACME</td>
<td>10-APR-11</td>
<td>12-APR-11</td>
<td>13-APR-11</td>
</tr>
<tr>
<td>ACME</td>
<td>14-APR-11</td>
<td>16-APR-11</td>
<td>18-APR-11</td>
</tr>
</tbody>
</table>
SET CONSTRAINT[S]

Purpose

Use the SET CONSTRAINTS statement to specify, for a particular transaction, whether a deferrable constraint is checked following each DML statement (IMMEDIATE) or when the transaction is committed (DEFERRED). You can use this statement to set the mode for a list of constraint names or for ALL constraints.

The SET CONSTRAINTS mode lasts for the duration of the transaction or until another SET CONSTRAINTS statement resets the mode.

Note:

You can also use an ALTER SESSION statement with the SET CONSTRAINTS clause to set all deferrable constraints. This is equivalent to making issuing a SET CONSTRAINTS statement at the start of each transaction in the current session.

You cannot specify this statement inside of a trigger definition.

SET CONSTRAINTS can be a distributed statement. Existing database links that have transactions in process are notified when a SET CONSTRAINTS ALL statement is issued, and new links are notified that it was issued as soon as they start a transaction.

Prerequisites

To specify when a deferrable constraint is checked, you must have the READ or SELECT privilege on the table to which the constraint is applied unless the table is in your schema.

Syntax

set_constraints::=

Semantics

constraint

Specify the name of one or more integrity constraints.

ALL

Specify ALL to set all deferrable constraints for this transaction.
IMMEDIATE

Specify IMMEDIATE to cause the specified constraints to be checked immediately on execution of each constrained DML statement. Oracle Database first checks any constraints that were deferred earlier in the transaction and then continues immediately checking constraints of any further statements in that transaction, as long as all the checked constraints are consistent and no other SET CONSTRAINTS statement is issued. If any constraint fails the check, then an error is signaled. At that point, a COMMIT statement causes the whole transaction to undo.

Making constraints immediate at the end of a transaction is a way of checking whether COMMIT can succeed. You can avoid unexpected rollbacks by setting constraints to IMMEDIATE as the last statement in a transaction. If any constraint fails the check, you can then correct the error before committing the transaction.

DEFERRED

Specify DEFERRED to indicate that the conditions specified by the deferrable constraint are checked when the transaction is committed.

Note:

You can verify the success of deferrable constraints prior to committing them by issuing a SET CONSTRAINTS ALL IMMEDIATE statement.

Examples

Setting Constraints: Examples

The following statement sets all deferrable constraints in this transaction to be checked immediately following each DML statement:

```
SET CONSTRAINTS ALL IMMEDIATE;
```

The following statement checks three deferred constraints when the transaction is committed. This example fails if the constraints were specified to be NOT DEFERRABLE.

```
SET CONSTRAINTS emp_job_nn, emp_salary_min,
hr.jhist_dept_fk@remote DEFERRED;
```

SET ROLE

Purpose

When a user logs on to Oracle Database, the database enables all privileges granted explicitly to the user and all privileges in the user's default roles. During the session, the user or an application can use the SET ROLE statement any number of times to enable or disable the roles currently enabled for the session.

You cannot enable more than 148 user-defined roles at one time.
Note:

- For most roles, you cannot enable or disable a role unless it was granted to you either directly or through other roles. However, a secure application role can be granted and enabled by its associated PL/SQL package. See the `CREATE ROLE` semantics for `USING package` and `Oracle Database Security Guide` for information about secure application roles.

- `SET ROLE` succeeds only if there are no definer's rights units on the call stack. If at least one DR unit is on the call stack, then issuing the `SET ROLE` command causes ORA-06565. See `Oracle Database PL/SQL Language Reference` for more information about definer's rights units.

- To run the `SET ROLE` command from PL/SQL, you must use dynamic SQL, preferably the `EXECUTE IMMEDIATE` statement. See `Oracle Database PL/SQL Language Reference` for more information about this statement.

You can see which roles are currently enabled by examining the `SESSION_ROLES` data dictionary view.

See Also:

- `CREATE ROLE` for information on creating roles
- `ALTER USER` for information on changing a user's default roles
- `Oracle Database Reference` for information on the `SESSION_ROLES` session parameter

Prerequisites

You must already have been granted the roles that you name in the `SET ROLE` statement.

Syntax

```
set_role::=  
```
Semantics

role

Specify one or more roles to be enabled for the current session. All roles not specified are disabled for the current session or until another SET ROLE statement is issued in the current session.

In the IDENTIFIED BY password clause, specify the password for a role. If the role has a password, then you must specify the password to enable the role.

Restriction on Setting Roles

You cannot specify a role identified globally. Global roles are enabled by default at login, and cannot be reenabled later.

ALL Clause

Specify ALL to enable all roles granted to you for the current session except those optionally listed in the EXCEPT clause.

Roles listed in the EXCEPT clause must be roles granted directly to you. They cannot be roles granted to you through other roles.

If you list a role in the EXCEPT clause that has been granted to you both directly and through another role, then the role remains enabled by virtue of the role to which it has been granted.

Restrictions on the ALL Clause

The following restrictions apply to the ALL clause:

- You cannot use this clause to enable roles with passwords that have been granted directly to you.
- You cannot use this clause to enable a secure application role, which is a role that can be enabled only by applications using an authorized package. Refer to Oracle Database Security Guide for information on creating a secure application role and Oracle Database 2 Day + Security Guide for a tutorial.

NONE

Specify NONE to disable all roles for the current session, including the DEFAULT role.

Examples

Setting Roles: Examples

To enable the role dw_manager identified by the password warehouse for your current session, issue the following statement:

SET ROLE dw_manager IDENTIFIED BY warehouse;

To enable all roles granted to you for the current session, issue the following statement:

SET ROLE ALL;

To enable all roles granted to you except dw_manager, issue the following statement:
SET ROLE ALL EXCEPT dw_manager;

To disable all roles granted to you for the current session, issue the following statement:

SET ROLE NONE;

SET TRANSACTION

Purpose

Use the SET TRANSACTION statement to establish the current transaction as read-only or read/write, establish its isolation level, assign it to a specified rollback segment, or assign a name to the transaction.

A transaction implicitly begins with any operation that obtains a TX lock:

• When a statement that modifies data is issued
• When a SELECT ... FOR UPDATE statement is issued
• When a transaction is explicitly started with a SET TRANSACTION statement or the DBMS_TRANSACTION package

Issuing either a COMMIT or ROLLBACK statement explicitly ends the current transaction.

The operations performed by a SET TRANSACTION statement affect only your current transaction, not other users or other transactions. Your transaction ends whenever you issue a COMMIT or ROLLBACK statement. Oracle Database implicitly commits the current transaction before and after executing a data definition language (DDL) statement.

See Also:

COMMIT and ROLLBACK

Prerequisites

If you use a SET TRANSACTION statement, then it must be the first statement in your transaction. However, a transaction need not have a SET TRANSACTION statement.

Syntax

set_transaction::=
Semantics

READ ONLY

The `READ ONLY` clause establishes the current transaction as a read-only transaction. This clause established **transaction-level read consistency**.

All subsequent queries in that transaction see only changes that were committed before the transaction began. Read-only transactions are useful for reports that run multiple queries against one or more tables while other users update these same tables.

This clause is not supported for the user `SYS`. Queries by `SYS` will return changes made during the transaction even if `SYS` has set the transaction to be `READ ONLY`.

**Restriction on Read-only Transactions**

Only the following statements are permitted in a read-only transaction:

- Subqueries—`SELECT` statements without the `for_update_clause`
- `LOCK TABLE`
- `SET ROLE`
- `ALTER SESSION`
- `ALTER SYSTEM`

READ WRITE

Specify `READ WRITE` to establish the current transaction as a read/write transaction. This clause establishes **statement-level read consistency**, which is the default.

**Restriction on Read/Write Transactions**

You cannot toggle between transaction-level and statement-level read consistency in the same transaction.

**ISOLATION LEVEL Clause**

- The `SERIALIZABLE` setting specifies serializable transaction isolation mode as defined in the SQL standard. If a serializable transaction contains data manipulation language (DML) that attempts to update any resource that may have been updated in a transaction uncommitted at the start of the serializable transaction, then the DML statement fails.
- The `READ COMMITTED` setting is the default Oracle Database transaction behavior. If the transaction contains DML that requires row locks held by another transaction, then the DML statement waits until the row locks are released.
USE ROLLBACK SEGMENT Clause

Note:
This clause is relevant and valid only if you are using rollback segments for undo. Oracle strongly recommends that you use automatic undo management to handle undo space. If you follow this recommendation and run your database in automatic undo mode, then Oracle Database ignores this clause.

Specify **USE ROLLBACK SEGMENT** to assign the current transaction to the specified rollback segment. This clause also implicitly establishes the transaction as a read/write transaction.

Parallel DML requires more than one rollback segment. Therefore, if your transaction contains parallel DML operations, then the database ignores this clause.

NAME Clause

Use the **NAME** clause to assign a name to the current transaction. This clause is especially useful in distributed database environments when you must identify and resolve in-doubt transactions. The *string* value is limited to 255 bytes.

If you specify a name for a distributed transaction, then when the transaction commits, the name becomes the commit comment, overriding any comment specified explicitly in the **COMMIT** statement.

See Also:

*Oracle Database Concepts* for more information about transaction naming

Examples

Setting Transactions: Examples

The following statements could be run at midnight of the last day of every month to count the products and quantities on hand in the Toronto warehouse in the sample Order Entry (oe) schema. This report would not be affected by any other user who might be adding or removing inventory to a different warehouse.

```sql
COMMIT;

SET TRANSACTION READ ONLY NAME 'Toronto';

SELECT product_id, quantity_on_hand FROM inventories
  WHERE warehouse_id = 5
ORDER BY product_id;

COMMIT;
```
The first `COMMIT` statement ensures that `SET TRANSACTION` is the first statement in the transaction. The last `COMMIT` statement does not actually make permanent any changes to the database. It simply ends the read-only transaction.

**TRUNCATE CLUSTER**

**Purpose**

> **Note:**
> You cannot roll back a `TRUNCATE CLUSTER` statement.

Use the `TRUNCATE CLUSTER` statement to remove all rows from a cluster. By default, Oracle Database also performs the following tasks:

- Deallocates all space used by the removed rows except that specified by the `MINEXTENTS` storage parameter
- Sets the `NEXT` storage parameter to the size of the last extent removed from the segment by the truncation process

Removing rows with the `TRUNCATE` statement can be more efficient than dropping and re-creating a cluster. Dropping and re-creating a cluster invalidates dependent objects of the cluster, requires you to re-grant object privileges on the cluster, and requires you to re-create the indexes and cluster on the table and respecify its storage parameters. Truncating has none of these effects.

Removing rows with the `TRUNCATE CLUSTER` statement can be faster than removing all rows with the `DELETE` statement, especially if the cluster has numerous indexes and other dependencies.

**See Also:**

- `DELETE` and `DROP CLUSTER` for information on other ways of dropping data from a cluster
- `TRUNCATE TABLE` for information on truncating a table

**Prerequisites**

To truncate a cluster, the cluster must be in your schema or you must have `DROP ANY TABLE` system privilege.

**See Also:**

"Restrictions on Truncating Tables"
Syntax

```
truncate_cluster::=
```

Semantics

**CLUSTER Clause**

Specify the schema and name of the cluster to be truncated. You can truncate only an indexed cluster, not a hash cluster. If you omit `schema`, then the database assumes the cluster is in your own schema.

When you truncate a cluster, the database also automatically deletes all data in the indexes of the cluster tables.

**STORAGE Clauses**

The `STORAGE` clauses let you determine what happens to the space freed by the truncated rows. The `DROP STORAGE` clause and `REUSE STORAGE` clause also apply to the space freed by the data deleted from associated indexes.

**DROP STORAGE**

Specify `DROP STORAGE` to deallocate all space from the deleted rows from the cluster except the space allocated by the `MINEXTENTS` parameter of the cluster. This space can subsequently be used by other objects in the tablespace. Oracle Database also sets the `NEXT` storage parameter to the size of the last extent removed from the segment in the truncation process. This is the default.

**REUSE STORAGE**

Specify `REUSE STORAGE` to retain the space from the deleted rows allocated to the cluster. Storage values are not reset to the values when the table or cluster was created. This space can subsequently be used only by new data in the cluster resulting from insert or update operations. This clause leaves storage parameters at their current settings.

If you have specified more than one free list for the object you are truncating, then the `REUSE STORAGE` clause also removes any mapping of free lists to instances and resets the high-water mark to the beginning of the first extent.

**Examples**

**Truncating a Cluster: Example**

The following statement removes all rows from all tables in the `personnel` cluster, but leaves the freed space allocated to the tables:

```
TRUNCATE CLUSTER personnel REUSE STORAGE;
```
The preceding statement also removes all data from all indexes on the tables in the personnel cluster.

TRUNCATE TABLE

Purpose

Note:
You cannot roll back a TRUNCATE TABLE statement, nor can you use a FLASHBACK TABLE statement to retrieve the contents of a table that has been truncated.

Use the TRUNCATE TABLE statement to remove all rows from a table. By default, Oracle Database also performs the following tasks:

- Deallocates all space used by the removed rows except that specified by the MINEXTENTS storage parameter
- Sets the NEXT storage parameter to the size of the last extent removed from the segment by the truncation process

Removing rows with the TRUNCATE TABLE statement can be more efficient than dropping and re-creating a table. Dropping and re-creating a table invalidates dependent objects of the table, and requires you to repeat the following actions:

- Grant object privileges on the table
- Create the indexes, integrity constraints, and triggers on the table
- Specify the storage parameters of the table

Truncating has none of these effects.

Removing rows with the TRUNCATE TABLE statement can be faster than removing all rows with the DELETE statement, especially if the table has numerous triggers, indexes, and other dependencies.

See Also:

- DELETE and DROP TABLE for information on other ways of removing data from a table
- TRUNCATE CLUSTER for information on truncating a cluster

Prerequisites

To truncate a table, the table must be in your schema or you must have the DROP ANY TABLE system privilege.

To specify the CASCADE clause, all affected child tables must be in your schema or you must have the DROP ANY TABLE system privilege.
You can truncate a private temporary table with the existing **TRUNCATE TABLE** command. Truncating a private temporary table will not commit and existing transaction. This applies to both transaction-specific and session-specific private temporary tables. Note that a truncated private temporary table will not go into the **RECYCLEBIN**.

**See Also:**

"Restrictions on Truncating Tables"

**Syntax**

```
truncate_table ::= TRUNCATE TABLE [schema.] table [PRESERVE | PURGE | MATERIALIZED VIEW LOG] [DROP | ALL | REUSE | STORAGE | CASCADE];
```

**Semantics**

**TABLE Clause**

Specify the schema and name of the table to be truncated. This table cannot be part of a cluster. If you omit *schema*, then Oracle Database assumes the table is in your own schema.

- You can truncate index-organized tables and temporary tables. When you truncate a temporary table, only the rows created during the current session are removed.
- Oracle Database changes the NEXT storage parameter of *table* to be the size of the last extent deleted from the segment in the process of truncation.
- Oracle Database also automatically truncates and resets any existing **UNUSABLE** indicators for the following indexes on *table*: range and hash partitions of local indexes and subpartitions of local indexes.
- If *table* is not empty, then the database marks **UNUSABLE** all nonpartitioned indexes and all partitions of global partitioned indexes on the table. However, when the table is truncated, the index is also truncated, and a new high water mark is calculated for the index segment. This operation is equivalent to creating a new segment for the index. Therefore, at the end of the truncate operation, the indexes are once again **USABLE**.
- For a domain index, this statement invokes the appropriate truncate routine to truncate the domain index data.
• If a regular or index-organized table contains LOB columns, then all LOB data and LOB index segments are truncated.

• If table is partitioned, then all partitions or subpartitions, as well as the LOB data and LOB index segments for each partition or subpartition, are truncated.

**Note:**

When you truncate a table, Oracle Database automatically removes all data in the table's indexes and any materialized view direct-path `INSERT` information held in association with the table. This information is independent of any materialized view log. If this direct-path `INSERT` information is removed, then an incremental refresh of the materialized view may lose data.

• All cursors are invalidated.

**Restrictions on Truncating Tables**

This statement is subject to the following restrictions:

• You cannot roll back a `TRUNCATE TABLE` statement.

• You cannot flash back to the state of the table before the truncate operation.

• You cannot individually truncate a table that is part of a cluster. You must either truncate the cluster, delete all rows from the table, or drop and re-create the table.

• You cannot truncate the parent table of an enabled foreign key constraint. You must disable the constraint before truncating the table. An exception is that you can truncate the table if the integrity constraint is self-referential.

• If a domain index is defined on table, then neither the index nor any index partitions can be marked `IN_PROGRESS`.

• You cannot truncate the parent table of a reference-partitioned table. You must first drop the reference-partitioned child table.

• You cannot truncate a duplicated table.

**MATERIALIZED VIEW LOG Clause**

The `MATERIALIZED VIEW LOG` clause lets you specify whether a materialized view log defined on the table is to be preserved or purged when the table is truncated. This clause permits materialized view master tables to be reorganized through export or import without affecting the ability of primary key materialized views defined on the master to be fast refreshed. To support continued fast refresh of primary key materialized views, the materialized view log must record primary key information.
Note:
The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

**PRESERVE**
Specify `PRESERVE` if any materialized view log should be preserved when the master table is truncated. This is the default.

**PURGE**
Specify `PURGE` if any materialized view log should be purged when the master table is truncated.

**See Also:**
*Oracle Database Administrator’s Guide* for more information about materialized view logs and the `TRUNCATE` statement.

**STORAGE Clauses**
The `STORAGE` clauses let you determine what happens to the space freed by the truncated rows. The `DROP STORAGE` clause, `DROP ALL STORAGE` clause, and `REUSE STORAGE` clause also apply to the space freed by the data deleted from associated indexes.

**DROP STORAGE**
Specify `DROP STORAGE` to deallocate all space from the deleted rows from the table except the space allocated by the `MINEXTENTS` parameter of the table. This space can subsequently be used by other objects in the tablespace. Oracle Database also sets the `NEXT` storage parameter to the size of the last extent removed from the segment in the truncation process. This setting, which is the default, is useful for small and medium-sized objects. The extent management in locally managed tablespace is very fast in these cases, so there is no need to reserve space.

**DROP ALL STORAGE**
Specify `DROP ALL STORAGE` to deallocate all space from the deleted rows from the table, including the space allocated by the `MINEXTENTS` parameter. All segments for the table, as well as all segments for its dependent objects, will be deallocated.

**Restrictions on DROP ALL STORAGE**
This clause is subject to the same restrictions as described in "Restrictions on Deferred Segment Creation".

**REUSE STORAGE**
Specify `REUSE STORAGE` to retain the space from the deleted rows allocated to the table. Storage values are not reset to the values when the table was created. This space
can subsequently be used only by new data in the table resulting from insert or update operations. This clause leaves storage parameters at their current settings.

This setting is useful as an alternative to deleting all rows of a very large table—when the number of rows is very large, the table entails many thousands of extents, and when data is to be reinserted in the future.

This clause is not valid for temporary tables. A session becomes unbound from the temporary table when the table is truncated, so the storage is automatically dropped.

If you have specified more than one free list for the object you are truncating, then the `REUSE STORAGE` clause also removes any mapping of free lists to instances and resets the high-water mark to the beginning of the first extent.

**CASCADE**

If you specify `CASCADE`, then Oracle Database truncates all child tables that reference a `table` with an enabled `ON DELETE CASCADE` referential constraint. This is a recursive operation that will truncate all child tables, grandchild tables, and so on, using the specified options.

**Examples**

**Truncating a Table: Example**

The following statement removes all rows from a hypothetical copy of the sample table `hr.employees` and returns the freed space to the tablespace containing `employees`:

```sql
TRUNCATE TABLE employees_demo;
```

The preceding statement also removes all data from all indexes on `employees` and returns the freed space to the tablespaces containing them.

**Preserving Materialized View Logs After Truncate: Example**

The following statements are examples of `TRUNCATE` statements that preserve materialized view logs:

```sql
TRUNCATE TABLE sales_demo PRESERVE MATERIALIZED VIEW LOG;

TRUNCATE TABLE orders_demo;
```

**UPDATE**

**Purpose**

Use the `UPDATE` statement to change existing values in a table or in the base table of a view or the master table of a materialized view.

**Prerequisites**

For you to update values in a table, the table must be in your own schema or you must have the `UPDATE` object privilege on the table.

For you to update values in the base table of a view:

- You must have the `UPDATE` object privilege on the view, and
• Whoever owns the schema containing the view must have the `UPDATE` object privilege on the base table.

The `UPDATE` ANY TABLE system privilege also allows you to update values in any table or in the base table of any view.

To update values in an object on a remote database, you must also have the `READ` or `SELECT` object privilege on the object.

If the `SQL92_SECURITY` initialization parameter is set to `TRUE` and the `UPDATE` operation references table columns, such as the columns in a `where_clause`, then you must also have the `SELECT` object privilege on the object you want to update.

Syntax

```
update ::= UPDATE hint dml_table_expression_clause ONLY ( dml_table_expression_clause ) t_alias update_set_clause where_clause returning_clause error_logging_clause ;
```

```
(dml_table_expression_clause ::=, update_set_clause ::=, where_clause ::=, returning_clause ::=, error_logging_clause::=)
```

```
DML_table_expression_clause ::= schema . table partition_extension_clause @ dblink view materialized view @ dblink ( subquery subquery_restriction_clause ) table_collection_expression
```

```
(partition_extension_clause ::=, subquery ::=--part of SELECT, subquery_restriction_clause ::=, table_collection_expression ::=)
```
**returning_clause::=**

```
RETURN
RETURNING
expr
INTO data_item,
```  

**error_logging_clause::=**

```
LOG ERRORS INTO schema . table ( simple_expression )
REJECT LIMIT integer UNLIMITED
```  

**Semantics**

**hint**

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

You can place a parallel hint immediately after the `UPDATE` keyword to parallelize both the underlying scan and `UPDATE` operations.

**See Also:**

- “Hints " for the syntax and description of hints
- *Oracle Database Concepts* for detailed information about parallel execution

**DML_table_expression_clause**

The `ONLY` clause applies only to views. Specify `ONLY` syntax if the view in the `UPDATE` clause is a view that belongs to a hierarchy and you do not want to update rows from any of its subviews.

**See Also:**

"Restrictions on the DML_table_expression_clause" and "Updating a Table: Examples"
**schema**

Specify the schema containing the object to be updated. If you omit `schema`, then the database assumes the object is in your own schema.

**table | view | materialized_view | subquery**

Specify the name of the table, view, materialized view, or the columns returned by a subquery to be updated. Issuing an `UPDATE` statement against a table fires any `UPDATE` triggers associated with the table.

- If you specify `view`, then the database updates the base table of the view. You cannot update a view except with `INSTEAD OF` triggers if the defining query of the view contains one of the following constructs:
  
  - A set operator
  - A `DISTINCT` operator
  - An aggregate or analytic function
  - A `GROUP BY`, `ORDER BY`, `MODEL`, `CONNECT BY`, or `START WITH` clause
  - A collection expression in a `SELECT` list
  - A subquery in a `SELECT` list
  - A subquery designated `WITH READ ONLY`
  - A recursive `WITH` clause
  - Joins, with some exceptions, as documented in Oracle Database Administrator’s Guide

- You cannot update more than one base table through a view.
- In addition, if the view was created with the `WITH CHECK OPTION`, then you can update the view only if the resulting data satisfies the view’s defining query.
- If `table` or the base table of `view` contains one or more domain index columns, then this statement executes the appropriate indextype update routine.
- You cannot update rows in a read-only materialized view. If you update rows in a writable materialized view, then the database updates the rows from the underlying container table. However, the updates are overwritten at the next refresh operation. If you update rows in an updatable materialized view that is part of a materialized view group, then the database also updates the corresponding rows in the master table.

**partition_extension_clause**

Specify the name or partition key value of the partition or subpartition within `table` targeted for updates. You need not specify the partition name when updating values in

---

**See Also:**

- Oracle Database Data Cartridge Developer’s Guide for more information on the indextype update routines
- CREATE MATERIALIZED VIEW for information on creating updatable materialized views
a partitioned table. However in some cases specifying the partition name can be more efficient than a complicated `where_clause`.

See Also:
"References to Partitioned Tables and Indexes" and "Updating a Partition: Example"

**dblink**

Specify a complete or partial name of a database link to a remote database where the object is located. You can use a database link to update a remote object only if you are using Oracle Database distributed functionality.

If you omit `dblink`, then the database assumes the object is on the local database.

**Note:**
Starting with Oracle Database 12c Release 2 (12.2), the `UPDATE` statement accepts remote LOB locators as bind variables. Refer to the “Distributed LOBs” chapter in *Oracle Database SecureFiles and Large Objects Developer’s Guide* for more information.

See Also:
"References to Objects in Remote Databases" for information on referring to database links

**subquery_restriction_clause**

Use the `subquery_restriction_clause` to restrict the subquery in one of the following ways:

**WITH READ ONLY**

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

**WITH CHECK OPTION**

Specify `WITH CHECK OPTION` to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

**CONSTRAINT constraint**

Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where n is an integer that makes the constraint name unique within the database.
**See Also:**

"Using the WITH CHECK OPTION Clause: Example"

**table_collection_expression**

The *table_collection_expression* lets you inform Oracle that the value of *collection_expression* should be treated as a table for purposes of query and DML operations. The *collection_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the *TABLE* collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

**Note:**

In earlier releases of Oracle, when *collection_expression* was a subquery, *table_collection_expression* was expressed as THE subquery. That usage is now deprecated.

You can use a *table_collection_expression* to update rows in one table based on rows from another table. For example, you could roll up four quarterly sales tables into a yearly sales table.

**t_alias**

Specify a **correlation name** (alias) for the table, view, or subquery to be referenced elsewhere in the statement. This alias is required if the *DML_table_expression_clause* references any object type attributes or object type methods.

**See Also:**

"Correlated Update: Example"

**Restrictions on the DML_table_expression_clause**

This clause is subject to the following restrictions:

- You cannot execute this statement if *table* or the base table of *view* contains any domain indexes marked IN_PROGRESS or FAILED.
- You cannot insert into a partition if any affected index partitions are marked UNUSABLE.
- You cannot specify the *order_by_clause* in the subquery of the *DML_table_expression_clause*. 

---

19-152
• If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the UPDATE statement will fail unless the SKIP_UNUSABLE_INDEXES session parameter has been set to TRUE.

See Also:
ALTER SESSION for information on the SKIP_UNUSABLE_INDEXES session parameter

update_set_clause

The update_set_clause lets you set column values.

column

Specify the name of a column of the object that is to be updated. If you omit a column of the table from the update_set_clause, then the value of that column remains unchanged.

If column refers to a LOB object attribute, then you must first initialize it with a value of empty or null. You cannot update it with a literal. Also, if you are updating a LOB value using some method other than a direct UPDATE SQL statement, then you must first lock the row containing the LOB. See for_update_clause for more information.

If column is a virtual column, you cannot specify it here. Rather, you must update the values from which the virtual column is derived.

If column is part of the partitioning key of a partitioned table, then UPDATE will fail if you change a value in the column that would move the row to a different partition or subpartition, unless you enable row movement. Refer to the row_movement_clause of CREATE TABLE or ALTER TABLE.

In addition, if column is part of the partitioning key of a list-partitioned table, then UPDATE will fail if you specify a value for the column that does not already exist in the partition_key_value list of one of the partitions.

subquery

Specify a subquery that returns exactly one row for each row updated.

• If you specify only one column in the update_set_clause, then the subquery can return only one value.
• If you specify multiple columns in the update_set_clause, then the subquery must return as many values as you have specified columns.
• If the subquery returns no rows, then the column is assigned a null.
• If this subquery refers to remote objects, then the UPDATE operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the subquery in the DML_table_expression_clause refers to any remote objects, then the UPDATE operation will run serially without notification.

You can use the flashback_query_clause within the subquery to update table with past data. Refer to the flashback_query_clause of SELECT for more information on this clause.
See Also:

- SELECT and “Using Subqueries”
- parallel_clause in the CREATE TABLE documentation

**expr**

Specify an expression that resolves to the new value assigned to the corresponding column.

**Note:**

Expressions for the syntax of `expr` and "Updating an Object Table: Example"

**DEFAULT**

Specify `DEFAULT` to set the column to the value previously specified as the default value for the column. If no default value for the corresponding column has been specified, then the database sets the column to null.

**Restriction on Updating to Default Values**

You cannot specify `DEFAULT` if you are updating a view.

**VALUE Clause**

The `VALUE` clause lets you specify the entire row of an object table.

**Restriction on the VALUE clause**

You can specify this clause only for an object table.

**Note:**

If you insert string literals into a `RAW` column, then during subsequent queries, Oracle Database will perform a full table scan rather than using any index that might exist on the `RAW` column.

See Also:

"Updating an Object Table: Example"

**where_clause**

The `where_clause` lets you restrict the rows updated to those for which the specified condition is true. If you omit this clause, then the database updates all rows in the table or view. Refer to Conditions for the syntax of condition.
The `where_clause` determines the rows in which values are updated. If you do not specify the `where_clause`, then all rows are updated. For each row that satisfies the `where_clause`, the columns to the left of the equality operator (=) in the `update_set_clause` are set to the values of the corresponding expressions to the right of the operator. The expressions are evaluated as the row is updated.

**returning_clause**

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.

When operating on a single row, a DML statement with a `returning_clause` can retrieve column expressions using the affected row, rowid, and `REFs` to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the `returning_clause` stores values from expressions, rowids, and `REFs` involving the affected rows in bind arrays.

**expr**

Each item in the `expr` list must be a valid expression syntax.

**INTO**

The `INTO` clause indicates that the values of the changed rows are to be stored in the variable(s) specified in `data_item` list.

**data_item**

Each `data_item` is a host variable or PL/SQL variable that stores the retrieved `expr` value.

For each expression in the `RETURNING` list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the `INTO` list.

**Restrictions**

The following restrictions apply to the `RETURNING` clause:

- The `expr` is restricted as follows:
  - For `UPDATE` and `DELETE` statements each `expr` must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same `returning_clause`. For `INSERT` statements, each `expr` must be a simple expression. Aggregate functions are not supported in an `INSERT` statement `RETURNING` clause.
  - Single-set aggregate function expressions cannot include the `DISTINCT` keyword.
- If the `expr` list contains a primary key column or other `NOT NULL` column, then the update statement fails if the table has a `BEFORE UPDATE` trigger defined on it.
- You cannot specify the `returning_clause` for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve `LONG` types with this clause.
- You cannot specify this clause for a view on which an `INSTEAD OF` trigger has been defined.
See Also:

Oracle Database PL/SQL Language Reference for information on using the BULK COLLECT clause to return multiple values to collection variables

error_logging_clause

The error_logging_clause has the same behavior in an UPDATE statement as it does in an INSERT statement. Refer to the INSERT statement error_logging_clause for more information.

See Also:

"Inserting Into a Table with Error Logging: Example"

Examples

Updating a Table: Examples

The following statement gives null commissions to all employees with the job SH_CLERK:

```sql
UPDATE employees
SET commission_pct = NULL
WHERE job_id = 'SH_CLERK';
```

The following statement promotes Douglas Grant to manager of Department 20 with a $1,000 raise:

```sql
UPDATE employees SET
  job_id = 'SA_MAN', salary = salary + 1000, department_id = 120
WHERE first_name||' '||last_name = 'Douglas Grant';
```

The following statement increases the salary of an employee in the employees table on the remote database:

```sql
UPDATE employees@remote
SET salary = salary*1.1
WHERE last_name = 'Baer';
```

The next example shows the following syntactic constructs of the UPDATE statement:

- Both forms of the update_set_clause together in a single statement
- A correlated subquery
- A where_clause to limit the updated rows

```sql
UPDATE employees a
SET department_id =
  (SELECT department_id
   FROM departments
   WHERE location_id = '2100'),
   (salary, commission_pct) =
  (SELECT 1.1*AVG(salary), 1.5*AVG(commission_pct)
```
FROM employees b
WHERE a.department_id = b.department_id)
WHERE department_id IN
(SELECT department_id
FROM departments
WHERE location_id = 2900
OR location_id = 2700);

The preceding UPDATE statement performs the following operations:

- Updates only those employees who work in Geneva or Munich (locations 2900 and 2700)
- Sets department_id for these employees to the department_id corresponding to Bombay (location_id 2100)
- Sets each employee's salary to 1.1 times the average salary of their department
- Sets each employee's commission to 1.5 times the average commission of their department

Updating a Partition: Example

The following example updates values in a single partition of the sales table:

UPDATE sales PARTITION (sales_q1_1999) s
SET s.promo_id = 494
WHERE amount_sold > 1000;

Updating an Object Table: Example

The following statement creates two object tables, people_demo1 and people_demo2, of the people_typ object created in Table Collections: Examples. The example shows how to update a row of people_demo1 by selecting a row from people_demo2:

CREATE TABLE people_demo1 OF people_typ;

CREATE TABLE people_demo2 OF people_typ;

UPDATE people_demo1 p SET VALUE(p) =
(SELECT VALUE(q) FROM people_demo2 q
WHERE p.department_id = q.department_id)
WHERE p.department_id = 10;

The example uses the VALUE object reference function in both the SET clause and the subquery.

Correlated Update: Example

For an example that uses a correlated subquery to update nested table rows, refer to "Table Collections: Examples".

Using the RETURNING Clause During UPDATE: Example

The following example returns values from the updated row and stores the result in PL/SQL variables bnd1, bnd2, bnd3:

UPDATE employees
SET job_id = 'SA_MAN', salary = salary + 1000, department_id = 140
WHERE last_name = 'Jones'
RETURNING salary*0.25, last_name, department_id
INTO :bnd1, :bnd2, :bnd3;
The following example shows that you can specify a single-set aggregate function in the expression of the returning clause:

```sql
UPDATE employees
  SET salary = salary * 1.1
  WHERE department_id = 100
  RETURNING SUM(salary) INTO :bnd1;
```
How to Read Syntax Diagrams

This appendix describes how to read syntax diagrams.

This reference presents Oracle SQL syntax in both graphic diagrams and in text (Backus-Naur Form—BNF). This appendix contains these sections:

- Graphic Syntax Diagrams
- Backus-Naur Form Syntax

Graphic Syntax Diagrams

Syntax diagrams are drawings that illustrate valid SQL syntax. To read a diagram, trace it from left to right, in the direction shown by the arrows.

Commands and other keywords appear in UPPERCASE inside rectangles. Type them exactly as shown in the rectangles. Parameters appear in lowercase inside ovals. Variables are used for the parameters. Punctuation, operators, delimiters, and terminators appear inside circles.

If the syntax diagram has more than one path, then you can choose any path. For example, in the following syntax you can specify either `NOPARALLEL` or `PARALLEL`:

```
parallel_clause ::= 
```

![Diagram showing parallel_clause with options]

If you have the choice of more than one keyword, operator, or parameter, then your options appear in a vertical list. For example, in the following syntax diagram, you can specify one or more of the four parameters in the stack:

```
physical_attributes_clause ::= 
```

![Diagram showing physical_attributes_clause with options]

The following table shows parameters that appear in the syntax diagrams and provides examples of the values you might substitute for them in your statements:
Table A-1  Syntax Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The substitution value must be the name of an object of the type specified by the parameter. For a list of all types of objects, see the section, &quot;Schema Objects&quot;.</td>
<td>employees</td>
</tr>
<tr>
<td>c</td>
<td>The substitution value must be a single character from your database character set.</td>
<td>T s</td>
</tr>
<tr>
<td>'text'</td>
<td>The substitution value must be a text string in single quotation marks. See the syntax description of 'text' in &quot;Text Literals&quot;.</td>
<td>'Employee records'</td>
</tr>
<tr>
<td>char</td>
<td>The substitution value must be an expression of data type CHAR or VARCHAR2 or a character literal in single quotation marks.</td>
<td>last_name = 'Smith'</td>
</tr>
<tr>
<td>condition</td>
<td>The substitution value must be a condition that evaluates to TRUE or FALSE. See the syntax description of condition in Conditions.</td>
<td>last_name &gt; 'A'</td>
</tr>
<tr>
<td>date</td>
<td>The substitution value must be a date constant or an expression of DATE data type.</td>
<td>TO_DATE('01-Jan-2002', 'DD-MON-YYYY')</td>
</tr>
<tr>
<td>expr</td>
<td>The substitution value can be an expression of any data type as defined in the syntax description of expr in &quot;About SQL Expressions&quot;.</td>
<td>salary + 1000</td>
</tr>
<tr>
<td>integer</td>
<td>The substitution value must be an integer as defined by the syntax description of integer in &quot;Integer Literals&quot;.</td>
<td>72</td>
</tr>
<tr>
<td>number</td>
<td>The substitution value must be an expression of NUMBER data type or a number constant as defined in the syntax description of number in &quot;Numeric Literals&quot;.</td>
<td>AVG(salary) = 15 * 7</td>
</tr>
<tr>
<td>raw</td>
<td>The substitution value must be an expression of data type RAW.</td>
<td>HEXITORAW('7D')</td>
</tr>
<tr>
<td>subquery</td>
<td>The substitution value must be a SELECT statement that will be used in another SQL statement. See SELECT.</td>
<td>SELECT last_name FROM employees</td>
</tr>
<tr>
<td>db_name</td>
<td>The substitution value must be the name of a nondefault database in an embedded SQL program.</td>
<td>sales_db</td>
</tr>
<tr>
<td>db_string</td>
<td>The substitution value must be the database identification string for an Oracle Net database connection. For details, see the user's guide for your specific Oracle Net protocol.</td>
<td>—</td>
</tr>
</tbody>
</table>

Required Keywords and Parameters

Required keywords and parameters can appear singly or in a vertical list of alternatives. Single required keywords and parameters appear on the main path,
which is the horizontal line you are currently traveling. In the following example, `library_name` is a required parameter:

```plaintext
drop_library ::= \\
    DROP LIBRARY (library_name) ;
```

If there is a library named `HQ_LIB`, then, according to the diagram, the following statement is valid:

```plaintext
DROP LIBRARY hq_lib;
```

If multiple keywords or parameters appear in a vertical list that intersects the main path, then one of them is required. You must choose one of the keywords or parameters, but not necessarily the one that appears on the main path. In the following example, you must choose `ALL`, `STANDBY`, or `NONE`:

```plaintext
security_clause ::= \\
    GUARD ALL STANDBY NONE
```

Optional Keywords and Parameters

If keywords and parameters appear in a vertical list above the main path, then they are optional. In the following example, instead of traveling down a vertical line, you can continue along the main path:

```plaintext
deallocate_unused_clause ::= \\
    DEALLOCATE UNUSED KEEP size_clause
```

```plaintext
size_clause ::= \\
    integer K M G T P E
```
According to the diagrams, all of the following statements are valid:

- DEALLOCATE UNUSED;
- DEALLOCATE UNUSED KEEP 1000;
- DEALLOCATE UNUSED KEEP 10G;
- DEALLOCATE UNUSED 8T;

Syntax Loops

Loops let you repeat the syntax within them as many times as you like. In the following example, after choosing one value expression, you can go back repeatedly to choose another, separated by commas.

```
query_partition_clause ::= PARTITION BY expr,
```

Multipart Diagrams

Read a multipart diagram as if all the main paths were joined end to end. The following example is a three-part diagram:

```
alter_java ::= ALTER JAVA SOURCE CLASS schema.object_name RESOLVER ( ( match_string, schema_name – ) ) COMPILE RESOLVE invoker_rights_clause;
```

According to the diagram, the following statement is valid:

```
ALTER JAVA SOURCE jsource_1 COMPILE;
```
Backus-Naur Form Syntax

Each graphic syntax diagram in this reference is followed by a link to a text description of the graphic. The text descriptions consist of a simple variant of Backus-Naur Form (BNF) that includes the following symbols and conventions:

<table>
<thead>
<tr>
<th>Symbol or Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ ]</td>
<td>Brackets enclose optional items.</td>
</tr>
<tr>
<td>{ }</td>
<td>Braces enclose items only one of which is required.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td>Ellipsis points show that the preceding syntactic element can be repeated.</td>
</tr>
<tr>
<td>delimiters</td>
<td>Delimiters other than brackets, braces, vertical bars, and ellipses must be entered as shown.</td>
</tr>
<tr>
<td><strong>boldface</strong></td>
<td>Words appearing in <strong>boldface</strong> are keywords. They must be typed as shown. (Keywords are case-sensitive in some, but not all, operating systems.) Words that are not in <strong>boldface</strong> are placeholders for which you must substitute a name or value.</td>
</tr>
</tbody>
</table>
Automatic and Manual Locking Mechanisms During SQL Operations

This appendix describes mechanisms that lock data either automatically or as specified by the user during SQL statements. For a general discussion of locking mechanisms in the context of data concurrency and consistency, see Oracle Database Concepts.

This appendix contains the following sections:

• Automatic Locks in DML Operations
• Automatic Locks in DDL Operations
• Manual Data Locking
• List of Nonblocking DDLs

List of Nonblocking DDLs

Nonblocking DDLs added at each release from 11.2 to 12.2.0.2 are listed here.

Release 11.2

The following nonblocking DDLs are added as of Release 11.2. Some nonblocking DDLs are downgraded to blocking in the presence of supplemental logging.

List of Nonblocking DDLs Added in 11.2

• create index online
• alter index rebuild online
• alter index rebuild partition online
• alter index rebuild subpartition online
• alter index visible / novisible

List of Nonblocking DDLs Added in 11.2 that Downgrade to Blocking During Supplemental Logging

• alter table add column not null with default value
• alter table add constraint enable novalidate

Release 12.1

The following nonblocking DDLs are added as of Release 12.1. Some nonblocking DDLs are downgraded to blocking in the presence of supplemental logging.

List of Nonblocking DDLs Added in 12.1
Automatic Locks in DML Operations

The purpose of a DML lock, also called a **data lock**, is to guarantee the integrity of data being accessed concurrently by multiple users. For example, a DML lock can prevent multiple customers from buying the last copy of a book available from an online bookseller. DML locks prevent destructive interference of simultaneous conflicting DML or DDL operations.

DML statements automatically acquire locks at both the table level and the row level. In the sections that follow, the acronym in parentheses after each type of lock or lock mode is the abbreviation used in the Locks Monitor of Oracle Enterprise Manager. Enterprise Manager might display "TM" for any table lock, rather than indicate the mode of table lock (such as RS or SRX).

The types of row and table locks are summarized here. For a more complete discussion of the types of row and table locks, see *Oracle Database Concepts*.

**Row Locks (TX)**

A **row lock**, also called a **TX lock**, is a lock on a single row of a table. A transaction acquires a row lock for each row modified by one of the following statements: **INSERT, UPDATE, DELETE, MERGE, and SELECT ... FOR UPDATE**. The row lock exists until the transaction commits or rolls back.
When a transaction obtains a row lock for a row, the transaction also acquires a table lock for the table in which the row resides. The table lock prevents conflicting DDL operations that would override data changes in a current transaction.

Table Locks (TM)

A transaction automatically acquires a table lock (TM lock) when a table is modified with the following statements: INSERT, UPDATE, DELETE, MERGE, and SELECT ... FOR UPDATE. These DML operations require table locks to reserve DML access to the table on behalf of a transaction and to prevent DDL operations that would conflict with the transaction. You can explicitly obtain a table lock using the LOCK TABLE statement, as described in "Manual Data Locking".

A table lock can be held in any of the following modes:

- A row share lock (RS), also called a subshare table lock (SS), indicates that the transaction holding the lock on the table has locked rows in the table and intends to update them. An SS lock is the least restrictive mode of table lock, offering the highest degree of concurrency for a table.

- A row exclusive lock (RX), also called a subexclusive table lock (SX), indicates that the transaction holding the lock has updated table rows or issued SELECT ... FOR UPDATE. An SX lock allows other transactions to query, insert, update, delete, or lock rows concurrently in the same table. Therefore, SX locks allow multiple transactions to obtain simultaneous SX and SS locks for the same table.

- A share table lock (S) held by one transaction allows other transactions to query the table (without using SELECT ... FOR UPDATE) but allows updates only if a single transaction holds the share table lock. Multiple transactions may hold a share table lock concurrently, so holding this lock is not sufficient to ensure that a transaction can modify the table.

- A share row exclusive table lock (SRX), also called a share-subexclusive table lock (SSX), is more restrictive than a share table lock. Only one transaction at a time can acquire an SSX lock on a given table. An SSX lock held by a transaction allows other transactions to query the table (except for SELECT ... FOR UPDATE) but not to update the table.

- An exclusive table lock (X) is the most restrictive mode of table lock, allowing the transaction that holds the lock exclusive write access to the table. Only one transaction can obtain an X lock for a table.

"Manual Data Locking"

Locks in DML Operations

Oracle Database automatically obtains row-level and table-level locks on behalf of DML operations. The type of operation determines the locking behavior. Table B-1 summarizes the information in this section.
Note:
The implicit SX locks shown for the DML statements in Table B-1 can sometimes be exclusive (X) locks for a short time owing to side effects from constraints.

Table B-1  Summary of Locks Obtained by DML Statements

¹ Yes, if no conflicting row locks are held by another transaction. Otherwise, waits occur.

Locks When Rows Are Queried

A query can be explicit, as in the SELECT statement, or implicit, as in most INSERT, MERGE, UPDATE, and DELETE statements. The only DML statement that does not necessarily include a query component is an INSERT statement with a VALUES clause. Because queries only read data, they are the SQL statements least likely to interfere with other SQL statements.

The following characteristics apply to a query without the FOR UPDATE clause:

- The query acquires no data locks. Therefore, other transactions can query and update a table being queried, including the specific rows being queried. Because queries without the FOR UPDATE clause do not acquire any data locks to block other operations, such queries are often referred to as nonblocking queries.
- The query does not have to wait for any data locks to be released. Therefore, the query can always proceed. An exception to this rule is that queries may have to wait for data locks in some very specific cases of pending distributed transactions.
Locks When Rows Are Modified

Some databases use a lock manager to maintain a list of locks in memory. Oracle Database, in contrast, stores lock information in the data block that contains the locked row. Each row lock affects only a single row.

Oracle Database uses a queuing mechanism for acquisition of row locks. If a transaction requires a row lock, and if the row is not already locked, then the transaction acquires a lock in the row’s data block. The transaction itself has an entry in the interested transaction list (ITL) section of the block header. Each row modified by this transaction points to a copy of the transaction ID stored in the ITL. Thus, 100 rows in the same block modified by a single transaction require 100 row locks, but all 100 rows reference a single transaction ID.

When a transaction ends, the transaction ID remains in the ITL section of the data block header. If a new transaction wants to modify a row, then it uses the transaction ID to determine whether the lock is active. If the lock is active, then the session of the new transaction asks to be notified when the lock is released; otherwise, the new transaction acquires the lock.

The characteristics of `INSERT`, `UPDATE`, `DELETE`, and `SELECT ... FOR UPDATE` statements are as follows:

- A transaction containing a DML statement acquires exclusive row locks on the rows modified by the statement. Therefore, other transactions cannot update or delete the locked rows until the locking transaction either commits or rolls back.

- In addition to these row locks, a transaction containing a DML statement that modifies data also requires at least a subexclusive table lock (SX) on the table that contains the affected rows. If the transaction already holds an S, SRX, or X table lock for the table, which are more restrictive than an SX lock, then the SX lock is not needed and is not acquired. If the containing transaction already holds only an SS lock, however, then Oracle Database automatically converts the SS lock to an SX lock.

- A transaction that contains a DML statement does not require row locks on any rows selected by a subquery or an implicit query.

  In the following sample `UPDATE` statement, the `SELECT` statement in parentheses is a subquery, whereas the `WHERE a > 5` clause is an implicit query:

  ```sql
  UPDATE t SET x = ( SELECT y FROM t2 WHERE t2.z = t.z ) WHERE a > 5;
  ```

  A subquery or implicit query inside a DML statement is guaranteed to be consistent as of the start of the query and does not see the effects of the DML statement of which it forms a part.

- A query in a transaction can see the changes made by previous DML statements in the same transaction, but not the uncommitted changes of other transactions.

Automatic Locks in DDL Operations

A **data dictionary (DDL) lock** protects the definition of a schema object while it is acted upon or referred to by an ongoing DDL operation. For example, when a user creates a procedure, Oracle Database automatically acquires DDL locks for all schema objects referenced in the procedure definition. The DDL locks prevent these objects from being altered or dropped before procedure compilation is complete.

Oracle Database acquires a DDL lock automatically on behalf of any DDL transaction requiring it. Users cannot explicitly request DDL locks. Only individual schema objects that are modified or referenced are locked during DDL operations. The whole data dictionary is never locked.

DDL operations also acquire DML locks on the schema object to be modified.

Exclusive DDL Locks

An **exclusive DDL lock** prevents other session from obtaining a DDL or DML lock.

Most DDL operations require exclusive DDL locks to prevent destructive interference with other DDL operations that might modify or reference the same schema object. For example, a **DROP TABLE** operation is not allowed to drop a table while an **ALTER TABLE** operation is adding a column to it, and vice versa. However, a query against the table is not blocked.

Exclusive DDL locks last for the duration of DDL statement execution and automatic commit. During the acquisition of an exclusive DDL lock, if another DDL lock is already held on the schema object by another operation, then the acquisition waits until the older DDL lock is released and then proceeds.

Share DDL Locks

A **share DDL lock** for a resource prevents destructive interference with conflicting DDL operations, but allows data concurrency for similar DDL operations.

For example, when a **CREATE PROCEDURE** statement is run, the containing transaction acquires share DDL locks for all referenced tables. Other transactions can concurrently create procedures that reference the same tables and acquire concurrent share DDL locks on the same tables, but no transaction can acquire an exclusive DDL lock on any referenced table.

A share DDL lock lasts for the duration of DDL statement execution and automatic commit. Thus, a transaction holding a share DDL lock is guaranteed that the definition of the referenced schema object is constant for the duration of the transaction.

Breakable Parse Locks

A **parse lock** is held by a SQL statement or PL/SQL program unit for each schema object that it references. Parse locks are acquired so that the associated shared SQL area can be invalidated if a referenced object is altered or dropped. A parse lock is called a **breakable parse lock** because it does not disallow any DDL operation and can be broken to allow conflicting DDL operations.
A **parse lock** is acquired in the shared pool during the parse phase of SQL statement execution. The lock is held as long as the shared SQL area for that statement remains in the shared pool.

## Manual Data Locking

Oracle Database always performs locking automatically to ensure data concurrency, data integrity, and statement-level read consistency. However, you can override the Oracle default locking mechanisms. This can be useful in situations such as the following:

- When your application requires consistent data for the duration of the transaction, not reflecting changes by other transactions, you can achieve transaction-level read consistency by using explicit locking, read-only transactions, serializable transactions, or by overriding default locking.
- When your application requires that a transaction have exclusive access to a resource so that the transaction does not have to wait for other transactions to complete, you can explicitly lock the data for the duration of the transaction.

You can override automatic locking at two levels:

- **Transaction.** You can override transaction-level locking with the following SQL statements:
  - `SET TRANSACTION ISOLATION LEVEL`
  - `LOCK TABLE`
  - `SELECT ... FOR UPDATE`
  
  Locks acquired by these statements are released after the transaction commits or rolls back.

- **Session.** A session can set the required transaction isolate level with an `ALTER SESSION SET ISOLATION LEVEL` statement.

> **Note:**

When overriding Oracle default locking, the database administrator or application developer should ensure that data integrity is guaranteed, data concurrency is acceptable, and deadlocks are not possible or, if possible, are appropriately handled. For more information on these criteria, see *Oracle Database Concepts.*
This appendix declares Oracle’s conformance to the SQL standards established by the American National Standards Institute (ANSI) and the International Organization for Standardization (ISO).

The ISO SQL standard consists of nine parts (SQL/Framework, SQL/Foundation, SQL/CLI, SQL/PSM, SQL/MED, SQL/OLB, SQL/Schemata, SQL/JRT, and SQL/XML). The ANSI SQL standard consists of the same nine parts.

The mandatory portion of SQL is known as Core SQL and is found in SQL:2016 Part 2 (Foundation) and Part 11 (Schemata). The Foundation features are analyzed in Annex F of Part 2 in the table "Feature taxonomy and definition for mandatory features." The Schemata features are analyzed in Annex F of Part 11 in the table "Feature taxonomy and definition for mandatory features."

This appendix contains the following sections:

- ANSI Standards
- ISO Standards
- Oracle Compliance to Core SQL
- Oracle Support for Optional Features of SQL/Foundation
- Oracle Compliance with SQL/CLI
- Oracle Compliance with SQL/PSM
- Oracle Compliance with SQL/MED
- Oracle Compliance with SQL/OLB
- Oracle Compliance with SQL/JRT
- Oracle Compliance with SQL/XML
- Oracle Compliance with FIPS 127-2
- Oracle Extensions to Standard SQL
- Oracle Compliance with Older Standards
- Character Set Support

**ANSI Standards**

The following documents of the American National Standards Institute (ANSI) relate to SQL:

These standards are identical to the corresponding ISO standards listed in the next section.

You can obtain a copy of ANSI standards from this address:

American National Standards Institute
25 West 43rd Street, fourth floor
New York, NY 10036 USA
Telephone: +1.212.642.4900
Fax: +1.212.398.0023
Web site: http://www.ansi.org/

You can also obtain the standards from their Web site:

http://webstore.ansi.org/default.aspx

A subset of ANSI standards, including the SQL standard, are INCITS standards. You can obtain these from the InterNational Committee for Information Technology Standards (INCITS) at:

http://www.incits.org/

ISO Standards

The following documents of the International Organization for Standardization (ISO) relate to SQL:

• ISO/IEC 9075-3:2016, Information technology—Database languages—SQL—Part 3: Call-Level Interface (SQL/CLI)
• ISO/IEC 9075-4:2016, Information technology—Database languages—SQL—Part 4: Persistent Stored Modules (SQL/PSM)
Oracle Compliance to Core SQL

The ANSI and ISO SQL standards require conformance claims to state the type of conformance and the implemented facilities. The minimum claim of conformance is called Core SQL and is defined in Part 2, SQL/Foundation, and Part 11, SQL/Schemata, of the standard. The following products provide full or partial conformance with Core SQL as described in the tables that follow:

- Oracle Database server, release 12.2
- OTT (Oracle Type Translator), release 12.2
- Pro*C/C++, release 12.2
- Pro*COBOL, release 12.2

The SQL standards conformance features can be used either as a guide to portability, or as a guide to functionality. From the standpoint of portability, the user is interested in conformance to both the precise syntax and semantics of the standard feature. From the standpoint of functionality, the user is less concerned about the precise syntax and more concerned with issues of semantics. The tables in this appendix use the following terms regarding support for standard syntax and semantics:

- **Full Support**: The feature is supported with standard syntax and semantics.
- **Partial Support**: Some, but not all, of the standard syntax is supported; whatever is supported has standard semantics.
- **Enhanced Support**: The standard semantics is supported, as well as additional functionality.
• Equivalent Support: The standard semantics is supported using non-standard syntax.

• Similar Support: Neither the standard's syntax nor semantics are supported precisely, but similar functionality is provided.

Oracle's support for the features of Core SQL is listed in Table C-1:

Table C-1  Oracle Support of Core SQL Features

</tbody>
</table>
| E051, Basic query specification | Oracle fully supports the following subfeatures:  
  • E051-01, SELECT DISTINCT  
  • E051-02, GROUP BY clause  
  • E051-04, GROUP BY can contain columns not in SELECT list  
  • E051-05, SELECT list items can be renamed  
  • E051-06, HAVING clause  
  • E051-07, Qualified * in SELECT list  
Oracle partially supports the following subfeatures:  
  • E051-08, Correlation names in FROM clause (Oracle supports correlation names, but not the optional AS keyword)  
Oracle has equivalent functionality for the following subfeature:  
  • E051-09, Rename columns in the FROM clause (column names can be renamed in a subquery in the FROM clause) |
| E061, Basic predicates and search conditions | Oracle fully supports this feature, except that Oracle comparison of character strings differs from the standard as follows: In the standard, two character strings of unequal length are compared by either padding the shorter string with spaces or a fictitious character that is less than all actual characters. The decision on padding is made on the basis of the character set. In Oracle, the decision is based on whether the comparands are of fixed or varying length. |
| E071, Basic query expressions | Oracle fully supports the following subfeatures:  
  • E071-01, UNION DISTINCT table operator  
  • E071-02, UNION ALL table operator  
  • E071-05, Columns combined by table operators need not have exactly the same type  
  • E071-06, table operators in subqueries  
Oracle has equivalent functionality for the following subfeature:  
  • E071-03, EXCEPT DISTINCT table operator: Use MINUS instead of EXCEPT DISTINCT |
| E081, Basic privileges | Oracle fully supports all subfeatures of this feature, except E081-09, USAGE privileges. In the standard, the USAGE privilege permits the user to use domains, collations, character sets, transliterations, user-defined types and sequence generators. Oracle does not support domains or transliterations. No privileges are required to access collations and character sets. The Oracle privilege to use a user-defined type is EXECUTE. The Oracle privilege to use a sequence type is SELECT. |
| E091, Set functions | Oracle fully supports this feature. |
| E101, Basic data manipulation | Oracle fully supports this feature. |
| E111, Single row SELECT statement | Oracle fully supports this feature. |

</tr>
</thead>
</table>
| T321, Basic SQL-invoked routines | Oracle fully supports these subfeatures:  
  - T321-03, function invocation  
  - T321-04, CALL statement  
Oracle supports these subfeatures with syntactic differences:  
  - T321-01, user-defined functions with no overloading  
  - T321-02, user-defined procedures with no overloading  
The Oracle syntax for CREATE FUNCTION and CREATE PROCEDURE differs from the standard as follows:  
  - In the standard, the mode of a parameter (IN, OUT, or INOUT) comes before the parameter name, whereas in Oracle it comes after the parameter name.  
  - The standard uses INOUT, whereas Oracle uses IN OUT.  
  - Oracle requires either IS or AS after the return type and before the definition of the routine body, while the standard lacks these keywords.  
  - If the routine body is in C (for example), then the standard uses the keywords LANGUAGE C EXTERNAL NAME to name the routine, whereas Oracle uses LANGUAGE C NAME.  
  - If the routine body is in SQL, then Oracle uses its proprietary procedural extension called PL/SQL.  
Oracle supports the following subfeature in PL/SQL but not in Oracle SQL:  
  - T321-05, RETURN statement  
Oracle provides equivalent functionality for the following subfeatures:  
  - T321-06, ROUTINES view: Use the ALL PROCEDURES metadata view.  
  - T321-07, PARAMETERS view: Use the ALL_ARGUMENTS and ALL_METHOD_PARAMS metadata views.  
| T631, IN predicate with one list element | Oracle fully supports this feature. |

Oracle Support for Optional Features of SQL/Foundation

Oracle's support for optional features of SQL/Foundation is listed in Table C-2:

<tr>
<td>B031, Basic dynamic SQL</td>
<td>Oracle supports dynamic SQL in two styles, documented in the embedded language manuals as “Oracle dynamic SQL” and “ANSI dynamic SQL.” ANSI dynamic SQL is an implementation of the standard, with the following restrictions: • Oracle supports a subset of the descriptor items. • For &lt;input using clause&gt;, Oracle only supports &lt;using input descriptor&gt;. • For &lt;output using clause&gt;, Oracle only supports &lt;into descriptor&gt;. • Dynamic parameters are indicated by a colon followed by an identifier rather than a question mark. Oracle dynamic SQL is similar to standard dynamic SQL, with the following modifications: • Parameters are indicated by a colon followed by an identifier, instead of a question mark. • Oracle's DESCRIBE SELECT LIST FOR statement replaces the standard's DESCRIBE OUTPUT. • Oracle provides DECLARE STATEMENT if you want to declare a cursor using a dynamic SQL statement physically prior to the PREPARE statement that prepares the dynamic SQL statement.</td>
</tr>
<tr>
<td>B032, Extended dynamic SQL</td>
<td>In ANSI dynamic SQL, Oracle only implements the ability to declare global statements and global cursors from this feature; the rest of the feature is not supported. In Oracle dynamic SQL, Oracle's DESCRIBE BIND VARIABLES is equivalent to the standard's DESCRIBE INPUT; the rest of this feature is not supported.</td>
</tr>
<tr>
<td>B122, Routine language C</td>
<td>Oracle supports external routines written in C, though Oracle does not support the standard syntax for creating such routines.</td>
</tr>
<tr>
<td>B128, Routine language SQL</td>
<td>Oracle supports routines written in PL/SQL, which is Oracle's equivalent to the standard procedural language SQL/PSM.</td>
</tr>
<tr>
<td>F032, CASCADE drop behavior</td>
<td>In Oracle, a DROP command invalidates all of the dropped object's dependent objects. Invalidated objects are effectively unusable until the dropped object is redefined in such a way to allow successful recompilation of the invalidated object.</td>
</tr>
<tr>
<td>F033, ALTER TABLE statement: DROP COLUMN clause</td>
<td>Oracle provides a DROP COLUMN clause, but without the RESTRICT or CASCADE options found in the standard.</td>
</tr>
</tbody>
</table>
Table C-2  (Cont.) Oracle Support for Optional Features of SQL/Foundation

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
</table>
| F034, Extended REVOKE statement | Oracle supports the following parts of this feature:  
  - F034-01, REVOKE statement performed by other than the owner of a schema object  
  - F034-03, REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION  
Oracle provides equivalent functionality for the following parts of this feature:  
  - CASCADE: In Oracle, a REVOKE invalidates all dependent objects, which become effectively unusable until the metadata is changed through subsequent CREATE and GRANT commands enabling the invalidated object to be successfully recompiled. |
| F052, Intervals and datetime arithmetic | Oracle only supports the INTERVAL YEAR TO MONTH and INTERVAL DAY TO SECOND data types. |
| F111, Isolations levels other than TRANSLATIONAL | In addition to TRANSLATIONAL, Oracle supports the READ COMMITTED isolation level. |
| F121, Basic diagnostics management | Much of the functionality of this feature is provided through the SQLCA in embedded languages. |
| F191, Referential delete actions | Oracle supports ON DELETE CASCADE and ON DELETE SET NULL. |
| F200, TRUNCATE TABLE | Oracle fully supports this feature, and extends it by permitting truncation of a table that references itself in a referential integrity constraint, and the ability to cascade to child tables with enabled ON DELETE CASCADE referential constraints. |
| F231, Privilege tables | Oracle makes this information available in the following metadata views:  
  - Instead of TABLE_PRIVILEGES, use ALL_TAB_PRIVS.  
  - Instead of COLUMN_PRIVILEGES, use ALL_COL_PRIVS.  
  - Oracle does not support USAGE privileges so there is no equivalent to USAGE_PRIVILEGES. |
| F281, LIKE enhancements | Oracle fully supports this feature. |
| F291, UNIQUE predicate | The IS A SET condition may be used to test whether a multiset is a set; that is, each row is unique. Thus, the equivalent of  
  UNIQUE <table subquery>  
is  
  CAST (<table subquery> AS MULTISET) IS A SET |
| F302, INTERSECT table operator | Oracle supports INTERSECT but not INTERSECT ALL.  
Syntactically, Oracle differs from the standard in that UNION, INTERSECT, and MINUS have the same precedence. |

<tbody>
<tr>
<td>F312, MERGE statement</td>
<td>The Oracle MERGE statement is almost the same as the standard, with these exceptions:</td>
</tr>
<tr>
<td></td>
<td>- Oracle does not support the optional AS keyword before a table alias.</td>
</tr>
<tr>
<td></td>
<td>- Oracle does not support the ability to rename columns of the table specified in the USING clause with a parenthesized list of column names following the table alias.</td>
</tr>
<tr>
<td></td>
<td>- Oracle does not support the &lt;override clause&gt;.</td>
</tr>
<tr>
<td>F314, MERGE statement with DELETE branch</td>
<td>Oracle has similar functionality, though in Oracle you must first update a row, after which you can delete it if the revised row meets a condition.</td>
</tr>
<tr>
<td>F321, User authorization</td>
<td>Oracle provides equivalent functionality for the following subfeatures:</td>
</tr>
<tr>
<td></td>
<td>- Use SYS_CONTEXT ('USERENV', 'SESSION_USER') instead of SESSION_USER</td>
</tr>
<tr>
<td></td>
<td>- Use SYS_CONTEXT ('USERENV', 'CURRENT_USER') instead of CURRENT_USER</td>
</tr>
<tr>
<td></td>
<td>Oracle does not support the following subfeatures:</td>
</tr>
<tr>
<td></td>
<td>- SYSTEM_USER</td>
</tr>
<tr>
<td></td>
<td>- SET SESSION AUTHORIZATION statement</td>
</tr>
<tr>
<td>F341, Usage tables</td>
<td>Oracle makes this information available in the views ALL_DEPENDENCIES, DBA_DEPENDENCIES, and USER_DEPENDENCIES.</td>
</tr>
<tr>
<td>F381, Extended schema manipulation</td>
<td>Oracle fully supports the following element of this feature:</td>
</tr>
<tr>
<td></td>
<td>- Oracle supports the standard syntax to add a table constraint using ALTER TABLE.</td>
</tr>
<tr>
<td></td>
<td>Oracle partially supports the following element of this feature:</td>
</tr>
<tr>
<td></td>
<td>- Oracle supports the standard syntax to drop a table constraint, except that Oracle does not support RESTRICT.</td>
</tr>
<tr>
<td></td>
<td>Oracle provides equivalent functionality for the following element of this feature:</td>
</tr>
<tr>
<td></td>
<td>- To alter the default value of a column, use the MODIFY option of ALTER TABLE.</td>
</tr>
<tr>
<td></td>
<td>Oracle does not support the following parts of this feature:</td>
</tr>
<tr>
<td></td>
<td>- DROP SCHEMA statement</td>
</tr>
<tr>
<td></td>
<td>- ALTER ROUTINE statement</td>
</tr>
<tr>
<td>F382, Alter column data type</td>
<td>Oracle supports this functionality, though with non-standard syntax. As an extension to the standard, Oracle allows you to reduce the size or precision of a column.</td>
</tr>
<tr>
<td>F383, Set column not null clause</td>
<td>Oracle provides equivalent functionality for the two subfeatures of this feature:</td>
</tr>
<tr>
<td></td>
<td>- To add a NOT NULL constraint to an existing column, use ALTER TABLE ... MODIFY</td>
</tr>
<tr>
<td></td>
<td>- To drop a NOT NULL constraint, use ALTER TABLE to drop the constraint by name</td>
</tr>
<tr>
<td>F384, Drop identity property clause</td>
<td>Oracle provides equivalent functionality using ALTER TABLE ... MODIFY (... DROP IDENTITY)</td>
</tr>
<tr>
<td>Feature ID, Feature</td>
<td>Support</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| F386, Set identity column generation clause | Oracle provides equivalent functionality. Oracle's syntax and semantics are the same as the standard, with this exception:  
  - Oracle does not support **RESTART**; use **START WITH** instead. When restarting an identity column, the values of the other parameters for the identity column are reset to their defaults unless explicitly set in the **ALTER TABLE** statement.
  
  Oracle's **START WITH LIMIT VALUE** option is an extension on the standard. |
| F391, Long identifiers | Oracle supports identifiers up to 128 characters in length. |
| F393, Unicode escapes in literals | The Oracle **UNISTR** function supports numeric escape sequences for all Unicode characters. |
| F394, Optional normal form specification | This feature adds the keywords **NFC**, **NFD**, **NFKC**, and **NKD** to the **NORMALIZE** function and the **IS NORMAL** predicate. Without these keywords, **NFC** is the default (see Feature T061, UCS support). Oracle supports all four normalization forms, with nonstandard syntax, as follows:  
  - For **NFC**, use **COMPOSE**  
  - For **NFD**, use **DECOMPOSE with the CANONICAL option**  
  - For **NFKD**, use **DECOMPOSE with the COMPATIBILITY option**  
  - For **NFKC**, use **DECOMPOSE with the CANONICAL option followed by COMPOSE**  
  
  Oracle does not support the **IS NORMAL** predicate. |
| F401, Extended joined table | Oracle supports **FULL** outer joins, **CROSS** joins, and **NATURAL** joins. |
| F402, Named column joins for LOBs, arrays and multisets | Oracle supports named column joins for columns whose declared type is nested table. Oracle does not support named column joins for LOBs or arrays. |
| F403, Partitioned join tables | Oracle supports this feature, except with **FULL** outer joins. |
| F411, Time zone specification | Oracle fully supports **TIMESTAMP WITH TIME ZONE**, but does not support **TIME WITH TIME ZONE**. |
| F421, National character | Oracle fully supports this feature. |
| F431, Read-only scrollable cursors | Oracle fully supports this feature. |
| F441, Extended set function support | Oracle supports the following parts of this feature:  
  - The ability in the **WHERE** clause to reference a column that is defined using an aggregate, either in a view or an inline view  
  - **COUNT** without **DISTINCT** of an expression  
  - Aggregates that reference columns that are outer references with respect to the aggregating query. However, Oracle defines the aggregating query as the innermost query containing the aggregate, rather than the innermost query that defines a range variable referenced in the aggregate. |
<p>| F442, Mixed column references in set functions | Oracle fully supports this feature. |</p>
<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>F461, Named character sets</td>
<td>Oracle supports many character sets with Oracle-defined names. Oracle does not support any other aspect of this feature.</td>
</tr>
<tr>
<td>F491, Constraint management</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>F492, Optional table constraint enforcement</td>
<td>ENFORCED in the standard is equivalent to ENABLE VALIDATE in Oracle. NOT ENFORCED in the standard is equivalent to DISABLE NOVALIDATE in Oracle. Other combinations of the ENABLE</td>
</tr>
<tr>
<td>F531, Temporary tables</td>
<td>Oracle supports GLOBAL TEMPORARY tables.</td>
</tr>
<tr>
<td>F555, Enhanced seconds precision</td>
<td>Oracle provides enhanced support for this feature, supporting up to 9 places after the decimal point.</td>
</tr>
<tr>
<td>F561, Full value expressions</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>F571, Truth value tests</td>
<td>Oracle’s LNNVL function is equivalent to the standard’s IS NOT TRUE predicate.</td>
</tr>
</tbody>
</table>
| F591, Derived tables                        | Oracle supports <derived table>, with the exception of:  
  • Oracle does not support the optional AS keyword before a table alias.  
  • Oracle does not support <derived column list>.                                                                                  |
| F641, Row and table constructors            | In Oracle, a row constructor may be used in an equality or inequality comparison with another row constructor or with a subquery. Oracle does not support anything else in this feature. |
| F690, Collation support                     | Oracle’s NLSSORT function may be used to change the collation of character expressions.                                                                                            |
| F693, SQL-sessions and client module collations | To set a session collation, use ALTER SESSION SET NLS_COMP = 'LINGUISTIC' and also set NLS_SORT to your desired collation. Oracle does not support client module collations. |
| F695, Translation support                   | The Oracle CONVERT function can convert between the database character set and the national character set. For other character sets, store the data in the RAW data type and use the PL/SQL package function UTL_RAW_CONVERT. Oracle does not provide the ability to add or drop character set conversions. |
| F721, Deferrable constraints                | Oracle fully supports this feature.                                                                                                                                                           |
| F731, INSERT column privileges              | Oracle fully supports this feature.                                                                                                                                                           |
| F761, Session management                    | Oracle provides the following equivalents for elements of this feature:  
  • The equivalent to the standard’s SET SESSION CHARACTERISTICS AS TRANSACTION SERIALIZABLE is ALTER SESSION SET ISOLATION_LEVEL = SERIALIZABLE.  
  • The equivalent to the standard’s SET SCHEMA is ALTER SESSION SET CURRENT_SCHEMA.  
  • The equivalent to the standard’s SET COLLATION is ALTER SESSION SET NLS_SORT. |
| F763, CURRENT_SCHEMA                        | Oracle’s equivalent is SYS_CONTEXT ('USERENV', 'CURRENT_SCHEMA')                                                                             |

<tr>
<td>S041, Basic reference types</td>
<td>Oracle's reference types are equivalent to reference types in the standard. To dereference a reference, dot notation is used, instead of -&gt; as in the standard.</td>
</tr>
</tbody>
</table>
| S043, Enhanced reference types | Oracle supports the following elements of this feature:  
  - DEREF operator to return the object referenced by a reference  
  - SCOPE clause as a constraint on columns of tables or materialized views  
  - Adding and dropping the scope of a column  
  - References that are either system-generated or derived from the primary key (but not from any other list of columns, nor from a list of attributes of the type) |
| S051, Create table of type | Oracle's object tables are equivalent to tables of structured type in the standard. |
| S081, Subtables | Oracle supports hierarchies of object views, but not of object base tables. To emulate a hierarchy of base tables, create a hierarchy of views on those base tables. |
| S091, Basic array support | Oracle VARRAY types are equivalent to array types in the standard. However, Oracle does not support storage of arrays of LOBs. To access a single element of an array using a subscript, you must use PL/SQL. Oracle supports the following aspects of this feature with nonstandard syntax:  
  - To construct an instance of varray type, including an empty array, use the varray type constructor.  
  - To unnest a varray in the FROM clause, use the TABLE operator.  
  - To get the cardinality of a varray, use the COUNT method in PL/SQL. |
| S092, Arrays of user-defined types | Oracle supports VARRAYs of object types. |
| S094, Arrays of reference types | Oracle supports VARRAYs of references. |
| S095, Array constructors by query | Oracle supports this using CAST (MULTISET (SELECT ...) AS varray_type). The ability to order the elements of the array using ORDER BY is not supported. |
| S097, Array element assignment | In PL/SQL, you can assign to array elements, using syntax that is similar to the standard (SQL/PSM). |
| S098, ARRAY_AGG | Oracle does not have an aggregate that results in a varray. Instead, the COLLECT aggregate may be used to create a multiset, which can be cast to an array of the element type. |
| S111, ONLY in query expressions | Oracle supports the ONLY clause for view hierarchies; Oracle does not support hierarchies of base tables. |
| S151, Type predicate | Oracle fully supports this feature. |
| S161, Subtype treatment | Oracle fully supports this feature. |
| S162, Subtype treatment for references | Supported, with a minor syntactic difference: The standard requires parentheses around the referenced type's name; Oracle does not support parentheses in this position. |

Table C-2  (Cont.) Oracle Support for Optional Features of SQL/Foundation

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>S271, Basic multiset support</td>
<td>Multisets in the standard are supported as nested table types in Oracle. The Oracle nested table data type based on a scalar type ST is equivalent, in standard terminology, to a multiset of rows having a single field of type ST and named \textit{column_value}. The Oracle nested table type based on an object type is equivalent to a multiset of structured type in the standard. Oracle supports the following elements of this feature on nested tables using the same syntax as the standard has for multisets:</td>
</tr>
</tbody>
</table>
|                     | \begin{itemize}  
|                     | \item The \texttt{CARDINALITY} function  
|                     | \item The \texttt{SET} function  
|                     | \item The \texttt{MEMBER} predicate  
|                     | \item The \texttt{IS A SET} predicate  
|                     | \item The \texttt{COLLECT} aggregate  
|                     | \end{itemize} |
|                     | All other aspects of this feature are supported with non-standard syntax, as follows: |
|                     | \begin{itemize}  
|                     | \item To create an empty multiset, denoted \texttt{MULTISET[]} in the standard, use an empty constructor of the nested table type.  
|                     | \item To obtain the sole element of a multiset with one element, denoted \texttt{ELEMENT (<multiset value expression>)} in the standard, use a scalar subquery to select the single element from the nested table.  
|                     | \item To construct a multiset by enumeration, use the constructor of the nested table type.  
|                     | \item To construct a multiset by query, use \texttt{CAST} with a multiset argument, casting to the nested table type.  
|                     | \item To unnest a multiset, use the \texttt{TABLE} operator in the FROM clause.  
|                     | \end{itemize} |
| S272, Multisets of user-defined types | Oracle's nested table type permits a multiset of structured types. Oracle does not have distinct types, so a multiset of distinct types is not supported. |
| S274, Multisets of reference types | A nested table type can have one or more columns of reference type. |
| S275, Advanced multiset support | Oracle supports the following elements of this feature on nested tables using the same syntax as the standard has for multisets: |
|                     | \begin{itemize}  
|                     | \item The \texttt{MULTISET UNION}, \texttt{MULTISET INTERSECTION}, and \texttt{MULTISET EXCEPT} operators  
|                     | \item The \texttt{SUBMULTISET} predicate  
|                     | \item = and <> predicates  
<p>|                     | \end{itemize} |
|                     | Oracle does not support the \texttt{FUSION} or \texttt{INTERSECTION} aggregates. |
| S281, Nested collection types | Oracle permits nesting of its collection types (varray and nested table). |
| S401, Distinct types based on array types | Oracle's varray types are strongly typed. |
| S403, \texttt{ARRAY_MAX_CARDINALITY} | In PL/SQL, the \texttt{LIMIT} method of a varray returns its maximum cardinality. |</p>
<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>S404, TRIM_ARRAY</td>
<td>In PL/SQL, the TRIM method of a varray can be used to trim the varray.</td>
</tr>
</tbody>
</table>
| T041, Basic LOB data type support | Oracle supports the following aspects of this feature:  
• The keywords BLOB, CLOB, and NCLOB  
• Concatenation, UPPER, LOWER on CLOBs  
Oracle provides equivalent support for the following aspects of this feature:  
• Use INSTR instead of POSITION.  
• Use LENGTH instead of CHAR_LENGTH.  
Oracle does not support the following aspects of this feature:  
• The keywords BINARY LARGE OBJECT, CHARACTER LARGE OBJECT, and NATIONAL CHARACTER LARGE OBJECT as synonyms for BLOB, CLOB, and NCLOB, respectively  
• <binary string literal>  
• The ability to specify an upper bound on the length of a BLOB or CLOB  
• Concatenation of BLOBS |
| T042, Extended LOB support | Oracle fully supports the following element of this feature:  
• TRIM function on a CLOB argument  
Oracle provides equivalent functionality for the following elements of this feature:  
• BLOB and CLOB substring, supported using SUBSTR  
• SIMILAR predicate, supported using REGEXPR_LIKE to perform pattern matching with a Perl-like syntax  
The following elements of this feature are not supported:  
• Comparison predicates with BLOB or CLOB operands  
• CAST with a BLOB or CLOB operand  
• OVERLAY (This may be emulated using SUBSTR and string concatenation.)  
• LIKE predicate with BLOB or CLOB operands |
| T051, Row types | Oracle object types can be used in place of the standard's row types. |
| T061, UCS support | Oracle provides equivalent functionality for the following elements of this feature:  
• Oracle supports the keyword CHAR instead of CHARACTERS, and BYTE instead of OCTETS, in a character data type declaration.  
• The Oracle COMPOSE function is equivalent to the standard's NORMALIZE function.  
Oracle does not support the IS NORMALIZED predicate. |
<p>| T071, BIGINT data type | On many implementations, BIGINT refers to a binary integer type with 64 bits, which supports almost 19 decimal digits. The Oracle NUMBER type supports 39 decimal digits. |</p>
<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>T111, Updatable joins, unions and columns</td>
<td>Oracle's updatable join views are similar to the standard's updatable join capabilities. Unlike the standard, Oracle does not require an updatable join view to display the strong candidate key in the <code>SELECT</code> list. Although an updatable join view might have more than one key-preserved table, only one of them may be modified using an <code>UPDATE</code> or <code>DELETE</code>, unlike the standard, which modifies all key-preserved tables of an updatable join.</td>
</tr>
<tr>
<td>T121, WITH (excluding RECURSIVE) in query expression</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>T122, WITH (excluding RECURSIVE) in subquery</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>T131, Recursive query</td>
<td>Oracle supports the use of a <code>WITH</code> clause element that references itself, but without the <code>RECURSIVE</code> keyword. Alternatively, Oracle's <code>START WITH</code> and <code>CONNECT BY</code> clauses can be used to perform many recursive queries.</td>
</tr>
<tr>
<td>T132, Recursive query in subquery</td>
<td>Oracle supports the use of a <code>WITH</code> clause element that references itself, but without the <code>RECURSIVE</code> keyword. Alternatively, Oracle's <code>START WITH</code> and <code>CONNECT BY</code> clauses can be used to perform many recursive queries.</td>
</tr>
<tr>
<td>T141, SIMILAR predicate</td>
<td>Oracle provides <code>REGEXP_LIKE</code> for pattern matching with a Perl-like syntax.</td>
</tr>
<tr>
<td>T172, AS subquery clause in table definition</td>
<td>Oracle's <code>AS</code> subquery feature of <code>CREATE TABLE</code> has substantially the same functionality as the standard, though there are some syntactic differences.</td>
</tr>
</tbody>
</table>
| T174, Identity columns | Oracle supports this feature, with the following syntactic differences:  
  • Oracle uses `NOMINVALUE` and `NOMAXVALUE` instead of the standard's `NO MINVALUE` and `NO MAXVALUE`.  
  • To restart an identity column, in an `ALTER TABLE MODIFY` statement, use `START WITH LIMIT VALUE` to restart at the highest value (for an increasing identity column) or the lowest value (for a decreasing identity column); use `START WITH number` to restart at a specific number.  
  `GENERATED BY DEFAULT ON NULL` is an Oracle extension. |
| T175, Generated columns | Oracle supports this feature, with the following restrictions:  
  • Generated columns are not supported in temporary tables.  
  • The data type of a generated column may not be LOB or XML. |
| T176, Sequence generator support | Oracle's sequences have the same capabilities as the standard's, though with different syntax. |
| T178, Identity columns: simple restart option | Oracle's `START WITH LIMIT VALUE` is the same as the standard's simple restart if the identity column has not cycled. |
## Table C-2  (Cont.) Oracle Support for Optional Features of SQL/Foundation

<tbody>
<tr>
<td>T180, System-versioned tables</td>
<td>Oracle’s Flashback capability is substantially the same as the standard’s system-versioned tables. Some key differences are:</td>
</tr>
<tr>
<td></td>
<td>· In Oracle you do not need to designate particular tables for journaling; all tables are journaled.</td>
</tr>
<tr>
<td></td>
<td>· In Oracle, LOB columns need to be individually designated for journaling, because of the potential for large amounts of data. The standard has no analogous provision.</td>
</tr>
<tr>
<td></td>
<td>· In Oracle you need a privilege in order to read historical data.</td>
</tr>
<tr>
<td></td>
<td>· In the standard, journaled tables have columns to record the start and end timestamps for the row. In Oracle, this is</td>
</tr>
<tr>
<td></td>
<td>provided through pseudocolumns.</td>
</tr>
<tr>
<td>T181, Application-time period tables</td>
<td>Oracle supports the following elements of this feature:</td>
</tr>
<tr>
<td></td>
<td>· Application-time period definition during CREATE TABLE</td>
</tr>
<tr>
<td></td>
<td>· Adding and dropping an application-time period definition using ALTER TABLE with a minor syntactic difference: Oracle requires parentheses around the period specification; the standard does not support parentheses in this position.</td>
</tr>
<tr>
<td></td>
<td>Oracle extends this feature:</td>
</tr>
<tr>
<td></td>
<td>· With the ability to have more than one application-time period per table.</td>
</tr>
<tr>
<td></td>
<td>· By making the start time and end time columns optional. In this case, Oracle will create these columns implicitly.</td>
</tr>
<tr>
<td></td>
<td>· By allowing NULL for the start time column to indicate that the row is considered valid for any point in time before the value of the end time column.</td>
</tr>
<tr>
<td></td>
<td>· By allowing NULL for the end time column to indicate that the row is considered valid for any point in time on or after the value of the start time column.</td>
</tr>
<tr>
<td></td>
<td>· By querying an application-time period table using the flashback query options VERSIONS PERIOD FOR and AS OF PERIOD FOR.</td>
</tr>
<tr>
<td>T201, Comparable data types for referential constraints</td>
<td>Oracle fully supports this feature.</td>
</tr>
</tbody>
</table>
Table C-2  (Cont.) Oracle Support for Optional Features of SQL/Foundation

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>T211, Basic trigger capability</td>
<td>Oracle's triggers differ from the standard as follows:</td>
</tr>
<tr>
<td></td>
<td>· Oracle does not provide the optional syntax <strong>FOR EACH STATEMENT</strong> for the default case, the statement trigger.</td>
</tr>
<tr>
<td></td>
<td>· Oracle does not support <strong>OLD TABLE</strong> and <strong>NEW TABLE</strong>; the transition tables specified in the standard (the multiset of before and after images of affected rows) are not available.</td>
</tr>
<tr>
<td></td>
<td>· The trigger body is written in PL/SQL, which is functionally equivalent to the standard's procedural language PSM, but not the same.</td>
</tr>
<tr>
<td></td>
<td>· In the trigger body, the new and old transition variables are referenced beginning with a colon.</td>
</tr>
<tr>
<td></td>
<td>· Oracle's row triggers are executed as the row is processed, instead of buffering them and executing all of them after processing all rows. The standard's semantics are deterministic, but Oracle's in-flight row triggers are more performant.</td>
</tr>
<tr>
<td></td>
<td>· Oracle's before-row and before-statement triggers can perform DML statements, which is forbidden in the standard. However, Oracle's after-row statements cannot perform DML, while it is permitted in the standard.</td>
</tr>
<tr>
<td></td>
<td>· When multiple triggers apply, the standard says they are executed in order of definition. In Oracle the execution order is nondeterministic, unless specified using <strong>FOLLOWS</strong>.</td>
</tr>
<tr>
<td></td>
<td>· Oracle uses the system privileges <strong>CREATE TRIGGER</strong> and <strong>CREATE ANY TRIGGER</strong> to regulate creation of triggers, instead of the standard's <strong>TRIGGER</strong> privilege, which is a table privilege.</td>
</tr>
<tr>
<td>T212, Enhanced trigger capability</td>
<td>This feature permits statements triggers, which Oracle supports, as described for feature T211, Basic trigger capability.</td>
</tr>
<tr>
<td>T213, INSTEAD OF triggers</td>
<td>Oracle supports <strong>INSTEAD OF</strong> triggers on views, with syntax and semantics agreeing with the standard except as noted for feature T211, Basic trigger capability. Oracle permits an <strong>INSTEAD OF</strong> trigger on a view that specified <strong>WITH CHECK OPTION</strong>, unlike the standard.</td>
</tr>
<tr>
<td>T241, START TRANSACTION statement</td>
<td>Oracle's <strong>SET TRANSACTION</strong> statement starts a transaction making it equivalent to the standard's <strong>START TRANSACTION</strong> rather than the standard's <strong>SET TRANSACTION</strong>. Oracle's <strong>READ ONLY</strong> transactions are at <strong>SERIALIZABLE</strong> isolation level.</td>
</tr>
<tr>
<td>T271, Savepoints</td>
<td>Oracle supports this feature, except:</td>
</tr>
<tr>
<td></td>
<td>· Oracle does not support <strong>RELEASE SAVEPOINT</strong>.</td>
</tr>
<tr>
<td></td>
<td>· Oracle does not support savepoint levels.</td>
</tr>
<tr>
<td>T285, Enhanced derived column names</td>
<td>This feature pertains only to derived columns in a <strong>SELECT</strong> list with no column alias and consisting of a SQL parameter reference. In that case, the column name defaults to the parameter name, the same as in the standard.</td>
</tr>
<tr>
<td>T323, Explicit security for external routines</td>
<td>The Oracle syntax **AUTHID { CURRENT USER</td>
</tr>
<tr>
<td>Feature ID, Feature</td>
<td>Support</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------</td>
</tr>
<tr>
<td>T324, Explicit security for SQL routines</td>
<td>Oracle's syntax `AUTHID { CURRENT USER</td>
</tr>
<tr>
<td>T325, Qualified SQL parameter reference</td>
<td>PL/SQL supports the use of a routine name to qualify a parameter name.</td>
</tr>
</tbody>
</table>
| T326, Table functions | Oracle provides equivalents for the following elements of this feature:  
  - `<multiset value constructor by query>` is supported using `CAST (MULTISET (<query expression>) AS <nested table type>)`  
  - `<table function derived table>` is supported using the TABLE operator in the FROM clause with a varray or nested table as the argument  
  - `<collection value expression>` is equivalent to an Oracle expression resulting in a varray or nested table  
  - `<returns table type>` is equivalent to a PL/SQL function that returns a nested table |
<p>| T331, Basic roles | Oracle supports this feature, except for <code>REVOKE ADMIN OPTION FOR &lt;role name&gt;</code>. |
| T341, Overloading of SQL-invoked functions and procedures | Oracle supports overloading of functions and procedures. However, the rules for handling certain data type combinations are not the same as the standard. For example, the standard permits the coexistence of two functions of the same name differing only in the numeric types of the arguments, whereas Oracle does not permit this. |
| T351, Bracketed comments | Oracle fully supports this feature. |
| T431, Extended grouping capabilities | Oracle fully supports this feature. |
| T432, Nested and concatenated GROUPING SETS | Oracle supports concatenated GROUPING SETS, but not nested GROUPING SETS. |
| T433, Multiargument function GROUPING | The Oracle <code>GROUP_ID</code> function can be used to conveniently distinguish groups in a grouped query, serving the same purpose as the standard multiargument GROUPING function. |
| T441, ABS and MOD functions | Oracle supports the ABS function. Oracle's MOD function is similar to the standard, though the behavior is different if the two arguments are of opposite sign. |
| T471, Result sets return value | PL/SQL ref cursors provide all the functionality of the standard's result set cursors. |
| T491, LATERAL derived tables | Oracle fully supports this feature. |
| T501, Enhanced EXISTS predicate | Oracle fully supports this feature. |
| T511, Transaction counts | Oracle supports the count of transactions committed and rolled back via the system views <code>V$STATNAME</code> and <code>V$SESSTAT</code>. |</p>
<table>
<thead>

<tr>
<td>T525, Default values for parameters of SQL-invoked functions</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>T571, Array-returning external SQL-invoked function</td>
<td>Oracle table functions returning a varray can be defined in external programming languages. When declaring such functions in SQL, use the CREATE FUNCTION command with the PIPELINED USING clause.</td>
</tr>
<tr>
<td>T572, Multiset-returning external SQL-invoked function</td>
<td>Oracle table functions returning a nested table can be defined in external programming languages. When declaring such functions in SQL, use the CREATE FUNCTION command with the PIPELINED USING clause. In the body of the function, use the OCITable interface. The function must be invoked within the TABLE operator in the FROM clause.</td>
</tr>
<tr>
<td>T581, Regular expressions substring functions</td>
<td>Oracle provides the REGEXP_SUBSTR function to perform substring operations using regular expression matching.</td>
</tr>
<tr>
<td>T591, UNIQUE constraints of possibly null columns</td>
<td>Oracle permits a UNIQUE constraint on one or more nullable columns. If the UNIQUE constraint is on a single column, then the semantics are the same as the standard (the constraint permits any number of rows that are null in the designated column). If the UNIQUE constraint is on two or more columns, then the semantics are nonstandard. Oracle permits any number of rows that are null in all the designated columns. Unlike the standard, if a row is non-null in at least one of the designated columns, then another row having the same values in the non-null columns of the constraint is a constraint violation and not permitted.</td>
</tr>
<tr>
<td>T611, Elementary OLAP operations</td>
<td>Oracle fully supports this feature, except that DISTINCT is only supported in conjunction with window partitioning but not with window framing.</td>
</tr>
<tr>
<td>T612, Advanced OLAP operations</td>
<td>Oracle supports the following elements of this feature: PERCENT_RANK, CUME_DIST, WIDTH_BUCKET, hypothetical set functions, PERCENTILE_CONT, PERCENTILE_DISC, and ROW_NUMBER. Oracle does not support the following elements of this feature:</td>
</tr>
<tr>
<td></td>
<td>• window names</td>
</tr>
<tr>
<td></td>
<td>• EXCLUDE</td>
</tr>
<tr>
<td></td>
<td>• ROW_NUMBER without ORDER BY</td>

<tr>
<td>T821, Basic SQL/JSON query operators</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>T822, SQL/JSON: IS JSON WITH UNIQUE KEYS predicate</td>
<td>Oracle fully supports this feature.</td>
</tr>
</tbody>
</table>
Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>T823, SQL/JSON: PASSING clause</td>
<td>Oracle supports the PASSING clause in JSON_EXISTS.</td>
</tr>
</tbody>
</table>
| T825, SQL/JSON: ON EMPTY and ON ERROR clauses | Oracle fully supports this feature, except that:  
  - The ON ERROR clause for JSON_EXISTS does not support UNKNOWN.  
  - JSON_TABLE does not support a column-level ON EMPTY clause. |
| T828, JSON_QUERY | Oracle fully supports this feature. |
| T829, JSON_QUERY: array wrapper options | Oracle fully supports this feature. |
| T832, SQL/JSON path language: item method | Oracle fully supports the following item methods:  
  - abs  
  - ceiling  
  - double  
  - floor  
Oracle provides the following comparable support:  
  - date and timestamp are comparable to the standard's datetime  
Oracle extends this feature by supporting the following item methods:  
  - length  
  - lower  
  - number  
  - string  
  - upper |
| T833, SQL/JSON path language: multiple subscripts | Oracle fully supports this feature, except that subscripts have to be specified in strictly monotonically increasing order. |
| T834, SQL/JSON path language: wildcard member accessor | Oracle fully supports this feature. |
| T835, SQL/JSON path language: filter expression | Oracle supports the filter expression as the last step of the SQL/JSON path expression in JSON_EXISTS. |
| T839, Formatted cast of datetimes to/from character strings | Oracle supports this feature with a minor syntactic difference: Oracle uses a comma instead of the keyword \texttt{FORMAT}. |

Oracle Compliance with SQL/CLI

The Oracle ODBC driver conforms to SQL/CLI.

Oracle Compliance with SQL/PSM

Oracle PL/SQL provides functionality equivalent to SQL/PSM, with minor syntactic differences, such as the spelling or arrangement of keywords.
Oracle Compliance with SQL/MED

Oracle does not comply with SQL/MED.

Oracle Compliance with SQL/OLB

Oracle SQLJ conforms to SQL/OLB:1999 and not yet to SQL/OLB:2016.

Oracle Compliance with SQL/JRT

Oracle fully supports stored routines and SQL types implemented in Java(TM). Oracle provides equivalent support for the creation and maintenance of such types and procedures. Oracle's capabilities are in general a superset of the functionality defined by the standard.

Oracle Compliance with SQL/XML

The XML data type in the standard is XML. The Oracle equivalent data type is XMLType. A feature of the standard is considered to be fully supported if the only difference between Oracle and the standard is the spelling of the data type name. Table C-3 describes Oracle's support for the features of SQL/XML.

Table C-3 Oracle Support for Features of SQL/XML

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>X010, XML type</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>X011, Arrays of XML types</td>
<td>Oracle supports this feature using named array types</td>
</tr>
<tr>
<td>X012, Multisets of XML type</td>
<td>The Oracle equivalent of a multiset of XML type is a nested table with a single column of XML type.</td>
</tr>
<tr>
<td>X013, Distinct types of XML</td>
<td>A distinct type can be emulated using an object type with a single attribute.</td>
</tr>
<tr>
<td>X014, Attributes of XML type</td>
<td>In Oracle, attributes of object types may be of type XMLType, but the syntax for creating object types is nonstandard.</td>
</tr>
<tr>
<td>X015, Fields of XML type</td>
<td>Oracle object types may be used instead of row types; Oracle supports object types with attributes of XMLType.</td>
</tr>
<tr>
<td>X016, Persistent XML values</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>X020, XMLConcat</td>
<td>Oracle fully supports this feature.</td>
</tr>
</tbody>
</table>
| X025, XMLCast        | Oracle supports this feature, with the following restrictions:  
  - The source expression must be of XMLType and the target data type may not be XMLType. (Since Oracle has only one XML type, there is no need to cast from XML to XML.)  
  - Oracle does not support XML passing mechanism; the behavior is the same as BY VALUE in the standard.  
  Oracle extends this feature with the ability to cast to type REF XMLTYPE. |
<p>| X031, XMLElement    | Oracle fully supports this feature. |</p>

</table>
| X040, Basic table mapping               | Oracle table mappings are available through a Java interface and through a package. Oracle table mappings have been generalized to map queries and not just tables. To map only a table: SELECT * FROM table_name. This provides support for the following elements of this feature:  
  - X041, Basic table mapping: null absent  
  - X042, Basic table mapping: null as nil  
  - X043, Basic table mapping: table as forest  
  - X044, Basic table mapping: table as element  
  - X045, Basic table mapping: with target namespace  
  - X046, Basic table mapping: data mapping  
  - X047, Basic table mapping: metadata mapping  
  - X049, Basic table mapping: hex encoding  
  Oracle does not support the following element of this feature:  
  - X048, Basic table mapping: base64 encoding  
<p>| X041, Basic table mapping: null absent   | See X040.                                                               |
| X042, Basic table mapping: null as nil   | See X040.                                                               |
| X043, Basic table mapping: table as forest | See X040.                                                         |
| X044, Basic table mapping: table as element | See X040.                                               |
| X045, Basic table mapping: with target namespace | See X040.                                                               |
| X046, Basic table mapping: data mapping  | See X040.                                                               |
| X047, Basic table mapping: metadata mapping | See X040.                                                               |
| X049, Basic table mapping: hex encoding  | See X040.                                                               |
| X060, XMLParse: Character string input and CONTENT option | Oracle does not support the {PRESERVE | STRIP} WHITESPACE syntax. The behavior is always STRIP WHITESPACE. |
| X061, XMLParse: Character string input and DOCUMENT option | Oracle does not support the {PRESERVE | STRIP} WHITESPACE syntax. The behavior is always STRIP WHITESPACE. |</p>
<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>X069, XMLSERIALIZE: INDENT</td>
<td>Oracle extends this feature with the ability to specify an indent size.</td>
</tr>
</tbody>
</table>
| X070, XMLSerialize: Character string serialization and CONTENT option | Oracle supports this feature, with this restriction:  
  - In the standard, the choice of DOCUMENT or CONTENT is optional; in Oracle, you must specify one of these.  
  Oracle extends this feature as follows: the standard requires a target data type; Oracle defaults to CLOB. |
| X071, XMLSerialize: Character string serialization and DOCUMENT option | Oracle fully supports this feature. |
| X072, XMLSerialize: Character string serialization | Oracle fully supports this feature. |
| X073, XMLSerialize: BLOB serialization and CONTENT option | Oracle fully supports this feature. |
| X074, XMLSerialize: BLOB serialization and DOCUMENT option | Oracle fully supports this feature. |
| X075, XMLSerialize: BLOB serialization | Oracle fully supports this feature. |
| X076, XMLSerialize: VERSION option | Use XMLRoot to set the XML version prior to serialization. |
| X077, XMLSerialize: explicit ENCODING option | Oracle fully supports this feature. |
| X080, Namespaces in XML publishing | In the Oracle implementation of XMLElement, XMLAttributes are used to define namespaces (XMLNamespaces is not implemented). However, XMLAttributes is not supported for XMLForest. |
| X086, XML namespace declarations in XMLTable | Oracle fully supports this feature. |
| X090, XML document predicate | In Oracle, you can test whether an XML value is a document by using the ISFRAGMENT method. |
| X096, XMLExists | Oracle fully supports this feature, with this exception: Oracle only supports passing by value, so the keywords BY VALUE are optional at the beginning of the PASSING clause, and not supported on individual arguments. |
| X120, XML parameters in SQL routines | Oracle fully supports this feature. |
| X121, XML parameters in external routines | Oracle supports XML values passed to external routines using a non-standard interface. |
| X141, IS VALID predicate: data drive case | The XMLISVALID method is equivalent to the IS VALID predicate, and supports the data-driven case. |
| X142, IS VALID predicate: ACCORDING TO clause | The XMLISVALID method is equivalent to the IS VALID predicate, and includes the equivalent of the ACCORDING TO clause. |

Oracle Compliance with FIPS 127-2

Oracle complied fully with last Federal Information Processing Standard (FIPS), which was FIPS PUB 127-2. That standard is no longer published. However, for users whose applications depend on information about the sizes of some database constructs that were defined in FIPS 127-2, the details of our compliance are listed in Table C-4.

Table C-4  Sizing for Database Constructs

<td>No limit</td>
</tr>
<tr>
<td>Cursors simultaneously open</td>
<td>10</td>
<td>(Note 6)</td>
</tr>
<tr>
<td>Items in a SELECT list</td>
<td>100</td>
<td>1,000</td>
</tr>
</tbody>
</table>

**Note 1:** The number of **SET** clauses in an **UPDATE** statement refers to the number items separated by commas following the **SET** keyword.

**Note 2:** The FIPS PUB defines the length of a collection of columns to be the sum of: twice the number of columns, the length of each character column in bytes, decimal precision plus 1 of each exact numeric column, binary precision divided by 4 plus 1 of each approximate numeric column.

**Note 3:** The Oracle limit for the maximum row length is based on the maximum length of a row containing a **LONG** value of length 2 gigabytes and 999 **VARCHAR2** values, each of length 4000 bytes: 2(254) + 231 + (999(4000)).

**Note 4:** The Oracle limit for a **UNIQUE** key is half the size of an Oracle data block (specified by the initialization parameter **DB_BLOCK_SIZE**) minus some overhead.

**Note 5:** Oracle places no limit on the number of columns in a **GROUP BY** clause or the number of sort specifications in an **ORDER BY** clause. However, the sum of the sizes of all the expressions in either a **GROUP BY** clause or an **ORDER BY** clause is limited to the size of an Oracle data block (specified by the initialization parameter **DB_BLOCK_SIZE**) minus some overhead.

**Note 6:** The Oracle limit for the number of cursors simultaneously open is specified by the initialization parameter **OPEN_CURSORS**. The maximum value of this parameter depends on the memory available on your operating system and exceeds 100 in all cases.
Oracle Extensions to Standard SQL

Oracle supports numerous features that extend beyond standard SQL. If you are concerned with the portability of your applications to other implementations of SQL, then use Oracle's FIPS Flagger to help identify the use of Oracle extensions to Entry SQL-92 in your embedded SQL programs. The FIPS Flagger is part of the Oracle precompilers and the SQL*Module compiler. The FIPS Flagger can also be enabled in SQL*Plus by using ALTER SESSION SET FLAGGER = ENTRY. While SQL-92 has been superseded by SQL:2016, there has been no conformance testing authority for any version of SQL since SQL-92; hence, Entry SQL-92 offers you the most assurance of portability.

See Also:  
Pro*COBOL Programmer's Guide and Pro*C/C++ Programmer's Guide for information on how to use the FIPS Flagger

Oracle Compliance with Older Standards

This release of Oracle Database conforms to SQL:2016, the most recent edition of the SQL standard when this guide was published, as itemized in preceding sections of this appendix. Oracle does not formally claim that this release of the database conforms to SQL-92—and in particular, to SQL-92 Entry Level—or to SQL:1999, because those standards have been superseded by SQL:2016. Some, mostly minor, changes between editions of the SQL standard might affect applications. The SQL standard, or a reference discussing that standard, can be consulted to determine the details of any incompatibilities that have been introduced. One important source is Annex E of SQL/Foundation:1999, SQL/Foundation:2003, SQL/Foundation:2008, SQL/Foundation:2011, and SQL/Foundation:2016.

In some cases, this release of Oracle Database might continue to recognize constructs from older editions of SQL. Such recognition is often allowed as a valid vendor extension. It is the general policy of Oracle to keep incompatibilities between versions of the database as few as possible. This policy extends to retention of older forms when that is feasible. In any case, the differences between older SQL and SQL:2016 (as noted above) are relatively inconsequential.

Character Set Support

Oracle supports most national, international, and vendor-specific encoded character set standards. A complete list of character sets supported by Oracle appears in Oracle Database Globalization Support Guide.

Unicode is a universal encoded character set that lets you store information from any language using a single character set. Unicode is required by modern standards such as XML, Java, JavaScript, and LDAP. Unicode is compliant with ISO/IEC standard 10646. For information on ISO standards, visit the Web site of the International Organization for Standardization:

http://www.iso.ch/
Oracle Database 18c complies with version 9.0 of the Unicode Standard. For up-to-date information on the Unicode Standard, visit the Web site of the Unicode Consortium:

http://www.unicode.org

Oracle supports the UTF-8 encoding scheme of the Unicode Standard through the AL32UTF8 character set, the UTF-16BE encoding scheme through the AL16UTF16 character set, and the UTF-16LE encoding scheme through the AL16UTF16LE character set. AL32UTF8 is valid as the client and database character set on ASCII-based platforms. AL16UTF16 is valid as the national (NCHAR) character set on all platforms. AL16UTF16LE is not valid as the client, database, or national character set.

Oracle implements two deprecated Unicode compatibility encoding forms: CESU-8 through the UTF8 character set and UTF-EBCDIC through the UTFE character set. The UTF8 and UTFE character sets are not guaranteed to include updates to the Unicode standard beyond version 3.0. UTF8 is valid as the client and database character set on ASCII-based platforms and as the national (NCHAR) character set on all platforms. UTFE is valid as the database character set on EBCDIC-based platforms.

All mentioned Oracle character sets are supported in conversion functions.

Oracle recommends that databases on ASCII-based platforms are created with the AL32UTF8 character set and the AL16UTF16 national (NCHAR) character set. Oracle recommends that you avoid the use of the NCHAR data types and the associated national character set as they are not supported by some RDBMS components, such as Oracle Text and Oracle XDB.

Oracle Database Globalization Support Guide for details on Oracle character set support
Oracle Regular Expression Support

Oracle's implementation of regular expressions conforms with the IEEE Portable Operating System Interface (POSIX) regular expression standard and to the Unicode Regular Expression Guidelines of the Unicode Consortium.

This appendix contains the following sections:

- Multilingual Regular Expression Syntax
- Regular Expression Operator Multilingual Enhancements
- Perl-influenced Extensions in Oracle Regular Expressions

Multilingual Regular Expression Syntax

Table D-1 lists the full set of operators defined in the POSIX standard Extended Regular Expression (ERE) syntax. Oracle follows the exact syntax and matching semantics for these operators as defined in the POSIX standard for matching ASCII (English language) data. For more complete descriptions of the operators, examples of their use, and Oracle multilingual enhancements of the operators, refer to Oracle Database Development Guide. Notes following the table provide more complete descriptions of the operators and their functions, as well as Oracle multilingual enhancements of the operators. Table D-2 summarizes Oracle support for and multilingual enhancement of the POSIX operators.

Table D-1  Regular Expression Operators and Metasymbols

<table>

<td>Specifies character classes (for example, [:alpha:]). It matches any character within the character class.</td>
</tr>
<tr>
<td>[=]</td>
<td>Specifies equivalence classes. For example, [=a=] matches all characters having base letter ‘a’.</td>
</tr>
</tbody>
</table>

Regular Expression Operator Multilingual Enhancements

When applied to multilingual data, Oracle’s implementation of the POSIX operators extends beyond the matching capabilities specified in the POSIX standard. Table D-2 shows the relationship of the operators in the context of the POSIX standard.

- The first column lists the supported operators.
- The second and third columns indicate whether the POSIX standard (Basic Regular Expression—BRE and Extended Regular Expression—ERE, respectively) defines the operator.
- The fourth column indicates whether Oracle’s implementation extends the operator’s semantics for handling multilingual data.

Oracle lets you enter multibyte characters directly, if you have a direct input method, or you can use functions to compose the multibyte characters. You cannot use the Unicode hexadecimal encoding value of the form ‘\\xxxx’. Oracle evaluates the characters based on the byte values used to encode the character, not the graphical representation of the character. All accented characters are considered word characters.

Perl-influenced Extensions in Oracle Regular Expressions

Oracle Database regular expression functions and conditions accept a number of Perl-influenced operators that are in common use, although not part of the POSIX standard. Table D-3 lists those operators. For more complete descriptions with examples, refer to Oracle Database Development Guide.

Table D-3  Perl-influenced Operators in Oracle Regular Expressions

<table>

Oracle SQL Reserved Words and Keywords

This appendix contains the following sections:

- Oracle SQL Reserved Words
- Oracle SQL Keywords

Oracle SQL Reserved Words

This section lists Oracle SQL reserved words. You cannot use Oracle SQL reserved words as nonquoted identifiers. Quoted identifiers can be reserved words, although this is not recommended.

**Note:**
In addition to the following reserved words, Oracle uses system-generated names beginning with "SYS_" for implicitly generated schema objects and subobjects. Oracle discourages you from using this prefix in the names you explicitly provide to your schema objects and subobjects to avoid possible conflict in name resolution.

The `V$RESERVED_WORDS` data dictionary view provides additional information on each reserved word, including whether it is always reserved or is reserved only for particular uses. Refer to *Oracle Database Reference* for more information.

Words followed by an asterisk (*) are also ANSI reserved words.

Appendix E
Oracle SQL Reserved Words
**Note 1:** This keyword is only reserved for use as an attribute name.

**Note 2:** You cannot use the uppercase word **ROWID**, either quoted or nonquoted, as a column name. However, you can use the uppercase word as a quoted identifier that is not a column name, and you can use the word with one or more lowercase letters (for example, "Rowid" or "rowid") as any quoted identifier, including a column name.

### Oracle SQL Keywords

Oracle SQL keywords are not reserved. However, Oracle uses them internally in specific ways. Therefore, if you use these words as names for objects and object parts, then your SQL statements may be more difficult to read and may lead to unpredictable results.

You can obtain a list of keywords by querying the **V$RESERVED_WORDS** data dictionary view. All keywords in the view that are not listed as always reserved or reserved for a specific use are Oracle SQL keywords. Refer to *Oracle Database Reference* for more information.
Extended Examples

The body of the SQL Language Reference contains examples for almost every reference topic. This appendix contains lengthy examples that are not appropriate in the context of a single SQL statement. These examples are intended to provide uninterrupted the series of steps that you would use to take advantage of particular Oracle functionality. They do not replace the syntax diagrams and semantics found for each individual SQL statement in the body of the reference. Use the cross-references provided to access additional information, such as privileges required and restrictions, as well as syntax.

This appendix contains the following sections:

- Using Extensible Indexing
- Using XML in SQL Statements

Using Extensible Indexing

This section provides examples of the steps entailed in a simple but realistic extensible indexing scenario.

Suppose you want to rank the salaries in the HR.employees table and then find those that rank between 10 and 20. You could use the DENSE_RANK function, as follows:

```sql
SELECT last_name, salary FROM
(SELECT last_name, DENSE_RANK() OVER
    (ORDER BY salary DESC) rank_val, salary FROM employees)
WHERE rank_val BETWEEN 10 AND 20;
```

See Also:

- DENSE_RANK

This nested query is somewhat complex, and it requires a full scan of the employees table as well as a sort. An alternative would be to use extensible indexing to achieve the same goal. The resulting query will be simpler. The query will require only an index scan and a table access by rowid, and will therefore perform much more efficiently.

The first step is to create the implementation type position_im, including method headers for index definition, maintenance, and creation. Most of the type body uses PL/SQL, which is shown in italics.

The type must created with the AUTHID CURRENT_USER clause because of the EXECUTE IMMEDIATE statement inside the function ODCIINDEXCREATE(). By default that function runs with the definer rights. When the function is called in the subsequent creation of the domain index, the invoker does not have the same rights.
CREATE OR REPLACE TYPE position_im AUTHID CURRENT_USER AS OBJECT

  DBMS_SQL.PARSE(cnum, range_query_stmt, DBMS_SQL.NATIVE);
  /* set context as the cursor number */
  SCTX := position_im(cnum, 0, 0, 0);
  /* return success */
  RETURN ODCICONST.SUCCESS;
END;
The next step is to create the functional implementation function_for_position_between for the operator that will be associated with the indextype. (The PL/SQL blocks are shown in parentheses.)

This function is for use with an index-based function evaluation. Therefore, it takes an index context and scan context as parameters.

See Also:

- Oracle Database Data Cartridge Developer's Guide for information on creating index-based functional implementation
- CREATE FUNCTION and Oracle Database PL/SQL Language Reference

```
CREATE OR REPLACE FUNCTION function_for_position_between
    (col NUMBER, lower_pos NUMBER, upper_pos NUMBER, indexctx IN SYS.ODCIIndexCtx, scanctxt IN OUT position_im
```
RETURN NUMBER AS

rid ROWID;
storage_tab_name VARCHAR2(65);
lower_bound_stmt VARCHAR2(2000);
upper_bound_stmt VARCHAR2(2000);
col_val_stmt VARCHAR2(2000);
lower_bound NUMBER;
upper_bound NUMBER;
column_value NUMBER;

BEGIN
IF (indexctx.IndexInfo IS NOT NULL) THEN
    storage_tab_name := indexctx.IndexInfo.INDEXSCHEMA || '.' ||
    indexctx.IndexInfo.INDEXNAME || '_STORAGE_TAB';

    IF (scanctx IS NULL) THEN
        /* This is the first call. Open a cursor for future calls.
           First, do some error checking
        */
        IF (lower_pos > upper_pos) THEN
            RAISE_APPLICATION_ERROR(-20101,
            'Upper Position must be greater than or equal to Lower Position');
        END IF;
        IF (lower_pos <= 0) THEN
            RAISE_APPLICATION_ERROR(-20101,
            'Both Positions must be greater than zero');
        END IF;
        /* Obtain the upper and lower value bounds for the range we're interested in. */
        upper_bound_stmt := 'Select MIN(col_val) FROM (Select /*+ INDEX_DESC(' ||
            storage_tab_name || ' */ DISTINCT ' ||
            'col_val FROM ' || storage_tab_name || ' ORDER BY ' ||
            'col_val DESC) WHERE rownum <= ' || lower_pos;
    EXECUTE IMMEDIATE upper_bound_stmt INTO upper_bound;
    IF (lower_pos != upper_pos) THEN
        lower_bound_stmt := 'Select MIN(col_val) FROM (Select /*+ INDEX_DESC(' ||
            storage_tab_name || ' */ DISTINCT ' ||
            'col_val FROM ' || storage_tab_name || ' WHERE col_val < ' || upper_bound || ' ORDER BY ' ||
            'col_val DESC) WHERE rownum <= ' ||
            (upper_pos - lower_pos);
    EXECUTE IMMEDIATE lower_bound_stmt INTO lower_bound;
    ELSE
        lower_bound := upper_bound;
    END IF;
    IF (lower_bound IS NULL) THEN
        lower_bound := upper_bound;
    END IF;
    /* Store the lower and upper bounds for future function invocations for the positions. */
    scanctx := position_im(0, 0, lower_bound, upper_bound);
    END IF;
    /* Fetch the column value corresponding to the rowid, and see if it falls within the determined range. */
    col_val_stmt := 'Select col_val FROM ' || storage_tab_name ||
        ' WHERE base_rowid = ''' || indexctx.Rid || '''
    EXECUTE IMMEDIATE col_val_stmt INTO column_value;
    IF (column_value <= scanctx.upper_bound AND
        column_value >= scanctx.lower_bound AND
        scanflg = ODCICONST.RegularCall) THEN

Next, create the `position_between` operator, which uses the `function_for_position_between` function. The operator takes an indexed `NUMBER` column as the first argument, followed by a `NUMBER` lower and upper bound as the second and third arguments.

**See Also:**

CREATE OPERATOR

```sql
CREATE OR REPLACE OPERATOR position_between
    BINDING (NUMBER, NUMBER, NUMBER) RETURN NUMBER
    WITH INDEX CONTEXT, SCAN CONTEXT position_im
    USING function_for_position_between;
```

In this `CREATE OPERATOR` statement, the `WITH INDEX CONTEXT, SCAN CONTEXT` clause is included so that the index context and scan context are passed in to the functional evaluation, which is index based.

Now create the `position_indextype` indextype for the `position_operator`:

**See Also:**

CREATE INDEXTYPE

```sql
CREATE INDEXTYPE position_indextype
    FOR position_between(NUMBER, NUMBER, NUMBER)
    USING position_im;
```

The operator `position_between` uses an index-based functional implementation. Therefore, a domain index must be defined on the referenced column so that the index information can be passed into the functional evaluation. So the final step is to create the domain index `salary_index` using the `position_indextype` indextype:

**See Also:**

CREATE INDEX
CREATE INDEX salary_index ON employees(salary)
   INDEXTYPE IS position_indextype;

Now you can use the position_between operator function to rewrite the original query as follows:

```
SELECT last_name, salary FROM employees
  WHERE position_between(salary, 10, 20)=1
  ORDER BY salary DESC, last_name;
```

<table>

Using XML in SQL Statements

This section describes some of the ways you can use XMLType data in the database.

**XMLType Tables**

The sample schema oe contains a table warehouses, which contains an XMLType column warehouse_spec. Suppose you want to create a separate table with the warehouse_spec information. The following example creates a very simple XMLType table with one CLOB column:

```
CREATE TABLE xwarehouses OF XMLTYPE
  XMLTYPE STORE AS CLOB;
```

You can insert into such a table using XMLType syntax, as shown in the next statement. (The data inserted in this example corresponds to the data in the warehouse_spec column of the sample table oe.warehouses where warehouse_id = 1.)

```
INSERT INTO xwarehouses VALUES
  (xmltype("<?xml version="1.0"?>
  <Warehouse>
  <WarehouseId>1</WarehouseId>
  <WarehouseName>Southlake, Texas</WarehouseName>

```
<Building>Owned</Building>  
/Area>25000</Area>  
<Docks>2</Docks>  
<DockType>Rear load</DockType>  
<WaterAccess>true</WaterAccess>  
<RailAccess>N</RailAccess>  
<Parking>Street</Parking>  
<VClearance>10</VClearance>  
</Warehouse>);

See Also:

*Oracle XML DB Developer's Guide* for information on XMLType and its member methods

You can query this table with the following statement:

```
SELECT e.getClobVal() FROM xwarehouses e;
```

CLOB columns are subject to all of the restrictions on LOB columns. To avoid these restrictions, create an XMLSchema-based table. The XMLSchema maps the XML elements to their object-relational equivalents. The following example registers an XMLSchema locally. The XMLSchema (xwarehouses.xsd) reflects the same structure as the xwarehouses table. (XMLSchema declarations use PL/SQL and the DBMS_XMLSCHEMA package, so the example is shown in italics.)

*Oracle XML DB Developer's Guide* for information on creating XMLSchemas

begin
    dbms_xmlschema.registerSchema(
        'http://www.example.com/xwarehouses.xsd',
        'http://www.example.com/2001/XMLSchema
            targetNamespace="http://www.example.com/xwarehouses.xsd"'  
            xmlns:who="http://www.example.com/xwarehouses.xsd"  
            version="1.0">

    <simpleType name="RentalType">  
        <restriction base="string">  
            <enumeration value="Rented"/>  
            <enumeration value="Owned"/>  
        </restriction>
    </simpleType>

    <simpleType name="ParkingType">  
        <restriction base="string">  
            <enumeration value="Street"/>  
            <enumeration value="Lot"/>  
        </restriction>
    </simpleType>

    <element name = "Warehouse"

"positiveInteger"/>

FALSE);

Now you can create an XMLSchema-based table, as shown in the following example:
CREATE TABLE xwarehouses OF XMLTYPE
XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
ELEMENT "Warehouse";

By default, Oracle stores this as an object-relational table. Therefore, you can
insert into it as shown in the example that follows. (The data inserted in this
example corresponds to the data in the warehouse_spec column of the sample table
oe.warehouses where warehouse_id = 1.)
INSERT INTO xwarehouses VALUES(
xmltype.createxml('<?xml version="1.0"?>
<who:Warehouse xmlns:who="http://www.example.com/xwarehouses.xsd"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://www.example.com/xwarehouses.xsd
http://www.example.com/xwarehouses.xsd">
<WarehouseId>1</WarehouseId>
<WarehouseName>Southlake, Texas</WarehouseName>
<Building>Owned</Building>
<Area>25000</Area>
<Docks>2</Docks>
<DockType>Rear load</DockType>
<WaterAccess>true</WaterAccess>
<RailAccess>false</RailAccess>
<Parking>Street</Parking>
<VClearance>10</VClearance>
</who:Warehouse>'));
...

You can define constraints on an XMLSchema-based table. To do so, you use the
XMLDATA pseudocolumn to refer to the appropriate attribute within the Warehouse XML
element:
ALTER TABLE xwarehouses ADD (PRIMARY KEY(XMLDATA."WarehouseId"));

Because the data in xwarehouses is stored object relationally, Oracle rewrites queries
to this XMLType table to go to the underlying storage when possible. Therefore the
following queries would use the index created by the primary key constraint in the
preceding example:

F-10


SELECT * FROM xwarehouses x
    WHERE EXISTSNODE(VALUE(x), '/Warehouse[WarehouseId="1"]',
    'xmlns:who="http://www.example.com/xwarehouses.xsd"') = 1;

SELECT * FROM xwarehouses x
    WHERE EXTRACTVALUE(VALUE(x), '/Warehouse/WarehouseId',
    'xmlns:who="http://www.example.com/xwarehouses.xsd"') = 1;

You can also explicitly create indexes on XMLSchema-based tables, which greatly
enhance the performance of subsequent queries. You can create object-relational
views on XMLType tables, and you can create XMLType views on object-relational
tables.

See Also:

- XMLDATA Pseudocolumn for information on the XMLDATA pseudocolumn
- "Creating an XMLType View: Example"
- Creating an Index on an XMLType Table: Example

XMLType Columns

The sample table oe.warehouses was created with a warehouse_spec column of type
XMLType. The examples in this section create a shortened form of the oe.warehouses
table, using two different types of storage.

The first example creates a table with an XMLType table stored as a CLOB. This table
does not require an XMLSchema, so the content structure is not predetermined:

CREATE TABLE xwarehouses (
    warehouse_id    NUMBER,
    warehouse_spec  XMLTYPE)
XMLTYPE warehouse_spec STORE AS CLOB
(TABLESPACE example
    STORAGE (INITIAL 6144)
    CHUNK 4000
    NOCACHE LOGGING);

The following example creates a similar table, but stores the XMLType data in an
object-relational XMLType column whose structure is determined by the specified
XMLSchema:

CREATE TABLE xwarehouses (
    warehouse_id    NUMBER,
    warehouse_spec  XMLTYPE)
XMLTYPE warehouse_spec STORE AS OBJECT RELATIONAL
    XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
    ELEMENT "Warehouse";
