1 About Creating Product Offerings

About Pricing Components	1-1
About Pricing Setup Components	1-3
Prerequisites for Creating Product Offerings	1-4
About Changesets	1-5
Making Changes to Your Product Offerings	1-5
Deleting Charge Offers	1-6
Logging Changes to Product Offerings	1-6
About Product Offering Ownership	1-6

Part I Creating Pricing Setup Components

2 Creating Pricing Setup Components

About Setup Components	2-1
Configuring Setup Components	2-2
Configuring Ratable Usage Metrics (RUMs)	2-5
Setting up Service and Event Definitions	2-6
Using Service and Account Attributes with ECE for Usage Rating	2-7
Setting Up the Service-Event Map	2-8
Configuring Balance Elements	2-9
Adding Rounding Rules to Balance Elements	2-10
Enabling Single Currency Graph	2-11
About Offer Profiles	2-12

3 Synchronizing Pricing Setup Components

About Synchronizing Setup Components	3-1
About the SyncPDC Utility	3-2
Prerequisites for Running SyncPDC	3-2
About Configuring SyncPDC	3-2
Running SyncPDC	3-7
Scheduling Synchronization	3-8
Running SyncPDC Immediately	3-8
Running SyncPDC at a Scheduled Time	3-8
Running SyncPDC Immediately and at a Scheduled Time	3-9
Running SyncPDC at Recurring Scheduled Time	3-9
Synchronizing BRM Data with PDC to Use ECE for Usage Rating	3-10
Stopping SyncPDC	3-10
Generating Synchronization Reports	3-10
Handling Synchronization Failures	3-11
Reprocessing a Failed Synchronization	3-12
Changing Display Names	3-12

4 Configuring Deliverables

About Creating Deliverables	4-1
Configuring Deliverables	4-2
Configuring Deliverables for Physical Goods	4-5
Configuring Deliverables for One-Time Activities	4-6
Configuring Deliverables for Metered Services	4-7
Configuring Deliverables for Continuous Services	4-8
Loading Deliverables into the PDC Database	4-10

5 Configuring Policy Specifications

About Configuring Policy Specifications	5-1
Configuring Policy Specifications	5-1

6 Configuring Item Type Selectors

About Configuring Item Type Selectors	6-1
Loading the OOB_ItemTypeSelector.XML File	6-4
Configuring Item Type Selectors	6-5

7 Configuring Value Maps

About Value Maps	7-1
------------------	-----

Loading the Sample Value Map into the Database	7-2
Configuring Value Maps Using SampleValueMap.XML	7-2

Part II Creating Pricing Components

8 Configuring Charge Offers

About Charge Offers and Charges	8-1
Configuring Charge Offer Usage and Ownership	8-3
Applying Recurring Charges on a Specific DOM	8-5
Configuring Charge Offers and Revenue Recognition	8-5
Restricting the End Time of Granted Balances That Start on First Usage	8-6
Configuring How Pricing Configurations for Date Ranges are Applied	8-7
Charge Offers and General Ledger	8-8
Configuring Full Day Proration	8-8

9 Configuring Charges in Charge Offers

About Charges	9-1
Specifying When a Charge is Effective	9-2
Specifying Whether to Charge Inactive, Canceled, or SuspendedActive Accounts	9-3
Configuring Taxation in Charges	9-4
Configuring In-Advance Billing in Charges	9-5
Configuring Cycle Alignment for Recurring Charges	9-5
About Prorating Recurring Charges and Rollovers	9-5
About Creating Charge Offers with Over 500 Charges	9-6

10 Configuring Pricing in Charge Offers

Configuring Pricing in Charges	10-1
Configuring Validity Periods for Noncurrency Credit Balances	10-2
Granting Noncurrency Balances in Increments	10-3
Specifying Rounding in Balance Impacts	10-4
Specifying if a Balance Impact is Discountable	10-4
About Minimum Charges	10-5
About Conditional Balance Impacts	10-5
About Prorating Charges	10-7
Configuring Dynamic Charging for One-Time and Recurring Events	10-7
Configuring Dynamic Pricing for Usage Events	10-8

11 Pricing Configurations in Charge Offers

Configuring Pricing Based on Quantity Ranges	11-1
Configuring Pricing to Consume Granted Allowances Before Charging	11-2
Configuring Effective Dates for Pricing	11-3
About Defining Pricing Based on Multiple RUMs	11-3
About Price Overrides	11-4
About Fold Charge Pricing	11-4
Granting First Usage Balances During Rating	11-5

12 Creating Discount Offers

About Discount Offers and Discounts	12-1
Configuring How Discount Offers are Purchased and Applied	12-4
Applying Multiple Discount Offers to an Event	12-4
Configuring Mutually Exclusive Discount Offers	12-5
Applying Discounts Based on Quantity	12-6
About Discount Filters	12-6
About Discount Triggers	12-8
About Using Temporary Balances in Discounts	12-8
Using Functions to Calculate a Balance Impact	12-8
Applying Multiple Discount Versions to an Event	12-9
About Billing-Time Discounts	12-9
Configuring Effective Dates for Discounts	12-9
Configuring Discount Validity	12-10
Applying Discounts That Are Valid for Only Part of a Cycle	12-10
Applying a Discount After the Discount Offer Is Inactivated or Canceled	12-11
Configuring Validity Periods for Noncurrency Credit Balance Impacts	12-11
Discounts and Tax Calculation	12-12
Discounts and General Ledger	12-12
About Snowball Discounts	12-12
Defining How Snowball Discounts Are Distributed	12-13

13 Creating Subscription Terms

About Subscription Terms	13-1
About Early Termination Fees	13-2
About Automatic Renewals	13-2
About Bundle Terms and Package Terms	13-2
About Obsolete Subscription Terms	13-3
Creating Subscription Terms	13-3

14 Creating Bundles

About Creating Bundles	14-1
Configuring Bundle Settings	14-2
About Activating First-Usage Discount Offers	14-3
About Granting First-Usage Balance Impacts In First-Usage Charges	14-4
Associating Terms with Bundles	14-4
Customizing Offers In Bundles	14-4
About the Validity Periods of Offers in Bundles	14-5
Setting Proration for Offers in a Bundle	14-7
About Add-On Charge Offers in Bundles	14-7
About Purchasing the Same Offer Multiple Times	14-8
About Customizing Charges and Discounts in Bundles	14-9
Creating Dependencies for Bundles	14-9
Transitioning between Bundles	14-10
Prorating Charges During Bundle Transitions	14-10

15 Creating Packages and Package Lists

Creating Packages	15-1
Associating Terms with Packages	15-2
Grouping Services	15-3
Transitioning between Packages	15-3
Prorating Charges During Package Transitions	15-3
Defining Generation Changes	15-4
Creating Package Lists	15-4
Specifying the Package List Segment and Type	15-5

16 Sharing Charges and Discounts

About Sharing Discounts and Charges	16-1
About First-Usage Start Time for Shared Balances	16-2
About Discount Sharing	16-2
About Chargeshare Offers	16-2

Part III Charging Scenarios

17 Charging Based on Date and Time

About Charging Based on Date and Time	17-1
About Special Day Calendars	17-1

Rating Events Split across Time Periods	17-3
---	------

18 Charging Based on Event Attributes

About Impact Categories	18-1
About Zone Models	18-2
Alternate Zone Models	18-3
Displaying Zoning Information on an Invoice	18-4
About Value Maps	18-4
About Selectors	18-5
About Usage Scenario (USC) Selectors	18-6
About Mapping Services	18-6
Mapping Service Codes and Service Classes	18-7
Mapping Usage Classes	18-7

19 Implementing Recurring Charges

About Recurring Charges	19-1
About Cycle Forward Charges	19-1
About the First Cycle Forward Charge in a New Account	19-2
About Cycle Arrears Charges	19-2
About Cycle Forward Arrears Charges	19-3
About Implementing Cycle Forward Arrears Charging	19-3
About Creating Recurring Charges in PDC	19-4
Specifying When Recurring Charges are Charged	19-4
Allowing Recurring Charges to Be Prorated	19-5
About Recurring Charges Events	19-5

20 Advanced Configuration for Recurring Charges

Configuring Flexible Cycle Forward Charges	20-1
Charging Cycle Forward Fees Associated with Flexible Cycles	20-2
Applying Cycle Forward Fees in Parallel	20-2
About Enforcing Cycle Forward Fee Processing Prior to Billing	20-4
About Aggregating Service Charges to Account Items	20-5
Handling Skipped Billing	20-6
Using the pin_bill_day Script to Apply Parallel Cycle Forward Fees	20-6
About Limitations and Impacts of Applying Cycle Forward Fees in Parallel	20-7
Applying Recurring Charges Based on Charge Offer Priority	20-7
Customizing the Cycle Interval for Specified Charge Offers	20-8

21	Working with Extended Rating Attributes	
	About Extended Rating Attributes	21-1
	About Sharing ERAs	21-1
	Creating Friends and Family ERAs	21-1
	Default ERAs	21-1

22	Configuring Closed User Groups	
	Configuring Closed User Groups	22-1

Part IV Managing Balances

23	Managing Balances during Charging	
	Tracking Balances in Balance Groups	23-1

24	Managing Sub-Balances	
	About Sub-Balances	24-1
	About Noncurrency Sub-Balances	24-2
	How Balances in Validity-Based Sub-Balances Are Updated	24-3
	Restricting the Validity of Noncurrency Sub-Balances That Start on First Usage	24-3
	Configuring Custom Sub-Balances	24-4
	Defining and Loading Custom Sub-Balances	24-7
	Specifying the Order in Which Sub-Balances Are Consumed	24-8
	Setting the Default Consumption Rule	24-10
	Configuring the Default Consumption Rule in ECE	24-11
	Deleting Expired Sub-Balances	24-11
	Configuring Time-Stamp Rounding for Cycle Events	24-12
	Configuring Time-Stamp Rounding for Purchase Events	24-12

25	Configuring Dynamic Quota	
	Configuring Dynamic Quota	25-1
	Configuring Dynamic Quota Selectors	25-6

26	About Folds	
	About Folds	26-1
	About Applying Folds Only For Account-Level Products	26-2

27 Applying Credit Limits to Balances

About Credit Limits	27-1
About Credit Thresholds and Floors	27-1
Handling Credit Limit Conflicts	27-2
Allowing Customers to Exceed Their Credit Limit	27-2
Configuring the Maximum Number of Subscription Retries	27-3

28 About Rollovers

About Rollovers	28-1
When Rollover Events Occur	28-2
About Rolling Over Noncurrency Balances during Package Transition	28-2
About Rolling Over Balances That Expire in Midcycle	28-3
Prorating Rollover Balances	28-4
Rollover Example	28-5

29 Configuring Balance Impact Rounding

About Balance Impact Rounding	29-1
About Rounding Rules	29-1
How BRM Applies Rounding	29-2
About Rounding and A/R Actions	29-4
About Rounding Billed and Unbilled Items	29-4
About Rounding for Specific Event Types	29-4
About Rounding Counter Balances for Discounting	29-4
About G/L Report Rounding	29-5
About Rounding Modes	29-5
About Rounding Modes That Correct for Loss of Precision	29-6
When Rounding Is Not Applied	29-7
Configuring Balance Impact Rounding	29-7
About Configuring Rounding Rules	29-7
About Rounding Mode Values in the BRM API	29-7
Configuring Rounding Rules for Counter Balances	29-8
About Rounding Modes for Discount Expressions	29-8
Configuring to Record Rounding Differences in the G/L	29-9
Defining a G/L ID for Rounding Differences	29-9
Mapping the Rounding G/L ID to an Event	29-10
Configuring BRM to Record Rounding Differences	29-11
Rounding Examples	29-11
Correcting for Precision Loss When Rounding Down	29-12
Rounding Using Different Modes	29-13

Configuring Balance Impact Rounding in ECE	29-13
Configuring Rounding for a Currency Balance Impact	29-14
Configuring Rounding for a Noncurrency Balance Impact	29-15
Configuring Rounding When Authorizing Multiple RUMs	29-16

Part V XML Pricing Interface for PDC

A New Pricing Terminology

New Pricing Terminology	A-1
-------------------------	-----

Preface

This guide describes how to create product offerings for Oracle Communications Billing and Revenue Management (BRM) in Pricing Design Center (PDC).

Audience

This guide is intended for pricing analysts and others involved in pricing, rating, and rerating.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

Diversity and Inclusion

Oracle is fully committed to diversity and inclusion. Oracle respects and values having a diverse workforce that increases thought leadership and innovation. As part of our initiative to build a more inclusive culture that positively impacts our employees, customers, and partners, we are working to remove insensitive terms from our products and documentation. We are also mindful of the necessity to maintain compatibility with our customers' existing technologies and the need to ensure continuity of service as Oracle's offerings and industry standards evolve. Because of these technical constraints, our effort to remove insensitive terms is ongoing and will take time and external cooperation.

1

About Creating Product Offerings

Learn how to create product offerings for Oracle Communications Billing and Revenue Management (BRM) in Pricing Design Center (PDC).

Topics in this document:

- [About Pricing Components](#)
- [About Pricing Setup Components](#)
- [Prerequisites for Creating Product Offerings](#)
- [About Changesets](#)
- [Making Changes to Your Product Offerings](#)
- [About Product Offering Ownership](#)

PDC includes sample product offerings for a broadband service and for a telco service in the `PDC_home/apps/samples/data` directory, where `PDC_home` is the directory in which PDC is installed.

About Pricing Components

BRM allows you to configure product offerings that you sell to your customers. You configure the prices and terms for the products you sell in PDC.

In PDC, your product offerings are called *packages*. A package groups charges and discounts together. Packages can also be associated with terms that govern the agreement between you and the customer who purchases the package.

Before assembling a package, you use PDC to create the pricing components that constitute the package:

- **Charge offers:** Charge offers define the charging rules, deliverables, and taxes for using your services. For example, a charge offer could specify to:
 - Charge \$35 per month for an online newspaper service
 - Grant 25 newspaper articles per month
 - Charge 10 cents per minute for mobile voice usage
 - Charge a one-time \$50 installation fee
- **Discount offers:** Discount offers define the rules for applying discounts to charges. For example, a discount offer could specify to:
 - Apply a 50% discount to the first six months of a newspaper subscription
 - Provide the first 500 minutes of a service for free
 - Provide every fifth movie download for free
- **Terms:** Subscription terms specify how long the customer must commit to the service, what happens if they cancel early, and when the subscription period ends.

For example, the terms for a telephony service might specify a 1-year commitment with a 1-month grace period, after which an early termination fee of \$25 is applied. The subscription automatically renews after one year.

After you create charge offers, discount offers, and terms, you group them into the following pricing components:

- **Bundles:** Bundles group charge offers and discount offers together for a single service. For example, you could create:
 - A bundle for a cable service that charges \$50 per month for a standard subscription and premium channels, and provides a 20% discount for the first six months of the standard subscription.
 - A bundle for an Internet service that charges \$65 per month for high-speed internet and \$9 per month for a modem rental.

Bundles can also be associated with terms.

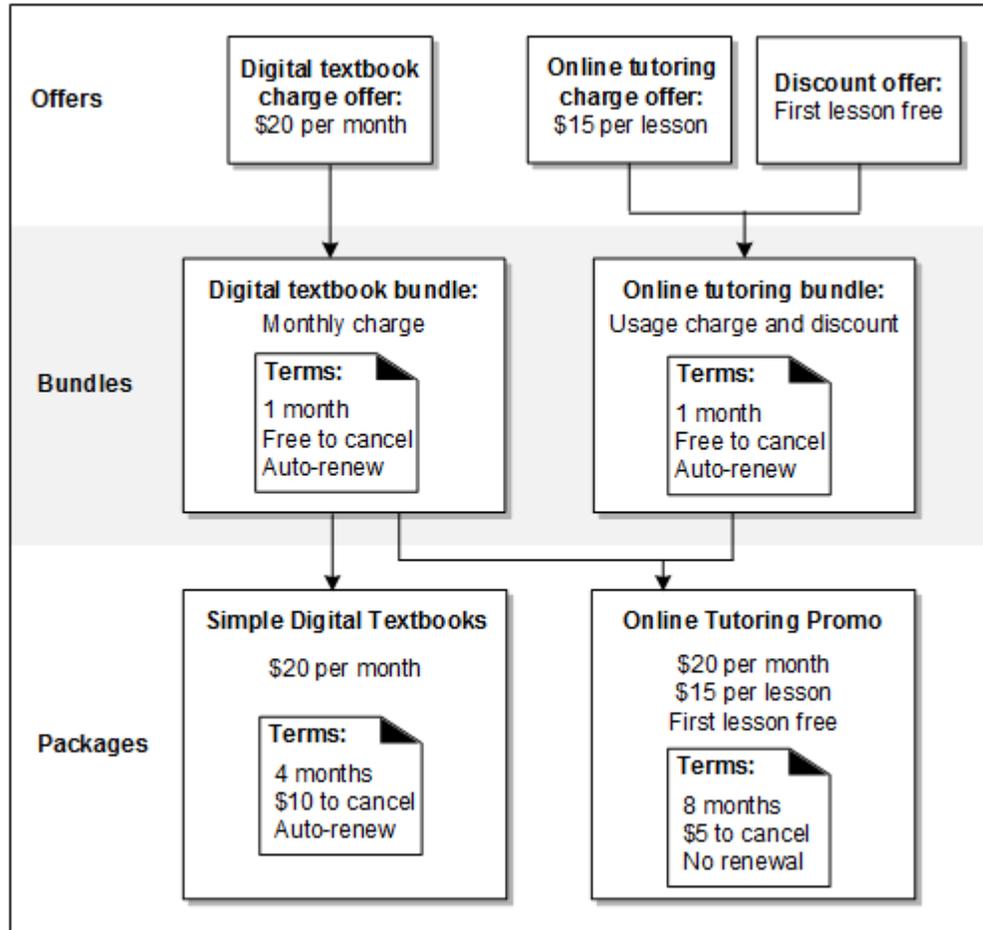

- **Packages:** Packages contain one or more bundles. You use packages to offer multiple services to subscribers. For example, you can include two bundles: one for an Internet service and one for a conferencing service.

Packages can also be associated with terms, and those terms govern any required bundles. Optional add-on bundles can be governed by separate, preset terms.

- **Package lists:** Package lists contain a group of packages offered to a single type of subscriber, such as those in a regional group.

[Figure 1-1](#) shows how charge offers and discount offers are organized into bundles and packages with associated terms.

Figure 1-1 Grouping Offers into Bundles and Packages

About Pricing Setup Components

Before configuring your product offerings, you first configure prerequisite components defining the services you are selling, the events your customers will be charged for, the tax codes to apply, and the revenue tracking information. In BRM, these prerequisite components are called *pricing setup components*. You might need users with specialized skills to configure them.

You use PDC to create these pricing setup components:

- **Services:** Services define what you base your charges on. For example, the GSM service definition enables you to charge for usage based on a customer's phone number.
- **Events:** An event is an online action, such as a phone call, an SMS message, or a data download. Data about the event is recorded in BRM. For example, when your customer makes a phone call, an event is generated that contains information about that phone call, such as the date and time the call was made. Events are also recorded for customer actions, such as purchasing a charge offer.
- **Ratable usage metrics (RUMs):** RUMs specify how to measure events for rating, such as:
 - Duration: The length of an event in units such as seconds or minutes.
 - Occurrence: The number of events generated during a specified period.

- **Service-event maps:** Service-event maps define which events can be used for a service and which RUMs can be used for each service-event combination. These maps determine which events are available when you define charge and discount offers.
- **Balance elements:** Balance elements are currency or noncurrency assets, such as U.S. dollars, minutes, or gigabytes. They can also be counters, such as tokens or points, that track the number of dollars spent or minutes talked.
- **Deliverables:** Deliverables specify when and how much revenue can be recognized from a customer's purchase of your products and services. For example, a textbook's deliverable could specify that 100% of the purchase price is recognized when the book ships from the warehouse.
- **Tax codes:** Tax codes specify the percentage of tax to apply to a charge, the jurisdiction (state or local), and how to calculate the charge.
- **Tax exemption codes:** Tax exemption codes specify the percentage by which to reduce the taxes owed for a charge.

You can also define these pricing setup components for additional charging functionality:

- **Time Models:** Time models are a set of time periods, such as 8pm to midnight and midnight to 6am. You use time models to charge different prices for a service based on the day and time.
- **Special day calendars:** Special day calendars define a set of dates, such as holidays or weekends. You add special day calendars to time models to charge different prices based on the calendar date.
- **Impact categories:** Impact categories are a set of event attributes, such as a call's origin and destination location. You use impact categories to apply different rates to events based on their attributes. For example, calls from America to Italy could be charged 10 cents per minute, and calls from America to Canada could be charged 9 cents per minute.
- **Zone models:** Zone models are a set of time zones, such as Pacific Time or Eastern Time. You use zone models to charge different prices based on your customer's time zone.
- **Value maps:** Value maps are hierarchical structures of zones and zone values. Each zone contains values that apply to a single event attribute, such as an area code, an IP address, or a broadband bit rate.
- **Selectors:** A selector is a series of rules that associates the values of event attributes, service attributes, account attributes, or custom rules to a result. Selectors can be applied to charges, discounts, items, taxes, and tax exemptions.
- **Policy specifications:** Policy specifications define a gradation of QoS based on the subscriber's service usage.
- **Extended attribute templates:** Extended attributes store additional information used by external systems, such as an enterprise product catalog. When using the XML Pricing Interface, you create extended attribute templates that configure the extended attributes that can be used for pricing components.
- **Custom analyzer rules:** A custom analyzer rule is a named expression that is used in selector rules to guide a price. For example, you can create custom rules for calls to friends and family on a subscriber's birthday, or to configure supplementary services, such as call forwarding and call blocking.

Prerequisites for Creating Product Offerings

Before you can start creating your product offerings, complete the following tasks:

- **Set up your general ledger.** Configure how your company records financial transactions for accounting purposes. See "Setting Up Your General Ledger" in *BRM Collecting General Ledger Data*.
- **Define your tax codes, tax exemption codes, and tax suppliers.** Define the amount or percentage of taxes to apply to charges, the tax jurisdictions (state or local), and the company or company division responsible for collecting taxes. See "About Calculating Taxes" in *BRM Calculating Taxes*.
- **Define provisioning tags.** Define the custom provisioning tasks needed to implement a service on the network, such as creating a voice mailbox. You must define provisioning tags if you use charge offer or discount offer provisioning. See "Creating Provisioning Tags" in *BRM Provisioning Services*.
- **Create your pricing setup components.** Configure the prerequisite components that define the services you are selling, the events that customers will be charged for, the tax codes to apply, and the revenue tracking information. See "[Creating Pricing Setup Components](#)".

About Changesets

In PDC, you create and modify all setup and pricing components in the context of a changeset. A changeset tracks the changes you make to setup and pricing components. Each user has one or more changesets, which only that user can access.

If you do not have a changeset, PDC automatically creates one for you when you log in. This changeset becomes your active changeset. When you create a setup or pricing component, a draft of the new component is added to your active changeset. When you modify a component, the updated component remains in the changeset in which it was created. If you have multiple changesets, only one can be active, but you can designate a different changeset as your active changeset at any time.

Note:

If no changeset is active after you log into PDC, you must either manually set the desired changeset as active or create a new changeset and make it active before performing any operations in the PDC application.

You submit the changeset to publish the pricing components in a changeset to the BRM database. You must submit an entire changeset; you cannot submit only some components.

You can import components from an XML file into a new or an existing open changeset. The imported components can be immediately submitted for publication.

To share your changesets with other users, you can export the components from a changeset into an XML file. Optionally, you can include all the components referenced by the components in the exported changeset, whether or not the components are part of that changeset.

Making Changes to Your Product Offerings

You can make changes to your product offerings at any time. For example, if you offer a new service, you can create new product offerings to charge for that service.

You can also change charges for existing charge offers, add charge offers to existing bundles, and so forth.

Deleting Charge Offers

You cannot delete a charge offer if any account owns it. To delete a charge offer, cancel it in all accounts.

Logging Changes to Product Offerings

To get notified when product offerings change, BRM can create messages in the **cm.pinlog** file when product offerings are updated. For information about **cm.pinlog** and other log files, see "Using Logs to Monitor Components" in *BRM System Administrator's Guide*.

To log product offering changes, set the **fm_rate log_refresh_product** entry in the Connection Manager (CM) **pin.conf** to **1**. If this entry is absent or set to **0**, BRM does not log changes to the product offerings.

Note:

Charge offers that are used while rating events are cached by rating. The cache is refreshed when a charge offer is modified based on the CM **pin.conf** entry **refresh_product_interval**. This entry specifies the time after which the cache needs to be refreshed. If this entry is not specified, the default refresh interval is one hour. When the cache is refreshed and **log_refresh_product** is enabled, a debug message is created in the **cm.pinlog** file indicating the **/product** object POID that was refreshed.

To log product offering changes:

1. Open the CM configuration file (*BRM_home/sys/cm/pin.conf*).
2. Set the value for the **fm_rate log_refresh_product** entry to **1**.

```
- fm_rate log_refresh_product 1
```
3. Save the file.
4. Stop and restart the CM.

About Product Offering Ownership

During account creation, the customer chooses a package. A package is a set of bundles, each of which, in turn, is a set of charge offers. Therefore, what the customer owns is not a package, but a collection of charge offers and discount offers.

If you create different charge offers for the same service, different customers might use the same service, but pay different charges, based on the charge offers that they own.

For example, you might have two customer accounts that use the same service but have different charge offers, as shown in the following example:

Account 1

Broadband charge offer 1:

- Service: IP
- Cycle forward event: \$20

- Usage events: \$2

Account 2

Broadband charge offer 2:

- Service: IP
- Cycle forward event: \$10
- Usage events: \$1

When BRM rates events for these customers, the charges for Account 1 differ from those for Account 2, even though the services and the events being rated are the same types.

When you manage a customer's account, you manage their charge offers. For example, you can change the charge offer status or customize the charge offer's pricing. When you create your product offerings, it is essential to consider how the charge offers will be managed after they have been purchased.

Part I

Creating Pricing Setup Components

This part describes how to create Oracle Communications Billing and Revenue Management (BRM) pricing setup components in Pricing Design Center (PDC).

This part contains the following chapters:

- [Creating Pricing Setup Components](#)
- [Synchronizing Pricing Setup Components](#)
- [Configuring Deliverables](#)
- [Configuring Policy Specifications](#)
- [Configuring Item Type Selectors](#)
- [Configuring Value Maps](#)

2

Creating Pricing Setup Components

Learn how to create the Oracle Communications Billing and Revenue Management (BRM) pricing setup components in Pricing Design Center (PDC).

Topics in this document:

- [About Setup Components](#)
- [Configuring Setup Components](#)
- [Configuring Ratable Usage Metrics \(RUMs\)](#)
- [Setting up Service and Event Definitions](#)
- [Setting Up the Service-Event Map](#)
- [Configuring Balance Elements](#)
- [About Offer Profiles](#)

About Setup Components

Setup components are the prerequisite data that you configure before creating product offerings. For example, before creating product offerings, you must configure the ratable usage metrics (RUMs) that define how to measure events.

Some setup components are defined in PDC, and some components are managed in BRM and need to be loaded into PDC.

The following setup components are defined in PDC. Any modifications to these components are also handled by PDC and are transformed into the BRM database and Oracle Communications Elastic Charging Engine (ECE).

- Balance elements
- Custom rules
- Deliverables
- Impact categories
- Item type selector
- Policy specifications
- Profile attribute specifications
- Ratable Usage Metrics (RUMs)
- Service-event maps
- Special day calendars
- Tax codes
- Tax exemption codes
- Value maps
- Zone models

- Extended attribute templates

The following setup components are managed in the BRM server and ECE. Any modifications to these components are also handled by the BRM server and ECE and must be synchronized with PDC.

- Account definition
- Business profiles
- Event definitions
- General ledger (G/L) IDs
- Provisioning tag names
- Service definitions
- Tax suppliers

 **Note:**

Some of the pricing setup data is optional. You must configure the optional pricing setup data only if you plan to use the related feature or perform certain business functions. For example, you configure a zone model only if you use zoning to determine a price in your charge offer.

Configuring Setup Components

You configure the setup components in PDC by using the following applications:

- **PDC UI.** Use to create and modify setup components using a graphical user interface. See *PDC Online Help* for more information.
- **ImportExportPricing utility.** Use to import setup components defined in an XML file into PDC. See "[Importing and Exporting Pricing and Setup Components](#)" for more information.
- **SyncPDC utility.** Use to synchronize setup components defined in BRM with PDC. See "[Synchronizing Pricing Setup Components](#)" for more information.

[Table 2-1](#) lists the setup components, the order in which you should configure the data, whether the setup component is required or optional, and the application you use to configure them.

Table 2-1 Setup Components and the Application You Use to Configure Them

Pricing Setup Data	Required/Optional	Application
RUMs	Required	PDC UI or ImportExportPricing utility
Service-event maps	Required	PDC UI or ImportExportPricing utility
Impact categories	Optional	PDC UI or ImportExportPricing utility
Zone models	Optional	PDC UI or ImportExportPricing utility
Special day calendars	Optional	PDC UI or ImportExportPricing utility

Table 2-1 (Cont.) Setup Components and the Application You Use to Configure Them

Pricing Setup Data	Required/Optional	Application
Services	Required	Defined in BRM and pushed to PDC by the SyncPDC utility Modified in PDC by the ImportExportPricing utility
Events	Required	Defined in BRM and pushed to PDC by the SyncPDC utility Modified in PDC by the ImportExportPricing utility
Profile attributes	Required	Defined in BRM and pushed to PDC by the SyncPDC utility Modified in PDC by the ImportExportPricing utility
Account attributes	Required	Defined in BRM and pushed to PDC by the SyncPDC utility Modified in PDC by the ImportExportPricing utility
Tax codes	Optional	PDC UI or ImportExportPricing utility.
Tax suppliers	Optional	Defined in BRM and pushed to PDC by the SyncPDC utility Modified in PDC by the ImportExportPricing utility
Tax exemption codes	Optional	PDC UI or ImportExportPricing utility
G/L IDs	Required for some target engines	Defined in BRM and pushed to PDC by the SyncPDC utility Modified in PDC by the ImportExportPricing utility
Deliverables	Required for deliverable-based revenue recognition	ImportExportPricing utility
Provisioning tag names	Optional	SyncPDC utility or ImportExportPricing utility
Balance elements	Required	PDC UI or ImportExportPricing utility
Value maps	Optional	ImportExportPricing utility
Custom analyzer rules	Optional	PDC UI or ImportExportPricing utility
Profile attribute specifications	Optional	ImportExportPricing utility
Item type selector	Required for ECE	PDC UI or ImportExportPricing utility
Business Profile	Required for BRM and ECE	SyncPDC utility
Policy Specifications	Optional	PDC UI or ImportExportPricing utility
Extended attribute templates	Optional	ImportExportPricing utility

Sample XML files for each setup component are in the *PDC_home\apps\Samples\Examples* directory, where *PDC_home* is the directory in which the PDC software is installed.

The **Examples** directory contains the following sample and ready-to-use files:

- **PDCSampleBE.xml**: Contains all currency balance elements and some frequently used noncurrency balance elements. You can load this file to create balance elements to use when configuring pricing quickly.

- **PDCSampleRum.xml**: Contains commonly used ratable usage metrics (RUMs). You can load this file to quickly create RUMs for creating a service-event map and configuring pricing.
- **OOB_ProfileSpecifications.xml**: Contains profile attribute specifications referenced in the following custom rules: **Friends&Family**, **SpecialDay**, and **ClosedUserGroup**. This XML file references the names used in the provisioning tags provided by default with the BRM installation.

 **Note:**

You must load the **OOB_ProfileSpecifications.xml** file before loading the **OOB_CRs.xml** file.

- **OOB_CRs.xml**: Contains the custom rules: **Friends&Family**, **SpecialDay**, and **ClosedUserGroup**. You can use these custom rules in a generic selector when configuring a charge based on a subscriber's Friends & Family, Special Day, or Closed User Group profile.
- **Sample_ServiceCUG_ProfileSpecification.xml**: Contains the profile attribute specification for configuring a service-level closed user group. See "[Configuring Closed User Groups](#)" for more information.
- **Sample_ServiceCUG_CR.xml**: Contains the custom rule for configuring a service-level closed user group. See "[Configuring Closed User Groups](#)" for more information.
- **OOB_ItemTypeSelector.xml**: Contains the default billing item assignments BRM supports without any additional configuration. You must load this file if you are using ECE. See "[Loading the OOB_ItemTypeSelector.XML File](#)" for more information.
- **Sample_ItemTypeSelector.xml**: Contains the item type selector rules for defining separate bill items for international and national calls. You can use this as a template to quickly create the item type selector for tracking international calls and national calls separately. See "[Configuring Item Type Selectors](#)" for more information.
- **SampleDeliverable.xml**: Contains sample deliverables. You can use this as a template to add and modify the elements as required. See "[Configuring Deliverables](#)" for more information.
- **SamplePolicyLabel.xml**: Contains policy labels referenced in the policy specifications. You can use this as a template to add and modify the elements as required. See "[Configuring Policy Specifications](#)".
- **SamplePolicySpecification.xml**: Contains policy specifications referenced in the charge offers and discount offers used for policy-driven charging. You can use this as a template to add and modify the elements as required. See "[Configuring Policy Specifications](#)".
- **Sample_ProductSpecCharacteristicTemplate.xml**: Contains sample extended attribute configurations that can be used in charge offers, discount offers, chargeshare offers, bundles, and packages. You can use this as a template to add or modify extended attributes as required. See "[Configuring Product Specification Attributes for Pricing Components](#)".
- **Sample_Tax_Code.xml**: Contains sample tax codes for both custom and Vertex tax calculation. You can use this as a template to add or modify tax codes. See "Creating Tax Codes Using ImportExportPricing (Patch Set 6 and Later)" in *BRM Calculating Taxes*.
- **Sample_Tax_Exemption_Code.xml**: Contains sample tax exemptions. You can use this as a template to add or modify tax exemptions to be applied at the product level. See

"Creating Product-Level Tax Exemption Codes Using ImportExportPricing (Patch Set 6 and Later)" in *BRM Calculating Taxes*.

- **SampleValueMap.xml**: Contains sample value map event attributes. You can use this as a template to associate zone names with values to enable location-based charging. See "Location-Based Charging" in *ECE Implementing Charging*.

You can load the updated sample XML files into PDC using the **ImportExportPricing** utility. See "[ImportExportPricing](#)" for the utility's syntax and parameter descriptions.

 **Note:**

The **Examples** directory also contains sample pricing profile files that are provided only for reference and for use as templates for creating custom pricing profiles. You should not load the sample pricing profile files after installing PDC.

Configuring Ratable Usage Metrics (RUMs)

RUMs are ways in which you can measure events. The most common RUMs are Duration and Volume.

Before you create product offerings, you must define the RUMs available for rating. You define RUMs when you create the service-event map. For each event, you specify the RUMs that can be used for rating it.

When you define RUMs, you define the following RUM attributes:

- The unit of measurement. For example, to rate duration, you might specify seconds or minutes. To measure bytes, you might specify megabytes or kilobytes.
- How to calculate the quantity. In PDC, use the RUM expression. For example, if you specify Minute as the unit of measurement, and you specify 1 as the expression, the duration is calculated in 1-minute increments.

You can also perform calculations on fields in the event by using the following operators:

- Add: +
- Subtract: -
- Multiply: *
- Divide: /
- How to round quantities:
 - Half Up: A fraction of .5 or greater is rounded up. For example, 1.5 is rounded to 2.
 - Half Down: A fraction of .5 or less is rounded down. For example, 1.5 is rounded to 1.
 - None
 - Round Up: Any fraction is always rounded up.
 - Round Down: Any fraction is always rounded down.
- Type:
 - Whole: Select this type if the RUM cannot be split; for example, Occurrence.
 - Partial: Select this type if the RUM can be split; for example, Duration.
 - Conditional: Select this type to configure charges with conditional balance impacts.

You create RUMs by using one of the following:

- The PDC UI. For more information, see "Creating a RUM Configuration" in *PDC Online Help*.
- The **ImportExportPricing** utility. For information about creating RUMs using the utility and an XML file, see the sample RUM XML file (*PDC_home/apps/Samples/Examples/PDCSampleRum.xml*) and "[ImportExportPricing](#)".

Setting up Service and Event Definitions

BRM provides a preconfigured set of service and event definitions. When you run the **SyncPDC** utility, the preconfigured service and event definitions are stored in PDC. For the list of preconfigured events, see the *BRM_home/sys/data/pricing/example/pin_event_map* file, where *BRM_home* is the directory in which you installed BRM.

Note:

Before you run the **SyncPDC** utility for the first time, ensure that only those services and events that are relevant to your business are available in the **pin_event_map** file.

If you use ECE for usage rating, the preconfigured event definitions are automatically enriched with the required information for ECE when you run the **SyncPDC** utility. You can use these definitions for pricing and charging without any further enrichment. Enriching includes:

- Adding user-defined charging attributes.
- Defining charge operation types.
- Mapping event attributes to the external network format.

For example, you add specific attributes that ECE uses to apply a session-based charge for a transaction.

You can also create your own service and event definitions:

- To offer new services and events
- To add additional attributes for provisioning, networking, charging, or billing

You can define the custom services and events in Developer Center and use the **SyncPDC** utility to synchronize the definitions with PDC. If you are defining a new service or event, ensure that you do the following:

1. Create a subclass for the new service or event in Developer Center. See "Creating Service and Event Storable Classes" in *BRM Developer's Guide* for more information.
2. Create a substructure in the event subclass; for example, `USAGE_INFO`, and add `USER_IDENTITY` and `CALLED_ID` fields in Developer Center. See "Substructure" and "Creating Custom Fields" in *BRM Developer's Guide* for more information.
3. Map the event to the corresponding service by editing the **pin_event_map** file and then running the **load_event_map** utility.
4. Synchronize the service and event definitions with PDC by running the **SyncPDC** utility. See "[Synchronizing Pricing Setup Components](#)" for more information.

The service and event definitions are loaded into PDC.

5. If you are using ECE for usage rating, enrich the event definitions with the information ECE requires for processing usage requests. See ["Enabling Charging for Custom Events"](#) for more information.

The enriched event definition is published to ECE.

6. If you are using ECE for usage rating and you want to use any service or account attributes for usage rating, ensure that only those service or account attributes are loaded into the ECE cache. See ["Using Service and Account Attributes with ECE for Usage Rating"](#) for more information.

Using Service and Account Attributes with ECE for Usage Rating

If you want to use any service or account attributes for ECE usage rating, ensure only those service or account attributes are loaded into the ECE cache by doing the following:

1. Export the service or account definition into an XML file by running the following command:

```
ImportExportPricing -export -metadata MetaDataObjectType -n "ObjectName"
```

where:

- *MetaDataObjectType* is the metadata object type, which can be EVENT_ATTRIBUTE_SPEC, PRODUCT_ATTRIBUTE_SPEC, PROFILE_ATTRIBUTE_SPEC, or CUSTOMER_ATTRIBUTE_SPEC. If you do not specify *MetaDataObjectType*, the utility exports all metadata components from the PDC database into the XML file.
- *ObjectName* is the name of the service or account to export to the XML file.

For example, this command would export the definition for TelcoGSM to the **productattr_export_config.xml** file:

```
ImportExportPricing -export -metadata PRODUCT_ATTRIBUTE_SPEC -n "TelcoGSM"
```

2. Open the XML file in a text editor.
3. Search for the attributes you want to use for usage rating and add the following entries for each attribute:

```
<attributeItemSupportedBy>
  <targetApplicationSpecName>Pricing</targetApplicationSpecName>
  <targetApplicationSpecName>Convergent Charging</targetApplicationSpecName>
</attributeItemSupportedBy>
```

4. Save and close the file.
5. Import the XML file into PDC by running this command:

```
ImportExportPricing -import -metadata FileOrDirectoryName -ow
```

For example:

```
ImportExportPricing -import -metadata productattr_export_config.xml -ow
```

The utility loads the service or account definition into PDC.

ECE Pricing Updater publishes only the service or account attributes you want to use for usage rating to ECE. Only those attributes are loaded into the ECE cache.

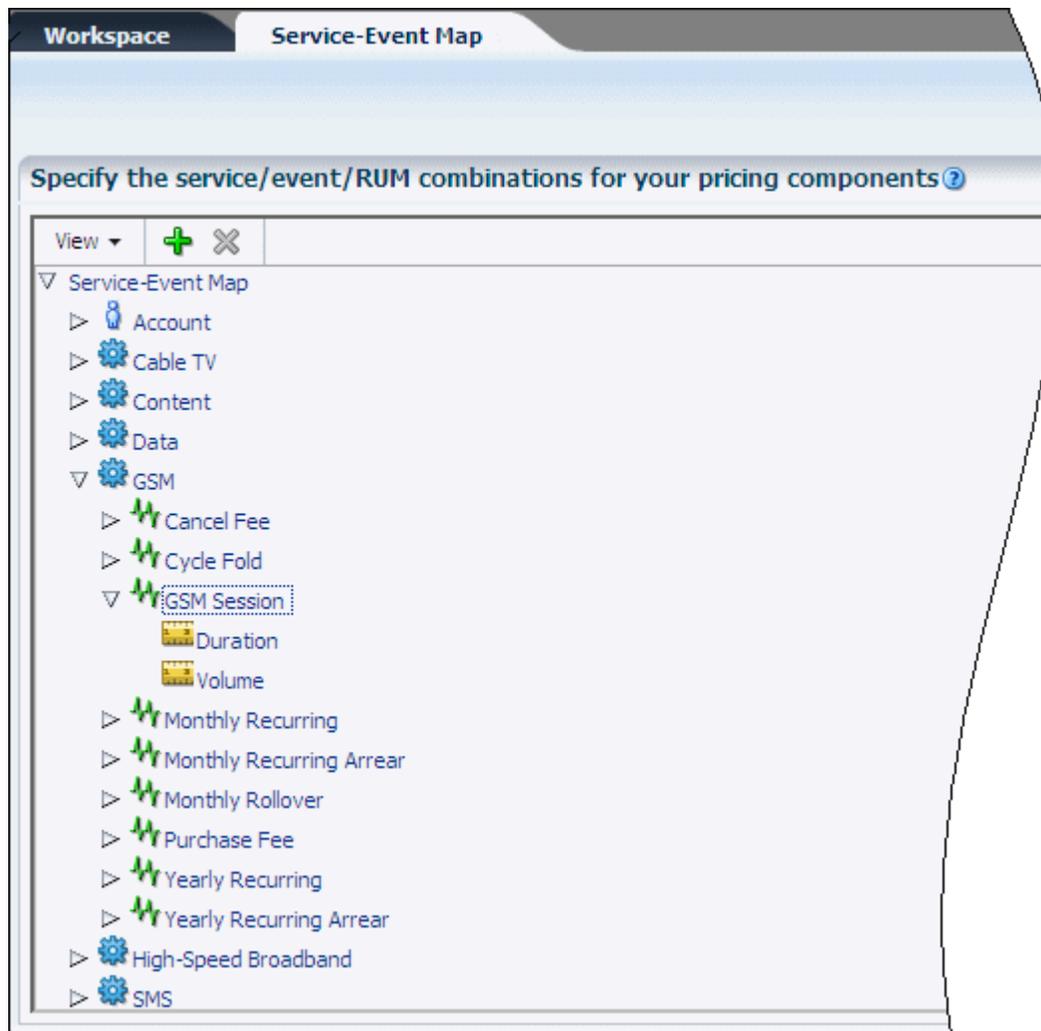

Setting Up the Service-Event Map

Before you can create charge offers, you must set up a service-event map. The service-event map lists all the services to which charge offers can apply. For each service, the map specifies which events can have charges configured for that service. The map also specifies the RUMs to use for rating each event combination.

For events that do not apply to a specific service, you map those events to **Account** in the service-event map.

For example, in [Figure 2-1](#), the events Cancel Fee, Cycle Fold, GSM Session, Monthly Recurring, and Monthly Recurring Arrear are mapped to the GSM service. The RUMs, Duration and Volume, are mapped to the GSM Session event.

Figure 2-1 Service-Event Map in PDC

Configuring Balance Elements

Before you can create pricing components, you must use PDC to create balance elements. A balance element represents a:

- Currency, such as US dollars or euros.
- Noncurrency asset, such as minutes or gigabytes.
- Counter, such as loyalty points or tokens. Counters are noncurrency assets that allow you to track balances, such as the amount spent or megabytes downloaded by a customer.
- Temporary balance, such as minutes or gigabytes. Temporary balances are noncurrency assets that retain their balances while processing the discounts for one event. After all discounts for an event are completed, temporary balance elements are reset to 0.

When you configure pricing in a charge or a discount, you specify the balance elements that are debited or credited. For example, a charge of 1 dollar per minute for a phone call debits the USD balance element.

When you create balance elements, you define the following:

- The balance element name, such as Canadian Dollar or Free Minutes.
- The reference code for the balance element.
For currency balance elements, the default reference code is used. For noncurrency balance elements, you must enter a unique reference code.
- The balance element ID, such as 124. Currency balance element IDs are defined in an ISO standard.
- The abbreviation or symbol used for display, such as \$, Can\$, or Minute.
- For noncurrency balance elements, whether used as a counter or for temporarily tracking balances.
- Whether the balance element can be used in a fold charge.
- Whether to notify customers when their balance is about to expire.
- The order in which to consume sub-balances. For example, if a customer's balance contains minutes with different validity periods, you specify which minutes to use first according to the starting or ending validity date. See "[Specifying the Order in Which Sub-Balances Are Consumed](#)".
- The rounding rules. See "[Adding Rounding Rules to Balance Elements](#)".

You create balance elements by using one of the following:

- The PDC UI. For more information, see "Creating Currency Balance Elements" in *PDC Online Help*.
- The **ImportExportPricing** utility. For information about creating balance elements using the utility and an XML file, see the sample balance element XML file (*PDC_home/apps/Samples/Examples/PDCSampleBE.xml*) and "[ImportExportPricing](#)".

For information about how to add multiple currency balance elements for subscriber currencies under a single pricing tier, see "[Enabling Single Currency Graph](#)" for more information.

Adding Rounding Rules to Balance Elements

Rounding rules allow you to control the precision of charge calculations. PDC provides a set of default rounding rules, but you can add new rounding rules for specific events.

When adding a rounding rule, you define the following:

- The processing stage in which to apply the rounding rule:
 - Accounts receivable (A/R)
 - Charging
 - Discounting
 - Taxation
- The event category that the rounding rule applies to:
 - Billing-time discount
 - One-time
 - Recurring
 - Fold
 - Rollover
 - Usage
 - Remittance
- The event that the rounding rule applies to. The applicable events are based on the event category. For example, Basic Usage is an option for the Usage event category.
- If the selected event has child events, whether to use the rounding rule for both parent and child events.
- How to round additional numbers beyond the precision value:
 - Up: For example, 10.151 rounds to 10.16.
 - Down: For example, 10.159 rounds to 10.15.
 - Down Alt: Performs the same rounding as Down, except that it compensates for possible loss of precision by first rounding with a mode of Nearest using a scale two digits greater than the scale you configure. See ["About Rounding Modes That Correct for Loss of Precision"](#).
 - Nearest: The last significant digit remains the same if the additional digit is 0 through 4. The last significant digit is rounded up if the additional digit is 5 through 9. For example, 10.144 rounds to 10.14, and 10.145 rounds to 10.15.
 - Even: If the additional digit is 0 through 4, the last significant digit remains the same. If the additional digit is 6 through 9, the last significant digit is rounded up. If the additional digit is 5, the last significant digit is rounded to the nearest even digit. For example, 10.155 rounds to 10.16, and 10.165 rounds to 10.16.
 - Floor: Rounds numbers toward a negative value (that is, the rounded number is always less than the unrounded number). This enables you to round balance impacts so that customers always benefit. For example, if the scale is 2, a credit to a customer of -7.999 is rounded to -8.00, and a debit of 7.999 is rounded to 7.99.
 - Floor Alt: Performs the same rounding as Floor, except that it compensates for possible loss of precision by first rounding with a mode of Nearest using a scale that is

two digits greater than the scale you configure. See "[About Rounding Modes That Correct for Loss of Precision](#)".

- The rounding precision. For example, to round US dollars to cents, specify a precision value of two places after the decimal point.
- The minimum and maximum tolerance values and the tolerance percentage that determines how the rounding rule is applied to the balance element. For example, you can specify a tolerance of 4 digits after the decimal point.

For more information about rounding balance elements, see "[Configuring Balance Impact Rounding](#)".

Enabling Single Currency Graph

To enable a single currency graph:

Note:

A single currency graph can be used only with ECE.

1. Go to the `PDC_home/apps/bin` directory.
2. Export the pricing data by running the `ImportExportPricing` utility.

For example, to export the data to a file named `chargeoffer_export_pricing.xml`, run the following command:

```
./ImportExportPricing -export chargeoffer -pricing
```

3. In the `chargeoffer_export_pricing.xml` file, search for the `balanceElementNumCode` attribute. By default, only one currency code is available. You can add more currency codes.

For example:

```
-<subscriberCurrency>
  <currencyCode>USD</currencyCode>
  <currencyCode>EUR</currencyCode>
-<applicableRum>
  <applicableRumName>Duration</applicableRumName>
  <minQuantity>1.0</minQuantity>
  <minQuantityUnit>NONE</minQuantityUnit>
  <incrementQuantity>1.0</incrementQuantity>
  <incrementQuantityUnit>NONE</incrementQuantityUnit>
  <roundingMode>NEAREST</roundingMode>
-<crpRelDateRange>
  -<absoluteDateRange>
    <startDate>0</startDate>
    <endDate>inf</endDate>
  </absoluteDateRange>
-<crpCompositePopModel>
  <name>Pricing</name>
  -<usageChargePopModel>
    -<priceTier>
      <distributionMethod>FROM_BAL_IMPACT</distributionMethod>
    -<tierBasis>
      <rumTierExpression/>
    </tierBasis>
    <enforceCreditLimit>>false</enforceCreditLimit>
```

```

        <rumName>Duration</rumName>
        <currencyCode>USD</currencyCode>
        -<priceTierValidityPeriod>
            <lowerBound>0</lowerBound>
            <validFrom>0</validFrom>
        -<priceTierRange>
            <upperBound>NO_MAX</upperBound>
        -<scaledCharge>
            <price>0.0</price>
            <unitOfMeasure>NONE</unitOfMeasure>
            <balanceElementNumCode>840</balanceElementNumCode>
            <discountable>true</discountable>
            <priceType>CONSUMPTION</priceType>
            <incrementStep>1.0</incrementStep>
            <incrementRounding>NONE</incrementRounding>
        </scaledCharge>
    </priceTierRange>
</priceTierValidityPeriod>
<applicableQuantity>ORIGINAL</applicableQuantity>
</priceTier>
</usageChargePopModel>
</crpCompositePopModel>
</crpRelDateRange>
</applicableRum>
</subscriberCurrency>

```

4. Save the XML file as **import_pricing.xml** file.
5. Import the **import_pricing.xml** file using the **ImportExportPricing** utility.

For example:

```
./ImportExportPricing -import -pricing import_pricing.xml -ow
```

6. Add, edit, or remove balance impacts for all the supported subscriber currencies.

About Offer Profiles

Offer profiles are made up of one or more policy labels, each of which defines a gradation in the quality of service (QoS) based on usage amounts.

For example, you can have an offer profile called **Platinum** for a data service and define its balance element as **Megabytes Used**. You can define a policy labeled **Fair Usage**, which has three levels, **Low QoS**, **Medium QoS**, and **High QoS**, with each level containing a usage range valid for that quality of service.

3

Synchronizing Pricing Setup Components

Learn how to synchronize Oracle Communications Billing and Revenue Management (BRM) setup components, such as services and events, with Pricing Design Center (PDC) by using the **SyncPDC** utility.

Topics in this document:

- [About Synchronizing Setup Components](#)
- [About the SyncPDC Utility](#)
- [Changing Display Names](#)

About Synchronizing Setup Components

When configuring a new PDC system, you use the **SyncPDC** utility to synchronize the setup components defined in the billing and rating system with PDC. See "[Configuring Setup Components](#)" for more information.

Note:

Ensure that **/event/realtimeDiscount** does not exist in BRM during synchronization.

SyncPDC synchronizes the following setup components:

- Account definitions
- Business profiles
- Event definitions
- General ledger (G/L) IDs
- Profile definitions
- Provisioning tags
- Service definitions
- Tax suppliers

After these setup components are synchronized with PDC, you perform any modifications in the system in which they were initially defined and then resynchronized.

SyncPDC synchronizes only the changes from the previous synchronization. It generates reports for the components that it synchronizes. See "[Generating Synchronization Reports](#)" for more information.

When synchronizing setup components, **SyncPDC** creates display names in PDC for the corresponding data objects and their fields. For example, it creates the **GsmTelephony** PDC name for the **/service/gsm/telephony** service name in BRM. You can change the PDC display name in PDC. For example, you can change **EventTelcoGsmVoice** to **Voice Call**. If you later

run **SyncPDC** to resynchronize this event, it retains the name change. See "[Changing Display Names](#)" for more information about updating PDC display names.

If you delete a setup component (or any of its fields) from the billing or rating system, you must manually remove the corresponding PDC component (or its fields) from the PDC database. See "[Deleting Setup Components](#)" for more information.

About the SyncPDC Utility

The **SyncPDC** utility runs as a server process in the background, continuously checking for data to synchronize from BRM or the rating system with PDC. You can schedule it to run immediately, at a specified time, or regularly at a specified time. At any given time, you can stop the synchronization by stopping **SyncPDC**. See "[Stopping SyncPDC](#)" for more information.

Prerequisites for Running SyncPDC

Before you run **SyncPDC**, do the following:

- Start the transformation engines for the rating systems. See "Starting the Transformation Engines" in *BRM System Administrator's Guide*.
- Include the `PDC_home\apps\bin` directory in your PATH environment variable, where `PDC_home` is the directory in which you installed the PDC software.
- Configure the `BRM_Integration_Pack_Home\apps\syncpdc\SyncPDCCConfiguration.xml` file. See [Table 3-1](#), for more information.
- Ensure the Event Type is set correctly in BRM.

To run **SyncPDC**, you must have **Pricing Design Admin** role privileges.

About Configuring SyncPDC

SyncPDC uses the `SyncPDCCConfiguration.xml` file, which contains configuration settings for **SyncPDC** as well as connection information for Oracle WebLogic Server Administration, the PDC server, and the cross-reference database. This file is generated during PDC installation and is located in the `BRM_Integration_Pack_Home\apps\syncpdc` directory. By default, this file contains the values that you provide during BRM Integration Pack installation. You can change the default values by updating this file.

To update `SyncPDCCConfiguration.xml`:

1. Open the `BRM_Integration_Pack_Home\apps\syncpdc\SyncPDCCConfiguration.xml` file in a text editor or an XML editor.
2. Edit the file. See [Table 3-1](#) for more information.
3. Save and close the file.

[Table 3-1](#) lists the elements in `SyncPDCCConfiguration.xml`, the usage of each element, and a description of how to specify each element based on the default version of the file.

Table 3-1 Elements in the SyncPDCCConfiguration.xml File

Element	Syntax	Description
Configuration	<Configuration>	The root element of <code>SyncPDCCConfiguration.xml</code> .

Table 3-1 (Cont.) Elements in the SyncPDCConfiguration.xml File

Element	Syntax	Description
walletConfiguration	<pre><walletConfiguration> <pdWalletLocation>BRMIntegrationPackWallet</pdWalletLocation> </walletConfiguration></pre>	Specifies the Oracle wallet that stores the sensitive information, such as database passwords, where <i>BRMIntegrationPackWallet</i> is the complete path to the Oracle wallet in BRM Integration Pack.
xrefDatabase	<pre><xrefDatabase> <connectionInfo> <login>CrossRefUserName</login> <hostName>CrossRefHostName</ hostName> <port>CrossRefPort</port> <serviceName>CrossRefServiceName</ serviceName> </connectionInfo> </xrefDatabase></pre>	<p>Contains details about the cross-reference database, where:</p> <ul style="list-style-type: none"> • <i>CrossRefUserName</i> specifies the cross-reference database user name • <i>CrossRefHostName</i> specifies the IP address or the host name of the computer on which the cross-reference database is configured • <i>CrossRefPort</i> specifies the port number assigned to the cross-reference database • <i>CrossRefServiceName</i> specifies the name of the cross-reference database service
pricingServer	<pre><pricingServer> <connectionInfo> <hostName>PricingServerHostName</ hostName> <port>PricingServerPort</port> <adminUser>AdminUserName</ adminUser> <pdUser>PDCUser</pdUser> </connectionInfo> </pricingServer></pre>	<p>Contains details about the PDC server, where:</p> <ul style="list-style-type: none"> • <i>PricingServerHostName</i> specifies the IP address or the host name of the computer on which PDC is deployed • <i>PricingServerPort</i> specifies the port number of the domain on which PDC is deployed • <i>AdminUserName</i> specifies the user name of the PDC server administrator • <i>PDCUser</i> specifies the PDC user name
transformationHome	<pre><transformationHome>TransformationHome </transformationHome></pre>	Specifies the path to the directory that stores the transformation process IDs, where <i>TransformationHome</i> is the complete path to the directory.
syncPDCLogFileLocation	<pre><syncPDCLogFileLocation>SyncPDCLogFile </syncPDCLogFileLocation></pre>	Specifies the path to the directory that stores SyncPDC log files, where <i>SyncPDCLogFile</i> is the complete path and the name of the log file.
brand	<pre><brand>BrandOption</brand></pre>	Specifies whether PDC supports branding, where <i>BrandOption</i> is enabled or disabled .
pdcssl	<pre><pdcssl>SSLOption</pdcssl></pre>	<p>Specifies whether the PDC server supports SSL, where <i>SSLOption</i> is:</p> <ul style="list-style-type: none"> • enabled to specify that PDC supports SSL. If SSL is enabled, SyncPDC uses the t3s://Host:Port URL to access PDC • disabled to specify that PDC does not support SSL. If SSL is disabled, SyncPDC uses the t3://Host:Port URL to access PDC

Table 3-1 (Cont.) Elements in the SyncPDCConfiguration.xml File

Element	Syntax	Description
retryInfo	<pre><retryInfo> <retryInterval>RetryInterval</ retryInterval> <maxRetries>MaxRetries</maxRetries> </retryInfo></pre>	<p>Contains the information about when and how many times SyncPDC should retry the synchronization process if it fails initially, where:</p> <ul style="list-style-type: none"> • <i>RetryInterval</i> specifies the interval in seconds after which SyncPDC again tries to synchronize the data that was not previously synchronized • <i>MaxRetries</i> specifies the maximum number of retries
ECESync	<pre><ECESync>ECESyncOption</ECESync></pre>	<p>Specifies to synchronize BRM data with PDC, where <i>ECESyncOption</i> is:</p> <ul style="list-style-type: none"> • true to synchronize BRM data with PDC to use Oracle Communications Elastic Charging Engine (ECE) for usage rating • false to synchronize BRM data with PDC to use real-time and batch rating engines for usage rating
pdcXML	<pre><pdcXML>PDCData</pdcXML></pre>	<p>Specifies the path to the directory where SyncPDC creates the XML files containing the extracted data in PDC format, where <i>PDCData</i> is the complete path to the directory.</p>
reportFileLocation	<pre><reportFileLocation>ReportLocation</ reportFileLocation></pre>	<p>Specifies the path to the directory where SyncPDC stores the report of the synchronization process, where <i>ReportLocation</i> is the complete path to the directory.</p>
brmExtractedXML	<pre><brmExtractedXML>BRMData </brmExtractedXML></pre>	<p>Specifies the path to the directory where SyncPDC creates the XML files containing the data extracted from the BRM database, where <i>BRMData</i> is the complete path to the directory.</p>
pdcExtractedXML	<pre><pdcExtractedXML>PDCData </pdcExtractedXML></pre>	<p>Specifies the path to the directory where SyncPDC creates the XML files containing the data extracted from the PDC database, where <i>PDCData</i> is the complete path to the directory.</p>
archiveFileLocation	<pre><archiveFileLocation>ArchiveFile</ archiveFileLocation></pre>	<p>Specifies the path to the directory where a successfully processed file is archived, where <i>ArchiveFile</i> is the complete path to the directory. No archive file is created if there is no change from the previous synchronization.</p>
skipBREMmigration	<pre><skipBREMmigration>SkipOption</ skipBREMmigration></pre>	<p>Specifies whether to skip synchronization of pipeline configuration data, where <i>SkipOption</i> is either true or false.</p> <p>This element is ignored when ECE is enabled in your PDC system, where the ECESync option is set to true.</p> <p>The default value is false when you use PDC with Realtime Rating and Batch Rating Engines.</p>

Table 3-1 (Cont.) Elements in the SyncPDCConfiguration.xml File

Element	Syntax	Description
fieldSelection	<pre> <fieldSelection> <targetEngine>TargetRatingEngine</ targetEngine> <eventFields> <eventName>EventName</eventName> <fullyQualified_name>EventFieldName</ fullyQualified_name> </eventFields> </fieldSelection> </pre>	<p>Contains the information about the target rating engine and the BRM event fields provided as input to the target rating engine for usage rating.</p> <p><targetEngine> element specifies the target rating engine used for usage rating, where: <i>TargetRatingEngine</i> is one of the following:</p> <ul style="list-style-type: none"> • Convergent Charging. Specifies that ECE is used for usage rating. • Realtime Charging. Specifies that the real-time rating engine is used for usage rating. • Batch Charging. Specifies that the batch rating engine is used for usage rating. <p><eventFields> element specifies the fields that are provided as input to <i>TargetRatingEngine</i>, where:</p> <ul style="list-style-type: none"> • <i>EventName</i> specifies the class name of the BRM event; for example, /event. • <i>EventFieldName</i> specifies the fully qualified name of the BRM event field that is provided as input to <i>TargetRatingEngine</i>; for example, PIN_FLD_NAME. <p>Note: Each <fieldSelection> element can have multiple <eventFields> elements but only one <targetEngine> element. To support multiple target rating engines, add the <fieldSelection> element for each target rating engine.</p> <p>Similarly, each <eventFields> element can have multiple <fullyQualified_name> elements but only one <eventName> element. To rate multiple events, add the <eventFields> element for each event.</p>

Table 3-1 (Cont.) Elements in the SyncPDCConfiguration.xml File

Element	Syntax	Description
syncPDCBREConfig	<pre> <syncPDCBREConfig> <containerDesc> <param> <paramname>ParamName</paramname> <paramvalue>ParamValue</ paramvalue> </param> </containerDesc> <eventExtension> <param> <paramname>BRMBatchRatingEventName </paramname> <paramvalue>EventExtensionBlockName</ paramvalue> </param> </eventExtension> <serviceExtension> <param> <paramname>BRMServiceName</ paramname> <paramvalue>ServiceExtensionBlockN ame</paramvalue> </param> </serviceExtension> </syncPDCBREConfig> </pre>	<p>Contains the information about EDR container description data and delayed events and services for batch rating engine.</p> <p>The <containerDesc> element specifies the EDR container description data that is used by the batch rating engine, where:</p> <ul style="list-style-type: none"> • <i>ParamName</i> specifies the field name that defines the EDR container description name • <i>ParamValue</i> specifies the value of <i>ParamName</i>. The EDR container description data that matched <i>ParamValue</i> is used as the base to synchronize EDR fields for events and services <p>The <eventExtension> element specifies the mapping of a delayed event to the extension block name used in the batch rating engine, where:</p> <ul style="list-style-type: none"> • <i>BRMBatchRatingEventName</i> specifies the delayed event name • <i>EventExtensionBlockName</i> specifies the extension block name to which the delayed event is mapped <p>Add <param> elements to the <eventExtension> elements for each <i>BRMBatchRatingEventName</i> and <i>EventExtensionBlockName</i> to include.</p> <p>The <serviceExtension> element specifies the mapping of a BRM service to the extension block name used in the batch rating engine, where:</p> <ul style="list-style-type: none"> • <i>BRMServiceName</i> specifies the BRM service name • <i>ServiceExtensionBlockName</i> specifies the extension block name to which the BRM service is mapped <p>Add <param> elements to the <serviceExtension> elements for each <i>BRMServiceName</i> and <i>ServiceExtensionBlockName</i> to include.</p> <p>For more information about the EDR container description, see the BRM documentation.</p>

Table 3-1 (Cont.) Elements in the SyncPDCConfiguration.xml File

Element	Syntax	Description
scheduling	<pre><scheduling> <runOnStartup>StartupOption</ runOnStartup> <startAt>StartTime</startAt> <interval>Interval</interval> </scheduling></pre>	<p>Contains the scheduling configurations for SyncPDC.</p> <p>If the <scheduling> element is not present or its child elements are not defined correctly, SyncPDC runs immediate only once.</p> <p><i>StartupOption</i> specifies whether SyncPDC should run immediately:</p> <ul style="list-style-type: none"> true specifies that SyncPDC runs immediately in addition to the scheduled time false specifies that SyncPDC does not run immediately but at the scheduled time <p><i>StartTime</i> specifies the time in <i>HH:MM</i> format when you want SyncPDC to start, where:</p> <ul style="list-style-type: none"> <i>HH</i> specifies hours between 00 and 23 <i>MM</i> specifies minutes between 00 and 59 <p><i>Interval</i> specifies the frequency in <i>N:A</i> format at which you want to run SyncPDC, where:</p> <ul style="list-style-type: none"> <i>N</i> is an integer <i>A</i> is D for days, H for hours, or M for minutes <p>For example, to run SyncPDC every two days, enter:</p> <pre><interval>2:D</interval></pre> <p>Note: 24:H is not same as 1:D due to daylight saving time.</p>

Running SyncPDC

To run **SyncPDC**:

1. Ensure that transformation engines are running. See "Starting the Transformation Engines" in *BRM System Administrator's Guide*.
2. Go to the `BRM_Integration_Pack_Home\apps\syncpdc` directory.
3. Enter the following command:

```
startSyncPDC
```

The **Enter Wallet Password** prompt appears.

4. Enter the BRM Integration Pack wallet password.

A series of messages appears on the command prompt that indicate the synchronization status.

For example:

```
Clean up work item SYNC_EVENT...
Work item SYNC_EVENT started (item 1 of 8).
  Processing EXTRACT work action...
  Work action EXTRACT completed.
  Processing ANALYZE work action...
  Work action ANALYZE completed.
  Processing TRANSFORM work action...
```

```
Work action TRANSFORM completed.  
Processing LOAD work action...  
Work action LOAD completed.  
Work item SYNC_EVENT completed.
```

After the synchronization is complete, check the synchronization report available in the directory defined in the `<reportFileLocation>` element of the `SyncPDCConfiguration.xml` file.

Scheduling Synchronization

You can schedule the data synchronization from BRM or rating systems with PDC by:

- [Running SyncPDC Immediately](#)
- [Running SyncPDC at a Scheduled Time](#)
- [Running SyncPDC Immediately and at a Scheduled Time](#)
- [Running SyncPDC at Recurring Scheduled Time](#)

Running SyncPDC Immediately

To run **SyncPDC** immediately instead of waiting for the next scheduled run time:

1. Open the `BRM_Integration_Pack_Home/apps/syncpdc/SyncPDCConfiguration.xml` file in a text editor or an XML editor.
2. Set the `<runOnStartup>` element to **true**:

```
<runOnStartup>true</runOnStartup>
```
3. Save and close the file.
4. (Optional) If **SyncPDC** is already running in the background, stop it.
See "[Stopping SyncPDC](#)" for more information.
5. Run **SyncPDC**. See "[Running SyncPDC](#)" for more information.

Running SyncPDC at a Scheduled Time

To run **SyncPDC** at a schedule time:

1. Open the `BRM_Integration_Pack_Home/apps/syncpdc/SyncPDCConfiguration.xml` file in a text editor or an XML editor.
2. Set the `<runOnStartup>` element to **false**:

```
<runOnStartup>>false</runOnStartup>
```
3. Set the `<startAt>` element to the start time:

```
<startAt>HH:MM</startAt>
```

where:

- *HH* specifies hours between 00 and 23
- *MM* specifies minutes between 00 and 59

For example, to run **SyncPDC** at 11:50 pm, enter:

```
<startAt>23:50</startAt>
```

4. Save and close the file.

5. Run **SyncPDC**.

See "[Running SyncPDC](#)" for more information.

Running SyncPDC Immediately and at a Scheduled Time

To run **SyncPDC** immediately and at a schedule time:

1. Open the *BRM_Integration_Pack_Home\apps\syncpdc\SyncPDCConfiguration.xml* file in a text editor or an XML editor.

2. Set the `<runOnStartup>` element to **true**:

```
<runOnStartup>true</runOnStartup>
```

3. Set the `<startAt>` element to the start time:

```
<startAt>HH:MM</startAt>
```

where:

- *HH* specifies hours between 00 and 23
- *MM* specifies minutes between 00 and 59

For example, to run **SyncPDC** immediately and at 11:50 pm, enter:

```
<runOnStartup>true</runOnStartup>  
<startAt>23:50</startAt>
```

4. Save and close the file.

5. Run **SyncPDC**.

See "[Running SyncPDC](#)" for more information.

Running SyncPDC at Recurring Scheduled Time

To run **SyncPDC** at recurring scheduled time:

1. Open the *BRM_Integration_Pack_Home\apps\syncpdc\SyncPDCConfiguration.xml* file in a text editor or an XML editor.

2. Set the `<runOnStartup>` element to **false**:

```
<runOnStartup>false</runOnStartup>
```

3. Set the `<startAt>` element to the start time:

```
<startAt>HH:MM</startAt>
```

where:

- *HH* specifies hours between 00 and 23
- *MM* specifies minutes between 00 and 59

4. Specify the `<interval>` element as follows:

```
<interval>N:A</interval>
```

where:

- *N* is an integer
- *A* is **D** for days, **H** for hours, or **M** for minutes

For example, to run **SyncPDC** at 11:50 pm everyday, enter:

```
<runOnStartup>>false</runOnStartup>  
<startAt>23:50</startAt>  
<interval>1:D</interval>
```

5. Save and close the file.
6. Run **SyncPDC**.
See "[Running SyncPDC](#)" for more information.

Synchronizing BRM Data with PDC to Use ECE for Usage Rating

To synchronize BRM data with PDC to use ECE for usage rating:

1. Open the *BRM_Integration_Pack_Home\apps\syncpdc\SyncPDCConfiguration.xml* file in a text editor or an XML editor.
2. Set the **<ECESync>** element to **true**:

```
<ECESync>true</ECESync>
```
3. Save and close the file.
4. Run **SyncPDC**.
See "[Running SyncPDC](#)" for more information.

Stopping SyncPDC

You can stop **SyncPDC** at any time. If you stop **SyncPDC** while it is synchronizing data, it finishes the synchronization before stopping.

To stop **SyncPDC**, enter the following command:

```
stopSyncPDC
```

A series of messages appears, indicating progress.

For example:

```
Previous process id :4381  
Killing child processes ...  
Killing process ...  
Cleaning temporary files ...  
[1] + Killed
```

Generating Synchronization Reports

SyncPDC generates reports for the components that it synchronizes. If there are no changes from the previous synchronization, **SyncPDC** does not create a report.

You specify the location of the **SyncPDC** report in the **<reportFileLocation>** element of the **SyncPDCConfiguration.xml** file.

When synchronizing data from BRM with PDC, the **SyncPDC** report lists the object type for each setup component that is synchronized. It lists the PDC display name and the corresponding BRM or rating system name for each of the setup component objects. It also provides the total number of object types for each setup component that are synchronized.

[Figure 3-1](#) shows a sample **SyncPDC** report for BRM data.

Figure 3-1 Sample SyncPDC Report for BRM Data

SyncPDC Report. Generated on 20120730_235025_832

Report Type: SyncPDC, Object Type: Event

PDC Internal Id	PDC Event Name	BRM Event Name
d672f756-ed1c-4be8-93dd-ea4f787ea809	Event	/event
9a34af04-9f86-4c5f-8b99-b884c6c47490	EventActivityContent	/event/activity/content
2c65f382-ad3a-4920-b30d-63785e3ef954	EventActivitySettlement	/event/activity/settlement
b7338796-3c4c-4564-88ca-15cc5e289ecd	EventActivityTelco	/event/activity/telco
51a87729-e4ab-466f-80de-9d37f7890aa8	EventBillingCycleDiscount	/event/billing/cycle/discount
c0576f18-54cc-4f8a-9ed6-754ca44dbead	EventBillingCycleDiscountMostcalled	/event/billing/cycle/discount/mostcalled
b05c6917-305d-4b43-bb3a-b9f6faa6b9c1	EventBillingCycleFold	/event/billing/cycle/fold
b260e6d5-601e-442b-9f96-f56c58e11df7	EventBillingCycleRolloverMonthly	/event/billing/cycle/rollover/monthly
51b0ae22-7101-4b47-af55-1a122ea48419	EventBillingFeeFailed_payment	/event/billing/fee/failed_payment
c37e96ed-0202-47ee-a45a-043dc8699adb	EventBillingIncentive	/event/billing/incentive
f13ad160-3093-4a60-9574-a3957952ea86	EventBillingProductFeeCancel	/event/billing/product/fee/cancel
3bad8520-2c95-4b1c-a22b-78c87b3e0cfb	EventBillingProductFeeCycleCycle_arrear	/event/billing/product/fee/cycle/cycle_arrear
927f9fca-f02a-4e16-98ce-ea8c12d193ea	EventBillingProductFeeCycleCycle_forward_annual	/event/billing/product/fee/cycle/cycle_forward_annual

Total number of BRM event objects synchronized: 13

When synchronizing data from ECE with PDC, the **SyncPDC** report provides the status of loading the XML files containing ECE data.

Figure 3-2 shows a sample **SyncPDC** report for ECE data.

Figure 3-2 Sample SyncPDC Report for ECE Data

Start Load ECE Report:

Import File Name	Status
PdcService.xml	SUCCESS
Customer.xml	SUCCESS
PdcEvent.xml	FAILED

Successfully Imported Files: 2

Failed to Import Files: 1

End Load ECE Report.

Handling Synchronization Failures

The most common reasons for a synchronization failure are as follows:

- The billing or rating system is down
- After billing or rating system data was modified, the billing or rating system was not restarted. Hence, no data is available for synchronization with PDC
- The PDC system is down
- The transformation engines are down
- The transformation engines failed to process the PDC data and update the cross-reference database
- The billing or rating system database or the PDC database is down

Reprocessing a Failed Synchronization

To reprocess a failed synchronization:

1. Identify and fix the cause of the synchronization failure.

For information about synchronization failures, check the **SyncPDC** log file located in the directory specified in the **<syncPDCLogFileLocation>** element of the **SyncPDCConfiguration.xml** file.

2. Run **SyncPDC**.

See "[Running SyncPDC](#)" for more information.

SyncPDC synchronizes the data that failed to synchronize earlier and ignores the data that was already synchronized.

Changing Display Names

When synchronizing setup components, **SyncPDC** creates display names in PDC for the corresponding data objects and their fields. You can change the default display names that **SyncPDC** creates.

To change the display name of a setup component:

1. Export the setup component to an XML file by using the **ImportExportPricing** utility.
See "[Exporting Pricing and Setup Components from PDC](#)" for more information.
2. Open the XML file in a text editor or an XML editor.
3. Change the display name of the setup component in the XML file.
4. Save and close the file.
5. Import the updated XML file to PDC by using **ImportExportPricing**.

See "[Importing Pricing and Setup Components](#)" for more information.

If you later run **SyncPDC** to synchronize any changes from the billing or rating system with PDC, **SyncPDC** retains the updated component name.

4

Configuring Deliverables

Learn how to use Oracle Communications Pricing Design Center (PDC) deliverables to specify how and when revenue is recognized by your company.

Topics in this document:

- [About Creating Deliverables](#)
- [Configuring Deliverables](#)
- [Loading Deliverables into the PDC Database](#)

About Creating Deliverables

 **Note:**

Deliverables are supported only by Oracle Communications Billing and Revenue Management (BRM) 12.0.0.3.0 with Interim Patch 31426340 and later, and PDC 12.0.0.3.0 with Interim Patch 31426374 and later.

A deliverable is a good or service that provides value to your customers, such as an eBook, a night in a hotel room, or a month of telephony service. In BRM, a deliverable defines the type of good or service you are selling, its standalone selling price, its revenue earning schedule, and its revenue G/L ID.

You create deliverables if your company supports deliverable-based revenue recognition. See "About Deliverable-Based Revenue Recognition" in *BRM Collecting General Ledger Data*.

The type of deliverable that you create depends on the good or service that your company is selling.

- **One-time activities:** These are discrete services that are performed by your company or by your customers, such as a company installing a service at the customer's home. All of the revenue from one-time activities is recognized at once, either at the time of purchase or when a milestone has been marked as completed.
- **Physical goods:** These are tangible products that you sell to your customers, such as DVDs, cell phones, and eBooks. All of the revenue from physical goods is recognized at once, either at the time of purchase or when a milestone has been marked as completed.
- **Metered services:** These are services with limits on how much customers can use in a cycle, such as 100 free minutes or 20 eBooks a month. The revenue from metered services is recognized on a linear earning schedule at a frequency that you specify. For example, if a customer has a one-year contract for a monthly service, your company recognizes 1/12th of the revenue at the end of each month.
- **Continuous services:** These allow customers to use an unlimited amount of a service over a specified time period, such as unlimited data for a month or unlimited access to a website for a month. The revenue from continuous services is recognized on a linear earning schedule at a frequency that you specify. For example, if a customer has a one-

year contract for a monthly service, your company recognizes 1/12th of the revenue at the end of each month.

To create deliverables, do the following:

1. Ensure that deliverable-based revenue recognition is enabled in BRM. See "Enabling Deliverable-Based Revenue Recognition" in *BRM Collecting General Ledger Data*.
2. Configure your deliverables in an XML configuration file. See "[Configuring Deliverables](#)".
3. Load the XML configuration file into the PDC database by using the **ImportExportPricing** utility. See "[Loading Deliverables into the PDC Database](#)".

After you create your deliverables, you associate them with your charge offers.

Configuring Deliverables

To configure your deliverables, you can create your own XML configuration file that follows the format specified in the XML Schema Definition (XSD) file. Alternatively, you can make a copy of the *PDC_home/apps/Samples/Examples/SampleDeliverable.xml* file and then customize it for your business needs.

The deliverable XML configuration file contains the following:

- A **deliverables** section, which is the top-level section that applies to all deliverable types. The elements in this section specify the deliverable's name, type, and associated G/L ID. See "[About the deliverables Section](#)".
- An **entitlements** subsection, which applies to only service-based deliverables: one-time activities, continuous services, and metered services. The elements in this subsection specify the type of service you are offering and its validity period. See "[About the entitlements Subsection](#)".
- A **revenueBasisItem** subsection, which applies to all deliverables. The elements in this subsection define the good's or service's standalone selling price and its earning schedule. See "[About the revenueBasisItem Subsection](#)".

For physical goods, this subsection is nested under the **deliverables** section. For service-based deliverables, this subsection is nested under **entitlements**.

For information about how to configure the XML file based on the type of good or service you are selling, see the following:

- [Configuring Deliverables for Physical Goods](#)
- [Configuring Deliverables for One-Time Activities](#)
- [Configuring Deliverables for Metered Services](#)
- [Configuring Deliverables for Continuous Services](#)

About the deliverables Section

[Table 4-1](#) describes all of the elements in the **deliverables** section.

Table 4-1 Elements in the deliverables Section

Element	Description
name	Specifies the name of the deliverable.
description	Provides a description of the deliverable.

Table 4-1 (Cont.) Elements in the deliverables Section

Element	Description
priceListName	Set this to Default .
obsolete	Specifies whether the deliverable configuration is obsolete (true) or still active (false).
deliverableType	Specifies whether the deliverable is for a product or service: PRODUCT : Use this value for physical goods. SERVICE : Use this value for one-time activities, metered services, and continuous services.
productType	Specifies the type of product: PHYSICAL_GOODS : Use this value for physical goods. ADMINISTRATIVE : Use this value for one-time activities, metered services, and continuous services. Note : This field is required if deliverableType is PRODUCT .
permittedType	Specifies the type of service that the deliverable can be associated with: PRODUCT : Use this if the deliverable can be associated with a specific service type. CUSTOMER : Use this if the deliverable can be associated with Account.
permittedName	If permittedType is PRODUCT , set this to the name of the service. If permittedType is CUSTOMER , set this to Account .
revenueGlid	Specifies the revenue G/L ID to use for tracking early termination fees.

About the entitlements Subsection

[Table 4-2](#) describes all of the elements in the **entitlements** subsection. This subsection applies to only one-time activities, metered services, and continuous services.

Table 4-2 Elements in the entitlements Subsection

Element	Description
entitlementType	Specifies the type of service entitlement: ALLOWANCE_ONE_TIME : Use this for one-time activities. FEATURE : Use this for continuous services. ALLOWANCE_RECURRING : Use this for metered services.
name	Specifies the name of the service entitlement.
description	Provides a description of the service entitlement.
resourceBalElemNumCode	(ALLOWANCE_ONE_TIME and ALLOWANCE_RECURRING entitlement types only) Specifies the noncurrency balance element numeric code for tracking the service you are offering. For example, you might enter the numerical code for gigabytes for an allowance of data.
featureValue	(FEATURE entitlement types only) Describes the type of continuous service you are providing, such as unlimited data for a month or unlimited text messages for a week.

Table 4-2 (Cont.) Elements in the entitlements Subsection

Element	Description
allowanceValidityMode	(ALLOWANCE_ONE_TIME and ALLOWANCE_RECURRING entitlement types only) Specifies the validity period for the allowance granted to your customer: CURRENT_BILLING : The allowance expires after the current billing cycle. MULTIPLE_BILLING : The allowance expires after the specified number of billing cycles, such as 3 billing cycles. CURRENT_RECURRING : The allowance expires after the current frequency period, such as the current quarter or the current bimonthly period. MULTIPLE_RECURRING : The allowance expires after the specified number of frequency periods, such as two quarters or two bimonthly periods. ALWAYS : The allowance never expires. For example, if the data granted to your customer expires at the end of the billing cycle, you would enter CURRENT_BILLING.
allowanceValidityPeriod	(ALLOWANCE_ONE_TIME and ALLOWANCE_RECURRING entitlement types only) Specifies the number of cycles or periods for the allowance's validity mode. 1 : Use this if allowanceValidityMode is set to CURRENT_BILLING , CURRENT_RECURRING , or ALWAYS . <i>IntegerValue</i> : Specify the number of billing cycles or frequency periods that the allowance is valid, such as 3 for 3 billing cycles. Use this if allowanceValidityMode is set to MULTIPLE_BILLING or MULTIPLE_RECURRING .
allowanceValue	(ALLOWANCE_ONE_TIME and ALLOWANCE_RECURRING entitlement types only) Specifies the amount of a resource that is granted to the customer, such as 20 eBooks, 200 domestic texts, or 1 night in a hotel room.
subscriptionCycle	(ALLOWANCE_RECURRING entitlement types only) Specifies the frequency at which the allowance is granted to the customer. The supported values are: MONTHLY , BIMONTHLY , QUARTERLY , SEMI_ANNUAL , and ANNUAL .

About the revenueBasisItem Subsection

Table 4-3 describes all of the elements in the **revenueBasisItem** subsection.

Table 4-3 Elements Supported in the revenueBasisItem Subsection

Element	Description
type	Specifies the type of revenue: RATE_BASED : Use this for metered services and one-time activities. VALUE_BASED : Use this for continuous services and physical goods.
amount	Specifies the amount for the standalone selling price, such as 100, 150, or 200.
currencyBalElemNumCode	Specifies the ISO currency number for the standalone selling price, such as 840 for US Dollars or 978 for Euros.
timeUnit	Set this to MONTH .
timeValue	Specifies the number of months that the amount is valid, such as 2 for 2 months. The default is 1 .

Table 4-3 (Cont.) Elements Supported in the revenueBasisItem Subsection

Element	Description
milestoneType	Specifies when the revenue is recognized for physical goods: IMMEDIATE: Use this to recognize the revenue at the time of purchase. FUTURE: Use this to recognize revenue when a milestone is marked as completed. Note: The milestoneType element applies only to physical goods. However, you must enter a value for all other deliverable types to prevent an error when you load the XML configuration file.
scalable	Specifies whether the rate is scalable (true) or not (false).
quantity	(ALLOWANCE_RECURRING and ALLOWANCE_ONE_TIME entitlement types only) Specifies the quantity of the service.

Configuring Deliverables for Physical Goods

To configure a deliverable for a physical good, add the following to your XML configuration file:

- In the top-level **deliverables** section, add a name, description, and other information about your product. Ensure that you set these elements as follows:

- Set **deliverableType** to **PRODUCT**
- Set **productType** to **PHYSICAL_GOODS**

- In the **revenueBasisItem** subsection, do the following:

- Set **type** to **VALUE_BASED**
- Specify the standalone selling price for the physical good that you are selling. For example, for a standalone selling price of 20 US Dollars, you would enter:

```
<amount>20.00</amount>
<currencyBalElemNumCode>840</currencyBalElemNumCode>
```

- Specify whether the revenue is recognized at purchase (IMMEDIATE) or when a milestone is marked as completed (FUTURE). For example:

```
<milestoneType>IMMEDIATE</milestoneType>
```

- Specify the validity period for the physical good. For example, for 1 month, you would enter:

```
<timeUnit>MONTH</timeUnit>
<timeValue>1</timeValue>
```

The following example shows how to configure a deliverable for an Internet modem and handset with a standalone selling price of 99 US Dollars, an immediate earning schedule, and a validity period of 1 month.

```
<deliverables xmlns:cim="http://xmlns.oracle.com/communications/platform/
model/Config">
  <name>Internet Modem and Handset</name>
  <description>Internet Modem and Handset</description>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <deliverableType>PRODUCT</deliverableType>
  <productType>PHYSICAL_GOODS</productType>
```

```

<revenueGlid>1000005</revenueGlid>
<revenueBasisItem>
  <type>VALUE_BASED</type>
  <amount>99</amount>
  <currencyBalElemNumCode>840</currencyBalElemNumCode>
  <timeUnit>MONTH</timeUnit>
  <timeValue>1</timeValue>
  <milestoneType>IMMEDIATE</milestoneType>
  <scalable>true</scalable>
</revenueBasisItem>
</deliverables>

```

Configuring Deliverables for One-Time Activities

To configure a deliverable for a one-time activity, add the following to your XML configuration file:

- In the top-level **deliverables** section, add a name, description, and other information about the one-time activity. Ensure that you set these elements as follows:
 - Set **deliverableType** to **SERVICE**
 - Set **productType** to **ADMINISTRATIVE**
- In the **entitlements** subsection, add a name and description, and then ensure that you set the following elements:

- Set **entitlementType** to **ALLOWANCE_ONE_TIME**
- Specify the noncurrency balance element numeric code for tracking the service you are offering. For example:

```
<resourceBalElemNumCode>1000101</resourceBalElemNumCode>
```

- Specify the validity period for the allowance. For example, for a validity period of 2 billing cycles, you would enter:

```
<allowanceValidityMode>MULTIPLE_BILLING</allowanceValidityMode>
<allowanceValidityPeriod>2</allowanceValidityPeriod>
```

- In the **revenueBasisItem** subsection, add the following:
 - Set **type** to **RATE_BASED**
 - Specify the standalone selling price for the one-time activity. For example, for a standalone selling price of 100 Euros, you would enter:

```
<amount>100.00</amount>
<currencyBalElemNumCode>978</currencyBalElemNumCode>
```

The following example shows how to configure a deliverable for an Internet Modem Handset Installation with a standalone selling price of 200 US Dollars:

```

<deliverables xmlns:cim="http://xmlns.oracle.com/communications/platform/
model/Config">
  <name>Internet Modem Handset_Installation</name>
  <description>Internet Modem Handset_Installation</description>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <deliverableType>SERVICE</deliverableType>
  <productType>ADMINISTRATIVE</productType>
  <revenueGlid>1000002</revenueGlid>

```

```

<entitlement>
  <entitlementType>ALLOWANCE_ONE_TIME</entitlementType>
  <name>Installation Entitlement</name>
  <resourceBalElemNumCode>1000101</resourceBalElemNumCode>
  <allowanceValidityMode>CURRENT_BILLING</allowanceValidityMode>
  <revenueBasisItem>
    <type>RATE_BASED</type>
    <amount>200.0</amount>
    <currencyBalElemNumCode>840</currencyBalElemNumCode>
    <timeUnit>MONTH</timeUnit>
    <timeValue>1</timeValue>
    <milestoneType>IMMEDIATE</milestoneType>
    <scalable>true</scalable>
    <quantity>1</quantity>
  </revenueBasisItem>
</entitlement>
</deliverables>

```

Configuring Deliverables for Metered Services

To configure a deliverable for a metered service, add the following to your XML configuration file:

- In the top-level **deliverables** section, add a name, description, and other information about the metered service. Ensure that you set these elements as follows:
 - Set **deliverableType** to **SERVICE**
 - Specify the type of service that the deliverable can be associated with. For example, for telephony services, you would enter:

```

<permittedType>PRODUCT</permittedType>
<permittedName>TelcoGsmTelephony</permittedName>

```

- In the **entitlements** subsection, add a name and description, and then ensure that you set the following elements:

- Set **entitlementType** to **ALLOWANCE_RECURRING**
- Specify the allowance amount that is granted to the customer, such as 100 minutes or 10 gigabytes. For example, for 100 text messages, you would enter:

```

<allowanceValue>100.00</allowanceValue>
<resourceBalElemNumCode>9305</resourceBalElemNumCode>

```

- Specify the validity period for the allowance. For example, if a granted data allowance of 5 GB expires after 1 billing cycle, you would enter:

```

<allowanceValidityMode>CURRENT_BILLING</allowanceValidityMode>
<allowanceValidityPeriod>1</allowanceValidityPeriod>

```

- Specify the frequency at which the allowance is granted to the customer. For example, if a data allowance of 5 GB is granted every month, you would enter:

```

<subscriptionCycle>MONTHLY</subscriptionCycle>

```

- In the **revenueBasisItem** subsection, add the following:
 - Set **type** to **RATE_BASED**

- Specify the standalone selling price for the service. For example, for a standalone selling price of 100 Euros, you would enter:

```
<amount>100.00</amount>
<currencyBalElemNumCode>978</currencyBalElemNumCode>
```

- Specify the validity period for the metered service. For example, for 1 month, you would enter:

```
<timeUnit>MONTH</timeUnit>
<timeValue>1</timeValue>
```

The following example shows how to configure a deliverable for VOIP service that grants 200 minutes per month and that has a standalone selling price of 100 US dollars:

```
<deliverables xmlns:cim="http://xmlns.oracle.com/communications/platform/
model/Config">
  <name>VoiceCallsOverIP</name>
  <description>VoiceCallsOverIP</description>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <deliverableType>SERVICE</deliverableType>
  <permittedType>PRODUCT</permittedType>
  <permittedName>Ip</permittedName>
  <revenueGlid>1000001</revenueGlid>
  <entitlement>
    <entitlementType>ALLOWANCE_RECURRING</entitlementType>
    <name>VoiceCallOverIPEntitlement</name>
    <resourceBalElemNumCode>1000101</resourceBalElemNumCode>
    <allowanceValidityMode>CURRENT_BILLING</allowanceValidityMode>
    <allowanceValidityPeriod>1</allowanceValidityPeriod>
    <allowanceValue>200</allowanceValue>
    <subscriptionCycle>MONTHLY</subscriptionCycle>
    <revenueBasisItem>
      <type>RATE_BASED</type>
      <amount>100.0</amount>
      <currencyBalElemNumCode>840</currencyBalElemNumCode>
      <timeUnit>MONTH</timeUnit>
      <timeValue>1</timeValue>
      <milestoneType>IMMEDIATE</milestoneType>
      <scalable>>false</scalable>
      <quantity>1</quantity>
    </revenueBasisItem>
  </entitlement>
</deliverables>
</cim:ConfigObjects>
```

Configuring Deliverables for Continuous Services

To configure a deliverable for a continuous service, add the following to your XML configuration file:

- In the top-level **deliverables** section, add a name, description, and other information about the continuous service. Ensure that you set these elements as follows:
 - Set **deliverableType** to **SERVICE**

- Specify whether the deliverable can be associated with a service or an account. For example, for VOIP services, you would enter:

```
<permittedType>PRODUCT</permittedType>
<permittedName>Ip</permittedName>
```

- In the **entitlements** subsection, add a name and description, and then ensure that you set the following elements:

- Set **entitlementType** to **FEATURE**
- Specify the name and value of the continuous service you are offering. For example, for an unlimited number of minutes for VOIP calls, you would enter:

```
<featureValue>UnlimitedCallMinutes</featureValue>
```

- In the **revenueBasisItem** subsection, add the following:

- Set **type** to **VALUE_BASED**
- Specify the standalone selling price for the service. For example, for a standalone selling price of 20 US dollars, you would enter:

```
<amount>20.00</amount>
<currencyBalElemNumCode>840</currencyBalElemNumCode>
```

- Specify the validity period for the continuous service. For example, for 1 month, you would enter:

```
<timeUnit>MONTH</timeUnit>
<timeValue>1</timeValue>
```

The following example shows how to configure a deliverable for unlimited data for a month that has a standalone selling price of 100 US dollars:

```
<deliverables xmlns:cim="http://xmlns.oracle.com/communications/platform/
model/Config">
  <name>DataDownload</name>
  <description>DataDownload</description>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <deliverableType>SERVICE</deliverableType>
  <permittedType>PRODUCT</permittedType>
  <permittedName>Ip</permittedName>
  <revenueGlid>1000001</revenueGlid>
  <entitlement>
    <entitlementType>FEATURE</entitlementType>
    <name>DataDownloadEntitlement</name>
    <featureValue>UnlimitedDataDownload</featureValue>
    <revenueBasisItem>
      <type>VALUE_BASED</type>
      <amount>100</amount>
      <currencyBalElemNumCode>840</currencyBalElemNumCode>
      <timeUnit>MONTH</timeUnit>
      <timeValue>1</timeValue>
      <milestoneType>IMMEDIATE</milestoneType>
      <scalable>>true</scalable>
    </revenueBasisItem>
  </entitlement>
</deliverables>
```

Loading Deliverables into the PDC Database

To load your deliverables into the PDC database:

1. Go to the directory in which you saved your deliverable XML configuration file.
2. Run the following command:

```
ImportExportPricing -import -config FileOrDirectoryName
```

where *FileOrDirectoryName* specifies either the full path and file name of the import XML file or the directory in which the import XML files reside.

See "[Importing and Exporting Pricing and Setup Components](#)" for more information.

5

Configuring Policy Specifications

Learn how to configure policy specifications for Oracle Communications Billing and Revenue Management (BRM) in Pricing Design Center (PDC).

Topics in this document:

- [About Configuring Policy Specifications](#)

About Configuring Policy Specifications

You configure policy specifications in PDC for policy-driven charging.

Note:

Policy specifications can be used only with Oracle Communications Elastic Charging Engine (ECE).

After you configure policy specifications, you can import the policy specifications and policy labels from the customized XML files into the PDC database by running the following command:

```
ImportExportPricing -import -config FileOrDirectoryName
```

where *FileOrDirectoryName* specifies either the full path and file name of the import XML file or the directory in which the import XML files reside.

The policy specification is imported into the PDC database and transformed to BRM and ECE.

Configuring Policy Specifications

To configure policy specifications:

1. Make a copy of the *PDC_home\apps\Samples\Examples\SamplePolicyLabel.xml* file to customize.
2. Open the file in a text editor or XML editor.
3. Add or modify the elements as required.
4. Save and close the file.
5. Make a copy of the *PDC_home\apps\Samples\Examples\SamplePolicySpecification.xml* file to customize.
6. Open the file in a text editor or XML editor.
7. Add or modify the elements as required.
8. Save and close the file.
9. Go to the directory where you have saved the files.

10. Import the policy specifications and policy labels from the customized XML files into the PDC database by running the following command:

```
ImportExportPricing -import -config FileOrDirectoryName
```

The policy specifications and policy labels are imported into the PDC database and transformed to ECE.

After you configure policy specifications, you can export the policy specifications and policy labels in PDC to XML files by running the following command:

```
ImportExportPricing -export -config POLICY_SPECIFICATION  
ImportExportPricing -export -config POLICY_LABEL
```

You can load the updated sample XML files into PDC by using the **ImportExportPricing** utility. See "[ImportExportPricing](#)" for the utility's syntax and parameter descriptions.

6

Configuring Item Type Selectors

Learn how to configure item type selectors in Pricing Design Center (PDC) to track balances in Oracle Communications Billing and Revenue Management (BRM) product offerings.

Topics in this document:

- [About Configuring Item Type Selectors](#)
- [Loading the OOB_ItemTypeSelector.XML File](#)
- [Configuring Item Type Selectors](#)

About Configuring Item Type Selectors

You configure item type selectors in PDC so that balance impacts can be tracked appropriately for different bill items.

By default, BRM tracks balances for the following bill items: cycle arrears items, cycle forward items, cycle forward arrears items, cycle tax items, cycle incentive items, and usage items. You can load the **OOB_ItemTypeSelector.xml** file into PDC to configure the item type selectors for these bill items in PDC. See "[Loading the OOB_ItemTypeSelector.XML File](#)" for more information.

If you want to use custom bill items, you can configure item type selectors to create rules to assign balance impact to the custom bill items. You can use the **Sample_ItemTypeSelector.xml** file as a template to configure the item type selectors for custom bill items. See "[About Configuring Item Type Selectors](#)" for more information.

[Table 6-1](#) lists the elements that are supported in the item type selector XML file, the usage of each element, and a description of how to specify each element in the XML file.

Table 6-1 Elements Supported in the Item Type Selector XML File

Element	Syntax	Description
itemTypeSelectors	<code><itemTypeSelectors></code>	The root element of ItemTypeSelector.xml .
name	<code><name>ItemTypeSelectorName</name></code>	<i>ItemTypeSelectorName</i> specifies the item type selector name.
description	<code><description>ItemTypeSelectorDescription</description></code>	<i>ItemTypeSelectorDescription</i> contains the description of the item type selector.
priceListName	<code><priceListName>PriceListName </priceListName></code>	<i>PriceListName</i> specifies the price list name. BRM uses only one internal price list. The only value is Default .
applicableToName	<code><applicableToName>ApplicableToName</applicableToName></code>	<i>ApplicableToName</i> specifies the service name or Account . The attributes of this service or account are used in the rules.

Table 6-1 (Cont.) Elements Supported in the Item Type Selector XML File

Element	Syntax	Description
eventSpecName	<code><eventSpecName>EventName</eventSpecName></code>	<i>EventName</i> specifies the name of any event. The attributes of this event are used in the rules.
itemGroup	<code><itemGroup>ItemGroupName</itemGroup></code>	<p>Specifies the item group to be used for aggregating the balance impacts; where <i>ItemGroupName</i> specifies the name of the item group. The <itemGroup> element is associated with the <itemTag> element in BRM.</p> <p>To aggregate balance impacts based on the item configuration value in the business profile, specify the item configuration value as <i>ItemGroupName</i>. See "Improving Performance by Using Multiple Item Configurations" in <i>BRM System Administrator's Guide</i> for more information on item configuration.</p> <p>Note: If you specify the item configuration value as <i>ItemGroupName</i>, Oracle recommends that you do not change that value in the business profile. The default value is Default.</p>
applicableToAllBalImpact	<code><applicableToAllBalImpact>BalanceImpactsOption</applicableToAllBalImpact></code>	<p>Specifies whether this item type selector is applicable to all balance impacts, where <i>BalanceImpactsOption</i> is:</p> <ul style="list-style-type: none"> true if the item type selector applies for all the balance impacts false if the item type selector applies only to specific balance impacts
rule	<pre> <rule> <ruleName>RuleName</ruleName> <ruleOrder>RuleOrder</ruleOrder> <expression>Expression</expression> <specName>ItemSpecificationName</specName> </rule> </pre>	<p>Contains the rules for assigning the balance impacts to the bill items, where:</p> <ul style="list-style-type: none"> <i>RuleName</i> specifies the rule name. <i>RuleOrder</i> specifies the order in which the rules must be applied. <i>Expression</i> contains the details to derive which items to assign balance impacts to. <p>Note: You can add multiple rules in the item type selector. Each rule points to the item specification in the same item type selector.</p> <p>Each rule in the item type selector can refer to a different attribute. For example, Rule 1 can use an event attribute, Rule 2 can use an attribute of the charging result, and Rule 3 can use a service attribute.</p>

Table 6-1 (Cont.) Elements Supported in the Item Type Selector XML File

Element	Syntax	Description
expression	<pre> <expression> <separator>Delimiter</separator> <operation>Operator</operation> <fieldName> FieldName</fieldName> <fieldKind>FieldKind</fieldKind> <fieldValue>FieldValue</fieldValue> </expression> </pre>	<p>Contains the details to derive which items to assign balance impacts to.</p> <ul style="list-style-type: none"> • <i>Delimiter</i> specifies the character that is used to separate the field values. • <i>Operator</i> specifies the operator to be used in the expression. The valid values are: <ul style="list-style-type: none"> EQUAL_TO NOT_EQUAL_TO GREATER_THAN GREATER_THAN_EQUAL LESS_THAN LESS_THAN_EQUAL IN_LIST REGEX • <i>FieldName</i> specifies the field name. If you specify CHARGING_RESULT_SPEC as the <i>FieldKind</i>, the valid values are: <ul style="list-style-type: none"> TAX_CODE GLID RUM BALANCE_ELEMENT ZONE_RESULT TIMEMODEL_TAG_NAME GENERIC_SELECTOR_RESULT ORIG_ZONE_RESULT PRICING_NAME TIME_MODEL_NAME ZONE_MODEL_NAME EVALUATED_ZONE_MODEL_NAME EVALUATED_ZONE CHARGE_RATE_PLAN_NAME • <i>FieldKind</i> specifies the type of attributes to be selected for assigning the balance impacts. The valid values are: <ul style="list-style-type: none"> PRODUCT_SPEC_FIELD EVENT_SPEC_FIELD CUSTOMER_SPEC_FIELD CHARGING_RESULT_SPEC • <i>FieldValue</i> specifies the field value that is used for tracking balance impacts.

Table 6-1 (Cont.) Elements Supported in the Item Type Selector XML File

Element	Syntax	Description
itemSpec	<pre><itemSpec> <name>ItemSpecificationName</name> <description>ItemSpecificationDescription</description> <priceListName>PriceListName </priceListName> <type>ItemType</type> <default>DefaultOption</default> <aggregationType>AggregationType</aggregationType> <category>ChargeCategory</category> </itemSpec></pre>	<p>Contains the details about the item specification, where:</p> <ul style="list-style-type: none"> • <i>ItemSpecificationName</i> specifies the item specification name. The item specification name is associated with the item tag field in BRM. • <i>ItemSpecificationDescription</i> contains the description of the item specification. • <i>PriceListName</i> specifies the price list name. The valid value is Default. • <i>ItemType</i> specifies the type of the bill item for assigning balance impacts. This must match the item type created in BRM. • <i>DefaultOption</i> specifies whether a item specification is the default specification for the bill item. The valid values are true and false. • <i>AggregationType</i> specifies whether the item accumulates charges or tracks each charge separately. The valid values are: <ul style="list-style-type: none"> CUMULATIVE_NONPRECREATE, which specifies that the bill item accumulates charges through out the billing cycle and the bill item need not be pre-created in BRM INDIVIDUAL_NONPRECREATE, which specifies that the bill item stores a charge for a single event and the bill item need not be pre-created in BRM CUMULATIVE_PRECREATE, which specifies that the bill item accumulates charges through out the billing cycle and the bill item needs to be pre-created in BRM • <i>Category</i> specifies the charge category. See "Configuring Charges in Charge Offers" for more information. <p>Note: You can add multiple item specifications, but you can add only one default item specification. You can use the same item specification in multiple item type selectors, but the item specification name must be unique.</p>

Loading the OOB_ItemTypeSelector.XML File

To load the **OOB_ItemTypeSelector.xml** file:

1. If you have created custom bill items in BRM, make a backup copy of the customized **config_item_tags.xml** and **config_item_types.xml** files in BRM.
2. Go to the **PDC_hometapps/Samples/Examples** directory.
3. Import the default billing item assignments from the **OOB_ItemTypeSelector.xml** file into the PDC database by running the following command:

```
ImportExportPricing -import -config /OOB_ItemTypeSelector.xml -ow
```

The item type selector is imported into the PDC database and the existing item tag-to-item type mapping in the BRM database is overwritten.

Configuring Item Type Selectors

To configure an item type selector:

1. Create the custom bill item in the database by subclassing the **Item** storable object. For example, you can create an **Item/National** object for tracking the charges for national calls. See "Creating Custom Fields and Storable Classes" in *BRM Developer's Guide*.
2. Make a copy of the `PDC_home/apps/Samples/Examples/Sample_ItemTypeSelector.xml` file to customize.
3. Open the file in a text editor or XML editor.
4. Add or modify the elements as required. See [Table 6-1](#) for the usage and description of each element.
5. Save and close the file.

 **Note:**

You can save the file with a different name and location or use the original file.

6. Go to the directory where you have saved the file.
7. Import the item type selector from the customized XML file into the PDC database by running the following command:

```
ImportExportPricing -import -config FileOrDirectoryName
```

where *FileOrDirectoryName* specifies either the full path and file name of the import XML file or the directory in which the import XML files reside.

The item type selector is imported into the PDC database and transformed to BRM and Oracle Communications Elastic Charging Engine (ECE).

7

Configuring Value Maps

Learn how to configure value maps in Pricing Design Center (PDC) to group event attributes into manageable categories in Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Value Maps](#)
- [Loading the Sample Value Map into the Database](#)
- [Configuring Value Maps Using SampleValueMap.XML](#)

About Value Maps

You create value maps to associate zone names with values that apply to a single event attribute, such as an area code or an IP address. This allows you to set up services for location-based charging, which charges your customers based on their location.

You can configure value maps in PDC using the **SampleValueMap.xml** file and **ImportExportPricing** utility. For custom zones, use the **SampleValueMap.xml** as a template to map your zone names with a list of event attributes.

[Table 7-1](#) lists the elements that are supported in the sample value map XML file, the usage of each element, and a description of how to specify each element in the XML file.

Table 7-1 Elements Supported in the Sample Value Map XML File

Element	Syntax	Description
valueMap	<valueMap>	The root element of the SampleValueMap.xml file.
name	<name> <i>valueMapName</i> </name>	<i>valueMapName</i> specifies the name of the value map.
description	<description> <i>valueMapDescription</i> </description>	<i>valueMapDescription</i> specifies the description of the value map.
priceListName	<priceListName> <i>PriceListName</i> </priceListName>	<i>PriceListName</i> specifies the price list name. BRM uses only one internal price list. The only value is Default .
obsolete	<obsolete> <i>Boolean Value</i> </obsolete>	Boolean flag to obsolete the promoted objects.
exactMatch	<exactMatch> <i>Boolean Value</i> </exactMatch>	Boolean value. When true , the event attribute when compared with <i>keyName</i> or <i>valueMapValue</i> , must be an exact match. If false , the event attribute contains <i>keyName</i> or <i>valueMapValue</i> .
validityPeriod	<validityPeriod>	Root key of the validity period.

Table 7-1 (Cont.) Elements Supported in the Sample Value Map XML File

Element	Syntax	Description
validFrom	<validFrom>value</validFrom>	Value describes the start time for the value map. If <i>value</i> is set to zero, there is no start time. Otherwise, it is in the format of YYYYMMDD (For example: 20240131).
valueMapKey	<valueMapKey>	valueMapKey contains the <i>keyName</i> and 0 or more <i>valueMapKey</i> entries.
keyName	<keyName>keyName</keyName>	<i>keyName</i> describes the group name for the list of <i>valueMapValue</i> entries. This is a required field.
valueMapValue	<valueMapValue>value</valueMapValue>	<i>value</i> describes the value to be compared. This is a required field.

Loading the Sample Value Map into the Database

To load the **SampleValueMap.xml** file:

1. Go to the `PDC_home\apps\Samples\Examples` directory.
2. Import the **SampleValueMap.xml** file into the PDC database by running the following command:

```
ImportExportPricing -import -config /SampleValueMap.xml -ow
```

The sample value map is imported into the PDC database and the existing mapping in the BRM database is overwritten.

Configuring Value Maps Using SampleValueMap.XML

To configure value maps:

1. Make a copy of the `PDC_home\apps\Samples\Examples\SampleValueMap.xml` file to customize.
2. Open the file in a text editor or XML editor.
3. Add or modify the elements as required. See [Table 7-1](#) for the usage and description of each element.
4. Save and close the file.

 **Note:**

You can save the file with a different name and location or use the original file.

5. Go to the directory where you have saved the file.

6. Import the value map from the customized XML file into the PDC database by running the following command:

```
ImportExportPricing -import -config FileOrDirectoryName
```

where *FileOrDirectoryName* specifies either the full path and file name of the import XML file or the directory in which the import XML files reside.

Part II

Creating Pricing Components

This part describes how to create Oracle Communications Billing and Revenue Management (BRM) pricing components in Pricing Design Center (PDC).

This part contains the following chapters:

- [Configuring Charge Offers](#)
- [Configuring Charges in Charge Offers](#)
- [Configuring Pricing in Charge Offers](#)
- [Pricing Configurations in Charge Offers](#)
- [Creating Discount Offers](#)
- [Creating Subscription Terms](#)
- [Creating Bundles](#)
- [Creating Packages and Package Lists](#)
- [Sharing Charges and Discounts](#)

Configuring Charge Offers

Learn how charge offers function in Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Charge Offers and Charges](#)
- [Configuring Charge Offer Usage and Ownership](#)
- [Applying Recurring Charges on a Specific DOM](#)
- [Configuring Charge Offers and Revenue Recognition](#)
- [Restricting the End Time of Granted Balances That Start on First Usage](#)
- [Configuring How Pricing Configurations for Date Ranges are Applied](#)
- [Charge Offers and General Ledger](#)
- [Configuring Full Day Proration](#)

About Charge Offers and Charges

Charge offers determine the price of one or more events associated with a service. For example:

- For a mobile phone service:
 - 10 cents per call on peak time
 - 5 cents per call on off-peak time
 - \$20 setup fee
- For a video download service:
 - \$10 monthly fee
 - \$1 fee per video download

A charge offer includes one or more charges. [Figure 8-1](#) shows a charge offer in PDC. This charge offer includes two charges:

- ConvergentUsage charges 10 cents per minute for voice usage.
- Monthly Recurring Charge charges a 20-dollar monthly fee, and credits 100 minutes per month.

Figure 8-1 Charge Offer in PDC

Charge Offer [Edit] [Validate] [Save As] [Used By] [Delete]

General Information

Name: Voice Service Type: Subscription
 Description: 10 cents per minute, 20 dollars per month, 100 included megabytes Applicable To: Wireless Voice

Charges [Add Charge]

ConvergentUsage **Monthly Recurring Charge**

Charge Actions

Pricing Details: Pricing

Quantity Range: 0 - No maximum

Impact	Amount	Balance Element	Per Unit	Amount Is Valid
Debit	0.10 US Dollar	US Dollar	Minute	Not Applicable

Each charge can have one or more balance impacts. In [Figure 8-1](#) the balance impact for usage is 10 cents per minute. The charge is determined primarily by the following columns in the balance impact in PDC:

- **Impact:** Can be a debit or a credit.
- **Amount:** The amount of the balance impact.
- **Balance Element:** The type of balance that is impacted. For a debit impact, this is usually a currency balance. For a credit impact, this is usually a noncurrency balance.
- **Per Unit:** What the charge is based on; for example, number of megabytes downloaded or number of minutes used.

The **Per Unit** value is typically the RUM that the charge is based on, or a measurement related to it. For example, if the RUM used to rate the event is seconds, the **Per Unit** value can be seconds, minutes, or hours.

For usage charges, you can also use the following options for the **Per Unit** value:

- **Fixed Charge:** Use this option to charge a flat fee for the event. Fixed charges are unaffected by the quantity of the event.
- **Amount Used:** This bases the charge on the quantity of the event is measured. For example, to charge for SMS messages, each event is one message, so **Amount Used** is always one message. If the **Amount** column is **.10** and the **Per Unit** column is **Amount Used**, the charge is 10 cents for each SMS message.

[Figure 8-2](#) shows a balance impact that charges for the amount used. This balance impact could be used for charging an SMS service, a video download, and so on.

Figure 8-2 Balance Impact With No RUM Specified

Impact	Amount	Balance Element	Per Unit
Debit	0.50	US Dollar	Amount Used

The options available in a balance impact depend on the charge offer type and the charge type. For example, the **Per Unit** value is not used for one-time charges such as purchase fees, or for recurring charges. In those cases, the event is always charged the same amount.

[Figure 8-3](#) shows the balance impacts for a charge that charges a recurring \$20 monthly fee, and credits 500 minutes every month.

Figure 8-3 Balance Impacts for Monthly Fee and Monthly Megabyte Credit

Impact	Amount	Balance Element
Debit	20.00	US Dollar
Credit	500.00	Included Megabytes

When you create a charge offer, you do the following:

1. Create the charge offer in PDC. In the charge offer, you define charge offer attributes such as the service that the charges apply to, how a customer can purchase and own the charge offer, tax settings, and so on. See "[Configuring Charge Offer Usage and Ownership](#)".

If you configured product specification attributes for charge offers in XML templates, you can set their values. See "[Configuring Product Specification Attributes for Pricing Components](#)".
2. Create one or more charges. For each charge, you define the type of charge; for example, a monthly fee or a usage fee, how to measure the charge, and other properties. See "[Configuring Charges in Charge Offers](#)".
3. Define the pricing for each charge. The pricing specifies one or more balance impacts, and how to apply the balance impacts; for example, based on the quantity of the event. See "[Configuring Pricing in Charge Offers](#)".

Configuring Charge Offer Usage and Ownership

When you create a charge offer, you associate it with one of the following:

- **A single service.** For example, to charge for GSM usage, associate the charge offer with the GSM telco service.
Multiple charge offers can be associated with the same service.
- **No service.** In this case, you associate the charge offer with **Account**. You might create a charge offer for late charges or for coupons.
You cannot charge for usage events with a charge offer set to **Account**.

When you create a charge offer, you specify the charge offer type and the settings that control how the charge offer can be purchased and owned. The *charge offer type* determines how the charge offer can be used:

- **Subscription:** These charge offers are purchased and owned by subscribers, and the charges apply only to the charge offer owner. Most charge offers are subscription charge offers. They can charge for any event type.
- **Item:** These charge offers contain charges that are applied only once, for example, a purchase fee or cancel fee. Item charge offers cannot include recurring charges or usage charges.
- **System:** These charge offers apply to all subscribers who use a particular service. System charge offers are not owned by subscribers and are exclusively for usage charges. They cannot be used with subscription charges such as purchase or recurring events.

In addition to defining the service and the charge offer type, you can define the following settings:

- When the charge offer can be purchased, which can be immediately, or in a specified date range.

 **Note:**

To be added to a bundle, a charge offer must have a purchase period that is the same as or greater than the bundle's purchase period.

- The validity period for the charge offer. For example, the validity period specifies when the customer can use the service that the charge offer applies to. The validity period is not set in the charge offer itself. It is set when you configure the bundle that the charge offer belongs to. See "[About the Validity Periods of Offers in Bundles](#)".
- The provisioning tag to associate with the charge offer.
You must create provisioning tags in BRM before you can assign them in charge offers. See "Creating Provisioning Tags" in *BRM Provisioning Services*.
- The policy specification to associate with the charge offer.
You must configure policy specifications in PDC before you can assign them in charge offers. See "[Configuring Policy Specifications](#)".
- The tax supplier that will collect the taxes.
You need to define tax suppliers in BRM before you can assign them in charge offers. See "Creating Tax Suppliers" in *BRM Calculating Taxes*.
- The charge offer priority. When multiple charge offers apply to the same service-event pair, BRM can consider the charge offers in the order of their priority. If a portion of the event remains unrated after BRM applies all the charges in the charge offer with the highest priority, each subsequent priority charge offer is analyzed until the entire event is rated.
- How the charge offer can be owned or purchased.
 - **Owned:** For example, if a charge offer provides an email service, you might want to limit the number of email login names that a customer can own.
 - **Purchased:** For example, if a charge offer includes an item such as a t-shirt, you might want to limit the number of t-shirts that can be purchased simultaneously.
 - **Partially purchased:** For example, if a charge offer gives customers 300 minutes of off-peak calls for \$30, customers might be permitted to purchase half that amount for half the price.
- Whether this charge offer can be automatically shared with all members of a billing hierarchy.

- Whether to send notification messages to your customers when their subscription that contains this charge offer is about to expire or renew.
- The tax exemption selector to apply to the charge offer.

When you create a charge offer, to ensure a full day proration, set the rounding values for the following:

- **The validity period:** You can specify that the validity period starts at the purchase time or midnight of the day the product is purchased. Alternatively, you can set to use the systemwide setting in the CM pin.conf file.
- **The charging scale:** You can specify whether to charge for a full day or a partial day for the first day of the billing cycle. Alternatively, you can set to use the validity period setting.

You configure charge offer settings by using one of the following:

- The PDC UI. For more information, see "Creating a Charge Offer" in *PDC Online Help*.
- The **ImportExportPricing** utility. For information about how to configure charge offer settings using the utility and an XML file, see the sample charge offer XML file (*PDC_home\apps\Samples\Examples\SampleChargeOfferWithPSCAttributes.xml*), "[Charge Offer Configuration Examples](#)", and "[ImportExportPricing](#)".

Applying Recurring Charges on a Specific DOM

By default, all recurring charges in a charge offer are aligned with your customer's billing day of month (DOM). For example, if customers have a billing DOM of the 1st and purchase a charge offer on January 10, the recurring charge is prorated and applied on January 10 for the interval January 10 to February 1. For subsequent cycles, the recurring charge is applied on the billing date (for the interval February 1 to March 1, March 1 to April 1, and so on).

You can configure PDC to instead apply recurring charges on a specific DOM. For example, apply recurring charges on the 5th of each month, regardless of the billing or purchase date. This is useful for charge offers with validity that is defined in hours, minutes, and seconds rather than days, weeks, and months.

You can configure PDC to apply recurring charges on a specific DOM by using the following:

- The PDC UI. To do so, use the **Cycle Alignment Day of Month** field in the charge offer settings. See "Specifying Charge Offer Settings" in *PDC Online Help*.
- The **ImportExportPricing** utility. To do so, in your input XML file, set the **purchaseCycleDOM** element under the **chargeOffering** element. See "[Aligning Recurring Charges and Product Validity to a Specific Day of the Month](#)".

Configuring Charge Offers and Revenue Recognition

When you create a charge offer, you specify how your company will recognize the revenue that is associated with it. Revenue recognition is an accounting principle that specifies when your company can recognize the money it receives from the products and services that it sell to customers.

If your company uses deliverable-based revenue recognition and the charge offer contains a recurring or one-time charge, add one or more deliverables to the charge offer. See "About Event-Based Revenue Recognition" in *BRM Collecting General Ledger Data* for more information.

If your company uses event-based revenue recognition, leave this section blank. See "About Deliverable-Based Revenue Recognition" in *BRM Collecting General Ledger Data* for more information.

Restricting the End Time of Granted Balances That Start on First Usage

You can configure BRM to automatically restrict the validity period of granted noncurrency balances to end no later than the end time of the charge offer or discount offer that grants the balance.

When you configure balance validity to start on first usage and end on a date relative to the start date (when first usage occurs), you cannot know the actual end date when setting up the offer. Restricting the balance end time to the offer's end time ensures that the balance cannot continue to be consumed after the offer expires.

Note:

When an offer is *canceled*, the validity period end time of balances granted by that charge offer or discount offer is set to the time of the cancellation.

When you restrict balance validity end time, BRM sets the end time to the offer's end time at the time of the grant. When the customer consumes the granted balance for the first time, the relative end time is calculated:

- If the calculated end time is *later* than the granting offer's end time, the balance validity period uses the offer's end time.
- If the calculated end time is *earlier* than the granting offer's end time, the balance validity period uses the calculated end time.

To enable this feature, run the **pin_bus_params** utility to change the **RestrictResourceValidityToOffer** business parameter. See "pin_bus_params" in *BRM Developer's Guide* for more information about this utility.

To restrict balance validity end times to charge offer or discount offer end times:

1. Go to `BRM_home/sys/data/config`.

2. Create an XML file from the `/config/business_params` object:

```
pin_bus_params -r BusParamsMultiBal bus_params_multi_bal.xml
```

3. In the file, change **FALSE** to **TRUE**:

```
<RestrictResourceValidityToOffer>FALSE</RestrictResourceValidityToOffer>
```

4. Save the file as `bus_params_multi_bal.xml`.

5. Load the XML file into the BRM database:

```
pin_bus_params bus_params_multi_bal.xml
```

6. Stop and restart the CM.

7. (Multischema systems only) Run the **pin_multidb** script with the **-R CONFIG** parameter. For more information, see "pin_multidb" in *BRM System Administrator's Guide*.

Configuring How Pricing Configurations for Date Ranges are Applied

When adding a charge to a charge offer, you can specify that different pricing configurations are effective during different date ranges by adding date ranges to the balance impacts. On the charge offer, you can configure how these different pricing configurations are chosen.

You can decide whether customers who subscribe during one date range will keep the same pricing configuration after that range ends, or move to the new pricing configuration. You can also determine whether the pricing configuration is chosen based on the service instantiation date or the purchase date.

This is useful when you add new pricing configurations with new date ranges after customers have already subscribed to a charge offer.

You specify what happens after one date range ends in the charge offer settings. Existing subscriptions can:

- Move to the pricing configuration for the next date range, with the balance impacts configured for the next date range. This is the default behavior.
- Continue to use the old pricing configuration, with the balance impacts configured for the old date range. With this option, you are effectively maintaining separate versions of the same charge offer for different customers.
You can configure BRM to determine the pricing configuration for new subscriptions based on:
 - The purchase date: Any subscriptions purchased within the new date range will use the new pricing configuration.
 - The service instantiation date: Any new services instantiated during the new date range will use the new pricing configuration. This option is useful if your services often have a long delay between purchase and instantiation date. It allows customers who purchase at the old price to take advantage of the new price if it comes into effect before their new service is available.

See "[Configuring Effective Dates for Pricing](#)" for more information about configuring date ranges.

The following examples describe how these configurations determine the pricing configuration that applies to existing and new subscriptions. In the examples, you have an existing charge offer with a balance impact that credits 1GB of free data every week. You add a new balance impact crediting 1.5GB, set the end date of the old balance impact to June 10th, and set the start date for the new balance impact to June 11th. Depending on your charge offer settings, the following happens:

- If you configured the charge offer to move to the new pricing, all subscriptions get 1GB until June 10th, and 1.5GB thereafter.
- If you configured the charge offer to use the old pricing for existing subscriptions, but determine pricing for new subscriptions based on the purchase date, subscriptions purchased before June 10th continue to get 1GB, even for events occurring after June 10th. Subscriptions purchased after June 10th get 1.5GB.
- If you configured the charge offer to use the old pricing for existing subscriptions, but determine pricing for new subscriptions based on the service instantiation date, subscriptions instantiated before June 10th continue to get 1GB, even for events occurring

after June 10th. Subscriptions instantiated after June 10th get 1.5GB, even if they were purchased before.

You can also make these configurations in XML when importing pricing components using the **ImportExportPricing** utility. See "[Using Date Ranges for Versioning](#)".

Charge Offers and General Ledger

You assign a general ledger ID (G/L ID) to balance impacts. This enables you to track revenue for each type of charge; for example, you can assign different G/L IDs for monthly fees and usage charges.

Configuring Full Day Proration

When you create a charge offer, you can set the rounding values for the following:

- **The validity period:** You can specify that the validity period starts at the purchase time or midnight of the day the product is purchased. Alternatively, you can set to use the systemwide setting in the CM **pin.conf** file.
- **The charging scale:** You can specify whether to charge for a full day or a partial day for the first day of the billing cycle. Alternatively, you can set to use the validity period setting.

You can configure full day proration using the following:

- The PDC UI. See "Offer Settings Subsection" in *PDC Online Help*.
- The **ImportExportPricing** utility. To do so, in your input XML file, set the **<validityRounding>** and **<scaleRounding>** elements under the **<ChargeOffering>** element. See "[Setting Full Day Proration](#)".

9

Configuring Charges in Charge Offers

Learn how to configure charges in your Oracle Communications Billing and Revenue Management (BRM) charge offers.

Topics in this document:

- [About Charges](#)
- [Specifying When a Charge is Effective](#)
- [Specifying Whether to Charge Inactive, Canceled, or Suspended Active Accounts](#)
- [Configuring Taxation in Charges](#)
- [Configuring In-Advance Billing in Charges](#)
- [Configuring Cycle Alignment for Recurring Charges](#)
- [About Prorating Recurring Charges and Rollovers](#)
- [About Creating Charge Offers with Over 500 Charges](#)

About Charges

Each charge in a charge offer has a charge category and a charge type. The charge category determines which events the charge can be configured for:

- **Usage events:** Charges for the use of a service, such as telephone calls or broadband sessions.
- **Recurring events:** Ongoing charges that are not generated or affected by usage, such as a monthly subscription fee.
- **One-time events:** Nonrecurring charges, such as setup or cancellation fees.
- **Rollover events:** Charges that extend the validity of unused balances to succeeding cycles. For example, included minutes are often rolled over.
- **Fold events:** Charges used to zero-out a balance or convert one balance into another. For example, you could configure a fold charge to zero-out unused included hours at the end of each month or convert frequent flyer miles to a dollar amount. Fold charges must be associated with an existing charge selector whose event matches the fold event (see "[About Selectors](#)").

The charge type depends on the charge category. For example:

- If the charge category is **Recurring**, the charge type could be monthly or yearly.
- If the charge category is **Usage**, the charge type could be voice usage or data download.

In addition to the charge category and charge type, you define the following:

- The pricing profile to use with the charge. Pricing profiles specify the pricing features that are displayed in the PDC UI. See "[Working with Profiles](#)" for more information.
- The RUM to use to measure the event; for example, **Duration**, **Occurrence**, or **Messages**. See "[Configuring Ratable Usage Metrics \(RUMs\)](#)" for more information.

- Whether to continue applying charges or stop applying charges to accounts with an Inactive status, Canceled status, or Suspended Active state. See "[Specifying Whether to Charge Inactive, Canceled, or SuspendedActive Accounts](#)" for more information.
- The currency specified for a charge, such as U.S. dollars or euro. This currency defines the currency balance element that you can select when configuring pricing for the charge.
- How and when to apply taxes. See "[Configuring Taxation in Charges](#)" for more information.
- The dates during which the charge is effective. By default, this period starts immediately and never ends. See "[Specifying When a Charge is Effective](#)" for more information.
- Settings for recurring charges and rollovers. See:
 - [Configuring In-Advance Billing in Charges](#)
 - [Configuring Cycle Alignment for Recurring Charges](#)
 - [About Prorating Recurring Charges and Rollovers](#)

Specifying When a Charge is Effective

You can apply a date range to a charge; for example, set a fixed start date and an end date; or specify a date range relative to when the charge offer was purchased. If you include multiple charges in a charge offer, you can configure multiple date ranges for each charge.

If you want to apply the same charge with multiple variations applied in different date ranges, you can use multiple date ranges in a single charge. You can use different pricing for each date range. For example, you could create a charge that charges \$10 for the first date range, and \$30 for the second date range.

BRM supports the following types of charge date ranges:

- **Fixed:** Specifies a period that starts and ends on particular dates. For example:
 - Immediately through 6/1/2012
 - 6/1/2012 through 1/1/2013
 - 1/1/2013 through never endsFixed date ranges cannot overlap.
- **Relative:** Begins at a time relative to the time the charge is purchased and continues for a specified length of time, such as days, hours, minutes, or seconds. The purchase date is the day the charge offer is added to the account. Unlike fixed date ranges, relative date ranges can overlap.

Note:

In addition to specifying date ranges for charges, you can specify date ranges for the balance impacts in a charge. See "[Configuring Effective Dates for Pricing](#)" for information.

Specifying Whether to Charge Inactive, Canceled, or SuspendedActive Accounts

By default, PDC applies charges to only active accounts with an active service. However, you can configure PDC to also apply charges to accounts with:

- An **Inactive** status.
- A **Cancelled** status.
- A **SuspendedActive** custom life cycle state. This option is valid only if your system includes a custom life cycle state named **SuspendedActive**.

Note:

These settings affect the rerating process. If you specify to not charge accounts with an **Inactive**, **Cancelled**, or **SuspendedActive** status, charges are not applied to those accounts during the rerating process. If you specify to charge accounts with an **Inactive**, **Cancelled**, or **SuspendedActive** status, charges are applied to only **Active** accounts during the rerating process.

To configure BRM to apply charges to **Inactive**, **Cancelled**, or **SuspendedActive** accounts:

1. Enable the **ApplyChargeOnInactiveOrCancelledProduct** business parameter by doing the following:
 - a. Go to `BRM_home/sys/data/config`.
 - b. Create an XML file from the `/config/business_params` object:

```
pin_bus_params -r BusParamsSubscription bus_params_subscription.xml
```
 - c. In the file, set **<ApplyChargeOnInactiveOrCancelProduct>** to **enabled**:

```
<ApplyChargeOnInactiveOrCancelProduct>enabled</
ApplyChargeOnInactiveOrCancelProduct>
```
 - d. Save the file as `bus_params_subscription.xml`.
 - e. Load the XML file into the BRM database:

```
pin_bus_params bus_params_subscription.xml
```
 - f. Stop and restart the CM.
 - g. (Multischema systems only) Run the `pin_multidb` script with the **-R CONFIG** parameter. For more information, see "pin_multidb" in *BRM System Administrator's Guide*.
2. Create a custom life cycle state named **SuspendedActive**. See "Creating Custom Service Life Cycles" in *BRM Managing Customers*.
3. When you create a charge, specify whether the charge should be applied to accounts with an **Inactive** status, **Cancelled** status, or **SuspendedActive** state. To do so, use one of the following:
 - PDC.

When adding a charge, set the **Stop Charging** list in the Create Charge dialog box. For more information, see "Adding a New Charge" in *PDC Online Help*.

- The **ImportExportPricing** utility.

For each charge defined in your import XML file, set the **<validIfCancelled>**, **<validIfInactive>**, or **<validIfSuspendedActive>** element to **true** to *not* apply charges or to **false** to apply charges. For example, the following specifies to *not apply* charges to accounts with a **Cancelled** status and to apply charges to accounts with an **Inactive** status or a **SuspendedActive** state:

```
<chargeOffering xmlns:pdc="http://xmlns.oracle.com/communications/
platform/model/pricing" externalID="externalID">
  <name>col</name>
  <internalId>4ae7317b-ba27-49f1-aa45-ab00710b417a</internalId>
  <pricingProfileName>Product Offering</pricingProfileName>
  ...
  <chargeEventMap>
    <eventName>EventBillingCycleDiscount</eventName>
    <validIfCancelled>true</validIfCancelled>
    <validIfInactive>false</validIfInactive>
    <validIfSuspendedActive>false</validIfSuspendedActive>
    ...
  </chargeEventMap>
</chargeOffering>
```

For more information, see "[Importing and Exporting Pricing and Setup Components](#)".

Configuring Taxation in Charges

You can specify when and how to calculate taxes for each charge in a charge offer. In each charge, you set the following:

- When to apply taxes:
 - **Event time:** Taxes are calculated when the event is rated and then added to the customer's account balance. This way, you always have an accurate reading of a customer's account balance at any time in the accounting cycle.
 - **Billing time:** Taxes are applied to the charge when the customer's bill is generated. Deferring tax calculation to the billing process reduces rounding errors because all events of the same type are calculated together. For example, taxes are calculated on the total amount of usage fees rather than on individual usage events.
 - **Dynamically:** Taxes are calculated at billing time using the tax rate at the time the event occurred. This provides the benefits of billing-time taxation while allowing you to change tax rates in the middle of a billing cycle. For example, assume a recurring charge's tax rate changes from 2% to 3% on May 15. If a billing cycle ends on May 30, BRM would use the 2% rate to calculate the charge's April 30 through May 14 taxes and the 3% rate to calculate the charge's May 15 through May 29 taxes.
 - **None:** Do not apply taxes.
- How to apply taxes:
 - Using a specified tax code to calculate the tax amount.
 - Using a tax selector, which assigns a tax code based on account, service, event, and service attributes.

 **Note:**

- You need to define tax codes before you can assign them to charges. For information, see "Creating Tax Codes" in *BRM Calculating Taxes*.
- In the PDC 12.0 Patch Set 5 release, you must also manually create tax codes in PDC. See "Moving Existing Tax Codes from BRM to PDC for Patch Set 5" in *BRM Patch Set Release Notes*.

You can configure the taxes to apply and when to calculate taxes by using the following:

- The PDC UI. To do so, use the Taxation section of the Create Charge dialog box. See "Taxation Section" in *PDC Online Help*.
- The **ImportExportPricing** utility. To do so, in your input XML file, set the `<taxTime>` and `<taxCode>` elements under the `<ChargeRatePlan>` element. See "[Setting Taxation for Charges](#)".

Configuring In-Advance Billing in Charges

In-advance billing enables you to charge customers in advance in the first bill. For each charge, you can configure how far in advance to bill the customer. For example, if a customer purchases an offer on May 1 and the offer's \$10 monthly fee is billed three months in advance, the total charge in the customer's first bill is \$30. The total charge in the next (June) bill is \$10, but from an accounting perspective, the \$10 fee applies to August, not to June.

Configuring Cycle Alignment for Recurring Charges

Recurring charges are based on BRM system events that occur on cycles. You can apply recurring charges in the following ways:

- On the charge offer purchase date. For example, if the billing date is the 1st of the month and the charge offer is purchased on January 10, the charge is applied on the 10th of every month (for the interval January 10 to February 10, February 10 to March 10, and so on).
- On the customer's current billing date (default). Using the previous example, the charge is prorated and applied on January 10 for the interval January 10 to February 1. For subsequent cycles, the charge is applied on the billing date (for the interval February 1 to March 1, March 1 to April 1, and so on).

About Prorating Recurring Charges and Rollovers

By default, PDC prorates any recurring charges and rollover amounts when customers do the following in the middle of their billing cycle:

- Purchase charge offers
- Cancel charge offers
- Change their billing day of month (DOM)

For example, if a customer cancels a subscription 15 days into a 30-day billing cycle, the customer is charged half of the cycle fee and receives half of the available rollover balance from the previous month.

However, you can configure PDC to apply the full charge or rollover amount, or to not apply a charge or rollover of any available balance in these cases. For example, assume a customer's billing day of month (DOM) is the 15th and on November 30 he purchases a subscription with a \$30 monthly fee. If you configure PDC to charge the full amount, the full \$30 monthly charge would be applied to the customer's December 15 bill. If you configure PDC to charge nothing, no monthly charge would be applied to the customer's December 15 bill.

You configure whether to prorate recurring charges and rollovers by using the following:

- The PDC UI. See "Adding a New Charge" in *PDC Online Help*.
- The **ImportExportPricing** utility. To do so, set the **<prorateFirst>**, **<prorateLast>**, and **<prorateCycle>** elements in your import XML file. For more information, see "[Prorating Recurring Fees and Rollovers](#)".

About Creating Charge Offers with Over 500 Charges

While creating large charge offers with 500 or more charges, PDC may generate the following error:

```
java.sql.SQLException: ORA-12899: value too large for column
```

To fix this, first try extending the VARCHAR2 data type to MAX_STRING_SIZE in your Oracle database. For more information, see "[1.203 MAX_STRING_SIZE](#)" in *Oracle Database Reference*.

Note:

If the size of your charge offer data exceeds MAX_STRING_SIZE, check with Oracle Support before completing this step.

If you still receive an error after extending the VARCHAR2 data type, do this:

1. Go to the *BRM_Integration_Pack_home/PDC_BRM/sqlscripts/custom_scripts* directory, where *BRM_Integration_Pack_home* is the directory in which BRM Integration Pack is installed.
2. Do one of the following depending on the exception you receive:
 - For the following exception:

```
SEVERE: Error inserting data in crossref table for BRE rateplan
java.sql.SQLException: ORA-12899:
value too large for column "XREF_BRE_RATEPLAN"."COMPOSITE_PM_IDS"
(actual: 22015, maximum: 4000)
```

In SQL*Plus, connect to your PDC database as the Xref user and then run the **UpdateXrefBreCompositePMIDsCol.sql** SQL script:

```
sqlplus XrefUser@database_alias
Enter password: password
```

```
SQL> @UpdateXrefBreCompositePMIDsCol.sql
```

where:

- *XrefUser* is the login name for the Xref schema user.
- *database_alias* is the PDC database alias.
- *password* is the password for *XrefUser*.
- For the following exception:

```
SEVERE: Error inserting data in pdc table java.sql.SQLException:  
ORA-12899: value too large for column  
"BCSIMPLEATTRIBUTEITEM"."PERMITTEDVALUES" (actual: 22015, maximum: 4000)
```

In SQL*Plus, connect to your PDC database as the PDC user and then run the **UpdateSimpleAttrItemPermittedValuesCol.sql** SQL script:

```
sqlplus pdcUser@database_alias  
Enter password: password
```

```
SQL> @UpdateSimpleAttrItemPermittedValuesCol.sql
```

where:

- *pdcUser* is the login name for the PDC schema user.
 - *database_alias* is the PDC database alias.
 - *password* is the password for *pdcUser*.
3. Enter **exit** to quit SQL*Plus.
 4. If the script runs successfully, restart the WebLogic Server, real-time rating engine (RRE), and batch rating engine (BRE).

Configuring Pricing in Charge Offers

Learn how to configure pricing in Oracle Communications Billing and Revenue Management (BRM) charge offers.

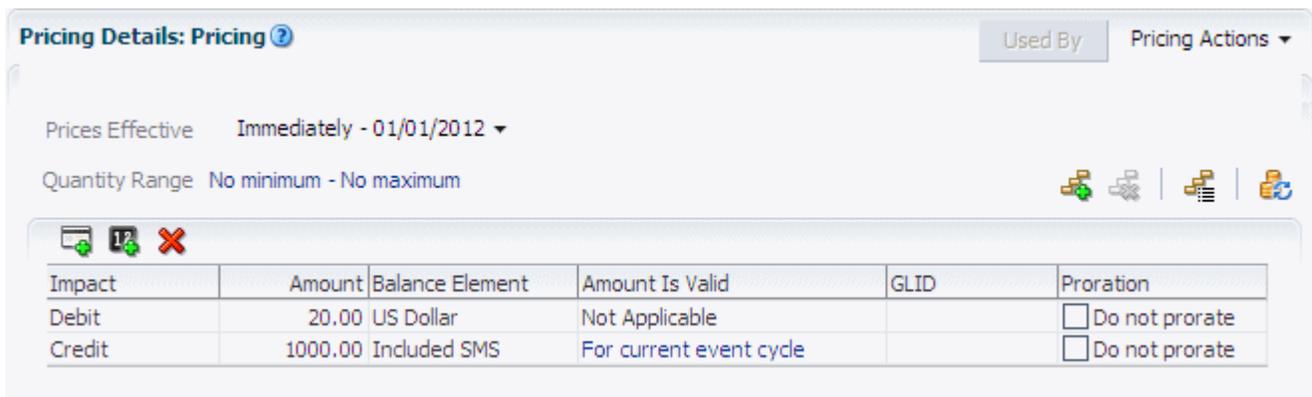

Topics in this document:

- [Configuring Pricing in Charges](#)
- [Configuring Validity Periods for Noncurrency Credit Balances](#)
- [Granting Noncurrency Balances in Increments](#)
- [Specifying Rounding in Balance Impacts](#)
- [Specifying if a Balance Impact is Discountable](#)
- [About Minimum Charges](#)
- [About Conditional Balance Impacts](#)
- [About Prorating Charges](#)
- [Configuring Dynamic Charging for One-Time and Recurring Events](#)
- [Configuring Dynamic Pricing for Usage Events](#)

Configuring Pricing in Charges

Each charge can contain one or more balance impacts. You configure balance impacts in the pricing table. [Figure 10-1](#) shows an example of the pricing table. Each row in the table represents a balance impact.

Figure 10-1 Pricing Table for a Charge

The screenshot shows the 'Pricing Details: Pricing' interface. It includes a 'Used By' field and a 'Pricing Actions' dropdown. Below these are 'Prices Effective' (Immediately - 01/01/2012) and 'Quantity Range' (No minimum - No maximum). A table below displays two balance impacts:

Impact	Amount	Balance Element	Amount Is Valid	GLID	Proration
Debit	20.00	US Dollar	Not Applicable		<input type="checkbox"/> Do not prorate
Credit	1000.00	Included SMS	For current event cycle		<input type="checkbox"/> Do not prorate

A balance impact is defined by how much to charge (the **Amount** column in the balance impact) for a given amount (the **Per Unit** column in the balance impact). When configuring pricing for a charge, you can also do the following:

- Configure when to grant noncurrency balances. See "[Configuring Validity Periods for Noncurrency Credit Balances](#)".
- Configure how to round balance impacts. See "[Specifying Rounding in Balance Impacts](#)".
- Specify if a balance impact can be discounted. See "[Specifying if a Balance Impact is Discountable](#)".
- Specify a minimum amount to charge. See "[About Minimum Charges](#)".
- Disable proration for a charge if proration is enabled for a charge offer. See "[About Prorating Charges](#)".
- Use a price selector to choose a pricing configuration based on the values of specified event, service, or account attributes. See "[About Selectors](#)".

Configuring Validity Periods for Noncurrency Credit Balances

When you create an offer that credits noncurrency balances, such as granting minutes, you can configure a validity period for the balance impact. This is useful if you want to limit how long a customer can keep minutes in their balance before they need to purchase more minutes. [Figure 10-2](#) shows a balance impact that grants 100 minutes that are available for one billing cycle.

Figure 10-2 Balance Impact for Minutes

Impact	Amount	Balance Element	Amount Is Valid
Credit ▼	100.00	Included Minutes ▼	From first usage - 1 Billing Cycles From Validity Start

You can specify the following fixed validity periods:

- For the current accounting cycle
- For the current billing cycle
- For the current recurring cycle

You can also define validity period start and end times. You can start a validity period at these times:

- When the event occurs.
- At first usage of the service.

If a balance is shared among accounts in a sharing group, the balance validity period is set when any account in the group first impacts the balance. Because the same balance is shared with all accounts in the group, the validity period of that balance applies to all accounts.

- From a specified date.
- Relative to a specified date.

You can end a validity period based on:

- A date relative to the start date (measure in minutes, hours, days, months, or in account, billing, or recurring cycles)
- On a specified date.

- No end date.

If a charge offer or discount offer is canceled after being used, the validity end time of any balance granted by the offer is set to the time of the cancellation.

 **Note:**

A charge offer that is valid from first usage should not grant a credit balance, such as included minutes, that is also valid from first usage. If it does, the granted balance cannot be consumed by the first usage event. See "[About Granting First-Usage Balance Impacts In First-Usage Charges](#)" for more information.

Granting Noncurrency Balances in Increments

 **Note:**

This functionality is supported only for recurring and one-time charges that have validity periods with a specified end date.

When you credit noncurrency balances, such as free minutes, in a one-time allotment or in a recurring cycle, you can choose to grant the noncurrency balance in smaller portions on an incremental basis, such as every 5 hours or every 2 days. For example, a one-time allotment of 50 Gigabytes that is valid for one month could be distributed to customers as one Gigabyte per day or 10 Gigabytes every seven days.

To configure PDC to grant a noncurrency balance in increments, you split the noncurrency balance into multiple validity periods and specify the following:

- The total validity period for the credit of noncurrency resources.
- The length of each incremental validity period, in terms of seconds, minutes, hours, days, or months.
- When the incremental bucket of noncurrency resources expire: at the end of the incremental validity period or at the end of the total validity period.

PDC calculates the amount of noncurrency resources allocated to each incremental bucket (except the last bucket) as follows:

```
(incremental validity period/total validity period) * (grant amount)
```

The amount for the last incremental bucket is calculated as follows:

```
(grant amount) - (total amount granted in previous buckets)
```

For example, assume your customers are granted a one-time allotment of 400 free minutes with a one-month total validity period. The 400 free minutes are split into multiple 7-day validity periods, with each incremental bucket of free minutes expiring at the end of its 7-day incremental validity period. [Table 10-1](#) shows how these 400 free minutes would be distributed to your customers in the month of June.

Table 10-1 Schedule for Distributing 400 Free Minutes in 7-Day Validity Periods

Bucket	Bucket Size Calculation	Bucket Size	Validity Start Date (starting at 12:00:00am)	Validity End Date (ending at 11:59:59pm)
1	$(7/30) * 400$	93 Free Minutes	June 1	June 7
2	$(7/30) * 400$	93 Free Minutes	June 8	June 14
3	$(7/30) * 400$	93 Free Minutes	June 15	June 21
4	$(7/30) * 400$	93 Free Minutes	June 22	June 28
5	$400 - (93 * 4)$	28 Free Minutes	June 29	June 30

You can configure multiple validity periods for noncurrency balances by using one of the following:

- The PDC UI. To do so, when adding balance impacts, set the **Distribute Credit**, **Frequency**, and **Unused Credit Valid Until** fields. For more information, see "Adding Multiple Validity Periods to Noncurrency Balance Impacts" in *PDC Online Help*.

Distribute Credit

Frequency Period

Unused Credit Valid Until

Credit an even portion of 400.0 Free Minutes used every 7 day, unused credit expires after 7 day

- A third-party application calling the PCM_OP_PRICE_SET_PRICE_LIST opcode and setting the opcode's PIN_FLD_SPLIT_DETAILS input list parameter. See "Committing Price List Data to the BRM Database" in *BRM Configuring Pipeline Rating and Discounting*.

Specifying Rounding in Balance Impacts

In a balance impact, you can specify the number of units to which the charge applies. For example, for a mobile phone service, you might charge 0.40 US dollars for every minute of usage in 2-minute increments. In this case, if the unit is Minute, the Increment is 2.

If you specify an increment, you can select a rounding option. Rounding is based on the specified increment. For example, if a 3-minute-and-50-second call is rated in 2-minute increments, it is handled as follows:

- No Rounding: Not applicable. (Applies only to an increment of 1.)
- Round Down: Charge for 2 minutes (\$0.80).
- Round Up: Charge for 4 minutes (\$1.60).

Specifying if a Balance Impact is Discountable

When creating a balance impact, you can specify if it is discountable in a bundle. By default, balance impacts are discountable. When a charge type is discounted in a bundle, the discount

applies to all instances of the charge type that are discountable. For example, you might have a charge offer that charges for two cycle events. You charge a monthly fee for one event, and you grant included minutes for the other event. If you specify a percentage discount for cycle charges in the bundle, the discount applies to both cycle charges. To discount only the monthly fee, you must make the balance impact for the monthly fee discountable and the balance impact that grants included minutes nondiscountable.

About Minimum Charges

You can set a minimum charge for each balance element impacted by a pricing instance. Minimum charges are configured per price tier (see "[About Defining Pricing Based on Multiple RUMs](#)") and effective period.

If you define different minimum charges in different price tiers for the same balance element, the largest minimum charge is used during rating. For example, if one step defines a minimum charge of \$2 and another a minimum charge of \$1, \$2 is used.

When multiple price tiers are applied to a charge, the minimum price is applied if the total of the charges does not meet the minimum charge. It is not applied for each of the price tiers if they each do not meet the minimum charge.

About Conditional Balance Impacts

A conditional balance impact is a balance impact that credits or debits a customer's balance only when the customer uses a charge offer for the first time within a specified period; for example, the first time in a day or the first time in two days. For example, you can use conditional balance impacts to grant daily included minutes to a customer, instead of using recurring events.

You can align the start time of the conditional balance impact period with the start time of the associated charge offer, the start of a calendar day, or the event occurrence. You can also specify whether the balance is available from the start time of the period or from the time the event occurs.

Conditional balance impacts can only be used with charge offers that are associated with a service, not with the charge offers associated with an account.

The following example shows how to configure conditional balance impacts for granting daily included minutes.

In this example:

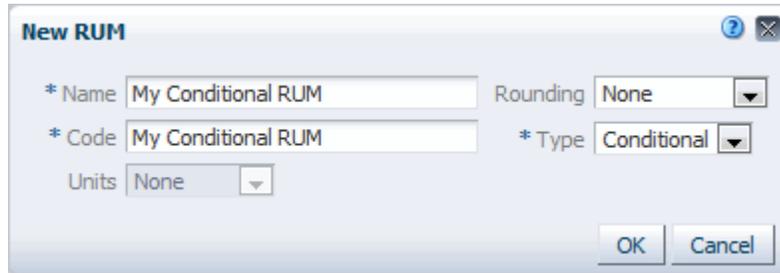

- The customer is granted 40 included minutes at \$5 per day.
- The included minutes are valid for a day.
- The customer is not charged on the days that the offer is not used.

To configure conditional balance impacts for granting daily included minutes:

1. Create a RUM of type **Conditional** for the desired service and usage event. See the discussion about creating a new RUM configuration in the PDC Help.

[Figure 10-3](#) shows a RUM of type **Conditional**.

Figure 10-3 New RUM Configuration

2. Create a charge offer. See the discussion about creating a charge offer in the PDC Help.
3. Add a new charge to the charge offer. When you add the charge, ensure that you select the following values:

Charge Category: Usage

Pricing Profile: Convergent Usage

Measured By: The RUM that you created in step 1. Optionally, you can select additional RUMs.

See the discussion about adding a new charge in the PDC Help.

4. Configure conditional balance impacts to grant 40 minutes at \$5 per day on the days the charge offer is used.

Figure 10-4 shows the conditions configured for granting daily included minutes.

Figure 10-4 Conditions for Granting Daily Included Minutes

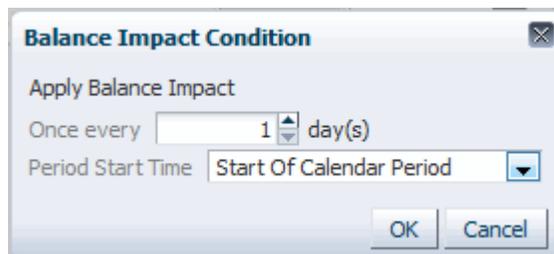

Figure 10-5 shows the validity period for the conditional balance impact.

Figure 10-5 Validity Period for a Conditional Balance Impact

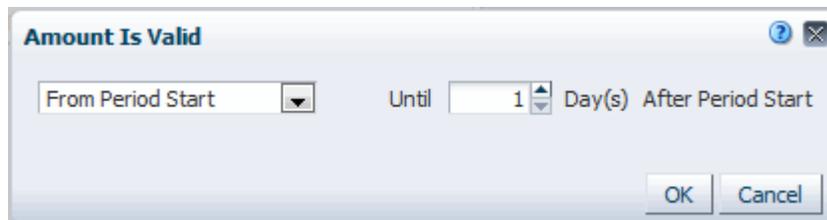

Figure 10-6 shows the conditional balance impacts used in this example for granting daily included minutes.

Figure 10-6 Conditional Balance Impacts for Granting Daily Included Minutes

Impact	Condition	Amount	Balance Element	Per Unit	Amount Is Valid
Debit	Once every 1 day(s)	5.00 US Dollar			Fixed Charge Not Applicable
Credit	Once every 1 day(s)	40	Included Minutes		Fixed Charge From Period Start - 1 Day(s) After Period Start

About Prorating Charges

You can specify to not prorate a recurring charge when proration is enabled in the charge offer itself. The proration settings are specified in the charge offer; this option only enables or disables proration for each recurring charge.

Configuring Dynamic Charging for One-Time and Recurring Events

You can configure PDC to dynamically change one-time and recurring fees per customer based on the date. For example, when a customer purchases a product, you could charge a default amount of \$50, but charge \$45 in June and \$40 in July.

You set up your system to dynamically change one-time and recurring fees by doing the following:

- Creating a pricing tag and specifying the event type, date ranges, and amount associated with it. For example, you could create a pricing tag named **Price1** that is associated with the following:
 - Event type: **/event/billing/product/fee/purchase**
 - Date range: January 1, 2025 through February 3, 2025
 - Amount: \$75
 BRM stores the pricing tag data in **/offering_override_values** objects.
- Adding the pricing tag, such as **Price1**, to the balance impacts in your one-time and recurring charges.

When rating events, PDC determines whether the pricing tag in a balance impact matches a pricing tag and date range combination defined in the account's **/offering_override_values** object. If it does, PDC charges the amount associated with the pricing tag. If it does not find a match, PDC charges the default amount.

To dynamically change one-time and recurring fees, do the following:

1. Define each pricing tag and its event type, time frame, and rate. To do so, customize your third-party client application to call the **Create Override Charges for Offer** endpoint in the Billing Care REST API.
For more information, see "*REST API Reference for Billing Care*".
2. Add a pricing tag to a balance impact by using one of the following:

- PDC.

When adding a balance impact to a one-time or recurring charge, click the Price Tag icon and then enter a pricing tag name in the Price Tag dialog box. For more information, see "Adding Pricing Tags for One-Time and Recurring Charges" in *PDC Online Help*.

- The **ImportExportPricing** utility.

For each one-time or recurring charge defined in your import XML file, add the **<priceTag>** element and include the following elements underneath it:

- **<attributeName>**: The name of the attribute.
- **<tagName>**: Set this to a unique pricing tag name.
- **<tagScope>**: Set this to **EVENT_PROFILE**.
- **<description>**: Set this to a description of the pricing tag name.

This shows an example of a pricing tag named **PriceTag1** added to a one-time charge:

```
<oneTimeCharge>
  <price>199.00</price>
  <unitOfMeasure>NONE</unitOfMeasure>
  <balanceElementNumCode>840</balanceElementNumCode>
  <discountable>true</discountable>
  <priceType>CONSUMPTION</priceType>
  <impactType>SCALED</impactType>
  <priceTag>
    <attributeName>price</attributeName>
    <tagName>PriceTag1</tagName>
    <tagScope>EVENT_PROFILE</tagScope>
    <description>Description for OneTime PT 199.00</description>
  </priceTag>
</oneTimeCharge>
```

For information on importing the pricing XML file into the PDC database, see "[Importing and Exporting Pricing and Setup Components](#)".

Configuring Dynamic Pricing for Usage Events

Dynamic pricing allows you to override the price specified in the product offerings at run time.

To override the price, you create a pricing XML file with dynamic tags and import the file into the PDC database by using the **ImportExportPricing** utility.

Dynamic tags are the XML elements that are used for overriding the value of the pricing attributes. Oracle Communications Elastic Charging Engine (ECE) uses these attributes to determine the price when processing a usage event.

Note:

Ensure that you create a unique dynamic tag across multiple charge offers since the tags are not scoped to charge offers at run time.

Dynamic tags are used for different pricing within a rate plan. PDC provides a sample XML file for dynamic tags in the *PDC_home/apps/Samples/Examples* directory, where *PDC_home* is the directory in which you installed PDC. The dynamic tag (**priceTag**) consists of the following fields:

- **attributeName.** The name of the attribute. The value of the attribute is dynamically determined during rating.
- **tagName.** The unique identifier of the dynamic tag.
- **tagScope.** The scope of the dynamic tag. Following are the available tag scopes:
 - EVENT_PROFILE
 - PRODUCT_PROFILE
 - CUSTOMER_PROFILE

 **Note:**

Only the EVENT_PROFILE tag scope is supported for charges with the Convergent Usage pricing profile.

- **Description.** (Optional) The description of the dynamic tag.

For example:

```
<fixedCharge>
  <price>20.0</price>
  <unitOfMeasure>NONE</unitOfMeasure>
  <balanceElementNumCode>840</balanceElementNumCode>
  <discountable>true</discountable>
  <priceType>CONSUMPTION</priceType>
  <priceTag>
    <attributeName>price</attributeName>
    <tagName>PRICE_TAG_FIXED_PRICE</tagName>
    <tagScope>EVENT_PROFILE</tagScope>
  </priceTag>
</fixedCharge>
```

In this example, the default price is 20.0. This is used by default if an overriding price is not specified.

For information on importing the pricing XML file into the PDC database, see "[Importing and Exporting Pricing and Setup Components](#)".

For information on enabling ECE to override the default value of the pricing attributes at run time, see "Pre-Rating Extension - Overriding Price in Product Offerings" in *ECE Implementing Charging*.

11

Pricing Configurations in Charge Offers

Learn about various pricing configurations that you can use in Oracle Communications Billing and Revenue Management (BRM) charge offers using Pricing Design Center (PDC).

Topics in this document:

- [Configuring Pricing Based on Quantity Ranges](#)
- [Configuring Pricing to Consume Granted Allowances Before Charging](#)
- [Configuring Effective Dates for Pricing](#)
- [About Defining Pricing Based on Multiple RUMs](#)
- [About Price Overrides](#)
- [About Fold Charge Pricing](#)
- [Granting First Usage Balances During Rating](#)

See also "[Configuring Charge Offers](#)" and "[Configuring Charges in Charge Offers](#)".

Configuring Pricing Based on Quantity Ranges

To calculate a charge based on the amount of usage or frequency of occurrence, you can create quantity ranges in charge pricing. For example, pricing for a telephony service might contain the following quantity ranges based on the total duration of calls during a month:

- No Minimum to 500 minutes: 10 cents per minute
- 500 to 1000 minutes: 5 cents per minute
- 1000 minutes to No Maximum: 1 cent per minute

Important:

If you enable Oracle Communications Elastic Charging Engine (ECE) to generate midsession rated events, note that each midsession event marks the end of a subsession of the network session. For the subsequent subsession, the network session's duration and volume counters are reset to 0. Therefore, if you use midsession rated events, do not base your pricing on cumulative duration or volume across an entire network session.

To define pricing based on quantity, you do the following:

- Add quantity ranges and configure different balance impacts for each range. For example:
 - 0 - 10 minutes: 10 cents per minute
 - 10 - 60 minutes: 5 cents per minute
 - 60 minutes and above: 2 cents per minute
- Specify how to apply the charge to the quantity ranges, which can be one of the following:

- **Pick the quantity range containing the value:** ECE selects a single quantity range that contains the value of the quantity range expression. For example, if the customer uses 70 minutes, ECE charges \$1.40 (70 minutes x \$0.02 per minute).
- **Distribute value across applicable quantity ranges:** ECE selects one or more quantity ranges that overlap the value of the quantity range expression. For example, if the customers uses 70 minutes, ECE charges \$3.70 [(10 minutes x \$0.10) + (50 minutes x \$0.05 per minute) + (10 minutes x \$0.02 per minute)].

When setting quantity range properties, you can also specify what happens when customers reach or exceed their credit limit for the charge. See "[Allowing Customers to Exceed Their Credit Limit](#)".

When you use quantity ranges in combination with time ranges, you can specify if the quantity consumed is relevant to a new time range. See "[Rating Events Split across Time Periods](#)" for more information.

Configuring Pricing to Consume Granted Allowances Before Charging

You can create usage charges that consume a customer's granted allowances before charging for any usage. For example, you could create a usage charge that first consumes a customer's monthly allowance of free GBs of data and then charges \$10 for any subsequent GBs used. You implement this functionality by adding quantity ranges to usage charges.

Note:

Consuming granted allowances before charging for usage fees is supported by the ECE rating engine only.

Figure 11-1 shows how to create sample quantity ranges in a usage charge using the PDC UI.

Figure 11-1 Sample Pricing for Consuming Free MegaBytes Before Charging

Quantity Range	Impact	Amount	Balance Element	Per Unit	Increment	Amount Is Valid	GLID	Discounting	Appl
Until balance of MB Transferred is consumed	Debit	1.0 MB Transferred	Amount Used	Amount Used	1.0 No Rounding	Not Applicable	Not Set	Do not discou...	Neve
Until balance of MB Used is consumed	Debit	1.0 MB Used	Amount Used	Amount Used	1.0 No Rounding	Not Applicable	Not Set	Do not discou...	Neve
0 - 200	Debit	0.15 US Dollar	Megabyte	Megabyte	1.0 No Rounding	Not Applicable	Not Set	Do not discou...	Neve
200 - No maximum	Debit	0.1 US Dollar	Megabyte	Megabyte	1.0 No Rounding	Not Applicable	Not Set	Do not discou...	Neve

This example specifies to first consume the entire balance of transferred MBs, then consume the entire balance of MB used, then charge 15 cents per MB for the next 200 MBs, and then charge 10 cents per MB for any subsequent MBs.

Using this example, assume a customer has 200 transferred MBs and 250 used MBs in a month. If the customer consumes 800 MBs of data in that month, ECE will deplete the 200 transferred MBs, deplete the 250 used MBs, charge \$30 for 200 MBs, and charge \$10 for the remaining 150 MBs.

You configure usage charges to consume granted allowances before applying charges by using:

- The PDC UI. To do so, use the Add Quantity Range dialog box. See "Adding Ranges for Usage Pricing" in *PDC Online Help*.
- The **ImportExportPricing** utility. To do so, in your input XML file, set the **<upperBoundExpression>** element under the **<priceTierRange>** element. See "[Consuming Granted Allowances Before Applying Usage Charges](#)".

 **Note:**

Allowances are consumed before applying standard usage charges. In configurations with both discount sharing groups and shared allowances, PDC first charges for usage that exceeds the member's allowance. Then, it applies the discount sharing group discount based on the remaining usage. For more information on discount sharing group discounts, see "[About Discount Sharing](#)".

Configuring Effective Dates for Pricing

You can apply a date range to a pricing configuration; for example, set a fixed start date and an end date. You can include multiple date ranges in a pricing configuration. This enables you to implement future price changes for a charge without creating multiple versions of the charge. For example, you could create a charge that has a \$10 recurring charge valid for one month, and \$20 after that.

Date ranges cannot overlap; for example:

- Immediately through 6/1/2015
- 6/1/2015 through 1/1/2016
- 1/1/2016 through never ends

When configuring the charge offer, you can also configure whether customers who subscribe during one date range will keep the same pricing configuration after that range ends, or move to the pricing configuration on the next date range, and whether the pricing configuration is chosen based on the service instantiation date or the purchase date. See "[Configuring How Pricing Configurations for Date Ranges are Applied](#)" for more information about how the pricing configurations are determined.

About Defining Pricing Based on Multiple RUMs

To configure pricing for multiple RUMs within a charge, you use multiple price tiers, one for each RUM. [Figure 11-2](#) shows a charge that contains two price tiers, Volume and Duration.

Figure 11-2 Volume and Duration Price Tiers

Quantity Range No minimum - No maximum

Impact	Amount	Balance Element	Per Unit	Increment	GLID
Debit	0.10	US Dollar	Minute	1 Minutes No Rounding	
Credit	1000.00	Included Minutes	Minute	1 Minutes No Rounding	

About Price Overrides

A price override enables you to replace the balance impact of a record imported from another system or to adjust the balance impact by a specified percentage or a fixed amount. For example, you might charge for content downloads that have already been rated by another service provider. A price override enables you to charge a different amount.

About Fold Charge Pricing

A fold charge is used to zero-out a balance, such as unused minutes or to convert one balance to another.

A fold is configured using a charge selector. The event for the charge selector must be the **Fold** event. After you have configured the charge selector, select it in the charge offer.

The pricing in a fold charge should have a debit for the balance that you are converting and one or more credits for the balances that you are converting to.

Figure 11-3 shows the pricing for a fold that converts Frequent Flyer Miles balance to US Dollar balance, \$1 for each frequent flyer mile.

Figure 11-3 Fold Pricing to Convert One Balance to Another

Quantity Range 0 - No maximum

Impact	Amount	Balance Element	Per Unit	GLID
Debit	1	Frequent Flier Miles	Amount Used	Not Set
Credit	1.00	US Dollar	Amount Used	Not Set

See "About Folds" for information about how fold balances are managed.

Granting First Usage Balances During Rating

ECE can grant first-usage balance impacts during rating. For example, you could create a charge offer that includes these balance impacts:

- Debit 5 cents per minute if there are no included minutes.
- Credit 1 minute for each minute paid at 5 cents per minute. These minutes are valid on first usage.

In this example, the charges occur as follows:

1. A subscriber has used up all their included minutes, and is being charged 5 cents per minute.
2. After ten minutes, the subscriber terminates the call. The subscriber is granted 10 minutes.
3. The next call that the subscriber makes uses the ten minutes, granted as first-usage balance impacts.

You can also grant first-usage balance impacts by using a discount. For example, you could create:

- A charge offer that charges 5 cents per minute.
- A discount that credits one SMS message for each called minute.

In this example, the charges occur as follows:

1. A subscriber makes a 10-minute call.
2. The subscriber terminates the call. The subscriber is granted 10 SMS messages, valid at first usage, with a validity end date after 30 days.

12

Creating Discount Offers

Learn how to create discount offers in Pricing Design Center (PDC) for Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Discount Offers and Discounts](#)
- [Configuring How Discount Offers are Purchased and Applied](#)
- [Applying Discounts Based on Quantity](#)

- [About Snowball Discounts](#)

About Discount Offers and Discounts

A discount offer is a purchasable product offering, similar to a charge offer. You can use discount offers to do the following:

- Reduce a charge by a percentage. For example, reduce a monthly fee by 50%.
- Track usage or spending by using counters, and discount the charge for an event based on the value of the counter. For example, a discount can track usage and apply a 25% discount to the charge of an event when over 1000 minutes have been used.
- Consume or grant balance impacts. For example, if an event is charged one dollar per minute, you can use a discount offer to allow the customer to use their included minutes and credit the corresponding charge. The discount offer would include a discount with two balance impacts:
 - Consume one minute for every dollar charged.
 - Credit one dollar for every minute consumed.

A discount offer includes one or more discounts. Every discount has one or more balance impacts. The balance is represented by a currency or noncurrency balance element. A debit balance must be a noncurrency balance element, such as minutes.

[Figure 12-1](#) shows a balance impact for a 10 percent discount on a monthly recurring charge.

Figure 12-1 Discount Reducing a Charge by a Percentage

Impact	Balance Element	Amount	Per Unit	What to Discount
Credit	US Dollar	10.00	Percent of	Charge

A discount is calculated based on two elements in the balance impact, the values in the **Per Unit** column and the **What to Discount** column. The **Per Unit** value is how to apply the balance element amount to the **What to Discount** value.

In [Figure 12-1](#), the **Per Unit** value is a percentage, applied to the charge (the **What to Discount** value). Because the event is charged in US Dollars, the balance impact is also in US Dollars. A currency balance element must be the same balance element in the charge that the discount is granted to.

The **Per Unit** value can be a percentage, an absolute value, or incremental; for example, apply the discount for every 10 gigabytes downloaded. The **What to Discount** value can be based on a charge, a quantity, a balance, or a calculation of multiple values.

[Figure 12-2](#) shows a discount that grants 5 minutes for every 10 gigabytes of data downloaded. The **What to Discount** value in this case is the value that is used to calculate the discount by applying the **Per Unit** value.

Figure 12-2 Grant 5 Minutes for Every 10 Gigabytes

Impact	Balance Element	Amount	Per Unit	What to Discount
Credit	Included Minutes	5.00	For every 10 of	Balance[Gigabytes Counter]

[Figure 12-3](#) shows a discount that credits \$5 on a purchase fee. In this case, the **Per Unit** value is Fixed, so the **What to Discount** value is not needed for calculating the discount, and is set to **Not Applicable**.

Figure 12-3 \$5 Discount on a Purchase Fee

Impact	Balance Element	Amount	Per Unit	What to Discount
Credit	US Dollar	5.00	Fixed	Not Applicable

A discount offer applies to a single service. You can also configure a discount offer to apply to the account. In that case, a discount would apply to charges for the same event for any service owned by the account. Discount offers that apply to a service are not valid when the service is inactive or canceled. Account discount offers are valid even if no service is active.

Within each discount offer, each discount has a discount type based on the events configured for the service that the discount offer applies to. Discount types are organized in discount categories as follows:

- **Usage:** These discount types discount usage events. For example, you might use the following:
 - The ConvergentUsage discount type to discount Wireless Voice events.

- The ConvergentData discount type to discount Wireless Data events.
- **Recurring:** These discount types discount recurring events, such as a monthly fee. For example, recurring discount types might be Monthly Recurring Event and Annual Recurring Event.
- **One-time:** These discount types discount one-time events, such as purchase events or cancel events.
- **Billing Time:** This discount type is calculated when billing is run, instead of when the charge is rated. See "[About Billing-Time Discounts](#)" for information.

For recurring discounts, note the following:

- Although a charge offer cannot contain both cycle forward and cycle arrears charges, a discount offer can contain both types of cycle discounts as long as their frequency (monthly, yearly, and so on) is the same.
- A recurring discount is applied to all the recurring charges for the same service. For example, if there are different Monthly Recurring Event charges for the same service, the Monthly Recurring Event discount applies to all of them. You can use discount filters to apply different discounts to them, by selecting different pricing names. See "[About Discount Filters](#)".

When you create a discount offer in PDC, you configure settings that apply to the offer, for example, when the discount offer is available for purchase. See "[Configuring How Discount Offers are Purchased and Applied](#)".

When you create a discount, you can define the following:

- You can calculate discounts based on quantity, for example, the quantity of minutes use. See "[Applying Discounts Based on Quantity](#)".
- You can use filters to specify criteria that a charge must satisfy to be eligible for the discount. See "[About Discount Filters](#)".
- You can use discount triggers to restrict the application of a discount until certain conditions are met. See "[About Discount Triggers](#)".
- You can use the results of one discount to calculate another discount for the same event. See "[About Using Temporary Balances in Discounts](#)".
- You can calculate discounts based on data in the BRM database, or other data that is not directly configurable in PDC. See "[Using Functions to Calculate a Balance Impact](#)".
- You can use rules to apply multiple filters, triggers, and pricing to the same event. See "[Applying Multiple Discount Versions to an Event](#)".
- You can use counters to create a value that can provide a discount when billing is run. See "[About Billing-Time Discounts](#)".
- You can use date ranges to apply different discounts based on a fixed date range. See "[Configuring Effective Dates for Discounts](#)".
- You can configure how a discount is applied when it is valid for only part of a cycle. See "[Configuring Discount Validity](#)".
- You can create a billing-time discount that distributes a percentage discount to all accounts in a discount sharing group. See "[About Snowball Discounts](#)".
- If you configured product specification attributes for discount offers in XML templates, you can set their values. See "[Configuring Product Specification Attributes for Pricing Components](#)".

Configuring How Discount Offers are Purchased and Applied

You can control how a discount offer is purchased and applied by configuring the following:

- Subscription discount offers and system discount offers:
 - **Subscription:** The discount offer applies only to the customer who owns the discount offer.
 - **System:** The discount offer applies to all customers who use the specified service. Use system discounts when you do not want to re-create the same discount multiple times in your product offerings.
- A range of dates during which the discount offer can be purchased. To be added to a bundle, a discount offer must have a purchase period that is the same as or greater than the bundle's purchase period.
You can also specify the effective period for the discount offer when you configure the bundle that the discount offer belongs to. For example, you can set the discount to be effective one month after it is purchased. See "[About the Validity Periods of Offers in Bundles](#)".
- How many instances of the discount offer that the customer can purchase and own.
- Whether the discount offer can be automatically shared with all members of a billing hierarchy.
- The priority of each discount offer. Offers with higher priority numbers are applied before those with lower priority numbers.
- How to apply multiple discount offers to a single charge. See "[Applying Multiple Discount Offers to an Event](#)" for information.
- How to configure mutually-exclusive discount offers. See "[Configuring Mutually Exclusive Discount Offers](#)" for information.
- What happens when a customer purchases the same subscription discount offer multiple times. The discount offer can be purchased as a new subscription or a replacement of the existing subscription. See "[Purchasing the Same Offer in a Bundle Multiple Times](#)".

Applying Multiple Discount Offers to an Event

The same charge or portion of a charge can be eligible for multiple discount offers. When this occurs, BRM uses the discount offer priority and the following options to determine how to apply the discount offers to the charge:

- **Original Charge:** The discount offer is applied to the original charge amount, regardless of whether that amount was reduced by previous discount offers.
- **Remaining Charge:** The discount offer is applied to whatever charge amount remains after previous discount offers are applied.
- **Remaining Charge and Quantity:** The discount offer is applied only to the part of the charge and quantity that were not discounted already by a previous discount offer. For this option, the discount offer can be used only if:
 - Part of the charge has not yet been evaluated for a discount.
 - The discount offer consumes noncurrency balances or reduces currency charges.
 - The discount does not grant balances.

For example, a bundle includes the following discount offers:

- First priority: 10% off
- Second priority: 20% off

The customer makes a 100-minute call at \$0.10 a minute for a total charge of \$10. The discount for the charge is calculated as follows:

- Using **Original Charge**:
 - First discount: 10% of \$10 = \$1 discount
 - Second discount: 20% of \$10 (the original charge) = \$2 discount
 - Total discount = \$3
- Using **Remaining Charge**:
 - First discount: 10% of \$10 = \$1
 - Second discount: 20% of \$9 (the remaining charge) = \$1.80
 - Total discount = \$2.80
- Using **Remaining Charge and Quantity**:
 - First discount: 10% of \$10 = \$1
 - Second discount: Not applied because there is no remaining charge that has not been discounted.
 - Total discount = \$1

Configuring Mutually Exclusive Discount Offers

You configure discount offer exclusions to prevent a discount offer from being used or purchased when another discount offer or package is owned. You can use two methods to configure mutually exclusive discounts:

- Discount offer-to-discount offer exclusions. You can configure a discount offer to exclude the application of other discount offers, when both discount offers apply to the same event. You configure discount offer-to-discount offer exclusions when you create discount offers.
- Discount offer-to-package exclusions. You can configure a package to exclude specified discount offers. You specify discount-to-package exclusions when you create packages.

Discount offer-to-package exclusions can be configured to operate in two ways:

- **At purchase.** If an exclusion relationship exists between a discount offer and a package, a customer can own the discount offer or the package, but not both. Further, the customer cannot own any discount offers associated with the package if the customer owns the excluded discount offer.
- **At run time during charging.** In this case, the customer is allowed to purchase the excluded discount, but it is not applied during charging or billing.

When configuring discount exclusions, note the following:

- To exclude a billing-time discount, you must also exclude the counter discount associated with the billing-time discount. See "[About Billing-Time Discounts](#)" for more information.
- Discount exclusion takes precedence over discount priority; a discount can be excluded even if it has a higher priority than the discount that is excluding it.
- System discounts can be excluded.
- Shared discounts can be excluded.

Discount exclusions are disabled by default. To enable discount exclusions, see "Enabling Mutually Exclusive Discount Offers" in *BRM Managing Customers*.

Applying Discounts Based on Quantity

To apply discounts based on usage amount or on an amount in a balance, you can create quantity ranges. For example, a discount for a mobile phone service might contain the following quantity ranges:

- 0 through 500 minutes: No discount
- 500 through 1000 minutes: 10% off
- 1000 minutes through No Maximum: 15% off

In this example, the quantity is based on how many minutes are used. You can also base the quantity on the charge, an amount in a balance, or calculated value

With one exception, the start and end values of all quantity ranges must be a decimal. The exception is that a calculated value can be used to specify the end value of the last quantity range. For example, to use all the minutes in a balance, the calculation would be:

0 - Balance[Included Minutes]

In addition to specifying what to base the quantity on (usage, charges, and so on), you specify how to apply the discount to the quantity ranges. There are two options:

- **Pick the quantity range containing the value:** Applies the discount in the range that contains the entire quantity amount. Using the previous example, if the value is 700, the ranges are applied as follows:
 - 0–500 range does not qualify.
 - 500–1000. The discount for this range is applied to the entire result.
 - 1000–No Maximum does not qualify.
- **Distribute value across applicable quantity ranges:** The pricing in each range is applied to the amount of the basis that falls within it. If the value is 700, the ranges are applied as follows:
 - 0–500. The discount for this range is applied to the first 500 minutes.
 - 500–1000. The discount for this range is applied to minutes from 500 to 700.
 - 1000–No Maximum does not qualify.

When you distribute the value across ranges, you can use StepCharge or StepQuantity for the What to Discount value. This ensures that the discount is applied to only part of the quantity range:

- StepCharge bases the discount on the charge that applies to the quantity range, not the entire charge.
- StepQuantity bases the discount on the event quantity that applies to the quantity range.

About Discount Filters

A discount filter specifies criteria that a charge or a portion of a charge must satisfy to be eligible for the discount. For example, a discount might apply only to calls made on weekends or during December.

Filter criteria can be defined by specific values (such as a time period from a specified time model) or by using regular expressions.

You can create filters based on several values; for example, the amount consumed by the event, a balance element, a time period (peak and off-peak) and so on.

Figure 12-4 shows a discount filter that applies a discount to the event if it is measured in volume (not duration) and the balance element is a prepaid balance.

Figure 12-4 Discount Filter

The screenshot shows a 'Filter Details' form with the following fields and values:

Field	Value
* Name	Shared Megabytes Filter
Description	Shared Megabytes Filter
Date Range	Immediately - Never Ends
Balance Element	Prepaid Bal
GLID	
Measured By	Volume
Time Period	
Impact Category	
Generic Selector Result	

When creating a discount filter:

- You can specify a date range that defines when the filter is valid.
- If a discount has multiple filters, all filters are applied.
- A filter can be reused by multiple discounts.
- You can enter NOT operator in the following fields to specify the values to be excluded:
 - **GLID**
 - **Time Period**
 - **Impact Category**
 - **Generic Selector Result**

Note:

PDC does not validate the expressions entered in the fields.

Click the **Search** icon to search for existing filters and add to the discount.

About Discount Triggers

You can use discount triggers to restrict the application of a discount until certain conditions are met. For example:

- The number of domestic call minutes is less than or equal to 100.
- The bytes used in a GPRS session must be greater than 1 MB.

Figure 12-5 shows a discount trigger in PDC.

Figure 12-5 Discount Trigger

Expression	Operator	Value
Balance[Included Domestic Minutes]	Less Than or Equal To	100.00

If a trigger condition includes multiple conditions, all conditions must be met for the discount to be granted.

A discount can have only one trigger. A trigger can be used by multiple discounts.

About Using Temporary Balances in Discounts

Typically, you use temporary balances when you need the results of one discount to calculate another discount for the same event.

For example, consider a discount that awards 5 text messages if the amount of data transferred in a data usage event exceeds 1 megabyte and the session duration exceeds 30 minutes. In this situation, Discount 1 would determine the amount of data sent or received and store it in Temporary Balance A. Discount 2 would determine the duration of the session and store it in Temporary Balance B. Discount 3 would grant 5 text messages if the data in Temporary Balance A exceeds 1 megabyte and the session length in Temporary Balance B exceeds 30 minutes.

You can only use noncurrency balances for temporary balances. Rounding rules do not apply to them.

Unlike other balances, temporary balances are maintained only while a single event is being discounted. If multiple discounts are applied to a single event, the temporary balance is maintained until all the discounts are processed.

For billing-time discounts, temporary balances are maintained only while a single discount is processed. Therefore, you cannot use temporary balances for billing-time discounts to pass a balance impact from one discount offer to another.

Using Functions to Calculate a Balance Impact

Use a function in a discount to calculate a value that is not directly configurable in PDC. The function typically performs a database query, for example, the total charges for the ten most frequently called numbers. This amount can then be discounted.

For example, suppose you want to implement a 10% discount on data usage from an access point. To implement this discount, you could include a function as the **What to Discount** value:

Function["AccessPoint"]

When BRM processes this discount, the usage amounts for the access point is substituted into the **What to Discount** value. A 10% discount is applied to AccessPointX usage.

Applying Multiple Discount Versions to an Event

You can apply multiple versions of a discount to the same event. To do so, you create multiple discount rules. For example, you might use discount rules to apply a discount in peak or off-peak times. A discount rule includes all of the elements of a discount; filters, triggers, and pricing. The rules are applied in the order that they appear in PDC.

You can use the same criteria (**Original Charge**, **Remaining Charge**, and **Remaining Charge and Quantity**) for applying multiple discount rules as you do when you apply different discount offers to the same event. See "[Applying Multiple Discount Offers to an Event](#)".

About Billing-Time Discounts

Billing-time discounts are calculated at the end of the billing cycle. This enables you to apply discounts based on the aggregation of a balance during a billing cycle. For example, you can create a billing-time discount to do the following:

- Reduce a balance by \$10 if the total usage charges for the billing cycle are more than \$100.
- Grant 10 text messages if the total minutes used during the billing cycle are more than 500.

Billing-time discounts are typically based on balances accumulated by using a counter. The counter can be used to apply usage, recurring, or one-time discounts.

For example, you can create a billing-time discount that grants 10 minutes for every \$100 in usage charges. To create a billing-time discount, you set up the following discounts:

- A non-billing-time discount that increments a counter to track Dollars Spent. Every \$1 charged increments the counter by 1.
- A billing-time discount grants 10 minutes if the Dollars Spent counter is over 100 at billing time.

Configuring Effective Dates for Discounts

You can add a date range to a discount by specifying a fixed start date and end date (discount date ranges cannot be relative). The date range is the period during which the discount is effective.

This enables you to use different versions of the same discount during different time periods by adding multiple date ranges to a single discount rather than by creating multiple discounts.

You can use different discount rules and pricing for each date range. For example, you could create a discount that applies a 10% discount for the first date range and a 20% discount for the second date range.

Date ranges cannot overlap in the same discount. For example:

- Immediately through 6/1/2016
- 6/1/2016 through 1/1/2017

- 1/1/2017 through never ends

Note:

Date ranges for different discounts in the same discount offer can overlap.

Configuring Discount Validity

You can configure discount validity for the following cases:

- [Applying Discounts That Are Valid for Only Part of a Cycle](#)
- [Applying a Discount After the Discount Offer Is Inactivated or Canceled](#)
- [Configuring Validity Periods for Noncurrency Credit Balance Impacts](#)

Applying Discounts That Are Valid for Only Part of a Cycle

You can specify how to apply a discount when it is valid for only part of a cycle. There are three scenarios:

- Discounts that are valid from mid-cycle to the end of the cycle. *Mid-cycle* is any time after the accounting cycle start time and before the accounting cycle end time.
- Discounts that are valid from the start of a cycle but end in mid-cycle.
- Discounts that are valid for part of a cycle, in the middle of the cycle.

For each scenario, you specify whether the discount is applied for the full cycle, applied to part of the cycle, or is not applied at all.

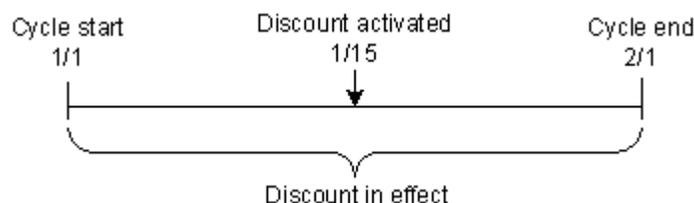

For example, [Figure 12-6](#) shows a discount that becomes valid in mid-cycle, but is applied to the entire cycle.

Note:

In this example, if the discount is a usage discount, the charges would need to be rerated to apply the discount to the events that occurred before the discount was valid.

Figure 12-6 Valid Mid-cycle - Full Discount

[Figure 12-7](#) shows a discount that becomes valid in mid-cycle that is applied to only part of the cycle.

Figure 12-7 Valid Mid-cycle - Partial Discount

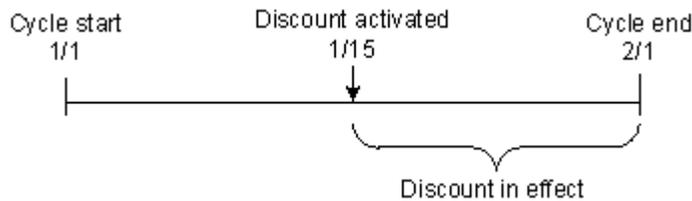

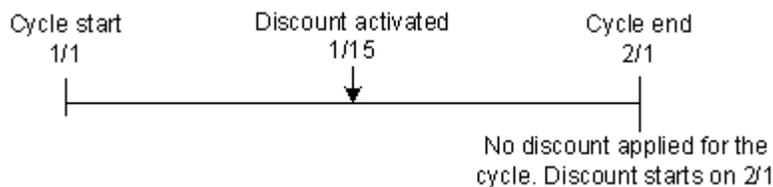

Figure 12-8 shows a discount that becomes valid in mid-cycle, but no discount is applied.

Figure 12-8 Valid Mid-cycle - No Discount

Applying a Discount After the Discount Offer Is Inactivated or Canceled

For each discount, you specify whether to apply the discount after the discount offer is canceled or inactivated. This controls how to apply discounts to events that occurred prior to the discount offer cancellation or inactivation. The options are:

- Don't stop discounting if the discount offer is inactive or canceled
- Stop discounting if the discount offer is inactivated
- Stop discounting if the discount offer is canceled
- Stop discounting if the discount offer is inactivated or canceled

Configuring Validity Periods for Noncurrency Credit Balance Impacts

When you create a discount balance impact that credits noncurrency balances, such as granting minutes, you can configure a validity period for the balance impact. This is useful if you want to limit how long a customer can keep minutes in their balance before they need to purchase more minutes. Figure 12-9 shows a balance impact that grants 100 minutes that are available for one billing cycle.

Figure 12-9 Balance Impact for Minutes

Impact	Amount	Balance Element	Amount Is Valid
Credit ▼	100.00	Included Minutes ▼	From first usage - 1 Billing Cycles From Validity Start

You can specify a validity period corresponding to the current accounting cycle or the current billing cycle. You can also define validity period start and end times. You can start a validity period:

- When the event occurs.
- At first usage. Balances that start on first usage are added to the account balance at the time of the grant, but the validity starts when the subscriber uses the service for the first time.
- From a specified date.
- Relative to a specified date.

You can end a validity period based on:

- A date relative to the start date (measure in minutes, hours, days, months, or in account, billing, or recurring cycles)
- On a specified date.
- No end date.

If a charge offer or discount offer is canceled after being used, the validity end time of any balance granted by the offer is set to the time of the cancellation.

Discounts and Tax Calculation

You can apply a tax code to a discount. You need to define tax codes before you can assign them in discounts. You can reference the tax code directly, or you can use a tax code selector.

For information, see "About Calculating Taxes" and "Creating Tax Codes" in *BRM Calculating Taxes*.

Discounts and General Ledger

You assign a general ledger ID (G/L ID) to discount balance impacts. This enables you to track revenue for each type of discount.

About Snowball Discounts

A snowball discount is a type of shared billing-time discount that distributes a percentage discount to all accounts in a discount sharing group. A discount sharing group allows one account (the group owner) to share discounts with other accounts (the group members).

To implement a snowball discount, you use two discounts:

- A discount that increments a counter.
- A billing-time discount that calculates and distributes the discount based on the counter balance. In PDC, you designate this a snowball discount.

For example, a discount sharing group has one owner and three members. The owner purchases a discount offer that includes a snowball discount that grants \$0.01 for every minute of telephone usage. At the end of the billing cycle, the group used 4,000 minutes. A total of \$40 is granted to the group. If the discount is configured to divide the grant evenly, the owner and each member receive \$10.

You can also configure the discount to distribute the grant based on the minutes used for each account. For example, if the owner uses 2,500 minutes, and each member uses 500 minutes, the owner receives a \$25 grant, and each member gets a \$5 grant.

In addition to creating the counter discount and the billing-time discount, you need to do the following:

- Set up a discount sharing group by defining the group owner, group members, and a list of the discounts that the group will share. See "[About Discount Sharing](#)" for more information.
- Specify how the snowball discount is distributed in the `pin_snowball_distribution` file and run the `load_pin_snowball_distribution` utility.

The distribution you specify in the `pin_snowball_distribution` file becomes the default distribution. You can customize this behavior by modifying the policy opcode `PCM_OP_SUBSCRIPTION_POL_SNOWBALL_DISCOUNT`.

- If the discount is to be distributed unevenly, for example, if each member gets a percentage based on its usage, configure sub-balance contributors. Specify the contributors in the `pin_sub_bal_contributor` file and load the file by running the `load_pin_sub_bal_contributor` utility. See "[Defining and Loading Custom Sub-Balances](#)" for information.

Defining How Snowball Discounts Are Distributed

To specify how snowball discounts are distributed, edit the `pin_snowball_distribution` file and then run the `load_pin_snowball_distribution` utility to load the file's contents into the `/config/snowball_distribution` object in the BRM database.

You set two values in the `pin_snowball_distribution` file:

- The name of the discount offer.
- Either zero or the balance element ID for the counter discount.
 - If set to zero, the discount is distributed evenly among all members of the discount sharing group.
 - If set to a balance element ID, the discount is distributed based on how much each account contributed to the amount in the counter balance.

Note:

If you specify a balance element, you must configure sub-balance contributors to enable BRM to track each account's contribution. See "[Defining and Loading Custom Sub-Balances](#)" for information.

For example, the following entries in the `pin_snowball_distribution` file specify that **snowball one** is distributed evenly and **snowball two** is distributed based on the amount each account contributed to the counter (balance element ID 1000501) at the end of the billing cycle.

```
snowball one : 0
snowball two : 1000501
```

Note:

The `load_pin_snowball_distribution` utility overwrites existing snowball distribution rules. If you are updating snowball distribution rules, you cannot load new snowball distribution rules only. You must load complete sets of snowball distribution rules each time you run the `load_pin_snowball_distribution` utility.

To configure snowball distribution rules:

1. Edit the **pin_snowball_distribution** file in *BRM_home/sys/data/pricing/example*. The **pin_snowball_distribution** file includes instructions.
2. Save the **pin_snowball_distribution** file.
3. Use the following command to run the **load_pin_snowball_distribution** utility:

```
load_pin_snowball_distribution pin_snowball_distribution
```

If you do not run the utility from the directory in which the file is located, you must include the complete path to the file, for example:

```
load_pin_snowball_distribution BRM_home/sys/data/pricing/example
```

 **Note:**

If you copy the **pin_snowball_distribution** file to the directory from which you run the **load_pin_snowball_distribution** utility, you do not have to specify the path or file name. The file must be named **pin_snowball_distribution**.

4. Stop and restart the Connection Manager (CM).

To verify that the network elements were loaded, you can display the **/config/snowball_distribution** object by using the Object Browser, or use the **robj** command with the **testnap** utility. See "Reading an Object and Writing Its Contents to a File" in *BRM Developer's Guide*.

Creating Subscription Terms

Learn how to create subscription terms and add them to your packages and bundles in Oracle Communications Billing and Revenue Management (BRM). Subscription terms define the commitment periods and options for canceling and renewing the services you offer.

Topics in this document:

- [About Subscription Terms](#)
- [About Early Termination Fees](#)
- [About Automatic Renewals](#)
- [About Bundle Terms and Package Terms](#)
- [About Obsolete Subscription Terms](#)
- [Creating Subscription Terms](#)

About Subscription Terms

Note:

- Subscription terms are supported only by BRM 12.0.0.3.0 with Interim Patch 31426340 and later, and PDC 12.0.0.3.0 with Interim Patch 31426374 and later.
- Subscription terms work end-to-end only when Appliance Standards Codification (ASC) 606 is enabled in BRM. See "Enabling Deliverable-Based Revenue Recognition" in *BRM Collecting General Ledger Data*.

Subscription terms specify a contract's commitment period, such as 1 month, 1 year, or 2 years.

Terms also specify whether customers:

- Can cancel their contract before the commitment period ends
- Are charged an early termination fee for canceling early
- Have a grace period, during which the early termination fee is waived
- Have their contracts renewed automatically when the commitment period ends

For example, a term might specify a 1-year commitment period, allow early cancellation with a \$250 early termination fee, and renew automatically with the same terms.

BRM includes standard terms that you can use for your contracts or use as examples when creating your own terms.

After you create subscription terms, you can associate them with your packages and bundles.

About Early Termination Fees

You can charge your customers an early termination fee if they cancel their contract early. You can use this fee to recoup the cost of equipment or discounts given to customers at the start of a contract. For example, you could use it to recoup the cost of a cell phone that was provided for free with a wireless service contract.

An early termination fee can be one of these:

- A flat fee, such as 100 US dollars or 75 euros.
- A fee that is reduced in equal amounts over the contract's term. For example, in a 1-year commitment period with an early termination fee of \$60, you could reduce the fee by \$5 each month. A customer canceling after 1 month would pay \$55, and a customer canceling after 8 months would pay \$20.
- The balance remaining in the customer's contract. For example, in a 1-year commitment period with a \$50 monthly charge, you would charge \$50 for each month remaining in the contract. A customer canceling with 5 months remaining would pay \$250, and a customer canceling with 3 months remaining would pay \$150.

You can also add a grace period, allowing your customers to cancel a contract within the first few days or weeks after purchase without incurring the early termination fee.

About Automatic Renewals

You can set contracts to renew automatically at the end of the commitment period with the same terms or with different terms. For example, you can create a subscription term that automatically renews with the same 1-year commitment or with a different monthly commitment.

When a contract is renewed, time-based discounts, such as a first-year discount, aren't renewed. Time-based discounts that exceed the contract commitment period, such as a two-year discount, are still in effect, but the end date for the discount remains the same.

Your customers can renew their contracts manually at any time, regardless of the commitment period, through your service representative or your customer care application.

About Bundle Terms and Package Terms

After you create subscription terms, you can associate them with your packages and bundles. A package's terms apply to all required bundles in the package, but any optional bundles are governed by their own, independent terms.

For example, assume you have a package that has a \$20 early termination fee. That package includes a required bundle for digital textbooks and an optional bundle for online tutoring. If a customer cancels the digital textbook service after the first month, they must pay the \$20 fee and the entire package is canceled, including the online tutoring service. But the terms for the online tutoring service might let the customer cancel it at any time without paying an early termination fee or canceling the rest of the package.

About Obsolete Subscription Terms

 **Note:**

When a package is obsolete, it does not obsolete the term that is associated with it. You must obsolete the subscription term separately.

When you obsolete a subscription term, it does not impact your customers' existing contracts. Those contracts continue to be governed by the same terms. Your new product offerings, however, can no longer include the obsolete term.

You cannot obsolete a subscription term when:

- A package and the bundles associated with the package all use the same subscription term. Before you can obsolete the term, you must change the package and its bundles to use a different subscription term.
- The term is set to automatically renew at the end of its commitment period. Before you can obsolete the term, you must change its auto-renew setting to **No**.

Creating Subscription Terms

When creating terms, you specify the following:

- The commitment period.
- Whether to allow early cancellation of the contract and whether to apply an early termination fee:
 - **Allowed, No Penalty:** Contracts can be canceled early, and customers will not be charged an early termination fee.
 - **Allowed, with Penalty:** Contracts can be canceled early, but customers will be charged an early termination fee for doing so.
 - **Not Allowed:** Contracts cannot be canceled early.
- If applying an early termination fee, whether to apply a flat fee, a fee that reduces over time, or the remaining contract balance. You can also specify:
 - Whether to add a grace period during which no early termination fee is applied.
 - The revenue general ledger ID to associate with the early termination fee. If you do not select a general ledger ID, the early termination fee is distributed across the deliverables in the contract.
- Select whether to automatically renew the contract, and which terms to renew with.

After you have created terms, they can be associated with your packages and bundles.

[Figure 13-1](#) shows a sample subscription term that has a 1-year commitment period, allows early cancellation with a \$240 early termination fee that reduces by \$20 each month, has a 10-day grace period, and renews automatically with the same terms.

Creating Bundles

Learn how to use bundles to group charge offers and discount offers for a single service that you want to sell together in Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Creating Bundles](#)
- [Configuring Bundle Settings](#)
- [Associating Terms with Bundles](#)
- [Customizing Offers In Bundles](#)
- [Creating Dependencies for Bundles](#)
- [Transitioning between Bundles](#)

About Creating Bundles

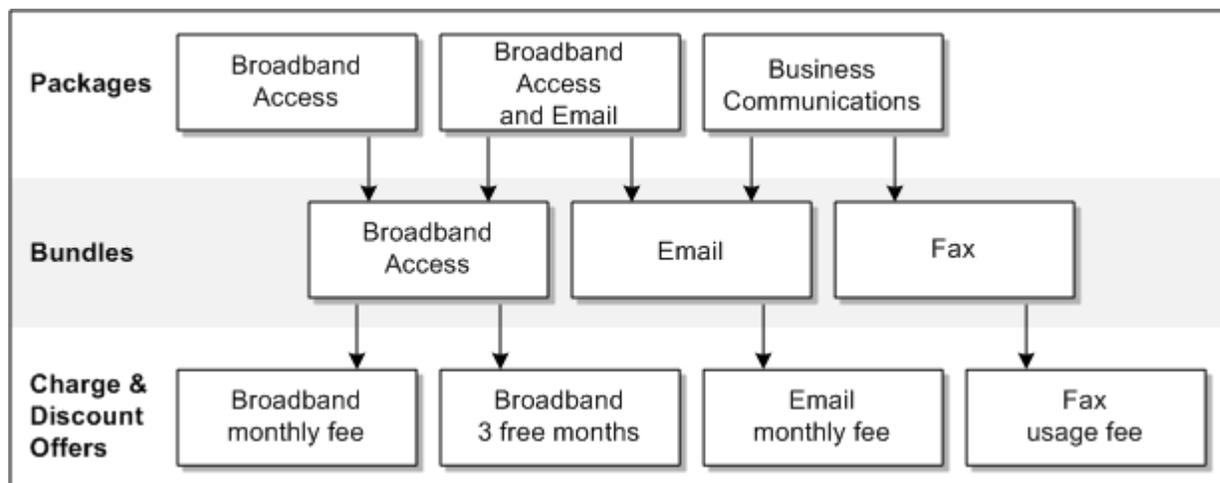

A bundle is a set of charge offers, discount offers, or both. You typically use bundles to group offers that you want to sell together.

Each bundle is associated with a single service. Only offers that apply to that service can be included in the bundle. For example:

- A package that provides only broadband access includes only broadband access bundles (such as cable and premium cable).
- A package that provides broadband access and VOIP includes at least two bundles, one for broadband access and one for VOIP.
- A package that provides VOIP and cable TV includes at least two bundles, one for VOIP and one for cable TV.

Figure 14-1 shows bundles that are associated with a single service.

Figure 14-1 Bundles Are Always Associated with a Single Service

One bundle can contain any number of charge offers and discount offers, and two different bundles can contain the same offer. Grouping offers in different ways in different bundles adds flexibility to your pricing structure without requiring you to create additional charge offers or discount offers.

Creating a bundle involves these high-level tasks:

1. Configuring the bundle's validity dates, the service or account it is associated with, and other settings.
See "[Configuring Bundle Settings](#)".
2. Optionally, adding subscription terms. Subscription terms govern the agreement between you and the customer who purchases the bundle. When customers purchase a bundle with a subscription term, it becomes a contract.
See "[Associating Terms with Bundles](#)".
3. Adding one or more charge offers and discount offers.
4. Optionally, customizing the charge offers and discount offers.
See "[Customizing Offers In Bundles](#)".
5. Optionally, defining any dependencies between this bundle and other bundles.
See "[Creating Dependencies for Bundles](#)".
6. Optionally, specifying whether customers can transition from this bundle to another specified bundle.
See "[Transitioning between Bundles](#)".
7. Optionally, configuring PDC to save extra information about the bundle that may be useful to external applications.
See "[Configuring Product Specification Attributes for Pricing Components](#)".

Configuring Bundle Settings

You can configure bundles in the following ways:

- **Associate the bundle to a service or an Account.** When creating a bundle, you can associate it with a specific service. That is the only service to which the offers in the bundle apply.

Alternatively, you can associate the bundle with **Account**. You might do this, for example, to create a bundle for late charges or for coupons. The offers in the bundle can then be used to rate any event associated with **Account** in the service-event map. Each account can own only one bundle that applies to **Account**.
- **Bill customers when they purchase the bundle.** Usually, you bill a customer at the end of the customer's billing cycle. *On-purchase billing*, however, enables you to bill a customer immediately for a purchase, even if the customer's billing cycle has not ended. When you create a bundle, you can flag it for on-purchase billing. When a customer purchases the bundle, a bill is generated immediately for the purchase fees associated with the bundle.

 **Note:**

On-purchase billing works with purchase fees only, not with recurring, usage, or cancellation fees.

- **Align balance impacts on first usage.** You can configure a bundle to synchronize the start date of all balance impacts whose validity period starts on first usage. This ensures that all balance impacts in the bundle's charge offers are set to the same validity period when one of them is activated for the first time.

For information about how it affects discount offers, see "[About Activating First-Usage Discount Offers](#)".

For information about how it affects charge offers, see "[About Granting First-Usage Balance Impacts In First-Usage Charges](#)".

- **Permit CSRs to customize bundles.** If your CSRs (customer service representatives) can discount or change the effective period of charges in bundles at purchase time, you can specify whether to prohibit, allow, or require such modifications in a particular bundle. For example, if customer input is required to set the date on which an offer's purchase fee is applied, you can specify that a bundle must be modified.
- **Specify when a bundle can be purchased.** By default, the time period during which a bundle can be purchased starts immediately and never ends. You can change the default start date, end date, or both.

To be added to a bundle, an offer must have a purchase period that is the same as or greater than the bundle purchase period. If the purchase period of an offer in a bundle exceeds the bundle purchase period, the bundle purchase period overrides the offer purchase period.

About Activating First-Usage Discount Offers

Discount offers that start on first usage can be activated when the customer first uses a service, when the first cycle fee is applied, or when the account's bill is generated, depending on which fees are discounted and when the discount is triggered. For example, a first-usage discount on SMS messaging is activated when the customer sends the first SMS message, a first-usage discount on cycle fees is activated when the first cycle fee is applied, and a first-usage billing-time discount is activated when the first bill is generated for the account.

It is possible that a discount on a particular service might not be activated when a customer first uses that service. For example, if long-distance calls are discountable for a telephony service, a customer might make multiple local calls, which do not trigger the discount's effective period, before making a long-distance call.

There are some cases in which a discount's balance impact is negated by a second discount. If this occurs, the first discount's validity period is still set.

For example, a customer purchases a bundle that includes discount offer A and discount offer B:

- Discount offer A is configured to start when first used, gives 10% off of all calls, and has a higher priority, so it is applied first.
- Discount offer B is configured to start immediately and makes all birthday calls free.

If a customer makes a first-usage call on his birthday and is charged \$5.00 for the call, discount offer A is applied first, which reduces the balance by \$.50, and discount offer A's validity period is set. Then discount offer B backs out all charges. In this case, the validity period of discount offer A remains set.

About Granting First-Usage Balance Impacts In First-Usage Charges

A charge offer that is valid from first usage should not grant a credit balance, such as included minutes, that is also valid from first usage. If it does, the granted balance cannot be consumed by the first usage event.

For example, consider a charge offer that is valid on first usage and has these charges:

- A recurring event that grants minutes. The balance impact is set to first usage.
- A charge that consumes minutes until there are none, and then consumes money.

When the first usage event for this charge offer occurs, the charges are processed in this order:

1. The first usage event is charged, and it consumes a monetary balance, because no minutes have been granted.
2. The recurring event, with a balance impact set to first usage, can now be charged. It grants minutes.
3. Subsequent usage events now have minutes to consume.

Because the included minutes are valid from first usage, they are not granted until after the first usage event is rated. Hence, the first usage event cannot consume any of the minutes included in the charge offer. Therefore, the customer is charged for a call that should have consumed minutes.

However, if a discount offer that is valid from first usage grants a credit balance that is valid at first usage, the granted balance is available for consumption because discounting occurs after the balances are granted.

Associating Terms with Bundles

Note:

Adding terms to bundles is supported only by BRM 12.0.0.3.0 with Interim Patch 31426340 and later, and PDC 12.0.0.3.0 with Interim Patch 31426374 and later.

You can associate your bundles with subscription terms, which govern the agreement between you and the customer who purchases the bundle. Subscription terms specify the bundle's commitment period, whether customers are allowed to cancel the bundle early, and whether customers are charged an early termination fee for doing so.

If you add a subscription term to a bundle, it applies only if the bundle is *optional* in a package.

If a package specifies that the bundle is *required*, the bundle's terms will be overridden by the package's terms. See "[About Bundle Terms and Package Terms](#)".

Customizing Offers In Bundles

You can customize the charge offers and bundle offers in a bundle in the following ways:

- **Customize the offer quantity.** You can customize bundles to provide more than one of the same charge offer or discount offer. For example, if a bundle for a cable service

includes a charge offer that provides one set-top box and you want to include three set-top boxes with the cable service, enter 3 for the charge offer in that bundle.

- **Override the offer's validity period.** You can override the validity start and end dates in a charge offer or discount offer, such as from January through March to a new validity period of January through July. See "[About the Validity Periods of Offers in Bundles](#)".
- **Set the status of offers at purchase.** You can specify whether an offer is *active* or *inactive* at the time of purchase. For example, an offer might be inactive at purchase so that the purchase or first month's fee is only applied after you get confirmation that the hardware was received and successfully configured. By default, offers are active.

For offers with inactive status, you can specify a reason for that status.

- **Configure how to set a charge offer's cycle alignment when its bundle is reactivated.** Suppose a customer suspends and later reactivates their subscription. In that case, you can specify whether the charge offer's cycle alignment is based on the original billing or purchase date, or reactivation date.

By default, the cycle is aligned with the original billing or purchase dates, depending on how the charge's cycle alignment is configured. You can instead select the **Renewal Mode** option for the charge offer to use the reactivation date instead of the original date. When you select this option, the following scenarios are possible:

- If the charge's cycle is set to align with the purchase date, the reactivated charge offer's cycle aligns with the reactivation date.
 - If the charge's cycle is set to align with the purchase date, but the charge offer specifies that the cycle alignment should be a specific day of the month, the reactivated charge offer's cycle aligns with whichever is later, the reactivation date or the day of the month specified in the charge offer.
 - If the charge's cycle is set to align with the billing date, the reactivated charge offer's cycle will align with the billing date (regardless of whether you select the **Renewal Mode** option).
- **Configure how to prorate an offer's cycle fees.** You can specify to prorate an offer's fees using a 30-day month or the actual number of days in the month. See "[Setting Proration for Offers in a Bundle](#)".
 - **Specify whether a charge offer can be purchased as an add-on product.** You can specify that a charge offer is optional, meaning it can be purchased with the bundle or later on. See "[About Add-On Charge Offers in Bundles](#)".
 - **Configure what happens when a customer purchases the same offer more than once.** You can specify whether the additional offer is purchased as a new subscription or as a replacement. See "[About Purchasing the Same Offer Multiple Times](#)".
 - **Customize charges and discounts for a customer.** See "[About Customizing Charges and Discounts in Bundles](#)".

About the Validity Periods of Offers in Bundles

You can configure the start time and end time for each charge offer and discount offer in a bundle. The time between the start time and the end time is called the *validity period*. A customer cannot use a service provided by an offer unless the offer is valid.

 **Note:**

- You specify when a charge offer or a discount offer can be **purchased** in the offer itself. You cannot apply a validity period when you create a charge offer or a discount offer; you can only apply it in the bundle configuration.
- You can apply validity periods to individual charges and discounts configured within offers. However, the validity periods specified in a bundle take precedence over the validity periods specified in the charges and discounts. For example, you might want to allow a customer to purchase a charge offer, but not allow the customer to use the service until it is activated on the network.

In bundles, you set the validity period of offers by specifying the start and end times of the offer and of the offer's cycle and usage charge periods.

- **Offer start and end times:** Specify when a customer can use the service or benefit from the discount. The offer start time is when the purchase fee is charged. It is also the earliest time that the offer's fees can begin to accumulate in an account balance.
- **Recurring and usage charge periods:** Specify when recurring and usage events can be charged or discounted. These validity periods must not begin before the offer start time.

You can set *start* times as follows:

- **Immediately:** (Default) The offer or charge is valid and can be activated immediately. The purchase fee is charged as soon as the offer is added to the account.
- **Relative to Purchase:** The purchase fee is charged when the offer is added to the account, but the customer cannot use the service or benefit from the discount until the relative period ends.

When a charge offer's charge period has a relative start time, the events are not rated and the fees are not charged until the relative period ends, even if the service has been activated. This option enables you to waive subscription or usage fees for a period of time.

When a discount offer's charge period has a relative start time, the discount is not applied to cycle or usage fees until the relative period ends.

- **First Usage of Any Offer in a Bundle:** When a customer first uses any service in a bundle, all offers in the bundle are activated and all purchase fees are charged. The charge periods also begin at that time. The validity period start time is set to the start time of the event that first uses the service or triggers the discount offer.

Setting charge offers and discount offers to start when they are first used enables you to delay charging customers for the services they purchase until they start using those services or to delay activating discount offers until they can be applied to customers' usage. This is useful when you offer limited-time services or discount offers that expire relative to when they are activated.

 **Note:**

Charge offers that start on first usage must include usage fees.

You can set the *end* times as follows:

- **Never:** (Default) After it is activated, the offer is effective indefinitely, and its recurring and usage fees can be charged or discounted indefinitely.
- **Relative to Start:** After the relative period ends, the offer is not effective and the recurring or usage fees are not charged or discounted.

If the offer end time specified in the bundle is earlier than the recurring or usage charge end time, the offer end time overrides the charge end time.

Setting Proration for Offers in a Bundle

When creating bundles, you can specify how cycle charges and discounts are prorated at the charge offer or discount offer level. You can specify to calculate prorated cycle charges and discounts using:

- **A 30-day month:** Prorated cycle charges and discounts are calculated based on a 30-day month, regardless of the number of days in the billing cycle. For example, if a bundle was owned for 6 days in a cycle, the prorated charge would be the cycle charge multiplied by 0.20 ($6 \div 30$).
- **The actual number of days in a billing cycle:** Prorated cycle charges and discounts are calculated based on the actual number of days in a particular cycle, such as 28 days in February, 31 days in March, and 30 days in April. For example, if a bundle was owned for 6 days in March, the prorated charge would be the cycle charge multiplied by 0.19 ($6 \div 31$).
- **The system-wide proration setting:** Prorated cycle charges and discounts are calculated according to the system-wide setting in your CM `pin.conf` file. See "Enabling 30-Day-Based Proration" in *BRM Configuring and Running Billing*.

You can configure proration at the offer level in your bundles by using the following:

- The PDC UI. When customizing an offer in your bundle, use the **Proration** list. For more information, see "Customizing an Offer in a Bundle" in *PDC Online Help*.
- The **ImportExportPricing** utility. In your XML file, set the `<prorationBasedOn>` element under `<bundledProductOfferingItem>`. For more information, see "[Configuring Proration for Offers in Bundles](#)".

About Add-On Charge Offers in Bundles

You can include add-on charge offers in your bundles. All charge offers in bundles are base charge offers by default, which means they can be purchased without any prerequisites. Add-on charge offers require customers to own a valid base charge offer.

When you create an add-on charge offer, you specify how to determine its validity start date. The add-on charge offer's validity start date is the end date of the charge offer that you specify. For example, assume charge offer A has a validity period from June 1 through June 15. If you specify to align add-on charge offer B's validity period with charge offer A, charge offer B's validity start date would be June 15.

You can specify that an add-on charge offer's validity dates align with:

- The base charge offer that you specify
- The active base charge offer that expires first
- The active base charge offer that expires last
- The active charge offer that expires first
- The active charge offer that expires last

You configure an add-on charge offer in a bundle by using the following:

- The PDC UI. When customizing a charge offer in a bundle, set the **This is an add-on charge offer** option. For more information, see "Customizing an Offer in a Bundle" in *PDC Online Help*.
- The **ImportExportPricing** utility. In your XML file, set the `<addOnOfferingValidityMode>` element under `<bundledProductOfferingItem>`. For more information, see "[Configuring Add-On Charge Offers In Bundles](#)".

About Purchasing the Same Offer Multiple Times

You can specify what happens if customers purchase the same charge offer or discount offer more than once.

For both charge offers and discount offers, you can specify whether the additional offer is purchased as a new subscription or a replacement of the existing subscription:

- **Create a new subscription and keep the old one:** The additional charge offer or discount offer is purchased as a new, unrelated subscription. The balance impacts and validity periods of the old and new subscriptions are completely independent. This is the default option.
- **Create a new subscription and cancel the old one:** The additional charge offer or discount offer replaces the existing subscription. The existing subscription is canceled, any configured proration is applied, and the new subscription is created, with all balance impacts and validity periods set as though for a new purchase.

For example, on June 1st, a customer purchases an add-on bundle that grants 3GB of data and is valid for 7 days. On June 3rd, after using 1GB, they purchase the bundle again. The old charge offer is canceled, any remaining balance is prorated, and the new 3GB balance is created, with a validity end date of June 10th.

For both charge offers and discount offers, you can also specify whether the additional offer is purchased as an extension of the existing subscription if it is purchased during a specified grace period. The grace period can be any number of seconds, minutes, hours, or days. The default grace period is 0 days.

- **Extend the old subscription, setting validity to whichever is later, the new or existing validity:** The additional charge offer is purchased as an extension to the existing subscription if it is purchased within the specified grace period. The new balance impacts are added to the existing balance group. The validity period for the balance is then set to either the old validity end date or the new validity end date, whichever is later.

For example, on June 1st, a customer purchases an add-on bundle that grants 3GB of data, is valid for 7 days, and has a grace period of 4 days. On June 3rd, after using 1GB, they purchase the bundle again. The new 3GB balance is added to the remaining balance, for a total of 5GB. BRM compares the validity periods of the old and new charge offer and sets the validity end date for the total balance to the later of the two end dates, June 10th.

- **Extend the old subscription, adding the new validity to the old validity:** The additional charge offer is purchased as an extension to the existing subscription if it is purchased during the specified grace period. The new balance impacts are added to the existing balance group. The validity period for the balance is then set by adding the new validity period to whatever remains of the old validity period.

For example, on June 1st, a customer purchases an add-on bundle that grants 3GB of data, is valid for 7 days, and has a grace period of 4 days. On June 3rd, after using 1GB, they purchase the bundle again. The new 3GB balance is added to the remaining balance,

for a total of 5GB. BRM adds the validity period of the new charge offer to the old charge offer, and sets the validity end date for the total balance to June 15th.

You configure how to handle multiple purchases of the same offer by using one of the following:

- The PDC UI. To do so, when customizing the offers in your bundles, use the **Behavior** list and **Grace Period** fields. For more information, see "Customizing an Offer in a Bundle" in *PDC Online Help*.

Figure 14-2 Offer Customization

The screenshot shows a form titled "Purchase" with the subtitle "When purchasing multiple instances of the same offer". It contains two main fields: "Behavior" and "Grace Period". The "Behavior" field is a dropdown menu currently set to "Extend the old subscription, adding the new validity to the old validity". The "Grace Period" field consists of a text input box containing the number "3" and a dropdown menu set to "Day(s)".

- The **ImportExportPricing** utility. To do so, set the `<purchaseMode>`, `<gracePeriodOffset>`, and `<gracePeriodUnit>` elements in your import XML file. For more information, see "[Purchasing the Same Offer in a Bundle Multiple Times](#)".

About Customizing Charges and Discounts in Bundles

In addition to adding discount offers to a bundle, you can reduce one-time and recurring charges in charge offers by specifying a flat percentage discount for each charge category in the bundle itself. For example, you can discount all recurring charges and one-time charges by 10%. You cannot use a bundle to apply discounts to usage charges.

When you discount a charge category in a bundle, the discount applies to all charge types that apply to that charge category. For example, you might have a charge offer that includes two recurring charges; Monthly Fee and Grant Minutes. If you specify a percentage discount for recurring charges in the bundle, the discount applies to both recurring charges. To discount only the Monthly Fee charge, you must make the balance impact for Monthly Fee discountable and the balance impact for Grant Minutes nondiscountable.

Unlike discount offers, discounts configured in bundles cannot be tracked in the general ledger because they are not associated with a general ledger (G/L) ID. In addition, unlike discount offers, bundle-configured discounts are difficult to display on a customer's bill because they are not separate items.

Note:

Because of the limitations associated with discounts configured in bundles, Oracle recommends that you use discount offers instead. See "[Creating Discount Offers](#)" for more information.

Creating Dependencies for Bundles

You can set up the following dependent relationships between bundles:

- **Prerequisite:** Specifies that an account must own a particular bundle to be able to purchase another particular bundle. A prerequisite can include bundles for different

services. For example, to own a GPRS bundle, an account might be required to own a GSM bundle.

- **Mutually Exclusive:** Sets up a mutually exclusive relationship between two bundles so that if an account owns one of the bundles, it cannot own the other. For example, if you set up a mutually exclusive relationship between a Corporate Voice bundle and a Residential Voice bundle, customers who purchase one cannot purchase the other.

Transitioning between Bundles

You can configure rules for transitioning from one bundle to another. PDC supports the following types of transitions:

- **Upgrade** to a bundle that is typically more expensive and has more features.
- **Downgrade** to a bundle that is typically less expensive and has fewer features.

Transition rules enable you to limit the bundles that customers can transition to and remain fully provisioned. While transitioning from one bundle to another, your customers retain their devices, such as phone numbers, and their services.

Note:

Transitioning between bundles affects only the charge offers and discount offers related to the service to which the bundle applies; the service itself remains the same. To define a transition that adds a new service, you create a transition for a package. See "[Transitioning between Packages](#)" for more information.

For information about customizing bundle transitions, see "Customizing Bundle Transitions" in *BRM Opcode Guide*.

Prorating Charges During Bundle Transitions

You can also configure how PDC handles charges when customers transition bundles in the middle of their billing cycle. Charges can be applied from the original bundle, applied from the new bundle, or prorated for both bundles.

For example, assume a customer's billing day of month (DOM) is the 15th and on June 30 he transitions from Bundle A to Bundle B. If you configure PDC to:

- Prorate the charges, the customer's July 15 bill would include charges for Bundle A prorated from June 15 through June 30, and charges for Bundle B prorated from July 1 through July 14. This is the default.
- Apply the original bundle's charges, the customer's July 15 bill would include charges for Bundle A only.
- Apply the new bundle's charges, the customer's July 15 bill would include charges for Bundle B only.

You configure how to prorate charges during bundle transitions by using the following:

- The PDC UI. For information, see "Defining Transition Rules for Bundles" in *PDC Online Help*.
- The **ImportExportPricing** utility. In your input XML file, set the **<prorationType>** element under the **<bundleTransition>** element to one of the following:

- **PRORATE_CHARGE**: Specifies to prorate charges for both bundles. This is the default.
- **ORIGINAL_CHARGE**: Specifies to apply the full charges from the original bundle.
- **TRANSFER_CHARGE**: Specifies to apply the full charges from the new bundle.

For information, see "[Transitioning Bundles](#)".

Creating Packages and Package Lists

Learn how to create packages and package lists to offer your services to customers in Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [Creating Packages](#)
- [Associating Terms with Packages](#)
- [Grouping Services](#)
- [Transitioning between Packages](#)
- [Creating Package Lists](#)

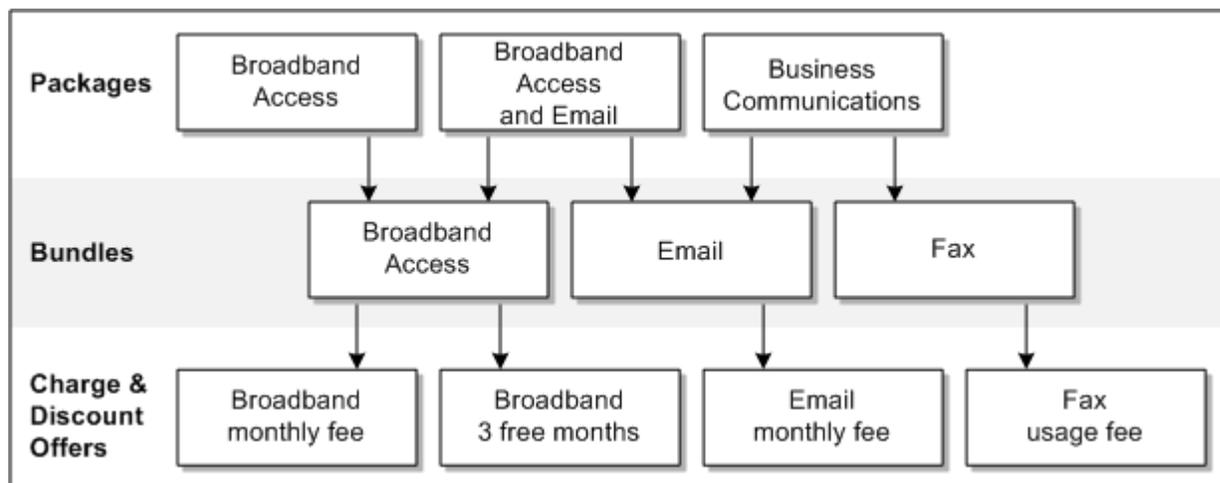

Creating Packages

A package is a collection of bundles. You use packages to offer your services to customers. For example, if your company sells broadband access, email, and IP fax service, you might offer the following packages:

- A package that sells only broadband access
- A package that sells broadband access and email
- A package that sells email and IP fax service

Figure 15-1 shows how you can include bundles and the services to which they apply in a variety of packages.

Figure 15-1 A Bundle Can Be Included in Multiple Packages

A package can contain any number of bundles, and two different packages can share the same bundle. By grouping bundles into packages, you simplify the choices presented to your customers.

You have the following options when creating packages:

- **Bill customers when the package is purchased.** Usually, you bill a customer at the end of the customer's billing cycle. On-purchase billing, however, enables you to bill a customer immediately for a purchase, even if the customer's billing cycle has not ended. When you create a package, you can flag it for on-purchase billing. When a customer purchases a package that is flagged for on-purchase billing, a bill is generated immediately for the purchase fees associated with the package.

 **Note:**

On-purchase billing works with purchase fees only. It does not work with recurring, usage, or cancellation fees.

- **Activate all offers in the package when the first service is used.** You can specify to activate all offers in a package when any of the offers are activated on first usage. For example, assume a package includes bundle 1 with offers A and B, and bundle 2 with offer C. If the first service a customer uses is in charge offer B on 15 May, all offers (A, B, and C) are activated on 15 May.
- **Configure required and optional bundles in a package.** *Required bundles* are automatically purchased when a package is purchased. By default, all bundles are required. *Optional bundles* can be purchased at a later time.
- **Restrict discounts in a package.** When creating a package, you can prohibit specified discount offers from being purchased or used while the package is owned.

If an exclusion relationship exists between a discount offer and a package, a customer can own the discount offer or the package, but not both. Further, the customer cannot own any discount offers associated with the package if the customer owns the excluded discount offer.

See "[Configuring Mutually Exclusive Discount Offers](#)" for information about configuring discount exclusion.

- **Set values for any product specification attributes defined in XML templates.** See "[Configuring Product Specification Attributes for Pricing Components](#)".

See the following topics for more package configuration features:

- [Associating Terms with Packages](#)
- [Grouping Services](#)
- [Transitioning between Packages](#)

Associating Terms with Packages

You can associate your packages with subscription terms, which govern the agreement between you and the customer who purchases the package. When a customer purchases a package with subscription terms, it becomes a contract.

 **Note:**

Adding terms to packages is supported only by BRM 12.0.0.3.0 with Interim Patch 31426340 and later, and PDC 12.0.0.3.0 with Interim Patch 31426374 and later.

Subscription terms specify the commitment period, whether customers are allowed to cancel their contract early, and whether customers are charged an early termination fee for doing so.

A package's terms apply to all required bundles in the package, but any optional bundles are governed by their own, independent terms. See "[About Bundle Terms and Package Terms](#)".

Grouping Services

In packages, you can combine services into service groups. A service group consists of one subscription service, and one or more member services. For example, if the subscription service is GSM, the member services could be Voice and SMS.

Service groups provide the following benefits:

- Member services can benefit from discounts owned by the subscription service.
- Member services can be associated with the devices owned by the subscription service.
- Customers can purchase services as a group.

The subscription service can be a service that subscribers use, such as telephony or broadband access, or it can be a representational service with no associated usage fees. Together, the subscription service and member services form a *service group*.

For example, in [Figure 15-1](#), the GSM service is a subscription service, and SMS and Voice are its member services.

Grouped services usually apply to a particular device, such as a cable box. An account can contain multiple service groups.

To subscribe to a service group, customers subscribe to its subscription service.

Transitioning between Packages

You can configure rules for transitioning from one package to another. Each transition rule applies to a particular service. The package being transitioned to and the package being transitioned from must both contain that service, though each package can contain additional services that the other package does not contain.

PDC supports the following types of transitions:

- **Upgrade** to a package that is typically more expensive and has more features. For example, a customer might transition from a package that provides broadband and cable TV services to a package that provides broadband, cable TV, and VOIP services. That transition adds a service and a bundle and possibly changes the bundles for the existing services.
- **Downgrade** to a package that is typically less expensive and has fewer features.

Transitions enable you to limit the packages that customers can switch to while remaining fully provisioned. When transitioning to a designated package, your customers retain their devices, such as phone numbers, and their services.

Prorating Charges During Package Transitions

You can also configure how PDC handles charges when customers transition packages in the middle of their billing cycle. Charges can be applied from the original package, applied from the new package, or prorated for both packages. For example, assume a customer's billing day of

month (DOM) is the 15th and on June 30 he transitions from Package A to Package B. If you configure PDC to:

- Prorate the charges, the customer's July 15 bill would include charges for Package A prorated from June 15 through June 30, and charges for Package B prorated from July 1 through July 14. This is the default.
- Apply charges from the original package, the customer's July 15 bill would contain charges for Package A only.
- Apply charges from the new package, the customer's July 15 bill would contain charges for Package B only.

You configure how to prorate charges during package transitions by using the following:

- The PDC UI. See "Defining Transition Rules for Bundles" in *PDC Online Help*.
- The **ImportExportPricing** utility. In your input XML file, set the **<prorationType>** element under the **<packageTransition>** element to one of the following:
 - **PRORATE_CHARGE**: Specifies to prorate charges for both packages. This is the default.
 - **ORIGINAL_CHARGE**: Specifies to apply the full charges from the original package.
 - **TRANSFER_CHARGE**: Specifies to apply the full charges from the new package.

For information, see "[Transitioning Bundles](#)".

Defining Generation Changes

A generation change enables you to transition customers between 2G (second generation) and 3G (third generation) wireless packages and services. Packages are called 2G or 3G depending on whether the wireless service they provide runs on a 2G or 3G wireless network.

When creating a 2G or 3G package, you can set up generation change rules to specify which packages can replace the package when it is transitioned to a different generation.

For generation changes, the packages do not have to provide the same service.

Note:

The same package cannot be used in both a transition rule and a generation change.

Creating Package Lists

A package list is a group of packages that is usually offered to a single type of customer. For example, you might create the following package lists:

- A package list that includes packages for customers above a certain age.
- A package list that includes packages for customers in a particular location, such as Canada.
- A package list that includes promotional discounts offered for a limited time.

You can create any number of package lists, and each package list can contain any number of packages. Different package lists can contain the same package.

The package list does not have to include all your packages. You can create packages and not include them in a package list until you need them. Or you can offer one set of packages to one group of potential customers and another set of packages to another group.

To make a package available for customers to purchase, you must include the package in a package list.

You can assign the following statuses to a package list:

- **Active:** Use this status to indicate that customers can purchase packages in the list as soon as the list is added to your system.
- **Inactive:** Use this status to indicate that the list is not visible to customers and customers cannot purchase packages from the list.

Specifying the Package List Segment and Type

The package list segment identifies the customer segment that the package list is offered to, and the package list type identifies the type of packages that are added to the package list.

The package list segment and type determines the package list name. By default, the package list segment must be **CSR**. The package list type can be either **New** or **Add-on**. For example:

- The **CSR-New** package list contains packages that create accounts and add the services and bundles in the packages to the new accounts.
- The **CSR-Add-on** package list contains packages that add services and bundles to existing accounts.

The package list segment and type are case sensitive and together uniquely identify package lists. For example, **CSR-New** and **CSR-new** are two different package lists.

Sharing Charges and Discounts

Learn how to set up charge sharing for Oracle Communications Billing and Revenue Management (BRM) in Pricing Design Center (PDC).

Topics in this document:

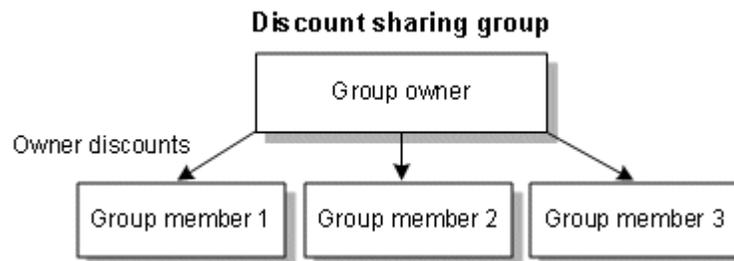

- [About Sharing Discounts and Charges](#)
- [About First-Usage Start Time for Shared Balances](#)
- [About Discount Sharing](#)
- [About Chargeshare Offers](#)

About Sharing Discounts and Charges

BRM enables accounts to share discounts and charges by joining groups that consist of an owner account and one or more member accounts. A sharing group can be one of the following types:

- **Discount sharing group:** The owner shares its discounts with the members. [Figure 16-1](#) shows a group owner providing discounts to three group members:

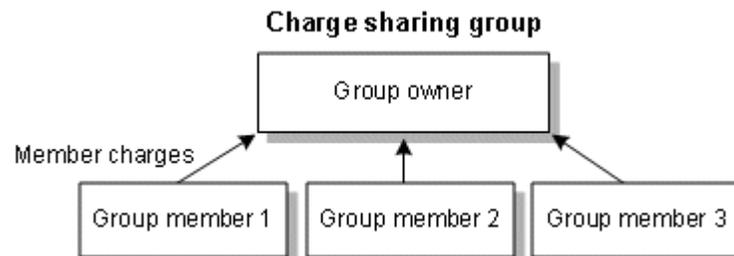

Figure 16-1 Discount Sharing Group

See "[About Discount Sharing](#)" for more information.

- **Charge sharing group:** The owner assumes charges that are incurred by the members. [Figure 16-2](#) shows a group owner receiving charges from three group members:

Figure 16-2 Charge Sharing Group

See "[About Chargeshare Offers](#)" for more information.

About First-Usage Start Time for Shared Balances

If a balance is shared among accounts in a sharing group, the balance validity period is set when any account in the group first impacts the balance. Because the same balance is shared with all accounts in the group, the validity period of that balance applies to all accounts.

About Discount Sharing

Discount sharing occurs when an account shares its discounts with other accounts. For example, a group of employees might share a pool of minutes in their company's mobile phone account, or a parent might purchase discounts on her email service and want those discounts to apply to her children's email services as well.

To share discounts in BRM, you create discount sharing groups. You set up the discounts in PDC.

BRM supports shared discounts by enabling a discount to apply either to the account that generates the event (the discount user), to the account that owns the discount, or to both.

With discount sharing, you sometimes need several discounts to specify how balances are granted or consumed for each account. For example, to offer 20% discount on usage to each member account when the total usage for all member accounts exceeds 1,000 minutes, you set up a discount with a counter to track the usage for each account and another discount to apply the percentage off based on the aggregated usage recorded in the counter balance.

About Chargeshare Offers

Charge sharing enables an account to sponsor the charges of other accounts. The owner account in a charge sharing group receives the balance impact of sponsored charges incurred by the member accounts. For example, charge sharing enables a company to pay for all of its employees' mobile phone services or a parent to pay for his child's SMS and email services.

To share charges in BRM, you create charge sharing groups. You then set up chargeshare offers and chargeshares in PDC to determine how charges are shared among the members of the charge sharing groups. If you configured product specification attributes for chargeshare offers in XML templates, you can set their values. See "[Configuring Product Specification Attributes for Pricing Components](#)".

A chargeshare uses rules that contain filters to determine whether an event qualifies for charge sharing, triggers to specify conditions that must be met before the chargeshare applies, and pricing to determine the charge sharing amounts and balance impacts.

Setting up chargeshare offers and chargeshares is similar to setting up discount offers and discounts. See "[Creating Discount Offers](#)" for more information.

Part III

Charging Scenarios

This part describes various charging scenarios you can configure using Oracle Communications Billing and Revenue Management (BRM) pricing components and setup components in Pricing Design Center (PDC).

This part contains the following chapters:

- [Charging Based on Date and Time](#)
- [Charging Based on Event Attributes](#)
- [Implementing Recurring Charges](#)
- [Advanced Configuration for Recurring Charges](#)
- [Working with Extended Rating Attributes](#)
- [Configuring Closed User Groups](#)

17

Charging Based on Date and Time

Learn how to charge for usage events based on data and time in Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Charging Based on Date and Time](#)
- [About Special Day Calendars](#)
- [Rating Events Split across Time Periods](#)

About Charging Based on Date and Time

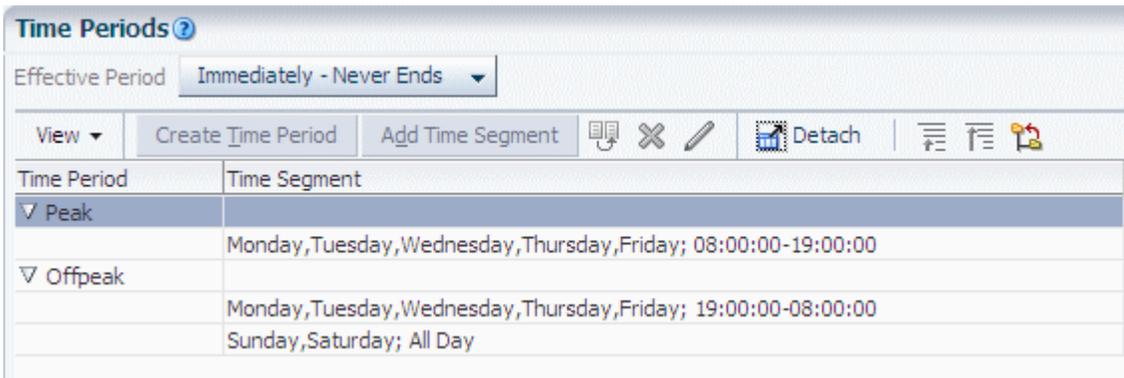

You can configure charge offer pricing to charge different amounts depending on the date and time. For example, you can create different pricing for peak and off-peak times. To do so, you use time models.

A time model is a set of time periods. Each time period contains one or more time segments. A time segment represents a particular time, such as a day of the week or a range of several hours.

By default, a time period is immediately and forever effective. To add effective periods to a time period, you specify only the start date of the new period. That date becomes the end date of the previous period. The end date of the final effective period is always **Forever**.

You can define time segments by using months, days of the month, days of the week, time of day, and a calendar of special days. For example, [Figure 17-1](#) shows an Offpeak and a Peak time period whose time segments are defined by days of the week and time of day.

Figure 17-1 Peak and Offpeak Time Periods in a Time Model

Time Period	Time Segment
▼ Peak	Monday, Tuesday, Wednesday, Thursday, Friday; 08:00:00-19:00:00
▼ Offpeak	Monday, Tuesday, Wednesday, Thursday, Friday; 19:00:00-08:00:00
	Sunday, Saturday; All Day

About Special Day Calendars

A special day calendar is a set of dates, such as holidays, for which you want to charge special prices for your services. Each date must be one of the following types:

- **Fixed:** A specific date valid only in *one year*, such as May 8, 2011, for Mother's Day in the U.S.
- **Recurring:** A date that is valid *every year*, such as July 4 for Independence Day in the U.S.

Figure 17-2 shows a special day calendar that has fixed and recurring dates.

Figure 17-2 Special Day Calendar

The screenshot displays the 'Special Day Calendars' interface. At the top, there is a 'View' dropdown and three icons: a green plus sign, a red X, and a document icon. Below this is a list of calendars, with '* Special Day Calendars' and 'U.S. Holidays' visible. The 'U.S. Holidays' calendar is selected and highlighted in yellow.

Below the calendar list is a section titled 'Special Day Definitions for Selected Calendar'. It also has a 'View' dropdown and the same three icons. Below this is a table with three columns: 'Type', '* Special Days', and 'Description'.

Type	* Special Days	Description
Fixed	Jan 17 2011	Martin Luther King Jr. Day
Fixed	May 30 2011	Memorial Day
Recurring	Jul 04	Independence Day
Fixed	Sep 05 2011	Labor Day
Fixed	Nov 24 2011	Thanksgiving
Fixed	Nov 25 2011	Thanksgiving
Fixed	Dec 26 2011	Christmas

To configure pricing for special days in a charge, you associate a special day calendar with a time model. You must then configure at least one time period that applies to the special days. The time model should cover all 24 hours of the special days.

Note:

The same time period cannot apply to both regular days of the week and special days. If you configure a time period that applies to both, the time model receives a validation error.

The same calendar can be associated with multiple time models, but you can also create different calendars for different time models.

For more information, see "Creating Special Day Calendars" in *PDC Online Help*.

Rating Events Split across Time Periods

Events sometimes overlap time periods. For example, if off-peak rating starts at 7:30 p.m., and a call begins at 7:10 p.m. and ends at 7:35 p.m., the call overlaps the boundary between peak and off-peak rates.

When an event crosses multiple time periods, you can specify the way to charge for an event if it is priced differently by time period:

- **Start Time:** Applies the charges defined in the time period in which the event begins.
- **End Time:** Applies the charges defined in the time period in which the event ends.
- **Split:** Applies charges according to the time period in which each portion of the event falls.

If you split charges across time periods, and you configure pricing based on quantity, you can specify the way a price step is selected when part of the event was already charged in another time period.

- **Dependent On:** Dependent on the quantity already used. When selecting a price step, BRM considers the amount of the event that occurred in the previous time period.
- **Independent Of:** Independent of the quantity already used. When selecting a price step, BRM does not consider the amount of the event that occurred in the previous time period.

For example, you might create pricing such as:

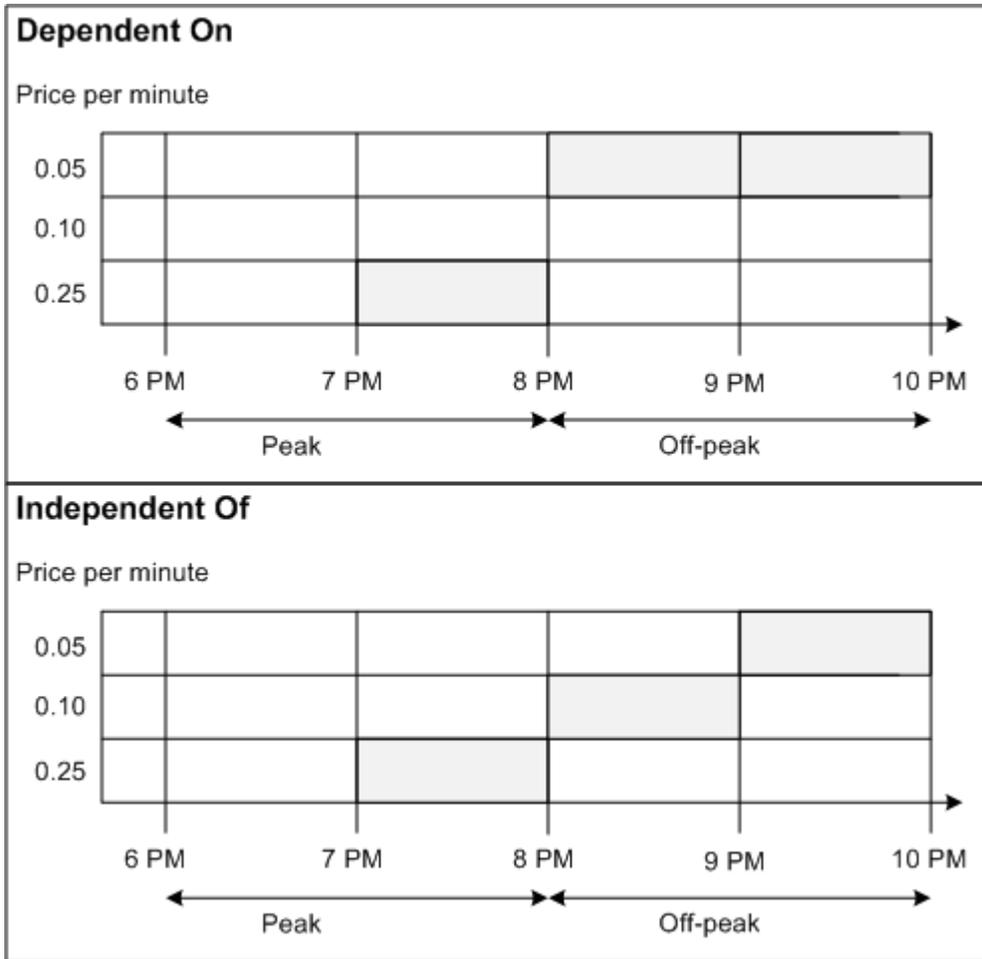

- Off-peak pricing between 8 PM and 6 AM.
- During peak time, charge 25 cents per minute.
- During off-peak time, charge:
 - \$0.10 per minute for the first hour
 - \$0.05 per minute for subsequent hours

A phone call starts at 7 p.m. and ends at 10 p.m. This results in one hour of peak time, and two hours of off-peak time.

- If the selection quantity is **Dependent On** the quantity already used, the hour charged as peak time is considered as the first hour, and the entire off-peak portion of the call is charged \$0.05 per minute.
- If the selection quantity is **Independent Of** the quantity already used, the hour charged as peak time is **not** considered as the first hour, and the off-peak portion of the call is charged \$0.10 per minute for the first hour, and \$0.05 for the second hour.

Figure 17-3 shows how the call is charged.

Figure 17-3 Quantity-Based Pricing Split by Time Periods

Charging Based on Event Attributes

Learn how to charge for usage events based on event attributes in Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Impact Categories](#)
- [About Zone Models](#)
- [About Value Maps](#)
- [About Selectors](#)
- [About Usage Scenario \(USC\) Selectors](#)
- [About Mapping Services](#)

About Impact Categories

You use impact categories to enable the same charge to apply different pricing based on the values of various event attributes. For example, to configure different pricing for calls made to different countries, you add impact categories for each destination country to the charge. When a call occurs, the pricing associated with the impact category for that call's destination is applied to the call. For example, to charge usage for a mobile phone service, you might create the following impact categories:

- Impact Category: **Bolivia** Balance Impact: **.10 per minute**
- Impact Category: **France** Balance Impact: **.05 per minute**

You create an impact category for each zone and usage scenario that you define. A usage scenario describes the type of call, for example, a long-distance mailbox inquiry. For example, you can create impact categories to rate:

- Local calls.
- Long distance calls.
- Local call forwarding.
- Long distance call forwarding.

Impact categories for zones are used as follows:

- *Base* zone impact categories are used as the results of rules in zone models and in Usage Scenario (USC) selectors.
- *Derived* zone impact categories are used as the results of rules in USC selectors and Access Point Name (APN) selectors. They are considered derived because the rules in USC and APN selectors use additional attributes to remap base zone impact categories to different zone impact categories. For example, a USC selector rule might specify that if the base zone impact category is China and the usage type is **Friends & Family**, the selector returns the Friends & Family derived zone impact category.

You can group multiple impact categories into a single group node to apply the same pricing to all of them.

About Zone Models

You use zone models to charge for calls based on their origin and destination. BRM supports the following types of zone models:

- **Standard:** A zone model based on the origin and destination numbers of a call. It contains rules that associate a pair of origin and destination numbers with a zone impact category (see "About Impact Categories").

To specify origin and destination numbers, you must include an international access code (the code used to dial *out of* the country in which the phone number is located). Optionally, you can also include a country code (the code used to dial *in to* the country in which the phone number is located), an area code, a region code, a city code, a phone number prefix, and so on—up to and including the entire phone number.

Figure 18-1 shows zone rules associated with the same impact category.

Figure 18-1 Multiple Zone Rules Associated with the Same Impact Category

Service Type	* Origin	* Destination	* Zone Impact Category ▲▼	Results		Validity
				Alternate Zone Model		
*	910	303	Local 2	None		Immediately - Never Ends
**	408	530	Long Distance 1	None		Immediately - Never Ends
**	408	303	Mobile	None		Immediately - Never Ends
**	408	415	Mobile	None		Immediately - Never Ends
**	510	942	New Zealand	None		Immediately - Never Ends
**	525	312	New Zealand	None		Immediately - Never Ends
**	512	303	New Zealand	None		Immediately - Never Ends
**	650	408	South Asia	None		Immediately - Never Ends
**	548	320	Taiwan	None		Immediately - Never Ends
**	717	530	Thailand	None		Immediately - Never Ends

- **Geographical:** A zone model based on the distance between the origin and the destination of a call. Geographical zone models include the following:
 - Zone rules that associate a distance with a zone impact category.
 - A list of area codes. Each area code is associated with one or more pairs of longitude and latitude coordinates.

When a customer makes a call, BRM uses the data in the area code list to compute the distance between the origin number and the destination number. BRM then assigns an impact category to the call event by using the zone rule whose distance most closely matches the computed distance.

Geographical zone models are useful in the following situations:

- Customers are located close to the border between two area codes. For example, if a customer in one area code calls a person two blocks away in another area code, you do not want to charge for a long-distance call.
- The distance covered by an area code is very large and you want to use several rates within the same area code. You do this by associating different pairs of latitude and longitude coordinates with the same area code in a geographical zone model.

When creating charges, you must select a zone model to get a list of impact categories that can be added to the charge. For example, Figure 18-2 shows how the selected zone model determines which impact categories are available.

Figure 18-2 Using Zone Models to Select Impact Categories

Add Impact Categories

Add Impact Categories From:

* Zone Model

USC Selector

APN Selector

Select the impact categories to add

Impact Category Name Contains

- All
- China
- France
- Germany
- India
- Intnat
- Japan
- Local 1
- Local 2

Add impact categories as a group

 **Note:**

Optionally, you can also select a USC or APN selector to provide enhanced zone impact categories. See "[About Selectors](#)" and "[About Impact Categories](#)" for more information.

Alternate Zone Models

In both standard and geographical zone models, each rule results in the application of a zone impact category and, optionally, an alternate zone model (see the rules in [Figure 18-1](#)). Alternate zone models enable you to define more granular zone rules and reuse them in multiple zone models.

For example, in a zone model for calls that originate in the U.S., you might include a rule with the following parameters:

- **Origin:** 011
- **Destination:** 00
- **Impact Category:** 00 General
- **Alternate Zone Model:** US to 00 Country Codes

In this example, the alternate zone model might contain rules for various combinations of calls from the U.S. (011 international access code) to numbers with the 00 international access code and a particular country code, such as **00 44** for calls to the U.K., **00 91** for calls to India, and so on.

When a call is made from the U.S. to a 00 international access code in this example, BRM first checks whether the country code of the destination number matches a rule in the alternate zone model. If it does, BRM uses the impact category associated with the rule in the alternate zone model to calculate the call's charge. If it does not, BRM uses the 00 General impact category to calculate the charge.

See "[Creating Pricing Setup Components](#)" for more information about configuring zone models.

Displaying Zoning Information on an Invoice

You can enter a zone description that can be included in invoices. To do so, enter the zone description in the **Description** field in the following dialog boxes:

- Standard Zone
- Geographical Zone
- Usage Scenario Mapping

You can use a maximum of 2,000 characters in the description.

About Value Maps

A value map is a hierarchical structure that associates zone names with values that apply to a single event attribute, such as an area code, an IP address, or a broadband bit rate. A value map can have multiple nested zones.

You use value maps in charge selectors to group event attribute values into manageable categories. For example, to apply the same charge to all calls made from the San Francisco Bay Area to Los Angeles, you might use a California Area Codes value map that includes the following zones:

- **Northern California**
 - **San Francisco Bay Area**
 - * 408
 - * 415
 - * 510
 - * 650
 - * 707
- **Southern California**
 - **Los Angeles**
 - * 213
 - * 323

Instead of creating charge selector rules for all possible combinations of those area codes, you associate the California Area Codes value map with the charge selector and then create only one rule in which **San Francisco Bay Area** is the origin call value and **Los Angeles** is the destination call value.

**Note:**

In PDC, value maps are used only with charge selectors (see "[About Selectors](#)").

See "[Creating Pricing Setup Components](#)" for information about configuring value maps.

About Selectors

You use selectors to apply different charges, discounts, prices, tax codes, or tax exemption codes to the same event based on the value of one or more service, event, or customer attributes. For example, you could charge different fees for phone calls depending on a call's origin and destination.

A selector assigns a result to events that have specific attributes. For example, it could assign the SFtoNYC result to calls made from San Francisco to New York City, and the SFtoCHC result to calls made from San Francisco to Chicago. Later, when you add the selector to a charge offer, you can map one or more results to a specific charge, discount, price, and so on. For example, you could map result SFtoNYC to a 5 cent per minute charge and result SFtoCHC to a 4 cent per minute charge.

You can create the following types of selectors:

- **Charge selector:** Determines the charge to use based on the values of specified event, service, or account attributes. You can use a charge selector instead of a charge in a charge offer.
- **Discount selector:** Determines the discount to use based on the values of specified event, service, or account attributes. You can use a discount selector instead of a discount in a discount offer.
- **Generic selector:** Determines the result tag based on the values of specified event attributes, service attributes, or custom rules that are used in a charge offer to guide pricing.
- **Price selector:** Determines the appropriate pricing to use based on the values of specified event, service, or account attributes. You can use a price selector instead of a pricing instance in a charge offer.
- **Usage Scenario (USC) selector:** Determines a new impact category based on the zone impact category and specific event attributes, such as differentiated network services or friends-and-family calls.
- **Access Point Name (APN) selector:** Determines a new impact category based on the zone impact category and access point name that applies to the event.
- **Tax selector:** Determines the tax code to apply based on values of specified event, service, account, or profile attributes. You use a tax selector instead of a tax code in charges, discounts, and charge shares.
- **Tax Exemption selector:** Determines the tax exemption code to apply based on values of specified event, service, account, or profile attributes. You use a tax exemption selector in charge offers.

When creating a selector, you create rules and choose the attributes to be used in them. Each rule uses the same fields, and you must specify a value for all the fields in every rule. For some rules, the value of a field might not be relevant, so you can use a wildcard (*) to indicate that any value is acceptable.

The execution sequence of the rules is important, so you can reorder them as necessary. The rules tables include a search mechanism to make it easy to find a rule.

In all selectors except charge selectors, rules have an effective period. By default, the period starts immediately and never ends. You can modify and add effective periods.

You can create selectors using:

- PDC UI. See *PDC Online Help* for more information.
- The **ImportExportPricing** utility. See "[XML Examples of Creating Pricing Components](#)" for more information.

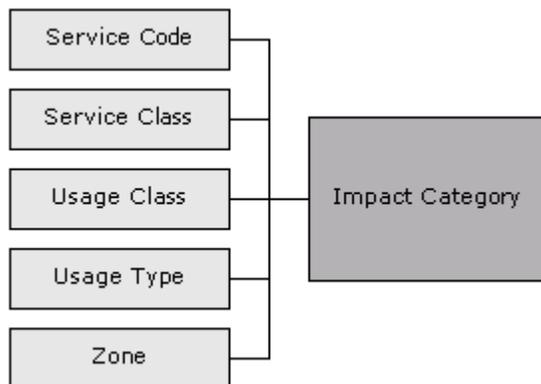

About Usage Scenario (USC) Selectors

A Usage Scenario (USC) selector contains rules that map existing impact categories to new impact categories based on usage attributes. For example, if you provide a friends-and-family discount, you can create separate impact categories for national friends and international friends.

You define USC selector rules by specifying values for the existing impact category, the event usage attributes used to evaluate the USC rule, and the new impact category. When an event's usage attribute values match a rule, the new impact category is returned by the USC selector.

USC selectors bring together the data from service codes, usage classes, and zones, as shown in [Figure 18-3](#).

Figure 18-3 Usage Scenario Mapping Factors

The impact category is included as part of the charges.

You define usage scenario mapping to rate differentiated network services, such as mailbox inquiries and friends-and-family discounts.

You can use multiple attributes to define an impact category, or you can use only one attribute.

About Mapping Services

Incoming events from multiple switches often use different codes to represent the same service or supplementary service. To process these events, you must normalize that data by mapping external service codes to internal service codes, service classes, and usage classes.

- An internal *service code* represents a service such as voice or fax.
- An internal *service class* represents a variation on the service (for example, a GPRS quality of service (QoS) or a telephone service used only for emergency calls).
- An internal *usage class* represents a supplementary service (for example, call forwarding or a voice mail box). The data used for rating usage classes comes from the network.

To create internal service mappings, you set up the data that specifies how to map the external data to the internal codes. For example, you can specify that if the external service code is **011**, the internal service code is **TEL**.

You organize service codes, service classes, and usage classes in *map groups*. A map group specifies the set of services and usage scenarios to be used for rating. You can create any number of map groups.

Mapping Service Codes and Service Classes

To create service code and service class mappings, you specify which external data is used to determine the internal service codes and service classes. For example, you can specify that if the external service code is **011**, the internal service code is **/service/telco/gsm/telephony**.

The mappings are based on the following data:

- External service code
- Usage class
- Location area indicator
- VAS event product code
- Quality of service requested
- Quality of service used
- Record type

Multiple service codes can be mapped to a single BRM service type. For the best performance, use as few service mappings as possible. For example, map the TEL, SMS, DATA, and FAX service codes to a single **/service/telco/gsm** BRM service type.

Mapping Usage Classes

To create usage class mappings, you set up the data that specifies how to map the external data to the internal usage class. For example, you can specify that if the external supplementary service code for call forwarding is **41**, the internal usage code is **CW**. In addition, you can use various event attributes to create variations on supplementary service for rating purposes.

For example:

- Service code mapping: Use the usage class to create special virtual services and charge offers; for example, you can use the combination of telephony and call forwarding to create value-added services.
- Service class mapping: Use the usage class to create special sub-services or quality of services (for example, service agreements).
- Usage scenario mapping: Use the usage class to map to impact categories.
- Pricing adjustment: Use the usage class to provide discounts or adjustments in individual events.

The mappings are based on the following data:

- External usage class
- Tariff class and subclass
- Record type
- Connect type and Connect subtype, for example, anonymous, from another network, or direct
- Transit area code
- APN address when you use GPRS or UMTS technology
- SS (supplementary service) packet

Implementing Recurring Charges

Learn how to implement and manage recurring charges in Pricing Design Center (PDC) for Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Recurring Charges](#)
- [About Cycle Forward Charges](#)
- [About Cycle Arrears Charges](#)
- [About Cycle Forward Arrears Charges](#)
- [About Creating Recurring Charges in PDC](#)
- [About Recurring Charges Events](#)

See also "[Advanced Configuration for Recurring Charges](#)".

About Recurring Charges

Recurring charges are ongoing charges that are not generated or affected by usage, such as a charge for a monthly subscription fee. For example:

- A 30-dollar monthly fee for a mobile phone service
- A 5-dollar fee for an automatically renewing smartphone app

Recurring charges do not use Elastic Charging Engine (ECE) for rating. Instead, recurring charges are applied when you run BRM billing utilities.

There are three types of recurring charges:

- A *cycle forward charge* applies a recurring charge in advance. The advantage of using a cycle forward charge is that you collect payments sooner.
- A *cycle arrears charge* applies a recurring charge to the previous month. The advantage of using a cycle arrears charge is that all of the usage charges and recurring charges for a particular month are included in the same bill.
- A *cycle forward arrears charge* applies a recurring charge to the previous month, identical to a cycle arrears charge. The advantage of using a cycle forward arrears charge is that the customer is not charged until the end of the month, but the balance impact is made at the beginning of the month, and can be recognized as unearned revenue at the beginning of the month.

About Cycle Forward Charges

To charge a fee in advance, create a charge offer that includes a *cycle forward* charge type, for example, **Monthly Recurring Charge**. You can charge fees in advance at any interval; for example, by using a **Quarterly Recurring Charge** or a **Yearly Recurring Charge** charge type. You can define your own recurring charge types; for example, weekly, or every five months (see "[Configuring Flexible Cycle Forward Charges](#)" for more information).

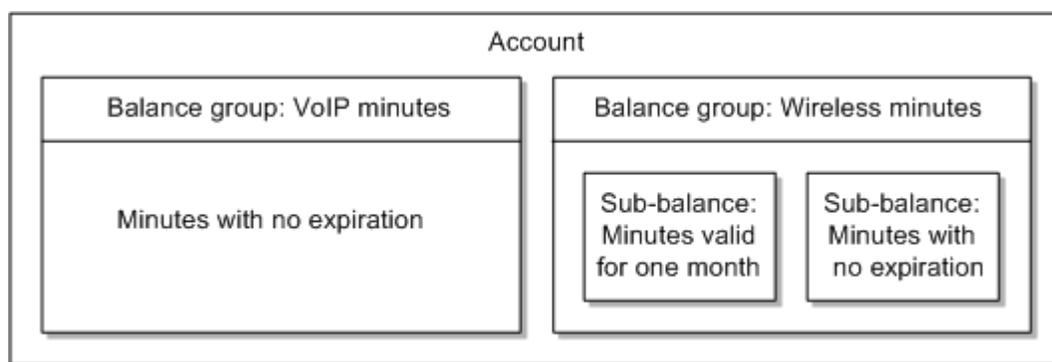

Monthly recurring charges are typically applied at the beginning of an accounting cycle, but they do not need to be synchronized to the start or end of an accounting cycle.

Cycle forward balance impacts are recorded in */item/cycle_forward* bill items.

About the First Cycle Forward Charge in a New Account

A cycle forward fee incurred at account creation is included in the cycle forward item created when the account is created. Therefore, the first bill includes two cycle forward fees. [Figure 19-1](#) shows an account created on May 15, with the first bill on June 15. The first cycle forward item includes the charge for the month from May 15 - June 15. The second cycle forward item includes the charge for June 15 - July 15. Both charges are included in the June 15 bill.

Figure 19-1 Cycle Forward Fees for New Account

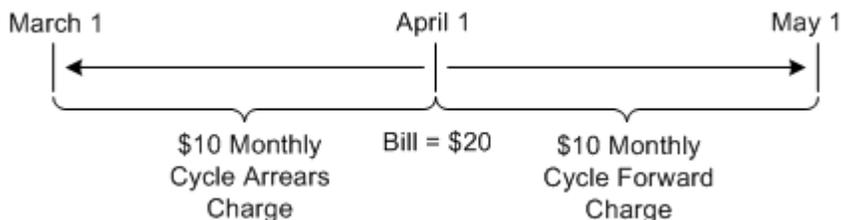

About Cycle Arrears Charges

To charge a fee at the end of the month, create a charge offer that includes a *cycle arrears* charge type, for example, **Monthly Recurring Charge Arrear**. Cycle arrears charges apply a charge to the previous billing cycle; the customer pays for the month that has already occurred. Cycle arrears charges are always monthly.

In [Figure 19-2](#), the customer is charged for a cycle forward fee and for a cycle arrears fee. The bill created on April 1 includes:

- A \$10 cycle arrears fee for March
- A \$10 cycle forward fee for April

Figure 19-2 Cycle Forward Charge and Cycle Arrears Charge

Cycle arrears balance impacts are recorded in *litem/cycle_arrear* bill items.

About Cycle Forward Arrears Charges

To charge a fee at the end of the month, and recognize unbilled revenue when you run general ledger reports, create a charge offer that includes a *cycle forward arrears* charge type, for example, **Monthly Recurring Charge Forward Arrear**

Just like a cycle arrears charge, a cycle forward arrears charge charges the customer for the previous billing cycle. The difference between cycle arrears charges and cycle forward arrears charges is:

- The balance impact for a *cycle arrears charge* is applied at the **end** of the accounting cycle.
- The balance impact for a *cycle forward arrears charge* is applied at the **beginning** of the accounting cycle.

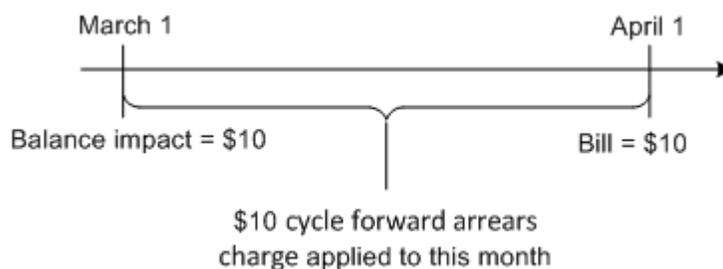

However, for both types of charges, the charge is not billed until the end of the billing cycle. Therefore, to the customer, there is no difference in how the charge is billed. The difference appears to your accounting department when you collect general ledger data. Cycle forward arrears charge types allow you to recognize unbilled revenue for the charge when you collect general ledger data before the end of the accounting cycle.

There are no multi-month cycle forward arrears fees.

Cycle forward arrears balance impacts are recorded in *litem/cycle_forward_arrear* bill items. However, the cycle forward arrears event is assigned to the item that belongs to the **next** accounting cycle. This way, the fee is tracked in the account balance for the current cycle, but it is not billed until the end of the cycle.

Figure 19-3 shows a cycle forward arrears charge applied on March 1, and billed on April 1. In this case, the balance impact occurs on March 1, but the charge is included in the bill item for April 1.

Figure 19-3 Cycle Forward Arrears Charge

About Implementing Cycle Forward Arrears Charging

Cycle forward arrears events are standard in BRM. However, you must enable delayed billing if you charge for cycle forward arrears events. If you do not otherwise need delayed billing, you can enable delayed billing, but set the delayed billing period to **0**.

For information about configuring delayed billing, see "Setting Up Delayed Billing" in *BRM Configuring and Running Billing*.

About Creating Recurring Charges in PDC

You create a recurring charge in PDC by assigning a recurring charge type to a charge offer. You then apply the same attributes as any charge; for example:

- How the event is measured. Recurring charges are always measured by occurrence.
- When to stop charging; for example, when the associated charge offer is inactivated or closed.
- Tax calculation settings.
- General Ledger (G/L) impacts. You can configure general ledger (G/L) reporting to report earned revenue and unearned revenue. Unearned revenue applies only to cycle forward events and cycle forward arrears events. It never applies to usage events or cycle arrears events.
- Balance impact details, such as the amount to charge, balance element, and so on.

In addition, you can specify when the balance impact of a recurring charge is applied, and whether to prorate recurring charges. See:

- [Specifying When Recurring Charges are Charged](#)
- [Allowing Recurring Charges to Be Prorated](#)

Note:

A single charge offer cannot include multiple recurring charges that have the same frequency and type of balance impact, such as a cycle fee. For example, if you add a monthly cycle forward event to a charge offer, you cannot also add a monthly cycle arrears or monthly cycle forward arrears event to the same charge offer. Instead, Oracle recommends that you create separate charge offers for each cycle forward event.

Specifying When Recurring Charges are Charged

In PDC, you can configure the balance impact for recurring charges to occur at the following times:

- On the customer's current billing date. This is the default. If the recurring charge is in a charge offer that is purchased mid-cycle, you can prorate a charge to cover the time between the purchase data and the first billing date.
For example, if the billing date is the 1st of the month and the charge offer is purchased on January 10, the charge is prorated and applied on January 10 for the interval January 10 to February 1. For subsequent cycles, the charge is applied on the billing date (for the interval February 1 to March 1, March 1 to April 1, and so on).
- On the charge offer purchase date. For example, if the billing date is the 1st of the month and the charge offer is purchased on January 10, the charge is applied on the 10th of every month (for the interval January 10 to February 10, February 10 to March 10, and so on).
- At a specified time before the time period covered by the charge; for example, one month in advance. For example:

- If you charge a one-month cycle forward fee one month in advance, and the billing day of month (DOM) is the 1st, the charge on May 1st applies to June 1 - June 30. Without in-advance billing, a cycle forward charge on May 1 applies to May 1 - May 31.
- If you charge a one-month cycle forward fee 15 days in advance, and the billing day of month (DOM) is the 1st, the charge on May 1 applies to May 15 - June 15, the charge on June 1 applies to June 15 - July 15, and so on.

When you charge cycle forward fees in advance, the first cycle forward charge might be larger than the subsequent charges. For example, if a charge offer is purchased on May 1 with in-advance billing of 15 days, the charge on May 1 includes one month in advance (May 15 - June 15) plus 15 days (May 1 - May 14). Subsequent charges are for June 15 - July 15, and so on.

If you create pricing components using the **ImportExportPricing** utility, you can also apply recurring charges on a specific day of the month. For example, you can apply the recurring charge on the 5th day of each month regardless of the billing or purchase date. This is useful for offers with validity that is defined in hours, minutes, and seconds rather than days, weeks, and months. See "[Aligning Recurring Charges and Product Validity to a Specific Day of the Month](#)" for more information.

Allowing Recurring Charges to Be Prorated

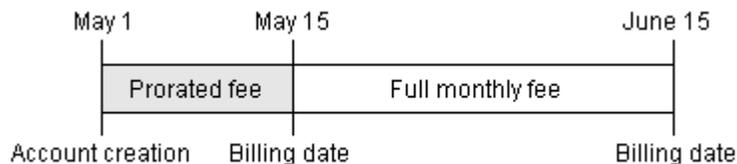

You can enable recurring charges to be prorated. A prorated charge typically charges a portion of the fee, based on how long it has been applied. You can also specify to apply no fee, or the full amount. You can specify to prorate charges in the following cases:

- When a charge offer is purchased mid-cycle. This can occur at account creation or when a charge offer is purchase by an existing account.
- When a charge offer that includes a recurring charge is canceled mid-cycle.

If a recurring charge includes more than one balance impact, you can specify which balance impacts should be prorated. For example, if the charge can be prorated, and there are two balance impacts, you can specify to prorate one of the balance impacts but not the other.

[Figure 19-4](#) shows a cycle forward charge applied at account creation on May 1. The billing day of month is May 15, so the cycle forward charge is prorated for the two weeks between account creation and the first billing date.

Figure 19-4 Prorating Cycle Charges for a Monthly Fee

About Recurring Charges Events

Like all charges, recurring charges are rated by applying a balance impact to an event. Recurring charges are applied to *cycle events*. The cycle events are:

- `/event/billing/product/fee/cycle/cycle_forward_monthly`

- `/event/billing/product/fee/cycle/cycle_forward_bimonthly`
- `/event/billing/product/fee/cycle/cycle_forward_quarterly`
- `/event/billing/product/fee/cycle/cycle_forward_semiannual`
- `/event/billing/product/fee/cycle/cycle_forward_annual`
- `/event/billing/product/fee/cycle/cycle_arrear`
- `/event/billing/product/fee/cycle/cycle_forward_arrear`

Cycle events are created when you run the `pin_cycle_fees` billing utility. The `pin_cycle_fees` utility is typically included in the `pin_bill_day` script that runs daily.

Advanced Configuration for Recurring Charges

Learn how to configure advanced functionality for recurring charges in Pricing Design Center (PDC) for Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [Configuring Flexible Cycle Forward Charges](#)
- [Applying Cycle Forward Fees in Parallel](#)
- [Applying Recurring Charges Based on Charge Offer Priority](#)
- [Customizing the Cycle Interval for Specified Charge Offers](#)

See also "Implementing Recurring Charges".

Configuring Flexible Cycle Forward Charges

By default, BRM supports monthly, bimonthly, quarterly, semi-annual, and annual cycle forward charges. You can also configure BRM to support *flexible cycle forward charges*. Flexible cycle forward charges can use daily, weekly, monthly, or multimonth cycles that are not restricted to billing or accounting cycles.

You can use flexible cycle forward charges to grant free balances, provide discounts, or charge fees at any time during the accounting cycle. For example, you can set up a cycle forward fee to grant minutes every week or every day rather than once a month. Or you can set up a monthly cycle forward fee to grant minutes on the 15th of every month, which differs from the monthly accounting cycle that begins on the 1st of every month.

Because flexible cycles are not aligned with accounting cycles, cycle forward fees are always prorated.

You set up flexible cycle forward charges by configuring flexible cycle forward events.

To set up flexible cycles:

1. Define a custom cycle forward event subclass using Storable Class Editor in Developer Center. The name of the custom cycle forward event must use this syntax:

```
/event/billing/product/fee/cycle/cycle_forward_customName
```

where *customName* is your custom name for the event subclass. For example, create **/event/billing/product/fee/cycle/cycle_forward_10days** to define a cycle forward event that occurs every ten days.

Note:

Use the **/event/billing/product/fee/cycle/cycle_forward_quarterly** object specification as a model.

2. Map the new event to a valid purchase level:
 - a. In the service-event map configuration file (*BRM_home/sys/data/pricing/example/pin_event_map*), add an entry for the new cycle forward event. The entry must use the following format:

```
purchase_level:event_type:event_description:count: unit
```

where:

- *count* specifies the frequency of the cycle. It must be a positive number.
- *unit* must be **day**, **week**, **month**, or **year**.

For example, to map a biannual (24-month duration) cycle forward event to an account purchase type, the **pin_event_map** entry is:

```
/account:/event/billing/product/fee/cycle/cycle_forward_biannual:Biannual Cycle Forward Event:24:month
```

or

```
/account:/event/billing/product/fee/cycle/cycle_forward_biannual:Biannual Cycle Forward Event:2:year
```

See "Creating Service and Event Storable Classes" in *BRM Developer's Guide*.

- b. Run the **load_event_map** utility.
3. Map the new event type to a valid ratable usage metric (RUM):
 - a. In the usage map configuration file, add an entry for the new cycle forward event. For example:

```
/event/billing/product/fee/cycle/cycle_forward_biannual:Occurrence: 0: 0: 0: 0: 0: 0: 0: cycle_forward_biannual
```
 - b. Run the **load_usage_map** utility.
4. Stop and restart the CM.
5. Use PDC to create charge offers that include your new cycle forward fee.

Charging Cycle Forward Fees Associated with Flexible Cycles

Cycle forward fees are charged when you run monthly billing or the **pin_cycle_forward** billing utility.

When a cycle forward event is generated, balance impacts are applied using balance validity dates.

If a cycle forward event balance impact for a noncurrency balance is set up with a relative cycle start date, balance impacts are applied either to the current cycle or to a future cycle.

For example, if the relative cycle is set to **1** and the cycle is from January 1 to March 1, a sub-balance is created with a validity period from January 1 to March 1. If the relative cycle is set to **2**, a sub-balance is created with a validity period from March 1 to May 1.

Applying Cycle Forward Fees in Parallel

For accounts with multiple services (for example, a wholesale market customer account), you can configure BRM to apply cycle forward fees in parallel for multiple services instead of

applying cycle forward fees sequentially for each service, thereby reducing the time to complete billing.

When you configure BRM to apply cycle forward fees in parallel, you can also configure BRM to:

- Enforce cycle fee processing prior to billing. By doing so, BRM eliminates the process of applying cycle forward fees during billing and improves the performance of the billing process.
- Use a single item at the account level to accumulate the cycle charges for all the services. By doing so, BRM reduces the number of items to process and improves overall system performance, which is important when you bill for wholesale customer accounts. When BRM applies cycle forward fees in parallel with service charges aggregated to a single account item, the account can have only a single bill unit (**/billinfo** object). Even though the account item aggregates the service charges, the respective service balance groups are still updated with the service charges.

Before configuring BRM to apply cycle forward fees in parallel, your configuration must meet these requirements:

- The number of services attached to a single balance group must be less than 10 in order to get the performance benefit of applying cycle forward fees in parallel.
- There should be no dependency on the order of applying cycle forward fees for account groups (hierarchical, charge sharing, or discount sharing). This is because the cycle forward fees are applied by the **pin_cycle_fees** utility instead of by the billing application that gives more control on the order of processing accounts in hierarchies.

Applying parallel cycle forward fees involves the following processes:

1. Running the **pin_cycle_fees** utility in parallel at the services level, which processes cycle forward fees aligned to the accounting cycle.

 **Note:**

When the parallel fee processing feature is enabled, cycle forward fees are applied by the **pin_cycle_fees** utility, which is run before the **pin_deferred_act** utility. However, when the parallel cycle forward fees processing fees feature is not enabled, cycle forward fees are applied by the billing application after running **pin_deferred_act**.

2. Running the **pin_update_journals** utility to post-process cycle forward fees.
3. Running the **pin_bill_accts** utility for regular billing.
4. Running the **pin_cycle_fees** utility to process flexible cycle forward fees.
5. Running the **pin_update_journals** utility to post-process flexible cycle forward fees.

To configure BRM to apply cycle forward fees in parallel, run the **pin_bus_params** utility to change the **StagedBillingFeeProcessing** business parameter. For information about this utility, see "pin_bus_params" in *BRM Developer's Guide*.

1. Go to `BRM_home/sys/data/config`.
2. Create an XML file from the `/config/business_params` object:

```
pin_bus_params -r BusParamsBilling bus_params_billing.xml
```
3. Search for this line:

```
<StagedBillingFeeProcessing>0</StagedBillingFeeProcessing>
```

The default is **0**. (BRM applies the cycle forward fees as part of the billing process.)

 **Note:**

The cycle fee processing at the time of billing is only with reference to the cycle forward fees aligned with the accounting cycle boundary.

4. Do one of these:
 - To apply cycle forward fees in parallel by service, specify **1**.
 - To enforce cycle fee processing prior to billing and apply cycle forward fees in parallel by service, specify **2**.
 - To apply cycle forward fees in parallel by service with service charges aggregated to a single account item, specify **3**.
5. Save the file as **bus_params_billing.xml**.
6. Load the XML file into the BRM database:

```
pin_bus_params bus_params_billing.xml
```
7. Stop and restart the CM.
8. (Multischema systems only) Run the **pin_multidb** script with the **-R CONFIG** parameter. For more information, see "pin_multidb" in *BRM System Administrator's Guide*.

About Enforcing Cycle Forward Fee Processing Prior to Billing

When BRM enforces cycle fee processing prior to billing, the following processes are impacted:

- The **pin_cycle_fees** utility performs additional error processing to set the error status (as needed) on the corresponding bill unit

 **Note:**

If you customize **pin_cycle_fees** and use the application global structure **PIN_FLD_EXTENDED_INFO** provided by the multithreaded application framework to hold custom information at run time, you must consider that **pin_cycle_fees** stores the error processing information in a single array element **PIN_FLD_ERROR_INFO** under **PIN_FLD_EXTENDED_INFO**.

- The billing process stops if any of the following conditions is true:
 - The **BILLING_STATUS_FLAGS** field of the **/billinfo** object indicates that there was an error processing one of the cycle forward fees.
 - There is at least one service for which cycle fee processing (regular, deferred, deferred purchase, or deferred cancellation) has not been completed for the accounting cycle being billed.
- In rare cases, if billing is due for a bill unit for more than one accounting cycles, special handling is required. See "[Handling Skipped Billing](#)" for more information.

About Aggregating Service Charges to Account Items

When applying cycle forward fees in parallel by service with service charges aggregated to a single account item, multiple threads of `pin_cycle_fees` updates a single item. To avoid updating the same item by multiple threads, `pin_cycle_fees` logs the item and journal updates to temporary tables as follows:

- Logs item updates to the `/tmp_events_to_process` object in the `TMP_EVENTS_TO_PROCESS_T` table.
- Logs journal updates to the `/tmp_journals_to_process` object in the `TMP_JOURNALS_TO_PROCESS_T` table.

The `pin_update_journals` utility processes the temporary item and journal data and updates the main item and journal tables.

To ensure efficient access of these temporary tables, Oracle recommends the following:

- **Resetting high water mark.** Records are frequently inserted into and deleted from the temporary tables, which can fragment the temporary tables. Reset the high water mark for the temporary tables as the BRM schema user.

Run these commands every time before calling the `pin_bill_accts` inside the `pin_bill_day` script.

```
ALTER TABLE TMP_JOURNALS_TO_PROCESS_T ENABLE ROW MOVEMENT;
ALTER TABLE TMP_JOURNALS_TO_PROCESS_T SHRINK SPACE;
ALTER TABLE tmp_events_to_process_t ENABLE ROW MOVEMENT;
ALTER TABLE tmp_events_to_process_t SHRINK SPACE;
```

For more information about the high water mark, see the Oracle Database documentation.

- **Presetting statistics.** Preset the statistics of the temporary tables that are created during BRM installation by running the following commands as a one-time activity. This enables BRM to avoid a full scan of these tables.

```
Exec
dbms_stats.set_table_stats('SCHEMA_NAME','TMP_EVENTS_TO_PROCESS_T','','',200000000,40000000,1250) ;
```

```
Exec
dbms_stats.set_index_stats('SCHEMA_NAME','I_TMP_EVENTS_ID','',numrows=>200000000,num1blks=>1000000,numdist=>200000000,avg1blk=>1,avgdblks=>1,clstfct=>200000000);
```

```
Exec
dbms_stats.set_column_stats('SCHEMA_NAME','TMP_EVENTS_TO_PROCESS_T','POID_ID0','','disctcnt=>200000000,density=>1/200000000,nullcnt=>0,srec=>srec_eve,avgclen=>11);
```

```
Exec
dbms_stats.set_table_stats('SCHEMA_NAME','TMP_JOURNALS_TO_PROCESS_T','','',20000000,40000000,1250);
```

```
Exec
dbms_stats.set_index_stats('SCHEMA_NAME','I_TMP_JOURNALS_ID','',numrows=>200000000,num1blks=>1000000,numdist=>200000000,avg1blk=>1,avgdblks=>1,clstfct=>200000000);
```

```
Exec
dbms_stats.set_column_stats('SCHEMA_NAME','TMP_JOURNALS_TO_PROCESS_T','POID_ID0','','distcnt=>200000000,density=>1/200000000,nullcnt=>0,srec=>srec_eve,avgclen=>11);
```

```
Exec dbms_stats.lock_table_stats('SCHEMA_NAME','TMP_EVENTS_TO_PROCESS_T');
Exec dbms_stats.lock_table_stats('SCHEMA_NAME','TMP_JOURNALS_TO_PROCESS_T');
```

where *SCHEMA_NAME* is the BRM database user; for example, **pin1**.

Handling Skipped Billing

In rare cases, if billing is due for a bill unit for more than one accounting cycles, special handling is required. This multiple cycle overdue billing is referred to as skipped billing.

For example, assume that the current date is December 1 and BRM did not perform billing for the cycles ending November 1 and October 1. In this case, when you run **pin_bill_day** on the current date, three bills are due to be created.

When BRM tries to calculate the cycle forward fees, the following happens:

- **pin_cycle_fees** applies cycle forward fees due only as of October 1 because October 1 billing has not been processed yet.
- **pin_bill_accts** performs billing only on October 1 and stops with an error when performing billing on November 1 because cycle forward fees due as of November 1 have not been processed yet.

To handle the case of skipped billing used in this example:

1. Run **pin_cycle_fees**, **pin_update_journals**, and **pin_deferred_act** in the following sequence:

```
pin_cycle_fees -defer_purchase
pin_cycle_fees -defer_cycle_fees
pin_cycle_fees -defer_cancel
pin_cycle_fees -regular_cycle_fees
pin_update_journals
pin_deferred_act
```

2. Run **pin_bill_accts**.
3. Repeat step 1 and step 2 twice more, which performs billing for November 1 and December 1.

Using the pin_bill_day Script to Apply Parallel Cycle Forward Fees

To support applying cycle forward fees in parallel, the **pin_bill_day** script includes the following commented out sections:

- **Pre-Billing Parallel Cycle Fee Processing:** Includes the following entries for **pin_cycle_fees** and **pin_update_journals**:

```
##### pin_cycle_fees -defer_purchase
##### pin_cycle_fees -defer_cycle_fees
##### pin_cycle_fees -defer_cancel
##### pin_cycle_fees -regular_cycle_fees
##### pin_update_journals
```

- **Post-Billing Parallel Cycle Fee Processing:** Includes the following entry for **pin_update_journals**:

```
##### pin_update_journals
```

To apply cycle forward fees in parallel by using the **pin_bill_day** script:

1. Make sure that the **StagedBillingFeeProcessing** parameter is not set to **0**.
2. Open the *BRM_home/bin/pin_bill_day* script in a text editor.
3. Uncomment these entries in the **Pre-Billing Parallel Cycle Fee Processing** section:

```
##### pin_cycle_fees -defer_purchase
##### pin_cycle_fees -defer_cycle_fees
##### pin_cycle_fees -defer_cancel
##### pin_cycle_fees -regular_cycle_fees
##### pin_update_journals
```

4. Uncomment this entry in the **Post-Billing Parallel Cycle Fee Processing** section:

```
##### pin_update_journals
```

5. Save and close the file.
6. Run **pin_bill_day**.

About Limitations and Impacts of Applying Cycle Forward Fees in Parallel

Configuring BRM to apply cycle forward fees in parallel includes these limitations and impacts:

- In rare cases, when the **pin_cycle_fees** utility successfully creates temporary item and journal data and the subsequent run of the **pin_update_journals** utility fails to update the item and journal tables, you must investigate and correct the problem in processing the temporary item and journal data before performing any accounts receivable action or generating ledger reports.
- If the parallel fee processing feature is configured to enforce cycle fee processing before billing, balance impact events that occur before the **pin_cycle_fees** utility runs are cancelled with an error.
- If the parallel fee processing feature is *not* configured to enforce cycle fee processing before billing, balance impact events that occur before the **pin_cycle_fees** utility runs result in triggered billing that can be slow due to serial application of cycle forward fees.
- Performance of the following operations is not improved because parallel cycle fee processing does not apply to these operations:
 - Trial billing
 - Bill Now
 - Billing on purchase
 - Account creation
 - Purchase of bundles
 - Billing time discount
 - Cycle fold
 - Rollover
 - Account activation, account inactivation, or account cancellation
 - Rerating

Applying Recurring Charges Based on Charge Offer Priority

When multiple charge offers in a bundle include recurring charges, you can configure BRM to apply recurring charges in the order of charge offer priority. You can apply recurring charges based on charge offer priority during the following operations:

- Bundle purchase or cancellation, for all the charge offers per bundle.
- Billing, for all the charge offers in a bundle per bill unit.

 **Important:**

This parameter does not prioritize charge offers for recurring charges applied by **pin_cycle_fees-defer_cancel** and does not prioritize customized charge offers.

To enable this feature, run the **pin_bus_params** utility to change the **UsePrioritySubscriptionFees** business parameter. For information about this utility, see "pin_bus_params" in *BRM Developer's Guide*.

To apply recurring charges based on charge offer priority:

1. Go to *BRM_home/sys/data/config*.
2. Create an XML file from the */config/business_params* object:

```
pin_bus_params -r BusParamsSubscription bus_params_subscription.xml
```
3. In the file, change **disabled** to **enabled**:

```
<UsePrioritySubscriptionFees>enabled</UsePrioritySubscriptionFees>
```
4. Save the file as **bus_params_subscription.xml**.
5. Load the XML file into the BRM database:

```
pin_bus_params bus_params_subscription.xml
```
6. Stop and restart the CM.
7. (Multischema systems only) Run the **pin_multidb** script with the **-R CONFIG** parameter. For more information, see "pin_multidb" in *BRM System Administrator's Guide*.

Customizing the Cycle Interval for Specified Charge Offers

To customize the time interval for applying cycle forward and cycle arrears fees for a specified charge offer, use the **PCM_OP_SUBSCRIPTION_POL_SPEC_CYCLE_FEE_INTERVAL** policy opcode.

This policy opcode is called by **PCM_OP_SUBSCRIPTION_CYCLE_FORWARD** and **PCM_OP_SUBSCRIPTION_CYCLE_ARREARS**. The type of cycle event is passed in the **PIN_FLD_SCOPE** field in the input flist.

By default, this policy opcode is an empty hook to facilitate customization of the cycle forward and cycle arrears start (**CHARGED_FROM_T**) and end dates (**CHARGED_TO_T**) for a specific charge offer. The start and end dates provided are used to calculate the scale to determine the cycle fee amount to charge or refund.

For example, if a charge offer is purchased on April 1, 2009 with a monthly cycle forward fee of \$30 and the purchase, usage, and cycle end dates are set to April 20, 2009, the cycle fee amount is based on the scale for the period April 1, 2009 to April 20, 2009 (20 days) divided by the unit interval from April 1, 2009 to April 30, 2009 (30 days). The cycle fee charged is $20/30 * \$30$, or \$20.

If the charge offer is canceled on April 15, 2009, the refund amount is based on the scale for the period April 15, 2009 to April 20, 2009 (5 days) divided by the unit interval from April 1, 2009 to April 20, 2009 (20 days). Because the refund amount is refunded from the charged amount (\$20), the refund is $5/20 * (20/30 * \$30)$, or \$5. Here, the scale value $20/30$ is the original charge scale or the period the charge offer was valid during the cycle.

The PIN_FLD_SCALE value in the input and output flists is the original charge scale and is used only to calculate the refund scale.

To change the scale (for example if you do not want to refund the full amount), change the start and end dates. The refund scale is calculated based on the dates that you provide.

Working with Extended Rating Attributes

Learn how to apply special charges or discounts based on a specific attribute of a service or account by creating extended rating attributes (ERAs) in Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Extended Rating Attributes](#)
- [Creating Friends and Family ERAs](#)
- [Default ERAs](#)

About Extended Rating Attributes

Extended rating attributes (ERAs) provide special charges or discounts based on a specific attribute of a service or account, such as a telephone number. For example, you use ERAs to offer special friends and family rates or a birthday discount.

About Sharing ERAs

You can share the ERA values you configure for one service with other services by using profile sharing groups. For example, you can share the same list of phone numbers for a friends and family ERA among all the customers whose phone numbers are included in the list.

You can share service ERAs only.

For more information, see "Creating and Managing Profile Sharing Groups" in *BRM Managing Customers*.

Creating Friends and Family ERAs

BRM has built-in support for friends and family ERAs. This feature enables you to create an ERA with multiple lists, each containing phone numbers, APN addresses, email addresses, or other values. You can also use profile sharing to share a friends and family ERA with multiple services.

Default ERAs

[Table 21-1](#) summarizes the default account-level ERAs.

Table 21-1 Default ERAs

Function	Name
Assign an account to a business segment for business intelligence reporting.	Business Intelligence Segment ERA
Assign an account to a customer group, or assign an arbitrary quality level to an account.	Customer type or quality ERA

Table 21-1 (Cont.) Default ERAs

Function	Name
Assign an account to a group of accounts that share certain telephony properties.	Corporate agreement ERA
Create a closed user group, such as a group of all mobile numbers in a company.	Closed user group ERA
Give a discount for calls made on a specific calendar date.	Special day discount ERA
Define the home cells for a customer and allow discounts while calling from this area.	Home cell assignment ERA
Provide discounts to calls made to specific numbers or regions, such as all numbers in a country or area code.	Home region code ERA
Provide discounts to calls made to specific numbers, such as those for friends and family members.	Friends and family ERA
Assign a Quality of Service to a service.	Service-level agreement ERA

Configuring Closed User Groups

Learn how to configure closed user groups for Oracle Communications Billing and Revenue Management (BRM) in Pricing Design Center (PDC).

Topics in this document:

- [Configuring Closed User Groups](#)

Configuring Closed User Groups

You can configure closed user groups for applying special prices for events that originate and terminate between a list of subscribers. For example, you can configure a closed user group for applying special rates on calls between employees of a small company.

To identify the members of a closed user group and apply special prices, you configure a custom rule and add it to a generic selector. The custom rule evaluates the groups to which the originating and terminating subscribers belong. If the originating and terminating subscribers belong to even one common closed user group, the custom rule evaluates as true. The generic selector guides to the price based on how the custom rule is evaluated at runtime.

You can configure closed user groups at the account level or at the service level. To configure closed user groups at the account level, use the **OOB_ProfileSpecifications.xml** and **OOB_CRs.xml** files as templates. To configure closed users groups at the service level, use the **Sample_ServiceCUG_ProfileSpecification.xml** and **Sample_ServiceCUG_CR.xml** files as templates. See [Table 22-1](#) for the usage and description of each element.

If you configure a closed user group at the account level, associate the closed user group names with the appropriate service identifiers for the account when the customer purchases the charge offer with a closed user group. For example, map the phone numbers to the appropriate closed user group names.

If you configure a closed user group at the service level, configure only the appropriate closed user group names when the customer purchases the charge offer with a closed user group.

[Table 22-1](#) lists the elements in the custom rules XML file, the usage of each element, and a description of how to specify each element in the XML file.

Table 22-1 Elements in the Custom Rules XML File

Element	Syntax	Description
customAnalyzerRules	<customAnalyzerRules>	The root element of the rule.
name	<name>RuleName</name>	<i>RuleName</i> specifies the custom rule name.
description	<description>RuleDescription</description>	<i>RuleDescription</i> contains the description of the custom rule.

Table 22-1 (Cont.) Elements in the Custom Rules XML File

Element	Syntax	Description
priceListName	<code><priceListName>PriceListName </priceListName></code>	<i>PriceListName</i> specifies the price list name. BRM uses only one internal price list. The only value is Default .
profileSpecName	<code><profileSpecName>ProfileAttributeSpecificationName</profileSpecName></code>	<i>ProfileAttributeSpecificationName</i> specifies the name of the profile attribute specification used for configuring the rule.
customRuleExpression	<code><customRuleExpression> <dynamicFieldCRExpression> <operator>Operator</operator> <FieldIdentifier> ... </FieldIdentifier> </dynamicFieldCRExpression> </customRuleExpression></code>	Contains the expression to evaluate closed user groups, where <i>Operator</i> specifies the operator to be used in the expression. The valid value is INTERSECT .
FieldIdentifier	<code><FieldIdentifier> <qualifier>Qualifier</qualifier> <fieldSelector> ... </fieldSelector> </FieldIdentifier></code>	Contains the details to identify the fields for evaluating closed user groups, where <i>Qualifier</i> specifies the qualifier for identifying the fields. The valid values are: <ul style="list-style-type: none"> ORIGINATING TERMINATING In the <FieldIdentifier> element, you can define fields from the service, account, and event attribute specifications.
FieldSelector	<code><fieldSelector> <operator>ConditionOperator</operator> <selectorFieldName>SelectorFieldName</selectorFieldName> <selectorFieldKind>SelectorFieldKind</selectorFieldKind> <conditionFieldName>ConditionFieldName</conditionFieldName> <conditionFieldKind>ConditionFieldKind</conditionFieldKind> </fieldSelector></code>	Identifies the closed user group names that match the given product identifier (PUID); for example, a phone number, for both the originating and terminating subscribers. <p>Note: You can use the <FieldSelector> element for configuring account-level closed user groups only, where:</p> <ul style="list-style-type: none"> <i>ConditionOperator</i> specifies the operator to be used in the condition. The valid value is EQUAL TO. You must specify the <i>ConditionOperator</i> if you want to define the conditions for selecting fields. If the <i>ConditionOperator</i> is null, you cannot specify <i>ConditionFieldName</i> and <i>ConditionFieldKind</i>. <i>SelectorFieldName</i> specifies the selector field name. You must define the selector fields based on the condition fields. <i>SelectorFieldKind</i> specifies the type of attributes used for field selection. You can specify any service, event, or account attribute. <i>ConditionFieldName</i> specifies the condition field name. <i>ConditionFieldKind</i> specifies the type of attributes used for selection. You can specify any service, event, or account attribute.

Part IV

Managing Balances

This part describes how to manage balances using Oracle Communications Billing and Revenue Management (BRM) and Pricing Design Center (PDC).

This part contains the following chapters:

- [Managing Balances during Charging](#)
- [Managing Sub-Balances](#)
- [Configuring Dynamic Quota](#)
- [About Folds](#)
- [Applying Credit Limits to Balances](#)
- [About Rollovers](#)
- [Configuring Balance Impact Rounding](#)

Managing Balances during Charging

Learn how balances are managed in Oracle Communications Billing and Revenue Management (BRM) product offerings created using Pricing Design Center (PDC).

Topics in this document:

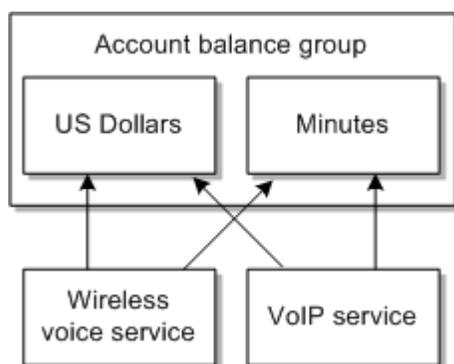

- [Tracking Balances in Balance Groups](#)

Tracking Balances in Balance Groups

Using a service can affect multiple types of balances. For example, a phone service might be charged in both dollars and minutes. In this case, the service usage would be associated with a balance group that includes two balances, one for dollars and one for minutes. *Balance groups* are collections of multiple balances that apply to one or more services.

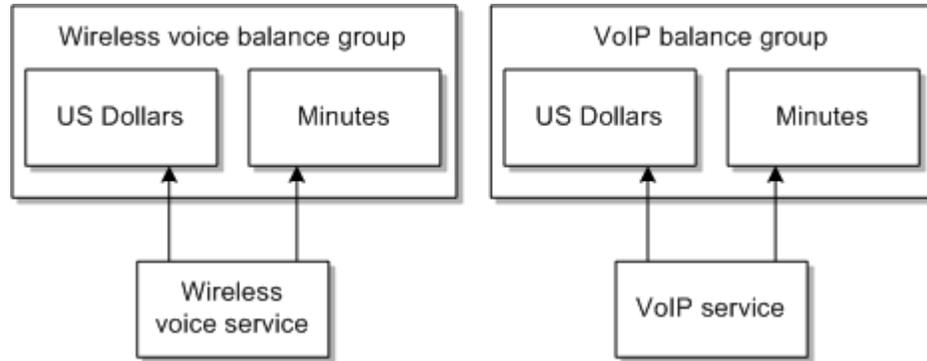

You create balance groups when you create packages in PDC. By default, a package contains one balance group: the account balance group. Balances for every service in the package share that balance group, which means that balances such as included minutes are shared among all services. [Figure 23-1](#) shows a default balance group with two types of balances, both of which are used by two services.

Figure 23-1 Default Balance Group for Two Services

To track and control the allocation and consumption of balances for specific services, you can create multiple balance groups and assign services to their own balance groups, or group sets of services by balance group. [Figure 23-2](#) shows two services that each use their own balance group.

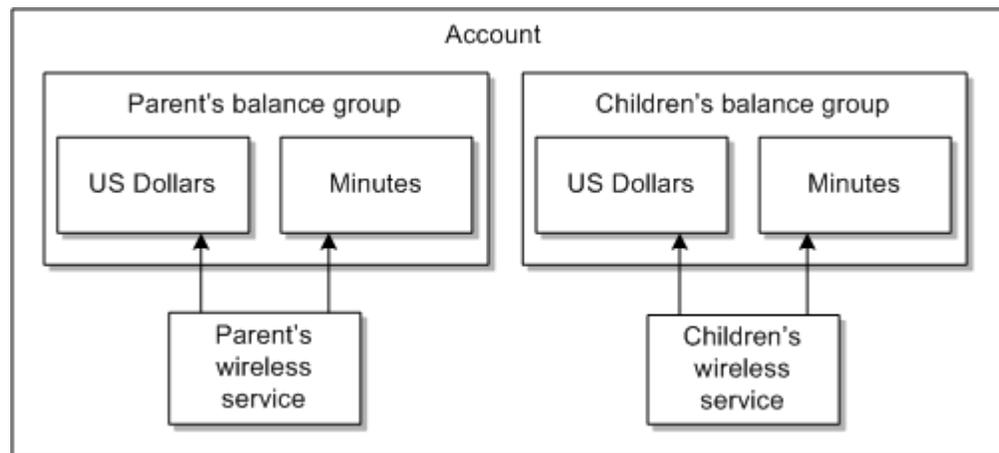

Figure 23-2 Two Balance Groups for Two Services

In addition to creating different balance groups for different services, you can create different balance groups for different packages that are purchased by the same account. For example, consider a family of four that has a mobile phone service for each family member. The bundle for each service includes 300 minutes. If the package has only the default account balance group, all four family members' included minutes go into the same account balance, which would contain 1200 included minutes. One teenager could then use 1000 minutes, leaving only 200 minutes to be shared by the other three family members.

To avoid that situation, you could create a package with two mobile phone services in the same bundle for the parents and an optional add-on package in its own balance group. When the parents purchase add-on packages for the children, each child's included minutes are tracked separately in a separate balance group. [Figure 23-3](#) shows two balance groups, created by purchasing separate packages in the same account.

Figure 23-3 Separate Balance Groups By Purchasing Separate Packages

You can set different credit limits for the same balance element in each balance group. For example, the parents might request a credit limit of \$10 on the US Dollar balance element in each child's balance group to control overage charges but request a \$100 credit limit on the US Dollar balance in the balance group for their mobile phone services. See ["Applying Credit Limits to Balances"](#) for more information.

About Sub-Balances

Each balance in a balance group can include one or more sub-balances. A balance includes sub-balances when portions of the balance are valid at different times or when a portion of the balance is a loan. For example, a balance of minutes might include 300 minutes that are valid only for the current month and 1000 minutes that never expire. [Figure 24-1](#) shows an account with two balance groups, one for each service. In the balance group for wireless minutes, there are balances with different expiration dates. Therefore, there are two sub-balances for wireless minutes.

Figure 24-1 Balance Group With Sub-balances

A currency sub-balance can store the balances for multiple services. For example, an account that owns two charge offers that cost \$25.00 per offer has a starting currency sub-balance of \$50.00, providing the services are associated with the same balance group and have the same validity period.

A currency balance can also store sub-balances for loans. For example, if an account subscribed to a monthly package that costs \$25.00 only has a balance of \$15.00 at subscription renewal time, you can grant a loan for the remaining \$10.00. The balance would then consist of two sub-balances; a \$15 regular sub-balance and a \$10 loan sub-balance.

Sub-balances include the following information:

- The sub-type. This indicates whether the sub-balance is a loan or not.
- The start time and end time for which the sub-balance is valid. Balances with the same validity periods are stored in the same sub-balance. Balances with unique validity periods are stored in separate sub-balances. For more information, see "[How Balances in Validity-Based Sub-Balances Are Updated](#)".
- The current amount of the sub-balance.
- The fields in the event record or object (referred to as "contributors") that contribute to how sub-balances are created, updated, and retrieved. For example, to retrieve the total available balance for a specific service, the service object is specified. To deduct minutes for a phone call, the session object is specified. A separate sub-balance is kept for each unique contributor. .
- Rollover data such as the rollover period and the balance amount that is rolled over, if any. See "[About Rollovers](#)".
- The ID of the offer that granted the balance (referred to as the "grantor object.")

If the **timestamp_rounding** entry in the CM **pin.conf** file is enabled, the start time of the balances granted by cycle events is rounded to midnight. However, the start time of the balances granted by purchase events is not rounded to midnight.

You can configure sub-balances to track various types of balances and usage. See "[Configuring Custom Sub-Balances](#)".

About Noncurrency Sub-Balances

A noncurrency sub-balance typically has a limited validity period (for example, the period during which minutes can be used). Noncurrency sub-balances can contain various types of balances, such as the following:

- Minutes
- Frequent flyer miles
- Loyalty points
- Number of emails or text messages

A noncurrency sub-balance can also keep track of the total balances used for discounts that are shared among several accounts. In this case, the sub-balance acts as a counter to keep track of the total consumed balance.

When granting a noncurrency balance, if a sub-balance already exists, BRM compares the new balance data with the following data in the existing valid sub-balances:

- Contributor
- Grantor object
- Rollover data
- Valid-from date
- Valid-to date

If the data matches, BRM adds the amount to the existing sub-balance; otherwise, it creates a new sub-balance.

For information about configuring sub-balances, see "[Configuring Custom Sub-Balances](#)".

How Balances in Validity-Based Sub-Balances Are Updated

By default, BRM stores balances with the same validity periods in the same sub-balance, provided they are associated with the same balance group. BRM automatically creates a new sub-balance for balances with a unique validity period, if one does not already exist.

For example, an account owns two services that each include 100 minutes that are always valid. The account has a balance of 200 minutes stored in a single sub-balance. When the customer uses minutes from each service, the minutes are consumed from the common sub-balance.

Balances with different validity periods are tracked in separate sub-balances. For example, an account owns two services that each include 100 minutes. Minutes for service 1 expire at the end of the month, and minutes for service 2 expire at the end of the year. Each set of minutes is stored in a separate sub-balance.

Note:

When noncurrency balances are configured to start on first usage, BRM creates a new sub-balance for each balance whether or not they have the same validity period. See "[Restricting the Validity of Noncurrency Sub-Balances That Start on First Usage](#)".

You can specify the order in which sub-balances are consumed by setting up balance consumption rules. See "[Specifying the Order in Which Sub-Balances Are Consumed](#)".

You can also limit how validity-based balances such as minutes are summed by configuring sub-balances. For example, you might want to limit usage of minutes to a specific service or a specific call session. See "[Configuring Custom Sub-Balances](#)".

You can configure BRM to round time stamps to midnight for balances granted by cycle and purchase events. See the following:

- [Configuring Time-Stamp Rounding for Cycle Events](#)
- [Configuring Time-Stamp Rounding for Purchase Events](#)

For more information, see "Configuring Timestamp Rounding" in *BRM Configuring and Running Billing*.

Restricting the Validity of Noncurrency Sub-Balances That Start on First Usage

When a noncurrency balance is configured to start on first usage (when the customer first uses the service), BRM always creates a new sub-balance for that balance when it is granted. A new sub-balance is created for each balance even when a charge offer or discount offer grants multiple first-usage balances of the same type. A balance that has a first-usage start time will remain available for consumption for as long as the balance is not used.

 **Note:**

If a balance is shared among accounts in a sharing group, the balance validity period is set when any account in the group first impacts the balance. Because the same balance is shared with all accounts in the group, the validity period of that balance applies to all accounts.

You can configure BRM to automatically restrict the validity period of granted noncurrency balances to end no later than the end time of the charge offer or discount offer that grants the balance. Restricting the balance end time to the offer's end time ensures that the balance cannot continue to be consumed after the offer expires.

 **Note:**

When an offer is *canceled*, the validity period end time of balances granted by that charge offer or discount offer is set to the time of the cancellation.

To enable this feature, run the **pin_bus_params** utility to change the **RestrictResourceValidityToOffer** business parameter. See "pin_bus_params" in *BRM Developer's Guide* for more information.

To restrict balance validity end times to charge offer or discount offer end times:

1. Go to `BRM_home/sys/data/config`.
2. Create an XML file from the `/config/business_params` object:

```
pin_bus_params -r BusParamsMultiBal bus_params_multi_bal.xml
```
3. In the file, change **FALSE** to **TRUE**:

```
<RestrictResourceValidityToOffer>TRUE</RestrictResourceValidityToOffer>
```
4. Save the file as `bus_params_multi_bal.xml`.
5. Load the XML file into the BRM database:

```
pin_bus_params bus_params_multi_bal.xml
```
6. Stop and restart the CM.
7. (Multischema systems only) Run the **pin_multidb** script with the **-R CONFIG** parameter. See "pin_multidb" in *BRM System Administrator's Guide* for more information.

Configuring Custom Sub-Balances

As described in "About Sub-Balances", BRM automatically creates sub-balances when portions of the balance are valid at different times. You do not need to configure sub-balances based on validity times.

You can configure custom sub-balances to track balances based on other values. For example:

- Minutes per call session
- Frequent flyer miles per service instance
- Friends and family calls to specific locations

You configure custom sub-balances by editing and loading a configuration file.

To customize the allocation and consumption of balances, you configure sub-balances by specifying the following values:

- *Balance element ID*. This is the ID for the type of balance in the sub-balance, such as dollars or minutes.
- *Event type*. This is the type of event that impacts the sub-balance, such as GSM usage events (*levent/session/telco/gsm*).
- *Contributors*. Contributors can be any field in the event record, or from an object related to the charge, such as a service object or account object.

For example, you might configure a custom sub-balance to track balance impacts for:

- Dollars
- Charged by GPRS events
- Tracked by each GPRS session

Sub-balance contributors define how to track sub-balances. For example, if the contributor is a service object, sub-balances are tracked separately for each service instance.

Sub-balance contributors are specified by a field name from the event, or from an object related to the charge, such as a service object or account object. Some fields you might want to use as contributors include:

- The service object.

Specify a service field to track sub-balances for specific service instances such as fax, telephony, and text messaging.

 **Note:**

Specifying the service object in the configuration is one way of creating service balances. The other way is to create a balance group for the service when you create your packages in PDC.

- The session object.

Specify a session field to track balances per session instance. This is useful when you offer discounts for certain levels of usage (for example, 10 frequent flyer miles per hour of phone calls).

- The charge offer object.

When several charge offers in the same package have different rollover rules, tracking balances per charge offer permits BRM to update the minutes for each charge offer.

- The phone number field.

Specify a phone number field to track balances for called telephone numbers.

- The account object.

Specify the account field to track balances that are shared among several accounts, such as earned minutes. When minutes are distributed, they can be divided based on each account's usage level.

There are two types of contributors:

- Retrieving contributor.* This is the field from which BRM retrieves the amount to add to the sub-balance. For example, if the retrieving contributor is the service for a GPRS event, a separate balance summary is retrieved from each unique GPRS service object.

All sub-balances with common retrieving contributors are summed when sub-balances are retrieved. For example, to retrieve the total balance for specific services, specify the service object as the retrieving contributor.
- Updating contributor.* Whereas the retrieving contributor determines the balance amount to retrieve from a charge, the updating contributor specifies how to apply the amount to a sub-balance. For example, to add or deduct minutes for specific broadband sessions, specify the session object as the updating contributor.

Table 24-1 shows contributor configurations to track balances for GSM services; in this case, one sub-balance for dollars and one sub-balance for minutes.

Table 24-1 Contributor Configurations

Balance Element	Event Type	Retrieving Contributor	Updating Contributor
Dollars	/event/session/gsm	PIN_FLD_SERVICE_OBJ	PIN_FLD_SERVICE_OBJ
Minutes	/event/session/gsm	PIN_FLD_SERVICE_OBJ	PIN_FLD_SERVICE_OBJ

Each row in this example specifies a sub-balance:

- Dollars balance impact

 - Dollars** is a currency sub-balance that is created in the account balance group.
 - /event/session/gsm** is the event type that will impact the dollars sub-balance.
 - PIN_FLD_SERVICE_OBJ is the retrieving contributor, so the dollars balance for each unique GSM service is summed when retrieving balance information.

If you specify an asterisk instead of PIN_FLD_SERVICE_OBJ for the retrieving contributor, dollars for *all* GSM services owned by the account would be summed when retrieving balance information.
 - PIN_FLD_SERVICE_OBJ is the updating contributor, so a separate sub-balance is created to track dollars for every unique GSM service that the account owns, such as telephony, fax, and SMS.
- Minutes balance impact

 - Minutes** is a noncurrency sub-balance that is created in the account balance group.
 - /event/session/gsm** is the event type that will impact the minutes balance.
 - PIN_FLD_SERVICE_OBJ is the retrieving contributor, so the minutes balance for each unique GSM service is summed when retrieving balance information.

If you specify an asterisk instead of PIN_FLD_SERVICE_OBJ for the retrieving contributor, minutes for *all* GSM services owned by the account would be summed when retrieving balance information.
 - PIN_FLD_SERVICE_OBJ is the updating contributor, so a separate sub-balance is created to track minutes for every unique GSM service that includes minutes. Additional minutes and consumption of minutes are restricted to the GSM service instance.

When a balance impact affects more than one sub-balance, the sub-balances are updated in the following order:

1. **By validity period.** By default, sub-balances are updated in chronological order based on the validity start date or end date. You specify the order in which sub-balances are used by setting up balance consumption rules. See "[Specifying the Order in Which Sub-Balances Are Consumed](#)".
2. **By contributor.** Sub-balances with specific field contributors are impacted before sub-balances that accept all contributors (with an asterisk or empty contributor values). See "[Configuring Custom Sub-Balances](#)".

Defining and Loading Custom Sub-Balances

See "[Configuring Custom Sub-Balances](#)" for information.

To configure sub-balances, you edit the sub-balance configuration file and then run the **load_pin_sub_bal_contributor** utility to load the contents of the file into the **/config/sub_bal_contributor** object in the BRM database.

Each line in the **pin_sub_bal_contributor** file defines the usage for which a sub-balance is created. The configurations apply to all sub-balances in the BRM database, but they are implemented at the balance group level. That is, when a usage event occurs, if the account has more than one balance group, only the sub-balances within the specified balance groups are impacted.

To add sub-balance configurations, use this syntax:

```
balance_type:event_type:retrieving_contributor:updating_contributor
```

For example:

```
1000003:/event/session/gprs:PIN_FLD_SESSION_OBJ:PIN_FLD_SESSION_OBJ
```

where:

- **1000003** is the balance element ID for frequent flyer miles.
- **/event/session/gprs** is the event type that impacts the frequent flyer miles balance.
- **PIN_FLD_SESSION_OBJ** is the retrieving contributor. Therefore, a separate balance summary is retrieved for each unique GPRS session.
- **PIN_FLD_SESSION_OBJ** is the updating contributor. Therefore, separate sub-balances are created or updated for each unique GPRS session.

The contributors can be a specific field or an asterisk (*) to indicate any contributor. For example, the following entry retrieves and tracks dollars (balance element type 840) in a single sub-balance for all events with any contributor:

```
840:/event:*:*
```

To configure several sub-balances for one balance element, leave subsequent balance element fields empty. If no balance element is specified, the previous balance element specified is used. For example, the next two configurations use the same balance element (100002):

```
100002 : /event/session/telco/gsm : PIN_FLD_SESSION_OBJ : PIN_FLD_SESSION_OBJ
      : /event/session/call : PIN_FLD_SERVICE_OBJ : PIN_FLD_SERVICE_OBJ
```

After editing the file, you load it into the BRM database.

 **Note:**

When you run the **load_pin_sub_bal_contributor** utility, it replaces the existing sub-balance configurations. If you are updating a set of sub-balance configurations, you cannot load new configurations only. You load complete sets of sub-balance configurations each time you run the **load_pin_sub_bal_contributor** utility.

Use the following command to run the **load_pin_sub_bal_contributor** utility:

```
load_pin_sub_bal_contributor pin_sub_bal_contributor
```

If you are not in the same directory as the **pin_sub_bal_contributor** file, include the complete path to the file. For example:

```
load_pin_sub_bal_contributor BRM_home/sys/data/pricing/example/pin_sub_bal_contributor
```

For more information, see "[load_pin_sub_bal_contributors](#)".

To verify that the sub-balance configurations loaded correctly, display the **/config/sub_bal_contributor** object by using Object Browser, or use the **robj** command with the **testnap** utility.

Specifying the Order in Which Sub-Balances Are Consumed

In a balance group, balances for the same type of balance element are combined into a single balance. For example, an account that owns two charge offers that each include 300 minutes has a starting included minute balance of 600 minutes, providing the services are associated with the same balance group and have the same validity period for the included minutes.

When portions of a balance are valid at different times, however, BRM creates multiple sub-balances for that balance in the balance group. For example, a balance group might include 300 minutes that are valid only for the current billing cycle and 1000 minutes that never expire. Because the included minutes have different validity periods, they are tracked in different sub-balances.

When a customer uses a service, BRM must know which sub-balance to use first. To specify the order in which sub-balances are consumed, you use consumption rules. The rules are based on the start and end times of the sub-balances, for example consume the sub-balance with the earliest validity start time first.

For example, you can specify whether a subscriber with the following minute sub-balances uses the Anytime Minutes or the rollover Anytime Minutes first:

- 100 Anytime Minutes that are valid March 1 to April 30
- 50 rollover Anytime Minutes that are valid February 1 to March 30

If the minute balance is associated with a rule that says to consume the sub-balance that expires first, the 50 rollover Anytime Minutes are used first.

If the minute balance is associated with a rule that says to consume the sub-balance with the latest start time, the 100 Anytime Minutes are used first.

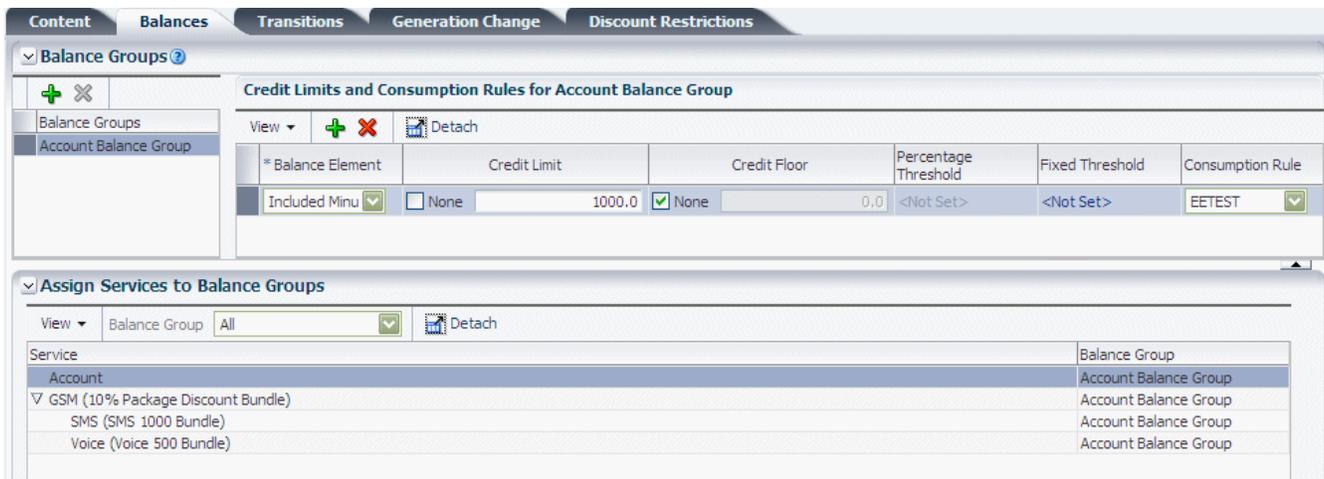

[Table 24-2](#) lists the balance consumption rules that BRM supports.

Table 24-2 Supported Consumption Rules

Consumption Rule	Description
Earliest start time (EST)	Consume the sub-balance with the earliest validity start time first.
Latest start time (LST)	Consume the sub-balance with the latest validity start time first.
Earliest expiration time (EET)	Consume the sub-balance with the earliest validity end time first.
Latest expiration time (LET)	Consume the sub-balance with the latest validity end time first.
Earliest start time and latest expiration time (ESTLET)	Consume the sub-balance with the earliest validity start time first. If multiple sub-balances have the same start time, use the one with the latest end time first.
Earliest start time and earliest expiration time (ESTEET)	Consume the sub-balance with the earliest validity start time first. If multiple sub-balances have the same start time, use the one with the earliest validity end time first.
Latest start time and earliest expiration time (LSTEET)	Consume the sub-balance with the latest validity start time first. If multiple sub-balances have the same validity start time, use the one with the earliest validity end time first.
Latest start time and latest expiration time (LSTLET)	Consume the sub-balance with the latest validity start time first. If multiple sub-balances have the same validity start time, use the one with the latest validity end time first.
Earliest expiration time and earliest start time (EETEST)	Consume the sub-balance with the earliest validity end time first. If multiple sub-balances have the same validity end time, use the one with the earliest validity start time first.
Earliest expiration time and latest start time (EETLST)	Consume the sub-balance with the earliest validity end time first. If multiple sub-balances have the same validity end time, use the one with the latest validity start time first.
Latest expiration time and earliest start time (LETEST)	Consume the sub-balance with the latest validity end time first. If multiple sub-balances have the same validity end time, use the one with the earliest validity start time first.
Latest expiration time and latest start time (LETLST)	Consume the sub-balance with the latest validity end time first. If multiple sub-balances have the same validity end time, use the one with the latest validity start time first.

As shown in [Figure 24-2](#), you associate consumption rules with balances in packages.

Figure 24-2 Consumption Rules for Balance Groups

You can also set systemwide and default balance element settings. BRM reads and uses the consumption rule settings in the order shown below:

1. **Loan consumption rules.** If a loan sub-balance is present, it will be consumed first. If there are multiple loan sub-balances, they are consumed according to the existing consumption rules.
2. **Package consumption rules.** Your product offerings can include consumption rules for each service that you support, defined differently in each package. This enables you to have different consumption rules for the same balance based in the packages purchased by the customer. When a customer purchases a package, the package's balance element-to-consumption rule mapping is stored in the customer's **/balance_group** object. If there are any conflicting rules for the same balance element, BRM uses the rule from the most recently purchased package.
3. **Systemwide service consumption rules.** You can specify a systemwide consumption rule for each service that you support. BRM uses the systemwide settings only if a rule is not defined for the balance element in the customer's purchased packages. BRM stores systemwide settings in the **/config/beid** object.
You define systemwide consumption rules for each balance element that you support by using the **pin_beid** file and **load_pin_beid** utility. See "load_pin_beid" in *BRM Configuring Pipeline Rating and Discounting* for more information.
4. **Default consumption rule.** You can specify a default consumption rule that applies to all balance elements. This setting is used only if a consumption rule is not defined for the balance element in the customer's purchased packages or if there is not a systemwide service rule. BRM stores the default balance element setting in the **/config/business_params** object.
You define the default consumption rule in the **/config/business_params** object. See "[Setting the Default Consumption Rule](#)" for more information.

Setting the Default Consumption Rule

The default consumption rule applies to all balance elements in your system. The default setting is earliest start time and earliest expiration time (ESTEET). You can change this setting by running the **pin_bus_params** utility to change the **SortValidityBy** business parameter. See "pin_bus_params" in *BRM Developer's Guide* for more information.

To set the default balance element consumption rule:

1. Go to `BRM_home/sys/data/config`.
2. Create an XML file from the **/config/business_params** object:

```
pin_bus_params -r BusParamsMultiBal bus_params_multi_bal.xml
```
3. In the file, change **ESTEET** to one of the values listed in [Table 24-2](#):

```
<SortValidityBy>ESTEET</SortValidityBy>
```
4. Save the file as **bus_params_multi_bal.xml**.
5. Load the XML file into the BRM database:

```
pin_bus_params bus_params_multi_bal.xml
```
6. Stop and restart the CM.
7. (Multischema systems only) Run the **pin_multidb** script with the **-R CONFIG** parameter. See "pin_multidb" in *BRM System Administrator's Guide* for more information.

Configuring the Default Consumption Rule in ECE

When ECE receives a usage request for which no consumption rules are configured, ECE applies its own systemwide default consumption rule for processing the usage request.

To configure the default consumption rule in ECE:

1. Access the ECE configuration MBeans:
 - a. Log on to the driver machine.
 - b. Start the ECE charging servers (if they are not started).
 - c. Connect to the ECE charging server node enabled for JMX management.
This is the charging server node set to **start CohMgt = true** in the *ECE_home/occeserver/config/eceTopology.conf* file.
 - d. Start a JMX editor that enables you to edit MBean attributes, such as JConsole.
 - e. In the editor's MBean hierarchy, find the ECE configuration MBeans.
2. Expand the **ECE Configuration** node.
3. Expand **charging.server**.
4. Expand **Attributes**.
5. Set the **systemConsumptionRule** attribute to one of the following systemwide consumption rules:
 - **EARLIEST_START**
 - **LATEST_START**
 - **EARLIEST_EXPIRATION**
 - **LATEST_EXPIRATION**
 - **EARLIEST_START_LATEST_EXPIRATION**
 - **EARLIEST_START_EARLIEST_EXPIRATION**
 - **LATEST_START_LATEST_EXPIRATION**
 - **LATEST_START_EARLIEST_EXPIRATION**
 - **EARLIEST_EXPIRATION_EARLIEST_START**
 - **EARLIEST_EXPIRATION_LATEST_START**
 - **LATEST_EXPIRATION_EARLIEST_START**
 - **LATEST_EXPIRATION_LATEST_START**
 - **NONE**: When the attribute is set to **NONE**, the default consumption rule is not configured, and the order for consuming balances is undefined.

By default, this attribute is set to **EARLIEST_START_EARLIEST_EXPIRATION**.

6. Save your changes.

Deleting Expired Sub-Balances

To delete expired sub-balances, use the **pin_sub_balance_cleanup** utility. See "pin_sub_balance_cleanup" in *BRM System Administrator's Guide*.

Configuring Time-Stamp Rounding for Cycle Events

You can configure BRM to round time stamps to midnight for balances granted by cycle events. For more information, see "Configuring Timestamp Rounding" in *BRM Configuring and Running Billing*.

To configure BRM to round time stamps to midnight for the resources granted by cycle events:

1. Open the CM configuration file (*BRM_home/sys/cm/pin.conf*) in a text editor.
2. Set the **timestamp_rounding** entry to **1**.
3. Save and close the file.

Note:

When a charge offer's purchase, cycle, and usage start and end units are set to 1 (seconds), 2 (minutes), or 3 (hours), and the validity period is less than 24 hours, time stamps are not rounded, regardless of your system configuration. If the validity is greater than 24 hours, the cycle end time stamp is rounded for the purpose of calculating the scale to determine the cycle fee amount to charge.

Configuring Time-Stamp Rounding for Purchase Events

You can configure BRM to round time stamps to midnight for balances granted by purchase events. For more information, see "Configuring Timestamp Rounding" in *BRM Configuring and Running Billing*.

To enable this feature, run the **pin_bus_params** utility to change the **TimestampRoundingForPurchaseGrant** business parameter. See "pin_bus_params" in *BRM Developer's Guide* for more information.

To configure BRM to round time stamps to midnight for the resources granted by purchase events:

1. Open the CM configuration file (*BRM_home/sys/cm/pin.conf*) in a text editor.
2. Set the **timestamp_rounding** entry to **1**.
3. Save and close the file.
4. Go to *BRM_home/sys/data/config*.
5. Create an XML file from the */config/business_params* object:

```
pin_bus_params -r BusParamsRating bus_params_rating.xml
```

6. In the file, change **disabled** to **enabled**:

```
<TimestampRoundingForPurchaseGrant>enabled</TimestampRoundingForPurchaseGrant>
```

7. Save the file as **bus_params_rating.xml**.
8. Load the XML file into the BRM database:

```
pin_bus_params bus_params_rating.xml
```

9. Stop and restart the CM.

10. (Multischema systems only) Run the **pin_multidb** script with the **-R CONFIG** parameter. See "pin_multidb" in *BRM System Administrator's Guide* for more information.

Configuring Dynamic Quota

Learn how to configure dynamic quota in Pricing Design Center (PDC) to allocate the available quota dynamically for each parallel session of a subscriber based on the rules you configure.

Topics in this document:

- [Configuring Dynamic Quota Selectors](#)

Configuring Dynamic Quota

Note:

You can use Dynamic Quota Configuration only in Oracle Communications Elastic Charging Engine (ECE).

Dynamic quota allows you to allocate the available quota dynamically for each parallel session of a subscriber based on the rules you configure. This enables the subscribers to run concurrent online charging sessions effortlessly. This also enables you to optimize the network usage effectively. For more information on dynamic quota, see "Managing Dynamic Quotas for Online Sessions" in *ECE Implementing Charging*.

You can define the rules for determining the dynamic quota allocation by configuring dynamic quota selectors in PDC. The rules can reference any of, or a combination of, the event, service, and customer attributes, and profile attribute specifications. You can configure the dynamic quota selector for each service and event combination.

ECE evaluates the rules defined in the dynamic quota selector at run time to derive the quota to be allocated for a session and the quota attributes, such as quota holding time (QHT), volume quota threshold (VQT), and quota validity time (VT). Dynamic quotas change in real time based on the dynamic quota selector rules as ECE grants and redistributes the quotas.

You configure dynamic quota selectors by importing the rules in XML files by using the **ImportExportPricing** utility. You can use the **SampleDynamicQuotaSelector.xml** file in the *PDC_home/apps/Samples/Examples* directory (where *PDC_home* is the directory in which the PDC software is installed) to create the XML files for configuring dynamic quota selectors. See "[Configuring Dynamic Quota Selectors](#)" for more information.

[Table 25-1](#) lists the elements that are supported in the dynamic quota selector XML file, the usage of each element, and a description of how to specify each element in the XML file.

Table 25-1 Elements Supported in the Dynamic Quota Selector XML File

Element	Syntax	Description
dynamicQuotaSelectors	<code><dynamicQuotaSelectors>DynamicQuotaSelector</dynamicQuotaSelectors></code>	<i>DynamicQuotaSelector</i> specifies the root element of the DynamicQuotaSelector.xml file.

Table 25-1 (Cont.) Elements Supported in the Dynamic Quota Selector XML File

Element	Syntax	Description
name	<code><name>DynamicQuotaConfiguration</name></code>	<i>DynamicQuotaConfiguration</i> specifies the dynamic quota selector name. For example, Generic Selector ABC.
description	<code><description>DynamicQuotaSelectorDescription</description></code>	<i>DynamicQuotaSelectorDescription</i> specifies the description of the dynamic quota selector.
priceListName	<code><priceListName>PriceListName </priceListName></code>	<i>PriceListName</i> specifies the price list name. The valid value is Default .
applicableToName	<code><applicableToName>ApplicableToName</applicableToName></code>	<i>ApplicableToName</i> specifies the service name. The attributes of this service are used in the rules.
eventSpecName	<code><eventSpecName>EventName</eventSpecName></code>	<i>EventName</i> specifies the name of an event. The attributes of this event are used in the rules.
validityPeriod	<code><validFrom>Validfromdate</validFrom></code>	<i>Validfromdate</i> specifies the date from which the rule is valid. The valid format is YYYYMMDD . Note: It is mandatory to mention the date from when the rule is valid. If no date is specified, the rule is valid from immediate effect.
applicableToAllChildEvent	<code><applicableToAllChildEvent>ChildEventsOption</applicableToAllChildEvent></code>	Specifies whether the dynamic quota selector is applicable to the child events, where <i>ChildEventsOption</i> is: <ul style="list-style-type: none"> True if the dynamic quota selector applies to all the child events. False if the dynamic quota selector applies to only the specific event type.
rule	<code><rule> <ruleName>RuleName</ruleName> <ruleOrder>RuleOrder</ruleOrder> <configuration>DynamicQuotaConfiguration</configuration> <requestedUnits>RequestedUnitsForAllocation</requestedUnits> <dynamicQuotaFieldToValueExpression>FieldToValueExpression</dynamicQuotaFieldToValueExpression> <dynamicQuotaComplexExpression>ComplexExpression</dynamicQuotaComplexExpression> </rule></code>	Specifies the rules for allocating dynamic quotas, where: <ul style="list-style-type: none"> <i>RuleName</i> specifies the rule name. <i>RuleOrder</i> specifies the order in which the rules must be applied. <i>DynamicQuotaConfiguration</i> contains the configurations for dynamic quotas. <i>RequestedUnitsForAllocation</i> contains the requested units for allocating dynamic quotas. <i>FieldToValueExpression</i> contains the attributes used for deriving the quota. <i>ComplexExpression</i> contains the complex conditions for deriving the quota. Note: You can add multiple rules in the dynamic quota selector. Each rule in the dynamic quota selector can refer to a different attribute. For example, Rule 1 can use an event attribute, Rule 2 can use a balance expression, and Rule 3 can use a service attribute.

Table 25-1 (Cont.) Elements Supported in the Dynamic Quota Selector XML File

Element	Syntax	Description
<i>DynamicQuotaConfiguration</i>	<pre><configuration> <key>key</key> <value>value</value> <unit>unit</unit> </configuration></pre>	<p>Specifies the quota attribute configurations, where:</p> <ul style="list-style-type: none"> • <i>key</i> specifies the quota attribute. The valid values are: <ul style="list-style-type: none"> VOLUME_QUOTA_THRESHOLD. Specifies how long a granted quota can be idle before the reservation is released. QUOTA_HOLDING_TIME. Specifies how much of the granted quota must be consumed before a subscriber can request additional quota. This attribute is configured per service, event, and number of granted units. VALIDITY_TIME. Specifies whether validity time can be set to a fixed value per service-event combination at runtime. This attribute is independent of the number of units in the granted quota. • <i>value</i> specifies the quota attribute value. • <i>unit</i> specifies the unit for measurement. The valid values are: <ul style="list-style-type: none"> Seconds Minutes Hours Days Bytes Kbytes Mbytes Gbytes None <p>Note: You must add the <i>DynamicQuotaConfiguration</i> element for each valid quota attribute.</p>

Table 25-1 (Cont.) Elements Supported in the Dynamic Quota Selector XML File

Element	Syntax	Description
<i>RequestedUnitsForAllocation</i>	<pre> <requestedUnits> <fieldName>fieldname</fieldName> <unit>unit</unit> <dynamicQuotaBinaryExpression>dynamicQuotaBinaryExpression</dynamicQuotaBinaryExpression> </requestedUnits> <requestedUnits> <fieldName>fieldname</fieldName> <unit>unit</unit> <numberExpression>numberExpression</numberExpression> </requestedUnits> </pre>	<p>Specifies the details about the requested units, where:</p> <ul style="list-style-type: none"> <i>fieldName</i> specifies the fully qualified requested attribute field name. This is specified in the event specification. For example, <i>EventDelayedSessionTelcoGsm.REQUESTED_UNITS.INPUT_VOLUME</i>. <i>unit</i> specifies the unit for measurement. The valid values are: <ul style="list-style-type: none"> Seconds Minutes Hours Days Bytes Kbytes Mbytes Gbytes None <i>dynamicQuotaBinaryExpression</i> specifies the condition for deriving the quota. <i>numberExpression</i> specifies a valid number; for example, 10.0.
<i>dynamicQuotaBinaryExpression</i>	<pre> <dynamicQuotaBinaryExpression> <leftOperand> <numberExpression>numberExpression</numberExpression> <balanceExpression>balanceExpression</balanceExpression> </leftOperand> <rightOperand> <balanceExpression>balanceExpression</balanceExpression> <numberExpression>numberExpression</numberExpression> </rightOperand> <dynamicQuotaBinaryOperator>Operator</dynamicQuotaBinaryOperator> </dynamicQuotaBinaryExpression> </pre>	<p>Specifies the condition for deriving the quota, where:</p> <ul style="list-style-type: none"> <i>numberExpression</i> specifies a valid number; for example, 10.0. <i>balanceExpression</i> specifies the currency or noncurrency balance element defined in PDC. <i>Operator</i> specifies the arithmetic operators. The valid values are: <ul style="list-style-type: none"> Add Subtract Multiply Divide

Table 25-1 (Cont.) Elements Supported in the Dynamic Quota Selector XML File

Element	Syntax	Description
<i>FieldToValueExpression</i>	<pre><dynamicQuotaFieldToValueExpression> <separator>Delimiter</separator> <operation>Operator</operation> <fieldName>FieldName</fieldName> <fieldKind>FieldKind</fieldKind> <fieldValue>FieldValue</fieldValue> </dynamicQuotaFieldToValueExpression></pre>	<p>Specifies the attributes used for deriving the quota, where:</p> <ul style="list-style-type: none"> <i>Delimiter</i> specifies the character that is used to separate the field values. Note: This is applicable only when the <i>operator</i> is IN_LIST. <i>Operator</i> specifies the operator to be used in the expression. The valid values are: EQUAL_TO NOT_EQUAL_TO GREATER_THAN GREATER_THAN_EQUAL LESS_THAN LESS_THAN_EQUAL IN_LIST CONTAINS <i>FieldName</i> specifies the fully qualified field name. For example, EventSessionTelcoGsm.REQUESTED_UNITS.NUMBER_OF_UNITS. <i>FieldKind</i> specifies the type of attributes. The valid values are: PRODUCT_SPEC_FIELD EVENT_SPEC_FIELD CUSTOMER_SPEC_FIELD PROFILE_SPEC_FIELD <i>FieldValue</i> specifies the field value that is used to track the balance impacts. <p>Note: You can add multiple <i>FieldToValueExpression</i> elements in a rule to derive the quota based on a combination of attributes.</p>
<i>ComplexExpression</i>	<pre><dynamicQuotaComplexExpression> <operator>Operator</operator> <value>Value</value> <dynamicQuotaBinaryExpression>dynamicQuotaBinaryExpression</dynamicQuotaBinaryExpression> </dynamicQuotaComplexExpression></pre>	<p>Specifies complex conditions for deriving the quota, where:</p> <ul style="list-style-type: none"> <i>Operator</i> specifies the operator to be used in the expression. The valid values are: EQUAL_TO NOT_EQUAL_TO GREATER_THAN GREATER_THAN_EQUAL LESS_THAN LESS_THAN_EQUAL <i>Value</i> is a numeric value. For example, 0.004. <i>dynamicQuotaBinaryExpression</i> specifies the condition for deriving the quota.

Configuring Dynamic Quota Selectors

To configure a dynamic quota selector:

1. Make a copy of the *PDC_home/apps/Samples/Examples/Sample_DynamicQuotaSelector.xml* file to customize.
2. Open the file in a text editor or XML editor.
3. Add or modify the elements as required. See [Table 25-1](#) for the usage and description of each element.
4. Save and close the file.

 **Note:**

You can save the file with a different name.

5. Go to the directory where you have saved the file.
6. Import the dynamic quota selector from the customized XML file into the PDC database by running the following command:

```
ImportExportPricing -import -config FileOrDirectoryName
```

where *FileOrDirectoryName* is the name of the customized XML file, such as **Dynamic_QuotaSelector.xml**. Alternatively, enter the path to the directory containing multiple XML files to import.

The dynamic quota selector is imported into the PDC database and published to ECE.

26

About Folds

Learn how to use folds in Oracle Communications Billing and Revenue Management (BRM) product offerings.

Topics in this document:

- [About Folds](#)
- [About Applying Folds Only For Account-Level Products](#)

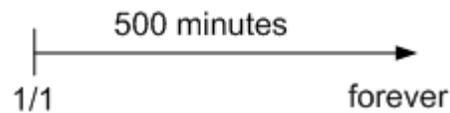

About Folds

When a fold event occurs, BRM checks whether the balance is valid or expired. The balance is folded if the sub-balance is expired or if the sub-balance is always valid.

For example,

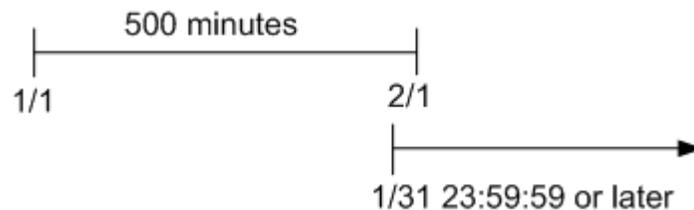

- 500 minutes are valid forever; therefore the balance can be folded at any time as shown in [Figure 26-1](#).

Figure 26-1 Minutes Valid Forever

- 500 minutes that expire on February 1 can be folded after January 31 23:59:59. The end time of the fold event must be January 31 23:59:59 or later as shown in [Figure 26-2](#).

Figure 26-2 500 Minutes Expiring on February 1st

 **Note:**

If you use delayed billing, folds occur at the end of the delayed billing period. This is to ensure that delayed events can continue to consume granted balances before final billing is run. However, free balances are granted at the beginning of each cycle, before the fold event occurs. If the newly granted balances do not have a configured validity period (that is, their validity period never ends), the fold event will remove those balances.

When you use fold events to remove unused balances and you also use delayed billing, you should always configure a validity period for the granted balances. This prevents fold events from removing balances that are granted at the beginning of a cycle before final billing is run.

About Applying Folds Only For Account-Level Products

If a fold is configured at account level, the fold is applicable to all the services in the account. The fold is then applied to the first service that is retrieved. If the resource balance is non-zero after applying the fold to the first service, the fold is applied again to the next service until the resource balance is zero.

To apply the fold only to account-level products, you can configure an account-level balance group to track the resource that you want to fold. The fold is then applied to only the products associated with the account-level balance group and not to all the services in the account.

Applying Credit Limits to Balances

Learn how to implement and manage credit limits in Oracle Communications Billing and Revenue Management (BRM) product offerings.

Topics in this document:

- [About Credit Limits](#)
- [About Credit Thresholds and Floors](#)
- [Handling Credit Limit Conflicts](#)
- [Allowing Customers to Exceed Their Credit Limit](#)

See also "[Managing Balances during Charging](#)".

About Credit Limits

A credit limit is the maximum amount of a balance element that can accumulate in a balance group. When a credit limit is reached, businesses typically deny customers access to the services associated with the balance group. For example, you might set a credit limit of \$100 for a telephony package and deny service when customers who reach that limit try to place a call.

You can also configure charges to allow customers to exceed their credit limits. See "[Allowing Customers to Exceed Their Credit Limit](#)".

You set credit limits for balance elements in packages.

About Credit Thresholds and Floors

You can use credit thresholds to notify customers when they are approaching the credit limit of a balance. A credit threshold specifies the balance total that triggers a notification to the customer. You can specify the threshold in the following ways:

- As a *fixed value*, such as \$100 or 30 minutes.
- As a *percentage* of the credit limit, such as 90%. For example, if the credit limit is \$100 and the threshold is 90%, the threshold amount is reached when the customer has a balance of \$90 (that is, when the customer has used 90% of the balance).

The *credit floor* is the starting point for a credit threshold and is the lowest number that the balance can be (that is, the number that represents no use of the balance).

For currency balances, the credit floor is 0.

For noncurrency balance elements, such as prepaid hours, you must specify a credit floor. You can use a negative number for the floor. For example, suppose you give 100 prepaid hours and set the credit limit to 0. When the credit limit is reached, the customer has no hours remaining and cannot use the service. To notify the customer when only 10 hours remain, set the credit threshold and floor as follows:

- Set the credit floor to -100. This number indicates none of the balance has been used.

- Set the credit threshold to 90%.

The threshold is reached at 90% of -100 hours (that is, when the customer has 10 prepaid hours left).

The credit threshold can be triggered both when a balance is increasing and when it is decreasing. You can customize BRM to perform different actions in each case. For example, if the credit threshold is crossed when the balance is increasing, service could be turned off. If the threshold is crossed when the balance is decreasing, service could be restored.

Handling Credit Limit Conflicts

There might be occasions when customers purchase packages with credit limits that conflict with the credit limit set on their account or another service. There are two ways to handle credit limit conflicts:

- When you create your product offerings, if two services have different credit limits, create new balance groups for the services. This enables credit limits for each service to be set and tracked independently. See "[Tracking Balances in Balance Groups](#)".
- Specify which credit limit takes precedence when a new credit limit conflicts with an existing credit limit. You do this by setting the **credit_limit_conflict** entry in the CM configuration file.

To specify credit limit precedence:

1. Open the CM configuration file (*BRM_home/sys/cm/pin.conf*).
2. Add the **credit_limit_conflict** entry:

```
-fm_bill credit_limit_conflict value
```

where *value* is one of these values:

- **replace** to use the new credit limit.
- **ignore** to ignore the new credit limit and keep the existing credit limit.
- **add** to add the new credit limit to the existing credit limit and create a new limit.
- **minimum** to use the credit limit that specifies the smaller amount.
- **maximum** to use the credit limit that specifies the greater amount.

If this entry is not present, the new credit limit is used by default.

3. Stop and restart the CM.

Allowing Customers to Exceed Their Credit Limit

When configuring properties for quantity ranges in charges, you can specify what happens to subscriptions when customers exceed their credit limits. You can do the following:

If you do not want to allow customers to exceed their credit limit, you can specify that:

- The subscription succeeds and the resources are prorated according to the available balance. For example, if the subscription grants 2GB of data and costs \$10, but the customer only has \$8 in their account, the \$8 would be used and the customer would be granted 1.6GB of data.
In the PDC UI, this is the **Enforce Credit Limit** option.
- The subscription fails. After retrying the subscription the configured maximum number of times, a notification event is sent to an external system for further processing.

In the PDC UI, this is the **Rental Failure** option.

You configure the maximum number of retries in the **max_retry_count** subscription business parameter. The default is **0**, which sends the failure notification immediately without retrying. See "Using Event Notification" in *BRM Developer's Guide* for information about notifications and "[Configuring the Maximum Number of Subscription Retries](#)" for information about the maximum number of retries.

The current number of retries for the subscription is recorded in the **PIN_FLD_RETRY_COUNT** field of the **/purchased_product** object.

If you create charge offers in XML using the `ImportExportPricing` utility, you can also configure the maximum retries and their interval at the offer level. See "[Enforcing or Exceeding Credit Limits](#)" for more information. If nothing is configured for the offer, the business parameter is used.

If you want to allow customers to exceed their credit limit, you can specify that:

- The subscription succeeds and all available balance is used. The remaining amount is recorded as a negative account balance to be paid at the next top up for prepaid customers or next bill for postpaid customers.
In the PDC UI, this is the **Do not enforce credit limit** option. You typically use this option for postpaid customers.
- The subscription succeeds and all available balance is used. The remaining amount is recorded as an outstanding amount to be paid at the next top up for prepaid customers or next bill for postpaid customers.
In the PDC UI, this is the **Deduct Rental** option. You typically use this option for prepaid customers.
- The subscription succeeds. If the customer is eligible for a loan, all available balance is used and a loan is granted for the remaining amount. If the customer is not eligible for a loan, the subscription fails.
In the PDC UI, this is the **Loan** option.

See "About Loans" in *BRM Configuring and Collecting Payments* for more information about loans.
- The subscription succeeds without using the available balance. The entire amount is recorded as an outstanding amount to be paid at the next top up for prepaid customers or next bill for postpaid customers.
In the PDC UI, this is the **Outstanding Amount** option.
- The subscription succeeds without using the available balance. Billing will be skipped for this cycle; during rating all balance impacts are dropped and the unrated quantity is set to 0. The cycle forward date is moved to next cycle. Services are still available.
In the PDC UI, this is the **Skip Cycle** option.

If you create charges using the `ImportExportPricing` utility, you have additional options for exceeding credit limits. See "[Enforcing or Exceeding Credit Limits](#)" for more information.

Configuring the Maximum Number of Subscription Retries

When a customer's subscription fails due to insufficient credit, the subscription can be retried a configured number of times before sending a failure notification to an external system.

The maximum number of retries is configured in the **max_retry_count** field in the business parameters for subscriptions. By default, this is set to **0**, which sends the notification immediately without retrying.

To change **max_retry_count**, use the **pin_bus_params** utility:

1. Go to `BRM_home/sys/data/config`.
2. Run the `pin_bus_params` utility to create an XML file from the `/config/business_params` object:

```
pin_bus_params -r BusParamsSubscription bus_params_subscription.xml
```

3. Search for this line:

```
<MaxRetryCount>0</MaxRetryCount>
```

The default is **0** (no retries).

4. Specify the new maximum number of retries.
5. Save the file as **bus_params_subscription.xml**.
6. Load the XML file into the BRM database:

```
pin_bus_params bus_params_subscription.xml
```

7. Stop and restart the CM.
8. (Multischema systems only) Run the `pin_multidb` script with the **-R CONFIG** parameter.

See "pin_bus_params" in *BRM Developer's Guide* and "pin_multidb" in *BRM System Administrator's Guide* for more information about these utilities.

If you create charge offers in XML using the `ImportExportPricing` utility, you can also configure the maximum retries and their interval at the offer level. See "[Enforcing or Exceeding Credit Limits](#)" for more information. If nothing is configured for the offer, the business parameter is used.

About Rollovers

Learn how rollovers are managed in Oracle Communications Billing and Revenue Management (BRM) product offerings.

Topics in this document:

- [About Rollovers](#)
- [When Rollover Events Occur](#)
- [About Rolling Over Noncurrency Balances during Package Transition](#)
- [About Rolling Over Balances That Expire in Midcycle](#)
- [Prorating Rollover Balances](#)
- [Rollover Example](#)

About Rollovers

A rollover is a type of charge that credits unused balances at the end of a billing cycle to the account balance for the next cycle. For example, minutes are often rolled over from one month to the next. Balances from rollovers are different from granted balances, which are valid between two specific dates.

You define rollovers in charge offers in Oracle Communications Pricing Design Center (PDC). When defining rollovers, you specify the following:

- The period in which the rollover is valid. You can specify start and end time dates.
- The balance to roll over.
- The type of cycle to which the rollover applies (for example, monthly).
- The maximum number of cycles that a balance can be rolled over to.
- The maximum amount that can be rolled over in a cycle.
- The maximum value for a rollover balance.
- A G/L ID for the rollover charge.

BRM maintains each rollover balance as a sub-balance.

BRM validates whether a rollover sub-balance can be rolled over by checking the rules that govern the rollover (such as the amount to roll over, the maximum rollover amount allowed, the maximum number of cycles to roll over, and so on).

When a rollover event occurs, one of three things happens to the rollover sub-balance:

- **If the full amount is eligible for rollover**, BRM does one of the following:
 - If the existing rollover sub-balance has the same properties as the new rollover sub-balance (such as the balance type, rollover rules, valid-from and valid-to dates, sub-balance contributors, and so on), BRM adds the rolled over amount to the existing rollover sub-balance.

- If the existing rollover sub-balance has different properties than the new rollover sub-balance, BRM creates a new rollover sub-balance for the rolled over amount. The rollover sub-balance validity period has the same valid-from date as the original sub-balance, and its valid-to date is extended to the end of the new cycle.
- **If only a portion of the balance is eligible for rollover**, the amount in the rollover sub-balance is divided into a nonrollover sub-balance and a rollover sub-balance. The nonrollover sub-balance has the same valid-to date as the original rollover sub-balance. Its balance is used for late-arriving usage events. The valid-to date for the rollover sub-balance is extended to the end of the new cycle. Its balances are available for the customer to use in the new cycle.
- **If none of the balance is eligible for rollover**, the rollover sub-balance is not changed. This condition occurs when the rollover sub-balance has already been rolled over the maximum number of times allowed. Amounts in this rollover sub-balance are available only for late-arriving usage events.

 **Note:**

BRM memory limits might limit the number of months you can roll over a rollover sub-balance. The number of rollover sub-balances that BRM must maintain varies according to the number of rollover cycles allowed. You set the maximum number of rollover cycles allowed when configuring the rollover balance impact in PDC.

When Rollover Events Occur

Rollover sub-balances can be rolled over to another cycle as soon as they surpass the valid-to date (expire). Most rollover sub-balances expire on the account's billing day of month (DOM). However, some rollover sub-balances may expire in the middle of a cycle due to a charge offer or service cancellation or due to flexible cycles.

Because many BRM features depend on rollover sub-balances being rolled over the day after they expire, BRM rolls over balances at the following times:

- **At the end of the billing cycle:** BRM automatically rolls over all eligible rollover sub-balances to the next cycle as part of the billing process. This catches all rollover sub-balances that expire on the account's billing DOM.
- **When you run the `pin_bill_day` script:** The `pin_bill_day` script automatically runs the `pin_rollover` utility as part of the billing process. The `pin_rollover` utility rolls over any rollover sub-balances that have expired but have not been rolled over to the next cycle. This catches any rollover sub-balances that expired in the middle of the cycle.

About Rolling Over Noncurrency Balances during Package Transition

When your customers transition from one package to another, you can specify that noncurrency balances be rolled over from one package to another if both packages are in at least one package list together.

To specify that noncurrency balances rollover between packages during package transition, you must perform these tasks:

- If you use a custom application for customer management, provide the trigger for controlled rollover in the input list to the PCM_OP_SUBSCRIPTION_TRANSITION_PLAN opcode.
- When you create your package lists, ensure that packages between which you want to allow rollovers are in at least one package list together.

These general rules apply to controlled rollovers:

- Controlled rollovers are not affected by the charge offer cycle rollover settings.
- A controlled rollover does not count as a rollover sub-balance and hence is not restricted to the maximum rollover quantity and the rollover units per period settings for the cycle rollover.
- The cycle grants of noncurrency balances that have been prorated during the package transition are rolled over to the next package.

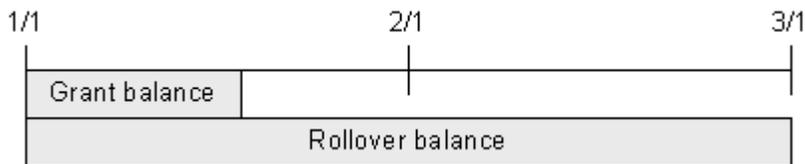

About Rolling Over Balances That Expire in Midcycle

A balance can expire in the middle of a cycle: for example, when the balance is valid for only minutes, hours, or days or when the balance is valid for one or more months and starts in the middle of a month.

If a balance's validity period does not end when the cycle ends, the rollover sub-balance is valid for the entire cycle in which the balance is granted and for the whole of the next cycle.

In [Figure 28-1](#), a monthly cycle event grants 60 minutes that are valid for two weeks from the grant date. The minutes are granted on January 1. On January 14, when the balance of minutes expires, any remaining balances that can be rolled over are added to a new rollover sub-balance, which is valid from January 1 to March 1:

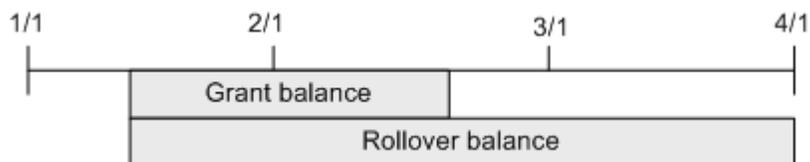

Figure 28-1 Grant and Rollover Balance Date Validity Example 1

The same rollover period applies when the validity period of the minutes ends after the cycle in which they are granted. In [Figure 28-2](#), a monthly cycle event grants 300 minutes that are valid for six week from the grant date. The minutes are granted on January 1. On February 11, when the balance expires, any remaining balances that can be rolled over are added to a new rollover sub-balance, which is valid from January 1 to March 1:

If the balance's validity period does not start at the beginning of the last cycle, the balances are rolled over for one entire cycle.

Figure 28-2 Grant and Rollover Balance Date Validity Example 2

Prorating Rollover Balances

Customers typically purchase and cancel charge offers at some point in the middle of a cycle. When you set up a rollover in PDC, you can specify whether rollover sub-balances are prorated for the first and last cycles based on the number of days in the cycles that the charge offer is owned.

Table 28-1 describes the rollover proration options:

Table 28-1 Rollover Proration Options

Proration Option	Description
Roll over entire amount	Roll over the available monthly rollover balances.
No rollover	Do not roll over any available monthly rollover balances.
Prorate rollover amount	Calculate the rollover balances based on the percentage of the cycle that the customer owned the rollover.

If you choose to prorate the rollover amount, BRM uses the equation in Figure 28-3 to calculate the amount to roll over:

Figure 28-3 Calculation for Amount to Roll Over

$$\frac{\text{ValidFrom} - \text{ValidTo}}{\text{DaysInCycle}} \times \text{Rollover}$$

where:

- *ValidFrom* is the validity period's starting date. For example, if the validity period is from March 15 to April 14, ValidFrom is March 15.
- *ValidTo* is the validity period's ending date. For example, if the validity period is from March 15 to April 14, ValidTo is April 14.
- *DaysInCycle* is the number of days in the current cycle. For example, if the validity period is from March 15 to April 14, DaysInCycle is 31.
- *Rollover* is the available monthly rollover balance, such as 100 minutes.

For example, suppose:

- A customer buys a charge offer on January 15 that grants 500 minutes of use during each cycle.
- A rollover is set up so that up to 200 unused minutes roll over into the following cycle.
- The usage cycle is a calendar month.
- The customer does not use any minutes during the first cycle.

Table 28-2 describes how the rollover is handled, depending on the purchase midcycle proration setting:

Table 28-2 Impact of Proration Options

Proration Option	Amount Rolled Over into February
Roll over entire amount	200 minutes are rolled over from January into February. In February, the customer has 700 minutes (200 rolled over plus the 500 minutes February grant).
No rollover	No minutes are rolled over from January into February. In February, the customer has only the February grant of 500 minutes.
Prorate rollover amount	Approximately 110 minutes are rolled over from January into February: $(17/31) * 200 = 109.67$ In February, the customer has about 610 minutes (110 rolled over plus the 500 minutes February grant).

A similar set of results applies to the last-month proration calculation specified in the cancel midcycle proration setting.

Rollover Example

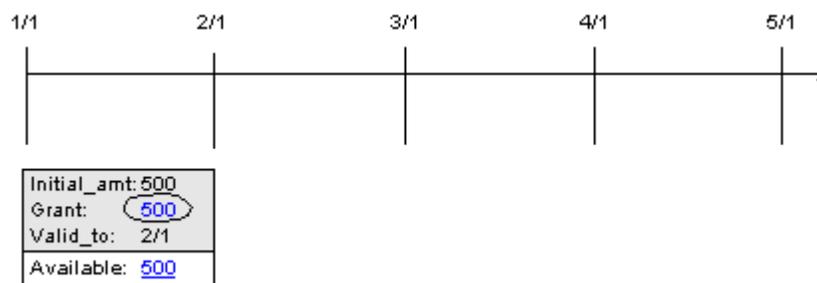

In this example, the customer's charge offer includes:

- 500 minutes granted at the beginning of each usage cycle.
- A rollover specifying that:
 - Up to 100 unused minutes from each month can be rolled over.
 - The maximum number of rollover cycles is 2.
 - A limit of 150 *total* rollover minutes from previous months can be rolled over into a new month.

Other assumptions:

- Cycles are monthly and start on the first day of each calendar month.
 - The charge offer with the rollover is valid starting January 1.
 - The customer consumes no minutes until March.
1. On January 1, the customer is granted 500 minutes for use during January as shown in [Figure 28-4](#). The minutes are maintained in a sub-balance.

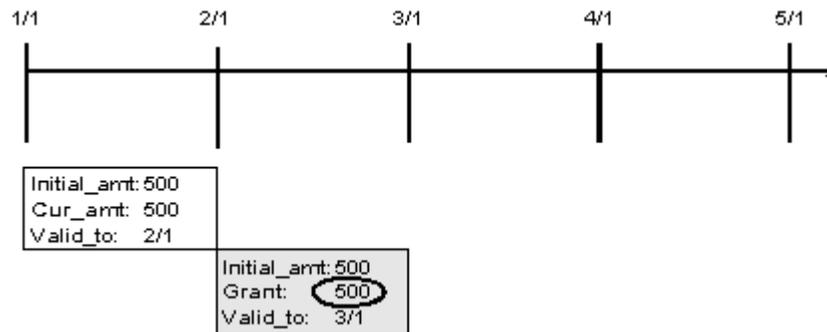

Figure 28-4 Initial 500 Minutes Grant in January

2. On February 1:

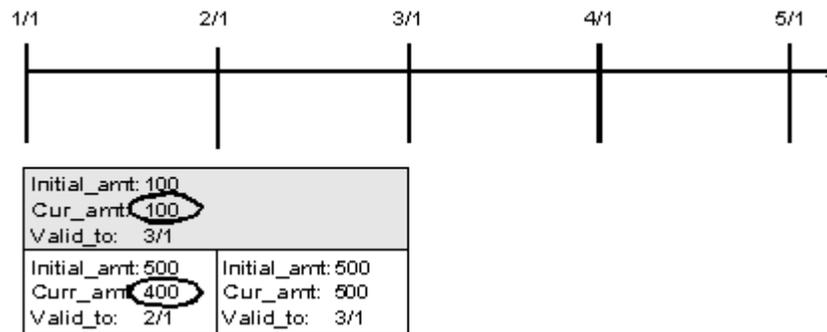

- The cycle forward event creates a new sub-balance to track the grant of 500 minutes for use during February as shown in [Figure 28-5](#).

Figure 28-5 February Minutes Grant

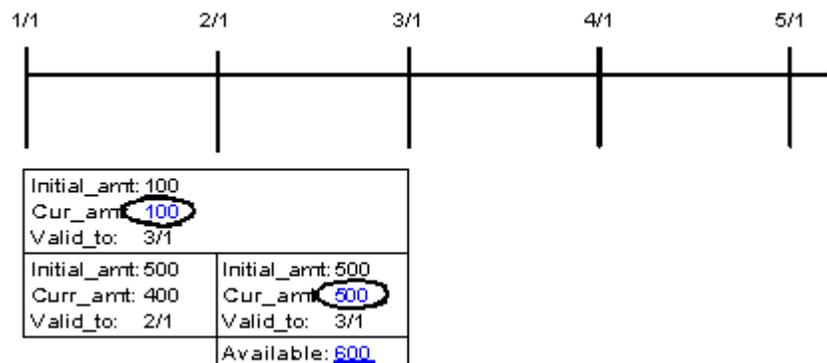

- The cycle rollover event creates a new sub-balance for tracking unused January minutes that roll over into February. 100 minutes are put in the new sub-balance, and they are valid until March 1. The original sub-balance for January is decremented 100 minutes, leaving 400 minutes available for late-arriving January events as shown in [Figure 28-6](#).

Figure 28-6 January Minutes Rollover

The customer now has 600 minutes (500 granted February 1 plus 100 rolled over from January) available for use during February as shown in [Figure 28-7](#).

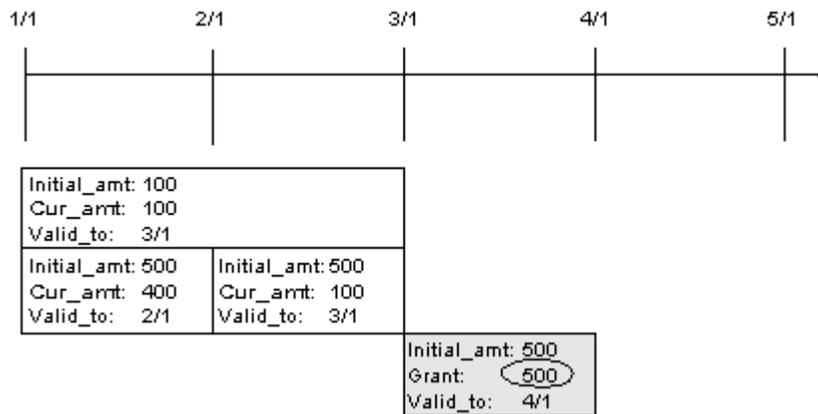

Figure 28-7 February Total Minutes Available

3. On March 1:

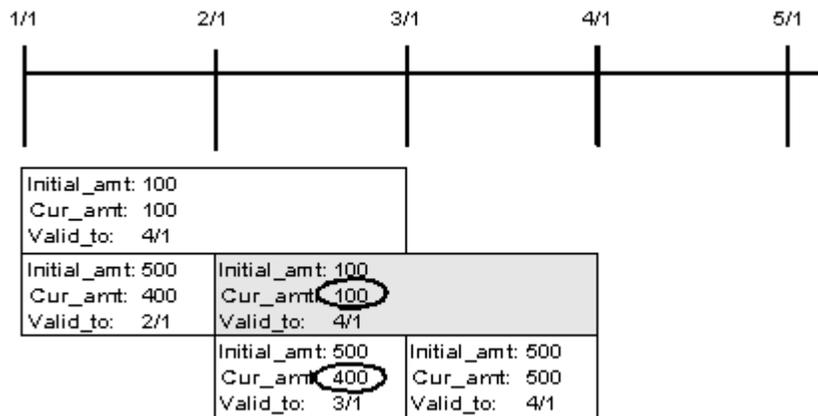

- The cycle forward event creates a new sub-balance to track the grant of 500 minutes for use during March as shown in [Figure 28-8](#).

Figure 28-8 March Minutes Grant

- The cycle rollover event creates a new sub-balance for tracking unused February minutes that roll over into March as shown in [Figure 28-9](#). 100 minutes are put in the new sub-balance, and they are valid until April 1. The original sub-balance for February is decremented by 100 minutes, leaving 400 minutes available for late-arriving February events.

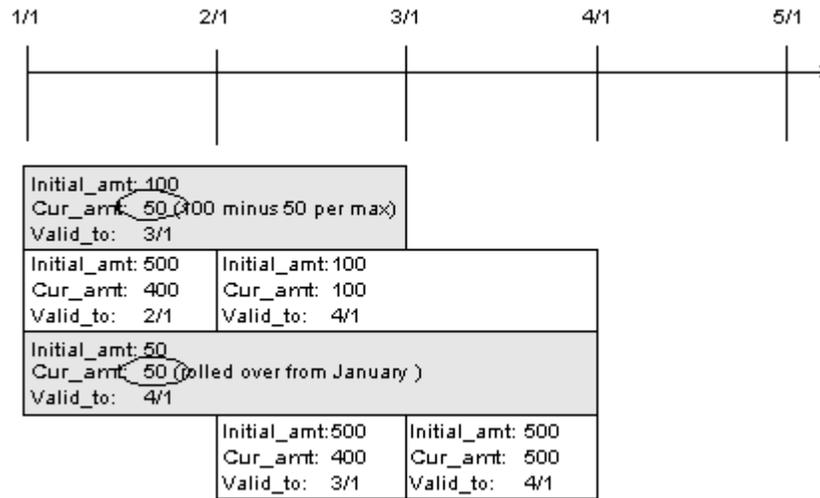

Figure 28-9 February Minutes Rollover

- The cycle rollover event divides the January rollover minutes into two sub-balances to enforce the rule that only 150 *total* rollover minutes for a balance can carry forward into a new month. Because 100 free February minutes are already rolled over, only 50 minutes can be rolled over from the January rollover sub-balance for use in March.

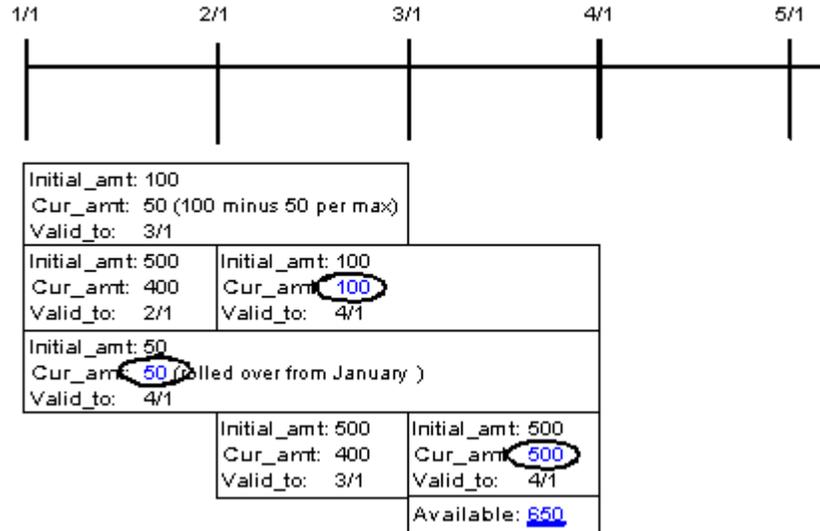

One new sub-balance contains 50 minutes available for use for late-arriving February and January events. The other contains 50 rollover minutes that the customer can use in March. The balances for each month are shown in [Figure 28-10](#).

Figure 28-10 Remaining January Minutes Rollover

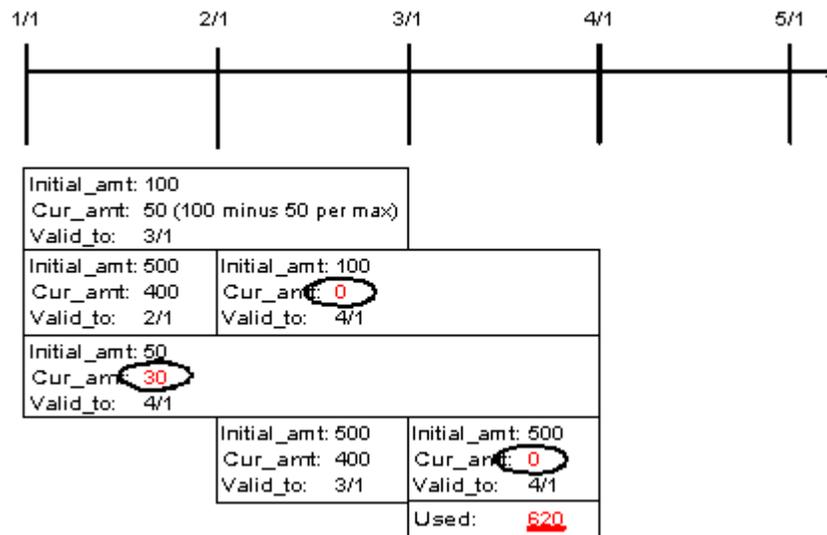

The customer now has 650 minutes (500 granted March 1 plus 100 rolled over from February plus 50 rolled over from January) available for use during March as shown in Figure 28-11.

Figure 28-11 March Total Minutes Available

- During March, the customer consumes 620 minutes as shown in Figure 28-12. Sub-balances are used starting with the newest sub-balance, as indicated by the sub-balance valid-from dates:
 - All 500 minutes from the March grant are consumed, leaving a zero balance.
 - All 100 February rollover minutes are consumed, leaving a zero balance.
 - 20 of the 50 January rollover minutes are consumed, leaving 30.

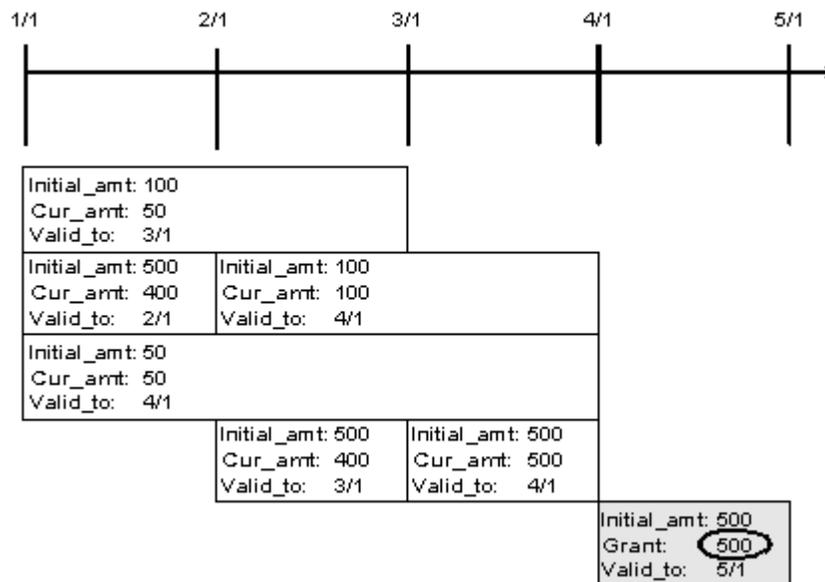

Figure 28-12 March Minutes Usage

- On April 1, the cycle forward event creates a new sub-balance to track the grant of 500 minutes for use during April as shown in Figure 28-13.

No minutes roll over into April from the March and February rollovers because these balances were consumed in March. The 30 minutes remaining from the January rollover are not rolled over into April because the maximum number of cycles a grant can be rolled over is set to 2.

Figure 28-13 April Minutes Grant

The customer has only 500 minutes available for April.

 **Note:**

If two charge offers contributing to the same balance group have rollover charges configured for the same balance with the same rollover frequency, either of the charge offers can be used to roll over the balances. In this case, rollover results may vary depending on the charge offer that is selected first.

Configuring Balance Impact Rounding

Learn how to configure balance impact rounding rules in Oracle Communications Billing and Revenue Management (BRM) product offerings.

Topics in this document:

- [About Balance Impact Rounding](#)
- [Configuring Balance Impact Rounding](#)
- [Configuring Balance Impact Rounding in ECE](#)

About Balance Impact Rounding

BRM enables you to create various rounding rules for different balance elements, events, and processes such as rating and discounting. You create rounding rules for several reasons:

- To increase the accuracy of rating and discounting results.
- To process usage fees more efficiently. For example, an infinite number such as 5.333... is more easily processed when it is rounded.
- To round for various currencies that use a different number of digits to the right of the decimal (for example, 10.25 dollars and 10 yen).
- To comply with currency conversion rules.
- To bill customers an amount that they can actually pay.

About Rounding Rules

You can configure balance impact rounding based on the following rounding criteria:

- The *rounding scale* is the number of significant digits to the right of the decimal point. For example, a scale of 2 applied to 10.321111 rounds to 10.32.
- The *rounding mode* defines whether the number is rounded up, down, or not at all, based on the value of the digit following the last significant digit. See "[About Rounding Modes](#)".
- The process to which the rounding configuration applies. You can specify one of these processes: rating, discounting, taxation, and accounts receivable (A/R). A/R includes actions such as billing, payments, adjustments, cancellations, and G/L reporting.

Specifying the process enables you to round differently based on the operation. For example, you can round up using six decimal places for rating and round down using two decimal places for billing.

- The event type to which the rounding configuration applies. This enables you to round differently for events that represent specific types of usage, cycle fees, discounts, and rollovers. For example, US dollars and purchase events (**levent/purchase**).

[Table 29-1](#) show how a US dollars balance element and purchase event combination can be rounded various ways for various processes:

Table 29-1 Currency Balance Element and Event Type

For a US Dollars Balance Element	For This Process	Use This Rounding Scale	Use This Rounding Mode
Event type = /event/billing/product/fee/purchase	Rating	6	Down
Event type = /event/billing/product/fee/purchase	Discounting	6	Up
Event type = /event/billing/product/fee/purchase	A/R	2	Nearest
Event type = /event/billing/product/fee/purchase	Taxation	2	Nearest

You can specify any combination of scale and mode for balance element, event, and process combinations.

After each process that performs rounding (rating, discounting, and so forth), the balance impact of the event contains the rounded amount.

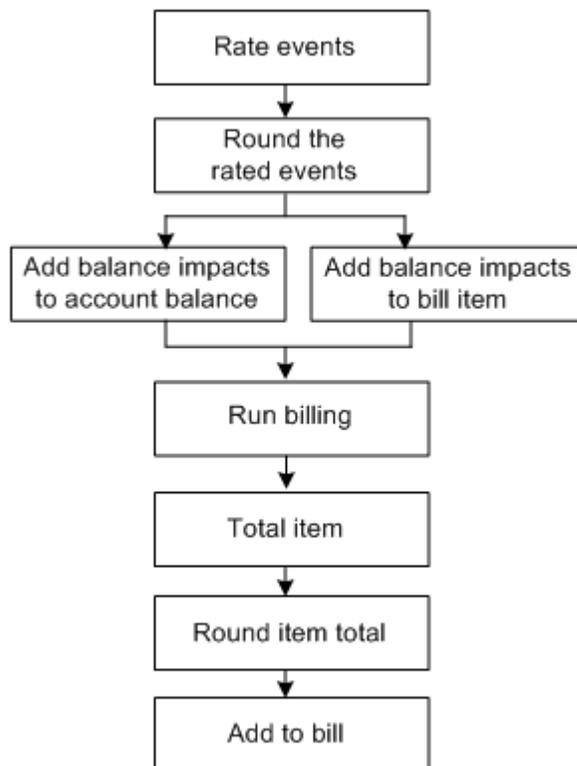

How BRM Applies Rounding

Rating, discounting, and taxation produce balance impacts, which are rounded and applied to the customer's account balance. The balance impacts are rounded to the scale and mode configured for the event, balance element, and process combination.

Balance impacts for an account are stored in bill items, which are associated with the customer's bill. When you run billing, the item totals are rounded according to the A/R rounding rule. Item totals are rounded before being added to the bill so that the bill itself never needs rounding. Before billing, item totals are unrounded and their amounts reflect the scale configured for the associated events.

Figure 29-1 show the general process of balance impact rounding:

Figure 29-1 BRM Balance Impact Rounding

Assuming that rounding is configured for all events and all processes (rating, discounting, taxation, and A/R), rounding is performed in the following order:

- 1. Purchase and cycle fees.** When a package is purchased, the purchase and cycle fees are rounded, if necessary, and a balance impact is generated with the rounded amount. Purchase and cycle fees typically only need rounding when a user purchases or cancels an offer in the middle of the billing cycle. In this case, cycle fees and noncurrency grant amounts are prorated, if necessary, and then rounded.
- 2. Usage fees.** As customers use their services, the usage events are rated, the usage fees are rounded, and balance impacts are generated with the rounded amounts.
- 3. Discount fees.** If a usage discount applies, the discount is calculated on the rounded usage fee, and then the discount is rounded and a discount balance impact is generated with the rounded amount. If there are multiple usage discounts, each discount is rounded in sequence.
- 4. Taxes.** If tax should be applied to the event, the tax is calculated on the rounded fee, and then the tax is rounded and a balance impact is generated with the rounded amount.
- 5. Billing discounts.** When you run billing, if a billing-time discount applies, it is applied to the total of the rounded usage items, and then the discount is rounded and a discount balance impact is generated with the rounded amount.
- 6. Bills.** When the bill is generated, the total amount in each item is rounded, and then all item totals are summed and included in the bill.
- 7. Rollover.** If there are any rollover amounts, the rollover is calculated on the total rounded usage, and then the rollover amount is rounded and applied to the next billing cycle. For example, if 100 minutes can be rolled over and the customer used 60.4 minutes, the

unused amount of 39.6 minutes is rounded and then added to the account balance for the next cycle.

To round for rollover, you configure a rounding rule for the noncurrency balance element and cycle forward event combination. Rollovers are typically rounded up.

About Rounding and A/R Actions

When entering amounts for A/R actions such as adjustments and refunds, customer service representatives (CSRs) typically use a *natural scale*: that is, the scale commonly used in the marketplace for that balance element. For example, a person who purchases a book using US dollars cannot make change smaller than one cent (.01 dollars), making 2 the natural scale for US dollars. However, if a CSR reverses or adjusts an event before billing, the scale used is the one in the event's balance impact. By default, this is the natural scale, unless you change this to use a scale other than natural.

About Rounding Billed and Unbilled Items

The balance impacts of events associated with items can have a high scale. Before billing, item totals reflect the scale of their associated events. During billing, item totals are rounded using the A/R rounding configuration so that customers' bills display the natural scale for the balance element. However, the events associated with billed items still retain their pre-billing scale.

If any operation is performed on billed items: for example, event and item adjustments, BRM rounds the balance impact of the operation according to the A/R rounding rule to maintain G/L integrity. Because actions on billed items are rounded when they occur, only pending items are rounded when billing is run.

About Rounding for Specific Event Types

When you configure a rounding rule for a specific event type, such as cycle or session events, that rounding rule applies to those events only for the process specified. If you do not configure a rule for every process, all other processes for that event type use the default rounding rule. The default rounding rule specifies natural scale for all events and the rounding mode most commonly used for the process. A rule for all events is specified by using an asterisk (*) as the default event type.

For example, given the configuration in [Table 29-2](#), during rating, session events are rounded down and have a scale of 6. During taxation, however, session events use the default rule of rounding to the nearest with a scale of 2:

Table 29-2 Rounding for Specific Event Types

Balance Element	Event Type	Process	Rounding Scale	Rounding Mode
US dollars	/event/session	Rating	6	Down
US dollars	* (all events)	Taxation	2	Nearest

About Rounding Counter Balances for Discounting

For discount rounding, the rounding configurations are used to round only the balance impacts of discounting, not input balances, such as counters. To configure counter rounding, see "[Configuring Rounding Rules for Counter Balances](#)".

About G/L Report Rounding

G/L report rounding uses the rounding rule configured for A/R actions. The rounded totals in G/L reports might differ slightly from the total of the rounded bills. This is because item totals are rounded for billing, and journal entries are rounded for G/L reports. Also, G/L reports are rounded differently before and after billing. For more information, see "About Rounding and G/L Reports" in *BRM Collecting General Ledger Data*.

If there is any difference between the rounded journal entries in G/L reports and the rounded bill items, BRM records the difference in the G/L. You configure a G/L ID for the rounding difference and configure BRM to record the differences. See "[Configuring to Record Rounding Differences in the G/L](#)".

About Rounding Modes

A rounding mode defines whether a number is rounded up, down, or not at all. The rounding mode rounds to the specified scale. For example, using a scale of 2, rounding up 10.2369 results in 10.24. If the scale is 3, rounding up results in 10.237.

The following rounding mode values that you can use are defined in the *BRM_home/include/pin_bill.h* file:

- 0: PIN_BEID_ROUND_NEAREST
This mode rounds up or down depending on the value of the digit following the last significant digit. If the additional digit is 0-4, the last significant digit remains the same. If the additional digit is 5-9, the last significant digit is rounded up. For example, if the scale is 2, 10.144 rounds to 10.14 and 10.145 rounds to 10.15. This is the most common rounding method.
- 1: PIN_BEID_ROUND_UP
This mode rounds up when the digit following the last significant digit is greater than 0. For example, if the scale is 2, 10.151 rounds to 10.16. If the scale is 1, it rounds to 10.2.
- 2: PIN_BEID_ROUND_DOWN
This mode truncates all digits following the last significant digit. For example, if the scale is 2, 10.159 rounds to 10.15. If the scale is 1, it rounds to 10.1.
- 3: PIN_BEID_ROUND_EVEN
This mode rounds one of three ways depending on the value of the digit following the last significant digit:
 - If it is less than 5, truncate all digits following the last significant digit.
 - If it is greater than 5, round up.
 - If it is 5, round to the nearest even digit. For example, if the scale is 2, 10.155 and 10.165 both round to 10.16 because 6 is an even number.
- 4: PIN_BEID_ROUND_FLOOR
This mode rounds numbers toward a negative value (that is, the rounded number is always less than the unrounded number). This enables you to round balance impacts so that customers always benefit. For example, if the scale is 2, a credit to a customer of -7.999 is rounded to -8.00, and a debit of 7.999 is rounded to 7.99.
- The following two modes perform the same rounding as their nonalternative counterparts (ROUND_FLOOR and ROUND_DOWN), except that they compensate for possible loss of

precision when rounding down by first rounding with a mode of NEAREST using a scale that is two digits greater than the scale you configure.

- 5: PIN_BEID_ROUND_FLOOR_ALT
- 6: PIN_BEID_ROUND_DOWN_ALT

For more information, see "[About Rounding Modes That Correct for Loss of Precision](#)".

About Rounding Modes That Correct for Loss of Precision

Some calculations produce results that are slightly less than expected when a value is rounded down. For example, when BRM prorates a \$60.00 cycle fee for 20 out of 30 active days, the calculation is $(20/30) * \$60.00$. The expected result is a fee of \$40.00. However, because 20/30 evaluates to 0.666, when this is multiplied by 60 and rounded down, the actual result is a fee of \$39.99.

BRM provides two alternative rounding modes that compensate for possible precision loss when rounding down: ROUND_DOWN_ALT and ROUND_FLOOR_ALT. These modes perform the same rounding as their nonalternative counterparts (ROUND_DOWN and ROUND_FLOOR) after first compensating for loss of precision.

Note:

ROUND_DOWN_ALT and ROUND_FLOOR_ALT are not supported in the BRM PCM Java API and in discount expressions.

When these modes are used, if a decimal should be rounded down, BRM performs two rounding functions: The decimal is rounded by using the ROUND_NEAREST rounding mode and a scale that is two more than the scale that you request. It is then rounded down.

For example, if you configure the rounding mode as ROUND_DOWN_ALT and a rounding scale of 2, and the decimal to round is 7.999..., BRM truncates the infinite decimal to the system maximum and then rounds this decimal to the nearest using a scale of 4 (2 more than the configured scale of 2), which results in 8.0000. This decimal is then rounded down using the configured scale of 2, resulting in 8.00 as shown in [Table 29-3](#):

Table 29-3 Rounding Modes That Correct for Precision

Do This	Why
7.999...	Original decimal
7.999999999999999	Truncated to the system max
8.0000	ROUND_NEAREST, using requested scale + 2
8.00	ROUND_DOWN to the requested scale of 2

Had the original decimal of 7.999... not been rounded to the nearest first and only rounded down, the result would be 7.99.

To compensate for possible loss of precision, the alternative rounding modes consider two decimal places more than the nonalternative rounding modes. Therefore, the greatest amount that will be modified by using the alternative rounding modes, and still compensate for loss of precision, is less than the greatest amount that will be modified by using the nonalternative rounding modes.

When Rounding Is Not Applied

When the requested rounding scale is greater than the scale of the number being processed, rounding is not required. This occurs when:

- You configure a rounding scale equal to or greater than the maximum number of digits allowed by the system. For example, if the system allows 15 digits and you set the rounding scale to 15 or greater, rounding has no effect.
- You call a rounding function and request a scale that is equal to or greater than the current scale of the decimal: for example, when the decimal is 10.89766 and the scale requested is 5 or greater.
- A computation or expression results in a decimal with a scale that is equal to or less than the configured or requested scale: for example, when a computation results in the decimal 1.98 and the configured scale is 2 or greater.

Configuring Balance Impact Rounding

To set up rounding, perform the following tasks:

- [Configuring Rounding Rules for Counter Balances](#)
- [Configuring to Record Rounding Differences in the G/L](#)

About Configuring Rounding Rules

You configure rounding for balance element and event type combinations (for example, US dollars and **!event/session/telco/gsm** events). For each balance element and event combination, you specify a rounding scale, a rounding mode, and the process for which this rule applies.

 **Note:**

You do not need to configure rounding for all of the processes. However, you must configure rounding for every balance element and event type that has a balance impact.

About Rounding Mode Values in the BRM API

The rounding modes you specify have corresponding modes in the BRM API. When BRM invokes a decimal data type function, it converts the rounding mode in the **!config/beid** object into the corresponding rounding parameter used by the decimal data type function. If you call decimal data type functions in custom applications, specify the function's rounding mode, not the BEID rounding mode.

[Table 29-4](#) shows the BEID rounding modes and the corresponding rounding parameters for the decimal data type functions:

Table 29-4 BEID Rounding Modes

BEID Rounding Mode (specified in pin_bill.h)	Rounding Mode Parameter for pbo_decimal functions
0: PIN_BEID_ROUND_NEAREST	5: ROUND_HALF_UP
1: PIN_BEID_ROUND_UP	1: ROUND_UP
2: PIN_BEID_ROUND_DOWN	2: ROUND_DOWN
3: PIN_BEID_ROUND_EVEN	7: ROUND_HALF_EVEN
4: PIN_BEID_ROUND_FLOOR	4: ROUND_FLOOR
5: PIN_BEID_ROUND_FLOOR_ALT	8: ROUND_FLOOR_ALT
6: PIN_BEID_ROUND_DOWN_ALT	9: ROUND_DOWN_ALT
N/A	3: ROUND_CEILING
N/A	6: ROUND_HALF_DOWN
N/A	10: ROUND_UNNECESSARY

Configuring Rounding Rules for Counter Balances

You use Oracle Communications Pricing Design Center (PDC) to configure rounding rules for counter balances. When you configure discounts, use discount expressions to specify how to round the balance. Use the following discount expression syntax:

```
round(expression, rounding_scale, rounding_mode)
```

where *expression* defines the balance to round. This can be any discount expression. To round a counter balance, use the **Balance** expression. For more information, see the discussion about configuring discounts in PDC Help.

For example, to round a counter balance down to two decimal places for balance element ID 100099, use the following expression:

```
round( Balance(100099), 2, ROUND_DOWN )
```

About Rounding Modes for Discount Expressions

Rounding modes for discount expressions have slightly different names. [Table 29-5](#) lists the rounding mode values you can specify.

Table 29-5 Rounding Modes for Discount Expressions

Discount Expression Rounding Mode	Rounding Mode
ROUND_PLAIN	Nearest
ROUND_UP	Up
ROUND_DOWN	Down
ROUND_BANKERS	Even

For a definition of what these modes represent, see "[About Rounding Modes](#)".

Configuring to Record Rounding Differences in the G/L

To record any difference between rounded bill items and the rounded total in the G/L, perform the following tasks:

- [Defining a G/L ID for Rounding Differences](#)
- [Mapping the Rounding G/L ID to an Event](#)
- [Configuring BRM to Record Rounding Differences](#)

For information about how rounding is performed in G/L reports, see "About Rounding and G/L Reports" in *BRM Collecting General Ledger Data*.

Defining a G/L ID for Rounding Differences

You define a G/L ID for rounding to include the rounding difference in G/L reports so that they can be accurately reconciled.

To define G/L IDs, you edit the G/L ID configuration file and then run the **load_pin_glid** utility to load the contents of the file into the **/config/glid** object in the BRM database.

 **Note:**

The **load_pin_glid** utility needs a configuration (**pin.conf**) file in the directory from which you run the utility.

To define a rounding G/L ID:

1. If necessary, edit the G/L ID configuration file in *BRM_home/sys/data/pricing/example/pin_glid*. If the following entry is not present, add it:

```

#=====
# G/L ID for rounding adjustments
#=====
glid
id 1512
descr Rounding Epsilon
gl_acct billed      gross   rounding.debit  rounding.credit
gl_acct billed      net     rounding.debit  rounding.credit
gl_acct billed      disc    rounding.credit  rounding.debit
gl_acct billed_earned gross   rounding.debit  rounding.credit
gl_acct billed_earned net     rounding.debit  rounding.credit
gl_acct billed_earned disc    rounding.credit  rounding.debit
gl_acct unbilled    gross   rounding.debit  rounding.credit
gl_acct unbilled    net     rounding.debit  rounding.credit
gl_acct unbilled    disc    rounding.credit  rounding.debit
gl_acct unbilled_earned gross   rounding.debit  rounding.credit
gl_acct unbilled_earned net     rounding.debit  rounding.credit
gl_acct unbilled_earned disc    rounding.credit  rounding.debit
)

```

 **Note:**

The **load_pin_glid** utility overwrites existing G/L IDs. If you are updating G/L IDs, you cannot load new G/L IDs only. You must load complete sets of G/L IDs each time you run the **load_pin_glid** utility.

2. Save and close the file.
3. Use the following command to run the **load_pin_glid** utility:

```
load_pin_glid pin_glid_file
```

Mapping the Rounding G/L ID to an Event

Because the rounding difference is not a rated event, you must map the G/L ID to an event type. G/L ID mapping is defined in the **reasons.locale** file. You can find a sample of this file in the **BRM_home/sys/messages/reasoncodes** directory. The sample file is named **reasons.en_US** and contains the following default entry for the rounding G/L ID mapping:

```
DOMAIN = "Others" ;
STR
    EVENT-GLID
        .
        .
        .
        /event/journal/epsilon"          1512 ;
    EVENT-GLID-END
```

 **Note:**

/event/journal/epsilon is a dummy event type used for reference only.

To change the G/L ID for rounding, you must edit and reload the file. The G/L ID you define in the **reasons.locale** and **pin_glid** files must match. See "[Configuring to Record Rounding Differences in the G/L](#)".

To map the G/L ID for rounding to an event, you use the **load_localized_strings** utility to load the contents of the file into the **/config/map_glid** object. When you run the **load_localized_strings** utility, use this command:

```
load_localized_strings reasons.locale
```

 **Note:**

- If you are loading a localized version of this file, use the correct file extension for your locale.
- The **load_localized_strings** utility overwrites the existing G/L ID maps. If you are updating this object, you cannot load new G/L ID maps only. You must load complete sets of G/L ID maps each time you run the **load_localized_strings** utility.

For information on loading the **reasons.locale** file, see "Creating a Localized Version of BRM" in *BRM Developer's Guide*.

Configuring BRM to Record Rounding Differences

By default, rounding differences are not recorded in G/L reports. You can enable recording the difference between rounded bill items and the rounded total by running the **pin_bus_params** utility to change the **GenerateJournalEpsilon** business parameter. For information about this utility, see *BRM Developer's Guide*.

To enable BRM to record rounding differences:

1. Go to `BRM_home/sys/data/config`.
2. Create an XML file from the `/config/business_params` object:
`pin_bus_params -r BusParamsBilling bus_params_billing.xml`

3. In the file, change **disabled** to **enabled**:

```
<GenerateJournalEpsilon>enabled</GenerateJournalEpsilon>
```

4. Save the file as `bus_params_billing.xml`.
5. Load the XML file into the BRM database:
`pin_bus_params bus_params_billing.xml`
6. Stop and restart the CM.
7. (Multischema systems only) Run the `pin_multidb` script with the **-R CONFIG** parameter. For more information, see *BRM System Administrator's Guide*.

Rounding Examples

Rounding is performed after rating, discounting, taxation, and A/R actions such as billing and adjustments.

Table 29-6 shows the resulting balance impacts of rounded charges for rating, discounting, taxation, and billing. This example rounds to the nearest mode and uses these scales:

- 2 for purchase events, taxation, and A/R
- 5 for rating and discounting

Table 29-6 Rounding Examples

Action / Process	Calculated Charge	Rounded Charge & Balance Impact	Account Balance
Purchase package Rate cycle fee	9.95	9.95	9.95
Use service Rate usage	5.23456789	5.23457	15.18456
Discount usage fee 10%	0.523456789	0.52346	14.66111
Tax usage event 3% (after discount)	0.1413333 = 3% * (rounded usage fee - rounded discount)	0.14	14.80111

Table 29-6 (Cont.) Rounding Examples

Action / Process	Calculated Charge	Rounded Charge & Balance Impact	Account Balance
Run billing Apply billing-time discount of 5% off total usage	0.24250... = 5% * usage item total after A/R rounding (The usage total does not include the cycle fee.)	0.2425	14.55861
Create bill	14.55861 = Total of all items	14.56 (No balance impact)	14.56

Correcting for Precision Loss When Rounding Down

This example shows the results of rounding when you use the ROUND_DOWN_ALT and ROUND_FLOOR_ALT modes. For more information, see ["About Rounding Modes That Correct for Loss of Precision"](#).

The ROUND_DOWN_ALT and ROUND_FLOOR_ALT modes produce different results than ROUND_DOWN and ROUND_FLOOR only when the three digits following the last significant digit are 995 or greater. (The last significant digit is the digit in the decimal place corresponding to the scale: If the scale is 2, the last significant digit in the number 1.23456 is 3.)

For example:

[Table 29-7](#) shows some rounding results of the ROUND_DOWN_ALT and ROUND_FLOOR_ALT modes as compared to their nonalternative rounding counterparts (ROUND_DOWN and ROUND_FLOOR) for various decimal values and rounding scales.

Table 29-7 Rounding Results

Decimal	Scale	Rounding Mode	Rounding Mode	Rounding Mode	Rounding Mode
NA	NA	DOWN	DOWN_ALT	FLOOR	FLOOR_ALT
1.5256	2	1.52	1.52	1.52	1.52
-1.5256	0	-1	-1	-2	-2
12.8999...	0	12	12	12	12
12.8999...	1	12.8	12.9	12.8	12.9
12.8999...	2	12.89	12.90	12.89	12.90
-12.8999...	1	-12.8	-12.9	-12.8	-12.9
-12.8999...	2	-12.89	-12.900	-12.89	-12.90
-6.9990	2	-6.99	-6.99	-7.00	-7.00
-6.9990	3	-6.999	-6.999	-6.999	-6.999
7.999...	0	7	8	7	8
7.999...	1	7.9	8.0	7.9	8.0
7.999...	2	7.99	8.00	7.99	8.00
-7.999...	0	-7	-8	-8	-8
-7.999...	2	-7.99	-8.00	-8.00	-8.00

Rounding Using Different Modes

The aggregated effects of rounding on the final balance impact is determined by the mode and scale that you configure. The higher the scale, the less effect the rounding mode has on the final balance impact.

For example, [Table 29-8](#) shows the impact of various rounding mode combinations for rating a usage fee of \$1.1234567 that includes a 10% discount. Both rating and discounting use a scale of 6:

Table 29-8 Rounding Modes

Processing Stage (Rating and Discounting)	Rating: Round Down Discounting: Round Down	Rating: Round Down Discounting: Round Up	Rating: Round Up Discounting: Round Down	Rating: Round Up Discounting: Round Up
Round for rating	1.123456	1.123456	1.123457	1.123457
Calculate 10% discount	.1123456	.1123456	.1123457	.1123457
Round discounted amount	.112345	.112346	.112345	.112346
Apply discount to usage fee to get final balance impact	1.011111	1.011110	1.011112	1.011111

In this example, the difference in the final balance impacts is small because the scale is high and probably will not change the final amount on the bill. However, when many events are summed in an item, or the scale is small, such as 2 or 3, the differences become greater.

 **Note:**

If you calculate the discount without rounding the event, the configuration where rating is rounded down and discounting is rounded up returns the most accurate result. Therefore, this is the best mode configuration to use when you discount events.

Configuring Balance Impact Rounding in ECE

You can configure rounding for a currency and noncurrency balance impact by specifying rules for how Oracle Communications Elastic Charging Engine (ECE) rounds the rating impact amounts it calculates. The rules you specify are applied at the system level so the rounding of the rating impact amounts apply across all charges, discounts, and chargeshares. The rounding is also applied to reverse rating calculations and taxation calculations.

The rules you can specify for rounding are as follows:

- Scale
You can specify a rule for how many digits to the right of the decimal point to allow. The default scale is **2**.
- Rounding mode

You can specify a rule for the rounding behavior according to the Java math rounding enum. The default is **HALF_UP**.

See the Java SE API Reference documentation for information about using the Java math rounding enum.

For information about configuring rounding for currency and noncurrency balance impacts, see "[Configuring Rounding for a Currency Balance Impact](#)" and "[Configuring Rounding for a Noncurrency Balance Impact](#)".

Example of Currency Rounding for a Charge

If you allow two digits to the right of the decimal point and you round down towards zero (**DOWN** rounding mode), ECE takes a calculated charge of 0.509 USD and rounds it to 0.50 USDs.

Example of Noncurrency Rounding for a Charge

If you allow zero digits to the right of the decimal point and you round towards positive infinity (**UP** rounding mode), ECE takes a charge of 0.509 bonus point and rounds the value to 1 bonus point.

Examples of Currency Rounding for Discounts

If you allow zero digits to the right of the decimal point and you round down towards zero (**DOWN** rounding mode), ECE takes a discount of -2.5 USD and rounds the value to -2 USD.

If you allow zero digits to the right of the decimal point and you round towards negative infinity (**FLOOR** rounding mode), ECE takes a discount of -2.5 USD and rounds the value to -3 USD.

If you allow two digits to the right of the decimal point and you round down towards zero (**DOWN** rounding mode), ECE takes a discount of -0.075 USD and rounds the value to -0.07 USD.

Configuring Rounding for a Currency Balance Impact

You can configure rounding for a currency balance impact by specifying rules for how ECE rounds the rating impact amounts it calculates.

The rules you specify are applied as a systemwide configuration for rounding the rating impact amounts of all charges, discounts and chargseshares. The rounding is also applied to all reverse rating calculations and taxation calculations.

See "[Configuring Rounding for a Noncurrency Balance Impact](#)" for information about configuring rounding for noncurrency balance impacts.

To configure rounding for a currency balance impact:

1. Access the ECE configuration MBeans:
 - a. Log on to the driver machine.
 - b. Start the ECE charging servers (if they are not started).
 - c. Connect to the ECE charging server node enabled for JMX management.

This is the charging server node set to **start CohMgt = true** in the *ECE_home/occeserver/config/eceTopology.conf* file.
 - d. Start a JMX editor that enables you to edit MBean attributes, such as JConsole.
 - e. In the editor's MBean hierarchy, find the ECE configuration MBeans.

2. Expand the **ECE Configuration** node.
3. Expand **charging.server**.
4. Expand **Attributes**.
5. Specify values for the following attributes:
 - **currencyScale**: Enter the number of digits you allow to the right of the decimal point for a calculated impact amount.
For example, enter **2** if you allow two digits to the right of the decimal point.
The default is **2**.
 - **currencyRoundingMode**: Enter the rounding mode that determines the rounding behavior by entering the string representation of the Java math rounding enum.
See the Java SE API Reference documentation for information about using the Java math rounding enum.
For example, enter **UP** to round up away from zero or **DOWN** to round down towards zero.
The default is **HALF_UP**.
6. Save your changes.

Configuring Rounding for a Noncurrency Balance Impact

You can configure rounding for a noncurrency balance impact. The rules you specify are applied as a systemwide setting and apply for rounding the rating impact amounts of all charges, discounts, and chargeshares. The rounding is also applied to all reverse rating calculations and taxation calculations.

To configure rounding for a noncurrency balance impact:

1. Access the ECE configuration MBeans:
 - a. Log on to the driver machine.
 - b. Start the ECE charging servers (if they are not started).
 - c. Connect to the ECE charging server node enabled for JMX management.
This is the charging server node set to **start CohMgt = true** in the *ECE_home/occeserver/config/eceTopology.conf* file.
 - d. Start a JMX editor that enables you to edit MBean attributes, such as JConsole.
 - e. In the editor's MBean hierarchy, find the ECE configuration MBeans.
2. Expand the **ECE Configuration** node.
3. Expand **charging.server**.
4. Expand **Attributes**.
5. Specify values for the following attributes:
 - **nonCurrencyScale**: Enter the number of digits you allow to the right of the decimal point for a calculated impact amount.
For example, enter **2** if you allow two digits to the right of the decimal point.
The default is **2**.
 - **nonCurrencyRoundingMode**: Enter the rounding mode that determines the rounding behavior by entering the string representation of the Java math rounding enum.

See the Java SE API Reference documentation for information about using the Java math rounding enum.

For example, enter **UP** to round up away from zero or **DOWN** to round down towards zero.

The default is **HALF_UP**.

6. Save your changes.

For information about configuring rounding for currency balance impacts, see "[Configuring Rounding for a Currency Balance Impact](#)".

Configuring Rounding When Authorizing Multiple RUMs

When ECE receives an online charging request for a specified amount of usage, ECE uses the customer's product offerings to determine if the customer's balance amount is sufficient for the requested amount. If the request applies to multiple RUMs; for example, occurrence and duration, fractional values of the authorized balance quantity might result. You can enable ECE to round up the authorized balance quantities to the nearest whole number.

If your business requires that your customers must be able to use *all* of their balances, configure ECE to round up the authorized balance quantity. However, rounding up the authorized balance quantity may result in customers exceeding their credit limits.

You configure whether to round up the fractional value of the impacted balance quantity as a systemwide setting. ECE authorizes an additional RUM unit when the quantity is a fraction.

To configure rounding when authorizing multiple RUMs:

1. Access the ECE configuration MBeans:
 - a. Log on to the driver machine.
 - b. Start the ECE charging servers (if they are not started).
 - c. Connect to the ECE charging server node enabled for JMX management.

This is the charging server node set to **start CohMgt = true** in the *ECE_home1/occeserver/config/eceTopology.conf* file.
 - d. Start a JMX editor that enables you to edit MBean attributes, such as JConsole.
 - e. In the editor's MBean hierarchy, find the ECE configuration MBeans.
2. Expand the **ECE Configuration** node.
3. Expand **charging.server**.
4. Expand **Attributes**.
5. Set the **reverseRateUseAllBalances** attribute to one of the following values:
 - To round up the fractional value of the authorized balance quantity, enter **true**.

This option allows customers to use all balances even if they might exceed their credit limits by a small amount.
 - To disallow the fractional value of the authorized balance quantity to be rounded up, enter **false**.

This option does not allow customers to exceed their credit limits.

The default is **false**.

6. Save your changes.

Part V

XML Pricing Interface for PDC

This part describes how to use the Pricing Design Center (PDC) XML Pricing Interface to create product offerings.

This part contains the following chapters:

- [Importing and Exporting Pricing and Setup Components](#)
- [XML Examples of Creating Pricing Components](#)
- [PDC XML Tags](#)

Importing and Exporting Pricing and Setup Components

Learn how to import and export pricing and setup components in Oracle Communications Billing and Revenue Management (BRM) by using the **ImportExportPricing** utility.

Topics in this document:

- [About Using the XML Pricing Interface to Create Product Offerings](#)
- [About the ImportExportPricing Utility](#)
- [Exporting Pricing and Setup Components from PDC](#)
- [Importing Pricing and Setup Components](#)
- [Listing Pricing or Setup Components](#)
- [Publishing Setup Components](#)
- [Deleting Setup Components](#)

About Using the XML Pricing Interface to Create Product Offerings

As an alternative to using PDC, you can create and modify product offerings in an XML file and then use the **ImportExportPricing** command-line utility to do the following:

- Import all or some product offerings configured in an XML file into the PDC database.
The utility creates any new pricing and setup components, and modifies any changed components in the PDC database.
- Export all or some product offerings from the PDC database into an XML file for editing.
If you export the data into an existing XML file, the utility overwrites the entire XML file.

You can also use the **ImportExportPricing** utility to move product offerings from a PDC database to another PDC database.

To create or modify product offerings in an XML file, you use a text editor or an XML editor. You define the pricing and setup components that you want to create by adding XML tags to the file. See "[PDC XML Tags](#)" for information about the required and optional XML tags. You can add the XML tags to:

- One consolidated XML file containing all of the pricing or setup components
- Separate XML files for each type of pricing or setup component

For information about the PDC XML tags that you use to create pricing and setup components, see "[PDC XML Tags](#)".

The XML files that you create must conform to the format detailed in the XSD files for pricing or setup components. See "[About the XSD Files](#)" for more information.

Some pricing components have dependencies on other pricing and setup components. Before loading such pricing components, ensure that the prerequisite data is available in the PDC database. See [Table 30-1](#) for more information.

If you create XML files for specific pricing or setup components, you must load the XML files in the order based on the dependencies. See "[About Dependencies between Pricing and Setup Components](#)" for more information.

About the ImportExportPricing Utility

The **ImportExportPricing** utility is a command-line interface for importing pricing and setup components to and for exporting pricing and setup components from the PDC database by using XML files.

ImportExportPricing is a role-based utility that authenticates and authorizes users based on their role. A user's role determines what tasks they can perform and information they can see.

Users of this utility can have the following roles:

- **Pricing Design Admin:** Users with this role can import and export all pricing and setup components.
- **Pricing Reviewer:** Users with this role can only export all pricing and setup components.
- **Pricing Analyst:** Users with this role can import only pricing components and cannot import setup components and profile data. Users can export all pricing and setup components.

ImportExportPricing allows you to filter the data that you want to import to or export from PDC. For example, you can export all pricing and setup components from PDC or specify specific pricing and setup components to export.

You can use **ImportExportPricing** to:

- Export pricing and setup components from the PDC database to an XML file. See "[Exporting Pricing and Setup Components from PDC](#)" for more information.
- Import pricing and setup components defined in an XML file into the PDC database. See "[Importing Pricing and Setup Components](#)" for more information.
- List pricing or setup components available in the PDC database. See "[Listing Pricing or Setup Components](#)" for more information.
- Delete setup components from the PDC database if it is not prerequisite data for any other component. See "[Deleting Setup Components](#)" for more information.

About Dependencies between Pricing and Setup Components

Before importing a pricing component, you must import the setup components that the pricing component references. You must ensure that the setup components referenced by the pricing components are either in the XML file or are already imported into PDC.

For example, to import a charge, you must ensure that the balance elements that it references already exist in PDC.

This section assumes that the following prerequisite data is already available in PDC:

- Service
- Event
- Account Attributes

- Service-Event Map
- Profiles

Table 30-1 lists the prerequisites for importing the pricing components into PDC. Some of the prerequisites are optional depending on your business functions.

Table 30-1 Prerequisite Data for Importing Pricing Components

Pricing Component	Prerequisite Pricing Component	Prerequisite Setup Component
Discount Filter	None	None
Time Model	None	None
APN Selector	None	Impact Categories and Zone Models
Pricing	None	RUMs, Balance Elements, G/L IDs, and Tax Codes
USC Selector	None	Impact Categories and Zone Models
Tax Selector	None	Tax Codes
Tax Exemption Selector	None	Tax Exemption Codes
Discount Trigger	None	Balance Elements
Generic Selector	None	Custom Rules and Profile Attribute Specification
Price Selector	Pricing	None
Charge	Time Models, Pricing, USC Selectors, APN Selectors, and Price Selectors	RUMs, Balance Elements, Tax Codes, G/L IDs, and Zone Models
Charge Selector	Charges	Value Maps and Zone Models
Charge Offer	Charge Selectors and Charges	RUMs, Deliverables, Tax Codes, Tax Suppliers, Provisioning Tags, and Extended Attribute Templates
Discount	Pricing, Discount Trigger, and Discount Filter	Balance Elements, Tax Codes, and G/L IDs
Discount Selector	Discounts	None
Discount Offer	Discount Selectors and Discounts	Provisioning Tags and Extended Attribute Templates
Discount Offer Exclusion	Discount Offer	None
Bundle	Charge Offers, Discount Offers, and Subscription Terms	Extended Attribute Templates
Bundle Dependency	Bundles	None
Bundle Transition	Bundles	None
Package	Bundles and Subscription Terms	Balance Elements and Extended Attribute Templates
Package Discount Restriction	Bundles	None
Package List	Packages	None
Package Transition	Packages	None
Subscription Terms	None	G/L IDs and Balance Elements

Table 30-1 (Cont.) Prerequisite Data for Importing Pricing Components

Pricing Component	Prerequisite Pricing Component	Prerequisite Setup Component
Subscription Terms Auto Renew	Subscription Terms	None
Chargeshare	Pricing, Trigger, Filter, and Charge Selector Spec	Balance Elements, Tax Codes, and G/L IDs
Chargeshare Offer	Distribution Charge	Extended Attribute Templates

About the XSD Files

ImportExportPricing uses separate XSD files for importing or exporting pricing components, setup components, and profile data. The XSD files are available in their respective directories in the *PDC_home/apps/xsd* directory, where *PDC_home* is the directory in which the PDC software is installed. The XSD files describe the structure of the XML document. The XML file you create must comply with the structure defined in the XSD.

The XSD defines the following items for an XML file:

- The elements and attributes, their data types, and the default and fixed values for the elements and attributes.
- Elements that are child elements, and the number and order of the child elements.
- If an element can be empty or can include text.

Prerequisites for Using the ImportExportPricing Utility

To use **ImportExportPricing**, you must:

- Ensure that the XML files used by this utility conform to the format detailed in the corresponding XSD files. See "[About the XSD Files](#)" for more information.
- Ensure *PDC_home/apps/bin* is in your PATH environment variable.

Exporting Pricing and Setup Components from PDC

Exporting by using **ImportExportPricing** involves extracting the pricing and setup components from the PDC database into XML files.

Before exporting pricing or setup components, consider the following:

- You can export all or a subset of pricing and setup components.
- When exporting pricing components, the utility does not export the setup component referenced by pricing components. You must export the setup components explicitly.

ImportExportPricing enables you to export the following from a PDC database to an XML file:

- All pricing and setup components. See "[Exporting All Pricing and Setup Components](#)" for more information.
- A subset of pricing and setup components. See "[Exporting a Subset of Pricing and Setup Components](#)" for more information.

Exporting All Pricing and Setup Components

To export all pricing and setup components to XML files, enter the following command:

```
ImportExportPricing -export [Prefix] -appsvruser ApplicationServerUserName -pdcuser PdcUserName
```

See "[ImportExportPricing](#)" for a description of the parameters used in this command.

For example, the following command exports all pricing components, setup components, and profile data in the PDC database in a UNIX environment to the **MyData_export_pricing.xml**, **MyData_export_config.xml**, and **MyData_export_profile.xml** files, respectively:

```
ImportExportPricing -export MyData -appsvruser weblogic -pdcuser pdcuser
```

Exporting a Subset of Pricing and Setup Components

You can export specific pricing and setup components based on the object type, modification time, and the user who modified the data. You can also filter the exported data based on the object name.

For example commands for exporting a subset of data, see the following:

- [Example 1: Exporting a Subset of Pricing Components](#)
- [Example 2: Exporting Only Setup Components Managed in BRM](#)
- [Example 3: Exporting Only G/L IDs](#)
- [Example 4: Exporting All Pricing Reference Objects](#)
- [Example 5: Exporting Only Metadata Objects](#)
- [Example 6: Exporting Setup Components Modified After a Specific Time](#)
- [Example 7: Exporting Pricing Components Modified by Specific Users](#)
- [Example 8: Exporting Only Extended Attribute Template Objects](#)

Example 1: Exporting a Subset of Pricing Components

The following example exports discount and charge pricing components from the PDC database to the **MyPricingComponents_export_pricing.xml** file:

```
ImportExportPricing -export MyPricingComponents -pricing ALTERATION_RATE_PLAN,CHARGE_RATE_PLAN -appsvruser weblogic -pdcuser pdcuser
```

Example 2: Exporting Only Setup Components Managed in BRM

The following example exports all BRM-managed setup components from the PDC database into the **MySetupComponents_export_config.xml** file:

```
ImportExportPricing -export MySetupComponents -brmObject
```

Example 3: Exporting Only G/L IDs

The following example exports G/L IDs into the **GL_IDs_export_config.xml** file:

```
ImportExportPricing -export GL_IDs -brmobject GLID
```

Example 4: Exporting All Pricing Reference Objects

The following example exports the ChargeOffer-RealtimeUsage and ChargeOffer-Batch reference objects, including the corresponding metadata and setup components, from the PDC database to the **MyChargeOffers_export_pricing.xml**, **MyChargeOffers_export_metadata.xml**, and **MyChargeOffers_export_config.xml** files:

```
ImportExportPricing -export MyChargeOffers -pricing CHARGE_OFFERING -name "ChargeOffer-RealtimeUsage,ChargeOffer-Batch" -expAllRefs
```

Example 5: Exporting Only Metadata Objects

The following example exports all event, service, account, and profile attribute specifications from the PDC database in a UNIX environment to the **MySetupComponents_export_meta_config.xml** file:

```
ImportExportPricing -export MySetupComponents -metadata
```

Example 6: Exporting Setup Components Modified After a Specific Time

The following example exports all setup components modified after 2010-01-05T19:05:09GMT+05:30 from the PDC database in a UNIX environment to the **MySetupComponents_export_config.xml** file:

```
ImportExportPricing -export MySetupComponents -config -ma 2010-01-05T19:05:09GMT+05:30 -appsvruser weblogic -pdcuser pdcuser
```

Example 7: Exporting Pricing Components Modified by Specific Users

The following example exports pricing components modified by User1 and User2 from the PDC database in a UNIX environment to the **MyPricingComponents_export_pricing.xml** file:

```
ImportExportPricing -export MyPricingComponents -pricing -mby User1, User2 -appsvruser weblogic -pdcuser pdcuser
```

Example 8: Exporting Only Extended Attribute Template Objects

The following example exports all ProductSpecCharacteristicTemplate objects, which define the extended attributes available to pricing components, from the PDC database in a UNIX environment to the **MyExtendedAttributes_export_config.xml** file:

```
ImportExportPricing -export MyExtendedAttributes -config PSCTEMPLATE
```

Exporting Promoted and Failed Components

By default, **ImportExportPricing** exports only successfully promoted and transformed objects. Running the **ImportExportPricing** utility with the **inclFailedObjs** parameter exports the most currently promoted components in addition to the failed components.

To export only successfully promoted and transformed pricing components, run the following command:

```
ImportExportPricing -export -pricing -inclFailedObjs -appsvruser ApplicationServerUserName -pdcuser PdcUserName
```

Exporting Only Obsoleted Components

You can export only obsoleted versions of pricing and setup components. For example, the following command exports all obsoleted pricing components (including metadata and setup components) from PDC in a UNIX environment to the **MyPricingObsoleteComponents_export_pricing.xml** file:

```
ImportExportPricing -export MyPricingObsoleteComponents -pricing -expObsolete -
appsvruser weblogic -pdcuser pdcuser
```

About Supported Pricing and Setup Components

[Table 30-2](#) lists the type of pricing components you can import to or export from PDC using the **ImportExportPricing** utility.

Table 30-2 Supported Pricing Components and Their Representation in the Command Line and XML File

Pricing Component Type	Represented in the Command Line and XML File As ...
Charge	CHARGE_RATE_PLAN
Discount	ALTERATION_RATE_PLAN
Chargeshare	DISTRIBUTION_RATE_PLAN
Rollover	ROLLOVER_RATE_PLAN
Discount Selector	ALTERATION_RATE_PLAN_SELECTOR
Generic Selector	GENERIC_SELECTOR
Charge Selector	CHARGE_RATE_PLAN_SELECTOR
Price Selector	PRICE_MODEL_SELECTOR
APN Selector	APN_MAP
USC Selector	USC_MAP
Tax Selector	TAX_SELECTOR
Tax Exemption Selector	TAX_EXEMPTION_SELECTOR
Time Model	TIME_MODEL
Trigger	TRIGGER_SPEC
Filter	CHARGE_SELECTOR_SPEC
Discount Pricing	ALTERATION_POP_MODEL
Rollover Rules	ROLLOVER_POP_MODEL
Recurring Pricing	RECURRING_POP_MODEL
One-Time Pricing	ONE_TIME_POP_MODEL
Charge Offer	CHARGE_OFFERING
Discount Offer	ALTERATION_OFFERING
Chargeshare Offer	DISTRIBUTION_OFFERING
Discount Exclusion	ALTERATION_EXCLUSION
Subscription Terms	SUBSCRIPTION_TERMS
Subscription Terms Auto Renew	SUBSCRIPTION_TERMS_AUTO_RENEW
Bundle	BUNDLED_PRODUCT_OFFERING
Bundle Transition	BUNDLE_TRANSITION
Bundle Dependency	BUNDLE_DEPENDENCY
Package	PACKAGE_OBJ

Pricing Component Type	Represented in the Command Line and XML File As ...
Discount Restriction	PACKAGE_EXCLUSION
Package Transition	PACKAGE_TRANSITION
Package List	PACKAGE_LIST

Table 30-3 lists the type of setup components you can import to or export from PDC using **ImportExportPricing**.

Table 30-3 Supported Setup Components and their Representation in the Command Line and XML File

Setup Component Type	Represented in the Command Line and XML File As ...
Value Map	VALUE_MAP
Event	EVENT_ATTRIBUTE_SPEC
Service	PRODUCT_ATTRIBUTE_SPEC
Account Attribute	CUSTOMER_ATTRIBUTE_SPEC
RUM	RUM_CONFIGURATION
Impact Category for Zones	ZONE_RESULT_CONFIGURATION
Service-Event Map	ATTRIBUTE_SPEC_MAP
Balance Element	BALANCE_ELEMENT
Deliverable	DELIVERABLE
G/L ID	GLID
Tax Code	TAX_CODE
Tax Exemption Code	TAX_EXEMPTION_CODE
Tax Supplier	TAX_SUPPLIER
Geographical Zone Model	GEO_ZONE_MODEL
Standard Zone Model	STANDARD_ZONE_MODEL
Provisioning Tag	PROVISIONING_TAG
Special Day Calendar	HOLIDAY_CALENDAR
Custom Rule	CUSTOM_ANALYZER_RULE
Profile Attribute Specification	PROFILE_ATTRIBUTE_SPEC
Extended Attribute Template	PSCTEMPLATE

Importing Pricing and Setup Components

Importing pricing and setup components using the **ImportExportPricing** utility involves retrieving data from one or more XML files and loading them into the PDC database. Your XML files must conform to the format detailed in the XSD files for pricing or setup components. See "[About the XSD Files](#)" for more information.

Before importing pricing and setup components, consider the following:

- If you import pricing and setup components together, the utility imports setup components before importing the pricing components. If setup components are not imported successfully, the utility does not import the pricing components. When importing data, you

must include the **-metadata**, **-config**, **-pricing**, **-profile**, or **-customfields** parameter at the command.

- During import, the utility modifies the objects in the database:
 - If the **-ow** parameter is used and the objects already exist in the database, the utility overwrites the existing objects. The utility generates an error if the **-ow** parameter is not used and the objects already exist in the database.
 - If the object does not exist in the database, the utility creates the object, regardless of the usage of the **-ow** parameter.
 - If the **-ignoreID** parameter is used, the utility ignores the internal IDs in the XML files. The utility looks up the internal IDs by object name or generates internal IDs for new objects. Use this option to avoid conflicts when importing data from another environment.

Use this parameter with the **-ow** parameter when importing existing data.

For the list and description of parameters to use with **ImportExportPricing** for importing components into PDC, see "[Import Mode](#)".

You can import pricing and setup components from a single XML file or from a directory containing multiple XML files.

Importing from a Single XML File

You can import data from a single XML file that contains your pricing and setup components.

For example, to import metadata objects from an XML file into the PDC database, run the following command:

```
ImportExportPricing -import -metadata FileName
```

where *FileName* is the file name and path to your import XML file.

The **ImportExportPricing** utility imports the data from the XML file into the PDC database and commits the data. If there is an error, all data imported before the error occurred is persisted in the database.

Importing Multiple XML Files from a Directory

The **ImportExportPricing** utility can import pricing and setup components from multiple XML files located in a directory.

Note:

The XML files in the directory must contain only one type of configuration object: only metadata objects, only setup components, or only pricing components.

To import data from multiple XML files in a directory:

1. Create your import XML files. Ensure the files contain only one type of configuration object, such as only pricing components, only setup components, or only metadata objects.
2. (Optional) Create an **import_order.cfg** file listing the order in which to import the XML files. For example, you could specify to import **chargeRatePlans.xml** before **chargeOffers.xml**.

 **Note:**

- Ensure **import_order.cfg** does not contain empty lines.
- Without the file, **ImportExportPricing** imports your XML files in a random order.

3. Copy your import XML files and **import_order.cfg** file to your input directory. Your input directory can include one or more subdirectories, but the **import_order.cfg** file must be at the top level of your input directory.
4. Set the ownership and permissions of the input directory, its subdirectories, your import XML files, and **import_order.cfg** file to **chown 1000:0** and **chmod 755**.
5. Run the **ImportExportPricing** utility in **import** mode. For example, to import pricing setup components from multiple XML files in a directory into the PDC database:

```
ImportExportPricing -import -config DirectoryName
```

where *DirectoryName* is a directory present in the current location. The input path can be an absolute or relative directory location.

The **ImportExportPricing** utility imports the data from your XML files into the PDC database and commits the data. If there is an error, all data imported before the error occurred is persisted in the database.

Listing Pricing or Setup Components

You can use the **ImportExportPricing** utility to display components available in the PDC database. For the list and description of parameters to use, see "[Type Mode](#)".

The following example command displays the metadata components available in the PDC database:

```
ImportExportPricing -type metadata
```

Publishing Setup Components

You can use the **ImportExportPricing** utility with the **-publish** and **-target** parameters to publish components from PDC to the specified target engines, such as the batch rating engine, real-time rating engine, or ECE. For the list and description of parameters to use for publishing components, see "[Publish Mode](#)".

The following example command publishes all setup components from PDC to ECE:

```
ImportExportPricing -publish config -target ece
```

Deleting Setup Components

You can use the **ImportExportPricing** utility with the **-delete** parameter to delete setup components from the PDC database. See "[Delete Mode](#)" for a description of parameters used in this command.

For example, the following command deletes the setup components defined in the **/Temp/ComponentsToDelete.xml** file from the PDC database:

```
ImportExportPricing -delete /Temp/ComponentsToDelete.xml
```

Deleting Pricing Profiles

You can also use the **ImportExportPricing** utility to delete pricing profiles if they are not being used by any pricing component. For example, the following command deletes the pricing profile data defined in the `/Temp/ProfilesToDelete.xml` file from the PDC database:

```
ImportExportPricing -delete /Temp/ProfilesToDelete.xml
```

Keeping Only the Latest Versions of Successfully Promoted PDC Components

You can keep only the latest versions of successfully promoted PDC components and delete all older versions in PDC or in the associated target engines and by using the **-keep** parameter. For the list and description of parameters to use for deleting older versions of PDC components, see "[Keep Mode](#)".

For example, the following command keeps the last three successfully promoted versions of pricing components in the PDC database and deletes all older versions of the pricing components:

```
ImportExportPricing -keep pricing -numVersion 3
```

Note:

PDC keeps versions of the successfully promoted components if they are available in the PDC database. For example, if you want to keep the latest two versions of successfully promoted components and there is only one version available in the PDC database, PDC keeps only that one version.

Obsoleting PDC Components

You can use the **ImportExportPricing** utility to obsolete PDC components with a Promoted status if they are not referenced by any other pricing components.

To obsolete PDC components:

1. Export the PDC component that you want to obsolete into an XML file. See "[Exporting Pricing and Setup Components from PDC](#)" for more information.
2. In the XML file, set the **<obsolete>** element for the PDC component to **true**:

```
<obsolete>>true</obsolete>
```
3. Import the PDC component into the PDC database with the **-ow** parameter. See "[Importing Pricing and Setup Components](#)" for more information.

For example:

```
ImportExportPricing -import -pricing export_pricing.xml -ow
```

The imported PDC component is obsoleted.

 **Note:**

If you want to reuse an obsoleted PDC component, set the **<obsolete>** element for that component to **false** and import it into the PDC database.

XML Examples of Creating Pricing Components

Learn how to use the XML examples as a guideline for creating your own pricing components using the Oracle Communications Pricing Design Center (PDC) XML Pricing Interface.

Topics in this document:

- [Bundle Configuration Examples](#)
- [Charge Offer Configuration Examples](#)
- [Discount Offer Configuration Examples](#)
- [Package Configuration Examples](#)
- [Selector Configuration Examples](#)

For a list of PDC XML tags that you can use to create pricing components, see "[PDC XML Tags](#)".

Bundle Configuration Examples

To configure bundle functionality by using the PDC XML Pricing Interface, see the following examples:

- [Activating Offers in Bundles](#)
- [Configuring Add-On Charge Offers In Bundles](#)
- [Configuring Proration for Offers in Bundles](#)
- [Purchasing the Same Offer in a Bundle Multiple Times](#)
- [Setting Charge Offer Cycle Alignment for Reactivated Bundles](#)
- [Transitioning Bundles](#)

Activating Offers in Bundles

When creating bundles in XML, you can specify whether to activate all charge offers in a bundle when one of the charge offers is activated on first usage. To do so, you use the **<firstUsageActivation>** element under the **<bundledProductOffering>** element.

Set the **<firstUsageActivation>** element to one of the following:

- **true**: Activates all charge offers in the bundle upon first usage of any charge offer in the bundle.

For example, assume a bundle contains charge offers A, B, and C. If the first service a customer uses is in charge offer B, all charge offers (A, B, and C) are activated at that time.

- **false**: When one charge offer in a bundle is activated on first usage, the other charge offers in the bundle are not activated.

For example, assume a bundle contains charge offers A, B, and C. If the first service a customer uses is in charge offer B, only charge offer B is activated at that time. This is the default.

The following shows an example of a bundle with the **<firstUsageActivation>** element set:

```
<bundledProductOffering xmlns:pdc="http://xmlns.oracle.com/communications/
platform/model/pricing">
  <name>Bundle for Data</name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Product Offering</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <timeRange>0/inf</timeRange>
  <productSpecName>TelcoGsmTelephony</productSpecName>
  <billOnPurchase>>false</billOnPurchase>
  <customize>OPTIONAL</customize>
  <firstUsageActivation>true</firstUsageActivation>
  <groupBalanceElements>>false</groupBalanceElements>
  <bundledProductOfferingItem>
    .....
    .....
    .....
  </bundledProductOfferingItem>
</bundledProductOffering>
```

Configuring Add-On Charge Offers In Bundles

When creating bundles in XML, you can include add-on charge offers. By default, all charge offers in bundles are base charge offers, which means they can be purchased without any prerequisites. Add-on charge offers require customers to own a valid base charge offer.

You configure an add-on charge offer in a bundle by doing the following:

1. Including the **<addOnOfferingValidityMode>** element under **<bundledProductOfferingItem>**.
2. Specifying the add-on charge offer's validity. The add-on charge offer's validity start date is the end date of a charge offer that you specify. For example, assume charge offer A has a validity period from June 1 through June 15. If you specify to align add-on charge offer B's validity period with charge offer A, charge offer B's validity start date would be June 15.

You specify the charge offer on which to align an add-on charge offer's validity dates by setting the **<addOnOfferingValidityMode>** element to one of the following:

- **BASE_OFFER:** Aligns the validity dates with the specified base charge offer.
- **BASE_OFFER_EXPIRY_FIRST:** Aligns the validity dates with the active base charge offer that expires first.
- **BASE_OFFER_EXPIRY_LAST:** Aligns the validity dates with the active base charge offer that expires last.
- **BASE_OR_ADD_ON_OFFER_EXPIRY_FIRST:** Aligns the validity dates with the active charge offer that expires first.
- **BASE_OR_ADD_ON_OFFER_EXPIRY_LAST:** Aligns the validity dates with the active charge offer that expires last.

- If you set `<addOnOfferingValidityMode>` to `BASE_OFFER`, add the `<baseChargeOfferingName>` element set to the name of the base charge offer on which to set validity dates.

 **Note:**

Do not include the `<baseChargeOfferingName>` element for the other `<addOnOfferingValidityMode>` values: `BASE_OFFER_EXPIRY_FIRST`, `BASE_OFFER_EXPIRY_LAST`, `BASE_OR_ADD_ON_OFFER_EXPIRY_FIRST`, and `BASE_OR_ADD_ON_OFFER_EXPIRY_LAST`.

- Setting the validity period for all charges in the add-on charge offer to the default value (immediate to never expires).

To do so, add the following elements under `<purchaseStart>`, `<purchaseEnd>`, `<usageStart>`, `<usageEnd>`, `<cycleStart>`, and `<cycleEnd>`:

- `<offset>` set to `0`
- `<mode>` set to `NOW_TO_NEVER`

The following shows sample XML for creating an add-on charge offer that uses the same validity period as the **Sample01** base charge offer:

```
<bundledProductOfferingItem>
  <purchaseStart>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </purchaseStart>
  <purchaseEnd>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </purchaseEnd>
  <usageStart>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </usageStart>
  <usageEnd>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </usageEnd>
  <cycleStart>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </cycleStart>
  <cycleEnd>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </cycleEnd>
  <status>1</status>
  <statusCode>0</statusCode>
  <renewalMode>>false</renewalMode>
  <quantity>1.0</quantity>
  <purchaseChargeAdjustment>0.0</purchaseChargeAdjustment>
  <usageChargeAdjustment>0.0</usageChargeAdjustment>
</bundledProductOfferingItem>
```

```

<cycleChargeAdjustment>0.0</cycleChargeAdjustment>
<purchaseMode>NEW_INSTANCE</purchaseMode>
<addOnOfferingValidityMode>BASE_OFFER</addOnOfferingValidityMode>
<baseChargeOfferingName>Sample01</baseChargeOfferingName>
<chargeOfferingName>MyChargeOffer</chargeOfferingName>
</bundledProductOfferingItem>

```

Configuring Proration for Offers in Bundles

When creating bundles in XML, you can set how to prorate cycle charges and discounts at the offer level.

To configure proration for an offer in a bundle, set the **<prorationBasedOn>** element under **<bundledProductOfferingItem>** to one of the following:

- **PRORATE_30_DAYS**: Prorated charges and discounts are based on a 30-day month.
- **PRORATE_DAYS_IN_MONTH**: Prorated charges and discounts are based on the actual number of days in a month, such as 30 for June or 31 for May.
- **Not Set**: Prorated charges are calculated according to the system-wide setting in the CM **pin.conf** file. See "Examples of 30-Day-Based Proration" in *BRM Configuring and Running Billing*.

The following shows sample XML for configuring the **Sample01** charge offer to use 30-day proration:

```

<bundledProductOfferingItem>
  ...
  <status>1</status>
  <statusCode>0</statusCode>
  <renewalMode>>false</renewalMode>
  <quantity>1.0</quantity>
  <purchaseChargeAdjustment>0.0</purchaseChargeAdjustment>
  <usageChargeAdjustment>0.0</usageChargeAdjustment>
  <cycleChargeAdjustment>0.0</cycleChargeAdjustment>
  <prorationBasedOn>PRORATE_30_DAYS</prorationBasedOn>
  <purchaseMode>NEW_INSTANCE</purchaseMode>
  <addOnOfferingValidityMode>BASE_OFFER_EXPIRY_FIRST</
addOnOfferingValidityMode>
  <chargeOfferingName>Sample01</chargeOfferingName>
</bundledProductOfferingItem>

```

Purchasing the Same Offer in a Bundle Multiple Times

When creating bundles in XML, you can specify what happens if customers purchase the same charge offer or discount offer more than once.

For both charge offers and discount offers, you can specify whether the additional offer is purchased as a new subscription or a replacement of the existing subscription. To do so, in the definition of the bundle containing the charge offer or discount offer, set the value for the **<purchaseMode>** element under the **<bundledProductOfferingItem>** element to one of the following:

- **NEW_INSTANCE**: The additional charge offer or discount offer is purchased as a new, unrelated subscription. The balance impacts and validity periods of the old and new subscription are completely independent. This is the default option.

- **OVERWRITE:** The additional charge offer or discount offer replaces the existing subscription. The existing subscription is canceled, any configured proration is applied, and the new subscription is created, with all balance impacts and validity periods set as though for a new purchase.

For example, on June 1st, a customer purchases an add-on bundle that grants 3GB of data and is valid for 7 days. On June 3rd, after using 1GB, they purchase the bundle again. The old charge offer is canceled, any remaining balance is prorated, and the new 3GB balance is created, with a validity end date of June 10th.

For both charge offers and discount offers, you can also specify whether the additional offer is purchased as an extension of the existing subscription if it is purchased within a specified grace period. To do so, in the definition of charge offers, you can also set the value for the **<purchaseMode>** element under the **<bundledProductOfferingItem>** element to one of the following:

- **LONGEST_DATE:** The additional charge offer is purchased as an extension to the existing subscription if it is purchased within the grace period. The new balance impacts are added to the existing balance group. The validity period for the balance is then set to either the old validity end date or the new validity end date, whichever is later.

You specify the grace period under the **<bundledProductOfferingItem>** by setting the **<gracePeriodOffset>** element to the amount of time and the **<gracePeriodUnit>** element to **Seconds, Minutes, Hours, or Days**.

For example, on June 1st, a customer purchases an add-on bundle that grants 3GB of data, is valid for 7 days, and has a grace period of 4 days. On June 3rd, after using 1GB, they purchase the bundle again. The new 3GB balance is added to the remaining balance, for a total of 5GB. BRM compares the validity periods of the old and new charge offer and sets the validity end date for the total balance to the later of the two end dates, June 10th.

- **EXTEND:** The additional charge offer is purchased as an extension to the existing subscription if it is purchased with the grace period. The new balance impacts are added to the existing balance group. The validity period for the balance is then set by adding the new validity period to whatever remains of the old validity period.

You specify the grace period under the **<bundledProductOfferingItem>** by setting the **<gracePeriodOffset>** element to the amount of time and the **<gracePeriodUnit>** element to **Seconds, Minutes, Hours, or Days**.

For example, on June 1st, a customer purchases an add-on bundle that grants 3GB of data, is valid for 7 days, and has a grace period of 4 days. On June 3rd, after using 1GB, they purchase the bundle again. The new 3GB balance is added to the remaining balance, for a total of 5GB. BRM adds the validity period of the new charge offer to the old charge offer, and sets the validity end date for the total balance to June 15th.

The following shows a sample of the XML for a charge offer in a bundle with **<purchaseMode>** set to **EXTEND**, **<gracePeriodOffset>** set to **5**, and **<gracePeriodUnit>** set to **Day**.

```
<BundledProductOffering>
  <name>Extend Bundle</name>
  <description>Bundle with Extend Purchase Mode</description>
  <internalId>InternalID</internalId>
  <obsolete>>false</obsolete>
  <timeRange>0/inf</timeRange>
  <productSpecName>TelcoGsm</productSpecName>
  <billOnPurchase>>false</billOnPurchase>
  <customize>OPTIONAL</customize>
  <groupBalanceElements>>false</groupBalanceElements>
  <bundledProductOfferingItem>
```

```

    <purchaseStart>
      <offset>0</offset>
      <mode>NOW_TO_NEVER</mode>
    </purchaseStart>
  <purchaseEnd>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </purchaseEnd>
  <usageStart>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </usageStart>
  <usageEnd>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </usageEnd>
  <cycleStart>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </cycleStart>
  <cycleEnd>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </cycleEnd>
  <status>1</status>
  <statusCode>0</statusCode>
  <renewalMode>>true</renewalMode>
  <quantity>1.0</quantity>
  <purchaseChargeAdjustment>0.0</purchaseChargeAdjustment>
  <usageChargeAdjustment>0.0</usageChargeAdjustment>
  <cycleChargeAdjustment>0.0</cycleChargeAdjustment>
  <purchaseMode>EXTEND</purchaseMode>
  <gracePeriodOffset>5</gracePeriodOffset>
  <gracePeriodUnit>Day</gracePeriodUnit>
  <chargeOfferingName>Charge Offer - Purchase Fee</chargeOfferingName>
</bundledProductOfferingItem>
</BundledProductOffering>

```

The following shows a sample of the XML for a discount offer in a bundle with **<purchaseMode>** set to **OVERWRITE**.

```

<bundledProductOfferingItem>
  <purchaseStart>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </purchaseStart>
  <purchaseEnd>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </purchaseEnd>
  <usageStart>
    <offset>0</offset>
    <mode>NOW_TO_NEVER</mode>
  </usageStart>
  <usageEnd>

```

```

        <offset>0</offset>
        <mode>NOW_TO_NEVER</mode>
    </usageEnd>
    <cycleStart>
        <offset>0</offset>
        <mode>NOW_TO_NEVER</mode>
    </cycleStart>
    <cycleEnd>
        <offset>0</offset>
        <mode>NOW_TO_NEVER</mode>
    </cycleEnd>
    <status>1</status>
    <statusCode>0</statusCode>
    <renewalMode>true</renewalMode>
    <quantity>1.0</quantity>
    <purchaseChargeAdjustment>0.0</purchaseChargeAdjustment>
    <usageChargeAdjustment>0.0</usageChargeAdjustment>
    <cycleChargeAdjustment>0.0</cycleChargeAdjustment>
    <purchaseMode>OVERWRITE</purchaseMode>
    <alterationOfferingName>Discount Offer - Usage Discount</
alterationOfferingName>
</bundledProductOfferingItem>

```

Setting Charge Offer Cycle Alignment for Reactivated Bundles

When creating bundles in XML, you can specify when the cycle should align for charge offers if a customer suspends then reactivates the bundle.

In the definition of the bundle containing the charge offer, set the value for the **<renewalMode>** element under the **<bundledProductOfferingItem>** element to **true** or **false**. This setting is not valid for discount offers.

If **<renewalMode>** is set to **false**, the cycle aligns as described in "[Aligning Recurring Charges and Product Validity to a Specific Day of the Month](#)".

If **<renewalMode>** is set to **true**, the following scenarios are possible:

- When **<cycleFeeFlag>** under **chargeRatePlan** is set to **1**:
 - If **<purchaseCycleDOM>** under **chargeOffering** is not set, the cycle aligns with the reactivation date.
 - If **<purchaseCycleDOM>** is set, the cycle aligns with either **<purchaseCycleDOM>** or the reactivation date, whichever is later.
- When **<cycleFeeFlag>** is set to **0**, the cycle aligns with the billing date.

For sample of the XML for a charge offer in a bundle with **<renewalMode>** set to **true**, see "[Purchasing the Same Offer in a Bundle Multiple Times](#)".

Transitioning Bundles

When creating bundle transitions in XML, you can configure how PDC applies charges when customers transition bundles in the middle of their billing cycle by using the **<prorationType>** element under the **<bundleTransition>** element.

Set the **<prorationType>** element to one of the following:

- **PRORATE_CHARGE**: Specifies to prorate charges for both bundles. This is the default.

- **ORIGINAL_CHARGE:** Specifies to apply the full charges from the original bundle.
- **TRANSFER_CHARGE:** Specifies to apply the full charges from the new bundle.

The following shows an example of a bundle transition with the **<prorationType>** element set:

```
<bundleTransition xmlns:pdc="http://xmlns.oracle.com/communications/platform/
model/pricing">
  <name>sample package transition/name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Subscription</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <active>>true</active>
  <timeRange>0/inf</timeRange>
  <waivePurchaseFee>>true</waivePurchaseFee>
  <waiveCancelFee>>true</waiveCancelFee>
  <productSpecName>TelcoGsmTelephony</productSpecName>
  <prorationType>ORIGINAL_CHARGE</prorationType>
  <type>GENERATION_CHANGE</type>
  <fromBundleName>Bundle A</fromPackageName>
  <toBundleName>Bundle B</toPackageName>
</bundleTransition>
```

Charge Offer Configuration Examples

To configure charge offer functionality by using the PDC XML Pricing Interface, see the following examples:

- [Aligning Recurring Charges and Product Validity to a Specific Day of the Month](#)
- [Enforcing or Exceeding Credit Limits](#)
- [Offering Hourly Balance Impacts](#)
- [Consuming Granted Allowances Before Applying Usage Charges](#)
- [Prorating Recurring Fees and Rollovers](#)
- [Setting Full Day Proration](#)
- [Setting Taxation for Charges](#)
- [Using a Tax Exemption Selector](#)
- [Sharing Products Automatically with Sharing Group Members](#)
- [Using Date Ranges for Versioning](#)

Aligning Recurring Charges and Product Validity to a Specific Day of the Month

When creating charge offers in XML, you can use the **<purchaseCycleDOM>** and **<cycleFeeFlag>** fields to align recurring charges and product validity to a specific day of the month instead of the customer's billing date.

You can determine when to align recurring charges and product validity as follows:

- To align recurring charges and offer validity to a specific day of the month, set **<purchaseCycleDOM>** to an integer from 1-31 and set **<cycleFeeFlag>** to **1**.

- To align recurring charges and offer validity to the billing date, set **<purchaseCycleDOM>** to **0**. The value of **<cycleFeeFlag>** is irrelevant in this scenario.
- To align recurring charges to the billing date but set offer validity to a specific day of the month, set **<purchaseCycleDOM>** to an integer from 1-31 and set **<cycleFeeFlag>** to **0**.

▲ Caution:

You cannot change the **<purchaseCycleDOM>** value for a charge offer after it has been purchased. If you create a new version of the charge offer with a different value in **<purchaseCycleDOM>**, BRM does not update the value in any purchased products and continues to use the value that was configured for the initial purchase.

For example, to apply recurring charges for a charge offer on the 22nd day of the month, the XML input file would include the following:

```
<chargeRatePlan xmlns:pdc="http://xmlns.oracle.com/communications/platform/
model/pricing">
  <name>Charge for a Specific Day of the Month</name>
  <pricingProfileName>Subscription</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <applicableRums>Occurrence</applicableRums>
  <applicableQuantity>ORIGINAL</applicableQuantity>
  <taxTime>NONE</taxTime>
  <todMode>START_TIME</todMode>
  <applicableQtyTreatment>CONTINUOUS</applicableQtyTreatment>
  <permittedName>TelcoGsmTelephony</permittedName>
  <permittedType>PRODUCT</permittedType>
  <eventName>EventBillingProductFeeCycleCycle_forward_monthly</eventName>
  <cycleFeeFlag>1</cycleFeeFlag>
  <billOffset>0</billOffset>
  <subscriberCurrency>
    ...
  </subscriberCurrency>
</chargeRatePlan>
<chargeOffering xmlns:pdc="http://xmlns.oracle.com/communications/platform/
model/pricing">
  <name>Charge Offer for a Specific Day of the Month</name>
  <pricingProfileName>Product Offering</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <timeRange>0/inf</timeRange>
  <productSpecName>TelcoGsmTelephony</productSpecName>
  <offerType>SUBSCRIPTION</offerType>
  <priority>1</priority>
  <partial>>false</partial>
  <purchaseMin>-1.0</purchaseMin>
  <purchaseMax>-1.0</purchaseMax>
  <ownMin>-1.0</ownMin>
  <ownMax>-1.0</ownMax>
  <applicableQuantity>REMAINING</applicableQuantity>
```

```

<purchaseCycleDOM>22</purchaseCycleDOM>
<dateRangeImpactType>INSTANTIATED_DATE</dateRangeImpactType>
<chargeEventMap>
  <eventName>EventBillingProductFeeCycleCycle_forward_monthly</
eventName>
  <validIfCancelled>>false</validIfCancelled>
  <validIfInactive>>false</validIfInactive>
  <timezoneMode>EVENT</timezoneMode>
  <minQuantity>0</minQuantity>
  <minQuantityUnit>NONE</minQuantityUnit>
  <incrementQuantity>1</incrementQuantity>
  <incrementQuantityUnit>NONE</incrementQuantityUnit>
  <roundingMode>NEAREST</roundingMode>
  <prorateFirst>PRORATE_CHARGE</prorateFirst>
  <prorateLast>PRORATE_CHARGE</prorateLast>
  <chargeRatePlanInfo>
    <targetEngine>RRE</targetEngine>
  </chargeRatePlanInfo>
  <chargeRatePlanName>Charge for a Specific Day of the Month</
chargeRatePlanName>
</chargeEventMap>
</chargeOffering>
</pdc:PricingObjectsJXB>

```

If a customer with a billing date of the 14th of the month purchased the charge offer in this example on January 18, their first cycle forward fee would be applied on January 18, prorated to cover the period between January 18 and January 22 (the **<purchaseCycleDOM>** date.) The next fee would be applied on January 22, at the full amount to cover the period between January 22 and February 22. Bills would be generated on the 14th of each month.

However, if the value of **<cycleFeeFlag>** in the example above was **0**, the first cycle forward fee would be applied on January 18, prorated to cover the period between January 18 and February 14 (the billing date). The next fee would be applied on February 14, at the full amount to cover the period between February 14 and March 14. In the final month of the charge offer's duration, it would only be valid until the 22nd of the month (the **<purchaseCycleDOM>** date.) If the charge offer was valid for three months, the final fee would be prorated to cover the period from March 14 to March 22.

Note:

For charge offers in bundles that are suspended and then reactivated, you can specify that the cycle aligns with the reactivation date rather than the original purchase date using the **<renewalMode>** element under the **<bundledProductOfferingItem>** element. See "[Setting Charge Offer Cycle Alignment for Reactivated Bundles](#)" for information about how **<renewalMode>** interacts with **<purchaseCycleDOM>** and **<cycleFeeFlag>**.

Enforcing or Exceeding Credit Limits

When creating charges in XML, you can specify whether to enforce credit limits, or let customers exceed them.

To do so, set the **<enforceCreditLimit>** element under the price tier to one of the following:

- **NORMAL:** Enforce the credit limit. The subscription succeeds, but customers do not exceed their credit limit. Prorate the subscription according to the available balance.
- **DEFAULT:** The subscription succeeds and all available balance is used. The remaining amount is tracked as a negative account balance to be paid at the next top up for prepaid customers or current bill for postpaid customers.
- **LOAN:** The subscription succeeds. If the customer is eligible for a loan, all available balance is used and a loan is granted for the remaining amount. If the customer is not eligible for a loan, the subscription fails.
See "About Loans" in *BRM Configuring and Collecting Payments* for more information about loans.
- **DEDUCT_RENTAL:** The subscription succeeds and all available balance is used. The remaining amount is recorded as an outstanding amount to be paid at the next top up for prepaid customers or current bill for postpaid customers.
- **OUTSTANDING_AMOUNT:** The subscription succeeds without using the available balance. The entire amount is recorded as an outstanding amount to be paid at the next top up for prepaid customers or current bill for postpaid customers.
- **RENTAL_FAILURE:** Enforce the credit limit. The subscription fails. After retrying the subscription the configured maximum number of times, a notification event is sent to an external system for further processing.
- **AUTO_RENEW_CANCEL:** Enforce the credit limit. The subscription fails. After retrying the subscription the configured maximum number of times, a notification event is sent to an external system for further processing and the subscription is canceled. It will not automatically renew next cycle.
- **SKIP_CYCLE:** The subscription succeeds without using the available balance. Services will still be available, but billing will be skipped for this cycle. During rating all balance impacts are dropped and the unrated quantity is set to 0. The cycle forward date is moved to next cycle.
- **INSUFFICIENT_BALANCE:** The subscription succeeds if the customer's balance is at least a configured minimum amount. If they have enough balance for the full amount, the full amount is charged. If they have less than the full amount, but more than the minimum amount, the minimum amount is charged. If they have less than the minimum amount, the subscription fails and the behavior is the same as for **RENTAL_FAILURE**.
For this option, you can also configure:

- The minimum amount for currency resources in the **<creditLimitMinimumAmount>** element. By default, this is set to **0**, which means the subscription fails if the balance is less than the full amount. **<creditLimitMinimumAmount>** is not applicable for noncurrency resources.
- Whether or not to prorate the service according to the minimum amount in the **<creditLimitProrateQuantity>** element. By default, this is set to **true** and the service will be prorated. Set this to **false** to grant the full service for the minimum amount.

This option is useful if you want to offer your customers a small amount of their service, such as a few MB of data or minutes as an emergency stop-gap until they have enough balance to afford the full service.

For the **RENTAL_FAILURE**, **AUTO_RENEW_CANCEL**, and **INSUFFICIENT_BALANCE** options, you can also configure the following:

- The maximum number of times to retry the subscription before it fails. Configure this in the **<retryMaxCount>** element of the charge offer. The default is **0**, which sends the failure notification immediately without retrying.

- The frequency of subsequent retries. Configure this in the `<retryOffset>` and `<retryUnit>` elements of the charge offer. The default values are **1** for `<retryOffset>` and **DAY** for `<retryUnit>`. The possible values for `<retryUnit>` are:
 - SECOND
 - MINUTE
 - HOUR
 - DAY
 - WEEK
 - MONTH
 - YEAR

The `/purchased_product` object stores the current number of retries for the subscription in the `PIN_FLD_RETRY_COUNT` field and the date and time of the next retry in the `PIN_FLD_NEXT_RETRY_T` field.

If you do not configure the retry parameters at the offer level, the value for the `max_retry_count` business parameter is used. By default, this is set to **0**, which fails the subscription immediately without retrying. See "[Configuring the Maximum Number of Subscription Retries](#)" for more information about setting this parameter.

[Table 31-1](#) shows the mapping between `<enforceCreditLimit>` element values and the corresponding UI labels.

Table 31-1 Mapping XML Values and UI Labels

XML Value	UI Label
NORMAL	Prorate service according to available balance
DEFAULT	Use available balance, track remainder as negative account balance
LOAN	Use available balance, grant loan for remainder
DEDUCT_RENTAL	Use available balance, track remainder as outstanding
OUTSTANDING_AMOUNT	Do not use available balance, track entire amount as outstanding
RENTAL_FAILURE	Subscription fails
AUTO_RENEW_CANCEL	Subscription fails and is canceled
SKIP_CYCLE	Skip subscription charges until next cycle
INSUFFICIENT_BALANCE	Charge minimum configured amount

The following XML example specifies to charge a minimum amount and prorate the service when customers exceed their credit limit. It also specifies to retry failed subscriptions a maximum of 3 times, every 6 hours.

```
<chargeRatePlan xmlns:pcd="http://xmlns.oracle.com/communications/platform/model/pricing">
  <name>Credit Limit Sample Rate Plan</name>
  <internalId>InternalID</internalId>

Offering Hourly Balance Impacts

When creating charges in XML, you can configure hourly validity periods for the balance impacts that make up charges. This is useful for creating short-lived rewards, like free games or minutes. Hourly validity applies to conditional or non-conditional noncurrency credit balance impacts.

To configure hourly validity, use the following under the **priceTierValidityPeriod** element:

- For credit balance impacts, under the **priceValidity** element, set:
 - **startValidityMode** to **PERIOD_START**.
 - **endValidityMode** to **RELATIVE_TO_START**.
 - **relativeEndOffsetUnit** to **HOUR**.
- For conditional balance impacts, under **periodConditionExpression**, set:
 - **unit** to **HOUR**.
 - **periodStartTime** to **IMMEDIATE**.

The following shows sample XML that creates two conditional balance impacts defined in the price tier. The first debits USD 2.99 every day and the second credits ten games, valid for one day, once every four hours.

```

...
<priceTierValidityPeriod>
  <lowerBound>0</lowerBound>
  <validFrom>0</validFrom>
  <priceTierRange>
    <upperBound>NO_MAX</upperBound>
    <fixedCharge>
      <price>2.99</price>
      <unitOfMeasure>NONE</unitOfMeasure>
      <balanceElementNumCode>840</balanceElementNumCode>
      <discountable>true</discountable>
      <priceType>CONSUMPTION</priceType>
      <periodConditionExpression>
        <biConditionOperator>EQUAL_TO</biConditionOperator>
        <unit>DAY</unit>
        <value>1</value>
        <periodStartTime>IMMEDIATE</periodStartTime>
      </periodConditionExpression>
    </fixedCharge>
    <fixedCharge>
      <price>-10.0</price>
      <unitOfMeasure>NONE</unitOfMeasure>
      <balanceElementNumCode>1000004</balanceElementNumCode>
      <discountable>true</discountable>
      <priceType>GRANT</priceType>
      <priceValidity>
        <startValidityMode>PERIOD_START</
startValidityMode>
        <endValidityMode>RELATIVE_TO_PERIOD_START</

```

```

endValidityMode>
    <validityRange>0/inf</validityRange>
    <relativeStartOffset>-1</relativeStartOffset>
    <relativeEndOffset>1</relativeEndOffset>
    <relativeEndOffsetUnit>DAY</
relativeEndOffsetUnit>
    </priceValidity>
    <periodConditionExpression>
        <biConditionOperator>EQUAL_TO</
biConditionOperator>
        <unit>HOUR</unit>
        <value>4</value>
        <periodStartTime>IMMEDIATE</periodStartTime>
    </periodConditionExpression>
    </fixedCharge>
    </priceTierRange>
</priceTierValidityPeriod>

...

```

Because rounding time stamps for hourly charges would result in all hourly charges being valid for 24 hours, BRM does not round time stamps for charges with hourly validity, even if time-stamp rounding is enabled. For example, if a customer purchases a bundle that is valid for three hours at 3pm, it is valid until 6pm. However, if BRM applied time-stamp rounding, it would be valid until midnight.

Consuming Granted Allowances Before Applying Usage Charges

When configuring charges in XML, you can specify to consume a customer's granted allowance before charging any usage fees. For example, you could create a charge that first consumes a customer's monthly allowance of free movie rentals, charges \$5 for the next five movie rentals, and then charges \$4 for any subsequent movie rentals. You implement this functionality by adding to the charge a pricing tier with multiple ranges. For the example above, you would add a pricing tier with the following ranges:

1. Consume the entire monthly allowance of free movie rentals
2. One through five movie rentals: \$5 per movie rental
3. Six movie rentals and beyond: \$4 per movie rental

Note:

Consuming granted allowances before charging for usage fees is supported by the ECE rating engine only.

To configure charges that consume granted allowances before charging usage fees, add multiple price tier ranges. Under each **<priceTierRange>** element, include an **<upperBoundExpression>** element with one of the following sets of fields:

- To consume a granted allowance, include the following entries under **<upperBoundExpression>**. Set **<balanceElementNumCode>** to the ID of the noncurrency balance element to consume, such as the ID for free movie rentals.

```

<balanceTBExpression>
  <balanceElementNumCode>100002</balanceElementNumCode>
</balanceTBExpression>

```

- To charge for usage, include the following entries under **<upperBoundExpression>**. Set **<value>** to the end value for the quantity range.

```

<numberTBExpression>
  <value>5</value>
</numberTBExpression>

```

The following shows sample XML that creates a charge with two pricing tier ranges: one range for consuming a noncurrency balance element, and a second range from 0 through 600 for charging 50 cents per minute:

```

<priceTierValidityPeriod>
  <lowerBound>0</lowerBound>
  <validFrom>0</validFrom>
  <priceTierRange>
    <upperBoundExpression>
      <balanceTBExpression>
        <balanceElementNumCode>100002</balanceElementNumCode>
      </balanceTBExpression>
    </upperBoundExpression>
    <scaledCharge>
      <price>1.0</price>
      <unitOfMeasure>NONE</unitOfMeasure>
      <balanceElementNumCode>100002</balanceElementNumCode>
      <discountable>true</discountable>
      <priceType>CONSUMPTION</priceType>
      <incrementStep>1.0</incrementStep>
      <incrementRounding>NONE</incrementRounding>
    </scaledCharge>
  </priceTierRange>
  <priceTierRange>
    <upperBoundExpression>
      <numberTBExpression>
        <value>600</value>
      </numberTBExpression>
    </upperBoundExpression>
    <scaledCharge>
      <price>0.5</price>
      <unitOfMeasure>MINUTE</unitOfMeasure>
      <balanceElementNumCode>840</balanceElementNumCode>
      <discountable>true</discountable>
      <priceType>CONSUMPTION</priceType>
      <incrementStep>1.0</incrementStep>
      <incrementRounding>NONE</incrementRounding>
    </scaledCharge>
  </priceTierRange>
</priceTierValidityPeriod>

```

Prorating Recurring Fees and Rollovers

When creating charge offers in XML, you use the following XML elements to specify how to apply cycle fees and rollovers when customers purchase, cancel, or change their billing day of month (DOM) in the middle of a billing cycle:

- **<prorateFirst>**: Specifies how to apply cycle fees and rollovers when customers purchase subscriptions in the middle of their billing cycle.

- **<prorateLast>**: Specifies how to apply cycle fees and rollovers when customers cancel subscriptions in the middle of their billing cycle.
- **<prorateCycle>**: Specifies how to apply cycle fees when customers change their billing day of the month (DOM) during any billing cycle.

You can set these XML elements to one of the following:

- **NO_CHARGE**: Do not apply a cycle fee.
- **FULL_CHARGE**: Apply the full cycle fee.
- **PRORATE_CHARGE**: Calculate the cycle fee based on the amount of time the subscription was owned in the billing cycle. This is the default.

The following sample XML entries specify to not apply cycle fees when customers purchase subscriptions in the middle of their billing cycle, to prorate cycle fees when customers cancel subscriptions in the middle of their billing cycle, and to apply full cycle fees when customers change their billing DOM during any billing cycle:

```
<chargeEventMap>
  <eventName>EventDelayedSessionTelcoGsm</eventName>
  <validIfCancelled>>false</validIfCancelled>
  <validIfInactive>>false</validIfInactive>
  <timezoneMode>EVENT</timezoneMode>
  <minQuantity>1</minQuantity>
  <minQuantityUnit>none</minQuantityUnit>
  <incrementQuantity>1</incrementQuantity>
  <incrementQuantityUnit>none</incrementQuantityUnit>
  <roundingMode>NEAREST</roundingMode>
  <prorateFirst>NO_CHARGE</prorateFirst>
  <prorateLast>PRORATE_CHARGE</prorateLast>
  <prorateCycle>FULL_CHARGE</prorateCycle>
  <chargeRatePlanInfo>
    <targetEngine>ECE</targetEngine>
  </chargeRatePlanInfo>
  <chargeRatePlanName>recurring charge</chargeRatePlanName>
  <ratePlanIID>RatePlanID</ratePlanIID>
</chargeEventMap>
```

For more information, see "[About Prorating Recurring Charges and Rollovers](#)".

Setting Full Day Proration

To configure full day proration in XML, you use the **<validityRounding>** and **<scaleRounding>** elements under the **<ChargeOffering>** element.

<validityRounding> specifies whether to start the charge offer's validity period at the purchase time or midnight of the purchase day.

Set the **<validityRounding>** element to one of the following:

- **OFF**: Starts at the time of purchase.
- **ON**: Starts at midnight (00:00:00) of the day that the charge offer is purchased.
- **NOT_SET**: Uses your company's systemwide setting.

<scaleRounding> specifies how to calculate the scale.

Set the **<scaleRounding>** element to one of the following:

- **ON:** Calculate it based on full days.
- **OFF:** Calculate it based on the **<validityRounding>** setting.
- **NOT_SET:** Use the systemwide setting in the CM **pin.conf** file.
See "Configuring Timestamp Rounding" in BRM Configuring and Running Billing.

The following sample XML entries specify to start the validity period at midnight on the purchase day and charge for a full day on the first day of the billing cycle:

```
<?xml version="1.0" encoding="UTF-8"?>
<pd: PricingObjectsJXB xmlns:pd="http://xmlns.oracle.com/communications/

```

For more information, see "[Configuring Full Day Proration](#)".

Setting Taxation for Charges

When configuring charges in XML, you can specify the tax code to use for calculating taxes as well as when to apply taxes. You can also specify a tax selector to determine the appropriate tax code. To do so, set the following elements under **<chargeRatePlan>**:

If you are setting a specific tax code:

- **<taxCode>**: Set this to the name of the tax code.

If you are using a tax selector:

- **<taxSelectorName>**: Set this to the name of a previously defined tax selector.
- **<taxSelectorIID>**: Set this to the internal ID of the tax selector.

In both cases:

- **<taxTime>**: Specify when to apply taxes:
 - **NONE**: Do not apply taxes.
 - **EVENT_TIME**: Taxes are calculated when the event is rated, and they are added to the customer's account balance. This way, you always have an accurate reading of a customer's account balance at any time in the accounting cycle.
 - **BILLING_TIME**: Taxes are calculated when the bill is generated. Deferring tax calculation to the billing process reduces rounding errors because all events of the same type are calculated together. For example, taxes are calculated on the total amount of usage fees rather than on individual usage events.
 - **DYNAMIC**: Taxes are calculated at billing time using the tax rate at the time the event occurred. This provides the benefits of billing-time taxation while allowing you to change tax rates in the middle of a billing cycle. For example, assume a recurring charge's tax rate changes from 2% to 3% on May 15. If a billing cycle ends on May 30, BRM would use the 2% rate to calculate the charge's April 30 through May 14 taxes and the 3% rate to calculate the charge's May 15 through May 29 taxes.

For example, to apply the **VAT** tax code and calculate taxes at billing time, the XML input file would include the following:

```

<chargeRatePlan xmlns:pdc="http://xmlns.oracle.com/communications/platform/
model/pricing">
  <name>Sample Charge</name>
  <pricingProfileName>Subscription</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <taxCode>VAT</taxCode>
  <applicableRums>Occurrence</applicableRums>
  <applicableQuantity>ORIGINAL</applicableQuantity>
  <taxTime>BILLING_TIME</taxTime>
  <todMode>START_TIME</todMode>
  <applicableQtyTreatment>CONTINUOUS</applicableQtyTreatment>
  <permittedName>TelcoGsmTelephony</permittedName>

```

```

    <permittedType>PRODUCT</permittedType>
    <eventName>EventBillingProductFeeCycleCycle_forward_monthly</eventName>
    <cycleFeeFlag>1</cycleFeeFlag>
    <billOffset>0</billOffset>
    ...
</chargeRatePlan>

```

For example, to use the **Sample TAX_SELECTOR** tax code selector and calculate taxes when the event is rated, the XML input file would include the following:

```

<chargeRatePlan xmlns:pc="http://xmlns.oracle.com/communications/platform/
model/pricing">
  <name>20220105 $10 Monthly Charge</name>
  <description>$10 Monthly Charge</description>
  <pricingProfileName>Subscription</pricingProfileName>
  <obsolete>>false</obsolete>
  <taxSelectorName>Sample_TAX_SELECTOR</taxSelectorName>
  <taxSelectorIID>52407cd9-30f6-44b7-8519-eca5ba196d55</taxSelectorIID>
  <applicableRums>Occurrence</applicableRums>
  <applicableQuantity>ORIGINAL</applicableQuantity>
  <taxTime>EVENT_TIME</taxTime>
  <todMode>START_TIME</todMode>
  <applicableQtyTreatment>CONTINUOUS</applicableQtyTreatment>
  <eventName>EventBillingProductFeeCycleCycle_forward_monthly</eventName>
  <cycleFeeFlag>0</cycleFeeFlag>
  <billOffset>0</billOffset>
  . . .
</chargeRatePlan>

```

Using a Tax Exemption Selector

When creating charge offers in XML, you can use the **<taxExemptionSelector>** field to define a tax exemption selector for the charge offer.

To define a tax exemption selector, provide the name of a previously defined tax exemption selector in the **<taxExemptionSelector>** field.

For example, to use the **Sample TaxExemptionSelector** tax exemption selector for a charge offer, the XML input file would include the following:

```

<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<pc:PricingObjectsJXB xmlns:pc="http://xmlns.oracle.com/communications/
platform/model/pricing">
  <chargeOffering xmlns:pc="http://xmlns.oracle.com/communications/platform/
model/pricing">
    <name>20230105 ChargeOffer - $10 Monthly Charge</name>
    <description>The TelcoGprs offer charges $10 Monthly fee</description>
    <pricingProfileName>Product Offering</pricingProfileName>
    <priceListName>Default</priceListName>
    <obsolete>>false</obsolete>
    . . .
    <ownMin>-1.0</ownMin>
    <ownMax>-1.0</ownMax>
    <taxExemptionSelectorName>Sample TaxExemptionSelector</
taxExemptionSelectorName>

```

```

    <applicableQuantity>REMAINING</applicableQuantity>
    <purchaseCycleDOM>0</purchaseCycleDOM>
    . . .
  </chargeOffering>
</pdc:PricingObjectsJXB>

```

Sharing Products Automatically with Sharing Group Members

When creating charge offers in XML, you can specify whether the charge offer is automatically shared with all members of an automated product sharing group when it is purchased by the group's owner. To do so, you use the **<groupSharingEnabled>** element under the **<chargeOffering>** element.

Set the **<groupSharingEnabled>** element to one of the following:

- **true:** The charge offer is automatically shared with all members of an automated product sharing group when it is purchased by the group's owner.
- **false:** The charge offer is not automatically shared with members of an automated product sharing group.

The following XML example specifies to automatically share the **co1** charge offer with members of an automated product sharing group:

```

<chargeOffering xmlns:pdc="http://xmlns.oracle.com/communications/platform/
model/pricing" externalID="ExternalID">
  <name>co1</name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Product Offering</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <timeRange>0/inf</timeRange>
  <productSpecName>Ip</productSpecName>
  <offerType>SUBSCRIPTION</offerType>
  <priority>0</priority>
  <partial>>false</partial>
  <purchaseMin>-1.0</purchaseMin>
  <purchaseMax>-1.0</purchaseMax>
  <ownMin>-1.0</ownMin>
  <ownMax>-1.0</ownMax>
  <applicableQuantity>REMAINING</applicableQuantity>
  <purchaseCycleDOM>0</purchaseCycleDOM>
  <expiryNotification>>true</expiryNotification>
  <subscriptionDueNotification>>true</subscriptionDueNotification>
  <dateRangeImpactType>EVENT_DATE</dateRangeImpactType>
  <b>groupSharingEnabled</b><b>true</b></groupSharingEnabled>
  <validityRounding>NOT_SET</validityRounding>
  <scaleRounding>OFF</scaleRounding>
  <chargeEventMap>
    <eventName>EventSession</eventName>
    <validIfCancelled>>true</validIfCancelled>
    <validIfInactive>>true</validIfInactive>
    <validIfSuspendedActive>>true</validIfSuspendedActive>
    <timezoneMode>EVENT</timezoneMode>
    <minQuantity>1</minQuantity>
    <minQuantityUnit>none</minQuantityUnit>
    <incrementQuantity>1</incrementQuantity>
  </chargeEventMap>
</chargeOffering>

```

```

<incrementQuantityUnit>none</incrementQuantityUnit>
<roundingMode>NEAREST</roundingMode>
<prorateFirst>PRORATE_CHARGE</prorateFirst>
<prorateLast>PRORATE_CHARGE</prorateLast>
<prorateCycle>PRORATE_CHARGE</prorateCycle>
<chargeRatePlanInfo>
  <targetEngine>ECE</targetEngine>
</chargeRatePlanInfo>
...

```

Using Date Ranges for Versioning

When creating charge offers in XML, you can add balance impacts with new date ranges to create new versions of the same charge offer.

You use the **<dateRangeImpactType>** field on charge offers to specify whether existing subscriptions move to the new balance impacts or continue with the old balance impacts.

BRM determines which balance impacts to apply based on the value of **<dateRangeImpactType>** as follows:

- **EVENT_DATE**: The charge event date determines which balance impacts are applied. Any existing subscriptions will use the new balance impacts after the existing date range ends. This is the default behavior.
- **PURCHASE_DATE**: The original purchase date determines which balance impacts are applied. Any existing subscriptions will continue to use the old balance impacts. Any new subscriptions purchased within the new date range will use the new balance impacts.

Note:

If a customer transfers their subscription as part of a service group transfer and **<dateRangeImpactType>** is set to **PURCHASE_DATE**, the balance impacts will be determined based on the service transfer date, not the original purchase date.

- **INSTANTIATED_DATE**: The original service instantiation date determines which balance impacts are applied. Any existing subscriptions will continue to use the old balance impacts. Any new subscriptions instantiated during the new date range will use the new balance impacts. This option is useful if your services often have a long delay between purchase and instantiation date. It allows customers with existing subscriptions to continue with the old pricing, while those who purchase under the old pricing can take advantage of the new pricing if it comes into effect before their new service is available.

The following shows an example of a charge offer using **<dateRangeImpactType>**:

```

<ChargeOffering externalID="1234">
  <name>Charge Offering With Purchase Date Impact</name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Product Offering</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <timeRange>0/inf</timeRange>
  <productSpecName>TelcoGsmTelephony</productSpecName>
  <dateRangeImpactType>PURCHASE_DATE</dateRangeImpactType>
  <offerType>SUBSCRIPTION</offerType>
  <priority>0</priority>

```

```

    <partial>>false</partial>
    <purchaseMin>-1.0</purchaseMin>
    <purchaseMax>-1.0</purchaseMax>
    <ownMin>-1.0</ownMin>
    <ownMax>-1.0</ownMax>
    <applicableQuantity>REMAINING</applicableQuantity>
    <chargeEventMap>
        ...
    </chargeEventMap>
</ChargeOffering>

```

The following examples describe how the value of **<dateRangeliImpactType>** effects the balance impacts applied. In the examples, you have an existing charge offer with a charge with a credit balance impact 1GB of free data every week. You add a new balance impact crediting 1.5GB, set the end date of the old balance impact to June 10th, and set the start date for the new balance impact to June 11th. Depending on the value of **<dateRangeliImpactType>** for the charge offer, the following happens:

- If **<dateRangeliImpactType>** is set to **EVENT_DATE**, all subscriptions get 1GB until June 10th, and 1.5GB thereafter.
- If **<dateRangeliImpactType>** is set to **PURCHASE_DATE**, subscriptions purchased before June 10th continue to get 1GB, even for events occurring after June 10th. Subscriptions purchased after June 10th get 1.5GB.
- If **<dateRangeliImpactType>** is set to **INSTANTIATED_DATE**, subscriptions instantiated before June 10th continue to get 1GB, even for events occurring after June 10th. Subscriptions instantiated after June 10th get 1.5GB, even if they were purchased before.

Discount Offer Configuration Examples

To configure discount offer functionality by using the PDC XML Pricing Interface, see the following examples:

- [Consuming Noncurrency Resources for Discounts in Order of Expiration](#)
- [Sharing Discount Offers Automatically with Sharing Group Members](#)
- [Using a Tax Selector](#)

Consuming Noncurrency Resources for Discounts in Order of Expiration

When creating discount offers in XML for rating in Oracle Communications Billing and Revenue Management Elastic Charging Engine (ECE), you can specify whether to consume noncurrency resources for the discounts in order of earliest expiry, or in order of any discount rules configured.

To do so, set the **<resourcesConsumptionOrder>** element under the discount (**alterationRatePlan**) to one of the following:

- **EARLIEST_EXPIRY**: Consume noncurrency resources according to which resource expires first. For example, if the customer is subscribed to one discount that grants minutes that expire monthly and another that grants minutes that expire yearly, the minutes expiring monthly should be consumed first. If all resources have the same validity dates, the discount rule order will be used.
- **RULE_ORDER**: Consume balances according to the configured discount rules, without taking validity into account.

The following XML example specifies to consume noncurrency resources in order of earliest expiration.

```
<alterationRatePlan xmlns:pdc="http://xmlns.oracle.com/communications/
platform/model/pricing">
  <name>Consumption Order Example Discount</name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Standard Discount ECE</pricingProfileName>

      </arpCompositePopModel>
    </alterationConfiguration>
  </arpDateRange>
</alterationRatePlan>
```

```

                                <priceValidity>
startValidityMode>                                <startValidityMode>IMMEDIATE</
                                                <endValidityMode>NEVER</endValidityMode>
                                                <validityRange>0/inf</validityRange>
                                                <relativeStartOffset>-1</
relativeStartOffset>                                <relativeEndOffset>-1</relativeEndOffset>
                                                </priceValidity>
                                                </percentAlteration>
                                                </tierRange>
                                                </priceTier>
                                                </alterationPopModel>
                                                </arpCompositePopModel>
                                                </alterationConfiguration>
                                                </arpDateRange>
</alterationRatePlan>

```

Sharing Discount Offers Automatically with Sharing Group Members

When creating discount offers in XML, you can specify whether the discount offer is automatically shared with all members of an automated discount offer sharing group when it is purchased by the group's owner. To do so, you use the **<groupSharingEnabled>** element under the **<alterationOffering>** element.

Set the **<groupSharingEnabled>** element to one of the following:

- **true:** The discount offer is shared with all members of an automated discount offer sharing group when it is purchased by the group's owner.
- **false:** The discount offer is not shared with members of an automated discount offer sharing group.

The following XML example specifies to automatically share the **do1** discount offer with members of an automated discount offer sharing group:

```

<alterationOffering xmlns:pdc="http://xmlns.oracle.com/communications/
platform/model/pricing" externalID="ExternalID">
  <name>do1</name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Product Offering</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <timeRange>0/inf</timeRange>
  <productSpecName>Ip</productSpecName>
  <offerType>SUBSCRIPTION</offerType>
  <priority>0</priority>
  <purchaseMin>-1.0</purchaseMin>
  <purchaseMax>-1.0</purchaseMax>
  <ownMin>-1.0</ownMin>
  <ownMax>-1.0</ownMax>
  <applicableChargeAndQuantity>REMAINING_CHARGE</
applicableChargeAndQuantity>
  <groupSharingEnabled>true</groupSharingEnabled>
  ...

```

Using a Tax Selector

You can specify a tax selector for both a subscription and for a convergent pricing profile (for ECE).

You can specify the tax selector for a subscription at both the discount (**alterationRatePlan**) level and the tierRange level. In both cases, you use the **<taxSelectorName>** parameter to set the tax selector.

For example, to use the **Sample_TAX_SELECTOR** tax selector for a subscription discount and the **Sample_TAX_SELECTOR_2** tax selector for a tierRange, the XML input file would include the following:

```
<alterationRatePlan xmlns:fdc="http://xmlns.oracle.com/communications/
platform/model/pricing">
  <name>20230302-0855 DiscountRatePlan</name>
  <pricingProfileName>Subscription Discount</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <taxSelectorName>Sample_TAX_SELECTOR</taxSelectorName>
  <arpDateRange>
    <startDate>0</startDate>
    <endDate>inf</endDate>
    <alterationConfiguration>
      <applicableChargeAndQuantity>REMAINING_CHARGE</
applicableChargeAndQuantity>
      <arpCompositePopModel>
        <name>Pricing</name>
        <alterationPopModel>
          <priceTier>
            . . .
            <tierRange>
              . . .
              <percentAlteration>
                . . .
                <priceType>CONSUMPTION</priceType>
                <taxTime>EVENT_TIME</taxTime>
                <taxSelectorName>Sample_TAX_SELECTOR_2</
taxSelectorName>
              </percentAlteration>
            . . .
          </tierRange>
        </priceTier>
      </alterationPopModel>
    </arpCompositePopModel>
  </alterationConfiguration>
</arpDateRange>
</alterationRatePlan>
```

You specify the tax selector for a convergent pricing profile (for ECE) at the discount (**alterationRatePlan**) level using the **<taxSelectorName>** parameter.

For example, to use the **Sample_TAX_SELECTOR** tax selector for a convergent pricing profile discount, the XML input file would include the following:

```
<alterationRatePlan xmlns:pdc="http://xmlns.oracle.com/communications/
platform/model/pricing">
  <name>20230227 - DiscountRatePlan</name>
  <pricingProfileName>Standard Discount</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <taxSelectorName>Sample_TAX_SELECTOR</taxSelectorName>
  <resourcesConsumptionOrder>RULE_ORDER</resourcesConsumptionOrder>
  . . .
</alterationRatePlan>
```

Package Configuration Examples

To configure package functionality by using the PDC XML Pricing Interface, see the following examples:

- [Activating Offers in Packages](#)
- [Setting Loan Thresholds for Packages](#)
- [Transitioning Packages](#)

Activating Offers in Packages

When creating packages in XML, you can specify whether to activate all charge offers across all bundles in a package when one of the charge offers is activated on first usage. To do so, you use the **<firstUsageActivation>** element under the **<package>** element.

Set the **<firstUsageActivation>** element to one of the following:

- **true:** Activates all charge offers in the package upon first usage of any charge offer in the package.
For example, assume a package contains bundle 1 with charge offers A and B, and bundle 2 with charge offer C. If the first service a customer uses is in charge offer B, all charge offers (A, B, and C) are activated at that time.
- **false:** When one charge offer in the package is activated on first usage, only that charge offer is activated. The other charge offers are not affected.
For example, assume a package contains bundle 1 with charge offers A and B, and bundle 2 with charge offer C. If the first service a customer uses is in charge offer B, only charge offer B is activated at that time. This is the default.

The following shows an example of a package with the **<firstUsageActivation>** element set:

```
<package xmlns:pdc="http://xmlns.oracle.com/communications/platform/model/
pricing">
  <name>PackageWithPSCAttributes</name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Subscription</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <billOnPurchase>>false</billOnPurchase>
  <firstUsageActivation>true</firstUsageActivation>
```

```

    <productSpecPackageItem>
      <name>TelcoGsmTelephony</name>
      <balanceSpecificationName>Account Balance Group</
balanceSpecificationName>
      <productSpecName>TelcoGsmTelephony</productSpecName>
      <bundledProductOfferingAssociation>
        <optional>>false</optional>
        <cancelWithService>>false</cancelWithService>
        <bundledProductOfferingName>bundleForPkg</bundledProductOfferingName>
      </bundledProductOfferingAssociation>
    </productSpecPackageItem>
  </balanceSpecification>
  <name>Account Balance Group</name>
</balanceSpecification>
</package>

```

Setting Loan Thresholds for Packages

When creating balance credit profiles for packages in XML, you can use the following types in **<thresholdLevel>** elements to set balance thresholds below which a customer is offered a loan:

- **PERCENTAGE_LOAN**: When this percent of the balance is consumed, the customer is offered a loan. The percentage must be in 5% increments.
- **ABSOLUTE_LOAN**: When the balance falls below this fixed number, which must be greater than the credit floor and less than the credit ceiling, the customer is offered a loan.

You can set multiple thresholds, each contained within a separate **<thresholdLevel>** element.

When the customer subscribes to the package, the thresholds are stored in the **/config/credit_profile** object associated with their balance group. For more information about loan thresholds and what happens when they are breached, see "About Loan Thresholds" in *BRM Configuring and Collecting Payments*.

The following sample XML entries specify several threshold types. The **PERCENTAGE_LOAN** and **ABSOLUTE_LOAN** types are used for offering loans, and the **PERCENTAGE** and **ABSOLUTE** types are used for different notifications or automatic top-ups:

```

<package>
  <name>Package for Loan Thresholds</name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Subscription</pricingProfileName>
  <priceListName>Default Price List</priceListName>
  <obsolete>>false</obsolete>
  <billOnPurchase>>false</billOnPurchase>
  <productSpecPackageItem>
    <name>TelcoGsmTelephony</name>
    <balanceSpecificationName>Account Balance Group</
balanceSpecificationName>
    <productSpecName>TelcoGsmTelephony</productSpecName>
    <bundledProductOfferingAssociation>
      <optional>>false</optional>
      <cancelWithService>>false</cancelWithService>
      <bundledProductOfferingName>Bundle for Voice</
bundledProductOfferingName>
    </bundledProductOfferingAssociation>

```

```

    </productSpecPackageItem>
  <balanceSpecification>
    <name>Account Balance Group</name>
    <balanceElementSpecification>
      <balanceElementNumCode>840</balanceElementNumCode>
      <consumptionRule>EARLIEST_EXPIRATION</consumptionRule>
      <balanceCreditProfile>
        <floor>10.0</floor>
        <ceiling>100.0</ceiling>
        <thresholdLevel>
          <threshold>90.0</threshold>
          <type>PERCENTAGE</type>
        </thresholdLevel>
        <thresholdLevel>
          <threshold>25.0</threshold>
          <type>ABSOLUTE</type>
        </thresholdLevel>
        <thresholdLevel>
          <threshold>95.0</threshold>
          <type>PERCENTAGE_LOAN</type>
        </thresholdLevel>
        <thresholdLevel>
          <threshold>5.0</threshold>
          <type>ABSOLUTE_LOAN</type>
        </thresholdLevel>
      </balanceCreditProfile>
    </balanceElementSpecification>
  </balanceSpecification>
</package>

```

Transitioning Packages

When creating package transitions in XML, you can configure how PDC applies charges when customers transition packages in the middle of their billing cycle by using the **<prorationType>** element under the **<packageTransition>** element.

Set the **<prorationType>** element to one of the following:

- **PRORATE_CHARGE**: Specifies to prorate charges for both packages. This is the default.
- **ORIGINAL_CHARGE**: Specifies to apply the full charges from the original package.
- **TRANSFER_CHARGE**: Specifies to apply the full charges from the new package.

The following shows an example that applies the full charge from the original package when the package is transitioned in the middle of a billing cycle:

```

<packageTransition xmlns:fdc="http://xmlns.oracle.com/communications/platform/
model/pricing">
  <name>sample package transition</name>
  <internalId>InternalID</internalId>
  <pricingProfileName>Subscription</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <active>>true</active>
  <timeRange>0/inf</timeRange>
  <waivePurchaseFee>>true</waivePurchaseFee>

```

```

    <waiveCancelFee>true</waiveCancelFee>
    <productSpecName>TelcoGsmTelephony</productSpecName>
    <prorationType>ORIGINAL_CHARGE</prorationType>
    <type>UPGRADE</type>
    <fromPackageName>Package A</fromPackageName>
    <toPackageName>Package B</toPackageName>
  </packageTransition>

```

Selector Configuration Examples

To configure selector functionality by using the PDC XML Pricing Interface, see the following examples:

- [Configuring Tax Selectors](#)
- [Configuring Tax Exemption Selectors](#)

Configuring Tax Selectors

You can configure tax selectors, which are used to apply different tax codes based on the value of one or more service, event, profile, or customer attributes. You do this using the **<taxSelector>** element.

The following shows an example of a **<taxSelector>** element:

```

<?xml version="1.0" encoding="UTF-8" standalone="yes"?><pd: PricingObjectsJXB
xmlns:pd="http://xmlns.oracle.com/communications/platform/model/pricing">
<taxSelector xmlns:pd="http://xmlns.oracle.com/communications/platform/model/
pricing">
  <name>Sample_TAX_SELECTOR</name>
  <description>Sample TAX_SELECTOR</description>
  <pricingProfileName>Convergent Usage</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <stereotype>TAX_SELECTOR</stereotype>
  <productSpecName>TelcoGsmSms</productSpecName>
  <eventSpecName>EventDelayedSessionTelcoGsm</eventSpecName>
  <validityPeriod>
    <validFrom>0</validFrom>
    <rule>
      <name>Rule1</name>
      <result>
        <resultName>VAT</resultName>
      </result>
      <fieldToValueExpression>
        <operation>REGEX</operation>
        <separator>;</separator>
        <fieldName>EventDelayedSessionTelcoGsm.CALLED_ID</fieldName>
        <fieldValue>1800.*</fieldValue>
        <fieldKind>EVENT_SPEC_FIELD</fieldKind>
      </fieldToValueExpression>
    </rule>
    <rule>
      <name>Rule2</name>
      <result>

```

```

        <resultName>toll</resultName>
    </result>
    <fieldToValueExpression>
        <operation>REGEX</operation>
        <seperator>;</seperator>
        <fieldName>EventDelayedSessionTelcoGsm.CALLED_ID</fieldName>
        <fieldValue>.*</fieldValue>
        <fieldKind>EVENT_SPEC_FIELD</fieldKind>
    </fieldToValueExpression>
</rule>
</validityPeriod>
</taxSelector></pdc:PricingObjectsJXB>

```

Configuring Tax Exemption Selectors

You can configure tax exemption selectors, which are used to apply different tax exemptions based on the value of one or more service, event, profile, or customer attributes. You do this using the **<taxExemptionSelector>** element.

The following shows an example of a **<taxExemptionSelector>** element:

```

<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<pdc:PricingObjectsJXB xmlns:pdc="http://xmlns.oracle.com/communications/
platform/model/pricing">
<taxExemptionSelector xmlns:pdc="http://xmlns.oracle.com/communications/
platform/model/pricing">
    <name>Sample TaxExemptionSelector</name>
    <description>Sample TaxExemptionSelector</description>
    <pricingProfileName>Product Offering</pricingProfileName>
    <priceListName>Default</priceListName>
    <obsolete>>false</obsolete>
    <stereotype>TAX_EXEMPTION_SELECTOR</stereotype>
    <productSpecName>TelcoGprs</productSpecName>
    <eventSpecName>EventSessionTelcoGprs</eventSpecName>
    <customerSpecName>Account</customerSpecName>
    <validityPeriod>
        <validFrom>0</validFrom>
        <rule>
            <name>TES_rule1</name>
            <result>
                <resultName>USATaxExemptionCode</resultName>
            </result>
            <fieldToValueExpression>
                <operation>EQUAL_TO</operation>
                <seperator>;</seperator>
                <fieldName>TelcoGprs.GPRS_INFO.ROUTING_AREA</fieldName>
                <fieldValue>National</fieldValue>
                <fieldKind>PRODUCT_SPEC_FIELD</fieldKind>
            </fieldToValueExpression>
            <fieldToValueExpression>
                <operation>EQUAL_TO</operation>
                <seperator>;</seperator>

Charge Offer

This section describes the XML tags that you use to configure charge offers in the XML pricing interface.

Charge offers determine the price of one or more events associated with a service. For more information, see "[Configuring Charge Offers](#)".

chargeOffering

This is the main tag for configuring a charge offer in PDC. [Table 32-1](#) describes the fields in the **chargeOffering** tag.

Table 32-1 chargeOffering

Field Name	Description
name	Unique name of the charge offer. PDC does not allow creation of offerings with duplicate names. It is VARCHAR2 (255).
description	Description of the charge offer. It is VARCHAR2 (255).
internalId	Unique ID (UUID) internally generated by PDC while committing the pricing configuration. It is a unique internal ID for all charge offer, discount offer, bundles, and configurations in PDC and cannot be the same for any other pricing or configuration entity.
applicableQuantity	This can be REMAINING or ORIGINAL based on the charge offer type.
dateRangeImpactType	<p>When you add balance impacts with new date ranges to an existing charge offer, whether existing subscriptions move to the new balance impact or continue with the old balance impact:</p> <ul style="list-style-type: none"> • EVENT_DATE: The charge event date determines which balance impacts are applied. • PURCHASE_DATE: The original purchase date determines which balance impacts are applied. • INSTANTIATED_DATE: The original service instantiation date determines which balance impacts are applied. For products that have the first usage attribute for Purchase, this field is set with actual purchase time and will be used to filter the products for events prior to their subscription (for backdated or future dated scenarios). <p>See "Using Date Ranges for Versioning" for information and examples.</p>
expiryNotification	<p>Boolean flag for triggering notifications to be sent to your customers when the charge offer is about to expire.</p> <p>See "Specifying Which Expiring Products Trigger Notifications" in <i>BRM Managing Customers</i>.</p>
groupSharingEnabled	<p>Boolean flag to enable the charge offer to be shared with all members of a product sharing group when it is purchased by the group's owner.</p> <p>See "Sharing Products Automatically with Sharing Group Members" for information and examples.</p>
obsolete	Boolean flag to obsolete the promoted (or active) objects.
offerType	<p>The type of charge offer:</p> <ul style="list-style-type: none"> • Item: A one-time purchase fee. Only item is created for the charges and there is no purchased product instance for this subscription. • Subscription: Charges for any type and combination of events, including one-time, recurring, usage, rollover, remittance, and fold. These charges apply only to the subscriber who owns the charge offer. Item and purchased product instance are created in BRM for this option. • System: Charges that apply to all subscribers who use a particular service. These type of offers do not require subscription and are effective on the subscriber at the system level.

Table 32-1 (Cont.) chargeOffering

Field Name	Description
ownMax	Specify the maximum number of charge offers that a customer can own at one time. -1 means unlimited. For example, if a website charge offer provides 100 MB of disk space, you can limit customers to 500 MB by setting the maximum ownership quantity to 5.
ownMin	Specify the minimum number of charge offers that a customer can own at one time. -1 means unlimited.
partial	Boolean flag to enable partial purchases. This option is used to determine whether customers can purchase only part of a charge offer.
policySpecification	Policy specification is made up of one or more counter policies, each of which defines a gradation in the quality of service (QoS) based on the subscriber's service usage. For example, you can have a policy specification named Platinum for a data service and a balance element for it as Megabytes Used. You can define a counter policy labeled Fair Usage, which has three levels, Low QoS, Medium QoS, and High QoS, with each level containing a usage range valid for that quality of service, such as 100-150, 150-200, and 200-No Maximum megabytes.
priceListName	This is configured as Default by default.
pricingProfileName	The pricing profile determines which features are supported for the charge. PDC determines the pricingProfileName once the charge category and charge type are selected. Possible values: <ul style="list-style-type: none"> • Convergent Usage • Product Offering • Standard ChargeSharing • Standard Discount • Subscription ChargeSharing • Subscription Discount • Subscription To find out the actual pricingProfileName loaded in the system, query the PDC database: <pre>select name, pricingProfileType from aPricingProfile where entityClass = 'PricingProfileDAO' order by pricingProfileType, name;</pre>
priority	Priority for the charge offer. When more than one charge offer applies to the same event, this priority determines the order in which your billing system considers the charge offers. The higher the number, the higher the priority. 0 is the lowest priority.
productSpecName	The service type to which the charge offer applies.
provisioningTag	Provisioning tag for the charge offer. In BRM, provisioning tags are used to implement extended rating attributes (ERAs), such as a discount for calls to friends and family on a subscriber's birthday, or to configure telco service extensions and supplementary services, such as call forwarding and call blocking.

Table 32-1 (Cont.) chargeOffering

Field Name	Description
purchaseCycleDOM	How to align product validity: <ul style="list-style-type: none"> <i>Integer</i>: Aligns offer validity to a specific day of the month, with valid values from 1 through 31. 0: Aligns offer validity to the billing date. See " Aligning Recurring Charges and Product Validity to a Specific Day of the Month " for information and examples.
purchaseMax	Specify the maximum number of charge offers that a customer can buy at one time. -1 means unlimited.
purchaseMin	Specify the minimum number of charge offers that a customer can buy at one time. -1 means unlimited.
subscriptionDueNotification	Boolean flag for triggering notifications to be sent to your customers before the subscription is due for renewal. See "Specifying Which Subscription Renewals Trigger Notifications" in <i>BRM Managing Customers</i> .
TaxExemptionSelectorGroup	This XML tag contains information about the tax exemption selector to be used for the charge offer. See " TaxExemptionSelectorGroup ".
taxSupplier	Select a supplier tax ID for the charge offer. This ID specifies the company or corporate division that sells the product and is responsible for collecting taxes for it.
timeRange	The time range during which the offer is available for purchase in the format <i>startingTime</i> <i>endingTime</i> . The default is 0/inf , which specifies a time range from now to never ends.
validityRounding	Specify whether to start the charge offer's validity period at the purchase time or midnight of the purchase day. <ul style="list-style-type: none"> OFF: Starts at the time of purchase. This overrides the CM pin.conf setting at the charge offer level. ON: Starts at midnight (00:00:00) of the day that the charge offer is purchased. This overrides the CM pin.conf setting at the charge offer level. NOT_SET: Uses the systemwide setting in the CM pin.conf file. This is the default.
scaleRounding	Specify how to calculate the scale: <ul style="list-style-type: none"> OFF: Calculates it based on the <validityRounding> setting. ON: Calculates it based on full days.
ChargeEventMap	The XML tag inside the ChargeOffering (CO) XML tag which illustrates the event details related with the CO. This tag can occur multiple times in the CO tag based on how many events are mapped inside a Single CO. See " chargeEventMap ". Note : You can map multiple events inside the CO but for override capability, you must only map single type of event under each CO. There will be one-to-one mapping of CO with ChargeEventMap.

TaxExemptionSelectorGroup

The **TaxExemptionSelectorGroup** tag represents the tax exemption selector information for the charge offer. [Table 32-2](#) describes the fields in the **TaxExemptionSelectorGroup** tag.

Table 32-2 TaxExemptionSelectorGroup

Field Name	Description
taxExemptionSelectorName	The name of the tax exemption selector
taxExemptionSelectorIID	The ID of the tax exemption selector

chargeEventMap

The **chargeEventMap** tag is present for each individual event type that a product offering will rate. It maps a given event type to the charging rules for those events. [Table 32-3](#) describes the fields in the **chargeEventMap** tag.

Table 32-3 chargeEventMap

Field Name	Description
eventName	Name of the event. For example, EventDelayedSessionTelcoGsm (/event/delayed/session/telco/gsm in BRM) is used for usage events, while EventBillingProductFeeCycleCycle_forward_monthly (/event/billing/product/fee/cycle/cycle_forward_monthly) represents a monthly recurring fee (in-advance).
validIfCancelled	Charge even if the instantiated product offering status is canceled. BRM offering statuses are: <ul style="list-style-type: none"> • 1 = active • 2 = inactive • 3 = canceled
validIfInactive	Charge even if the instantiated product offering status is inactive.
timezoneMode	Determines the time zone used to rate an event: <ul style="list-style-type: none"> • From ACCOUNT: Uses the time zone in which the account is registered. • From EVENT: Uses the time zone in which the event occurs. For example, if you make a call from California and your account is registered in New York: <ul style="list-style-type: none"> • If you select From Account, New York time is used. • If you select From Event, California time is used.
minQuantity	Minimum value that the RUM quantity is rounded to. Value smaller than min_quantity is rounded to min_quantity. Minimum quantity starts from 0 by default. For example, if an event had a duration of 10 seconds, and the minimum quantity is configured as 30, then 30 seconds would be rated. If the duration of the event were 45 seconds, 45 seconds would be rated.
minQuantityUnit	Unit in which min_quantity is expressed. Possible values are: <ul style="list-style-type: none"> • NONE (0) • SECOND (1) • MINUTE (2) • HOUR (3) • DAY (4)

Table 32-3 (Cont.) chargeEventMap

Field Name	Description
incrementQuantity	Incremental value to round RUM Quantity to. RUM Quantity is always rounded to an integral multiple of the Incremental Quantity. For example, if the incrementQuantity is configured as 30 for a RUM of seconds, then the amount to rate would be rounded to that increment (see roundingMode) and a 43 second call would be rated as 60 seconds (if rounding up) or 30 seconds (if rounding down).
incrementQuantityUnit	Units that incrementQuantity is specified in (see "minQuantityUnit").
roundingMode	Specifies how RUM quantity is rounded. Possible values are: <ul style="list-style-type: none"> Up (0) Down (1) Nearest (2)
prorateFirst	How to apply cycle fees and rollovers when customers <i>purchase</i> subscriptions in the middle of their billing cycle: <ul style="list-style-type: none"> NO_CHARGE: Do not apply a cycle fee. FULL_CHARGE: Apply the full cycle fee. PRORATE_CHARGE: Calculate the cycle fee based on the amount of time the subscription was owned in the billing cycle. This is the default.
prorateLast	How to apply cycle fees and rollovers when customers <i>cancel</i> subscriptions in the middle of their billing cycle: <ul style="list-style-type: none"> NO_CHARGE: Do not apply a cycle fee. FULL_CHARGE: Apply the full cycle fee. PRORATE_CHARGE: Calculate the cycle fee based on the amount of time the subscription was owned in the billing cycle. This is the default.
prorateCycle	How to apply cycle fees when customers change their billing day of the month (DOM) during any billing cycle: <ul style="list-style-type: none"> NO_CHARGE: Do not apply a cycle fee. FULL_CHARGE: Apply the full cycle fee. PRORATE_CHARGE: Calculate the cycle fee based on the amount of time the subscription was owned in the billing cycle. This is the default.
chargeRatePlanName	Name of the charge configuration inside the CO at a granular and more detailed level. Charge Configuration name can be any name such as OneTime charge, MRC, Rollover, FreeSMS, FreeVoice, and so on.
ratePlanIID	Charge rate plan IID generated internally by PDC system for the chargeEventMap XML tag.
chargeRatePlanInfo	The target engine where the pricing or configuration information is published. ECE means Rating Engine, BRE means batch rating sync to Pipeline component in BRM, and RRE means Realtime sync to BRM system. See " chargeRatePlanInfo ".

chargeRatePlanInfo

The **chargeRatePlanInfo** tag represents the target engine where information about the charge offer is to be published. [Table 32-4](#) describes the field in the **chargeRatePlanInfo** tag.

Table 32-4 chargeRatePlanInfo

Field Name	Description
targetEngine	The target engine where the information about this charge offer is to be published. Possible values are: <ul style="list-style-type: none"> • BRE • ECE • RRE This is automatically taken care of by the ImportExportPricing utility.

chargeRatePlan

The root tag for configuring the charge rate plan. This captures details such as the target rating engine, tax code, time model, and so on. [Table 32-5](#) describes the fields in the **chargeRatePlan** tag.

Table 32-5 chargeRatePlan

Field Name	Description
priceListName	This is configured as Default by default.
pricingProfileName	Convergent Usage for usage events. Subscription for one-time and recurring events.
taxCode	The tax code used for the charge. You can use either this parameter or TaxSelectorGroup, but not both.
TaxSelectorGroup	The name of the tax selector group to use for the charge. You can use either this parameter or taxCode, but not both.
applicableRums	Displays the RUMs used in the charge. RUMs specify the units used to measure an event and how to calculate the measurement. In a charge, the pricing for each RUM is contained in a price tier. If a charge uses multiple RUMs, each tier appears in a subtab in the Pricing Details section of the charge tab.
applicableQuantity	Applicable quantity types. Valid values are: <ul style="list-style-type: none"> • ORIGINAL • REMAINING

Table 32-5 (Cont.) chargeRatePlan

Field Name	Description
taxTime	When the charge is taxed: <ul style="list-style-type: none"> • NONE: Do not apply taxes. • EVENT_TIME: Taxes are calculated when the event is rated, and they are added to the customer's account balance. This way, you always have an accurate reading of a customer's account balance at any time in the accounting cycle. • BILLING_TIME: Taxes are calculated when the bill is generated. Deferring tax calculation to the billing process reduces rounding errors because all events of the same type are calculated together. For example, taxes are calculated on the total amount of usage fees rather than on individual usage events. • DYNAMIC: Taxes are calculated at billing time using the tax rate at the time the event occurred. This provides the benefits of billing-time taxation while allowing you to change tax rates in the middle of a billing cycle. For example, assume a recurring charge's tax rate changes from 2% to 3% on May 15. If a billing cycle ends on May 30, BRM would use the 2% rate to calculate the charge's April 30 through May 14 taxes and the 3% rate to calculate the charge's May 15 through May 29 taxes.
todMode	Indicates if events should be rated using startTime, endTime, or split to use both.
applicableQtyTreatment	Indicates if applicable quantity should be treated continuous or isolated.
permittedName	The service to which the charge applies.
permittedType	Specifies whether it is a product or a customer type.
cycleFeeFlag	How to align recurring charges: <ul style="list-style-type: none"> • 0: Recurring charges are aligned to the billing date. For example, if the billing date is the 1st of the month and the charge offer is purchased on January 10, the charge is prorated and applied on January 10 for the interval January 10 to February 1. For subsequent cycles, the charge is applied on the billing date (for the interval February 1 to March 1, March 1 to April 1, and so on). • 1: Recurring charges are applied on the product purchase date. Using the previous example, the charge is applied on the 10th of every month (for the interval January 10 to February 10, February 10 to March 10, and so on). See "Aligning Recurring Charges and Product Validity to a Specific Day of the Month" for information and examples.
billOffset	Specifies the offset (in days or months) to bill in advance.
subscriberCurrency	The three letter ISO code for currency.

TaxSelectorGroup

The **TaxSelectorGroup** tag represents the tax selector information for the charge. describes the fields in the **TaxSelectorGroup** tag.

Table 32-6 TaxExemptionSelectorGroup

Field Name	Description
taxSelectorName	The name of the tax selector
taxSelectorID	The ID of the tax selector

subscriberCurrency

[Table 32-7](#) describes the fields in subscriberCurrency tag.

Table 32-7 subscriberCurrency

Field Name	Description
crpRelDateRange	Charge rate plan relative date range. See " crpRelDateRange ".
crpCompositePopModel	Generic pop model. It can be one-time, recurring, or usage type. See " crpCompositePopModel ".
applicableRum	RUMs are ways in which you can measure events. The most common RUMs are Duration and Volume. Before you create product offerings, you must define the RUMs available for rating. You define RUMs when you create the service-event map. For each event, you specify the RUMs that can be used for rating it. See " applicableRum ".

crpRelDateRange

[Table 32-8](#) describes the relative date range validity of the charge rate plan.

Table 32-8 crpRelDateRange

Field Name	Description
absoluteDateRange	Container for defining the effective date range for a fixed period. See " absoluteDateRange ".
relativeDateRange	Container for defining a relative date range for a product purchase. See " relativeDateRange ".

absoluteDateRange

[Table 32-9](#) describes the absolute date range validity of the charge rate plan.

Table 32-9 absoluteDateRange

Field Name	Description
startDate	Start date for the fixed period.
endDate	End date for the fixed period.

relativeDateRange

[Table 32-10](#) describes the relative date range details.

Table 32-10 relativeDateRange

Field Name	Description
startOffset	Number of days, hours, minutes, or seconds after the purchase time that the charge takes effect.
startUnit	Days, hours, minutes, or seconds after the purchase time that the charge takes effect.
endOffset	Number of days, hours, minutes, or seconds after the start time that the charge is no longer effective.
endUnit	Days, hours, minutes, or seconds after the start time that the charge is no longer effective.
base	Indicates the base type. Valid value: PRODUCT_PURCHASE

crpCompositePopModel

[Table 32-11](#) describes the fields in the **crpCompositePopModel** tag.

Table 32-11 crpCompositePopModel

Field Name	Description
oneTimePopModel	OneTimeProdOfferPriceModel to define the Balance Impacts for OneTime event types. For example, Product Purchase Fee, Product Cancel Fee, and so on. See " oneTimePopModel ".
recurringPopModel	A RecurringProdOfferPriceModel to define the Balance Impacts for Recurring event types. For example, Monthly Cycle Forward fee. See " recurringPopModel ".
usageChargePopModel	UsageProdOfferPriceModel to define the Balance Impacts for Usage event types. For example, Telco Gsm Telephony Usage charges. See " usageChargePopModel ".

applicableRum

[Table 32-12](#) describes the fields in the **applicableRum** tag.

Table 32-12 applicableRum

Field Name	Description
minQuantity	Minimum value that the RUM quantity is rounded to. Value smaller than min_quantity is rounded to min_quantity.
minQuantityUnit	The unit for minQuantity . Possible values are: <ul style="list-style-type: none"> • NONE (0) • SECOND (1) • MINUTE (2) • HOUR (3) • DAY (4)
incrementQuantity	Incremental value to round RUM Quantity to. RUM Quantity is always rounded to an integral multiple of the Incr Quantity.
incrementQuantityUnit	Units that incrementQuantity is specified in.

Table 32-12 (Cont.) applicableRum

Field Name	Description
roundingMode	Specifies how RUM quantity is rounded. Possible values are: <ul style="list-style-type: none"> • Up (0) • Down (1) • Nearest (2)

oneTimePopModel

[Table 32-13](#) describes the field in the **oneTimePopModel** tag.

Table 32-13 oneTimePopModel

Field Name	Description
priceTier	Container object to define the price tier. See " priceTier (OneTimePriceTier) ".

priceTier (OneTimePriceTier)

[Table 32-14](#) describes the fields in the **priceTier** tag.

Table 32-14 priceTier (OneTimePriceTier)

Field Name	Description
lowerBound	Starting value for the range.
tierBasis	Container object to define charge tier expression. See " tierBasis ".
enforceCreditLimit	Whether to enforce credit limits or let customers exceed them. See " Enforcing or Exceeding Credit Limits " for information and possible values.
tierRange	Container object to define charge tier range. See " tierRange ".

tierBasis

[Table 32-15](#) describes the field in the **tierBasis** tag.

Table 32-15 tierBasis

Field Name	Description
AChargeTierExpression	Base abstract entity for Tier Expression.

tierRange

[Table 32-16](#) describes the fields in the **tierRange** tag.

Table 32-16 tierRange

Field Name	Description
oneTimeCharge	Nonrecurring charges, such as setup or cancellation fees. See " oneTimeCharge ".
recurringCharge	Ongoing charges that are not generated or affected by usage, such as a monthly subscription fee. See " recurringCharge ".

oneTimeCharge

[Table 32-17](#) describes the fields in the **oneTimeCharge** tag.

Table 32-17 oneTimeCharge

Field Name	Description
price	The amount to debit or credit.
unitOfMeasure	The type of unit, such as Minute or Byte, to which the charge applies.
balanceElementNumCode	Numeric code for the balance element.
discountable	Boolean flag to make a balance impact discountable.
priceType	Type of impact: grant or consumption .
impactType	Used to specify whether the impact is fixed or scaled.

recurringPopModel

[Table 32-18](#) describes the fields in the **recurringPopModel** tag.

Table 32-18 recurringPopModel

Field Name	Description
priceTier	Defines recurring product offer price model. See " priceTier (RecurringPriceTier) ".

priceTier (RecurringPriceTier)

[Table 32-19](#) describes the fields in the **priceTier (RecurringPriceTier)** tag.

Table 32-19 priceTier (RecurringPriceTier)

Field Name	Description
lowerBound	Starting value for the range.
tierBasis	Container object to define charge tier expression.
enforceCreditLimit	Whether to enforce credit limits or let customers exceed them. See " Enforcing or Exceeding Credit Limits " for information and possible values.
tierRange	Container object to define charge tier range.

recurringCharge

[Table 32-20](#) describes the fields in the **recurringCharge** tag.

Table 32-20 recurringCharge

Field Name	Description
price	The amount of debit or credit.
unitOfMeasure	The type of unit, such as Minute or Byte, to which the charge applies.
balanceElementNumCode	Numeric code for the balance element.
discountable	Boolean flag to make a balance impact discountable.
priceType	Type of impact: grant or consumption .
impactType	Used to specify whether the impact is fixed or scaled.
proratable	Boolean flag to set proration.

usageChargePopModel

[Table 32-21](#) describes the fields in the **usageChargePopModel** tag.

Table 32-21 usageChargePopModel

Field Name	Description
priceTier	Defines usage charge product offer price model. See " priceTier ".

priceTier

[Table 32-22](#) describes the fields in the **priceTier** tag.

Table 32-22 priceTier

Field Name	Description
distributionMethod	Quantity range selection: <ul style="list-style-type: none"> UP_FRONT: Pick the quantity range containing the value. FROM_BAL_IMPACT: Distribute value across applicable quantity ranges.
tierBasis	Container object to define charge tier expression.
priceTierValidityPeriod	Validity period for the price tier. See " priceTierValidityPeriod ".

priceTierValidityPeriod

[Table 32-23](#) describes the fields in the **priceTierValidityPeriod** tag.

Table 32-23 priceTierValidityPeriod

Field Name	Description
lowerBound	Starting value for the range.
validFrom	Defines the start of the validity period. 0 means immediate.

Table 32-23 (Cont.) priceTierValidityPeriod

Field Name	Description
priceTierRange	Container object to define price tier range. See " priceTierRange ".

priceTierRange

[Table 32-24](#) describes the fields in the **priceTierRange** tag.

Table 32-24 priceTierRange

Field Name	Description
upperBound	End value for the range. Supported for backward compatibility.
upperBoundExpression	Defines the end value for a quantity range or the noncurrency balance element to consume. See " upperBoundExpression ". Supported in PDC Patch Set 8 and later.
scaledCharge	Defines scaled charge pop. See " scaledCharge ".
fixedCharge	Defines fixed charge pop.

upperBoundExpression

[Table 32-25](#) describes the fields in the **upperBoundExpression** tag.

Table 32-25 upperBoundExpression

Field Name	Description
balanceTBExpression	Defines the granted allowance to consume. See " balanceTBExpression ".
numberTBExpression	Defines the end value for a quantity range. See " numberTBExpression ".

balanceTBExpression

[Table 32-26](#) describes the fields in the **balanceTBExpression** tag.

Table 32-26 balanceTBExpression

Field Name	Description
balanceElementNumCode	The ID for the noncurrency balance element.

numberTBExpression

[Table 32-27](#) describes the field in the **numberTBExpression** tag.

Table 32-27 numberTBExpression

Field Name	Description
value	The end value for a quantity range.

scaledCharge

[Table 32-28](#) describes the fields in the **scaledCharge** tag.

Table 32-28 scaledCharge

Field Name	Description
price	The amount to debit or credit.
unitOfMeasure	The type of unit, such as Minute or Byte, to which the charge applies.
balanceElementNumCode	Numeric code for the balance element, such as 640 for US dollars.
discountable	Boolean flag to make a balance impact discountable.
priceType	Type of impact: GRANT or CONSUMPTION .
incrementStep	The number of units to which the charge applies. For example, for a mobile phone service, you might charge 0.40 US dollars for every minute of usage in 2-minute increments. In this example: <ul style="list-style-type: none"> • Amount is 0.40. • Balance Element is US dollars. • Per Unit is Minute. • Increment is 2.
incrementRounding	The type of rounding, which is based on the specified increment. For example, if a 3-minute-and-50-second call is rated in 2-minute increments, it is handled as follows: <ul style="list-style-type: none"> • None: Not applicable. (Applies only to an increment of 1). • Round Down: Charge for 2 minutes (\$0.80). • Round Up: Charge for 4 minutes (\$1.60).

Discount Offer

This section describes the XML tags that you use to configure discount offers in the XML pricing interface.

A discount offer is a purchasable product offering, similar to a charge offer. You can use discount offers to reduce a charge by a percentage, or to consume or grant balance elements. For more information, see "[Creating Discount Offers](#)".

alterationOffering

This is the main tag for configuring discount offers in PDC. Most of the tags are the same as for charge offers, except for the tags mentioned below. [Table 32-29](#) describes the fields in the **alterationOffering** tag.

Table 32-29 alterationOffering

Field Name	Description
applicableChargeAndQuantity	<p>Determines how the discounts are applied to the charge when a charge is eligible for multiple discount offers.</p> <ul style="list-style-type: none"> • ORIGINAL_CHARGE: The discount offer is applied to the original charge amount, regardless of whether that amount was reduced by previous discount offers. • REMAINING_CHARGE: The discount offer is applied to the remaining charge amount after previous discount offers are applied. • UNUSED_CHARGE_QUANTITY: The discount offer is applied only to the part of the charge and quantity that have not been used as the basis for a previous discount offer. <p>This option is not valid for discount offers that credit a balance.</p>
alterationEventMap	<p>This is the XML tag inside the AlterationOffering (DO) XML tag which illustrates the event details related with the DO. This tag can occur multiple times in the DO tag based on how many events are mapped inside a Single DO.</p> <p>Note: You can map multiple events inside the DO but for override capability, you must only map single type of event under each DO. There will be one-to-one mapping of DO with alterationEventMap.</p>
groupSharingEnabled	<p>Boolean flag to enable the discount offer to be shared with all members of an automated discount sharing group when it is purchased by the group's owner.</p> <p>See "Sharing Discount Offers Automatically with Sharing Group Members" for information and examples.</p>

AlterationEventMap

This is the mapping between event and alterationRatePlan (discount). [Table 32-30](#) describes the fields in AlterationEventMap tag.

Table 32-30 AlterationEventMap

Field Name	Description
snowball	<p>Displays if this discount is a snowball discount. Possible values are:</p> <ul style="list-style-type: none"> • true: enable • false: disable <p>In Oracle Communications Billing and Revenue Management (BRM), a snowball discount is a type of shared billing-time discount that distributes a discount to all accounts in a discount sharing group.</p>

Table 32-30 (Cont.) AlterationEventMap

Field Name	Description
validAtStartNotValidAtEnd	How to apply discounts when they are valid from the start of a cycle but end in mid-cycle. Possible values are: <ul style="list-style-type: none"> FULL_DISCOUNT: The discount is applied to the full cycle. PRORATE_DISCOUNT: The discount is prorated. NO_DISCOUNT: The discount is <i>not</i> applied. NOT_APPLICABLE: The discount is not applicable.
notValidAtStartValidAtEnd	How to apply discounts when they are valid from mid-cycle to the end of the cycle. Possible values are: <ul style="list-style-type: none"> FULL_DISCOUNT: The discount is applied to the full cycle. PRORATE_DISCOUNT: The discount is prorated. NO_DISCOUNT: The discount is <i>not</i> applied. NOT_APPLICABLE: The discount is not applicable.
notValidAtStartNotValidAtEnd	How to apply discounts when they start mid-cycle and also end mid-cycle. Possible values are: <ul style="list-style-type: none"> FULL_DISCOUNT: The discount is applied to the full cycle. PRORATE_DISCOUNT: The discount is prorated. NO_DISCOUNT: The discount is <i>not</i> applied. NOT_APPLICABLE: The discount is not applicable.
alterationRatePlanName	This refers to the name of the discount configuration inside the DO at a granular and more detailed level. Discount Configuration name can be any name such as OneTime discount, Recurring Discount, RatingTimeDiscount, and so on.
ratePlanIID	Discount rate plan IID generated internally by PDC system for the alterationEventMap XML tag.

alterationRatePlan

Root tag for the alteration rate plan configuration. [Table 32-31](#) describes the fields in the **alterationRatePlan** tag.

For an example rate plan configuration, see "[Consuming Noncurrency Resources for Discounts in Order of Expiration](#)".

Table 32-31 alterationRatePlan

Field Name	Description
internalId	PDC system generated internal id for the objects.

Table 32-31 (Cont.) alterationRatePlan

Field Name	Description
pricingProfileName	Standard Discount for usage event. Subscription Discount for onetime and recurring events.
priceListName	This is configured as Default by default.
obsolete	Boolean flag to obsolete the promoted objects.
taxCode	The tax code used for the discount. You can use either this parameter or TaxSelectorGroup, but not both.
TaxSelectorGroup	The name of the tax selector group to use for the discount. You can use either this parameter or taxCode, but not both.
resourcesConsumptionOrder	Whether to consume noncurrency resources for the discounts in order of earliest expiry, or in order of any discount rules configured: <ul style="list-style-type: none"> • EARLIEST_EXPIRY: Consume noncurrency resources according to which resource expires first. For example, if the customer is subscribed to one discount that grants minutes that expire monthly and another that grants minutes that expire yearly, the minutes expiring monthly should be consumed first. If all resources have the same validity dates, the discount rule order will be used. • RULE_ORDER: Consume balances according to the configured discount rules, without taking validity into account.
arpDateRange	Alteration rate plan relative date range.

TaxSelectorGroup

The **TaxSelectorGroup** tag represents the tax selector information for the discount. [Table 32-32](#) describes the fields in the **TaxSelectorGroup** tag.

Table 32-32 TaxExemptionSelectorGroup

Field Name	Description
taxSelectorName	The name of the tax selector
taxSelectorID	The ID of the tax selector

arpDateRange

[Table 32-33](#) describes the fields in the **arpDateRange** tag.

Table 32-33 arpDateRange

Field Name	Description
startDate	Start date for a date range in a discount.
endDate	End date for a date range in a discount.
alterationConfiguration	Defines configuration details for the alteration.

alterationConfiguration

[Table 32-34](#) describes the fields in the **alterationConfiguration** tag.

Table 32-34 alterationConfiguration

Field Name	Description
applicableChargeAndQuantity	<p>Select how to apply the discount.</p> <p>By default, a discount rule applies the discounts in the same way as the discount offer that contains the rule.</p> <ul style="list-style-type: none"> • Original Charge: The discount offer is applied to the original charge amount, regardless of whether that amount was reduced by previous discount offers. • Remaining Charge: The discount offer is applied to the remaining charge amount after previous discount offers are applied. • Remaining Charge and Quantity: The discount offer is applied only to the part of the charge and quantity that have not been used as the basis for a previous discount offer.
arpCompositePopModel	Alteration rate plan composite pop model. Holds information about the pricing/ballImpact used in alteration offer pricing.

arpCompositePopModel

[Table 32-35](#) describes the fields in the **arpCompositePopModel** tag.

Table 32-35 arpCompositePopModel

Field Name	Description
alterationPopModel	Defines alteration product offer price model.

alterationPopModel

[Table 32-36](#) describes the fields in the **alterationPopModel** tag.

Table 32-36 alterationPopModel

Field Name	Description
priceTier	If a pricing uses more than one RUM, a tab appears for each RUM. These tabs are called price tiers.

priceTier

[Table 32-37](#) describes the fields in the **priceTier** tag.

Table 32-37 priceTier

Field Name	Description
distributionMethod	Quantity range selection: <ul style="list-style-type: none"> • UP_FRONT: Pick the quantity range containing the value. • FROM_BAL_IMPACT: Distribute value across applicable quantity ranges.
tierBasis	Container object to define charge tier expression.
lowerBound	Starting value for the range. Expressions are supported.
tierRange	Container object to define charge tier range.

tierBasis

[Table 32-38](#) describes the fields in the **tierBasis** tag.

Table 32-38 tierBasis

Field Name	Description
tierExpressions	Defines expression for the tier.

tierRange

[Table 32-39](#) describes the fields in the **tierRange** tag.

Table 32-39 tierRange

Field Name	Description
upperBound	Maximum value of the range. Expressions are supported.
percentAlteration	Defines percentage Alteration value.

percentAlteration

[Table 32-40](#) describes the fields in the **percentAlteration** tag.

Table 32-40 percentAlteration

Field Name	Description
price	It is applied towards the amount that is discounted.
unitOfMeasure	The type of unit, such as Minute or Byte, to which the discount applies.
balanceElementNumCode	Select the currency or noncurrency balance element to debit or credit.
alterationAppliesTo	Select the balance to apply the discount to. <ul style="list-style-type: none"> • User Balance: The balance of the account or service that generates the event. • Sharer Balance: The balance of the account or service that owns the discount.

Table 32-40 (Cont.) percentAlteration

Field Name	Description
alterationBasedOn	Defines on how much alteration/discount should get applied. It is defined at the pricing level.
priceType	Type of impact - grant or consumption
taxCode	The tax code used for the discount.
glid	Used for selecting the required GL Information for a given balance impact.
priceValidity	Defines validity for the price.

alterationBasedOn

[Table 32-41](#) describes the fields in the **alterationBasedOn** tag.

Table 32-41 alterationBasedOn

Field Name	Description
expression	An expression which represents What to Discount field in the UI.

priceValidity

[Table 32-42](#) describes the fields in the **priceValidity** tag.

Table 32-42 priceValidity

Field Name	Description
priceValidity	To define the validity period for the credited amount in the balance impact.
startValidityMode	Defines start validity mode: <ul style="list-style-type: none"> • FOREVER • IMMEDIATE • ABSOLUTE • RELATIVE • FIRST_USAGE • PERIOD_START
endValidityMode	Defines end validity mode: <ul style="list-style-type: none"> • NEVER • ABSOLUTE • RELATIVE_TO_START • RELATIVE_TO_PERIOD_START
validityRange	Defines the validity range. DateTimeRange should be defined as YYYYMMDDTHHMMSS or YYYYMMDDTHHMMSS.

Table 32-42 (Cont.) priceValidity

Field Name	Description
relativeStartOffset	To make the amount valid in any number of accounting cycles, billing cycles, months, days, hours, minutes, or seconds from the event occurrence. For example, if you specify two accounting cycles, the amount will be valid after two accounting cycles from when the event occurs.
relativeEndOffset	The amount validity ends relative to the validity start time. Enter the number of accounting cycles, billing cycles, months, days, calendar days, hours, minutes, or seconds from the validity start time when the validity ends.
relativeStartOffsetUnit	Accounting cycles, billing cycles, months, days, hours, minutes, or seconds.
relativeEndOffsetUnit	Accounting cycles, billing cycles, months, days, calendar days, hours, minutes, or seconds.

Chargeshare Offer

This section describes the XML tags that you use to configure chargeshares in the XML pricing interface.

A chargeshare offer contains one or more chargeshares that specify how charges are shared among the members of a group. Charge sharing enables an account to sponsor the charges of other accounts in the group. The sponsoring account receives the balance impact of charges incurred by the group member accounts. For more information, see "[Sharing Charges and Discounts](#)".

distributionOffering

Table 32-43 describes the fields in the **distributionOffering** tag.

Table 32-43 distributionOffering

Field Name	Description
name	Unique name for the chargeshare offer.
description	Description for the chargeshare offer.
internalId	Unique id internally generated by PDC while committing the pricing configuration. It cannot be same for any other pricing or configuration entity.
pricingProfileName	Pricing profile to associate with the chargeshare offer.
priceListName	This is configured as Default by default.
obsolete	Boolean flag to obsolete the promoted (or active) objects.

Table 32-43 (Cont.) distributionOffering

Field Name	Description
timeRange	The time range during which the offer is available for purchase. Format: starttime/endtime Examples: <ul style="list-style-type: none"> • <code><timeRange>0/inf</timeRange></code> indicates the offer is available for purchase immediately and there is no end date. • <code><timeRange>20220712T001137/20220730T01144</timeRange></code> indicates the offer can be purchased only within the time period mentioned.
productSpecName	The service type to which the charge offer applies.
offerType	Select Use for Aggregation. The ChargeShare offer is set for aggregation.

distributionEventMap

This is the XML tag inside the **distributionOffering** (charge offer) XML tag which illustrates the event details related with the chargeshare offer. This tag can occur multiple times in the discount offer tag based on how many events are mapped inside a single discount offer.

Table 32-44 describes the fields in the **distributionEventMap** tag.

**Note:**

You can map multiple events inside the discount offer, but for override capability, only map single type of event under each discount offer. There will be one-to-one mapping of discount offer with **distributionEventMap**.

Table 32-44 distributionEventMap

Field Name	Description
eventName	The name of the event. For example, EventDelayedSessionTelcoGsm (<code>/event/delayed/session/telco/gsm</code> in BRM) would be used for usage events, while EventBillingProductFeeCycleCycle_forward_monthly (<code>/event/billing/product/fee/cycle/cycle_forward_monthly</code>) would represent a monthly recurring fee (in-advance).
validIfCancelled	Charge even if the instantiated product offering status is canceled. BRM offering statuses are: <ul style="list-style-type: none"> • 1 = active • 2 = inactive • 3 = canceled
validIfInactive	Charge even if the instantiated product offering status is inactive.

Table 32-44 (Cont.) distributionEventMap

Field Name	Description
timezoneMode	<p>Determines the time zone which will be used to rate an event:</p> <ul style="list-style-type: none"> From ACCOUNT: Uses the time zone in which the account is registered. From EVENT: Uses the time zone in which the event occurs. <p>For example, if you make a call from California and your account is registered in New York:</p> <ul style="list-style-type: none"> If you select From Account, New York time is used. If you select From Event, California time is used.
minQuantity	<p>Minimum value that the RUM quantity is rounded to. Value smaller than min_quantity is rounded to min_quantity. Minimum quantity starts from 0 by default. For example, if an event had a duration of 10 seconds, and the minimum quantity was configured as 30, then 30 seconds would be rated. If the duration of the event were 45 seconds, 45 seconds would be rated (as it is larger than the minimum configured).</p>
minQuantityUnit	<p>Unit in which min_quantity is expressed. Possible values are:</p> <ul style="list-style-type: none"> NONE (0) SECOND (1) MINUTE (2) HOUR (3) DAY (4)
incrementQuantity	<p>Incremental value to round RUM Quantity to. RUM Quantity is always rounded to an integral multiple of the Incremental Quantity. For example, if the incrementQuantity was configured as 30 for a RUM of seconds, then the amount to rate would be rounded to that increment (see "roundingMode") and a 43 second call would be rated as 60 seconds (if rounding up) or 30 seconds (if rounding down).</p>
incrementQuantityUnit	<p>Unit associated with the increment quantity. For example, for an increment of 60 seconds, you would enter Seconds.</p>
roundingMode	<p>How to round the RUM quantity. Possible values are:</p> <ul style="list-style-type: none"> Up (0) Down (1) Nearest (2)
prorateFirst	<p>Proration setting when purchased mid-cycle. It can be either FULL_CHARGE or PRORATE_CHARGE.</p>
prorateLast	<p>The proration setting when canceled mid-cycle. It can be either FULL_CHARGE or PRORATE_CHARGE.</p>

Table 32-44 (Cont.) distributionEventMap

Field Name	Description
distributionRatePlanName	The name of the charge configuration inside the discount offer at a granular level. Enter any name, such as One-time charge, MRC, Rollover, FreeSMS, FreeVoice, and so on.
ratePlanIID	Charge rate plan IID generated internally by the PDC system for the distributionEventMap XML tag.
distributionRatePlanInfo	The target engine where the pricing or configuration information is published. <ul style="list-style-type: none"> • ECE = ECE rating engine • BRE = Batch rating synchronized to Pipeline Manager • RRE = Real-time rating synchronized to BRM

distributionRatePlanInfo

[Table 32-45](#) describes the fields in the **distributionRatePlanInfo** tag.

Table 32-45 distributionRatePlanInfo

Field Name	Description
targetEngine	The target engine where to publish information about the discount offer. Possible values are: <ul style="list-style-type: none"> • BRE • ECE • RRE This is automatically taken care by the ImportExportPricing utility in PDC as per the charge type and charge category.

distributionRatePlan

Root tag for the distribution rate plan configuration. [Table 32-46](#) describes the fields in the **distributionRatePlan** tag.

Table 32-46 distributionRatePlan

Field Name	Description
internalId	PDC system-generated internal ID for the objects.
pricingProfileName	Convergent Usage for usage events. Subscription for one-time and recurring events.
priceListName	This is configured as Default .
obsolete	Boolean flag to obsolete the promoted objects.
taxCode	The tax code used for the chargeshare. You can use either this parameter or TaxSelectorGroup, but not both.
TaxSelectorGroup	The name of the tax selector group to use for the chargeshare. You can use either this parameter or taxCode, but not both.
drpDateRange	Distribution rate plan relative date range.

TaxSelectorGroup

The **TaxSelectorGroup** tag represents the tax selector information for the chargeshare. [Table 32-47](#) describes the fields in the **TaxSelectorGroup** tag.

Table 32-47 TaxExemptionSelectorGroup

Field Name	Description
taxSelectorName	The name of the tax selector
taxSelectorID	The ID of the tax selector

drpDateRange

[Table 32-48](#) describes the fields in the **drpDateRange** tag.

Table 32-48 drpDateRange

Field Name	Description
startDate	Start date for a date range in a charge share.
endDate	End date for a date range in a charge share.
distributionConfiguration	Container object to define configurations for the distribution rate plan.

distributionConfiguration

[Table 32-49](#) describes the fields in the **distributionConfiguration** tag.

Table 32-49 distributionConfiguration

Field Name	Description
drpCompositePopModel	Distribution rate plan composite pop model. Holds information about the pricing/ballImpact used in the distribution offer pricing.

drpCompositePopModel

[Table 32-50](#) describes the fields in the **drpCompositePopModel** tag.

Table 32-50 drpCompositePopModel

Field Name	Description
alterationPopModel	An alteration pop model rate plan element which contains the price tier information.

alterationPopModel

[Table 32-51](#) describes the fields in the **alterationPopModel** tag.

Table 32-51 alterationPopModel

Field Name	Description
priceTier	If a pricing uses more than one RUM, enter the price tier name.

priceTier

[Table 32-52](#) describes the fields in the **priceTier** tag.

Table 32-52 priceTier

Field Name	Description
distributionMethod	Quantity range selection: <ul style="list-style-type: none"> UP_FRONT: The quantity range containing the value. FROM_BAL_IMPACT: Distribute the value across applicable quantity ranges.
tierBasis	Container object to define charge tier expression.
lowerBound	Starting value for the range. Expressions are supported.
tierRange	Container object to define charge tier range.

tierBasis

[Table 32-53](#) describes the fields in the **tierBasis** tag.

Table 32-53 tierBasis

Field Name	Description
chargeTierExpression	Expression for the charge tier.

chargeTierExpression

[Table 32-54](#) describes the fields in the **chargeTierExpression** tag.

Table 32-54 chargeTierExpression

Field Name	Description
useTierComponent	Defines which of the tiers would qualify for impact. Conventionally, it maps to Threshold/Tiered discount. Either we directly fall under a quantityRange bucket or split it across quantity ranges.
preRated	A Boolean flag to indicate that the charge is prerated.

lowerBound

[Table 32-55](#) describes the fields in the **lowerBound** tag.

Table 32-55 lowerBound

Field Name	Description
numberTBExpression	The number expression for charge tier bound.

numberTBExpression

[Table 32-56](#) describes the fields in the **numberTBExpression** tag.

Table 32-56 numberTBExpression

Field Name	Description
value	Numeric value for Tier Bound. <ul style="list-style-type: none"> • Float.POSITIVE_INFINITY for Inf • Float.NEGATIVE_INFINITY for -Inf

tierRange

[Table 32-57](#) describes the fields in the **tierRange** tag.

Table 32-57 tierRange

Field Name	Description
upperBound	Maximum value of the range. Expressions are supported.
percentAlteration	Defines percentage discount value.

upperBound

[Table 32-58](#) describes the fields in the **upperBound** tag.

Table 32-58 upperBound

Field Name	Description
numberTBExpression	The number expression for charge tier bound.

numberTBExpression

[Table 32-59](#) describes the fields in the **numberTBExpression** tag.

Table 32-59 numberTBExpression

Field Name	Description
value	Numeric value for tier bound: <ul style="list-style-type: none"> • Float.POSITIVE_INFINITY for Inf • Float.NEGATIVE_INFINITY for -Inf

percentAlteration

[Table 32-60](#) describes the fields in the **percentAlteration** tag.

Table 32-60 percentAlteration

Field Name	Description
price	The amount that is discounted.
unitOfMeasure	The type of unit, such as Minute or Byte, to which the discount applies.
balanceElementNumCode	The currency or noncurrency balance element to debit or credit.
alterationAppliesTo	The balance to apply the discount to: <ul style="list-style-type: none"> • User Balance: The balance of the account or service that generates the event. • Sharer Balance: The balance of the account or service that owns the discount.
alterationBasedOn	Defines on how much the discount should get applied. It is defined at the pricing level.
priceType	Type of impact. Valid values are: <ul style="list-style-type: none"> • GRANT • CONSUMPTION • AGGREGATE
priceValidity	To define the validity period for the credited amount in the balance impact.

alterationBasedOn

[Table 32-61](#) describes the fields in the **alterationBasedOn** tag.

Table 32-61 alterationBasedOn

Field Name	Description
chargeBasisExpression	Defines an expression for various fields such as QuantityRange , DiscountTrigger , tierBasis (DRUM), and BalanceImpact (Pricing).

chargeBasisExpression

[Table 32-62](#) describes the fields in the **chargeBasisExpression** tag.

Table 32-62 chargeBasisExpression

Field Name	Description
useTierComponent	Defines which tiers qualify for impact. Conventionally, it maps to Threshold/Tiered discount. Either we directly fall under a quantityRange bucket or split it across quantity ranges.
preRated	A Boolean flag for indicating whether the charge is pre-rated.

priceValidity

[Table 32-63](#) describes the fields in the **priceValidity** tag.

Table 32-63 priceValidity

Field Name	Description
startValidityMode	Defines the start validity mode: <ul style="list-style-type: none"> • FOREVER • IMMEDIATE • ABSOLUTE • RELATIVE • FIRST_USAGE • PERIOD_START
endValidityMode	Defines the end validity mode: <ul style="list-style-type: none"> • NEVER • ABSOLUTE • RELATIVE_TO_START • RELATIVE_TO_PERIOD_START
validityRange	Defines the validity range in the following format: YYYYMMDDTHHMMSS or YYYYMMDDTHHMMSS.
relativeStartOffset	To make the amount valid in any number of accounting cycles, billing cycles, months, days, hours, minutes, or seconds from the event occurrence. For example, if you specify two accounting cycles, the amount will be valid after two accounting cycles from when the event occurs.
relativeEndOffset	The amount validity ends relative to the validity start time. Enter the number of accounting cycles, billing cycles, months, days, calendar days, hours, minutes, or seconds from the validity start time when the validity ends.

Bundle

This section describes the XML tags that you use to configure bundles with the XML pricing interface.

Bundles group together charge offers and discount offers belonging to the same service. See "[Creating Bundles](#)".

bundledProductOffering

This is the main tag for configuring a bundle in PDC. [Table 32-64](#) describes the fields in the **bundledProductOffering** tag.

Table 32-64 bundledProductOffering

Field Name	Description
name	Unique name of the bundle. It is VARCHAR2(255).
description	Description of the bundle. It is VARCHAR2(255).

Table 32-64 (Cont.) bundledProductOffering

Field Name	Description
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It is unique for all bundles, charge offers, discount offers, and configurations in PDC, and cannot be the same for any other pricing or configuration entity.
pricingProfileName	The pricing profile determines which features are supported for the charge. PDC determines the pricingProfileName after the charge category and charge type are selected. Possible values are: <ul style="list-style-type: none"> • Convergent Usage • Product Offering • Standard ChargeSharing • Standard Discount • Subscription ChargeSharing • Subscription Discount • Subscription
priceListName	This is configured as Default .
obsolete	Boolean flag to obsolete the promoted (or active) objects.
timeRange	(Optional) Set the purchase start and end dates to specify when the bundle can be purchased in the following format: [YYYYMMDDTHHMMSS/YYYYMMDDTHHMMSS] The default is 0/inf . For the start date, you can enter Immediately, or enter a specific start date and time. For the end date, you can enter inf (never) or a specific end date and time. The purchase period excludes the end date. For example, a bundle with a start date of May 1 and an end date of May 10 is available from May 1 through May 9.
productSpecName	The service type to which the charge offer applies.
assignedType	The type of configuration attribute specification: PRODUCT or CUSTOMER .
billOnPurchase	(Optional) Boolean flag for immediately generating a bill for any purchase fees when the customer purchases the bundle. This does not generate a bill for any other charges, such as recurring, usage, or cancellation fees.

Table 32-64 (Cont.) `bundledProductOffering`

Field Name	Description
<code>customization</code>	<p>(Optional) Whether a CSR can change a customer's default price and effective time period of a charge or discount offer:</p> <ul style="list-style-type: none"> • PROHIBITED: Prevents CSRs from changing the price and the effective period of a bundle. • REQUIRED: Forces CSRs to change the price and the effective period of a bundle. • OPTIONAL: Gives CSRs the option to change the price and the effective period of a bundle. This is the default.
<code>firstUsageActivation</code>	<p>(Optional) Boolean flag for activating all charge offers within a bundle on first usage:</p> <ul style="list-style-type: none"> • true: All charge offers in a bundle are activated when the first charge offer is activated. • false: When one charge offer in a bundle is activated on first usage, the other charge offers in the bundle are not activated. This is the default. <p>See "Activating Offers in Bundles" for information and examples.</p>
<code>groupBalanceElements</code>	<p>(Optional) Boolean flag to synchronize the start date of all balance elements to the date of first usage when one of them is activated for the first time.</p> <p>This setting applies only to those balance elements that are configured to start on first usage, and only to those first-usage balance elements that are granted by the offers in the bundle.</p>
<code>bundledProductOfferingItem</code>	<p>Details about a charge offer or discount offer inside the bundle. For example it can include the purchaseStart, purchaseEnd, usageStart, usageEnd, cycleStart, and cycleEnd fields. See "bundledProductOfferingItem".</p>

bundledProductOfferingItem

This is the main tag for configuring the item associated with the charge offer or discount offer in PDC. [Table 32-65](#) describes the fields in the `bundledProductOfferingItem` tag.

Table 32-65 bundledProductOfferingItem

Field Name	Description
addOnOfferingValidityMode	<p>(Optional) Adding this field specifies that the charge offer can be purchased as an add-on product after the bundle has been purchased. The validity mode for the add-on charge offer can be one of the following:</p> <ul style="list-style-type: none"> • BASE_OFFER: Aligns the validity dates with the base charge offer. When set to BASE_OFFER, you must also include the baseChargeOfferingName field. • BASE_OFFER_EXPIRY_FIRST: Aligns the validity dates with the active base charge offer that expires first. • BASE_OFFER_EXPIRY_LAST: Aligns the validity dates with the active base charge offer that expires last. • BASE_OR_ADD_ON_OFFER_EXPIRY_FIRST: Aligns the validity dates with the active charge offer that expires first. • BASE_OR_ADD_ON_OFFER_EXPIRY_LAST: Aligns the validity dates with the active charge offer that expires last. <p>See "Configuring Add-On Charge Offers In Bundles" for information and examples.</p>
baseChargeOfferingName	<p>The name of the base charge offer on which to set the validity dates for an add-on offer.</p> <p>Note: Include this field only when addOnOfferingValidityMode is set to BASE_OFFER.</p>
chargeOfferingName	<p>Displays the name of the charge offer or discount offer. This field is not editable.</p>
cycleChargeAdjustment	<p>(Optional) The adjustments to apply to the offer's recurring charges. The default is 0.</p>
gracePeriodOffset	<p>(Optional) The length of the grace period during which an additional offer can be purchased as an extension of an existing subscription. The default is 0.</p> <p>Note: This field applies only if purchaseMode is set to EXTEND or OVERWRITE.</p> <p>See "Purchasing the Same Offer in a Bundle Multiple Times" for information and examples.</p>
gracePeriodUnit	<p>(Optional) The unit of the grace period in gracePeriodOffset. The valid values are SECOND, MINUTE, HOUR, and DAY. The default is DAY.</p> <p>Note: This field applies only if purchaseMode is set to EXTEND or OVERWRITE.</p> <p>See "Purchasing the Same Offer in a Bundle Multiple Times" for information and examples.</p>

Table 32-65 (Cont.) bundledProductOfferingItem

Field Name	Description
prorationBasedOn	<p>The number of days in a month to use for calculating a prorated cycle charge or discount in an offer:</p> <ul style="list-style-type: none"> • PRORATE_30_DAYS: Prorated charge or discount is based on a 30-day month. • PRORATE_DAYS_IN_MONTH: Prorated charge or discount is based on the actual number of days in the month, such as 30 for June or 31 for May. • Not Set or missing: Prorated according to the system-wide setting in the CM pin.conf file. See "Examples of 30-Day-Based Proration" in <i>BRM Configuring and Running Billing</i>. <p>See "Setting Proration for Offers in a Bundle" for more information.</p>
purchaseChargeAdjustment	<p>(Optional) The adjustment to apply to the offer's purchase and cancel charges. The default is 0.</p>
purchaseMode	<p>(Optional) What happens if customers purchase the same charge offer or discount offer more than once. Possible values are:</p> <ul style="list-style-type: none"> • NEW_INSTANCE: The additional offer is purchased as a new, unrelated subscription. This is the default. • LONGEST_DATE: The additional offer is purchased as an extension to the existing subscription if it is purchased within the grace period. • EXTEND: The additional offer is purchased as an extension to the existing subscription if it is purchased with the grace period. • OVERWRITE: The additional offer replaces the existing subscription. <p>See "Purchasing the Same Offer in a Bundle Multiple Times" for information and examples.</p>
quantity	<p>(Optional) The quantity of charge offers or discount offers included in the bundle. The default is 1.</p> <p>For example, if a bundle for a cable service includes a charge offer that provides one set-top box and you want to include three set-top boxes with the cable service, enter 3 for the charge offer in that bundle.</p>

Table 32-65 (Cont.) bundledProductOfferingItem

Field Name	Description
renewalMode	(Optional) How to align recurring charge offers if a customer suspends and then reactivates a bundle: <ul style="list-style-type: none"> • true: Aligns the recurring charge offer as follows: <ul style="list-style-type: none"> – When cycleFeeFlag is set to 0, the cycle aligns with the billing date. – When cycleFeeFlag is set to 1 and purchaseCycleDOM is not set, the cycle aligns with the reactivation date. – When cycleFeeFlag is set to 1 and purchaseCycleDOM is set, the cycle aligns with either purchaseCycleDOM or the reactivation date, whichever is later. • false: Aligns the recurring charge offer according to the setting in purchaseCycleDOM. This is the default. See "Setting Charge Offer Cycle Alignment for Reactivated Bundles" for information and examples.
status	(Optional) The initial status of the product offering: 1 (active) or 0 (inactive). The default is 1 .
statusCode	(Optional) A customer-defined reason code if a product offering's status is inactive.
usageChargeAdjustment	(Optional) The adjustments to apply to an offer's usage charge. The default is 0 .

Subscription Terms

This section describes the XML tags that you use to configure subscription terms with the XML pricing interface.

Subscription terms specify a contract's commitment period, such as 1 month, 1 year, or 2 years, and capture details about the term, such as the early termination penalty, auto contract renewal, and so on. For more information, see "[Creating Subscription Terms](#)".

terms

[Table 32-66](#) describes the fields in the **terms** tag.

Table 32-66 terms

Field Name	Description
name	Unique name of the term to create.
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.

Table 32-66 (Cont.) terms

Field Name	Description
pricingProfileName	The pricing profile determines which features are supported for the term. Possible values are: <ul style="list-style-type: none"> • Convergent Usage • Product Offering • Standard ChargeSharing • Standard Discount • Subscription ChargeSharing • Subscription Discount • Subscription
priceListName	This is configured as Default .
obsolete	Boolean flag to obsolete the promoted (or active) objects.
termLength	The length of the commitment period. For example, for a 6-month commitment period, you would enter 6.
termUnit	The unit of the commitment period: DAY, WEEK, MONTH, or YEAR . For example, for a 6-month commitment period, you would enter MONTH.
earlyTerminationOption	Whether to allow early cancellation of the contract and whether to apply an early termination fee. Possible values are: <ul style="list-style-type: none"> • ALLOWED_NO_PENALTY: Contracts can be canceled early, and customers will not be charged an early termination fee. • ALLOWED_WITH_PENALTY: Contracts can be canceled early, but customers will be charged an early termination fee for doing so. • NOT_ALLOWED: Contracts cannot be canceled early.
terminationGraceLength	The length of the grace period, during which the early termination fee is waived. For example, for a 10-day grace period, you would enter 10.
terminationGraceUnit	The unit of the grace period: DAY, WEEK, MONTH, or YEAR . For example, for a 10-day grace period, you would enter DAY.
penaltyRevenueGlidInt	Select the revenue general ledger ID to associate with the early termination fee. If you do not select a general ledger ID, the early termination fee is distributed across the deliverables in the contract.
penaltyAmount	Amount for the penalty.
penaltyBalElemNumCodeInt	The balance element numeric code for the penalty amount.

Table 32-66 (Cont.) terms

Field Name	Description
penaltyOptions	The type of early termination fee to apply: <ul style="list-style-type: none"> • FULL_CHARGE: The fee is the full penalty amount. • USED_CONTRACT_UNITS: The fee is reduced in equal amounts over the contract's term. • CONTRACT_BALANCE: The fee is the balance remaining in the customer's contract.
autoRenew	Boolean flag specifying whether to automatically renew the contract: true or false . The default is false .

Time Model

This section describes the XML tags that you use to configure time models with the XML pricing interface.

A time model is a set of time periods that are used to set up different prices in a charge. Each time period consists of one or more time segments. A time segment can be represented using days of the week, days of the month, time of day, months of the year, or special days defined in a calendar. For more information, see "[Charging Based on Date and Time](#)".

timeModel

This is the main tag for configuring a time model in PDC. [Table 32-67](#) describes the fields in the **timeModel** tag.

Table 32-67 timeModel

Field Name	Description
name	Unique name for the time model.
pricingProfileName	The pricing profile determines which features are supported for the time model. Possible values are: <ul style="list-style-type: none"> • Convergent Usage • Product Offering • Standard ChargeSharing • Standard Discount • Subscription ChargeSharing • Subscription Discount • Subscription
description	Description for the time model.
priceListName	This is configured as Default .
obsolete	Boolean flag to obsolete the promoted (or active) objects.

Table 32-67 (Cont.) timeModel

Field Name	Description
usesSpecialDayCalendar	It is an optional field. Specifies a special day calendar in this time model. If included, the time model must include at least one time period with a special day calendar. Otherwise, the time model validation will fail.
validityPeriod	Contains the time period details along with the time segment details.
validFrom	The start date.

timePeriod

[Table 32-68](#) describes the fields in the **timePeriod** tag.

Table 32-68 timePeriod

Field Name	Description
tagName	Each time period within a time model should have a unique name.

timeSegment

[Table 32-69](#) describes the fields in the **timeSegment** tag.

Table 32-69 timeSegment

Field Name	Description
timeSpecification	Displays the time segments for the time periods. A time segment defines the specific times in the time period. A time segment can include: <ul style="list-style-type: none"> • Days of the week • Time of day • Months of the year • Days of the month • Special days in a calendar
daysOfWeek	The days of the week for the time segment. To specify all days of the week, enter Any Day of the Week . To include specific days, enter one or more days. It has nested day tags.
timeOfDay	The time interval for the time segment. To set the time interval to 24 hours of the day, enter All Day . To set a specific time, enter a start and end time.

Table 32-69 (Cont.) timeSegment

Field Name	Description
monthsOfYear	The months of the year for the time segment. To specify all months, enter Any Month of the Year . To include specific months, enter one or more months. It has nested month tags.
daysOfMonth	The days of the month for the time segment. To specify all days of the month, enter Any Day of the Month . To include specific days, enter one or more days.
holiday	Select to use special days defined in the special day calendar. You cannot have both normal days and special days included in the time period. They are mutually exclusive.

Charge Selector

This section describes the XML tags that you use to configure charge selectors with the XML pricing interface.

A charge selector is used to charge different fees for the same event based on the value of one or more attributes, such as subscriber (account), service, event, and custom rules (if applicable). For more information, see "[About Selectors](#)".

chargeSelector

[Table 32-70](#) describes the fields in the **chargeSelector** tag.

Table 32-70 chargeSelector

Field Name	Description
name	Name of the charge selector. The name must be unique across all USC, APN, and charge selectors.
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.
description	Description for the charge selector.
eventName	The event type to which the charge selector applies.
pricingProfileName	The pricing profile for the charge selector. Only charges associated with the selected profile can be used as the result of each charge selector rule.
priceListName	This is configured as Default .
obsolete	Boolean flag to obsolete the promoted (or active) objects.

Table 32-70 (Cont.) chargeSelector

Field Name	Description
stereoType	Type of object: CHARGE_RATE_PLAN_SELECTOR.
productSpecName	The service to which the charge selector applies.
eventSpecName	The event type to which the charge selector applies. Enter a fold event type if you are creating the charge selector for a fold charge.
customerSpecName	Tag used for "Account" as a service.
rumName	Name of the RUM.
measuredBy	The RUMs to which the charge selector applies. RUMs specify the units used to measure an event and how to calculate the measurement.

ruleAttributes

Use the **ruleAttributes** tag to select the subscriber, service, and event fields to use in the charge selector rules. [Table 32-71](#) describes the fields in **ruleAttributes** tag.

Table 32-71 ruleAttributes

Field Name	Description
selectorOptions	Possible values: <ul style="list-style-type: none"> • Zoning Not Used • Use Value Map • Use Zone Model
modelData	Key-value pairs. For example: <pre><modelData> <key>ZONING_OPTION</key> <value>ZONING_NONE</value> </modelData></pre>

rules

Use the **rules** tag to define charge selector rules. To create rules for a charge selector, you must first specify the subscriber, service, or event attributes to use in the rules. [Table 32-72](#) describes the fields in the **rules** tag.

Table 32-72 rules

Field Name	Description
validityPeriod	It indicates when the rules in the charge selector are valid. The default effective period starts immediately and never ends.

Table 32-72 (Cont.) rules

Field Name	Description
priority	The priority, starting with 1. The rules are evaluated in order of priority.
name	Unique name for the rule.
fieldName	An operator and value. The operator can be: <ul style="list-style-type: none"> • Equals or Not Equals • Matches or Not Matches • In or Not In
fieldToValueExpression	It has these fields: operation , seperator , fieldName , fieldValue , and fieldKind . For example: <pre><fieldToValueExpression> <operation>EQUAL_TO</operation> <seperator>;</seperator> <fieldName>TelcoGsmTelephony.NAME</ fieldName> <fieldValue>abc</fieldValue> <fieldKind>PRODUCT_SPEC_FIELD</ fieldKind> </fieldToValueExpression></pre>
impactCategory	Enter the impact category to use for determining the charge.
chargeRatePlanName	The item to find, configure, or modify the charge used when the rule is true. <ul style="list-style-type: none"> • Search to add an existing charge • Create to configure a new charge • Edit to modify the current charge The charge must contain a price selector that associates the results impact category with a pricing instance.
balanceElementNumCode	Numeric code for the balance element.
glid	The required GL information for a given balance impact.
result	It has resultName, chargeSelector name, and resultData with key-value pairs.

Generic Selector

This section describes the XML tags that you use to configure generic selectors with the XML pricing interface.

A generic selector is a set of rules that map service and event attributes and expressions to a result. You use a generic selector in a charge to apply prices based on the rule results. For more information, see "[About Selectors](#)".

genericSelector

[Table 32-73](#) describes the fields in the **genericSelector** tag.

Table 32-73 genericSelector

Field Name	Description
name	Name for the generic selector.
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.
description	Description for the generic selector.
productSpecName	(Optional) If you plan to use service attributes to create generic selector rules, enter the desired service.
eventSpecName	(Optional) If you plan to use event attributes to create generic selector rules, enter the desired event.
pricingProfileName	Pricing profile for the generic selector. Only charges associated with the selected profile can be used as the result of each generic selector rule.
priceListName	This is configured as Default .
obsolete	Boolean flag to obsolete the promoted (or active) objects.
stereoType	Type of object: GENERIC_SELECTOR .

ruleAttributes

[Table 32-74](#) describes the fields in the **ruleAttributes** tag.

Table 32-74 ruleAttributes

Field Name	Description
field	Displays the fields that you have selected to define generic selector rules. The same fields are used for all the rules in the generic selector. You can override the default values and set specific values in the rule to limit the fields that you want used in a rule.
valueType	Select the type of value that the field contains. <ul style="list-style-type: none"> • Single Value: The field contains a single value. • Value of Another Field: The field contains the value of another field. If you select this option, in the Default column, select the other field.

Table 32-74 (Cont.) ruleAttributes

Field Name	Description
operator	Displays the relationship between the rule's default field value and the value in the subscriber, service, or event field. The equal sign appears next to the field names when you define the rules. The value of the field in the subscriber, service, or event must match the value of the field in the rule.
default	Enter a default value for the field. An asterisk (*) specifies the field can contain any value. If the field is limited to predefined values, a list of values appears. Select a value from the list.

rules

Table 32-75 describes the fields in the **rules** tag.

Table 32-75 rules

Field Name	Description
validityPeriod	It indicates when the rules in the generic selector are valid. The default effective period starts immediately and never ends.
name	Name for the rule.
priority	The priority order, starting with 1. The rules are evaluated in order of priority.
fieldName	Enter an operator and enter a value. Operator can be: <ul style="list-style-type: none"> • Equals or Not Equals • Matches or Not Matches • In or Not In For example: <pre><fieldToValueExpression> <operation>EQUAL_TO</operation> <seperator>;</seperator> <fieldName>EventDelayedSessionTelcoGsm.NUMBER_OF_UNITS</fieldName> <fieldValue>*</fieldValue> <fieldKind>EVENT_SPEC_FIELD</fieldKind> </fieldToValueExpression></pre>

Table 32-75 (Cont.) rules

Field Name	Description
result	<p>The result is used in a charge to guide to a price. Provide a string value to map to this rule.</p> <p>For example:</p> <ul style="list-style-type: none"> • If the general selector rule determines that this is a Closed User Group (CUG) call, you could name the result ClosedUserGroup. • If the general selector rule determines that this is a call to friends and family, you could name the result Friends&Family. • If the general selector rule determines that this is a call with low QoS, you could name the result LowQoS.

Price Selector

This section describes the XML tags that you use to configure price selectors with the XML pricing interface.

A price selector associates event, service, and account attributes with prices. You use a price selector in a charge to apply prices based on price selector rules. For more information, see "[About Selectors](#)".

priceSelector

[Table 32-76](#) describes the fields in the **priceSelector** tag.

Table 32-76 priceSelector

Field Name	Description
name	Unique name for the price selector.
description	Description for the price selector.
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.
productSpecName	(Optional) The service for which you want to create the price selector.
eventSpecName	(Optional) The event for which you want to create the price selector rules.
customerSpecName	Tag used for "Account" as a service.
pricingProfileName	The pricing profile for the generic selector. Only charges associated with the selected profile can be used as the result of each generic selector rule.
priceListName	This is configured as Default .
obsolete	Boolean flag to obsolete the promoted (or active) objects.
stereoType	Type of object: PRICE_MODEL_SELECTOR .

ruleAttributes

[Table 32-77](#) describes the fields in the **ruleAttributes** tag.

Table 32-77 ruleAttributes

Field Name	Description
field	Displays the fields that you have selected to define price selector rules. The same fields are used for all rules in the price selector. You can override the default values and set specific values in the rule to limit the fields that you want used in a rule.
valueType	The type of value that the field contains: <ul style="list-style-type: none"> • Single Value: The field contains a single value. • Value of Another Field: The field contains the value of another field. If you enter this option, enter the name of the field in the default field.
operator	Displays the relationship between the rule's default field value and the value in the subscriber, service, or event field. The value of the field in the subscriber, service, or event must match the value of the field in the rule.
default	Enter a default value for the field. An asterisk (*) specifies the field can contain any value. If the field is limited to predefined values, a list of values appears.

rules

[Table 32-78](#) describes the fields in the **rules** tag.

Table 32-78 rules

Field Name	Description
validityPeriod	The rules in the price selector are valid. The default effective period starts immediately and never ends.
name	Provide a name for the rule.
priority	The priority order, starting with priority 1. The rules are evaluated in order of priority.
price	The existing pricing instance to associate with the rule.

Table 32-78 (Cont.) rules

Field Name	Description
fieldName	<p>Select an operator and enter a value. Operator can be:</p> <ul style="list-style-type: none"> • Equals or Not Equals • Matches or Not Matches • In or Not In <p>For example:</p> <pre><fieldToValueExpression> <operation>REGEX</operation> <seperator>;</seperator> <fieldName>Account.CUST_A.ACCOUNT_NO< /fieldName> <fieldValue>abc</fieldValue> <fieldKind>CUSTOMER_SPEC_FIELD</ fieldKind> </fieldToValueExpression></pre>

Discount Selector

This section describes the XML tags that you use to configure discount selectors with the XML pricing interface.

A discount selector consists of rules that associate account, service, and event attributes and custom rules with discounts. You use a discount selector to determine which discount to apply to an event. For more information, see "[About Selectors](#)".

discountSelector

[Table 32-79](#) describes the fields in the **discountSelector** tag.

Table 32-79 discountSelector

Field Name	Description
name	Unique name for the discount selector.
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.
description	Description for the discount selector.
productSpecName	(Optional) Service for which you want to create the discount selector.
eventSpecName	(Optional) Event for which you want to create the discount selector.
pricingProfileName	Pricing profile to associate with the discount selector.
priceListName	This is configured as Default .

Table 32-79 (Cont.) discountSelector

Field Name	Description
obsolete	Boolean flag to obsolete the promoted (or active) objects.
stereoType	Type of object: DISCOUNT_SELECTOR .

ruleAttributes

Table 32-80 describes the fields in the **ruleAttributes** tag.

Table 32-80 ruleAttributes

Field Name	Description
field	Displays the fields in your discount selector rules. The same fields are used for all rules in the discount selector. You can override the default values and set specific values in the rule to limit the fields that you want used in a rule.
valueType	Type of value that the field contains: <ul style="list-style-type: none"> • Single Value: The field contains a single value. • Value of Another Field: The field contains the value of another field. If you enter this option, enter a field name in the default field.
operator	Displays the relationship between the rule's default field value and the value in the subscriber, service, event, custom rule, or profile field: Equals , Matches , or Maps .
default	Enter a default value for the field. An asterisk (*) specifies that the field can contain any value. If the operator is Equals or Maps to, an asterisk (*) specifies the field can contain any value. If the operator is Matches, a dot followed by an asterisk (.*) specifies the field can contain any value. If the field is limited to predefined values, a list of values appear. Select a value from the list. If Value of Another Field is selected for Value Type, the Select Field dialog box appears. In the Select Field dialog box, select the field you want.

rules

Table 32-81 describes the fields in the **rules** tag.

Table 32-81 rules

Field Name	Description
validityPeriod	When the rules in the discount selector are valid. The default effective period starts immediately and never ends.
name	The name for the rule.
priority	The priority order of the rule, starting with priority 1.

Table 32-81 (Cont.) rules

Field Name	Description
discount	An existing discount to associate with the rule.
fieldToValueExpression	<p>An operator and a value. The operator can be:</p> <ul style="list-style-type: none"> • Equals or Not Equals • Matches or Not Matches • In or Not In <p>For example:</p> <pre><fieldToValueExpression> <operation>REGEX</operation> <seperator>;</seperator> <fieldName>Account.CUST_A.ACCOUNT_NO</ fieldName> <fieldValue>abc</fieldValue> <fieldKind>CUSTOMER_SPEC_FIELD</fieldKind> </fieldToValueExpression></pre>

USC Selector

This section describes the XML tags that you use to configure USC selectors in the XML pricing interface.

A Usage Scenario (USC) selector contains rules that map existing impact categories to new impact categories based on usage attributes and custom rules. For more information, see "[About Selectors](#)".

USCSelector

[Table 32-82](#) describes the fields in the **USCSelector** tag.

Table 32-82 USCSelector

Field Name	Description
name	Unique name for the USC selector. The name must be unique across USC, APN, and charge selectors.
description	Description for the USC selector.
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.
pricingProfileName	Pricing profile to associate with the USC selector.
priceListName	This is configured as Default .
obsolete	Boolean flag to obsolete the promoted (or active) objects.
stereoType	Type of object: USC_MAP .

rulesAndConditions

This section is used to create rules to map existing impact categories to new impact categories. [Table 32-83](#) describes the fields in the **rulesAndConditions** tag.

Table 32-83 rulesAndConditions

Field Name	Description
validityPeriod	<p>(Optional) The start and end dates to specify a time period during which the rules in the USC selector are valid.</p> <p>The default effective period starts immediately and never ends.</p> <p>For example, if starts from Immediately, validFrom value is 0.</p>
priority	<p>The priority in numerical order, starting with 1. The rules are evaluated in order of priority. The priority numbers of all rules affected by the move are changed.</p>
name	Name for the USC selector rule.
ruleData	<p>Zone model to use for this USC selector rule:</p> <ul style="list-style-type: none"> • key: ZONE_MODEL • value: Corresponding value of the zone model.
result	<p>The new impact category to use for determining the price for the event.</p> <p>The inner tag resultName has the impact category name.</p>
zoneImpactCategory	<p>The operator and the existing zone impact categories that you want to map to the new impact category in this USC selector rule.</p> <p>The default value <code>.*</code> specifies that the rule applies for all zone impact categories.</p> <p>Note: You can use Not Matches only if you are using ECE for usage charging.</p> <p>For example:</p> <pre><fieldToValueExpression> <operation>REGEX</operation> <separator>;</separator> <fieldName>AnyEvent.RETAIL_ZONE</ fieldName> <fieldValue>.*</fieldValue> <fieldKind>EVENT_SPEC_FIELD</ fieldKind> </fieldToValueExpression></pre>

Table 32-83 (Cont.) rulesAndConditions

Field Name	Description
usageClass	<p>The operator and the existing usage class values to use for evaluating the rule.</p> <p>The default value .* specifies that the rule applies for all usage classes.</p> <p>Note: You can use Not Matches only if you are using ECE for usage charging.</p> <p>For example:</p> <pre data-bbox="920 577 1442 856"><fieldToValueExpression> <operation>REGEX</operation> <seperator>;</seperator> <fieldName>AnyEvent.USAGE_CLASS</ fieldName> <fieldValue>CONF</fieldValue> <fieldKind>EVENT_SPEC_FIELD</ fieldKind> </fieldToValueExpression></pre>
usageType	<p>The operator and the existing usage type values to use for evaluating the rule.</p> <p>The default value .* specifies that the rule applies for all usage types.</p> <p>Note: You can use Not Matches only if you are using ECE for usage charging.</p>
customRule	<p>The operator and the existing custom rule to use for evaluating the rule.</p> <p>The default value .* specifies that the rule applies for all custom rules.</p> <p>Note: You can use Not Matches only if you are using ECE for usage charging.</p> <p>Example:</p> <pre data-bbox="920 1381 1409 1564"><crSelectorExpression> <rightOperand>CUST_RULE_CUSTOMER1</ rightOperand> <operator>NONE</operator> </crSelectorExpression></pre>

Table 32-83 (Cont.) rulesAndConditions

Field Name	Description
serviceClass	<p>The operator and the existing service class values to use for evaluating the rule.</p> <p>The default value .* specifies that the rule applies for all service classes.</p> <p>Note: You can use Not Matches only if you are using ECE for usage charging.</p> <p>For example:</p> <pre><fieldToValueExpression> <operation>REGEX</operation> <separator>;</separator> <fieldName>AnyEvent.SERVICE_CLASS</ fieldName> <fieldValue>DEF</fieldValue> <fieldKind>EVENT_SPEC_FIELD</ fieldKind> </fieldToValueExpression></pre>
serviceCode	<p>The operator and the existing service code values to use for evaluating the rule.</p> <p>The default value .* specifies that the rule applies for all service classes.</p> <p>Note: You can use Not Matches only if you are using ECE usage charging.</p> <p>For example:</p> <pre><fieldToValueExpression> <operation>REGEX</operation> <separator>;</separator> <fieldName>AnyEvent.SERVICE_CODE</ fieldName> <fieldValue>FAX</fieldValue> <fieldKind>EVENT_SPEC_FIELD</ fieldKind> </fieldToValueExpression></pre>
quantityValue	<p>(Optional) Enter the maximum quantity of usage for the event, such as duration.</p> <p>The quantity of usage for the event must be less than or equal to the quantity value.</p>
newUsageType	<p>(Optional) The new usage type to assign to the event.</p>

APN Selector

This section describes the XML tags that you use to configure Access Point Name (APN) selectors with the XML pricing interface.

An APN selector consists of rules that map APNs to new impact categories based on event attribute values. You use APN selectors to redefine the impact category for events that are associated with specific APNs. For more information, see "[About Selectors](#)".

APN Selectors

[Table 32-84](#) describes the fields in the `apnSelectors` tag.

Table 32-84 APN Selectors

Field Name	Description
<code>name</code>	Unique name for the APN selector. The name must be unique across USC, APN, and charge selectors.
<code>description</code>	Description for the APN selector.
<code>internalId</code>	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.
<code>pricingProfileName</code>	Pricing profile to associate with the APN selector.
<code>priceListName</code>	This is configured as Default .
<code>obsolete</code>	Boolean flag to obsolete the promoted (or active) objects.
<code>stereoType</code>	Type of object: APN_MAP .

rules

Use the `rules` tag to create rules to associate specific APNs with new impact categories.

[Table 32-85](#) describes the fields in the `rules` tag.

Table 32-85 rules

Field Name	Description
<code>validityPeriod</code>	(Optional) The start and end dates to specify a time period during which the rules in the USC selector are valid. The default effective period starts immediately and never ends.
<code>priority</code>	The priority in numerical order, starting with 1. The rules are evaluated in order of priority.
<code>name</code>	Name for the APN selector rule.
<code>modelData</code>	Zone model to use for this USC selector rule. <ul style="list-style-type: none"> key: ZONE_MODEL value: Corresponding value of the zone model.

Table 32-85 (Cont.) rules

Field Name	Description
APNName	<p>The operator and the existing APN name to use for evaluating the rule.</p> <p>The default value .* specifies that the rule applies for all APNs.</p> <p>Note: You can use Not Matches only if you are using ECE for usage charging.</p> <p>For example:</p> <pre data-bbox="922 577 1445 892"> <fieldToValueExpression> <operation>REGEX</operation> <separator>;</separator> <fieldName>AnyEvent.ACCESS_POINT_NAME </fieldName> <fieldValue>.*</fieldValue> <fieldKind>EVENT_SPEC_FIELD</ fieldKind> </fieldToValueExpression> </pre>
serviceCode	<p>The operator and the existing service codes to use for evaluating the rule.</p> <p>The default value .* specifies that the rule applies for all service codes.</p> <p>Note: You can use Not Matches only if you are using ECE for usage charging.</p> <p>For example:</p> <pre data-bbox="922 1207 1445 1522"> <fieldToValueExpression> <operation>REGEX</operation> <separator>;</separator> <fieldName>AnyEvent.SERVICE_CODE</ fieldName> <fieldValue>FAX</fieldValue> <fieldKind>EVENT_SPEC_FIELD</ fieldKind> </fieldToValueExpression> </pre>

Table 32-85 (Cont.) rules

Field Name	Description
zoneImpactCategory	<p>The operator and existing zone impact categories associated with the APNs.</p> <p>The default value <code>.*</code> specifies that the rule applies for all zone impact categories.</p> <p>For example:</p> <pre><fieldToValueExpression> <operation>REGEX</operation> <separator>;</separator> <fieldName>AnyEvent.RETAIL_ZONE</ fieldName> <fieldValue>.*</fieldValue> <fieldKind>EVENT_SPEC_FIELD</ fieldKind> </fieldToValueExpression></pre>
result	<p>The new impact category to associate with the APNs.</p> <p>The inner tag resultName has the impact category name.</p>

Package

This section describes the XML tags that you use to configure packages with the XML pricing interface.

A package consists of one or more bundles that you make available to your customers for purchase. For more information, see "[Creating Packages](#)".

Package

[Table 32-86](#) describes the fields in the **package** tag.

Table 32-86 Package

Field Name	Description
name	Unique name given for a package.
description	Description for the package.
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.
pricingProfileName	Pricing profile to associate with the package.
priceListName	This is configured as Default by default.
obsolete	Boolean flag to obsolete the promoted (or active) objects.

Table 32-86 (Cont.) Package

Field Name	Description
billOnPurchase	(Optional) Boolean flag for billing customers immediately for a purchase, even if the customer's billing cycle has not ended. When a customer purchases a package that is flagged for on-purchase billing, a bill is generated immediately for the purchase fees associated with the package. This does not generate a bill for any other charges, such as recurring, usage, or cancellation fees.
firstUsageActivation	(Optional) Boolean flag for activating all charge offers within a package on first usage: <ul style="list-style-type: none"> • true: All charge offers in a package are activated on first usage. • false: When one charge offer in a package is activated on first usage, the other charge offers in the package are not activated. This is the default. See " Activating Offers in Packages " for information and examples.
customerSpecPackageItem	Tag used for holding the bundle association attributes under "Account" in a package.
productSpecPackageItem	Tag used for holding the bundle association attributes under "Service*" (such as TelcoGsmSms, TelcoGsmSms, and so on) in a package.
balanceSpecification	By default, balances for all services are tracked in the account balance group. To track balances for specific services in the package, you associate the services with their own balance groups. For each balance group, you can specify credit limits, credit thresholds, and consumption rules for balance elements used by the services in that group. See " Setting Loan Thresholds for Packages " for examples.
subscriptionTermsID	Internal ID for the subscription terms object.
subscriptionTermsName	Name for the subscription terms object.
productSpecCharacteristic	Key-value pair for defining special characteristics in a product.

Package List

This section describes the XML tags that you use to configure package lists using the XML pricing interface.

A package list enables you to group related packages that you can sell to your customers. For more information, see "[Creating Package Lists](#)".

Package List

[Table 32-87](#) describes the fields in the **packageList** tag.

Table 32-87 Package List

Field Name	Description
name	Name for the package list.
description	Description for the package list.
internalId	Unique ID internally generated by PDC while committing the pricing configuration. It cannot be the same as any other pricing or configuration entity.
pricingProfileName	Pricing profile to associate with the package list.
priceListName	This is configured as Default by default.
obsolete	Boolean flag to obsolete the promoted (or active) objects.
type	Type of packages you want to add to your package list. The combination of the package list segment and type are case-sensitive and uniquely identify a package list when the package list is used in BRM.
segment	The customer segment that the package list is offered to. The combination of the package list segment and type are case-sensitive and uniquely identify a package list.
packageListStatus	Whether you want the package list to be available for purchase as soon as it is added to the database: <ul style="list-style-type: none"> • Active: Indicates that customers can purchase packages in the list as soon as the list is added to your system. • Inactive: Indicates that the list is not visible to customers, and customers cannot purchase packages from the list.

Tax Selector

This section describes the XML tags that you use to configure tax selectors with the XML pricing interface.

A tax selector allows you to use attributes in **/account**, **/service**, **/event**, or **/profile** objects to set a tax rate. See "[About Selectors](#)" for more information.

taxSelector

[Table 32-88](#) describes the fields in the **taxSelector** tag.

Table 32-88 taxSelector

Field Name	Description
name	Unique name of the tax selector.
description	Description of the tax selector.
pricingProfileName	Pricing profile to associate with the tax selector.
priceListName	This is configured as Default by default.

Table 32-88 (Cont.) taxSelector

Field Name	Description
obsolete	Boolean flag to obsolete the promoted (or active) objects.
stereoType	Set to TAX_SELECTOR .
productSpecName	(Optional) The service for which you want to create the tax selector.
eventSpecName	(Optional) The event for which you want to create the tax selector.
customerSpecName	(Optional) Tag used for "Account" as a service.
validityPeriod	Indicates when the rules in the tax selector are valid. The default effective period starts immediately and never ends.

validityPeriod

[Table 32-89](#) describes the fields in the **validityPeriod** tag.

Table 32-89 validityPeriod

Field Name	Description
validFrom	This contains the start date of the validity period, or 0 to indicate that it has no start date.
rule	This contains the characteristics of the rule to be checked.

rule

[Table 32-89](#) describes the fields in the **rule** tag.

Table 32-90 rule

Field Name	Description
name	This contains the name of the rule.
result	This contains one element, resultName , which contains the name of a tax code defined in the system.

Table 32-90 (Cont.) rule

Field Name	Description
fieldToValueExpression	<p>Enter the information for the comparison, as shown below:</p> <pre> <fieldToValueExpression> <operation>REGEX</operation> <seperator>;</seperator> <fieldName>EventDelayedSessionTelcoGs m.CALLED_ID</fieldName> <fieldValue>1800.*</fieldValue> <fieldKind>EVENT_SPEC_FIELD</ fieldKind> </fieldToValueExpression> </pre>

Tax Exemption Selector

This section describes the XML tags that you use to configure tax exemption selectors with the XML pricing interface.

A tax exemption selector allows you to use attributes in **/account**, **/service**, **/event**, or **/profile** objects to set a tax exemption rate. See ["About Selectors"](#) for more information.

taxExemptionSelector

[Table 32-88](#) describes the fields in the **taxExemptionSelector** tag.

Table 32-91 taxExemptionSelector

Field Name	Description
name	Unique name of the tax exemption selector.
description	Description of the tax exemption selector.
pricingProfileName	Pricing profile to associate with the tax exemption selector.
priceListName	This is configured as Default by default.
obsolete	Boolean flag to obsolete the promoted (or active) objects.
stereoType	Set to TAX_EXEMPTION_SELECTOR .
productSpecName	The service for which you want to create the tax exemption selector.
eventSpecName	The event for which you want to create the tax exemption selector.
customerSpecName	Tag used for "Account" as a service.
validityPeriod	Indicates when the rules in the tax exemption selector are valid. The default effective period starts immediately and never ends.

validityPeriod

[Table 32-89](#) describes the fields in the **validityPeriod** tag.

Table 32-92 validityPeriod

Field Name	Description
validFrom	This contains the start date of the validity period, or 0 to indicate that it has no start date.
rule	This contains the characteristics of the rule to be checked.

rule

[Table 32-89](#) describes the fields in the **rule** tag.

Table 32-93 rule

Field Name	Description
name	This contains the name of the rule.
result	This contains one element, resultName , which contains the name of a tax exemption code defined in the system.
fieldToValueExpression	Enter the information for the comparison, as shown below: <pre><fieldToValueExpression> <operation>EQUAL_TO</operation> <seperator>;</seperator> <fieldName>TelcoGprs.GPRS_INFO.ROUTIN G_AREA</fieldName> <fieldValue>National</fieldValue> <fieldKind>PRODUCT_SPEC_FIELD</ fieldKind> </fieldToValueExpression></pre>

Part VI

Customization and Administration

This part describes how to customize and maintain Pricing Design Center (PDC) and Oracle Communications Billing and Revenue Management (BRM) product offerings.

This part contains the following chapters:

- [Enabling Charging for Custom Events](#)
- [Using the PDC Web Service](#)
- [Working with Profiles](#)
- [Configuring Product Specification Attributes for Pricing Components](#)
- [Replicating Data Between PDC Systems](#)

Enabling Charging for Custom Events

Learn how to enrich custom events in Pricing Design Center (PDC) with information required by Oracle Communications Elastic Charging Engine (ECE) to process usage charging requests from the network.

Topics in this document:

- [Overview of Enriching Event Definitions](#)
- [About Charging Operation Types](#)
- [About Charging Operation Type Versions](#)
- [About Mapping Network Attributes to Event Attributes](#)
- [Before Enriching Event Definitions](#)
- [Enriching Event Definitions](#)
- [Editing Event Definitions](#)

Overview of Enriching Event Definitions

Oracle Communications Billing and Revenue Management (BRM) includes a set of commonly-used event definitions, such as the events used by GSM and GPRS services. If you create custom events and services by using BRM Developer Center, you need to use PDC to enrich the event definitions with additional information required by ECE.

You do the following to enrich an event definition:

- Add **USER_IDENTITY** and **CALLED_ID** attributes. The **USER_IDENTITY** attribute is required for all events. The **CALLED_ID** attribute is required only if you use zoning or other charging scenarios that are based on the call destination.
- Add transient attributes if required. These are attributes that are used specifically for usage charging and do not need to be stored persistently in the event for rerating. For example, you can add the **CELL_ID** attribute to retrieve cell load information, but the **CELL_ID** value does not need to be stored in the event object.
- Add usage charging operation types (for example, initiating a session-based charge for an event). See "[About Charging Operation Types](#)" for more information.
- Define the network mapping for the events; for example, if you are using Diameter Gateway, you map the request attributes that are received from the Diameter network to event attributes. This mapping is used by the ECE charging client at runtime to populate the event. See "[About Mapping Network Attributes to Event Attributes](#)" for more information.

About Charging Operation Types

A charging operation type is a type of operation that ECE uses for usage charging; for example, the **Initiate** operation type is used for initiating a session-based charge and the **Price_Enquiry** operation type is used for enquiring about price information. Each charging operation type requires a set of event attributes to be specified.

When you add the charging operation type in the event definition, you associate the charging operation type with the group of event attributes that are necessary to perform the charging operation on the event. For example:

- The attributes for session-based charging are associated with the **Initiate**, **Update**, and **Terminate** operation types.
- The attributes for event-based charging are associated with the **Debit**, **Refund**, and **Price_Enquiry** charging operation types.

Table 33-1 lists the charging operation types that are used in ECE.

Table 33-1 Charging Operation Types Used in ECE

Operation Type	Description
Initiate	Initiates a session-based charging operation.
Update	Modifies a session-based charging operation.
Terminate	Terminates a charging operation.
Cancel	Cancels a session-based charging operation.
Refund_Amount	Refunds a specific amount to a specific balance.
Refund_Unit	Refunds a calculated amount, based on units consumed, to the impacted balances.
Debit_Amount	Debits a specific amount to a specific balance.
Debit_Unit	Debits a calculated amount, based on Units consumed, to the impacted balances.
Price_Enquiry	Generates a price estimation without any balance reservations occurring. It is used when there isn't a high probability of receiving a charging request. For example, Price_Enquiry might be called to get the price of an event charge to display in a content portal.
Start_Accounting	Starts tracking usage without incurring balance impacts.
Update_Accounting	Continues tracking usage without incurring balance impacts.

See "[Enriching Event Definitions](#)" for information on how to add charging operation types and associating them with the event attributes.

About Charging Operation Type Versions

A set of charging operation types has a version, which is indicated by the **<externalVersion>** element.

When you modify the charging operation types in PDC, use the same version number to replace the existing set of charging operation types with the updated set of charging operation types. The updated charging operation types are published to ECE.

You increase the charging operation type version number if you want to use both the existing set of charging operation types and the updated set of charging operation types. For example, when incrementally upgrading the network mediation software program (client), you may want both the set of charging operation types active at the same time. Both old and new versions of the charging operation types are stored in PDC and published to ECE.

You must update the version number in your mediation specification file to associate the usage request builder with the event definition to which it applies.

The following is the syntax for the charging operation type version:

```

<opVersion>
  <externalVersion>version_number</externalVersion>
  <opTypes>
    ...
  </opTypes>
  <opTypes>
    ...
  </opTypes>
</opVersion>

```

where *version_number* is the version number for the set of charging operation types.

About Mapping Network Attributes to Event Attributes

The data that ECE needs for charging is sent to ECE as network attributes from clients. For example, the call destination might be sent to ECE as the **Service-Information.PS-Information.Called-Station-Id** attribute. To charge for usage, ECE needs to:

- Map network attributes to event attributes.
- Indicate whether the network attribute is from a 4G network or a 5G network:
 - For 4G networks, add the network attribute to the **<networkAttributeItem>** element. ECE rating uses this to calculate the value of the event attribute (specified by **<name>**), which will be stored in the field specified by **<persistedName>**.
 - For 5G networks, add the network attribute to the **<networkAttributeItem5g>** element. ECE rating uses this to calculate the value of the event attribute (specified by **<name>**), which will be stored in the field specified by **<persistedName5g>**.

Note:

The **<persistedName5g>** element is used only with the HTTP Gateway. See "Connecting ECE to a 5G Client" in *ECE Implementing Charging*.

For example, the following shows how to map the **Service-Information.PS-Information.Called-Station-Id** attribute from a 5G network to the **CALLED_ID** event attribute. The calculated value of the **CALLED_ID** event attribute will be stored in the **my_called_id_c** field in the BRM database.

```

<simpleAttributeItem>
  <name>CALLED_ID</name>
  <description>CALLED_ID</description>
  <type>STRING</type>
  <persistedName5g>my_called_id_c</persistedName5g>
  <attributeItemSupportedBy>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>Convergent Charging</targetApplicationSpecName>
  </attributeItemSupportedBy>
  <networkAttributeItem5g>Service-Information.PS-Information.Called-Station-Id</networkAttributeItem5g>
</simpleAttributeItem>

```

Before Enriching Event Definitions

Before enriching an events definition:

- Create a new event subclass (for example, **levent/cloud/library**) in Development Center. See *BRM Developer's Guide* for more information.
- When you created the event subclass, define a substruct; for example, USAGE_INFO. Add your custom fields to the substruct. Ensure that the fields for storing the user identity and called ID (if you are using zoning in your charge offer) are added to the substruct in the event class.
See the discussion about substructure in *BRM Developer's Guide* for more information.
- The event is mapped to the corresponding service (for example, **service/cloud/library**). See "Setting Up the Service-Event Map" for more information.
- The service and event definitions are synchronized with PDC by running the **SyncPDC** utility. See "Creating Pricing Setup Components" for more information.

Enriching Event Definitions

To enrich an event definition:

1. Export the event definition from PDC into an XML file by running the following command:

```
ImportExportPricing -export FileNamePrefix -metadata EVENT_ATTRIBUTE_SPEC -n
"eventname"
```

where *eventname* is the name of the event to be exported into an XML file.

For example, this command exports the definition for EventCloudLibrary to the **EventCloudLibrary_export_metadata.xml** file:

```
ImportExportPricing -export EventCloudLibrary -metadata EVENT_ATTRIBUTE_SPEC -n
EventCloudLibrary
```

2. Open the event definition file in a text editor.

The following example shows the event definition for the EventCloudLibrary event:

```
<eventAttributeSpec>
  <name>EventCloudLibrary</name>
  <description>EventCloudLibrary</description>
  <internalId>c06de0cc-6105-4cd3-92c9-ad8011e5fe7b</internalId>

  <priceListName>Default</priceListName>
  <obsolete>>false</obsolete>
  <attributeSpecSupportedBy>
    <targetApplicationSpecName>Billing</targetApplicationSpecName>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>Convergent Charging</targetApplicationSpecName>
    <targetApplicationSpecName>Realtime Charging</targetApplicationSpecName>
  </attributeSpecSupportedBy>
  <status>ENABLED</status>
  <className>/event/cloud/library</className>
  <complexAttributeItem>
    <name>USAGE_INFO</name>
    <description>USAGE_INFO</description>
    <type>STRUCT</type>
    <persistedName5g>cloudlibrary_usage_info_t</persistedName5g>
    <simpleAttributeItem>
      <name>MY_IDENTITY</name>
      <description>MY_IDENTITY</description>
      <type>STRING</type>
      <persistedName5g>my_identity_c</persistedName5g>
      <attributeItemSupportedBy>
        <targetApplicationSpecName>Pricing</targetApplicationSpecName>
```

```

        <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
</simpleAttributeItem>
<simpleAttributeItem>
    <name>MY_CALLED_ID</name>
    <description>MY_CALLED_ID</description>
    <type>STRING</type>
    <persistedName5g>my_called_id_c</persistedName5g>
    <attributeItemSupportedBy>
        <targetApplicationSpecName>Pricing</targetApplicationSpecName>
        <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
</simpleAttributeItem>
<simpleAttributeItem>
    <name>SERVICE_PROVIDER</name>
    <description>SERVICE_PROVIDER_C</description>
    <type>STRING</type>
    <persistedName5g>service_provider_c</persistedName5g>
    <attributeItemSupportedBy>
        <targetApplicationSpecName>Pricing</targetApplicationSpecName>
        <targetApplicationSpecName>Convergent Charging</
targetApplicationSpecName>
    </attributeItemSupportedBy>
    <length>60</length>
</simpleAttributeItem>
<simpleAttributeItem>
    <name>SERVICE_STATUS</name>
    <description>SERVICE_STATUS_C</description>
    <type>STRING</type>
    <persistedName5g>service_status_c</persistedName5g>
    <attributeItemSupportedBy>
        <targetApplicationSpecName>Pricing</targetApplicationSpecName>
        <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
    <length>60</length>
</simpleAttributeItem>
<simpleAttributeItem>
    <name>SERVICE_TYPE</name>
    <description>SERVICE_TYPE_C</description>
    <type>STRING</type>
    <persistedName5g>service_type_c</persistedName5g>
    <attributeItemSupportedBy>
        <targetApplicationSpecName>Pricing</targetApplicationSpecName>
        <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
    <length>60</length>
</simpleAttributeItem>
</complexAttributeItem>
<eventType>SESSION_USAGE</eventType>
<baseEventSpec>EventCloud</baseEventSpec>
<virtualColumn>>false</virtualColumn>
<unit>MONTHS</unit>
<frequency>0</frequency>
</eventAttributeSpec>

```

3. Add `USER_IDENTITY` and `CALLED_ID` (if you are using zoning in your product offerings) attributes as simple attribute items immediately under the `<className>` element by doing the following:

- a. Search for the following element:

```
<className>EventClassName</className>
```

where *EventClassName* is the class name of the event.

For example:

```
<className>/event/cloud/library</className>
```

- b. Add the **USER_IDENTITY** and **CALLED_ID** attributes as simple attribute items immediately under the **<className>** element:

```
<className>/event/cloud/EventUsage</className>
<simpleAttributeItem>
  <name>USER_IDENTITY</name>
  <description>USER_IDENTITY</description>
  <type>STRING</type>
  <persistedName5g>PersistedNameofAttribute</persistedName5g>
  <attributeItemSupportedBy>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
  </attributeItemSupportedBy>
</simpleAttributeItem>

<simpleAttributeItem>
  <name>CALLED_ID</name>
  <description>CALLED_ID</description>
  <type>STRING</type>
  <persistedName5g>PersistedNameofAttribute</persistedName5g>
  <attributeItemSupportedBy>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
  </attributeItemSupportedBy>
</simpleAttributeItem>
```

where *PersistedNameofAttribute* specifies the name of the BRM database table and column associated with the attributes used for storing the user identity and called ID; for example, `cloudlibrary_usage_info_t.my_identity_c` and `cloudlibrary_usage_info_t.my_called_id_c`.

4. Add the event attributes that you use in ratable usage metric (RUM) expressions for **Initiate** or **Update** charging operations as top-level attributes under the **<className>** element.

The following example shows the event attributes used in the RUM expressions for charging the EventCloudLibrary event:

```
<simpleAttributeItem>
  <name>DURATION</name>
  <description>DURATION</description>
  <type>UNIT_VALUE</type>
  <unitType>TimeUnit</unitType>
  <attributeItemSupportedBy>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
  </attributeItemSupportedBy>
</simpleAttributeItem>
<simpleAttributeItem>
  <name>SPECIFIC_UNIT</name>
  <description>SPECIFIC_UNIT</description>
  <type>UNIT_VALUE</type>
  <unitType>Occurrence</unitType>
  <attributeItemSupportedBy>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
  </attributeItemSupportedBy>
</simpleAttributeItem>
```

5. Add REQUESTED_UNITS and USED_UNITS attributes as complex attribute items in the file:

```
<complexContent>
  <complexType>
    <name> REQUESTED_UNITS</name>
    <description>REQUESTED_UNITS</description>
    <attributeItemSupportedBy>
      <targetApplicationSpecName>Pricing</targetApplicationSpecName>
      <targetApplicationSpecName>Convergent Charging</targetApplicationSpecName>
    </attributeItemSupportedBy>
  </complexType>
</complexContent>
<complexContent>
  <complexType>
    <name>USED_UNITS</name>
    <description>USED_UNITS</description>
    <attributeItemSupportedBy>
      <targetApplicationSpecName>Pricing</targetApplicationSpecName>
      <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
  </complexType>
</complexContent>
```

6. Copy the event attributes you added in step 4 (if applicable) and paste them in both REQUESTED_UNITS and USED_UNITS complex attribute items:

For example:

```
<complexContent>
  <complexType>
    <name>REQUESTED_UNITS</name>
    <description>REQUESTED_UNITS</description>
    <attributeItemSupportedBy>
      <targetApplicationSpecName>Pricing</targetApplicationSpecName>
      <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
    <simpleAttributeItem>
      <name>DURATION</name>
      <description>DURATION</description>
      <type>UNIT_VALUE</type>
      <unitType>TimeUnit</unitType>
      <attributeItemSupportedBy>
        <targetApplicationSpecName>Pricing</targetApplicationSpecName>
        <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
      </attributeItemSupportedBy>
    </simpleAttributeItem>
    <simpleAttributeItem>
      <name>SPECIFIC_UNIT</name>
      <description>SPECIFIC_UNIT</description>
      <type>UNIT_VALUE</type>
      <unitType>Occurrence</unitType>
      <attributeItemSupportedBy>
        <targetApplicationSpecName>Pricing</targetApplicationSpecName>
        <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
      </attributeItemSupportedBy>
    </simpleAttributeItem>
  </complexType>
</complexContent>
<complexContent>
  <complexType>
    <name>USED_UNITS</name>
    <description>USED_UNITS</description>
    <attributeItemSupportedBy>
      <targetApplicationSpecName>Pricing</targetApplicationSpecName>
      <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
  </complexType>
</complexContent>
```

```

    </attributeItemSupportedBy>
  <simpleAttributeItem>
    <name>DURATION</name>
    <description>DURATION</description>
    <type>UNIT_VALUE</type>
    <unitType>TimeUnit</unitType>
    <attributeItemSupportedBy>
      <targetApplicationSpecName>Pricing</targetApplicationSpecName>
      <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
  </simpleAttributeItem>
  <simpleAttributeItem>
    <name>SPECIFIC_UNIT</name>
    <description>SPECIFIC_UNIT</description>
    <type>UNIT_VALUE</type>
    <unitType>Occurrence</unitType>
    <attributeItemSupportedBy>
      <targetApplicationSpecName>Pricing</targetApplicationSpecName>
      <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
  </simpleAttributeItem>
</complexAttributeItem>

```

7. (Optional) Add transient attributes if required for usage charging:

For example:

```

<simpleAttributeItem>
  <name>CELL_ID</name>
  <description>CELL_ID</description>
  <type>STRING</type>
  <attributeItemSupportedBy>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
  </attributeItemSupportedBy>
</simpleAttributeItem>

```

8. Add the charging operation types that you intend to use for usage charging and associate them with the group of event attributes that are necessary to perform the charging operation (for example: **Initiate**, **Terminate**, **Update**, and **Cancel**).

The syntax for adding charging operation types is as follows:

```

<opTypes>
  <opType>ChargingOperationType</opType>
  <action>Input</action>
  <item>
    <attributeItemName>EventAttribute</attributeItemName>
    <optional>[true|false]</optional>
  </item>
</opTypes>

```

where:

- *ChargingOperationType* is the charging operation type to be used. See [Table 33-1](#) for the list of charging operation types that are used in ECE.
- *EventAttribute* is the event attribute that is used as input for performing the charging operation.

The following example shows the charge operation type and required attributes to initiate a charging session for the EventCloudLibrary event:

```

<opTypes>
  <opType>Initiate</opType>

```

```

<action>INPUT</action>
<item>
  <attributeItemName>START_T</attributeItemName>
  <optional>>false</optional>
</item>
<item>
  <attributeItemName>DURATION</attributeItemName>
  <optional>>true</optional>
</item>
<item>
  <attributeItemName>END_T</attributeItemName>
  <optional>>true</optional>
</item>
<item>
  <attributeItemName>USAGE_INFO</attributeItemName>
  <optional>>false</optional>
</item>
<item>
  <attributeItemName>USAGE_INFO.SERVICE_TYPE</attributeItemName>
  <optional>>false</optional>
</item>
<item>
  <attributeItemName>USAGE_INFO.SERVICE_STATUS</attributeItemName>
  <optional>>true</optional>
</item>
<item>
  <attributeItemName>USAGE_INFO.SERVICE_PROVIDER</attributeItemName>
  <optional>>true</optional>
</item>
<item>
  <attributeItemName>USED_UNITS</attributeItemName>
  <optional>>false</optional>
</item>
<item>
  <attributeItemName>USED_UNITS.DURATION</attributeItemName>
  <optional>>true</optional>
</item>
<item>
  <attributeItemName>USED_UNITS.SPECIFIC_UNIT</attributeItemName>
  <optional>>true</optional>
</item>
<item>
  <attributeItemName>REQUESTED_UNITS</attributeItemName>
  <optional>>true</optional>
</item>
<item>
  <attributeItemName>REQUESTED_UNITS.DURATION</attributeItemName>
  <optional>>true</optional>
</item>
<item>
  <attributeItemName>REQUESTED_UNITS.SPECIFIC_UNIT</attributeItemName>
  <optional>>true</optional>
</item>
</opTypes>

```

9. (Optional) Update the charging operation type version number. See "[About Charging Operation Type Versions](#)" for more information.
10. Define the network mapping for the events used for charging by doing the following:
 - a. Search for the event attribute that you want to map to the network attribute.
 - b. Do one of these:

- If you have a 4G network, add the **networkAttributeItem** entry:

```
<networkAttributeItem>NetworkAttribute</networkAttributeItem>
```

- If you have a 5G network, add the **networkAttributeItem5g** entry:

```
<networkAttributeItem5g>NetworkAttribute</networkAttributeItem5g>
```

where *NetworkAttribute* is the attribute of requests received from the network.

The following example shows the mapping for a 5G network and the EventCloudLibrary event:

```
<simpleAttributeItem>
  <name>MY_CALLED_ID</name>
  <description>MY_CALLED_ID</description>
  <type>STRING</type>
  <persistedName5g>my_called_id_c</persistedName5g>
  <attributeItemSupportedBy>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
  </attributeItemSupportedBy>
  <networkAttributeItem5g>Service-Information.PS-
Information.Called-Station-Id</networkAttributeItem5g>
</simpleAttributeItem>
...
<complexAttributeItem>
  <name> REQUESTED_UNITS </name>
  <description>REQUESTED_UNITS</description>
  <type>STRUCT</type>
  <attributeItemSupportedBy>
    <targetApplicationSpecName>Pricing</targetApplicationSpecName>
    <targetApplicationSpecName>Convergent Charging</targetApplicationSpecName>
  </attributeItemSupportedBy>
  <simpleAttributeItem>
    <name>DURATION</name>
    <description>DURATION</description>
    <type>UNIT_VALUE</type>
    <unitType>TimeUnit</unitType>
    <attributeItemSupportedBy>
      <targetApplicationSpecName>Pricing</targetApplicationSpecName>
      <targetApplicationSpecName>ConvergentCharging</targetApplicationSpecName>
    </attributeItemSupportedBy>
    <networkAttributeItem5g>Multiple-Services-Credit-Control.Requested-Service-
Unit.CC-Time</networkAttributeItem5g>
  </simpleAttributeItem>
  <simpleAttributeItem>

<length>60</length>
</simpleAttributeItem>
</complexAttributeItem>

```

11. Save and close the file.
12. Import the XML file into PDC by running the following command:

```
ImportExportPricing -import -metadata FileOrDirectoryName -ow
```

For example:

```
ImportExportPricing -import -metadata EventCloudLibrary_export_metadata.xml -ow
```

The EventCloudLibrary event definition is loaded into PDC. The ECE Pricing Updater publishes the enriched event definition to ECE.

13. Update the version number in your mediation specification file to associate the usage request builder with the event definition to which it applies. See the discussion about editing the mediation specification file in *BRM Implementing Charging* for more information.

You may need to restart your charging client to receive usage requests that adhere to the enriched event definition.

Editing Event Definitions

To edit an event definition, update the event definition in PDC by using the **ImportExportPricing** utility. When you edit an event definition, ensure that you use the same event type and service type, and update the charging operation type version as appropriate. See "[About Charging Operation Type Versions](#)" for more information.

When you create your usage request builder, you must associate it with the service, event type, and charging operation type version in the event definition to which it applies. You may need to restart your charging client to receive usage requests that adhere to the enriched event definition.

Using the PDC Web Service

Learn how to use the Oracle Communications Pricing Design Center (PDC) Web Service.

Topics in this document:

- [About the PDC Web Service API](#)
- [About Using the PDC Web Service](#)
- [Creating and Modifying Pricing Components](#)
- [Exporting Components](#)

About the PDC Web Service API

The PDC Web service application programming interface (API) allows other Oracle applications as well as third-party applications to interact with PDC. Use the PDC Web service API to:

- Create, modify, and export pricing components.
- Create, modify, and export setup components.
- Create and export metadata and custom data.

To use the PDC Web service API, the external application must call the PDC Web service API through a custom client application. You can use any language that supports Web services to access the API, for example, Java.

About Using the PDC Web Service

To use the PDC Web service, you must:

- Ensure that the SSL port for the WebLogic Server domain is enabled. See "Configuring SSL for the WebLogic Server Domain" in *PDC Installation Guide* for more information.
- Ensure that the following system properties are set in WebLogic Server:
 - `weblogic.security.TrustKeyStore`
 - `weblogic.security.CustomTrustKeyStoreFileName`
 - `weblogic.security.CustomTrustKeyStorePassPhrase`
 - `weblogic.security.CustomTrustKeyStoreType`

See the discussion about setting the system properties in the WebLogic Server Administration Console Help for more information.

- Ensure that the following BindingProvider properties are set in WebLogic Server:
 - `BindingProvider.USERNAME_PROPERTY`
 - `BindingProvider.PASSWORD_PROPERTY`

See the discussion about setting the BindingProvider properties in the WebLogic Server Administration Console Help for more information.

Creating and Modifying Pricing Components

To create or modify components with the PDC Web service:

- Create the XML file containing the components. See "[About Creating the XML Files](#)" for more information.
- Use the PDC Web service to create or modify the components defined in the XML file. The PDC APIs are exposed as Web service operations through the **PricingGateway.wsdl** file. This file defines the Web service that can be called as well as the attributes required to call a specific operation.

You can use the PDC Web services for the tasks shown in [Table 34-1](#).

Table 34-1 Create and Modify Components

Task	Operation
Create pricing components.	CreatePricing
Modify promoted pricing components.	ModifyPricing
Create pricing components and publish the components to the Oracle Communications Billing and Revenue Management (BRM) database.	CreatePricingAndSubmit
Modify promoted pricing components and publish the components to the BRM database.	ModifyPricingAndSubmit
Create setup components.	createBusinessConfig
Create setup components and publish the setup components to a billing system such as BRM.	createBusinessConfigAndSubmit
Modify setup components.	modifyBusinessConfig
Modify setup components and publish the setup components to a billing system such as BRM.	modifyBusinessConfigAndSubmit
Create metadata.	createMetadata
Create custom data.	createCustomFields

About Creating the XML Files

You need to create an XML file containing the components you want to use. You can create:

- One consolidated XML file containing all the components
- Separate XML files for each type of component (for example, charge offers, discount offers, packages, and so on)

The XML files that you create must conform to the format detailed in the XSD files for pricing components.

The PDC Web service uses the **PricingGateway.xsd** file for creating or modifying components in PDC. The XSD files describe the structure of the XML document. The XML file you create must comply with the structure defined in the XSD. The **PricingGateway.xsd** file is available at:

`http://hostName:sslPortNumber/pdc/PricingGatewayPort?xsd=1`

where:

- *hostName* is the host name of the machine on which PDC is deployed.

- *sslPortNumber* is the SSL port number of the domain on which PDC is deployed.

Sample Code to Call the PDC Web Service

Use the following sample code to call the PDC Web service:

```

PricingGatewayPortType pricingGatewayPortType
= (PricingGatewayPortType) Service.getPort(new
QName("urn:PricingGateWay", "PricingGatewayPort"),
PricingGatewayPortType.class);

Map<String, Object> rc = ((BindingProvider)pricingGatewayPortType).getRequestContext();
rc.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, http://hostName:sslPortNumber/pdc/
PricingGatewayPort?WSDL);
rc.put(BindingProvider.USERNAME_PROPERTY, pdcUserName);
rc.put(BindingProvider.PASSWORD_PROPERTY, pdcUserPassword);

UserContextType userContext = new UserContextType();
userContext.setUserid("pdcUserName");

PricingInputXMLType pricingInputXMLType = new PricingInputXMLType();
pricingInputXMLType.setUserContext(userContext);
ByteArrayOutputStream bs = new ByteArrayOutputStream();
ZipOutputStream out = new ZipOutputStream(bs);
    FileInputStream fl = null;
    try {
        fl = new FileInputStream(new File(pricing.xml));
        // Set the compression ratio
        out.setLevel(Deflater.BEST_COMPRESSION);
        ZipEntry ze = new ZipEntry(PDC);
        out.putNextEntry(ze);
        byte[] data = new byte[BUFFER_SIZE];          int count = 0;
        BufferedInputStream in = new BufferedInputStream(fl);
        while ((count = in.read(data, 0, BUFFER_SIZE)) != -1){
            out.write(data, 0, count);
        }
    } catch (Exception e) {
        throw e;
    } finally {
        if (fl != null) {
            fl.close();
        }
        if (bs != null) {
            bs.flush();
        }
        if (out != null) {
            out.flush();
            out.close();
        }
    }
    byte[] bytesToRet = null;
    if (bs != null) {
        bytesToRet = bs.toByteArray();
    }
pricingInputXMLType.setXmlBinaryString(bytesToRet);

PDCResponseType pDCResponseType =
pricingGatewayPortType.createPricingAndSubmit(pricingInputXMLType);

```

CreatePricing

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of pricing component. If the validation is successful, it retrieves the data from the XML file and creates the pricing components in PDC.

The **CreatePricing** operation does not publish the pricing components to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType  
createPricing(oracle.communications.brm.pdc.server.service.types.PricingInputXMLType  
param) throws oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

ModifyPricing

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of pricing component. If the validation is successful, it retrieves the data from the XML file and updates the existing pricing components in PDC.

The **ModifyPricing** operation does not publish the pricing components to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType  
modifyPricing(oracle.communications.brm.pdc.server.service.types.PricingInputXMLType  
param) throws oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

CreatePricingAndSubmit

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of pricing component. If the validation is successful, it retrieves the data from the XML file, creates the pricing components in PDC, and publishes the pricing components to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType  
createPricingAndSubmit(oracle.communications.brm.pdc.server.service.types.PricingInputXML  
Type param) throws oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

ModifyPricingAndSubmit

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of pricing component. If the validation is successful, it retrieves the data from the XML file, updates the existing pricing components in PDC, and publishes the pricing components to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType  
modifyPricingAndSubmit(oracle.communications.brm.pdc.server.service.types.PricingInputXML  
Type param) throws oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

createBusinessConfig

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of business config component. If the validation is successful, it retrieves the data from the XML file and creates business config components in PDC.

The **createBusinessConfig** operation does not publish the business config components to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType  
createBusinessConfig(oracle.communications.brm.pdc.server.service.types.PricingInputXMLType  
param) throws oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

createBusinessConfigAndSubmit

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of business config component. If the validation is successful, it retrieves the data from the XML file, creates business config components in PDC, and publishes the business config components to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType  
createBusinessConfigAndSubmit(oracle.communications.brm.pdc.server.service.types.PricingInputXMLType  
param) throws  
oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

modifyBusinessConfig

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of business config component. If the validation is successful, it retrieves the data from the XML file and updates the existing business config components in PDC.

The **modifyBusinessConfig** operation does not publish the business config components to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType  
modifyBusinessConfig(oracle.communications.brm.pdc.server.service.types.PricingInputXMLType  
param) throws oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

modifyBusinessConfigAndSubmit

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of business config component. If the validation is successful, it retrieves the data from the XML file and updates the existing business config components in PDC, and publishes the business config components to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType
modifyBusinessConfigAndSubmit(oracle.communications.brm.pdc.server.service.types.PricingI
nputXMLType param) throws
oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

createMetadata

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of metadata component. If the validation is successful, it retrieves the data from the XML file and creates metadata components in PDC.

The **createMetadata** operation does not publish the metadata components to the BRM database.

Syntax:

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType
createMetadata(oracle.communications.brm.pdc.server.service.types.PricingInputXMLType
param) throws oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

createCustomFields

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **PricingGateway.xsd** file and the rules for each type of custom fields. If the validation is successful, it retrieves the data from the XML file and creates custom fields in PDC.

The **createCustomFields** operation does not publish the custom fields to the BRM database.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.PDCResponseType
createCustomFields(oracle.communications.brm.pdc.server.service.types.PricingInputXMLType
param) throws oracle.communications.brm.pdc.server.service.PricingExceptionResponse;
```

Exporting Components

You can use the PDC Web services for the tasks shown in [Table 34-2](#).

Table 34-2 Export Tasks

Task	Operation
Export pricing components.	getPricingObjects
Export setup components.	getBusinessConfigObjects
Export metadata components.	getMetadataObjects
Export BRM components.	getBRMObjects
Export custom fields.	getCustomFields

PDC Web services use the **RetrieveInputXMLType** object as input for exporting the PDC components. You can create the **RetrieveInputXMLType** object.

- Using the Setter Method. See "[Creating RetrieveInputXMLType Object Using Setter Method](#)".
- Using the XML. See "[Creating RetrieveInputXMLType Object Using XML](#)".

Creating RetrieveInputXMLType Object Using Setter Method

You can create the **RetrieveInputXMLType** object using setter methods (for example, pojos) with the required parameters to export components from PDC system.

For example, to export pricing components you can create the object as follows:

```
getPricingObjects() {
    RetrieveResponseType response = new RetrieveResponseType();
    RetrieveInputXMLType request = new RetrieveInputXMLType();
    ObjectType objectType = new ObjectType();
    WSPricingObject pricingObject = new WSPricingObject();
    pricingObject.getPricingObjectType().add(WSPricingObjectType.ALTERATION_EXCLUSION);
    objectType.setPricingObject(pricingObject);
    request.setObjectType(objectType);
    request.setAllReferences(false);
    request.setIncludeFailedObjects(false);
    request.setObsolete(false);
    request.setReferences(false);
    UserContextType userContext = new UserContextType();
    userContext.setUserid("pdcuser");
    request.setUserContext(userContext);
    response = pricingGatewayPortType.getPricingObjects(request);
    return response;
}
```

Creating RetrieveInputXMLType Object Using XML

The PDC Web services use the **RetrievePricingGateway.xsd** file for exporting components from PDC. The XSD file describes the structure of the XML file. The XML file you create must comply with the structure defined in the XSD. The **RetrievePricingGateway.xsd** file is available at:

<http://hostName:sslPortNumber/pdc/PricingGatewayPort?xsd=2>

where:

- *hostName* is the host name of the machine on which PDC is deployed.
- *sslPortNumber* is the SSL port number of the domain on which PDC is deployed.

You need to manually set the required parameters in the XML file for indicating the objects that you want to export from the PDC system. The **RetrieveInputXMLType** object is then created by parsing this XML.

Parameters for Exporting PDC Components

[Table 34-3](#) describes the parameters used for exporting PDC components.

Table 34-3 Parameters for Exporting PDC Components

Parameter	Description
objectType	Specifies the object type to export. The valid values are pricingObject , businessConfigObject , brmObject , and metadataObject . You can specify the pricing object type for exporting. For example, ALTERATION_RATE_PLAN, USC_MAP and so on. If pricing object type is not specified, all the pricing components are considered for exporting. This parameter is also applicable for setup components, metadata, and cross-reference data.
references	Specifies whether to export data including references.
allReferences	Specifies whether to export data including all references. This is applicable only when exporting pricing objects. When allReferences is set to true for pricing objects, the response is written separately into pricingObjectResponse , configObjectResponse , and metadataObjectResponse fields. If the export allReferences is not set for pricing objects, the pricing object responses are written into response field.
obsolete	Specifies whether to export obsolete data.
includeFailedObjects	Specifies whether to export data including failed objects.
modifiedAfterDate	Specifies whether to export data based on modified date. ModifiedAfterDate supports the following formats: <ul style="list-style-type: none"> <i>yyyy-mm-dd</i> Example: 2010-01-05 <i>yyyy-mm-dd'T'hh:mm:ss</i> Example: 2010-01-05T23:59:59 <i>yyyy-mm-dd'T'hh:mm:ssz</i> Example: 2010-01-05T19:05:09GMT+05:30
modifiedByUser	Specifies whether to export data based on the user who modified the data.
objectName	Specifies whether to export data based on object name.
UserContext	Specifies whether to export data for a specific user.
productSpecName	Specifies whether to export data based on product specification. This is applicable only when exporting pricing components.

Web Service Response

The PDC Web service operation first validates the input XML by comparing the XML fields and its values against the values in the **RetrievePricingGateway.xsd** file. If the validation is successful, it retrieves the objects from PDC and returns the data in **RetrieveResponseType** object.

Here is the structure of the **RetrieveResponseType** object:

```
<xsd:complexType name="RetrieveResponseType">
  <xsd:annotation>
    <xsd:documentation>Get Object Webservice Response</xsd:documentation>
  </xsd:annotation>
  <xsd:sequence>
    <xsd:element name="status" type="xsd:string"/>
  </xsd:sequence>
</xsd:complexType>
```

```

<xsd:element name="errors" type="xsd:string" maxOccurs="unbounded" minOccurs="0"/>
<xsd:element name="response" type="xsd:base64Binary"/>
<xsd:element name="pricingObjectResponse" type="xsd:base64Binary"/>
<xsd:element name="configObjectResponse" type="xsd:base64Binary"/>
<xsd:element name="metadataObjectResponse" type="xsd:base64Binary"/>
</xsd:sequence>
</xsd:complexType>

```

The **RetrieveResponseType** object contains the status of operation and the exported object fields in the XML binary format based on the input provided in **RetrieveInputXml** file. The status field value is either SUCCEEDED or FAILED. The **RetrieveResponseType** object also capture errors occurred during the operation.

Processing the Response from Export/GET API

When an export or GET operation is successful, you receive a response with the requested object data. You get the response as follows:

```
response = pricingGatewayPortType.getPricingObjects(request);
```

You can process the response object by using the following code in your application:

```

processResponse(RetrieveResponseType response) {
byte[] zippedBinaryStr = response.getResponse();
for (int i = 0; i < response.getErrors().size(); i++) {
    System.out.println("Cause : \n" + response.getErrors().get(i) + "\n");
}
String status = response.getStatus(); //status values can be either SUCCEEDED or FAILED
}

```

Optionally, you can convert the response into the XML format by using the following code in your application:

```

private static void writeToFile(byte[] zippedBinaryStr, String filename) throws
Exception {
    try {
        FileOutputStream fpStream = new FileOutputStream(filename);
        BufferedOutputStream bufferedStream = new BufferedOutputStream(fpStream);
        extractZippedContentAndWriteXMLStream(zippedBinaryStr, bufferedStream);
        bufferedStream.flush();
        bufferedStream.close();
        fpStream.flush();
        fpStream.close();
    } catch (IOException e) {
        System.out.println("Exception caught when writing data to file");
        throw e;
    }
}

private static void extractZippedContentAndWriteXMLStream(byte[] binaryXMLString,
BufferedOutputStream bufferedFileStream) throws Exception {
    try (ByteArrayInputStream byteStrm = new ByteArrayInputStream(binaryXMLString);
        ZipInputStream in = new ZipInputStream((byteStrm))) {
        ZipEntry entry = in.getNextEntry();
        //Transfer bytes from the ZIP file to the output file
        if (entry != null && in.available() > 0) {
            byte[] buf = new byte[BUFFER_SIZE];
            int len = in.read(buf);
            while (len > 0) {
                bufferedFileStream.write(buf, 0, len);
                len = in.read(buf);
            }
        }
    }
}

```

```
        bufferedFileStream.flush();
    }
} catch (Exception e) {
    throw e;
}
}
```

where *filename* is the path to the XML file for storing the output.

getPricingObjects

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **RetrievePricingGateway.xsd** file. If the validation is successful, it retrieves the pricing objects from PDC and returns the data in **RetrieveResponseType** object.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.RetrieveResponseType
getPricingObjects(oracle.communications.brm.pdc.server.service.types.RetrieveInputXMLType
param) throws Exception;
```

getMetadataObjects

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **RetrievePricingGateway.xsd** file. If the validation is successful, it retrieves the metadata object from PDC and returns the data in **RetrieveResponseType** object.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.RetrieveResponseType
getMetadataObjects(oracle.communications.brm.pdc.server.service.types.RetrieveInputXMLType
e param) throws Exception;
```

getCustomFields

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **RetrievePricingGateway.xsd** file. If the validation is successful, it retrieves the custom fields from PDC and returns the data in **RetrieveResponseType** object.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.RetrieveResponseType
getCustomFields(oracle.communications.brm.pdc.server.service.types.RetrieveInputXMLType
param) throws Exception;
```

getBusinessConfigObjects

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **RetrievePricingGateway.xsd** file. If the validation is successful, it retrieves the business config from PDC and returns the data in **RetrieveResponseType** object.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.RetrieveResponseType
getBusinessConfigObjects(oracle.communications.brm.pdc.server.service.types.RetrieveInput
XMLType param) throws Exception;
```

getBRMObjects

This Web service operation validates the input XML by comparing the XML fields and values against the values in the **RetrievePricingGateway.xsd** file. If the validation is successful, it retrieves the BRM object from PDC and returns the data in **RetrieveResponseType** object.

Syntax

```
public oracle.communications.brm.pdc.server.service.types.RetrieveResponseType  
getBRMObjects(oracle.communications.brm.pdc.server.service.types.RetrieveInputXMLType  
param) throws Exception;
```

Working with Profiles

Learn about the profiles used by Pricing Design Center (PDC) as well as how to create custom profiles for Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Pricing Profiles](#)
- [About Default Pricing Profiles](#)
- [About Customizing Pricing Profiles](#)
- [Setting Up Custom Pricing Profiles](#)

About Pricing Profiles

A *pricing profile* specifies the pricing features that are displayed in the PDC UI. You use pricing profiles to adapt the UI to your business needs and to simplify the user experience. For example, if you do not use time to determine how much to charge for the use of your services, you can set up a pricing profile that does not include the time feature.

Pricing profiles are used with pricing, charges, discounts, chargeshares, selectors, and time models. You select a pricing profile for all those components except pricing when creating them. (PDC selects a profile for pricing that matches the pricing profile of the component that contains the pricing, such as a charge.)

A set of default pricing profiles is included with PDC (see "[About Default Pricing Profiles](#)"). You can also create custom pricing profiles (see "[About Customizing Pricing Profiles](#)").

About Default Pricing Profiles

During Oracle Communications Pricing Design Center (PDC) installation, depending on whether you selected to support Oracle Communications Elastic Charging Engine (ECE) or not, a set of default pricing profiles is loaded in the XML format. The XML files containing the default pricing profiles are located in the `PDC_home/apps/Samples/Examples` directory, where `PDC_home` is the directory in which the PDC software is installed.

[Table 35-1](#) lists the default pricing profiles that are loaded during PDC installation if ECE is selected. These pricing profiles are supported by ECE rating engine:

Table 35-1 Default Pricing Profiles That Are Loaded When ECE Is Selected

Profile Name	Description
Billing-time Discount	Contains all the features required to configure billing-time discounts in BRM (see Table 35-5). This profile can be used with a discount or a discount selector.
Convergent Usage	Contains all the pricing features supported by ECE (see Table 35-8). This profile can be used with a usage charge, time model, or generic selector.
Standard Chargesharing	Contains all the chargeshare features supported by ECE (see Table 35-10). This profile can be used with a chargeshare.

Table 35-1 (Cont.) Default Pricing Profiles That Are Loaded When ECE Is Selected

Profile Name	Description
Standard Discount	Contains all the discount features supported by ECE (see Table 35-9). This profile can be used with a discount or a discount selector.
Subscription ChargeSharing	Contains all the chargeshare features supported by the BRM offline rating engine (see Table 35-6). This profile can be used with a chargeshare.
Subscription Discount	Contains all the discount features supported by the BRM offline rating engine (see Table 35-5). This profile can be used with a discount or a discount selector.

See "[About Customizing Pricing Profiles](#)" for information about modifying the default pricing profiles.

About Customizing Pricing Profiles

Typically, you create a custom pricing profile by copying one of the default pricing profiles and then removing features that you do not need from the copy.

Note:

- In profile XML files, pricing features are defined in **<capability>** and **<subCapability>** elements.
- You cannot modify the Subscription pricing profile.

For example, if your business does not charge for services by time, you could remove the **TimeModeling** capability from the Online Usage default pricing profile.

Note:

If a capability is mandatory in the target engine profile associated with a pricing profile, the capability must be included in the pricing profile. Do not remove it. See "[About the PDC Target Engine Profiles](#)" for a list of capabilities supported by each PDC target engine profile. The list identifies the mandatory capabilities.

If two or more mandatory capabilities are mutually exclusive, you can remove all but one of them from a custom profile. If you include more than one, you must also include the exclusive constraint (**<exclusiveConstraint>**) between them. See the default pricing profiles for examples.

The following rules apply for *subcapabilities*:

- If only one subcapability exists for a particular capability in a target engine profile, the pricing profile must include that subcapability. Do not remove it.
- If multiple subcapabilities exist for a particular capability in a target engine profile, at least one of those subcapabilities must be included in the pricing profile. The custom pricing profile does not, however, have to use the same subcapability as the default pricing profile.

For example, suppose a target engine profile includes Capability X, which has Subcapabilities A, B, C, and D, and a default pricing profile uses Capability X with Subcapabilities A and B. If you customize a copy of that default pricing profile, the copy could include Capability X with Subcapability D. In this case, the custom pricing profile does not use the same subcapabilities as the default pricing profile.

- If you *add* capabilities to a custom pricing profile, ensure the profile contains capabilities for only one pricing type. See "[About Pricing Types](#)" for more information.
- Only capabilities that are supported by all the target engine profiles associated with a pricing profile can be added to a custom pricing profile. See "[About the PDC Target Engine Profiles](#)" for a list of capabilities supported by each PDC target engine profile. See "[About Associating Custom Pricing Profiles with Target Engine Profiles](#)" for information about associating pricing profiles with target engine profiles.

▲ Caution:

After pricing components are associated with a pricing profile, you should not modify that pricing profile. Doing so might invalidate the pricing components that reference the profile.

See "[Setting Up Custom Pricing Profiles](#)" for instructions on how to create custom profiles.

About Pricing Types

Each pricing profile can support only one pricing type. A *pricing type* performs the following functions:

- Indicates the type of pricing, such as a usage charge or a discount, that can be configured when the pricing profile is associated with a pricing component
- For custom profiles, determines the set of capabilities that are available for inclusion in the profile

In each pricing profile's XML file, the pricing type is specified in the **<pricingTypeValue>** element.

[Table 35-2](#) shows the pricing types supported by the default pricing profiles:

Table 35-2 Pricing Types Supported by the default Pricing Profiles

Default Pricing Profile	Supported Pricing Type
Online Usage	USAGE_CHARGE
Offline Usage	USAGE_CHARGE
Common Usage	USAGE_CHARGE
(For BRM) Standard Discount	DISCOUNT
Billing-time Discount	RECURRING_DISCOUNT
ChargeShare	CHARGE_SHARE
Convergent Usage	USAGE_CHARGE
(For ECE) Standard Discount	DISCOUNT
Standard Chagesharing	CHARGE_SHARE

About the PDC Target Engine Profiles

PDC uses the following target engine profiles:

Note:

During PDC installation, all the target engine profiles are loaded irrespective of whether ECE is supported or not.

- **BRM online rating:** Contains all the pricing capabilities (features) supported by the BRM online rating engine. See "[BRM Online Rating Target Engine Profile](#)" for a list of the capabilities in this profile.
- **BRM offline rating:** Contains all the pricing capabilities supported by the BRM offline rating engine. See "[BRM Offline Rating Target Engine Profile](#)" for a list of the capabilities in this profile.
- **Subscription:** Contains capabilities required to create components supported by the BRM subscription engine, such as recurring charges, one-time charges, rollovers, folds, and bundles. See "[Subscription Engine Profile](#)" for a list of the capabilities in this profile.
- **ECE rating:** Contains all the pricing capabilities supported by ECE. See "[ECE Rating Target Engine Profile](#)" for a list of the capabilities in this profile.
- **ECE subscription:** Contains capabilities to support product offerings. See "[ECE Subscription Engine Profile](#)" for a list of the capabilities in this profile.

Note:

- If a target engine capability is identified as mandatory in the following tables, it must be included in any pricing profile that is associated with the target engine profile.
- If two or more mandatory capabilities are mutually exclusive, you can remove all but one of them from a custom profile. If you include more than one, you must also include the exclusive constraint (**<exclusiveConstraint>**) between them. See the default pricing profiles for examples.
- You cannot customize a target engine profile.

BRM Online Rating Target Engine Profile

The name of the BRM online rating target engine profile is RRE_RATING.

The pricing type of all the capabilities in this profile is USAGE_CHARGE (see "[About Pricing Types](#)").

[Table 35-3](#) lists the capabilities contained in this target engine profile.

Table 35-3 Capabilities In the BRM Online Rating Target Engine Profile

Capability	Description
RateplanSelector	Enables you to use a charge selector when configuring a charge. Cannot be used with the EnhancedZoneModeling capability.
ChargeRateplan	(Mandatory) Enables you to configure charges for a charge offer.
SubscriberCurrency	(Mandatory) Enables you to specify a currency for a charge. Multicurrency: This subcapability enables you to select one or more currencies in the Currency field in the Create Charge dialog box .
MultiRumGraph	Enables you to select one or more RUMs in the Measured By field in the Create Charge dialog box.
AbsoluteRelativeDateTimeRange	Enables users to specify fixed and relative date ranges when configuring a charge.
EnhancedZoneModeling	Enables you to use zone models and Usage Scenario (USC) selectors when configuring a charge. USCSelector: This subcapability enables you to use USC selectors when configuring a charge. Cannot be used with the RateplanSelector capability.
TimeModeling	Enables you to use time models when configuring a usage charge. The following subcapabilities specify which attributes of a time model can be used: <ul style="list-style-type: none"> • MonthOfYear • DayOfWeek • TimeOfDay • DayOfMonth
UsageBI	(Mandatory if PriceSelector is not included) Enables you to configure one or more balance impacts for a usage charge. CreditLimitCheck: This subcapability enables you to specify whether to continue rating the remaining quantity after the credit limit is exceeded or to search for a charge that impacts a different balance element whose credit limit has not been exceeded and use that charge instead. StepsBasedOnUsageQuantity: This subcapability enables you to create price steps based on event quantity. StepsBasedOnBalanceElement: This subcapability enables you to create price steps based on balance element quantity. SingleRum: This subcapability enables you to select only one ratable usage metric (RUM) in the Measured By field in the Create Charge dialog box. Cannot be used with the PriceSelector capability.

BRM Offline Rating Target Engine Profile

The name of the BRM offline rating target engine profile is BRE_RATING.

This profile contains capabilities for the following pricing types:

- USAGE_CHARGE (see [Table 35-4](#))
- DISCOUNT and RECURRING_DISCOUNT (see [Table 35-5](#))
- CHARGE_SHARE (see [Table 35-6](#))

See "[About Pricing Types](#)" for more information.

[Table 35-4](#) lists the charging capabilities contained in this target engine profile:

Table 35-4 Charging Capabilities in the BRM Offline Rating Target Engine Profile

Capability	Description
ChargeRateplan	(Mandatory) Enables you to configure charges for a charge offer. MultiRum: This subcapability enables you to select one or more RUMs in the Measured By field in the Create Charge dialog box.
SubscriberCurrency	(Mandatory) Enables you to specify the currency to use in the charge. SingleCurrency This subcapability enables you to select only one currency in the Currency field in the Create Charge dialog box.
AbsoluteDateRange	Enables you to specify only fixed (not relative) date ranges when configuring a charge.
ZoneModeling	Enables you to use zone models when configuring a charge. Cannot be used with the EnhancedZoneModeling capability.
EnhancedZoneModeling	Enables you to use zone models, USC selectors, and Access Point Name (APN) selectors when configuring a charge. USCSelector: This subcapability enables you to use a USC selector when configuring a charge. APNSelector: This subcapability enables you to use an APN selector when configuring a charge. Cannot be used with the ZoneModeling capability.
TimeModeling	Enables you to use time models when configuring a usage charge. The following subcapabilities specify which attributes of a time model can be used: <ul style="list-style-type: none"> • Holiday: Special day calendars • DayOfWeek: Days of the week • TimeOfDay: Time of day • UsesEffectivity: Effective periods
PriceSelector	(Mandatory if UsageBI or PriceOverrideBI is not included) Enables you to use price selectors based on event, service, or account attributes when configuring a charge. AttributeBased: This subcapability provides support for results based on specified event, service, or account attributes or a combination of such attribute types. Cannot be used with the UsageBI or PriceOverride capabilities.
UsageBI	(Mandatory if PriceSelector or PriceOverrideBI is not included) Enables you to configure one or more balance impacts for a usage charge. MultiRum: This subcapability enables you to select one or more RUMs in the Measured By field in the Create Charge dialog box. StepsBasedOnUsageQuantity: This subcapability enables you to create price steps based on event quantity. MinimumCharge: This subcapability enables you to set a minimum charge for each balance impact. ChargingIncrement: This subcapability enables you to specify a charging increment. CreditWithoutValidity: This subcapability enables you to specify a credit balance impact without using validity periods. PriceTierUsesEffectivity: This subcapability enables you to set effective dates for the prices in a charge. Cannot be used with the PriceSelector or PriceOverrideBI capabilities.

Table 35-4 (Cont.) Charging Capabilities in the BRM Offline Rating Target Engine Profile

Capability	Description
PriceOverrideBI	(Mandatory if PriceSelector or UsageBI is not included) Enables you to process prerated events by adding to or replacing the existing charge. Cannot be used with the PriceSelector and UsageBI capabilities.

[Table 35-5](#) lists the discounting capabilities contained in this target engine profile:

Table 35-5 Discounting Capabilities in the BRM Offline Rating Target Engine Profile

Capability	Description
DiscountRateplanSelector	Enables you to use a discount selector when configuring a discount.
DiscountRateplan	(Mandatory) Enables you to configure discounts for a discount offer.
AbsoluteDateRange	(Mandatory) Enables you to specify fixed date ranges when configuring a discount.
DiscountOrChargeShareTrigger	Enables you to specify conditions that must be met before a discount can be applied to a charge.
DiscountOrChargeShareFilter	Enables you to specify criteria that a charge must satisfy to be eligible for a discount. This capability is included in the Standard Discount pricing profile but not in the Billing-time Discount pricing profile. EventBasedChargeSelectorSpec: This subcapability supports the use of event attributes to determine whether a charge qualifies for a particular discount.
DiscountOrChargeShareBI	(Mandatory) Enables you to configure one or more balance impacts for a discount.

[Table 35-6](#) lists the charge sharing capabilities contained in this target engine profile:

Table 35-6 Charge Sharing Capabilities in the BRM Offline Rating Target Engine Profile

Capability	Description
ChargeShareRateplan	(Mandatory) Enables you to configure chargeshares for a chargeshare offer.
AbsoluteDateRange	(Mandatory) Enables you to specify fixed date ranges when configuring a chargeshare.
DiscountOrChargeShareTrigger	Enables you to specify conditions that must be met before a chargeshare can be applied to a charge.
DiscountOrChargeShareFilter	Enables you to specify criteria that a charge must satisfy to be eligible for a chargeshare. EventBasedChargeSelectorSpec: This subcapability supports the use of event attributes to determine whether a charge qualifies for a particular chargeshare.
DiscountOrChargeShareBI	(Mandatory) Enables you to configure one or more balance impacts for a chargeshare.

Subscription Engine Profile

The name of the subscription engine profile is RRE_SUBSCRIPTION.

This profile contains capabilities for the PRODUCT_OFFERING pricing type (see [Table 35-7](#)).

See "About Pricing Types" for more information.

Table 35-7 lists the product offering capabilities contained in this engine profile:

Table 35-7 Product Offering Capabilities in the Subscription Engine Profile

Capability	Description
ChargeOffering	Enables you to configure a charge offer.
AlterationOffering	Enables you to configure a discount offer.
DistributionOffering	Enables you to configure a chargeshare offer.

ECE Rating Target Engine Profile

The name of the profile supported by ECE is ECE_RATING.

This profile contains capabilities for the following pricing types:

- USAGE_CHARGE (see Table 35-8)
- DISCOUNT (see Table 35-9)
- CHARGE_SHARE (see Table 35-10)

See "About Pricing Types" for more information.

Table 35-8 lists the charging capabilities contained in this target engine profile:

Table 35-8 Charging Capabilities in the ECE Rating Target Engine Profile

Capability	Description
ChargeRateplan	Enables you to configure charges for a charge offer.
SubscriberCurrency	(Mandatory) Enables you to specify the currency to use in the charge. SingleCurrency: This subcapability enables you to select only one currency in the Currency field in the Create Charge dialog box.
MultiRumGraph	Enables you to select one or more RUMs in the Measured By field in the Create Charge dialog box.
AbsoluteDateRange	Enables you to specify only fixed (not relative) date ranges when configuring a charge.
ZoneModeling	Enables you to use zone models when configuring a charge.
GenericSelector	Enables you to use generic selectors when configuring a charge.
TimeModeling	Enables you to use time models when configuring a usage charge. The following subcapabilities specify which attributes of a time model can be used: <ul style="list-style-type: none"> • Holiday: Special day calendars • MonthOfYear: Months of the year • DayOfWeek: Days of the week • TimeOfDay: Time of day • DayOfMonth: Days of month

Table 35-8 (Cont.) Charging Capabilities in the ECE Rating Target Engine Profile

Capability	Description
UsageBI	<p>(Mandatory) Enables you to configure one or more balance impacts for a usage charge.</p> <p>SingleRum: This subcapability enables you to select only one RUM in the Measured By field in the Create Charge dialog box.</p> <p>StepsBasedOnBalanceElement: This subcapability enables you to create price steps based on balance element quantity.</p> <p>StepsBasedOnUsageQuantity: This subcapability enables you to create price steps based on event quantity.</p> <p>StepsBasedOnBalanceElementWithThreshold: This subcapability enables you to create price steps based on balance element with threshold.</p> <p>StepsBasedOnUsageQuantityWithThreshold: This subcapability enables you to create price steps based on event quantity with threshold.</p>

Table 35-9 lists the discounting capabilities contained in this target engine profile:

Table 35-9 Discounting Capabilities in the ECE Rating Target Engine Profile

Capability	Description
DiscountRateplan	(Mandatory) Enables you to configure discounts for a discount offer.
AbsoluteDateRange	(Mandatory) Enables you to specify fixed date ranges when configuring a discount.
DiscountOrChargeShareTrigger	Enables you to specify conditions that must be met before a discount can be applied to a charge.
DiscountOrChargeShareFilter	<p>Enables you to specify criteria that a charge must satisfy to be eligible for a discount.</p> <p>This capability is included in the Standard Discount pricing profile but not in the Billing-time Discount pricing profile.</p> <p>EventBasedChargeSelectorSpec: This subcapability supports the use of event attributes to determine whether a charge qualifies for a particular discount.</p>
DiscountOrChargeShareBI	(Mandatory) Enables you to configure one or more balance impacts for a discount.

Table 35-10 lists the charge sharing capabilities contained in this target engine profile:

Table 35-10 Charge Sharing Capabilities in the ECE Target Engine Profile

Capability	Description
ChargeShareRateplan	(Mandatory) Enables you to configure chargeshares for a chargeshare offer.
AbsoluteDateRange	(Mandatory) Enables you to specify fixed date ranges when configuring a chargeshare.
DiscountOrChargeShareTrigger	Enables you to specify conditions that must be met before a chargeshare can be applied to a charge.
DiscountOrChargeShareFilter	<p>Enables you to specify criteria that a charge must satisfy to be eligible for a chargeshare.</p> <p>EventBasedChargeSelectorSpec: This subcapability supports the use of event attributes to determine whether a charge qualifies for a particular chargeshare.</p>

Table 35-10 (Cont.) Charge Sharing Capabilities in the ECE Target Engine Profile

Capability	Description
DiscountOrChargeShareBI	(Mandatory) Enables you to configure one or more balance impacts for a chargeshare.

ECE Subscription Engine Profile

The name of the ECE subscription engine profile is ECE_SUBSCRIPTION.

This profile contains capabilities for the PRODUCT_OFFERING pricing type (see [Table 35-11](#)).

See "[About Pricing Types](#)" for more information.

[Table 35-11](#) lists the product offering capabilities in this engine profile:

Table 35-11 Product Offering Capabilities in the ECE Subscription Engine Profile

Capability	Description
ChargeOffering	Enables you to configure a charge offer.
DiscountOffering	Enables you to configure a discount offer.
ChargeShareOffering	Enables you to configure a chargeshare offer.

Target Engine Profiles for the Default Pricing Profiles

The pricing capabilities (features) in a pricing profile are based on the capabilities in the target engine profiles with which it is associated. A pricing profile can be associated with one or more target engine profiles (see "[About Associating Custom Pricing Profiles with Target Engine Profiles](#)").

[Table 35-12](#) shows the default target engine profile or profiles for each default pricing profile:

Table 35-12 Target Engine Profiles Associated with the Default Pricing Profiles

Default Pricing Profile	Default Target Engine Profile	Target Engine Profile Pricing Capabilities
Online Usage	RRE_RATING	See Table 35-3 .
Offline Usage	BRE_RATING	See Table 35-4 .
Common Usage	RRE_RATING and BRE_RATING	See Table 35-3 and Table 35-4 .
Standard Discount	BRE_RATING	See Table 35-5 .
Billing-time Discount	BRE_RATING	See Table 35-5 .
ChargeShare	BRE_RATING	See Table 35-6 .
Convergent Usage	ECE_RATING	See Table 35-8 .
Standard Discount	ECE_RATING	See Table 35-9 .
Standard Chargesharing	ECE_RATING	See Table 35-10 .

About Associating Custom Pricing Profiles with Target Engine Profiles

Before you can publish pricing components that use a custom pricing profile to a rating engine, you must associate the pricing profile with at least one target engine profile. The associated target engine profiles determine which rating or subscription engines the components are published to.

The target engines must support all the capabilities in the pricing profile. See the tables in "[About the PDC Target Engine Profiles](#)" for the capabilities supported by each PDC target engine profile.

 **Note:**

When a component that uses a pricing profile is submitted for publication, PDC validates the pricing profile against its associated target engine profiles to ensure that the capabilities in the pricing profile are supported by the target engines.

If you associate a pricing profile with multiple target engine profiles, the pricing profile must contain only capabilities that are supported by *all* of the associated target engine profiles. See "[About Pricing Profiles](#)" for more information.

If a pricing profile is not associated with a target engine profile, any pricing components that use that profile are not published to a target engine.

See "[Target Engine Profiles for the Default Pricing Profiles](#)" for information about the target engine profiles associated with the default pricing profiles.

See "[Associating Custom Pricing Profiles with Target Engine Profiles](#)" for instructions on how to associate pricing profiles with target engine profiles.

About Importing Custom Pricing Profiles into PDC

You define a custom pricing profile in an XML file and use the **ImportExportPricing** utility to import the XML file into PDC. The XML file containing the custom pricing profile must conform to the format specified in the **profiles.xsd** file in *PDC_home\apps\xsd*.

See "[Prerequisites for Using the ImportExportPricing Utility](#)" for information about prerequisites for using the **ImportExportPricing** utility.

Setting Up Custom Pricing Profiles

To set up a custom pricing profile in PDC:

1. Create a custom pricing profile (see "[Creating Custom Pricing Profiles](#)").
2. Associate the profile with a target engine profile (see "[Associating Custom Pricing Profiles with Target Engine Profiles](#)").
3. Import the profile into PDC (see "[Importing Custom Pricing Profiles into PDC](#)").

Creating Custom Pricing Profiles

To create a custom pricing profile:

1. Make a copy of the default pricing profile to customize.
See "[About Default Pricing Profiles](#)" for descriptions and locations of the default pricing profiles.
2. Open the copy in a text or XML editor.
3. In the copy, modify the pricing profile name to distinguish the copy from the original:

```
<pricingProfile>
  <name>CustomPricingProfileName</name>
  . . .
```

where *CustomPricingProfileName* is the new name for the copy.

4. Add or delete pricing capabilities as necessary.

Note the following:

- If only one subcapability exists for a particular capability in the target engine profile, the pricing profile must include that subcapability.
- If multiple subcapabilities exist for a particular capability in a target engine profile, at least one of the subcapabilities must be included in the pricing profile. The custom pricing profile does not, however, have to use the same subcapability as the default pricing profile.

See "[About Customizing Pricing Profiles](#)" for more information.

5. Save your changes.

Associating Custom Pricing Profiles with Target Engine Profiles

To associate a custom pricing profile with a target engine profile:

1. Open the file containing the custom pricing profile in a text or XML editor.
2. Add the following entry to the **<profiles>** element:

```
<profileUsedBy>
  <pricingProfileName>CustomPricingProfile</pricingProfileName>
  <targetEngineProfileName>TargetEngineProfile1</targetEngineProfileName>
  <targetEngineProfileName>TargetEngineProfile2</targetEngineProfileName>
  <priceListName>Default</priceListName>
</profileUsedBy>
```

where:

- *CustomPricingProfile* is the name of the pricing profile that you are associating with the target engine profile.
- *TargetEngineProfile#* is the name of the target engine profile that you are associating with the custom pricing profile.

 **Note:**

For each additional target engine that you want to associate with the pricing profile, add another `<targetEngineProfileName>` entry to the `<profileUsedBy>` element.

3. Save and close the file.

See "[About Associating Custom Pricing Profiles with Target Engine Profiles](#)" for more information.

Importing Custom Pricing Profiles into PDC

To import a custom pricing profile into PDC, you must have the **Pricing Design Admin** role.

To import a custom pricing profile into PDC:

1. Verify that the custom pricing profile XML file is complete and follows the guidelines specified in the `profiles.xsd` file in the `PDC_home/apps/xsd` directory.
2. Go to the `PDC_home/apps/Samples/Examples` directory, and enter the following command:

UNIX

```
ImportExportPricing -import -profile ProfileFileName
```

where `ProfileFileName` specifies the full path and file name of the XML file containing the custom profile data.

 **Note:**

To run this command, you must have `PDC_home/apps/bin` in your PATH environment variable.

For example, the following command imports a custom pricing profile from the `MyPricingProfile.xml` file into the PDC database in a UNIX environment:

```
ImportExportPricing -import -profile /MyPricingProfile.xml
```

Configuring Product Specification Attributes for Pricing Components

Learn how to configure product specification attributes for pricing components created in XML, or in Pricing Design Center for Oracle Communications Billing and Revenue Management (BRM).

Topics in this document:

- [About Product Specification Attributes for Pricing Components](#)
- [Configuring Product Specification Attributes for Pricing Components](#)
- [Using Product Specification Attributes in Pricing Components](#)
- [About Validating Product Specification Attributes for Pricing Components](#)
- [Modifying Product Specification Attribute Definitions](#)

About Product Specification Attributes for Pricing Components

You can use product specification attributes on pricing components to save extra information that may be useful to external applications.

In the TM Forum data model, a product specification is a collection of attributes, or product specification characteristics, that describe a product. Although BRM and PDC do not use TM Forum product specifications or act on product specification attributes, you can choose to store the attribute information in the BRM database so that it can be queried and used by external applications.

In BRM, you create product specification attributes in a configuration template file and then provide values for them while creating your pricing components in PDC or in XML.

For example, if your external enterprise product catalog has an attribute for tracking the lifecycle status of a charge offer with relevant values beyond the two statuses offered by PDC (draft or promoted), you can use a product specification attribute to store that status. Your enterprise product catalog can then query or update that status as needed.

At a high level, the steps for using product specification attributes with pricing components are as follows:

1. Create product specification attributes in a configuration template file. See "[Configuring Product Specification Attributes for Pricing Components](#)".
2. Import the template file by using the **ImportExportPricing** utility. See "[Importing Pricing and Setup Components](#)".
3. Create pricing components in PDC or XML, including the product specification attribute values. See "[Using Product Specification Attributes in Pricing Components](#)".
When you create pricing components in PDC, the UI validates the values against the configuration template file.

When you import pricing components from an XML file using **ImportExportPricing**, the utility validates the values in the pricing component files against the configuration template

file. The import fails if any values don't conform to the configuration file. See "[About Validating Product Specification Attributes for Pricing Components](#)".

Afterwards, if you need to change your product specification attributes, follow the instructions in "[Modifying Product Specification Attribute Definitions](#)".

Configuring Product Specification Attributes for Pricing Components

You configure product specification attributes for pricing components in a **ProductSpecCharacteristicTemplate.xml** configuration file and import them along with other pricing setup components using the **ImportExportPricing** utility.

PDC provides a sample XML file for product specification attributes in the *PDC_home\apps\Samples/Examples* directory, where *PDC_home* is the directory in which you installed PDC.

In the configuration file, you use a separate template entry for each pricing component type. You can create template entries for the pricing components listed in [Table 36-1](#).

Table 36-1 Pricing Components That Support Product Specification Attributes

Pricing Component	pricingObjectType Value
Charge offer	CHARGE_OFFERING
Discount offer	ALTERATION_OFFERING
Chargeshare offer	DISTRIBUTION_OFFERING
Bundle	BUNDLED_PRODUCT_OFFERING
Package	PACKAGE_OBJ

You define the following elements for each attribute:

- **name:** The name of the attribute as it will appear when defining the pricing component. The name can be in any language using UTF-8 format.
- **type:** The type of value for the attribute. Can be:
 - ANY
 - BOOLEAN
 - DATE
 - NUMBER
- **optional:** Whether the attribute is optional (**true**) or not (**false**).
- **values:** A configured list of possible values for the attribute. If you provided values here, the import of pricing components will fail if an attribute contains a value that was not defined here. If you don't provide values here, the pricing components can include any value that matches the type. The values can be in any language using UTF-8 format.
- **description:** A description of the attribute. The description can be in any language using UTF-8 format.
- **cardinality:** Whether only one value can be specified for the attribute when creating the pricing component (**SINGLE**), or multiple values can be specified (**MULTIPLE**).

The following example shows the XML file to create two lifecycle status attributes for a charge offer:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<cim:ConfigObjects xmlns:cim="http://xmlns.oracle.com/communications/platform/
model/Config">
  <productSpecCharacteristicTemplates xmlns:cim="http://xmlns.oracle.com/
communications/platform/model/Config">
    <name>Charge Offer Product Specification Attribute Template</name>
    <internalId>1234</internalId>
    <priceListName>Default</priceListName>
    <obsolete>>false</obsolete>
    <pricingObjectType>CHARGE_OFFERING</pricingObjectType>
    <productSpecCharacteristics>
      <name>Status</name>
      <type>ANY</type>
      <optional>>true</optional>
      <values>Draft</values>
      <values>Test</values>
      <values>Release</values>
      <values>Suspend</values>
      <values>Retired</values>
      <description>Extended lifecycle status for the charge offer.</
description>
      <cardinality>SINGLE</cardinality>
    </productSpecCharacteristics>
    <productSpecCharacteristics>
      <name>Allowed Locations</name>
      <type>ANY</type>
      <optional>>true</optional>
      <values>ASIA</values>
      <values>USA</values>
      <values>EUROPE</values>
      <values>CANADA</values>
      <values>OCEANIA</values>
      <description>Locations where the charge offer can be sold.</
description>
      <cardinality>MULTIPLE</cardinality>
    </productSpecCharacteristics>
  </productSpecCharacteristicTemplates>
</cim:ConfigObjects>
```

Using Product Specification Attributes in Pricing Components

When creating pricing components in PDC or XML, you can use product specification attributes configured in the **ProductSpecCharacteristicTemplate.xml** file.

In PDC, any product specification attributes you configure in the template file appear in the Product Spec Characteristic Attributes (Custom Attributes) section for charge offers, discount offers, chargseshare offers, bundles, and packages. You can add or update the values.

In the XML file for your pricing component, use the **productSpecCharacteristic** element to add an attribute, and provide the **name** and a **value** element for each attribute. For example:

```
<chargeOffering externalID="1234">
  <name>ChargeOfferWithExtendedAttribute</name>
  <internalId>5678</internalId>
  <pricingProfileName>Product Offering</pricingProfileName>
  <priceListName>Default</priceListName>
  <obsolete>false</obsolete>
  <timeRange>0/inf</timeRange>
  <productSpecName>TelcoGsmTelephony</productSpecName>
  <productSpecCharacteristic>
    <name>Status</name>
    <value>Test</value>
  </productSpecCharacteristic>
  <productSpecCharacteristic>
    <name>Allowed Locations</name>
    <value>ASIA</value>
    <value>USA</value>
    <value>EUROPE</value>
  </productSpecCharacteristic>
  ...
</chargeOffering>
```

Keep the following in mind when defining values for product specification attributes:

- You can only use the attributes configured for the template with the same pricing type as the pricing component you are creating. In the example above, because you are creating a charge offer, all of the product specification attributes must come from the template configured for the CHARGE_OFFERING pricing type.
- Values are case sensitive.
- The value in the **name** must match one of the attributes you configured in the template file.
- The valid values are determined by the **type** and **value** elements configured for the attribute in the template file. [Table 36-2](#) describes the supported types.

Table 36-2 Supported Value Types

Configured Type	Supported Values
ANY	UTF-8 strings in any language. If any value elements were configured for the attribute in the template file, only those values are supported.
DATE	Dates in format YYYYMMDD. If any value elements were configured for the attribute in the template file, only those values are supported.
BOOLEAN	true or false
NUMBER	Numbers 0-9. Decimals are supported, using either a period or comma as a decimal separator, according to your localization settings. If any value elements were configured for the attribute in the template file, only those values are supported.

See "[About Validating Product Specification Attributes for Pricing Components](#)".

 **Caution:**

After importing your pricing components, if you update them using **ImportExportPricing**, you must include all product specification attributes names and values in the definition, regardless of whether you are updating them. Any product specification attributes you do not include when you import the updated file will be removed from the pricing component.

About Validating Product Specification Attributes for Pricing Components

The validation method for product specification attributes depends on where you create pricing components.

When you create pricing components in PDC, the UI validates the values of product specification attributes against the attribute configuration template. Error messages are displayed for any failed validations.

When you import pricing components using the **ImportExportPricing** utility, the utility validates that:

- A template exists in the configuration file for the pricing component type.
- The name of an attribute appears in the template for the pricing component. For example, an attribute specified for a discount offer must appear under the template for the ALTERATION_OFFERING price type.
- Each attribute appears only once in the pricing component definition.
- The value of the attribute matches the **type** element configured in the template. For example, an attribute with the BOOLEAN type can only have **true** or **false** as values.
- The value of the attribute matches one of the **value** elements configured in the template if the attribute configuration contains a specified list of values.
- A value is provided for any attributes where the **optional** element is set to **false**.

The UI and the utility only validate against the configuration file. They do not validate based on the meaning of the attributes. For example, the UI or utility cannot validate that the start date is earlier than the end date in product specification attributes for start and end dates, or that a location in a product specification attribute for allowed locations matches the currency defined for a pricing component.

You can optionally implement custom validations for charge offers, discount offers, and bundles created in XML using the following pricing policy opcodes:

- PCM_OP_PRICE_POL_VALID_PRODUCT
- PCM_OP_PRICE_POL_VALID_DISCOUNT
- PCM_OP_PRICE_POL_VALID_DEAL

See "About the PREP and VALID Opcodes" in *BRM Developer's Guide* for information about using VALID opcodes.

Modifying Product Specification Attribute Definitions

If you want to modify any existing product specification attribute definitions, you must do the following:

- Export, update, and then re-import the attribute configuration template.
- Export, update, and then re-import your pricing components, which have been modified to comply with the updated attribute configuration template.

Following this procedure ensures that any changes made to your attribute definitions do not invalidate the pricing components already stored in PDC.

The following example shows how to modify the attribute definitions for charge offers. You can use a similar procedure to modify attribute definitions for discount offers and charge share offers.

1. Export all charge offers from PDC. For example:

```
ImportExportPricing -export MyChargeOffers -config CHARGE_OFFERING
```

In this example, all charge offers are exported to the **MyChargeOffers_export_pricing.xml** file.

2. Export all attribute configuration template objects from PDC. For example:

```
ImportExportPricing -export ProductSpecCharacteristicTemplate -config  
PSCTEMPLATE
```

In this example, all attribute configuration template objects are exported to the **ProductSpecCharacteristicTemplate_export_config.xml** file.

3. Update your attribute configuration template XML file according to the information in "[Configuring Product Specification Attributes for Pricing Components](#)".
4. Import your modified attribute configuration template XML file into PDC. For example:

```
ImportExportPricing -import -config  
ProductSpecCharacteristicTemplate_export_config.xml -ow
```

5. Update the charge offers in your **MyChargeOffers_export_pricing.xml** file to comply with the latest attribute configuration template.
6. Import your updated charge offers into PDC. For example:

```
ImportExportPricing -import -pricing MyOffers_export_pricing.xml -ow
```

Replicating Data Between PDC Systems

Learn how to replicate Pricing Design Center (PDC) data from one Oracle Communications Billing and Revenue Management (BRM) system to another, such as from a development system to a test system.

Topics in this document:

- [About Replicating Data](#)
- [Replicating Setup Components Managed in BRM](#)
- [Replicating Data Between PDC Databases](#)

About Replicating Data

You replicate PDC data by extracting data from a *source* PDC database and then loading the data into a *destination* PDC database by using the **ImportExportPricing** utility. See "[Importing and Exporting Pricing and Setup Components](#)" for more information.

The target system must include both the BRM server components and a PDC database. If you create a new BRM installation, do not load the sample files in the *PDC_home/apps/samples/examples* directory after installing PDC, where *PDC_home* is the directory in which the PDC software is installed.

Replicating PDC data between two BRM systems involves the following tasks:

1. [Replicating Setup Components Managed in BRM](#)
2. [Replicating Data Between PDC Databases](#)

Replicating Setup Components Managed in BRM

Some setup components are managed in BRM and are then synchronized with PDC.

To ensure that all the setup components managed in the *source* BRM system are synchronized with the *destination* BRM and PDC systems, extract the setup components from the *source* BRM database and load them into the *destination* BRM database by using the BRM load utilities. When you replicate the PDC data, these components will be synchronized with the *destination* PDC system.

[Table 37-1](#) lists the type of setup components that are managed in BRM and their corresponding load utilities.

Table 37-1 Setup Components Managed in BRM and Their Corresponding Load Utilities in BRM

Setup Component Type	BRM Load Utility
Service	pin_deploy
Account	pin_deploy
Event	pin_deploy

Table 37-1 (Cont.) Setup Components Managed in BRM and Their Corresponding Load Utilities in BRM

Setup Component Type	BRM Load Utility
G/L ID	<code>load_pin_glid</code>
Tax Supplier	<code>load_tax_supplier</code>
Provisioning Tag	<code>load_config_provisioning_tags</code>

Replicating Data Between PDC Databases

To replicate data:

1. Extract the service, account, event, and profile attribute specifications from the *source* PDC database and load them into the *destination* PDC database by doing the following:
 - a. Export the service, account, event, and profile (if applicable) attribute specifications from the *source* PDC database by running the following command:

```
ImportExportPricing -export -metadata
```

The service, account, event, and profile (if applicable) attribute specifications are exported to the `export_meta_config.xml` file.

 **Note:**

Do not change the internal IDs of the exported attribute specifications.

- b. Ensure that the transformation engines are running. See the discussion about starting the transformation engines in *PDC Installation Guide* for more information.
 - c. Import the exported attribute specifications from the `export_meta_config.xml` file into the *destination* PDC database by running the following command:

```
ImportExportPricing -import -metadata export_meta_config.xml
```

2. Run the **SyncPDC** utility by doing the following:
 - a. Go to the `BRM_Integration_Pack_Home/apps/syncpdc` directory.
 - b. Enter the following command:

```
startSyncPDC
```

The **Enter Key Password** prompt appears.

- c. Enter the password PDC uses for accessing the PDC alias key in the keystore (`BRM_Integration_Pack_Home/apps/conf/pdc.jks`).
3. Extract all the setup components that are defined in PDC from the *source* PDC database and load them into the *destination* PDC database by doing the following:
 - a. Export all the setup components from the *source* PDC database by running the following command:

```
ImportExportPricing -export -config
```

The setup components are exported to the `export_config.xml` file.

- b. Import the exported setup components from the **export_config.xml** file into the *destination* PDC database by running the following command:

```
ImportExportPricing -import -config export_config.xml
```

- 4. Extract all the pricing components from the *source* PDC database and load them into the *destination* PDC database by doing the following:

- a. Export all the pricing components from the *source* PDC database by running the following command:

```
ImportExportPricing -export -pricing
```

The pricing components are exported to the **export_pricing.xml** file.

- b. Import all the pricing components from the **export_pricing.xml** file into the *destination* PDC database by running the following command:

```
ImportExportPricing -import -pricing export_pricing.xml
```

Part VII

Pricing Utilities

This part describes the utilities provided with Oracle Communications Billing and Revenue Management (BRM) Pricing Design Center (PDC).

This part contains the following chapters:

- [Pricing Utilities](#)

Pricing Utilities

Learn about the syntax and parameters for the Oracle Communications Pricing Design Center (PDC) utilities.

Topics in this document:

- [ImportExportPricing](#)
- [PDCWalletUtil.sh](#)
- [PDCBRMWalletUtil.sh](#)
- [load_pin_snowball_distribution](#)
- [load_pin_spec_rates](#)
- [load_pin_sub_bal_contributors](#)
- [pin_discount_cleanup](#)

ImportExportPricing

Use the **ImportExportPricing** utility to import and export pricing and setup components from the PDC database by using XML files. See "[Importing and Exporting Pricing and Setup Components](#)" for information on using this utility.

The XML files that are used for importing or exporting data must conform to the format detailed in the XML schema definition (XSD) files.

The utility uses separate XSD files for importing or exporting pricing components, setup components, and profile data. The XSD files are available in their respective directories in the *PDC_home/apps/xsd* directory, where *PDC_home* is the directory in which the PDC software is installed. See "[About the XSD Files](#)" for more information.

Location

PDC_home/apps/bin

Syntax Overview

You can run the **ImportExportPricing** utility in the following modes:

- **export**: Export pricing and setup components from the PDC database into XML files. See "[Export Mode](#)".
- **import**: Import pricing and setup components data from an XML file into the PDC database. See "[Import Mode](#)".
- **publish**: Publish setup components from PDC to the specified target engines, such as batch rating engine, real-time rating engine, and Oracle Communications Elastic Charging Engine (ECE). See "[Publish Mode](#)".
- **keep**: Retain the latest versions of successfully promoted PDC components, but delete old versions. See "[Keep Mode](#)".

- **delete**: Delete pricing profiles or pricing components that are managed in Oracle Communications Billing and Revenue Management (BRM). See "[Delete Mode](#)".
- **type**: Display the list of setup or pricing component types supported in PDC. See "[Type Mode](#)".

Results

The **ImportExportPricing** utility notifies you when it runs successfully. Otherwise, look in the **ImportExportPricing_username_timestamp.log** file, where *username* is the name of user who used the utility and *timestamp* is the timestamp of the log file in the format *yyyy-mm-dd_hh-mm-ss*. This file is in the directory from which the utility was started.

Export Mode

The **export** mode exports pricing and setup components from the PDC database into XML files.

export Mode Syntax

```
ImportExportPricing -export [Prefix] -config [SetupObjectType1,SetupObjectType2]
-metadadata [MetaDataObjectType1,MetaDataObjectType2]
-pricing [PricingObjectType1,PricingObjectType2]
-brmobject [brmObjectType1,brmObjectType2]
-profile
-customfields
[-n "ObjectName1,ObjectName2"]
[-pricingprofilename "Name1,Name2"]
[-productSpecName ProductSpecName1,ProductSpecName2]
[-expRefs|-expAllRefs] [-inclFailedObjs]
[-expObsolete]
[-ma|-modifiedAfter time]
[-mby|modifiedBy user1,user2]
[-l|-LogLevel level] [-v|-verbose] [-ow|-overwrite]
-appsvruser ApplicationServerUserName
-pdcuser PdcUserName -url appSvrUrl
[-h|-help]
```

export Mode Parameters

-export [Prefix]

Exports the data from a PDC database and generates a separate XML file for pricing components, setup components, and pricing profile data in the directory from which you run the utility. The utility generates the file names as:

- *Prefix_export_pricing.xml* for the file containing pricing components.
- *Prefix_export_config.xml* for the file containing setup components.
- *Prefix_export_profile.xml* for the file containing pricing profiles data.

If you do not specify *Prefix*, the utility generates the file name as follows:

- **export_pricing.xml** for the file containing pricing components. If this file already exists in PDC, the utility generates the file name as **export_pricing_timestamp.xml**, where *timestamp* is the server's local time in the format *yyyy-mm-dd_hh-mm-ss*.
- **export_config.xml** for the file containing setup components. If this file already exists in PDC, the utility generates the file name as **export_config_timestamp.xml**, where *timestamp* is the server's local time in the format *yyyy-mm-dd_hh-mm-ss*.

- **export_profile.xml** for the file containing pricing profile data. If this file already exists in PDC, the utility generates the file name as **export_profile_timestamp.xml**, where *timestamp* is the server's local time in the format *yyyy-mm-dd_hh-mm-ss*.

-config [SetupObjectType1, SetupObjectType2,...]

Exports all setup components that are defined in PDC from the PDC database to the XML file. Exports *SetupObjectType* from the PDC database to the XML file, where *SetupObjectType* is the setup component type listed in [Table 38-1](#).

If you do not specify *SetupObjectType*, the utility exports all setup components from the PDC database into the XML file.

Table 38-1 Setup Component Types and the Setup Components They Represent

Setup Component Type	Setup Component
VALUE_MAP	Value Map
EVENT_ATTRIBUTE_SPEC	Event
PRODUCT_ATTRIBUTE_SPEC	Service
CUSTOMER_ATTRIBUTE_SPEC	Account Attribute
RUM_CONFIGURATION	RUM
ZONE_RESULT_CONFIGURATION	Impact Category for Zones
ATTRIBUTE_SPEC_MAP	Service-Event Map
BALANCE_ELEMENT	Balance Element
GLID	G/L ID
TAX_CODE	Tax Code
TAX_EXEMPTION_CODE	Tax Exemption Code
TAX_SUPPLIER	Tax Supplier
GEO_ZONE_MODEL	Geographical Zone Model
STANDARD_ZONE_MODEL	Standard Zone Model
PROVISIONING_TAG	Provisioning Tag
HOLIDAY_CALENDAR	Special Day Calendar
CUSTOM_ANALYZER_RULE	Custom Rule
PROFILE_ATTRIBUTE_SPEC	Profile
DELIVERABLE	Deliverable
PSCTEMPLATE	Extended Attribute Template

-metadata [MetaDataObjectType1, MetaDataType2,...]

Exports the metadata object types specified in [Table 38-2](#) from the PDC database into the XML file.

If you do not specify *MetaDataObjectType*, the utility exports all metadata components from the PDC database into the XML file.

Table 38-2 Metadata Component Types and the Metadata Components They Represent

Metadata Component Type	Metadata Component
EVENT_ATTRIBUTE_SPEC	Event
PRODUCT_ATTRIBUTE_SPEC	Service
PROFILE_ATTRIBUTE_SPEC	Profile attribute
CUSTOMER_ATTRIBUTE_SPEC	Account attribute

-pricing [PricingObjectType1, PricingObjectType2,...]

Exports *PricingObjectType* from the PDC database to the XML file, where *PricingObjectType* is the pricing component type listed in [Table 38-3](#).

If you do not specify *PricingObjectType*, the utility exports all pricing components from the PDC database into the XML file.

Table 38-3 Pricing Component Types and the Pricing Components They Represent

Pricing Component Type	Pricing Component Represented
CHARGE_RATE_PLAN	Charge
ALTERATION_RATE_PLAN	Discount
DISTRIBUTION_RATE_PLAN	Chargeshare
ROLLOVER_RATE_PLAN	Rollover
ALTERATION_RATE_PLAN_SELECTOR	Discount Selector
GENERIC_SELECTOR	Generic Selector
CHARGE_RATE_PLAN_SELECTOR	Charge Selector
PRICE_MODEL_SELECTOR	Price Selector
APN_MAP	APN Selector
USC_MAP	USC Selector
TAX_SELECTOR	Tax Selector
TAX_EXEMPTION_SELECTOR	Tax Exemption Selector
TIME_MODEL	Time Model
TRIGGER_SPEC	Trigger
CHARGE_SELECTOR_SPEC	Filter
ALTERATION_POP_MODEL	Discount Pricing
ROLLOVER_POP_MODEL	Rollover Rules
RECURRING_POP_MODEL	Recurring Pricing
ONE_TIME_POP_MODEL	One-Time Pricing
CHARGE_OFFERING	Charge Offer
ALTERATION_OFFERING	Discount Offer
DISTRIBUTION_OFFERING	Chargeshare Offer
ALTERATION_EXCLUSION	Discount Exclusion
SUBSCRIPTION_TERMS	Subscription Terms
SUBSCRIPTION_TERMS_AUTO_RENEW	Subscription Terms with Automatic Renewal
BUNDLED_PRODUCT_OFFERING	Bundle
BUNDLE_TRANSITION	Bundle Transition
PACKAGE_OBJ	Package
PACKAGE_EXCLUSION	Discount Restriction
PACKAGE_TRANSITION	Package Transition
PACKAGE_LIST	Package List

-brmObject [brmObjectType1, brmObjectType2,...]

Exports BRM-mastered configuration objects from the PDC database into the XML file. This includes services, events, account attributes, tax suppliers, and G/L IDs.

-profile

Exports pricing profile data from the PDC database into the XML file.

-customfields

Exports custom field data from the PDC database into the XML file.

-n "ObjectName1, ObjectName2,..."

Filters the pricing or setup components based on the specified component names. You can use an asterisk (*) at the end of the name to search for variations of that name. For example, searching for **chargeoffergsm*** yields variations of that name, such as **chargeoffergsm1** and **chargeoffergsm2**.

 **Note:**

When you use the **-n** parameter, you must specify either **-config** or **-pricing**. The parameters **-n** and **-productSpecName** are mutually exclusive.

-pricingprofilename "Name1, Name2,..."

Exports pricing components scoped to the pricing profile names specified in the list.

If this parameter is used with the **-pricing** parameter when a list of pricing component types is specified, the utility exports all the pricing components of the specified type scoped to the pricing profiles names specified in the list.

If this parameter is specified with the **-pricing** parameter when no pricing components types are specified, the utility exports all the pricing components that are scoped to a pricing profile.

-productSpecName ProductSpecName1, ProductSpecName2,...

Filters the exported pricing components that are scoped to the specified services.

If you specify this parameter along with **-pricing PricingObjectType**, the utility exports all pricing component types that are scoped to *ProductSpecName*. You can use this parameter only for the following pricing component types:

- ALTERATION_OFFERING
- CHARGE_OFFERING
- DISTRIBUTION_OFFERING
- CHARGE_RATE_PLAN

If you specify this parameter without specifying *PricingObjectType*, the utility exports all pricing components scoped to the specified service.

 **Note:**

The parameters **-n** and **-productSpecName** are mutually exclusive.

-expRefs

Exports all pricing components referenced by *PricingObjectType*. For example, if multiple charge offers are referenced by bundles, this parameter exports all charge offers when exporting bundles. The utility ignores this parameter if it is used with the **-config** or **-metadata** parameter.

-expAllRefs

Exports all PDC components (including metadata, setup components, and pricing components) referenced by *PricingObjectType*. For example, if setup components, such as ratable usage metrics (RUMs) and tax codes are referenced by charge offers, then this

parameter exports RUMs and tax codes when exporting charge offers. This parameter applies only to the **-pricing** parameter.

-inclFailedObjs

Exports the setup or pricing objects that were last promoted objects (including those with a failed changeset status). By default, the utility exports only successfully transformed objects. The utility ignores this parameter if it is used with the **-metadata** parameter.

-expObsolete

Exports obsolete pricing and setup data along with the other pricing and configuration data. By default, the utility does not export obsolete pricing and setup data.

-ma *time* | -modifiedAfter *time*

Exports pricing components modified on or after the specified *time*. Enter the *time* in the format *yyyy-mm-dd_hh-mm-ss*. For example: 2010-01-05T19:05:09GMT+05:30.

-mby *user1, user2,...* | -modifiedBy *user1, user2,...*

Exports the pricing components created or modified by the specified users.

**Note:**

This parameter and **-productSpecName** are mutually exclusive.

-l *loglevel* | -loglevel *loglevel*

Specifies how much information the utility should log. The logs are stored in the **ImportExportPricing_username_timestamp.log** file, where *username* is the name of user who used the utility and *timestamp* is the time the log file was created in the format *yyyy-mm-dd_hh-mm-ss*.

Set *loglevel* to one of the following:

- FINE
- FINER
- FINEST
- INFO
- OFF
- SEVERE
- WARNING

The default is **INFO**.

-v | -verbose

Displays information about successful or failed processing as the utility runs.

-ow | -overwrite

Overwrites any existing XML file containing the exported pricing or setup components with the file specified in the **-export [Prefix]** parameter.

-appsvruser *ApplicationServerUserName*

Specifies the user name to access the Oracle WebLogic Server. If you do not specify this parameter, the utility prompts you to enter the user name at the command prompt.

-pdcuser PdcUserName

Specifies the user name to access PDC. If you do not specify this parameter, the utility prompts you to enter the user name at the command prompt.

-url appSvrUrl

Specifies the application server URL, which has the format **t3://hostname:port**

-h

Displays the syntax for this utility.

Import Mode

The **import** mode imports the component data from one or more XML files into the PDC database. See "[Importing Pricing and Setup Components](#)" for more information.

import Mode Syntax

```
ImportExportPricing -import -metadata FileOrDirectoryName
                        -config FileOrDirectoryName [-d|-delete]
                        -pricing FileOrDirectoryName
                        -profile FileName
                        -customfields FileName
                        [-l|-loglevel loglevel] [-v|-verbose] [-ow|-overwrite]
                        [-changeSetName ChangeSetName]
                        -ignoreID
                        -submitCS
                        -appsvruser ApplicationServerUserName
                        -pdcuser PdcUserName -url appSvrUrl
                        [-h|-help]
```

import Mode Parameters

-import

Imports data from one or more XML files that conform to the format detailed in the XSD file to the PDC database. In addition to the **-import** parameter, you must also include the **-metadata**, **-config**, **-pricing**, **-profile**, or **-customfields** parameter.

-metadata FileOrDirectoryName

Imports the metadata objects from *FileOrDirectoryName* to the PDC database. *FileOrDirectoryName* specifies either the full path and file name of the import XML file or the full path to the directory in which your import XML files reside. Ensure the user has at least read permission for the input directory, its subdirectories, and its files. See "[Importing Multiple XML Files from a Directory](#)" for more information.

-config FileOrDirectoryName

Imports the setup components from *FileOrDirectoryName* to the PDC database.

-pricing FileOrDirectoryName

Imports the pricing components from *FileOrDirectoryName* to the PDC database.

-profile FileName

Imports the profile data from *FileName* to the PDC database, where *FileName* is the name and path to the XML file that contains your profile data.

If you specify **-pricing** and **-config** parameters along with **-profile**, the utility imports profile data and setup components before importing the pricing components. If the import of the profile data and setup components is not successful, the utility does not import the pricing components.

-customfields *FileName*

Imports the profile data from *FileName* to the PDC database.

-ignoreID

Ignores the internal IDs in the specified XML file. The utility looks up the internal IDs by object name or generates internal IDs for new objects. Use this option to avoid conflicts when importing data from another environment.

Use this parameter with the **-ow** parameter when importing existing data.

-submitCS

Creates new or modified pricing data and adds it to a change set for the user to process at a later time. When this option is not specified, the changes to pricing data in the change set are committed and published to the target engine.

-l *loglevel*

Specifies how much information the utility should log. The logs are stored in the **ImportExportPricing_username_timestamp.log** file, where *username* is the name of user who used the utility and *timestamp* is the time the log file was created in the format *yyyy-mm-dd_hh-mm-ss*.

Set *loglevel* to one of the following:

- **FINE**
- **FINER**
- **FINEST**
- **INFO** (This is the default.)
- **OFF**
- **SEVERE**
- **WARNING**

-v

Displays information about successful or failed processing as the utility runs.

-ow

Overwrites any existing pricing or setup components available in the PDC database with the specified components. If the specified pricing or setup component does not exist in PDC, the utility creates new pricing or setup components.

 **Note:**

If you do not use the **-ow** parameter when importing data, the utility generates an error if an object with the same name already exists in PDC.

[-changeSetName *ChangeSetName*]

Specifies the name of the changeset used to import setup and pricing components into the PDC database. If you do not specify *ChangeSetName*, the utility generates the changeset name as **ieChangeSettimestamp**, where *timestamp* is the current timestamp in the format *yyyy-mm-dd_hh-mm-ss*.

-appsvruser *ApplicationServerUserName*

Specifies the user name to access the WebLogic Server. If you do not specify this parameter, the utility prompts you to enter the user name at the command prompt.

-pdcuser PdcUserName

Specifies the user name to access PDC. If you do not specify this parameter, the utility prompts you to enter the user name at the command prompt.

-h|-help

Displays the syntax for this utility.

Publish Mode

The **publish** mode publishes setup components from PDC to the specified target engines, such as the batch rating engine, the real-time rating engine, and Oracle Communications Elastic Charging Engine (ECE).

publish Mode Syntax

```
ImportExportPricing -publish [metadata|config|pricing|all] [ObjectType1,ObjectType2,...]
                        -target [rre|bre|ece|all]
```

publish Mode Parameters

-publish [metadata | config | pricing | all]

Publishes the following components from PDC to the specified target engines:

- **metadata**: Publishes the metadata components in PDC to the specified target engine.
- **config**: Publishes the setup components in PDC to the specified target engine.
- **pricing**: Publishes the pricing components in PDC to the specified target engine.
- **all**: Publishes all components in PDC to the specified target engine.

If you do not specify a component type, the utility publishes all components in PDC to the specified target engine.

-Publish [ObjectType1,ObjectType2,...]

Publishes the specified components to the target engine; for example, BALANCE_ELEMENT. You can specify [*Component*] or [*ObjectType*] for publishing the components. For the list of component types, see [Table 38-3](#).

-target [rre | bre | ece | all]

Publishes the components or object types to the specified target engine:

- **rre**: Publishes the components or object types to the real-time rating target engine.
- **bre**: Publishes the components or object types to the batch rating target engine.
- **ece**: Publishes the components or object types to the ECE rating target engine.
- **all**: Publishes the components or object types to all target engines mentioned above.

If you do not specify a target engine, the utility publishes to all target engines.

Keep Mode

The **keep** mode retains the latest versions of successfully promoted PDC components, but deletes the older versions.

keep Mode Syntax

```
ImportExportPricing -keep [config|pricing|all|metadata] [-numVersion N]
```

keep Mode Parameters

-keep [config | pricing | all | metadata]

Keeps only the latest versions of successfully promoted PDC components, and deletes older versions of the specified components that are obsolete in PDC or the associated target engines (for example ECE). The default value is **all**.

- **config**: Keeps the latest versions of setup components, but deletes older versions that are obsolete.
- **pricing**: Keeps the latest versions of pricing components, but deletes older versions that are obsolete. See [Table 38-3](#).
- **all**: Keeps the latest version of all PDC components.
- **metadata**: Keeps only the metadata components that are supported in your PDC system. By default, PDC supports the following metadata object types.

-numVersion N

Keeps the specified number of the most recent versions of all successfully promoted objects in the PDC database and deletes the remaining versions, where *N* is a positive integer that specifies the number of latest successful versions to be kept in the PDC database. If you do not specify a number, the utility keeps two by default.

Delete Mode

The **delete** mode deletes the specified setup components, as long as they are not used by other entities.

delete Mode Syntax

```
ImportExportPricing -d|-delete FileName
```

delete Mode Parameters

-d | -delete *FileName*

Deletes the setup components contained in *FileName* from the PDC database, where *FileName* is the XML file containing the setup components. The utility displays an error message if the data being deleted is dependent on other data.

Type Mode

The **type** mode displays the list of component types that are supported in your PDC system.

type Mode Syntax

```
ImportExportPricing -type|-t [config|pricing|brmObject|metadata]
```

type Mode Parameters

-type|-t [config | pricing | brmObject | metadata]

Displays the specified component types that are supported in your PDC system.

- **config**: Displays only the setup components that are supported in your PDC system.
- **pricing**: Displays only the pricing components that are supported in your PDC system. See [Table 38-3](#).

- **brmObject**: Displays only the BRM objects that are supported in your PDC system.
- **metadata**: Displays only the metadata components that are supported in your PDC system. See [Table 38-2](#).

If you do not specify a component type, the utility displays all components.

PDCWalletUtil.sh

Use the **PDCWalletUtil.sh** utility to create the PDC wallet, set the passwords stored in the wallet, or retrieve the passwords stored in the wallet. For example, you can set or retrieve the passwords for the WebLogic Server domain, PDC user, and database.

For more information, see "Changing the Password in the PDC Wallet" in *BRM System Administrator's Guide*.

Location

PDC_home/apps/bin

Syntax Overview

You can run the **PDCWalletUtil.sh** utility in the following modes:

- **create**: Create the PDC wallet in the specified location and with the specified password. See "[create Mode Syntax](#)".
- **set**: Set or change a password in the specified configuration entry. See "[set Mode Syntax](#)".
- **get**: Retrieves the password from the specified configuration entry. See "[get Mode Syntax](#)".

create Mode Syntax

```
./PDCWalletUtil.sh create walletLocation  
Enter wallet password: walletPassword
```

The **create** mode creates the PDC wallet in the specified location and with the specified password.

create Mode Parameters

walletLocation

The location in which to create the PDC wallet.

walletPassword

The PDC wallet password.

set Mode Syntax

```
./PDCWalletUtil.sh set walletLocation configEntry  
Enter wallet password: walletPassword  
Enter key password: keyPassword  
Enter key password again: keyPassword
```

The **set** mode sets or changes the password in the specified configuration entry.

set Mode Parameters

walletLocation

The location in which the PDC wallet resides.

configEntry

The configuration entry in which to store the password. The valid values are:

- **PDC_APP_SERVER_USER_PASSWORD**: The Oracle WebLogic server user password.
- **PDC_APP_USER_PASSWORD**: The PDC user password.
- **TARGET_PDC_ADMIN_PASSWORD**: The password of the Oracle WebLogic server user in the target system.
- **SOURCE_PDC_ADMIN_PASSWORD**: The password of the Oracle WebLogic server user in the source system.
- **TARGET_PDC_USER_PASSWORD**: The password of the PDC user in the target system.
- **SOURCE_PDC_USER_PASSWORD**: The password of the PDC user in the source system.

walletPassword

The PDC wallet password.

keyPassword

The password to be stored in the configuration entry.

get Mode Syntax

```
./PDCWalletUtil.sh get walletLocation configEntry  
Enter wallet password: walletPassword
```

The **get** mode retrieves the password from the specified configuration entry.

get Mode Parameters

walletLocation

The location in which the PDC wallet resides.

configEntry

The configuration entry from which to retrieve the password. The valid values are:

- **PDC_APP_SERVER_USER_PASSWORD**: The Oracle WebLogic server user password.
- **PDC_APP_USER_PASSWORD**: The PDC user password.
- **TARGET_PDC_ADMIN_PASSWORD**: The password of the Oracle WebLogic server user in the target system.
- **SOURCE_PDC_ADMIN_PASSWORD**: The password of the Oracle WebLogic server user in the source system.
- **TARGET_PDC_USER_PASSWORD**: The password of the PDC user in the target system.
- **SOURCE_PDC_USER_PASSWORD**: The password of the PDC user in the source system.

walletPassword

The PDC wallet password.

Results

The **PDCWalletUtil.sh** utility notifies you when it successfully creates the wallet or stores the password in the PDC wallet.

PDCBRMWalletUtil.sh

Use the **PDCBRMWalletUtil.sh** utility to create the BRM Integration Pack wallet and to set passwords stored in that wallet. For example, you can set passwords for the transformation cross-reference database, migration cross-reference database, and BRM database.

For more information, see "Changing Passwords in the Wallet" in *BRM System Administrator's Guide*.

Location

BRM_Integration_Pack_homelapps/bin

Syntax Overview

You can run the **PDCBRMWalletUtil.sh** utility in the following modes:

- **create**: Create the BRM Integration Pack wallet in the specified location and with the specified password. See "[create Mode Syntax](#)".
- **set**: Set or change the password in the specified configuration entry. See "[set Mode Syntax](#)".

create Mode Syntax

```
./PDCBRMWalletUtil.sh create walletLocation  
Enter wallet password: walletPassword
```

The **create** mode creates the BRM Integration Pack wallet in the specified location and with the specified password.

create Mode Parameters

walletLocation

The location in which to create the BRM Integration Packet wallet.

walletPassword

The password for the BRM Integration Pack wallet.

set Mode Syntax

```
./PDCBRMWalletUtil.sh set walletLocation configEntry  
Enter wallet password: walletPassword  
Enter key password: keyPassword  
Enter key password again: keyPassword
```

The **set** mode sets or changes the password in the specified configuration entry.

set Mode Parameters

walletLocation

The location in which the BRM Integration Packet wallet resides.

configEntry

The configuration entry in which to store the password. The valid values are:

- **MIGRATION_DB_PASSWORD**: The migration cross-reference database user password.
- **TRANS_XREF_DB_PASSWORD**: The transformation cross-reference database user password.
- **BRM_DB_PASSWORD**: The BRM database user password.

walletPassword

The password for the BRM Integration Pack.

keyPassword

The password to be stored in the configuration entry.

Results

The **PDCBRMWalletUtil.sh** utility notifies you when it successfully creates the wallet or stores the password in the BRM Integration Pack wallet.

load_pin_snowball_distribution

Use the **load_pin_snowball_distribution** utility to load snowball discount distribution rules into the **/config/snowball_distribution** object in the BRM database. You define how snowball discounts are distributed in the **pin_snowball_distribution** file in **BRM_home/sys/data/pricing/example**.

Note:

- The **load_pin_snowball_distribution** utility overwrites existing distribution rules. If you are updating distribution rules, you cannot load new distribution rules only. You must load complete sets of distribution rules each time you run the **load_pin_snowball_distribution** utility.
- To connect to the BRM database, the **load_pin_snowball_distribution** utility needs a configuration file in the directory from which you run the utility. See "Connecting BRM Utilities" in *BRM System Administrator's Guide*.

Location

BRM_home/bin

Syntax

```
load_pin_snowball_distribution [-d] [-v] [pin_snowball_distribution_file]
```

Parameters

-d

Creates a log file for debugging purposes. Use this parameter for debugging when the utility appears to have run with no errors, but the data has not been loaded into the database.

-v

Displays information about successful or failed processing as the utility runs.

Note:

This parameter is always used in conjunction with other parameters and commands. It is not position dependent. For example, you can enter **-v** at the beginning or end of a command to initiate the verbose parameter. To redirect the output to a log file, use the following syntax with the verbose parameter. Replace *filename.log* with the name of the log file:

```
load_pin_snowball_distribution other_parameters -v > filename.log
```

pin_snowball_distribution_file

The name and location of the file that defines the snowball distribution rules. The default **pin_snowball_distribution** file is in *BRM_home/sys/data/pricing/example*.

If you do not run the utility from the directory in which the file is located, you must include the complete path to the file, for example:

```
load_pin_snowball_distribution BRM_home/sys/data/pricing/example
```

load_pin_spec_rates

Use this utility to set up customized rating by loading the contents of the **pin_spec_rates** file into the BRM database.

For more information, see "Charging for Custom Events and Attributes" in *BRM Configuring Pipeline Rating and Discounting*.

Note:

- The **load_pin_spec_rates** overwrites the existing setup for administrative events charges. If you are updating a set of administrative events charges, you cannot load new charges only. You load complete sets of charges each time you run the **load_pin_spec_rates** utility.
- To connect to the BRM database, the **load_pin_spec_rates** utility needs a configuration file in the directory from which you run the utility. See "Creating Configuration Files for BRM Utilities".

Location

BRM_home/bin

Syntax

```
load_pin_spec_rates [pin_spec_rates_file]
```

Parameters

pin_spec_rates_file

The name and location of the file that maps opcodes to event types to be rated. The default is *BRM_home/sys/data/config/pin_spec_rates*.

If you copy the **pin_spec_rates** file to the same directory from which you run the **load_pin_spec_rates** utility, you do not have to specify either the path or the file name.

Results

If the utility does not notify you that it was successful, look in the **default.pinlog** file to find any errors. This file is either in the directory from which the utility was started or in a directory specified in the utility configuration file.

Note:

You must restart the Connection Manager for the new administrative event charges to take effect.

load_pin_sub_bal_contributors

Use this utility to load the configuration for contributor-based sub-balances into the BRM database. You define the sub-balance configuration in the *BRM_home/sys/data/pricing/example/pin_sub_bal_contributor* file.

For more information, see "[Defining and Loading Custom Sub-Balances](#)".

Note:

- The **load_pin_sub_bal_contributor** utility overwrites the existing sub-balance configurations. If you are updating a set of sub-balance configurations, you cannot load new configurations only. You load complete sets of sub-balance configurations each time you run the **load_pin_sub_bal_contributor** utility.
- To connect to the BRM database, the **load_pin_sub_bal_contributor** utility needs a configuration file in the directory from which you run the utility. See "Connecting BRM Utilities" in *BRM System Administrator's Guide*.

Location

BRM_home/bin

Syntax

```
load_pin_sub_bal_contributor [-d] [-v] pin_sub_bal_contributor_file
```

Parameters

-d

Creates a log file for debugging purposes. Use this parameter for debugging when the utility appears to have run with no errors, but the sub-balance configurations have not been loaded into the database.

-v

Displays information about successful or failed processing as the utility runs.

Note:

This parameter is always used with other parameters and commands. It is not position dependent. For example, you can enter **-v** at the beginning or end of a command to initiate the verbose parameter. To redirect the output to a log file, use the following syntax with the verbose parameter. Replace *filename.log* with the name of the log file:

```
load_pin_sub_bal_contributor other_parameter -v > filename.log
```

pin_sub_bal_contributor_file

The name and location of the file that defines the configuration for contributor-based sub-balances. The default **pin_sub_bal_contributor** file is in *BRM_home/sys/data/pricing/sample*.

If you copy the **pin_sub_bal_contributor** file to the directory from which you run the **load_pin_sub_bal_contributor** utility, you do not have to specify either the path or the file name.

Results

The **load_pin_sub_bal_contributor** utility notifies you when it successfully creates the */config/sub_bal_contributor* object.

If the **load_pin_sub_bal_contributor** utility does not notify you that it was successful, look in the **default.pinlog** file to find any errors. This log file is either in the directory from which the utility was started or in a directory specified in the utility configuration file.

Note:

You must restart the Connection Manager to make the new sub-balance configurations available.

pin_discount_cleanup

Use this utility to specify how to handle expired discounts:

- Change the status of active, expired discounts to canceled
- Change the status of inactive, expired discounts to canceled
- Delete expired discounts

You use this utility when you set discount midcycle purchase or cancel options that grant a full discount when the discount is canceled in the middle of an accounting cycle.

You can run this utility nightly or add it to the **pin_bill_day** script to be run automatically. See "Running Billing Utilities" in *BRM Configuring and Running Billing*.

Location

BRM_home/bin

where *BRM_home* is the directory in which the BRM server software is installed.

Syntax

```
pin_discount_cleanup -m close|close_inactive|delete [-n days] [-d date] [-v] [-t] [-help]
```

Parameters

-m close | close_inactive | delete

Specifies how to handle discounts that expire on the specified date. The default date is the current date.

- **close**
Changes the status of all active, expired discounts to canceled without deleting the discounts.
- **close_inactive**
Changes the status of all inactive, expired discounts to canceled without deleting the discounts.
- **delete**
Deletes all expired discounts.

-n days

The number of days prior to **-d date** for which to cancel or delete expired discounts. This is used in conjunction with the **-d date** parameter to determine the actual dates for canceling or deleting expired discounts. The default is 0.

-d date

The end date (in the format *MM/DD/YYYY*) for which to cancel or delete expired discounts. This is used in conjunction with the **-n days** parameter to determine the actual dates for canceling or deleting discounts. The default is the current date. For example, if you enter **-n 5** and **-d 07/15/2021**, the utility cancels or deletes all discounts that expired on 7/10/2021.

Note:

- The expire date cannot be greater than the current date. For instance, in the example above, if 7/10/2021 is greater than the current date, **pin_discount_cleanup** returns an error.
- If neither the **-n** or **-d** parameters are specified, the current date is used.

-v

Displays information about successful or failed processing as the utility runs.

 **Note:**

This parameter is always used in conjunction with other parameters and commands. It is not position dependent. For example, you can enter **-v** at the beginning or end of a command to initiate the verbose parameter. To redirect the output to a log file, use the following syntax with the verbose parameter. Replace **filename.log** with the name of the log file:

```
pin_discount_cleanup other_parameters -v > filename.log
```

-t

Displays the number of records processed (the number of expired discounts that were canceled or deleted).

-help

Displays the syntax and parameters for this utility.

Results

To check the results of running this utility, look in the log file (normally **default.pinlog**) for error messages. The log file is located in the directory from which the utility was started or in a directory specified in the utility's configuration file (**pin.conf**).

New Pricing Terminology

Learn about the pricing terminology changes for this release of Oracle Communications Billing and Revenue Management (BRM) and Pricing Design Center (PDC).

Topics in this document:

- [New Pricing Terminology](#)

New Pricing Terminology

Pricing terminology changed in this BRM release. [Table A-1](#) lists those differences.

Table A-1 Pricing Terminology

Previous Term	New Term
ChargeShare	chargeshare offer
ChargeShare model	chargeshare
deal	bundle
discount	discount offer
discount master	discount filter
discount model	discount
EVAL("function_name") discount expression	Function["function_name"] discount expression
plan	package
plan list	package list
product	charge offer
rate plan	charge
rate plan selector	charge selector
resource	balance element (design time) or balance (runtime)
subscription group	service group
