Preface

This manual describes the use of JSON data that is stored in Oracle Database. It covers how to store, generate, view, manipulate, manage, search, and query it.

- Audience
  Oracle Database JSON Developer's Guide is intended for developers building JSON Oracle Database applications.
- Documentation Accessibility
- Diversity and Inclusion
- Related Documents
  Oracle and other resources related to this developer's guide are presented.
- Conventions
  The conventions used in this document are described.
- Code Examples
  The code examples in this book are for illustration only. In many cases, however, you can copy and paste parts of examples and run them in your environment.

Audience

Oracle Database JSON Developer's Guide is intended for developers building JSON Oracle Database applications.

An understanding of JSON is helpful when using this manual. Many examples provided here are in SQL or PL/SQL. A working knowledge of one of these languages is presumed.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Diversity and Inclusion

Oracle is fully committed to diversity and inclusion. Oracle respects and values having a diverse workforce that increases thought leadership and innovation. As part of our initiative to build a more inclusive culture that positively impacts our employees, customers, and

partners, we are working to remove insensitive terms from our products and documentation. We are also mindful of the necessity to maintain compatibility with our customers' existing technologies and the need to ensure continuity of service as Oracle's offerings and industry standards evolve. Because of these technical constraints, our effort to remove insensitive terms is ongoing and will take time and external cooperation.

Related Documents

Oracle and other resources related to this developer's guide are presented.

*   *Oracle Database Error Messages Reference*. Oracle Database error message documentation is available only as HTML. If you have access to only printed or PDF Oracle Database documentation, you can browse the error messages by range. Once you find the specific range, use the search (find) function of your Web browser to locate the specific message. When connected to the Internet, you can search for a specific error message using the error message search feature of the Oracle Database online documentation.

Conventions

The conventions used in this document are described.

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.

Convention	Meaning
monospace	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Code Examples

The code examples in this book are for illustration only. In many cases, however, you can copy and paste parts of examples and run them in your environment.

- Pretty Printing of JSON Data
  To promote readability, especially of lengthy or complex JSON data, output is sometimes shown pretty-printed (formatted) in code examples.

- Execution Plans
  Some of the code examples in this book present execution plans. These are for illustration only. Running examples that are presented here in your environment is likely to result in different execution plans from those presented here.

- Reminder About Case Sensitivity
  JSON is case-sensitive. SQL is case-insensitive, but names in SQL code are implicitly uppercase.

Pretty Printing of JSON Data

To promote readability, especially of lengthy or complex JSON data, output is sometimes shown pretty-printed (formatted) in code examples.

Execution Plans

Some of the code examples in this book present execution plans. These are for illustration only. Running examples that are presented here in your environment is likely to result in different execution plans from those presented here.

Reminder About Case Sensitivity

JSON is case-sensitive. SQL is case-insensitive, but names in SQL code are implicitly uppercase.

When examining the examples in this book, keep in mind the following:

- SQL is case-insensitive, but names in SQL code are implicitly uppercase, unless you enclose them in double quotation marks (").

- JSON is case-sensitive. You must refer to SQL names in JSON code using the correct case: uppercase SQL names must be written as uppercase.

For example, if you create a table named `my_table` in SQL without using double quotation marks, then you must refer to it in JSON code as "`MY_TABLE`".

Part I

JSON Data and Oracle Database

Get started understanding JSON data and how you can use SQL and PL/SQL with JSON data stored in Oracle Database.

Schemaless development based on persisting application data in the form of JSON documents lets you quickly react to changing application requirements. You can change and redeploy your application without needing to change the storage schemas it uses.

SQL and relational databases provide flexible support for complex data analysis and reporting, as well as rock-solid data protection and access control. This is typically *not* the case for NoSQL databases, which have often been associated with schemaless development with JSON in the past.

Oracle Database provides all of the benefits of SQL and relational databases to JSON data, which you store and manipulate in the same ways and with the same confidence as any other type of database data.

- JSON Data (Standard)
  JSON as defined by its standards is described.

- JSON in Oracle Database
  Oracle Database supports JSON natively with relational database features, including transactions, indexing, declarative querying, and views.

ORACLE®

1
JSON Data (Standard)

JSON as defined by its standards is described.

- [Overview of JSON](#)
  JavaScript Object Notation (**JSON**) is defined in standards ECMA-404 (JSON Data Interchange Format), IETF RFC 8259, and ECMA-262 (ECMAScript Language Specification, third edition and later). The JavaScript dialect of ECMAScript is a general programming language used widely in web browsers and web servers.

- [JSON Syntax and the Data It Represents](#)
  Standard JSON values, scalars, objects, and arrays are described.

- [JSON Compared with XML](#)
  Both JSON and XML (Extensible Markup Language) are commonly used as data-interchange languages. Their main differences are listed here.

1.1 Overview of JSON

JavaScript Object Notation (**JSON**) is defined in standards ECMA-404 (JSON Data Interchange Format), IETF RFC 8259, and ECMA-262 (ECMAScript Language Specification, third edition and later). The JavaScript dialect of ECMAScript is a general programming language used widely in web browsers and web servers.

JSON is almost a subset of the object literal notation of JavaScript.[1]Because it can be used to represent JavaScript object literals, JSON commonly serves as a data-interchange language. In this it has much in common with XML.

Because it is (almost a subset of) JavaScript notation, JSON can often be used in JavaScript programs without any need for parsing or serializing. It is a text-based way of representing JavaScript object literals, arrays, and scalar data.

Although it was defined in the context of JavaScript, JSON is in fact a language-independent *data format*. A variety of programming languages can parse and generate JSON data.

JSON is relatively easy for humans to read and write, and easy for software to parse and generate. It is often used for serializing structured data and exchanging it over a network, typically between a server and web applications.

---

[1] JSON differs from JavaScript notation in this respect: JSON allows unescaped Unicode characters U+2028 (LINE SEPARATOR) and U+2029 (PARAGRAPH SEPARATOR) in strings. JavaScript notation requires control characters such as these to be escaped in strings. This difference can be important when generating JSONP (JSON with padding) data.

> **Note:**
>
> Is JSON a language? It's certainly not a *programming* language. In its specification it's referred to only as a "*data format*" and a "*notation*".
>
> Consider that the same question could be raised about XML, which is an abbreviation for "eXtensible Markup Language". Its name says it's a language, at least. Wikipedia says XML is "a markup language and file format for storing, transmitting, and reconstructing arbitrary data", and it says a markup language is "a text-encoding system consisting of a set of symbols inserted in a text document to control its structure, formatting, or the relationship between its parts." JSON isn't a markup language, but it and its uses have a lot in common with XML.
>
> Programming languages are a *subset* of languages. A language need not "program" or "do" anything. Like JSON, specification languages, and schema languages such as XML Schema and JSON Schema, are not programming languages.
>
> JSON has syntax, code, and data types. In this documentation we sometimes refer to JSON as a language, particularly where we talk about the *types* of its data: string, number, boolean,….

> - ECMA 262 and ECMA 262, 5.1 Edition for the ECMAScript Language Specifications (JavaScript)
> - JSON.org for information about JSON

1.2 JSON Syntax and the Data It Represents

Standard JSON values, scalars, objects, and arrays are described.

According to the JSON standard, a JSON **value** is one of the following JSON-language data types: object, array, number, string, Boolean (value `true` or `false`), or null (value `null`). All values except objects and arrays are **scalar**.

> **Note:**
>
> A JSON value of `null` is a *value* as far as SQL is concerned. It is not `NULL`, which in SQL represents the *absence* of a value (missing, unknown, or inapplicable data). In particular, SQL condition `IS NULL` returns false for a JSON `null` value, and SQL condition `IS NOT NULL` returns true.

Standard JSON has no *date* data type (unlike both XML and JavaScript). A date is represented in standard JSON using the available standard data types, such as *string*. There are some de facto standards for converting between dates and JSON strings. But typically programs using standard JSON data must, one way or another, deal with date representation conversion.

A **JavaScript object** is an associative array, or dictionary, of zero or more pairs of **property names** and associated JSON values.[2] A **JSON object** is a **JavaScript object literal**.[3] It is written as such a property list enclosed in braces (`{`, `}`), with name–value pairs separated by commas (`,`), and with the name and value of each pair separated by a colon (`:`). (Whitespace before or after the comma or colon is optional and insignificant.)

In JSON each property name and each string value *must* be enclosed in double quotation marks (`"`). In JavaScript notation, a property name used in an object literal can be, but need not be, enclosed in double quotation marks. It can also be enclosed in single quotation marks (`'`).

As a result of this difference, in practice, data that is represented using unquoted or single-quoted property names is sometimes referred to loosely as being represented in JSON, and some implementations of JSON, including the Oracle Database implementation, support the *lax syntax that allows the use of unquoted and single-quoted property names*.

A string in JSON is composed of Unicode characters, with backslash (`\`) escaping. A JSON number (numeral) is represented in decimal notation, possibly signed and possibly including a decimal exponent.

An object property is typically called a **field**. It is sometimes called a **key**, but this documentation generally uses "field" to avoid confusion with other uses here of the word "key". An object property name–value pair is often called an object **member** (but sometimes **member** can mean just the property). Order is not significant among object members.

> **Note:**
>
> - A JSON field name can be *empty* (written `""`).[4]
>
> - Each field name in a given JSON object is not necessarily unique; the same field name can be repeated. The SQL/JSON *path evaluation* that Oracle Database employs always uses only one of the object members that have a given field name; any *other members with the same name are ignored*. It is unspecified which of multiple such members is used.
>
>   See also Unique Versus Duplicate Fields in JSON Objects.

A **JavaScript array** has zero or more elements. A **JSON array** is represented by brackets (`[`, `]`) surrounding the representations of the array **elements** (also called **items**), which are separated by commas (`,`), and each of which is an object, an array, or a scalar value. Array *element order is significant*. (Whitespace before or after a bracket or comma is optional and insignificant.)

---

[2] JavaScript objects are thus similar to hash tables in C and C++, HashMaps in Java, associative arrays in PHP, dictionaries in Python, and hashes in Perl and Ruby.

[3] An object is created in JavaScript using either constructor `Object` or object literal syntax: `{...}`.

[4] In a few contexts an empty field name cannot be used with Oracle Database. Wherever it can be used, the name *must* be wrapped with double quotation marks.

Example 1-1   A JSON Object (Representation of a JavaScript Object Literal)

This example shows a JSON object that represents a purchase order, with top-level
field names `PONumber`, `Reference`, `Requestor`, `User`, `CostCenter`,
`ShippingInstruction`, `Special Instructions`, `AllowPartialShipment` and
`LineItems`.

```
{ "PONumber"             : 1600,
  "Reference"            : "ABULL-20140421",
  "Requestor"            : "Alexis Bull",
  "User"                 : "ABULL",
  "CostCenter"           : "A50",
  "ShippingInstructions" : { "name"    : "Alexis Bull",
                             "Address": { "street"  : "200 Sporting Green",
                                          "city"    : "South San Francisco",
                                          "state"   : "CA",
                                          "zipCode" : 99236,
                                          "country" : "United States of America" },
                             "Phone" : [ { "type"    : "Office",
                                           "number" : "909-555-7307" },
                                         { "type"    : "Mobile",
                                           "number" : "415-555-1234" } ] },
  "Special Instructions" : null,
  "AllowPartialShipment" : false,
  "LineItems"            : [ { "ItemNumber" : 1,
                              "Part"        : { "Description" : "One Magic Christmas",
                                                "UnitPrice"   : 19.95,
                                                "UPCCode"     : 13131092899 },
                              "Quantity"   : 9.0 },
                            { "ItemNumber" : 2,
                              "Part"        : { "Description" : "Lethal Weapon",
                                                "UnitPrice"   : 19.95,
                                                "UPCCode"     : 85391628927 },
                              "Quantity"   : 5.0 } ] }
```

- Most of the fields here have string values. For example: field `User` has value
  `"ABULL"`.

- Fields `PONumber` and `zipCode` have numeric values: `1600` and `99236`.

- Field `ShippingInstructions` has an object as its value. This object has three
  members, with fields `name`, `Address`, and `Phone`. Field `name` has a string value
  (`"Alexis Bull"`).

- The value of field `Address` is an object with fields `street`, `city`, `state`, `zipCode`,
  and `country`. Field `zipCode` has a numeric value; the others have string values.

- Field `Phone` has an array as value. This array has two elements, each of which is
  an object. Each of these objects has two members: fields `type` and `number` with
  their values.

- Field `Special Instructions` has a `null` value.

- Field `AllowPartialShipment` has the Boolean value `false`.

- Field `LineItems` has an array as value. This array has two elements, each of which is an object. Each of these objects has three members, with fields `ItemNumber`, `Part`, and `Quantity`.

- Fields `ItemNumber` and `Quantity` have numeric values. Field `Part` has an object as value, with fields `Description`, `UnitPrice`, and `UPCCode`. Field `Description` has a string value. Fields `UnitPrice` and `UPCCode` have numeric values.

Related Topics

- About Strict and Lax JSON Syntax
  On *input*, the Oracle default syntax for JSON is *lax*. It reflects the JavaScript syntax for object fields; the Boolean and `null` values are not case-sensitive; and it is more permissive with respect to numerals, whitespace, and escaping of Unicode characters. Oracle *outputs* JSON data that strictly respects the standard.

- Overview of JSON in Oracle Database
  Oracle Database supports JSON natively with relational database features, including transactions, indexing, declarative querying, and views. Unlike relational data, JSON data can be stored in the database, indexed, and queried without any need for a schema that defines the data.

> ✎ **See Also:**
>
> Example 4-3

1.3 JSON Compared with XML

Both JSON and XML (Extensible Markup Language) are commonly used as data-interchange languages. Their main differences are listed here.

JSON is most useful with simple, structured data. XML is useful for both structured and semi-structured data. JSON is generally data-centric, not document-centric; XML can be either. JSON is not a markup language; it is designed only for data representation. XML is both a document markup language and a data representation language.

- JSON has simple structure-defining and document-combining constructs: it lacks attributes, namespaces, inheritance, and substitution.

- JSON data types (that is, the data types in the JSON language) are few and predefined. XML data can be either typeless or based on an XML schema or a document type definition (DTD).

  (JSON data can be based on a schema that follows JSON Schema, but the structure that the schema imposes or informs is not generally thought of as defining data types.)

- The order of the members of a JavaScript object literal is insignificant. In general, order matters within an XML document.

- JSON lacks an equivalent of XML text nodes (XPath node test `text()`). In particular, this means that there is no mixed content (which is another way of saying that JSON is not a markup language).

Because of its simple definition and features, JSON data is generally easier to generate, parse, and process than XML data. Use cases that involve combining different data sources

generally lend themselves well to the use of XML, because it offers namespaces and other constructs facilitating modularity and inheritance.

> **See Also:**
>
> json-schema.org for information about JSON Schema.

2
JSON in Oracle Database

Oracle Database supports JSON natively with relational database features, including transactions, indexing, declarative querying, and views.

This documentation covers the use of database languages and features to work with JSON data that is stored in Oracle Database. In particular, it covers how to use SQL and PL/SQL with JSON data.

> **Note:**
>
> Oracle also provides a family of **Simple Oracle Document Access** (**SODA**) APIs for access to JSON data stored in the database. SODA is designed for schemaless application development without knowledge of relational database features or languages such as SQL and PL/SQL. It lets you create and store collections of documents in Oracle Database, retrieve them, and query them, without needing to know how the documents are stored in the database.
>
> There are several implementations of SODA:
>
> * SODA for REST — Representational state transfer (REST) requests perform collection and document operations, using any language capable of making HTTP calls.
> * SODA for Java — Java classes and interfaces represent databases, collections, and documents.
> * SODA for PL/SQL — PL/SQL object types represent collections and documents.
> * SODA for C — Oracle Call Interface (OCI) handles represent collections and documents.
> * SODA for In-Database JavaScript — Oracle Database Multilingual Engine for JavaScript (MLE) objects represent collections and documents.
> * SODA for Node.js — Node.js classes represent collections and documents.
> * SODA for Python — Python objects represent collections and documents.
>
> For complete information about SODA see Simple Oracle Document Access (SODA).

* Getting Started Using JSON with Oracle Database
  In general, you do the following when working with JSON data in Oracle Database: (1) create a table with a column of SQL data type `JSON`, (2) insert JSON data into the column, and (3) query the data in the column.

* Overview of JSON in Oracle Database
  Oracle Database supports JSON natively with relational database features, including transactions, indexing, declarative querying, and views. Unlike relational data, JSON data

can be stored in the database, indexed, and queried without any need for a schema that defines the data.

- JSON Data Type
  SQL data type `JSON` represents JSON data using a native binary format, **OSON**, which is Oracle's optimized format for fast query and update in both Oracle Database server and Oracle Database clients. You can create `JSON` type instances from other SQL data, and conversely.

- Oracle Database Support for JSON
  Oracle Database support for JavaScript Object Notation (JSON) is designed to provide the best fit between the worlds of relational storage and querying JSON data, allowing relational and JSON queries to work well together. Oracle SQL/JSON support is closely aligned with the JSON support in the SQL Standard.

2.1 Getting Started Using JSON with Oracle Database

In general, you do the following when working with JSON data in Oracle Database: (1) create a table with a column of SQL data type `JSON`, (2) insert JSON data into the column, and (3) query the data in the column.

1. Create a table with a primary-key column and a column of SQL data type `JSON` .

   The following statement creates table `j_purchaseorder` with primary key `id` and with `JSON` column `po_document`.

   ```
   CREATE TABLE j_purchaseorder
     (id            VARCHAR2 (32) NOT NULL PRIMARY KEY,
      date_loaded TIMESTAMP (6) WITH TIME ZONE,
      po_document JSON);
   ```

   You can alternatively insert JSON data into a column that has a data type other than `JSON` type, such as `VARCHAR2`. In that case, use an `is json` check constraint to ensure that the data inserted into the column is well-formed JSON data. See Example 4-2.

2. Insert JSON data into the `JSON` column, using any of the methods available for Oracle Database.

   The following statement uses a SQL `INSERT` statement to insert some simple JSON data into the third column of table `j_purchaseorder` (which is column `po_document` — see previous). Some of the JSON data is elided here (...).

   ```
   INSERT INTO j_purchaseorder
     VALUES (SYS_GUID(),
             to_date('30-DEC-2014'),
             '{"PONumber"             : 1600,
               "Reference"            : "ABULL-20140421",
               "Requestor"            : "Alexis Bull",
               "User"                 : "ABULL",
               "CostCenter"           : "A50",
               "ShippingInstructions" : {...},
               "Special Instructions" : null,
               "AllowPartialShipment" : true,
               "LineItems"            : [...]}');
   ```

The SQL string `'{"PONumber":1600,…}'` is automatically converted to `JSON` data type for the `INSERT` operation.

3. Query the JSON data. The return value is always a `VARCHAR2` instance that represents a JSON value. Here are some simple examples.

   The following query extracts, from each document in JSON column `po_document`, a *scalar* value, the JSON number that is the value of field `PONumber` for the objects in JSON column `po_document` (see also Example 15-1):

   ```
   SELECT po.po_document.PONumber FROM j_purchaseorder po;
   ```

   The following query extracts, from each document, an *array* of JSON phone objects, which is the value of field `Phone` of the object that is the value of field `ShippingInstructions` (see also Example 15-2):

   ```
   SELECT po.po_document.ShippingInstructions.Phone
     FROM j_purchaseorder po;
   ```

   The following query extracts, from each document, *multiple* values as an array: the value of field `type` for each object in array `Phone`. The returned array is not part of the stored data but is constructed automatically by the query. (The order of the array elements is unspecified.)

   ```
   SELECT po.po_document.ShippingInstructions.Phone.type
     FROM j_purchaseorder po;
   ```

2.2 Overview of JSON in Oracle Database

Oracle Database supports JSON natively with relational database features, including transactions, indexing, declarative querying, and views. Unlike relational data, JSON data can be stored in the database, indexed, and queried without any need for a schema that defines the data.

(The JSON data is schemaless, even though a *database schema* is used to define the table and column in which it is stored. Nothing in a database schema specifies the structure of the JSON data itself.)

You can *optionally* validate given JSON data against a *JSON schema*. But most uses of JSON data do not involve JSON Schema.

JSON data has often been stored in NoSQL databases such as Oracle NoSQL Database and Oracle Berkeley DB. These allow for storage and retrieval of data that is not based on any schema, but they do not offer the rigorous consistency models of relational databases.

To compensate for this shortcoming, a relational database is sometimes used in parallel with a NoSQL database. Applications using JSON data stored in the NoSQL database must then ensure data integrity themselves.

Native support for JSON by Oracle Database obviates such workarounds. It provides *all* of the benefits of relational database features for use with JSON, including transactions, indexing, declarative querying, and views.

Database queries with Structured Query Language (SQL) are declarative. With Oracle Database you can use SQL to join JSON data with relational data. And you can project JSON data relationally, making it available for relational processes and tools. You can also query, from within the database, JSON data that is stored outside Oracle Database in an external table.

You can access JSON data stored in the database the same way you access other database data, including using Oracle Call Interface (OCI), and Java Database Connectivity (JDBC).

With its native binary JSON format, **OSON**, Oracle extends the JSON language by adding scalar types, such as date and double, which are not part of the JSON standard. SQL data type `JSON` uses format OSON.

- **Data Types for JSON Data**
  SQL data type `JSON` is Oracle's binary JSON format for fast query and update. It extends the standard JSON scalar types (number, string, Boolean, and `null`), to include types that *correspond to SQL scalar types*. This makes conversion of scalar data between JSON and SQL simple and lossless.

- **JSON null and SQL NULL**
  When both SQL code and JSON code are involved, the code and descriptions of it can sometimes be confusing when "null" is involved. Keeping JSON-language `null` and SQL `NULL` values straight requires close attention sometimes. And SQL `NULL` can itself be confusing.

- **JSON Columns in Database Tables**
  Oracle Database places no restrictions on the tables that can be used to store JSON documents. A column containing JSON documents can coexist with any other kind of database data. A table can also have multiple columns that contain JSON documents.

- **Use SQL with JSON Data**
  In SQL, you can create and access JSON data in Oracle Database using `JSON` data type constructor `JSON`, specialized functions and conditions, or a simple dot notation. Most of the SQL functions and conditions belong to the SQL/JSON standard, but a few are Oracle-specific.

- **Use PL/SQL with JSON Data**
  You can use `JSON` data type instances with PL/SQL subprograms.

- **Use JavaScript with JSON Data**
  You can use Oracle Database Multilingual Engine (MLE) to exchange JSON data between PL/SQL or SQL code and JavaScript code running in the database

server. You can use the node-oracledb driver to run JavaScript code in a database client.

Related Topics

- JSON Data Type
  SQL data type `JSON` represents JSON data using a native binary format, **OSON**, which is Oracle's optimized format for fast query and update in both Oracle Database server and Oracle Database clients. You can create `JSON` type instances from other SQL data, and conversely.

- Simple Dot-Notation Access to JSON Data
  Dot notation is designed for easy, general use and common use cases of querying JSON data. For simple queries it is a handy alternative to using SQL/JSON query functions.

2.2.1 Data Types for JSON Data

SQL data type `JSON` is Oracle's binary JSON format for fast query and update. It extends the standard JSON scalar types (number, string, Boolean, and `null`), to include types that *correspond to SQL scalar types*. This makes conversion of scalar data between JSON and SQL simple and lossless.

Standard JSON, as a language or notation, has predefined data types: object, array, number, string, Boolean, and **null**. All JSON-language types except object and array are scalar types.

The standard defines JSON data in a *textual* way: it is composed of Unicode characters in a standard syntax.

When actual JSON data is used in a programming language or is stored in some way, it is realized using a data type in that particular language or storage format. For example, a JDBC client application might fill a Java string with JSON data, or a database column might store JSON data using a SQL data type.

It's important to keep these two kinds of data type in mind. For example, though the JSON-language type of JSON value `"abc"` is *string*, this value can be represented, or realized, using a value of any of several SQL data types: `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`.

SQL type **JSON** is designed specifically for JSON data. Oracle recommends that for use with Oracle Database you use `JSON` type for your JSON data.

`JSON` data type uses a binary format, **OSON**, which is Oracle's optimized binary JSON format for fast query and update in both Oracle Database server and Oracle Database clients. `JSON` type is available only if database initialization parameter `compatible` is at least `20`.

> **✎ Note:**
>
> To avoid confusion, this documentation generally refers to the types in the JSON language as "JSON-language types", and it refers to the SQL data type `JSON` as "`JSON` type". Paying close attention to this wording can help you keep straight which meaning of JSON "type" is meant in a given context.
>
> SQL code that makes use of JSON data can include expressions in both languages, SQL and JSON. Within SQL code, literal JSON code is typically enclosed within single-quote characters (`'`). Paying attention to this `'…'` language boundary can also help understanding.

When you a SQL type other than `JSON` for JSON data (`VARCHAR2`, `CLOB`, or `BLOB`), the JSON data is said to be **textual** — it is unparsed character data (even when it is stored as a `BLOB` instance).

You can *migrate* existing textual JSON data in the database to `JSON` type data, and Oracle recommends that you do so — see Migrating Textual JSON Data to JSON Data Type.

When JSON data is of SQL data type `JSON`, Oracle extends the set of standard *JSON-language* scalar types (number, string, Boolean, and `null`) to include several that *correspond to SQL scalar types*: binary, date, timestamp, timestamp with time zone, year-month interval, day-second interval, double, and float. This enhances the JSON language, and it makes conversion of scalar data between that language and SQL simple and lossless.

When JSON data is of SQL data type `VARCHAR2`, `CLOB`, or `BLOB`, only the standard JSON-language scalar types are supported. But when JSON data is of SQL type `JSON`, Oracle Database extends the set of standard JSON-language types to include several scalar types that correspond directly to SQL scalar data types, as follows:

- binary — Corresponds to SQL `RAW` or `BLOB`.

- date — Corresponds to SQL `DATE`.

- timestamp — Corresponds to SQL `TIMESTAMP`.

- timestamp with time zone — Corresponds to SQL `TIMESTAMP WITH TIME ZONE`.

- year-month interval — Corresponds to SQL `INTERVAL YEAR TO MONTH`.

- day-second interval — Corresponds to SQL `INTERVAL DAY TO SECOND`.

- double — Corresponds to SQL `BINARY_DOUBLE`.

- float — Corresponds to SQL `BINARY_FLOAT`.

> **Note:**
>
> You can use the JSON path-expression item method `type()` to determine the JSON-language type of any JSON scalar value.
>
> It returns the type name as one of these JSON strings: `"binary"`, `"date"`, `"timestamp"`, `"timestamp with time zone"`, `"yearmonthInterval"`, `"daysecondInterval"`, `"double"`, `"float"`, `"number"`, `"null"`, `"string"`, `"boolean"`. For example, if the targeted scalar JSON value is of type timestamp with time zone then `type()` returns the string `"timestamp with time zone"`. See:
>
> - SQL/JSON Path Expression Item Methods
> - Textual JSON Objects That Represent Extended Scalar Values

Here are some ways to *obtain* JSON scalar values of such Oracle-specific JSON-language types in your JSON data that is stored as `JSON` type:

- Use SQL/JSON generation functions with `RETURNING JSON`. Scalar SQL values used in generating array elements or object field values result in JSON scalar values of corresponding JSON-language types. For example, a `BINARY_FLOAT` SQL value results in a float JSON value.

- Use Oracle SQL function `json_scalar`. For example, applying it to a `BINARY_FLOAT` SQL value results in a float JSON value.

- Use a database client with client-side encoding to create an Oracle-specific JSON value as `JSON` type before sending that to the database.

- Instantiate PL/SQL object types for JSON with JSON data having Oracle-specific JSON scalar types. This includes updating existing such object-type instances.

- Use PL/SQL method `to_json()` on a PL/SQL DOM instance (`JSON_ELEMENT_T` instance).

Here are some ways to *make use of* JSON scalar values of Oracle-specific JSON-language types:

- Use SQL/JSON condition `json_exists`, comparing the value of a SQL bind variable with the result of applying an item method that corresponds to an Oracle-specific JSON scalar type.

- Use SQL/JSON function `json_value` with a `RETURNING` clause that returns a SQL type that corresponds to an Oracle-specific JSON scalar type.

Related Topics

- RETURNING Clause for SQL Query Functions
  SQL functions `json_value`, `json_query`, `json_serialize`, and `json_mergepatch`
  accept an optional **RETURNING** clause, which specifies the data type of the value
  returned by the function. This clause and the default behavior (no `RETURNING`
  clause) are described here.

- Oracle SQL Function JSON_SCALAR
  Oracle SQL function `json_scalar` accepts a SQL scalar value as input and returns
  a corresponding JSON scalar value as a `JSON` type instance. In particular, the
  value can be of an Oracle-specific JSON-language type (such as a date), which is
  not part of the JSON standard.

- PL/SQL Object Types for JSON
  You can use PL/SQL object types for JSON to read and write multiple fields of a
  JSON document. This can increase performance, in particular by avoiding multiple
  parses and serializations of the data.

- SQL/JSON Condition JSON_EXISTS
  SQL/JSON condition `json_exists` checks for the existence of a particular value
  within JSON data. It returns true if the data it targets matches one or more JSON
  values. If no JSON values are matched then it returns false.

2.2.2 JSON null and SQL NULL

When both SQL code and JSON code are involved, the code and descriptions of it can
sometimes be confusing when "null" is involved. Keeping JSON-language `null` and
SQL `NULL` values straight requires close attention sometimes. And SQL `NULL` can itself
be confusing.

- In the JSON language, `null` is both a value and the name of a (JSON-language)
  type. Type null has only one possible value, `null`.

- In SQL, *each data type* has a `NULL` value. There is a `NULL` value for type `VARCHAR2`,
  one for type `NUMBER`, …, and one for type `JSON` (Oracle's native binary format for
  JSON data).

NULL in SQL typically represents the *absence* of a value (missing, unknown, or
inapplicable data). But SQL does not distinguish the absence of a value from the
presence of a (SQL) `NULL` value.

A SQL value can hold a scalar JSON-language value, and JSON **null** is one such
value. The SQL value in this case is non-`NULL` (of whatever SQL type is being used to
hold the JSON data).

When a `JSON`-type instance (for example, a row of a `JSON`-type column) has the SQL
value `NULL` it generally means that there is *no JSON data present* in that instance.

A JSON value of `null` is a non-`NULL` value as far as SQL is concerned; it is not the
SQL value `NULL`. In particular, SQL condition `IS NULL` returns *false* for a JSON `null`
value, and SQL condition `IS NOT NULL` returns *true*. And SQL/JSON condition
`json_exists` returns *true* when the value whose existence it tests for is JSON `null`.

SQL/JSON function `json_value` extracts a *SQL scalar* value from its input JSON data.
If the value to be extracted is JSON `null`, then, by default, `json_value` returns SQL
`NULL`. (You can override this behavior for a given use of `json_value` by using an `ON`
`ERROR` handling clause or an `ON EMPTY` handling clause.)

The same is *not* true, however, for SQL/JSON function `json_query` or for a simple-dot-notation query. Those return *JSON* data. If your database supports `JSON` data type, and if the value to be extracted is JSON `null` then they both return that existing JSON `null` value as such; that is, they return what `json_scalar('null')` returns.

Remember that the purpose of `json_value` is to return a *SQL scalar value* that corresponds to a JSON scalar value that you extract from some JSON data. There is no SQL scalar value that corresponds to JSON `null` in the same way that, say, SQL value `TRUE` corresponds to JSON `true` or SQL number `42` corresponds to JSON number `42`. Oracle `JSON` data type has a `null` scalar value, but SQL does not have any equivalent scalar value.

Q: What's the SQL type of the JSON value `null`?

A: That depends on the code/context. It could be *any SQL type* that you can use to store JSON data — see Data Types for JSON Data.

Q: What determines the order of JSON `null` values and SQL `NULL` values, if both are present in a query result set?

A: By default, returned rows containing SQL `NULL` values are *last* in the sequence when sorting in *ascending* order, and they are *first* when sorting in *descending* order. You can use keywords `NULLS FIRST` or `NULLS LAST` to override this default behavior. See SELECT in *Oracle Database SQL Language Reference*.

When you extract a scalar value from JSON data, the following can occur:

1. The input JSON data itself is (SQL) `NULL`, so no value is selected. This is the case when a row of data is `NULL`, for example.

2. The input JSON data is not (SQL) `NULL` but the query (path expression, for example) does not select any scalar value — the targeted value is *missing*.

3. The query selects a JSON `null` value.

The behavior for Case 3 depends on whether your database supports `JSON` data type, that is, whether the value of initialization parameter `compatible` is at least 20.

All data in Table 2-1 is SQL data. Uppercase `NULL` indicates a SQL `NULL` value. JSON data shown indicates the content of a SQL type (such as `VARCHAR2` or `JSON`) that can contain JSON data. A JSON-language `null` value is written in lowercase.

Table 2-1   Handling of SQL NULL, missing, and JSON null Input for JSON-Type Data

Case	JSON Input Data	Dot Notation .a	JSON_VALUE('$.a')	JSON_QUERY('$.a')
Case 1: input data is NULL	NULL	NULL	NULL	NULL
Case 2: targeted data is missing	{}	NULL	NULL	NULL

Table 2-1 (Cont.) Handling of SQL NULL, missing, and JSON null Input for JSON-Type Data

Case	JSON Input Data	Dot Notation .a	JSON_VALUE('$.a')	JSON_QUERY('$.a')
Case 3, *with* `JSON` type support: JSON `null` value selected	`{"a":null}`	• With `JSON` type input: `JSON` type `null` value (the same thing that `json_scalar('null')` returns) • Otherwise: `NULL`	`NULL`	• With either `JSON` type input or `RETURNING JSON`: `JSON` type `null` value (same thing that `json_scalar('null')` returns) • Otherwise: the textual JSON `null` value of the `RETURNING` or input type (same thing that `json_serialize(json_scalar('null'))` returns)
Case 3, *without* `JSON` type support: JSON `null` value selected	`{"a":null}`	`NULL`	`NULL`	`NULL`

> **Note:**
>
> Oracle SQL `NULL` can itself be a bit confusing. Except for the large-object (LOB) data types (`BLOB`, `(N)CLOB`, and `BFILE`), Oracle SQL types that can have zero-length values do not distinguish a zero-length value from the `NULL` value. Such types include `RAW` and the character types, such as `(N)VARCHAR(2)` and `(N)CHAR`. This means, in effect, that an "empty string" value in such a type is no different from the `NULL` value of that type.

Related Topics

- Data Types for JSON Data
  SQL data type `JSON` is Oracle's binary JSON format for fast query and update. It extends the standard JSON scalar types (number, string, Boolean, and `null`), to include types that *correspond to SQL scalar types*. This makes conversion of scalar data between JSON and SQL simple and lossless.

- SQL/JSON Function JSON_VALUE
  SQL/JSON function `json_value` selects JSON data and returns a SQL scalar or an instance of a user-defined SQL object type or SQL collection type (varray, nested table).

- SQL/JSON Function JSON_QUERY
  SQL/JSON function `json_query` selects one or more values from JSON data and returns those values. You can thus use `json_query` to retrieve *fragments* of a JSON document.

- **Simple Dot-Notation Access to JSON Data**
  Dot notation is designed for easy, general use and common use cases of querying JSON data. For simple queries it is a handy alternative to using SQL/JSON query functions.

- **Error Clause for SQL Functions and Conditions**
  Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

- **Empty-Field Clause for SQL/JSON Query Functions**
  SQL/JSON query functions `json_value`, `json_query`, and `json_table` accept an optional **ON EMPTY** clause, which specifies the handling to use when a targeted JSON field is absent from the data queried. This clause and the default behavior (no `ON EMPTY` clause) are described here.

- **Comparison and Sorting of JSON Data Type Values**
  The canonical sort order for values of SQL data type `JSON` is described. It is used to compare all JSON values.

2.2.3 JSON Columns in Database Tables

Oracle Database places no restrictions on the tables that can be used to store JSON documents. A column containing JSON documents can coexist with any other kind of database data. A table can also have multiple columns that contain JSON documents.

When using Oracle Database as a JSON document store, your tables that contain JSON columns typically also have a few non-JSON housekeeping columns. These typically track metadata about the JSON documents.

If you use JSON data to add flexibility to a primarily relational application then some of your tables likely also have a column for JSON documents, which you use to manage the application data that does not map directly to your relational model.

Oracle recommends that you use data type `JSON` for JSON columns. If you instead use textual JSON storage (`VARCHAR2`, `CLOB`, or `BLOB`) then Oracle recommends that you use an `is json` *check constraint* to ensure that column values are valid JSON instances (see Example 4-2).

By definition, textual JSON data is encoded using a Unicode encoding, either UTF-8 or UTF-16. You can use `VARCHAR2` or `CLOB` data that is stored in a non-Unicode character set as if it were JSON data, but in that case Oracle Database automatically converts the character set to UTF-8 when processing the data.

Data stored using data type `JSON` or `BLOB` is independent of character sets and does not undergo conversion when processing the data.

2.2.4 Use SQL with JSON Data

In SQL, you can create and access JSON data in Oracle Database using `JSON` data type constructor `JSON`, specialized functions and conditions, or a simple dot notation. Most of the SQL functions and conditions belong to the SQL/JSON standard, but a few are Oracle-specific.

- SQL/JSON query functions `json_value`, `json_query`, and `json_table`.

  These evaluate SQL/JSON path expressions against JSON data to produce SQL values.

- Oracle SQL condition `json_textcontains` and SQL/JSON conditions `json_exists`, `is json`, and `is not json`.

  Condition `json_exists` checks for the existence of given JSON data; `json_textcontains` provides full-text querying of JSON data; and `is json` and `is not json` check whether given JSON data is well-formed.

  `json_exists` and `json_textcontains` check the data that matches a SQL/JSON path expression.

- A simple *dot notation* that acts similar to a combination of query functions `json_value` and `json_query`.

  This resembles a SQL object access expression, that is, attribute dot notation for an abstract data type (ADT). This is the *easiest* way to query JSON data in the database.

- SQL/JSON *generation* functions `json_object`, `json_array`, `json_objectagg`, and `json_arrayagg`.

  These gather SQL data to produce JSON object and array data (as a SQL value).

- Oracle SQL functions `json_serialize` and `json_scalar`, and Oracle SQL condition `json_equal`.

  Function `json_serialize` returns a textual representation of JSON data; `json_scalar` returns a `JSON` type scalar value that corresponds to a given SQL scalar value; and `json_equal` tests whether two JSON values are the same.

- `JSON` data type *constructor* `JSON`.

  This *parses* textual JSON data to create an instance of SQL data type `JSON`.

- Oracle SQL aggregate function `json_dataguide`.

  This produces JSON data that is a *data guide*, which you can use to discover information about the structure and content of other JSON data in the database.

As a simple illustration of querying, here is a dot-notation query of the documents stored in JSON column `po_document` of table `j_purchaseorder` (aliased here as `po`). It obtains all purchase-order requestors (JSON field `Requestor`).

```
SELECT po.po_document.Requestor FROM j_purchaseorder po;
```

2.2.5 Use PL/SQL with JSON Data

You can use `JSON` data type instances with PL/SQL subprograms.

You can manipulate JSON data within PL/SQL code using SQL code or PL/SQL object types.

You can generally use SQL code, including SQL code that accesses JSON data, within PL/SQL code.

The following SQL functions and conditions are also available as built-in PL/SQL functions: `json_value`, `json_query`, `json_object`, `json_array`, `json_scalar`, `json_serialize`, `json_exists`, `is json`, `is not json`, and `json_equal`.

There are also PL/SQL object types for JSON, which you can use for fine-grained construction and manipulation of In-Memory JSON data. You can construct object-type

data, introspect it, modify it, compare it, sort it, and serialize it back to textual JSON data.

You can use `JSON` data type instances as input and output of PL/SQL subprograms. You can manipulate `JSON`-type data in PL/SQL by instantiating JSON object types, such as `JSON_OBJECT_T`.

Oracle Database prior to Release 23c has no `BOOLEAN` data type. But for all Oracle Database releases PL/SQL has a `BOOLEAN` data type. For PL/SQL (as well as for SQL, starting with Release 23c):

- `json_exists`, `is json`, `is not json`, and `json_equal` are Boolean functions.

- `json_value` can return a `BOOLEAN` value. `json_table` columns with `json_value` semantics can be of type `BOOLEAN`.

- `json_scalar` can accept a `BOOLEAN` value as argument, in which case it returns a Boolean `JSON` type instance (`true` or `false`).

- `json_object`, `json_objectagg`, `json_array`, and `json_arrayagg` can generate JSON objects and arrays that contain values `true` and `false`, corresponding to PL/SQL values `TRUE` and `FALSE`.

  Similarly, if you pass SQL `TRUE` or `FALSE` to `json_transform` then these are mapped to JSON `true` and `false` if included in the transformation result.

- `json_exists` and `json_transform` can use `BOOLEAN` bind variables.

Using PL/SQL you can create JSON schemas from relational or object-relational data.

PL/SQL also provides subprograms to use JSON Schema, in package `DBMS_JSON_SCHEMA`:

- You can validate JSON data against a JSON schema using PL/SQL function or procedure `DBMS_JSON_SCHEMA.is_valid()`. The function returns `1` for valid and `0` for invalid (invalid data can optionally raise an error). The procedure returns `TRUE` for valid and `FALSE` for invalid as the value of an `OUT` parameter.

- You can use PL/SQL function `DBMS_JSON_SCHEMA.validate_report` to read a validity-check error report.

- You can use PL/SQL function `DBMS_JSON_SCHEMA.is_schema_valid` to check whether a given JSON schema is itself valid according to the JSON Schema standard.

- You can use PL/SQL function `DBMS_JSON_SCHEMA.describe` to *generate* a JSON schema from a table, view, object type, or collection type, or from a synonym that resolves to one of those.

> ✎ **See Also:**
>
> json-schema.org for information about JSON Schema

2.2.6 Use JavaScript with JSON Data

You can use Oracle Database Multilingual Engine (MLE) to exchange JSON data between PL/SQL or SQL code and JavaScript code running in the database server. You can use the node-oracledb driver to run JavaScript code in a database client.

MLE runs JavaScript code dynamically using (1) PL/SQL package `DBMS_MLE` and (2) MLE modules that persist in the database. Using MLE modules generally offers more flexibility and a better way of separating JavaScript code from PL/SQL code. MLE modules are analogous to PL/SQL packages, the difference being that the code is JavaScript instead of PL/SQL.

You can exchange JSON data between JavaScript code running in the database server and database storage in these ways:

- Use server-side MLE JavaScript driver mle-js-oracledb.

- Use JavaScript stored subprograms that refer to an MLE module. Subprogram arguments (`IN`, `OUT`, `INOUT`) and return values can be of `JSON` data type.

- Use procedures in PL/SQL package `DBMS_MLE` to exchange JSON values between PL/SQL code and JavaScript code.

The data-type mappings used by server-side MLE JavaScript driver mle-js-oracledb, between JSON values (objects, arrays, and scalars) and JavaScript values, are generally aligned with the mappings used by client-side JavaScript driver node-oracledb. The mappings between scalar values differ in some respects however — see MLE Type Conversions.

You can use PL/SQL procedure `DBMS_MLE.export_to_mle` to export JSON data from PL/SQL to a dynamic MLE execution context, and then use it there with JavaScript code. In the other direction, you can use PL/SQL procedure `DBMS_MLE.import_from_mle` to import objects from MLE JavaScript code to PL/SQL, and then use them in PL/SQL as JSON objects.

You use JavaScript function `importValue()` from built-in module `mle-js-bindings` to import, into the current dynamic MLE execution context, a value that was previously exported along with a JavaScript variable name, using PL/SQL procedure `DBMS_MLE.export_to_mle`. Function `importValue()` takes that variable name as argument and returns a JavaScript value, with all scalar values of the JSON data converted to the corresponding native JavaScript type.

Similarly, you use JavaScript function `exportValue()` to export a value from the current dynamic MLE execution context.

> - MLE Modules on GitHub for information about mle-js-oracledb and mle-js-bindings
>
> - Node.js node-oracledb on GitHub

2.3 JSON Data Type

SQL data type `JSON` represents JSON data using a native binary format, **OSON**, which is Oracle's optimized format for fast query and update in both Oracle Database server and Oracle Database clients. You can create `JSON` type instances from other SQL data, and conversely.

The other SQL data types that support JSON data, besides `JSON` type, are `VARCHAR2`, `CLOB`, and `BLOB`. This non-`JSON` type data is called **textual**, or **serialized**, JSON data. It is unparsed character data (even when stored as a `BLOB` instance, as the data is a sequence of UTF-8 encoded bytes).

Using data type `JSON` avoids costly parsing of textual JSON data and provides better query performance.

You can convert textual JSON data to `JSON` type data by *parsing* it with type constructor `JSON`. JSON text that you insert into a database column of type `JSON` is parsed implicitly — you need not use the constructor explicitly.

In the other direction, you can convert `JSON` type data to textual JSON data using SQL/JSON function `json_serialize`. JSON type data that you insert into a database column of a JSON textual data type (`VARCHAR2`, `CLOB`, or `BLOB`) is serialized implicitly — you need not use `json_serialize` explicitly.

Regardless of whether the `JSON` type data uses Oracle-specific scalar JSON types (such as date), the resulting serialized JSON data always conforms to the JSON standard.

You can create complex `JSON` type data from non-`JSON` type data using the SQL/JSON generation functions: `json_object`, `json_array`, `json_objectagg`, and `json_arrayagg`.

You can create a `JSON` type instance with a scalar JSON value using Oracle SQL function `json_scalar`. In particular, the value can be of an Oracle-specific JSON-language type, such as a date, which is not part of the JSON standard.

In the other direction, you can use SQL/JSON function `json_value` to query `JSON` type data and return an instance of a SQL object type or collection type.

`JSON` data type, its constructor `JSON`, and Oracle SQL function `json_scalar` can be used only if database initialization parameter `compatible` is at least `20`. Otherwise, trying to use any of them raises an error.

- JSON Data Type Constructor
  The `JSON` data type constructor, **JSON**, takes as input a textual JSON value (a scalar, object, or array), parses it, and returns the value as an instance of `JSON` type. Alternatively, the input can be an instance of a user-defined PL/SQL or SQL aggregate type.

- Oracle SQL Function JSON_SCALAR
  Oracle SQL function `json_scalar` accepts a SQL scalar value as input and returns a corresponding JSON scalar value as a `JSON` type instance. In particular, the value can be of an Oracle-specific JSON-language type (such as a date), which is not part of the JSON standard.

- **Oracle SQL Function JSON_SERIALIZE**
  Oracle SQL function `json_serialize` takes JSON data (of any SQL data type, `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`) as input and returns a *textual* representation of it (as `VARCHAR2`, `CLOB`, or `BLOB` data). `VARCHAR2(4000)` is the default return type.

- **JSON Constructor, JSON_SCALAR, and JSON_SERIALIZE: Summary**
  Relations among `JSON` data type constructor `JSON`, Oracle SQL function `json_scalar`, and Oracle SQL function `json_serialize` are summarized.

- **Textual JSON Objects That Represent Extended Scalar Values**
  Native binary JSON data (OSON format) extends the JSON language by adding scalar types, such as date, that correspond to SQL types and are not part of the JSON standard. Oracle Database also supports the use of textual JSON *objects* that *represent* JSON scalar values, including such nonstandard values.

- **Comparison and Sorting of JSON Data Type Values**
  The canonical sort order for values of SQL data type `JSON` is described. It is used to compare all JSON values.

2.3.1 JSON Data Type Constructor

The `JSON` data type constructor, **JSON**, takes as input a textual JSON value (a scalar, object, or array), parses it, and returns the value as an instance of `JSON` type. Alternatively, the input can be an instance of a user-defined PL/SQL or SQL aggregate type.

> **Note:**
>
> You can use constructor `JSON` only if database initialization parameter `compatible` is at least `20`. Otherwise, the constructor raises an error (regardless of what input you pass it).

For example, given SQL string `'{}'` as input, the `JSON` type instance returned is the empty object `{}`. The input `'{a : {"b":"beta", c:[+042, "gamma",]},}'` results in the `JSON` instance `{"a":{"b":"beta","c":[42,"gamma"]}}`.

(Note that this contrasts with the behavior of Oracle SQL function `json_scalar`, which does *not* parse textual input but just converts it to a JSON *string* value: `json_scalar('{}')` returns the JSON string `"{}"`. To produce the same JSON string using constructor `JSON`, you must add explicit double-quote characters: `JSON('"{}"')`.)

Textual input to constructor `JSON` can be either a literal SQL string or data of type `VARCHAR2`, `CLOB`, or `BLOB`. A SQL `NULL` value as input results in a `JSON` type instance of SQL `NULL`.

Non-textual input to the constructor can be an instance of any of the following user-defined data types:

- PL/SQL Varray
- PL/SQL record
- SQL object type
- PL/SQL index by `binary_integer` collection (IBBI)
- PL/SQL nested table
- PL/SQL associative array

A varray instance as argument results in a JSON *array*. The JSON-array elements are created from the elements of the varray collection (in order).

Each of the other instances results in a JSON *object*. The JSON-object members are created from the *attributes* of a record instance or a SQL object instance, the *indexes* of an IBBI or nested-table instance, and the *key–value pairs* of an associative-array instance.

The value returned by the constructor can be any JSON value that is supported by Oracle. This includes values of the standard JSON-language types: object, array, string, Boolean, `null`, and number. It also includes any non-standard Oracle scalar JSON values, that is, values of the Oracle-specific scalar types: double, float, binary, date, timestamp, day-second interval, and year-month interval. If the constructor is used with keyword **EXTENDED** then the values of the Oracle-specific types can be derived from Oracle extended-object patterns in the textual JSON input.

If the textual input is not well-formed JSON data then an error is raised. This includes the case where it has one or more objects in it that have duplicate field (key) names. It can, however, have lax JSON syntax. Other than this syntax relaxation, to be well-formed the input data must conform to RFC 8259.

If you need to ensure that the textual input uses only *strict* JSON syntax then use SQL condition `is json` to filter it. This code prevents acceptance of non-strict syntax:

```
SELECT JSON(jcol) FROM table WHERE jcol is json (STRICT);
```

As a convenience, when using textual JSON data to perform an `INSERT` or `UPDATE` operation on a `JSON` type column, the textual data is *implicitly wrapped* with constructor `JSON`.

Use cases for constructor `JSON` include on-the-fly parsing and conversion of textual JSON data to `JSON` type. (An alternative is to use condition `is json` in a `WHERE` clause.) You can pass the constructor a bind variable with a string value or data from an external table, for instance.

As one example, you can use constructor `JSON` to ensure that textual data that is not stored in the database with an `is json` check constraint is well-formed. You can then use the simple dot-notation query syntax with the resulting `JSON` type data. (You cannot use the dot notation with data that is not known to be well-formed.) Example 2-1 illustrates this.

Example 2-1   Converting Textual JSON Data to JSON Type On the Fly

This example uses simple dot-notation syntax to select a field from some textual JSON data that is not known to the database to be well-formed. It converts the data to `JSON` type data, before selecting. Constructor `JSON` raises an error if its argument is not well-formed. (Note that dot-notation syntax requires the use of a table alias — `j` in this case.)

```
WITH jtab AS
  (SELECT JSON(
     '{ "name" : "Alexis Bull",
        "Address": { "street" : "200 Sporting Green",
                     "city" : "South San Francisco",
                     "state" : "CA",
                     "zipCode" : 99236,
                     "country" : "United States of America" } }')
     AS jcol FROM DUAL)
  SELECT j.jcol.Address.city FROM jtab j;
```

2.3.2 Oracle SQL Function JSON_SCALAR

Oracle SQL function `json_scalar` accepts a SQL scalar value as input and returns a corresponding JSON scalar value as a `JSON` type instance. In particular, the value can be of an Oracle-specific JSON-language type (such as a date), which is not part of the JSON standard.

You can use function `json_scalar` only if database initialization parameter `compatible` is at least `20`. Otherwise it raises an error.

You can think of `json_scalar` as a scalar generation function. Unlike the SQL/JSON generation functions, which can return any SQL data type that supports JSON data, `json_scalar` always returns an instance of `JSON` type.

The argument to `json_scalar` can be an instance of any of these SQL data types: `JSON`, `BLOB`, `CLOB`, `NCLOB`, `VARCHAR2`, `VARCHAR`, `NVARCHAR2`, `CHAR`, `NCHAR`, `RAW`, `BOOLEAN`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `INTERVAL YEAR TO MONTH`. `INTERVAL DAY TO SECOND`, `NUMBER`, `BINARY_DOUBLE`, or `BINARY_FLOAT`.

The returned `JSON` type instance is a JSON-language scalar value supported by Oracle. For example, `json_scalar(current_timestamp)` returns an Oracle JSON value of type `timestamp` (as an instance of SQL data type `JSON`).

With `JSON` type input, `json_scalar` behaves as follows:

- Input that corresponds to a JSON *scalar* value is simply returned.

- Input that corresponds to a JSON *nonscalar* value results in an error. If the error handler is `NULL ON ERROR`, which it is by default, then SQL `NULL` (of `JSON` data type) is returned.

> **Tip:**
>
> Because `json_scalar` returns `NULL` by default for nonscalar input, and because comparison involving a nonscalar JSON value can be more costly than scalar-with-scalar comparison, a simple manual optimization when ordering or comparing JSON data is to do so after wrapping it with `json_scalar`, thus effectively pruning nonscalars from the data to be compared. (More precisely, they are replaced with `NULL`, which is quickly compared.)
>
> For example instead of this:
>
> ```
> SELECT data FROM customers c
>   ORDER BY c.data.revenue;
> ```
>
> Use this:
>
> ```
> SELECT data FROM customers c
>   ORDER BY json_scalar(c.data.revenue);
> ```

> **Note:**
>
> You can use the JSON path-expression item method `type()` to determine the JSON-language type of any JSON scalar value.
>
> It returns the type name as one of these JSON strings: `"binary"`, `"date"`, `"timestamp"`, `"timestamp with time zone"`, `"yearmonthInterval"`, `"daysecondInterval"`, `"double"`, `"float"`, `"number"`, `"null"`, `"string"`, `"boolean"`. For example, if the targeted scalar JSON value is of type timestamp with time zone then `type()` returns the string `"timestamp with time zone"`. See:
>
> - [SQL/JSON Path Expression Item Methods](#)
> - [Textual JSON Objects That Represent Extended Scalar Values](#)

Table 2-2   JSON_SCALAR Type Conversion: SQL Types to Oracle JSON Types

SQL Type (Source)	JSON Language Type (Destination)
`VARCHAR2`, `VARCHAR`, `NVARCHAR2`, `CHAR`, or `NCHAR`	string
`CLOB` or `NCLOB`	string
`BLOB`	binary
`RAW`	binary

Table 2-2   (Cont.) JSON_SCALAR Type Conversion: SQL Types to Oracle JSON Types

SQL Type (Source)	JSON Language Type (Destination)
BOOLEAN	boolean
NUMBER	number (or string if infinite or undefined value)
BINARY_DOUBLE	double (or string if infinite or undefined value)
BINARY_FLOAT	float (or string if infinite or undefined value)
DATE	date
TIMESTAMP	timestamp
TIMESTAMP WITH TIME ZONE	timestamp with time zone
INTERVAL DAY TO SECOND	daysecondInterval
INTERVAL YEAR TO MONTH	yearmonthInterval

An *exception* are the numeric values of positive and negative infinity, and values that are the undefined result of a numeric operation ("not a number" or NaN) — they cannot be expressed as JSON numbers. For those, json_scalar returns not numeric-type values but the JSON strings **"Inf"**, **"-Inf"**, and **"Nan"**, respectively.

A JSON type value returned by json_scalar remembers the SQL data type from which it was derived. If you then use json_value (or a json_table column with json_value semantics) to extract that JSON type value, and you use the corresponding type-conversion item method, then the value extracted has the original SQL data type. For example, this query returns a SQL TIMESTAMP value:

```
SELECT json_value(json_scalar(current_timestamp), '$.timestamp()')
  FROM DUAL;
```

Note that if the argument is a SQL *string* value (VARCHAR2. VARCHAR, NVARCHAR, CHAR, NCHAR, or CLOB) then json_scalar simply converts it to a *JSON string* value. It *does not parse* the input as JSON data.

For example, json_scalar('{}') returns the JSON string value "{}". Because constructor JSON parses a SQL string, it returns the empty JSON object {} for the same input. To produce the same JSON string using constructor JSON, the double-quote characters must be explicitly present in the input: JSON('"{}"').

If the argument to json_scalar is a SQL NULL value then you can obtain a return value of SQL NULL (the default behavior) or JSON null (using keywords JSON NULL ON NULL). (The default behavior of returning SQL NULL is the only exception to the rule that a JSON scalar value is returned.)

> **✏️ Note:**
>
> Be aware that, although function `json_scalar` preserves timestamp values, it drops any time-zone information from a timestamp. The time-zone information is taken into account by converting to UTC time. See Table 2-4.
>
> If you need to add explicit time-zone information as JSON data then record it separately from a SQL `TIMESTAMP WITH TIME ZONE` instance and pass that to a JSON generation function. Example 2-2 illustrates this.

Example 2-2   Adding Time Zone Information to JSON Data

This example inserts a `TIMESTAMP WITH TIME ZONE` value into a table, then uses generation function `json_object` to construct a JSON object. It uses SQL functions `json_scalar` and `extract` to provide the JSON timestamp and numeric time-zone inputs for `json_object`.

```
CREATE TABLE t (tz TIMESTAMP WITH TIME ZONE);
  INSERT INTO t
    VALUES (to_timestamp_tz('2019-05-03 20:00:00 -8:30',
                            'YYYY-MM-DD HH24:MI:SS TZH:TZM'));

-- This query returns the UTC timestamp value "2019-05-04T04:30:00"
SELECT json_scalar(tz) FROM t;

-- Create a JSON object that has 3 fields:
--  timestamp:       JSON timestamp value (UTC time):
--  timeZoneHours:   hours component of the time zone, as a JSON number
--  timeZoneMinutes: minutes component of the time zone, as a JSON number

SELECT json_object('timestamp'        : json_scalar(tz),
                   'timezoneHours'   : extract(TIMEZONE_HOUR FROM tz),
                   'timezoneMinutes' : extract(TIMEZONE_MINUTE FROM tz))
  FROM t;

-- That query returns a JSON object and prints it in serialized form.
-- The JSON timestamp value is serialized as an ISO 8601 date-time string.
-- The time-zone values (JSON numbers) are serialized as numbers.
--
-- {"timestamp"        : "2019-05-04T04:30:00",
--  "timezoneHours"   : -8,
--  "timezoneMinutes" : -30}
```

2.3.3 Oracle SQL Function JSON_SERIALIZE

Oracle SQL function `json_serialize` takes JSON data (of any SQL data type, `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`) as input and returns a *textual* representation of it (as `VARCHAR2`, `CLOB`, or `BLOB` data). `VARCHAR2(4000)` is the default return type.

You typically use `json_serialize` to transform the result of a query. The function supports an error clause and a returning clause. You can optionally do any combination of the following:

- Automatically escape all non-ASCII Unicode characters, using standard ASCII Unicode escape sequences (keyword **`ASCII`**).

- Pretty-print the result (keyword **PRETTY**).

- Order the members of objects in the result — ascending alphabetical order by field name (keyword **ORDERED**).

  The order is defined by the VARCHAR2 collation with binary ordering as represented in the AL32UTF8 character set. Put differently, characters are ordered according to their Unicode code points.

- Truncate the result to fit the return type (keyword **TRUNCATE**).

- Translate values of Oracle-specific scalar JSON-language types to Oracle extended-object patterns (keyword **EXTENDED**).

See Example 2-3 and Example 2-4.

By default, function json_serialize always produces JSON data that conforms to the JSON standard (RFC 8259), in which case the returned data uses only the *standard* data types of the JSON language: object, array, and the scalar types string, number, Boolean, and null.

The stored JSON data that gets serialized can also have values of scalar types that Oracle has added to the JSON language. JSON data of such types is converted when serialized according to Table 2-3. For example, a numeric value of JSON-language type double is serialized by converting it to a textual representation of a JSON number.

> **Note:**
>
> Input JSON *string* values are returned verbatim (no change). If you want to serialize a *non*string scalar JSON value using a different format from what is specified here, then first use a SQL conversion function such as to_char to produce the string value formatted as you want, and pass that value to json_serialize.

Table 2-3   JSON_SERIALIZE Converts Oracle JSON-Language Types To Standard JSON-Language Types

Oracle JSON Scalar Type (Reported by type())	Standard JSON Scalar Type	Notes
binary	string	Conversion is equivalent to the use of SQL function rawtohex: Binary bytes are converted to hexadecimal characters representing their values.
date	string	The string is in an ISO 8601 date format: *YYYY-MM-DD*. For example: "2019-05-21".

Table 2-3 (Cont.) JSON_SERIALIZE Converts Oracle JSON-Language Types To Standard JSON-Language Types

Oracle JSON Scalar Type (Reported by type())	Standard JSON Scalar Type	Notes
daysecondInterval	string	The string is in an ISO 8601 duration format that corresponds to a *ds_iso_format* specified for SQL function `to_dsinterval`.
		*P*d*DT*h*H*m*M*s*S*, where *d*, *h*, *m*, and *s* are digit sequences for the number of days, hours, minutes, and seconds, respectively. For example: `"P0DT06H23M34S"`.
		s can also be an integer-part digit sequence followed by a decimal point and a fractional-part digit sequence. For example: `P1DT6H23M3.141593S`.
		Any sequence whose value would be zero is omitted, along with its designator. For example: `"PT3M3.141593S"`. However, if all sequences would have zero values then the syntax is `"P0D"`.
double	number	Conversion is equivalent to the use of SQL function `to_number`.
float	number	Conversion is equivalent to the use of SQL function `to_number`.
timestamp	string	The string is in an ISO 8601 date-with-time format: *YYYY-MM-DDThh:mm:ss.ssssss*. For example: `"2019-05-21T10:04:02.340129"`.
timestamp with time zone	string	The string is in an ISO 8601 date-with-time format: *YYYY-MM-DDThh:mm:ss.ssssss(+|-)hh:mm* or, for a zero offset from UTC, *YYYY-MM-DDThh:mm:ss.ssssssZ* For example: `"2019-05-21T10:04:02.123000-08:00"` or `"2019-05-21T10:04:02.123000Z"`.
yearmonthInterval	string	The string is in an ISO 8601 duration format that corresponds to a *ym_iso_format* specified for SQL function `to_yminterval`.
		*P*y*Y*m*M*, where *y* is a digit sequence for the number of years and *m* is a digit sequence for the number of months. For example: `"P7Y8M"`.
		If the number of years or months is zero then it and its designator are omitted. Examples: `"P7Y"`, `"P8M"`. However, if there are zero years and zero months then the syntax is `"P0Y"`.

You can use `json_serialize` to convert binary JSON data to textual form (`CLOB` or `VARCHAR2`), or to transform textual JSON data by pretty-printing it or escaping non-ASCII Unicode characters in it. An important use case is serializing JSON data that is stored in a `BLOB` or `JSON` type column.

(You can use JSON data type only if database initialization parameter compatible is at least 20.)

A BLOB *result* is in the AL32UTF8 character set. But whatever the data type returned by json_serialize, the returned data represents textual JSON data.

> **Note:**
>
> You can use the JSON path-expression item method type() to determine the JSON-language type of any JSON scalar value.
>
> It returns the type name as one of these JSON strings: "binary", "date", "timestamp", "timestamp with time zone", "yearmonthInterval", "daysecondInterval", "double", "float", "number", "null", "string", "boolean". For example, if the targeted scalar JSON value is of type timestamp with time zone then type() returns the string "timestamp with time zone". See:
>
> - SQL/JSON Path Expression Item Methods
> - Textual JSON Objects That Represent Extended Scalar Values

> **See Also:**
>
> - JSON_SERIALIZE in *Oracle Database SQL Language Reference* for information about Oracle SQL function json_serialize
> - RAWTOHEX in *Oracle Database SQL Language Reference* for information about SQL function rawtohex
> - TO_NUMBER in *Oracle Database SQL Language Reference* for information about SQL function to_number

Example 2-3   Using JSON_SERIALIZE To Convert JSON type or BLOB Data To Pretty-Printed Text with Ordered Object Members

This example serializes, orders object members, and pretty-prints the JSON purchase order that has 1600 as the value of field PONumber data, which is selected from column po_document of table j_purchaseorder. The return-value data type is VARCHAR2(4000) (the default return type).

Example 4-1 shows the creation of a table with a JSON type column. You can also use json_serialize to serialize BLOB data.

```
SELECT json_serialize(po_document PRETTY ORDERED)
  FROM j_purchaseorder po
  WHERE po.po_document.PONumber = 1600;
```

Example 2-4   Using JSON_SERIALIZE To Convert Non-ASCII Unicode Characters to ASCII Escape Codes

This example serializes an object that has a string field value with a non-ASCII character (€). It also orders the fields alphabetically.

```
SELECT json_serialize('{"price" : 20, "currency" : "€"}' ASCII ORDERED)
  FROM DUAL;
```

The query returns `{"currency" : "\u20AC", "price" : 20}`.

2.3.4 JSON Constructor, JSON_SCALAR, and JSON_SERIALIZE: Summary

Relations among `JSON` data type constructor `JSON`, Oracle SQL function `json_scalar`, and Oracle SQL function `json_serialize` are summarized.

Both constructor `JSON` and function `json_scalar` accept an instance of a SQL type other than `JSON` and return an instance of `JSON` data type.

The constructor accepts only *textual* JSON data as input: a `VARCHAR2`, `CLOB`, or `BLOB` instance. It raises an error for any other input data type.

Function `json_scalar` accepts an instance of any of several scalar SQL types as input. For `VARCHAR2` or `CLOB` input it *always* returns a JSON-language *string*, as an instance of `JSON` type.

The value returned by the constructor can be any JSON value that is supported by Oracle, including values of the Oracle-specific scalar types: double, float, binary, date, timestamp, day-second interval, and year-month interval. If the constructor is used with keyword `EXTENDED` then the values can be derived from Oracle extended-object patterns in the textual JSON input.

The JSON value returned by `json_scalar` is always a scalar — same JSON-language types as for the constructor, except for the nonscalar types (object and array). For example, an instance of SQL type `DOUBLE` as input results in a `JSON` type instance representing a value of (Oracle-specific) JSON-language type double.

When Oracle SQL function `json_serialize` is applied to a `JSON` type instance, any non-standard Oracle scalar JSON value is returned as a standard JSON scalar value. But if `json_serialize` is used with keyword `EXTENDED` then values of Oracle-specific scalar JSON-language types can be serialized to Oracle extended-object patterns in the textual JSON output.

Table 2-4 summarizes the effects of using constructor `JSON` and SQL function `json_scalar` for various SQL values as JSON data, producing `JSON` type instances, and it shows the effect of serializing those instances.

The constructor *parses* the input, which must be textual JSON data (or else an error is raised). Function `json_scalar` converts its input SQL scalar value to a JSON-language scalar value. `VARCHAR2` or `CLOB` input to `json_scalar` always results in a JSON string value (the input is *not parsed* as JSON data).

Except for the following facts, the result of *serializing a value produced by the constructor* is the same textual representation as was accepted by the constructor (but the textual SQL data type need not be the same, among `VARCHAR2`, `CLOB`, and `BLOB`):

- The constructor accepts lax JSON syntax and `json_serialize` always returns strict syntax.

- If any input JSON objects have duplicate field names then all but one of the field–value pairs is dropped by the constructor.

- The order of field–value pairs in an object is not, in general, preserved: output order can differ from input order.

- If the textual data to which the constructor is applied contains extended JSON constructs (JSON objects that specify non-standard scalar JSON values), then the resulting `JSON` type data can (with keyword `EXTENDED`) have some scalar values that result from translating those constructs to SQL scalar values. If `json_serialize` (with keyword `EXTENDED`) is applied to the resulting `JSON` type data then the result can include some extended JSON constructs that result from translating in the reverse direction.

  The translations in these two directions are *not*, in general, inverse operations, however. They are exact inverses only for Oracle, not non-Oracle, extended JSON constructs. Because extended JSON constructs are translated to Oracle-specific JSON scalar values in `JSON` type, their serialization back to textual JSON data as extended JSON objects can be lossy when they are originally of a non-Oracle format.

Table 2-4   Effect of Constructor JSON and Oracle SQL Function JSON_SCALAR: Examples

Input SQL Value	SQL Type	JSON Value from JSON Constructor	JSON Scalar Value from JSON_SCALAR
`{a:1}`	`VARCHAR2`	• JSON object with field `a` and value `1` • `json_serialize` result: `{"a":1}`	• JSON string containing the text `{"a":1}` • `json_serialize` result: `"{\"a\":1}"` (escaped double-quote characters)
`[1,2,3]`	`VARCHAR2`	• JSON array with elements `1`, `2`, `3` • `json_serialize` result: `[1,2,3]`	• JSON string containing the text `[1,2,3]` • `json_serialize` result: `"[1,2,3]"`
`TRUE` (case-insensitive)	`BOOLEAN`	• JSON Boolean value `true` • `json_serialize` result: `true`	Same as `JSON` constructor.
`true`	`VARCHAR2`	• JSON Boolean value `true` • `json_serialize` result: `true`	• JSON string containing the text `true` • `json_serialize` result: `"true"`
`null`	`VARCHAR2`	• JSON value `null` • `json_serialize` result: `null`	• JSON string containing the text `null` • `json_serialize` result: `"null"`
`NULL`[1]	`VARCHAR2`	• SQL `NULL` (`JSON` type) — *not* JSON value `null` • `json_serialize` result: SQL `NULL`	• SQL `NULL` (`JSON` type) — *not* JSON value `null` • `json_serialize` result: SQL `NULL`
`"city"`	`VARCHAR2`	• JSON string containing the text `city` • `json_serialize` result: `"city"`	• JSON string containing the text `"city"` (including double-quote characters) • `json_serialize` result: `"\"city\""` (escaped double-quote characters)
`city`	`VARCHAR2`	Error — input is not valid JSON data (there is no JSON scalar value `city`)	• JSON string containing the text `city` • `json_serialize` result: `"city"`

Table 2-4   (Cont.) Effect of Constructor JSON and Oracle SQL Function JSON_SCALAR: Examples

Input SQL Value	SQL Type	JSON Value from JSON Constructor	JSON Scalar Value from JSON_SCALAR
`{"$numberDouble" : "1E300"}` or `{"$numberDouble" : 1E300}` (An extended JSON object.)	VARCHAR2	JSON scalar of type double	A JSON string with the same content as the input VARCHAR2 value
`{"$numberDecimal" : "1E300"}` or `{"$numberDecimal" : 1E300}` (An extended JSON object.)	VARCHAR2	JSON scalar of type number, tagged internally as having been derived from a `$numberDecimal` extended object	A JSON string with the same content as the input VARCHAR2 value
`{"$oid" : "deadbeefcafe0123456789ab"}` or `{"$rawid" : "deadbeefcafe0123456789ab"}` (An extended JSON object.)	VARCHAR2	JSON scalar of type binary, tagged internally as having been derived from a `$rawid` or `$oid` extended object	A JSON string with the same content as the input VARCHAR2 value
`{"$date" : "2020-11-24T12:34:56"}` or `{"$oracleDate" : "2020-11-24T12:34:56"}` (An extended JSON object.)	VARCHAR2	JSON scalar of type date, tagged internally as having been derived from an `$oracleDate` or `$date` extended object	A JSON string with the same content as the input VARCHAR2 value
`3.14`	VARCHAR2	• JSON number `3.14` • `json_serialize` result: `3.14`	• JSON string containing the text `3.14` • `json_serialize` result: `"3.14"`
`3.14`	NUMBER	Error — not textual JSON data (SQL types other than VARCHAR2, CLOB, and BLOB are not supported)	• JSON number value `3.14` • `json_serialize` result: `3.14`
`3.14`	BINARY_DOUBLE	Error — not textual JSON data (SQL types other than VARCHAR2, CLOB, and BLOB are not supported)	• JSON double value `3.14` (Oracle JSON language extension) • `json_serialize` result: `3.14`
`3.14`	NUMBER, tagged internally as having been derived from a `$numberDecimal` extended object	JSON scalar of type number, tagged internally as having been derived from a `$numberDecimal` extended object	A JSON string with the same content as the original extended object

Table 2-4   (Cont.) Effect of Constructor JSON and Oracle SQL Function JSON_SCALAR: Examples

Input SQL Value	SQL Type	JSON Value from JSON Constructor	JSON Scalar Value from JSON_SCALAR
A `RAW` value	`RAW`, tagged internally as having been derived from a `$rawid` or `$oid` extended object	JSON scalar of type binary, tagged internally as having been derived from a `$rawid` or `$oid` extended object	A JSON string with the same content as the original extended object
SQL date value from evaluating `to_date('20.07.1974')`	`DATE`	Error — not textual JSON data	• JSON date value (Oracle JSON language extension) • `json_serialize` result: ISO 8601 string `"1974-07-20T00:00:00"` (UTC date — input format is ignored)
SQL timestamp value from evaluating `to_timestamp('2019-05-23 11:31:04.123', 'YYYY-MM-DD HH24:MI:SS.FF')`	`TIMESTAMP`	Error — not textual JSON data	• JSON timestamp value (Oracle JSON language extension) • `json_serialize` result: ISO 8601 string `"2019-05-23T11:31:04.123000"`
SQL timestamp value from evaluating `to_timestamp_tz('2019-05-23 11:31:04.123 -8', 'YYYY-MM-DD HH24:MI:SS.FF TZH')`	`TIMESTAMP WITH TIMEZONE`	Error — not textual JSON data	• JSON timestamp with time zone value (Oracle JSON language extension) • `json_serialize` result: ISO 8601 string `"2019-05-23T11:31.03.123000-08:00"`

[1] This is the SQL `NULL` value for type `VARCHAR2`, *not* a SQL string with characters `NULL`.

Related Topics

• JSON Data Type Constructor
  The `JSON` data type constructor, **JSON**, takes as input a textual JSON value (a scalar, object, or array), parses it, and returns the value as an instance of `JSON` type. Alternatively, the input can be an instance of a user-defined PL/SQL or SQL aggregate type.

• Oracle SQL Function JSON_SCALAR
  Oracle SQL function `json_scalar` accepts a SQL scalar value as input and returns a corresponding JSON scalar value as a `JSON` type instance. In particular, the value can be of an Oracle-specific JSON-language type (such as a date), which is not part of the JSON standard.

- **Oracle SQL Function JSON_SERIALIZE**
  Oracle SQL function `json_serialize` takes JSON data (of any SQL data type, `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`) as input and returns a *textual* representation of it (as `VARCHAR2`, `CLOB`, or `BLOB` data). `VARCHAR2(4000)` is the default return type.

- **Textual JSON Objects That Represent Extended Scalar Values**
  Native binary JSON data (OSON format) extends the JSON language by adding scalar types, such as date, that correspond to SQL types and are not part of the JSON standard. Oracle Database also supports the use of textual JSON *objects* that *represent* JSON scalar values, including such nonstandard values.

2.3.5 Textual JSON Objects That Represent Extended Scalar Values

Native binary JSON data (OSON format) extends the JSON language by adding scalar types, such as date, that correspond to SQL types and are not part of the JSON standard. Oracle Database also supports the use of textual JSON *objects* that *represent* JSON scalar values, including such nonstandard values.

When you create native binary JSON data from textual JSON data that contains such **extended objects**, they can optionally be *replaced* with corresponding (native binary) JSON scalar values.

An example of an extended object is `{"$numberDecimal":31}`. It represents a JSON scalar value of the nonstandard type *decimal number*, and when interpreted as such it is replaced by a decimal number in native binary format.

For example, when you use the JSON data type constructor, `JSON`, if you use keyword `EXTENDED` then recognized extended objects in the textual input are replaced with corresponding scalar values in the native binary JSON result. If you do not include keyword `EXTENDED` then no such replacement occurs; the textual extended JSON objects are simply converted as-is to JSON objects in the native binary format.

In the opposite direction, when you use Oracle SQL function `json_serialize` to serialize binary JSON data as textual JSON data (`VARCHAR2`, `CLOB`, or `BLOB`), you can

use keyword `EXTENDED` to replace (native binary) JSON scalar values with corresponding textual extended JSON objects.

> **✎ Note:**
>
> If the database you use is an Oracle Autonomous Database then you can use PL/SQL procedure `DBMS_CLOUD.copy_collection` to create a JSON document collection from a file of JSON data such as that produced by common NoSQL databases, including Oracle NoSQL Database.
>
> If you use **ejson** as the value of the `type` parameter of the procedure, then recognized extended JSON objects in the input file are replaced with corresponding scalar values in the resulting native binary JSON collection. In the other direction, you can use function `json_serialize` with keyword `EXTENDED` to replace scalar values with extended JSON objects in the resulting textual JSON data.

These are the two main use cases for extended objects:

- *Exchange* (import/export):
    - Ingest existing JSON data (from somewhere) that contains extended objects.
    - Serialize native binary JSON data as textual JSON data with extended objects, for some use outside the database.

- *Inspection* of native binary JSON data: see what you have by looking at corresponding extended objects.

For exchange purposes, you can ingest JSON data from a file produced by common NoSQL databases, including Oracle NoSQL Database, converting extended objects to native binary JSON scalars. In the other direction, you can export native binary JSON data as textual data, replacing Oracle-specific scalar JSON values with corresponding textual extended JSON objects.

As an example of inspection, consider an object such as `{"dob" : "2000-01-02T00:00:00"}` as the result of serializing native JSON data. Is `"2000-01-02T00:00:00"` the result of serializing a native binary value of type date, or is the native binary value just a string? Using `json_serialize` with keyword `EXTENDED` lets you know.

The mapping of extended object fields to scalar JSON types is, in general, many-to-one: more than one kind of extended JSON object can be mapped to a given scalar value. For example, the extended JSON objects `{"$numberDecimal":"31"}` and `{"$numberLong:"31"}` are both translated as the value 31 of JSON-language scalar type number, and item method `type()` returns `"number"` for each of those JSON scalars.

Item method `type()` reports the JSON-language scalar type of its targeted value (as a JSON string). Some scalar values are distinguishable internally, even when they have the same scalar type. This generally allows function `json_serialize` (with keyword `EXTENDED`) to reconstruct the original extended JSON object. Such scalar values are distinguished internally either by using *different SQL types* to implement them or by *tagging them with the kind of extended JSON object* from which they were derived.

When `json_serialize` reconstructs the original extended JSON object the result is not always *textually* identical to the original, but it is always *semantically* equivalent. For example, `{"$numberDecimal":"31"}` and `{"$numberDecimal":31}` are semantically equivalent, even though the field values differ in type (string and number). They are translated to the same

internal value, and each is tagged as being derived from a `$numberDecimal` extended object (same tag). But when serialized, the *result for both* is `{"$numberDecimal":31}`. Oracle always uses the most directly relevant type for the field value, which in this case is the JSON-language value `31`, of scalar type number.

Table 2-5 presents correspondences among the various types used. It maps across (1) types of extended objects used as input, (2) types reported by item method `type()`, (3) SQL types used internally, (4) standard JSON-language types used as output by function `json_serialize`, and (5) types of extended objects output by `json_serialize` when keyword `EXTENDED` is specified.

Table 2-5   Extended JSON Object Type Relations

Extended Object Type (Input)	Oracle JSON Scalar Type (Reported by type())	SQL Scalar Type	Standard JSON Scalar Type (Output)	Extended Object Type (Output)
`$numberDouble` with value a JSON number, a string representing the number, or one of these strings: `"Infinity"`, `"-Infinity"`, `"Inf"`, `"-Inf"`, `"Nan"`[1]	double	`BINARY_DO UBLE`	number	`$numberDouble` with value a JSON number or one of these strings: `"Inf"`, `"-Inf"`, `"Nan"`[2]
`$numberFloat` with value the same as for `$numberDouble`	float	`BINARY_FL OAT`	number	`$numberFloat` with value the same as for `$numberDouble`
`$numberDecimal` with value the same as for `$numberDouble`	number	`NUMBER`	number	`$numberDecimal` with value the same as for `$numberDouble`
`$numberInt` with value a signed 32-bit integer or a string representing the number	number	`NUMBER`	number	`$numberInt` with value the same as for `$numberDouble`
`$numberLong` with value a JSON number or a string representing the number	number	`NUMBER`	number	`$numberLong` with value the same as for `$numberDouble`
`$binary` with value one of these: • a string of base-64 characters • An object with fields `base64` and `subType`, whose values are a string of base-64 characters and the number `0` (arbitrary binary) or `4` (UUID), respectively When the value is a string of base-64 characters, the extended object can also have field `$subtype` with value 0 or 4, expressed as a one-byte integer (0-255) or a 2-character hexadecimal string. representing such an integer	binary	`BLOB` or `RAW`	string Conversion is equivalent to the use of SQL function `rawtohex`.	One of the following: • `$binary` with value a string of base-64 characters • `$rawid` with value a string of 32 hexadecimal characters, if input had a `subType` value of `4` (UUID)

Table 2-5   (Cont.) Extended JSON Object Type Relations

Extended Object Type (Input)	Oracle JSON Scalar Type (Reported by type())	SQL Scalar Type	Standard JSON Scalar Type (Output)	Extended Object Type (Output)
`$oid` with value a string of 24 hexadecimal characters	binary	`RAW(12)`	string Conversion is equivalent to the use of SQL function `rawtohex`.	`$rawid` with value a string of 24 hexadecimal characters
`$rawhex` with value a string with an even number of hexadecimal characters	binary	`RAW`	string Conversion is equivalent to the use of SQL function `rawtohex`.	`$binary` with value a string of base-64 characters, right-padded with = characters
`$rawid` with value a string of 24 or 32 hexadecimal characters	binary	`RAW`	string Conversion is equivalent to the use of SQL function `rawtohex`.	`$rawid`
`$oracleDate` with value an ISO 8601 date string	date	`DATE`	string	`$oracleDate` with value an ISO 8601 date string
`$oracleTimestamp` with value an ISO 8601 timestamp string	timestamp	`TIMESTAMP`	string	`$oracleTimestamp` with value an ISO 8601 timestamp string
`$oracleTimestampTZ` with value an ISO 8601 timestamp string with a numeric time zone offset or with `Z`	timestamp with time zone	`TIMESTAMP WITH TIME ZONE`	string	`$oracleTimestampTZ` with value an ISO 8601 timestamp string with a numeric time zone offset or with `Z`
`$date` with value one of the following: • An integer millisecond count since January 1, 1990 • An ISO 8601 timestamp string • An object with field `numberLong` with value an integer millisecond count since January 1, 1990	timestamp with time zone	`TIMESTAMP WITH TIME ZONE`	string	`$oracleTimestampTZ` with value an ISO 8601 timestamp string with a numeric time zone offset or with `Z`
`$intervalDaySecond` with value an ISO 8601 interval string as specified for SQL function `to_dsinterval`	daysecondInterval	`INTERVAL DAY TO SECOND`	string	`$intervalDaySecond` with value an ISO 8601 interval string as specified for SQL function `to_dsinterval`
`$intervalYearMonth` with value an ISO 8601 interval string as specified for SQL function `to_yminterval`	yearmonthInterval	`INTERVAL YEAR TO MONTH`	string	`$intervalYearMonth` with value an ISO 8601 interval string as specified for SQL function `to_yminterval`

ORACLE

[1] The string values are interpreted case-insensitively. For example, `"NAN"` `"nan"`, and `"nAn"` are accepted and equivalent, and similarly `"INF"`, `"inFinity"`, and `"iNf"`. Infinitely large (`"Infinity"` or `"Inf"`) and small (`"-Infinity"` or `"-Inf"`) numbers are accepted with either the full word or the abbreviation.

[2] On output, only these string values are used — no full-word *Infinity* or letter-case variants.

2.3.6 Comparison and Sorting of JSON Data Type Values

The canonical sort order for values of SQL data type `JSON` is described. It is used to compare all JSON values.

You can directly compare or sort values of `JSON` data type of any kind — whether scalar, object, or array. This means you can use `JSON` type directly in a `WHERE` clause, an `ORDER BY` clause, or a `GROUP BY` clause. The canonical sort order is defined across *all* `JSON`-type values, including scalar values derived from Oracle extended-object patterns in textual JSON input.

> **✎ Note:**
>
> When comparing values of `JSON` data type *in SQL*, the size of the values being compared, *as encoded for SQL comparison*, must be less than 32K bytes. Otherwise, an error is raised. In practice, this SQL encoded-for-comparison size is roughly the size of a *textual* representation of the same JSON data.
>
> For example, in this query the encoded sizes of fields `dept` and `name` must each be less than 32K:
>
> ```
> SELECT *
>   FROM emp t
>   WHERE t.data.dept = 'SALES' ORDER BY t.data.name
> ```
>
> This limit applies to SQL clauses `ORDER BY` and `GROUP BY`, as well as to the use of SQL-value comparison operators (such as `>` in a `WHERE` clause).
>
> More precisely, the limit applies only to comparison and sorting done by SQL itself. It does not apply to comparison or sorting done within the *JSON* language. That is, there's no size limit for comparison or sorting done by a SQL operator for JSON, such as `json_transform` or `json_exists`. In particular, the limit doesn't apply to comparisons made in SQL/JSON path expressions.

The `JSON`-type sort (comparison) order is as follows:

- A *scalar* value sorts before a *nonscalar* value (after, with keyword `DESC`).

- An *object* sorts before an *array* (after, with keyword `DESC`).

- *Two arrays* are sorted by comparing their elements, in order. When two corresponding elements are unequal, the sort order of those elements determines the order of the two arrays. For example, with ascending sort order `[4, 2, 5]` sorts before `[4, 2, 9]` because `5` sorts before `9`.

  If all elements of one array are equal to the corresponding elements of a longer array, the shorter array sorts before the longer one. For example, with ascending sort order `[4, 2]` sorts before `[4, 2, 5]`, but it sorts after `[4, 1, 5]`.

- *Two objects* are sorted first by *field name*, then by *field value*, as follows:

  1. The members of each object are ordered by field name.

     Field names are compared as JSON `string` values, which uses the `VARCHAR2` collation with binary ordering as represented in the AL32UTF8 character set.

  2. Members of the sorted objects (from step 1) are compared, in order:

     - When two corresponding field names are different, the object with the field name that sorts first is sorted before the other object (after, with keyword `DESC`).

     - When two corresponding field names are the same, the field *values* are compared, according to the `JSON`-type sort order. (That is, field values are compared recursively.) The order of the two objects being compared follows that of their field values.

- Two *scalars of different type families* are sorted in this ascending order by family — so, for example, a number sorts before a string. (For descending sort the order is reversed.)

1. `null`

2. Numeric (`number`, `double`, `float`)

3. `string`

4. Nonidentifier `binary` (e.g., images)

5. Identifier `binary` (e.g., values from extended objects with field `$oid` or `$rawid`)

6. `boolean`

7. Date and time points (`date`, `timestamp`, or `timestamp with time zone`)

8. `yearmonthInterval`

9. `daysecondInterval`

There are two separate families for both date-time interval values and binary values, because the values need to be compared and sorted separately. Different months can have a different number of days. Binary values that are used as identifiers are typically tested for equality; equality testing, even when possible, is typically not useful for nonidentifier binary values.

• Two *scalars of the same type family* are sorted by the sort order defined for that family. For example, with ascending sort order, `100` sorts before `200.0` regardless of the numeric types used, and `"cat"` sorts before `"dog"` regardless of the character set used.

The scalar JSON comparison used is the *collation for the corresponding SQL scalar type*, except that a JSON `string` comparison uses the `VARCHAR2` collation with binary ordering as represented in the AL32UTF8 character set. For `boolean` values, `false` sorts before `true` (after, with keyword `DESC`).

You can compare any values of `JSON` type for purposes of sorting, such as is done by `ORDER BY`. But comparison for other purposes, for example in a comparison filter condition, is more limited.

Apart from sorting, you can compare any values that are in the *same* type family in any way. Values from *different* type families are always unequal: comparison for equality (==) yields false and comparison for inequality (!=, <>) yields true). Comparisons <, <=, >=, and > are meaningful and useful only within the same family; if used with values from different families then the comparison condition returns false. For example, a JSON object, number, or boolean is neither greater than nor less than a JSON array, string, or date.

> **Tip:**
>
> Because `json_scalar` returns `NULL` by default for nonscalar input, and because comparison involving a nonscalar JSON value can be more costly than scalar-with-scalar comparison, a simple manual optimization when ordering or comparing JSON data is to do so after wrapping it with `json_scalar`, thus effectively pruning nonscalars from the data to be compared. (More precisely, they are replaced with `NULL`, which is quickly compared.)
>
> For example instead of this:
>
> ```
> SELECT data FROM customers c
>   ORDER BY c.data.revenue;
> ```
>
> Use this:
>
> ```
> SELECT data FROM customers c
>   ORDER BY json_scalar(c.data.revenue);
> ```

You can use item method `type()` to help you identify the type family of a JSON value, which makes it useful for purposes of comparison or indexing. However, it provides only a rough guide for this, because it generally reports only on the *SQL data type* from which the JSON value was derived, or to which the JSON value can be mapped.

- `null` type family: `type()` returns **"null"**.

- *Numeric* type family: `type()` returns different type names for different kinds of numeric value:

  - **"double"**, for a JSON value (a number) that corresponds to a SQL `BINARY_DOUBLE` value. This includes, for example, values that were derived from an extended object with `$numberDouble`.

  - **"float"**, for a JSON value (a number) that corresponds to a SQL `BINARY_FLOAT` value. This includes, for example, values that were derived from an extended object with `$numberFloat`.

  - **"number"**, for a JSON value (a number) that was derived from either (1) a textual JSON number or a string numeral (corresponding to the standard JSON-language number type) or (2) an extended object with `$numberInt`, `$numberDecimal`, or `$numberLong`.

- `string` type family: `type()` returns **"string"**.

- *Binary* type families: `type()` returns **"binary"** for *both* the identifier and nonidentifier binary families, that is, a value that corresponds to a SQL `RAW` value. `type()` cannot distinguish values of these two families.

- `boolean` type family: `type()` returns **"boolean"**.

- *Date and time point* family returns different type names for different kinds:

  - **"date"** for a value that corresponds to a SQL `DATE` value. This includes, for example, values that were derived from an extended object with `$oracleDate`.

- **"timestamp"** for a value that corresponds to a SQL `TIMESTAMP` value. This includes, for example, values that were derived from an extended object with `$oracleTimestamp`.

- **"timestamp with time zone"** for a value that corresponds to a SQL `TIMESTAMP WITH TIME ZONE` value. This includes, for example, values that were derived from an extended object with `$date` or `$oracleTimestampTZ`. (A `$date` field has a timestamp-with-timezone value, because it allows fractional seconds, and the value is given for Coordinated Universal Time (UTC).)

- `yearMonthInterval` type family: `type()` returns **"yearmonthInterval"** for a value that corresponds to a SQL `INTERVAL YEAR TO MONTH` value. This includes, for example, values that were derived from an extended object with `$intervalYearMonth`.

- `daysecondInterval` type family: `type()` returns **"daysecondInterval"** for a value that corresponds to a SQL `INTERVAL DAY TO SECOND` value. This includes, for example, values that were derived from an extended object with `$intervalDaySecond`.

Related Topics

- Textual JSON Objects That Represent Extended Scalar Values
  Native binary JSON data (OSON format) extends the JSON language by adding scalar types, such as date, that correspond to SQL types and are not part of the JSON standard. Oracle Database also supports the use of textual JSON *objects* that *represent* JSON scalar values, including such nonstandard values.

- Oracle SQL Function JSON_SCALAR
  Oracle SQL function `json_scalar` accepts a SQL scalar value as input and returns a corresponding JSON scalar value as a `JSON` type instance. In particular, the value can be of an Oracle-specific JSON-language type (such as a date), which is not part of the JSON standard.

- TYPE Clause for SQL Functions and Conditions
  Oracle SQL function `json_transform`, SQL/JSON functions `json_query`, `json_value` and `json_table`, and SQL/JSON condition `json_exists` accept optional **TYPE** clauses, which specify whether JSON values are compared *strictly* with respect to JSON-language type, that is, as if the relevant "only" data-type conversion item methods were applied to the data being compared.

> Data Type Comparison Rules in *Oracle Database SQL Language Reference* for information about how Oracle Database compares values within each data type

2.4 Oracle Database Support for JSON

Oracle Database support for JavaScript Object Notation (JSON) is designed to provide the best fit between the worlds of relational storage and querying JSON data, allowing

relational and JSON queries to work well together. Oracle SQL/JSON support is closely aligned with the JSON support in the SQL Standard.

Oracle Database supports the JSON format as specified in ECMAScript edition 5.1.

- Support for RFC 8259: JSON Scalars
  Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

2.4.1 Support for RFC 8259: JSON Scalars

Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

For this support, database initialization parameter `compatible` must be `20` or greater.

In database releases prior to 21c only IETF RFC 4627 was supported. It allows only a JSON object or array, not a scalar, at the top level of a JSON document. RFC 8259 support includes RFC 4627 support (and RFC 7159 support).

If parameter `compatible` is `20` or greater then JSON data, regardless of how it is stored, supports RFC 8259 by default. But for a given JSON column you can use an `is json` check constraint to exclude the insertion of documents there that have top-level JSON scalars (that is, support only RFC 4627, not RFC 8259), by specifying the new `is json` keywords `DISALLOW SCALARS`.

With parameter `compatible 20` or greater you can also use keywords `DISALLOW SCALARS` with SQL/JSON function `json_query` (or with a `json_table` column that has `json_query` semantics) to specify that the return value must be a JSON object or array. Without these keywords a JSON scalar can be returned.

If parameter `compatible` is `20` or greater you can also use SQL data type `JSON`, its constructor `JSON`, and Oracle SQL function `json_scalar`. If `compatible` is less than `20` then an error is raised when you try to use them.

If `compatible` is `20` or greater you can nevertheless restrict some JSON data to *not* allow top-level scalars, by using keywords `DISALLOW SCALARS`. For example, you can use an `is json`

check constraint with `DISALLOW SCALARS` to prevent the insertion of documents that have a top-level scalar JSON value.

> ⚠️ **WARNING:**
>
> If you change the value of parameter `compatible` to `20` or greater then you cannot later return it to a lower value.

Part II
Store and Manage JSON Data

This part covers creating JSON columns in a database table, partitioning such tables, replicating them using Oracle GoldenGate, and character-set encoding of JSON data. It covers the use of SQL/JSON condition `is json` as a check constraint to ensure that the data in a column is well-formed JSON data.

- Overview of Storing and Managing JSON Data
  This overview describes data types for JSON columns and ensuring that JSON columns contain well-formed JSON data.

- Creating a Table With a JSON Column
  You can create a table that has JSON columns. Oracle recommends that you use `JSON` data type for this.

- SQL/JSON Conditions IS JSON and IS NOT JSON
  SQL/JSON conditions `is json` and `is not json` are complementary. They test whether their argument is syntactically correct, that is, *well-formed*, JSON data. With optional keyword `VALIDATE` they test whether the data is also *valid* with respect to a given JSON schema.

- JSON Schema
  You can create a JSON schema against which to validate the structure and type information of your JSON documents. You can validate data on the fly or do it with a check constraint to ensure that only schema-valid data is inserted in a JSON column.

- Character Sets and Character Encoding for JSON Data
  JSON data always uses the Unicode character set. In this respect, JSON data is simpler to use than XML data. This is an important part of the JSON Data Interchange Format (RFC 8259). For JSON data processed by Oracle Database, any needed character-set conversions are performed automatically.

- Considerations When Using LOB Storage for JSON Data
  LOB storage considerations for JSON data are described, including considerations when you use a client to retrieve JSON data as a LOB instance.

- Partitioning JSON Data
  You can partition a table using a JSON virtual column as the partitioning key. The virtual column is extracted from a JSON column using SQL/JSON function `json_value`.

- Replication of JSON Data
  You can use Oracle GoldenGate, Oracle XStreams, Oracle Data Guard, or Oracle Active Data Guard to replicate tables that have columns containing JSON data.

3

Overview of Storing and Managing JSON Data

This overview describes data types for JSON columns and ensuring that JSON columns contain well-formed JSON data.

Data Types for JSON Columns

You can store JSON data in Oracle Database using columns whose data types are `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. Whichever type you use, you can manipulate JSON data as you would manipulate any other data of those types. Storing JSON data using standard data types allows all features of Oracle Database, such as advanced replication, to work with tables containing JSON documents.

Oracle recommends that you use `JSON` data type, which stores JSON data in a native binary format.

If you instead use one of the other types, the choice of which one to use is typically motivated by the size of the JSON documents you need to manage:

- Use `VARCHAR2(4000)` if you are sure that your largest JSON documents do not exceed 4000 bytes (or characters)[1].

  If you use Oracle Exadata then choosing `VARCHAR2(4000)` can improve performance by allowing the execution of some JSON operations to be pushed down to Exadata storage cells, for improved performance.

- Use `VARCHAR2(32767)` if you know that some of your JSON documents are larger than 4000 bytes (or characters) and you are sure than none of the documents exceeds 32767 bytes (or characters)[1].

  With `VARCHAR2(32767)`, the first roughly 3.5K bytes (or characters) of a document is *stored in line*, as part of the table row. This means that the added cost of using `VARCHAR2(32767)` instead of `VARCHAR2(4000)` applies only to those documents that are larger than about 3.5K. If most of your documents are smaller than this then you will likely notice little performance difference from using `VARCHAR2(4000)`.

  If you use Oracle Exadata then push-down is enabled for any documents that are stored in line.

- Use `BLOB` (binary large object) or `CLOB` (character large object) storage if you know that you have some JSON documents that are larger than 32767 bytes (or characters)[1].

Ensure That JSON Columns Contain Well-Formed JSON Data

If you use `JSON` data type to store your JSON data (recommended) then the data is guaranteed to be well-formed JSON data — you cannot store it otherwise.

If you do *not* use `JSON` data type to store your JSON data then you can use SQL/JSON condition `is json` to check whether or not some JSON data is well formed. In this case

---

[1] Whether the limit is expressed in bytes or characters is determined by session parameter `NLS_LENGTH_SEMANTICS`.

Oracle strongly recommends that you apply an `is json` check constraint to any JSON column, unless you expect some rows to contain something other than well-formed JSON data.

The overhead of parsing JSON is such that evaluating the condition should not have a significant impact on insert and update performance, and omitting the constraint means you cannot use the simple dot-notation syntax to query the JSON data.

What constitutes well-formed JSON data is a gray area. In practice, it is common for JSON data to have some characteristics that do not strictly follow the standard definition. You can control which syntax you require a given column of JSON data to conform to: the standard definition (strict syntax) or a JavaScript-like syntax found in common practice (lax syntax). The default SQL/JSON syntax for Oracle Database is *lax*. Which kind of syntax is used is controlled by condition `is json`. Applying an `is json` check constraint to a JSON column thus enables the use of lax JSON syntax, by default.

Related Topics

- Character Sets and Character Encoding for JSON Data
  JSON data always uses the Unicode character set. In this respect, JSON data is simpler to use than XML data. This is an important part of the JSON Data Interchange Format (RFC 8259). For JSON data processed by Oracle Database, any needed character-set conversions are performed automatically.

- Overview of Inserting, Updating, and Loading JSON Data
  You can use database APIs to insert or modify JSON data in Oracle Database. You can use Oracle SQL function `json_transform` or `json_mergepatch` to update a JSON document. You can work directly with JSON data contained in file-system files by creating an external table that exposes it to the database.

- Simple Dot-Notation Access to JSON Data
  Dot notation is designed for easy, general use and common use cases of querying JSON data. For simple queries it is a handy alternative to using SQL/JSON query functions.

4
Creating a Table With a JSON Column

You can create a table that has JSON columns. Oracle recommends that you use `JSON` data type for this.

When using textual JSON data to perform an `INSERT` or `UPDATE` operation on a `JSON` type column, the data is implicitly wrapped with constructor `JSON`. If the column is instead `VARCHAR2`, `CLOB`, or `BLOB`, then use condition `is json` as a check constraint, to ensure that the data inserted is (well-formed) JSON data.

Example 4-1, Example 4-2 and Example 4-3 illustrate this. They create and fill a table that holds data used in examples elsewhere in this documentation. Example 4-1 and Example 4-2 are alternative ways to create the table, using `JSON` type and `VARCHAR2`, respectively.

For brevity, only two rows of data (one JSON document) are inserted in Example 4-3.

> **Note:**
>
> A check constraint can reduce performance for data `INSERT` and `UPDATE` operations. If you are sure that your application uses only well-formed JSON data for a particular column, then consider *disabling* the check constraint, but *do not drop* the constraint.

> **Note:**
>
> SQL/JSON conditions `is json` and `is not json` return true or false for any non-`NULL` SQL value. But they both return unknown (neither true nor false) for SQL `NULL`. When used in a check constraint, they do *not* prevent a SQL `NULL` value from being inserted into the column. (But when used in a SQL `WHERE` clause, SQL `NULL` is never returned.)

> **See Also:**
>
> - Loading External JSON Data for the creation of the full table `j_purchaseorder`
> - *Oracle Database SQL Language Reference* for information about `CREATE TABLE`

Example 4-1   Creating a Table with a JSON Type Column

This example creates table `j_purchaseorder` with `JSON` data type column `po_document`. Oracle recommends that you store JSON data as `JSON` type.

```
CREATE TABLE j_purchaseorder
   (id           VARCHAR2 (32) NOT NULL PRIMARY KEY,
    date_loaded TIMESTAMP (6) WITH TIME ZONE,
    po_document JSON);
```

Example 4-2   Using IS JSON in a Check Constraint to Ensure Textual JSON Data is Well-Formed

This example creates table `j_purchaseorder` with a `VARCHAR2` column for the JSON data. It uses a check constraint to ensure that the textual data in the column is well-formed JSON data. Always use such a check constraint if you use a data type other than `JSON` to store JSON data.

```
CREATE TABLE j_purchaseorder
   (id           VARCHAR2 (32) NOT NULL PRIMARY KEY,
    date_loaded TIMESTAMP (6) WITH TIME ZONE,
    po_document VARCHAR2 (23767)
    CONSTRAINT ensure_json CHECK (po_document is json));
```

Example 4-3   Inserting JSON Data Into a JSON Column

This example inserts two rows of data into table `j_purchaseorder`. The third column contains JSON data.

Note that if the data type of the third column is `JSON` (as in Example 4-1) and you insert textual data into that column, as in this example, the data is *implicitly wrapped* with the `JSON` constructor to provide `JSON` type data.

```
INSERT INTO j_purchaseorder
  VALUES (
    SYS_GUID(),
    to_date('30-DEC-2014'),
    '{"PONumber"             : 1600,
      "Reference"            : "ABULL-20140421",
      "Requestor"            : "Alexis Bull",
      "User"                 : "ABULL",
      "CostCenter"           : "A50",
      "ShippingInstructions" :
        {"name"    : "Alexis Bull",
         "Address" : {"street"  : "200 Sporting Green",
                      "city"    : "South San Francisco",
                      "state"   : "CA",
                      "zipCode" : 99236,
                      "country" : "United States of America"},
         "Phone"   : [{"type" : "Office", "number" : "909-555-7307"},
                      {"type" : "Mobile", "number" : "415-555-1234"}]},
      "Special Instructions" : null,
      "AllowPartialShipment" : true,
      "LineItems"            :
```

```
       [{"ItemNumber" : 1,
         "Part"        : {"Description" : "One Magic Christmas",
                          "UnitPrice"   : 19.95,
                          "UPCCode"     : 13131092899},
          "Quantity"   : 9.0},
         {"ItemNumber" : 2,
          "Part"        : {"Description" : "Lethal Weapon",
                          "UnitPrice"   : 19.95,
                          "UPCCode"     : 85391628927},
          "Quantity"   : 5.0}]}');

INSERT INTO j_purchaseorder
  VALUES (
    SYS_GUID(),
    to_date('30-DEC-2014'),

                                "Phone"   : "983-555-6509"},
      "Special Instructions" : "Courier",
      "LineItems"            :
        [{"ItemNumber" : 1,
          "Part"        : {"Description" : "Making the Grade",
                           "UnitPrice"   : 20,
                           "UPCCode"     : 27616867759},
          "Quantity"   : 8.0},
         {"ItemNumber" : 2,
          "Part"        : {"Description" : "Nixon",
                           "UnitPrice"   : 19.95,
                           "UPCCode"     : 717951002396},
          "Quantity"   : 5},
         {"ItemNumber" : 3,
          "Part"        : {"Description" : "Eric Clapton: Best Of 1981-1999",
                           "UnitPrice"   : 19.95,
                           "UPCCode"     : 75993851120},
          "Quantity"   : 5.0}]}');
```

- Determining Whether a Column Must Contain Only JSON Data
  How can you tell whether a given column of a table or view can contain only well-formed JSON data? Whenever this is the case, the column is listed in the following static data dictionary views: `DBA_JSON_COLUMNS`, `USER_JSON_COLUMNS`, and `ALL_JSON_COLUMNS`.

4.1 Determining Whether a Column Must Contain Only JSON Data

How can you tell whether a given column of a table or view can contain only well-formed JSON data? Whenever this is the case, the column is listed in the following static data dictionary views: **DBA_JSON_COLUMNS**, **USER_JSON_COLUMNS**, and **ALL_JSON_COLUMNS**.

Each of these views lists the column name, data type, and format (TEXT or BINARY); the table or view name (column TABLE_NAME); and whether the object is a table or a view (column OBJECT_TYPE).

A JSON data type column *always* contains only well-formed JSON data, so each such column is always listed, with its type as JSON.

For a column that is *not* JSON type to be considered JSON data it must have an is json check constraint. But in the case of a *view*, any one of the following criteria suffices for a column to be considered JSON data:

- The underlying data has the data type JSON.

- The underlying data has an is json check constraint.

- The column results from the use of a SQL/JSON generation function, such as json_object.

- The column results from the use of SQL/JSON function json_query.

- The column results from the use of Oracle SQL function json_mergepatch, json_scalar, json_serialize, or json_transform.

- The column results from the use of the JSON data type constructor, JSON.

- The column results from the use of SQL function treat with keywords AS JSON.

If an is json check constraint, which constrains a table column to contain only JSON data, is later *deactivated*, the column remains listed in the views. If the check constraint is *dropped* then the column is removed from the views.

> **Note:**
>
> If a check constraint *combines* condition is json with another condition using logical condition OR, then the column is *not* listed in the views. In this case, it is *not certain* that data in the column is JSON data. For example, the constraint jcol is json **OR** length(jcol) < 1000 does *not* ensure that column jcol contains only JSON data.

> **✎ See Also:**
>
> *Oracle Database Reference* for information about `ALL_JSON_COLUMNS` and the related data-dictionary views

5

SQL/JSON Conditions IS JSON and IS NOT JSON

SQL/JSON conditions `is json` and `is not json` are complementary. They test whether their argument is syntactically correct, that is, *well-formed*, JSON data. With optional keyword `VALIDATE` they test whether the data is also *valid* with respect to a given JSON schema.

You can use `is json` and `is not json` in a `CASE` expression or the `WHERE` clause of a `SELECT` statement. You can use `is json` in a check constraint.

If the data tested is syntactically correct and keyword `VALIDATE` is not present then `is json` returns true and `is not json` returns false.

If keyword `VALIDATE` is present then the data is tested to ensure that it is (or `IS NOT`) both well-formed and valid with respect to the specified JSON schema. Keyword `VALIDATE` (optionally followed by keyword `USING`) must be followed by a SQL string literal that is the JSON schema to validate against.

If an error occurs during parsing (or validating), the error is not raised, and the data is considered to *not* be well-formed (or not valid): `is json` returns false; `is not json` returns true. (If an error occurs other than during parsing or validating then that error is raised.)

Well-formed data means syntactically correct data. JSON data stored textually can be well-formed in two senses, referred to as strict and lax syntax. In addition, for textual JSON data you can specify whether a JSON object can have duplicate fields (keys).

For JSON data of *any* data type (textual or `JSON` type):

- You can specify whether a document of well-formed data can have a *scalar value at top level* (provided database initialization parameter `compatible` is `20` or greater). And you can specify that it must also be valid.

- You can specify that the data must (or must not, with `IS NOT JSON`) *validate* against a given JSON schema.

Whenever textual JSON data is *generated* inside the database it satisfies condition `is json` with keyword `STRICT`. This includes generation in these ways:

- Using a SQL/JSON generation function (unless you specify keyword `STRICT` with either `FORMAT JSON` or `TREAT AS JSON`, which means that you declare that the data is JSON data; you vouch for it, so its well-formedness is not checked)

- Using SQL function `json_serialize`

- Using SQL function `to_clob`, `to_blob`, or `to_string` on a PL/SQL DOM

- Using SQL/JSON function `json_query`

- Using SQL/JSON function `json_table` with `FORMAT JSON`

> **✎ Note:**
>
> JSON type data has only unique object keys (field names), and the notions of strict and lax syntax do not apply to it. When you serialize JSON data (of any data type) to produce textual JSON data the result always has strict syntax.
>
> If JSON data is stored using JSON data type and you use an `is json` check constraint then:
>
> - If you specify keywords `DISALLOW SCALARS`, the JSON column cannot store documents with top-level scalar JSON values.
>
> - If you specify no keywords or you specify any other keywords than `DISALLOW SCALARS`, the `is json` constraint is ignored. The keywords change nothing.

You can omit the keywords `CHECK` and `IS JSON`. For example, these two check constraints are equivalent; they each ensure that the value of column `jcol` is a JSON string:

```
CHECK (jcol IS JSON VALIDATE '{"type": "string"}')
```

```
jcol VALIDATE '{"type": "string"}'
```

- [Unique Versus Duplicate Fields in JSON Objects](#)
  The JSON standard recommends that a JSON object *not* have duplicate field names. Oracle Database enforces this for JSON type data by raising an error. If stored textually, Oracle recommends that you do *not* allow duplicate field names, by using an `is json` check constraint with keywords `WITH UNIQUE KEYS`.

- [About Strict and Lax JSON Syntax](#)
  On *input*, the Oracle default syntax for JSON is *lax*. It reflects the JavaScript syntax for object fields; the Boolean and `null` values are not case-sensitive; and it is more permissive with respect to numerals, whitespace, and escaping of Unicode characters. Oracle *outputs* JSON data that strictly respects the standard.

- [Specifying Strict or Lax JSON Syntax](#)
  The default JSON syntax for Oracle Database is lax. Strict or lax syntax matters *only* for SQL/JSON conditions `is json` and `is not json`. All other SQL/JSON functions and conditions use lax syntax for interpreting input and strict syntax when returning output.

Related Topics

- [Creating a Table With a JSON Column](#)
  You can create a table that has JSON columns. Oracle recommends that you use JSON data type for this.

- [Support for RFC 8259: JSON Scalars](#)
  Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

5.1 Unique Versus Duplicate Fields in JSON Objects

The JSON standard recommends that a JSON object *not* have duplicate field names. Oracle Database enforces this for `JSON` type data by raising an error. If stored textually, Oracle recommends that you do *not* allow duplicate field names, by using an `is json` check constraint with keywords `WITH UNIQUE KEYS`.

If stored textually (`VARCHAR2`, `CLOB`, `BLOB` column), JSON data is, by default, allowed to have duplicate field names, simply because checking for duplicate names takes additional time. This default behavior for JSON data stored textually can result in *inconsistent behavior*, so Oracle recommends against relying on it.

You can override this default behavior, to instead raise an error if an attempt is made to insert data containing an object with duplicate fields. You do this by using an `is json` check constraint with the keywords `WITH UNIQUE KEYS`. (These keywords have no effect for data inserted into a `JSON` type column.)

Whether duplicate field names are allowed in well-formed textual JSON data is orthogonal to whether Oracle uses strict or lax syntax to determine well-formedness.

5.2 About Strict and Lax JSON Syntax

On *input*, the Oracle default syntax for JSON is *lax*. It reflects the JavaScript syntax for object fields; the Boolean and `null` values are not case-sensitive; and it is more permissive with respect to numerals, whitespace, and escaping of Unicode characters. Oracle *outputs* JSON data that strictly respects the standard.

Standards ECMA 404, the *JSON Data Interchange Format*, and ECMA 262, the *ECMAScript Language Specification*, define JSON syntax.

According to these specifications (prior to ECMAScript edition 5.1), each JSON field and each string value *must* be enclosed in double quotation marks (`"`). Oracle supports this **strict JSON syntax**, and it always respects this syntax on output, but this is *not* the default syntax for data on input.

In JavaScript notation, a field used in an object literal can be, but need not be, enclosed in double quotation marks. It can also be enclosed in single quotation marks (`'`). ECMA 262, 5.1 Edition relaxed the strict syntax in several ways, including allowing such fields. Oracle supports this syntax specified by ECMAScript 5.1.

By *default*, Oracle uses a *lax* JSON syntax when it accepts data on input. This syntax differs in one detail from that specified by ECMAScript 5.1: Oracle allows the inclusion in JSON strings of unescaped line and paragraph separator characters (U+2028 and U+2029). (This is also the case for JSON5, which, apart from this difference, is a proper subset of ECMAScript 5.1.)

In addition, in practice, some *JavaScript implementations* (but not the JavaScript standard) allow one or more of the following:

- Case variations for `true`, `false`, and `null` (for example, `TRUE`, `True`, `TrUe`, `fALSe`, `NulL`).

- An extra comma (`,`) after the last element of an array or the last member of an object (for example, `[a, b, c,]`, `{a:b, c:d,}`).

- Numerals with one or more leading zeros (for example, `0042.3`).

- Fractional numerals that lack `0` before the decimal point (for example, `.14` instead of `0.14`).

- Numerals with no fractional part after the decimal point (for example, `342.` or `1.e27`).

- A plus sign (`+`) preceding a numeral, meaning that the number is non-negative (for example, `+1.3`).

This syntax too is allowed on input as part of the Oracle default (lax) JSON syntax. (See the JSON standard for the strict numeral syntax.)

In addition to the ASCII space character (U+0020), the JSON standard defines the following characters as *insignificant whitespace* (it is ignored) when used outside a quoted field or a string value:

- Tab, horizontal tab (`HT`, `^I`, decimal 9, U+0009, `\t`)

- Line feed, newline (`LF`, `^J`, decimal 10, U+000A, `\n`)

- Carriage return (`CR`, `^M`, decimal 13, U+000D, `\r`)

However, Oracle lax JSON syntax treats *all* of the ASCII control characters (Control+0 through Control+31), as well as the ASCII space character (decimal 32, U+0020), as insignificant whitespace characters (ignored outside a quoted field or a string value). The following are among the control characters:

- Null (`NUL`, `^@`, decimal 0, U+0000, `\0`)

- Bell (`NEL`, `^G`, decimal 7, U+0007, `\a`)

- Vertical tab (`VT`, `^K`, decimal 11, U+000B)

- Escape (`ESC`, `^[`, decimal 27, U+001B, `\e`)

- Delete (`DEL`, `^?`, decimal 127, U+007F)

Oracle strict syntax, like ECMAScript 5.1, treats all Unicode whitespace characters other than ASCII space character (decimal 32, U+0020) as insignificant. Also, in the strict syntax U+0020 is the only whitespace character allowed, unescaped, within a quoted field or a string value.

In Oracle lax JSON syntax, an object field that is *not* quoted can contain any Unicode character except whitespace and the JSON structural characters — left and right brackets (`[`, `]`) and curly braces (`{`, `}`), colon (`:`), and comma (`,`), but escape sequences are not allowed.

For both strict and lax JSON syntax, quoted object fields and string values can contain *any Unicode characters*. Each can be included by using the ASCII escape syntax `\u` followed by the four ASCII hexadecimal digits that represent the Unicode code point.

The following Unicode characters *must* be represented in fields and strings either by `\u` followed by their code point or by special escape sequences:

- ASCII control characters backspace (CONTROL-H), form feed (CONTROL-L), newline (line feed) (CONTROL-J), carriage return (CONTROL-M), and (horizontal) tab (CONTROL-I).

  Use `\b` for **b**ackspace; `\f` for **f**orm feed; `\n` for **n**ewline ; `\r` for carriage **r**eturn; and `\t` for **t**ab.

- Double quotation mark (`"`), slash (`/`), and backslash (`\`) characters.

  To escape these, precede each with a backslash character: `\"`, `\/`, and `\\`, respectively.

  Table 5-1 shows some examples of JSON syntax.

Table 5-1   JSON Object Field Syntax Examples

Example	Well-Formed?
`"part number": 1234`	Lax and strict: yes. Space characters are allowed.
`part number: 1234`	Lax (and strict): **no**. Whitespace characters, including space characters, are not allowed in unquoted names.
`"part\tnumber": 1234`	Lax and strict: yes. Escape sequence for tab character is allowed.
`"part    number": 1234`	Lax: yes, **strict: no**. Unescaped tab character is allowed only in the lax syntax. Space (U+0020) is the only unescaped whitespace character allowed in the strict syntax.
`"\"part\"number": 1234`	Lax and strict: yes. Escaped double quotation marks are allowed, if name is quoted.
`\"part\"number: 1234`	Lax and strict: **no**. The field name must be quoted to contain embedded double quotation marks.
`'\"part\"number': 1234`	Lax: yes, **strict: no**. Single-quoted names (object fields and strings) are allowed for lax syntax only. Escaped double quotation mark is allowed in a quoted name.
`"pärt : number":1234`	Lax and strict: yes. Any Unicode character is allowed in a quoted name. This includes whitespace characters and characters, such as colon (`:`), that are structural in JSON.
`part:number:1234`	Lax (and strict): **no**. Structural characters are not allowed in unquoted names.

5.3 Specifying Strict or Lax JSON Syntax

The default JSON syntax for Oracle Database is lax. Strict or lax syntax matters *only* for SQL/JSON conditions `is json` and `is not json`. All other SQL/JSON functions and conditions use lax syntax for interpreting input and strict syntax when returning output.

If you need to be sure that particular textual JSON data has strictly correct syntax, then check it first using `is json` or `is not json`.

You specify that data is to be checked as strictly well-formed according to the JSON standard by appending **(STRICT)** (parentheses included) to an `is json` or an `is not json` expression.

Example 5-1 illustrates this. It is identical to Example 4-2 except that it uses `(STRICT)` to ensure that all data inserted into the column is well-formed according to the JSON standard.

> **See Also:**
>
> *Oracle Database SQL Language Reference* for information about `CREATE TABLE`

Example 5-1   Using IS JSON in a Check Constraint to Ensure Textual JSON Data is Strictly Well-Formed

The JSON column is data type `VARCHAR2`. Because the type is not `JSON` type an `is json` check constraint is needed. This example imposes *strict*, that is, standard, JSON syntax.

```
CREATE TABLE j_purchaseorder
  (id          VARCHAR2 (32) NOT NULL PRIMARY KEY,
   date_loaded TIMESTAMP (6) WITH TIME ZONE,
   po_document VARCHAR2 (32767)
   CONSTRAINT ensure_json CHECK (po_document is json (STRICT)));
```

Related Topics

- About Strict and Lax JSON Syntax
  On *input*, the Oracle default syntax for JSON is *lax*. It reflects the JavaScript syntax for object fields; the Boolean and `null` values are not case-sensitive; and it is more permissive with respect to numerals, whitespace, and escaping of Unicode characters. Oracle *outputs* JSON data that strictly respects the standard.

6
JSON Schema

You can create a JSON schema against which to validate the structure and type information of your JSON documents. You can validate data on the fly or do it with a check constraint to ensure that only schema-valid data is inserted in a JSON column.

Most uses of JSON data are schema*less*. Applications that use JSON data can then quickly react to changing requirements. You can change and redeploy an application without needing to change the storage schemas it uses.

However, sometimes you might want some JSON data to conform to a schema. You might want to ensure that all data stored in a given column has the structure defined by a schema, or you might want to check whether a given JSON document has such a structure, before processing it.

A **JSON schema** is a JSON document that respects the **JSON Schema** standard, which is a Request For Comments (RFC) draft.

JSON schemas can in turn be used to describe or validate other JSON documents. See json-schema.org. A JSON schema specifies the *structure* and the *types* of allowed values of JSON data that it considers *valid*. "Validity" is always with respect to a given schema. ("Well-formedness", on the other hand, just means syntactically correct.)

The JSON schemas supported by Oracle Database are self-contained. They cannot include or import other JSON schemas. (If you try to do so, the schema keywords you use for that are simply ignored, as if they were user-defined keywords.) However, you can use a properly defined application usage *domain* as a JSON schema, and domains allow for export and import of other domains. (They also allow for dependency tracking and evolution.)

This is an example of a simple JSON schema that uses only standard fields (keywords):

```
{"type"        : "object",
 "properties" : {"firstName" : {"type"        : "string",
                                "minLength" : 1},
                "salary"    : {"type"        : "number",
                                "minimum"    : 10000}},
 "required"    : ["firstName"]}
```

It specifies that a valid document is a JSON object that has a field `firstName` and optionally a field `salary`. The object can contain additional fields, besides `firstName`, which is required and which must be a string of at least one character, and `salary`, which is optional but if present must be a number at least as large as 10,000.

- Validating JSON Documents with a JSON Schema
  A JSON schema typically specifies the allowed structure and data typing of other JSON documents — their **validity** with respect to that schema. A typical use of a JSON schema is thus to validate JSON data.

- JSON Schema Validation With Type Casting To Extended Scalar Values
  If you use `VALIDATE CAST` in an `IS JSON` check constraint for a `JSON`-type column, then data to be inserted can be automatically type-cast to Oracle-specific JSON-language

scalar values, to accommodate the JSON schema. For example, an ISO 8601 date string can be converted to a JSON date value.

- Generating JSON Schemas
  You can generate (create) a JSON schema from an existing set of JSON documents or from other database objects/data.

- JSON Schemas Generated with DBMS_JSON_SCHEMA.DESCRIBE
  The mapping is described that PL/SQL function `DBMS_JSON_SCHEMA.describe` uses to generate a JSON schema from a database table, view, JSON-relational duality view, object-type instance, collection-type instance (varray or nested table), or domain.

- Explicitly Declaring Column Check Constraints Precheckable or Not
  When you create or alter a table you can explicitly declare individual column check constraints to be precheckable (or not) outside the database. If any constraint you declare to be precheckable is not actually precheckable then an error is raised.

6.1 Validating JSON Documents with a JSON Schema

A JSON schema typically specifies the allowed structure and data typing of other JSON documents — their **validity** with respect to that schema. A typical use of a JSON schema is thus to validate JSON data.

You can validate JSON data against a JSON schema in any of these ways:

- Use condition `is json` (or `is` **not** `json`) with keyword **VALIDATE** and the name of a JSON schema, to test whether targeted data is valid (or invalid) against that schema. The schema can be provided as a literal string or an application usage domain. Keyword `VALIDATE` can optionally be followed by keyword `USING`.

  You can use `VALIDATE` with condition `is json` anywhere you can use that condition. This includes use in a `WHERE` clause, or as a check constraint to ensure that only valid data is inserted in a column. Example 6-1 illustrates its use in a `WHERE` clause.

  When used as a check constraint for a `JSON`-type column, you can alternatively omit `is json`, and just use keyword `VALIDATE` directly. These two table creations are equivalent, for a `JSON`-type column:

```
CREATE TABLE tab (jcol JSON VALIDATE '{"type" : "object"}');
```

```
CREATE TABLE tab (jcol JSON CONSTRAINT jchk
  CHECK (jcol IS JSON VALIDATE '{"type" : "object"}'));
```

When using `VALIDATE` with condition `is json` as a check constraint, if the JSON schema specifies that a field in the data to be inserted must satisfy an `extendedType` requirement of being of an Oracle-specific JSON-language scalar type, such as date, then by default a scalar value that's not of that type causes the insertion to fail, even if the value could be type-cast to the required type.

But if `VALIDATE` is used together with keyword **CAST**, then such type-casting is performed when possible. For example, an input string in a supported ISO 8601 date-time format can be automatically cast to a JSON-language date scalar value. See JSON Schema Validation With Type Casting To Extended Scalar Values.

- Use a domain as a check constraint for `JSON` type data. For example:

```
CREATE DOMAIN jd AS JSON CONSTRAINT jchkd
  CHECK (jd IS JSON VALIDATE '{"type" : "object"}');
```

```
CREATE TABLE jtab(jcol JSON DOMAIN jd);
```

When creating a domain from a schema, you can alternatively omit the constraint and `is json`, and just use keyword `VALIDATE` directly. This domain creation is equivalent to the previous one:

```
CREATE DOMAIN jd AS JSON VALIDATE '{"type" : "object"}';
```

- Use PL/SQL function or procedure **is_valid** in package `DBMS_JSON_SCHEMA`. You can use the function in SQL queries. It just returns `1` if the data is valid and `0` if invalid. The *procedure* returns an `OUT` parameter that indicates whether valid or invalid, and another `OUT` parameter that returns a JSON object that provides full information: the validity (`true` or `false`) and any reasons for invalidity.

  For example, this use of the procedure checks data `myjson` (`JSON`) against schema `myschema` (`JSON`), providing output in parameters `validity` (`BOOLEAN`) and `errors` (`JSON`).

```
DBMS_JSON_SCHEMA.is_valid(myjson, myschema, validity, errors);
```

- If you use *procedure* (not function) `is_valid`, then you have access to the validation errors report as an `OUT` parameter. If you use *function* `is_valid` then you don't have access to such a report. Instead of using function `is_valid`, you can use PL/SQL function `DBMS_JSON_SCHEMA.validate_report` in a SQL query to validate and return the same full validation information that the reporting `OUT` parameter of procedure `is_valid` provides, as a `JSON` type instance. The JSON data accepted by this function as input can be of data type `JSON` or `VARCHAR2` (not `CLOB` or `BLOB`).

  For example, this query tries to validate the textual JSON document that is the first argument against the JSON schema that is the second argument, and it returns a validation report as `myreport`.

```
SELECT DBMS_JSON_SCHEMA.validate_report('{"name" : "scott",
                                          "role" : "developer"}',
                                         '{"type" : "array"}')
  AS myreport;
```

- Use PL/SQL `JSON_ELEMENT_T` Boolean method `schema_validate()`. It accepts a JSON schema as argument, of type `JSON`, `VARCHAR2`, or `JSON_ELEMENT_T`.

  For example, if `d` is a PL/SQL instance of type `JSON_ELEMENT_T` then this code returns a `BOOLEAN` value that indicates whether the JSON data `d` is valid (`TRUE`) or not (`FALSE`) against the JSON schema passed as argument. That is, it checks whether the data is a JSON object.

  ```
  isvalid := d.schema_validate('{"type" : "object"}');
  ```

JSON Schema is itself defined as a JSON schema. That schema defines what the JSON Schema standard allows as a valid JSON schema; that is, it defines what forms of JSON document are JSON schemas. You can use PL/SQL function `DBMS_JSON_SCHEMA.is_schema_valid` to validate any JSON schema, that is, validate it against the JSON Schema-defining schema.

Static dictionary views **DBA_JSON_SCHEMA_COLUMNS**, **ALL_JSON_SCHEMA_COLUMNS**, and **USER_JSON_SCHEMA_COLUMNS** describe a JSON schema that you can use as a check constraint.

Each row of these views contains the name of the table, the JSON column, and the constraint defined by the JSON schema, as well as the JSON schema itself and an indication of whether the cast mode is specified for the JSON schema. Views `DBA_JSON_SCHEMA_COLUMNS` and `ALL_JSON_SCHEMA_COLUMNS` also contain the name of the table owner.

Example 6-1   Validating JSON Data Against a JSON Schema with Condition IS JSON

This query selects only data that validates against the literal JSON schema shown, which requires that field `PONumber` have a numeric value of at least `0`.

This works even if column `j_purchaseorder` was created without any schema validation check constraint.

```
SELECT po_document
  FROM j_purchaseorder
  WHERE po_document IS JSON VALIDATE
    '{"type"       : "object",
      "properties" : {"PONumber": {"type"    : "number",
                                   "minimum" : 0}}}'
```

6.2 JSON Schema Validation With Type Casting To Extended Scalar Values

If you use `VALIDATE CAST` in an `IS JSON` check constraint for a `JSON`-type column, then data to be inserted can be automatically type-cast to Oracle-specific JSON-language scalar values, to accommodate the JSON schema. For example, an ISO 8601 date string can be converted to a JSON date value.

If the JSON schema specifies that a field in the data to be inserted must satisfy an `extendedType` requirement of being of a particular Oracle-specific scalar type, then by default a scalar value that is not of that type causes the insertion to fail, even if the value could be type-cast to the required type. But if `VALIDATE` is used together with keyword **CAST**, then such scalar type-casting is performed when possible.

Example 6-2   JSON Schema Validation With Type Casting In an IS JSON Check Constraint

```
-- Constrain dataOfBirth to be of scalar type date.
CREATE TABLE mytable (
  jcol JSON VALIDATE
       '{"type"       : "object",
         "properties" : {"dateOfBirth" : {"extendedType" : "date"}}}');

-- Try to insert dataOfBirth field with ISO date string.
INSERT INTO mytable VALUES ('{"dateOfBirth" : "2018-04-11"}');

ERROR at line 1:
ORA-40875: JSON schema validation error

CREATE OR REPLACE TABLE mytable (
  jcol JSON VALIDATE CAST
       '{"type"       : "object",
         "properties" : {"dateOfBirth" : {"extendedType" : "date"}}}');
```

```
INSERT INTO mytable VALUES ('{"dateOfBirth" : "2018-04-11"}');

1 row created.

-- Query with item-method type() shows the value is a DATE.
SELECT d.jcol.dateOfBirth.type() FROM mytable d;

D.JCOL.DATEOFBIRTH.TYPE()
------------------------
date
```

Related Topics

- Validating JSON Documents with a JSON Schema
  A JSON schema typically specifies the allowed structure and data typing of other
  JSON documents — their **validity** with respect to that schema. A typical use of a
  JSON schema is thus to validate JSON data.

- Textual JSON Objects That Represent Extended Scalar Values
  Native binary JSON data (OSON format) extends the JSON language by adding
  scalar types, such as date, that correspond to SQL types and are not part of the
  JSON standard. Oracle Database also supports the use of textual JSON *objects*
  that *represent* JSON scalar values, including such nonstandard values.

6.3 Generating JSON Schemas

You can generate (create) a JSON schema from an existing set of JSON documents
or from other database objects/data.

If you generate a JSON schema from an existing set of JSON documents, the schema
is a hierarchical *JSON data guide*: a JSON document with fields (JSON Schema and
Oracle-specific) that describe the fields commonly found in the documents.

In general, a data guide serves as a guide to understanding the structure of an existing
set of JSON documents. As generated, it is typically not appropriate for validation
purposes, but it can serve as the basis for a manually defined schema to be used for
validating.

See Data-Guide Formats and Ways of Creating a Data Guide and Table 23-2.

Instead of generating a JSON schema from a set of JSON documents, you can
generate it from other database data. To do this you use PL/SQL function
DBMS_JSON_SCHEMA.**describe**, passing it any of the following to define the schema:

- An existing relational *table*, *view*, or JSON-relational *duality view*. It corresponds to
  an object in the JSON schema. See Table 6-1 for the mapping from a database
  table, view, or duality view to a JSON schema.

  The generated schema is not dependent on the table, view, or duality view. The
  definition of that database object is used only when the schema is generated; later
  changes to the object definition have no effect on the schema.

- An existing SQL user-defined *object-type* instance or *collection-type* instance (a varray or a nested table). An object-type instance corresponds to an object in the JSON schema. A collection-type instance corresponds to a JSON array. See Table 6-1 for the mapping from a database object-type or collection-type instance to a JSON schema.

  The generated schema is not dependent on the object or collection type. The definition of the type is used only when the schema is generated; later changes to the type definition have no effect on the schema.

  If the type of an object-type instance to be described is a subtype of another object type then the generated schema (description) includes all fields that correspond to attributes inherited from the supertype.

- An application usage *domain*.

  You can use a domain to indicate the intended use of data of a given type. A domain specification can include a data type, a default value, a collation specification, check constraints, display format, intended ordering, and domain-description metadata in JSON format. A domain does not define a subtype — it does not, itself, restrict the operations that can be performed on the data type that it informs.

  For example, a domain can specify that a given `VARCHAR2` column contains email addresses. It can impose relevant usage constraints and validation rules as check constraints.

- A SQL *synonym* for a SQL table, view, object type, collection type, domain, or duality view.

  The resulting JSON schema is the same as what would be generated from the table, view, object type, collection type, domain, or duality view.

See JSON Schemas Generated with DBMS_JSON_SCHEMA.DESCRIBE for the mapping from a database table, view, object type or collection type to a JSON schema.

6.4 JSON Schemas Generated with DBMS_JSON_SCHEMA.DESCRIBE

The mapping is described that PL/SQL function `DBMS_JSON_SCHEMA.describe` uses to generate a JSON schema from a database table, view, JSON-relational duality view, object-type instance, collection-type instance (varray or nested table), or domain.

Generating a schema from a database *synonym* is the same as generating it from the synonymous database object. For example, a JSON schema generated from a synonym of a table is the same as a schema generated directly from that table.

Table 6-1 specifies the mapping of the general properties of a database object (a table, view, JSON-relational duality view, object-type instance, or collection-type instance) to JSON Schema fields.

The Oracle-specific JSON Schema fields are `dbColumn`, `dbConstraintExpression`, `dbConstraintName`, `dbDomain`, `dbFieldProperties`, `dbForeignKey`, `dbNoPrecheck`, `dbObject`, `dbObjectProperties`, `dbObjectType`, `dbPrimaryKey`, `dbUnique`, `extendedType`, `sqlPrecision`, `sqlScale`, and `title`.

For a *table*, regular *view*, or JSON-relational *duality view*, schema field `dbObjectType` has value **`"table"`**, **`"view"`**, or **`"dualityView"`**, meaning that the schema was derived (generated) from a table, regular view, or duality view, respectively. Field `type` has value **`"object"`**, meaning that the schema expects valid JSON data to be a JSON object.

For an *object-type* or *collection-type* instance, schema field `dbObjectType` has value **`"type"`**, meaning that the schema was derived from a user-defined database data-type instance. Field `type` has value **`"object"`** or **`"array"`**, meaning that the schema was derived from an object-type instance or a collection-type instance, respectively, and that the schema expects valid JSON data to be a JSON object or array, respectively.

For an application usage domain, schema field `dbObjectType` has value **`"domain"`**, meaning that the schema was derived from a domain.

For the *columns* of a *table*, *view*, or *duality view*, and the *attributes* of an *object-type* instance, schema field **`properties`** has as its value a JSON object whose field names correspond to the column or attribute names. The value of each such schema field is a JSON object whose fields, together, specify the JSON values allowed as valid — a value that corresponds to the column or attribute value. For an object-type instance: if the object type is a subtype of another object type then the value of `properties` includes all fields that correspond to attributes inherited from the supertype.

Columns with a `NOT NULL` constraint correspond to mandatory fields in the data that is valid according to the generated JSON schema; these column names are the elements of the array value of schema field **`required`**. The names of primary-key columns and unique columns are the elements of the array value of schema field **`dbPrimaryKey`** and schema field **`dbUnique`**, respectively.

A schema describing a table includes a subschema for each column that has a check constraint for which there is *known* to be a corresponding JSON schema, provided that constraint is not declared `NOPRECHECK` in the table definition. The included subschema is the corresponding JSON schema — it *describes the data that's allowed in the column*

An application can use this column-description schema to validate data to be stored in the column before sending it to the database. If that application data is already in the form of JSON then it can use the JSON schema directly to perform this precheck. Otherwise, it can use it as a declarative specification (description) of what needs to be checked.

Any column check constraint that the database has determined *cannot be prechecked* (that is, has no corresponding JSON schema), or that has been declared NOPRECHECK in the table definition, is instead listed in the (array) value of schema field dbNoPrecheck.

When you use CREATE TABLE or ALTER TABLE the database *automatically* determines whether column check constraints are known to be precheckable. For constraints created or last altered prior to Oracle Database 23c, the precheckability is unknown, so the output of function describe includes no JSON schema for such a constraint, nor does it list the constraint in array dbNoPrecheck.

Known prECHECKability of column check constraints is also recorded in column **PRECHECK** of static dictionary views **ALL_CONSTRAINTS**, **DBA_CONSTRAINTS**, and **USER_CONSTRAINTS**. The column value is PRECHECK if the constraint has been determined to be precheckable, NOPRECHECK if it has been determined or declared manually not to be precheckable, and NULL if no determination or declaration has yet been made. By default, the value is thus NULL for check constraints created prior to Oracle Database Release 23c.

For the *elements* of a *collection-type* instance, schema field **items** has as value a JSON object whose fields, together, specify the JSON values allowed for each element of the JSON array — a value that corresponds to values allowed for the collection elements. Schema field **maxItems** specifies the maximum number of elements for the JSON array.

Table 6-1   JSON Schema Fields Derived From Properties of a Database Object

Field (Keyword)	Value Description
dbColumn *Oracle-specific.*	Name of the referenced column.
dbConstraintExpression *Oracle-specific.*	SQL expression defining a check constraint that has no equivalent JSON schema or that has been declared NOPRECHECK in the table definition. See dbNoPrecheck.
dbConstraintName *Oracle-specific.*	Name of a check constraint that has no equivalent JSON schema or that has been declared NOPRECHECK in the table definition. See dbNoPrecheck.
dbDomain *Oracle-specific.* Used only for annotation, not for validation.	Fully qualified name of the associated domain. Present only for a column that is associated with a domain.
dbFieldProperties *Oracle-specific.*	Information about which operations are allowed on a JSON-relational duality view *column* or a field in a JSON document supported by the view. The value is an array, with these possible elements: **"update"** and **"check"**. Their descriptions are the same as dbObjectProperties elements "updatable" and "check" (respectively), but for dbFieldProperties they apply only to the given column or its corresponding document field.

Table 6-1   (Cont.) JSON Schema Fields Derived From Properties of a Database Object

Field (Keyword)	Value Description
dbForeignKey *Oracle-specific.* Used only for annotation, not for validation.	A JSON array whose elements specify objects in the JSON value to be validated that correspond to foreign-key columns of the table or view.
dbNoPrecheck *Oracle-specific.*	Array of objects for check constraints that have no equivalent JSON schema or that have been declared NOPRECHECK in the table definition.. The fields in each object are dbConstraintName and dbConstraintExpression. Whether a given check constraint is precheckable is also available from column PRECHECK of static dictionary views ALL_CONSTRAINTS, DBA_CONSTRAINTS, and USER_CONSTRAINTS.
dbObject *Oracle-specific.*	Fully qualified name of the database object.

dbObjectProperties
 	
Oracle-specific.
	Information about which operations are allowed on a JSON-relational duality view as a whole. The value is an array, with these possible elements:
	
	• **"insertable"** — If present then allow insertion of an entire top-level JSON object into the view definition using standard INSERT syntax.
	• **"deletable"** — If present then allow deletion of an entire top-level JSON object from the view definition using standard DELETE syntax.
	• **"updatable"** — If present then allow all of these operations:
	  – Update entire top-level JSON objects.
	  – Update fields of existing objects.
	  – Insert new members into existing objects.
	  – Delete members from existing objects.
	• **"check"** — If present then one or more fields of a document supported by the view contribute to the calculation of the ETAG value (value of field etag of the object that is the value of document field _metadata).

dbObjectType *Oracle-specific.* Used only for annotation, not for validation.	The type of the database object that the schema is derived from: **"table"**, **"view"**, **"dualityView"**, **"type"**, or **"domain"**.
dbPrimaryKey *Oracle-specific.* Used only for annotation, not for validation.	A JSON array whose elements name fields in the JSON value to be validated that correspond to primary-key columns of the table or view.
dbUnique *Oracle-specific.* Used only for annotation, not for validation.	A JSON array whose elements name the fields in the JSON value to be validated that correspond to the unique columns of the table or view.

Table 6-1   (Cont.) JSON Schema Fields Derived From Properties of a Database Object

Field (Keyword)	Value Description
`description` Used only for annotation, not for validation.	A comment describing the JSON value to be validated by the schema — typically its intended purpose or meaning.
extendedType *Oracle-specific.*	The JSON-language types specified for the JSON value to be validated by the schema. The value is a string or an array of strings. The types named by the strings can include the standard types that are supported by standard JSON Schema keyword `type`. But they can also include the Oracle-specific types `"binary"`, `"double"`, `"float"`, `"date"`, `"timestamp"`, `"timestampTz"`, `"ymInterval"`, and `"dsInterval"`. If keywords `type` and `extendedType` are used together then they must specify compatible types; otherwise no data targeted by the fields is considered valid. (The validity of the schema itself is not affected by such incompatibility.) For validation provided by Oracle Database, JSON-language type compatibility is defined by whether Oracle SQL function `json_serialize` can convert between instances of the types — see Oracle SQL Function JSON_SERIALIZE.
`items`	A JSON object that specifies each element of a JSON array. For a schema derived from a collection type, its fields together specify a JSON value that corresponds to an element in an instance of the collection type.
`maxItems`	A JSON number that specifies the maximum number of elements allowed in a JSON array. For a schema derived from a collection type, it is the maximum number of elements allowed for an instance of the collection type.
`maxLength`	Maximum length, in characters, of the JSON string to be validated.
`minLength`	Minimum length, in characters, of the JSON string to be validated.
`properties`	A JSON object whose fields specify the values of the same fields in the JSON object to be validated. The fields specify data that corresponds to table or view column data or object-type attribute data.
`required`	A JSON array whose elements name the fields that are required in the JSON value to be validated. For a schema derived from a table or view, they name the `NOT NULL` columns of the table or view.

Table 6-1   (Cont.) JSON Schema Fields Derived From Properties of a Database Object

Field (Keyword)	Value Description
`sqlPrecision` *Oracle-specific.* Used only for annotation, not for validation.	The precision of instances of a JSON-language numeric type (`number`, `double`, `float`) or `timestamp` type.
`sqlScale` *Oracle-specific.* Used only for annotation, not for validation.	The scale of instances of JSON-language numeric types.
`title` Used only for annotation, not for validation.	*Oracle-specific* use: The name of the database object (table, view, JSON-relational duality view, object type, collection type, or domain) that the schema is derived from.
`type`	The JSON-language types specified for the JSON value to be validated by the schema. The value is a string or an array of strings. The types named by the strings include only the standard types (not Oracle-specific types), `"null"`, `"boolean"`, `"object"`, `"array"`, `"number"`, and `"string"`, as well as `"integer"` which matches any number with a zero fractional part.

6.5 Explicitly Declaring Column Check Constraints Precheckable or Not

When you create or alter a table you can explicitly declare individual column check constraints to be precheckable (or not) outside the database. If any constraint you declare to be precheckable is not actually precheckable then an error is raised.

A **precheckable** check constraint is one that (1) has an equivalent JSON schema and (2) has not been explicitly declared to *not* be precheckable.

If a column constraint is precheckable then an application can prevalidate data before sending it to the database. This client-side detection of invalid data can make an application more resilient and reduce potential system downtime.

If an application uses JSON data then it can use the equivalent JSON schema directly to perform the precheck. If not, the schema can serve as a description of the kind of validation that's needed.

When you create or alter a table, its column check constraints are *automatically* examined to see whether they are precheckable. This information about known precheckability is then made available in two places:

- The JSON schema produced by PL/SQL function **DBMS_JSON_SCHEMA.describe** for an existing table.

  The JSON schema that's equivalent to a check constraint is included in the schema that describes the table. Check constraints that are *not* precheckable are listed in table schema property `dbNoPrecheck`.

- Column **PRECHECK** of static dictionary views **ALL_CONSTRAINTS**, **DBA_CONSTRAINTS**, and **USER_CONSTRAINTS**.

  The view rows list check constraints. The value of column `PRECHECK` is `PRECHECK` if the constraint is known to be precheckable, `NOPRECHECK` if known to not be precheckable, and `NULL` otherwise.

  `NULL` indicates that the constraint's precheckability has not yet been determined (set). This is the case by default for constraints created prior to Oracle Database 23c.

You can explicitly prevent the creation or altering of a table that has a check constraint that is not precheckable. You do this by adding keyword **PRECHECK** to the constraint in a `CREATE` or `ALTER TABLE` statement. If the constraint is not precheckable then an error is raised.

In particular, you can use keyword `PRECHECK` with `ALTER TABLE` on column check constraints created before Oracle Database Release 23c, which introduced automatic determination of precheckability. If no error is raised for a constraint to which you apply keyword `PRECHECK`, the constraint is known to be precheckable. In that case, PL/SQL function `DBMS_JSON_SCHEMA.describe` and dictionary views `ALL_CONSTRAINTS`, `DBA_CONSTRAINTS`, and `USER_CONSTRAINTS` are handled as described above for a precheckable constraint.

If you use keyword **NOPRECHECK** then you are, in effect, declaring that the constraint is *not* precheckable, which generally means that the data won't be prechecked outside the database. Use of `NOPRECHECK` doesn't imply that there's no JSON schema equivalent to the constraint, and it doesn't prevent an application from prechecking. It just says not to expect that the data is precheckable.

By default, even if a column constraint is precheckable, and even if data to be inserted in the column is in fact prechecked by an application, the database still uses the check constraint to validate the data on its side. That is, the data is both prevalidated by the app and validated by the database.

If you add keywords **DISABLE RELY** to a constraint, along with keyword `PRECHECK`, then the database does *not* use the constraint to validate the column data, and it doesn't guarantee that the constraint is satisfied. The query optimizer *assumes* that the constraint is satisfied, so it generates an execution plan that might fail if the data is invalid. Use `DISABLE RELY` if you want *applications alone* to be responsible for validating the column data.

Example 6-3   Prechecking Column Constraints

Table `employees` of sample schema `hr` includes columns `salary` and `commission_pct`, as follows (from `describe hr.employees`):

```
Name            Null?    Type
-------------- -------- -----------
SALARY          NOT NULL NUMBER(8,2)
COMMISSION_PCT NOT NULL NUMBER(2,2)
```

In order to inform the database that applications expect to be able to precheck these two columns, a developer adds column constraints with keyword `PRECHECK`: the salary must be at least 2000, and the salary times the commission percentage must be less than 6000.

```
ALTER TABLE employees
  ADD CONSTRAINT min_salary CHECK (salary >= 2000) PRECHECK;

ALTER TABLE employees
  ADD CONSTRAINT max_bonus CHECK ((salary * commission_pct) < 6000) PRECHECK;
```

Check constraint `max_bonus` is not precheckable, because it has no equivalent JSON schema. As a result, the constraint creation raises an error.

```
ORA-40544: CHECK expression of 'MAX_BONUS' constraint not possible to use as PRECHECK
condition
```

Constraint `max_bonus` has no corresponding JSON schema, which by definition means that it's not "precheckable". An application *can* nevertheless prevalidate the salary and commission percentages of a row that it wants to insert or update, to ensure that the constraint is satisfied. It just can't do so using a JSON schema that's equivalent to the SQL expression `(salary * commission_pct) < 6000`.

`PRECHECK` needs to be removed from the constraint creation, for it to be accepted (no error raised):

```
ALTER TABLE employees
  ADD CONSTRAINT max_bonus CHECK ((salary * commission_pct) < 6000);
```

After defining the check constraints, the output of `DBMS_JSON_SCHEMA.describe` for table `hr.employees` includes the JSON schema that's equivalent to constraint `min_salary`, and the array value of field `dbNoPrecheck` contains an entry for constraint `max_bonus`.

```
SELECT DBMS_JSON_SCHEMA.describe('EMPLOYEES');
```

```
{"title"        : "EMPLOYEES",
 "dbObject"     : "HR.EMPLOYEES",
 "dbObjectType" : "table",
 ...
 "dbNoPrecheck" : [ {"dbConstraintName"       : "MAX_BONUS",
```

```
                    "dbConstraintExpression" :
                      "(salary * commission_pct) < 6000"} ],
 ...
 "properties"      : {...
                    "SALARY" : {"extendedType" : "number",
                                "allOf"       : [ {"exclusiveMinimum" : 2000} ]}
                    ...
                  }}
```

Character Sets and Character Encoding for JSON Data

JSON data always uses the Unicode character set. In this respect, JSON data is simpler to use than XML data. This is an important part of the JSON Data Interchange Format (RFC 8259). For JSON data processed by Oracle Database, any needed character-set conversions are performed automatically.

Oracle Database uses character set UTF-8 internally when it processes JSON data (parsing, querying). If the data that is input to such processing, or the data that is output from it, must be in a different character set from UTF-8, then character-set conversion is carried out accordingly.

Character-set conversion can affect performance. And in some cases it can be **lossy**. Conversion of input data to UTF-8 is a lossless operation, but conversion to output can result in *information loss* in the case of characters that cannot be represented in the output character set.

If your JSON data is stored in the database as *Unicode* then no character-set conversion is needed for storage or retrieval. This is the case if any of these conditions apply:

- Your JSON data is stored as `JSON` type or `BLOB` instances.

- The database character set is AL32UTF8 (Unicode UTF-8).

- Your JSON data is stored as `CLOB` instances that have character set AL16UTF16.

Oracle recommends that you store JSON data using `JSON` data type *and* that you use AL32UTF8 as the database character set if at all possible.

Regardless of the database character set, JSON data that is stored using data type `JSON` or `BLOB` never undergoes character-set conversion for storage or retrieval. JSON data can be stored using data type `BLOB` as AL32UTF8, AL16UTF16, or AL16UTF16LE.

If you *transform* JSON data using SQL/JSON functions or PL/SQL methods and you return the result of the transformation using data type `BLOB` then the result is encoded as AL32UTF8. This is true even if the input `BLOB` data uses another Unicode encoding.

For example, if you use SQL/JSON function `json_query` to extract some JSON data from `BLOB` input and return the result as `BLOB`, it is returned using AL32UTF8.

Lossy character-set conversion can occur if application of a SQL/JSON function or a PL/SQL method specifies a return data type of `VARCHAR2` or `CLOB` and the database character set is not AL32UTF8. If input JSON data was stored in a `BLOB` or `JSON` type instance then, even if it is ultimately written again as `BLOB` or `JSON` type, if some of it was temporarily changed to `VARCHAR2` or `CLOB` then the resulting `BLOB` data can suffer from lossy conversion. This can happen, for example, if you use Oracle SQL function `json_serialize`.

8
Considerations When Using LOB Storage for JSON Data

LOB storage considerations for JSON data are described, including considerations when you use a client to retrieve JSON data as a LOB instance.

General Considerations

When database initialization parameter `compatible` is at least `20`, Oracle recommends that you use `JSON` data type to store JSON data, not LOB storage. But if you do use LOB storage then Oracle recommends that you use `BLOB`, not `CLOB` storage.
Using `BLOB` instead of `CLOB` storage is particularly relevant if the database character set is the Oracle-recommended value of AL32UTF8. In AL32UTF8 databases, `CLOB` instances are stored using the UCS2 character set, which means that each character requires two bytes. This doubles the storage needed for a document if most of its content consists of characters that are represented using a single byte in character set AL32UTF8.

Even in cases where the database character set is not AL32UTF8, choosing `BLOB` over `CLOB` storage has the advantage that it avoids the need for character-set conversion when storing the JSON document (see Character Sets and Character Encoding for JSON Data).

When using large objects (LOBs), Oracle recommends that you do the following:

- Use the clause **LOB (***COLUMN_NAME***) STORE AS (CACHE)** in your `CREATE TABLE` statement, to ensure that read operations on the JSON documents are optimized using the database buffer cache.

- Use SecureFiles LOBs.

SQL/JSON functions and conditions work with JSON data without any special considerations, whether the data is stored as `BLOB` or `CLOB`. From an application-development perspective, the API calls for working with `BLOB` content are nearly identical to those for working with `CLOB` content.

A downside of choosing `BLOB` storage over `CLOB` (for JSON or any other kind of data) is that it is sometimes more difficult to work with `BLOB` content using command-line tools such as SQL*Plus. For instance:

- When selecting data from a `BLOB` column, if you want to view it as printable text then you must use SQL function `to_clob`.

- When performing insert or update operations on a `BLOB` column, you must explicitly convert character strings to `BLOB` format using SQL function `rawtohex`.[1]

---

[1] The return value of SQL function `rawtohex` is limited to 32767 bytes. The value is truncated to remove any converted data beyond this length.

> - *Oracle Database SQL Language Reference* for information about SQL function `rawtohex`

Considerations When Using a Client To Retrieve JSON Data As a LOB Instance

If you use a client, such as Oracle Call Interface (OCI) or Java Database Connectivity (JDBC), to retrieve JSON data from the database then the following considerations apply.

There are three main ways for a client to retrieve a LOB that contains JSON data from the database:

- Use the LOB locator interface, with a LOB locator returned by a SQL/JSON operation[2]
- Use the LOB data interface
- Read the LOB content directly

In general, Oracle recommends that you use the LOB data interface or you read the content directly.

If you use the LOB locator interface:

- Be aware that the LOB is *temporary* and *read-only*.
- Be sure to read the content of the current LOB *completely* before fetching the next row. The next row fetch can render this content *unreadable*.

  Save this current-LOB content, in memory or to disk, if your client continues to need it after the next row fetch.

- *Free* the fetched LOB locator after each row is read. Otherwise, performance can be reduced, and memory can leak.

Consider also these *optimizations* if you use the LOB locator interface:

- Set the LOB prefetch size to a large value, such as 256 KB, to minimize the number of round trips needed for fetching.
- Set the batch fetch size to a large value, such as 1000 rows.

Example 8-1 and Example 8-2 show how to use the LOB locator interface with JDBC.

Example 8-3 and Example 8-4 show how to use the LOB locator interface with ODP.NET.

Each of these examples fetches a LOB row at a time. To ensure that the current LOB content remains readable after the next row fetch, it also reads the full content.

If you use the LOB data interface:

---

[2] The SQL/JSON functions that can return a LOB locator are these, when used with `RETURNING CLOB` or `RETURNING BLOB`: `json_serialize`, `json_value`, `json_query`, `json_table`, `json_array`, `json_object`, `json_arrayagg`, and `json_objectagg`.

- In OCI, use data types `SQLT_BIN` and `SQLT_CHR`, for `BLOB` and `CLOB` data, respectively.
- In JDBC, use data types `LONGVARBINARY` and `LONGVARCHAR`, for `BLOB` and `CLOB` data, respectively.

Example 8-5 and Example 8-6 show how to use the LOB data interface with JDBC.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide*

Example 8-7 and Example 8-8 show how to read the full LOB content *directly* with JDBC.

Example 8-9 and Example 8-10 show how to read the full LOB content *directly* with ODP.NET.

Example 8-1   JDBC Client: Using the LOB Locator Interface To Retrieve JSON BLOB Data

```
static void test_JSON_SERIALIZE_BLOB() throws Exception {
  try(
      OracleConnection conn = getConnection();
      OracleStatement stmt = (OracleStatement)conn.createStatement();
      ) {
    stmt.setFetchSize(1000); // Set batch fetch size to 1000 rows.

    // Set LOB prefetch size to be 256 KB.
    ((OraclePreparedStatement)stmt).setLobPrefetchSize(256000);

    // Query the JSON data in column jblob of table myTab1,
    // serializing the returned JSON data as a textual BLOB instance.
    String query =
      "SELECT json_serialize(jblob RETURNING BLOB) FROM myTab1";
    ResultSet rs = stmt.executeQuery(query);

    while(rs.next()) { // Iterate over the returned rows.
      Blob blob = rs.getBlob(1);

      // Do something with the BLOB instance for the row...

      // Read full content, to be able to access past current row.
      String val =
        new String(blob.getBytes(1,
                                 (int)blob.length()),
                                 StandardCharsets.UTF_8);

      // Free the LOB at the end of each iteration.
      blob.free();
    }
    rs.close();
    stmt.close();
```

```
    }
}
```

Example 8-2   JDBC Client: Using the LOB Locator Interface To Retrieve JSON CLOB Data

```
static void test_JSON_SERIALIZE_CLOB() throws Exception {
  try(
      OracleConnection conn = getConnection();
      OracleStatement stmt = (OracleStatement)conn.createStatement();
      ){
    stmt.setFetchSize(1000); // Set batch fetch size to 1000 rows.

    // Set LOB prefetch size to be 256 KB.
    ((OraclePreparedStatement)stmt).setLobPrefetchSize(256000);

    // Query the JSON data in column jclob of table myTab2,
    // serializing the returned JSON data as a textual CLOB instance.
    //
    // Note: If your client driver does not support Oracle Database
    // 21c and later then keyword VALUE is ignored, so the LOB is
    // returned by reference instead of by value.
    String query =
      "SELECT json_serialize(jclob RETURNING CLOB VALUE) FROM myTab2";

    ResultSet rs = stmt.executeQuery(query);

    while(rs.next()) { // Iterate over the returned rows.
      Clob clob = rs.getClob(1);

      // Do something with the CLOB instance for the row...

      // Read full content, to be able to access past current row.
      String val = clob.getSubString(1, (int)clob.length());

      // Free the LOB at the end of each iteration.
      //
      // If your client driver supports Oracle Database 21c and
      // later then you need not call free().
      clob.free();
    }
    rs.close();
    stmt.close();
  }
}
```

Example 8-3   ODP.NET Client: Using the LOB Locator Interface To Retrieve JSON BLOB Data

```
static void test_JSON_SERIALIZE_BLOB()
{
  try
  {
    using (OracleConnection conn =
```

```
  new OracleConnection(
    "user id=<schema>;password=<password>;data source=oracle"))
{
  conn.Open();
  OracleCommand cmd = conn.CreateCommand();

  // Set LOB prefetch size to be 256 KB.
  cmd.InitialLOBFetchSize = 256000;

  // Query the JSON  data in column jblob of table myTab1,
  // serializing the returned JSON data as a textual BLOB instance.
  cmd.CommandText =
    "SELECT json_serialize(jblob RETURNING BLOB) FROM myTab1";

  OracleDataReader rs = cmd.ExecuteReader();

  // Iterate over the returned rows.
  while (rs.Read())
  {
    OracleBlob blob = rs.GetOracleBlob(0);

    // Do something with the BLOB instance for the row...

    // Read full content, to be able to access past current row.
    String val = Encoding.UTF8.GetString(blob.Value);

    blob.Close();
    blob.Dispose();
  }
  rs.Close();
  }
}
catch (Exception e)
{
  throw e;
}
}
```

Example 8-4   ODP.NET Client: Using the LOB Locator Interface To Retrieve JSON CLOB Data

```
static void test_JSON_SERIALIZE_CLOB()
{
  try
  {
    using (OracleConnection conn =
      new OracleConnection(
        "user id=<schema>;password=<password>;data source=oracle"))
    {
      conn.Open();
      OracleCommand cmd = conn.CreateCommand();

      // Set LOB prefetch size to be 256 KB.
```

```
    cmd.InitialLOBFetchSize = 256000;

    // Query the JSON data in column jclob of table myTab2,
    // serializing the returned JSON data as a textual CLOB instance.
    cmd.CommandText =
      "SELECT json_serialize(jclob RETURNING CLOB) FROM myTab2";

    OracleDataReader rs = cmd.ExecuteReader();

    // Iterate over the returned rows.
    while (rs.Read())
    {
      OracleClob clob = rs.GetOracleClob(0);

      // Do something with the CLOB instance for the row...

      // Read full content, to be able to access past current row.
      String val = clob.Value;

      clob.Close();
      clob.Dispose();
    }
    rs.Close();
  }
}
catch (Exception e)
{
  throw e;
}
}
```

Example 8-5   JDBC Client: Using the LOB Data Interface To Retrieve JSON BLOB Data

```
static void test_JSON_SERIALIZE_LONGVARBINARY() throws Exception {
  try(
      OracleConnection conn = getConnection();
      OracleStatement  stmt = (OracleStatement)conn.createStatement();
      ){

    // Query the JSON data in column jblob of table myTab1,
    // serializing the returned JSON data as a textual BLOB instance.
    String query =
      "SELECT json_serialize(jblob RETURNING BLOB) FROM myTab1";
    stmt.defineColumnType(1, OracleTypes.LONGVARBINARY, 1);
    ResultSet rs = stmt.executeQuery(query);

    while(rs.next()) { // Iterate over the returned rows.
      BufferedReader br =
        new BufferedReader(
              new InputStreamReader(rs.getBinaryStream( 1 )));
      int size = 0;
      int data = 0;
```

```
        data = br.read();
        while( -1 != data ){
            System.out.print( (char)(data) );
          data = br.read();
          size++;
        }
        br.close();
    }
    rs.close();
    stmt.close();
  }
}
```

Example 8-6   JDBC Client: Using the LOB Data Interface To Retrieve JSON CLOB Data

```
static void test_JSON_SERIALIZE_LONGVARCHAR() throws Exception {
  try(
      OracleConnection conn = getConnection();
      OracleStatement  stmt = (OracleStatement)conn.createStatement();
      ){

    // Query the JSON data in column jclob of table myTab2,
    // serializing the returned JSON data as a textual CLOB instance.
    String query =
      "SELECT json_serialize(jclob RETURNING CLOB) FROM myTab2";
    stmt.defineColumnType(1, OracleTypes.LONGVARCHAR, 1);
    ResultSet rs = stmt.executeQuery(query);

    while(rs.next()) { // Iterate over the returned rows.
      Reader reader = rs.getCharacterStream(1);
      int size = 0;
      int data = 0;
      data = reader.read();
      while( -1 != data ){
        System.out.print( (char)(data) );
        data = reader.read();
        size++;
      }
      reader.close();
    }
    rs.close();
    stmt.close();
  }
}
```

Example 8-7   JDBC Client: Reading Full BLOB Content Directly with getBytes

```
static void test_JSON_SERIALIZE_BLOB_2() throws Exception {
  try(
      OracleConnection con = getConnection();
      OracleStatement stmt = (OracleStatement)con.createStatement();
      ){
    stmt.setFetchSize(1000); // Set batch fetch size to 1000 rows.
```

```
    // set LOB prefetch size to be 256 KB.
    ((OracleStatement)stmt).setLobPrefetchSize(256000);

    // Query the JSON data in column jblob of table myTab1,
    // serializing the returned JSON data as a textual BLOB instance.
    String query =
      "SELECT json_serialize(jblob RETURNING BLOB) FROM myTab1";
    ResultSet rs = stmt.executeQuery(query);

    while(rs.next()) { // Iterate over the returned rows.
      String val = new String(rs.getBytes(1), StandardCharsets.UTF_8);
    }
    rs.close();
    stmt.close();
    }
  }
```

Example 8-8   JDBC Client:Reading Full CLOB Content Directly with getString

```
static void test_JSON_SERIALIZE_CLOB_2() throws Exception {
  try(
      OracleConnection conn = getConnection();
      OracleStatement  stmt = (OracleStatement)conn.createStatement();
      ){
    stmt.setFetchSize(1000); // Set batch fetch size to 1000 rows.

    // Set LOB prefetch size to be 256 KB.
    ((OracleStatement)stmt).setLobPrefetchSize(256000);

    // Query the JSON data in column jclob of table myTab2,
    // serializing the returned JSON data as a textual CLOB instance.
    String query =
      "SELECT json_serialize(jclob RETURNING CLOB) FROM myTab2";
    ResultSet rs = stmt.executeQuery(query);

    while(rs.next()) { // Iterate over the returned rows.
      String val = rs.getString(1);
    }
    rs.close();
    stmt.close();
    }
  }
```

Example 8-9   ODP.NET Client: Reading Full BLOB Content Directly with getBytes

```
static void test_JSON_SERIALIZE_BLOB_2()
{
  try
  {
    using (OracleConnection conn =
      new OracleConnection(
        "user id=scott;password=tiger;data source=oracle"))
    {
```

```
        conn.Open();
        OracleCommand cmd = conn.CreateCommand();

        // Set LOB prefetch size to be 256 KB.
        cmd.InitialLOBFetchSize = 256000;

        // Query the JSON data in column blob of table myTab1,
        // serializing the returned JSON data as a textual BLOB instance.

        cmd.CommandText =
          "SELECT json_serialize(blob RETURNING BLOB) FROM myTab1";
        OracleDataReader rs = cmd.ExecuteReader();

        // Iterate over the returned rows.
        while (rs.Read())
        {
          long len = rs.GetBytes(0, 0, null, 0, 0); /* Get LOB length */
          byte[] obuf = new byte[len];
          rs.GetBytes(0, 0, obuf, 0, (int)len);
          String val = Encoding.UTF8.GetString(obuf);
        }
        rs.Close();
      }
    }
  catch (Exception e)
  {
    throw e;
  }
}
```

Example 8-10   ODP.NET Client: Reading Full CLOB Content Directly with getString

```
static void test_JSON_SERIALIZE_CLOB_2()
{
  try
  {
    using (OracleConnection conn =
      new OracleConnection(
        "user id=<schema>;password=<password>;data source=oracle"))
    {
      conn.Open();
      OracleCommand cmd = conn.CreateCommand();

      // Set LOB prefetch size to be 256 KB.
      cmd.InitialLOBFetchSize = 256000;

      // Query the JSON data in column clob of table myTab2,
      // serializing the returned JSON data as a textual CLOB instance.

      cmd.CommandText =
        "SELECT json_serialize(clob RETURNING CLOB) FROM myTab2";

      OracleDataReader rs = cmd.ExecuteReader();
```

```
      // Iterate over the returned rows.
      while (rs.Read())
      {
        String val = rs.GetString(0);
      }
      rs.Close();
    }
  }
  catch (Exception e)
  {
    throw e;
  }
}
```

9
Partitioning JSON Data

You can partition a table using a JSON virtual column as the partitioning key. The virtual column is extracted from a JSON column using SQL/JSON function `json_value`.

Partition on a Non-JSON Column When Possible

You can partition a table using a JSON virtual column, but it is generally preferable to use a non-JSON column. A partitioning key specifies which partition a new row is inserted into. A partitioning key defined as a JSON virtual column uses SQL/JSON function `json_value`, and the partition-defining `json_value` expression is *evaluated each time a row is inserted*. This can be costly, especially for insertion of large JSON documents.

Rules for Partitioning a Table Using a JSON Virtual Column

- The virtual column that serves as the partitioning key must be defined using SQL/JSON function `json_value`.

- The data type of the virtual column is defined by the `RETURNING` clause used for the `json_value` expression.

- The `json_value` path used to extract the data for the virtual column must not contain any predicates. (The path must be streamable.)

- The JSON column referenced by the expression that defines the virtual column can have an `is json` check constraint, but it *need not* have such a constraint.

> ✏️ **See Also:**
>
> *Oracle Database SQL Language Reference* for information about `CREATE TABLE`

Example 9-1   Creating a Partitioned Table Using a JSON Virtual Column

This example creates table `j_purchaseorder_partitioned`, which is partitioned using virtual column `po_num_vc`. That virtual column references JSON column `po_document` (which uses `CLOB` storage). The `json_value` expression that defines the virtual column extracts JSON field `PONumber` from `po_document` as a number.

```
CREATE TABLE j_purchaseorder_partitioned
  (id VARCHAR2 (32) NOT NULL PRIMARY KEY,
   date_loaded TIMESTAMP (6) WITH TIME ZONE,
   po_document JSON,
   po_num_vc NUMBER GENERATED ALWAYS AS
     (json_value (po_document, '$.PONumber' RETURNING NUMBER)))
  PARTITION BY RANGE (po_num_vc)
   (PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (2000));
```

10
Replication of JSON Data

You can use Oracle GoldenGate, Oracle XStreams, Oracle Data Guard, or Oracle Active Data Guard to replicate tables that have columns containing JSON data.

In particular, you can replicate textual JSON data (`VARCHAR2`, `CLOB`, or `BLOB`) in the primary server to `JSON` type data in the secondary. You can also replicate textual data to textual data or `JSON` type data to `JSON` type data.

All *indexes* on the JSON data are also replicated also. However, on the replica database, you must carry out any Oracle Text operations that you use to maintain a JSON search index. Here are examples of such procedures:

- `CTX_DDL.sync_index`

- `CTX_DDL.optimize_index`

Be aware that Oracle GoldenGate requires tables that are to be replicated to have a nonvirtual primary key column; the *primary key column cannot be virtual*.

Part III

Insert, Update, and Load JSON Data

The usual ways to insert, update, and load data in Oracle Database work with JSON data. You can also create an external table from the content of a JSON dump file.

- Overview of Inserting, Updating, and Loading JSON Data
  You can use database APIs to insert or modify JSON data in Oracle Database. You can use Oracle SQL function `json_transform` or `json_mergepatch` to update a JSON document. You can work directly with JSON data contained in file-system files by creating an external table that exposes it to the database.

- Oracle SQL Function JSON_TRANSFORM
  Oracle SQL function `json_transform` modifies JSON documents. You specify *operations* to perform and SQL/JSON path expressions that target the *places to modify*. The operations are applied to the input data in the order specified: each operation acts on the data that results from applying all of the preceding operations.

- Oracle SQL Function JSON_MERGEPATCH
  You can use Oracle SQL function `json_mergepatch` to update specific portions of a JSON document. You pass it a JSON Merge Patch document, which specifies the changes to make to a specified JSON document. JSON Merge Patch is an IETF standard.

- Loading External JSON Data
  You can create a database table of JSON data from the content of a JSON dump file.

11

Overview of Inserting, Updating, and Loading JSON Data

You can use database APIs to insert or modify JSON data in Oracle Database. You can use Oracle SQL function `json_transform` or `json_mergepatch` to update a JSON document. You can work directly with JSON data contained in file-system files by creating an external table that exposes it to the database.

Use Standard Database APIs to Insert or Update JSON Data

All of the usual database APIs used to insert or update `VARCHAR2` and large-object (LOB) columns can be used for JSON columns. If the JSON column is of data type `JSON` (recommended) then textual data you input is automatically converted to `JSON` type.

If you insert or update a JSON column using a client (such as JDBC for Java or Oracle Call Interface for C and C++) that supports `JSON` type then you can bind client data directly to `JSON` type instances — no conversion from text to `JSON` type is needed.

A column of data type `JSON` is *always* well-formed JSON data. If you use another data type to store JSON data then you specify that a JSON column must contain only well-formed JSON data by using SQL condition `is json` as a check constraint.

The database handles an `is json` check constraint the same as any other check constraint — it enforces rules about the content of the column. Working with a column of type `VARCHAR2`, `BLOB`, or `CLOB` that contains JSON documents is thus no different from working with any other column of that type.

For `JSON` type data, condition `is json` is inappropriate, except if you use keywords `DISALLOW SCALARS` (which disallows JSON documents with top-level scalars). Use of any other `is json` keywords with `JSON` type data raises an error.

Inserting a JSON document into a JSON column, or updating data in such a column, is straightforward if the column is of data type `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. See Example 4-3 for an example of using SQL to insert.

You can also use a client, such as JDBC for Java or Oracle Call Interface for C or C++, to do this. You can even use an older client, which does not support or recognize `JSON` data type, to insert JSON data into a `JSON` type column — the data is implicitly converted for `JSON` type.

> **✎ Note:**
>
> In addition to the usual ways to insert, update, and load JSON data, you can use *Simple Oracle Document Access* (SODA) APIs. SODA is designed for schemaless application development without knowledge of relational database features or languages such as SQL and PL/SQL. It lets you create and store collections of documents of any kind (not just JSON), retrieve them, and query them, without needing to know how the documents are stored in the database. SODA also provides query features that are specific for JSON documents. There are implementations of SODA for several languages, as well as for representational state transfer (REST). See Simple Oracle Document Access (SODA).

Use JSON Transform or JSON Merge Patch To Update a JSON Document

You can use Oracle SQL function `json_transform` or `json_mergepatch` to modify specific portions of a JSON document. These functions are not only for updating stored JSON data. You can also use them to modify JSON data on the fly, for further use in a query. The database need not be updated to reflect the modified data.

In addition to providing the input JSON data to each function, you provide the following:

- For `json_transform`, a sequence of modification operations to be performed on parts of the data. Each operation consists of the operation name (e.g. `REMOVE`) followed by pairs of (1) a SQL/JSON path expression that targets some data to modify and (2) an update operation to be performed on that data. The operations are applied to the input data, in the order specified. Each operation acts on the result of applying the preceding operations.

- For `json_mergepatch`, a JSON Merge Patch document, which is a JSON document that specifies the changes to make to a given JSON document. JSON Merge Patch is an IETF standard.

`json_transform` provides a superset of what you can do with `json_mergepatch`.

When `json_transform` updates a JSON document on disk, the operation is typically performed in place, *piecewise*, if the data is `JSON` type; the entire document need not be replaced. Other methods of updating might replace the entire document. With such methods you can specify fine-grained modifications for a JSON document, but when you need to save the changes to disk the entire updated document is written.

Updating with `json_transform` (regardless of the data type) is also piecewise in another sense: you specify only the document pieces to change, and how. A client need send only the locations of changes (using SQL/JSON path expressions) and the update operations to be performed. This contrasts with sending a complete document to be modified and receiving the complete modified document in return.

On the other hand, `json_mergepatch` can be easier to use in some contexts where the patch document is *generated* by comparing two versions of a document. You need not specify or think in terms of specific modification locations and operations — the generated patch takes care of where to make changes, and the changes to be made are implicit. For example, the database can pass part of a JSON document to a client, which changes it in some way and passes back the update patch for the document

fragment. The database can then apply the patch to the stored document using `json_mergepatch`.

Use PL/SQL Object Types To Update a JSON Document

Oracle SQL functions `json_transform` and `json_mergepatch` let you modify JSON data in a *declarative* way. For `json_transform`, you specify where to make changes and what changes to make, but now in detail how to make them. For `json_mergepatch`, you specify document-version differences: a patch.

For complex use cases that are not easily handled by these SQL functions you can use PL/SQL code — in particular JSON PL/SQL object-type methods, such as `remove()` — to modify JSON data *procedurally*. There are no limitations on the kinds of changes you can make with PL/SQL (it is a Turing-complete programming language). You can parse JSON data into an instance of object-type `JSON_ELEMENT_T`, make changes to it, serialize it (if textual JSON data is needed), and then store it back in the database.

Use an External Table to Work With JSON Data in File-System Files

External tables make it easy to access JSON documents that are stored as separate files in a file system. Each file can be exposed to Oracle Database as a row in an external table. An external table can also provide access to the content of a dump file produced by a NoSQL database. You can use an external table of JSON documents to, in effect, *query the data in file-system files directly*. This can be useful if you need only process the data from all of the files in a one-time operation.

But if you instead need to make multiple queries of the documents, and especially if different queries select data from different rows of the external table (different documents), then for better performance consider copying the data from the external table into an ordinary database table, using an `INSERT` as `SELECT` statement — see Example 14-4. Once the JSON data has been loaded into a JSON column of an ordinary table, you can index the content, and then you can efficiently query the data in a repetitive, selective way.

12

Oracle SQL Function JSON_TRANSFORM

Oracle SQL function `json_transform` modifies JSON documents. You specify *operations* to perform and SQL/JSON path expressions that target the *places to modify*. The operations are applied to the input data in the order specified: each operation acts on the data that results from applying all of the preceding operations.

Function `json_transform` is *atomic*: if attempting any of the operations raises an error then none of the operations take effect. `json_transform` either succeeds completely, so that the data is modified as required, or the data remains unchanged. `json_transform` returns the original data, modified as expressed by the arguments.

You can use `json_transform` in a SQL `UPDATE` statement, to update the documents in a JSON column. Example 12-1 illustrates this.

You can use it in a `SELECT` list, to modify the selected documents. The modified documents can be returned or processed further. Example 12-2 illustrates this.

Function `json_transform` can accept as input, and return as output, any SQL data type that supports JSON data: `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. (Data type `JSON` is available only if database initialization parameter `compatible` is `20` or greater.)

The default return (output) data type is the same as the input data type.

Unlike Oracle SQL function `json_mergepatch`, which has limited applicability (it is suitable for updating JSON documents that primarily use *objects* for their structure, and that do not make use of explicit `null` values), `json_transform` is a *general* modification function.

When you specify more than one operation to be performed by a single invocation of `json_transform`, the operations are performed in sequence, in the order specified. Each operation thus acts on the data that results from applying all of the preceding operations.

Following the sequence of operations you specify, you can include optional `RETURNING` and `PASSING` clauses.

- The `RETURNING` clause specifies the return data type. It is the same as for SQL/JSON function `json_query`. (However, the *default* return type for `json_query` is different: for `JSON` type input the `json_query` default return type is also `JSON`, but for other input types it is `VARCHAR2(4000)`.)

- The `PASSING` clause specifies SQL bindings of bind variables to SQL/JSON variables. It is the same as for SQL/JSON condition `json_exists` and the SQL/JSON query functions.

The last part of an operation specification is an optional set of *handlers*. Different operations allow different handlers and provide different handler defaults. (An error is raised if you provide a handler for an operation that disallows it.)

Most `json_transform` operations modify your data directly. Operations `NESTED PATH` and `CASE` can modify data indirectly, by controlling the performance of other operations. The same is

---

[1] Do not confuse the SQL return type for function `json_transform` with the type of the SQL *result expression* that follows an equal sign (**=**) in a modification operation.

true of a `SET` operation used to set a SQL/JSON variable: the variable value can affect the behavior of operations that directly modify data.

Here is a brief description of the `json_transform` operations. See JSON_TRANSFORM Operations and NESTED PATH Operation: Scoping a Sequence of Operations for more complete descriptions.

- `APPEND` — Append values to an array.

- `CASE` — Conditionally perform `json_transform` operations.

- `COPY` — Replace the elements of an array.

- `INSERT` — Insert data at a given location (an object field value or an array position).

- `INTERSECT` — Remove array elements other than those in a specified set (set intersection). Remove any duplicates. The operation can accept a sequence of *multiple values* matched by the RHS path expression.

- `KEEP` — Remove the data that's *not* targeted by any of the specified path expressions.

- `MERGE` — Merge specified fields into an object (possibly creating the object).

- `MINUS` — Remove a set of array elements (set difference). Remove any duplicates. The operation can accept a sequence of *multiple values* matched by the RHS path expression.

- `NESTED PATH` — Define a scope (a particular part of your data) in which to apply a sequence of operations.

- `PREPEND` — Prepend values to an array.

- `REMOVE` — Remove the data that's specified by a path expression.

- `RENAME` — Rename a field.

- `REPLACE` — Replace data at a given location.

- `SET` — Set a SQL/JSON variable to a specified value, or insert or replace data at a given location.

- `SORT` — Sort the elements of an array (change their order).

- `UNION` — Add missing array elements from a specified set (set union). Remove any duplicates.

JSON_TRANSFORM Path Expressions: Targeted Data and RHS

Immediately following the keyword for each kind of operation is the path expression for the data targeted by that operation.

Operation `KEEP` is an *exception* in that the keyword is followed by one *or more* path expressions, which target the data to keep — all data *not* targeted by at least one of these path expressions is removed.

For all *modification* operations *except* `KEEP`, `REMOVE`, and `SORT`, the path expression is followed by an equal sign (**=**) and then a *result expression*. This is evaluated and the resulting value is used to modify the targeted data. [1]

- For operation `RENAME`, the result expression must evaluate to a SQL string. Otherwise, an error is raised.

- For all *modification* operations *except* `RENAME`, the result expression must evaluate to a SQL value that is of `JSON` data type or that can be rendered as a JSON value. Otherwise, an error is raised because of the inappropriate SQL data type. (This is the same requirement as for the value part of a name–value pair provided to SQL/JSON generation function `json_object`.)

- If the result expression evaluates to a SQL value that is not `JSON` type, you can convert it to JSON data by following the expression immediately with keywords **FORMAT JSON**. This is particularly useful to convert the SQL string `'true'` or `'false'` to the corresponding JSON-language value `true` or `false`. Example 12-7 illustrates this.

The path expression to the left of the equal sign, which targets the JSON data to update, is sometimes referred to as the **left-hand side**, or **LHS**. The LHS is always a SQL/JSON path expression.

The result expression is sometimes referred to as the **right-hand side**, or **RHS** of the operation.

The RHS can be either[2] a SQL expression or keyword **PATH** followed by a SQL/JSON path expression wrapped with single quotation marks (').

A `json_transform` RHS path expression is more general that the path expressions allowed elsewhere. It is an expression that can combine multiple path expressions using elementary *arithmetic operations*: **+** (addition), **–** (subtraction), ***** (multiplication), and **/** (division), and you can nest or otherwise group these operations. The only restriction on using arithmetic operations is that you cannot use them within a predicate. For example, this use of a `+` operation in a predicate raises an error at compile time:

```
$.a?(@.x == (@.y + 4)).b - 2
```

An RHS path expression can also include SQL/JSON *variables*, which are either assigned in previous `json_transform` operations or are passed from SQL using a `PASSING` clause that follows the RHS path expression.

For example, this `SET` operation updates the value of field `compensation` to be the sum of these values, where the variable values are passed using a `PASSING` clause.

- Field `salary` multiplied by `0.02`, passed to the path expression as SQL/JSON variable `$factor`

- field `commission`

- `1000`, passed as SQL/JSON variable `$bonus`

```
SET '$.compensation' = PATH '($.salary * $factor) + $.commission + $bonus'
                            PASSING 1000 AS "bonus", 0.02 AS "factor"
```

This example is equivalent. It uses operation `SET` to assign the two variables:

```
SET '$bonus' = 1000,
SET '$factor' = 0.02,
SET '$.compensation' = PATH '($.salary * $factor) + $.commission + $bonus'
```

---

[2] An error is raised if you include both a SQL expression and a path expression.

An RHS can use one or more relative path expressions, where an at-sign character (`@`) refers to the current node as defined by the innermost enclosing `NESTED PATH` context.

`$` in an RHS refers to the current node of the top-level context. If there is no enclosing `NESTED PATH` expression then `@` is the same as `$` in an RHS path expression.

An RHS path expression can specify a single value or a sequence of values. Anything else raises an error. For most operations it must target a single JSON value. (But such a single value could be the result of aggregating multiple values, for example `$.a[*].sum()`.)

However, for operations that expect (require) an LHS that targets an *array* and that accept an *RHS path expression*, that path expression can yield a *sequence* of multiple values. (A single matching value is treated as a sequence of that one value.) These operations are `APPEND`, `PREPEND`, `COPY`, `MINUS`, `UNION`, and `INTERSECT`.

For example, with any of these operations, the RHS path expression `$.b[0 to 2]` yields, as a sequence, the first through third *elements* of the array that is the value of field `b`.

If a path expression in an RHS targets an array, then the entire array is used as the (single) value to be combined with the LHS array.[3]

But if the RHS explicitly targets some or all *elements* of an array, then those elements are used as a sequence of multiple values. These values are combined with the targeted array *together*, in a single operation. For operations such as `APPEND` and `PREPEND`, which add the RHS sequence values to the LHS array, the order of the sequence values is thus preserved in the resulting array.

For example, supposing that array `a` has value `[30,20]` and array `b` has value `[2,4,6,8]`.

- This operation prepends array `b` as a single element to `a`:

  ```
  PREPEND '$.a' = PATH '$.b'
  ```

  Array `a` is set to the value `[[2,4,6,8],30,20]`.

- This operation prepends the second and fourth elements of array `b` to array `a`:

  ```
  PREPEND '$.a' = PATH '$.b[2,4]'
  ```

  The multiple values matched by the RHS path expression are prepended to array `a` *together*, not individually (a single act prepends them all), so the sequence order is reflected in the resulting array. Array `a` is set to `[4,8,30,20]`, *not* `[8,4,30,20]`.

- This operation prepends all elements of array `b`, together, to array `a`:

  ```
  PREPEND '$.a' = PATH '$.b[*]'
  ```

  Array `a` is set to `[2,4,6,8,30,20]`.

---

[3] This is, in effect, just a case of handling a single RHS path-matching value, in this case an array, as if it were a singleton sequence of that value.

> **Note:**
>
> PREPEND and INTERSECT are the only LHS array-targeting operations for which it really matters that multiple values matching an RHS path expression are handled *together*, as a block, as opposed to being handled, in order, *individually*.
>
> For example, if RHS path-matching values 3 and 4 are APPENDed, together as a unit, to LHS-targeted array [1,2], the result is the same as if elements 3 and 4 are appended individually, in turn, to the array. The result is in both cases [1,2,3,4]. Adding 3, then 4 is the same as adding 3 and 4 together, keeping them in sequence order.
>
> In the case of INTERSECT, if multiple RHS values (with at least two that differ) were handled individually then the result would be the empty array, []. In effect, after handling the first value in the sequence the resulting intersection would be the singleton array with that value. Handling a different value in the sequence would then result in an empty intersection.

JSON_TRANSFORM Operations

Operation NESTED PATH is described in [NESTED PATH Operation: Scoping a Sequence of Operations](#). This section describes the other json_transform operations:

*   **REMOVE** — Remove the input data that's targeted by the specified path expression. An error is raised if you try to remove all of the data; that is, you *cannot* use REMOVE '$'. By default, *no* error is raised if the targeted data does not exist (IGNORE ON MISSING).

*   **KEEP** — Remove *all* parts of the input data that are *not* targeted by at least one of the specified path expressions. A *topmost* object or array is not removed; it is *emptied*, becoming an empty object ({}) or array ([]).

    You can downscope the use of operation KEEP by using it within a NESTED PATH operation. Data outside the scope defined by the nested path is unaffected by the KEEP pruning. [Example 12-15](#) illustrates this.

*   **RENAME** — Rename the field that's targeted by the specified path expression to the value of the SQL expression that follows the equal sign (=). By default, *no* error is raised if the targeted field does not exist (IGNORE ON MISSING).

*   **SET** — Set what the LHS specifies to the value specified by what follows the equal sign (=). The LHS can be either a SQL/JSON variable or a path expression that targets data.

    –   When the LHS specifies a SQL/JSON *variable*, the variable is dynamically assigned to whatever is specified by the RHS. (The variable is created if it does not yet exist.) The variable continues to have that value until it is set to a different value by a subsequent SET operation (in the same json_tranform invocation).

        If the RHS is a SQL expression then its value is assigned to the LHS variable. If the RHS is a path expression then its targeted data is assigned to the variable.

        Setting a variable is a control operation; it can affect how subsequent operations modify data, but it does not, itself, directly modify data.

    –   When the LHS specifies a *path expression*, the default behavior is like that of SQL UPSERT: *replace* existing targeted data with the new value, or *insert* the new value at

the targeted location if the path expression matches nothing. (See operator `INSERT` about inserting an array element past the end of the array.)

- **`REPLACE`** — Replace the data that's targeted by the specified path expression with the value of the specified SQL expression that follows the equal sign (=). By default, *no* error is raised if the targeted data does not exist (`IGNORE ON MISSING`).

  (`REPLACE` has the effect of `SET` with clause `IGNORE ON MISSING`.)

- **`INSERT`** — Insert the value of the specified SQL expression at the location that's targeted by the specified path expression that follows the equal sign (=), which must be either the field of an object or an array position (otherwise, an error is raised). By default, an error is raised if a targeted object field already exists.

  (`INSERT` for an object field has the effect of `SET` with clause `CREATE ON MISSING` (default for `SET`), except that the default behavior for `ON EXISTING` is `ERROR`, not `REPLACE`.)

  You can specify an array position *past* the current end of an array. In that case, the array is lengthened to accommodate insertion of the value at the indicated position, and the intervening positions are filled with JSON `null` values.

  For example, if the input JSON data is `{"a":["b"]}` then `INSERT '$.a[3]'=42` returns `{"a":["b", null, null 42]}` as the modified data. The elements at array positions 1 and 2 are `null`.

- **`APPEND`** — Append the values that are specified by the RHS to the array that's targeted by the LHS path expression. The operation can accept a sequence of *multiple values* matched by the RHS path expression.

  An error is raised if the LHS path expression targets an existing field whose value is not an array.

  `APPEND` has the effect of `INSERT` for an array position of `last+1`.

  If the RHS targets an array then the LHS array is updated by appending the elements of the RHS array to it, in order. See Example 12-10.

  > 💡 **Tip:**
  >
  > You can use handler `CREATE ON MISSING` to create a missing array-valued field targeted by the LHS, filling it from the values specified by the RHS. For example:
  >
  > ```
  > SELECT json_transform('{"a":[1,2,3]}',
  >                       APPEND '$.b' = PATH '$.a[0,2]'
  >                       CREATE ON MISSING)
  >   FROM DUAL;
  > ```
  >
  > That results in this data:
  >
  > ```
  > { "a" : [1,2,3], "b" : [1,3] }
  > ```

- **`PREPEND`** — Prepend the values that are specified by the RHS to the array that's targeted by the LHS path expression. The operation can accept a sequence of *multiple values* matched by the RHS path expression.

An error is raised if the LHS path expression targets an existing field whose value is not an array.

When prepending a single value, `PREPEND` has the effect of `INSERT` for an array position of `0`.

If the RHS targets an array then the LHS array is updated by prepending the elements of the RHS array to it, in order.

See also:

– Note about multiple values matching the RHS path expression of a `PREPEND` operation being handled together, not individually

– Example 12-11.

• **COPY** — Replace the elements of the array that's targeted by the LHS path expression with the values that are specified by the RHS. An error is raised if the LHS path expression does not target an array. The operation can accept a sequence of *multiple values* matched by the RHS path expression.

• **MINUS** — Remove all elements of the array that's targeted by the LHS path expression that are equal to a value specified by the RHS. Remove any duplicate elements. **Note:** This is a *set*-intersection operation; the order of *all* array elements is undefined after the operation.

• **INTERSECT** — Remove all elements of the array that's targeted by the LHS path expression that are *not* equal to any value specified by the RHS. Remove any duplicate elements. **Note:** This is a *set*-intersection operation; the order of *all* array elements is undefined after the operation.

See also: Note about multiple values matching the RHS path expression of an `INTERSECT` operation being handled together, not individually.

• **UNION** — Add the values specified by the RHS to the array that's targeted by the LHS path expression. Remove any duplicate elements. The operation can accept a sequence of *multiple values* matched by the RHS path expression.

Note: This is a *set*-intersection operation; the order of *all* array elements is undefined after the operation.

• **SORT** — Sort the elements of the array targeted by the specified path. The result includes all elements of the array (none are dropped); the only possible change is that they are reordered.

There are two ways to sort. With either way you can use the keywords **REMOVE NULLS**, which removes any JSON `null` values from the values to be sorted.

– *Basic element sort:* Sort the array elements by their *values*, according to the canonical `JSON`-type sort order.

The path to the targeted array is optionally followed by keyword **ASC** (default) or **DESC**, for ascending or descending sort order, respectively, *or* by keyword **REVERSE**, which means reverse the order of the elements.

The path and optional keyword `ASC` or `DESC` is optionally followed by keyword **UNIQUE**, which means remove any duplicate array elements.

– *Path-directed sort:* Sort array elements by the values targeted in an **ORDER BY** clause, which specifies one or more paths relative to the array.

Each path is optionally followed by keyword **ASC** (default) or **DESC**, for ascending or descending sort order, respectively.

Sort each pair of elements first by comparing the values targeted by the first ORDER BY path, then by comparing the values targeted by the second ORDER BY path, and so on.

Each step in a path must be *simple*: it must target a single JSON value: an array step must target a single array element. A step cannot be a descendant step or include a predicate, a wildcard, or an item method. Otherwise, a compile-time error is raised.

The simplest example is just ORDER BY followed by the single path @. Being relative to the array, this means order the array elements by comparing each of them with each of the others. In other words, ORDER BY '@' is just another way to specify the basic element sort.

Each ORDER BY path is checked, in turn, against each pair of array elements.

* If *one* element of the pair is matched by the path and the other is not, then the element that is not matched sorts before the element that is matched (after it, with keyword DESC).

* Otherwise (neither element is matched by the path *or* both elements are matched by it):

    * If this is the *last* path to be checked, then the two elements sort according to their values, using the canonical JSON-type sort order (a deep comparison is done). The element with the lower value sorts before the other (after it, with keyword DESC).

    * Otherwise, the order of the two elements is not determined by this path alone — check the same pair using the next ORDER BY path.

Reasons for an ORDER BY path to *not* match for a given element include a value of the wrong type and a missing value. These are examples of not matching an array element *E*:

* The path targets a string but the targeted value within *E* is a number (wrong type).

* The path targets a field of an object, but there is no such object or no such field within *E* (missing value).

* The path targets an array element that is out of bounds (missing value).

The single-path clause ORDER BY '@.name' sorts an array having these elements as follows:

```
[ "cat", "dog", {"animal":cat"}, {"name":"cow"}, {"name":"horse"} ]
```

– Elements "cat", "dog", and {"animal":cat"} don't match the path. They sort before the other elements, and they are sorted by their canonical values.

– Elements {"name":"cow"} and {"name":"horse"} match the path. They are sorted after the other elements, and they are sorted by their values of field name.

The two-path clause ORDER BY '@.name', '@.age' DESC sorts an array having these elements as follows:

```
[ "cat", "dog", {"animal":cat"},
  {"name":"cow"}, {"name":"cow", "age":2},
```

```
{"name":"horse", "age":6, "color":"black"},
{"name":"horse", "age":3} ]
```

- – Elements `"cat"`, `"dog"`, and `{"animal":cat"}` don't match either path. They sort before the other elements, and they are sorted by their canonical values.

- – Element `{"name":"cow"}` matches only the first path. It sorts before the elements that match both paths.

- – Elements `{"name":"cow", "age":2}`, `{"name":"horse", "age":6,` `"color":"black"}`, and `{"name":"horse", "age":3}` match both paths. They sort after the other elements, and they are sorted by their values of, first, field `name` (ascending), and then, field `age` (descending).

- **MERGE** — Add fields (name and value) matched by the RHS path expression to the object that's targeted by the LHS path expression. Ignore any fields specified by the RHS that are already in the targeted LHS object. If the same field is specified more than once by the RHS then use only the last one in the sequence of matches.

> 💡 **Tip:**
>
> You can use handler `CREATE ON MISSING` to create a missing object targeted by the LHS, filling it from the fields specified by the RHS.

- **CASE** — Conditionally perform a sequence of `json_transform` operations.

  This is a control operation; it conditionally applies other operations, which in turn can modify data.

  The *syntax* is keyword `CASE` followed by zero or more `WHEN` clauses, followed optionally by an `ELSE` clause, followed by `END`.

  - – A **WHEN** clause is keyword `WHEN` followed by a path expression, followed by a `THEN` clause.

    The path expression contains a filter condition, which checks for the existence of some data.

  - – A **THEN** or an **ELSE** clause is keyword `THEN` or `ELSE`, respectively, followed by parentheses (`()`) containing zero or more `json_transform` operations.

    The operations of a `THEN` clause are performed if the condition of its `WHEN` clause is satisfied. The operations of the optional `ELSE` clause are performed if the condition of *no* `WHEN` clause is satisfied.

  The syntax of the `json_transform CASE` operation is thus essentially the same as an Oracle SQL searched `CASE` expression, the differences being (1) the predicate that's tested and (2) the resulting effect of each `THEN`/`ELSE` branch.

  - – For SQL, the predicate tested is a SQL comparison. For `json_transform`, the predicate is a path expression that checks for the existence of some data. (The check is essentially done using `json_exists`.)

  - – For SQL, each `THEN`/`ELSE` branch holds a SQL expression to evaluate, and its value is returned as the result of the `CASE` expression. For `json_transform`, each `THEN`/`ELSE` branch holds a (parenthesized) sequence of `json_transform` operations, which are performed in order.

The conditional path expressions of the `WHEN` clauses are tested in order, until one succeeds (those that follow are not tested). The `THEN` operations for the successful `WHEN` test are then performed, in order.

If none of the `WHEN` tests succeeds and there is an `ELSE` clause then its operations are performed, in order.

NESTED PATH Operation: Scoping a Sequence of Operations

A nested-path operation defines a scope — a particular part of your data — in which to apply a sequence of operations. The main use case for a nested-path operation is *iterating over array elements*.

As a construct for downscoping, a nested-path operation limits modification to a subset of your data. It is not, itself, a modification operation.

The operations performed within the scope of a nested-path operation can include other nested-path operations. That is, you can use a nested path within a nested path,..., defining narrower scopes within wider ones, to act on data at any level. In particular, nested paths let you act on the elements of an array nested anywhere.

A nested scope is defined by a *target path* that immediately follows keywords **NESTED PATH** (keyword `PATH` can be omitted). That path is followed by the sequence of *scoped operations*, within parentheses (`(`, `)`).

The *context item for the target path* is specified in that path using `$`, if the `NESTED PATH` operation with that target is in the topmost (outermost) context. It is specified using `@` otherwise, that is, if the `NESTED PATH` operation with that target is inside another `NESTED PATH`.

The targeted data specified by the target path becomes the *context item for the scoped operations*. In those operations, it is denoted `@`, instead of `$`.

For example, `'$.employees[*]'` can be used as the target path in the topmost context; `'@.employees[*]'` can be used as the target path in a nested scope. The object with targeted field `employees` is at the top level in the first case; it is at some lower level in the second case.

In either case, the target path defines each element in array `employees` as the context item for the scoped operations — *each operation is applied to one of those elements at a time, in array order*.

Similarly, `'$.employees[2 to 10]'` applies the scoped operations to the third through eleventh employees, in turn; and `'$.employees[3,7]'` applies them to the fourth and then the seventh employee. (Likewise, with `@` in place of `$`.)

In the following code, the targeted path is `$.LineItems[*]`, so occurrences of `@` in the parenthesized sequence of operations are an abbreviation for `$.LineItems[*]`. This code changes the `UnitPrice` of each element in array `LineItems`, by multiplying it by `1.02`.

```
NESTED PATH '$.LineItems[*]'
  (SET '@.UnitPrice' = PATH '@.UnitPrice * 1.02'
```

Note that to target each of the elements of an array, instead of the array itself, you must *explicitly include* `[*]` after the name of the targeted field whose value is the array — there is no implicit iteration. You can target the array itself (for example

'`$.employees`') if, in a scoped operation, you want to refer to specific array elements, such as the third element, `@[2]`, but this is not a common use case.

You *cannot* use `$` in the *LHS* of an operation in a nested-path scope; you must use `@` instead. This is another way of saying that the transformation/modification for a nested scope is limited to that scope; the operations performed cannot act outside it.

You can, however, use `$` in the *RHS* of a scoped operation. For example, this code first gives each employee a raise of 10% (`*` factor `1.1`), and then assigns each employee the same bonus, which is the value of **$**`.department.bonus`.

```
NESTED PATH '$.employees[*]'
  (SET '@.salary' = PATH '@.salary * 1.1',
   SET '@.bonus'  = PATH '$.department.bonus')
```

Occurrences of `$` in the RHS of a scoped operation always refer to the topmost (outermost) context of the `json_transform` invocation.

Within a nested operation (to reiterate):

- `@` refers to the data targeted by the nested path.

- `$` refers to the topmost (outermost) context item, and it can only be used in the RHS of an operation.

JSON_TRANSFORM Operation Handlers

These are the handlers for `json_transform` operations:

- **ON EMPTY** — Specifies what happens if a value targeted by an RHS is JSON `null` or is missing.

    – **NULL** ON EMPTY — Return JSON `null`.

    – **ERROR** ON EMPTY — Raise an error.

    – **IGNORE** ON EMPTY — Leave the data unchanged (no modification).

- **ON ERROR** — Specifies what happens if trying to resolve an RHS path results in an error.

    – **NULL** ON ERROR — Return JSON `null`.

    – **ERROR** ON ERROR — Raise an error.

    – **IGNORE** ON ERROR — Leave the data unchanged (no modification).

- **ON EXISTING** — Specifies what happens if a path expression matches the data; that is, it targets at least one value. (This handler is irrelevant, and so is ignored, for an LHS that is a SQL/JSON variable.)

    – **ERROR** ON EXISTING — Raise an error.

    – **IGNORE** ON EXISTING — Leave the data unchanged (no modification).

    – **REPLACE** ON EXISTING — Replace data at the targeted location with the value of the SQL result expression.

    – **REMOVE** ON EXISTING — Remove the targeted data.

- **ON MISMATCH** — Specifies what happens if the type of the data targeted by the LHS is unexpected. It applies, in particular, to a MERGE operation, which requires the (LHS)

targeted data to be an *object*, and to operations that require the targeted data to be an *array*.

  – **NULL** ON MISMATCH — Return JSON `null`.

  – **ERROR** ON MISMATCH — Raise an error.

  – **IGNORE** ON MISMATCH — Leave the data unchanged (no modification).

  – **CREATE** ON MISMATCH — Wrap the targeted value in a (singleton) array.

  – **REPLACE** ON MISMATCH — Replace the targeted value with the *empty* array (`[]`).

* **ON MISSING** — Specifies what happens if a path expression does *not* match the data; that is, it does not target at least one value. (This handler is irrelevant, and so is ignored, for an LHS that is a SQL/JSON variable.)

  – **ERROR** ON MISSING — Raise an error.

  – **IGNORE** ON MISSING — Leave the data unchanged (no modification).

  – **CREATE** ON MISSING — Add data at the targeted location.

  Note that for a path-expression *array step*, an ON MISSING handler does *not* mean that the targeted array itself is missing from the data — that is instead covered by handler ON EMPTY. An ON MISSING handler covers the case where *one or more of the positions* specified by the array step does not match the data. For example, array step [2] does not match data array ["a", "b"] because that array has no element at position 2.

* **ON NULL** — Specifies what happens if the value of the RHS SQL result expression is NULL. (This handler applies only when the RHS is a SQL expression. If the RHS uses keyword PATH then ON NULL is ignored.)

  – **NULL** ON NULL — Use a JSON **null** value for the targeted location.

  – **ERROR** ON NULL — Raise an error.

  – **IGNORE** ON NULL — Leave the data unchanged (no modification).

  – **REMOVE** ON NULL — Remove the targeted data.

  The default behavior for all handlers that allow ON NULL is NULL ON NULL.

The handlers allowed for the various operations are as follows.

* **APPEND**:

  – ERROR ON MISSING (default), IGNORE ON MISSING, CREATE ON MISSING, NULL ON MISSING. Create means insert a singleton array at the targeted location. The single array element is the value of the SQL result expression.

  – ERROR ON MISMATCH (default), IGNORE ON MISMATCH, REPLACE ON MISMATCH, CREATE ON MISMATCH.

  – NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL.

  – IGNORE ON EMPTY (default), ERROR ON EMPTY.

* **CASE**: *no* handlers.

* **COPY**:

- — CREATE ON MISSING (default), IGNORE ON MISSING, ERROR ON MISSING, NULL ON MISSING.

- — NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL.

- — IGNORE ON EMPTY (default), ERROR ON EMPTY.

- **INSERT**:

  - — ERROR ON EXISTING (default), IGNORE ON EXISTING, REPLACE ON EXISTING.

  - — CREATE ON MISSING (default).

  - — NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL, REMOVE ON NULL.

  - — ERROR ON ERROR (default), IGNORE ON ERROR.

- **INTERSECT**:

  - — ERROR ON MISSING (default), IGNORE ON MISSING, CREATE ON MISSING, NULL ON MISSING.

  - — ERROR ON MISMATCH (default).

  - — NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL.

- **KEEP**: IGNORE ON MISSING (default), ERROR ON MISSING.

- **MERGE**:

  - — ERROR ON MISSING (default), IGNORE ON MISSING, CREATE ON MISSING, NULL ON MISSING.

  - — ERROR ON MISMATCH (default), IGNORE ON MISMATCH.

  - — NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL.

  - — ERROR ON EMPTY (default), IGNORE ON EMPTY.

- **MINUS**:

  - — ERROR ON MISSING (default), IGNORE ON MISSING, CREATE ON MISSING.

  - — ERROR ON MISMATCH (default).

  - — NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL.

- **NESTED PATH**: *no* handlers.

- **PREPEND**: Same as APPEND.

- **REMOVE**:

  - — REMOVE ON EXISTING (default).

  - — IGNORE ON MISSING (default), ERROR ON MISSING.

- **RENAME**:

  - — REPLACE ON EXISTING (default).

  - — IGNORE ON MISSING (default), ERROR ON MISSING.

- **REPLACE**:

  - — REPLACE ON EXISTING (default).

  - — IGNORE ON MISSING (default), ERROR ON MISSING, CREATE ON MISSING.

- NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL, REMOVE ON NULL.

- NULL ON EMPTY (default), IGNORE ON EMPTY, ERROR ON EMPTY.

- ERROR ON ERROR (default), IGNORE ON ERROR.

- **SET**:

  - REPLACE ON EXISTING (default), IGNORE ON EXISTING, ERROR ON EXISTING.

  - CREATE ON MISSING (default), IGNORE ON MISSING, ERROR ON MISSING.

  - NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL, REMOVE ON NULL.

  - NULL ON EMPTY (default), IGNORE ON EMPTY, ERROR ON EMPTY.

  - ERROR ON ERROR (default), IGNORE ON ERROR.

- **SORT**:

  - IGNORE ON MISSING (default), ERROR ON MISSING, NULL ON MISSING.

  - IGNORE ON MISMATCH (default), ERROR ON MISMATCH, NULL ON MISMATCH.

  - ERROR ON EMPTY (default), IGNORE ON EMPTY.

- **UNION**:

  - ERROR ON MISSING (default), IGNORE ON MISSING, CREATE ON MISSING, NULL ON MISSING.

  - ERROR ON MISMATCH (default).

  - NULL ON NULL (default), IGNORE ON NULL, ERROR ON NULL.

- **WHEN**: *no* handlers

Example 12-1   Updating a JSON Column Using JSON_TRANSFORM

This example updates all documents in j_purchaseorder.po_document, setting the value of field lastUpdated to the current timestamp.

If the field already exists then its value is replaced; otherwise, the field and its value are added. (That is, the default handlers are used: REPLACE ON EXISTING and CREATE ON MISSING.)

```
UPDATE j_purchaseorder SET po_document =
  json_transform(po_document, SET '$.lastUpdated' = SYSTIMESTAMP);
```

Example 12-2   Modifying JSON Data On the Fly With JSON_TRANSFORM

This example selects all documents in j_purchaseorder.po_document, returning pretty-printed, updated copies of them, where field "Special Instructions" has been removed.

It does nothing (no error is raised) if the field does not exist: IGNORE ON MISSING is the default behavior.

The return data type is CLOB. (Keyword PRETTY is not available for JSON type.)

```
SELECT json_transform(po_document,
                      REMOVE '$."Special Instructions"'
```

```
                           RETURNING CLOB PRETTY)
       FROM j_purchaseorder;
```

Example 12-3   Adding a Field Using JSON_TRANSFORM

These two uses of json_tranform are equivalent. They each add field Comments with value
"Helpful". An error is raised if the field already exists. The input for the field value is literal
SQL string 'Helpful'. The default behavior for SET is CREATE ON MISSING.

```
json_transform(po_document, INSERT '$.Comments' = 'Helpful')
```

```
json_transform(po_document, SET '$.Comments' = 'Helpful'
                                      ERROR ON EXISTING)
```

Example 12-4   Removing a Field Using JSON_TRANSFORM

This example removes occurrences of field LineItems where the value of field
LineItems.Part.UPCCode is 85391628927. It does nothing (no error is raised) if the field does
not exist: IGNORE ON MISSING is the default behavior.

```
json_transform(po_document,
               REMOVE '$.LineItems?(@.Part.UPCCode == $v1)'
               PASSING 85391628927 AS "v1")
```

The UPC code used for filtering is provided as the value of SQL/JSON variable $v1, which
corresponds to SQL bind variable v1 from the PASSING clause. This technique avoids query
recompilation, which can be important for queries that you use often.

Example 12-5   Creating or Replacing a Field Value Using JSON_TRANSFORM

This example sets the value of field Address to the JSON object {"street":"8 Timbly
Lane", "city":"Penobsky", "state":"Utah"}. It *creates* the field if it does not exist, and it
replaces any existing value for the field. The input for the field value is a literal SQL string.
The updated field value is a JSON object, because FORMAT JSON is specified for the input
value.

```
json_transform(po_document,
               SET '$.Address' =
                    '{"street":"8 Timbly Rd.",
                      "city":"Penobsky",
                      "state":"UT"}'
                    FORMAT JSON)
```

If database initialization parameter compatible is 20 or greater than an alternative to using
keywords FORMAT JSON is to apply JSON data type constructor JSON to the input data for the
field value.

```
json_transform(po_document,
               SET '$.Address' =
                    JSON('{"street":"8 Timbly Rd.",
```

```
                              "city":"Penobsky",
                              "state":"UT"}'))
```

Without using either `FORMAT JSON` or constructor `JSON`, the `Address` field value would be a JSON *string* that corresponds to the SQL input string. Each of the double-quote (`"`) characters in the input would be escaped in the JSON string:

```
"{\"street\":\"8 Timbly Rd.\","city\":\"Penobsky\",\"state\":\"UT\"}"
```

Example 12-6   Replacing an Existing Field Value Using JSON_TRANSFORM

This example sets the value of field `Address` to the JSON object `{"street":"8 Timbly Lane", "city":"Penobsky", "state":"Utah"}`. It replaces an existing value for the field, and it does nothing if the field does not exist. The only difference between this example and Example 12-5 is the presence of handler `IGNORE ON MISSING`.

```
json_transform(po_document,
               SET '$.Address' =
                   '{"street":"8 Timbly Rd.",
                     "city":"Penobsky",
                     "state":"UT"}'
                   FORMAT JSON
                   IGNORE ON MISSING)
```

Example 12-7   Using FORMAT JSON To Set a JSON Boolean Value

This example sets the value of field `AllowPartialShipment` to the JSON-language Boolean value `true`. Without keywords `FORMAT JSON` it would instead set the field to the JSON-language *string* `"true"`.

```
json_transform(po_document,
               SET '$.AllowPartialShipment' = 'true' FORMAT JSON)
```

Example 12-8   Setting an Array Element Using JSON_TRANSFORM

This example sets the first element of array `Phone` to the JSON string `"909-555-1212"`.

```
json_transform(po_document,
               SET '$.ShippingInstructions.Phone[0]' = '909-555-1212')
```

If the value of array `Phone` before the operation is this:

```
[ {"type":"Office","number":"909-555-7307"},
  {"type":"Mobile","number":"415-555-1234"} ]
```

Then this is the value after the modification:

```
[ "909-555-1212",
  {"type":"Mobile","number":415-555-1234"} ]
```

Chapter 12

Example 12-9   Appending an Element To an Array Using JSON_TRANSFORM

These two uses of `json_tranform` are equivalent. They each append element
`"909-555-1212"` to array `Phone`.

```
json_transform(po_document,
               APPEND '$.ShippingInstructions.Phone' =
                      '909-555-1212')
```

```
json_transform(po_document,
               INSERT '$.ShippingInstructions.Phone[last+1]' =
                      '909-555-1212')
```

Example 12-10   Appending Multiple Elements To an Array Using JSON_TRANSFORM

This example appends phone numbers `"415-555-1234"` and `"909-555-1212"`, in that order,
to each `Phone` field whose value is an array. Nonarray `Phone` fields are ignored (not matched).
So each resulting `Phone` field ends with `[ ..., "415-555-1234", "909-555-1212" ]`.

The elements to append, and the order in which to append them, are provided here by an
array, which in this case is the literal JSON value `[ "415-555-1234", "909-555-1212" ]`,
constructed in SQL using the `JSON` constructor.

This array is passed to the `APPEND` operation as the value of SQL/JSON variable `$new`. The
elements to be appended are all of the array elements, in order; they are specified in the
RHS path expression using `[*]`.

```
json_transform(po_document,
               SET '$new' = JSON('[ "415-555-1234", "909-555-1212" ]'),
               APPEND '$.ShippingInstructions.Phone' =
                      PATH '$new[*]')
```

As an alternative to using the JSON constructor, you can use `FORMAT JSON`:

```
json_transform(po_document,
               SET '$new' = '[ "415-555-1234", "909-555-1212" ]' FORMAT JSON,
               APPEND '$.ShippingInstructions.Phone' =
                      PATH '$new[*]')
```

Example 12-11   Prepending Multiple Elements To an Array Using JSON_TRANSFORM

This example is similar to Example 12-10. It prepends phone numbers `"415-555-1234"` and
`"909-555-1212"` to each `Phone` field whose value is an array. So each resulting `Phone` field
starts with `["415-555-1234", "909-555-1212",...]`.

```
json_transform(po_document,
               SET '$new' = JSON('[ "415-555-1234", "909-555-1212" ]'),
               PREPEND '$.ShippingInstructions.Phone' =
                      PATH '$new[*]')
```

ORACLE   12-17

Example 12-12   Removing Array Elements That Satisfy a Predicate Using JSON_TRANSFORM

This example removes all objects in the `LineItems` array whose `UPCCode` is `85391628927`. These are the array elements that satisfy the specified predicate, which requires an object with field `Part` whose value is an object with field `UPCCode` of value `85391628927`.

```
json_transform(po_document,
                REMOVE '$.LineItems[*]?(@.Part.UPCCode == 85391628927)')
```

Example 12-13   Sorting Elements In an Array By Field Values Using JSON_TRANSFORM

This example sorts the objects in array `LineItems` first by field `Part.UnitPrice` and then by field `ItemNumber`, in both cases from higher to lower number (keyword `DESC`). (Ascending order, `ASC`, is the default.)

```
SELECT json_transform(po_document,
                       SORT '$.LineItems'
                         ORDER BY '$.Part.UnitPrice' DESC,
                                  '$.ItemNumber' DESC
                       RETURNING VARCHAR2(4000))
  FROM j_purchaseorder;
```

Here is one row of the result. The elements are sorted by descending `UnitPrice` value. Those elements that have the same `UnitPrice` value are sorted by descending `ItemNumber` value.

```
{"LineItems" :
 [ {"ItemNumber" : 1,
    "Part" :
    {"Description" : "Making the Grade",
     "UnitPrice"   : 20,
     "UPCCode"     : 27616867759},
    "Quantity" : 8},
   {"ItemNumber" : 3,
    "Part" :
    {"Description" : "Eric Clapton: Best Of 1981-1999",
     "UnitPrice"   : 19.95,
     "UPCCode"     : 75993851120},
    "Quantity" : 5},
   {"ItemNumber" : 2,
    "Part" :
    {"Description" : "Nixon",
     "UnitPrice"   : 19.95,
     "UPCCode"     : 717951002396},
    "Quantity" : 5} ]}
```

Example 12-14   Updating Each Element of an Array Using JSON_TRANSFORM

This example uses operation NESTED PATH to increase the unit price of each line item by a factor of 1.2, and to add a new field, TotalPrice, calculated from the updated unit price, to each array element (object).

```
json_transform(po_document,
               NESTED PATH '$.LineItems[*]'
                   (SET '@.TotalPrice' = PATH '@.Quantity * @.Part.UnitPrice'))
```

Example 12-15   Downscoping with NESTED PATH, To Limit JSON_TRANSFORM Pruning by KEEP

This example limits the scope of a KEEP operation to a specific nested path. Data outside that scope *is not pruned*. The result is that only elements of array LineItems have fields other than UnitPrice and Quantity removed.

```
json_transform(po_document,
               NESTED PATH '$.LineItems[*]'
                   (KEEP '@.UnitPrice', '@.Quantity')))
```

Example 12-16   JSON_TRANSFORM: Controlling Modifications with SET and CASE

This example uses CASE and SET to set field TotalPrice conditionally, creating it if it doesn't exist. When applied to the data each WHEN test is tried in turn, until one succeeds. The SET operation corresponding to that successful test is then performed. the second applies when Quantity is at least 5 but smaller than 7. When no WHEN clause applies (Quantity is not smaller than 7)

- The first WHEN clause applies to data with field Quantity smaller than 5. Field TotalPrice is calculated with no discount.

- The second WHEN clause applies to data with field Quantity at least 5 but smaller than 7. Field TotalPrice is calculated with a discount of 10%.

- When neither WHEN test succeeds (ELSE clause), TotalPrice is calculated with a discount of 15%.

  Note that this clause applies also when field Quantity does not exist or is a non-numeric JSON value that does not compare less than 7.

```
json_transform(
  po_document,
  NESTED PATH '$.LineItems[*]'
    ( CASE WHEN '@?(@.Quantity < 5)' THEN
            ( -- No discount
              SET '@.TotalPrice' = PATH '@.Quantity * @.UnitPrice' )
          WHEN '@?(@.Quantity < 7)' THEN
            ( -- 10% discount
              SET '@.TotalPrice' = PATH '@.Quantity * @.UnitPrice * 0.9' )
          ELSE
            ( -- 15% discount
              SET '@.TotalPrice' = PATH '@.Quantity * @.UnitPrice * 0.85' )
      END ))
```

Oracle SQL Function JSON_MERGEPATCH

You can use Oracle SQL function `json_mergepatch` to update specific portions of a JSON document. You pass it a JSON Merge Patch document, which specifies the changes to make to a specified JSON document. JSON Merge Patch is an IETF standard.

Function `json_mergepatch` returns the modified JSON data.

You can use it in an `UPDATE` statement, to update the documents in a JSON column. Example 13-3 illustrates this.

You can use it in a `SELECT` list, to modify the selected documents. The modified documents can be returned or processed further. Example 13-4 illustrates this.

Function `json_mergepatch` can accept as input, and return as output, any SQL data type that supports JSON data: `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. Data type `JSON` is available only if database initialization parameter `compatible` is `20` or greater.

The default return type depends on the input data type. If the input type is `JSON` then `JSON` is also the default return type. Otherwise, `VARCHAR2` is the default return type.

JSON Merge Patch is suitable for updating JSON documents that primarily use *objects* for their structure and do not make use of explicit `null` values. You cannot use it to add, remove, or change array elements (except by explicitly replacing the whole array). And you cannot use it to set the value of a field to `null`.

JSON Merge Patch acts a bit like a UNIX `patch` utility: you give it (1) a *source* document to patch and (2) a *patch* document that specifies the changes to make, and it returns a copy of the source document updated (patched). The patch document specifies the differences between the source and the result documents. For UNIX `patch` the differences are in the form of UNIX `diff` utility output. For JSON Merge Patch both source and patch are JSON documents.

You can think of JSON Merge Patch as *merging* the contents of the source and the patch. When merging two objects, one from source and one from patch, a member with a field that is in one object but not in the other is kept in the result. An exception is that a patch member with field value is `null` is ignored when the source object has no such field.

When merging object members that have the same field:

- If the patch field value is `null` then the field is dropped from the source — it is not included in the result.

- Otherwise, the field is kept in the result, but its value is the *result of merging* the source field value with the patch field value. That is, the merging operation in this case is recursive — it dives down into fields whose values are themselves objects.

A little more precisely, JSON Merge Patch acts as follows:

- If the *patch* is *not* a JSON object then *replace* the source by the patch.

- Otherwise (the patch is an object), do the following:

   1. If the *source* is *not* an object then act as if it were the empty object (`{}`).

2. Iterate over the (*p-field*:*p-value*) members of the patch object.

– If the *p-value* of the patch member is `null` then *remove* the corresponding member from the source.

– Otherwise, **recurse**: *Replace* the value of the corresponding source field with the *result of merge-patching* that value (as the next source) with the *p-value* (as the next patch).

If a patch field value of `null` did not have a special meaning (remove the corresponding source member with that field) then you could use it as a field value to set the corresponding source field value to `null`. The special removal behavior means you *cannot* set a source field value to `null`.

Examples:

- Patch member `"PONumber":99999` overrides a source member with field `PONumber`, *replacing its value* with the patch-specified value, `99999`.

  `json_mergepatch('{"User":"ABULL", "PONumber":1600}',`
  `'{"PONumber":99999}')` results in `{"User":"ABULL", "PONumber":99999}`.

- Patch member `"tracking":123456` overrides a missing source member with field `tracking`, *adding* that patch member to the result. And source member `"PONumber":1600` overrides a missing patch member with field `PONumber` — it is kept in the result.

  `json_mergepatch('{"PONumber":1600}', '{"tracking":123456}')` results in `{"PONumber":1600, "tracking":123456}"`.

- Patch member `"Reference":null` overrides a source member with field `Reference`, *removing* it from the result.

  `json_mergepatch('{"PONumber":1600, "Reference":"ABULL-20140421"}',`
  `'{"Reference":null}')` results in `{"PONumber":1600}`.

- Patch value `[4,5,6]` overrides the corresponding source value, `[1,2,3]`, *replacing* it.

  `json_mergepatch('{"PONumber":1600, "LineItems":[1,2,3]}',`
  `'{"LineItems":[4,5,6]}')` results in `{"PONumber":1600, "LineItems":`
  `[4,5,6]}`.

> **Note:**
>
> The merge-patch procedure — in particular the fact that there is no recursive behavior for a non-object patch — means that you *cannot* add, remove, or replace values of an array individually. To make such a change you must *replace the whole array*. For example, if the source document has a member `Phone:["999-555-1212", "415-555-1234"]` then to remove the second phone number you can use a patch whose content has a member `"Phone":["999-555-1212"]`.

Example 13-1   A JSON Merge Patch Document

If applied to the document shown in Example 1-1, this JSON Merge Patch document does the following:

- Adds member `"Category" : "Platinum"`.

- Removes the member with field `ShippingInstructions`.

- Replaces the value of field `Special Instructions` with the string `"Contact User SBELL"`.

- Replaces the value of field `LineItems` with the empty array, `[]`

- Replaces member `"AllowPartialShipment" : null` with member `"Allow Partial Shipment" : false` (in effect *renaming* the field, since the field value was already `false`).

```
{ "Category" : "Platinum",
  "ShippingInstructions" : null,
  "Special Instructions" : "Contact User SBELL",
  "LineItems" : [],
  "AllowPartialShipment" : null,
  "Allow Partial Shipment" : false }
```

Example 13-2   A Merge-Patched JSON Document

This example shows the document that results from merge-patching the document in Example 1-1 with the patch of Example 13-1.

```
{ "PONumber" : 1600,
  "Reference" : "ABULL-20140421",
  "Requestor" : "Alexis Bull",
  "User" : "ABULL",
  "CostCenter" : "A50",
  "Special Instructions" : "Contact User SBELL",
  "Allow Partial Shipment" : false,
  "LineItems" : [],
  "Category" : "Platinum" }
```

Example 13-3   Updating a JSON Column Using JSON_MERGEPATCH

This example updates all documents in `j_purchaseorder.po_document`, removing field `"Special Instructions"`.

```
UPDATE j_purchaseorder SET po_document =
  json_mergepatch(po_document, '{"Special Instructions":null}');
```

Example 13-4   Modifying JSON Data On the Fly With JSON_MERGEPATCH

This example selects all documents in `j_purchaseorder.po_document`, returning pretty-printed, updated copies of them, where field `"Special Instructions"` has been removed. The return data type in this example is `CLOB`. (Keyword `PRETTY` is not available for `JSON` type.)

```
SELECT json_mergepatch(po_document, '{"Special Instructions":null}'
                       RETURNING CLOB PRETTY)
  FROM j_purchaseorder;
```

14
Loading External JSON Data

You can create a database table of JSON data from the content of a JSON dump file.

This topic shows how you can load a full table of JSON documents from the data in a JSON dump file, `PurchaseOrders.dmp` which you can obtain from GitHub at `https://github.com/oracle/db-sample-schemas/tree/master/order_entry`.

The file contains JSON objects, one per line. This format is compatible with the export format produced by common NoSQL databases, including Oracle NoSQL Database.

You can query such an external table directly or, for better performance if you have multiple queries that target different rows, you can load an ordinary database table from the data in the external table.

Example 14-1 creates a *database directory* that corresponds to file-system directory `$ORACLE_HOME`/demo/schema/order_entry. Example 14-2 then uses this database directory to create and fill an *external table*, `json_dump_file_contents`, with the data from the dump file, `PurchaseOrders.dmp`. It bulk-fills the external table completely, copying all of the JSON documents to column `json_document`.

Example 14-4 then uses an `INSERT` as `SELECT` statement to copy the JSON documents from the external table to JSON column `po_document` of ordinary database table `j_purchaseorder`.

Because we chose `BLOB` storage for JSON column `json_document` of the external table, column `po_document` of the ordinary table must also be of type `BLOB`. Example 14-3 creates table `j_purchaseorder` with `BLOB` column `po_document`.

> **Note:**
>
> You need system privilege `CREATE ANY DIRECTORY` to create a database directory.

> **See Also:**
>
> - *Oracle Database Concepts* for overview information about external tables
> - *Oracle Database Utilities* and *Oracle Database Administrator's Guide* for detailed information about external tables
> - *Oracle Database Data Warehousing Guide*
> - *Oracle Database SQL Language Reference* for information about `CREATE TABLE`

Example 14-1   Creating a Database Directory Object for Purchase Orders

You must replace `folder-containing-dump-file` here by the folder where you placed the dump file that you downloaded from GitHub at `https://github.com/oracle/db-sample-schemas/tree/master/order_entry`. (That folder must be accessible by the database.)

```
CREATE OR REPLACE DIRECTORY order_entry_dir
  AS 'folder-containing-dump-file';
```

Example 14-2   Creating an External Table and Filling It From a JSON Dump File

```
CREATE TABLE json_dump_file_contents (data JSON)
  ORGANIZATION EXTERNAL
    (TYPE ORACLE_BIGDATA
     ACCESS PARAMETERS (com.oracle.bigdata.fileformat = jsondoc)
     LOCATION (order_entry_dir:'PurchaseOrders.dmp'))
  PARALLEL
  REJECT LIMIT UNLIMITED;
```

Example 14-3   Creating a Table With a JSON Column for JSON Data

Table `j_purchaseorder` has primary key `id` and JSON column `po_document`, which is stored using data type `BLOB`. The *LOB cache option* is turned on for that column.

```
DROP TABLE j_purchaseorder;

CREATE TABLE j_purchaseorder
  (id            VARCHAR2 (32) NOT NULL PRIMARY KEY,
   date_loaded TIMESTAMP (6) WITH TIME ZONE,
   po_document JSON);
```

Example 14-4   Copying JSON Data From an External Table To a Database Table

```
INSERT INTO j_purchaseorder (id, date_loaded, po_document)
  SELECT SYS_GUID(), SYSTIMESTAMP, data
    FROM json_dump_file_contents;
```

Part IV

Query JSON Data

You can query JSON data using a simple dot notation or, for more functionality, using SQL/JSON functions and conditions. You can create and query a *data guide* that summarizes the structure and type information of a set of JSON documents.

To query particular JSON fields, or to map particular JSON fields to SQL columns, you can use the SQL/JSON *path language*. In its simplest form a path expression consists of one or more field names separated by periods (`.`). More complex path expressions can contain filters and array indexes.

Oracle provides two ways of querying JSON content:

- *A dot-notation syntax*, which is essentially a table alias, followed by a JSON column name, followed by one or more field names — all separated by periods (`.`). An array step can follow each of the field names. This syntax is designed to be simple to use and to return JSON values whenever possible.

- *SQL/JSON functions and condition*s, which completely support the path language and provide more power and flexibility than is available using the dot-notation syntax. You can use them to create, query, and operate on JSON data stored in Oracle Database.

  - Condition `json_exists` tests for the existence of a particular value within some JSON data.

  - Conditions `is json` and `is not json` test whether some data is well-formed JSON data. The former is used especially as a check constraint.

  - Function `json_value` selects a scalar value from some JSON data, as a SQL value.

  - Function `json_query` selects one or more values from some JSON data, as a SQL string representing the JSON values. It is used especially to retrieve fragments of a JSON document, typically a JSON object or array.

  - Function `json_table` projects some JSON data as a virtual table, which you can also think of as an inline view.

Because the path language is part of the query language, no fixed schema is imposed on the data. This design supports *schemaless development*. A "schema", in effect, gets defined on the fly at *query time*, by your specifying a given path. This is in contrast to the more usual approach with SQL of defining a schema (a set of table rows and columns) for the data at *storage time*.

Oracle SQL condition `json_equal` does not accept a path-expression argument. It just compares two JSON values and returns true if they are equal, false otherwise. For this comparison, insignificant whitespace and insignificant object member order are ignored. For example, JSON objects are equal if they have the same members, regardless of their order. However, if either of two compared objects has one or more duplicate fields then the value returned by `json_equal` is unspecified.

You can generate and query a JSON *data guide*, to help you develop expressions for navigating your JSON content. A data guide can give you a deep understanding of the structure and type information of your JSON documents. Data guide information can be updated automatically, to keep track of new documents that you add.

- **Simple Dot-Notation Access to JSON Data**
  Dot notation is designed for easy, general use and common use cases of querying JSON data. For simple queries it is a handy alternative to using SQL/JSON query functions.

- **SQL/JSON Path Expressions**
  Oracle Database provides SQL access to JSON data using SQL/JSON path expressions.

- **Clauses Used in SQL Functions and Conditions for JSON**
  Clauses `PASSING`, `RETURNING`, wrapper, error, empty-field, and on-mismatch are described for SQL functions that use JSON data. Each clause is used in one or more of the SQL functions and conditions `json_value`, `json_query`, `json_table`, `json_serialize`, `json_transform`, `json_mergepatch`, `is json`, `is not json`, `json_exists`, and `json_equal`.

- **SQL/JSON Condition JSON_EXISTS**
  SQL/JSON condition `json_exists` checks for the existence of a particular value within JSON data. It returns true if the data it targets matches one or more JSON values. If no JSON values are matched then it returns false.

- **SQL/JSON Function JSON_VALUE**
  SQL/JSON function `json_value` selects JSON data and returns a SQL scalar or an instance of a user-defined SQL object type or SQL collection type (varray, nested table).

- **SQL/JSON Function JSON_QUERY**
  SQL/JSON function `json_query` selects one or more values from JSON data and returns those values. You can thus use `json_query` to retrieve *fragments* of a JSON document.

- **SQL/JSON Function JSON_TABLE**
  SQL/JSON function `json_table` projects specific JSON data to columns of various SQL data types. You use it to map parts of a JSON document into the rows and columns of a new, virtual table, which you can also think of as an inline view.

- **Full-Text Search Queries**
  You can use Oracle SQL condition `json_textcontains` in a `CASE` expression or the `WHERE` clause of a `SELECT` statement to perform a *full-text* search of JSON data. You can use PL/SQL procedure `CTX_QUERY.result_set` to perform *facet* search over JSON data.

- **JSON Data Guide**
  A JSON data guide lets you discover information about the structure and content of JSON documents stored in Oracle Database.

> *Oracle Database SQL Language Reference* for complete information about the syntax and semantics of the SQL/JSON functions and conditions

15
Simple Dot-Notation Access to JSON Data

Dot notation is designed for easy, general use and common use cases of querying JSON data. For simple queries it is a handy alternative to using SQL/JSON query functions.

Just as for SQL/JSON query functions, the JSON column that you query must be known to contain only well-formed JSON data. That is, (1) it must be of data type `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`, and (2) if the type is not `JSON` then the column must have an `is json` check constraint.

This query selects the value of field `PONumber` from JSON column `po_document` and returns it as a JSON value:

```
SELECT po.po_document.PONumber FROM j_purchaseorder po;
```

The returned value is an instance of `JSON` data type if the column is of `JSON` type; otherwise, it is a `VARCHAR2(4000)` value.

But JSON values are generally not so useful in SQL. Instead of returning JSON data, you often want to return an instance of a (non-`JSON`) SQL scalar data type. You do that by applying an *item method* to the targeted data. This query, like the previous one, selects the value of field `PONumber`, but it returns it as a SQL `NUMBER` value:

```
SELECT po.po_document.PONumber.number() FROM j_purchaseorder po;
```

An item method transforms the targeted JSON data, The transformed data is then processed and returned by the query in place of that original data. When you use dot-notation syntax you generally want to use an item method.

A dot-notation query *with* an item method always returns a (non-`JSON`) SQL scalar value. It has the effect of using SQL/JSON function `json_value` to convert a JSON scalar value to a SQL scalar value.

A dot-notation query *without* an item method always returns *JSON* data. It has the effect of using SQL/JSON function `json_query` (or `json_table` with a column that has `json_query` semantics).

Example 15-1 shows equivalent dot-notation and `json_value` queries. Example 15-2 shows equivalent dot-notation and `json_query` queries.

Dot Notation With an Item Method

A dot-notation query that uses an item method is equivalent to a `json_value` query with a `RETURNING` clause that returns a scalar SQL type — the type that is indicated by the item method.

For example: if item method `number()` is applied to JSON data that can be transformed to a number then the result is a SQL `NUMBER` value; if item method `date()` is applied to data that is in a supported ISO 8601 date or date-time format then the result is a SQL `DATE` value; and so on.

> **✎ Note:**
>
> If a query result includes a JSON string, and if the result is *serialized*, then the string appears in textual form. In this form, its content is enclosed in double-quote characters ("), some characters of the content might be escaped, and so on.
>
> Be aware that serialization is *implicit* in some cases — for example, when you use a client such as SQL*Plus.
>
> Suppose that column `t.jcol` is of data type `JSON`, with content `{"name":"orange"}`. This SQL*Plus query prints its result, a JSON string of data type `JSON`, using double-quote characters:
>
> ```
> SELECT t.data.name FROM fruit t;
>
> NAME
> ----
> "orange"
> ```
>
> You can convert the JSON string to a SQL string having the same content, by using item method `string()`. SQL*Plus serializes (prints) the result without surrounding (single- or double-) quote characters:
>
> ```
> SELECT t.data.name.string() FROM fruit t;
>
> NAME.STRING()
> -------------
> orange
> ```

Dot Notation Without an Item Method

If a dot-notation query does *not* use an item method then a SQL value representing *JSON* data is returned. In this case:

- If the queried data is of type `JSON` then so is the returned data.

- Otherwise, the queried data is textual (type `VARCHAR2`, `CLOB`, or `BLOB`), and the returned data is of type `VARCHAR2(4000)`.

If a dot-notation query does not use an item method then the returned JSON data depends on the targeted JSON data, as follows:

- If a *single* JSON value is targeted, then that value is returned, whether it is a JSON scalar, object, or array.

- If *multiple* JSON values are targeted, then a JSON *array*, whose elements are those values, is returned. (The order of the array elements is undefined.)

This behavior contrasts with that of SQL/JSON functions `json_value` and `json_query`, which you can use for more complex queries. They can return `NULL` or raise an error if the path expression you provide them does not match the queried JSON data. They accept optional clauses to specify the data type of the return value (`RETURNING` clause), whether or not to wrap multiple values as an array (wrapper clause), how to handle

errors generally (`ON ERROR` clause), and how to handle missing JSON fields (`ON EMPTY` clause).

When a single value JSON value is targeted, the dot-notation behavior is similar to that of function `json_value` for a *scalar* JSON value, and it is similar to that of `json_query` for an *object* or *array* value.

When multiple values are targeted, the behavior is similar to that of `json_query` with an array wrapper.

Dot Notation Syntax

The dot-notation *syntax* is a table alias (mandatory) followed by a dot, that is, a period (`.`), the name of a JSON column, and one or more pairs of the form `.` *json_field* or `.` *json_field* followed by *array_step*, where *json_field* is a JSON field name and *array_step* is an array step expression as described in Basic SQL/JSON Path Expression Syntax.

Each *json_field must* have the syntax of a valid SQL identifier[1], and the column *must* be of `JSON` data type or have an `is json` check constraint, which ensures that it contains well-formed JSON data. If either of these rules is not respected then an error is raised at query compile time. (If the column is not of data type `JSON` then the check constraint must be *present* to avoid raising an error; however, it need not be active. If you deactivate the constraint then this error is not raised.)

For the dot notation for JSON queries, *unlike the case generally for SQL*, unquoted identifiers (after the column name) are treated *case sensitively*, that is, just as if they were quoted. This is a convenience: you can use JSON field names as identifiers without quoting them. For example, you can write `t.jcolumn.friends` instead of `t.jcolumn."friends"` — the meaning is the same. This also means that if you query a JSON field whose name is uppercase, such as `FRIENDS`, then you must write `t.jcolumn.FRIENDS`, not `t.jcolumn.friends`.

Here are some examples of dot notation syntax. All of them refer to JSON column `po_document` of a table that has alias `po`.

- `po.po_document.PONumber` — The value of field `PONumber` as a JSON value. The value is returned as an instance of `JSON` type if column `po_document` is `JSON` type; otherwise, it is returned as a SQL `VARCHAR2(4000)` value.

- `po.po_document.PONumber.number()` — The value of field `PONumber` as a SQL `NUMBER` value. Item method `number()` ensures this.

- `po.po_document.LineItems[1]` — The second element of array `LineItems` (array positions are zero-based), returned as JSON data (`JSON` type or `VARCHAR2(4000)`, depending on the column data type).

- `po.po_document.LineItems[*]` — All of the elements of array `LineItems` (`*` is a wildcard), as JSON data.

- `po.po_document.ShippingInstructions.name` — The value of field `name`, a child of the object that is the value of field `ShippingInstructions`, as JSON data.

Matching of a JSON dot-notation expression against JSON data is the same as matching of a SQL/JSON path expression, including the relaxation to allow implied array iteration (see SQL/JSON Path Expression Syntax Relaxation). The JSON column of a dot-notation expression corresponds to the context item of a path expression, and each identifier used in the dot notation corresponds to an identifier used in a path expression.

---

[1] In particular, this means that you *cannot* use an empty field name (`""`) with dot-notation syntax.

For example, if JSON column `jcolumn` corresponds to the path-expression context item, then the expression `jcolumn.friends` corresponds to path expression `$.friends`, and `jcolumn.friends.name` corresponds to path expression `$.friends.name`.

For the latter example, the context item could be an object or an array of objects. If it is an array of objects then each of the objects in the array is matched for a field `friends`. The value of field `friends` can itself be an object or an array of objects. In the latter case, the first object in the array is used.

> **Note:**
>
> Other than (1) the *implied* use of a wildcard for array elements (see SQL/ JSON Path Expression Syntax Relaxation) and (2) the explicit use of a wildcard between array brackets (`[*]`), you *cannot* use wildcards in a path expression when you use the dot-notation syntax. This is because an asterisk (`*`) is not a valid *SQL identifier*.
>
> For example, this raises a syntax error:
> `mytable.mycolumn.object1.*.object2`.
>
> Dot-notation syntax is a handy alternative to using simple path expressions; it is not a replacement for using path expressions in general.

> *Oracle Database SQL Language Reference* for information about dot notation used for SQL object and object attribute access (object access expressions)

Example 15-1   JSON Dot-Notation Query Compared With JSON_VALUE

Given the data from Example 4-3, each of these queries returns the JSON number `1600`. If the JSON column is textual (not `JSON` type) then the queries return the `VARCHAR2` string `'1600'`, which represents the JSON number.

```
SELECT po.po_document.PONumber FROM j_purchaseorder po;

SELECT json_value(po_document, '$.PONumber') FROM j_purchaseorder;
```

Each of these queries returns the `SQL NUMBER` value `1600`.

```
SELECT po.po_document.PONumber.number() FROM j_purchaseorder po;

SELECT json_value(po_document, '$.PONumber.number()')
  FROM j_purchaseorder;
```

Example 15-2   JSON Dot-Notation Query Compared With JSON_QUERY

Each of these queries returns a JSON array of phone objects. If the JSON column is textual (not `JSON` type) then the queries return `VARCHAR2` value representing the array.

```
SELECT po.po_document.ShippingInstructions.Phone
  FROM j_purchaseorder po;

SELECT json_query(po_document, '$.ShippingInstructions.Phone')
  FROM j_purchaseorder;
```

Each of these queries returns an array of phone types, just as in Example 20-1. If the JSON column is textual (not `JSON` type) then the queries return a `VARCHAR2` value representing the array.

```
SELECT po.po_document.ShippingInstructions.Phone.type
  FROM j_purchaseorder po;

SELECT json_query(po_document, '$.ShippingInstructions.Phone.type'
                  WITH WRAPPER)
  FROM j_purchaseorder;
```

  Comparisons in SQL/JSON path-expression filter conditions are statically typed at compile time. If the effective types of the operands of a comparison are not known to be the same then an attempt is sometimes made to reconcile them by type-casting.

16.1 Overview of SQL/JSON Path Expressions

Oracle Database provides SQL access to JSON data using SQL/JSON path expressions.

SQL/JSON path expressions are somewhat analogous to XQuery or XPath expressions for XML data. They provide SQL access to JSON data similarly to how SQL/XML allows SQL access to XML data using XQuery expressions.

SQL/JSON path expressions have a simple syntax. A path expression selects zero or more JSON values that **match**, or satisfy, it.

SQL/JSON condition `json_exists` returns true if at least one value matches, and false if no value matches. If a single value matches, then SQL/JSON function `json_value` returns that value if it is scalar, and raises an error if it is nonscalar. If no value matches the path expression then `json_value` returns SQL `NULL`.

SQL/JSON function `json_query` returns *all* of the matching values, that is, it can return multiple values. You can think of this behavior as returning a sequence of values, as in XQuery, or you can think of it as returning multiple values. (No user-visible sequence is manifested.)

In all cases, path-expression matching attempts to match each *step* of a path expression, in turn. If matching any step fails then no attempt is made to match the subsequent steps, and matching of the path expression fails. If matching each step succeeds then matching of the path expression succeeds.

The maximum length of the text of a SQL/JSON path expression is 32K bytes. However, the *effective* length of a path expression is essentially unlimited, because the expression can make use of SQL/JSON variables that are bound to string values, *each* of which is limited to 32K bytes.

16.2 SQL/JSON Path Expression Syntax

SQL/JSON path expressions are matched by SQL/JSON functions or conditions
against JSON data, to select or test portions of it. Path expressions can use wildcards
and array ranges. Matching is case-sensitive.

You pass a SQL/JSON path expression and some JSON data to a SQL/JSON function
or condition. The path expression is matched against the data, and the matching data
is processed by the particular SQL/JSON function or condition. You can think of this
matching process in terms of the path expression *returning* the matched data to the
function or condition.

- [Basic SQL/JSON Path Expression Syntax](#)
  The basic syntax of a SQL/JSON path expression is presented. It is composed of
  a context-item symbol ($) followed by zero or more object, array, and descendant
  steps, each of which can be followed by a filter expression, followed optionally by
  a function step. Examples are provided.

- [SQL/JSON Path Expression Syntax Relaxation](#)
  The basic SQL/JSON path-expression syntax is relaxed to allow implicit array
  wrapping and unwrapping. This means that you need not change a path
  expression in your code if your data evolves to replace a JSON value with an array
  of such values, or vice versa. Examples are provided.

- [Negation in Path Expressions](#)
  Negation in a path expression can be confusing when the data matched by the
  path is multiple. Some simple examples are explained.

- [About Strict and Lax JSON Syntax](#)
  On *input*, the Oracle default syntax for JSON is *lax*. It reflects the JavaScript
  syntax for object fields; the Boolean and `null` values are not case-sensitive; and it
  is more permissive with respect to numerals, whitespace, and escaping of Unicode
  characters. Oracle *outputs* JSON data that strictly respects the standard.

- [Diagrams for Basic SQL/JSON Path Expression Syntax](#)
  Syntax diagrams and corresponding Backus-Naur Form (BNF) syntax descriptions
  are presented for the basic SQL/JSON path expression syntax.

16.2.1 Basic SQL/JSON Path Expression Syntax

The basic syntax of a SQL/JSON path expression is presented. It is composed of a
context-item symbol ($) followed by zero or more object, array, and descendant steps,

each of which can be followed by a filter expression, followed optionally by a function step. Examples are provided.

However, this basic syntax is extended by relaxing the matching of arrays and nonarrays against nonarray and array patterns, respectively — see SQL/JSON Path Expression Syntax Relaxation.

Matching of data against SQL/JSON path expressions is case-sensitive.

- A SQL/JSON **basic path expression** (also called just a *path expression* here) is an *absolute path expression* or a *relative path expression*.

- An **absolute path expression** begins with a *dollar* sign (**$**), which represents the path-expression **context item**, that is, the JSON data to be matched. Matching data is located by evaluating a SQL expression that is passed as argument to the SQL/JSON function. The dollar sign is followed by zero or more *nonfunction steps*, followed by an optional *function step*.

- A **relative path expression** is an *at* sign (**@**) followed by zero or more *nonfunction steps*, followed by an optional *function step*. It has the same syntax as an *absolute path expression*, except that it uses an at sign instead of a dollar sign (`$`).

  A relative path expression is used inside a *filter expression* (*filter*, for short). The *at sign* represents the path-expression **current filter item**, that is, the JSON data that matches the part of the (surrounding) path expression that precedes the filter containing the relative path expression. A relative path expression is matched against the current filter item in the same way that an absolute path expression is matched against the context item.

- A **nonfunction step** is an *object step*, an *array step*, or a *descendant step*, followed by an optional *filter expression*.

- A single **function step** is *optional* in a *basic path expression* (absolute or a relative). If present, it is the last step of the path expression. It is a period (**.**), sometimes read as "dot", followed by a SQL/JSON **item method**, followed by a left parenthesis (**(**), possibly an *argument list*, and then a right parenthesis (**)**). The parentheses can have whitespace between them (such whitespace is insignificant).

  The item method is applied to (1) the *data* that is targeted by the rest of the same path expression, which *precedes* the function step and (2) the *arguments*, if any, within the parentheses. The item method is used to transform the targeted data. The SQL function or condition that is passed the path expression as an argument uses the transformed data in place of the targeted data.

  Only some item methods allow for an argument list between the parentheses. The arguments are *scalar* JSON values, separated by commas (**,**). Some item methods require one or more such arguments. Other methods allow, but don't require, such arguments.

- An **object step** is a period (**.**), followed by an object field name or an asterisk (*****) wildcard, which stands for (the values of) *all* fields. A field name can be *empty*, in which case it *must* be written as `""` (no intervening whitespace). A nonempty field name must start with an uppercase or lowercase letter A to Z and contain only such letters or decimal digits (0-9), or else it must be enclosed in double quotation marks (**"**).

  An object step returns the *value* of the field that is specified. If a wildcard is used for the field then the step returns the values of *all* fields, in no special order.

- An **array step** is a left bracket (`[`) followed by *either* an asterisk (`*`) wildcard, which stands for *all* array elements, *or* one or more specific array indexes or range specifications separated by commas (`,`), followed by a right bracket (`]`).

  An error is raised if you use *both* an asterisk and either an array index or a range specification. And an error is raised if no index or range specification is provided: `[]` is not a valid array step.

  An **array index** specifies a single array **position**, which is a whole number (0, 1, 2,...). An array index can thus be a literal whole number: `0`, `1`, `2`,… Array position and indexing are zero-based, as in the JavaScript convention for arrays: the first array element has index `0` (specifying position 0).

  The last element of a nonempty array of any size can be referenced using the index `last`.

  An array index can also have the form `last - ` *N*, where – is a minus sign (hyphen) and *N* is a literal whole number (`0`, `1`, `2`,…) that is no greater than the array size minus 1.

  The next-to-last array element can be referenced using index `last-1`, the second-to-last by index `last-2`, and so on. Whitespace surrounding the minus sign (hyphen) is ignored.

  For the array `["a", "b", 42]`, for example, the element at index `1` (position 1) is the string "b" — the second array element. The element at index `2`, or index `last`, is the number `42`. The element at index `0`, or `last-2`, is "a".

  For Oracle SQL function `json_transform`, you can also use an index of the form `last + ` *N*, where *N* is a whole number. This lets you append new elements to an existing array, by specifying positions beyond the current array size minus 1. Whitespace surrounding the plus sign is ignored. You cannot use an index of this form in combination with other indexes, including in a range specification (see next). An error is raised in that case.

  A **range specification** has the form *N* to *M*, where *N* and *M* are array indexes, and where `to` is preceded and followed by one or more whitespace characters.[1]

  Range specifications *N* to *M* and *M* to *N* are equivalent. Each is equivalent to explicitly specifying *N*, *M*, and the indexes between *N* and *M*, all in *ascending order*.

  That is, the order of *N* and *M* is *not* significant; the range of the third through sixth elements can be written as `2 to 5` or `5 to 2`. For a six-element array the same range can be written as `2 to last` or `last to 2`. The range specification *N* to *N* (same index *N* on each side of `to`) is equivalent to the single index *N* (it is not equivalent to `[`*N*`, `*N*`]`).

  The order in which array indexes and ranges are specified in an array step *is* significant; it is reflected in the array that results from the function that uses the path expression.

  Multiple range specifications in the same array step are treated independently. In particular, overlapping ranges result in repetition of the elements in the overlap.

  For example, suppose that you query using SQL/JSON function `json_query` with array wrapper (which wraps multiple query results to return a single JSON array), passing it a path expression with this array step: `[3 to 1, 2 to 4, last-1 to`

---

[1] The `to` in a range specification is sometimes informally called the array *slice* operator.

`last-2, 0, 0]`. The data returned by the query will include an array that is made from these elements of an array in your queried data, in order:

- second through fourth elements (range `3 to 1`)

- third through fifth elements (range `2 to 4`)

- second-from-last through next-to-last elements (range `last-1 to last-2`)

- first element (index `0`)

- first element again (index `0`)

When matching the array `["1", "2", "3", "4", "5", "6", "7", "8", "9"]` in your data, the array in the query result would be `["2", "3", "4", "3", "4", "5", "7", "8", "1", "1"]`.

If you use array indexes that specify positions *outside the bounds* (0 through the array size minus 1) of an array in your data, no error is raised. The specified path expression simply does not match the data — the array has no such position. (Matching of SQL/JSON path expressions follows this rule generally, not just for array steps.)

This is the case, for example, if you try to match an index of `last-6` against an array with fewer than 7 elements. For an array of 6 elements, `last` is 5, so `last-6` specifies an invalid position (less than 0).

It is also the case if you try to match *any* array step against an *empty* array. For example, array steps `[0]` and `[last]` both result in no match against the data array `[]`. Step `[0]` doesn't match because `[]` has no first element, and step `[last]` doesn't match because `[]` has no element with index `-1` (array length minus 1).

It is also the case, if you use an index `last+`*N* (*N* non-zero) other than with function `json_transform`. For `json_transform` this is used not to match an existing array element but to specify where, when modifying an existing array, to insert a new element.

Because a range specification is equivalent to an explicit, ascending sequence of array indexes, any of those implicit indexes which are out of bounds cannot match any data. Like explicit indexes, they are ignored.

Another way to think of this is that range specifications are, in effect, *truncated* to the nearest bound (`0` or `last`) for a given data array. For example when matching the array `["a", "b", "c"]`, the range specifications `last-3 to 1`, `2 to last+1`, and `last-3 to last+1` are, in effect, truncated to `0 to 1`, `2 to 2`, and `0 to 2`, respectively. The (implicit) out-of-bounds indexes for those ranges, `last-3` (which is `-1`, here) and `last+1` (which is `3`, here), are ignored.

- A **descendant** step is two consecutive periods (`..`), sometimes read as "dot dot", followed by a field name (which has the same syntax as for an *object step*).

  It *descends recursively* into the objects or arrays that match the step immediately preceding it (or into the context item if there is no preceding step).

  At each descendant level, for each object and for each array element that is an object, it gathers the values of all fields that have the specified name. It returns all of the gathered field values.

For example, consider this query and data:

```
json_query(some_json_column, '$.a..z' WITH ARRAY WRAPPER)
```

```
{ "a" : { "b" : { "z" : 1 },
          "c" : [ 5, { "z" : 2 } ],
          "z" : 3 },
  "z" : 4 }
```

The query returns an array, such as `[1,2,3]`, whose elements are `1`, `2`, and `3`. It gathers the value of each field `z` within the step that immediately precedes the dot dot (`..`), which is field **a**. The topmost field `z`, with value 4, is *not* matched because it is not within the value of field `a`.

The value of field `a` is an object, which is descended into.

– It has a field `z`, whose value (**3**) is gathered. It also has a field `b` whose value is an object, which is descended into to gather the value of its field `z`, which is **1**.

– It also has a field `c` whose value is an array, which has an element that is an object with a field `z`, whose value (**2**) is gathered.

The JSON values gathered are thus `3`, `1`, and `2`. They are wrapped in an array, in an undefined order. One of the possible return values is `[1,2,3]`.

- A **filter expression** (**filter**, for short) is a question mark (**?**) followed by a *filter condition* enclosed in parentheses (**()**). A filter is satisfied if its condition is satisfied, that is, returns true.

- A **filter condition** applies a predicate (a Boolean function) to its arguments. It is defined recursively as one of the following, where each of *cond*, *cond1*, and *cond2* stands for a filter condition.[2]

  – `!` *cond*: The *negation* of *cond*, meaning that *cond* must *not* be satisfied. `!` is a prefix unary predicate. (See Negation in Path Expressions.)

  – `(` *cond* `)`: Parentheses are used for *grouping*, separating filter condition *cond* as a unit from other filter conditions that may precede or follow it.

    You can also use parentheses wherever they have no effect, if you find the code more readable. For example, if you prefer you can place them around the argument(s) to a predicate, as in `exists(cond)` instead of just `existscond`.

    Parentheses are needed whenever the beginning and end of the condition argument are otherwise unclear. They're needed, for instance, in `!(cond)` whenever *cond* is a *comparison* condition (see below). For example, you must use `!(@.x > 5)`, not `!@.x > 5`. (But you can use either `!exists@.x` or `!(exists@.x)`.)

  – *cond1* `&&` *cond2*: The *conjunction* (*and*) of *cond1* and *cond2*, requiring that both be satisfied. `&&` is an infix binary predicate.

  – *cond1* `||` *cond2*: The inclusive *disjunction* (*or*) of *cond1* and *cond2*, requiring that *cond1*, *cond2*, or both, be satisfied. `||` is an infix binary predicate.

---

2 Filter conditions and filter expressions are sometimes referred to informally as "*predicates*". But a filter condition is actually the application of a predicate to its arguments.

- **exists** followed by a *relative path expression*: The condition that the targeted data *exists* (is present). `exists` is a prefix unary predicate.

- A *relative path expression*, followed by **in**, followed by a *value list*, meaning that the value is one of those in the *value list*. `in` is an infix binary predicate.

  An `in` filter condition with two or more value-list elements is equivalent to a disjunction (`||`) of equality (`==`) comparisons for the elements of the value list.[3] For example, these are equivalent:

  ```
  @.z in ("a", "b", c")
  ```

  ```
  (@.z == "a") || (@.z == "b") || (@.z == "c")
  ```

  A **value list** is `(` followed by a list of zero or more JSON literal values or *SQL/JSON variables* separated by commas (`,`), followed by `)`.[4] A value list can only follow `in`; otherwise, an error is raised.

  * If each *variable* in the list is of `JSON` data type, then each listed value (whether literal or the value of a variable) is compared for equality against the targeted JSON data, using the *canonical sort order* described in Comparison and Sorting of JSON Data Type Values. Condition `in` is satisfied if *any* of the listed values is equal to the targeted data.

  * Otherwise (at least one *variable* is *not* of `JSON` data type), all values in the list (whether literal or variable) must be *scalar* values of the *same* JSON-language type — for example, they must all be strings — otherwise, an error is raised.

    A JSON `null` value is an *exception* to this same-type restriction: `null` is always allowed in a value list. It is matched (only) by a `null` value in the targeted data.

-

- A **comparison**, which is one of the following:

  * A JSON scalar value, followed by a *comparison predicate*, followed by another JSON scalar value.

  * A *relative path expression*, followed by a *comparison predicate*, followed by another *relative path expression*.

  * A JSON scalar value or a *SQL/JSON variable*, followed by a *comparison predicate*, followed by a *relative path expression*.

  * A *relative path expression*, followed by a *comparison predicate*, followed by a JSON scalar value or a *SQL/JSON variable*.

  * A *relative path expression*, followed by any of the keywords `has substring`, `starts with`, `like`, `like_regex`, `regex like`, `regex`, `eq_regex`, `ci_like_regex`, or `ci_regex`, followed by either a JSON string or a *SQL/JSON variable* that is bound to a SQL string (which is automatically converted from the database character set to UTF8).

    For all of these predicates, a pattern that is the empty string (`""`) matches data that is the empty string. And for all except `like_regex`, a pattern that is a

---

[3] An `in` condition with a singleton value list is equivalent to a single equality comparison. For example, `@.z in ("a")` is equivalent to `@.z == "a"`. An `in` condition with *no* values (for example `@.z in ()`) is unmatchable.

[4] An empty value list (no values or variables) does not raise an error, but it also is never matched.

nonempty string does *not* match data that is the empty string. For `like_regex` a nonempty pattern *does* match empty-string data.

* **has substring** means that the matching data value has the specified string as a *substring*.

* **starts with** means that the matching data value has the specified string as a *prefix*.

* **like** means that the JSON string data value matches the specified string, which is interpreted as a SQL `LIKE` pattern that uses SQL `LIKE4` character-set semantics. A percent sign (`%`) in the pattern matches zero or more characters. An underscore (`_`) matches a single character.

> **Note:**
>
> Unlike the case for SQL `LIKE`, you cannot choose the *escape character* for path-expression predicate `like` — it is always character `` ` ``, GRAVE ACCENT (U+0060), also known sometimes as backquote or backtick.
>
> In database releases prior to 21c there is no escape character for path-expression predicate `like`. For such releases Oracle recommends that you avoid using character `` ` ``, GRAVE ACCENT (U+0060) in `like` patterns.

* **like_regex** or its synonym **regex like** (no underscore) means that the JSON string data value matches the specified string, which is interpreted as a SQL `REGEXP LIKE` *regular expression* pattern that uses SQL `LIKE4` character-set semantics.

  ci_like_regex is the same as `like_regex`, except that matching is case-*in*sensitive.

  `like_regex` and `ci_like_regex` are *exceptional* among the pattern-matching comparisons, in that their pattern *matches* the empty JSON string (`""`).

* **eq_regex** and its synonyms **regex equals** (no underscore) and **regex** are the same as `like_regex`, except for these two differences:

  * `eq_regex` matches its regular expression pattern against the entire JSON string data value — *the full string must match* the pattern for the comparison to be satisfied. `like_regex` is satisfied if any portion of the JSON string matches the pattern.

  * The `eq_regex` pattern does not match the empty JSON string (`""`).

  ci_regex is the same as `eq_regex`, except that matching is case-*in*sensitive.

A **SQL/JSON variable** is a dollar sign (`$`) followed by the name of a variable that is bound in a `PASSING` clause. (See PASSING Clause for SQL Functions and Conditions for the required syntax of a SQL/JSON variable name.)

A **comparison predicate** is **==**, **<>**, **!=**[5], **<**, **<=**, **>=**, or **>**, meaning equals, does not equal, is less than, is less than or equal to, is greater than or equal to, and is greater than, respectively. (See Negation in Path Expressions, for more about using the not-equals predicate, `<>` or its Oracle alias `!=`.)

The predicates that you can use in filter conditions are thus `&&`, `||`, `!`, `exists`, `==`, `<>`, `!=`, `<`, `<=`, `>=`, `>`, `in`, `has substring`, `starts with`, `like`, `like_regex`, `regex like`, `regex`, `eq_regex`, `ci_like_regex`, and `ci_regex`.

As an example, the filter condition `(a || b) && (!(c) || d < 42)` is satisfied if both of the following criteria are met:

- At least one of the filter conditions `a` and `b` is satisfied: `(a || b)`.

- Filter condition `c` is *not* satisfied or the number `d` is less than or equal to 42, or both are true: `(!(c) || d < 42)`.

Condition predicate `!` has precedence over `&&`, which has precedence over `||`. You can always use parentheses to control grouping.

If the preceding example, `(a || b) && (!(c) || d < 42)`, did *not* use parentheses for grouping, so that it was just `a || b && !(c) || d < 42`, then it would instead be satisfied if at least one of the following criteria is met:

- Condition `b && !(c)` is satisfied, which means that each of the conditions `b` and `!(c)` is satisfied (which in turn means that condition `c` is not satisfied).

- Condition `a` is satisfied.

- Condition `d < 42` is satisfied.

At least one side of a comparison must *not* be a SQL/JSON variable.

If the data targeted by a comparison is of `JSON` data type, and if *all* SQL/JSON variables used in the comparison are also of `JSON` type, then comparison uses the *canonical sort order* described in Comparison and Sorting of JSON Data Type Values.

Otherwise, the default *type* for a comparison is defined at compile time, based on the type(s) for the non-variable side(s). You can use a type-specifying *item method* to override this default with a different type. The type of your matching data is automatically converted, for the comparison, to fit the determined type (default or specified by item method). For example, `$.a > 5` imposes numerical comparison because `5` is a number, `$.a > "5"` imposes string comparison because `"5"` is a string.

---

[5]   `!=` is an Oracle alias for the SQL/JSON standard comparison predicate `<>`.

> **Tip:**
>
> For queries that you use often, use a `PASSING` clause to define SQL bind variables, which you use as SQL/JSON variables in path expressions. This can improve performance by *avoiding query recompilation* when the (variable) values change.
>
> For example, this query passes the value of bind variable `v1` as SQL/JSON variable `$v1`:
>
> ```
> SELECT po.po_document FROM j_purchaseorder po
>   WHERE json_exists(po.po_document,
>                     '$.LineItems.Part?(@.UPCCode == $v1)'
>                     PASSING '85391628927' AS "v1");
> ```

> **Note:**
>
> Oracle SQL function `json_textcontains` provides powerful full-text search of JSON data. If you need only simple string pattern-matching then you can instead use a path-expression filter condition with any of these pattern-matching comparisons: `has substring`, `starts with`, `like`, `like_regex`, or `eq_regex`.

Basic Path-Expression Examples

Here are some examples of path expressions, with their meanings spelled out in detail.

- `$` — The context item.

- `$.friends` — The value of field `friends` of a context-item object. The dot (.) immediately after the dollar sign (`$`) indicates that the context item is a JSON *object*.

- `$.friends[0]` — An object that is the first element of an array that is the value of field `friends` of a context-item object. The bracket notation indicates that the value of field `friends` is an *array*.

- `$.friends[0].name` — Value of field `name` of an object that is the first element of an array that is the value of field `friends` of a context-item object. The second dot (.) indicates that the first element of array `friends` is an object (with a `name` field).

- `$.friends[*].name` — Value of field `name` of *each* object in an array that is the value of field `friends` of a context-item object.

- `$.*[*].name` — Field `name` values for each object in an array value of a field of a context-item object.

- `$.friends[3, 8 to 10, 12]` — The fourth, ninth through eleventh, and thirteenth elements of an array `friends` (field of a context-item object). The elements are returned in the order in which they are specified: fourth, ninth, tenth, eleventh, thirteenth.

If an array to be matched has fewer than 13 elements then there is no match for index `12`. If an array to be matched has only 10 elements then, in addition to not matching index `12`, the range `8 to 10` is in effect truncated to positions 8 and 9 (elements 9 and 10).

- `$.friends[12, 3, `**`10 to 8,`**` 12]` — The thirteenth, fourth, ninth through eleventh, and thirteenth elements of array `friends`, *in that order*. The elements are returned in the order in which they are specified. The range `10 to 8` specifies the same elements, *in the same order*, as the range `8 to 10`. The thirteenth element (at position 12) is returned twice.

- `$.friends[`**`last-1, last, last, last`**`]` — The next-to-last, last, last, and last elements of array `friends`, in that order. The *last element is returned three times*.

- `$.friends[`**`last to last-1,`**` last, last]` — Same as the previous example. Range `last to last-1`, which is the same as range `last-1 to last`, returns the next-to-last through the last elements.

- `$.friends[3].cars` — The value of field `cars` of an object that is the fourth element of an array `friends`. The dot (.) indicates that the fourth element is an object (with a `cars` field).

- `$.friends[3].`**`*`** — The values of *all* of the fields of an object that is the fourth element of an array `friends`.

- `$.friends[3].cars[0].year` — The value of field `year` of an object that is the first element of an array that is the value of field `cars` of an object that is the fourth element of an array `friends`.

- `$.friends[3].cars[0]`**`?(@.year > 2016)`** — The first object of an array `cars` (field of an object that is the fourth element of an array `friends`), *provided that* the value of its field `year` is, or can be converted to, a number greater than 2016. A `year` value such as `"2017"` is converted to the number `2017`, which satisfies the test. A `year` value such as `"recent"` fails the test — no match.

- `$.friends[3].cars[0]?(@.year.`**`number()`**` > 2016)` — Same as the previous. Item method `number()` allows only a number or a string value that can be converted to a number, and that behavior is already provided by numeric comparison predicate `>`.

- `$.friends[3].cars[0]?(@.year.`**`numberOnly()`**` > 2016)` — Same as the previous, but only if the `year` value *is* a number. Item method `numberOnly()` excludes a car with a `year` value that is a string numeral, such as `"2017"`.

- `$.friends[3]`**`?(@.addresses.city == "San Francisco")`** — An object that is the fourth element of an array `friends`, provided that it has an `addresses` field whose value is an object with a field `city` whose value is the string `"San Francisco"`.

- `$.friends`**`[*]`**`.addresses`**`?(@.city starts with "San ").zip`** — Zip codes of all `addresses` of `friends`, where the name of the address `city` starts with "San ". (In this case the filter is not the last path step.)

- `$.friends`**`[*]`**`.addresses`**`?(@.city has substring "Fran").zip`** — Zip codes of all `addresses` of `friends`, where the name of the address `city` contains "Fran".

- `$.friends[*].addresses`**`?(@.city like "S_n%").zip`** — Zip codes of all `addresses` of `friends`, where the name of the address `city` is "S" followed by any single character, then "n", then any sequence of zero or more characters. Underscore (_) matches a single character, and percent (%) matches multiple characters.

- `$.friends[*].addresses`**`?(@.city like_regex "n +F").zip`** — Zip codes of all `addresses` of `friends`, where the name of the address `city` contains "n" followed by at least one space character. Matching is case-sensitive, and it is not anchored at the start of the `city` string.

- `$.friends[*].addresses`**`?(@.city ci_regex "s.+o").zip`** — Zip codes of all `addresses` of `friends`, where the name of the address `city` starts with "s" or "S" and ends with "o" or "O". Matching is case-insensitive (`ci_`) and the entire `city` string must match (no `like_`).

- `$..zip` — All values of a `zip` field, anywhere, at any level.

- `$.friends[3]`**`?(@.addresses.city == "San Francisco" && @.addresses.state == "Nevada")`** — Objects that are the fourth element of an array `friends`, provided that *there is a match for an address* with a `city` of "`San Francisco`" *and there is a match for an address* with a `state` of "`Nevada`".

  Note: The filter conditions in the conjunction do *not* necessarily apply to the *same* object — the filter tests for the existence of an object with city San Francisco and for the existence of an object with state Nevada. It does *not* test for the existence of an object with both city San Francisco and state Nevada. See Using Filters with JSON_EXISTS.

- `$.friends[3]`**`.addresses`**`?(@.city == "San Francisco" && @.state == "Nevada")` — An object that is the fourth element of array `friends`, provided that object has a match for `city` of "`San Francisco`" and a match for `state` of "`Nevada`".

  Unlike the preceding example, in this case the filter conditions in the conjunction, for fields `city` and `state`, apply to the *same* `addresses` object. The filter applies to a given `addresses` object, which is outside it.

- `$.friends[3].addresses?(@.city == `**`$City`**` && @.state == `**`$State`**`)` — Same as the previous, except the values used in the comparisons are SQL/JSON *variables*, `$City` and `$State`. The variable values would be provided by SQL bind variables `City` and `State` in a `PASSING` clause: `PASSING ... AS "City", ... AS "State"`. Use of variables in comparisons can improve performance by avoiding query recompilation.

16.2.2 SQL/JSON Path Expression Syntax Relaxation

The basic SQL/JSON path-expression syntax is relaxed to allow implicit array wrapping and unwrapping. This means that you need not change a path expression in your code if your data evolves to replace a JSON value with an array of such values, or vice versa. Examples are provided.

Basic SQL/JSON Path Expression Syntax defines the basic SQL/JSON path-expression syntax. The actual path expression syntax supported relaxes that definition as follows:

- If a path-expression step targets (expects) an array but the actual data presents no array then the data is implicitly wrapped in an array.

- If a path-expression step targets (expects) a nonarray but the actual data presents an array then the array is implicitly unwrapped.

This relaxation allows for the following abbreviation: `[*]` can be elided whenever it precedes the object accessor, `.`, followed by an object field name, with no change in effect. The reverse

is also true: `[*]` can always be inserted in front of the object accessor, `.`, with no change in effect.

This means that the object step `[*].`*prop*, which stands for the value of field *prop* of each element of a given array of objects, can be abbreviated as `.`*prop*, and the object step `.`*prop*, which looks as though it stands for the *prop* value of a single object, stands also for the *prop* value of each element of an array to which the object accessor is applied.

This is an important feature, because it means that you need not change a path expression in your code if your data evolves to replace a given JSON value with an array of such values, or vice versa.

For example, if your data originally contains objects that have field `Phone` whose value is a single object with fields `type` and `number`, the path expression `$.Phone.number`, which matches a single phone number, can still be used if the data evolves to represent an array of phones. Path expression `$.Phone.number` matches either a single phone object, selecting its number, or an array of phone objects, selecting the number of each.

Similarly, if your data mixes both kinds of representation — there are some data entries that use a single phone object and some that use an array of phone objects, or even some entries that use both — you can use the same path expression to access the phone information from these different kinds of entry.

Here are some example path expressions from section Basic SQL/JSON Path Expression Syntax, together with an explanation of equivalences.

- `$.friends` – The value of field `friends` of *either*:

  – The (single) context-item object.

  – (equivalent to `$[*].friends`) Each object in the context-item array.

- `$.friends[0].name` – Value of field `name` for *any* of these objects:

  – The first element of the array that is the value of field `friends` of the context-item object.

  – (equivalent to `$.friends.name`) The value of field `friends` of the context-item object.

  – (equivalent to `$[*].friends.name`) The value of field `friends` of each object in the context-item array.

  – (equivalent to `$[*].friends[0].name`) The first element of each array that is the value of field `friends` of each object in the context-item array.

  The context item can be an object or an array of objects. In the latter case, each object in the array is matched for a field `friends`.

  The value of field `friends` can be an object or an array of objects. In the latter case, the first object in the array is used.

- `$.*[*].name` – Value of field `name` for *any* of these objects:

  – An element of an array value of a field of the context-item object.

  – (equivalent to `$.*.name`) The value of a field of the context-item object.

  – (equivalent to `$[*].*.name`) The value of a field of an object in the context-item array.

    – (equivalent to `$[*].*[*].name`) Each object in an array value of a field of an object in the context-item array.

- Basic SQL/JSON Path Expression Syntax
  The basic syntax of a SQL/JSON path expression is presented. It is composed of a context-item symbol (`$`) followed by zero or more object, array, and descendant steps, each of which can be followed by a filter expression, followed optionally by a function step. Examples are provided.

- Negation in Path Expressions
  Negation in a path expression can be confusing when the data matched by the path is multiple. Some simple examples are explained.

16.2.3 Negation in Path Expressions

Negation in a path expression can be confusing when the data matched by the path is multiple. Some simple examples are explained.

A *negation* filter condition has this form: predicate `!` (read "not") followed by a filter condition, perhaps in parentheses: `!( condition )`. Its semantics are to succeed (return true) whenever the `condition` fails (returns false).

SQL/JSON condition `json_exists` checks for the *existence* of given JSON data. And the SQL query functions, such as `json_value`, find and return *existing* JSON data. Predicate `!` checks that the existence posited by its argument condition is false, which means it checks for *non*existence.

The infix not-equals comparison predicate, which can be written `!=` or `<>`, checks whether its two arguments are different (returning true) or the same (returning false).

That all likely sounds straightforward, but when the data matched by a path expression is multiple, things can seem to get complicated...

Consider these documents:

```
{"customer" : "A",
 "locations" : [ {"country" : "France"} ]}

{"customer"  : "B",
 "locations" : [ {"country" : "Germany"} ]}

{"customer"  : "C",
 "locations" : [ {"country" : "France"}, {"country" : "Spain"} ]}

{"customer"  : "D",
 "locations" : [ {"country" : "Spain"} ]}

{"customer"  : "E",
 "locations" : []}

{"customer"  : "F"}
```

Consider these path expressions:

```
-- Path 1: locations that include the country of France.
$.locations?( @.country == "France" )

-- Path 2: locations that include a country other than France.
$.locations?( @.country != "France" )

-- Path 3: locations that do NOT include the country of France.
$.locations?( !(@.country == "France") )

-- Path 4: locations with one or more countries, NONE of which is
France.
$.locations?( exists@.country && !(@.country == "France") )

-- Path 5: locations with a country other than France or Germany.
$.locations?( (@.country != "France") || (@.country != "Germany") )
```

- *Path 1* returns the documents for customers *A* and *C*, because their `locations` array has an element with field `country` whose value is `"France"`.

- *Path 2* returns the documents for customers *B*, *C*, and *D*, because their `locations` array has an element with field `country` whose value is *not* `"France"` (`"Spain"` for *C* and *D*, `"Germany"` for *B*). No path returns the document for customer *E*, because its `locations` array has no such element (country France or not): its `locations` array has no elements at all. And none of the paths return the document for customer *F*, because it has no `locations` field.

- *Path 3* returns the documents for customers *B*, *D*, and *E*, because their `locations` array does *not* have an element with field `country` whose value is `"France"`. Path 3 does *not* return the documents for customers *A* and *C*, because their `locations` array does have an element with field `country` whose value is `"France"`. And it doesn't return the document for customer *F*, because it has no `locations` field.

  Note in particular that paths 2 and 3 have different results. Including a country other than France isn't the same thing as not including the country of France. Path 2 *requires a country* that is *not* France, whereas path 3 requires there *not be any country* whose value is France. Path 2 includes *C* and excludes *E*, because Germany is not France and *E* has no country. Path 3 includes *E* and excludes *C*, because *E* has no country and *C*'s locations include France.

- *Path 4* returns the documents for customers *B* and *D*. It is the same as path 3, except that it requires that field `country` exist, which excludes the document for customer *E*.

- *Path 5* returns the documents for all customers except *F*, which has no `locations` field. The `!=` tests succeed for customer *E* because it has no `country` field to compare. And any document with a `country` field succeeds because every country is either not France or not Germany. Only the document for customer *F* has no *country* field.

Consider also these paths that use predicate **in**:

```
-- Path 6: locations that include France or Germany.
@.locations?( @.country in ("France", "Germany") )
```

```
-- Path 7: locations that do NOT include France or Germany.
@.locations?( !(@.country in ("France", "Germany")) )

-- Path 8: locations that have one or more countries, NONE of which is
France or Germany.
@.locations?( exists(@.country)
              &&
              !(@.country in ("France", "Germany")) )
```

- *Path 6* returns the documents for customers *A*, *B*, and *C*, because their `locations` array has a `country` field whose value is `in` the set ("`France`", "`Germany`") — "`France`" for *A* and *C*, "`Germany`" for *B*.

- *Path 7* excludes documents for customers in France and Germany. It returns the documents for customer *D*, which is located only in Spain, and customer *E*, which has an empty `locations` array. It doesn't return the document for customer *F* because it has no `locations` field.

- *Path 8* returns only the document for customer *D*. Documents for customers *A*, *B*, and *C* are excluded because they have a location in France or Germany. The document for customer *E* is excluded because it has no `country` field, and the document for customer *F* is excluded because it has no `locations` field.

16.3 SQL/JSON Path Expression Item Methods

The Oracle item methods available for a SQL/JSON path expression are presented. How they act on targeted JSON data is described in general terms and for each item method.

General Behavior of Item Methods

An item method is applied to the JSON data that is targeted by (the rest of) the path expression that is *terminated* by that method. The method is used to transform that data. The SQL function or condition that is passed the path expression uses the transformed data in place of the targeted data. In some cases the application of an item method acts as a filter, removing the targeted data from the result set.

If an item-method conversion fails for any reason, such as its argument being of the wrong type, then the path cannot be matched (it refers to no data), and *no error is raised*. In particular, this means that such an error is *not* handled by an error clause in the SQL function or condition to which the path expression is passed.

An item method always transforms the targeted JSON data to (possibly other) *JSON* data, which is always scalar. But a query using a path expression (with or without an item method) can return data as a *SQL* scalar data type. That is the case for a `json_value` query or an equivalent dot-notation query.

- The return value of SQL/JSON function `json_query` (or a `json_table` column expression that has `json_query` semantics) is always *JSON data*, of SQL data type `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. The default return data type is `JSON` if the targeted data is also of `JSON` type. Otherwise, it is `VARCHAR2`.

- The return value of SQL/JSON function `json_value` (or a `json_table` column expression that has `json_value` semantics) is always of a SQL data type other than `JSON` type: a scalar type, an object type, or a collection type; it does *not* return JSON data. Though the path expression targets JSON data and an item method transforms targeted JSON data to JSON data, `json_value` converts the resulting JSON data to a scalar SQL value in a data type that does not necessarily support JSON data.

- A dot-notation query with an item method implicitly applies `json_value` with a `RETURNING` clause that specifies a scalar SQL type to the JSON data that is targeted and possibly transformed by an item method. Thus, a dot-notation query with an item method always returns a *SQL scalar value*.

Application of an Item Method to an Array

With the exception of item methods `count()`, `size()` and `type()`, if an array is targeted by an item method then the method is *applied to each of the array elements*, not to the array itself. The results of these applications are returned in place of the array, as multiple values. That is, the resulting set of matches includes the converted array elements, not the targeted array.

(This is similar, in its effect, to the implied unwrapping of an array when a nonarray is expected for an object step.)

For example, `$.a.`*method*`()` applies item-method *method()* to each element of array `a`, to convert that element and use it in place of the array.

- For a `json_value` query that specifies a SQL collection type (varray or nested table) as the return type, an instance of that collection type is returned, corresponding to the JSON array that results from applying the item method to each of the array elements, unless there is a type mismatch with respect to the collection type definition.

- For a `json_value` query that returns any other SQL type, SQL `NULL` is returned. This is because mapping the item method over the array elements results in multiple return values, and that represents a mismatch for `json_value`.

- For `json_query` or a `json_table` column expression with `json_query` semantics, you can use a wrapper clause to capture all of the converted array-element values as an array. For example, this query:

```
SELECT json_query('[ "alpha", 42, "10.4" ]', '$[*].stringOnly()'
                WITH ARRAY WRAPPER)
  FROM dual;
```

returns this JSON array: `[ "alpha", "10.4" ]`. The SQL data type returned is the same as the JSON data that was targeted: `JSON`, `VARCHAR2(4000)`, `CLOB`, or `BLOB`.

Item methods `count()`, `size()` and `type()` are *exceptional* in this regard. When applied to an array they treat it as such, instead of acting on its elements. For example:

```
SELECT json_value('[ 19, "Oracle", {"a":1}, [1,2,3] ]', '$.type()')
  FROM dual;
```

returns the single `VARCHAR2` value `'array'` — `json_value` returns `VARCHAR2(4000)` by default.

A similar query, but with `json_query` instead of `json_value`, returns the single *JSON* string `"array"`, of whatever SQL data type is used for the input JSON data: `JSON`, `VARCHAR2(4000)`, `CLOB`, or `BLOB`.

> **Note:**
>
> The same thing that happens for `json_value` (with a SQL return type other than an object or collection type) happens for a simple *dot notation* query. The presence of an item method in dot notation syntax always results in `json_value`, not `json_query`, semantics. This must produce a single scalar SQL value (which can be used with SQL `ORDER BY`, `GROUP BY`, and comparisons or join operations). But an item method applied to an array value results in multiple values, which `json_value` semantics rejects — SQL `NULL` is returned.

Data-Type Conversion Item Methods

The following item methods are data-type conversion methods: `binary()`, `binaryOnly()`, `boolean()`, `booleanOnly()`, `date()`, `dateTimeOnly()`, `dateWithTime()`, `idOnly()`, `number()`, `numberOnly()`, `double()`, `dsInterval()`, `float()`, `number()`, `numberOnly()`, `string()`, `stringOnly()`, `timestamp()`, `toBoolean()`, `toDateTime()`, and `ymInterval()`.

As mentioned, an item method always transforms its targeted JSON data to (possibly other) JSON data. But when the method is used in a `json_value` query, (or another function that returns SQL data), the JSON data resulting from its transformation is in turn converted to a SQL return value. If present, a `RETURNING` clause specifies the SQL type for that data; if absent, each item method results in a particular default SQL type. For example, the default SQL type for item-method `string()` is `VARCHAR2(4000)`.

In a query that has `json_value` semantics, a value targeted by a **data-type conversion** item method can generally be thought of as being *interpreted as a SQL value* of that method's default SQL data type, meaning that the value is handled as if it were controlled by a `RETURNING` clause with that SQL data type.

For example, item-method `string()` interprets its target as would `json_value` with clause `RETURNING VARCHAR2(4000)`. A Boolean JSON value is thus treated by `string()` as `"true"` or `"false"`; a `null` value is treated by `string()` as `"null"`; and a number is treated by `string()` as a numeral in a canonical string form.

The data-type conversion methods *without* "only" in their name allow conversion, when possible, of a JSON value — in some cases even a value that is not in the type family named by the method — to the method's JSON type, and they then interpret the result as a value of the method's default SQL type.

The "only" data-type conversion methods convert *only* JSON values that are in the type family named by the method. Other targeted values are filtered out. They convert the value to

the default JSON type for the method, and then interpret the result as a value of the method's default SQL type.

For `numberOnly()`, the family type is number (numeric JSON types), its default JSON type for the family is `number`, and the default SQL type is `NUMBER`. For `dateTimeOnly()`, the default family type is `timestamp`, and the default SQL type is `TIMESTAMP`.

(When an "only" method targets an array, the conversion applies to each array element, as usual.)

An aggregate method, such as `avg()`, converts targeted values to the method's default type, and then interprets them as the method's default SQL type. For `avg()`, targeted values of type `number`, `float`, and `double` are all converted to JSON type `number`, and are interpreted as SQL `NUMBER` values.

Nonaggregate methods, such as `abs()`, do no conversion within the relevant type family. So `abs()` converts the string `"-3.14"` to a JSON number, but it leaves a targeted JSON float or double value as it is, and interprets it as a SQL `BINARY_FLOAT` or `BINARY_DOUBLE` value, respectively.

Table 16-1   Item Method Data-Type Conversion

Item Method	Input JSON-Language Type	Output JSON-Language Type	SQL Type	Notes
`binary()`	binary (both identifier and nonidentifier)	binary	`RAW` or `BLOB`	None.
`binary()`	string	binary	`RAW` or `BLOB`	Error if any input characters are not hexadecimal numerals.
`binaryOnly()`	binary (both identifier and nonidentifier)	binary	`RAW` or `BLOB`	None.
`boolean()`	boolean	boolean	`BOOLEAN`	None.
`boolean()`	string	boolean	`BOOLEAN`	Error if input is not `"true"` or `"false"`
`booleanOnly()`	boolean	boolean	`BOOLEAN`	None.
`date()`	date, timestamp, or timestamp with time zone	date	`DATE`	JSON output is UTC with no time components.
`date()`	string	date	`DATE`	JSON output is UTC with no time components. Error if input is not ISO UTC, with no time components.
`dateTimeOnly()`	date, timestamp, or timestamp with time zone	timestamp	`TIMESTAMP`	None.
`dateWithTime()`	date, timestamp, or timestamp with time zone	date	`DATE`	UTC, with no fractional seconds.

Table 16-1   (Cont.) Item Method Data-Type Conversion

Item Method	Input JSON-Language Type	Output JSON-Language Type	SQL Type	Notes
dateWithTime()	string	date	DATE	UTC, with no fractional seconds. Error if input is not ISO.
double()	number, double, or float	double	BINARY_DOUBLE	None.
double()	string	double	BINARY_DOUBLE	Error if input is not a number representation.
float()	number, double, or float	float	BINARY_FLOAT	Error if input is out of range.
float()	string	float	BINARY_FLOAT	Error if input is not a number representation.
idOnly()	binary identifier	binary identifier	RAW	None.
number()	number, double, or float	number	NUMBER	Error if input is out of range.
number()	string	number	NUMBER	Error if input is not a number representation.
numberOnly()	number, double, or float	number	NUMBER	None.
string()	Any.	string	VARCHAR2 or CLOB	Resulting SQL value is in the database character set, even though the output JSON-language string is UTF-8.
stringOnly()	string	string	VARCHAR2 or CLOB	Resulting SQL value is in the database character set, even though the input and output JSON-language strings are UTF-8.
timestamp()	date, timestamp, or timestamp with time zone	timestamp	TIMESTAMP	None.
timestamp()	string	timestamp	TIMESTAMP	Error if input is not ISO UTC.
toBoolean()	boolean	boolean	BOOLEAN	None.
toBoolean()	string	boolean	BOOLEAN	Error if input string is not "true" or "false"

Table 16-1   (Cont.) Item Method Data-Type Conversion

Item Method	Input JSON-Language Type	Output JSON-Language Type	SQL Type	Notes
`toBoolean()`	number, double, or float	boolean	`BOOLEAN`	Zero is converted to `false`. All other numeric values are converted to `true`.
`toDateTime()`	date, timestamp, or timestamp with time zone	timestamp	`TIMESTAMP`	None.
`toDateTime()`	string	timestamp	`TIMESTAMP`	Error if input is not ISO UTC.
`toDateTime()`	number, double, or float	timestamp	`TIMESTAMP`	Numbers are interpreted as the number of seconds since 1970-01-01. Only non-negative numbers are matched.

Item-Method Descriptions

- `abs()`: The *absolute value* of the targeted JSON number. Corresponds to the use of SQL function `ABS`.

- `atan()`: The trigonometric *arctangent* function of the targeted JSON number (in radians). Corresponds to the use of SQL function `ATAN`.

- `avg()`: The *average* of all targeted JSON numbers. If any targeted value is not a number then an error is raised. Corresponds to the use of SQL function `AVG` (without any optional behavior). This is an aggregate method.

- `binary()`: A SQL `RAW` interpretation of the targeted JSON value, which can be a hexadecimal string or a JSON binary value. If a string, SQL function `hextoraw` is used for conversion to a SQL `RAW` value. This item method is applicable only to JSON data stored as `JSON` type.

- `binaryOnly()`: A SQL `RAW` interpretation of the targeted JSON value, but only if it is a JSON binary value. Acts as a filter, allowing matches only for JSON binary values. (Only JSON data stored as `JSON` type can have JSON binary values.)

- `boolean()`: A SQL `BOOLEAN` interpretation of the targeted JSON value.

> **✎ Note:**
>
> Prior to Release 23c, this used a SQL `VARCHAR2(20)` interpretation. If you need to obtain a `VARCHAR2` value (for compatibility reasons, for example) then you can wrap the value with SQL function `to_char`.

- `booleanOnly()`: A SQL `BOOLEAN` interpretation of the targeted JSON data, but only if it is a JSON Boolean value (`true` or `false`); otherwise, there is no match. Acts as a filter, allowing matches only for JSON Boolean values.

> **✎ Note:**
>
> Prior to Release 23c, this used a SQL `VARCHAR2(20)` interpretation. If you need to obtain a `VARCHAR2` value (for compatibility reasons, for example) then you can wrap the value with SQL function `to_char`.

- **`ceiling()`**: The targeted JSON number, *rounded up* to the nearest integer. Corresponds to the use of SQL function `CEIL`.

- **`concat()`**: The *concatenation* of the (two or more) string arguments. This item method can only be used on the RHS of a path expression (otherwise an error is raised).

- **`cos()`**: The trigonometric *cosine* function of the targeted JSON number (in radians). Corresponds to the use of SQL function `COS`.

- **`cosh()`**: The trigonometric *hyperbolic-cosine* function of the targeted JSON number (in radians). Corresponds to the use of SQL function `COSH`.

- **`count()`**: The number of targeted JSON values, regardless of their types. This is an aggregate method.

- **`date()`**: A SQL `DATE` interpretation of the targeted JSON value. The targeted value must be either (1) a JSON `string` in a supported ISO 8601 format for a date or a date with time or (2) (if the data is of SQL type `JSON`) a `date`, `timestamp`, or `timestamp with time zone` value. Otherwise, there is no match.

  A SQL `DATE` value has no time component (it is set to zero). But before any time truncation is done, if the value represented by an ISO 8601 date-with-time string has a time-zone component then the value is first converted to UTC, to *take any time-zone information into account*.

  For example, the JSON string `"2021-01-01T05:00:00+08:00"` is interpreted as a SQL `DATE` value that corresponds to the UTC string `"2020-12-31 00:00:00"`.

  The resulting date faithfully reflects the time zone of the data — target and result represent the same date — but the result can differ from what a simple time truncation would produce. (This behavior is similar to that of Oracle SQL function `json_scalar`.)

- **`dateTimeOnly()`**: A SQL `TIMESTAMP` interpretation of the targeted JSON value. The targeted value must be a `date`, `timestamp`, or `timestamp with time zone` value. (Only JSON data stored as `JSON` type can have such values.)

- **`dateWithTime()`**: Like `date()`, except that the time component of an ISO 8601 date-with-time format is *preserved* in the SQL `DATE` instance.

- **`double()`**: A SQL `BINARY_DOUBLE` interpretation of the targeted JSON string or number.

- **`dsInterval()`**: A SQL `INTERVAL DAY TO SECOND` interpretation of the targeted JSON string. The targeted string data must be in one of the supported ISO 8601 duration formats; otherwise, there is no match.

- **`exp()`**: The mathematical *exponential* function of the targeted JSON number. That is, the mathematical constant *e* (Euler's number, 2.71828183...), raised to the power of the targeted JSON number. Corresponds to the use of SQL function `EXP`.

- **`float()`**: A SQL `BINARY_FLOAT` interpretation of the targeted JSON string or number.

- **`floor()`**: The targeted JSON number, *rounded down* to the nearest integer. Corresponds to the use of SQL function `FLOOR`.

- **idOnly()**: A SQL `RAW` interpretation of the targeted JSON value. Acts as a filter, allowing matches only for JSON binary values that are tagged internally as having been derived from an extended object with field `$rawid` or `$oid`. (Only JSON data stored as `JSON` type can have JSON binary values.)

- **indexOf()**: The *position* (index) of the *first* element of the specified JSON array that is *equal* to the specified JSON value. The array is the first argument, and the value to check for equality is the second argument. This item method can only be used on the RHS of a path expression (otherwise an error is raised).

  One or two optional arguments are also accepted: the first argument is the array position of the first element to check (positions before that are skipped). The second is the maximum number of array elements to check. (You can, for example, use the optional arguments to loop over an array to locate matching elements, in array order.)

  – For data that is of `JSON` data type, *all* JSON-language values are comparable. Comparison is according to the canonical sort order.

  – For data that is *not* of `JSON` type, only *scalar* JSON values are comparable. Nonscalar data values are ignored, and the specified JSON value to locate must be scalar (otherwise an error is raised).

- **length()**: The *number of characters* in the targeted JSON string, interpreted as a SQL `NUMBER`. Corresponds to the use of SQL function `LENGTH`.

- **listagg()**: The *concatenation* of the targeted JSON values, which must be strings (otherwise an error is raised). Accepts an optional delimiter-string argument, which is inserted between consecutive targeted strings. Corresponds to the use of SQL function `LISTAGG`. This is an aggregate method.

- **log()**: The mathematical *logarithm* function of the targeted JSON number. Corresponds to the use of SQL function `LOG`. This method takes an optional numeric argument, which is the logarithm base. The default base is the mathematical constant *e* (Euler's number, 2.71828183...), which means that by default this computes the *natural* logarithm.

- **lower()**: The *lowercase* string that corresponds to the characters in the targeted JSON string. Corresponds to the use of SQL function `LOWER`.

- **maxDateTime()**: The *maximum* of all targeted JSON *dates with times*. Item method `dateWithTime()` is first applied implicitly to each of the possibly multiple values. Their maximum (a single `TIMESTAMP` value) is then returned. Targeted JSON values that cannot be converted to dates with times are ignored.

- **maxNumber()**: The *maximum* of all targeted JSON *numbers*. Item method `number()` is first applied implicitly to each of the possibly multiple values. Their maximum (a single `NUMBER` value) is then returned. Targeted JSON values that cannot be converted to numbers are ignored.

- **maxString()**: The *greatest* of all targeted JSON *strings*, using collation order. Item method `string()` is first applied implicitly to each of the possibly multiple values. The greatest of these (a single `VARCHAR2` value) is then returned. Targeted JSON values that cannot be converted to strings are ignored.

- **minDateTime()**: The *minimum* of all targeted JSON *dates with times*. Item method `dateWithTime()` is first applied implicitly to each of the possibly multiple values. Their minimum (a single `TIMESTAMP` value) is then returned. Targeted JSON values that cannot be converted to dates with times are ignored.

- **minNumber()**: The *minimum* of all targeted JSON *numbers*. Item method `number()` is first applied implicitly to each of the possibly multiple values. Their minimum (a single `NUMBER` value) is then returned. Targeted JSON values that cannot be converted to numbers are ignored.

- **minString()**: The *least* of all targeted JSON *strings*, using collation order. Item method `string()` is first applied implicitly to each of the possibly multiple values. The least of these (a single `VARCHAR2` value) is then returned. Targeted JSON values that cannot be converted to strings are ignored.

- **number()**: A SQL `NUMBER` interpretation of the targeted JSON string or number.

- **numberOnly()**: A SQL `NUMBER` interpretation of the targeted JSON data, but only if it is a JSON number; otherwise, there is no match. Acts as a filter, allowing matches only for JSON numbers.

- **pow()**: The mathematical *power* function of the targeted JSON number. This raises the targeted JSON number to the specified power, which is a required numeric argument. Corresponds to the use of SQL function `POWER`.

- **round()**: The targeted JSON number, *rounded away from zero* to the nearest integer. Corresponds to the use of SQL function `ROUND` (without optional behavior of specifying the number of digits).

- **sin()**: The trigonometric *sine* function of the targeted JSON number (in radians). Corresponds to the use of SQL function `SIN`.

- **sinh()**: The trigonometric *hyperbolic-sine* function of the targeted JSON number (in radians). Corresponds to the use of SQL function `SINH`.

- **size()**: If *multiple* JSON values are targeted then the result of applying `size()` to each targeted value. Otherwise:

  – If the single targeted value is a *scalar* then 1.

  – If the single targeted value is an *array* then the number of array elements.

  – If the single targeted value is an *object* then 1.

  This item method can be used with `json_query`, in addition to `json_value` and `json_table`. If applied to data that is an array, no implicit iteration over the array elements occurs: the resulting value is just the number of array elements. (This is an exception to the rule of implicit iteration.)

- **stddev()**: The statistical *standard-deviation* function of the targeted JSON values, which must be numbers (otherwise an error is raised). Corresponds to the use of SQL function `STDDEV`. This is an aggregate method.

- **string()**: A SQL `VARCHAR2(4000)` interpretation of the targeted scalar JSON value.

- **stringOnly()**: A SQL `VARCHAR2(4000)` interpretation of the targeted scalar JSON value, but only if it is a JSON string; otherwise, there is no match. Acts as a filter, allowing matches only for JSON strings.

- **substr()**: A *substring* of the targeted JSON string. Corresponds to the use of SQL function `SUBSTR`, but it is zero-based, not one-based. The starting position of the substring in the targeted string is a required argument. The maximum length of the substring is an optional (second) argument.

- **sum()**: The *sum* of all targeted JSON numbers. If any targeted value is not a number then an error is raised. Corresponds to the use of SQL function `SUM` (without any optional behavior).

- **`tan()`**: The trigonometric *tangent* function of the targeted JSON number (in radians). Corresponds to the use of SQL function `TAN`.

- **`tanh()`**: The trigonometric *hyperbolic-tangent* function of the targeted JSON number (in radians). Corresponds to the use of SQL function `TANH`.

- **`timestamp()`**: A SQL `TIMESTAMP` interpretation of the targeted JSON value. The targeted string data must be either (1) a JSON `string` in a supported ISO 8601 format for a date or a date with time or (2) (if the data is of SQL type `JSON`) a `date`, `timestamp`, or `timestamp with time zone` value. Otherwise, there is no match.[6]

- **`toBoolean()`**: A SQL `VARCHAR2(20)` interpretation of the targeted JSON value. This is the same as method `boolean()`, except that the targeted value can be a numeric value, in which case zero corresponds to `false` and any other number corresponds to `true`.

- **`toDateTime()`**: A SQL `TIMESTAMP` interpretation of the targeted JSON value. The targeted string data must be either (1) a JSON `string` in a supported ISO 8601 format for a date or a date with time, (2) a non-negative numeric value, or (3) (if the data is of SQL type `JSON`) a `date`, `timestamp`, or `timestamp with time zone` value. Otherwise, there is no match.[7]

- **`type()`**: The name of the *JSON-language data type family* of the targeted data, or one of its family members, interpreted as a SQL `VARCHAR2(20)` value. For example, for the numeric type family, the value returned can be `"double"`, `"float"`, or `"number"`. See Comparison and Sorting of JSON Data Type Values.

  This item method can be used with `json_query`, in addition to `json_value` and `json_table`. If applied to data that is an array, no implicit iteration over the array elements occurs: the resulting value is `"array"`. (This is an exception to the rule of implicit iteration.)

  - `"null"` for a `null` value.

  - `"boolean"` for a Boolean value (`true` or `false`).

  - `"number"` for a number.

  - `"string"` for a string.

  - `"array"` for an array.

  - `"object"` for an object.

  - `"double"` for a number that corresponds to a SQL `BINARY_DOUBLE` value. (For `JSON` type data only.)

  - `"float"` for a number that corresponds to a SQL `BINARY_FLOAT` value. (For `JSON` type data only.)

  - `"binary"` for a value that corresponds to a SQL `RAW` value. (For `JSON` type data only.)

  - `"date"` for a value that corresponds to a SQL `DATE` value. (For `JSON` type data only.)

---

[6] Applying item method `timestamp()` to a supported ISO 8601 string `<ISO-STRING>` has the effect of SQL `sys_extract_utc(to_utc_timestamp_tz(<ISO-STRING>))`.

[7] Applying item method `toDateTime()` to a supported ISO 8601 string `<ISO-STRING>` has the effect of SQL `sys_extract_utc(to_utc_timestamp_tz(<ISO-STRING>))`. A non-negative numeric value is interpreted as the number of seconds since 1970-01-01.

- – "timestamp" for a value that corresponds to a SQL TIMESTAMP value. (For JSON type data only.)

- – "timestamp with time zone" for a value that corresponds to a SQL TIMESTAMP WITH TIME ZONE value. (For JSON type data only.)

- – "daysecondInterval" for a value that corresponds to a SQL INTERVAL DAY TO SECOND value. (For JSON type data only.)

- – "yearmonthInterval" for a value that corresponds to a SQL INTERVAL YEAR TO MONTH value. (For JSON type data only.)

- **upper()**: The *uppercase* string that corresponds to the characters in the targeted JSON string. Corresponds to the use of SQL function UPPER.

- **variance()**: The statistical *variance* function of the targeted JSON values, which must be numbers (otherwise an error is raised). Corresponds to the use of SQL function VARIANCE. This is an aggregate method.

- **ymInterval()**: A SQL INTERVAL YEAR TO MONTH interpretation of the targeted JSON string. The targeted string data must be in one of the supported ISO 8601 duration formats; otherwise, there is no match.

Item methods abs(), ceiling(), double(), floor(), size(), and type() are part of the SQL/JSON standard. The other methods are *Oracle extensions* to the SQL/JSON standard: atan(), avg(), binary(), binaryOnly(), boolean(), booleanOnly(), concat(), cos(), cosh(), date(), dateTimeOnly(), dateWithTime(), double(), dsInterval(), exp(), float(), idOnly(), indexOf(), length(), listagg(), log(), lower(), maxDateTime(), maxNumber(), maxString(), minDateTime(), minNumber(), minString(), number(), numberOnly(), pow(), round(), sin(), sinh(), stddev(), string(), stringOnly(), substr(), sum(), tan(), tanh() , timestamp(), toBoolean(), toDateTime(), upper(), variance(), and ymInterval().

Item methods avg(), count(), listagg(), maxNumber(), minNumber(), maxString(), minString(), stddev(), sum(), and variance() are *aggregate* item methods. Instead of acting individually on each targeted value they act on all targeted values *together*. For example, if a path expression targets multiple values that can be converted to numbers then sum() returns the sum of those numbers.

Note that when a path expression targets an *array*, applying an aggregate item method to it, the array is handled as a single value — there is *no implicit iteration* over the array elements. For example, count() counts any targeted array as one value, and size() returns the size of the array, not the sizes of its elements.

If you want an aggregate item method to act on the array elements then you need to explicitly iterate over those elements, using wildcard *. For example, if the value of field LineItems in a given document is an array then $.LineItems.count() returns 1, but $.LineItems**[*]**.count() returns the number of array elements.

An aggregate item method applies to a *single JSON document* at a time, just like the path expression (or dot-notation) of which it is part. It aggregates the multiple values that the path expression targets in that document. In a query it returns a row for each document. It does *not* aggregate information across multiple documents, returning a single row for all documents, as do SQL aggregate functions. See Example 16-1 and Example 16-2.

Item Methods and JSON_VALUE RETURNING Clause

Because some item methods interpret the targeted JSON data as if it were of a SQL data type, they can be used with `json_value` in place of a `RETURNING` clause, and they can be used with `json_table` in place of a column type specification. That is, the *item methods can be used to specify the returned SQL data type* for the extracted JSON data.

You can also use such item methods *together with* a `json_value RETURNING` clause or a `json_table` column type specification. What happens if the SQL data type to use for extracted JSON data is controlled by *both* an item method and either a `json_value RETURNING` clause or a `json_table` column type?

- If the two data types are compatible then the data type for the `RETURNING` clause or the column is used. For these purposes, `VARCHAR2` is compatible with both `VARCHAR2` and `CLOB`.

- If the data types are incompatible then a static, compile-time *error* is raised.

Table 16-2   Compatibility of Type-Conversion Item Methods and RETURNING Types

Item Method	Compatible RETURNING Clause Data Types
`string()`, `stringOnly()`, `minString()`, or `maxString()`	`VARCHAR2` or `CLOB`, except that `string()` returns SQL `NULL` for a JSON `null` value
`number()`, `numberOnly()`, `avg()`, `sum()`, `count()`, `minNumber()`, or `maxNumber()`	`NUMBER`
`double()`	`BINARY_DOUBLE`
`float()`	`BINARY_FLOAT`
`date()`	`DATE`, with truncated time component (set to zero), corresponding to `RETURNING DATE TRUNCATE TIME`. If the JSON value is an ISO string with time-zone information, the represented date-with-time is first converted to UTC, to take the time zone into account.
`dateWithTime()`	`DATE`, with time component, corresponding to `RETURNING DATE PRESERVE TIME`
`timestamp()`, `toDateTime()`	`TIMESTAMP`
`ymInterval()`	`INTERVAL YEAR TO MONTH`
`dsInterval()`	`INTERVAL DAY TO SECOND`
`boolean()`, `booleanOnly()`, or `toBoolean()`	`VARCHAR2`, `BOOLEAN`
`binary()`	`RAW`

Using a `RETURNING` clause or a column specification, you can specify a length for character data and a precision and scale for numerical data. This lets you assign a more precise SQL data type for extraction than what is provided by an item method for target-data comparison purposes.

For example, if you use item method `string()` and `RETURNING VARCHAR2(150)` then the data type of the returned data is `VARCHAR2(150)`, not `VARCHAR2(4000)`.

Example 16-1   Aggregating Values of a Field for Each Document

This example uses item method `avg()` to aggregate the values of field `Quantity` across all `LineItems` elements of a JSON document, returning the average *for each document* as a separate result row.

```
SELECT json_value(po_document,
                  '$.LineItems[*].Quantity.avg()')
  FROM j_purchaseorder;
```

Example 16-2   Aggregating Values of a Field Across All Documents

This example uses SQL function `avg` to aggregate the average line-item `Quantity` values for all JSON documents, returning the overall average *for the entire set of documents* as a single

row. The average quantity for all line items of a given document is computed using item method `avg()`.

```
SELECT avg(json_value(po_document,
                      '$.LineItems[*].Quantity.avg()'))
  FROM j_purchaseorder;
```

Related Topics

- Basic SQL/JSON Path Expression Syntax
  The basic syntax of a SQL/JSON path expression is presented. It is composed of a context-item symbol (`$`) followed by zero or more object, array, and descendant steps, each of which can be followed by a filter expression, followed optionally by a function step. Examples are provided.

- Simple Dot-Notation Access to JSON Data
  Dot notation is designed for easy, general use and common use cases of querying JSON data. For simple queries it is a handy alternative to using SQL/JSON query functions.

- ISO 8601 Date, Time, and Duration Support
  International Standards Organization (ISO) standard 8601 describes an internationally accepted way to represent dates, times, and durations. Oracle Database supports the most common ISO 8601 formats as proper Oracle SQL date, time, and interval (duration) values. The formats that are supported are essentially those that are numeric-only, language-neutral, and unambiguous.

- Types in Comparisons
  Comparisons in SQL/JSON path-expression filter conditions are statically typed at compile time. If the effective types of the operands of a comparison are not known to be the same then an attempt is sometimes made to reconcile them by type-casting.

- RETURNING Clause for SQL Query Functions
  SQL functions `json_value`, `json_query`, `json_serialize`, and `json_mergepatch` accept an optional **RETURNING** clause, which specifies the data type of the value returned by the function. This clause and the default behavior (no `RETURNING` clause) are described here.

- SQL/JSON Function JSON_VALUE
  SQL/JSON function `json_value` selects JSON data and returns a SQL scalar or an instance of a user-defined SQL object type or SQL collection type (varray, nested table).

- SQL/JSON Function JSON_TABLE
  SQL/JSON function `json_table` projects specific JSON data to columns of various SQL data types. You use it to map parts of a JSON document into the rows and columns of a new, virtual table, which you can also think of as an inline view.

- Wrapper Clause for SQL/JSON Query Functions JSON_QUERY and JSON_TABLE
  SQL/JSON query functions `json_query` and `json_table` accept an optional wrapper clause, which specifies the form of the value returned by `json_query` or used for the data in a `json_table` column. This clause and the default behavior (no wrapper clause) are described here. Examples are provided.

- Textual JSON Objects That Represent Extended Scalar Values
  Native binary JSON data (OSON format) extends the JSON language by adding scalar
  types, such as date, that correspond to SQL types and are not part of the JSON
  standard. Oracle Database also supports the use of textual JSON *objects* that *represent*
  JSON scalar values, including such nonstandard values.

- Oracle SQL Function JSON_SCALAR
  Oracle SQL function `json_scalar` accepts a SQL scalar value as input and returns a
  corresponding JSON scalar value as a `JSON` type instance. In particular, the value can be
  of an Oracle-specific JSON-language type (such as a date), which is not part of the
  JSON standard.

16.4 Types in Comparisons

Comparisons in SQL/JSON path-expression filter conditions are statically typed at compile
time. If the effective types of the operands of a comparison are not known to be the same
then an attempt is sometimes made to reconcile them by type-casting.

A SQL/JSON path expression targets JSON data, so the operands of a comparison are
JSON values. Strict type comparison of standard JSON values is straightforward: JSON data
types string, number, null, object, and array are mutually exclusive and incomparable.

But values of `JSON` type *are* comparable (see Comparison and Sorting of JSON Data Type
Values). And in path expressions, comparison operands are sometimes *interpreted*
(essentially cast) as values of SQL data types. This is the case, for example, when some item
methods, such as `number()`, are used. This section addresses the type-checking of such
effective values.

You can prevent such type-casting in either of these ways:

- Explicitly using "only" item methods. For example, applying method `numberOnly()`
  prevents implicit type-casting to a number.

- Use the clause `TYPE (STRICT)` (with `json_transform`, `json_value`, `json_transform`, or
  `json_exists`). This has the same effect as applying the relevant "only" item methods
  throughout the path expression being used.

SQL is a statically typed language; types are determined at compile time. The same applies
to SQL/JSON path expressions, and in particular to comparisons in filter conditions. This
means that you get the same result for a query regardless of how it is evaluated — whether
functionally or using features such as indexes, materialized views, and In-Memory scans.

To realize this:

- If the types of both operands are *known* and they are the *same* then type-checking is
  satisfied.

- If the types of both operands are *unknown* then a compile-time error is raised.

- If the type of one operand is known and the other is unknown then the latter operand is
  cast to the type of the former.

  For example, in `$.a?(@.b.c == 3)` the type of `$a.b.c` is unknown at compile time. The
  path expression is compiled as `$.a?(@.b.c.`**`number()`** `== 3)`. At runtime an attempt is
  thus made to cast the data that matches `$a.b.c` to a number. A string value `"3"` would be
  cast to the number `3`, satisfying the comparison.[8]

---

[8] To prevent such casting here, you can explicitly apply item method `numberOnly()`: `$.a?(@.b.c.`**`numberOnly()`** `==`
  `3)`. Data with a string value `"3"` would simply not match; it would be filtered out.

- If the types of both operands are *known* and they are *not* the same then an attempt is made to cast the type of one to the type of the other. Details are presented below.

An attempt is made to reconcile comparison operands used in the following combinations, by type-casting. You can think of a type-casting item method being implicitly applied to one of the operands in order to make it type-compatible with the other operand.

- Number compared with double — `double()` is implicitly applied to the number to make it a double value.

- Number compared with float — `float()` is implicitly applied to the number to make it a float value.

- String in a supported ISO 8601 format compared with date — `date()` is implicitly applied to the string to make it a date value. For this, the UTC time zone (Coordinated Universal Time, zero offset) is used as the default, taking into account any time zone specified in the string.

- String in a supported ISO 8601 format compared with timestamp without time zone — `timestamp()` is implicitly applied to the string to make it a timestamp value. For this, the UTC time zone (Coordinated Universal Time, zero offset) is used as the default, taking into account any time zone specified in the string.

Comparison operands used in the following combinations are *not* reconciled; a *compile-time error* is raised.

- Number, double, or float compared with any type other than number, double, or float.

- Boolean compared with any type other than Boolean.

- Date or timestamp compared with string, unless the string has a supported ISO 8601 format.

- Date compared with any non-date type other than string (in supported ISO 8601 format).

- Timestamp (with or without time zone) compared with any non-timestamp type other than string (in supported ISO 8601 format).

- Timestamp compared with timestamp with time zone.

- JSON null type compared with any type other than JSON null.

> **Note:**
>
> When comparing values of JSON data type *in SQL*, the size of the values being compared, *as encoded for SQL comparison*, must be less than 32K bytes. Otherwise, an error is raised. In practice, this SQL encoded-for-comparison size is roughly the size of a *textual* representation of the same JSON data.
>
> For example, in this query the encoded sizes of fields dept and name must each be less than 32K:
>
> ```
> SELECT *
>   FROM emp t
>   WHERE t.data.dept = 'SALES' ORDER BY t.data.name
> ```
>
> This limit applies to SQL clauses ORDER BY and GROUP BY, as well as to the use of SQL-value comparison operators (such as > in a WHERE clause).
>
> More precisely, the limit applies only to comparison and sorting done by SQL itself. It does not apply to comparison or sorting done within the *JSON* language. That is, there's no size limit for comparison or sorting done by a SQL operator for JSON, such as json_transform or json_exists. In particular, the limit doesn't apply to comparisons made in SQL/JSON path expressions.

Related Topics

- SQL/JSON Path Expression Item Methods
  The Oracle item methods available for a SQL/JSON path expression are presented. How they act on targeted JSON data is described in general terms and for each item method.

- ISO 8601 Date, Time, and Duration Support
  International Standards Organization (ISO) standard 8601 describes an internationally accepted way to represent dates, times, and durations. Oracle Database supports the most common ISO 8601 formats as proper Oracle SQL date, time, and interval (duration) values. The formats that are supported are essentially those that are numeric-only, language-neutral, and unambiguous.

- TYPE Clause for SQL Functions and Conditions
  Oracle SQL function json_transform, SQL/JSON functions json_query, json_value and json_table, and SQL/JSON condition json_exists accept optional **TYPE** clauses, which specify whether JSON values are compared *strictly* with respect to JSON-language type, that is, as if the relevant "only" data-type conversion item methods were applied to the data being compared.

17

Clauses Used in SQL Functions and Conditions for JSON

Clauses `PASSING`, `RETURNING`, wrapper, error, empty-field, and on-mismatch are described for SQL functions that use JSON data. Each clause is used in one or more of the SQL functions and conditions `json_value`, `json_query`, `json_table`, `json_serialize`, `json_transform`, `json_mergepatch`, `is json`, `is not json`, `json_exists`, and `json_equal`.

- **PASSING Clause for SQL Functions and Conditions**
  Oracle SQL function `json_transform`, SQL/JSON functions `json_value` and `json_query`, and SQL/JSON condition `json_exists` accept an optional `PASSING` clause, which binds SQL values to SQL/JSON variables for use in path expressions.

- **RETURNING Clause for SQL Query Functions**
  SQL functions `json_value`, `json_query`, `json_serialize`, and `json_mergepatch` accept an optional **RETURNING** clause, which specifies the data type of the value returned by the function. This clause and the default behavior (no `RETURNING` clause) are described here.

- **Wrapper Clause for SQL/JSON Query Functions JSON_QUERY and JSON_TABLE**
  SQL/JSON query functions `json_query` and `json_table` accept an optional wrapper clause, which specifies the form of the value returned by `json_query` or used for the data in a `json_table` column. This clause and the default behavior (no wrapper clause) are described here. Examples are provided.

- **Error Clause for SQL Functions and Conditions**
  Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

- **Empty-Field Clause for SQL/JSON Query Functions**
  SQL/JSON query functions `json_value`, `json_query`, and `json_table` accept an optional **ON EMPTY** clause, which specifies the handling to use when a targeted JSON field is absent from the data queried. This clause and the default behavior (no `ON EMPTY` clause) are described here.

- **ON MISMATCH Clause for SQL/JSON Query Functions**
  You can use an **ON MISMATCH** clause with SQL/JSON functions `json_value`, `json_query`, and `json_table`, to handle type-matching exceptions. It specifies handling to use when a targeted JSON value does not match the specified SQL return value. This clause and its default behavior (no `ON MISMATCH` clause) are described here.

- **TYPE Clause for SQL Functions and Conditions**
  Oracle SQL function `json_transform`, SQL/JSON functions `json_query`, `json_value` and `json_table`, and SQL/JSON condition `json_exists` accept optional **TYPE** clauses, which specify whether JSON values are compared *strictly* with respect to JSON-language type, that is, as if the relevant "only" data-type conversion item methods were applied to the data being compared.

17.1 PASSING Clause for SQL Functions and Conditions

Oracle SQL function `json_transform`, SQL/JSON functions `json_value` and `json_query`, and SQL/JSON condition `json_exists` accept an optional `PASSING` clause, which binds SQL values to SQL/JSON variables for use in path expressions.

Keyword **PASSING** is followed by one or more comma-separated SQL/JSON variable bindings, such as `42 AS "d"`.

Each binding is composed of (1) a SQL expression to be evaluated; (2) keyword **AS**; and (3) a SQL/JSON variable name.[1] The binding `42 AS "d"` binds the value of expression `42` to the SQL/JSON variable named `d`, which can be used in a path-expression such as `$.PONumber?(@ > `**$d**`)`.

If you use a `PASSING` clause together with a **TYPE (STRICT)** clause, then *each* value that's compared with a SQL/JSON variable in the path expression is compared *strictly* with respect to its JSON-language type, just as if the relevant "only" data-type conversion item method were applied to the value. The type used for comparison is that of the SQL/JSON variable.

For example, with `TYPE (STRICT)` specified, a comparison such as `$.PONumber?(@ > $d)` for a *numeric* value of variable `$d` is treated implicitly as if it were `$.PONumber?(@.numberOnly() > $d)`. So these two queries behave the same: only `PONumber` fields whose value is numeric are considered, because the value of `$d` is numeric.

```
SELECT count(*) FROM j_purchaseorder
WHERE json_exists(po_document, '$.PONumber?(@.numberOnly() > $d)'
PASSING to_number(:1) AS "d");
```

```
SELECT count(*) FROM j_purchaseorder
WHERE json_exists(po_document, '$.PONumber?(@ > $d)'
PASSING to_number(:1) AS "d" TYPE(STRICT));
```

The expression to evaluate must be of data type `JSON`, `VARCHAR2`, `NUMBER`, `BINARY_DOUBLE`, `DATE`, `TIMESTAMP`, or `TIMESTAMP WITH TIME ZONE`; otherwise, an error is raised.

If the expression evaluates to a SQL `NULL` value, the effect depends on the SQL type of that `NULL` value, as follows:

- Passing `NULL` of SQL type `JSON` raises an error.

- Passing `NULL` of SQL type `VARCHAR2` binds the variable to an empty JSON string, `""`.

- Passing `NULL` of SQL type `RAW` binds the variable to a zero-length JSON binary value.

- Passing `NULL` of any other SQL type binds the variable to a JSON `null` value.

---

[1] Wrapping a SQL/JSON variable name in double-quote (`"`) characters in a `PASSING` clause is necessary only if you want a case-sensitive name.

> **✎ Note:**
>
> A SQL/JSON variable name has the syntax of a SQL identifier, but with these restrictions:
>
> - A SQL/JSON variable name *never includes quote characters*, even when the SQL identifier used to define it includes them.
>
>   In a `PASSING` clause for JSON functions and conditions, the SQL identifier that follows keyword `AS` can be a quoted identifier or an unquoted identifier — for example, `AS "d"` or `AS d`. This *defines a SQL/JSON variable* named `d` in the first case (no quote characters in the name), and `D` in the second case (implicitly uppercase). (The SQL identifier in the first case is `"d"`, not `d`, and in the second case it is `D`, not `d`.)
>
> - A SQL/JSON variable name must contain only *ASCII alphanumeric* characters or the *ASCII underscore* character (decimal code 95). In addition, the name must *start* with a letter or an underscore character, not a digit. For example, `42 AS "2d"`, `42 AS "d+"`, and `42 AS "dã"` each raise an error, the first because it starts with a numeral, the second because it contains an ASCII character that's not alphanumeric (**+**), and the third because it contains a non-ASCII character (**ã**).
>
> A **SQL/JSON variable** is **$** followed by a SQL/JSON variable *name* — for example, `$d` is the variable with name `D`.
>
> A SQL/JSON variable, not a SQL identifier, is used in a SQL/JSON path expression. In particular, this means that *quote characters are never present* — you just use the name directly. For example, `$.PONumber?(@ > $"d")` raises an error; `$.PONumber?(@ > $d)` has correct syntax.

> JSON_EXISTS Condition in *Oracle Database SQL Language Reference* for information about the `PASSING` clause

17.2 RETURNING Clause for SQL Query Functions

SQL functions `json_value`, `json_query`, `json_serialize`, and `json_mergepatch` accept an optional **RETURNING** clause, which specifies the data type of the value returned by the function. This clause and the default behavior (no `RETURNING` clause) are described here.

For `json_value`, you can use any of these SQL data types in a `RETURNING` clause: `VARCHAR2`, `NVARCHAR2`, `CHAR`, `NCHAR`, `BOOLEAN`, `NUMBER`, `BINARY_DOUBLE`, `BINARY_FLOAT`, `DATE` (with optional keywords `PRESERVE TIME` or `TRUNCATE TIME`), `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `INTERVAL YEAR TO MONTH`, `INTERVAL DAY TO SECOND`, `SDO_GEOMETRY`, `RAW`[2], `CLOB`, and `NCLOB`. You can also use a user-defined object type or a collection type.

(See Using SQL/JSON Function JSON_VALUE With a Boolean JSON Value for information about return types when a JSON Boolean value is targeted.)

> **Note:**
>
> An instance of Oracle SQL data type `DATE` includes a time component. And in your JSON data you can use a string that represents an ISO 8601 date-with-time value, that is, it can have a time component.
>
> By default, `json_value` with `RETURNING DATE` returns a SQL `DATE` value that has a zero time component (zero hours, minutes, and seconds). By default, a time component in the queried JSON scalar value is *truncated* in the returned SQL `DATE` instance. But before any time truncation is done, if the value represented by an ISO 8601 date-with-time string has a time-zone component then the value is first converted to UTC, to *take any time-zone information into account*.
>
> You can use `RETURNING DATE` **PRESERVE TIME** to override this default truncating behavior and preserve the time component, when present, of the queried JSON scalar value. (Using `RETURNING DATE TRUNCATE TIME` has the same effect as just `RETURNING DATE`, the default behavior.)
>
> (The same considerations apply to item methods `date()`, which corresponds to `TRUNCATE TIME`, and `dateWithTime()`, which corresponds to `PRESERVE TIME`.)

For `json_query`, `json_serialize`, and `json_mergepatch` you can use `VARCHAR2`, `CLOB`, `BLOB`, or `JSON`.[3]

---

[2] You can use `RAW` as the return type only when the input data is of `JSON` data type.

[3] `JSON` data type is available only if database initialization parameter `compatible` is `20` or greater.

A `BLOB` result is in the AL32UTF8 character set. Whatever the data type returned by `json_serialize`, the returned data represents textual JSON data.

You can optionally specify a length for `VARCHAR2` (default: `4000`) and a precision and scale for `NUMBER`.

Data type `SDO_GEOMETRY` is for Oracle Spatial and Graph data. In particular, this means that you can use `json_value` with GeoJSON data, which is a format for encoding geographic data in JSON.

For `json_query` (only), if database initialization parameter `compatible` is `20` or greater, and if the input data is of data type `JSON`:

- The default return type (no `RETURNING` clause) is also `JSON`.

  Otherwise, the default return type is `VARCHAR2(4000)`.

- Regardless of the return data type, by default the data returned can be a *scalar* JSON value.

  You can override this behavior by including keywords `DISALLOW SCALARS` just after the return data type. The `json_query` invocation then returns only nonscalar JSON values (which provides the same behavior as if RFC 8259 were not supported).

The `RETURNING` clause also accepts optional keywords, `PRETTY` and `ASCII`, *unless* the return data type is `JSON`. If both are present then `PRETTY` must come before `ASCII`. Keyword `PRETTY` is not allowed for `json_value`.

The effect of keyword **PRETTY** is to pretty-print the returned data, by inserting newline characters and indenting. The default behavior is not to pretty-print.

The effect of keyword **ASCII** is to automatically escape all non-ASCII Unicode characters in the returned data, using standard ASCII Unicode escape sequences. The default behavior is not to escape non-ASCII Unicode characters.

> **Tip:**
>
> You can pretty-print the entire context item by using only `$` as the path expression.

If `VARCHAR2` is specified in a `RETURNING` clause then scalars in the value are represented as follows:

- Boolean values are represented by the lowercase strings `"true"` and `"false"`.

- The `null` value is represented by SQL `NULL`.

- A JSON number is represented in a canonical form. It can thus appear differently in the output string from its representation in textual input data. When represented in canonical form:

  - It can be subject to the precision and range limitations for a SQL `NUMBER`.

  - When it is not subject to the SQL `NUMBER` limitations:

    * The precision is limited to forty (40) digits.

    * The optional exponent is limited to nine (9) digits plus a sign (`+` or `-`).

       *   The entire text, including possible signs (-, +), decimal point (.), and exponential indicator (E), is limited to 48 characters.

The **canonical form** of a JSON number:

– Is a JSON number. (It can be parsed in JSON data as a number.)

– Does not have a leading plus (+) sign.

– Has a decimal point (.) only when necessary.

– Has a single zero (0) before the decimal point if the number is a fraction (between zero and one).

– Uses exponential notation (E) only when necessary. In particular, this can be the case if the number of output characters is too limited (by a small N for `VARCHAR2(N)`).

Oracle extends the SQL/JSON standard in the case when the returning data type is `VARCHAR2(N)`, by allowing optional keyword **TRUNCATE** immediately after the data type. When `TRUNCATE` is present and the value to return is wider than N, the value is truncated — only the first N characters are returned. If `TRUNCATE` is absent then this case is treated as an error, handled as usual by an error clause or the default error-handling behavior.

Function `json_value` also accepts an optional `TYPE` clause. If you use **TYPE (STRICT)** then the value that's projected (returned) is compared strictly with respect to its JSON-language type, just as if the relevant "only" data-type conversion item method were applied to it.

For example, these two queries are equivalent. Only `PONumber` fields whose value is numeric are considered (projected).

```
SELECT json_value(po_document, '$.PONumber.numberOnly()') FROM
j_purchaseorder
  RETURNING NUMBER;
```

```
SELECT json_value(po_document, '$.PONumber') FROM j_purchaseorder
  RETURNING NUMBER TYPE (STRICT);
```

For any of the SQL functions for JSON that can return a LOB, by default the LOB is returned by *reference*. You can instead have it return a *value*-based LOB by following the return type (`CLOB`, `BLOB`, or `NCLOB`, depending on the function) with the keyword **VALUE**. For example:

```
SELECT json_value(...) FROM ... RETURNING CLOB VALUE;
```

Related Topics

• [Error Clause for SQL Functions and Conditions](#)
Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

- **Using JSON_VALUE To Instantiate a User-Defined Object-Type or Collection-Type Instance**
  You can use SQL/JSON function `json_value` to instantiate an instance of a user-defined SQL object type or collection type. You do this by targeting a JSON object or array in the path expression and specifying the object or collection type, respectively, in the `RETURNING` clause.

- **Support for RFC 8259: JSON Scalars**
  Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

- **TYPE Clause for SQL Functions and Conditions**
  Oracle SQL function `json_transform`, SQL/JSON functions `json_query`, `json_value` and `json_table`, and SQL/JSON condition `json_exists` accept optional **TYPE** clauses, which specify whether JSON values are compared *strictly* with respect to JSON-language type, that is, as if the relevant "only" data-type conversion item methods were applied to the data being compared.

>
> - GeoJSON.org

17.3 Wrapper Clause for SQL/JSON Query Functions JSON_QUERY and JSON_TABLE

SQL/JSON query functions `json_query` and `json_table` accept an optional wrapper clause, which specifies the form of the value returned by `json_query` or used for the data in a `json_table` column. This clause and the default behavior (no wrapper clause) are described here. Examples are provided.

The JSON data targeted by a path expression for `json_query` or a `json_table` column can be a single JSON value (scalar, object, or array value), or it can be multiple JSON values. With an optional wrapper clause you can wrap the targeted data in an array before returning it.

For example, if the targeted data is the set of values `"A50"` and `{"a": 42}` you can specify that those be wrapped to return the array `[ "A50", {"a": 42} ]` (or `[ {"a": 42}, "A50" ]` — you cannot control the element order). Or if the only targeted value is `42` then you can wrap that and return the array `[42]`.

Prior to Oracle Database 21c only RFC 4627 was supported, not RFC 8259. A single scalar JSON value could not be returned in this context — wrapping it in an array was necessary, to avoid raising an error. This is still the case if database initialization parameter `compatible` is less than `20`. And even when RFC 8259 is supported you might sometimes want to wrap the result in an array.

The behavior of a wrapper clause (or its absence, which is the same as using keywords `WITHOUT WRAPPER`) depends on (1) whether or not the targeted JSON data is a *single scalar value* and (2) whether returning a single scalar value is allowed for the particular invocation of the SQL/JSON function.

Without wrapping, returning a single scalar value or multiple values (scalar or not) raises an error if either of the following is true:

- Database initialization parameter `compatible` is less than `20`.

- Keywords `DISALLOW SCALARS` are used in the `RETURNING` clause.

The `ON EMPTY` clause takes precedence over the wrapper clause. The default for the former is `NULL ON EMPTY`, which means that if no JSON values match the path expression then SQL `NULL` is returned. If you want an empty JSON array (`[]`) returned instead then specify `EMPTY ARRAY ON EMPTY`. If you want an error raised instead then specify `ERROR ON EMPTY`.

The wrapper clause for nonempty matches is as follows:

- **`WITH WRAPPER`** – Use a JSON array that contains *all* of the JSON values that match the path expression. The order of the array elements is unspecified.

- **`WITHOUT WRAPPER`** – Use the JSON value or values that match the path expression.

  Raise an error if either of these conditions holds:

  – The path expression matches multiple values.

  – Returning a scalar value is not allowed, and the path expression matches a single scalar value (not an object or array).

- **`WITH CONDITIONAL WRAPPER`** – Use a value that represents *all* of the JSON values that match the path expression.

  If multiple JSON values match then this is the same as `WITH WRAPPER`.

  If only one JSON value matches:

  – If returning a scalar value is allowed, or if the single matching value is an *object* or an *array*, then this is the same as `WITHOUT WRAPPER`.

  – Otherwise, this is the same as `WITH WRAPPER`.

The default behavior is `WITHOUT WRAPPER`.

You can use keyword **`UNCONDITIONAL`** if you find that it makes your code clearer: `WITH WRAPPER` and `WITH UNCONDITIONAL WRAPPER` mean the same thing.

You can add keyword **`ARRAY`** immediately before keyword `WRAPPER`, if you find it clearer: `WRAPPER` and `ARRAY WRAPPER` mean the same thing.

> **✏ Note:**
>
> You cannot use an array wrapper with `json_query` if you use clause `OMIT QUOTES`; a compile-time error is raised if you do that.

Table 17-1 illustrates the wrapper-clause possibilities. The array wrapper is shown in **_bold italics_**.

Table 17-1   JSON_QUERY Wrapper Clause Examples

JSON Values Matching Path Expression	WITH WRAPPER	WITHOUT WRAPPER	WITH CONDITIONAL WRAPPER
`{"id": 38327}` (single object)	**_[_**`{"id": 38327}`**_]_**	`{"id": 38327}`	`{"id": 38327}` (same as `WITHOUT WRAPPER`)
`[42, "a", true]` (single array)	**_[_**`[42, "a", true]`**_]_**	`[42, "a", true]`	`[42, "a", true]` (same as `WITHOUT WRAPPER`)
`42`	**_[_**`42`**_]_**	• `42`, if returning a single scalar value is allowed • Error, if returning a single scalar value is not allowed	• `42`, if returning a single scalar value is allowed (same as `WITHOUT WRAPPER`) • **_[_**`42`**_]_**, if returning a single scalar value is not allowed (same as `WITH WRAPPER`)
`42, "a", true` (multiple values)	**_[_**`42, "a", true`**_]_**	Error (multiple values)	**_[_**`42, "a", true`**_]_** (same as `WITH WRAPPER`)
none	Determined by the `ON EMPTY` clause. • SQL `NULL` by default (`NULL ON EMPTY`) • **_[]_** with clause `EMPTY ARRAY ON EMPTY`	Error (no values)	Same as `WITH WRAPPER`.

Consider, for example, a `json_query` query to retrieve a JSON object. What happens if the path expression matches multiple JSON values (of any kind)? You might want to retrieve the matched values instead of raising an error. For example, you might want to pick one of the values that is an object, for further processing. Using an array wrapper lets you do this.

A conditional wrapper can be convenient if the only reason you are using a wrapper is to avoid raising an error and you do not need to distinguish those error cases from non-error cases. If your application is looking for a single object or array and the data matched by a path expression is just that, then there is no need to wrap that expected value in a singleton array.

On the other hand, with an unconditional wrapper you know that the resulting array is always a wrapper — your application can count on that. If you use a conditional wrapper then your application might need extra processing to interpret a returned array. In Table 17-1, for instance, note that the same array (`[42, "a", true]`) is returned for the very different cases

of a path expression matching that array and a path expression matching each of its elements.

Related Topics

*   Support for RFC 8259: JSON Scalars
    Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

17.4 Error Clause for SQL Functions and Conditions

Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

By default, SQL functions and conditions for JSON avoid raising runtime errors. For example, when JSON data is syntactically invalid, `json_exists` and `json_equal` return false and `json_value` returns `NULL`.

But in some cases you can also specify an error clause, which overrides the default behavior. The error handling you can specify varies, but each SQL function and condition for JSON that lets you specify error handling supports at least the `ERROR ON ERROR` behavior of raising an error.

The optional error clause can take these forms:

*   **ERROR ON ERROR** – Raise the error (no special handling).

*   **NULL ON ERROR** – Return `NULL` instead of raising the error.

    Not available for `json_exists`.

*   **FALSE ON ERROR** – Return false instead of raising the error.

    Available *only* for `json_exists` and `json_equal`, for which it is the *default*.

*   **TRUE ON ERROR** – Return true instead of raising the error.

    Available *only* for `json_exists` and `json_equal`.

*   **EMPTY OBJECT ON ERROR** – Return an empty object (`{}`) instead of raising the error.

    Available *only* for `json_query`.

*   **EMPTY ARRAY ON ERROR** – Return an empty array (`[]`) instead of raising the error.

    Available *only* for `json_query`.

*   **EMPTY ON ERROR** – Same as `EMPTY ARRAY ON ERROR`.

*   **DEFAULT** `'literal_return_value'` **ON ERROR** – Return the specified value instead of raising the error. The value must be a constant at query compile time.

    Not available:

    –   For `json_exists`, `json_equal`, `json_serialize`, `json_scalar`, `json_mergepatch`, or a `json_table` column value clause that has `json_exists` behavior

    –   For `json_query` or a `json_table` column value clause that has `json_query` behavior

- For *row*-level error-handing for `json_table`

- When `SDO_GEOMETRY` is specified either as the `RETURNING` clause data type for `json_value` or as a `json_table` *column* data type

The *default* behavior is **NULL** `ON ERROR`, except for conditions `json_exists` and `json_equal`.

> **Note:**
>
> There are two levels of error handling for `json_table`, corresponding to its two levels of path expressions: row and column. When present, a column error handler overrides row-level error handling. The default error handler for both levels is `NULL ON ERROR`.

> **Note:**
>
> An `ON EMPTY` clause overrides the behavior specified by `ON ERROR` for the error of trying to match a missing field.

> **Note:**
>
> The `ON ERROR` clause takes effect only for runtime errors that arise when a syntactically correct SQL/JSON path expression is matched against JSON data. A path expression that is syntactically incorrect results in a compile-time syntax error; it is not handled by the `ON ERROR` clause.

Related Topics

- Empty-Field Clause for SQL/JSON Query Functions
  SQL/JSON query functions `json_value`, `json_query`, and `json_table` accept an optional **ON EMPTY** clause, which specifies the handling to use when a targeted JSON field is absent from the data queried. This clause and the default behavior (no `ON EMPTY` clause) are described here.

- SQL/JSON Function JSON_TABLE
  SQL/JSON function `json_table` projects specific JSON data to columns of various SQL data types. You use it to map parts of a JSON document into the rows and columns of a new, virtual table, which you can also think of as an inline view.

- SQL/JSON Function JSON_QUERY
  SQL/JSON function `json_query` selects one or more values from JSON data and returns those values. You can thus use `json_query` to retrieve *fragments* of a JSON document.

- SQL/JSON Function JSON_VALUE
  SQL/JSON function `json_value` selects JSON data and returns a SQL scalar or an instance of a user-defined SQL object type or SQL collection type (varray, nested table).

- **Oracle SQL Function JSON_SERIALIZE**
  Oracle SQL function `json_serialize` takes JSON data (of any SQL data type, `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`) as input and returns a *textual* representation of it (as `VARCHAR2`, `CLOB`, or `BLOB` data). `VARCHAR2(4000)` is the default return type.

- **SQL/JSON Condition JSON_EXISTS**
  SQL/JSON condition `json_exists` checks for the existence of a particular value within JSON data. It returns true if the data it targets matches one or more JSON values. If no JSON values are matched then it returns false.

- **ON MISMATCH Clause for SQL/JSON Query Functions**
  You can use an **ON MISMATCH** clause with SQL/JSON functions `json_value`, `json_query`, and `json_table`, to handle type-matching exceptions. It specifies handling to use when a targeted JSON value does not match the specified SQL return value. This clause and its default behavior (no `ON MISMATCH` clause) are described here.

> - *Oracle Database SQL Language Reference* for detailed information about the error clause for SQL conditions for JSON

17.5 Empty-Field Clause for SQL/JSON Query Functions

SQL/JSON query functions `json_value`, `json_query`, and `json_table` accept an optional **ON EMPTY** clause, which specifies the handling to use when a targeted JSON field is absent from the data queried. This clause and the default behavior (no `ON EMPTY` clause) are described here.

You generally handle errors for SQL/JSON functions and conditions using an error clause (`ON ERROR`). However, there is a special case where you might want different handling from this general error handling: when querying to match given JSON fields that are missing from the data. Sometimes you do not want to raise an error just because a field to be matched is absent. (A missing field is normally treated as an error.)

You typically use a `NULL ON EMPTY` clause in conjunction with an accompanying `ON ERROR` clause. This combination specifies that other errors are handled according to the `ON ERROR` clause, but the error of trying to match a missing field is handled by just returning `NULL`. If no `ON EMPTY` clause is present then an `ON ERROR` clause handles also the missing-field case.

In addition to `NULL ON EMPTY` there are `ERROR ON EMPTY` and `DEFAULT ... ON EMPTY`, which are analogous to the similarly named `ON ERROR` clauses.

If only an `ON EMPTY` clause is present (no `ON ERROR` clause) then missing-field behavior is specified by the `ON EMPTY` clause, and other errors are handled the same as if `NULL ON ERROR` were present (it is the `ON ERROR` default). If both clauses are absent then only `NULL ON ERROR` is used.

> **✐ Note:**
>
> When SQL/JSON function `json_value` is used in PL/SQL code with a `RETURNING` type that is a *record* type or an *index-table* type, a `NULL` value cannot be returned, because values of these types cannot be atomically `NULL`.
>
> For this reason, clauses `NULL ON MISMATCH` and `NULL ON EMPTY` cannot return a `NULL` value for these collection types. Instead of returning `NULL`, a compile-time error is raised. (There is no such exception for PL/SQL code with a `RETURNING` type for SQL objects, varrays, or nested tables, because values of these types can be atomically `NULL`.)

Use NULL ON EMPTY for an Index Created on JSON_VALUE

`NULL ON EMPTY` is especially useful for the case of a functional index created on a `json_value` expression. The clause has no effect on whether or when the index is picked up, but it is effective in allowing some data to be indexed that would otherwise not be because it is missing a field targeted by the `json_value` expression.

You generally want to use `ERROR ON ERROR` for the queries that populate the index, so that a query path expression that results in multiple values or complex values raises an error. But you sometimes do not want to raise an error just because the field targeted by a path expression is missing — you want that data to be indexed. Example 29-4 illustrates this use of `NULL ON EMPTY` when creating an index on a `json_value` expression.

Related Topics

- Creating B-Tree Indexes for JSON_VALUE
  You can create a B-tree function-based index for SQL/JSON function `json_value`. You can use the standard syntax for this, explicitly specifying `json_value`, or you can use dot-notation syntax with an item method. Indexes created in either of these ways can be used with both dot-notation queries and `json_value` queries.

- Error Clause for SQL Functions and Conditions
  Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

17.6 ON MISMATCH Clause for SQL/JSON Query Functions

You can use an **ON MISMATCH** clause with SQL/JSON functions `json_value`, `json_query`, and `json_table`, to handle type-matching exceptions. It specifies handling to use when a targeted

JSON value does not match the specified SQL return value. This clause and its default behavior (no `ON MISMATCH` clause) are described here.

> **Note:**
>
> Clause `ON MISMATCH` applies only when neither of the clauses `ON EMPTY` and `ON ERROR` applies. It applies when the targeted JSON data matches the path expression, in general, but the *type* of that targeted data does not match the specified return type. More precisely, `ON MISMATCH` applies when the targeted *data cannot be converted to the return type*. For example, targeted value `"cat"`, a JSON string, cannot be converted to a SQL `NUMBER` value.
>
> Clause `ON EMPTY` applies when the field targeted by a path expression does not exist in the queried data.
>
> Clause `ON ERROR` applies when any error is raised while processing the query. This includes the cases of invalid query syntax and targeting of multiple values in a `json_value` query or a `json_query` query without an array wrapper.

When a query returns a SQL value that reflects the JSON data targeted by function `json_value`, `json_query`, or `json_table`, the *types* of the targeted data and the value to be returned must match, or else an error is raised.

If an `ON ERROR` handler is specified then its behavior applies as the default behavior for `ON MISMATCH`: it is the behavior for a type mismatch if *no* `ON MISMATCH` clause is given.

You can use one or more `ON MISMATCH` clauses to specify type mismatch behavior in the following ways.

- **IGNORE ON MISMATCH** — Explicitly specify the default behavior: ignore the mismatch. The object or collection returned can contain one or more SQL `NULL` values because of mismatches against the targeted JSON data.

  This value is available only if the query targets an instance of a *user-defined object or collection type*, which can be the case only when `json_value` (or a `json_table` column with `json_value` semantics) is used. An error is raised if data of another type is targeted.

- **NULL ON MISMATCH** — Return SQL `NULL` as the value.

> **Note:**
>
> When SQL/JSON function `json_value` is used in PL/SQL code with a `RETURNING` type that is a *record* type or an *index-table* type, a `NULL` value cannot be returned, because values of these types cannot be atomically `NULL`.
>
> For this reason, clauses `NULL ON MISMATCH` and `NULL ON EMPTY` cannot return a `NULL` value for these collection types. Instead of returning `NULL`, a compile-time error is raised. (There is no such exception for PL/SQL code with a `RETURNING` type for SQL objects, varrays, or nested tables, because values of these types can be atomically `NULL`.)

- **`ERROR ON MISMATCH`** — Raise an error for the mismatch.

When function `json_value` (or a `json_table` column with `json_value` semantics) returns a user-defined object-type or collection-type instance, each of the `ON MISMATCH` clause types can be followed, in parentheses (`(…)`), by one or more clauses that each indicates a *kind* of mismatch to handle, separated by commas (`,`). These are the possible mismatch kinds:

- **`MISSING DATA`** — Some JSON data was needed to match the object-type or collection-type data, but it was missing.

- **`EXTRA DATA`** — One or more JSON fields have no corresponding object-type or collection-type data. For example, for JSON field `address` there is no object-type attribute with the same name (matching case-insensitively, by default).

- **`TYPE ERROR`** — A JSON scalar value has a data type that is incompatible with the corresponding return SQL scalar data type. This can be because of general type incompatibility, as put forth in Table 17-2, or because the SQL data type is too constraining (e.g., `VARCHAR(2)` is too short for JSON string `"hello"`).

If no such kind-of-mismatch clause (e.g. `EXTRA DATA`) is present for a given handler (e.g. `NULL ON MISMATCH`) then that handler applies to all kinds of mismatch.

You can have any number of `ON MISMATCH` clauses of different kinds, but if two or more such contradict each other then a query compile-time error is raised.

> **Note:**
>
> When an "only" item method is used (an item method with "only" in its name), only a value of the specified type input type is compatible. For example, if item method `booleanOnly()` is used, then only an input value of JSON-language type boolean is compatible with (can be converted to) the destination SQL types listed (`BOOLEAN`, `VARCHAR2`, and `CLOB`).
>
> In this context, item method `idOnly()` is an *exception*, in that it requires its input to not just be of JSON-language type family binary but to also be suitable as an identifier. See also Comparison and Sorting of JSON Data Type Values.

Table 17-2   Compatible Scalar Data Types: Converting JSON to SQL

JSON Language Type (Source)	SQL Type (Destination)	Notes
binary	RAW	Supported only for JSON data stored as SQL type JSON.
binary	BLOB	Supported only for JSON data stored as SQL type JSON.
binary	CLOB	Supported only for JSON data stored as SQL type JSON.
boolean	BOOLEAN	The instance value is the SQL Boolean value TRUE or FALSE.
boolean	VARCHAR2	The instance value is the SQL string "true" or "false".
boolean	CLOB	The instance value is the SQL string "true" or "false".
date	DATE, with a (possibly zero) time component[1]	Supported only for JSON data stored as SQL type JSON.
date	TIMESTAMP	Time component is padded with zeros. Supported only for JSON data stored as SQL type JSON.
daysecondInterval	INTERVAL DAY TO SECOND	Supported only for JSON data stored as SQL type JSON.
double	BINARY_DOUBLE	Supported only for JSON data stored as SQL type JSON.
double	BINARY_FLOAT	Supported only for JSON data stored as SQL type JSON.
double	NUMBER	Supported only for JSON data stored as SQL type JSON.
double	VARCHAR2	Supported only for JSON data stored as SQL type JSON.
double	CLOB	Supported only for JSON data stored as SQL type JSON.
float	BINARY_FLOAT	Supported only for JSON data stored as SQL type JSON.
float	BINARY_DOUBLE	Supported only for JSON data stored as SQL type JSON.
float	NUMBER	Supported only for JSON data stored as SQL type JSON.
float	VARCHAR2	Supported only for JSON data stored as SQL type JSON.
float	CLOB	Supported only for JSON data stored as SQL type JSON.
null	Any SQL data type.	The instance value is SQL NULL.
number	NUMBER	None.
number	BINARY_DOUBLE	None.
number	BINARY_FLOAT	None.

Table 17-2   (Cont.) Compatible Scalar Data Types: Converting JSON to SQL

JSON Language Type (Source)	SQL Type (Destination)	Notes
number	VARCHAR2	None.
number	CLOB	None.
string	VARCHAR2	None.
string	CLOB	None.
string	NUMBER	The JSON string must be numeric.
string	BINARY_DOUBLE	The JSON string must be numeric.
string	BINARY_FLOAT	The JSON string must be numeric.
string	DATE, with a (possibly zero) time component[1]	The JSON string must have a supported ISO 8601 format.
string	TIMESTAMP	The JSON string must have a supported ISO 8601 format.
string	INTERVAL YEAR TO MONTH	The JSON string must have a supported ISO 8601 duration format.
string	INTERVAL DAY TO SECOND	The JSON string must have a supported ISO 8601 duration format.
timestamp	TIMESTAMP	Supported only for JSON data stored as SQL type JSON,
timestamp	DATE, with a (possibly zero) time component[1]	Supported only for JSON data stored as SQL type JSON.
yearmonthInterval	INTERVAL YEAR TO MONTH	Supported only for JSON data stored as SQL type JSON.

[1]   For example, a DATE instance with a zero time component is returned by a json_value RETURNING DATE
    clause that does not specify preservation of the time component.

Example 17-1   Using ON MISMATCH Clauses

This example uses the following object-relational data with various queries. The queries are the same except for the type-mismatch behavior. Each query targets a non-existent JSON field middle.

```
CREATE TYPE person_T AS OBJECT (
  first    VARCHAR2(30),
  last     VARCHAR2(30),
  birthyear NUMBER);
```

This query returns the object person_t('Grace', 'Hopper', 1906). Field middle is ignored, because the default error handler is NULL ON ERROR.

```
SELECT json_value('{"first":     "Grace",
                    "middle":    "Brewster",
                    "last":      "Hopper",
```

```
                     "birthyear": "1906"}',
                   '$'
                   RETURNING person_t)
FROM DUAL;
```

This query raises an error because of the extra-data mismatch: field `middle` is extra.

```
SELECT json_value('{"first":    "Grace",
                    "middle":   "Brewster",
                    "last":     "Hopper",
                    "birthyear": "1906"}',
                   '$'
                   RETURNING person_t
                   ERROR ON MISMATCH (EXTRA DATA))
FROM DUAL;
ORA-40602: extra data for object type conversion
```

This query uses three `ON MISMATCH` clauses. It returns the object `person_t('Grace',
'Hopper', NULL)`. The clause `ERROR ON MISMATCH (EXTRA DATA)` would, by itself,
raise an error, but the `IGNORE ON MISMATCH (TYPE ERROR)` causes that error to be
ignored.

```
SELECT json_value('{"first":    "Grace",
                    "middle":   "Brewster",
                    "last":     "Hopper",
                    "birthyear": "1906"}',
                   '$'
                   RETURNING person_t
                   ERROR ON MISMATCH (EXTRA DATA)
                   ERROR ON MISMATCH (MISSING DATA)
                   IGNORE ON MISMATCH (TYPE ERROR))
FROM DUAL;
```

Related Topics

*   Using JSON_VALUE To Instantiate a User-Defined Object-Type or Collection-Type
    Instance
    You can use SQL/JSON function `json_value` to instantiate an instance of a user-
    defined SQL object type or collection type. You do this by targeting a JSON object
    or array in the path expression and specifying the object or collection type,
    respectively, in the `RETURNING` clause.

17.7 TYPE Clause for SQL Functions and Conditions

Oracle SQL function `json_transform`, SQL/JSON functions `json_query`, `json_value`
and `json_table`, and SQL/JSON condition `json_exists` accept optional **TYPE** clauses,
which specify whether JSON values are compared *strictly* with respect to JSON-
language type, that is, as if the relevant "only" data-type conversion item methods
were applied to the data being compared.

Keyword `TYPE` is followed, in parentheses, by keyword `STRICT` or `LAX`.

- `TYPE` (**LAX**) specifies the default behavior (same as no `TYPE` clause), which is that JSON values can be implicitly interpreted (essentially cast) as values of SQL data types for purposes of comparison. This type-casting is explained in Types in Comparisons.

  For example, a comparison such as `'$.PONumber?(@ > 20)` implicitly interprets a `PONumber` value of `"314"` as the number `314` (because it is compared with the number 20). That comparison is true, just as if the expression were `'$.PONumber?(@.`**number()** `> 20)`

- `TYPE` (**STRICT**) has the same effect as applying "only" item methods.

  For example, `'$.PONumber?(@ > 20)` behaves as if it were `'$.PONumber?(@.`**numberOnly()** `> 20)`. For a `PONumber` value of `"314"` the comparison is false, just as if the expression were `'$.PONumber?(@.`**numberOnly()** `> 20)`.

SQL/JSON Condition JSON_EXISTS

SQL/JSON condition `json_exists` checks for the existence of a particular value within JSON data. It returns true if the data it targets matches one or more JSON values. If no JSON values are matched then it returns false.

Condition `json_exists` lets you use a SQL/JSON path expression as a row filter, to select rows based on the content of JSON documents. You can use `json_exists` in a `CASE` expression or the `WHERE` clause of a `SELECT` statement.

If initialization parameter `compatible` has value `23` or greater then you can also use `json_exists` in the `SELECT` part of a query, to obtain its Boolean result as an explicit SQL `BOOLEAN` value. For example, this query returns the value `TRUE`, indicating that field `a` *exists*:

```
SELECT json_exists('{a : null}', '$.a') FROM DUAL;
```

Error handlers `ERROR ON ERROR`, `FALSE ON ERROR`, and `TRUE ON ERROR` apply. The default is `FALSE ON ERROR`. The handler takes effect when any error occurs, but typically an error occurs when the given JSON data is not well-formed (using lax syntax). Unlike the case for conditions `is json` and `is not json`, condition `json_exists` *expects* the data it examines to be well-formed JSON data.

The second argument to `json_exists` is a SQL/JSON path expression followed by an optional `PASSING` clause and an optional error clause.

For `json_exists`, the following have *no effect* in a path-expression *array step*: the order of indexes and ranges, multiple occurrences of an array index, and duplication of a specified position due to range overlaps. All that counts is the *set* of specified positions, not how they are specified, including the order or number of times they are specified. All that is checked is the existence of a match for at least one specified position.

The optional filter expression of a SQL/JSON path expression used with `json_exists` can refer to SQL/JSON variables, whose values are passed from SQL by binding them with the `PASSING` clause. The following SQL data types are supported for such variables: `VARCHAR2`, `NUMBER`, `BINARY_DOUBLE`, `DATE`, `TIMESTAMP`, and `TIMESTAMP WITH TIMEZONE`.

> **Tip:**
>
> For queries that you use often, use a `PASSING` clause to define SQL bind variables, which you use as SQL/JSON variables in path expressions. This can improve performance by *avoiding query recompilation* when the (variable) values change.
>
> For example, this query passes the value of bind variable `v1` as SQL/JSON variable `$v1`:
>
> ```
> SELECT po.po_document FROM j_purchaseorder po
>   WHERE json_exists(po.po_document,
>                     '$.LineItems.Part?(@.UPCCode == $v1)'
>                     PASSING '85391628927' AS "v1");
> ```

- **Using Filters with JSON_EXISTS**
  You can use SQL/JSON condition `json_exists` with a path expression that has one or more filter expressions, to select documents that contain matching data. Filters let you test for the existence of documents that have particular fields that satisfy various conditions.

- **JSON_EXISTS as JSON_TABLE**
  SQL/JSON condition `json_exists` can be viewed as a special case of SQL/JSON function `json_table`.

Related Topics

- **RETURNING Clause for SQL Query Functions**
  SQL functions `json_value`, `json_query`, `json_serialize`, and `json_mergepatch` accept an optional **RETURNING** clause, which specifies the data type of the value returned by the function. This clause and the default behavior (no `RETURNING` clause) are described here.

- **Error Clause for SQL Functions and Conditions**
  Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

- **Basic SQL/JSON Path Expression Syntax**
  The basic syntax of a SQL/JSON path expression is presented. It is composed of a context-item symbol (`$`) followed by zero or more object, array, and descendant steps, each of which can be followed by a filter expression, followed optionally by a function step. Examples are provided.

- **PASSING Clause for SQL Functions and Conditions**
  Oracle SQL function `json_transform`, SQL/JSON functions `json_value` and `json_query`, and SQL/JSON condition `json_exists` accept an optional `PASSING` clause, which binds SQL values to SQL/JSON variables for use in path expressions.

> **✦ See Also:**
>
> *Oracle Database SQL Language Reference* for information about `json_exists` and the `PASSING` clause

18.1 Using Filters with JSON_EXISTS

You can use SQL/JSON condition `json_exists` with a path expression that has one or more filter expressions, to select documents that contain matching data. Filters let you test for the existence of documents that have particular fields that satisfy various conditions.

SQL/JSON condition `json_exists` returns true for documents containing data that matches a SQL/JSON path expression. If the path expression contains a filter, then the data that matches the path to which that filter is applied must also satisfy the filter, in order for `json_exists` to return true for the document containing the data.

A filter applies to the path that immediately precedes it, and the test is whether both (a) the given document has some data that matches that path, and (b) that matching data satisfies the filter. If both of these conditions hold then `json_exists` returns true for the document.

The path expression immediately preceding a filter defines the scope of the patterns used in it. An at-sign (@) within a filter refers to the data targeted by that path, which is termed the *current item* for the filter. For example, in the path expression `$.LineItems?(@.Part.UPCCode == 85391628927)`, @ refers to an occurrence of array `LineItems`.

Example 18-1   JSON_EXISTS: Path Expression Without Filter

This example selects purchase-order documents that have a line item whose part description contains a UPC code entry.

```
SELECT po.po_document FROM j_purchaseorder po
  WHERE json_exists(po.po_document, '$.LineItems.Part.UPCCode');
```

Example 18-2   JSON_EXISTS: Current Item and Scope in Path Expression Filters

This example shows three *equivalent* ways to select documents that have a line item whose part contains a UPC code with a value of `85391628927`.

```
SELECT po.po_document FROM j_purchaseorder po
  WHERE json_exists(po.po_document,
                    '$?(@.LineItems.Part.UPCCode == 85391628927)');

SELECT po.po_document FROM j_purchaseorder po
  WHERE json_exists(po.po_document,
                    '$.LineItems?(@.Part.UPCCode == 85391628927)');

SELECT po.po_document FROM j_purchaseorder po
  WHERE json_exists(po.po_document,
                    '$.LineItems.Part?(@.UPCCode == 85391628927)');
```

- In the first query, the scope of the filter is the context item, that is, an entire purchase order. @ refers to the context item.

- In the second query, the filter scope is a `LineItems` array (and each of its elements, implicitly). `@` refers to an element of that array.

- In the third query, the filter scope is a `Part` field of an element in a `LineItems` array. `@` refers to a `Part` field.

Example 18-3   JSON_EXISTS: Filter Conditions Depend On the Current Item

This example selects purchase-order documents that have both a line item with a part that has UPC code `85391628927` *and* a line item with an order quantity greater than 3. The scope of each filter, that is, the current item, is in this case the context item. Each filter condition applies independently (to the same document); the two conditions do *not* necessarily apply to the *same* line item.

```
SELECT po.po_document FROM j_purchaseorder po
  WHERE json_exists(po.po_document,
                    '$?(@.LineItems.Part.UPCCode == 85391628927
                        && @.LineItems.Quantity > 3)');
```

Example 18-4   JSON_EXISTS: Filter Downscoping

This example looks similar to Example 18-3, but it acts quite differently. It selects purchase-order documents that have a line item with a part that has UPC code *and with* an order quantity greater than 3. The scope of the current item in the filter is at a lower level; it is not the context item but a `LineItems` array element. That is, the *same line item* must satisfy both conditions, for `json_exists` to return true.

```
SELECT po.po_document FROM j_purchaseorder po
  WHERE json_exists(po.po_document,
                    '$.LineItems[*]?(@.Part.UPCCode == 85391628927
                                     && @.Quantity > 3)');
```

Example 18-5   JSON_EXISTS: Path Expression Using Path-Expression exists Condition

This example shows how to downscope one part of a filter while leaving another part scoped at the document (context-item) level. It selects purchase-order documents that have a `User` field whose value is `"ABULL"` and documents that have a line item with a part that has UPC code *and with* an order quantity greater than 3. That is, it selects the same documents selected by Example 18-4, as well as all documents that have `"ABULL"` as the user. The argument to path-expression predicate **exists** is a path expression that specifies particular line items; the predicate returns true if a match is found, that is, if any such line items exist.

(If you use this example or similar with SQL*Plus then you must use `SET DEFINE OFF` first, so that SQL*Plus does not interpret `&& exists` as a substitution variable and prompt you to define it.)

```
SELECT po.po_document FROM j_purchaseorder po
  WHERE json_exists(po.po_document,
                    '$?(@.User == "ABULL"
                        && exists(@.LineItems[*]?(
                                  @.Part.UPCCode == 85391628927
                                  && @.Quantity > 3)))');
```

- Basic SQL/JSON Path Expression Syntax
  The basic syntax of a SQL/JSON path expression is presented. It is composed of a context-item symbol ($) followed by zero or more object, array, and descendant steps, each of which can be followed by a filter expression, followed optionally by a function step. Examples are provided.

18.2 JSON_EXISTS as JSON_TABLE

SQL/JSON condition `json_exists` can be viewed as a special case of SQL/JSON function `json_table`.

Example 18-6 illustrates the equivalence: the two `SELECT` statements have the same effect.

In addition to perhaps helping you understand `json_exists` better, this equivalence is important practically, because it means that you can use either to get the same effect.

In particular, if you use `json_exists` more than once, or you use it in combination with `json_value` or `json_query` (which can also be expressed using `json_table`), to access the same data, then a single invocation of `json_table` presents the advantage that the data is parsed only once.

Because of this, the optimizer often automatically rewrites multiple invocations of `json_exists`, `json_value` and `json_query` (any combination) to fewer invocations of `json_table`.

> **Note:**
>
> You can use SQL hint `NO_JSON_TABLE_TRANSFORM` to prevent rewriting of multiple invocations of `json_exists`, `json_value` and `json_query` (any combination) to fewer invocations of `json_table`.

Example 18-6   JSON_EXISTS Expressed Using JSON_TABLE

```
SELECT select_list
  FROM table WHERE json_exists(column,
                               json_path error_handler ON ERROR);

SELECT select_list
  FROM table,
       json_table(column, '$' error_handler ON ERROR
         COLUMNS ("COLUMN_ALIAS" NUMBER EXISTS PATH json_path)) AS "JT"
  WHERE jt.column_alias = 1;
```

Related Topics

- JSON_TABLE Generalizes SQL/JSON Query Functions and Conditions
  SQL/JSON function `json_table` generalizes SQL/JSON condition `json_exists` and SQL/JSON functions `json_value` and `json_query`. Everything that you can do using these functions you can do using `json_table`. For the jobs they accomplish, the syntax of these functions is simpler to use than is the syntax of `json_table`.

19
SQL/JSON Function JSON_VALUE

SQL/JSON function `json_value` selects JSON data and returns a SQL scalar or an instance of a user-defined SQL object type or SQL collection type (varray, nested table).

- If `json_value` targets a single *scalar* JSON value then it returns a scalar SQL value. You can specify the SQL data type for the returned scalar value. By default it is `VARCHAR2(4000)`.

  If `json_value` targets the JSON scalar value `null` it returns SQL `NULL` of whatever the SQL return type is. (For example, for the default return type `VARCHAR2(4000)` it does not return the SQL string `'null'`.) This means, in particular, that you cannot use `json_value` to distinguish the JSON value `null` from the absence of a value; SQL `NULL` indicates both cases.

- If `json_value` targets a JSON *array*, and you specify a SQL *collection type* (varray or nested table) as the return type, then `json_value` returns an instance of that collection type.

  The elements of a targeted JSON array provide the elements of the returned collection-type instance. A scalar JSON array element produces a scalar SQL value in the returned collection instance (see previous). A JSON array element that is an object (see next) or an array is handled recursively.

- If `json_value` targets a JSON *object*, and you specify a user-defined SQL *object type* as the return type, then `json_value` returns an instance of that object type.

  The field values of a targeted JSON object provide the attribute values of the returned object-type instance. The field names of the targeted JSON object are compared with the SQL names of the SQL object attributes. A scalar field value produces a scalar SQL value in the returned object-type instance (see above). A field value that is an array (see previous) or an object is handled recursively,

  Ultimately it is the names of JSON fields with scalar values that are compared with the names of scalar SQL object attributes. If the names do not match exactly, case-sensitively, then a *mismatch error* is handled at query compile time.

You can also use `json_value` to create function-based B-tree indexes for use with JSON data — see Indexes for JSON Data.

Function `json_value` has two required arguments, and it accepts some optional clauses.

The first argument to `json_value` is a SQL expression that returns an instance of a scalar SQL data type (that is, not an object or collection data type). A scalar value returned from `json_value` can be of any of these data types: `VARCHAR2`, `NVARCHAR2`, `CHAR`, `NCHAR`, `BOOLEAN`, `NUMBER`, `BINARY_DOUBLE`, `BINARY_FLOAT`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `INTERVAL YEAR TO MONTH`, `INTERVAL DAY TO SECOND`, `SDO_GEOMETRY`, `RAW`[1], `CLOB`, and `NCLOB`.

---

[1] You can use `RAW` as the return type only when the input data is of `JSON` data type, and only if the underlying JSON-language scalar type is binary. Otherwise, an error is processed (handled).

> **Note:**
>
> In general, if you produce SQL character data of a type other than NVARCHAR2, NCLOB, and NCHAR from a JSON string, and if the character set of that target data type is not Unicode-based, then the conversion can undergo a *lossy* character-set conversion for characters that can't be represented in the character set of that SQL type.

The first argument can be a table or view column value, a PL/SQL variable, or a bind variable with proper casting. The result of evaluating the SQL expression is used as the *context item* for evaluating the path expression.

The second argument to json_value is a SQL/JSON path expression followed by optional clauses RETURNING, PASSING, ON ERROR, ON EMPTY, and ON MISMATCH. The path expression must target a single scalar value, or else an error occurs.

The *default* error-handling behavior is NULL ON ERROR, which means that no value is returned if an error occurs — an error is not raised. In particular, if the path expression targets a nonscalar value, such as an array, no error is raised, by default. To ensure that an error is raised, use ERROR ON ERROR.

In a path-expression *array step*, if only one position is specified then it is matched against the data. Otherwise, there is no match (by default, NULL is returned).

> **Note:**
>
> Each field name in a given JSON object is not necessarily unique; the same field name may be repeated. The streaming evaluation that Oracle Database employs always uses only one of the object members that have a given field name; any other members with the same field name are ignored. It is unspecified which of multiple such members is used.
>
> See also Unique Versus Duplicate Fields in JSON Objects.

* Using SQL/JSON Function JSON_VALUE With a Boolean JSON Value
  JSON has Boolean values true and false. When SQL/JSON function json_value evaluates a path expression to JSON true or false, it can return a BOOLEAN or a VARCHAR2 value ('true' or 'false'), or a NUMBER value (1 for true, 0 for false).

* Using JSON_VALUE To Instantiate a User-Defined Object-Type or Collection-Type Instance
  You can use SQL/JSON function json_value to instantiate an instance of a user-defined SQL object type or collection type. You do this by targeting a JSON object or array in the path expression and specifying the object or collection type, respectively, in the RETURNING clause.

* JSON_VALUE as JSON_TABLE
  SQL/JSON function json_value can be viewed as a special case of function json_table.

Related Topics

- RETURNING Clause for SQL Query Functions
  SQL functions `json_value`, `json_query`, `json_serialize`, and `json_mergepatch` accept an optional **RETURNING** clause, which specifies the data type of the value returned by the function. This clause and the default behavior (no `RETURNING` clause) are described here.

- Error Clause for SQL Functions and Conditions
  Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

- Empty-Field Clause for SQL/JSON Query Functions
  SQL/JSON query functions `json_value`, `json_query`, and `json_table` accept an optional **ON EMPTY** clause, which specifies the handling to use when a targeted JSON field is absent from the data queried. This clause and the default behavior (no `ON EMPTY` clause) are described here.

- PASSING Clause for SQL Functions and Conditions
  Oracle SQL function `json_transform`, SQL/JSON functions `json_value` and `json_query`, and SQL/JSON condition `json_exists` accept an optional `PASSING` clause, which binds SQL values to SQL/JSON variables for use in path expressions.

19.1 Using SQL/JSON Function JSON_VALUE With a Boolean JSON Value

JSON has Boolean values `true` and `false`. When SQL/JSON function `json_value` evaluates a path expression to JSON `true` or `false`, it can return a `BOOLEAN` or a `VARCHAR2` value (`'true'` or `'false'`), or a `NUMBER` value (`1` for `true`, `0` for `false`).

By default, `json_value` returns a `VARCHAR2` (string) value. If the targeted data is a JSON Boolean value then *by default* the returned value is the *string* `'true'` or `'false'`. Example 19-1 illustrates this — the query returns `'true'`.

With a `RETURNING` clause you can specify the return data type. Example 19-2 illustrates the use of `RETURNING BOOLEAN` to return a `BOOLEAN` value (`true` or `false`) in SQL — the query returns `true`. Example 19-3 illustrates the same thing in PL/SQL, and it shows the use of clause `ERROR ON ERROR`.

By default, `RETURNING NUMBER` raises an error when the targeted data is a JSON Boolean value. However, if you include the clause **ALLOW BOOLEAN TO NUMBER CONVERSION** then no error is raised; in that case, `1` is returned for a `true` JSON value, and `0` is returned for a `false` value. Example 19-4 illustrates this — the query returns `1`.

SQL/JSON function `json_table` generalizes other SQL/JSON query functions, including `json_value`. When you use it to project a JSON Boolean value, `json_value` is used implicitly, and the resulting SQL value is returned as a `VARCHAR2` value, by default. By default, the data type of the projection column is therefore `VARCHAR2`.

But just as for `json_value`, you can project a JSON Boolean value as a `BOOLEAN` value. And you can project it as a `NUMBER` value, by specifying `NUMBER` data type for the column and including the clause `ALLOW BOOLEAN TO NUMBER CONVERSION`.

Example 19-1   JSON_VALUE: Returning a JSON Boolean Value as VARCHAR2

Returning a `VARCHAR2` is the *default* behavior for function `json_value`.

```
SELECT json_value(po_document, '$.AllowPartialShipment')
  FROM j_purchaseorder;
```

Example 19-2   JSON_VALUE: Returning a JSON Boolean Value to SQL as BOOLEAN

This example returns a SQL `BOOLEAN` value for Boolean JSON data. (`BOOLEAN` data type is available in Oracle SQL starting with Release 23c.)

```
SELECT json_value(po_document, '$.AllowPartialShipment'
                  RETURNING BOOLEAN)
  FROM j_purchaseorder;
```

Example 19-3   JSON_VALUE: Returning a JSON Boolean Value to PL/SQL as BOOLEAN

This example uses clause `ERROR ON ERROR`, to raise an error in case of error. (User exception-handling code can then handle the error.)

```
DECLARE
  b     BOOLEAN;
  jdata CLOB;
BEGIN
  SELECT po_document INTO jdata FROM j_purchaseorder
    WHERE rownum = 1;
  b := json_value(jdata, '$.AllowPartialShipment'
                  RETURNING BOOLEAN
                  ERROR ON ERROR);
END;
/
```

Example 19-4   JSON_VALUE: Returning a JSON Boolean Value to SQL as NUMBER

This examples uses clause `ALLOW BOOLEAN TO NUMBER CONVERSION` to return the SQL `NUMBER` value `1`, meaning *true*. Without that clause, `RETURNING NUMBER` raises an error for Boolean JSON data.

```
SELECT json_value(po_document, '$.AllowPartialShipment'
                  RETURNING NUMBER
                  ALLOW BOOLEAN TO NUMBER CONVERSION)
  FROM j_purchaseorder;
```

- JSON_TABLE Generalizes SQL/JSON Query Functions and Conditions
  SQL/JSON function `json_table` generalizes SQL/JSON condition `json_exists` and SQL/
  JSON functions `json_value` and `json_query`. Everything that you can do using these
  functions you can do using `json_table`. For the jobs they accomplish, the syntax of these
  functions is simpler to use than is the syntax of `json_table`.

19.2 Using JSON_VALUE To Instantiate a User-Defined Object-Type or Collection-Type Instance

You can use SQL/JSON function `json_value` to instantiate an instance of a user-defined SQL
object type or collection type. You do this by targeting a JSON object or array in the path
expression and specifying the object or collection type, respectively, in the `RETURNING` clause.

The elements of a targeted JSON *array* provide the elements of a returned *collection*-type
instance. The JSON array elements must correspond, one-to-one, with the collection-type
elements. If they do not then a mismatch error occurs. A JSON array element that is an
object (see next) or an array is handled recursively.

The fields of a targeted JSON *object* provide the attribute values of a returned *object*-type
instance. The JSON fields must correspond, one-to-one, with the object-type attributes. If
they do not then a mismatch error occurs.

The field names of the targeted JSON object are compared with the SQL names of the object
attributes. A field value that is an array or an object is handled recursively, so that ultimately it
is the names of JSON fields with scalar values that are compared with the names of scalar
SQL object attributes. If the names do not match (case insensitively, by default), then a
mismatch error occurs.

If all names match then the corresponding data types are checked for compatibility. If there is
any type incompatibility then a mismatch error occurs. Table 17-2 specifies the compatible
scalar data types — any other type combinations are incompatible, which entails a mismatch
error.

A *mismatch error* occurs at query compile time if any of the following are true. By *default*,
mismatch errors are *ignored*, but you can change this error handling by including one or more
`ON MISMATCH` clauses in your invocation of `json_value`.

- The fields of a targeted JSON object, or the elements of a targeted JSON array, do not
  correspond in number and kind to the attributes of the specified object-type instance, or
  to the elements of the specified collection-type instance, respectively.

- The fields of a targeted JSON object do not have the *same names* as the attributes of a
  specified object-type instance. By default this matching is case-insensitive.

- The JSON and Oracle SQL *scalar data types* of a JSON value and its corresponding
  object attribute value or collection element value are not *compatible*, according to
  Table 17-2.

You can use `json_value` to return an object-type or collection-type instance in PL/SQL, as
well as SQL. However, the behavior of clauses `NULL ON MISMATCH` and `NULL ON EMPTY` is
slightly different when returning a record-type or an index table-type instance, because values
of these types cannot be atomically `NULL`. See their documentation for details.

Example 19-5   Instantiate a User-Defined Object Instance From JSON Data with JSON_VALUE

This example defines SQL object types `shipping_t` and `addr_t`. Object type `shipping_t` has attributes `name` and `address`, which have types `VARCHAR2(30)` and `addr_t`, respectively.

Object type `addr_t` has attributes `street` and `city`.

The example uses `json_value` to select the JSON object that is the value of field `ShippingInstructions` and return an instance of SQL object type `shipping_t`. Names of the object-type attributes are matched against JSON object field names *case-insensitively*, so that, for example, attribute `address` (which is the same as `ADDRESS`) of SQL object-type `shipping_t` matches JSON field `address`.

(The query output is shown pretty-printed here, for clarity.)

```
CREATE TYPE addr_t AS OBJECT
  (street VARCHAR2(100),
   city   VARCHAR2(30));

-- Create after type addr_t, because that's referred to here.
--
CREATE TYPE shipping_t AS OBJECT
  (name    VARCHAR2(30),
   address addr_t);

-- Query data to return shipping_t instances:
SELECT json_value(po_document, '$.ShippingInstructions'
                  RETURNING shipping_t)
  FROM j_purchaseorder;

JSON_VALUE(PO_DOCUMENT,'$.SHIPPINGINSTRUCTIONS'RETURNING
--------------------------------------------------------
SHIPPING_T('Alexis Bull',
           ADDR_T('200 Sporting Green',
                  'South San Francisco'))
SHIPPING_T('Sarah Bell',
           ADDR_T('200 Sporting Green',
                  'South San Francisco'))
```

Example 19-6   Instantiate a Collection Type Instance From JSON Data with JSON_VALUE

This example defines SQL collection type `items_t` and SQL object types `part_t` and `item_t`. An instance of collection type `items_t` is a varray of `item_t` instances. Attribute `part` of object-type `item_t` is itself of SQL object-type `part_t`.

It then uses `json_value` to select the JSON

(The query output is shown pretty-printed here, for clarity.)

```
CREATE TYPE part_t AS OBJECT
  (description VARCHAR2(30),
   unitprice   NUMBER);
```

```
CREATE TYPE item_t AS OBJECT
  (itemnumber NUMBER,
   part        part_t);

CREATE TYPE items_t AS VARRAY(10) OF item_t;

-- Query data to return items_t collections of item_t objects
SELECT json_value(po_document, '$.LineItems' RETURNING items_t)
  FROM j_purchaseorder;

JSON_VALUE(PO_DOCUMENT,'$.LINEITEMS'RETURNINGITEMS_TUSIN
------------------------------------------------------
ITEMS_T(ITEM_T(1, PART_T('One Magic Christmas', 19.95)),
        ITEM_T(2, PART_T('Lethal Weapon', 19.95)))
ITEMS_T(ITEM_T(1, PART_T('Making the Grade', 20)),
        ITEM_T(2, PART_T('Nixon', 19.95)),
        ITEM_T(3, PART_T(NULL, 19.95)))
```

19.3 JSON_VALUE as JSON_TABLE

SQL/JSON function `json_value` can be viewed as a special case of function `json_table`.

Example 19-7 illustrates the equivalence: the two SELECT statements have the same effect.

In addition to perhaps helping you understand `json_value` better, this equivalence is important practically, because it means that you can use either function to get the same effect.

In particular, if you use `json_value` more than once, or you use it in combination with `json_exists` or `json_query` (which can also be expressed using `json_table`), to access the same data, then a single invocation of `json_table` presents the advantage that the data is parsed only once.

Because of this, the optimizer often automatically rewrites multiple invocations of
json_exists, json_value and json_query (any combination) to fewer invocations of
json_table.

> **✎ Note:**
>
> You can use SQL hint NO_JSON_TABLE_TRANSFORM to prevent rewriting of
> multiple invocations of json_exists, json_value and json_query (any
> combination) to fewer invocations of json_table.

Example 19-7   JSON_VALUE Expressed Using JSON_TABLE

```
SELECT json_value(column, json_path
                    RETURNING data_type error_hander ON ERROR)
  FROM table;

SELECT jt.column_alias
  FROM table,
       json_table(column, '$' error_handler ON ERROR
          COLUMNS ("COLUMN_ALIAS" data_type PATH json_path)) AS "JT";
```

    the syntax of these functions is simpler to use than is the syntax of json_table.

20

SQL/JSON Function JSON_QUERY

SQL/JSON function `json_query` selects one or more values from JSON data and returns those values. You can thus use `json_query` to retrieve *fragments* of a JSON document.

The JSON data that you query is the first argument to `json_query`. More precisely, it is a SQL expression that returns an instance of a SQL data type that contains JSON data: type `JSON`[1], `VARCHAR2`, `CLOB`, or `BLOB`. It can be a table or view column value, a PL/SQL variable, or a bind variable with proper casting. The result of evaluating the expression is used as the *context item* for evaluating the path expression (described next).

The second argument to `json_query` is a SQL/JSON path expression followed by optional clauses `RETURNING`, `PASSING`, `WRAPPER`, `QUOTES`, `ON ERROR`, and `ON EMPTY`. The path expression can target any number of JSON values.

In a path-expression *array step*, each of the specified positions is matched against the data, in order, no matter how it is specified. The order of array indexes and ranges, multiple occurrences of an index, and duplication of a specified position due to range overlaps all matter.

In the `RETURNING` clause you can specify data type `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. A `BLOB` result is in the AL32UTF8 character set.

The default return type (no `RETURNING` clause) depends on the input data type. If the input type is `JSON` then `JSON` is also the default return type. Otherwise, `VARCHAR2` is the default return type.

The value returned always contains well-formed JSON data. This includes ensuring that non-ASCII characters in string values are escaped as needed. For example, an ASCII TAB character (Unicode character CHARACTER TABULATION, U+0009) is escaped as `\t`. Keywords `FORMAT JSON` are not needed (or available) for `json_query` — JSON formatting is implicit for the return value.

The wrapper clause determines the form of the returned string value.

If (1) the JSON value to be returned by `json_query` is a string, and (2) the returning data type is textual, not `JSON` type, then the JSON string-delimiting double-quote characters are *included* in the returned value. In this context you must use keywords **OMIT QUOTES** if you want to omit the delimiting double-quote characters.

For example, if the return type is `VARCHAR2` (the default, if the input data is not of `JSON` type), then the JSON string `"hello"`, which has only the five characters `hello`, is returned as the seven-character `VARCHAR2` value `"hello"`.

---

[1] Database initialization parameter `compatible` must be at least 20 to use data type `JSON`.

> **Note:**
>
> You cannot use an array wrapper with `json_query` if you use clause `OMIT QUOTES`; a compile-time error is raised if you do that.

The error clause for `json_query` can specify `EMPTY ON ERROR`, which means that an empty array (`[]`) is returned in case of error (no error is raised).

If initialization parameter `compatible` is `20` or greater then Oracle Database supports IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level.

If parameter `compatible` is less than `20` then only RFC 4627 is supported. It allows only a JSON object or array, not a scalar, at the top level of a JSON document. RFC 8259 includes support for RFC 4627 (and RFC 7159).

If RFC 8259 is not supported, and if the value targeted by a `json_query` path-expression argument targets multiple values or a single scalar value, then you must use keywords `WITH WRAPPER` to return the value(s) wrapped in an array. Otherwise, an error is raised.

If RFC 8259 is supported then `json_query` can return scalar JSON values, by default. To require `json_query` to return only nonscalar JSON values, use keywords `DISALLOW SCALARS` in the `RETURNING` clause. In that case the behavior is the same as if RFC 8259 were not supported — you must use `WITH WRAPPER`.

Example 20-1 shows an example of using SQL/JSON function `json_query` with an array wrapper. For each document it returns a `VARCHAR2` value whose contents represent a JSON array with elements the phone types, in an unspecified order. For the document in Example 4-3 the phone types are "`Office`" and "`Mobile`", and the array returned is either `[ "Mobile", "Office" ]` or `[ "Office", "Mobile" ]`.

Note that if path expression `$.ShippingInstructions.Phone.type` were used in Example 20-1 it would give the same result. Because of SQL/JSON path-expression syntax relaxation, `[*].type` is equivalent to `.type`.

> **See Also:**
>
> - *Oracle Database SQL Language Reference* for information about `json_query`
> - IETF RFC 8259

Example 20-1   Selecting JSON Values Using JSON_QUERY

```
SELECT json_query(po_document, '$.ShippingInstructions.Phone[*].type'
                  WITH WRAPPER)
  FROM j_purchaseorder;
```

- JSON_QUERY as JSON_TABLE
  SQL/JSON function `json_query` can be viewed as a special case of function `json_table`.

Related Topics

- SQL/JSON Path Expression Syntax Relaxation
  The basic SQL/JSON path-expression syntax is relaxed to allow implicit array wrapping and unwrapping. This means that you need not change a path expression in your code if your data evolves to replace a JSON value with an array of such values, or vice versa. Examples are provided.

- RETURNING Clause for SQL Query Functions
  SQL functions `json_value`, `json_query`, `json_serialize`, and `json_mergepatch` accept an optional **RETURNING** clause, which specifies the data type of the value returned by the function. This clause and the default behavior (no `RETURNING` clause) are described here.

- Wrapper Clause for SQL/JSON Query Functions JSON_QUERY and JSON_TABLE
  SQL/JSON query functions `json_query` and `json_table` accept an optional wrapper clause, which specifies the form of the value returned by `json_query` or used for the data in a `json_table` column. This clause and the default behavior (no wrapper clause) are described here. Examples are provided.

- Error Clause for SQL Functions and Conditions
  Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

- Empty-Field Clause for SQL/JSON Query Functions
  SQL/JSON query functions `json_value`, `json_query`, and `json_table` accept an optional **ON EMPTY** clause, which specifies the handling to use when a targeted JSON field is absent from the data queried. This clause and the default behavior (no `ON EMPTY` clause) are described here.

- Support for RFC 8259: JSON Scalars
  Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

- PASSING Clause for SQL Functions and Conditions
  Oracle SQL function `json_transform`, SQL/JSON functions `json_value` and `json_query`, and SQL/JSON condition `json_exists` accept an optional `PASSING` clause, which binds SQL values to SQL/JSON variables for use in path expressions.

20.1 JSON_QUERY as JSON_TABLE

SQL/JSON function `json_query` can be viewed as a special case of function `json_table`.

Example 20-2 illustrates the equivalence: the two `SELECT` statements have the same effect.

In addition to perhaps helping you understand `json_query` better, this equivalence is important practically, because it means that you can use either function to get the same effect.

In particular, if you use `json_query` more than once, or you use it in combination with `json_exists` or `json_value` (which can also be expressed using `json_table`), to access the same data, then a single invocation of `json_table` presents the advantage that the data is parsed only once.

Because of this, the optimizer often automatically rewrites multiple invocations of json_exists, json_value and json_query (any combination) to fewer invocations of json_table.

> **✎ Note:**
>
> You can use SQL hint NO_JSON_TABLE_TRANSFORM to prevent rewriting of multiple invocations of json_exists, json_value and json_query (any combination) to fewer invocations of json_table.

Example 20-2   JSON_QUERY Expressed Using JSON_TABLE

The keywords FORMAT JSON are used only if *data_type* is not JSON type. (Keywords FORMAT JSON cannot be used with JSON type.)

```
SELECT json_query(column, json_path
                   RETURNING data_type array_wrapper
                             error_handler ON ERROR)
  FROM table;

SELECT jt.column_alias
  FROM table,
       json_table(column, '$' error_handler ON ERROR
         COLUMNS ("COLUMN_ALIAS" data_type FORMAT JSON array_wrapper
                  PATH json_path)) AS "JT";
```

*   [JSON_TABLE Generalizes SQL/JSON Query Functions and Conditions](#)
    SQL/JSON function json_table generalizes SQL/JSON condition json_exists and SQL/JSON functions json_value and json_query. Everything that you can do using these functions you can do using json_table. For the jobs they accomplish, the syntax of these functions is simpler to use than is the syntax of json_table.

21
SQL/JSON Function JSON_TABLE

SQL/JSON function `json_table` projects specific JSON data to columns of various SQL data types. You use it to map parts of a JSON document into the rows and columns of a new, virtual table, which you can also think of as an inline view.

You can then insert this virtual table into a pre-existing database table, or you can query it using SQL — in a join expression, for example.

A common use of `json_table` is to create a *view* of JSON data. You can use such a view just as you would use any table or view. This lets applications, tools, and programmers operate on JSON data without consideration of the syntax of JSON or JSON path expressions.

Defining a view over JSON data in effect maps a kind of *schema* onto that data. This mapping is *after the fact*: the underlying JSON data can be defined and created without any regard to a schema or any particular pattern of use. Data first, schema later.

Such a schema (mapping) imposes no restriction on the kind of JSON documents that can be stored in the database (other than being well-formed JSON data). The view exposes only data that conforms to the mapping (schema) that defines the view. To change the schema, just redefine the view — no need to reorganize the underlying JSON data.

You use `json_table` in a SQL `FROM` clause. It is a **row source**: it generates a row of virtual-table data for each JSON value selected by a *row path expression* (row pattern). The columns of each generated row are defined by the *column path expressions* of the `COLUMNS` clause.

Typically a `json_table` invocation is laterally joined, implicitly, with a source table in the `FROM` list, whose rows each contain a JSON document that is used as input to the function. `json_table` generates zero or more new rows, as determined by evaluating the row path expression against the input document.

The first argument to `json_table` is a SQL expression. It can be a table or view column value, a PL/SQL variable, or a bind variable with proper casting. The result of evaluating the expression is used as the *context item* for evaluating the row path expression.

The second argument to `json_table` is the SQL/JSON row path expression followed by an optional error clause for handling the row and the (required) `COLUMNS` clause, which defines the columns of the virtual table to be created. There is no `RETURNING` clause.

There are two levels of error handling for `json_table`, corresponding to the two levels of path expressions: row and column. When present, a column error handler overrides row-level error handling. The default error handler for both levels is `NULL ON ERROR`.

In a row path-expression *array step*, the order of indexes and ranges, multiple occurrences of an array index, and duplication of a specified position due to range overlaps all have the usual effect: the specified positions are matched, in order, against the data, producing one row for each position match.

As an alternative to passing the context-item argument and the row path expression, you can use simple dot-notation syntax. (You can still use an error clause, and the `COLUMNS` clause is

still required.) Dot notation specifies a table or view column together with a simple path to the targeted JSON data. For example, these two queries are equivalent:

```
json_table(t.j, '$.ShippingInstructions.Phone[*]' ...)

json_table(t.j.ShippingInstructions.Phone[*] ...)
```

And in cases where the row path expression is only '`$`', which targets the entire document, you can omit the path part. These queries are equivalent:

```
json_table(t.j, '$' ...)

json_table(t.j ...)
```

Example 21-1 illustrates the difference between using the simple dot notation and using the fuller, more explicit notation.

You can also use the dot notation in any `PATH` clause of a `COLUMNS` clause, as an alternative to using a SQL/JSON path expression. For example, you can use just `PATH 'ShippingInstructions.name'` instead of `PATH '$.ShippingInstructions.name'`.

Example 21-1   Equivalent JSON_TABLE Queries: Simple and Full Syntax

This example uses `json_table` for two equivalent queries. The first query uses the simple, dot-notation syntax for the expressions that target the row and column data. The second uses the full syntax.

Except for column `Special Instructions`, whose SQL identifier is quoted, the SQL column names are, in effect, uppercase. (Identifier `Special Instructions` contains a space character.)

In the first query the column names are written exactly the same as the names of the targeted object fields, including with respect to letter case. Regardless of whether they are quoted, they are interpreted case-sensitively for purposes of establishing the default path (the path used when there is no explicit `PATH` clause).

The second query has:

- Separate arguments of a JSON column-expression and a SQL/JSON row path-expression

- Explicit column data types of `VARCHAR2(4000)`

- Explicit `PATH` clauses with SQL/JSON column path expressions, to target the object fields that are projected

```
SELECT jt.*
  FROM j_purchaseorder po,
       json_table(po.po_document
         COLUMNS ("Special Instructions",
                  NESTED LineItems[*]
                    COLUMNS (ItemNumber NUMBER,
```

```
                              Description PATH Part.Description))
    ) AS "JT";

SELECT jt.*
  FROM j_purchaseorder po,
       json_table(po.po_document,
         '$'
         COLUMNS (
           "Special Instructions" VARCHAR2(4000)
                                  PATH '$."Special Instructions"',
           NESTED PATH '$.LineItems[*]'
             COLUMNS (
               ItemNumber  NUMBER        PATH '$.ItemNumber',
               Description VARCHAR(4000) PATH '$.Part.Description'))
       ) AS "JT";
```

- **SQL NESTED Clause Instead of JSON_TABLE**
  In a `SELECT` clause you can often use a `NESTED` clause instead of SQL/JSON function `json_table`. This can mean a simpler query expression. It also has the advantage of including rows with non-`NULL` relational columns when the JSON column is `NULL`.

- **COLUMNS Clause of SQL/JSON Function JSON_TABLE**
  The mandatory `COLUMNS` clause for SQL/JSON function `json_table` defines the columns of the virtual table that the function creates.

- **JSON_TABLE Generalizes SQL/JSON Query Functions and Conditions**
  SQL/JSON function `json_table` generalizes SQL/JSON condition `json_exists` and SQL/JSON functions `json_value` and `json_query`. Everything that you can do using these functions you can do using `json_table`. For the jobs they accomplish, the syntax of these functions is simpler to use than is the syntax of `json_table`.

- **Using JSON_TABLE with JSON Arrays**
  A JSON value can be an array or can include one or more arrays, nested to any number of levels inside other JSON arrays or objects. You can use `json_table` with a `NESTED PATH` clause to project specific elements of an array.

- **Creating a View Over JSON Data Using JSON_TABLE**
  To improve query performance you can create a view over JSON data that you project to columns using SQL/JSON function `json_table`. To further improve query performance you can create a *materialized view* and place the JSON data *in memory*.

Related Topics

- **Error Clause for SQL Functions and Conditions**
  Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or condition. This clause and the default behavior (no error clause) are summarized here.

- **SQL/JSON Function JSON_QUERY**
  SQL/JSON function `json_query` selects one or more values from JSON data and returns those values. You can thus use `json_query` to retrieve *fragments* of a JSON document.

- **Creating Multivalue Function-Based Indexes for JSON_EXISTS**
  For JSON data that is stored as `JSON` data type you can use a multivalue function-based index for SQL/JSON condition `json_exists`. Such an index targets scalar JSON values, either individually or within a JSON array.

> `json_table`

21.1 SQL NESTED Clause Instead of JSON_TABLE

In a `SELECT` clause you can often use a `NESTED` clause instead of SQL/JSON function `json_table`. This can mean a simpler query expression. It also has the advantage of including rows with non-`NULL` relational columns when the JSON column is `NULL`.

The `NESTED` clause is a shortcut for using `json_table` with an ANSI left outer join. That is, these two queries are equivalent:

```
SELECT ...
  FROM mytable NESTED jcol COLUMNS (...);
```

```
SELECT ...
  FROM mytable t1 LEFT OUTER JOIN
       json_table(t1.jcol COLUMNS (...)
       ON 1=1;
```

Using a left outer join with `json_table`, or using the `NESTED` clause, allows the selection result to include rows with relational columns where there is no corresponding JSON-column data, that is, where the JSON column is `NULL`. The only semantic difference between the two is that if you use a `NESTED` clause then the JSON column itself is not included in the result.

The `NESTED` clause provides the same `COLUMNS` clause as `json_table`, including the possibility of nested columns. These are the advantages of using `NESTED`:

- You need not provide a table alias, even if you use the simple dot notation.

- You need not provide an `is json` check constraint, even if the JSON column is not `JSON` type. (The constraint is needed for `json_table` with the simple dot notation, unless the column is `JSON` type.)

- You need not specify `LEFT OUTER JOIN`.

The `NESTED` clause syntax is simpler, it allows all of the flexibility of the `COLUMNS` clause, and it performs an implicit left outer join. This is illustrated in Example 21-2.

Example 21-3 shows the use of a `NESTED` clause with the simple dot notation.

Example 21-2   Equivalent: SQL NESTED and JSON_TABLE with LEFT OUTER JOIN

These two queries are equivalent. One uses SQL/JSON function `json_table` with an explicit `LEFT OUTER JOIN`. The other uses a SQL `NESTED` clause.

```
SELECT id, requestor, type, "number"
  FROM j_purchaseorder LEFT OUTER JOIN
```

```
          json_table(po_document
            COLUMNS (Requestor,
                      NESTED ShippingInstructions.Phone[*]
                        COLUMNS (type, "number")))
          ON 1=1);

SELECT id, requestor, type, "number"
  FROM j_purchaseorder NESTED
       po_document
         COLUMNS (Requestor,
                   NESTED ShippingInstructions.Phone[*]
                     COLUMNS (type, "number");
```

The output is the same in both cases:

```
7C3A54B183056369E0536DE05A0A15E4 Alexis Bull Office 909-555-7307
7C3A54B183056369E0536DE05A0A15E4 Alexis Bull Mobile 415-555-1234
7C3A54B183066369E0536DE05A0A15E4 Sarah Bell
```

If table `j_purchaseorder` had a row with non-`NULL` values for columns `id` and `requestor`, but a `NULL` value for column `po_document` then that row would appear in both cases. But it would not appear in the `json_table` case if `LEFT OUTER JOIN` were absent.

Example 21-3   Using SQL NESTED To Expand a Nested Array

This example selects columns `id` and `date_loaded` from table `j_purchaseorder`, along with the array elements of field `Phone`, which is nested in the value of field `ShippingInstructions` of JSON column `po_document`. It expands the `Phone` array value as columns `type` and `number`.

(Column specification `"number"` requires the double-quote marks because `number` is a reserved term in SQL.)

```
SELECT *
  FROM j_purchaseorder NESTED
       po_document.ShippingInstructions.Phone[*]
         COLUMNS (type, "number")
```

21.2 COLUMNS Clause of SQL/JSON Function JSON_TABLE

The mandatory `COLUMNS` clause for SQL/JSON function `json_table` defines the columns of the virtual table that the function creates.

It consists of the keyword **COLUMNS** followed by the following entries, enclosed in parentheses. Other than the optional `FOR ORDINALITY` entry, each entry in the `COLUMNS` clause is either a *regular* column specification or a *nested* columns specification.

*   At most one entry in the `COLUMNS` clause can be a column name followed by the keywords **FOR ORDINALITY**, which specifies a column of generated row numbers (SQL data type `NUMBER`). These numbers start with one. For example:

    ```
    COLUMNS (linenum FOR ORDINALITY, ProductID)
    ```

An *array step* in a row path expression can lead to any number of rows that match the path expression. In particular, the order of array-step indexes and ranges, multiple occurrences of an array index, and duplication of a specified position due to range overlaps produce one row for each position match. The ordinality row numbers reflect this.

- A **regular column** specification consists of a column name followed by an optional data type for the column, which can be any SQL data type that can be used in the RETURNING clause of `json_value`, followed by an optional value clause and an optional PATH clause. The default data type is VARCHAR2(4000).

  The column data type can thus be any of these: JSON, VARCHAR2, NUMBER, DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, or SDO_GEOMETRY.

  Data type SDO_GEOMETRY is used for Oracle Spatial and Graph data. In particular, this means that you can use `json_table` with GeoJSON data, which is a format for encoding geographic data in JSON.

  Oracle extends the SQL/JSON standard in the case when the returning data type for a column is VARCHAR2(N), by allowing optional keyword **TRUNCATE** immediately after the data type. When TRUNCATE is present and the value to return is wider than N, the value is truncated — only the first N characters are returned. If TRUNCATE is absent then this case is treated as an error, handled as usual by an error clause or the default error-handling behavior.

- A **nested columns** specification consists of the keyword **NESTED** followed by an optional **PATH** keyword, a SQL/JSON row path expression, and then a COLUMNS clause. This COLUMNS clause specifies columns that represent nested data. The row path expression used here provides a refined context for the specified nested columns: each nested column path expression is relative to the row path expression. You can nest columns clauses to project values that are present in arrays at different levels to columns of the same row.

  A COLUMNS clause at any level (nested or not) has the same characteristics. In other words, the COLUMNS clause is defined recursively. For each level of nesting (that is, for each use of keyword NESTED), the nested COLUMNS clause is said to be the **child** of the COLUMNS clause within which it is nested, which is its **parent**. Two or more COLUMNS clauses that have the same parent clause are **siblings**.

  The virtual tables defined by parent and child COLUMNS clauses are joined using an *outer* join, with the parent being the outer table. The virtual columns defined by sibling COLUMNS clauses are joined using a union join.

  Example 21-1 and Example 21-9 illustrate the use of a nested columns clause.

The only thing required in a regular column specification is the column name. Defining the column projection in more detail, by specifying a scalar data type, value handling, or a target path, is optional.

- The optional **value** clause specifies how to handle the data projected to the column: whether to handle it as would `json_value`, `json_exists`, or `json_query`. This value handling includes the return data type, return format (pretty or ASCII), wrapper, and error treatment.

  If you use keyword **EXISTS** then the projected data is handled as if by `json_exists` (regardless of the column data type).

  Otherwise:

- For a column of data type JSON, the projected data is handled as if by json_query.

- For a non-JSON type column (any type that can be used in a json_value RETURNING clause), the projected data is handled *by default* as if by json_value. But if you use keywords **FORMAT JSON** then it is handled as if by json_query. You typically use FORMAT JSON only when the projected data is a JSON object or array. (An error is raised if you use FORMAT JSON with a JSON type column.)

For example, here the value of column FirstName is projected directly using json_value semantics, and the value of column Address is projected as a JSON string using json_query semantics:

```
COLUMNS (FirstName, Address FORMAT JSON)
```

json_query semantics imply that the projected JSON data is well-formed. If the column is a non-JSON type then this includes ensuring that non-ASCII characters in string values are escaped as needed. For example, a TAB character (CHARACTER TABULATION, U+0009) is escaped as \t. (For JSON type data, any such escaping is done when the JSON data is created, not when json_query is used.)

When the column has json_query semantics:

- If database initialization parameter compatible is at least 20 then you can use keywords DISALLOW SCALARS to affect the json_query behavior by excluding scalar JSON values.

- You can override the default wrapping behavior by adding an explicit *wrapper clause*.

You can override the default error handling for a given handler (json_exists, json_value, or json_query) by adding an explicit *error clause* appropriate for it.

- The optional **PATH** clause specifies the portion of the row that is to be used as the column content. The column path expression following keyword PATH is matched against the context item provided by the virtual row. The column path expression must represent a *relative* path; it is relative to the path specified by the row path expression.

If the PATH clause is not present then the behavior is the same as if it were present with a path of '$.*<column-name>*', where *<column-name>* is the column name. That is, the name of the object field that is targeted is taken implicitly as the column name.

For purposes of specifying the targeted field *only*, the SQL identifier used for *<column-name>* is interpreted *case-sensitively*, even if it is not quoted. The SQL name of the column itself follows the usual rule: if it is enclosed in double quotation marks (") then the letter case used is significant; otherwise, it is not (it is treated as if uppercase).

For example, these two COLUMNS clauses are equivalent. For SQL, case is significant *only* for column Comments (because it is quoted). The other two columns have case-*in*sensitive names (that is, their names are treated case-insensitively), regardless of whether a PATH clause is used. In the first COLUMNS clause the first two columns are *written* with mixed case that matches the field names they target implicitly.

```
COLUMNS(ProductId, Quantity NUMBER, "Comments")

COLUMNS(productid   VARCHAR2(4000) PATH '$.ProductId',
        quantity    NUMBER         PATH '$.Quantity',
        "Comments"  VARCHAR2(4000) PATH '$.Comments')
```

Example 21-1 presents equivalent queries that illustrate this.

You can also use the dot notation in a `PATH` clause, as an alternative to a SQL/JSON path expression. Example 21-2 and Example 21-9 illustrate this.

In a column path-expression *array step*, the order of indexes and ranges, multiple occurrences of an array index, and duplication of a specified position due to range overlaps have the effect they would have for the particular semantics use for the column: `json_exists`, `json_query`, or `json_value`:

- `json_exists` — All that counts is the *set* of specified positions, not how they are specified, including the order or number of times they are specified. All that is checked is the existence of a match for at least one specified position.

- `json_query` — Each occurrence of a specified position is matched against the data, in order.

- `json_value` — If only one position is specified then it is matched against the data. Otherwise, there is no match — by default (`NULL ON ERROR`) a SQL `NULL` value is returned.

A columns clause with `json_value` semantics also accepts the optional keyword combination **TYPE (STRICT)** following the `PATH` clause. This has the same meaning and behavior as when it is used in connection with the `RETURNING` clause of `json_value`. For example, these two queries are equivalent. Only `PONumber` fields whose value is numeric are considered (projected).

```
SELECT jt.ponumb
  FROM j_purchaseorder,
       json_table(po_document, '$'
         COLUMNS (ponumb NUMBER PATH '$.PONumber.numberOnly()')) jt
```

```
SELECT jt.ponumb
  FROM j_purchaseorder,
       json_table(po_document, '$'
         COLUMNS (ponumb NUMBER PATH '$.PONumber' TYPE (STRICT))) jt
```

Related Topics

- RETURNING Clause for SQL Query Functions
  SQL functions `json_value`, `json_query`, `json_serialize`, and `json_mergepatch` accept an optional **RETURNING** clause, which specifies the data type of the value returned by the function. This clause and the default behavior (no `RETURNING` clause) are described here.

- Wrapper Clause for SQL/JSON Query Functions JSON_QUERY and JSON_TABLE
  SQL/JSON query functions `json_query` and `json_table` accept an optional wrapper clause, which specifies the form of the value returned by `json_query` or used for the data in a `json_table` column. This clause and the default behavior (no wrapper clause) are described here. Examples are provided.

- Error Clause for SQL Functions and Conditions
  Some SQL query functions and conditions for JSON data accept an optional error clause, which specifies handling for a runtime error that is raised by the function or

condition. This clause and the default behavior (no error clause) are summarized here.

- Empty-Field Clause for SQL/JSON Query Functions
  SQL/JSON query functions `json_value`, `json_query`, and `json_table` accept an optional **ON EMPTY** clause, which specifies the handling to use when a targeted JSON field is absent from the data queried. This clause and the default behavior (no `ON EMPTY` clause) are described here.

- SQL/JSON Function JSON_QUERY
  SQL/JSON function `json_query` selects one or more values from JSON data and returns those values. You can thus use `json_query` to retrieve *fragments* of a JSON document.

- Support for RFC 8259: JSON Scalars
  Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

- TYPE Clause for SQL Functions and Conditions
  Oracle SQL function `json_transform`, SQL/JSON functions `json_query`, `json_value` and `json_table`, and SQL/JSON condition `json_exists` accept optional **TYPE** clauses, which specify whether JSON values are compared *strictly* with respect to JSON-language type, that is, as if the relevant "only" data-type conversion item methods were applied to the data being compared.

21.3 JSON_TABLE Generalizes SQL/JSON Query Functions and Conditions

SQL/JSON function `json_table` generalizes SQL/JSON condition `json_exists` and SQL/JSON functions `json_value` and `json_query`. Everything that you can do using these functions you can do using `json_table`. For the jobs they accomplish, the syntax of these functions is simpler to use than is the syntax of `json_table`.

If you would otherwise use any of `json_exists`, `json_value`, or `json_query` more than once, or use them in combination, to access the same data, then you can instead use a single invocation of `json_table`. This can often make a query more readable, and it ensures that the query is optimized to read the data only once.

Because of this, the optimizer typically *automatically rewrites* multiple invocations of `json_exists`, `json_value` and `json_query` (any combination) to fewer invocations of `json_table`. (You can examine an execution plan, to check whether such rewriting occurs for a given query.)

Example 21-4 and Example 21-5 illustrate this. They each select the requestor and the set of phones used by each object in column `j_purchaseorder.po_document`. But the example with `json_table` reads that column only once, not four times.

These examples use `BOOLEAN` SQL values to represent a Boolean JSON values. (Oracle SQL support for data type `BOOLEAN` is introduced in Oracle Database Release 23c.)

A JSON value of `null` is a *value* as far as SQL is concerned; it is *not* `NULL`, which in SQL represents the absence of a value (missing, unknown, or inapplicable data). In these examples, if the JSON value of object attribute `zipCode` is `null` then the SQL `BOOLEAN` value `TRUE` is returned.

Example 21-4   Accessing JSON Data Multiple Times to Extract Data

This example uses four invocations of SQL functions to access SQL column `j_purchaseorder.po_document`, so it reads that column four times.

```
SELECT json_value(po_document, '$.Requestor' RETURNING VARCHAR2(32)),
       json_query(po_document, '$.ShippingInstructions.Phone'
                 RETURNING VARCHAR2(100))
  FROM j_purchaseorder
  WHERE json_exists(po_document, '$.ShippingInstructions.Address.zipCode')
    AND json_value(po_document,  '$.AllowPartialShipment'
                 RETURNING BOOLEAN) = TRUE;
```

Example 21-5   Using JSON_TABLE to Extract Data Without Multiple Reads

This example uses a single `json_table` invocation to access SQL column `j_purchaseorder.po_document`, so it reads that column only once.

The example uses `BOOLEAN` SQL values for both virtual columns:

- Column `partial` corresponds to a JSON Boolean value in the data (field `AllowPartialShipment`). `json_value` semantics are used for this column.

- Column `has_zip` results from the use of `json_table` keyword `EXISTS`, which says to use the semantics of `json_exists`.

Note: If the JSON data is of `JSON` data type then do not use keywords `FORMAT JSON`; otherwise, an error is raised.

```
SELECT jt.requestor, jt.phones
  FROM j_purchaseorder,
       json_table(po_document, '$'
         COLUMNS (
           requestor VARCHAR2(32 CHAR) PATH '$.Requestor',
           phones    VARCHAR2(100 CHAR) FORMAT JSON
                     PATH '$.ShippingInstructions.Phone',
           partial   BOOLEAN PATH '$.AllowPartialShipment',
           has_zip   BOOLEAN EXISTS
                     PATH '$.ShippingInstructions.Address.zipCode')) jt
  WHERE jt.partial AND jt.has_zip;
```

The `WHERE` clause could alternatively be written this way:

```
WHERE jt.partial = TRUE AND jt.has_zip = TRUE
```

Related Topics

- Using SQL/JSON Function JSON_VALUE With a Boolean JSON Value
  JSON has Boolean values `true` and `false`. When SQL/JSON function `json_value` evaluates a path expression to JSON `true` or `false`, it can return a `BOOLEAN` or a `VARCHAR2` value (`'true'` or `'false'`), or a `NUMBER` value (`1` for `true`, `0` for `false`).

21.4 Using JSON_TABLE with JSON Arrays

A JSON value can be an array or can include one or more arrays, nested to any number of levels inside other JSON arrays or objects. You can use `json_table` with a `NESTED PATH` clause to project specific elements of an array.

Example 21-6 projects the requestor and associated phone numbers from the JSON data in column `po_document`. The entire JSON array `Phone` is projected as a column of JSON data, `ph_arr`. To format this JSON data as a `VARCHAR2` column, the keywords `FORMAT JSON` are needed if the JSON data is not of `JSON` data type (and those keywords raise an error if the type is `JSON` data).

What if you wanted to project the individual *elements* of JSON array `Phone` and not the array as a whole? Example 21-7 shows one way to do this, which you can use if the array elements are the only data you need to project.

If you want to project both the requestor and the corresponding phone data then the row path expression of Example 21-7 (`$.Phone[*]`) is not appropriate: it targets only the (phone object) elements of array `Phone`.

Example 21-8 shows one way to target both: use a *row path expression* that targets both the name and the entire phones array, and use *column path expressions* that target fields `type` and `number` of individual phone objects.

In Example 21-8 as in Example 21-6, keywords `FORMAT JSON` are needed if the JSON data is not of `JSON` data type, because the resulting `VARCHAR2` columns contain JSON data, namely arrays of phone types or phone numbers, with one array element for each phone. In addition, unlike the case for Example 21-6, a wrapper clause is needed for column `phone_type` and column `phone_num`, because array `Phone` contains multiple objects with fields `type` and `number`.

Sometimes you might not want the effect of Example 21-8. For example, you might want a column that contains a single phone number (one row per number), rather than one that contains a JSON array of phone numbers (one row for all numbers for a given purchase order).

To obtain that result, you need to tell `json_table` to project the array elements, by using a `json_table` **NESTED** path clause for the array. A `NESTED` path clause acts, in effect, as an additional row source (row pattern). Example 21-9 illustrates this.

You can use any number of `NESTED` keywords in a given `json_table` invocation.

In Example 21-9 the outer `COLUMNS` clause is the parent of the nested (inner) `COLUMNS` clause. The virtual tables defined are joined using an outer join, with the table defined by the parent clause being the outer table in the join.

(If there were a second columns clause nested directly under the same parent, the two nested clauses would be sibling COLUMNS clauses.)

Example 21-6   Projecting an Entire JSON Array as JSON Data

```
SELECT jt.*
  FROM j_purchaseorder,
       json_table(po_document, '$'
         COLUMNS (requestor VARCHAR2(32 CHAR) PATH '$.Requestor',
                  ph_arr    VARCHAR2(100 CHAR) FORMAT JSON
                              PATH '$.ShippingInstructions.Phone')
                ) AS "JT";
```

Example 21-7   Projecting Elements of a JSON Array

```
SELECT jt.*
  FROM j_purchaseorder,
       json_table(po_document, '$.ShippingInstructions.Phone[*]'
         COLUMNS (phone_type VARCHAR2(10) PATH '$.type',
                  phone_num  VARCHAR2(20) PATH '$.number')) AS "JT";
```

```
PHONE_TYPE      PHONE_NUM
----------      ---------
Office          909-555-7307
Mobile          415-555-1234
```

Example 21-8   Projecting Elements of a JSON Array Plus Other Data

```
SELECT jt.*
  FROM j_purchaseorder,
       json_table(po_document, '$'
         COLUMNS (
           requestor  VARCHAR2(32 CHAR) PATH '$.Requestor',
           phone_type VARCHAR2(50 CHAR) FORMAT JSON WITH WRAPPER
                      PATH '$.ShippingInstructions.Phone[*].type',
           phone_num  VARCHAR2(50 CHAR) FORMAT JSON WITH WRAPPER
                      PATH '$.ShippingInstructions.Phone[*].number')) AS "JT";
```

```
REQUESTOR     PHONE_TYPE          PHONE_NUM
---------     ----------          ---------
Alexis Bull   ["Office", "Mobile"]  ["909-555-7307", "415-555-1234"]
```

Example 21-9   JSON_TABLE: Projecting Array Elements Using NESTED

This example shows two equivalent queries that project array elements. The first query uses the simple, dot-notation syntax for the expressions that target the row and column data. The second uses the full syntax.

Except for column number, whose SQL identifier is quoted ("number"), the SQL column names are, in effect, uppercase. (Column number is lowercase.)

In the first query the column names are written exactly the same as the field names that are targeted, including with respect to letter case. Regardless of whether they are

quoted, they are interpreted case-sensitively for purposes of establishing the proper path.

The second query has:

- Separate arguments of a JSON column-expression and a SQL/JSON row path-expression

- Explicit column data types of `VARCHAR2(4000)`

- Explicit `PATH` clauses with SQL/JSON column path expressions, to target the object fields that are projected

```
SELECT jt.*
  FROM j_purchaseorder po,
       json_table(po.po_document
         COLUMNS (Requestor,
                  NESTED ShippingInstructions.Phone[*]
                    COLUMNS (type, "number"))) AS "JT";
```

```
SELECT jt.*
  FROM j_purchaseorder po,
       json_table(po.po_document, '$'
         COLUMNS (Requestor VARCHAR2(4000) PATH '$.Requestor',
                  NESTED
                    PATH '$.ShippingInstructions.Phone[*]'
                    COLUMNS (type     VARCHAR2(4000) PATH '$.type',
                             "number" VARCHAR2(4000) PATH '$.number'))
       ) AS "JT";
```

Related Topics

- Creating a View Over JSON Data Using JSON_TABLE
  To improve query performance you can create a view over JSON data that you project to columns using SQL/JSON function `json_table`. To further improve query performance you can create a *materialized view* and place the JSON data *in memory*.

- SQL/JSON Function JSON_TABLE
  SQL/JSON function `json_table` projects specific JSON data to columns of various SQL data types. You use it to map parts of a JSON document into the rows and columns of a new, virtual table, which you can also think of as an inline view.

21.5 Creating a View Over JSON Data Using JSON_TABLE

To improve query performance you can create a view over JSON data that you project to columns using SQL/JSON function `json_table`. To further improve query performance you can create a *materialized view* and place the JSON data *in memory*.

Example 21-10 defines a view over JSON data. It uses a `NESTED` path clause to project the elements of array `LineItems`.

Example 21-11 defines a materialized view that has the same data and structure as Example 21-10.

In general, you cannot update a view directly (whether materialized or not). But if a materialized view is created using keywords `REFRESH` and `ON STATEMENT`, as in Example 21-11, then the view is updated automatically whenever you update the base table.

You can use `json_table` to project any fields as view columns, and the view creation (materialized or not) can involve joining any tables and any number of invocations of `json_table`.

The only differences between Example 21-10 and Example 21-11 are these:

- The use of keyword `MATERIALIZED`.

- The use of `BUILD IMMEDIATE`.

- The use of `REFRESH FAST ON STATEMENT WITH PRIMARY KEY`.

The use of `REFRESH FAST` means that the materialized view will be refreshed incrementally. For this to occur, you must use either `WITH PRIMARY KEY` or `WITH ROWID` (if there is no primary key). Oracle recommends that you specify a primary key for a table that has a JSON column and that you use `WITH PRIMARY KEY` when creating a materialized view based on it. You can use `REFRESH FAST` with a multiple-table materialized-join view and (single or multiple-table) materialized-aggregate views.

You could use `ON COMMIT` in place of `ON STATEMENT` for the view creation. The former synchronizes the view with the base table only when your table-updating transaction is committed. Until then the table changes are not reflected in the view. If you use `ON STATEMENT` then the view is immediately synchronized after each DML statement. This also means that a view created using `ON STATEMENT` reflects any rollbacks that you might perform. (A subsequent `COMMIT` statement ends the transaction, preventing a rollback.)

Example 21-10   Creating a View Over JSON Data

```
CREATE VIEW j_purchaseorder_detail_view
  AS SELECT jt.*
      FROM j_purchaseorder po,
          json_table(po.po_document, '$'
          COLUMNS (
             po_number        NUMBER(10)          PATH '$.PONumber',
             reference        VARCHAR2(30 CHAR)   PATH '$.Reference',
             requestor        VARCHAR2(128 CHAR)  PATH '$.Requestor',
             userid           VARCHAR2(10 CHAR)   PATH '$.User',
             costcenter       VARCHAR2(16)        PATH '$.CostCenter',
             ship_to_name     VARCHAR2(20 CHAR)
                              PATH '$.ShippingInstructions.name',
             ship_to_street   VARCHAR2(32 CHAR)
                              PATH '$.ShippingInstructions.Address.street',
             ship_to_city     VARCHAR2(32 CHAR)
                              PATH '$.ShippingInstructions.Address.city',
             ship_to_county   VARCHAR2(32 CHAR)
                              PATH '$.ShippingInstructions.Address.county',
             ship_to_postcode VARCHAR2(10 CHAR)
                              PATH '$.ShippingInstructions.Address.postcode',
             ship_to_state    VARCHAR2(2 CHAR)
```

```
                          PATH '$.ShippingInstructions.Address.state',
            ship_to_zip      VARCHAR2(8 CHAR)
                          PATH '$.ShippingInstructions.Address.zipCode',
            ship_to_country  VARCHAR2(32 CHAR)
                          PATH '$.ShippingInstructions.Address.country',
            ship_to_phone    VARCHAR2(24 CHAR)
                          PATH '$.ShippingInstructions.Phone[0].number',
          NESTED PATH '$.LineItems[*]'
            COLUMNS (
              itemno        NUMBER(38)        PATH '$.ItemNumber',
              description VARCHAR2(256 CHAR) PATH '$.Part.Description',
              upc_code      NUMBER            PATH '$.Part.UPCCode',
              quantity      NUMBER(12,4)      PATH '$.Quantity',
              unitprice     NUMBER(14,2)      PATH '$.Part.UnitPrice'))) jt;
```

Example 21-11   Creating a Materialized View Over JSON Data

```
CREATE MATERIALIZED VIEW j_purchaseorder_materialized_view
  BUILD IMMEDIATE
  REFRESH FAST ON STATEMENT WITH PRIMARY KEY
  AS SELECT jt.*
      FROM j_purchaseorder po,
          json_table(po.po_document, '$'
            COLUMNS (
              po_number        NUMBER(10)        PATH '$.PONumber',
              reference        VARCHAR2(30 CHAR)  PATH '$.Reference',
              requestor        VARCHAR2(128 CHAR) PATH '$.Requestor',
              userid           VARCHAR2(10 CHAR)  PATH '$.User',
              costcenter       VARCHAR2(16)       PATH '$.CostCenter',
              ship_to_name     VARCHAR2(20 CHAR)
                          PATH '$.ShippingInstructions.name',
              ship_to_street   VARCHAR2(32 CHAR)
                          PATH '$.ShippingInstructions.Address.street',
              ship_to_city     VARCHAR2(32 CHAR)
                          PATH '$.ShippingInstructions.Address.city',
              ship_to_county   VARCHAR2(32 CHAR)
                          PATH '$.ShippingInstructions.Address.county',
              ship_to_postcode VARCHAR2(10 CHAR)
                          PATH '$.ShippingInstructions.Address.postcode',
              ship_to_state    VARCHAR2(2 CHAR)
                          PATH '$.ShippingInstructions.Address.state',
              ship_to_zip      VARCHAR2(8 CHAR)
                          PATH '$.ShippingInstructions.Address.zipCode',
              ship_to_country  VARCHAR2(32 CHAR)
                          PATH '$.ShippingInstructions.Address.country',
              ship_to_phone    VARCHAR2(24 CHAR)
                          PATH '$.ShippingInstructions.Phone[0].number',
            NESTED PATH '$.LineItems[*]'
              COLUMNS (
                itemno        NUMBER(38)        PATH '$.ItemNumber',
                description VARCHAR2(256 CHAR) PATH '$.Part.Description',
                upc_code      NUMBER            PATH '$.Part.UPCCode',
                quantity      NUMBER(12,4)      PATH '$.Quantity',
                unitprice     NUMBER(14,2)      PATH '$.Part.UnitPrice'))) jt;
```

• JSON Query Rewrite To Use a Materialized View Over JSON_TABLE
  You can enhance the performance of queries that access particular JSON fields by
  creating, and indexing, a materialized view over such data that's defined using
  SQL/JSON function `json_table`.

22

Full-Text Search Queries

You can use Oracle SQL condition `json_textcontains` in a `CASE` expression or the `WHERE` clause of a `SELECT` statement to perform a *full-text* search of JSON data. You can use PL/SQL procedure `CTX_QUERY.result_set` to perform *facet* search over JSON data.

- Oracle SQL Condition JSON_TEXTCONTAINS
  You can use Oracle SQL condition `json_textcontains` in a `CASE` expression or the `WHERE` clause of a `SELECT` statement to perform a full-text search of JSON data.

- JSON Facet Search with PL/SQL Procedure CTX_QUERY.RESULT_SET
  If you have created a JSON search index then you can also use PL/SQL procedure `CTX_QUERY.result_set` to perform *facet* search over JSON data. This search is optimized to produce various kinds of search hits all at once, rather than, for example, using multiple separate queries with SQL function `contains`.

22.1 Oracle SQL Condition JSON_TEXTCONTAINS

You can use Oracle SQL condition `json_textcontains` in a `CASE` expression or the `WHERE` clause of a `SELECT` statement to perform a full-text search of JSON data.

Oracle Text technology underlies condition `json_textcontains`. This condition acts like SQL function `contains` when the latter uses parameter `INPATH`. The syntax of the search-pattern argument of `json_textcontains` is the same as that of SQL function `contains`. This means, for instance, that you can query for text that is near some other text, or query use fuzzy pattern-matching. If the search-pattern argument contains a character or a word that is *reserved* with respect to Oracle Text search then you must *escape* that character or word.

To be able to use condition `json_textcontains` you must first do *one* of the following; otherwise, an error is raised when you use `json_textcontains`. (You cannot do both — an error is raised if you try.)

- Create a JSON search index for the JSON column.

- Store the column of JSON data to be queried in the In-Memory Column Store (IM column store), specifying keyword `TEXT`. The column must of data type `JSON`; otherwise an error is raised. (`JSON` type is available only if database initialization parameter `compatible` is at least `20`.)

> ✏️ **Note:**
>
> By default, a JSON search index supports case-insensitive searching. To enable or disable case-sensitive indexing, use the `mixed_case` attribute of the `BASIC_LEXER` preference when creating the index. See BASIC_LEXER in *Oracle Text Reference*.

> **Note:**
>
> Oracle SQL function `json_textcontains` provides powerful full-text search of JSON data. If you need only simple string pattern-matching then you can instead use a path-expression filter condition with any of these pattern-matching comparisons: `has substring`, `starts with`, `like`, `like_regex`, or `eq_regex`.

Example 22-1 shows a full-text query that finds purchase-order documents that contain the keyword `Magic` in any of the line-item part descriptions.

- Overview of In-Memory JSON Data
  You can populate JSON data into the In-Memory Column Store (IM column store), to improve the performance of ad hoc and full-text queries.

- Populating JSON Data Into the In-Memory Column Store
  Use `ALTER TABLE … INMEMORY` to populate a column of JSON data, or a table with such a column, into the In-Memory Column Store (IM column store), to improve the performance of JSON queries.

- [JSON Search Index for Ad Hoc Queries and Full-Text Search](#)
  A JSON search index is a *general* index. It can improve the performance of both (1) ad hoc structural queries, that is, queries that you might not anticipate or use regularly, and (2) full-text search. It is an Oracle Text index that is designed specifically for use with JSON data.

22.2 JSON Facet Search with PL/SQL Procedure CTX_QUERY.RESULT_SET

If you have created a JSON search index then you can also use PL/SQL procedure `CTX_QUERY.result_set` to perform *facet* search over JSON data. This search is optimized to produce various kinds of search hits all at once, rather than, for example, using multiple separate queries with SQL function `contains`.

To search using procedure `CTX_QUERY.result_set` you pass it a **result set descriptor** (RSD), which specifies (as a JSON object with predefined operator fields `$query`, `$search`, and `$facet`) the JSON values you want to find from your indexed JSON data, and how you want them grouped or aggregated. The values you can retrieve and act on are either JSON scalars or JSON arrays of scalars.

(Operator-field `$query` is also used in SODA query-by-example (QBE) queries. You can use operator `$contains` in the value of field `$query` for full-text matching similar to that provided by Oracle SQL condition `json_textcontains`.)

The RSD fields serve as an ordered template, specifying what to include in the output result set. (In addition to the found JSON data, a result set typically includes a list of search-hit rowids and some counts.)

A `$facet` field value is a JSON array of facet objects, each of which defines JSON data located at a particular path and perhaps satisfying some conditions, and perhaps an aggregation operation to apply to that data.

You can aggregate facet data using operators `$count, $min, $max, $avg,` and `$sum.` For example, `$sum` returns the sum of the targeted data values. You can apply an aggregation operator to *all* scalar values targeted by a path, or you can apply it separately to **buckets** of such values, defined by different ranges of values.

Finally, you can obtain the counts of occurrences of distinct values at a given path, using operator `$uniqueCount`.

For example, consider this `$facet` value:

```
[ {"$uniqueCount" : "zebra.name"},
  {"$sum"         : {"path"  : "zebra.price",
                     "bucket : [{"$lt"  : 3000},
                               {"$gte" : 3000}]},
  {"$avg"         : "zebra.rating"} ]
```

When query results are returned, the value of field `$facet` in the output is an array of three objects, with these fields:

- `zebra.name` — The number of occurrences of each zebra name.

- `zebra.price` — The sum of zebra prices, in two buckets: prices less than 3000 and prices at least 3000.

- `zebra.rating` — The average of all zebra ratings. (Zebras with no rating are ignored.)

```
[ {"zebra.name"   : [ {"value":"Zigs",
                        "$uniqueCount:2},
                      {"value":"Zigzag",
                        "$uniqueCount:1},
                      {"value":"Storm",
                        "$uniqueCount:1} ]},
  {"zebra.price"  : [ {"value":1000,
                        "$uniqueCount:2},
                      {"value":3000,
                        "$uniqueCount:2},
                      {"value":2000,
                        "$uniqueCount:1} ]},
  {"zebra.rating" : {"$avg":4.66666666666666666667}} ]
```

JSON Data Guide

A JSON data guide lets you discover information about the structure and content of JSON documents stored in Oracle Database.

Some ways that you can use this information include:

- Generating a JSON Schema document that describes the set of JSON documents.

- Creating views that you can use to perform SQL operations on the data in the documents.

- Automatically adding or updating virtual columns that correspond to added or changed fields in the documents.

- Overview of JSON Data Guide
  A data guide is a summary of the structural and type information contained in a set of JSON documents. It records metadata about the fields used in those documents.

- Persistent Data-Guide Information as Part of a JSON Search Index
  JSON data-guide information can be saved persistently as part of the JSON search index infrastructure. This information is then updated automatically as new JSON content is added. You specify this optional behavior when you create a JSON search index.

- Data-Guide Formats and Ways of Creating a Data Guide
  There are two formats for a data guide: flat and hierarchical. Both are made available to SQL and PL/SQL as `CLOB` data. You can construct a data guide from the data-guide information stored in a JSON search index or by scanning JSON documents.

- JSON Data-Guide Fields
  The predefined fields of a JSON data guide are described. They include JSON Schema fields (keywords) and Oracle-specific fields.

- Data-Dictionary Views For Persistent Data-Guide Information
  You can query static data-dictionary views to see which tables have JSON columns with data guide-enabled JSON search indexes and to extract JSON object field information that is recorded in dataguide-enabled JSON search indexes.

- Specifying a Preferred Name for a Field Column
  You can project JSON fields from your data as non-JSON columns in a database view or as non-JSON virtual columns added to the same table that contains the JSON column. You can specify a preferred name for such a column.

- Creating a View Over JSON Data Based on Data-Guide Information
  Based on data-guide information, you can create a database view whose columns project particular scalar fields from a set of JSON documents. You can choose the fields to project by editing a hierarchical data guide or by specifying a SQL/JSON path expression and possibly a minimum frequency of field occurrence.

- Adding and Dropping Virtual Columns For JSON Fields Based on Data-Guide Information
  Based on data-guide information for a JSON column, you can project scalar fields from that JSON data as virtual columns in the same table. The scalar fields projected are those that are not under an array.

- Change Triggers For Data Guide-Enabled Search Index
  When JSON data changes, some information in a data guide-enabled JSON
  search index is automatically updated. You can specify a procedure whose
  invocation is triggered whenever this happens. You can define your own PL/SQL
  procedure for this, or you can use the predefined change-trigger procedure
  `add_vc`.

- Multiple Data Guides Per Document Set
  A data guide reflects the shape of a given set of JSON documents. If a JSON
  column contains different types of documents, with different structure or type
  information, you can create and use different data guides for the different kinds of
  documents.

- Querying a Data Guide
  A data guide is information about a set of JSON documents. You can query it from
  a flat data guide that you obtain using either Oracle SQL function `json_dataguide`
  or PL/SQL function `DBMS_JSON.get_index_dataguide`. In the latter case, a data
  guide-enabled JSON search index must be defined on the JSON data.

- A Flat Data Guide For Purchase-Order Documents
  The fields of a sample flat data guide are described. It corresponds to a set of
  purchase-order documents.

- A Hierarchical Data Guide For Purchase-Order Documents
  The fields of a sample hierarchical data guide are described. It corresponds to a
  set of purchase-order documents.

>
> JSON Schema

23.1 Overview of JSON Data Guide

A data guide is a summary of the structural and type information contained in a set of
JSON documents. It records metadata about the fields used in those documents.

For example, for the JSON object presented in Example 1-1, a data guide specifies
that the document has, among other things, an object `ShippingInstructions` with
fields `name`, `Address`, and `Phone`, of types string, object, and array, respectively. The
structure of object `Address` is recorded similarly, as are the types of the elements in
array `Phone`.

JSON data-guide information can be saved persistently as part of a JSON search
index infrastructure. This information is then updated automatically as new JSON
content is added. You specify this optional data-guide support when you create a
JSON search index.

You can use a data guide:

- As a basis for developing applications that involve data mining, business
  intelligence, or other analysis of JSON documents.

- As a basis for providing user assistance about requested JSON information,
  including search.

- To check or manipulate new JSON documents before adding them to a document set (for example: validate, type-check, or exclude certain fields).

For such purposes you can:

- Query a data guide directly for information about the document set, such as field lengths or which fields occur with at least a certain frequency.

- Create views, or add virtual columns, that project particular JSON fields of interest, based on their significance according to a data guide.

> **Note:**
>
> In general, a data guide serves as a guide to the structure of an existing set of JSON documents. To *validate* JSON data, use a JSON schema, not a data guide.

> **Note:**
>
> - The advantages of virtual columns over a view are that you can build an index on a virtual column and you can obtain statistics on it for the optimizer.
>
> - The number of virtual columns per table is limited by the value of initialization parameter `MAX_COLUMNS`. By default that value is `STANDARD`, which means 1000 columns maximum. See MAX_COLUMNS in *Oracle Database Reference*.

The following data-guide capabilities apply:

> **Note:**
>
> - Path length: 4000 bytes. A path longer than 4000 bytes is *ignored* by a data guide.
>
> - Number of children under a parent node: 5000. A node that has more than 5000 children is *ignored* by a data guide.
>
> - Field value length: 32767 bytes. If a JSON field has a value longer than 32767 bytes then the data guide reports the length as 32767.
>
> - Data-guide behavior is undefined for data that contains zero-length (empty) object field name (`""`).

Related Topics

- JSON Data-Guide Fields
  The predefined fields of a JSON data guide are described. They include JSON Schema fields (keywords) and Oracle-specific fields.

- JSON Search Index for Ad Hoc Queries and Full-Text Search
  A JSON search index is a *general* index. It can improve the performance of both (1) ad hoc structural queries, that is, queries that you might not anticipate or use regularly, and

(2) full-text search. It is an Oracle Text index that is designed specifically for use with JSON data.

- Querying a Data Guide
  A data guide is information about a set of JSON documents. You can query it from a flat data guide that you obtain using either Oracle SQL function `json_dataguide` or PL/SQL function `DBMS_JSON.get_index_dataguide`. In the latter case, a data guide-enabled JSON search index must be defined on the JSON data.

- Creating a View Over JSON Data Based on a Hierarchical Data Guide
  You can use a hierarchical data guide to create a database view whose columns project specified JSON fields from your documents. The fields projected are those in the data guide. You can edit the data guide to include only the fields that you want to project.

- Adding and Dropping Virtual Columns For JSON Fields Based on Data-Guide Information
  Based on data-guide information for a JSON column, you can project scalar fields from that JSON data as virtual columns in the same table. The scalar fields projected are those that are not under an array.

23.2 Persistent Data-Guide Information as Part of a JSON Search Index

JSON data-guide information can be saved persistently as part of the JSON search index infrastructure. This information is then updated automatically as new JSON content is added. You specify this optional behavior when you create a JSON search index.

You can use `CREATE SEARCH INDEX` with keywords `FOR JSON` to create a search index, a data guide, or both at the same time. The default behavior is to create a search index without data-guide support.

To create persistent data-guide information as part of a JSON search index you specify **DATAGUIDE** as **ON** in the `PARAMETERS` clause for `CREATE SEARCH INDEX`. You can enable data-guide support *without enabling support for search*, by also specifying **SEARCH_ON NONE**. Example 23-1 illustrates this.

You can use `ALTER INDEX ... REBUILD` to enable or disable data-guide support for an *existing* JSON search index. Example 23-2 illustrates this — it enables data-guide support for the search index of Example 29-24.

> **Note:**
>
> To create a data guide-enabled JSON search index, or to data guide-enable an existing JSON search index, you need database privilege `CTXAPP` and Oracle Database Release 12c (12.2.0.1) or later.

> **Note:**
>
> A data guide-enabled JSON search index can be built only on a column that is known to contain JSON data, which means that it is either of `JSON` data type or it has an `is json` check constraint. In the latter case, for the data-guide information in the index to be updated, the check constraint must be enabled.
>
> If the check constraint becomes disabled for some reason then you must *rebuild the data-guide information* in the index and *re-enable the check constraint*, to resume automatic data-guide support updating, as follows:
>
> ```
> ALTER INDEX index_name REBUILD ('dataguide off');
> ALTER INDEX index_name REBUILD ('dataguide on');
> ALTER TABLE table_name ENABLE CONSTRAINT
> is_json_check_constraint_name;
> ```
>
> In particular, using SQL*Loader (`sqlldr`) disables `is json` check constraints.

When you enable persistent data-guide information it is part of the search index infrastructure, so it is always *live*: its content is automatically updated whenever the index is synchronized. Changes in the indexed data are reflected in the search index, including in its data-guide information, only after the index is synchronized.

In addition, update of data-guide information in a search index is always *additive*: none of it is ever deleted. This is another reason that the index often does not accurately reflect the data in its document set: deletions within the documents it applies to are *not* reflected in its data-guide information. If you need to ensure that such information accurately reflects the current data then you must drop the JSON search index and create it anew.

The persistent data-guide information in a search index can also include *statistics*, such as how frequently each JSON field is used in the document set. Statistics are present only if you explicitly gather them on the document set (gather them on the JSON search index, for example). They are not updated automatically — gather statistics anew if you want to be sure they are up to date. Example 23-3 gathers statistics on the JSON data indexed by JSON search index `po_search_idx`, which is created in Example 29-24.

> **Note:**
>
> When a local data guide-enabled JSON search index is created in a *sharding* environment, each individual shard contains the data-guide information for the JSON documents stored in that shard. For this reason, if you invoke data guide-related operations on the shard *catalog* database then they will have no effect.

Considerations for a Data Guide-Enabled Search Index on a Partitioned Table

The data-guide information in a data guide-enabled JSON search index that is local to a partitioned table is not partitioned. It is shared among all partitions.

Because the data-guide information in the index is only additive, dropping, merging, splitting, or truncating partitions has no impact on the index.

Exchanging a partitioned table with a table that is not partitioned updates the data-guide information in an index on the partitioned table, but any data guide-enabled index on the non-partitioned table must be rebuilt.

Avoid Persistent Data-Guide Information If Serializing Hash-Table Data

If you serialize Java hash tables or associative arrays (such as are found in JavaScript) as JSON objects, then avoid the use of persistent data-guide information.

The default hash-table serialization provided by popular libraries such as GSON and Jackson produces textual JSON documents with object field names that are taken from the hash-table key entries and with field values taken from the corresponding Java hash-table values. Serializing a single Java hash-table entry produces a new (unique) JSON field and value.

Persisted data-guide information reflects the shape of your data, and it is updated automatically as new JSON documents are inserted. Each hash-table key–value pair results in a separate entry in the JSON search index. Such serialization can thus greatly increase the size of the information maintained in the index. In addition to the large size, the many index updates affect performance negatively, making DML slow.

If you serialize a hash table or an associative array instead as a JSON array of objects, each of which includes a field derived from a hash-table key entry, then there are no such problems.

The default serialization of a hash table or associative array as a JSON object is indistinguishable from an object that has field names assigned by a developer. A JSON data guide cannot tell which (metadata-like) field names have been assigned by a developer and which (data-like) names might have been derived from a hash table or associative array. It treats all field names as essentially metadata, as if specified by a developer.

For example:

- If you construct an application object using a hash table that has `animalName` as the hash key and sets of animal properties as values then the resulting default serialization is a single JSON object that has a *separate field* (`"cat"`, `"mouse"`,...) for each hash-table entry, with the field value being an object with the corresponding animal properties. This can be problematic in terms of data-guide size and performance because of the typically large number of fields (`"cat"`, `"mouse"`,...) derived from the hash key.

- If you instead construct an application array of `animal` structures, each of which has a field `animalName` (with value `"cat"` or `"mouse"`...) then the resulting serialization is a JSON array of objects, each of which has the same field, `animalName`. The corresponding data guide has no size or performance problem.

Example 23-1   Enabling Persistent Support for a JSON Data Guide But Not For Search

```
CREATE SEARCH INDEX po_dg_only_idx
  ON j_purchaseorder (po_document) FOR JSON
    PARAMETERS ('DATAGUIDE ON SEARCH_ON NONE');
```

Example 23-2   Enabling JSON Data-Guide Support For an Existing JSON Search Index

```
ALTER INDEX po_search_idx REBUILD PARAMETERS ('DATAGUIDE ON');
```

Example 23-3   Gathering Statistics on JSON Data Using a JSON Search Index

```
EXEC DBMS_STATS.gather_index_stats(docuser, po_search_idx, NULL, 100);
```

23.3 Data-Guide Formats and Ways of Creating a Data Guide

There are two formats for a data guide: flat and hierarchical. Both are made available to SQL and PL/SQL as `CLOB` data. You can construct a data guide from the data-guide information stored in a JSON search index or by scanning JSON documents.

- You can use a *flat* data guide to *query* data-guide information such as field frequencies and types.

  A flat data guide is represented in JSON as an *array* of objects, each of which represents the JSON data of a specific *path* in the document set. A Flat Data Guide For Purchase-Order Documents describes a flat data guide for the purchase-order data of Example 1-1.

- You can use a *hierarchical* data guide to create a view, or to add virtual columns, using particular fields that you choose on the basis of data-guide information.

A hierarchical data guide is represented in JSON as an *object* with nested JSON data, in the same format as that defined by JSON Schema. A Hierarchical Data Guide For Purchase-Order Documents describes a hierarchical data guide for the purchase-order data of Example 1-1.

You use PL/SQL function DBMS_JSON.**get_index_dataguide** to obtain a data guide from the data-guide information stored in a JSON search index.

You can also use SQL aggregate function **json_dataguide** to scan your document set and construct a data guide for it, whether or not it has a data guide-enabled search index. The data guide accurately reflects the document set at the moment of function invocation.

A data guide can include statistical fields, such as how frequently each JSON field is used in the document set.

- If you use SQL function json_dataguide then statistical fields are present only if specify DBMS_JSON.gather_stats in the third argument. They are computed dynamically (up-to-date) at the time of the function call.

- If you use PL/SQL function DBMS_JSON.get_index_dataguide then statistical fields are present only if you have gathered them on the JSON search index. They are *not* updated automatically — gather them anew if you want to be sure they are up to date.

Table 23-1   SQL and PL/SQL Functions to Obtain a Data Guide

Uses Data Guide-Enabled Search Index?	Flat Data Guide	Hierarchical Data Guide
Yes	PL/SQL function **get_index_dataguide** with format DBMS_JSON.**FORMAT_FLAT**	PL/SQL function **get_index_dataguide** with format DBMS_JSON.**FORMAT_HIERARCHICAL**
No	SQL function **json_dataguide**, with no format argument or with **DBMS_JSON.FORMAT_FLAT** as the format argument	SQL function **json_dataguide**, with **DBMS_JSON.FORMAT_HIERARCHICAL** as the format argument

Advantages of obtaining a data guide based on a data guide-enabled JSON search index include:

- Additive updates to the document set are automatically reflected in the persisted data-guide information whenever the index is synced.

- Because this data-guide information is persisted, obtaining a data guide based on it (using PL/SQL function get_index_dataguide) is typically faster than obtaining a data guide by analyzing the document set (using SQL function json_dataguide).

Advantages of obtaining a data guide without using a data guide-enabled JSON search index include assurance that the data guide is accurate and the lack of index maintenance overhead. In addition, a data guide that is not derived from an index is appropriate in some particular use cases:

- The JSON data is in an external table. You cannot create an index on it.

- The JSON column could be indexed, but the index would not be very useful. This can be the case, for example, if the column contains different kinds of documents. In this case, it can sometimes be helpful to add a column to the table that identifies the kind of document stored in the JSON column. You can then use the data guide with SQL aggregate functions and `GROUP BY`. See Multiple Data Guides Per Document Set.

23.4 JSON Data-Guide Fields

The predefined fields of a JSON data guide are described. They include JSON Schema fields (keywords) and Oracle-specific fields.

A given occurrence of a field in a data guide corresponds to a field that is present in one or more JSON documents of the document set.

JSON Schema Data-Guide Fields (Keywords)

A JSON Schema is a JSON document that contains a JSON object, which can itself contain child objects (subschemas). Fields that are defined by JSON Schema are called JSON Schema **keywords**. Table 23-2 describes the keywords that can be used in an Oracle JSON data guide. Keywords `properties`, `items`, and `oneOf` are used only in a hierarchical JSON data guide (which is a JSON schema). Keyword `type` is used in both flat and hierarchical data guides.

Table 23-2   JSON Schema Data-Guide Fields (Keywords)

Field (Keyword)	Value Description
`properties`	An object whose members represent the properties of a JSON object used in JSON data that is represented by the hierarchical data guide (JSON schema).
`items`	An object whose members represent the elements (items) of an array used in JSON data represented by the hierarchical data guide (JSON schema).
`oneOf`	An array, each of whose items represents one or more occurrences of a JSON field in the JSON data represented by the hierarchical data guide (JSON schema).
`type`	A string naming the type of some JSON data represented by the (flat or hierarchical) data guide.
	The possible values are: `"number"`, `"string"`, `"boolean"`, `"null"`, `"object"`, `"array"`, `"GeoJSON"`, and, for `JSON` type data, `"double"`, `"float"`, `"binary"`, `"date"`, `"timestamp"`, `"yearmonthInterval"`, and `"daysecondInterval"`.
	If option `DBMS_JSON.DETECT_DATETIME` is passed as a flag parameter to function `json_dataguide`, then any string field value in your data that conforms to an Oracle-supported ISO date or time format is recorded as having `type` `"timestamp"`, not `"string"`.

Oracle-Specific Data-Guide Fields

In addition to JSON Schema keywords, a JSON data guide can contain Oracle data guide-specific fields. The field names all have the prefix **o:**. They are described in Table 23-3.

Table 23-3   Oracle-Specific Data-Guide Fields

Field	Value Description
`o:path`	Path through the JSON documents to the JSON field. Used only in a *flat* data guide. The value is a simple SQL/JSON path expression (no filter expression), possibly with relaxation (implicit array wrapping and unwrapping), and possibly with a wildcard array step. It has no array steps with array indexes or range specifications, and it has no function step. See SQL/JSON Path Expression Syntax.
`o:length`	Maximum length of the JSON field value, in bytes. The value is always a power of two. For example, if the maximum length of all actual field values is 5 then the value of `o:length` is 8, the smallest power of two greater than or equal to 5.
`o:preferred_column_name`	An identifier, case-sensitive and unique to a given data guide, that you prefer as the name to use for a view column or a virtual column that is created using the data guide.
	This field is absent if the data guide was obtained using SQL function `json_dataguide` with format parameter `DBMS_JSON.FORMAT_FLAT` or without any format parameter (`DBMS_JSON.FORMAT_FLAT` is the default).

Table 23-3   (Cont.) Oracle-Specific Data-Guide Fields

Field	Value Description
`o:frequency`	Percentage of JSON documents that contain the given field. Duplicate occurrences of a field under the same array are ignored. (Available only if statistics were gathered on the document set.)
	This field is absent if the data guide was obtained using SQL function `json_dataguide`, unless the third parameter specified `DBMS_JSON.gather_stats`.
	If the data guide was created using PL/SQL function `get_index_dataguide` then all documents in the document set are taken into account. Otherwise, only the documents targeted by the `json_dataguide` query are considered.
`o:num_nulls`	Number of documents whose value for the targeted scalar field is JSON `null`. (Available only if statistics were gathered on the document set.)
	This field is absent if the data guide was obtained using SQL function `json_dataguide`, unless the third parameter specified `DBMS_JSON.gather_stats`.
	If the data guide was created using PL/SQL function `get_index_dataguide` then all documents in the document set are taken into account. Otherwise, only the documents targeted by the `json_dataguide` query are considered.
`o:high_value`	Highest value for the targeted scalar field, among all documents examined. (Available only if statistics were gathered on the document set.)
	This field is absent if the data guide was obtained using SQL function `json_dataguide`, unless the third parameter specified `DBMS_JSON.gather_stats`.
	If the data guide was created using PL/SQL function `get_index_dataguide` then all documents in the document set are taken into account. Otherwise, only the documents targeted by the `json_dataguide` query are considered.
`o:low_value`	Lowest value for the targeted scalar field, among all documents examined. (Available only if statistics were gathered on the document set.)
	This field is absent if the data guide was obtained using SQL function `json_dataguide`, unless the third parameter specified `DBMS_JSON.gather_stats`.
	If the data guide was created using PL/SQL function `get_index_dataguide` then all documents in the document set are taken into account. Otherwise, only the documents targeted by the `json_dataguide` query are considered.

Table 23-3   (Cont.) Oracle-Specific Data-Guide Fields

Field	Value Description
`o:last_analyzed`	Date and time when statistics were last gathered on the document set. (Available only if statistics were gathered on the document set.)
	This field is absent if the data guide was obtained using SQL function `json_dataguide`, unless the third parameter specified `DBMS_JSON.gather_stats`.
	If the data guide was created using PL/SQL function `get_index_dataguide` then all documents in the document set are taken into account. Otherwise, only the documents targeted by the `json_dataguide` query are considered.
`o:sample_size`	Total number of JSON documents selected by a query that uses SQL function `json_dataguide` with its the third parameter specifying `DBMS_JSON.gather_stats`. You can use a `SAMPLE` clause in the query to further control the sample size.
	This field is absent if the data guide was obtained in some other way.

The data-guide information for documents that contain a JSON array with *only scalar* elements records the path and type for both (1) the array and (2) all of the array elements *taken together*. For the *elements*:

- The `o:path` value is the `o:path` value for the array, followed by an array with a wildcard (`[*]`), which indicates all array elements.

- The `type` value is the type `string`, if the scalar types are *not the same* for all elements in all documents. If *all* of the scalar elements the array have the *same* type, across *all* documents, then that type is recorded.

For example, if, in *all* documents, *all* of the elements in the array value for object field `serial_numbers` are JSON numbers, then `type` for the array elements is `number`. Otherwise it is `string`.

When present, the default value of field `o:preferred_column_name` depends on whether the data guide was obtained using SQL function `json_dataguide` (with format `DBMS_JSON.FORMAT_HIERARCHICAL`) or using PL/SQL function `DBMS_JSON.get_index_dataguide`:

- `get_index_dataguide` — Same as the corresponding JSON field name, prefixed with the JSON column name followed by **$**, and with any non-ASCII characters removed. If the resulting field name already exists in the same data guide then it is suffixed with a new sequence number, to make it unique.

  The JSON column-name part is uppercase unless that column was defined using escaped lowercase letters (for example, `'PO_Column'` instead of `po_column`).

  For example, the default value for field `User` for data in JSON column `po_document` is **PO_DOCUMENT$**`User`.

- `json_dataguide` (hierarchical format) — Same as the corresponding JSON field name.

You can, however, control column naming when you create a view or a virtual column based on the data guide, by specifying the following parameters to `DBMS_JSON` procedures `create_view`, `get_view_sql`, and `add_virtual_columns`:

- **colNamePrefix** => *prefix* — Prefix the column names specified by `o:preferred_column_name` with *prefix*.

- **mixedCaseColumns** => `FALSE` — Make column names be case-insensitive. (They are case-sensitive by default.)

- **resolveNameConflicts** => `TRUE` (default) — Resolve any name conflicts: if the resulting field name already exists in the same data guide then it is suffixed with a new sequence number, to make it unique (same behavior that `get_index_dataguide` provides).

You can use PL/SQL procedure `DBMS_JSON.rename_column` to set the value of `o:preferred_column_name` for a given field and type. This procedure has no effect if data-guide information is not persisted as part of a JSON search index.

Field `o:preferred_column_name` is used to name a new, virtual column in the table that contains the JSON column, or it is used to name a column in a new view that also contains the other columns of the table. In either case, a name specified by field `o:preferred_column_name` must be *unique* with respect to the other column names of the table. In addition, the name must be *unique* across all JSON fields of any type in the document set. When you use `DBMS_JSON.get_index_dataguide`, the default name is *guaranteed* to be unique in these ways.

If the name you specify with `DBMS_JSON.rename_column` causes a name conflict then the specified name is ignored and a system-generated name is used instead.

23.5 Data-Dictionary Views For Persistent Data-Guide Information

You can query static data-dictionary views to see which tables have JSON columns with data guide-enabled JSON search indexes and to extract JSON object field information that is recorded in dataguide-enabled JSON search indexes.

Tables that do not have JSON columns with data guide-enabled indexes are not present in the views.

You can use the following views to *find columns* that have data guide-enabled JSON search indexes. The views have columns `TABLE_NAME` (the table name), `COLUMN_NAME` (the JSON column name), and `DATAGUIDE` (a data guide).

- `USER_JSON_`**`DATAGUIDES`** — tables owned by the current user
- `ALL_JSON_`**`DATAGUIDES`** — tables accessible by the current user
- `DBA_JSON_`**`DATAGUIDES`** — all tables

If the JSON column has a data guide-enabled JSON search index then the value of column `DATAGUIDE` is the data guide for the JSON column, in flat format as a `CLOB` instance. If it does not have a data guide-enabled index then there is no row for that column in the view.

You can use the following views to extract JSON field path and type information that is recorded in dataguide-enabled JSON search indexes. The views have columns `TABLE_NAME`, `COLUMN_NAME`, `PATH`, `TYPE`, and `LENGTH`. Columns `PATH`, `TYPE`, and `LENGTH` correspond to the values of data-guide fields `o:path`, `o:type`, and `o:length`, respectively.

- `USER_JSON_DATAGUIDE_`**`FIELDS`** — tables owned by the current user
- `ALL_JSON_DATAGUIDE_`**`FIELDS`** — tables accessible by the current user
- `DBA_JSON_DATAGUIDE_`**`FIELDS`** — all tables

In the case of both types of view, a view whose name has the prefix `ALL_` or `DBA_` also has column `OWNER`, whose value is the table owner.

> - *Oracle Database Reference* for information about `ALL_JSON_DATAGUIDE_FIELDS` and the related data-dictionary views

23.6 Specifying a Preferred Name for a Field Column

You can project JSON fields from your data as non-JSON columns in a database view or as non-JSON virtual columns added to the same table that contains the JSON column. You can specify a preferred name for such a column.

The document fields are projected as columns when you use procedure `DBMS_JSON.create_view`, `DBMS_JSON.create_view_on_path`, or `DBMS_JSON.add_virtual_columns`.

A data guide obtained from your JSON document set is used to define this projection. The name of each projected column is taken from data-guide field `o:preferred_column_name` for the JSON data field to be projected.

If your JSON data has a data guide-enabled search index then you can use procedure `DBMS_JSON.rename_column` to set the value of `o:preferred_column_name` for a given document field and type. Example 23-4 illustrates this. It specifies preferred names for the columns to be projected from various fields, as described in Table 23-4.

A hierarchical data guide is populated with field `o:preferred_column_name`. When you use procedure `DBMS_JSON.create_view` or `DBMS_JSON.add_virtual_columns`, you can pass parameters that further control the naming of projected columns:

- `colNamePrefix => prefix` — Prefix the names specified by `o:preferred_column_name` with *prefix*.
- `mixedCaseColumns => FALSE` — Make column names be case-insensitive. (They are case-sensitive by default.)
- `resolveNameConflicts => TRUE` (default) — Resolve any name conflicts.

Table 23-4   Preferred Names for Some JSON Field Columns

Field	JSON Type	Preferred Column Name
`PONumber`	`number`	**`PONumber`**
`Phone` (phone as string, not object – just the number)	`string`	**`Phone`**
`type` (phone type)	`string`	**`PhoneType`**
`number` (phone number)	`string`	**`PhoneNumber`**
`ItemNumber` (line-item number)	`number`	**`ItemNumber`**

Table 23-4   (Cont.) Preferred Names for Some JSON Field Columns

Field	JSON Type	Preferred Column Name
Description (part description)	string	**PartDescription**

Example 23-4   Specifying Preferred Column Names For Some JSON Fields

```
BEGIN
  DBMS_JSON.rename_column(
    'J_PURCHASEORDER', 'PO_DOCUMENT',
    '$.PONumber',
    DBMS_JSON.TYPE_NUMBER, 'PONumber');
  DBMS_JSON.rename_column(
    'J_PURCHASEORDER', 'PO_DOCUMENT',
    '$.ShippingInstructions.Phone',
    DBMS_JSON.TYPE_STRING, 'Phone');
  DBMS_JSON.rename_column(
    'J_PURCHASEORDER', 'PO_DOCUMENT',
    '$.ShippingInstructions.Phone.type',
    DBMS_JSON.TYPE_STRING, 'PhoneType');
  DBMS_JSON.rename_column(
    'J_PURCHASEORDER', 'PO_DOCUMENT',
    '$.ShippingInstructions.Phone.number',
    DBMS_JSON.TYPE_STRING, 'PhoneNumber');
  DBMS_JSON.rename_column(
    'J_PURCHASEORDER', 'PO_DOCUMENT',
    '$.LineItems.ItemNumber',
    DBMS_JSON.TYPE_NUMBER, 'ItemNumber');
  DBMS_JSON.rename_column(
    'J_PURCHASEORDER', 'PO_DOCUMENT',
```

```
        '$.LineItems.Part.Description',
        DBMS_JSON.TYPE_STRING, 'PartDescription');
END;
/
```

23.7 Creating a View Over JSON Data Based on Data-Guide Information

Based on data-guide information, you can create a database view whose columns project particular scalar fields from a set of JSON documents. You can choose the fields to project by editing a hierarchical data guide or by specifying a SQL/JSON path expression and possibly a minimum frequency of field occurrence.

You can create multiple views based on the same JSON document set, projecting different fields. See Multiple Data Guides Per Document Set.

You can create a view by projecting JSON fields using SQL/JSON function `json_table` — see Creating a View Over JSON Data Using JSON_TABLE.

An alternative is to use PL/SQL procedure `DBMS_JSON.create_view` or `DBMS_JSON.create_view_on_path`, to create a view by projecting fields that you choose based on available data-guide information.

The data-guide information can come from either:

- A hierarchical data guide that includes the fields to project, and possibly a SQL/JSON path expression.

- A data guide-enabled JSON search index, together with a SQL/JSON path expression, and possibly a minimum field frequency.

In the former case, use procedure **create_view**. You can edit a (hierarchical) data guide to specify fields that you want included. In this case you do *not* need a data guide-enabled search index.

In the latter case, use procedure **create_view_on_path**. In this case you need a data guide-enabled search index, but you do *not* need a data guide.

In either case, you can provide a SQL/JSON path expression, to specify a field to be expanded for the view. This is required for procedure `create_view_on_path`. To specify a path for procedure `create_view`, use optional parameter *PATH*. The path $ creates a view starting from the JSON document root.

For procedure `create_view_on_path`, you can also provide a minimum frequency of occurrence, using optional parameter *FREQUENCY*. The resulting view includes only JSON fields along the path whose frequency is greater than the specified frequency.

When you specify a path, all descendant fields under it are expanded. A view column is created for each *scalar* value in the resulting sub-tree. The fields in the document set that are projected include both:

- All scalar fields present, at any level, in the data that is targeted by the path expression.

- All scalar fields, anywhere in the document, that are not under an array.

The path argument you provide must be a *simple* SQL/JSON path expression (no filter expression), possibly with relaxation (implicit array wrapping and unwrapping), but with no array steps and no function step. See SQL/JSON Path Expression Syntax.

Regardless of whether you use procedure `create_view` or `create_view_on_path`, in addition to the JSON fields that are projected as columns, all *non*-JSON columns of the table are also columns of the view.

The data guide that serves as the basis for a given view definition is static and does not necessarily faithfully continue to reflect the current data in the document set. The fields that are projected for the view are determined when the view is created.

In particular, if you use `create_view_on_path` (which requires a data guide-enabled search index) then what counts are the fields specified by the given path expression and that have at least the given frequency (default 0), based on the *index data at the time of the view creation*.

There is also PL/SQL function `DBMS_JSON.get_view_sql`, which does not create a view, but instead returns the SQL DDL code that would create a view. You can, for example, edit that DDL to create different views. You can also optionally obtain only the SQL `SELECT` statement that the view-creation DDL would use. In this case, if more than columns would be needed for the view than the maximum number allowed, then the `SELECT` statement would involve joins of multiple `json_table` expressions. (The maximum number of columns allowed in a table (default: 1000) is defined by initialization parameter `MAX_COLUMNS`. See MAX_COLUMNS in *Oracle Database Reference*.)

- Creating a View Over JSON Data Based on a Hierarchical Data Guide
  You can use a hierarchical data guide to create a database view whose columns project specified JSON fields from your documents. The fields projected are those in the data guide. You can edit the data guide to include only the fields that you want to project.

- Creating a View Over JSON Data Based on a Path Expression
  You can use the information in a data guide-enabled JSON search index to create a database view whose columns project JSON fields from your documents. The fields projected are the scalar fields not under an array plus the scalar fields in the data targeted by a specified SQL/JSON path expression.

23.7.1 Creating a View Over JSON Data Based on a Hierarchical Data Guide

You can use a hierarchical data guide to create a database view whose columns project specified JSON fields from your documents. The fields projected are those in the data guide. You can edit the data guide to include only the fields that you want to project.

You can obtain a hierarchical data guide using SQL function `json_dataguide` with argument `DBMS_JSON.FORMAT_HIERARCHICAL`.

You can edit the data guide obtained to include only specific fields, change the length of given types, or rename fields. The resulting data guide specifies which fields of the JSON data to project as columns of the view.

You use PL/SQL procedure `DBMS_JSON.create_view` to create the view.

Example 23-5 illustrates this using a data guide obtained with `json_dataguide` with argument `DBMS_JSON.FORMAT_HIERARCHICAL`.

If you create a view using the data guide obtained with `json_dataguide` then GeoJSON data in your documents is supported. In this case the view column corresponding to the GeoJSON data has SQL data type `SDO_GEOMETRY`. For that you pass constant `DBMS_JSON.GEOJSON` or `DBMS_JSON.GEOJSON+DBMS_JSON.PRETTY` as the third argument to `json_dataguide`.

>
> - *Oracle Database PL/SQL Packages and Types Reference* for information about `DBMS_JSON.create_view`
>
> - *Oracle Database PL/SQL Packages and Types Reference* for information about `DBMS_JSON.get_index_dataguide`
>
> - *Oracle Database PL/SQL Packages and Types Reference* for information about `DBMS_JSON.rename_column`
>
> - *Oracle Database SQL Language Reference* for information about SQL function `json_dataguide`
>
> - *Oracle Database SQL Language Reference* for information about PL/SQL constant `DBMS_JSON.FORMAT_HIERARCHICAL`

Example 23-5   Creating a View Using a Hierarchical Data Guide Obtained With JSON_DATAGUIDE

This example creates a view that projects all of the fields present in the hierarchical data guide that is obtained by invoking SQL function `json_dataguide` on `po_document` of table `j_purchaseorder`. The second and third arguments passed to `json_dataguide` are used, respectively, to specify that the data guide is to be hierarchical and pretty-printed.

The view column names come from the values of field `o:preferred_column_name` of the data guide that you pass to `DBMS_JSON.create_view`. By default, the view columns are thus named the same as the projected fields.

Because the columns must be uniquely named in the view, *you must ensure* that the field names themselves are unique. Optional parameter `RESOLVENAMECONFLICTS` does this by default (value `true`), but if you specify it as `false` then the names are not guaranteed to be unique. In this case (`false`), an alternative is to edit the data guide returned by `json_dataguide` to make the value of `o:preferred_column_name` unique. If parameter `RESOLVENAMECONFLICTS` is `false`, then an error is raised by `DBMS_JSON.create_view` if the names for the columns are not unique.

Although this example does not do so, you can provide a column-name prefix using `DBMS_JSON.create_view` with parameter `colNamePrefix`. For example, to get the same effect as that provided when you use a data guide obtained from the information in a data guide-enabled JSON search index, you could specify parameter `colNamePrefix` as `'PO_DOCUMENT$'`, that is, the JSON column name, `PO_DOCUMENT` followed by `$`. See Example 23-8.

```
DECLARE
  dg CLOB;
  BEGIN
    SELECT json_dataguide(po_document,
                          FORMAT DBMS_JSON.FORMAT_HIERARCHICAL,
                          DBMS_JSON.PRETTY)
      INTO dg
      FROM j_purchaseorder
      WHERE extract(YEAR FROM date_loaded) = 2014;
    DBMS_JSON.create_view('MYVIEW',
                          'J_PURCHASEORDER',
                          'PO_DOCUMENT',
                          dg);
  END;
/

DESCRIBE myview

- JSON Data-Guide Fields

  The predefined fields of a JSON data guide are described. They include JSON Schema fields (keywords) and Oracle-specific fields.

23.7.2 Creating a View Over JSON Data Based on a Path Expression

You can use the information in a data guide-enabled JSON search index to create a database view whose columns project JSON fields from your documents. The fields projected are the scalar fields not under an array plus the scalar fields in the data targeted by a specified SQL/JSON path expression.

For example, if the path expression is `$` then all scalar fields are projected, because the root (top) of the document is targeted. Example 23-6 illustrates this. If the path is `$.LineItems.Part` then only the scalar fields that are present (at any level) in the data targeted by `$.LineItems.Part` are projected (in addition to scalar fields elsewhere that are not under an array). Example 23-7 illustrates this.

If you gather statistics on your JSON document set then the data-guide information in a data guide-enabled JSON search index records the frequency of occurrence, across the document set, of each path to a field that is present in a document. When you create the view, you can specify that only the (scalar) fields with a given minimum frequency of occurrence (as a percentage) are to be projected as view columns. You do this by specifying a non-zero value for parameter *FREQUENCY* of procedure `DBMS_JSON.create_view_on_path`.

For example, if you specify the path as `$` and the minimum frequency as `50` then all scalar fields (on any path, since `$` targets the whole document) that occur in at least half (50%) of the documents are projected. Example 23-8 illustrates this.

The value of argument *PATH* is a simple SQL/JSON path expression (no filter expression), possibly with relaxation (implicit array wrapping and unwrapping), but with no array steps and no function step. See SQL/JSON Path Expression Syntax.

No frequency filtering is done in *either* of the following cases — targeted fields are *projected regardless of their frequency* of occurrence in the documents:

- You never gather statistics information on your set of JSON documents. (No frequency information is included in the data guide-enabled JSON search index.)

- The *FREQUENCY* argument of `DBMS_JSON.create_view_on_path` is *zero* (0).

> **✎ Note:**
>
> When the *FREQUENCY* argument is non-zero, even if you have gathered
> statistics information on your document set, the index contains *no* statistical
> information for any documents added after the most recent gathering of
> statistics. This means that any *fields added after that statistics gathering are
> ignored* (not projected).

Example 23-6   Creating a View That Projects All Scalar Fields

All scalar fields are represented in the view, because the specified path is $.

(Columns whose names are *italic* in the describe command output are those that
have been renamed using PL/SQL procedure DBMS_JSON.rename_column. Underlined
rows are missing from Example 23-8.)

```
EXEC DBMS_JSON.create_view_on_path('VIEW2',
                                   'J_PURCHASEORDER',
                                   'PO_DOCUMENT',
                                   '$');

DESCRIBE view2;
 Name                            Null?    Type
 ------------------------------- -------- ------------------
 ID                              NOT NULL RAW(16)
 DATE_LOADED                              TIMESTAMP(6) WITH TIME ZONE
 PO_DOCUMENT$User                         VARCHAR2(8)
 PONumber                                 NUMBER
 PO_DOCUMENT$Reference                    VARCHAR2(16)
 PO_DOCUMENT$Requestor                    VARCHAR2(16)
 PO_DOCUMENT$CostCenter                   VARCHAR2(4)
 PO_DOCUMENT$AllowPartialShipment  VARCHAR2(4)
 PO_DOCUMENT$name                         VARCHAR2(16)
 Phone                                    VARCHAR2(16)
 PO_DOCUMENT$city                         VARCHAR2(32)
 PO_DOCUMENT$state                        VARCHAR2(2)
 PO_DOCUMENT$street                       VARCHAR2(32)
 PO_DOCUMENT$country                      VARCHAR2(32)
 PO_DOCUMENT$zipCode                      NUMBER
 PO_DOCUMENT$SpecialInstructions  VARCHAR2(8)
 PO_DOCUMENT$UPCCode                      NUMBER
 PO_DOCUMENT$UnitPrice                    NUMBER
```

```
PartDescription                    VARCHAR2(32)
PO_DOCUMENT$Quantity               NUMBER
ItemNumber                         NUMBER
PhoneType                          VARCHAR2(8)
PhoneNumber                        VARCHAR2(16)
```

Example 23-7   Creating a View That Projects Scalar Fields Targeted By a Path Expression

Fields `Itemnumber`, `PhoneType`, and `PhoneNumber` are *not* represented in the view. The only fields that are projected are those scalar fields that are not under an array plus those that are present (at any level) in the data that is targeted by `$.LineItems.Part` (that is, the scalar fields whose paths start with `$.LineItems.Part`). (Columns whose names are *italic* in the `describe` command output are those that have been renamed using PL/SQL procedure `DBMS_JSON.rename_column`.)

```
SQL> EXEC DBMS_JSON.create_view_on_path('VIEW4',
                                        'J_PURCHASEORDER',
                                        'PO_DOCUMENT',
                                        '$.LineItems.Part');

SQL> DESCRIBE view4;
 Name                             Null?    Type
 -------------------------------- -------- ------------------
 ID                               NOT NULL RAW(16)
 DATE_LOADED                      TIMESTAMP(6) WITH TIME ZONE
 PO_DOCUMENT$User                 VARCHAR2(8)
 PONumber                         NUMBER
 PO_DOCUMENT$Reference            VARCHAR2(16)
 PO_DOCUMENT$Requestor            VARCHAR2(16)
 PO_DOCUMENT$CostCenter           VARCHAR2(4)
 PO_DOCUMENT$AllowPartialShipment VARCHAR2(4)
 PO_DOCUMENT$name                 VARCHAR2(16)
 Phone                            VARCHAR2(16)
 PO_DOCUMENT$city                 VARCHAR2(32)
 PO_DOCUMENT$state                VARCHAR2(2)
 PO_DOCUMENT$street               VARCHAR2(32)
 PO_DOCUMENT$country              VARCHAR2(32)
 PO_DOCUMENT$zipCode              NUMBER
 PO_DOCUMENT$SpecialInstructions  VARCHAR2(8)
 PO_DOCUMENT$UPCCode              NUMBER
 PO_DOCUMENT$UnitPrice            NUMBER
 PartDescription                  VARCHAR2(32)
```

Example 23-8   Creating a View That Projects Scalar Fields Having a Given Frequency

All scalar fields that occur in all (100%) of the documents are represented in the view. Field `AllowPartialShipment` does not occur in all of the documents, so there is no column `PO_DOCUMENT$AllowPartialShipment` in the view. Similarly for fields `Phone`, `PhoneType`, and `PhoneNumber`.

(Columns whose names are *italic* in the `describe` command output are those that have been renamed using PL/SQL procedure `DBMS_JSON.rename_column`.)

```
SQL> EXEC DBMS_JSON.create_view_on_path('VIEW3',
                                         'J_PURCHASEORDER',
                                         'PO_DOCUMENT',
                                         '$',
                                         100);
```

```
SQL> DESCRIBE view3;
 Name                             Null?    Type
 -------------------------------- -------- -------------------
 ID                               NOT NULL RAW(16)
 DATE_LOADED                               TIMESTAMP(6) WITH TIME ZONE
 PO_DOCUMENT$User                          VARCHAR2(8)
 PONumber                                  NUMBER
 PO_DOCUMENT$Reference                     VARCHAR2(16)
 PO_DOCUMENT$Requestor                     VARCHAR2(16)
 PO_DOCUMENT$CostCenter                    VARCHAR2(4)
 PO_DOCUMENT$name                          VARCHAR2(16)
 PO_DOCUMENT$city                          VARCHAR2(32)
 PO_DOCUMENT$state                         VARCHAR2(2)
 PO_DOCUMENT$street                        VARCHAR2(32)
 PO_DOCUMENT$country                       VARCHAR2(32)
 PO_DOCUMENT$zipCode                       NUMBER
 PO_DOCUMENT$SpecialInstructions  VARCHAR2(8)
 PO_DOCUMENT$UPCCode                       NUMBER
 PO_DOCUMENT$UnitPrice                     NUMBER
 PartDescription                           VARCHAR2(32)
 PO_DOCUMENT$Quantity                      NUMBER
 ItemNumber                                NUMBER
```

Related Topics

- Specifying a Preferred Name for a Field Column
  You can project JSON fields from your data as non-JSON columns in a database view or as non-JSON virtual columns added to the same table that contains the JSON column. You can specify a preferred name for such a column.

- SQL/JSON Path Expressions
  Oracle Database provides SQL access to JSON data using SQL/JSON path expressions.

23.8 Adding and Dropping Virtual Columns For JSON Fields Based on Data-Guide Information

Based on data-guide information for a JSON column, you can project scalar fields from that JSON data as virtual columns in the same table. The scalar fields projected are those that are not under an array.

You can do all of the following with a virtual column, with the aim of improving performance:

- Build an index on it.

- Gather statistics on it for the optimizer.

- Load it into the In-Memory Column Store (IM column store).

> **Note:**
>
> The number of virtual columns per table is limited by the value of initialization parameter `MAX_COLUMNS`. By default that value is `STANDARD`, which means 1000 columns maximum. See MAX_COLUMNS in *Oracle Database Reference*.

You use PL/SQL procedure `DBMS_JSON.add_virtual_columns` to add virtual columns based on data-guide information for a JSON column. Before it adds virtual columns, procedure `add_virtual_columns` first drops any existing virtual columns that were projected from fields in the same JSON column by a previous invocation of `add_virtual_columns` or by data-guide change-trigger procedure `add_vc` (in effect, it does what procedure `DBMS_JSON.drop_virtual_columns` does).

There are two alternative sources of the data-guide information that you provide to procedure `add_virtual_columns`:

- It can come from a *hierarchical data guide* that you pass as an argument. All scalar fields in the data guide that are not under an array are projected as virtual columns. All other fields in the data guide are ignored (not projected).

  In this case, you can edit the data guide before passing it, so that it specifies the scalar fields (not under an array) that you want projected. You do *not* need a data guide-enabled search index in this case.

- It can come from a *data guide-enabled JSON search index*.

  In this case, you can specify, as the value of argument *FREQUENCY* to procedure `add_virtual_columns`, a minimum frequency of occurrence for the scalar fields to be projected. You need a data guide-enabled search index in this case, but you do not need a data guide.

You can also specify that added virtual columns be *hidden*. The SQL `describe` command does not list hidden columns.

- If you pass a (hierarchical) data guide to `add_virtual_columns` then you can specify projection of particular scalar fields (not under an array) as *hidden* virtual columns by adding `"o:hidden":` **true** to their descriptions in the data guide.

- If you use a data guide-enabled JSON search index with `add_virtual_columns` then you can specify a PL/SQL **TRUE** value for argument *HIDDEN*, to make *all* of the added virtual columns be hidden. (The default value of *HIDDEN* is `FALSE`, meaning that the added virtual columns are not hidden.)

- [Adding Virtual Columns For JSON Fields Based on a Hierarchical Data Guide](#)
  You can use a hierarchical data guide to project scalar fields from JSON data as virtual columns in the same table. All scalar fields in the data guide that are not under an array are projected as virtual columns. All other fields in the data guide are ignored (not projected).

- **Adding Virtual Columns For JSON Fields Based on a Data Guide-Enabled Search Index**
  You can use a data guide-enabled search index for a JSON column to project scalar fields from that JSON data as virtual columns in the same table. Only scalar fields not under an array are projected. You can specify a minimum frequency of occurrence for the fields to be projected.

- **Dropping Virtual Columns for JSON Fields Based on Data-Guide Information**
  You can use procedure `DBMS_JSON.drop_virtual_columns` to drop all virtual columns that were added for JSON fields in a column of JSON data.

Related Topics

- **In-Memory JSON Data**
  A column of JSON data can be stored in the In-Memory Column Store (IM column store) to improve query performance.

23.8.1 Adding Virtual Columns For JSON Fields Based on a Hierarchical Data Guide

You can use a hierarchical data guide to project scalar fields from JSON data as virtual columns in the same table. All scalar fields in the data guide that are not under an array are projected as virtual columns. All other fields in the data guide are ignored (not projected).

You can obtain a hierarchical data guide using Oracle SQL function `json_dataguide`.

You can edit the data guide obtained, to include only specific scalar fields (that are not under an array), rename those fields, or change the lengths of their types. The resulting data guide specifies which such fields to project as new virtual columns. Any fields in the data guide that are not scalar fields not under an array are ignored (not projected).

You use PL/SQL procedure `DBMS_JSON.add_virtual_columns` to add the virtual columns to the table that contains the JSON column containing the projected fields. That procedure first drops any existing virtual columns that were projected from fields in the same JSON column by a previous invocation of `add_virtual_columns` or by data-guide change-trigger procedure `add_vc` (in effect, it does what procedure `DBMS_JSON.drop_virtual_columns` does).

Example 23-9 illustrates this. It projects scalar fields that are not under an array, from the data in JSON column `po_document` of table `j_purchaseorder`. The fields projected are those that are indicated in the hierarchical data guide.

Example 23-10 illustrates passing a data-guide argument that specifies the projection of two fields as virtual columns. Data-guide field `o:hidden` is used to hide one of these columns.

Example 23-9   Adding Virtual Columns That Project JSON Fields Using a Data Guide Obtained With JSON_DATAGUIDE

This example uses a hierarchical data guide obtained using function `json_dataguide` with JSON column `po_document`.

The added virtual columns are all of the columns in table `j_purchaseorder` except for `ID`, `DATE_LOADED`, and `PODOCUMENT`.

- Parameter `resolveNameConflicts` is `TRUE`, to ensure that any name conflicts get resolved. (Optional, for clarity; this is anyway the default value.)

- Parameter `colNamePrefix` is `'PO_DOCUMENT$'`, to use that as the default prefix for column names.

- Parameter `mixedCaseColumns` is `TRUE`, to make column names be case-sensitive, that is, to distinguish uppercase and lowercase letters.

```
DECLARE
  dg CLOB;

Example 23-10   Adding Virtual Columns, Hidden and Visible

In this example only two fields are projected as virtual columns: PO_Number and PO_Reference. The data guide is defined locally as a literal string. Data-guide field o:hidden is used here to hide the virtual column for PO_Reference. (For PO_Number the o:hidden: false entry is not needed, as false is the default value.)

```
DECLARE
  dg CLOB;
BEGIN
  dg := '{"type" : "object",
          "properties" :
            {"PO_Number"     : {"type" : "number",
                                "o:length" : 4,
                                "o:preferred_column_name" : "PO_Number",
                                "o:hidden" : false},
             "PO_Reference" : {"type" : "string",
                               "o:length" : 16,
                               "o:preferred_column_name" : "PO_Reference",
                               "o:hidden" : true}}}';

- JSON Data-Guide Fields
  The predefined fields of a JSON data guide are described. They include JSON Schema fields (keywords) and Oracle-specific fields.

23.8.2 Adding Virtual Columns For JSON Fields Based on a Data Guide-Enabled Search Index

You can use a data guide-enabled search index for a JSON column to project scalar fields from that JSON data as virtual columns in the same table. Only scalar fields not under an array are projected. You can specify a minimum frequency of occurrence for the fields to be projected.

You use procedure `DBMS_JSON.add_virtual_columns` to add the virtual columns.

Example 23-11 illustrates this. It projects all scalar fields that are not under an array to table `j_purchaseorder` as virtual columns.

If you gather statistics on the documents in the JSON column where you want to project fields then the data-guide information in the data guide-enabled JSON search index records the frequency of occurrence, across that document set, of each field in a document.

When you add virtual columns you can specify that only those fields with a given minimum frequency of occurrence are to be projected.

You do this by specifying a non-zero value for parameter *FREQUENCY* of procedure `add_virtual_columns`. Zero is the default value, so if you do not include argument *FREQUENCY* then all scalar fields (not under an array) are projected. The frequency of a given field is the number of documents containing that field divided by the total number of documents in the JSON column, expressed as a percentage.

Example 23-12 projects all scalars (not under an array) that occur in all (100%) of the documents as virtual columns.

If you want to *hide* all of the added virtual columns then specify a **TRUE** value for argument *HIDDEN*. (The default value of parameter *HIDDEN* is FALSE, meaning that the added virtual columns are not hidden.)

Example 23-13 projects, as hidden virtual columns, the scalar fields (not under an array) that occur in all (100%) of the documents.

> - *Oracle Database PL/SQL Packages and Types Reference* for information about `DBMS_JSON.rename_column`

Example 23-11   Projecting All Scalar Fields Not Under an Array as Virtual Columns

The added virtual columns are all of the columns in table `j_purchaseorder` except for `ID`, `DATE_LOADED`, and `PODOCUMENT`. This is because no *FREQUENCY* argument is passed to `add_virtual_columns`, so all scalar fields (that are not under an array) are projected.

(Columns whose names are *italic* in the `describe` command output are those that have been renamed using PL/SQL procedure `DBMS_JSON.rename_column`.)

```
EXEC DBMS_JSON.add_virtual_columns('J_PURCHASEORDER', 'PO_DOCUMENT');

DESCRIBE j_purchaseorder;
 Name                                      Null?    Type
 ----------------------------------------- -------- -----------------------------
 ID                                        NOT NULL RAW(16)
 DATE_LOADED                                        TIMESTAMP(6) WITH TIME ZONE
 PO_DOCUMENT                                        CLOB
 PO_DOCUMENT$User                                   VARCHAR2(8)
 PONumber                                           NUMBER
 PO_DOCUMENT$Reference                              VARCHAR2(16)
 PO_DOCUMENT$Requestor                              VARCHAR2(16)
 PO_DOCUMENT$CostCenter                             VARCHAR2(4)
 PO_DOCUMENT$AllowPartialShipment                   VARCHAR2(4)
 PO_DOCUMENT$name                                   VARCHAR2(16)
 Phone                                              VARCHAR2(16)
 PO_DOCUMENT$city                                   VARCHAR2(32)
 PO_DOCUMENT$state                                  VARCHAR2(2)
 PO_DOCUMENT$street                                 VARCHAR2(32)
 PO_DOCUMENT$country                                VARCHAR2(32)
 PO_DOCUMENT$zipCode                                NUMBER
 PO_DOCUMENT$SpecialInstructions                    VARCHAR2(8)
```

Example 23-12   Projecting Scalar Fields With a Minimum Frequency as Virtual Columns

All scalar fields that occur in all (100%) of the documents are projected as virtual columns. The result is the same as that for Example 23-11, except that fields `AllowPartialShipment` and `Phone` are not projected, because they do not occur in 100% of the documents.

(Columns whose names are *italic* in the `describe` command output are those that have been renamed using PL/SQL procedure `DBMS_JSON.rename_column`.)

```
EXEC DBMS_JSON.add_virtual_columns('J_PURCHASEORDER', 'PO_DOCUMENT', 100);
```

```
DESCRIBE j_purchaseorder;
 Name                                      Null?     Type
 ----------------------------------------- -------- ----------------------------
 ID                                        NOT NULL RAW(16)
 DATE_LOADED                                        TIMESTAMP(6) WITH TIME ZONE

23.8.3 Dropping Virtual Columns for JSON Fields Based on Data-Guide Information

You can use procedure `DBMS_JSON.drop_virtual_columns` to drop all virtual columns that were added for JSON fields in a column of JSON data.

Procedure `DBMS_JSON.drop_virtual_columns` drops all virtual columns that were projected from fields in a given JSON column by an invocation of `add_virtual_columns` or by data-guide change-trigger procedure `add_vc`. Example 23-14 illustrates this for fields projected from column `po_document` of table `j_purchaseorder`.

>
> - *Oracle Database PL/SQL Packages and Types Reference* for information about `DBMS_JSON.add_virtual_columns`
>
> - *Oracle Database PL/SQL Packages and Types Reference* for information about `DBMS_JSON.drop_virtual_columns`

Example 23-14   Dropping Virtual Columns Projected From JSON Fields

```
EXEC DBMS_JSON.drop_virtual_columns('J_PURCHASEORDER', 'PO_DOCUMENT');
```

23.9 Change Triggers For Data Guide-Enabled Search Index

When JSON data changes, some information in a data guide-enabled JSON search index is automatically updated. You can specify a procedure whose invocation is triggered whenever this happens. You can define your own PL/SQL procedure for this, or you can use the predefined change-trigger procedure `add_vc`.

The data-guide information in a data guide-enabled JSON search index records structure, type, and possibly statistical information about a set of JSON documents. Except for the statistical information, which is updated only when you gather statistics, relevant changes in the document set are automatically reflected in the data-guide information stored in the index.

You can define a PL/SQL procedure whose invocation is automatically triggered by such an index update. The invocation occurs when the index is updated. Any errors that occur during the execution of the procedure are ignored.

You can use the predefined change-trigger procedure `add_vc` to automatically add virtual columns that project JSON fields from the document set or to modify existing such columns, as needed. The virtual columns added by `add_vc` follow the same naming rules as those you add by invoking procedure

`DBMS_JSON.add_virtual_columns` for a JSON column that has a data guide-enabled search index.

In either case, any error that occurs during the execution of the procedure is *ignored*.

Unlike `DBMS_JSON.add_virtual_columns`, `add_vc` does *not* first drop any existing virtual columns that were projected from fields in the same JSON column. To drop virtual columns projected from fields in the same JSON column by `add_vc` or by `add_virtual_columns`, use procedure `DBMS_JSON.drop_virtual_columns`.

You specify the use of a trigger for data-guide changes by using the keywords **DATAGUIDE ON CHANGE** in the `PARAMETERS` clause when you create or alter a JSON search index. Only one change trigger is allowed per index: altering an index to specify a trigger automatically replaces any previous trigger for it.

Example 23-15 alters existing JSON search index `po_search_idx` to use procedure `add_vc`.

Example 23-15   Adding Virtual Columns Automatically With Change Trigger ADD_VC

This example adds predefined change trigger `add_vc` to JSON search index `po_search_idx`.

It first drops any existing virtual columns that were projected from fields in JSON column `po_document` either by procedure `DBMS_JSON.add_virtual_columns` or by a pre-existing `add_vc` change trigger for the same JSON search index.

Then it alters the search index to add change trigger `add_vc` (if it was already present then this is has no effect).

Finally, it inserts a new document that provokes a change in the data guide. Two virtual columns are added to the table, for the two scalar fields not under an array.

```
EXEC DBMS_JSON.drop_virtual_columns('J_PURCHASEORDER', 'PO_DOCUMENT');

ALTER INDEX po_search_idx REBUILD
  PARAMETERS ('DATAGUIDE ON CHANGE add_vc');

INSERT INTO j_purchaseorder
  VALUES (
    SYS_GUID(),
    to_date('30-JUN-2015'),
    '{"PO_Number"     : 4230,
      "PO_Reference"  : "JDEER-20140421",
      "PO_LineItems"  : [ {"Part_Number"  : 230912362345,
                           "Quantity"      : 3.0} ]}');

DESCRIBE j_purchaseorder;
 Name                          Null?    Type
 ------------------------- -------- ----------------------------
 ID                        NOT NULL RAW(16)
 DATE_LOADED                        TIMESTAMP(6) WITH TIME ZONE
 PO_DOCUMENT                        CLOB
 PO_DOCUMENT$PO_Number              NUMBER
 PO_DOCUMENT$PO_Reference           VARCHAR2(16)
```

- **User-Defined Data-Guide Change Triggers**
  You can define a procedure whose invocation is triggered automatically whenever a given data guide-enabled JSON search index is updated. Any errors that occur during the execution of the procedure are ignored.

Related Topics

- **Adding and Dropping Virtual Columns For JSON Fields Based on Data-Guide Information**
  Based on data-guide information for a JSON column, you can project scalar fields from that JSON data as virtual columns in the same table. The scalar fields projected are those that are not under an array.

> **✎ See Also:**

> - *Oracle Database PL/SQL Packages and Types Reference* for information about `DBMS_JSON.add_virtual_columns`
>
> - *Oracle Database PL/SQL Packages and Types Reference* for information about `DBMS_JSON.drop_virtual_columns`

23.9.1 User-Defined Data-Guide Change Triggers

You can define a procedure whose invocation is triggered automatically whenever a given data guide-enabled JSON search index is updated. Any errors that occur during the execution of the procedure are ignored.

Example 23-16 illustrates this.

A user-defined procedure specified with keywords `DATAGUIDE ON CHANGE` in a JSON search index `PARAMETERS` clause must accept the parameters specified in Table 23-5.

Table 23-5   Parameters of a User-Defined Data-Guide Change Trigger Procedure

Name	Type	Description
`table_name`	VARCHAR2	Name of the table containing column `column_name`.
`column_name`	VARCHAR2	Name of a JSON column that has a data guide-enabled JSON search index.
`path`	VARCHAR2	A SQL/JSON path expression that targets a particular field in the data in column `column_name`. This path is affected by the index change that triggered the procedure invocation. For example, the index change involved adding this path or changing its type value or its type-length value.
`new_type`	NUMBER	A new type for the given path.
`new_type_length`	NUMBER	A new type length for the given path.

Example 23-16   Tracing Data-Guide Updates With a User-Defined Change Trigger

This example first drops any existing virtual columns projected from fields in JSON column `po_document`.

It then defines PL/SQL procedure `my_dataguide_trace`, which prints the names of the table and JSON column, together with the path, type and length fields of the added virtual column. It then alters JSON search index `po_search_idx` to specify that this procedure be invoked as a change trigger for updates to the data-guide information in the index.

It then inserts a new document that provokes a change in the data guide, which triggers the output of trace information.

Note that the `TYPE` argument to the procedure must be a number that is one of the `DBMS_JSON` constants for a JSON type. The procedure tests the argument and outputs a user-friendly string in place of the number.

```
EXEC DBMS_JSON.drop_virtual_columns('J_PURCHASEORDER', 'PO_DOCUMENT');

CREATE OR REPLACE PROCEDURE my_dataguide_trace(tableName VARCHAR2,
                                               jcolName  VARCHAR2,
                                               path      VARCHAR2,
                                               type      NUMBER,
                                               tlength   NUMBER)
  IS
    typename VARCHAR2(10);
  BEGIN
    IF    (type = DBMS_JSON.TYPE_NULL)    THEN typename := 'null';
    ELSIF (type = DBMS_JSON.TYPE_BOOLEAN) THEN typename := 'boolean';
    ELSIF (type = DBMS_JSON.TYPE_NUMBER)  THEN typename := 'number';
    ELSIF (type = DBMS_JSON.TYPE_STRING)  THEN typename := 'string';
    ELSIF (type = DBMS_JSON.TYPE_OBJECT)  THEN typename := 'object';
    ELSIF (type = DBMS_JSON.TYPE_ARRAY)   THEN typename := 'array';
    ELSE                                       typename := 'unknown';
    END IF;
    DBMS_OUTPUT.put_line('Updating ' || tableName || '(' || jcolName
                      || '): Path = ' || path || ', Type = ' || type
                      || ', Type Name = ' || typename
                      || ', Type Length = ' || tlength);
  END;
/

ALTER INDEX po_search_idx REBUILD
  PARAMETERS ('DATAGUIDE ON CHANGE my_dataguide_trace');

23.10 Multiple Data Guides Per Document Set

A data guide reflects the shape of a given set of JSON documents. If a JSON column contains different types of documents, with different structure or type information, you can create and use different data guides for the different kinds of documents.

Data Guides For Different Kinds of JSON Documents

JSON documents need not, and typically do not, follow a prescribed schema. This is true even for documents that are used similarly in a given application; they may differ in structural ways (shape), and field types may differ.

A JSON data guide summarizes the structural and type information of a given set of documents. In general, the more similar the structure and type information of the documents in a given set, the more useful the resulting data guide.

A data guide is created for a given column of JSON data. If the column contains very different kinds of documents (for example, purchase orders and health records) then a single data guide for the column is likely to be of limited use.

One way to address this concern is to put different kinds of JSON documents in different JSON columns. But sometimes other considerations decide in favor of mixing document types in the same column.

In addition, documents of the same general type, which you decide to store in the same column, can nevertheless differ in relatively systematic ways. This includes the case of *evolving* document shape and type information. For example, the structure of tax-information documents could change from year to year.

When you create a data guide you can decide which information to summarize. And you can thus create different data guides for the same JSON column, to represent different subsets of the document set.

An additional aid in this regard is to have a separate, non-JSON, column in the same table, which is used to label, or categorize, the documents in a JSON column.

In the case of the purchase-order documents used in our examples, let's suppose that their structure can evolve significantly from year to year, so that column `date_loaded` of table `j_purchaseorder` can be used to group them into subsets of reasonably similar shape. Example 23-17 adds a purchase-order document for 2015, and Example 23-18 adds a purchase-order document for 2016. (Compare with the documents for 2014, which are added in Example 4-3.)

Using a SQL Aggregate Function to Create Multiple Data Guides

Oracle SQL function `json_dataguide` is in fact an *aggregate* function. An aggregate function returns a single result row based on groups of rows, rather than on a single row. It is typically used in a `SELECT` list for a query that has a `GROUP BY` clause, which divides the rows of a queried table or view into groups. The aggregate function applies to each group of rows, returning a single result row for each group. For example, aggregate function `avg` returns the average of a group of values.

Function `json_dataguide` aggregates JSON data to produce a summary, or specification, of it, which is returned in the form of a JSON document. In other words, for each group of JSON documents to which they are applied, they return a data guide.

If you omit `GROUP BY` then this function returns a single data guide that summarizes all of the JSON data in the subject JSON column.

Example 23-19 queries the documents of JSON column `po_document`, grouping them to produce three data guides, one for each year of column `date_loaded`.

Example 23-17   Adding a 2015 Purchase-Order Document

The 2015 purchase-order format uses only part number, reference, and line-items as its top-level fields, and these fields use prefix `PO_`. Each line item contains only a part number and a quantity.

```
INSERT INTO j_purchaseorder
  VALUES (
    SYS_GUID(),
    to_date('30-JUN-2015'),
    '{"PO_Number"     : 4230,
      "PO_Reference"  : "JDEER-20140421",
      "PO_LineItems"  : [ {"Part_Number"  : 230912362345,
                           "Quantity"     : 3.0} ]}');
```

Example 23-18   Adding a 2016 Purchase-Order Document

The 2016 format uses `PO_ID` instead of `PO_Number`, `PO_Ref` instead of `PO_Reference`, `PO_Items` instead of `PO_LineItems`, `Part_No` instead of `Part_Number`, and `Item_Quantity` instead of `Quantity`.

```
INSERT INTO j_purchaseorder
  VALUES (
```

```
        SYS_GUID(),
        to_date('30-MAR-2016'),
        '{"PO_ID"    : 4230,
          "PO_Ref"   : "JDEER-20140421",
          "PO_Items" : [ {"Part_No"       : 98981327234,
                          "Item_Quantity" : 13} ]}');
```

Example 23-19   Creating Multiple Data Guides With Aggregate Function JSON_DATAGUIDE

This example uses aggregate SQL function `json_dataguide` to obtain three flat[1] data guides, one for each year-specific format. The data guide for 2014 is shown only partially — it is the same as the data guide from A Flat Data Guide For Purchase-Order Documents, except that no statistics fields are present. (Data guides returned by functions `json_dataguide` do not contain any statistics fields.

```
SELECT extract(YEAR FROM date_loaded), json_dataguide(po_document)
  FROM j_purchaseorder
  GROUP BY extract(YEAR FROM date_loaded)
  ORDER BY extract(YEAR FROM date_loaded) DESC;

EXTRACT(YEARFROMDATE_LOADED)
----------------------------
JSON_DATAGUIDE(PO_DOCUMENT)
----------------------------
                        2016
[
  {
    "o:path" : "$.PO_ID",
    "type" : "number",
    "o:length" : 4
  },
  {
    "o:path" : "$.PO_Ref",
    "type" : "string",
    "o:length" : 16
  },
  {
    "o:path" : "$.PO_Items",
    "type" : "array",
    "o:length" : 64
  },
  {
    "o:path" : "$.PO_Items.Part_No",
    "type" : "number",
    "o:length" : 16
  },
  {
    "o:path" : "$.PO_Items.Item_Quantity",
    "type" : "number",
    "o:length" : 2
  }
```

---

[1] If function json_dataguide were passed `DBMS_JSON.FORMAT_HIERARCHICAL` as optional second argument then the result would be three hierarchical data guides.

```
]
                          2015
[
  {
    "o:path" : "$.PO_Number",
    "type" : "number",
    "o:length" : 4
  },
  {
    "o:path" : "$.PO_LineItems",
    "type" : "array",
    "o:length" : 64
  },
  {
    "o:path" : "$.PO_LineItems.Quantity",
    "type" : "number",
    "o:length" : 4
  },
  {
    "o:path" : "$.PO_LineItems.Part_Number",
    "type" : "number",
    "o:length" : 16
  },
  {
    "o:path" : "$.PO_Reference",
    "type" : "string",
    "o:length" : 16
  }
]

                          2014
[
  {
    "o:path" : "$.User",
    "type" : "string",
    "o:length" : 8
  },
  {
    "o:path" : "$.PONumber",
    "type" : "number",
    "o:length" : 4
  },
...

23.11 Querying a Data Guide

A data guide is information about a set of JSON documents. You can query it from a
flat data guide that you obtain using either Oracle SQL function `json_dataguide` or
PL/SQL function `DBMS_JSON.get_index_dataguide`. In the latter case, a data guide-
enabled JSON search index must be defined on the JSON data.

>   PL/SQL constant `DBMS_JSON.FORMAT_FLAT`

Example 23-20   Querying a Data Guide Obtained Using JSON_DATAGUIDE

This example uses SQL/JSON function `json_dataguide` to obtain a flat data guide. It
then queries the relational columns projected on the fly by SQL/JSON function
`json_table` from fields `o:path`, `type`, and `o:length`. It returns the projected columns
ordered lexicographically by the path column created, `jpath`.

If `DBMS_JSON.GATHER_STATS` were included in a third argument to `json_dataguide` then
the data guide returned would also include statistical fields.

```
WITH dg_t AS (SELECT json_dataguide(po_document) dg_doc
                FROM j_purchaseorder)
  SELECT jt.*
    FROM dg_t,
         json_table(dg_doc, '$[*]'
           COLUMNS
             jpath   VARCHAR2(40) PATH '$."o:path"',
             type    VARCHAR2(10) PATH '$."type"',
             tlength NUMBER       PATH '$."o:length"') jt
  ORDER BY jt.jpath;

JPATH                                   TYPE          TLENGTH
--------------------------------------- ------------- -------
$."Special Instructions"                string              8
```

```
          $.AllowPartialShipment                          boolean           4
          $.CostCenter                                    string            4
          $.LineItems                                     array           512
          $.LineItems.ItemNumber                          number            1
          $.LineItems.Part                                object          128
          $.LineItems.Part.Description                    string           32
          $.LineItems.Part.UPCCode                        number           16
          $.LineItems.Part.UnitPrice                      number            8
          $.LineItems.Quantity                            number            4
          $.PONumber                                      number            4
          $.PO_LineItems                                  array            64
          $.Reference                                     string           16
          $.Requestor                                     string           16
          $.ShippingInstructions                          object          256
          $.ShippingInstructions.Address                  object          128
          $.ShippingInstructions.Address.city             string           32
          $.ShippingInstructions.Address.country          string           32
          $.ShippingInstructions.Address.state            string            2
          $.ShippingInstructions.Address.street           string           32
          $.ShippingInstructions.Address.zipCode          number            8
          $.ShippingInstructions.Phone                    array           128
          $.ShippingInstructions.Phone                    string           16
          $.ShippingInstructions.Phone.number             string           16
          $.ShippingInstructions.Phone.type               string            8
          $.ShippingInstructions.name                     string           16
          $.User                                          string            8
```

Example 23-21   Querying a Data Guide With Index Data For Paths With Frequency at Least 80%

This example uses PL/SQL function `DBMS_JSON.get_index_dataguide` with format value `DBMS_JSON.FORMAT_FLAT` to obtain a flat data guide from the data-guide information stored in a data guide-enabled JSON search index. It then queries the relational columns projected on the fly from fields `o:path`, `type`, `o:length`, and `o:frequency` by SQL/JSON function `json_table`.

The value of field `o:frequency` is a statistic that records the frequency of occurrence, across the document set, of each field in a document. It is available *only if you have gathered statistics* on the document set. The frequency of a given field is the number of documents containing that field divided by the total number of documents in the JSON column, expressed as a percentage.

```
WITH dg_t AS
  (SELECT DBMS_JSON.get_index_dataguide('J_PURCHASEORDER',
                                        'PO_DOCUMENT',
                                        DBMS_JSON.FORMAT_FLAT) dg_doc

    FROM DUAL)
 SELECT jt.*
   FROM dg_t,
        json_table(dg_doc, '$[*]'
          COLUMNS
            jpath      VARCHAR2(40) PATH '$."o:path"',
            type       VARCHAR2(10) PATH '$."type"',
            tlength    NUMBER       PATH '$."o:length"',
            frequency NUMBER        PATH '$."o:frequency"') jt
```

```
    WHERE jt.frequency > 80;

JPATH                                      TYPE          TLENGTH  FREQUENCY
---------------------------------------- ------------- -------- ---------
$.User                                     string              8        100
$.PONumber                                 number              4        100
$.LineItems                                array             512        100
$.LineItems.Part                           object            128        100

• JSON Data-Guide Fields
  The predefined fields of a JSON data guide are described. They include JSON Schema fields (keywords) and Oracle-specific fields.

23.12 A Flat Data Guide For Purchase-Order Documents

The fields of a sample flat data guide are described. It corresponds to a set of purchase-order documents.

The only JSON Schema keyword used in a flat data guide is `type`. The other fields are all Oracle data-guide fields, which have prefix `o:`.

Example 23-22 shows a flat data guide for the purchase-order documents in table `j_purchaseorder`. Things to note:

• The values of `o:preferred_column_name` use prefix `PO_DOCUMENT$`. This prefix comes from using `DBMS_JSON.get_index_dataguide` to obtain this data guide.

• The value of `o:length` is 8 for path `$.User`, for example, in spite of the fact that the actual lengths of the field values are 5. This is because the value of `o:length` is always a power of two.

• The value of `o:path` for field `Special Instructions` is wrapped in double quotation marks (`"Special Instructions"`) because of the embedded space character.

Example 23-22   Flat Data Guide For Purchase Orders

Paths are **bold**. JSON schema keywords are *italic*. Preferred column names that result from using DBMS_JSON.rename_column are also *italic*. The formatting used is similar to that produced by using SQL/JSON function json_dataguide with format arguments DBMS_JSON.FORMAT_FLAT and DBMS_JSON.PRETTY.

Note that fields o:frequency, o:low_value, o:high_value, o:num_nulls, and o:last_analyzed are present. This can only be because statistics were gathered on the document set. Their values reflect the state as of the last statistics gathering.

See Example 23-3 for an example of gathering statistics for this data.

In order for statistics to be gathered, either the data guide needs to be based on a JSON search index or it needs to be created using function json_dataguide, specifying DBMS_JSON.GATHER_STATS in the third argument.

- JSON Data-Guide Fields
  The predefined fields of a JSON data guide are described. They include JSON
  Schema fields (keywords) and Oracle-specific fields.

- Specifying a Preferred Name for a Field Column
  You can project JSON fields from your data as non-JSON columns in a database
  view or as non-JSON virtual columns added to the same table that contains the
  JSON column. You can specify a preferred name for such a column.

23.13 A Hierarchical Data Guide For Purchase-Order Documents

The fields of a sample hierarchical data guide are described. It corresponds to a set of
purchase-order documents.

Example 23-23 shows a hierarchical data guide for the purchase-order documents in
table `j_purchaseorder`. The data guide was created using procedure
`DBMS_JSON.get_index_dataguide`.

Example 23-23   Hierarchical Data Guide For Purchase Orders

Field names are **bold**. JSON Schema keywords are *italic*. Preferred column names
that result from using `DBMS_JSON.rename_column` are also *italic*. The formatting used

is similar to that produced by using SQL/JSON function `json_dataguide` with format arguments `DBMS_JSON.FORMAT_HIERARCHICAL` and `DBMS_JSON.PRETTY`.

Note that statistical fields `o:frequency`, `o:low_value`, `o:high_value`, `o:num_nulls`, and `o:last_analyzed` are present in this example. This can only be because statistics were gathered on the document set. Their values reflect the state as of the last statistics gathering. See Example 23-3 for an example of gathering statistics for this data.

A hierarchical data guide created by SQL function `json_dataguide` would look similar to this example, but with these differences:

- The values of field `o:preferred_column_name` would the same as the field names in your JSON documents. That is, they would *not* be prefixed with `PO_DOCUMENT$`.

- Statistical fields would be present *only* if `json_dataguide` were invoked with `DBMS_JSON.GATHER_STATS` in its third argument. And in this case field `o:sample_size` would also be present, following field `o:last_analyzed`. (The value of `o:sample_size` would be `2` if there are two documents in the queried column of JSON data.)

  An overview is presented of JSON data generation: best practices, the SQL/JSON generation functions, a simple `JSON` constructor syntax, handling of input SQL values, and resulting generated data.

- **Handling of Input Values For SQL/JSON Generation Functions**
  The SQL/JSON generation functions take SQL values as input and return a JSON object or array. The input values are used to produce JSON object field–value pairs or JSON array elements. How the input values are used depends on their SQL data type.

- **SQL/JSON Function JSON_OBJECT**
  SQL/JSON function `json_object` constructs JSON objects from the results of evaluating its argument SQL expressions.

- **SQL/JSON Function JSON_ARRAY**
  SQL/JSON function `json_array` constructs a JSON array from the results of evaluating its argument SQL expressions.

- **SQL/JSON Function JSON_OBJECTAGG**
  SQL/JSON function `json_objectagg` constructs a JSON object by aggregating information from multiple rows of a grouped SQL query as the object members.

- **SQL/JSON Function JSON_ARRAYAGG**
  SQL/JSON function `json_arrayagg` constructs a JSON array by aggregating information from multiple rows of a grouped SQL query as the array elements. The order of array elements reflects the query result order, by default, but you can use the `ORDER BY` clause to impose array element order.

- **Read-Only Views Based On JSON Generation**
  You can create read-only views using JSON generation functions or constructor `JSON`. Anyone with access can use the views as if they were read-only tables. Users of the JSON data need not know or care whether it is stored as such or generated as needed.

24.1 Overview of JSON Generation

An overview is presented of JSON data generation: best practices, the SQL/JSON generation functions, a simple `JSON` constructor syntax, handling of input SQL values, and resulting generated data.

The best way to generate JSON data from non-JSON database data is to use SQL. The standard SQL/JSON functions, `json_object`, `json_array`, `json_objectagg`, and `json_arrayagg` are designed specifically for this. If the generated data is of `JSON` type then a handy alternative is to use the `JSON` data type constructor function, `JSON`.

Both make it easy to construct JSON data directly from a SQL query. They allow non-JSON data to be represented as JSON objects and JSON arrays. You can generate complex, hierarchical JSON documents by nesting calls to the generation functions or constructor `JSON`. Nested subqueries can generate JSON data that represents one-to-many relationships.[1]

The Best Way to Construct JSON Data from Non-JSON Data

Alternatives to using the SQL/JSON generation functions are generally error prone or inefficient.

- Using *string concatenation* to generate JSON documents is error prone. In particular, there are a number of complex rules that must be respected concerning when and how to escape special characters, such as double quotation marks ("). It is easy to overlook or misunderstand these rules, which can result in generating incorrect JSON data.

- Reading non-JSON result sets from the database and using *client-side application code* to generate JSON data is typically quite inefficient, particularly due to network overhead. When representing one-to-many relationships as JSON data, multiple `SELECT` operations are often required, to collect all of the non-JSON data needed. If the documents to be generated represent multiple levels of one-to-many relationships then this technique can be quite costly.

The SQL/JSON generation functions and constructor `JSON` do not suffer from such problems; they are designed for the job of constructing JSON data from non-JSON database data.

- They always construct well-formed JSON documents.

- By using SQL subqueries with the functions, you can generate an entire set of JSON documents using a single SQL statement, which allows the generation operation to be optimized.

- Because only the generated documents are returned to a client, network overhead is minimized: there is at most one round trip per document generated.

The SQL/JSON Generation Functions

- Functions **json_object** and **json_array** construct a JSON object or array, respectively. In the simplest case, `json_object` takes SQL name–value pairs as arguments, and `json_array` takes SQL values as arguments.

- Functions **json_objectagg**, and **json_arrayagg** are *aggregate* SQL functions. They transform information that is contained in the rows of a grouped SQL query into JSON objects and arrays, respectively. Evaluation of the arguments determines the number of object members and array elements, respectively; that is, the size of the result reflects the current queried data.

  For `json_objectagg` and `json_arrayagg`, the order of object members and array elements, respectively, is unspecified. For `json_arrayagg`, you can use an `ORDER BY` clause within the `json_arrayagg` invocation to control the array element order.

Result Returned by SQL/JSON Generation Functions

By default, the generated JSON data is returned from a generation function as a SQL `VARCHAR2(4000)` value. You can use the optional `RETURNING` clause to specify a different `VARCHAR2` size or to specify a `JSON`, `CLOB` or `BLOB` return value instead. When `BLOB` is the return type, the character set is AL32UTF8.

---

[1] The behavior of the SQL/JSON generation functions for JSON data is similar to that of the SQL/XML generation functions for XML data.

Unless the return type is `JSON`, the JSON values produced from the input SQL values are serialized to textual JSON. This serialization has the same effect as Oracle SQL function `json_serialize`.

> **Note:**
>
> Oracle SQL function `json_serialize` consistently serializes values of Oracle JSON-language scalar types, such as float and date, using standard formats.
>
> For example, it serializes a JSON date value using the ISO 8601 date format *YYYY-MM-DD*.
>
> If you want to generate a *textual* JSON object or array that contains a JSON string value in some other format, then provide a string in that format as input to the generation function. (String input to `json_serialize` is simply output as is.)
>
> For example, if you want `json_object` to produce an object with a string field that has a different ISO 8601 date format, then use SQL conversion function such as `to_char` to provide that string and pass it to `json_object`.

Handling of Input Values For SQL/JSON Generation Functions

The SQL/JSON generation functions take SQL values as input and, from them, produce JSON values inside the JSON object or array that is returned. How the input values produce the JSON values used in the output depends on their SQL data type.

Optional Behavior For SQL/JSON Generation Functions

You can optionally specify a SQL `NULL`-handling clause, a `RETURNING` clause, and keywords `STRICT` and `WITH UNIQUE KEYS`.

- `NULL`-handling clause — Determines how a SQL `NULL` value resulting from input evaluation is handled.
  - **NULL ON NULL** — An input SQL `NULL` value is converted to JSON `null` for output. This is the default behavior for `json_object` and `json_objectagg`.
  - **ABSENT ON NULL** — An input SQL `NULL` value results in no corresponding output. This is the default behavior for `json_array` and `json_arrayagg`.
- **RETURNING** clause — The SQL data type used for the function return value. The return type can be any of the SQL types that support JSON data: `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. The default return type (no `RETURNING` clause) is `VARCHAR2(4000)`.
- **STRICT** keyword — If present, the returned JSON data is checked to be sure it is well-formed. If `STRICT` is present and the returned data is not well-formed then an error is raised.

> **Note:**
>
> In general, you need not specify STRICT when generating data of JSON data type, and doing so can introduce a small performance penalty.
>
> When an input and the returned data are both of JSON type, if you do not specify STRICT then that input is used as is in the returned data; it is not checked for strict well-formedness.
>
> You might want to use STRICT when returning JSON type data if (1) the input data is also of JSON type and (2) you suspect that it is not completely strict. That could be the case, for example, if a client application created the input data and it did not ensure that each JSON string is represented by a valid UTF-8 sequence of bytes.

- **WITH UNIQUE KEYS** keywords, when generating *textual* JSON data — If present, the returned JSON object is checked to be sure there are no duplicate field names. If there are duplicates, an error is raised. These keywords are available only for json_object and json_objectagg.

  When generating textual JSON data, if WITH UNIQUE KEYS is absent (or if WITHOUT UNIQUE KEYS is present) then no check for unique fields is performed. In that case all fields are used, including any duplicates.

  WITH[OUT] UNIQUE KEYS has no effect when producing JSON-type data. An error is always raised when there are duplicate keys if the return type is JSON.

JSON Data Type Constructor

You can use constructor JSON with a special syntax as an alternative to using json_object and json_array when generating data of data type JSON. (You can use constructor JSON and JSON type only if database initialization parameter compatible is at least 20. Otherwise an error is raised.)

The only difference in behavior is that the return data type when you use the constructor is always JSON (there is no RETURNING clause for the constructor).

When employed as an alternative syntax for json_object or json_array, you follow constructor JSON directly with braces (**{}**) and brackets (**[]**), respectively, for object and array generation, instead of the usual parentheses (**()**).

- **JSON { … }** has the same effect as **JSON(**json_object(…)**)**, which has the same effect as json_object(… RETURNING JSON).

- **JSON […]** has the same effect as **JSON(**json_array(…)**)**, which has the same effect as json_array(… RETURNING JSON).

All of the behavior and syntax possibilities that json_object and json_array offer when they are used with RETURNING JSON are also available when you use constructor JSON with the special syntax. See Example 24-2, Example 24-3, Example 24-4, Example 24-5, Example 24-6, Example 24-7, and Example 24-8

JSON {…} and JSON […] provide alternative syntax only for json_object and json_array, not for the aggregate generation functions, json_objectagg and json_arrayagg. But you can pass a SQL *query* expression as argument to

`json_array`, and thus also use it as the (single) argument to `JSON [...]`. For example, these two queries are equivalent:

```
SELECT json_arrayagg(department_name)FROM departments;
```

```
SELECT json_array(SELECT department_name FROM departments) FROM DUAL;
```

And you can of course use constructor `JSON` (without the special syntax) on the result of an explicit call to `json_objectagg` or `json_arrayagg`. For example, these two queries are equivalent:

```
SELECT JSON(json_objectagg(department_name VALUE department_id))
  FROM departments;
```

```
SELECT json_objectagg(department_name VALUE department_id
                      RETURNING JSON)
  FROM departments;
```

Related Topics

- Handling of Input Values For SQL/JSON Generation Functions
  The SQL/JSON generation functions take SQL values as input and return a JSON object or array. The input values are used to produce JSON object field–value pairs or JSON array elements. How the input values are used depends on their SQL data type.

- ISO 8601 Date, Time, and Duration Support
  International Standards Organization (ISO) standard 8601 describes an internationally accepted way to represent dates, times, and durations. Oracle Database supports the most common ISO 8601 formats as proper Oracle SQL date, time, and interval (duration) values. The formats that are supported are essentially those that are numeric-only, language-neutral, and unambiguous.

- JSON Data Type Constructor
  The `JSON` data type constructor, **JSON**, takes as input a textual JSON value (a scalar, object, or array), parses it, and returns the value as an instance of `JSON` type. Alternatively, the input can be an instance of a user-defined PL/SQL or SQL aggregate type.

- Unique Versus Duplicate Fields in JSON Objects
  The JSON standard recommends that a JSON object *not* have duplicate field names. Oracle Database enforces this for `JSON` type data by raising an error. If stored textually, Oracle recommends that you do *not* allow duplicate field names, by using an `is json` check constraint with keywords `WITH UNIQUE KEYS`.

24.2 Handling of Input Values For SQL/JSON Generation Functions

The SQL/JSON generation functions take SQL values as input and return a JSON object or array. The input values are used to produce JSON object field–value pairs or JSON array elements. How the input values are used depends on their SQL data type.

The returned JSON object or array is of a SQL data type that supports JSON data: `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. The default return type is `VARCHAR2(4000)`. In all cases, the return value is known by the database to contain well-formed JSON data.

Unless it is of `JSON` data type, an input can optionally be followed by keywords **`FORMAT JSON`**, which declares that the value is to be considered as already representing JSON data (you vouch for it), so it is interpreted (parsed) as JSON data.

For example, if the input is `'{}'` then you might want it to produce the empty JSON *object*, {}, and not the JSON *string* `"{}"`. Example 24-1 illustrates the use of `FORMAT JSON` to cause an input `VARCHAR2` string `"{\"x\":5}"` to produce the JSON object `{"x":5}`.

Equivalently, if the input type is not `JSON` then you can apply SQL function **`treat`** with keywords **`AS JSON`** to it — the effect is the same as using `FORMAT JSON`.

If the input data is of `JSON` type then it is used as is. This includes the case where the `JSON` type constructor is used. (Do *not* use `FORMAT JSON` or `treat … AS JSON` in this case; otherwise, an error is raised.)

In some cases where an input is *not* of `JSON` type, and you do *not* use `FORMAT JSON` or `treat … AS JSON`, Oracle nevertheless knows that the result is JSON data. In such cases using `FORMAT JSON` or `treat … AS JSON` is not needed and is optional. This is the case, for example, if the input data is the result of using function `json_query` or one of the JSON generation functions.

If, one way or another, an input is known to be JSON data then it is used essentially *as is* to construct the result — it need not be processed in any way. This applies regardless of whether the input represents a JSON scalar, object, or array.

If an input is *not* known to be JSON data, then it produces a JSON value as follows (any other SQL value raises an error):

- An instance of a user-defined *SQL object type* produces a *JSON object* whose field names are taken from the object attribute names and whose field values are taken from the object attribute values (to which JSON generation is applied recursively).

- An instance of a *SQL collection type* produces a *JSON array* whose element values are taken from the collection element values (to which JSON generation is applied recursively).

- A `VARCHAR2`, `CLOB`, or `NVARCHAR` value is wrapped in double quotation marks (`"`), and characters are escaped when necessary to conform to the JSON standard for a *JSON string*. For example, input SQL input `'{}'` produces the JSON string `"{}"`.

- A numeric value produces a JSON numeric value.

  If database initialization parameter `compatible` is at least `20` then `NUMBER` input produces a JSON number value, `BINARY_DOUBLE` input produces a JSON double value, and `BINARY_FLOAT` input produces a JSON float value.

  If `compatible` is less than `20` then the value is a JSON number, regardless of the numeric input type (`NUMBER`, `BINARY_DOUBLE`, or `BINARY_FLOAT`).

  The numeric values of positive and negative infinity, and values that are the undefined result of a numeric operation ("not a number" or `NaN`), cannot be expressed as JSON numbers. They instead produce the JSON strings `"Inf"`, `"-Inf"`, and `"Nan"`, respectively.

- A `RAW` or `BLOB` value produces a hexadecimal JSON string, with double quotation marks, (`"`).

- A time-related value (`DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, `INTERVAL YEAR TO MONTH`, or `INTERVAL DAY TO SECOND`) produces a supported ISO 8601 format, and the result is enclosed in double quotation marks (`"`) as a JSON string.

- A `BOOLEAN` (SQL or PL/SQL) value of `TRUE` or `FALSE` produces JSON `true` or `false`, respectively.

- A SQL `NULL` value produces JSON `null`, regardless of the `NULL` data type.

> **Note:**
>
> For input of data types `CLOB` and `BLOB` to SQL/JSON generation functions, an empty instance is distinguished from SQL `NULL`. It produces an empty JSON string (`""`). But for input of data types `VARCHAR2`, `NVARCHAR2`, and `RAW`, Oracle SQL treats an empty (zero-length) value as `NULL`, so do *not* expect such a value to produce a JSON string.

Example 24-1   FORMAT JSON: Declaring an Input SQL Value To Be JSON Data

In this example, PL/SQL function `getX()` returns a `VARCHAR2` value that represents a JSON object. If `FORMAT JSON` were *not* used then the value returned by generation function

`json_array` would be a JSON singleton array with a *string* element, `[ "{\"x\":5} "]`, not a JSON *object* `[ {"x":5} ]`.

```
-- PL/SQL: Return a SQL string representing a JSON object
CREATE FUNCTION getX(n NUMBER) RETURN VARCHAR2 AS
BEGIN
  RETURN '{"x":'|| n ||'}';
END;

-- SQL: Generate JSON data from SQL
SELECT json_array(getX(5) FORMAT JSON) FROM DUAL;
```

Using `FORMAT JSON` does not ensure that the input is well-formed JSON data. If you need to do that then include keyword `STRICT` when you use the generation function:

```
SELECT json_array(getX(5) FORMAT JSON STRICT) FROM DUAL;
```

>
> Oracle Built-in Data Types

24.3 SQL/JSON Function JSON_OBJECT

SQL/JSON function `json_object` constructs JSON objects from the results of evaluating its argument SQL expressions.

It can accept any number of arguments, each of which is one of the following:

- An explicit field name–value pair. Example: `answer : 42`.

A *name–value* pair argument specifies an object member for the generated JSON object (except when the value expression evaluates to SQL `NULL` and the `ABSENT ON NULL` clause applies). The name and value are SQL expressions. The *name* expression must evaluate to a SQL *string*. The *value* expression must evaluate to a SQL value that is of `JSON` data type or that can be rendered as a JSON value. The name and value expressions are separated by keyword **`VALUE`** or a colon (**`:`**).

> **📝 Note:**
>
> Some client drivers might try to scan query text and identify bind variables before sending the query to the database. In some such cases a colon as name–value separator in `json_object` might be misinterpreted as introducing a bind variable. You can use keyword `VALUE` as the separator to avoid this problem (`'Name' VALUE Diderot`), or you can simply enclose the value part of the pair in parentheses: `'Name':(Diderot)`.

- A relational column name, possibly preceded by a table name or alias, or a view name followed by a dot (.). Example: `t1.address`.

  In this case, for a given row of data, the JSON-object member specified by the column-name argument has the column name as its field name and the column value as the field value.

  Regardless of whether it is quoted, the column name you provide is interpreted *case-sensitively*. For example, if you use `Email` as a column-name argument then the data in column `EMAIL` is used to produce object members with field name `Email` (not `EMAIL`).

- A table name or alias, or a view name, followed by a dot and an asterisk *wildcard* (.**`*`**). Example: `t1.*`. (The name or alias can also be prefixed by a database schema name, as in `myschema.t1.*`.)

  In this case, all columns of the table or view are used as input. Each is handled as if it were named explicitly. In particular, the column names are interpreted *case-sensitively*.

Alternatively, `json_object` accepts a *single* argument that is one of the following:

- An instance of a user-defined SQL object-type. Example: `json_object(my_sql_object_42)`.

  In this case, the resulting JSON-object field names are taken from the SQL object attribute names, and their values are taken from the SQL object attribute values (to which JSON generation is applied recursively).

- An asterisk *wildcard* (**`*`**). Example: `json_object(*)`.

  The wildcard acts as a shortcut to explicitly specifying *all* of the columns of a table or view, to produce the object members. The resulting JSON-object field names are the *uppercase* column names. You can use a wildcard with a table, a view, or a table alias, which is understood from the `FROM` list. The columns can be of any SQL data type.

  Note the difference between this case (`json_object(*)`) and the case described above, where the asterisk is preceded by an explicit table or view name (or table alias), followed by a dot: `json_object(`**`t.*`**`)`. In the `json_object(*)` case, the column names are *not* interpreted case-sensitively.

Another way of describing the use of asterisk wildcards with `json_object` is to say that it follows what is allowed for wildcards in a SQL `SELECT` list.

Just as for SQL/JSON condition `is json`, you can use keywords `STRICT` and `WITH UNIQUE KEYS` with functions `json_object` and `json_objectagg`. The behavior for each is the same as for `is json`.

Example 24-2   Using Name–Value Pairs with JSON_OBJECT

This example constructs a JSON object for each employee of table `hr.employees` (from standard database schema `HR`) whose salary is greater than 15000.

It passes explicit name–value pairs to specify the members of the JSON object. The object includes, as the value of its field `contactInfo`, an object with fields `mail` and `phone`.

The use of **RETURNING JSON** here specifies that the JSON data is returned as `JSON` data type, not the default return type, `VARCHAR2(4000)`.

```
SELECT json_object('id'         : employee_id,
                   'name'        : first_name || ' ' || last_name,
                   'contactInfo' : json_object('mail'  : email,
                                               'phone' : phone_number),
                   'hireDate'    : hire_date,
                   'pay'         : salary
                   RETURNING JSON)
  FROM hr.employees
  WHERE salary > 15000;

-- The query returns rows such as this (pretty-printed here for
clarity):

{"id"          : 101,
 "name"        : "Neena Kochhar",
 "contactInfo" : {"mail"  : "NKOCHHAR",
                  "phone" : "515.123.4568"},
 "hireDate"    : "21-SEP-05",
 "pay"         : 17000}
```

> **Note:**
>
> Because function `json_object` *always returns JSON data*, there is no need to specify `FORMAT JSON` for the value of input field `contactInfo`. But if the value of that field had been given as, for example, `'{"mail":' || email ', "phone":' || phone_number || '}'` then you would need to follow it with `FORMAT JSON` to have that string value interpreted as JSON data:
>
> ```
> "contactInfo" :
>    '{"mail":' || email ', "phone":' || phone_number || '}'
> FORMAT JSON,
> ```

Because the return type of the JSON data is JSON, this is an alternative syntax for the same query:

```
SELECT JSON { 'id'         : employee_id,
              'name'        : first_name || ' ' || last_name,
              'contactInfo' : JSON { 'mail'  : email,
                                     'phone' : phone_number }
              'hireDate'    : hire_date,
              'pay'         : salary }
  FROM hr.employees
  WHERE salary > 15000;
```

Example 24-3   Using Column Names with JSON_OBJECT

This example constructs a JSON object for the employee whose employee_id is 101. The fields produced are named after the columns, but case-sensitively.

The use of **RETURNING JSON** here specifies that the JSON data is returned as JSON data type, not the default return type, VARCHAR2(4000).

```
SELECT json_object(last_name,
                   'contactInfo' : json_object(email, phone_number),
                   hire_date,
                   salary,
                   RETURNING JSON)
  FROM hr.employees
  WHERE employee_id = 101;

-- The query returns rows such as this (pretty-printed here for clarity):

{"last_name"   : "Kochhar",
 "contactInfo" : {"email"        : "NKOCHHAR",
                  "phone_number" : "515.123.4568"},
 "hire-date"   : "21-SEP-05",
 "salary"      : 17000}
```

Because the return type of the JSON data is JSON, this is an alternative syntax for the same query:

```
SELECT JSON { last_name,
              'contactInfo' : JSON { email, phone_number },
              hire_date,
              salary}
  FROM hr.employees
  WHERE employee_id = 101;
```

Example 24-4   Using a Wildcard (*) with JSON_OBJECT

This example constructs a JSON object for each employee whose salary is greater than 15000. Each column of table employees is used to construct one object member, whose field name is the (uppercase) column name. Note that a SQL NULL value results in a JSON field value of null.

The use of **RETURNING JSON** here specifies that the JSON data is returned as JSON data type, not the default return type, VARCHAR2(4000).

```
SELECT json_object(* RETURNING JSON)
  FROM hr.employees
  WHERE salary > 15000;

-- The query returns rows such as this (pretty-printed here for
clarity):

JSON_OBJECT(*)
--------------
{"EMPLOYEE_ID":100,
 "FIRST_NAME":"Steven",
 "LAST_NAME":"King",
 "EMAIL":"SKING",
 "PHONE_NUMBER":"515.123.4567",
 "HIRE_DATE":"2003-06-17T00:00:00",
 "JOB_ID":"AD_PRES",
 "SALARY":24000,
 "COMMISSION_PCT":null,
 "MANAGER_ID":null,
 "DEPARTMENT_ID":90}

{"EMPLOYEE_ID":101,
 "FIRST_NAME":"Neena",
 "LAST_NAME":"Kochhar",
 "EMAIL":"NKOCHHAR",
 "PHONE_NUMBER":"515.123.4568",
 "HIRE_DATE":"2005-09-21T00:00:00",
 "JOB_ID":"AD_VP",
 "SALARY":17000,
 "COMMISSION_PCT":null,
 "MANAGER_ID":100,
 "DEPARTMENT_ID":90}

{"EMPLOYEE_ID":102,
 "FIRST_NAME":"Lex",
 "LAST_NAME":"De Haan",
 "EMAIL":"LDEHAAN",
 "PHONE_NUMBER":"515.123.4569",
 "HIRE_DATE":"2001-01-13T00:00:00",
 "JOB_ID":"AD_VP",
 "SALARY":17000,
 "COMMISSION_PCT":null,
 "MANAGER_ID":100,
 "DEPARTMENT_ID":90}
```

Because the return type of the JSON data is JSON, this is an alternative syntax for the same query:

```
SELECT JSON { * }
  FROM hr.employees
  WHERE salary > 15000;
```

Example 24-5   Using JSON_OBJECT With ABSENT ON NULL

This example queries table hr.locations from standard database schema HR to create JSON objects with fields city and province.

The default NULL-handling behavior for json_object is NULL ON NULL.

In order to prevent the creation of a field with a null JSON value, this example uses ABSENT ON NULL. The NULL SQL value for column state_province when column city has value 'Singapore' means that no province field is created for that location.

```
SELECT JSON_OBJECT('city'     : city,
                   'province' : state_province ABSENT ON NULL)
  FROM hr.locations
  WHERE city LIKE 'S%';

JSON_OBJECT('CITY'ISCITY,'PROVINCE'ISSTATE_PROVINCEABSENTONNULL)
----------------------------------------------------------------
{"city":"Southlake","province":"Texas"}
{"city":"South San Francisco","province":"California"}
{"city":"South Brunswick","province":"New Jersey"}
{"city":"Seattle","province":"Washington"}
{"city":"Sydney","province":"New South Wales"}
{"city":"Singapore"}
{"city":"Stretford","province":"Manchester"}
{"city":"Sao Paulo","province":"Sao Paulo"}
```

Because there is no RETURNING clause in this example, the JSON data is returned as VARCHAR2(4000), the default. If RETURNING JSON were used then you could use this alternative syntax for the query:

```
SELECT JSON {'city'     : city,
            'province' : state_province ABSENT ON NULL}
  FROM hr.locations
  WHERE city LIKE 'S%';
```

Example 24-6   Using a User-Defined Object-Type Instance with JSON_OBJECT

This example creates table po_ship with column shipping of object type shipping_t. (It uses SQL/JSON function json_value to construct the shipping_t instances from JSON data — see Example 19-5.)

It then uses json_object to generate JSON objects from the SQL object-type instances in column po_ship.shipping, returning them as JSON data type instances.

(The query output is shown pretty-printed here, for clarity.)

```
CREATE TABLE po_ship
  AS SELECT json_value(po_document, '$.ShippingInstructions'
                       RETURNING shipping_t)
  shipping
  FROM j_purchaseorder;

DESCRIBE po_ship;

Name        Null?    Type
---------  -------  ----------
SHIPPING             SHIPPING_T

SELECT json_object(shipping RETURNING JSON)
  FROM po_ship;

JSON_OBJECT(SHIPPING)
---------------------
{"NAME":"Alexis Bull",
 "ADDRESS":{"STREET":"200 Sporting Green",
            "CITY":"South San Francisco"}}
{"NAME":"Sarah Bell",
 "ADDRESS":{"STREET":"200 Sporting Green",
            "CITY":"South San Francisco"}}
```

Because the return type from `json_object` is JSON, this is an alternative syntax for the same query:

```
SELECT JSON {shipping} FROM po_ship;
```

24.4 SQL/JSON Function JSON_ARRAY

SQL/JSON function `json_array` constructs a JSON array from the results of evaluating its argument SQL expressions.

In the simplest case, the evaluated arguments you provide to `json_array` are SQL values that produce JSON values as the JSON array elements. The resulting array has an element for each argument you provide (except when an argument expression evaluates to SQL `NULL` and the `ABSENT ON NULL` clause applies). Array element order is the same as the argument order.

There are several kinds of SQL value that you can use as an argument to `json_array`, including SQL scalar, collection instance, and user-defined object-type instance. Alternatively, the argument can be a (sub)query expression, in which case the array elements are the values returned by the query, in order (or according to `ORDER BY`, if present).

Example 24-7   Using JSON_ARRAY with Value Arguments to Construct a JSON Array

This example constructs a JSON object for each employee job in database table `hr.jobs` (from standard database schema `HR`). The fields of the objects are the job title and salary range. The salary range (field `salaryRange`) is an array of two numeric values, the minimum and maximum salaries for the job. These values are taken from SQL columns `min_salary` and `max_salary`.

The use of `RETURNING JSON` here specifies that the JSON data is returned as `JSON` data type, not the default return type, `VARCHAR2(4000)`.

```
SELECT json_object('title'       VALUE job_title,
                'salaryRange' VALUE json_array(min_salary, max_salary)
                RETURNING JSON)
  FROM jobs;

JSON_OBJECT('TITLE'ISJOB_TITLE,'SALARYRANGE'ISJSON_ARRAY(MIN_SALARY,
--------------------------------------------------------------------
{"title":"President","salaryRange":[20080,40000]}
{"title":"Administration Vice President","salaryRange":[15000,30000]}
{"title":"Administration Assistant","salaryRange":[3000,6000]}
{"title":"Finance Manager","salaryRange":[8200,16000]}
{"title":"Accountant","salaryRange":[4200,9000]}
{"title":"Accounting Manager","salaryRange":[8200,16000]}
{"title":"Public Accountant","salaryRange":[4200,9000]}
```

ORACLE®

```
{"title":"Sales Manager","salaryRange":[10000,20080]}
{"title":"Sales Representative","salaryRange":[6000,12008]}
{"title":"Purchasing Manager","salaryRange":[8000,15000]}
{"title":"Purchasing Clerk","salaryRange":[2500,5500]}
{"title":"Stock Manager","salaryRange":[5500,8500]}
{"title":"Stock Clerk","salaryRange":[2008,5000]}
{"title":"Shipping Clerk","salaryRange":[2500,5500]}
{"title":"Programmer","salaryRange":[4000,10000]}
{"title":"Marketing Manager","salaryRange":[9000,15000]}
{"title":"Marketing Representative","salaryRange":[4000,9000]}
{"title":"Human Resources Representative","salaryRange":[4000,9000]}
{"title":"Public Relations Representative","salaryRange":[4500,10500]}
```

Because the return type of the JSON data is JSON, this is an alternative syntax for the same query:

```
SELECT JSON { 'title'        VALUE job_title,
              'salaryRange' VALUE [ min_salary, max_salary ] }
  FROM jobs;
```

Example 24-8   Using JSON_ARRAY with a Query Argument to Construct a JSON Array

This query passes a subquery as argument to function json_array. The subquery invokes function json_object, which produces object values as the array elements. The array elements are ordered by the values of their field sal, by virtue of keywords ORDER BY, which sorts the subquery values by column salary.

The use of RETURNING JSON here specifies that the JSON data is returned as JSON data type, not the default return type, VARCHAR2(4000).

```
SELECT json_array(SELECT json_object('id'   : employee_id,
                                     'name' : last_name,
                                     'sal'  : salary)
                  RETURNING JSON
                  FROM employees
                  WHERE salary > 12000
                  ORDER BY salary) by_salary;
```

Because the return type of the JSON data is JSON, this is an alternative syntax for the same query:

```
SELECT JSON [ SELECT JSON {'id'   : employee_id,
                           'name' : last_name,
                           'sal'  : salary}
              FROM employees
              WHERE salary > 12000
              ORDER BY salary ] by_salary;
```

24.5 SQL/JSON Function JSON_OBJECTAGG

SQL/JSON function `json_objectagg` constructs a JSON object by aggregating information
from multiple rows of a grouped SQL query as the object members.

Unlike the case for SQL/JSON function `json_object`, where the number of members in the
resulting object directly reflects the number of arguments, for `json_objectagg` the size of the
resulting object reflects the current queried data. It can thus vary, depending on the data that
is queried.

Example 24-9   Using JSON_OBJECTAGG to Construct a JSON Object

This example constructs a single JSON object from table `hr.departments` (from standard
database schema `HR`) using field names taken from column `department_name` and field values
taken from column `department_id`.

Just as for SQL/JSON condition `is json`, you can use keywords `STRICT` and `WITH UNIQUE`
`KEYS` with functions `json_object` and `json_objectagg`. The behavior for each is the same as
for `is json`.

```
SELECT json_objectagg(department_name VALUE department_id)
  FROM departments;

-- The returned object is pretty-printed here for clarity.
-- The order of the object members is arbitrary.

JSON_OBJECTAGG(DEPARTMENT_NAMEISDEPARTMENT_ID)
---------------------------------------------
{"Administration":       10,
 "Marketing":            20,
 "Purchasing":           30,
 "Human Resources":      40,
 "Shipping":             50,
```

```
"IT":                    60,

24.6 SQL/JSON Function JSON_ARRAYAGG

SQL/JSON function `json_arrayagg` constructs a JSON array by aggregating
information from multiple rows of a grouped SQL query as the array elements. The
order of array elements reflects the query result order, by default, but you can use the
`ORDER BY` clause to impose array element order.

Unlike the case for SQL/JSON function `json_array`, where the number of elements in
the resulting array directly reflects the number of arguments, for `json_arrayagg` the
size of the resulting array reflects the current queried data. It can thus vary, depending
on the data that is queried.

Example 24-10   Using JSON_ARRAYAGG to Construct a JSON Array

This example constructs a JSON object for each employee of table `hr.employees`
(from standard database schema `HR`) who is a manager in charge of at least six

employees. The objects have fields for the manager id number, manager name, number of employees reporting to the manager, and id numbers of those employees.

The order of the employee id numbers in the array is determined by the ORDER BY clause for json_arrayagg. The default direction for ORDER BY is ASC (ascending). The array elements, which are numeric, are in ascending numerical order.

```
SELECT json_object('id'        VALUE mgr.employee_id,
                   'manager'   VALUE (mgr.first_name || ' '|| mgr.last_name),
                   'numReports' VALUE count(rpt.employee_id),
                   'reports'   VALUE json_arrayagg(rpt.employee_id
                                                  ORDER BY rpt.employee_id))
  FROM  employees mgr, employees rpt
  WHERE mgr.employee_id = rpt.manager_id
  GROUP BY mgr.employee_id, mgr.last_name, mgr.first_name
  HAVING count(rpt.employee_id) > 6;

-- The returned object is pretty-printed here for clarity.

JSON_OBJECT('ID'ISMGR.EMPLOYEE_ID,'MANAGER'VALUE(MGR.FIRST_NAME||''||MGR.LAST_NAME)
--------------------------------------------------------------------------------
{"id":         100,
 "manager":    "Steven King",
 "numReports": 14,
 "reports":    [101,102,114,120,121,122,123,124,145,146,147,148,149,201]}

{"id":         120,
 "manager":    "Matthew Weiss",
 "numReports": 8,
 "reports":    [125,126,127,128,180,181,182,183]}

{"id":         121,
 "manager":    "Adam Fripp",
 "numReports": 8,
 "reports":    [129,130,131,132,184,185,186,187]}

{"id":         122,
 "manager":    "Payam Kaufling",
 "numReports": 8,
 "reports":    [133,134,135,136,188,189,190,191]}

{"id":         123,
 "manager":    "Shanta Vollman",
 "numReports": 8,
 "reports":    [137,138,139,140,192,193,194,195]}

{"id":         124,
 "manager":    "Kevin Mourgos",
 "numReports": 8,
 "reports":    [141,142,143,144,196,197,198,199]}
```

Example 24-11   Generating JSON Objects with Nested Arrays Using a SQL Subquery

This example shows a SQL left outer join between two tables: `countries` and `regions`. Table `countries` has a foreign key, `region_id`, which joins with the primary key of table `regions`, also named `region_id`.

The query returns a JSON object for each row in table `regions`. Each of these *region* objects has a `countries` field whose value is an array of *country* objects — the countries in that region.

```
SELECT json_object(
        'region'   : region_name,
        'countries' :
        (SELECT json_arrayagg(json_object('id'   : country_id,
                                          'name' : country_name))
           FROM countries c
           WHERE c.region_id = r.region_id))
  FROM regions r;
```

The query results in objects such as the following:

```
{"region"    : "Europe",
 "countries" : [ {"id"    : "BE",
                  "name" : "Belgium"},
                 {"id"    : "CH",
                  "name" : "Switzerland"},
                 {"id"    : "DE",
                  "name" : "Germany"},
                 {"id"    : "DK",
                  "name" : "Denmark"},
                 {"id"    : "FR",
                  "name" : "France"},
                 {"id"    : "IT",
                  "name" : "Italy"},
                 {"id"    : "NL",
                  "name" : "Netherlands"},
                 {"id"    : "UK",
                  "name" : "United Kingdom"} ]}
```

24.7 Read-Only Views Based On JSON Generation

You can create read-only views using JSON generation functions or constructor `JSON`. Anyone with access can use the views as if they were read-only tables. Users of the JSON data need not know or care whether it is stored as such or generated as needed.

Example 24-12 illustrates this. The resulting view can be used as if it were a read-only *table* with columns `ID` (a department identification number) and `DATA` (JSON data for the department, including its employees). Using SQL*Plus command `describe` shows this:

```
describe department_view;
Name    Null?       Type
--------------------------
ID      NOT NULL    NUMBER(4)
DATA                JSON
```

Column `DATA` is of `JSON` data type, since the special `JSON` constructor syntax is used (`JSON {…}`). The underlying stored data comes from `HR` sample-schema `HR`, tables `DEPARTMENT`, `LOCATION`, `EMPLOYEES`, and `JOBS`.

Each row of the view provides information for single department: its ID, name, address, and employees. The address of a department is a JSON object.

The data for the employees of a department is an array of employee objects, each of which has the employee's ID, full name, and job title. The name is constructed from column data that stores the first and last names separately.

Querying the view evaluates the SQL code that invokes the JSON generation functions. Example 24-13 shows a query that returns a single document, for department `90`.

To improve read performance you can materialize the view.

Because JSON-generation views are read-only, you cannot update them (unless you use `INSTEAD OF` triggers[2]). If you need an updatable view that provides JSON data then you can create a JSON-relational *duality view*.

Example 24-12   Creating a View That Uses JSON Generation

```
CREATE VIEW department_view AS
  SELECT  dep.department_id id,
          JSON {'id'                : dep.department_id,
                'departmentName'     : dep.department_name,
                'departmentAddress' : JSON {'street'  : loc.street_address,
                                            'zip'     : loc.postal_code,
                                            'city'    : loc.city,
                                            'state'   : loc.state_province,
                                            'country' : loc.country_id},
                'employees'          : [ SELECT JSON {'id'    : emp.employee_id,
                                                      'name'  : emp.first_name || ' ' ||
emp.last_name,
                                                      'title' : (SELECT job_title
```

Part VI

PL/SQL Object Types for JSON

You can use PL/SQL object types for JSON to read and write multiple fields of a JSON document. This can increase performance, in particular by avoiding multiple parses and serializations of the data.

- Overview of PL/SQL Object Types for JSON
  PL/SQL object types allow fine-grained programmatic construction and manipulation of In-Memory JSON data. You can introspect it, modify it, and serialize it back to textual JSON data.

- Using PL/SQL Object Types for JSON
  Some examples of using PL/SQL object types for JSON are presented.

ORACLE®

25

Overview of PL/SQL Object Types for JSON

PL/SQL object types allow fine-grained programmatic construction and manipulation of In-Memory JSON data. You can introspect it, modify it, and serialize it back to textual JSON data.

The principal PL/SQL JSON object types are `JSON_ELEMENT_T`, `JSON_OBJECT_T`, `JSON_ARRAY_T`, and `JSON_SCALAR_T`. Another, less used object type is `JSON_KEY_LIST`, which is a varray of `VARCHAR2(4000)`. Object types are also called abstract data types (ADTs).

These JSON object types provide an In-Memory, hierarchical (tree-like), programmatic representation of JSON data that is stored in the database.[1]

You can use the object types to programmatically manipulate JSON data in memory, to do things such as the following:

- Check the structure, types, or values of existing JSON data. For example, check whether the value of a given object field satisfies certain conditions.

- Transform existing JSON data. For example, convert address or phone-number formats to follow a particular convention.

- Create JSON data using programming rules that match the characteristics of whatever the data represents. For example, if a product to be represented as a JSON object is flammable then include fields that represent safety information.

You *construct* an object-type instance in memory, either all at once, by parsing JSON text, or piecemeal, starting with an empty object or array instance and adding object members or array elements to it. You can construct an object-type instance directly from `JSON` type data using `JSON` type method `load()`.

PL/SQL object-type instances are *transient*. To persist the information they contain you must either store it in a database table or marshal it to a database client such as Java Database Connectivity (JDBC). For this, you need to convert the object-type instance to a persistable data type for JSON data: `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`.

Opposite to the use of method `load()`, you can use PL/SQL function `to_json` to convert an object-type instance to a `JSON` type instance.

An unused object-type instance is automatically garbage-collected; you cannot, and need not, free up the memory used by an instance that you no longer need.

Relations Among the JSON Object Types

Type `JSON_ELEMENT_T` is the supertype of the other JSON object types: each of them extends it as a subtype. Subtypes `JSON_OBJECT_T` and `JSON_ARRAY_T` are used for JSON objects and arrays, respectively. Subtype `JSON_SCALAR_T` is used for scalar JSON values: strings, numbers, the Boolean values `true` and `false`, and the value `null`.

---

[1] This is similar to what is available for XML data using the Document Object Model (DOM), a language-neutral and platform-neutral object model and API for accessing the structure of XML documents that is recommended by the World Wide Web Consortium (W3C).

You can construct an instance of type `JSON_ELEMENT_T` only by parsing JSON text. Parsing creates a `JSON_ELEMENT_T` instance, which is an In-Memory representation of the JSON data. You cannot construct an empty instance of type `JSON_ELEMENT_T` or type `JSON_SCALAR_T`.

Types `JSON_OBJECT_T` and `JSON_ARRAY_T` each have a constructor function of the same name as the type, which you can use to construct an instance of the type: an empty (In-Memory) representation of a JSON object or array, respectively. You can then fill this object or array as needed, adding object members or array elements, represented by PL/SQL object-type instances.

You can cast an instance of `JSON_ELEMENT_T` to a subtype instance, using PL/SQL function `treat`. For example, `treat(elt AS JSON_OBJECT_T)` casts instance `elt` as a JSON object (instance of `JSON_OBJECT_T`).

Parsing Function and JSON Type Constructor

Static function **parse** accepts an instance of type `VARCHAR2`, `CLOB`, or `BLOB` as argument, which it parses as JSON text to return an instance of type `JSON_ELEMENT_T`, `JSON_OBJECT_T`, or `JSON_ARRAY_T`.

In addition to parsing textual JSON data, you can construct object-type instances by passing existing `JSON` type data to constructors `JSON_OBJECT_T`, `JSON_ARRAY_T` and `JSON_SCALAR_T`. Alternatively, you can use method `load()` to construct object-type instances (`JSON_ELEMENT_T`, `JSON_OBJECT_T`, `JSON_ARRAY_T`, and `JSON_SCALAR_T`) from `JSON` type data.

Serialization Functions and TO_JSON

Parsing accepts input JSON data as text and returns an instance of a PL/SQL JSON object type. Serialization does essentially the opposite: you apply it to a PL/SQL object representation of JSON data and it returns a textual representation of that object. The serialization methods have names that start with prefix **to_**. For example, method `to_string()` returns a string (`VARCHAR2`) representation of the JSON object-type instance you apply it to.

Besides serializing an object-type instance to textual JSON data, you can use function `to_json` to convert an object-type instance to an instance of `JSON` data type.

Most serialization methods are member functions. For serialization as a `CLOB` or `BLOB` instance, however, there are two forms of the methods: a member *function* and a *member* procedure. The member function accepts no arguments. It creates a temporary LOB as the serialization destination. The member procedure accepts a LOB `IN OUT` argument (`CLOB` instance for method `to_clob()`, `BLOB` for method `to_blob()`). You can thus pass it the LOB (possibly empty) that you want to use for the serialized representation.

Getter and Setter Methods

Types `JSON_OBJECT_T` and `JSON_ARRAY_T` have getter and setter methods, which obtain and update, respectively, the values of a given object field or a given array element position.

There are two kinds of *getter* method:

- Method **get()** returns a reference to the original object to which you apply it, as an instance of type `JSON_ELEMENT_T`. That is, the object to which you apply it is

passed by reference: If you then modify the returned `JSON_ELEMENT_T` instance, your modifications apply to the original object to which you applied `get()`.

- Getter methods whose names have the prefix **get_** return a *copy* of any data that is targeted within the object or array to which they are applied. That data is *passed by value*, not reference.

  For example, if you apply method `get_string()` to a `JSON_OBJECT_T` instance, passing a given field as argument, it returns a copy of the string that is the value of that field. If you apply `get_string()` to a `JSON_ARRAY_T` instance, passing a given element position as argument, it returns a copy of the string at that position in the array.

Like the serialization methods, most getter methods are member functions. But methods `get_clob()` and `get_blob()`, which return the value of a given object field or the element at a given array position as a `CLOB` or `BLOB` instance, have two forms (like the serialization methods `to_clob()` and `to_blob()`): a member *function* and a member *procedure*. The member function accepts no argument other than the targeted object field or array position. It creates and returns a temporary LOB instance. The member procedure accepts also a LOB `IN OUT` argument (`CLOB` for `get_clob`, `BLOB` for `get_blob`). You can thus pass it the (possibly empty) LOB instance to use.

The *setter* methods are `put()`, `put_null()`, and (for `JSON_ARRAY_T` only) `append()`. These update the object or array instance to which they are applied, setting the value of the targeted object field or array element. Note: The setter methods *modify the existing instance*, instead of returning a modified copy of it.

Method **append()** adds a new element at the end of the array instance. Method **put_null()** sets an object field or array element value to JSON `null`.

Method **put()** requires a second argument (besides the object field name or array element position), which is the new value to set. For an array, `put()` also accepts an optional third argument, *OVERWRITE*. This is a `BOOLEAN` value (default `FALSE`) that says whether to *replace an existing value* at the given position.

- If the object already has a field of the same name then `put()` *replaces that value* with the new value.

- If the array already has an element at the given position then, by default, `put()` shifts that element and any successive elements forward (incrementing their positions by one) to make room for the new element, which is placed at the given position. But if optional argument *OVERWRITE* is present and is `TRUE`, then the existing element at the given position is simply *replaced* by the new element.

Introspection Methods

Type `JSON_ELEMENT_T` has introspection methods that you can use to determine whether an instance is a JSON object, array, scalar, string, number, or Boolean, or whether it is the JSON value `true`, `false`, or `null`. The names of these methods begin with prefix **is_**. They are predicates, returning a `BOOLEAN` value.

It also has introspection method **get_size()**, which returns the number of members of a `JSON_OBJECT_T` instance and the number of elements of a `JSON_ARRAY_T` instance (it returns 1 for a `JSON_SCALAR_T` instance).

Type `JSON_ELEMENT_T` also has introspection methods `is_date()` and `is_timestamp()`, which test whether an instance represents a date or timestamp. JSON has no native types for dates or timestamps; these are typically representing using JSON strings. But if a `JSON_ELEMENT_T`

instance is constructed using SQL data of SQL data type `DATE` or `TIMESTAMP` then this type information is kept for the PL/SQL object representation.

Date and timestamp data is represented using PL/SQL object type `JSON_SCALAR_T`, whose instances you cannot construct directly. You can, however, add such a value to an object (as a field value) or an array (as an element) using method `put()`. Retrieving it using method `get()` returns a `JSON_SCALAR_T` instance.

Types `JSON_OBJECT_T` and `JSON_ARRAY_T` have introspection method **`get_type()`**, which returns the JSON type of the targeted object field or array element (as a `VARCHAR2` instance). Type `JSON_OBJECT_T` also has introspection methods **`has()`**, which returns `TRUE` if the object has a field of the given name, and **`get_keys()`**, which returns an instance of PL/SQL object type `JSON_KEY_LIST`, which is a varray of type `VARCHAR2(4000)`. The varray contains the names of the fields [2] present in the given `JSON_OBJECT_T` instance.

Other Methods

Types `JSON_OBJECT_T` and `JSON_ARRAY_T` have the following methods:

- **`remove()`** — Remove the object member with the given field or the array element at the given position.

- **`clone()`** — Create and return a (deep) copy of the object or array to which the method is applied. Modifying any part of this copy has no effect on the original object or array.

Type `JSON_OBJECT_T` has method **`rename_key()`**, which renames a given object field.[2] If the new name provided already names an existing field then an error is raised.

Type `JSON_ELEMENT_T` has method **`schema_validate()`**, which validates a given instance against a JSON schema.

> - *Oracle Database PL/SQL Packages and Types Reference* for information about `JSON_KEY_LIST`

Example 26-1   Constructing and Serializing an In-Memory JSON Object

This example uses function `parse` to parse a string of JSON data that represents a JSON object with one field, `name`, creating an instance `je` of object type `JSON_ELEMENT_T`. This instance is tested to see if it represents an object, using introspection method (predicate) `is_object()`.

If it represents an object (the predicate returns `TRUE` for `je`), it is cast to an instance of `JSON_OBJECT_T` and assigned to variable `jo`. Method `put()` for object type `JSON_OBJECT_T` is then used to add object field `price` with value `149.99`.

Finally, `JSON_ELEMENT_T` instance `je` (which is the same data in memory as `JSON_OBJECT_T` instance `jo`) is serialized to a string using method `to_string()`, and this string is printed out using procedure `DBMS_OUTPUT.put_line`. The result printed out shows the updated object as `{"name":"Radio-controlled plane","price":149.99}`.

The updated transient object `je` is serialized here only to be printed out; the resulting text is not stored in the database. Sometime after the example code is run, the memory allocated for object-type instances `je` and `jo` is reclaimed by the garbage collector.

```
DECLARE
  je JSON_ELEMENT_T;
  jo JSON_OBJECT_T;
BEGIN
  je := JSON_ELEMENT_T.parse('{"name":"Radio controlled plane"}');
  IF (je.is_Object) THEN
    jo := treat(je AS JSON_OBJECT_T);
    jo.put('price', 149.99);
  END IF;
  DBMS_OUTPUT.put_line(je.to_string);
```

```
END;
/
```

Example 26-2   Using Method GET_KEYS() to Obtain a List of Object Fields

PL/SQL method `get_keys()` is defined for PL/SQL object type `JSON_OBJECT_T`. It returns an instance of PL/SQL object type `JSON_KEY_LIST`, which is a varray of `VARCHAR2(4000)`. The varray contains all of the field names for the given `JSON_OBJECT_T` instance.

This example iterates through the fields returned by `get_keys()`, adding them to an instance of PL/SQL object type `JSON_ARRAY_T`. It then uses method `to_string()` to serialize that JSON array and then prints the resulting string.

```
DECLARE
  jo          JSON_OBJECT_T;
  ja          JSON_ARRAY_T;
  keys        JSON_KEY_LIST;
  keys_string VARCHAR2(100);
BEGIN
  ja := new JSON_ARRAY_T;
  jo := JSON_OBJECT_T.parse('{"name":"Beda",
                             "jobTitle":"codmonki",
                             "projects":[ "json", "xml" ]}');
  keys := jo.get_keys;
  FOR i IN 1..keys.COUNT LOOP
     ja.append(keys(i));
  END LOOP;
  keys_string := ja.to_string;
  DBMS_OUTPUT.put_line(keys_string);
END;
/
```

The printed output is `["name","jobTitle","projects"]`.

Example 26-3   Using Method PUT() to Update Parts of JSON Documents

This example updates each purchase-order document in JSON column `po_document` of table `j_purchaseorder`. It iterates over the JSON array `LineItems` in each document (variable `li_arr`), calculating the total price and quantity for each line-item object (variable `li_obj`), and it uses method `put()` to add these totals to `li_obj` as the values of new fields `totalQuantity` and `totalPrice`. This is done by user-defined function `add_totals`.

The `SELECT` statement here selects one of the documents that has been updated.

```
CREATE OR REPLACE FUNCTION add_totals(purchaseOrder IN VARCHAR2) RETURN VARCHAR2 IS
  po_obj       JSON_OBJECT_T;
  li_arr       JSON_ARRAY_T;
  li_item      JSON_ELEMENT_T;
  li_obj       JSON_OBJECT_T;
  unitPrice    NUMBER;
  quantity     NUMBER;
  totalPrice   NUMBER := 0;
```

```
  totalQuantity NUMBER := 0;
BEGIN
  po_obj := JSON_OBJECT_T.parse(purchaseOrder);
  li_arr := po_obj.get_Array('LineItems');
  FOR i IN 0 .. li_arr.get_size - 1 LOOP
    li_obj := JSON_OBJECT_T(li_arr.get(i));
    quantity := li_obj.get_Number('Quantity');
    unitPrice := li_obj.get_Object('Part').get_Number('UnitPrice');
    totalPrice := totalPrice + (quantity * unitPrice);
    totalQuantity := totalQuantity + quantity;
  END LOOP;
  po_obj.put('totalQuantity', totalQuantity);
  po_obj.put('totalPrice', totalPrice);
  RETURN po_obj.to_string;
END;
/

UPDATE j_purchaseorder SET (po_document) = add_totals(po_document);

SELECT po_document FROM j_purchaseorder po
  WHERE po.po_document.PONumber = 1600;
```

That selects this updated document:

```
{"PONumber": 1600,
 "Reference": "ABULL-20140421",
 "Requestor": "Alexis Bull",
 "User": "ABULL",
 "CostCenter": "A50",
 "ShippingInstructions":
   {"name": "Alexis Bull",
    "Address": {"street": "200 Sporting Green",
                "city": "South San Francisco",
                "state": "CA",
                "zipCode": 99236,
                "country": "United States of America"},
    "Phone": [{"type": "Office", "number": "909-555-7307"},
              {"type": "Mobile", "number": "415-555-1234"}]},
 "Special Instructions": null,
 "AllowPartialShipment": true,
 "LineItems": [{"ItemNumber": 1,
                "Part": {"Description": "One Magic Christmas",
                         "UnitPrice": 19.95,
                         "UPCCode": 13131092899},
                "Quantity": 9.0},
               {"ItemNumber": 2,
                "Part": {"Description": "Lethal Weapon",
                         "UnitPrice": 19.95,
                         "UPCCode": 85391628927},
                "Quantity": 5.0}],
 "totalQuantity": 14,
 "totalPrice": 279.3}
```

GeoJSON Geographic Data

GeoJSON data is geographic JSON data. Oracle Spatial and Graph supports the use of GeoJSON objects to store, index, and manage GeoJSON data.

- Using GeoJSON Geographic Data
  GeoJSON objects are JSON objects that represent geographic data. Examples are provided of creating GeoJSON data, indexing it, and querying it.

ORACLE®

27
Using GeoJSON Geographic Data

GeoJSON objects are JSON objects that represent geographic data. Examples are provided of creating GeoJSON data, indexing it, and querying it.

GeoJSON Objects: Geometry, Feature, Feature Collection

GeoJSON uses JSON objects that represent various geometrical entities and combinations of these together with user-defined properties.

A **position** is an array of two or more spatial (numerical) coordinates, the first three of which generally represent longitude, latitude, and altitude.

A **geometry** object has a `type` field and (except for a geometry-collection object) a `coordinates` field, as shown in Table 27-1.

A **geometry collection** is a geometry object with `type GeometryCollection`. Instead of a `coordinates` field it has a `geometries` field, whose value is an array of geometry objects other than `GeometryCollection` objects.

Table 27-1   GeoJSON Geometry Objects Other Than Geometry Collections

`type` Field	`coordinates` Field
Point	A position.
MultiPoint	An array of positions.
LineString	An array of two or more positions.
MultiLineString	An array of `LineString` arrays of positions.
Polygon	A `MultiLineString`, each of whose arrays is a `LineString` whose first and last positions coincide (are equivalent). If the array of a polygon contains more than one array then the first represents the outside polygon and the others represent holes inside it.
MultiPolygon	An array of `Polygon` arrays, that is, multidimensional array of positions.

A **feature** object has a `type` field of value `Feature`, a `geometry` field whose value is a geometric object, and a `properties` field whose value can be any JSON object.

A **feature collection** object has a `type` field of value `FeatureCollection`, and it has a `features` field whose value is an array of feature objects.

Example 27-1 presents a feature-collection object whose `features` array has three features. The `geometry` of the first feature is of type `Point`; that of the second is of type `LineString`; and that of the third is of type `Polygon`.

Query and Index GeoJSON Data

You can use SQL/JSON query functions and conditions to examine GeoJSON data or to project parts of it as non-JSON data, including as Oracle Spatial and Graph `SDO_GEOMETRY` object-type instances. This is illustrated in Example 27-2, Example 27-3, and Example 27-5.

To improve query performance, you can create an Oracle Spatial and Graph index (type `MDSYS.SPATIAL_INDEX`) on function `json_value` applied to GeoJSON data. This is illustrated by Example 27-4.

Example 27-4 indexes only one particular element of an array of geometry features (the first element). A B-tree index on function `json_value` can target only a *scalar* value. To improve the performance of queries, such as that of Example 27-3, that target any number of array elements, you can do the following:

- Create an on-statement, refreshable *materialized view* of the array data, and place that view *in memory*.

- Create a spatial index on the array data.

This is shown in Example 27-6 and Example 27-7.

SDO_GEOMETRY Object-Type Instances and Spatial Operations

You can convert Oracle Spatial and Graph `SDO_GEOMETRY` object-type instances to GeoJSON objects and GeoJSON objects to `SDO_GEOMETRY` instances.

You can use Oracle Spatial and Graph operations on `SDO_GEOMETRY` objects that you obtain from GeoJSON objects. For example, you can use operator `sdo_distance` in PL/SQL package `SDO_GEOM` to compute the minimum distance between two geometry objects. This is the distance between the closest two points or two segments, one point or segment from each object. This is illustrated by Example 27-5.

JSON Data Guide Supports GeoJSON Data

A JSON data guide summarizes structural and type information contained in a set of JSON documents. If some of the documents contain GeoJSON data then that data is summarized in a data guide that you create using SQL aggregate function `json_dataguide`. If you use SQL function `json_dataguide` to create a view based on such a data guide, and you specify the formatting argument as `DBMS_JSON.GEOJSON` or `DBMS_JSON.GEOJSON+DBMS_JSON.PRETTY`, then a column that projects GeoJSON data from the document set is of SQL data type `SDO_GEOMETRY`.

Example 27-1   A Table With GeoJSON Data

This example creates table `j_geo`, which has a column, `geo_doc` of GeoJSON documents.

Only one such document is inserted here. It contains a GeoJSON object of `type`
`FeatureCollection`, and a `features` array of objects of `type Feature`. Those objects have
`geometry`, respectively, of `type Point`, `LineString`, and `Polygon`.

```
CREATE TABLE j_geo
  (id      VARCHAR2 (32) NOT NULL,
   geo_doc VARCHAR2 (4000) CHECK (geo_doc is json));

INSERT INTO j_geo
  VALUES (1,
         '{"type"      : "FeatureCollection",
           "features" : [{"type"         : "Feature",
                          "geometry"    : {"type" : "Point",
                                            "coordinates" : [-122.236111, 37.482778]},
                          "properties" : {"Name" : "Redwood City"}},
                         {"type"         : "Feature",
                          "geometry"    : {"type" : "LineString",
                                            "coordinates" : [[102.0, 0.0],
                                                             [103.0, 1.0],
                                                             [104.0, 0.0],
                                                             [105.0, 1.0]]},
                          "properties" : {"prop0" : "value0",
                                          "prop1" : 0.0}},
                         {"type"         : "Feature",
                          "geometry"    : {"type" : "Polygon",
                                            "coordinates" : [[[100.0, 0.0],
                                                             [101.0, 0.0],
                                                             [101.0, 1.0],
                                                             [100.0, 1.0],
                                                             [100.0, 0.0]]]},
                          "properties" : {"prop0" : "value0",
                                          "prop1" : {"this" : "that"}}}]}');
```

Example 27-2   Selecting a geometry Object From a GeoJSON Feature As an SDO_GEOMETRY Instance

This example uses SQL/JSON function `json_value` to select the value of field `geometry` from
the first element of array `features`. The value is returned as Oracle Spatial and Graph data,
not as JSON data, that is, as an instance of PL/SQL object type `SDO_GEOMETRY`, not as a SQL
string or LOB instance.

```
SELECT json_value(geo_doc, '$.features[0].geometry'
                  RETURNING SDO_GEOMETRY
                  ERROR ON ERROR)
  FROM j_geo;
```

The value returned is this, which represents a point with longitude and latitude (coordinates)
-122.236111 and 37.482778, respectively.

```
SDO_GEOMETRY(2001,
             4326,
             SDO_POINT_TYPE(-122.236111, 37.482778, NULL),
```

```
NULL,
NULL)
```

>
> *Oracle Database SQL Language Reference* for information about SQL/JSON
> function `json_value`

Example 27-3   Retrieving Multiple geometry Objects From a GeoJSON Feature As SDO_GEOMETRY

This example uses SQL/JSON function `json_table` to project the value of field `geometry` from *each* element of array `features`, as column `sdo_val` of a virtual table. The retrieved data is returned as `SDO_GEOMETRY`.

```
SELECT jt.*
  FROM j_geo,
       json_table(geo_doc, '$.features[*]'
         COLUMNS (sdo_val SDO_GEOMETRY PATH '$.geometry')) jt;
```

> **See Also:**
>
> *Oracle Database SQL Language Reference* for information about SQL/JSON
> function `json_table`

The following three rows are returned for the query. The first represents the same `Point` as in Example 27-2. The second represents the `LineString` array. The third represents the `Polygon`.

```
SDO_GEOMETRY(2001,
             4326,
             SDO_POINT_TYPE(-122.236111, 37.482778, NULL),
             NULL,
             NULL)

SDO_GEOMETRY(2002,
             4326,
             NULL,
             SDO_ELEM_INFO_ARRAY(1, 2, 1),
             SDO_ORDINATE_ARRAY(102, 0, 103, 1, 104, 0, 105, 1))

SDO_GEOMETRY(2003,
             4326,
             NULL,
             SDO_ELEM_INFO_ARRAY(1, 1003, 1),
             SDO_ORDINATE_ARRAY(100, 0, 101, 0, 101, 1, 100, 1, 100,
0))
```

The second and third elements of attribute SDO_ELEM_INFO_ARRAY specify how to interpret the coordinates provided by attribute SDO_ORDINATE_ARRAY. They show that the first row returned represents a *line string* (2) with straight segments (1), and the second row represents a *polygon* (2003) of straight segments (1).

Example 27-4   Creating a Spatial Index For Scalar GeoJSON Data

This example creates a json_value function-based index of type MDSYS.SPATIAL_INDEX on field geometry of the first element of array features. This can improve the performance of queries that use json_value to retrieve that value.

```
CREATE INDEX geo_first_feature_idx
  ON j_geo (json_value(geo_doc, '$.features[0].geometry'
                       RETURNING SDO_GEOMETRY))
  INDEXTYPE IS MDSYS.SPATIAL_INDEX;
```

Example 27-5   Using GeoJSON Geometry With Spatial Operators

This example selects the documents (there is only one in this table) for which the geometry field of the first features element is within 100 kilometers of a given point. The point is provided literally here (its coordinates are the longitude and latitude of San Francisco, California). The distance is computed from this point to each geometry object.

The query orders the selected documents by the calculated distance. The tolerance in meters for the distance calculation is provided in this query as the literal argument 100.

```
SELECT id,
       json_value(geo_doc, '$.features[0].properties.Name') "Name",
       SDO_GEOM.sdo_distance(
         json_value(geo_doc, '$.features[0].geometry'
                    RETURNING SDO_GEOMETRY),
         SDO_GEOMETRY(2001,
                      4326,
                      SDO_POINT_TYPE(-122.416667, 37.783333, NULL),
                      NULL,
                      NULL),
         100, -- Tolerance in meters
         'unit=KM') "Distance in kilometers"
  FROM  j_geo
  WHERE sdo_within_distance(
          json_value(geo_doc, '$.features[0].geometry'
                     RETURNING SDO_GEOMETRY),
          SDO_GEOMETRY(2001,
                       4326,
                       SDO_POINT_TYPE(-122.416667, 37.783333, NULL),
                       NULL,
                       NULL),
          'distance=100 unit=KM')
        = 'TRUE';
```

> **See Also:**
>
> *Oracle Database SQL Language Reference* for information about SQL/JSON function `json_value`

The query returns a single row:

```
ID    Name           Distance in kilometers
----- -------------- ----------------------
1     Redwood City   26.9443035
```

Example 27-6   Creating a Materialized View Over GeoJSON Data

```
CREATE OR REPLACE MATERIALIZED VIEW geo_doc_view
  BUILD IMMEDIATE
  REFRESH FAST ON STATEMENT WITH ROWID
  AS SELECT g.rowid, jt.*
       FROM j_geo g,
            json_table(geo_doc, '$.features[*]'
              COLUMNS (sdo_val SDO_GEOMETRY PATH '$.geometry')) jt;
```

Example 27-7   Creating a Spatial Index on a Materialized View Over GeoJSON Data

This example first prepares for the creation of the spatial index by populating some spatial-indexing metadata. It then creates the index on the `SDO_GEOMETRY` column, `sdo_val`, of materialized view `geo_doc_view`, which is created in Example 27-6. Except for the view and column names, the code for populating the indexing metadata is fixed — use it each time you need to create a spatial index on a materialized view.

```
-- Populate spatial-indexing metadata

INSERT INTO USER_SDO_GEOM_METADATA
  VALUES ('GEO_DOC_VIEW',
          'SDO_VAL',
          MDSYS.sdo_dim_array(
            MDSYS.sdo_dim_element('Longitude', -180, 180, 0.05),
            MDSYS.sdo_dim_element('Latitude', -90, 90, 0.05)),
          7
          4326);

-- Create spatial index on geometry column of materialized view

CREATE INDEX geo_all_features_idx ON geo_doc_view(sdo_val)
  INDEXTYPE IS MDSYS.SPATIAL_INDEX V2;
```

  You can enhance the performance of queries that access particular JSON fields by creating, and indexing, a materialized view over such data that's defined using SQL/ JSON function `json_table`.

28
Overview of Performance Tuning for JSON

Which performance-tuning approaches you take depend on the needs of your application. Some query use cases and recommended tuning for them are outlined here.

Query use cases can be divided into two classes: searching for or accessing data based on values of JSON fields that occur (1) at most once in a given document or (2) possibly more than once.

> ✏️ **See Also:**
>
> JSON in Oracle Database: Performance Considerations

Queries That Access the Values of Fields That Occur at Most Once in a Given Document

You can tune the performance of such queries in the same ways as for non-JSON data. The choices of which JSON fields to define virtual columns for or which to index, whether to place the column containing your JSON data in the In-Memory Column Store (IM column store), and whether to create materialized views that project some of its fields, are analogous to the non-JSON case.

However, in the case of JSON data it is generally *more* important to apply at least one such performance tuning than it is in the case non-JSON data. Without any such performance aid, it is typically more expensive to access a JSON field than it is to access (non-JSON) column data, because a JSON document must be traversed to locate the data you seek.

Create virtual columns from JSON fields or index JSON fields:

- If your queries use simple and highly selective search criteria, for a *single JSON field*:
  - Define a virtual column on the field.

    You can often improve performance further by placing the table in the IM column store or creating an index on the virtual column.
  - Create a function-based index on the field using SQL/JSON function `json_value`.

- If your queries involve *more than one field*:
  - Define a virtual column on each of the fields.

    You can often improve performance further by placing the table in the IM column store or creating a composite index on the virtual columns.
  - Create a composite function-based index on the fields using multiple invocations of SQL/JSON function `json_value`, one for each field.

Queries That Access the Values of Fields That Can Occur More Than Once in a Given Document

In particular, this is the case when you access fields that are contained within an array.

There are four techniques you can use to tune the performance of such queries:

- Use a multivalue function-based index for SQL/JSON condition `json_exists`.

  This is possible only for JSON data that is stored as `JSON` data type. Such an index targets scalar JSON values, either individually or within a JSON array.

- Place the table that contains the JSON data in the IM column store.

- Use a JSON search index.

  This indexes all of the fields in a JSON document along with their values, including fields that occur inside arrays. The index can optimize any path-based search, including those using path expressions that include filters and full-text operators. The index also supports range-based searches on numeric values.

- Use a *materialized view* of non-JSON columns that are projected from JSON field values using SQL/JSON function `json_table`.

  You can generate a separate row from each member of a JSON array, using the `NESTED PATH` clause with `json_table`.

  A materialized view is typically used for optimizing SQL-based reporting and analytics for JSON content.

29

Indexes for JSON Data

You can index scalar values in your JSON data using function-based indexes. In addition, you can define a JSON search index, which is useful for both ad hoc structural queries and full-text queries.

- **Overview of Indexing JSON Data**
  You can index *particular scalar values* within your JSON data using function-based indexes. You can index JSON data in a general way using a JSON search index, for *ad hoc structural* queries and *full-text* queries.

- **How To Tell Whether a Function-Based Index for JSON Data Is Picked Up**
  Whether or not a particular index is picked up for a given query is determined by the optimizer. To determine whether a given query picks up a given function-based index, look for the index name in the execution plan for the query.

- **Creating Bitmap Indexes for JSON_VALUE**
  You can create a bitmap index for SQL/JSON function `json_value`. A bitmap index can be appropriate whenever your queries target only a small set of JSON values.

- **Creating B-Tree Indexes for JSON_VALUE**
  You can create a B-tree function-based index for SQL/JSON function `json_value`. You can use the standard syntax for this, explicitly specifying `json_value`, or you can use dot-notation syntax with an item method. Indexes created in either of these ways can be used with both dot-notation queries and `json_value` queries.

- **Using a JSON_VALUE Function-Based Index with JSON_TABLE Queries**
  An index created using `json_value` with `ERROR ON ERROR` can be used for a query involving `json_table`. In this case the index acts as a constraint on the indexed path, to ensure that only one (non-`null`) scalar JSON value is projected for each item in the JSON data.

- **Using a JSON_VALUE Function-Based Index with JSON_EXISTS Queries**
  An index created using SQL/JSON function `json_value` with `ERROR ON ERROR` can be used for a query involving SQL/JSON condition `json_exists`.

- **Data Type Considerations for JSON_VALUE Indexing and Querying**
  For a function-based index created using SQL/JSON function `json_value` to be picked up for a given query, the data type returned by `json_value` in the query must match the type specified in the index.

- **Creating Multivalue Function-Based Indexes for JSON_EXISTS**
  For JSON data that is stored as `JSON` data type you can use a multivalue function-based index for SQL/JSON condition `json_exists`. Such an index targets scalar JSON values, either individually or within a JSON array.

- **Using a Multivalue Function-Based Index**
  A `json_exists` query in a `WHERE` clause can pick up a multivalue function-based index if (and only if) the data that it targets matches the scalar types specified in the index.

- **Indexing Multiple JSON Fields Using a Composite B-Tree Index**
  To index multiple fields of a JSON object you can create a composite B-tree index using multiple path expressions with SQL/JSON function `json_value` or dot-notation syntax.

ORACLE®

29-1

- JSON Search Index for Ad Hoc Queries and Full-Text Search
  A JSON search index is a *general* index. It can improve the performance of both (1) ad hoc structural queries, that is, queries that you might not anticipate or use regularly, and (2) full-text search. It is an Oracle Text index that is designed specifically for use with JSON data.

29.1 Overview of Indexing JSON Data

You can index *particular scalar values* within your JSON data using function-based indexes. You can index JSON data in a general way using a JSON search index, for *ad hoc structural* queries and *full-text* queries.

As always, function-based indexing is appropriate for queries that target particular functions, which in the context of SQL/JSON functions means particular SQL/JSON *path expressions*. This indexing is not very helpful for queries that are ad hoc, that is, arbitrary. Define a function-based index if you know that you will often query a particular path expression.

Regardless of the SQL data type you use to store JSON data, you can use a *B-tree or bitmap function-based index* for SQL/JSON function `json_value` queries. Such an index targets a *single* scalar JSON value. A bitmap index can be appropriate wherever the number of possible values for the function is small. For example, you can use a bitmap index for `json_value` if the values targeted are expected to be few.

For JSON data that is stored as `JSON` type you can use a *multivalue function-based index* for SQL/JSON condition `json_exists`. Such an index targets *scalar* JSON values, either individually or (especially) as elements of a JSON array.

Although a multivalue index can index a single scalar value, if you expect a path expression to target such a value then it is more performant to use a B-tree or bitmap index. Use a multivalue index especially to index a path expression that you expect to target an *array* of scalar values.

SQL/JSON path expressions that contain *filter expressions* can be used in *queries* that pick up a function-based index. But a path expression that you use to define a function-based *index* cannot contain filter expressions.

If you query in an ad hoc manner then define a **JSON search index**. This is a general index, *not targeted* to any specific path expression. It is appropriate for *structural* queries, such as looking for a JSON field with a particular value, and for *full-text* queries using Oracle SQL condition `json_textcontains`, such as looking for a particular word among various string values.

You can of course define both function-based indexes and a JSON search index for the same JSON column.

A JSON search index is an Oracle Text (full-text) index designed specifically for use with JSON data.

> **Note:**
>
> Oracle recommends that you use AL32UTF8 as the database character set. Automatic character-set conversion can take place when creating or applying an index. Such conversion can be lossy, which can mean that some data that you might expect to be returned by a query is not returned. See Character Sets and Character Encoding for JSON Data.

Static dictionary views **DBA_JSON_INDEXES**, **ALL_JSON_INDEXES**, and **USER_JSON_INDEXES** describe all indexes on JSON data in the database, all of them that are accessible by the current user, and all of them that are owned by the current user, respectively.

For *composite* indexes, static dictionary views **DBA_TABLE_VIRTUAL_COLUMNS**, **ALL_TABLE_VIRTUAL_COLUMNS**, and **USER_TABLE_VIRTUAL_COLUMNS** provide information about virtual columns that are created automatically for indexing. They supplement the `*_JSON_INDEXES` views.

Related Topics

- Using GeoJSON Geographic Data
  GeoJSON objects are JSON objects that represent geographic data. Examples are provided of creating GeoJSON data, indexing it, and querying it.

- JSON Search Index for Ad Hoc Queries and Full-Text Search
  A JSON search index is a *general* index. It can improve the performance of both (1) ad hoc structural queries, that is, queries that you might not anticipate or use regularly, and (2) full-text search. It is an Oracle Text index that is designed specifically for use with JSON data.

- JSON Query Rewrite To Use a Materialized View Over JSON_TABLE
  You can enhance the performance of queries that access particular JSON fields by creating, and indexing, a materialized view over such data that's defined using SQL/JSON function `json_table`.

29.2 How To Tell Whether a Function-Based Index for JSON Data Is Picked Up

Whether or not a particular index is picked up for a given query is determined by the optimizer. To determine whether a given query picks up a given function-based index, look for the index name in the execution plan for the query.

For example:

- Given the index defined in Example 29-3, an execution plan for each of the queries in these examples references an index scan with index `po_num_id1`: Example 29-5, Example 29-6, Example 29-7, Example 29-8, and Example 29-10

- Given the index defined in Example 29-14, an execution plan for the queries in examples Example 29-17 and Example 29-18 references an index scan with index `mvi_1`.

When a multivalue index is picked up, the execution plan also shows `(MULTI VALUE)` for the index range scan, and the filter used in the plan is `JSON_QUERY`, not `JSON_EXISTS2`. If the

execution plan does *not* use a multivalue index for a given `json_exists` query, then the filter is `JSON_EXISTS2`.

Related Topics

- JSON Query Rewrite To Use a Materialized View Over JSON_TABLE
  You can enhance the performance of queries that access particular JSON fields by creating, and indexing, a materialized view over such data that's defined using SQL/JSON function `json_table`.

29.3 Creating Bitmap Indexes for JSON_VALUE

You can create a bitmap index for SQL/JSON function `json_value`. A bitmap index can be appropriate whenever your queries target only a small set of JSON values.

Example 29-1   Creating a Bitmap Index for JSON_VALUE

This is an appropriate index to create *provided* there are only a few possible values for field `CostCenter` in your data.

```
CREATE BITMAP INDEX cost_ctr_idx ON j_purchaseorder
  (json_value(po_document, '$.CostCenter'));
```

29.4 Creating B-Tree Indexes for JSON_VALUE

You can create a B-tree function-based index for SQL/JSON function `json_value`. You can use the standard syntax for this, explicitly specifying `json_value`, or you can use dot-notation syntax with an item method. Indexes created in either of these ways can be used with both dot-notation queries and `json_value` queries.

Example 29-3 creates a function-based index for `json_value` on field `PONumber` of the object that is in column `po_document` of table `j_purchaseorder`. The object is passed as the path-expression context item.

The use of `ERROR ON ERROR` here means that if the data contains a record that has *no* `PONumber` field, has *more than one* `PONumber` field, or has a `PONumber` field with a *non-number* value then index creation fails. And if the index exists then trying to insert such a record fails.

An alternative is to create an index using the dot-notation syntax described in Simple Dot-Notation Access to JSON Data, applying an item method to the targeted data. Example 29-2 illustrates this.

The indexes created in both Example 29-3 and Example 29-2 can be picked up for either a query that uses dot-notation syntax or a query that uses `json_value`.

If you want to allow indexing of data that might be missing the field targeted by a `json_value` expression, then use a `NULL ON EMPTY` clause, together with an `ERROR ON ERROR` clause. Example 29-4 illustrates this.

Oracle *recommends* that you create a function-based index for `json_value` using one of the following forms. In each case the index can be used in both dot-notation and `json_value` queries that lead to a scalar result of the specified JSON data type.

- Dot-notation syntax, with an item method applied to the value to be indexed. The indexed values are only scalars of the data type specified by the item method.

- A `json_value` expression that specifies a **RETURNING** data type. It can optionally use `ERROR ON ERROR` and `NULL ON EMPTY`. The indexed values are only scalars of the data type specified by the `RETURNING` clause.

Indexes created in either of these ways can thus be used with both dot-notation queries and `json_value` queries.

> **✎ See Also:**
>
> CREATE INDEX in *Oracle Database SQL Language Reference*

Example 29-2   Creating a Function-Based Index for a JSON Field: Dot Notation

Item method `number()` causes the index to be of numeric type. Always apply an item method to the targeted data when you use dot notation to create a function-based index.

```
CREATE UNIQUE INDEX po_num_idx1 ON j_purchaseorder po
  (po.po_document.PONumber.number());
```

> **✎ Note:**
>
> By default, a function-based index does not include `NULL` values. If a `json_value` expression that's used by an index returns `NULL`, then by default the index is not used when obtaining a matching document. This implies that by default a function-based index isn't used if `NULL` is used as filter predicate (for example, `json_value ... IS NULL`) or if `json_value` is used in an `ORDER BY` clause.
>
> To index `NULL` values, and thus enable the use of `json_value` in an `ORDER BY` clause you need to add a *constant* value (any value) to the index creation statement:
>
> ```
> CREATE INDEX po_num_idx1 ON j_purchaseorder po
>   (po.po_document.PONumber.number(), 42);
> ```
>
> This does, however, increase the index size.

Example 29-3   Creating a Function-Based Index for a JSON Field: JSON_VALUE

Item method `number()` causes the index to be of numeric type. Alternatively you can instead use clause `RETURNING NUMBER`.

```
CREATE UNIQUE INDEX po_num_idx2 ON j_purchaseorder
  (json_value(po_document, '$.PONumber.number()'
              ERROR ON ERROR));
```

Example 29-4   Specifying NULL ON EMPTY for a JSON_VALUE Function-Based Index

Clause `RETURNING VARCHAR2(200)` causes the index to be a SQL string of maximum length 200 characters. You could use item method `string()` in the path expression instead, but in that case the default return type of `VARCHAR2(4000)` is used.

Because of clause `NULL ON EMPTY`, index `po_ref_idx1` can index JSON documents that have no `Reference` field.

```
CREATE UNIQUE INDEX po_ref_idx1 ON j_purchaseorder
  (json_value(po_document, '$.Reference'
              RETURNING VARCHAR2(200) ERROR ON ERROR
              NULL ON EMPTY));
```

Related Topics

- Empty-Field Clause for SQL/JSON Query Functions
  SQL/JSON query functions `json_value`, `json_query`, and `json_table` accept an optional **ON EMPTY** clause, which specifies the handling to use when a targeted JSON field is absent from the data queried. This clause and the default behavior (no `ON EMPTY` clause) are described here.

- Using GeoJSON Geographic Data
  GeoJSON objects are JSON objects that represent geographic data. Examples are provided of creating GeoJSON data, indexing it, and querying it.

29.5 Using a JSON_VALUE Function-Based Index with JSON_TABLE Queries

An index created using `json_value` with `ERROR ON ERROR` can be used for a query involving `json_table`. In this case the index acts as a constraint on the indexed path, to ensure that only one (non-`null`) scalar JSON value is projected for each item in the JSON data.

For the index to be used in this way each of these conditions must hold:

- The query `WHERE` clause refers to a column projected by `json_table`.

- The data type of that column matches the data type used in the index definition.

- The effective SQL/JSON path that targets that column matches the indexed path expression.

The query in Example 29-5 thus makes use of the index created in Example 29-3.

> **Note:**
>
> A function-based index created using a `json_value` expression or dot notation can be picked up for a corresponding occurrence in a query `WHERE` clause only if the occurrence is used in a SQL *comparison* condition, such as `>=`. In particular, it is not picked up for an occurrence used in condition `IS NULL` or `IS NOT NULL`.
>
> See *Oracle Database SQL Language Reference* for information about SQL comparison conditions.

Example 29-5   Use of a JSON_VALUE Function-Based Index with a JSON_TABLE Query

The index can be picked up because the column SQL type, `NUMBER(5)`, matches the type used in the index.

```
SELECT jt.*
  FROM j_purchaseorder po,
       json_table(po.po_document, '$'
         COLUMNS po_number  NUMBER(5) PATH '$.PONumber',
                 reference  VARCHAR2(30 CHAR) PATH '$.Reference',
                 requestor  VARCHAR2(32 CHAR) PATH '$.Requestor',
                 userid     VARCHAR2(10 CHAR) PATH '$.User',
                 costcenter VARCHAR2(16 CHAR) PATH '$.CostCenter') jt
  WHERE po_number = 1600;
```

29.6 Using a JSON_VALUE Function-Based Index with JSON_EXISTS Queries

An index created using SQL/JSON function `json_value` with `ERROR ON ERROR` can be used for a query involving SQL/JSON condition `json_exists`.

In order for a `json_value` function-based index to be picked up for one of the comparisons of the query, the type of that comparison must be the same as the returning SQL data type for the index. The SQL data types used are those mentioned for item methods `double()`, `float()`, `number()`, `string()`, `timestamp()`, `date()`, `dateWithTime()`, `dsInterval()`, and `ymInterval()` — see SQL/JSON Path Expression Item Methods.

For example, if the index returns a number then the comparison type must also be number. If the query filter expression contains more than one comparison that matches a `json_value` index, the optimizer chooses one of the indexes.

The *type of a comparison* is determined as follows:

1. If the SQL data types of the two comparison terms (sides of the comparison) are different then the type of the comparison is *unknown*, and the index is not picked up. Otherwise, the types are the same, and this type is the type of the comparison.

2. If a comparison term is of SQL data type *string* (a text literal) then the type of the comparison is the *type of the other comparison term*.

3. If a comparison term is a *path expression* with a function step whose *item method imposes a SQL match type* then that is also the type of that comparison term. The item methods that impose a SQL match type are `double()`, `float()`, `number()`, `string()`, `timestamp()`, `date()`, `dateWithTime()`, `dsInterval()`, and `ymInterval()`.

4. If a comparison term is a *path expression* with *no* such function step then its type is SQL *string* (text literal).

Example 29-3 creates a function-based index for `json_value` on field `PONumber`. The index indexes `NUMBER` values.

Each of the queries Example 29-6, Example 29-7, and Example 29-8 can make use of this index when evaluating its `json_exists` condition. Each of these queries uses a comparison that involves a simple path expression that is relative to the absolute path expression `$.PONumber`. The relative simple path expression in each case targets the current filter item, `@`, but in the case of Example 29-8 it transforms (casts) the matching data to SQL data type `NUMBER`.

Example 29-6   JSON_EXISTS Query Targeting Field Compared to Literal Number

This query makes use of the index because:

1. One comparison term is a path expression with no function step, so its type is SQL *string* (text literal).

2. Because one comparison term is of type string, the comparison has the type of the other term, which is *number* (the other term is a numeral).

3. The type of the (lone) comparison is the same as the type returned by the index: *number*.

```
SELECT count(*) FROM j_purchaseorder
  WHERE json_exists(po_document, '$.PONumber?(@ > 1500)');
```

Example 29-7   JSON_EXISTS Query Targeting Field Compared to Variable Value

This query can make use of the index because:

1. One comparison term is a path expression with no function step, so its type is SQL *string* (text literal).

2. Because one comparison term is of type string, the comparison has the type of the other term, which is *number* (the other term is a variable that is bound to a number).

3. The type of the (lone) comparison is the same as the type returned by the index: *number*.

```
SELECT count(*) FROM j_purchaseorder
  WHERE json_exists(po_document, '$.PONumber?(@ > $d)'
                    PASSING 1500 AS "d");
```

Example 29-8   JSON_EXISTS Query Targeting Field Cast to Number Compared to Variable Value

This query can make use of the index because:

1. One comparison term is a path expression with a function step whose item method (`number()`) transforms the matching data to a *number*, so the type of that comparison term is SQL *number*.

2. The other comparison term is a numeral, which has SQL type *number*. The types of the comparison terms match, so the comparison has this same type, *number*.

3. The type of the (lone) comparison is the same as the type returned by the index: *number*.

```
SELECT count(*) FROM j_purchaseorder
  WHERE json_exists(po_document, '$.PONumber?(@.number() > $d)'
                    PASSING 1500 AS "d");
```

Example 29-9   JSON_EXISTS Query Targeting a Conjunction of Field Comparisons

Just as for Example 29-6, this query can make use of the index on field `PONumber`. If a `json_value` index is also defined for field `Reference` then the optimizer chooses which index to use for this query.

```
SELECT count(*) FROM j_purchaseorder
  WHERE json_exists(po_document,
                    '$?(@.PONumber > 1500
                        && @.Reference == "ABULL-20140421")');
```

Related Topics

- Creating B-Tree Indexes for JSON_VALUE
  You can create a B-tree function-based index for SQL/JSON function `json_value`. You can use the standard syntax for this, explicitly specifying `json_value`, or you can use dot-notation syntax with an item method. Indexes created in either of these ways can be used with both dot-notation queries and `json_value` queries.

- SQL/JSON Path Expressions
  Oracle Database provides SQL access to JSON data using SQL/JSON path expressions.

- JSON Query Rewrite To Use a Materialized View Over JSON_TABLE
  You can enhance the performance of queries that access particular JSON fields by creating, and indexing, a materialized view over such data that's defined using SQL/JSON function `json_table`.

29.7 Data Type Considerations for JSON_VALUE Indexing and Querying

For a function-based index created using SQL/JSON function `json_value` to be picked up for a given query, the data type returned by `json_value` in the query must match the type specified in the index.

When `RETURNING DATE` is used with `json_value`, the same time-handling behavior (truncation or preservation) must be used in both the index and the query, for the index to be picked up. That is, either `RETURNING DATE PRESERVE TIME` must be used in both, or `RETURNING DATE TRUNCATE TIME` (or `RETURNING DATE`, since truncation is the default behavior) must be used in both.

By default, SQL/JSON function `json_value` returns a VARCHAR2 value. When you create a function-based index using `json_value`, unless you use a RETURNING clause or an item method to specify a different return data type, the index is not picked up for a query that expects a non-VARCHAR2 value.

For example, in the query of Example 29-10, `json_value` uses RETURNING NUMBER. The index created in Example 29-3 can be picked up for this query, because the indexed `json_value` expression specifies a return type of NUMBER. Without keywords RETURNING NUMBER in the index the return type it specifies would be VARCHAR2(4000) (the default) — the index would not be picked up for such a query.

Similarly, the index created in Example 29-2 can be picked up for the query because it uses item method `number()`, which also imposes a return type of NUMBER.

Now consider the queries in Example 29-11 and Example 29-12, which use `json_value` without a RETURNING clause, so that the value returned is of type VARCHAR2.

In Example 29-11, SQL function `to_number` explicitly converts the VARCHAR2 value returned by `json_value` to a number. Similarly, in Example 29-12, comparison condition > (greater-than) implicitly converts the value to a number.

Neither of the indexes of Example 29-3 and Example 29-2 is picked up for either of these queries. The queries might return the right results in each case, because of type-casting, but the indexes cannot be used to evaluate the queries.

Consider also what happens if some of the data cannot be converted to a particular data type. For example, given the queries in Example 29-10, Example 29-11, and Example 29-12, what happens to a PONumber value such as "alpha"?

For Example 29-11 and Example 29-12, the query stops in error because of the attempt to cast the value to a number. For Example 29-10, however, because the default error handling behavior is NULL ON ERROR, the non-number value "alpha" is simply filtered out. The value is indexed, but it is ignored for the query.

Similarly, if the query used, say, DEFAULT '1000' ON ERROR, that is, if it specified a numeric default value, then no error would be raised for the value "alpha": the default value of 1000 would be used.

> **✎ Note:**
>
> For a function-based index based on SQL/JSON function `json_value` to be picked up for a given query, the same return data type and handling (error, empty, and mismatch) must be used in both the index and the query.
>
> This means that if you *change* the return type or handling in a query, so that it no longer matches what is specified in the index, then you must *rebuild* any persistent objects that depend on that query pattern. (The same applies to materialized views, partitions, check constraints and PL/SQL subprograms that depend on that pattern.)

Example 29-10   JSON_VALUE Query with Explicit RETURNING NUMBER

```
SELECT count(*) FROM j_purchaseorder po
  WHERE json_value(po_document, '$.PONumber' RETURNING NUMBER) > 1500;
```

Example 29-11   JSON_VALUE Query with Explicit Numerical Conversion

```
SELECT count(*) FROM j_purchaseorder po
  WHERE to_number(json_value(po_document, '$.PONumber')) > 1500;
```

Example 29-12   JSON_VALUE Query with Implicit Numerical Conversion

```
SELECT count(*) FROM j_purchaseorder po
  WHERE json_value(po_document, '$.PONumber') > 1500;
```

29.8 Creating Multivalue Function-Based Indexes for JSON_EXISTS

For JSON data that is stored as `JSON` data type you can use a multivalue function-based index for SQL/JSON condition `json_exists`. Such an index targets scalar JSON values, either individually or within a JSON array.

The main use of a multivalue index is to index scalar values within arrays. This includes scalar array elements, but also scalar field values of object array elements.

A multivalue index can also index a single scalar value, but for queries that target a single value it is generally more performant to use a B-tree or bitmap index.

In a query, you use `json_exists` in the `WHERE` clause of a `SELECT` statement. Condition `json_exists` returns true if the data it targets matches the SQL/JSON path expression (or equivalent simple dot-notation syntax) in the query. Otherwise it returns false. It is common for the path expression to include a filter expression — matching then requires that the targeted data satisfy that filter.

You create a multivalue index using `CREATE INDEX` with keyword **MULTIVALUE**, and using either the syntax of SQL/JSON function `json_table` or simple dot-notation that you use in queries to specify the path to the indexed data. (However, you *cannot* use a SQL `NESTED` clause in place of `json_table` — a compile-time error is raised if you do that.)

You can create a *composite* function-based index, to index more than one virtual column, that is, more than one JSON field. A composite index acts like a *set* of function-based indexes. When used to query, you use function `json_table` to project specified JSON field values as virtual columns of SQL scalar values. Similarly, when used to define an index, the field values that `json_table` specifies are indexed as a composite function-based index.

When using `json_table` syntax to create a multivalue index you *must* use these error-handling clauses: `ERROR ON ERROR NULL ON EMPTY NULL ON MISMATCH`; otherwise, a query compile-time error is raised. When using simple dot-notation syntax without `json_table`, the behavior of these clauses is provided implicitly.

When using `json_table` syntax you can use a `FOR ORDINALITY` clause, to enable use of the index for queries that target specific array positions. (See COLUMNS Clause of SQL/JSON Function JSON_TABLE.)

For a multivalue index to be picked up by a query, the index must specify the SQL type of the data to be indexed, and the SQL type for the query result must match the type specified by the index.

If you create a non-composite multivalue index, that is, without using `json_table` syntax, then the index specification *must* include a *data-type conversion item method* (other than `binary()` and `dateWithTime()`), to indicate the SQL data type. See SQL/ JSON Path Expression Item Methods for information about the data-type conversion item methods.

If the index uses an item method with "only" in its name then only queries that use that same item method can pick up the index. Otherwise (with a non-"only" method or with no method), any query that targets a scalar value (possibly as an array element) that *can be converted* to the type indicated by the item method can pick up the index.

For example, a multivalue index that uses item method `numberOnly()` can only be picked up for a query that also uses `numberOnly()`. But an index that uses `number()`, or that uses no item method, can be picked up for a query that matches any scalar (such as the string `"3.14"`) that can be converted to a number.

If you create a *composite* multivalue index then the `json_table` virtual column type specifies the SQL type to use. This means that queries of data that *can be converted to* the specified SQL type can pick up the index.

However, just as in the non-composite index case, you can use a data-type conversion item method with "only" in its name, to override (further constrain) the specified column type. You use the item method in the column path expression.

For example, if the column type is specified as `NUMBER` then queries with matching data (such as the string `"3.14"`) that can be converted to a number can pick up the index. But if the column path expression uses item method `numberOnly()` then only queries that also use `numberOnly()` can pick up the index.

You can create more than one multivalue index for a given target. For example, you can create one index for a field `month` that uses item method `number()` and another for the same field that uses item method `string()`.

The following are *not* allowed, as ways to create a multivalue index:

- You cannot specify *sibling nested arrays* in the `json_table` expression used to create a composite multivalue index. An error is raised if you try. You can index multiple arrays, but they cannot be siblings, that is, they cannot have the same parent field.

- Using a SQL `NESTED` clause (see SQL NESTED Clause Instead of JSON_TABLE).

A type-error mismatch between the type of a scalar JSON value and the corresponding scalar SQL data type of a `json_table` virtual column can be because of type incompatibility, as put forth in Table 17-2, or because the SQL data type is too constraining — too small to store the data.

Error-handling `ERROR ON ERROR NULL ON EMPTY NULL ON MISMATCH` returns SQL `NULL` for the first kind of mismatch, but it raises an error for the second kind. For example, type incompatibility is tolerated when creating an index with SQL type `NUMBER` for JSON string data, but an error is raised if you try to create an index using SQL type `VARCHAR(2)` for data that has a JSON string value of `"hello"`, because the data has more than two characters.

Example 29-13   Table PARTS_TAB, for Multivalue Index Examples

Table `parts_tab`, with `JSON` data type column `jparts`, is used in multivalue index examples here. The JSON data includes field `subparts` whose value is an array with scalar elements.

```
CREATE TABLE parts_tab (id NUMBER, jparts JSON);

INSERT INTO parts_tab VALUES
  (1, '{"parts" : [{"partno"   : 3, "subparts" : [510, 580, 520]},
                   {"partno"   : 4, "subparts" : 730}]}');

INSERT INTO parts_tab VALUES
  (2, '{"parts" : [{"partno"   : 7, "subparts" : [410, 420, 410]},
                   {"partno"   : 4, "subparts" : [710, 730, 730]}]}');
```

Example 29-14   Creating a Multivalue Index for JSON_EXISTS

The multivalue index created here indexes the value of field `subparts`. The table alias (`t` in this case) is required when using simple dot notation syntax.

If the `subparts` value targeted by a query is an *array* then the index can be picked up for any array elements that are numbers. If the value is a *scalar* then the index can be picked up if the scalar is a number.

Given the data in table `parts_tab`, a `subparts` field in each of the objects of array `parts` in the first row (which has `id 1`) is indexed: the field in the first object because its array value has elements that are numbers (`510`, `580`, and `520`) the field in the second object because its value is a number (`730`).

If item method `number()` were used in the index definition, instead of `numberOnly()`, then non-number scalar values (such as the string `"730"`) that can be converted to numbers would also be indexed.

```
CREATE MULTIVALUE INDEX mvi ON parts_tab t
  (t.jparts.parts.subparts.numberOnly());
```

Example 29-15   Creating a Composite Multivalue Index for JSON_EXISTS

This example shows two equivalent ways to create a composite multivalue index that targets both field `partno` and field `subparts`. The composite index acts like a set of two function-based indexes that target those two fields.

The first query uses `json_table` syntax with a SQL/JSON path expression for the row pattern, `$.parts[*]`. The second uses simple dot notation for the row pattern. Otherwise, the code is the same for both. As must always be the case for multivalue index creation using `json_table`, the error handling is specified as `ERROR ON ERROR NULL ON EMPTY NULL ON MISMATCH`.

Column `PARTNUM` is given SQL data type `NUMBER(10)` here, which means that, for the index to be used for a query that targets field `partno`, the value of that field must be convertible to that data type.

- If type conversion is impossible because the types are generally incompatible, as put forth in Table 17-2, then the `NULL ON MISMATCH` error handler causes SQL `NULL` to be

returned. An example of this would be a `partno` string value of `"hello"` for the SQL `partNum` column of type `NUMBER(10)`.

- If, on the other hand, the SQL data type storage is too constraining then an error is raised — the index is not created. An example of this would be a `partno` string with more than 10 characters, such as `"1234567890123"`.

```
CREATE MULTIVALUE INDEX cmvi_1 ON parts_tab
  (json_table(jparts, '$.parts[*]'
    ERROR ON ERROR NULL ON EMPTY NULL ON MISMATCH
    COLUMNS (partNum NUMBER(10) PATH '$.partno',
      NESTED
        PATH '$.subparts[*]'
        COLUMNS (subpartNum NUMBER(20) PATH '$'))));
```

```
CREATE MULTIVALUE INDEX cmvi_1 ON parts_tab t
  (t.jparts.parts[*]
  ERROR ON ERROR NULL ON EMPTY NULL ON MISMATCH
  COLUMNS (partNum NUMBER(10) PATH '$.partno',
    NESTED subparts[*]
      COLUMNS (subpartNum NUMBER(20) PATH '$'))));
```

Example 29-16   Creating a Composite Multivalue Index That Can Target Array Positions

The code in this example is like that in Example 29-15, except that it also specifies virtual column `SEQ` for ordinality. That means that values in the column just before it, `SUBPARTNUM`, can be accessed by way of their (one-based) positions in array `subparts`. (The SQL data type of a `FOR ORDINALITY` column is always `NUMBER`.)

As always, at most one entry in a `COLUMNS` clause can be a column name followed by `FOR ORDINALITY`, which specifies a column of generated row numbers (SQL data type `NUMBER`), starting with one. Otherwise, an error is raised when creating the index.

In addition to that general rule for `json_table` syntax:

- When `json_table` is used to create a multivalue index, the `FOR ORDINALITY` column must be the *last* column of json_table. (This is not required when `json_table` is used in queries; it applies only to index creation.)

- In order for a multivalue index created using `json_table` *to be picked up* for a given query, the query must apply a filter expression to the JSON field corresponding to the *first* virtual column of the `json_table` expression.

In order for a query that targets array elements by their *position* to pick up a multivalue index for array positions, the index column for those array elements must be the one *immediately before* the `FOR ORDINALITY` column

(The code here uses simple dot notation for the row pattern; if it instead used a SQL/JSON path expression for the row pattern, the rest of the code would be the same.)

```
CREATE MULTIVALUE INDEX cmvi_2 ON parts_tab t
  (t.jparts.parts[*]
  ERROR ON ERROR NULL ON EMPTY NULL ON MISMATCH
  COLUMNS (partNum NUMBER(10) PATH '$.partno',
```

```
        NESTED subparts[*]
          COLUMNS (subpartNum NUMBER(20) PATH '$',
                   seq FOR ORDINALITY))));
```

- SQL/JSON Path Expression Item Methods
  The Oracle item methods available for a SQL/JSON path expression are presented. How
  they act on targeted JSON data is described in general terms and for each item method.

- Overview of Indexing JSON Data
  You can index *particular scalar values* within your JSON data using function-based
  indexes. You can index JSON data in a general way using a JSON search index, for *ad
  hoc structural* queries and *full-text* queries.

- Using a Multivalue Function-Based Index
  A `json_exists` query in a `WHERE` clause can pick up a multivalue function-based index if
  (and only if) the data that it targets matches the scalar types specified in the index.

- SQL/JSON Function JSON_TABLE
  SQL/JSON function `json_table` projects specific JSON data to columns of various SQL
  data types. You use it to map parts of a JSON document into the rows and columns of a
  new, virtual table, which you can also think of as an inline view.

- ON MISMATCH Clause for SQL/JSON Query Functions
  You can use an **ON MISMATCH** clause with SQL/JSON functions `json_value`, `json_query`,
  and `json_table`, to handle type-matching exceptions. It specifies handling to use when a
  targeted JSON value does not match the specified SQL return value. This clause and its
  default behavior (no `ON MISMATCH` clause) are described here.

29.9 Using a Multivalue Function-Based Index

A `json_exists` query in a `WHERE` clause can pick up a multivalue function-based index if (and
only if) the data that it targets matches the scalar types specified in the index.

A multivalue function-based index for SQL/JSON condition `json_exists` targets scalar JSON
values, either individually or as elements of a JSON array. You can define a multivalue index
only for JSON data that is stored as `JSON` data type.

Condition `json_exists` returns true if the data it targets matches the SQL/JSON path
expression (or equivalent simple dot-notation syntax) in the query. Otherwise it returns false.
It is common for the path expression to include a filter expression — matching then requires
that the targeted data satisfy that filter.

A multivalue index that is defined using a data-type conversion item method (such as
`numberOnly()`) that has "only" in its name can be picked up only by `json_exists` queries that
also use that same item method. That is, the *query must use the same item method explicitly*.
See Creating Multivalue Function-Based Indexes for JSON_EXISTS for more information.

A multivalue index defined using no item method, or using a data-type conversion item
method (such as `number()`) that does *not* have "only" in its name, can be picked up by a
query that targets a scalar value (possibly as an array element) that *can be converted* to the
type indicated by the item method. See SQL/JSON Path Expression Item Methods for
information about the data-type conversion item methods.

The examples here use SQL/JSON condition `json_exists` in a `WHERE` clause to check for a
`subparts` field value that matches `730`. They are discussed in terms of whether they can pick

up multivalue indexes `mvi`, `cmvi_1`, and `cmvi_2`, which are defined in Creating Multivalue Function-Based Indexes for JSON_EXISTS. Conversion of JSON scalar values to SQL scalar values is specified in Table 17-2.

Example 29-17   JSON_EXISTS Query With Item Method numberOnly()

This example uses item method `numberOnly()` in a `WHERE` clause. The query can pick up index `mvi` when the path expression targets either a *numeric* `subparts` value of `730` (e.g. `subparts : 730`) or an array `subparts` value with one or more *numeric* elements of `730` (e.g. `subparts:[630, 730, 690, 730]`). It *cannot* pick up index `mvi` for targeted *string* values of "730" (e.g. `subparts:"730"` or `subparts:["630", "730", 690, "730"]`).

If index `mvi` had instead been defined used item method `number()`, then this query could pick up the index for a numeric `subparts` value of `730`, a string `subparts` value of "730", or an array `subparts` value with numeric elements of `730` or string elements of "730".

```
SELECT count(*) FROM parts_tab
  WHERE json_exists(jparts, '$.parts.subparts?(@.numberOnly() ==
730)');
```

Example 29-18   JSON_EXISTS Query Without Item Method numberOnly()

These two queries do *not* use item method `numberOnly()`. The first uses method `number()`, which converts the targeted data to a number, if possible. The second does no type conversion of the targeted data.

Index `mvi` *cannot* be picked up by either of these queries, even if the targeted data is the number `730`. For the index to be picked up, a query *must* use `numberOnly()`, because the index is *defined* using `numberOnly()`.

```
SELECT count(*) FROM parts_tab t
  WHERE json_exists(jparts, '$.parts.subparts?(@.number() == 730)');

SELECT count(*) FROM parts_tab t
  WHERE json_exists(jparts, '$.parts.subparts?(@ == 730)');
```

Example 29-19   JSON_EXISTS Query Checking Multiple Fields

The filter expression in this query specifies the existence of a `partno` field that matches the SQL `NUMBER` value `4` (possibly by conversion from a JSON string), and a field `subparts` that matches the number `730`.

The query can pick up either of the indexes `cmvi_1` or `cmvi_2`. Both rows of the data match these indexes, because each row has a `parts.partno` value that matches the number `4` and a `parts.subparts` value that matches the number `730`. For the `subparts` match, the first row has a `subparts` value of `730`, and the second row has a `subparts` value that is an array with a value of `730`.

```
SELECT a FROM parts_tab
  WHERE json_exists(jparts,'$.parts[*]?(@.partno == 4 &&
                                        @.subparts == 730)');
```

Example 29-20   JSON_EXISTS Query Checking Array Element Position

This example is similar to Example 29-19, but in addition to requiring that field `partno` match the number `4`, the filter expression here requires that the value of field `subparts` match an *array* of at least two elements, and that the second element of the array match the number `730`.

This query can pick up index `cmvi_2`, including for positional predicate `[1]`. Index `cmvi_2` specifies virtual column `subpartNum`, which corresponds to JSON field `subparts`, as the penultimate column, just before the final, `FOR ORDINALITY`, column.

This query could also pick up index `cmvi_1`, but that index has no `FOR ORDINALITY` column, so making use of it would require an extra step, to evaluate the array-position condition, `[1]`. Using index `cmvi_2` requires no such extra step, so it is more performant for such queries.

```
SELECT a FROM parts_tab
  WHERE json_exists(jparts,'$.parts[*]?(@.partno == 4 &&
                                       @.subparts[1] == 730)');
```

  The Oracle item methods available for a SQL/JSON path expression are presented. How they act on targeted JSON data is described in general terms and for each item method.

* Overview of Indexing JSON Data
  You can index *particular scalar values* within your JSON data using function-based indexes. You can index JSON data in a general way using a JSON search index, for *ad hoc structural* queries and *full-text* queries.

* SQL/JSON Function JSON_TABLE
  SQL/JSON function `json_table` projects specific JSON data to columns of various SQL data types. You use it to map parts of a JSON document into the rows and columns of a new, virtual table, which you can also think of as an inline view.

* ON MISMATCH Clause for SQL/JSON Query Functions
  You can use an **ON MISMATCH** clause with SQL/JSON functions `json_value`, `json_query`, and `json_table`, to handle type-matching exceptions. It specifies handling to use when a targeted JSON value does not match the specified SQL return value. This clause and its default behavior (no `ON MISMATCH` clause) are described here.

29.10 Indexing Multiple JSON Fields Using a Composite B-Tree Index

To index multiple fields of a JSON object you can create a composite B-tree index using multiple path expressions with SQL/JSON function `json_value` or dot-notation syntax.

Example 29-21 illustrates this. A SQL query that references the corresponding JSON data (object fields) picks up the composite index. Example 29-22 illustrates this.

Alternatively, you can create virtual columns for the JSON object fields you want to index, and then create a composite B-tree index on those virtual columns. In that case a SQL query that references either the virtual columns or the corresponding JSON data (object fields) picks up the composite index. The query performance is the same in both cases.

The data does not depend logically on any indexes that are implemented to improve query performance. If you want this independence from implementation to be reflected in your code, then query the data directly (not virtual columns). Doing that ensures that the query behaves the same with or without the index — the index serves only to improve performance.

Example 29-21   Creating a Composite B-tree Index For JSON Object Fields

```
CREATE INDEX user_cost_ctr_idx ON
  j_purchaseorder(json_value(po_document, '$.User'
                             RETURNING VARCHAR2(20),
                  json_value(po_document, '$.CostCenter'
                             RETURNING VARCHAR2(6)));
```

Example 29-22   Querying JSON Data Indexed With a Composite B-tree Index

```
SELECT po_document FROM j_purchaseorder
  WHERE json_value(po_document, '$.User')       = 'ABULL'
    AND json_value(po_document, '$.CostCenter') = 'A50';
```

  You can enhance the performance of queries that access particular JSON fields by creating, and indexing, a materialized view over such data that's defined using SQL/JSON function json_table.

29.11 JSON Search Index for Ad Hoc Queries and Full-Text Search

A JSON search index is a *general* index. It can improve the performance of both (1) ad hoc structural queries, that is, queries that you might not anticipate or use regularly, and (2) full-text search. It is an Oracle Text index that is designed specifically for use with JSON data.

Full-text querying of JSON data is covered in Full-Text Search Queries. The present topic covers the creation and maintenance of JSON search indexes, which are required for full-text search and are also useful for ad hoc queries. Examples of *ad hoc* queries that are supported by a JSON search index are presented here.

Create a JSON search index for queries that involve full-text search. Create a JSON search index also for queries that aren't particularly expected or used regularly — that is, **ad hoc queries**. But to index queries for which you know the query pattern ahead of time, it's generally advisable to use a *function-based* index that targets such a specific pattern. If both function-based and JSON search indexes are applicable to given a query, it is the function-based index that's used.

For JSON data stored as JSON type, an alternative to creating and maintaining a JSON search index is to populate the JSON column into the In-Memory Column Store (IM column store) — see In-Memory JSON Data.

> **Note:**
>
> If you created a JSON search index using Oracle Database 12c Release 1 (12.1.0.2) then Oracle recommends that you *drop* that index and *create a new search index* for use with later releases, using `CREATE SEARCH INDEX` as shown here.

> **Note:**
>
> You **must rebuild** any JSON search indexes and Oracle Text indexes created prior to Oracle Database 18c if they index JSON data that contains object fields with names longer than 64 bytes. Otherwise, such fields might not be searchable until they are reindexed. See *Oracle Database Upgrade Guide* for more information.

You create a JSON search index using `CREATE SEARCH INDEX` with the keywords `FOR JSON`. Example 29-23 and Example 29-24 illustrate this.

The column on which you create a JSON search index can be of data type `JSON`, `VARCHAR2`, `CLOB`, or `BLOB`. It must be known to contain only well-formed JSON data, which means that it is either of type `JSON` or it has an `is json` check constraint. `CREATE SEARCH INDEX` raises an error if the column is not known to contain JSON data.

If the name of your JSON search index is present in the execution plan for your query, then you know that the index is in fact picked up for that query. You will see a line similar to that shown in Example 29-25.

You can specify a **PARAMETERS** clause when creating a search index, to override the default settings of certain configurable options. By default (no `PARAMETERS` clause), the index is *automatically maintained* — it is synchronized in the background, and both text and numeric ranges are indexed.

If your queries that make use of a JSON search index involve only full-text search or string-equality search, and never involve string-range search or numeric or temporal search (equality or range), then you can save some index maintenance time and disk space by specifying **TEXT** for parameter **SEARCH_ON**. The default value of `SEARCH_ON` is `TEXT_VALUE`, which means index numeric ranges as well as text.

By default, a JSON search index is maintained *asynchronously*. This can reduce the negative effect that synchronization can have on DML operations. (Until it is synchronized, an index doesn't reflect the addition or modification of data. Deletions are reflected immediately, however, even without synchronization.)

By default, a JSON search index is automatically synced in the background. You can override this behavior by modifying the index's synchronization settings for different use cases:

- Synchronize on commit.

  This is appropriate when commits are infrequent and it is important that the committed changes be immediately visible to other operations (such as queries). (A stale index can result in uncommitted changes not being visible.) Example 29-24 creates a search index that is synchronized on commit.

- Synchronize on demand, for example at a time when database load is reduced.

You generally do this infrequently — the index is synchronized less often than with on-commit or interval synchronizing. This method is typically appropriate when DML performance is particularly important.

If you need to invoke procedures in package `CTX_DDL`, such as `CTX_DDL.sync_index` to manually sync the index, then you need privilege `CTXAPP`.

Static dictionary view `CTX_USER_INDEXES` contains information about existing Oracle Text indexes, including JSON search indexes. For example, this query lists the synchronization and maintenance types for all Oracle Text indexes:

```
SELECT IDX_NAME, IDX_SYNC_TYPE, IDX_MAINTENANCE_TYPE FROM
CTX_USER_INDEXES;
```

> **Note:**
>
> To alter a JSON search index `j_s_idx`, you use `ALTER INDEX j_s_idx REBUILD ...` (*not* `ALTER SEARCH INDEX j_s_idx ...`).

Example 29-23   Creating a JSON Search Index with Default Behavior

This example creates a JSON search index that has the default behavior: it is automatically maintained (it is synchronized in the background), and both text and numeric ranges are indexed.

```
CREATE SEARCH INDEX po_search_idx ON j_purchaseorder (po_document)
  FOR JSON;
```

This code is equivalent. It uses the PARAMETERS clause to explicitly specify automatic maintenance.

```
CREATE SEARCH INDEX po_search_idx ON j_purchaseorder (po_document)
  FOR JSON PARAMETERS ('MAINTENANCE AUTO');
```

Example 29-24   Creating a JSON Search Index That Is Synchronized On Commit

This example uses a PARAMETERS clause to create an index that synchronizes new data on COMMIT.

```
CREATE SEARCH INDEX po_search_idx ON j_purchaseorder (po_document)
  FOR JSON PARAMETERS ('SYNC (ON COMMIT)');
```

Example 29-25   Execution Plan Indication that a JSON Search Index Is Used

```
|* 2|   DOMAIN INDEX     | PO_SEARCH_IDX |      |     |    4 (0)
```

Ad Hoc Queries of JSON Data

Example 29-26 shows some *non* full-text queries of JSON data that also make use of the JSON search index created in Example 29-24.

Example 29-26   Some Ad Hoc JSON Queries

This query selects documents that contain a shipping instructions address that includes a country.

```
SELECT po_document FROM j_purchaseorder
  WHERE json_exists(po_document,
                    '$.ShippingInstructions.Address.country');
```

This query selects documents that contain user `AKHOO` where there are more than 8 items ordered. It takes advantage of numeric-range indexing.

```
SELECT po_document FROM j_purchaseorder
  WHERE json_exists(po_document, '$?(@.User == "AKHOO"
                                    && @.LineItems.Quantity > 8)');
```

This query selects documents where the user is `AKHOO`. It uses `json_value` instead of `json_exists` in the `WHERE` clause.

```
SELECT po_document FROM j_purchaseorder
  WHERE json_value(po_document, '$.User') = 'AKHOO';
```

30.1 Overview of In-Memory JSON Data

You can populate JSON data into the In-Memory Column Store (IM column store), to improve the performance of ad hoc and full-text queries.

Using the IM column store for JSON data is especially useful for ad hoc analytical queries that scan a large number of small JSON documents.

If a JSON column is of data type `JSON` then you can also use the IM column store to provide support for full-text search. (`JSON` type is available only if database initialization parameter `compatible` is at least `20`.)

> **Note:**
>
> An alternative to placing a JSON column in the IM column store is to create a JSON search index on the column. This provides support for both ad hoc queries and full-text search.
>
> If a JSON search index is defined for a JSON column (of any data type), and that column is also populated into the IM column store, then the search index, *not* the IM column store, is used for queries of that column.
>
> Unlike the case for using the IM column store to support full-text search, JSON search index support is available for any JSON column, not just a column of data type `JSON`.

The IM column store is supported only for JSON documents smaller than 32,767 bytes. If you have a mixture of document sizes, those documents that are larger than 32,767 bytes are processed without the In-Memory optimization. For better performance, consider breaking up documents larger than 32,767 bytes into smaller documents.

The IM column store is an optional SGA pool that stores copies of tables and partitions in a special columnar format optimized for rapid scans. The IM column store supplements the row-based storage in the database buffer cache. You do not need to load the same object into both the IM column store and the buffer cache. The two caches are kept transactionally consistent. The database transparently sends online transaction processing (OLTP) queries (such as primary-key lookups) to the buffer cache and analytic and reporting queries to the IM column store.

You can think of the use of JSON data in memory as improving the performance of SQL/JSON path access. SQL functions and conditions `json_table`, `json_query`, `json_value`, `json_exists`, and `json_textcontains` all accept a SQL/JSON path argument, and they can all benefit from loading JSON data into the IM column store.

Once JSON documents have been loaded into memory, any subsequent path-based operations on them use the In-Memory representation, which avoids the overhead associated with reading the on-disk format.

If queried JSON data is populated into the IM column store, and if there are function-based indexes that can apply to that data, the optimizer chooses whether to use an index or to scan the data in memory. In general, if index probing results in few documents then a functional index can be preferred by the optimizer. In practice this means that the optimizer can prefer a functional index for very selective queries or DML statements.

On the other hand, if index probing results in many documents then the optimizer might choose to scan the data in memory, by scanning the function-based index expression as a virtual-column expression.

Ad hoc queries, that is, queries that are not used frequently to target a given SQL/JSON path expression, benefit in a general way from populating JSON data into the IM column store, by quickly scanning the data. But if you have some frequently used queries then you can often further improve their performance in these ways:

- Creating *virtual columns* that project scalar values (not under an array) from a column of JSON data and loading those virtual columns into the IM column store.

- Creating a *materialized view* on a frequently queried `json_table` expression and loading the view into the IM column store.

However, if you have a function-based index that projects a scalar value using function `json_value` then you need not explicitly create a virtual column to project it. As mentioned above, in this case the function-based index expression is automatically loaded into the IM column store as a virtual column. The optimizer can choose, based on estimated cost, whether to scan the function-based index in the usual manner or to scan the index expression as a virtual-column expression.

> **Note:**
>
> - The advantages of a virtual column over a materialized view are that you can build an index on it and you can obtain statistics on it for the optimizer.
>
> - The number of virtual columns per table is limited by the value of initialization parameter `MAX_COLUMNS`. By default that value is `STANDARD`, which means 1000 columns maximum. See MAX_COLUMNS in *Oracle Database Reference*.

> **Note:**
>
> A table with one or more columns of `JSON` data type has an additional, *hidden* virtual column for each such column. It has a system-generated name, which starts with `SYS_IME_OSON_`. As it is virtual, it does not use any space.
>
> This hidden column is used when data is loaded into the IM column store, to optimize in-memory performance. It's not listed when you use a `describe` command, and it's not affected by a `SELECT *` query. It is however listed when you query dictionary views such as `USER_TAB_COLS`.

Prerequisites For Using JSON Data In Memory

To be able to take advantage of the IM column store for JSON data, the following must *all* be true:

- Database compatibility is 12.2.0.0 or higher. For full-text support it must be 20 or higher.

- The value set for `max_string_size` in the Oracle instance start-up configuration file must be `'extended'`.

- Sufficient SGA memory must be configured for the IM column store.

- A DBA has specified that the tablespace, table, or materialized view that contains the JSON columns is eligible for population into the IM column store, using keyword `INMEMORY` in a `CREATE` or `ALTER` statement.

- Initialization parameters are set as follows:

  - `IMMEMORY_EXPRESSIONS_USAGE` is `STATIC_ONLY` or `ENABLE`.

    `ENABLE` allows In-Memory materialization of dynamic expressions, if used in conjunction with PL/SQL procedure `DBMS_INMEMORY.ime_capture_expressions`.

- – `IMMEMORY_VIRTUAL_COLUMNS` is `ENABLE`, meaning that the IM column store populates all virtual columns. (The default value is `MANUAL`.)
- The columns storing the JSON data must be known to contain well-formed JSON data. This is the case if the column is of `JSON` data type or it has an `is json` check constraint.

You can check the value of each initialization parameter using command `SHOW PARAMETER`. (You must be logged in as database user `SYS` or equivalent for this.) For example:

```
SHOW PARAMETER INMEMORY_VIRTUAL_COLUMNS
```

Related Topics

- Populating JSON Data Into the In-Memory Column Store
  Use `ALTER TABLE … INMEMORY` to populate a column of JSON data, or a table with such a column, into the In-Memory Column Store (IM column store), to improve the performance of JSON queries.

- Oracle SQL Condition JSON_TEXTCONTAINS
  You can use Oracle SQL condition `json_textcontains` in a `CASE` expression or the `WHERE` clause of a `SELECT` statement to perform a full-text search of JSON data.

- Support for RFC 8259: JSON Scalars
  Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

> **See Also:**
>
> *Oracle Database Reference* for information about parameter
> `INMEMORY_VIRTUAL_COLUMNS`

30.2 Populating JSON Data Into the In-Memory Column Store

Use `ALTER TABLE … INMEMORY` to populate a column of JSON data, or a table with such a column, into the In-Memory Column Store (IM column store), to improve the performance of JSON queries.

You specify that a table with one or more columns of JSON data is to be populated into the IM column store, by marking the table as **INMEMORY**. Example 30-1 illustrates this.

A column is guaranteed to contain only well-formed JSON data if (1) it is of data type `JSON` or (2) it is of type `VARCHAR2`, `CLOB`, or `BLOB` and it has an `is json` check constraint. (Database initialization parameter `compatible` must be at least `20` to use data type `JSON`.)

The IM column store is used for queries of documents that are smaller than 32,767 bytes. Queries of documents that are larger than that do not benefit from the IM column store.

> **Note:**
>
> If a JSON column in a table that is to be populated into the IM column store was created using a database that did not have a compatibility setting of at least 12.2 *or* did not have `max_string_size` set to `extended` (this is the case prior to Oracle Database 12c Release 2 (12.2.0.1), for instance) then you must first run script `rdbms/admin/utlimcjson.sql`. It prepares *all* existing tables that have JSON columns to take advantage of the In-Memory JSON processing that was added in Release 12.2.0.1. See Upgrading Tables With JSON Data For Use With the In-Memory Column Store.

After you have marked a table that has JSON columns as `INMEMORY`, an *In-Memory virtual column* is added to it for each JSON column. The corresponding virtual column is used for queries of a given JSON column. The virtual column contains the same JSON data as the corresponding JSON column, but in OSON format, regardless of the data type of the JSON column (`VARCHAR2`, `CLOB`, `BLOB`, or `JSON` type). **OSON** is Oracle's optimized binary JSON format for fast query and update in both Oracle Database server and Oracle Database clients.

Populating JSON data into the IM column store using `ALTER TABLE … INMEMORY` provides support for *ad hoc* structural queries, that is, queries that you might not anticipate or use regularly.

If a column is of data type `JSON` then you can populate it into the IM column store using `ALTER TABLE … INMEMORY` **TEXT**, to provide support for *full-text search*. (Using `ALTER TABLE … INMEMORY` both with and without keyword `TEXT` for the same JSON column provides support for both ad hoc and full-text queries.)

> **Note:**
>
> If a JSON search index is defined for a JSON column (of any data type) that is populated into the IM Column Store then the search index, *not* the IM Column Store, is used for queries of that column.

> **See Also:**
>
> - *Oracle Database In-Memory Guide* for information about `ALTER TABLE ... INMEMORY`
>
> - *Oracle Database In-Memory Guide* for information about IM column store support for full-text search
>
> - *Oracle Database In-Memory Guide* for information about IM column store support for JSON data stored as `JSON` type or textually

Example 30-1   Populating JSON Data Into the IM Column Store For Ad Hoc Query Support

```
SELECT COUNT(1) FROM j_purchaseorder
  WHERE json_exists(po_document,
                    '$.ShippingInstructions?(
                       @.Address.zipCode == 99236)');

-- The execution plan shows: TABLE ACCESS FULL

-- Specify table as INMEMORY, with default PRIORITY setting of NONE,
-- so it is populated only when a full scan is triggered.

ALTER TABLE j_purchaseorder INMEMORY;

-- Query the table again, to populate it into the IM column store.
SELECT COUNT(1) FROM j_purchaseorder
  WHERE json_exists(po_document,
                    '$.ShippingInstructions?(
                       @.Address.zipCode == 99236)');

-- The execution plan for the query now shows:
-- TABLE ACCESS INMEMORY FULL
```

Example 30-2   Populating a JSON Type Column Into the IM Column Store For Full-Text Query Support

This example populates column `po_document` of table `j_purchaseorder` into the IM column store for full-text support (keyword `TEXT`).

```
ALTER TABLE j_purchaseorder INMEMORY TEXT (po_document);
```

If column `po_document` is *not* of `JSON` data type, and if no JSON search index is defined on the column, then JSON full-text querying is not supported. Trying to use `json_textcontains` to search the data raises an error in that case.

Related Topics

- Oracle SQL Condition JSON_TEXTCONTAINS
  You can use Oracle SQL condition `json_textcontains` in a `CASE` expression or the `WHERE` clause of a `SELECT` statement to perform a full-text search of JSON data.

- Support for RFC 8259: JSON Scalars
  Starting with Release 21c, Oracle Database can support IETF RFC 8259, which allows a JSON document to contain only a JSON scalar value at top level. This support also means that functions that return JSON data can return scalar JSON values.

30.3 Upgrading Tables With JSON Data For Use With the In-Memory Column Store

A table with JSON columns created using a database that did not have a compatibility setting of at least 12.2 *or* did not have `max_string_size = extended` must first be upgraded, before it can be populated into the In-Memory Column Store (IM column store). To do this, run script `rdbms/admin/utlimcjson.sql`.

Script `rdbms/admin/utlimcjson.sql` upgrades *all* existing tables that have JSON columns so they can be populated into the IM column store. To use it, *all* of the following must be true:

- Database parameter `compatible` must be set to `12.2.0.0` or higher.

- Database parameter `max_string_size` must be set to `extended`.

- The JSON columns being upgraded must be known to contain well-formed JSON data. This is the case for a column of data type `JSON`[1] or a non-`JSON` type column that has an `is json` check constraint defined on it.

Related Topics

- Overview of In-Memory JSON Data
  You can populate JSON data into the In-Memory Column Store (IM column store), to improve the performance of ad hoc and full-text queries.

---

[1] Database initialization parameter `compatible` must be at least `20` to use data type `JSON`.

31

JSON Query Rewrite To Use a Materialized View Over JSON_TABLE

You can enhance the performance of queries that access particular JSON fields by creating, and indexing, a materialized view over such data that's defined using SQL/JSON function `json_table`.

Example 21-11 shows how to create a materialized view over JSON data using function `json_table`. That example creates a virtual column for each JSON field expected in the data.

You can instead create a materialized view that projects only certain fields that you query often. If you do that, and if the following conditions are *all* satisfied, then queries that match the column data types of any of the projected fields can be *rewritten automatically* to go against the materialized view.

- The materialized view is created with `REFRESH FAST ON STATEMENT`.

- The materialized view definition includes either `WITH PRIMARY KEY` or `WITH ROWID` (if there is no primary key).

- The materialized view joins the parent table and only one virtual table defined by `json_table`.

- The columns projected by `json_table` use `ERROR ON ERROR`.

Automatic query rewrite is supported if those conditions are satisfied. You do not need to specify `ENABLE QUERY REWRITE` in the view definition. Rewriting applies to queries that use any of the following in a `WHERE` clause: simple dot notation, condition `json_exists`, or function `json_value`.

Columns that do not specify `ERROR ON ERROR` are also allowed, but queries are not rewritten to use those columns. If you use `ERROR ON ERROR` for the `json_table` row pattern, the effect is the same as if you specify `ERROR ON ERROR` for *each* column.

If some of your JSON data lacks a given projected field, using `NULL ON EMPTY` allows that field to nevertheless be picked up when it is present — no error is raised when it is missing.

Automatic query rewrite to use a materialized view can enhance performance. Performance can be further enhanced if you also create an index on the materialized view.

Example 31-1 creates such a materialized view. Example 31-2 creates an index for it.

Example 31-1   Creating a Materialized View of JSON Data To Support Query Rewrite

This example creates materialized view `mv_for_query_rewrite`, which projects several JSON fields to relational columns. Queries that access those fields in a `WHERE` clause using simple dot notation, condition `json_exists`, or function `json_value` can be automatically rewritten to instead go against the corresponding view columns.

An example of such a query is that of Example 18-5, which has comparisons for fields `User`, `UPCCode`, and `Quantity`. All of these comparisons are rewritten to use the materialized view.

In order for the materialized view to be used for a given comparison of a query, the type of that comparison must be the same as the SQL data type for the corresponding view column. See Using a JSON_VALUE Function-Based Index with JSON_EXISTS Queries for information about the type of a comparison.

For example, view `mv_for_query_rewrite` can be used for a query that checks whether field `UPCCode` has numeric value `85391628927`, because the view column projected from that field has SQL type `NUMBER`. But the view cannot be used for a query that checks whether that field has string value "`85391628927`".

```
CREATE MATERIALIZED VIEW mv_for_query_rewrite
  BUILD IMMEDIATE
  REFRESH FAST ON STATEMENT WITH PRIMARY KEY
  AS SELECT po.id, jt.*
       FROM j_purchaseorder po,
            json_table(po.po_document, '$' ERROR ON ERROR NULL ON EMPTY
              COLUMNS (
                po_number       NUMBER        PATH '$.PONumber',
                userid          VARCHAR2(10)  PATH '$.User',
                NESTED PATH '$.LineItems[*]'
                  COLUMNS (
                    itemno      NUMBER        PATH '$.ItemNumber',
                    description VARCHAR2(256) PATH '$.Part.Description',
                    upc_code    NUMBER        PATH '$.Part.UPCCode',
                    quantity    NUMBER        PATH '$.Quantity',
                    unitprice   NUMBER        PATH '$.Part.UnitPrice'))) jt;
```

You can tell whether the materialized view is used for a particular query by examining the execution plan. If it is, then the plan refers to `mv_for_query_rewrite`. For example:

```
|* 4| MAT_VIEW ACCESS FULL | MV_FOR_QUERY_REWRITE |1|51|3(0)|00:00:01|
```

Example 31-2   Creating an Index Over a Materialized View of JSON Data

This example creates composite relational index `mv_idx` on columns `userid`, `upc_code`, and `quantity` of the materialized view `mv_for_query_rewrite` created in Example 31-1.

```
CREATE INDEX mv_idx ON mv_for_query_rewrite(userid,
                                            upc_code,
                                            quantity);
```

The execution plan snippet in Example 31-1 shows a full table scan (`MAT_VIEW ACCESS FULL`) of the materialized view. Defining index `mv_idx` can result in a better plan for the query. This is indicated by the presence of `INDEX RANGE SCAN` (as well as the name of the index, `MV_IDX`, and the material view, `MV_FOR_QUERY_REWRITE`).

```
|   4|MAT_VIEW ACCESS BY INDEX ROWID BATCHED|MV_FOR_QUERY_REWRITE|1|51|2(0)|00:00:01|

|* 5|                        INDEX RANGE SCAN|MV_IDX              |1|  |1(0)|00:00:01|
```

Appendixes

Appendixes here provide background material for using JSON data with Oracle Database.

- **ISO 8601 Date, Time, and Duration Support**
  International Standards Organization (ISO) standard 8601 describes an internationally accepted way to represent dates, times, and durations. Oracle Database supports the most common ISO 8601 formats as proper Oracle SQL date, time, and interval (duration) values. The formats that are supported are essentially those that are numeric-only, language-neutral, and unambiguous.

- **Oracle Database JSON Capabilities Specification**
  This appendix specifies capabilities for Oracle support of JSON data in Oracle Database.

- **Diagrams for Basic SQL/JSON Path Expression Syntax**
  Syntax diagrams and corresponding Backus-Naur Form (BNF) syntax descriptions are presented for the basic SQL/JSON path expression syntax.

- **Migrating Textual JSON Data to JSON Data Type**
  Oracle recommends that you use native binary JSON data (type `JSON`), rather than textual JSON data (type `VARCHAR2`, `CLOB`, or `BLOB`). How to migrate existing textual JSON data to `JSON` type is described. This involves (1) a pre-upgrade check, (2) migrating the data, and (3) dealing with dependent database objects.

A

ISO 8601 Date, Time, and Duration Support

International Standards Organization (ISO) standard 8601 describes an internationally accepted way to represent dates, times, and durations. Oracle Database supports the most common ISO 8601 formats as proper Oracle SQL date, time, and interval (duration) values. The formats that are supported are essentially those that are numeric-only, language-neutral, and unambiguous.

(Simple Oracle Document Access (SODA) does not support durations.)

Oracle Database Syntax for ISO Dates and Times

This is the syntax that Oracle Database supports for ISO dates and times:

- Date (only): `YYYY-MM-DD`

- Date with time: `YYYY-MM-DDThh:mm:ss[.s[s[s[s[s]]]]][Z|(+|-)hh:mm]`

where:

- `YYYY` specifies the *year*, as four decimal digits.

- `MM` specifies the *month*, as two decimal digits, `00` to `12`.

- `DD` specifies the *day*, as two decimal digits, `00` to `31`.

- `hh` specifies the *hour*, as two decimal digits, `00` to `23`.

- `mm` specifies the *minutes*, as two decimal digits, `00` to `59`.

- `ss[.s[s[s[s[s]]]]]` specifies the *seconds*, as two decimal digits, `00` to `59`, optionally followed by a decimal point and 1 to 6 decimal digits (representing the fractional part of a second).

- `Z` specifies *UTC* time (time zone 0). (It can also be specified by `+00:00`, but not by `-00:00`.)

- `(+|-)hh:mm` specifies the time-zone as *difference from UTC*. (One of `+` or `-` is required.)

For a time value, the time-zone part is optional. If it is absent then UTC time is assumed.

No other ISO 8601 date-time syntax is supported. In particular:

- Negative dates (dates prior to year 1 BCE), which begin with a hyphen (e.g. `-2018-10-26T21:32:52`), are not supported.

- Hyphen and colon separators are required: so-called "basic" format, `YYYYMMDDThhmmss`, is not supported.

- Ordinal dates (year plus day of year, calendar week plus day number) are not supported.

- Using more than four digits for the year is not supported.

Supported dates and times include the following:

- `2018-10-26T21:32:52`

- `2018-10-26T21:32:52+02:00`

- `2018-10-26T19:32:52Z`

- `2018-10-26T19:32:52+00:00`

- `2018-10-26T21:32:52.12679`

Unsupported dates and times include the following:

- `2018-10-26T21:32` (if a time is specified then all of its parts must be present)

- `2018-10-26T`**`25:`**`32:52+02:00` (the hours part, 25, is out of range)

- `18-10-26T21:32` (the year is not specified fully)

Oracle Database Syntax for ISO Durations

> **Note:**
>
> Oracle Database supports ISO durations, but Simple Oracle Document Access (SODA) does not support them.

There are two supported Oracle Database syntaxes for ISO durations, the *ds_iso_format* specified for SQL function `to_dsinterval` and the *ym_iso_format* specified for SQL function `to_yminterval`. (`to_dsinterval` returns an instance of SQL type `INTERVAL DAY TO SECOND`, and `to_yminterval` returns an instance of type `INTERVAL YEAR TO MONTH`.)

These formats are used for data types `daysecondInterval` and `yearmonthInterval`, respectively, which Oracle has added to the JSON language.

- **ds_iso_format:**

  P*d***DT***h***H***m***M***s***S*, where *d*, *h*, *m*, and *s* are digit sequences for the number of days, hours, minutes, and seconds, respectively. For example: `"P0DT06H23M34S"`.

  s can also be an integer-part digit sequence followed by a decimal point and a fractional-part digit sequence. For example: `P1DT6H23M3.141593S`.

  Any sequence whose value would be zero is omitted, along with its designator. For example: `"PT3M3.141593S"`. However, if all sequences would have zero values then the syntax is `"P0D"`.

- **ym_iso_format**

  P*y***Y***m***M**, where *y* is a digit sequence for the number of years and *m* is a digit sequence for the number of months. For example: `"P7Y8M"`.

  If the number of years or months is zero then it and its designator are omitted. Examples: `"P7Y"`, `"P8M"`. However, if there are zero years and zero months then the syntax is `"P0Y"`.

B

Oracle Database JSON Capabilities Specification

This appendix specifies capabilities for Oracle support of JSON data in Oracle Database.

Unless otherwise specified, an error is raised if a specification is not respected.

- General:
    - Number of nesting levels for a JSON object or array: 1000.
    - JSON field name length: 65535 bytes each.
- SQL/JSON path expressions:
    - Each use of a string in a SQL/JSON path expression: 32K bytes, whether the string is literal or is provided by a SQL/JSON variable, such as `$a`. (32K bytes is the maximum length of a SQL `VARCHAR2` value.)
    - Total length of path-expression *text*: 32K bytes. (It is passed as a string to SQL operators such as `json_exists`.)

        The *effective* length of a path expression is essentially unlimited, because the expression can make use of SQL/JSON variables that are bound to string values, each of which is limited to 32K bytes.

    See also Overview of SQL/JSON Path Expressions.

- Component length for dot-notation paths: 128 bytes. (This is the maximum length of a SQL identifier.)

    See also:
    - *Oracle Database Object-Relational Developer's Guide* for information about SQL dot-notation syntax
    - *Oracle Database SQL Language Reference* for information about SQL identifiers
- JSON data guide:

> **✎ Note:**
>
> - Path length: 4000 bytes. A path longer than 4000 bytes is *ignored* by a data guide.
> - Number of children under a parent node: 5000. A node that has more than 5000 children is *ignored* by a data guide.
> - Field value length: 32767 bytes. If a JSON field has a value longer than 32767 bytes then the data guide reports the length as 32767.
> - Data-guide behavior is undefined for data that contains zero-length (empty) object field name (`""`).

See Overview of JSON Data Guide for more information about JSON data guide.

- OSON and `JSON` data type:

  OSON is Oracle's optimized binary JSON format for query and update in both Oracle Database server and Oracle Database clients. An instance of `JSON` data type is stored using format OSON.

  – Total size of a `JSON` type instance: 32M bytes.

    See Data Types for JSON Data for more information about the storage of JSON data as `JSON` type

C

Diagrams for Basic SQL/JSON Path Expression Syntax

Syntax diagrams and corresponding Backus-Naur Form (BNF) syntax descriptions are presented for the basic SQL/JSON path expression syntax.

The basic syntax of SQL/JSON path expression is explained in Basic SQL/JSON Path Expression Syntax. This topic recapitulates that information in the form of syntax diagrams and BNF descriptions.

Figure C-1   json_basic_path_expression

D

Migrating Textual JSON Data to JSON Data Type

Oracle recommends that you use native binary JSON data (type `JSON`), rather than textual JSON data (type `VARCHAR2`, `CLOB`, or `BLOB`). How to migrate existing textual JSON data to `JSON` type is described. This involves (1) a pre-upgrade check, (2) migrating the data, and (3) dealing with dependent database objects.

Using data type `JSON` avoids costly parsing of textual JSON data and provides better query performance.

You can migrate the data (step 2) in any of the following ways. Each way involves creating a new table of the same shape as the original table, but with a `JSON`-type column instead of the textual JSON column.

- Populate the `JSON`-type column using a *query* of the textual JSON column in the original table. There are two ways to do this: `CREATE TABLE AS SELECT` (CTAS) or `INSERT` as `SELECT` (IAS).

- Use *Oracle Data Pump*, with data-only mode. Export the original table to a dump file, then import the dump file into the new table.

- Use *online redefinition*.

- Performing a Pre-Migration Check
  You use PL/SQL procedure `DBMS_JSON.json_type_convertible_check` to check whether a given column of textual JSON data can be converted to `JSON` data type.

- Populate JSON-Type Column By Querying Textual JSON
  With this migration approach you populate a new table by *querying* the original table. You do this as part of the `CREATE TABLE` statement or an `INSERT` statement. The new table has the same shape as the original, but with a `JSON`-type column instead of the textual JSON column.

- Using Oracle Data Pump to Migrate to JSON Data Type
  With this migration approach you use Oracle Data Pump, in data-only mode, to load the data from the original table that has a textual JSON column into a new table of the same shape, but with a `JSON`-type column.

- Using Online Redefinition to Migrate to JSON Data Type
  If PL/SQL procedure `DBMS_REDEFINITION.can_redef_table` gives you the go-ahead, then you can use online redefinition to migrate a textual JSON column to a `JSON`-type column without significantly affecting the availability of the table data. It remains accessible to both queries and DML during much of the migration process.

- Handling Dependent Objects
  For the `JSON`-type data that replaces your original, textual JSON data, you need to re-create any database objects that depend on that original data.

Related Topics

- JSON Data Type
  SQL data type `JSON` represents JSON data using a native binary format, **OSON**, which is Oracle's optimized format for fast query and update in both Oracle Database server and Oracle Database clients. You can create `JSON` type instances from other SQL data, and conversely.

D.1 Performing a Pre-Migration Check

You use PL/SQL procedure `DBMS_JSON.`**`json_type_convertible_check`** to check whether a given column of textual JSON data can be converted to `JSON` data type.

For example, this checks the convertibility of textual JSON column `po_document` of table `j_purchaseorder`, which is owned by database schema *table_owner*. The status of the convertibility check is written to table `my_precheck_table`.

```
EXECUTE DBMS_JSON.json_type_convertible_check(
                 owner => 'table_owner',
                 tableName => 'j_purchaseorder',
                 columnName => 'po_document',
                 statusTableName => 'my_precheck_table');
```

The result of checking is stored in the table named by the third parameter to the procedure (e.g., `my_precheck_table`). This table is created if it does not yet exist. By default, an existing table is truncated, but if the optional fifth parameter is `TRUE` then the procedure *appends* new result rows to the existing table.

By default, convertibility is checked by attempting to convert the data using (in effect) the `JSON` type constructor. If optional fourth parameter is `TRUE`, then convertibility is checked only using SQL condition `is json`, which just checks that the JSON data is well-formed, not whether it is actually convertible to `JSON` type.

The procedure checks each JSON value in the column to be checked. It logs each value that cannot be converted in the status table, along with the reason it's not convertible.

The procedure also logs its progress in the status table, in increments of 10% for a table of less than 10,000 rows, 5% for a table of 10,000 to 99,999 rows, and 1% for a table of 100,000 or more rows. A progress entry also shows you the number of errors found so far.

Table D-1 describes the resulting status table.

Table D-1   JSON-Type Convertibility-Check Status Table

Column Name	Data Type	Description
STAMP	TIMESTAMP(6)	Time and date this status row (log entry) was written.
SCHEMA_NAME	VARCHAR2(130)	Name of the database schema that owns table `TABLE_NAME`.
TABLE_NAME	VARCHAR2(130)	Database table containing textual JSON column `COLUMN_NAME`.

Table D-1   (Cont.) JSON-Type Convertibility-Check Status Table

Column Name	Data Type	Description
COLUMN_NAME	VARCHAR2(130)	Name of textual JSON column to be migrated to JSON-type data.
ERROR_ROW_ID	ROWID	Address of the row in which a convertibility error was detected.
ERROR_CODE	VARCHAR2(250)	Designation/description of the error in ERROR_ROW_ID. Example: JSON SYNTAX ERROR.
STATUS	VARCHAR2(100)	• If the log entry is because an error was found, then this is ERROR FOUND — see columns ERROR_CODE and ERROR_ROW_ID. • For a periodic, in-progress log, this is M% completed (Errors found: N), where *M* is the percentage of checking completed, and *N* is the number of errors found, so far. • If checking is finished then this is Process completed (Errors found: N), where *N* is the total number of errors found.

Example D-1   Locating Problematic JSON Data Reported By DBMS_JSON.JSON_TYPE_CONVERTIBLE_CHECK

This example shows how to select invalid data reported with error code JSON SYNTAX ERROR in status table my_precheck_table for ROWID AAAWf+AAEAAAAEMAAC of column po_document of table *table_owner*.j_purchaseorder.

```
SELECT po_document FROM table_owner.j_purchaseorder
  WHERE ROWID IN (SELECT pt.ERROR_ROW_ID
                  FROM my_precheck_table pt
                  WHERE pt.schema_name = table_owner
                    AND pt.table_name = j_purchaseorder
                    AND pt.column_name = po_document);
```

D.2 Populate JSON-Type Column By Querying Textual JSON

With this migration approach you populate a new table by *querying* the original table. You do this as part of the CREATE TABLE statement or an INSERT statement. The new table has the same shape as the original, but with a JSON-type column instead of the textual JSON column.

You submit the query as part of a CREATE TABLE AS SELECT (CTAS) statement or an INSERT as SELECT (IAS) statement. In either case, after populating the new table the old table is dropped (or renamed to some third name), and then the new table is renamed to the original table name.

The two approaches to creating and populating the new table are shown in Example D-2 and Example D-3.

Each of those examples migrates the data in textual-JSON BLOB column po_document of table j_purchaseorder created in Example 14-3. Each uses the JSON data type constructor to create native binary JSON data from the original textual JSON data. Each uses a new table,

`j_purchaseorder_`**new**, that has the same columns as the original — same names and same data, except that the JSON data is `JSON` type.

Renaming the new table is shown in Example D-4.

Example D-2   Using CREATE TABLE AS SELECT (CTAS) to Migrate to JSON Data Type

This example created the new table, `j_purchaseorder_`**new**, using code similar to that of Example 4-1, but it populates the table as it creates it, with a query of the textual JSON data in the original table.

```
CREATE TABLE j_purchaseorder_new PARALLEL NOLOGGING AS
SELECT id id, date_loaded date_loaded, JSON(po_document) po_document
  FROM j_purchaseorder;
```

> **See Also:**
>
> Optimizing Performance by Creating and Populating Tables in Parallel in *Oracle Database VLDB and Partitioning Guide* for information about using `CREATE TABLE AS SELECT` to create and populate a table in parallel

Example D-3   Using INSERT as SELECT (IAS) to Migrate to JSON Data Type

This example assumes that you've created the new table, `j_purchaseorder_`**new**, using code like that of Example 4-1. It populates the `JSON`-type column using an `INSERT` statement that queries the original, textual JSON data.

```
INSERT /*+ PARALLEL APPEND */
  INTO j_purchaseorder_new (id, date_loaded, po_document)
  SELECT id, date_loaded, JSON(po_document)
    FROM j_purchaseorder;
```

Optimizer hint `PARALLEL` requests the optimizer to invoke the `INSERT` statement in parallel.

Optimizer hint `APPEND` requests the optimizer to use direct-path insertion, which appends data to the end of the table, rather than using space already allocated to the table. Direct-path insertion can be considerably faster than conventional insertion.

> **See Also:**
>
> - PARALLEL Hint
> - APPEND Hint

Example D-4   Rename New Table To Original Table Name

This example renames the new table, which has a `JSON`-type column, to the name of the original table, which has a textual JSON column.

Before this renaming, it *drops* the original table. Alternatively, you can *rename* the original table, if you don't want to drop it immediately. But to be able to rename it you must *first drop any existing materialized views that depend on it* — see Handling Dependent Objects. You cannot rename a table as long as there are any such dependent materialized views.

> **✏ Note:**
>
> *Before dropping* the original table, *verify the integrity of the new table*: make sure it is complete and correct. It needs to have the same column names and data types as the original, except for the type of the JSON column.

```
DROP TABLE j_purchaseorder;
ALTER TABLE j_purchaseorder_new RENAME TO j_purchaseorder;
```

D.3 Using Oracle Data Pump to Migrate to JSON Data Type

With this migration approach you use Oracle Data Pump, in data-only mode, to load the data from the original table that has a textual JSON column into a new table of the same shape, but with a JSON-type column.

Follow these steps:

1. Create the new table, `j_purchaseorder_new`, using code similar to that of Example 4-1, that is, with the same shape as the original table, j_purchaseorder, but with a JSON-type column instead of the textual JSON column.

    ```
    CREATE TABLE j_purchaseorder_new (id VARCHAR2(32),
                                      date_loaded TIMESTAMP(6) WITH TIME ZONE,
                                      po_document JSON);
    ```

2. Use command-line client expdp, to export the data from the original table, j_purchaseorder, to a dump file, purchase_ord_txt.dmp. (*table_owner*, here, is the database schema that owns the table, and *password* is its password.)

```
expdp table_owner/password tables=j_purchaseorder directory=mydir
dumpfile=purchase_ord_txt.dmp logfile=expdp_po.log
```

3. Use command-line client impdp, to import the dumped data into the new table, using data-only mode.

    In this example, *table_owner*, is a placeholder for the database schema that owns the table; *password* is a placeholder for its password; and *dumpfile_dir* is a placeholder for the directory that contains the dump file.

```
impdp table_owner/password tables=j_purchaseorder directory=dumpfile_dir
dumpfile=purchase_ord_txt.dmp logfile=impdp_po.log
remap_table=j_purchaseorder:j_purchaseorder_new content=data_only
```

4. Drop the original table, or rename it to some third name, and then rename the new table to the original table name. This is shown in Example D-4.

> **See Also:**
>
> Oracle Data Pump

D.4 Using Online Redefinition to Migrate to JSON Data Type

If PL/SQL procedure `DBMS_REDEFINITION.can_redef_table` gives you the go-ahead, then you can use online redefinition to migrate a textual JSON column to a `JSON`-type column without significantly affecting the availability of the table data. It remains accessible to both queries and DML during much of the migration process.

With this approach, you copy the original table data to a new, interim table while the original table continues to handle its regular workload.

When migrating this way, the table available for regular workload is locked in the exclusive mode only during a small window of time, which is independent of the size of the table and the complexity of the redefinition. Online redefinition requires an amount of free space that is approximately equivalent to the space used by the table being redefined.

To perform online redefinition you must have *execute* privilege on package `DBMS_REDEFINITION`, and you must have the privilege to *create materialized views*, `CREATE MVIEW`.

table_owner, here, is the database schema that owns the table.

1. Invoke `DBMS_REDEFINITION.can_redef_table`, to check whether the table can be modified through online redefinition. Proceed to step 2 if no error is raised.

    ```
    EXEC DBMS_REDEFINITION.can_redef_table('table_owner',
    'j_purchaseorder');
    ```

2. Create interim table **j_purchaseorder_new**, using code similar to that of Example 4-1, that is, with the same shape as the original table, `j_purchaseorder`, but with a `JSON`-type column instead of the textual JSON column.

    ```
    CREATE TABLE j_purchaseorder_new (id VARCHAR2(32),
                                      date_loaded TIMESTAMP(6) WITH
    TIME ZONE,
                                      po_document JSON);
    ```

3. If there are any virtual columns in the original table (`j_purchaseorder`), then define identical columns in the interim table. For example, this code defines virtual columns `vc_user` and `vc_costcenter`, based on top-level fields `User` and `CostCenter`, respectively.

    ```
    ALTER TABLE j_purchaseorder_new ADD (vc_user GENERATED ALWAYS AS
       (json_value(po_document, '$.User' RETURNING VARCHAR2(20))));
    ALTER TABLE j_purchaseorder_new ADD (vc_costcenter GENERATED ALWAYS
    ```

```
AS
  (json_value(po_document, '$.CostCenter' RETURNING VARCHAR2(6))));
```

4. Use procedure DBMS_REDEFINITION.start_redef_table, applying the JSON data type constructor to the textual JSON column.

```
BEGIN
  DBMS_REDEFINITION.start_redef_table('table_owner',
                                      'j_purchaseorder',
                                      'j_purchaseorder_new',
                                      'ID ID, DATE_LOADED DATE_LOADED,
JSON(PO_DOCUMENT) PO_DOCUMENT',
                                      REFRESH_DEP_MVIEWS => 'Y',
                                      ENABLE_ROLLBACK => FALSE);
END;
/
```

5. If the original table contains dependents, such as constraints, indexes, and virtual private database (VPD) policies, then call procedure DBMS_REDEFINITION.copy_table_dependents to copy them to the interim table.

```
DECLARE
n_errors INTEGER;
BEGIN
  DBMS_REDEFINITION.copy_table_dependents('table_owner',
                                          'j_purchaseorder',
                                          'j_purchaseorder_new',
                                          NUM_ERRORS => n_errors,
                                          IGNORE_ERRORS => FALSE);
  DBMS_OUTPUT.put_line(n_errors);
END;
/
```

6. (Optional) If you issued a large number of DML operations on the original table during the previous steps, then consider using procedure DBMS_REDEFINITION.sync_interim_table to sync the data to the interim table, to minimize the downtime at the next step.

```
DBMS_REDEFINITION.sync_interim_table ('table_owner',
                                      'j_purchaseorder',
                                      'j_purchaseorder_new',
                                      PART_NAME => NULL,
                                      CONTINUE_AFTER_ERRORS => FALSE);
```

7. Check that the interim table works as you expect. Do whatever you feel is needed, to convince yourself that this is the case. The next step, step 8, which *cannot be undone*, swaps the names of the two tables, so what is now the interim table goes "live" with the original table name.

If your checking determines that the interim table is *not* working as expected, then you can use procedure DBMS_REDEFINITION.abort_redef_table to revert the changes made so far. It cleans up problems that may have recurred during redefinition and removes temporary objects, such as materialized view logs, that have been created so far.

You can use `abort_redef_table` to terminate the redefinition process any time after you invoke `start_redef_table` and before you invoke `DBMS_REDEFINITION.finish_redef_table`.

```
DBMS_REDEFINITION.abort_redef_table ('table_owner',
                                     'j_purchaseorder',
                                     'j_purchaseorder_new',
                                     PART_NAME => NULL);
```

8. Use procedure `DBMS_REDEFINITION.finish_redef_table` to finish online redefinition. *This action cannot be undone.* This swaps the names of the original and interim tables, which are both locked for a brief period. After the operation the table with the original name contains the redefined data, and the table with the interim name contains the original (old) data.

```
BEGIN
  DBMS_REDEFINITION.finish_redef_table('table_owner',
                                       'j_purchaseorder',
                                       'j_purchaseorder_new',
                                       DML_LOCK_TIMEOUT => 0);
END;
/
```

9. (Optional) Drop the interim table, which now contains the original (old) data, if you don't need it anymore. *Make sure that you drop the interim table, and not the table with the original name.* Specifying `PURGE` is optional; if you use `PURGE` then you cannot recover the dropped table.

```
DROP TABLE 'table_owner', 'j_purchaseorder_new' CASCADE CONSTRAINTS
PURGE;
```

D.5 Handling Dependent Objects

For the `JSON`-type data that replaces your original, textual JSON data, you need to re-create any database objects that depend on that original data.

In general, you need to re-create all of the following, similar to what was defined for the textual data: indexes, materialized views, virtual columns (and any indexes on them), virtual private database policies, and triggers.

However, defining virtual columns and indexes is *part of* using online redefinition to migrate the data — it needs to be done on the *interim* table. See Using Online Redefinition to Migrate to JSON Data Type.

To find out which database objects depend on your original (textual) data, you can query the relevant static dictionary views, for example: `USER_INDEXES`, `USER_TRIGGERS`, and `USER_VIEWS`. You can then use PL/SQL function `DBMS_METADATA.get_ddl` to obtain the DDL code that was used to re-create such objects. Example D-5 shows how to do this for an index.

Typically, when the base objects underlying a materialized view are modified you need to recompile the materialized view. If that's not possible, then you need to re-create it.

To check whether a materialized view needs to be recompiled, you can query static dictionary view `USER_MVIEWS`, as follows:

```
SELECT MVIEW_NAME, COMPILE_STATE FROM USER_MVIEWS;
```

If the `COMPILE_STATE` value is `NEEDS_COMPILE` then you can recompile the view using `ALTER MATERIALIZED VIEW … COMPILE`.

Example D-5   Obtaining Information Needed To Re-Create an Index

This example first queries static dictionary view `USER_INDEXES` to find any indexes on textual JSON data in table `j_purchaseorder`.

```
SELECT INDEX_NAME FROM USER_INDEXES
  WHERE TABLE_NAME = 'J_PURCHASEORDER';
```

Supposing that the query result shows such an index named `po_num_idx1`, you can use `DBMS_METADATA.get_ddl` to obtain the DDL code that was used to create that index. You can then use similar DDL to create such an index on the equivalent data that you are migrating to `JSON` data type.

```
SELECT DBMS_METADATA.get_ddl('INDEX', po_num_idx1) FROM DUAL;
```
